Abstract — **Although the oscillometric method has been widely used to measure arterial systolic and diastolic blood pressures, its potential for arterial blood flow measurement is still remained to be explored. Thus, the aim of the study was to noninvasively determine the arterial artery blood flow using an oscillometric blood flow measurement system. The system consisted of an elastic cuff, an air-pumping motor, a releaser valve, a pressure transducer, and an airflow meter. To build a nonlinear air cuff model, we detected the pumped airflow into the cuff and the cuff pressure using the airflow meter and pressure transducer during the inflation period, respectively. During the deflation period, only the pressure transducer was used to record the cuff pressure. Based on the air cuff model, the oscillometric blood flow waveform could be obtained by integrating the oscillometric pressure waveform. We compared the derived artery blood flow from the maximum amplitude of the oscillometric blood flow waveform with the Doppler-based blood flow calculated with diameters and blood velocities of the brachial arteries in 32 subjects undergoing diagnostic evaluation for peripheral arterial embolism. A linear regression coefficient of r = 0.72 was found between the oscillometry- and Doppler-based blood flow measurements for the 32 subjects. In conclusion, the oscillometric method can be applied to quantitatively measure the blood flow through a brachial artery.**

Keywords — **Oscillometry, Blood flow, Cuff mode, Doppler, Brachial artery.**

I. Introduction

The profile of the arterial blood flow is a potential marker of generalized arteriosclerotic disease. Several artery-related diseases, such as stenosis [1], aneurysm [2], atherosclerosis[3] and arterial stiffness[4], can be directly or indirectly diagnosed by measuring changes in the arterial blood flow. Therefore, the ability to measure the blood flow significantly helps medical physicians and researchers to understand not only the patency but also the hemodynamic characteristics of the artery of interest.

Several methods have been proposed for non-invasively assessing the forearm blood flow in normal, stress and diseased conditions. Doppler ultrasound can yield the maximum or average blood velocity in an artery of interest, and then the arterial blood flow can be obtained by multiplying the measured velocity by the cross-sectional area if the diameter of the artery is assumed to remain constant [5]. In the photoplethysmographic approach, the arterial blood flow is indirectly derived from the absorption of incident light by red blood cells and other constituents in an arterial vessel [6]. In electrical-impedance plethysmo-graphy, the blood flow is implicitly assessed by measuring changes in impedance for electrical current passing through the arterial lumen [7].

Oscillometry is most frequently used to measure the arterial blood pressure, but it can also quantify the blood flow in an artery of interest. This study investigated a proposed oscillometric flow measurement system for determining the brachial arterial blood flow.

II. Oscillometric flow measurement

A. System design

Fig. 1 shows a block diagram of our proposed oscillometric blood flow measurement system. The relationship between the cuff pressure and the cuff air volume (i.e. the cuff model) was constructed using a non-linear regression approach. During the deflation period, only the pressure

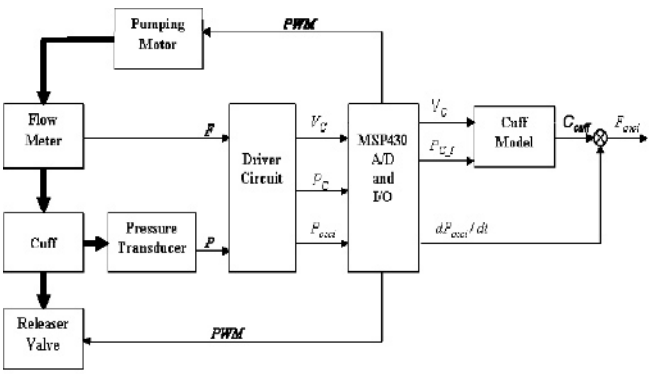

Fig. 1 Block diagram of the proposed measurement system. The thick arrows represent the air pathways and the thin arrows the electric current flow. F is the pumped flow, P_{C_I} is the cuff pressure during the inflation period, P_{osci} is the oscillometric pressure waveform during the deflation period, V_C is the cuff volume, C_{cuff} represents the slope of the cuff model, and F_{osci} is the oscillometric flow waveform.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 481–484, 2009
www.springerlink.com

transducer was used to record the cuff pressure, from which the oscillometric pressure waveform was extracted.

In the sensing module of Fig. 1, the cuff pressure is measured with a silicon-membrane pressure transducer (range: 3.45×10^4 N/m^2; SCX05DNC, SenSym). The output of the pressure transducer is calibrated using a mercury column sphygmomanometer. The oscillometric pressure waveform is obtained after band-pass filtering the analog cuff pressure signal from 0.1 to 3 Hz. The airflow meter (AWM3300, Honeywell) has a maximum operating range of 1000 sccm (ml min^{-1}). The cuff pressure, oscillometric pressure waveform and airflow signals are then digitized by a 12-bit A/D converter at a sampling rate of 250 Hz.

B. Brachial blood flow

The pumped airflow and cuff pressure were simultaneously recorded during the inflation period, with the airflow converted into the volume by integration:

$$V_c(t) = \frac{1}{60}\int_0^t F(s)ds\,, \tag{1}$$

where V_C is the cuff volume, F is the airflow and t is the time in seconds. It was assumed that initially the cuff was wrapped around the upper arm sufficiently tightly so that there was negligible residual air inside the cuff, with the cuff pressure being close to zero. This non-linear characteristic of the cuff model during the ascending pressure portion may be described by a hyperbolic function:

$$V_C = \frac{aP_{C_I}}{b + P_{C_I}} + cP_{C_I}\,, \tag{2}$$

where P_{C_I} is the air pressure inside the cuff during the inflation period, V_C is the volume of air pumped into the cuff, and a, b and c are constants. The slope of the cuff model is given by

$$C_{cuff}(P_{c_I}) = \frac{dV_c}{dP_{c_I}}. \tag{3}$$

During the deflation period, cuff pressures P_{C_D} and P_{osci} were respectively used as the input and output variables to describe the envelope of the oscillometric pressure waveform. According to the oscillometric pressure waveform, P_{osci} represents the change in the waveform superimposed on the cuff pressure since it resulted from the change in the arterial volume. Therefore, the change in the oscillometric volume (V_{osci}) embedded in the cuff volume can be calculated from C_{cuff} and P_{osci}:

$$dV_{osci}(P_{C_D}) = C_{cuff}(P_{C_D})dP_{osci}(P_{C_D})\,. \tag{4}$$

The change in the oscillometric volume is defined here as the instantaneous change in the vascular volume of the arterial segment of interest under the cuff. The oscillometric flow waveform is determined by differentiating the oscillometric volume waveform:

$$F_{osci}(t) = \frac{dV_{osci}(t)}{dt}. \tag{5}$$

III. Calibration and Experimental Material

A. System design

Eqs. (4) and (5) can be used to calculate the oscillometric flow from the oscillometric pressure. During the deflation period, an airflow pulse provided by a non-invasive blood pressure analyzer (CuffLink, DNI NEVADA) was used to simulate the arterial blood pulse. In the calibration process, the cuff was wrapped around a phantom and the pressure analyzer was connected to the cuff. We used an airflow meter (range: 100 sccm [ml min^{-1}]); AWM3100, Honeywell) to quantitatively record the airflow pulse generated by the pressure analyzer during the deflation period.

We compared the peak amplitudes of $F_{osci}(t)$ in the oscillometric flow waveform with those in the simulator-pumped pulse flow. Fig. 2 shows the estimated oscillometric volume and flow waveform obtained by using Eqs. (4) and (5). Because the pressure–volume relationship of the cuff model was almost linear at higher pressures (>60 mmHg), we only compared these data for these pressures. Fig. 3 compares the estimated peak F_{osci} values with the simulator-pumped pulse flows. The peak F_{osci} values were more precise at lower cuff pressures (r = 0.973) than at higher cuff pressures (r = 0.936).

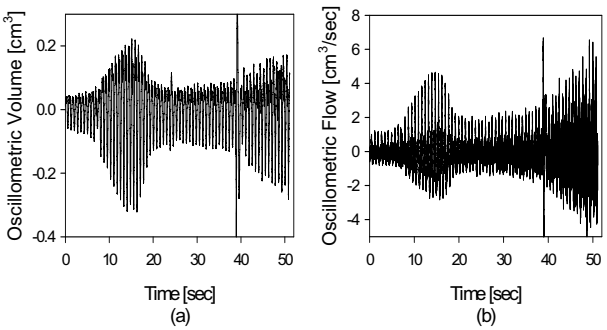

Fig. 2 The oscillometric flow was estimated by Eq. (4): (a) the oscillometric volume signal; (b) the oscillometric flow signal.

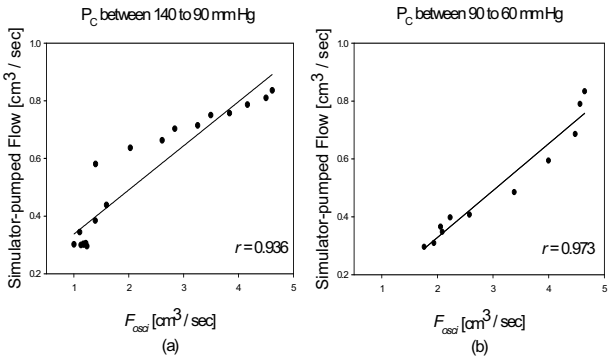

Fig. 3 The peak F_{osci} values compared with the simulator-pumped pulse flows. (a) The cuff pressure is limited above MAP; (b) The cuff pressure is limited below MAP.

B. Brachial blood flow

The experimental protocol was applied to 32 subjects (14 men and 18 women) aged 68 ± 15 years (mean ± SD; range: 19 to 93 years) undergoing diagnostic evaluations for peripheral arterial embolism. The brachial arterial blood pressure was measured with an electric sphygmomanometer (DINAMAP PROCARE 100, GE Medical Systems) in the left arm of each patient. Our designed instrument was used to measure the blood flow in the brachial artery. Thereafter, a duplex ultrasound scanner (7.5 MHz; M2410B, AGILENT, Hewlett Packard) was applied by a doctor to measure the pulse wave of peripheral vessels, and then to detect if an arterial or venous embolism was present and, if it was, to locate it. Finally, a duplex ultrasound scan was used to measure the arterial internal diameter and velocity of blood flow in the left brachial artery. The Doppler-based flow (F_{echo}) was then calculated by the multiplication of the arterial internal cross section and the maximum blood flow velocity.

IV. Results

Baseline hemodynamic data of the important variables for characterizing the patients are presented in Table 1, which indicates the wide range of arterial blood pressures. Since the amplitude of the oscillometric pressure waveform is maximal at the unloaded condition when the cuff pressure is equal to the mean arterial pressure, the maximum peak amplitude of the oscillometric flow waveform represented the optimal estimated blood flow $V_{p_}F_{osc}$. The proposed method was validated by comparing the oscillometry-based blood flow with the Doppler-based blood flow. The linear relation of the F_{echo} values with those of $V_{p_}F_{osci}$ is demonstrated in Fig. 4. The results indicated that for the peak value, the blood flow as measured using the oscillometry-based method was in reasonable agreement with the echocardiography-derived blood flow.

Table 1 Hemodynamic characteristics of the 32 patients in the study

Quantity	Value
Internal diameter of brachial artery (cm)	0.344 ± 0.079
Brachial blood flow velocity (cm s^{-1})	80.5 ± 21.7
Arterial compliance (10^{-3} cm^4 $dyne^{-1}$)	6.864 ± 2.645
MAP (mmHg)	92.3 ± 11.9
SBP (mmHg)	135.4 ± 23.6
DBP (mmHg)	67.5 ± 8.8

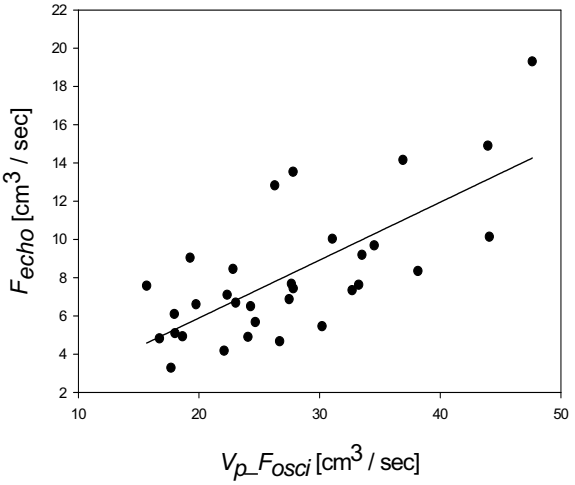

Fig. 4 Scatter plot of $V_{p_}F_{osci}$ vs. F_{echo}: n = 32, r = 0.72 (p < 0.0001), SEE = 2.52.

V. Discussion

Oscillometry has been extensively applied for assessments of systolic and diastolic pressures for many years [8], but few studies have used the method for blood flow measurements[9,10]. In the present study, an oscillometric blood flow measurement system was constructed for determining the brachial arterial blood flow. The system has been shown to be capable of detecting the pneumatic cuff pressure and volume simultaneously. Furthermore, the presence of moderate linear correlation coefficients between the oscillometry- and Doppler-based arterial blood flow measurements in the 32 subjects suggest that the oscillometry-based system can be dependably used to non-invasively determine the arterial blood flow. Thus, its ability to measure blood flow as demonstrated here might herald another use for automatic oscillometric blood pressure meters.

One of the important challenges in this study was deriving the pneumatic cuff model that mathematically describes the pneumatic cuff pressure–volume relationship. The model was established using real measurements of the cuff pressure and volume made by precise pressure sensors and flow meters. Furthermore, the non-linear relationship between the cuff pressure and cuff volume was found to be well fitted by a regression function (r = 0.999). Many biomechanical factors affect the systolic and diastolic characteristic ratios, and hence also oscillometric blood pressure measurements, such as the cuff elastance, mean arterial pressure, heart rate, pulse pressure, Young's modulus and arterial wall viscosity[11,12]. The cuff model was affected by the cuff elastance and Young's modulus of the tissue. The present and previous findings together suggest the need to consider more complicated systolic and diastolic characteristic ratios for oscillometric measurements according to the pneumatic cuff pressure–volume relationship.

Drzewiecki and co-workers have indicated that an occlusive arm cuff can be used as a volume sensor [9], suggesting that the blood flow can be obtained from the derivative of the cuff volume signal. Whitt and Drzewiecki used oscillometric data to non-invasively determine the flow from the derivative of the cuff pressure at a cuff pressure when the arterial compliance was nearly maximal[10]. According to these previous results, we performed oscillometry-based blood flow measurements after the cuff pressure–volume relationship was established during the inflation period.

VI. Conclusions

A measurement system has been successfully developed for detecting the brachial arterial blood flow using the oscillometric method. A mathematical model of the pneumatic cuff is established using data measured during the deflation period, which is then used to estimate the oscillometry-based arterial blood flow. The results showed a linear regression coefficient of r = 0.72 between the oscillometry- and Doppler-based brachial arterial blood flow measurements in 32 subjects, suggesting that the blood flow in the brachial artery can be quantitatively determined with the oscillometric technique once a satisfactory calibration procedure has been performed.

Abstract — **The purpose of this study is to build an automatic disease classification system using pulse waveform analysis, based on a Fuzzy C-means clustering algorithm. A self designed three-axis mechanism was used to detect the optimal site to accurately measure the pressure pulse waveform (PPW). Considering the artery as a cylinder, the sensor should detect the PPW with the lowest possible distortion and hence an analysis of the vascular geometry and an arterial model were used to design a standard positioning procedure based on the arterial diameter changed waveform for the *X*- and *Z*-axes. A fuzzy C-means algorithm was used to identify myocardial ischemia symptoms in 35 elderly subjects with the PPW of the radial artery. Two type parameters are used to make the features, one is a harmonic value of Fourier transfer, and the other is a form factor value. A receiver operating characteristics curve is used to determine the optimal decision function. The harmonic feature vector (H_2, H_3, H_4) performed at the level of 69% for sensitivity and 100% for specificity while the form factor feature vector (LFF, RFF) performed at the level of 100% for sensitivity and 53% for specificity. A negative group was used to determine the tolerance of the FCM algorithm. The harmonic feature vector (H_2, H_3, H_4) had a better correct result, at 57%.**

I. Introduction

Myocardial ischemia occurs as a result of the heart muscle being deprived of oxygen and is accompanied by inadequate removal of metabolites because of reduced blood flow or perfusion. In the case of a slight attack, myocardial ischemia subjects may complain of chest pains. But, in a more serious condition, sudden death will occur. In the clinic the Duke treadmill exercise score, a composite of measures of functional capacity and stress-induced ischemia, has been shown to predict prognosis in coronary artery diseases [1]. It has been reported that exercise electrocardiogram examination reveals the presence of chest pain during exercise or exertion, with the accuracy of diagnosis reaching 90% [2]. But the treadmill exercise is a dangerous and hard exercise for the patients. The patients must run until their heart rate attains at least 85% to 90% of the maximum heart rate for 1 minute, or until fatigue develops. Therefore, how to easily examine myocardial ischemia is a challenging study.

O'Rourke *et al*, have shown that arterial sclerosis is caused by the fracture and fragmentation of the elastic lamellae with the diabetes [3]. Consequently, many studies have been developed to assess arterial stiffness as a means of predicting the cardiovascular risk to the patient. Most of these studies have focused on the analysis of the pulse pressure waveform (PPW) measured from the radial artery. This kind of method is known as pulse waveform analysis (PWA). Research into PWA of the radial artery was initiated by the invention of a pulse waveform scanner by Vierordt in 1855 [4], which have since proven to be a safe and effective diagnostic tool. In 1993, Wang *et al*, used a Fourier transform to study the PPW, which would be affected by mechanical resonance between the heart and other organs [5]. Form factor (FF) value is a time domain feature that comes from the ratio of the standard deviation of the derivative signal. The FF value has been used in biomedical signal analysis, such as EEG and ECG [6]. The FF value is very sensitive to noise, and is only suitable for narrow band signals, not for wide band signals, such as EMG. Because PPW is a narrow band signal, the FF value also could be used to describe the PPW's characteristic in time domain.

A hard k-means algorithm executes a sharp classification, in which each object is either assigned to a class, or not. The application of fuzzy sets in a classification function causes the class membership to become a relative one and an object can belong to several classes at the same time but with different degrees [7]. Therefore, a fuzzy C-means (FCM) algorithm which is an unsupervised clustering method has a better performance than the hard k-mean algorithm for identifying the medical problems. A receiver operating characteristics (ROC) curve is used to determine the optimal decision function which is based on the feature centers derived by FCM.

In our studies, the radial artery can be regarded as a three-dimensional cylinder, and locating the best measuring point requires three axes to be considered. In order to get a standard measurement, we had designed a three-axis

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 485–489, 2009
www.springerlink.com

mechanism and a standard positioning procedure for detecting the optimal measurement site [8]. A modified sensor was designed to detect the arterial diameter changed waveform (ADCW) and PPW simultaneously. We analyzed the vascular geometry to estimate the optimal *X* position, and used an artery model to estimate the optimal *Z* position to get a standard PPW. In the PWA, the harmonic and FF values of the PPW being the frequency and time domain features were passed into the FCM algorithm to identify the myocardial ischemia symptoms that used the exercise electrocardiogram (ECG) as a reference. Furthermore, in order to test the clustering tolerance of FCM algorithm, a negative group was used whose treadmill ECG examination was normal.

II. Experimental materials and methods

A. Myocardial ischemia diagnosis

All subjects had to be free from any confounding factors such as infection of the respiratory tract, acute whole-body diseases, severe stenosis of the aorta, congestive uncontrolled heart failure, severely high blood pressure, chest pain under a resting condition, and severe arrhythmia. A standard diagnosis of myocardial ischemia was made based on a treadmill ECG showing horizontal or lower slope ST depression that followed the PPW measurement. Its lowest level had to reach the J point (the border between the QRS and ST phases), followed by a decrease of 0.1 mV every 80 msec. The treadmill ECG (SCHILLER STM-55, Polymed Chirurgical, Canada) measurements were made according to conventional methods at the hospital, in which the patient was allowed to run freely on the treadmill. The ECG monitoring device was attached to the patient to record the heartbeat. The speed and treadmill slope were increased every few minutes until any of the following four scenarios occurred: (1) patient could no longer continue running for any reason, (2) the heart rate reached a maximal value, (3) myocardial ischemia occurred, or (4) the ECG showed significant changes. Patients who showed scenario 1 were not included in the analysis. Scenario 2 was considered negative for ischemia if the ECG had not shown any significant change, while scenarios 3 and 4 were considered positive.

B. Features of PPW

The harmonic values of the PPW were obtained by Fourier transformation, as reported previously. The Fourier series is given by:

$$f(t) = H_0 + \sum_{k=1}^{N} H_k \cos(\frac{2\pi k}{T} t + \phi k), \tag{1}$$

where T is the beat time, H_0 is the mean value of the radial pulse, and the H_k values are the harmonic components of the PPW. The harmonic components were all normalized to H_1 before calculating differences.

The FF value of the PPW is as following:

$$FF = \frac{\sigma x \times \sigma x''}{(\sigma x')^2}, \tag{2}$$

where σx is the variance of the signal, $\sigma x'$ is the variance of the first derivative signal; $\sigma x''$ is the variance of the second derivative signal. The FF value of a sinusoidal wave is unity; other waveforms have FF values increasing with the extent of variations present in them.

C. Fuzzy C-Mean

In order to develop a diagnostic decision algorithm for myocardial ischemia, FCM is adopted. A feature vector belongs to a cluster to some degree that is specified by a membership matrix. The FCM function analyzes the PPW parameters and produces three outputs: (1) the membership matrix $\underline{\boldsymbol{U}}$, (2) the cluster centers $\{c_i, i=1, \ldots, K\}$, and (3) the PPW coding vector (row matrix) $\underline{\boldsymbol{S}}$. Four steps in the FCM function are depicted below. The cluster center $K=2$ in this paper.

Step 1: Initialize the membership matrix $\underline{\boldsymbol{U}}$ with random values between 0 and 1. The size of $\underline{\boldsymbol{U}}$ is $K \times L$, where K is number of clusters, and L is the length of input data. In this paper, L is the summation number of the positive group patients and the normal group. The element of membership matrix $\underline{\boldsymbol{U}}$, u_{ij}, is the probability that the jth feature vector belongs to the ith cluster ($1 \le i \le K$ and $0 \le j \le L-1$). Note that, for a given feature vector, summation of degrees of belongness equals unity. Elements of $\underline{\boldsymbol{U}}$ must satisfy the constraint below

$$\sum_{i=1}^{K} u_{ij} = 1, \quad 0 \le j \le L-1. \tag{3}$$

Step 2: Calculate fuzzy cluster centers for all K clusters according to

$$c_i = \frac{\sum_{j=0}^{L-1} v[j] \cdot u_{ij}}{\sum_{j=0}^{L-1} u_{ij}}, \quad 1 \le i \le K, \tag{4}$$

where $v[j]$ is the feature vector derived from normalized harmonic components and the FF values defined in Eq. (1) and (2)..

Step 3: Compute the cost function defined below

$$J(\underline{\boldsymbol{U}}, c_1, c_{2,\ldots,} c_K) = \sum_{i=1}^{K} J_i = \sum_{i=1}^{K} \sum_{j=0}^{L-1} u_{ij}^m D_{ij}^2, \tag{5}$$

where $D_{ij} = \|c_i - v[j]\|$ is the Euclidean distance between the *i*th cluster center and the *j*th feature vector. The weighting exponent, *m*, in Eq. (5) is selected to be *m*=2. The criterion requires *J* to be as small as possible. The iteration terminates if improvement of ***J*** over previous iteration is below a pre-specified threshold. Otherwise, the algorithm proceeds with next step to update the membership matrix $\underline{\boldsymbol{U}}$.

Step 4: Compute a new membership matrix $\underline{\boldsymbol{U}}$ whose element u_{ij} is adjusted by

$$u_{ij} = \frac{1}{\sum_{k=1}^{K} \left(\frac{D_{ij}}{D_{kj}} \right)^{2/m-1}}, \quad 1 \le i \le K, \quad 0 \le j \le L-1 \qquad (6)$$

According to the above equation, u_{ij} is inversely proportional to the squared distance from the feature $v[j]$ to the cluster center c_i.

The iteration process from *Step* 2 to *Step* 4 continues.

Four clustering results are determined: True Positive (*TP*), True Negative (*TN*), False Positive (*FP*) and False Negative (*FN*). A ROC curve is used to turn an optimal cluster performance which was defined by cluster specificity and sensitivity.

D. Experimental material

There were 16 patients in the positive group (11 male and 5 female, mean age 58.9 years with SD 11.6 years), 19 patients in normal group (9 male and 10 female, mean age 63.9 years with SD 13.7 years), 28 patients in negative group (18 male and 10 female, mean age 54.2 years with SD 9.1 years). The positive group is those who are judged as myocardial ischemia patients by treadmill ECG. The negative group is those who have the symptoms of myocardial ischemia but the treadmill ECG result shows no myocardial ischemia. The normal group is those who are healthy elders.

All the subjects were asked to stop smoking, stop alcohol intake, and avoid consuming stimulants (e.g., coffee and tea) and medications for at least 24 hours before participating in the experiments. They rested in a temperature-controlled room (at 22±1°C) for 30 minutes before the waveform examination was performed. During the waveform measurement, each subject was asked to sit on an adjustable-height chair. The subject's left or right hand was placed on a table at the same horizontal height as the heart with the palm pointing upwards and the wrist resting on a soft pillow. The radial artery PPW was measured at 10 mm proximal to the styloid process for both right and left hands. An exercise ECG was obtained immediately after PPW measurement.

III. Results

Traditional pulse signals contain one major peak and two following minor peaks within one period. The minor peaks of myocardial ischemia patients are more insignificant than those of a normal group. Figure 1 illustrates the typical PPW of myocardial ischemia patients (age 69 years, female) and normal subjects (age 56, female). Corresponding harmonics are also demonstrated in Fig. 2. From Fig. 2(a) we can see that the normal group has larger harmonic rhythms than positive group. Table 1 lists the harmonic features of left hand and the FF features of left and right hands for the positive groups and the normal group. Their corresponding t-test p values are also included. Therefore, the significant parameters ($p < 0.05$) were chosen as FCM clustering input features.

In the following step, Table 2 shows that the feature vectors are used as features in the FCM algorithm. After the FCM clustering steps for selected features, two cluster centers and two separate clustering groups are determined. The original decision function is determined by the perpendicular bisector on the cluster centers. One decision function

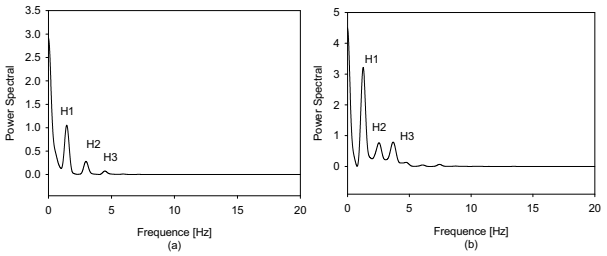

Fig 2. Frequency spectra of waveforms in Fig. 9: (a) positive group and (b) normal group. The harmonic peaks are denoted as H1, H2, and H3.

has corresponding sensitivity-specificity pairs for its clustering performances. Moving the original decision function with the same slope to get the other decision function, there are new clustering results and new sensitivity-specificity pairs. A ROC curve is then established by these sensitivity-specificity pairs of various decision functions. Figure 6 demonstrates three ROC curves from features with three input feature vectors, one is from (H_2, H_3, H_4), another is from (LFF, RFF), and the other is from (LFF, H2, H_4). The most optimal clustering performance is determined at the turnover of the ROC for different features, as shown in Table 2. The harmonic feature vector (H_2, H_3, H_4) has performances of 69% and 100% for sensitivity and specificity respectively, while the FF feature vector (LFF, RFF) has a performance of 100% for sensitivity and 53% for specificity. We also combined the harmonic and FF parameters as clustering features. We also combined with the harmonic and FF features as a feature vector to identify the myocardial ischemia. The two dimension feature vector (LFF, H_2) and three dimensions feature (LFF, H_2, H_4) all have 75% sensitivity and 100% specificity.

A negative group was used to understand the tolerance of the FCM algorithm. The PPW was analyzed to extract harmonic and FF parameters, and apply the corresponding decision function to the same feature distribution. We found that, using (H_2, H_3, H_4) features, there were 16 subjects classified in the normal group (57%). But when, using (LFF, RFF) as features, there were only 5 subjects classified in the normal group (18%). Using a mixed feature (LFF, H_2) there were 14 subjects classified in the normal group (50%).

IV. Discussions and conclusions

Spectrum feature, harmonic, and time-domain feature, FF, are used in this study. The harmonic value is a standard method for PWA analysis. Harmonic features had a sensitivity 69% and specificity 100% in this study. According to Wang [5], the second harmonic value and the forth harmonic value have corresponding physiological resonances with heart related diseases. This is the first time that the FF was applied in PWA. In Table 1, the FF features have lower p values between positive and normal subjects than harmonic features. The FF is a kind of time domain feature, and the two pulse's minor peaks of the PPW in the positive group are weaker than that of normal subjects. Therefore, the PPW variation of the positive group is lower, and results in a lower FF value than the normal group. The FF features have a sensitivity of 100% and a specificity of 53%, which is different from harmonic features, based clustering performance. The FF features demonstrate a better discrimination performance, but in different way.

A PWA based myocardial ischemia classification system was developed and tested. With the harmonic and FF features of PPW, higher identification specificity and sensitivity are achieved. The tolerance of the FCM algorithm is compared with the negative group. This system is non-invasive and is a standard measurement for the PPW. It is a good candidate for screening myocardial ischemia patients before further treadmill ECG examinations.

Study of the Effect of Short-Time Cold Stress on Heart Rate Variability

J.-J. Wang[1] and C.-C. Chen[1]

[1] Department of Biomedical Engineering, I-Shou University, Kaohsiung, Taiwan

Abstract — **The present work focuses on whether the heart rate variability (HRV) evaluated during the cold stress is different from that in the control condition. In fifteen subjects (12M & 3F, aging 21~24 yrs), a five-minute ECG record was performed in the room temperature condition (27°C), and the other five-minute ECG record was then measured in the cold stress during which an ice bag was placed on the forehead. After the R-R intervals were extracted from these two 5-minute ECG recording signals, we analyzed them using the time- and frequency-domain techniques. The results showed a significant decrease in PNN50 defined as the count of two continuous R-R intervals larger than 50 ms divided by the total number (control 25.4±20.9 versus cold stress 19.8±18.3 %, $p < 0.05$). In addition, there was a significant difference in the power in the high frequency range of 0.15 ~ 0.4 Hz (control 14.63±7.38 versus cold stress 12.03±5.14 ms^2, $p < 0.05$). Thus, as the human body encounters a short-term cold stress exposure, only a 5-minute HRV analysis can also demonstrate a significant reduction in the parasympathetic nervous activity.**

Keywords — **Heart rate variability, Cold stress, R-R interval, Power spectral alysis.**

I. Introduction

Heart-rate variability (HRV) analysis has been extensively used as a tool to examine the underlying mechanisms involved in autonomic control of the heart [1-4]. The two common forms of HRV analysis are often designated as time- and frequency-domain measures.

Time-domain HRV indices are derived either directly from interbeat intervals or from differences between adjacent interbeat intervals in the RR interval time series [1,2]. Frequency-domain measures such as power spectral analysis mathematically decompose the RR interval time series into its component frequencies [3,5-8]. Traditionally, spectral analysis of the rhythmic fluctuations in the beat-to-beat time series has led to the identification of three fairly distinct peaks: the very low frequency spectral power (VLFP, < 0.04 Hz), the low frequency spectral power (LFP, 0.04~0.15 Hz) and the high frequency spectral power (HFP, 0.15~0.4 Hz) [2]. The VLFP in the HRV spectra has been associated with thermoregulation [9]. The LFP reflects sympathetic and parasympathetic influences on cardiac control via baroreceptor-mediated regulation of blood pressure [10,11]. The HFP is a function of respiratory modulation of vagal activity [11].

Several previous results have demonstrated that whole-body, limb or local-skin cold stress really affects human thermoregulation and autonomic control of cardiac rhythm [12-18]. Nevertheless, how the short-term forehead cold stress influences the time- and frequency-domain indices of HRV deserves more investigations. Thus, the purpose of the study aimed to observe the effect of five-minute forehead cold stress on conventional HRV measures in healthy adults.

II. Methods

A. Subjects and protocol

Fifteen healthy college volunteers (12M and 3F) with an age range from 21 to 24 years were recruited in the study. Each subject was asked to be in supine position during the measurement period, and one 5-minute Lead II ECG record was performed in a room temperature condition (about 27°C) and the other in cold stress. In the cold stress experiment, a plastic bag containing crushed ice and water (-3°~-4°C) was placed on the volunteer's forehead for 5 minutes. The analog ECG signals were measured with a HRV measurement device (BioEngineering Sense Tech corp., Taiwan) and then digitalized with a sampling rate of 1000 Hz (MP100-UIM100C, BIOPAC System). After the R-R intervals were extracted from those 5-minute ECG records, they were further analyzed using the time- and frequency-domain methods.

B. Time-domain analysis

Time-domain measures derived from each 5-minute RR intervals (NN intervals) and used for assessing HRV in the study mainly include mean, standard deviation (SD), RMSSD, NN50 and pNN50. RMSSD is defined as the square root of the mean squared differences of the successive 5-minute NN intervals, as follows:

$$RMSSD = \sqrt{\frac{\sum (RR_i - RR_{i-1})^2}{n-1}} \quad (1)$$

NN50 is determined from the number of interval differences of the successive 5-minute NN intervals greater than 50 ms, whereas pNN50 is defined as the proportion

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 490–492, 2009
www.springerlink.com

derived by dividing NN50 by the total number of the 5-minute NN intervals [2].

C. Power spectral analysis

The 5-minute NN interval series was equal-spaced with a re-sampling rate of 4 Hz and a linear interpolation method was used to yield the new NN intervals, before the application of the fast Fourier transform to the new beat-to-beat interval time series. Several frequency bands of interest have been defined in the study, including the total power (< 0.4 Hz), the very low frequency spectral power (VLFP, < 0.04 Hz), the low frequency spectral power (LFP, 0.04~0.15 Hz) and the high frequency spectral power (HFP, 0.15~0.4 Hz) [2].

D. Statistical analysis

All continuous data are expressed as the mean value ± SD. Continuous time- and frequency-domain variables between the room temperature condition and the cold stress were compared using the paired *t* test. All results were analyzed using a two-sided significance level of 0.05. Data analyses were performed by using the statistical software SPSS 10.0 for Windows (SPSS Inc., Chicago, Illinois).

III. Results

Table 1 summaries the commonly used time-domain indices for assessing the RR interval variability. In the fifteen subjects, SD, NN50 and pNN50 were found to be significantly declined during the 5-minute cold stimulation than baseline (all $p<0.05$), with no significant difference in mean and RMSSD.

Table 2 lists the power spectral indices useful for assessing HRV. We found in the fifteen subjects that a significant decrement of VLFP, HFP and total power resulted from the 5-minute cold stress (all $p<0.05$), as compared with baseline, whereas no significant difference in LFP and LFP/LHP ratio was present.

Table 1 Comparison of various time-domain indices computed at room temperature and in cold stress (N=15)

Index	Room Temperature (27°C)	Cold stress (0°C)	p value
Mean (ms)	876±102	864±124	0.41
SD (ms)	61±19	48±11	<0.005
RMSSD (ms)	46.6±22.9	41.0±17.9	0.11
NN50 (count)	85±71	66±61	<0.05
pNN50 (%)	25.4±20.9	19.8±18.3	<0.05

Table 2 Comparison of various frequency-domain indices computed at room temperature and in cold stress (N=15)

Index	Room Temperature (27°C)	Cold stress (0°C)	p value
VLFP (ms^2)	109.7±13.2	105.9±15.2	<0.05
LFP (ms^2)	11.67±3.65	10.65±2.66	0.32
HFP (ms^2)	14.63±7.38	12.03±5.14	<0.05
Total power (ms^2)	135.8±19.0	128.5±20.2	<0.05
LFP/HFP	0.93±0.35	1.01±0.40	0.26

IV. Discussion

The current analysis of HRV shows that not only the traditional time-domain but also power spectral measures can be used to observe the RR interval variability before and during the forehead cold stress. Also, a 5-minute ECG record seems to be long enough for successfully assessing cold response.

The present results show that both the VLFP and HFP of HRV, but not both the LFP and LFP/LHP, become significantly smaller during the 5-minute forehead cold stress than at the room temperature in the fifteen healthy subjects. Mäkinen and coworkers have reported that acute whole-body cold exposure to a 10 °C environment increased total (36%), low (16%), and high frequency power (25%) and RMSSD (34%) [12]. Also, they have shown a cold-induced significant elevation in the HFP after cold acclimation, while other HRV parameters remained unchanged. Kinugasa and Hirayanagi have demonstrated that the HFP of HRV is significantly greater and the LFP/HFP ratio is significantly less at skin surface temperature of 18 °C than of 60 °C [19].

The heart rate fluctuation in response to the regional cold stress in the study is different from that in response to whole-body cold stress [12-16]. It is clear that at least, three factors including the localization, temperature and period of cold stress contribute to its effect on the HRV. This implies that more attention must be taken into account in comparing results from different cold stress conditions.

V. Conclusion

The analysis results indicate a significant reduction in the parasympathetic nervous activity in response to a 5-minute forehead cold stress. This suggests that it is appropriate for traditionally linear time-domain and power spectral measures to assess the short-term RR interval fluctuation caused by a regional cold stimulus.

A Reflection-Type Pulse Oximeter Using Four Wavelengths Equipped with a Gain-Enhanced Gated-Avalanche-Photodiode

T. Miyata[1], T. Iwata[2] and T. Araki[3]

[1] Niihama National College of Technology, Ehime, Japan
[2] Graduate School of Advanced Technology and Science, The University of Tokushima, Tokushima, Japan
[3] Graduate School of Engineering Science, Osaka University, Osaka, Japan

Abstract — **We propose a reflection-type pulse oximeter, which employs four kinds of light-emitting diodes (LEDs) and a gated avalanche photodiode (APD) for monitoring four different wavelengths. Wavelengths of the LEDs are 635 nm, 760nm, 810nm and 945nm. The four LEDs are driven by a pulse mode in a sequence manner at a frequency *f* (=10 kHz). The APD is operated in a gated "gain-enhanced" mode at a frequency 4*f* (= 40 kHz) in synchronized with the operation of the LEDs. Superposition of a transistor-transistor-logic (TTL) gate pulse on a direct-current (dc) bias that is set so as not exceeding the breakdown voltage of the APD makes the APD work in a gain-enhanced operation mode. Output signal from the APD is fed into a four-channel boxcar integrator that works to subtract the background signal and to enhance the precision in the analysis. The propose scheme is useful for the reflection-type pulse oximeter thanks to the capability of detecting a weak signal against disturbance such as a large background (BG) light.**

Keywords — **Pulse oximeter, avalanche photodiode, LED, gate mode, boxcar integrator.**

I. Introduction

Many optical techniques have proposed to measure blood components with a noninvasive manner. Among them, a pulse oximeter is one of the most popular instruments to measure the arterial oxygen saturation (SpO_2). The pulse oximeter has two types: a transmission type and reflection type [1]. Comparing the two types, the reflection type seems more promising because any region on the skin surface can be measured. However, for the reflection type, the weak reflection signal obtained from the skin surface and the relatively large background (BG) light incident on the light detector preclude precise measurements. In our previous report, in order to overcome the problem, we have proposed the reflection-type pulse oximeter by using a gain-enhanced operation mode of a gated avalanche photodiode (APD) and the lock-in light detection scheme [2].

The conventional transmission-type pulse oximeter consists of two LEDs with different peak emission wavelengths, typically 660 nm and 940 nm. On the other hand, three wavelengths (805 nm, 660 nm, 940 nm) can be used to improve the accuracy of the analysis of SpO_2 [3, 4]. Using the reflection-type pulse oximeter, also three wavelengths are useful for that. However, best experimental results are limited finger [1, 2, 5]. For the practical use, it should be applied to other skin surface that cannot apply transmission-type pulse oximeter, for example, wrist [6], neck, face [7], head, and other areas [8].

In our experiments, the intensity of pulsation from the wrist was lower in comparison than those from forefinger under measuring with three wavelengths (635 nm, 810 nm, 945 nm). Especially, that intensity was less than 10% of that from forefinger when the wavelength was 635 nm. As a result, the weak pulsation signal caused error in the calculation of SpO_2.In order to compensation for that, we introduce an additional wavelength (760 nm) to the system.

In this report, we propose a new light detection scheme, whose four kinds of wavelengths (635 nm, 760 nm, 810 nm, 945 nm) and the gain-enhanced gated APD and boxcar signal processing unit are effective for the reflection-type pulse oximeter thanks to the capability of detecting the weak signal against disturbance such as a large BG light.

II. Gain enhanced operation of a gated APD

Fig. 1 shows a schematic diagram for the gated APD [9]. The APD is dc-biased by a supply voltage through a bias-tee circuit. We set the value of the dc bias voltage so as to be slightly below the breakdown voltage (Vb) of the APD, because which is how one usually uses the APD for the purpose of high sensitive detection in dc operation mode.

In the proposed gate mode, we superimpose a transistor-transistor-logic (TTL) gate pulse, whose pulse height is 5.0 V, on the dc bias voltage so as not to exceed the breakdown voltage, through a coupling capacitor in the bias-tee circuit. The bias-tee circuit works as a filter to preventing the TTL gate pulse flow against the dc power supply while to applying the dc bias current to the APD. At that time, the multiplication factor of the APD is increased markedly because the gate pulse overdrives the APD effectively. On the one hand, however, the dark noise of the APD is also increased to some extent. A key point of the gated APD is that the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 493–496, 2009
www.springerlink.com

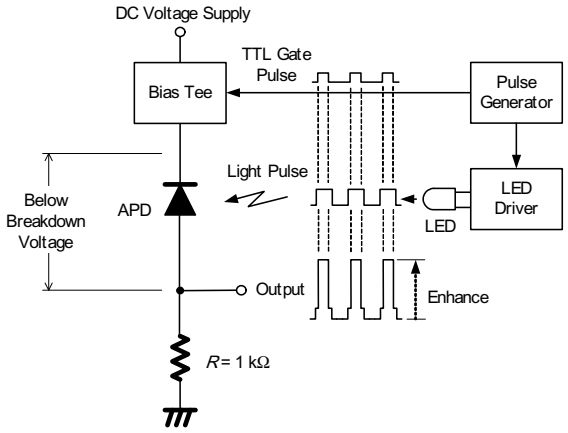

Fig. 1 A schematic diagram for explaining the gain-enhanced operation mode of the gated APD.

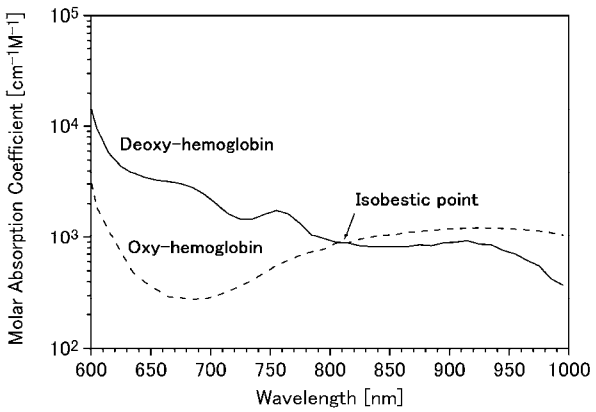

Fig. 2 Dependence of the molar absorption coefficient of oxy-hemoglobin and deoxy-hemoglobin on the wavelength [9].

over-all sensitivity for the signal light detection is enhanced in comparison with that of the conventional dc-biased APD, although depending on the incident light power and the value of the supply bias voltage. We operate the APD in an analogue mode for the purpose of detecting the weak signal light or picking up the weak signal superimposed on the large BG light. The attainable gain of the gated APD itself was enhanced about one hundred times in comparison with that of the conventional dc-biased APD.

III. Pulse Oximetry

For the calculation of the SpO_2, a ratio (ϕ) of two quotients, two ratios of alternative current (ac) amplitudes (I_{ac}) to dc ones (I_{dc}) of the photoplethysmographs (PPG) at the red (R) and the near-infrared (NIR) wavelengths, calculate according to the following the equation,

$$\phi(R/NIR) = \frac{I_{ac}(R)/I_{dc}(R)}{I_{ac}(NIR)/I_{dc}(NIR)}. \quad (1)$$

Then, the value of SpO_2 (S) is estimated by the following equation [3],

$$S = \frac{\phi E_{\mathrm{dNIR}} - E_{\mathrm{dR}}}{\phi(E_{\mathrm{dNIR}} - E_{\mathrm{oIR}}) + E_{\mathrm{oR}} - E_{\mathrm{dR}}}, \quad (2)$$

where E_o and E_d were molar absorption coefficients of oxy and de-oxy hemoglobin (see Fig. 2), respectively, and subscripts NIR and R indicate the near-infrared and red wavelengths, respectively.

Although previous equation (2) is useful for two wavelengths use, another formula considered the scattering light in the blood and tissue may have to be applied in the case of more than three wavelengths [4]. In either case, S is indicated by a function of ϕ,

$$S = f(\phi). \quad (3)$$

To verify the following combinations for SpO_2, for the calculation of the higher-accuracy ϕ, we propose the high sensitive detection scheme for weak pulsation from skin surface.

$$S_1 = f(\phi(^{635nm}/_{945nm}), \phi(^{810nm}/_{945nm})), \quad (4)$$

$$S_2 = f(\phi(^{760nm}/_{945nm}), \phi(^{810nm}/_{945nm})), \quad (5)$$

$$S_3 = f(\phi(^{635nm}/_{945nm}), \phi(^{760nm}/_{945nm}), \phi(^{810nm}/_{945nm})). \quad (6)$$

The $\phi(^{810\ \mathrm{nm}}/_{945\ \mathrm{nm}})$ is less affected by S, because of difference in the molar absorption coefficients between oxy and de-oxy hemoglobin is low (see Fig. 2).

IV. Experimental Setup

Fig. 3 shows a schematic block diagram of the reflection type pulse oximeter. For kind of wavelengths were used, a near-infrared light-emitting diode (LED, SLR938CV, λ = 945 nm, Sanyo), a red LED (GL5HD43, λ = 635 nm, Sharp), near-isobestic wavelength LED (L810-03AU, λ = 810 nm, epitex) and near-infrared LED (L760-03AU, λ = 760 nm, epitex), respectively. APD (S2382, Vb = 181 V, Hamamatsu Photonics Co.) was operated with the gain-

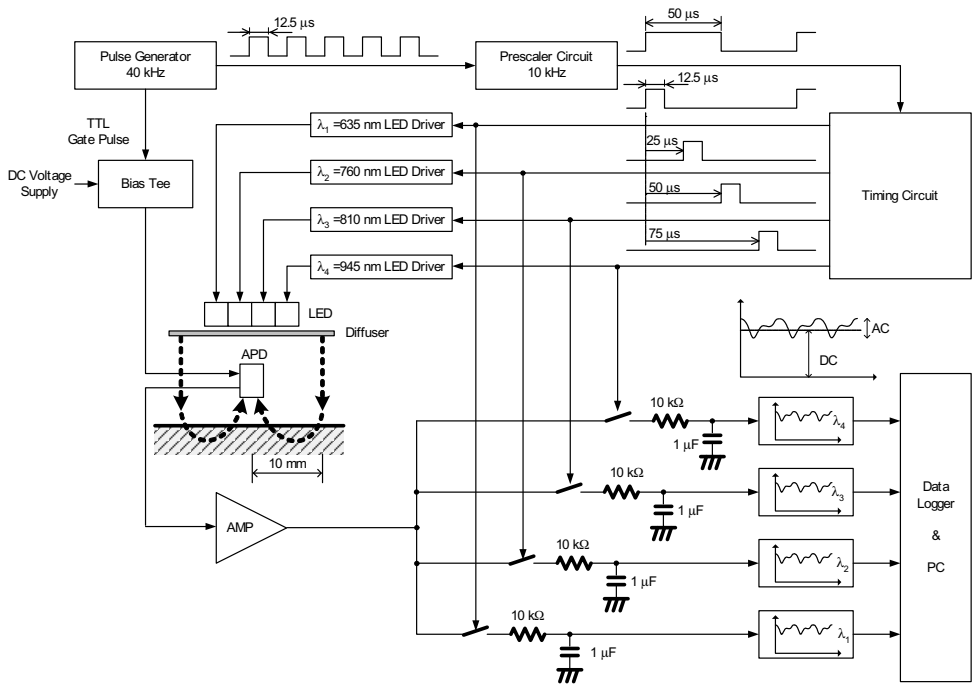

Fig. 3 Schematic block diagram of the reflection-type pulse oximeter.

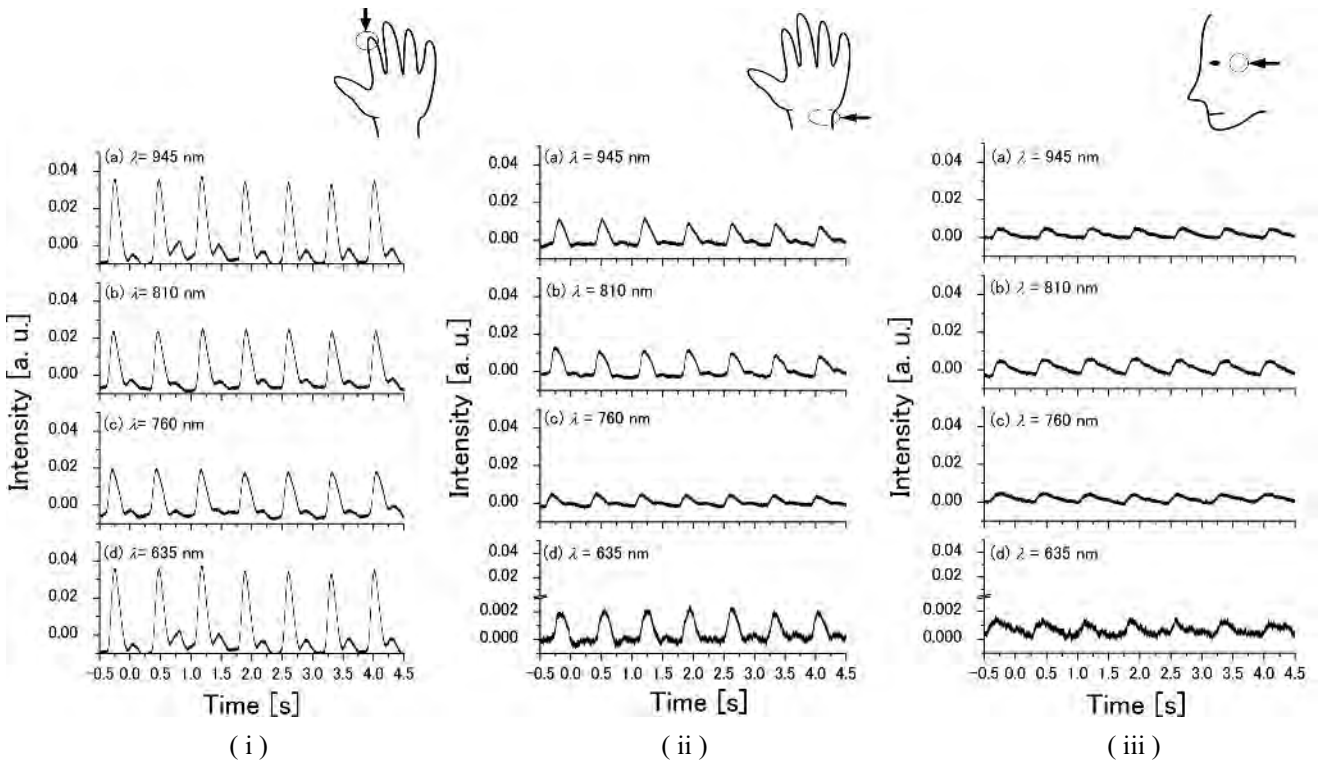

Fig. 4 Photoplethysmographs from skin surfaces at individual points: (i) from a forefinger, (ii) from a left wrist, and (iii) from a left temple area.

enhanced gate mode. A dc bias voltage was 173.4 V. Distance of between light source and APD were from 2.5 mm to 10 mm. The repetitive frequency and the duty ratio of emission from each LEDs were f =10 kHz and 0.125, respectively.

On the one hand, the gain-enhanced gate mode of operation for APD was attained by superposition of a transistor-transistor logic (TTL) pulse on the dc bias with not exceeding the breakdown voltage of the APD at a frequency $4f$ = 40 kHz.

Such four output signals obtained from the APD were fed into four gated integrators (R = 10 kΩ, C = 1 μF) separately whose reference timing of each LED. As the results, the photoplethysmographs for each wavelength can be obtained.

V. Results and discussion

Fig. 4 shows photoplethysmographs from skin surface: (i) from a left forefinger, (ii) from a left wrist, and (iii) from a left temple area. The signals are obtained by making local pressure with itself. These pulsation signals are weak signals embedded in the large dc reflection signals as BG signals. The intensity of the signals in each places, (ii) and (iii) when wavelength was 635 nm are 3 % and 1.7% as compared with that of forefinger as the case of (i). It is caused by the variation of optically penetration depth and pass depending on the pressure between the probe and the skin, the components under the skin, and so on. At that time, the intensity of the dc reflectance light is several thousand times as compared with those pulsations.

VI. Conclusions

We demonstrated that four kinds of LEDs (635 nm, 760nm, 810nm and 945nm), a gain-enhanced gated APD and boxcar integrator. The propose scheme is useful for the reflection-type pulse oximeter thanks to the capability of detecting a weak signal against disturbance such as a large background (BG) light. The system we have just posed has contributed to high accuracy of ϕ. The technique might be applicable to various wearable SpO_2 probe, for example, wristwatch type or glasses type.

Abstract — **Automatic blood pressure monitors are the most important healthcare products. The abnormal blood pressure values and waveform could indicate many cardiovascular diseases. The pressures measured using oscillometric method, which compared with invasive blood pressure devices, are often slight overestimation in SBP and underestimation in DBP.Recent studies indicated that the continuous pulse volume recording (PVR) could predict the central aortic blood pressure using a transfer function. Therefore, this study was implementing a novel device using the oscillometric method to predict the central aortic blood pressure to measure central blood pressure as well as the SBP, MBP and DBP automatically. The ensemble averaging 10 heart-beats of continuous PVR was used to extract the value of (cSBP), central SBP2 (cSBP2), central pulse pressure (cPP) and incisura point (inciP) for central blood pressure calculation. The method estimating the central blood pressure was correlated with the invasive measurement of pressure at aortic root at catheter Lab with high accuracy.**

I. Introduction

Automatic blood pressure monitors are the most important healthcare products. Most of them are using the oscillometric method with proprietary algorithms that is to determine the heart rate, systolic blood pressure, mean blood pressure and diastolic blood pressure. The cuff pressure (Bladder pressure) at the maximum of oscillometric amplitude determined by commercial automatic blood pressure monitors is the MBP. Pressures at the one half fold and 0.8-fold of the maximum oscillometric amplitude which before and after the MBP respectively are determined as the SBP and DBP generally [1]. The pressures measured using oscillometric method, which compared with invasive blood pressure devices, are often slight overestimation in SBP and underestimation in DBP.

Recently, many hypertension committees and cardiovascular associations agree that to estimate the central aortic blood pressure is the importance for preventing and diagnosing cardiac disease, such as hypertension, atherosclerosis. Central aortic blood pressures generally mean the systolic and diastolic pressure at the ascending aortic root. Systolic blood pressure represents the maximum force of the heart, and diastolic blood pressure means the pressure of heart against the pressure that generated by the impedance of circular system. So, it is important to estimate the central aortic blood pressure and pulse waveform accurately for evaluating the function of heart and diagnosing damage factors of cardiovascular diseases [2].

In the past, the evaluation of heart function was using invasive devices, such as Millar Catheter or Filled-Fluid. Invasive devices are more accurate than noninvasive blood pressure monitor and can acquire the pulse wave of blood pressure for estimating the cardiovascular functions. However, invasive devices may have disadvantages; 1) invasive devices may have risks of invading human body, 2) they must operate by an experienced expert, 3) cost expensive, 4) it is not suit for homecare utilization.

Many studies indicated that the continuous pulse volume recording (PVR) could have the ability to predict the central aortic blood pressure using a transfer function. In 1997, Todd J. Brinton et al. demonstrated that using the pattern recognition algorithm identifies characteristic phase changes directly from the continuous digital signals could have great potential clinical value to determine arterial pressure and vascular compliance [3]. Chen-Huan Chen et al. using mathematical transfer function from radial tonometry pressure estimated the central aortic pressure wave, and demonstrated that clinically acceptable prediction of central arterial pressure and the pressure waveform could be obtained by mathematic transfer function [4]. Further in 2006, James E. Sharman et al. presented that using generalized transfer function could noninvasively derive central blood pressure from radial pressure waveform even during exercise [5].

The aim of this study is to develop a novel automatic blood pressure monitor which can predict central blood pressure using transfer function. Furthermore, the data acquired from this novel blood pressure will be verified with invasive clinical data to prove the capability of the novel automatic blood pressure monitor.

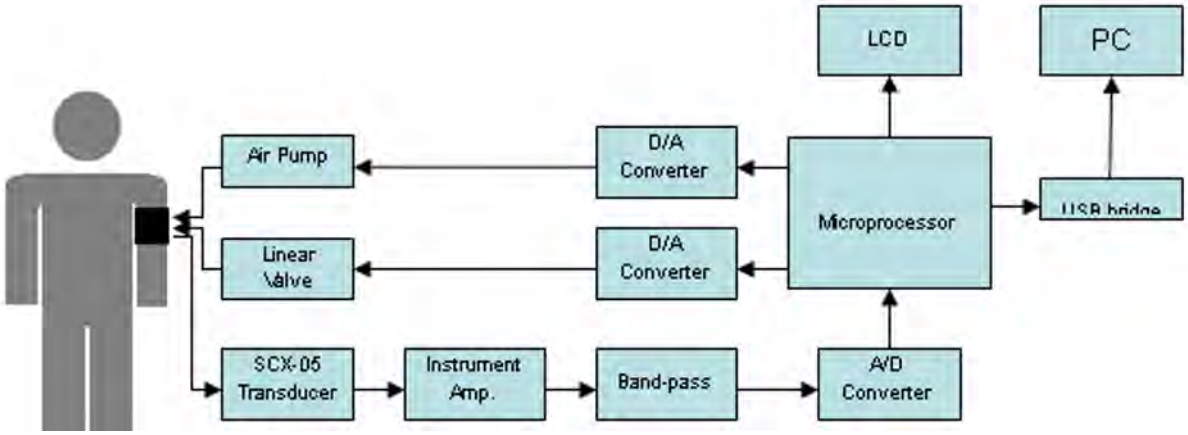

Fig.1 The block diagram of predictive central blood pressure monitor

II. Materials and Methods

A. Hardware System

In order to extract the specific blood pressure values, this study has developed a system and method with using microcontroller MSP430F149 (Texas Instruments). Several peripheral modules were used to acquire and store continuous PVR signal, such as pressure transducer for what, 12-bits analog to digital converter (ADC) for what, LCD module to present what, flash memory to store what, digital to analog converter (DAC) to do what and serial communication interface (USART) (Fig.1) for what.

This pressure transducer was using SCX-05 (HoneyWell) with a linear range of 0-300mmHg for acquiring the oscillometric signal of cuff pressure. The oscillometric waveform generated by the coupling of pressure changes in brachial artery to pressure changes in cuff. An instrumentational amplifier was seated behind the pressure transducer for reducing common mode signal and amplifying oscillometric signal. A band-pass filter was to mininimized the the effect of baseline shift. and the cutoff frequency was set at 0.5 to 30Hz. A 12-bit ADC which sampling rate of 120Hz was used to digitize the continuous pressure signal.

To accurate maintain the pressure in cuff, an air pump and an electrical controlled linear valve were used with the DAC module of MSP430F149 to adjust the inflating and deflating rate respectively. And, the LCD module will be presenting the real time oscillometric signal and displaying the SBP, DBP and heart rate that derived from oscillometric method. Assessment of the accuracy of this system was using the same data and the same algorithm at PC with the program written in C using Borland C++ Builder6, The data was transmitted to PC using USB to Serial Bridge Controller.

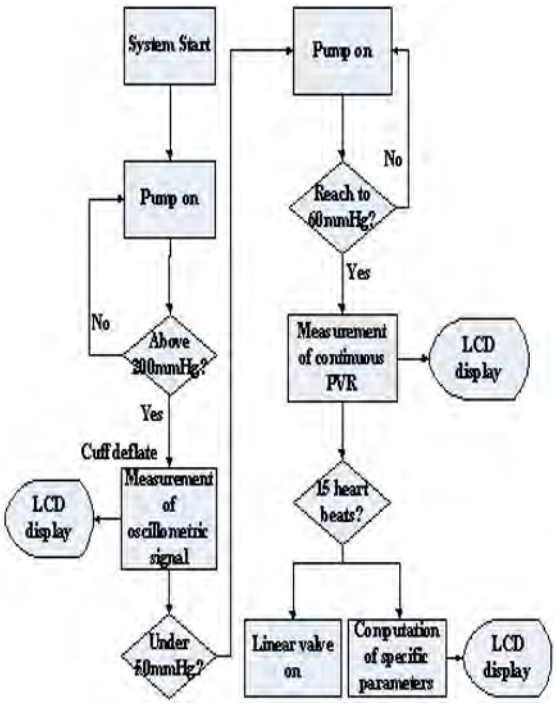

Fig.2 The procedure of measurement of central blood pressure

B. Measurement procedure

There were two steps in measurement procedure for acquire SBP, MBP, DBP and continuous PVR from oscillometric method (Fig.2):

- First step, using an air pump to inflat the cuff which was situated at the arm until the cuff pressure was above 200mmHg;, and the cuff pressure was remained for a few seconds to obtain a steady state. Then, the cuff was to deflat at a rate of 2-3mmHg per second. The

SBP, MBP and DBP were determined from the oscillation of cuff by using oscillometric method during the deflation state.

Fig.3 The prototype of central aortic blood pressure monitor

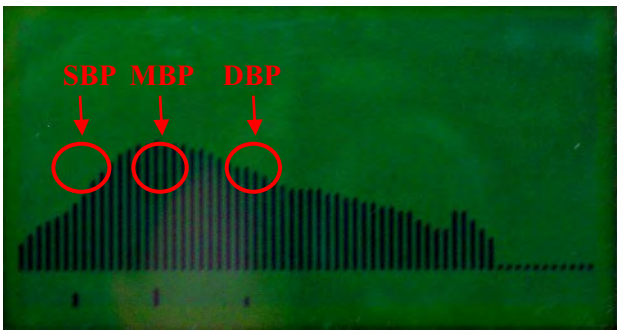

Fig.4 Amplitudes of oscillometric method. Red arrows indicated the amplitudes of SBP, MBP and DBP

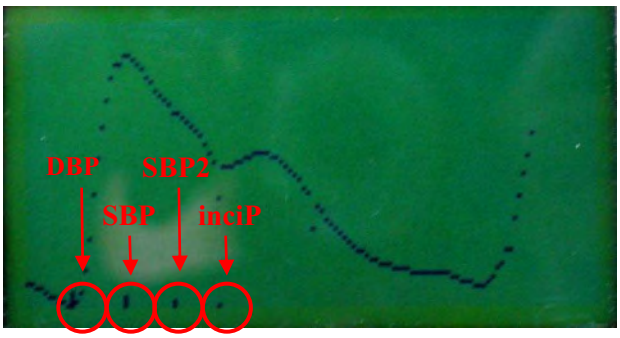

Fig.5 The ensemble averaging 10 heart-beats of continuous PVR waveform. Red arrows indicated the DBP, SBP, SBP2 and inciP of pressure waveform.

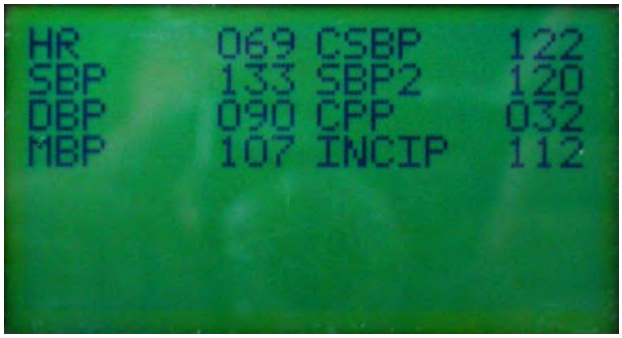

Fig.6 All parameters presented on the LCD module.

- Second step, after blood pressure values were determined. The air pump will be inflating the cuff pressure again and will be maintained the pressure at 60mmHg. The system waited for a steady state then acquired continuous PVR for 15 heart beats. After all acquisition was completed, the computation of specific parameters for pSBP, pSBP2, PP and pMBP were performed, and the LCD module will be presenting all the specific parameters and signal waveform as shown in Figure 5 and 6.

C. Algorithm

For assessing of central aortic blood pressure by oscillometric method, the continuous PVR signal must be normalized. In this study, the continuous PVR will be averaged using at least 10 selected heart beats for an average PVR signal. Specific parameters were derived from the average PVR dP/dt signal. All blood pressures could be determined by normalized PVR signal and calibrated with DBP and MBP from the oscillometric signal. Then, predictive central aortic blood pressures such as cSBP, cSBP2 and cPP could be derived by a transfer function which was developed previously by Dr. Chen and Dr. Cheng et al. in Taipei Veterans General Hospital in R.O.C.

III. Results and Discussions

In this study, the ability of this novel system can predict central aortic blood pressures by using oscillometric method using the acquired waveform and extracted data from noninvasive blood pressure device. The prototype of this new novel device in this study was shown in Figure 3.

After the procedure of first step described in previous section, the result of oscillometric amplitudes could show on LCD monitor, and specific parameter points indicated as SBP, MBP and DBP of oscillometric method (See Figure 4

for reference). The maximum amplitude (shown in Figure 4) indicated the oscillometric amplitude of MBP. The amplitude before the MBP and half fold of the maximum amplitude indicated the oscillometric amplitude of SBP. And, the amplitude after the MBP and 0.8-fold of the maximum amplitude indicated the oscillometric amplitude of DBP. The result of the ensemble averaging 10 heart-beats of continuous PVR waveform was shown in Figure 5. This waveform was used to extract the value of cSBP, cSBP2, cPP and inciP for central blood pressure calculation. The calculated result of all parameters could be presented on LCD module as shown in Figure 6.

IV. Conclusion

This development was based on the objective that was having hope of that people could use a blood pressure monitor at anytime to monitor their central aortic blood pressure, the cardiovascular diseases could be discovered in early stage.

The algorithm used to predict central aortic blood pressure is the computation result of the relationship between to area under PVR and the extracted parameters such as MBP and DBP. The transfer function is also including the ratio of the extracted value of cSBP, cSBP2, inciP and cPP. The result has been correlated to the invasive measurement at catheter Lab with high accuracy.

Furthermore, we will be proceeding in clinical validation to demonstrate the practicability of this novel automatic blood pressure monitor.

Design of a PDA-based Asthma Peak Flow Monitor System

C.-M. Wu[1] and C.-W. Su[1]

[1] Department of Electrical Engineering, National Central University, Taiwan, Republic of China

Abstract — **Recent study indicates that one of the important reasons that asthmatic condition could not be effectively controlled is that patients could not comply with the prescription of physician. One possible reason for this is that the conventional approach for physician to monitor the symptoms of asthmatic patients is based on the daily peak expiratory flow records of the patient. Because of the chronic essence of asthma, a long-term patient monitoring would be the necessary step to control the asthmatic condition. However, the asthmatic patients often stop following the prescription of physician once their symptoms of asthma are largely improved. This often leads to deterioration of treatment efficacy or even the patient's death. The main purpose of this study is to design an asthmatic peak expiratory flow monitor that is based on a personal digital assistant (PDA) and internet communication. Such a system would improve not only the communication between the asthmatic patients and physician but also the symptom of asthmatic patients.**

The device developed in this study is based on a Windows CE-based PDA. The peak expiratory flows (PEF) of asthmatic patient are converted into analog signals via a pneumotachometer (ADInstruments Inc., Sydney, Australia). These analog signals are digitized by a microcontroller and transferred to PDA by a serial interface (RS-232). The PEF data of asthmatic patients can be either stored in the database of PDA or synchronized with the computer in the office of physician to update the data through the internet or wireless local area network (LAN). The physician can also use the software program developed from this study to send short message to patients. Therefore, communication between the patients and physician not only will not be limited by time and distance, but also can achieve the goal of monitoring and improvement of patients' symptoms.

Keywords — **asthma, PDA, peak expiratory flow (PEF), monitor, LAN.**

I. Introduction

According to the report of National Heart, Lung, and Blood Institute, USA [1], long-term control of asthmatic symptoms with objective home peak expiratory flow (PEF) monitoring and corresponding action on medication becomes widely introduced in asthma patient self-management. Recent study indicates that one of the important reasons that asthmatic condition could not be effectively controlled is that patients could not comply with the prescription of physician. One possible reason for this is that the conventional approach for physician to monitor the symptoms of asthmatic patients is based on the daily peak expiratory flow records of the patient. Because of the chronic essence of asthma, a long-term patient monitoring would be the necessary step to control the asthmatic condition. However, the asthmatic patients often stop following the prescription of physician once their symptoms of asthma are largely improved. This often leads to deterioration of treatment efficacy or even the patient's death. Therefore, issues of home asthma telemonitoring (HAT) [2] were concerned highly in the management of patients with asthma. There are various types of commercial peak flow meters [3][4], but none of them show long-term graphic PEF records as well as update the data through internet or wireless local area network between the asthmatic patients and physician. Therefore, The main purpose of this study is to design an asthmatic peak expiratory flow monitor that is based on a personal digital assistant (PDA) and internet communication. Such a system would improve not only the communication between the asthmatic patients and physician but also the symptom of asthmatic patients.

II. Methods

A. Configuration of the system

The device developed in this study is based on a Windows CE-based PDA. The peak expiratory flows (PEF) of asthmatic patient are converted into analog signals via a pneu-

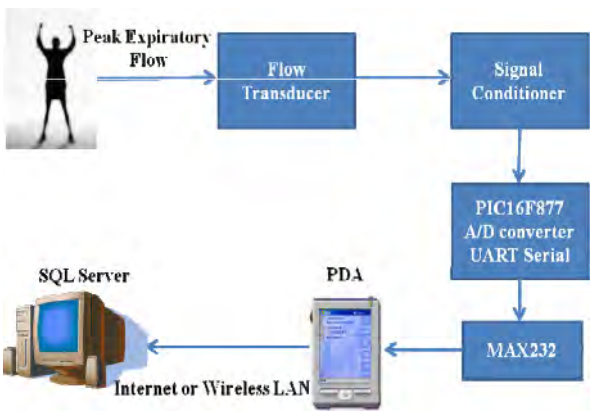

Fig. 1 Configuration of the system.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 501–504, 2009
www.springerlink.com

motachometer (ADInstruments Inc., Sydney, Australia). These analog signals are digitized by a microcontroller and transferred to PDA by a serial interface (RS-232). The PEF data of asthmatic patients can be either stored in the database of PDA or synchronized with the computer in the office of physician to update the data through the internet or wireless local area network (LAN). The configuration of the system is shown in Fig. 1.

B. Hardware Devices

The peak expiratory flow was measured with the respiratory flow head (MLT1000L) from ADInstruments Inc. (Sydney, Australia). The transduced signal was amplified and digitized by a microcontroller (PIC16F877, Microchip,Chandler AZ, USA) and transferred to PDA (iPAQ H3950, HP, Palo Alto CA, USA) by a serial interface (RS-232). Because we developed our own PEF data acquisition system, we have to verify the accuracy of the process. The output of signal conditioner for the flow transducer was verified with commercial Power Lab. system from ADInstruments Inc. The results of this verification are shown in Figs. 2 and 3.

In addition, the output of the A/D converter and RS232 connection was also verified with the interface provided by Microchip Inc. The results of this verification are shown in Figs. 4 and 5. The hardware device is shown in Fig. 6.

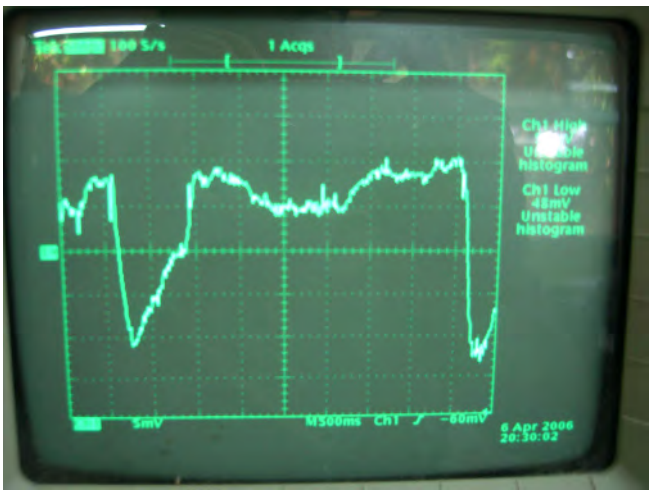

Fig. 2 Output of the signal conditioner on the oscilloscope.

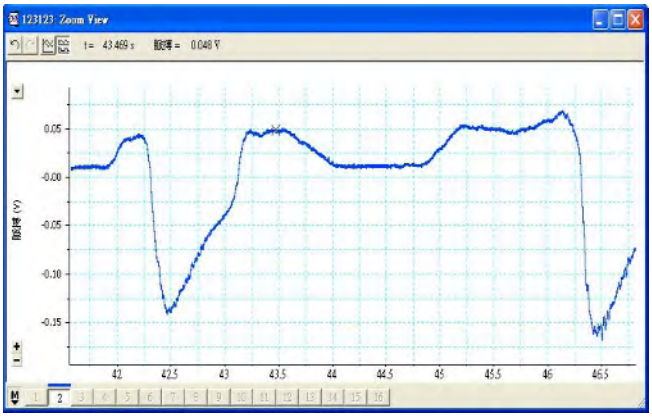

Fig 3. Output of the flow transducer from Power Lab system.

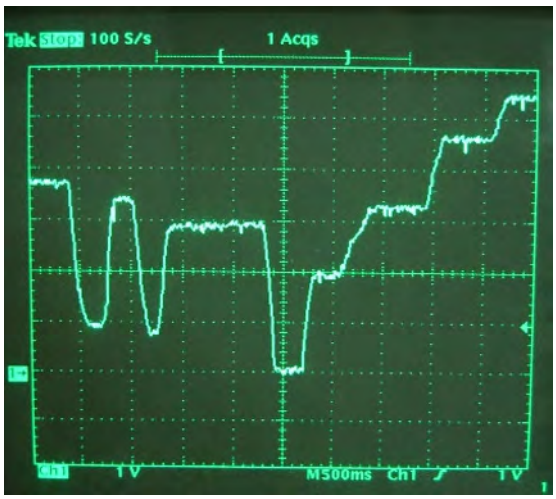

Fig. 4 Analog input signal for the microcontroller PIC16F877 shown on the oscilloscope.

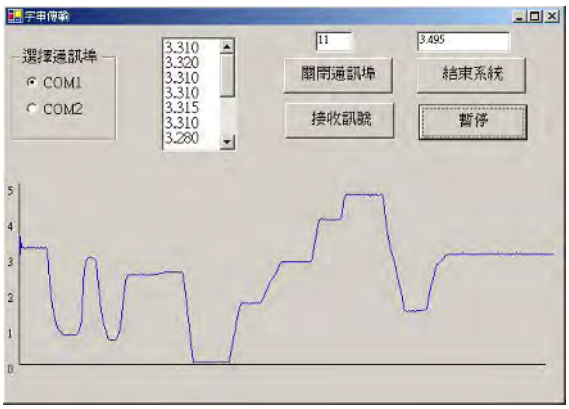

Fig. 5 Digitized signal transferred to the interface through RS232.

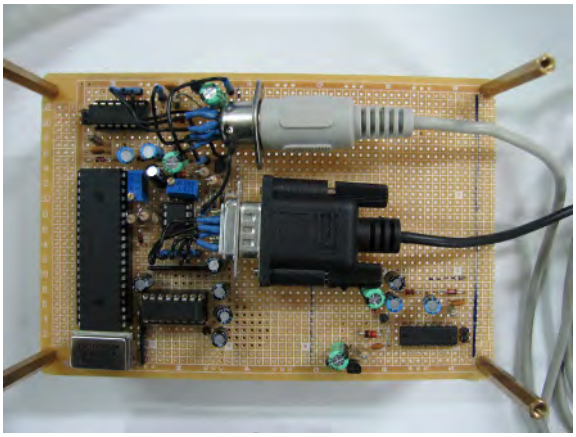

Fig. 6 Picture of the hardware device.

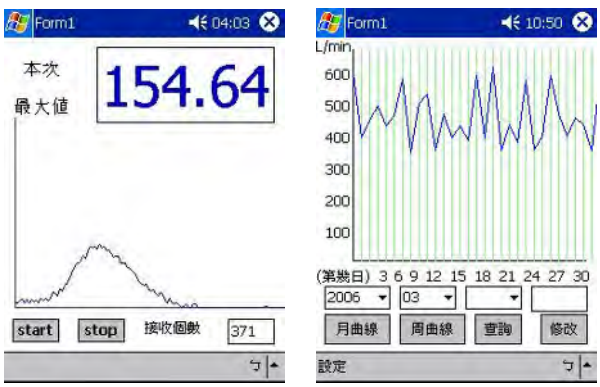
C. Software Development

The software developed in this study is based on a Windows CE-based PDA. The PEF data of asthmatic patients from the hardware device can be either stored in the database of PDA or synchronized with the computer in the office of physician to update the data through the internet or wireless local area network (LAN).

In order to protect the privacy of patient's medical record, the user account and password was designed to access the PEF monitor system through the PDA user interface. The database design on the PDA of patient and the computer in the physician office was based on Microsoft SQL CE 2.0 and Server 2000, respectively. Synchronization of data on both databases can be made by internet or wireless LAN (802.11b) connection through remote data access concept. Fig. 7 shows the user interface for this process.

(a) (b)

Fig. 7 (a) Receive patient medical record from remote physician office; (b) Transfer patient data to remote physician office.



The physician can also use the software program developed from this study to send short message to patients. Fig. 8 shows the patient receive message from the physician and read the contents of the message.

The user interface could record and display the PEF of the patient and store the PEF value to the database of the PDA (Fig. 9(a)). In addition, the patient could also graphically display the long-term PEF data (Fig. 9(b)).

(a) (b)

Fig. 8 (a) Patient receives 5 messages from the physician; and (b) read the contents of message.

(a) (b)

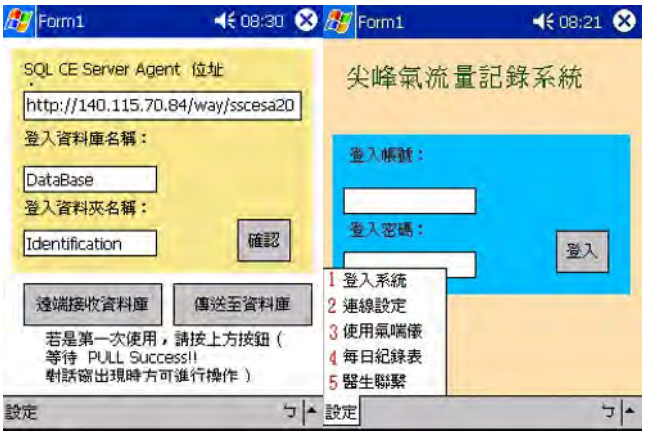


Fig. 9 (a) User interface to record the PEF; and (b) graphically display long-term PEF data.

III. Results

The final user interface on the PDA is shown in Fig. 10 (a). There are five functions developed for the user interface. The first function is to log-in the system with user name and password. The second function is to set up the internet or wireless LAN connection for patient and physician communication (Fig. 10(b)). The third function is to

measure the PEF. The fourth function is to store the measured PEF for the long-term display. The current version could show one month long PEF data. The final (fifth) function is to communicate with the physician.

Finally we verified the measured PEF of our monitor system with commercial Power Lab. system. During verification, the same flow transducer was used for both systems to measure PEF for one subject. Table 1 shows the measured PEF for both systems and the error between them. Fig. 11 depicts the prototype of our PEF monitor system

(a) (b)

Development of the Tongue Diagnosis System by Using Surface Coating Mirror

Y.J. Jeon[1], K.H. Kim[1], H.H. Ryu[1], J. Lee[1], S.W. Lee[1] and J.Y. Kim[1]

[1] Department of Medical Research, Korea Institute of Oriental Medicine, Korea

Abstract — **Tongue diagnosis consists of many parameters, including shape, substance and coating of the tongue and so on, to examine health condition and the property of a disease. A new instrument is demand, however, to exclude the effect of various medical examination environments and clinician's subjective sense. In this study, to acquire a clear image of the whole tongue, 500 mega pixel CCD camera and 35mm lens were used and a right angle shape body with surface coating mirror for sufficient object distance. To reduce a specular reflection on the surface of the tongue due to saliva, the LED lighting with a diffusing acrylic was applied. Furthermore, to adjust light interference in the color of the tongue, color charts were inserted. In further study, we will develop the tongue diagnosis algorithm so that this system can be used widely in clinical and research fields**

Keywords — **Tongue diagnosis, Coating of the tongue, Substance of the tongue, Surface coating mirror.**

I. Introduction

The tongue diagnosis is a unique diagnostic method in the Oriental medicine that studies a tongue to understand the condition of health and disease characteristics in human body, and it is based on the shape, substance, coating and movement of the tongue, etc. The shape of tongue represents shape changes in the body of tongue such as width and fissure of tongue, teeth mark, etc. And the substance of the tongue indicates color and quality of tongue's body. The coating of the tongue is a substance covered on the tongue as mosses, and its width, color and distributed area reflect various conditions of the body [1].

The shape, substance, coating and movement of the tongue, etc which constitute the tongue diagnosis are studied generally depending on visual information. And since this information can be affected by environment of examination such as lightning or weather, etc and the subjective sense of the Oriental medical doctor, it is difficult to obtain the objective and reproducible results. The studies to obtain a consistent environment of the tongue diagnosis and objective results are in progress to develop and bring the tongue diagnosis to be scientific [2, 3].

In order to obtain accurate images, the methods to control lightning angle, luminance, a position of measurer, the environment of image acquisition, the method to adjust the iris, a shutter and exposure of camera, and the methods to detect the required area of the tongue for diagnosis from the acquired images have been studied [4].

The tongue diagnosis system, developed in this study, focused on providing clear images of the tongue through securing a proper photographing distance, the lightning part which can suppress the reflection by sputum in maximum, securing area up to the inner tongue and the face contact region considering a testee's convenience to objectify and quantify the tongue diagnosis system.

II. Method

A. Hardware

Securing the proper photograph distance becomes a critical element in order to photograph clear images of the tongue; however, since securing the photograph distance by arranging a camera and a subject linearly can lower the overall design aspect and utilization, in this study the photograph unit and subject are arranged to be right angle and the surface coating mirror is positioned at the right angle to photograph. Figure 1 shows a detach map of the body part of the tongue diagnosis system developed. The photo unit consists of 35mm lens (HF35SA, Fujinon) and the camera (GRAS-50S5, Grasshopper) that supports 5 million pixels, and to connect the photograph unit perpendicular to subject, the surface coating mirror is installed at the right angle. The lightning unit was produced with LED of high luminance, and a diffusion acrylic was used to suppress the light reflection maximally from the sputum on the tongue's surface caused by the direct ray of LED, and the polarization filter was added to lens. Also, to compensate difference in color by effect of lightning, the color chart was attached near to the face contact region. Considering convenience of a testee, the face contact region was designed to have the increased contact area to have a comfortable contact ergonomically, and it was developed to be capable of photographing up to the inner tongue. The body part of the tongue diagnosis system developed as the above is connected with the desk unit. And to enable a testee to stick out his tongue easily, the body part and desk unit are connected so that the body part forms angle of about 45 degree with the desk unit. Figure 2 shows the actual tongue diagnosis system that the body part and desk unit are connected.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 505–507, 2009
www.springerlink.com

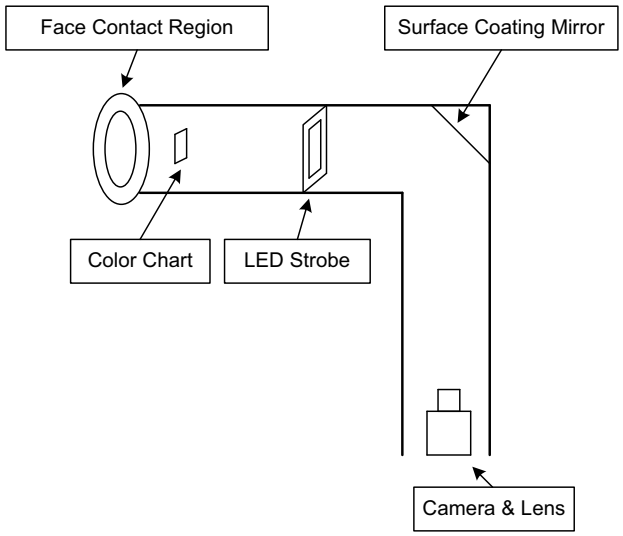

Fig. 1 The separation diagram of the body part of tongue diagnosis system

Fig. 2 The actual image of tongue diagnosis system

B. Software

The measurement program equipped with photographing and saving tongue's image and the database function of testee's information was produced with visual C. As shown in the block diagram(Fig. 3) with regard to the process of software driving, identifications and date of examination for a testee, opinions from the Oriental medical doctor, etc are inputted, and photograph is taken after qualifying whether the elements such as the position and size of the tongue's image of a testee are suitable for photographing. Figure 4 shows the actual image of the tongue taken with the measurement program. When photographing tongue is completed, the tongue area is automatically detected and when there is error in the detected area the detection area can be adjusted manually with the thick dot on the screen. And with the snake algorithm the curve between dots can be restructured [5].

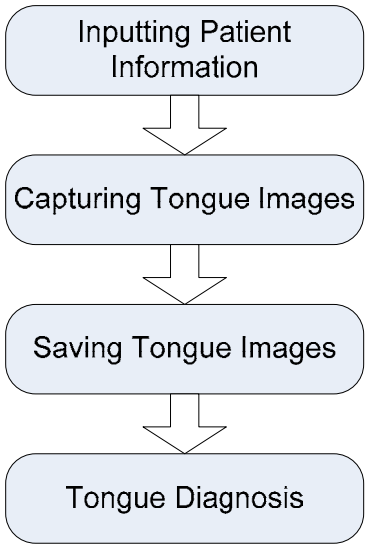

Fig. 3 The process of software driving

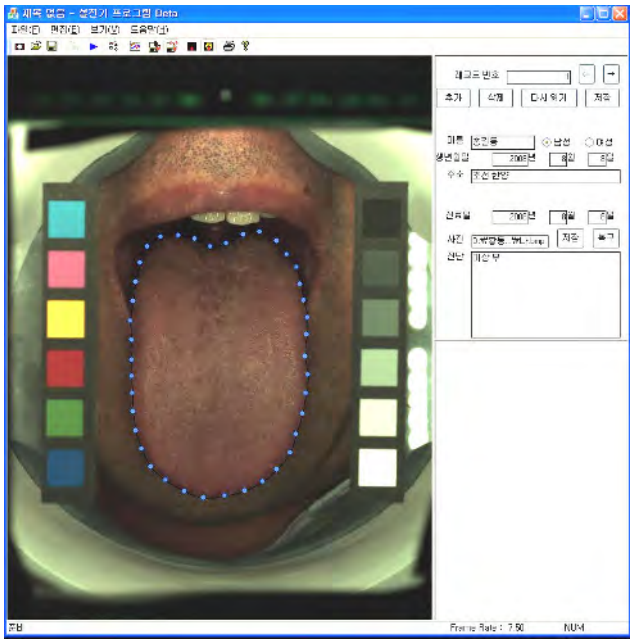

Fig. 4 The actual image of tongue taken with the measurement program

III. Conclusions

The tongue diagnosis system developed in this study allows securing sufficient photograph distance with the surface coating mirror in order to photograph clear images of the tongue. And the lightning unit was produced with the diffusion acrylic and polarization filter to suppress the reflection of light by sputum on the tongue's surface. Also, it allows photographing the color chart with the tongue in order to correct color affected by lightning and allows a testee to stick out his tongue easily by designing the face contact region.

Using this tongue diagnosis system, it was checked that the photographed images of the tongue could be classified as identical coating after photographing images of the tongue from the testee whose coating was clearly identified by the Oriental medical doctor as a yellow coating or a white coating on the tongue. In the future, advancement in accuracy of tongue area detection and adding the automatic algorithm of classifying coating and substance of the tongue to the tongue diagnosis system in this study are expected to contribute to the scientific tongue diagnosis.

Design a Moving Artifacts Detection System for a Radial Pulse Wave Analyzer

J. Lee[1], Y.J. Woo[1], Y.J. Jeon[1], Y.J. Lee[1] and J.Y. Kim[1]

[1] Korea Institute of Oriental Medicine, Daejeon, Korea

Abstract — **Despite recent studies on development of pulse wave analyzers and needs for commercializing them, the reproducibility is one of the most controversial issues as ever. Because the pulse pressure value, which is one of the important parameters to evaluate reproducibility, is very vulnerable to moving artifacts, the reproducibility can not be obtained easily.**

In this paper, we designed a moving artifacts detection system for a radial pulse wave analyzer so that it can be robust to this kinds of artifacts by excluding the contaminated parts from the pulse wave signal to be analyzed. This moving artifacts detection system was designed to consist of a three-axis accelerometer, an electromyography amplifier and a two-axis tilt sensor.

To assess the suitability of the system, we examined the characteristics of each sensor's output signals with regard to the three motions such as extension, flexion and rotation. And, we also examined the each sensor's response to the high-frequency and low-frequency moving artifacts while the pulse wave signal was acquired from a pressure sensor for the pulse diagnosis. From these results, we could find that the response to subject's motions would be reflected in electromyography signal first, accelerometer signals and tilt sensor sequentially. And, the facts that a stable pulse wave can be acquired in two seconds after high frequency or low frequency motions ended were also found.

Consequently, based on these findings, we set up some rules on the moving artifacts detection and designed an algorithm which is fit for our moving artifacts detection system.

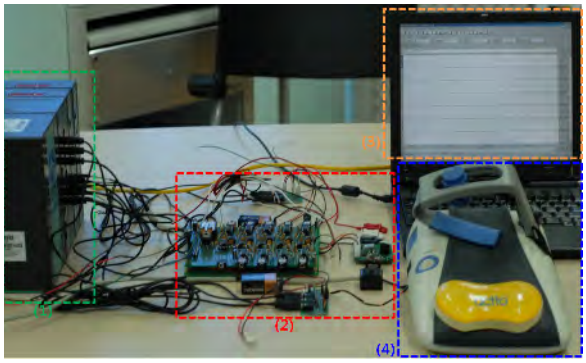
I. Introduction

Non-invasive radial artery pulse waveform has been widely used since the radial tonometry is simple to perform and well tolerated. Indeed, in contrast to the carotid artery, the radial artery is well supported by bony tissue, making optimal applanation easier to achieve. It has been, however, known that the deformation of pulse shape can be caused readily by moving artifacts, changing measuring position and hold-down pressure [1].

The first solution to guarantee reproducible radial pulse waveform is to keep the hold-down pressure constant along with using the high fidelity pressure sensors. But even though a system meets these requirements, it has been found that, with an automated system, 63% of the measured data was useless without a proper measurement procedure [2]. And also it has been known that the pulse waveform is a low frequency signal with the maximum frequency of around 30 Hz, and it is very susceptible to the moving artifacts [3]. The traditional band pass filters cannot be used since the moving artifacts' and the pulse waveform signal are in the same frequency range, and an algorithm is used to remove the noise by estimating the base line with the reference of the beginning of systolic period in every beat, but still it is susceptible to the moving artifacts which are in higher frequency than the heart beating frequency of 1H-1.5 Hz [4].

Therefore the best method to get good signal quality would be to identify the source of the moving artifacts and eliminate the data taken from the corresponding period for the analysis as well as to keep the SOP(standard operating procedure) for minimizing the moving artifacts.

This paper presents a system to detect the moving artifacts with the electromyogram taken from antebrachium, the acceleration signal taken from the wrist, and the performance of the system was evaluated.



II. Method and Reseults

A. System configuration

During the radial pulse waveform measurement, the subjects should be asked to keep the same posture as much as possible, but the moving artifacts will always be generated by the human factors including measurement posture and physiological and mental status, and the equipment factors including the hold-down pressure control and the structures to support the arm.

To remove moving artifacts during the measurement with the pulse diagnosis system, in this paper, a system which consists of an accelerometer, a tilt sensor, and electromyography amplifier is proposed. The accelerometer used in the system is MMA7260Q (Freescale Semiconductor Inc, USA) with low power consumption and the measurement range was set to ±1.5g with the high sensitivity of 800mV/g. The 2-axis polymer based electrolyte tilt sensor, DX-045-90 (Advanced Orientation Systems Inc, USA) was used. Its measurement range is maximum ±90°, and the response time is lower than 20 msec. Biopotential amplifier module MP150(BIOPAC Systems Inc, USA) was used to acquire

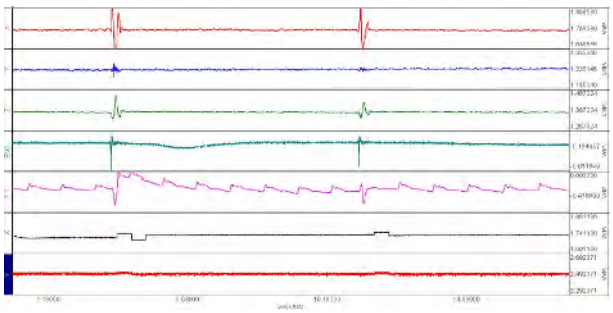
Fig. 1 Developed analog circuit and experimental setting

electromyogram signal which was amplified 1000 times. And the Pressure Sensor 1451(Measurement Specialties Inc, USA), which can measure the absolute pressure with superior linearity, was used to measure a pulse waveform. Biopac UIM module and MP150 module were used for the signal acquisition, and the total number of channels was seven, that is, three for the accelerometer, two for tilt sensor, one for electromyogram sensor, and one for the pulse waveform signal sensor. The developed analog circuit and experimental setting for moving artifact detection is shown in Fig. 1.

B. Experiments and results

With the proposed system for removing moving artifacts, the characteristics of the signals was observed for three movement patterns including extension, flexion, and rotation, and for low-frequency and high-frequency moving artifacts. The sensors attached near to the left hand of the subject are as shown in Fig. 2. The X axis of the accelerometer was attached to -y axis of the local coordinates, Y axis to -x, and Z axis to -z, and X axis of the tilt sensor was attached to z axis of the local coordinate, Y axis to x axis. The pulse waveform sensor was put to -z direction, and EMG electrode was attached near to the brachioradialis muscle.



(1) accelerometer (2) tilt sensor (3) pressure sensor (4) EMG electrode

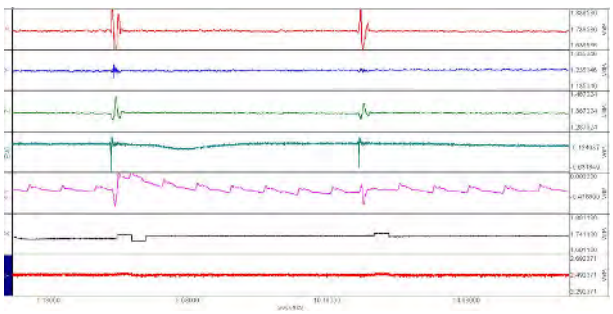


Fig. 2 Developed analog circuit and experimental setting

For the Z axis of the accelerometer, downward squared waveform was observed for the extension move, and relatively smaller upward squared waveform was observed for the flexion move since the wrist moving distance of flexion move was shorter than that of extension move. For the rotation move, prominent upward squared waveform was observed from both Y-axis and Z-axis. Electromyogram signal could be observed at the beginning of the all events, but it was hard to extract the differences among the different movement patterns, so it turned out to be not suitable for estimation of the movement. And, the tilt sensor required around 0.5 second of initial settling time, and there was a delay in the response time between the accelerometer signal and electromyogram.

The output signal characteristics for each sensor were observed when high-frequency and low-frequency moving artifacts were generated during the pulse diagnosis. In Fig. 3, an example of sensors' output signals is shown for high-frequency and low-frequency moving artifacts. The first panel is X axis signal of accelerometer, second panel is Y axis signal and third panel is Z axis signal of accelerometer. Electromyogram is shown in fourth panel and pulse pressure signal is shown in fifth panel. The sixth and seventh panel is for X axis and Y axis signal of tilt sensor respectively.

(a) high-frequency moving artifacts

(b) low-frequency moving artifacts

Fig. 3 An example of sensors' outputs for high-frequency and low-frequency moving artifacts

When a high-frequency moving artifacts was generated, with the electromyogram signal as a reference point, the noise in pulse pressure signal continued for around 0.2 seconds. And moving artifacts related response occurred in the electromyogram signal, the accelerometer signal and the tilt sensor signal sequentially. And also it was found that it took around 1.5 seconds to get the stabilized pulse waveform after moving artifacts response in the electromyogram signal ended. For low-frequency moving artifacts, the moving artifacts were detected first in the electromyogram signal, the accelerometer signal, and then tilt sensor signal. It took about 2 seconds to get the stable pulse waveform from the moment the muscle contraction stops.

From these results, it was confirmed that the suggested moving artifacts detection system comprising accelerometer, electromyogram, and tilt sensor could detect both low-frequency and high-frequency moving artifacts successfully.

C. Detection logic rules

The logic rules to detect the moving artifacts with suggested system comprising accelerometer, electromyogram amplifier, and tilt sensor based on the experimental results are summarized in Table 1. Every rule can be implemented by some simple equations – summation, square, differential and integration so that moving artifacts detection algorithm is expected to be embedded into the system easily.

Table 1 Summarized detection rules

# of rules	Description
1	It is considered that a moving artifact happens in the accelerometer only when a moving artifact is detected on at least one of X, Y, and Z axis signals.
2	It is considered that a moving artifact happens in electromyogram signal only when high impulse or muscle contraction is detected.
3	It is considered that a moving artifact happens in tilt sensor only when it is found on more than one of X and Y axis.
4	It is confirmed that a moving artifact occurs when moving artifacts happen in more than two sensors among the accelerometer, electromyogram, and tilt sensor.
5	The end point of the moving artifact for the total system is 2 seconds past the end of moving artifacts in electromyogram if the a moving artifact was found in electromyogram. If the moving artifact was not found in the electromyogram, then the end of the moving artifact in tilt sensor will be the end point of artifact of the system.

III. Conclusions

One of the most important parameters in radial pulse waveform is the magnitude of pulse pressure and it is very susceptible to the moving artifact. This paper presented a moving artifacts detection system configuration and an algorithm to detect moving artifacts.

The moving artifacts detection system comprises three-axis accelerometer, electromyogram, and two-axis tilt sensor. With the pulse waveform sensor placed on the pulse measurement position, the output signals' characteristics form each sensor by moving artifacts were reviewed. Based on these observations, the rules were set to detect the moving artifacts, and a detection algorithm was proposed. Applying the system to the pulse diagnosis system will improve the quality and reliability of the data, and it is expected to be possible to collect the data even in u-Healthcare environment where the system is greatly exposed to the moving artifacts like a wearable pulse diagnosis machine.

A Real-time Interactive Editor for 3D Image Registration

T. McPhail[1] and J. Warren[1]

[1] Rice University/Computer Science Department, Houston, TX, United States

Abstract — **Creating deformations between 3D volumes has received attention in areas such as animation, fluid dynamics, and medical imaging. Volume data often represents some anatomical structure or fluid which moves in a smooth, continuous manner. Particularly in the medical imaging community, there have been a number of attempts to automatically compute these smooth deformations between successive volume data sets, however due to the considerable amount of imaging artifacts, manual deformation methods are often required. There have been several human-assisted systems that facilitate manual deformation of volumetric data, however, they either do not facilitate real-time interaction from a user, or are too cumbersome for substantially large data sets. We present an interactive tool for creating and validating high-quality point-based and coordinate frame-based deformations. At its core, there is a visualization framework interactively renders deformed volumes and visually assesses the quality of deformations as volumes are manipulated.**

Keywords — **Volume Visualization, Deformation, Biomedical Imaging, Hardware Rendering.**

I. Introduction

Image deformation of volumetric data has many applications in medical imaging, image matching, fluid dynamics, and animation. Many standard approaches in these areas utilize automatic methods to generate deformations between sequences of images. However, automatically finding deformations for relatively noise-free images is an NP-complete problem [1, 2] because any algorithm can fall into local minima (see figure 1). The performance of such methods is worsened by the introduction of noisy images.

In radiation oncology, doctors are developing methods for determining the healthiness of human lungs from properties of the deformations between pairs of 3D computed tomography (CT) images. During the acquisition of these images, substantial imaging artifacts can be generated due to ct gating error [3] (see figure 3). Gating noise introduces features in one image that are not present in the next image, which makes automatic deformation an even harder problem.

In fields such as oncology, extremely high-quality deformations are needed, and ultimately assessed by humans for quality assurance. For this reason, we have chosen to create semi-automatic methods and tools to aid humans in generating and validating deformations. Ideally, we want to create an interactive environment that 1) interactively generates volume deformations and 2) gives real-time feedback for quality assurance.

A. Related Work

Substantial progress has been made in the area of volume visualization [4, 5, 6] However, the problem of integrating volume manipulation and visualization needs more attention. Systems for manipulating and visualizing volume data are either too cumbersome or non-intuitive for the user, and/or suffer from a lack of real-time interaction.

[7, 8] present techniques for generating volume deformations using skeletons and methods based on tradition skeletal animation. This work is intuitive for data which represent objects with rigid skeletal structure, but limits its effectiveness on a wider class of images. Both works do not have real-time capabilities. [8] shows results for near interactive performance, however, we desire a real-time solution.

[9, 10] have deformation frameworks that allow users to establish static correspondences between sets of landmarks for pairs of images, and induces deformations based on these correspondences. These environments have sub-real-time performance and use static landmark correspondences, not allowing users to manipulate these correspondences interactively. [11] provides one of the first true interactive volume deformation environments. The controlling handles for this tool are curved wires which limit its effectiveness much like [8]. Additionally, this environment only deforms a source image and does no comparison to a target image. It is also not clear if this method can generate the high-quality deformations needed for our purposes while maintaining interactive speeds.

B. Volume Deformation

Substantial work has also been done in the realm of volume deformation. Automatic deformation methods based on conservation of energy equations such as Optical Flow [12] and modified versions such as Compressible Combined Local Global registration [13] are extensively used in the medical fields. These methods are computationally intensive, having run-times on the order of hours depending on the size of deforming volume. Also, while these methods are theoretically sound, flow methods suffer from noise from real-world data which can yield unrealistic results (see figure 2).

Grid-based methods require the generation of a controlling grid which can be cumbersome to generate. For example, free-form deformations require an alignment of a lattice of control points with features in an image to generate C2 deformations using bivariate cubic splines. For 3D images, finite element methods require the generation of a tetrahedral mesh which can be time-intensive. This class of methods is typically not well-suited for fast interaction which is needed for the purposes of our framework.

Due to their performance and intuitive manipulation, we use several techniques that can be organized in a manner similar to Shepard interpolants (i.e. $f(v) = \sum \alpha_i w_i \cdot q_i$). Due to the methods' simple structure, the CPU can process these deformations in real-time for data with a reasonable set of control handles, p_i (e.g. $200 < |p_i| < 700$).

C. Contribution and Overview

We provide an intuitive environment for generating and validating 3D deformations between pairs of volume data images. In order to deform volumes, we provide two existing point-based methods and create a new frame-based method for generating deformations between pairs of subsequent images, S and T. To aid in user control, our system automatically finds a set of landmarks in S and their corresponding displacements and frames in T. Our main contribution is a rendering framework that facilitates interactive feature based deformations. At its core, we sample deformations on a uniform grid. This sampled deformation is stored as a RGB texture. We then use the synthesized texture to sample the respective volume data using conventional volume rendering techniques. This framework also provides real-time validation of the quality of the generated deformations.

The structure of the rest of the paper is as followed:

- Controlling and generating deformations (section 2 and 3)
- Volume rendering and our rendering framework (section 4)
- Implementation results and conclusion (sections 5 and 6)

II. Controlling Deformation

Our application provides a set of methods that generate deformations between pairs of input images. We first discuss generating control handles and establishing their correspondences between the two input images.

A. Handle Selection

Given a pair of 3D images, *S* and *T*, there are many techniques for producing deformations from *S* to *T*. A straightforward approach is to manually assign a displacement for each voxel in *S* (A displacement for a voxel *v* is the vector $d_v = f(v) - v$, where *f* is our deforming function). This approach is extremely accurate; however, manually producing displacements for each voxel in a 3D image is impractical for even moderate sized data. A more reasonable approach is to establish displacements for a subset of the voxels in *S* (300-500 voxels) and then create a mathematical function that blends these displacements to generate a deformation for all voxels in *S*. Even with this more tractable approach, the amount of work required can still be substantial. For this reason we have developed a computer-aided approach to select handles in a source image and setting the displacements of these handles in a target image.

We now consider the selection of handles that will control the deformation from a source image to a target image. We shall treat our source and target images as functions $S, T : \mathrm{N}^3 \mapsto \mathrm{N}$. Desirable control handles lie on features that are distinguishable in an image. These features lie on discontinuities, or edges of the images. To exploit this fact, we create $\widetilde{S} = \Omega * S$ and $\widetilde{T} = \Omega * T$ where $(*)$ is convolution and $\Omega : \mathrm{N}^3 \mapsto \mathrm{N}$ is a Sobel operator. We then generate $\hat{S} = | S - \widetilde{S} |$ and $\hat{S} = | S - \widetilde{S} |$ to enhance the edges of *S* and *T* respectively. From this enhanced image, we generate a set of control handles by repeatedly finding the brightest voxel in the image and blackening a ball of user-specified radius around the selected voxel. The resulting set of handles corresponds to the strongest features in the image.

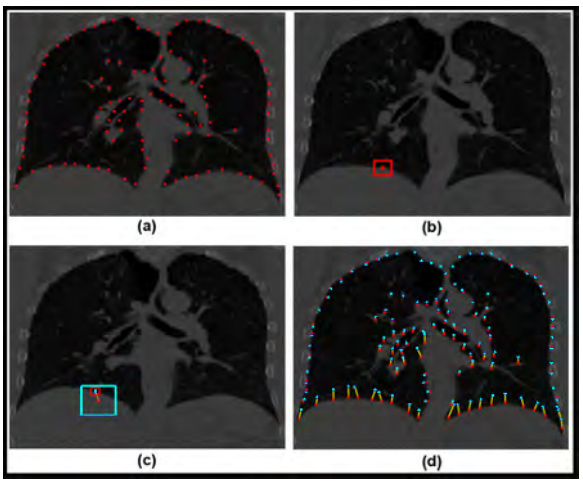

Fig. 4 Depiction of the automatic handle selection and correspondence process. (a)Source image with control handles. (b-c) Search for correspondence for a control handle, (d) Correspondences for all of the handles.

B. Handle Correspondences

We now wish to establish correspondences for our control handles between pairs of images. Using *S* and *T* as previously mentioned and given corresponding handles p_i and q_i, we generate 3D sub-windows, W_S and W_T centered about p_i and q_i respectively.

$$C[x,y,z] = \sum_i \sum_j \sum_k W_T[i,j,k] W_S[x+i-\alpha, y+j-\beta, z+k-\gamma] \tag{1}$$

The voxel location of the maximal value in *C* represents the best displacement so that W_S locally matches a window in *T* of the same size. However, there is no guarantee of a unique global maximum for *C*, so we create the function $\hat{C}$ that penalizes voxels that are far away from the control handle.

$$\hat{C}[x,y,z] = C[x,y,z] - \alpha \,|\, (x,y,z) = (p_{ix}, p_{iy}, p_{iz}) \,| \tag{2}$$

where (p_{ix}, p_{iy}, p_{iz}) is the location of the handle we are investigating. It should be noted that the size of W_T is substantially larger than that of W_S. This enables our editor to compare the local neighborhood of a handle in a source image, and find the best match within the target image. For more accurate correspondences, we iterate this process several times. During every successive iteration, each new target window W_T is centered at the corresponding match from the previous iteration. We also use the final correspondences to establish the best affine transformation centered at each control handle which is used by our frame-based deformation technique (the best affine transformation is explained in section 3).

III. Deformation Techniques

We now discuss building deformations using a set of controlling handles, either of the form of points or coordinate frames. We treat a 3D deformation as a function that maps points in a source volume to points in a target volume.

Imagine a set of control handles p_i associated with S that are moved to q_i associated with T. Now in order for a deformation function, f, to provide meaningful results there are several properties that the deformation must satisfy:

- Smoothness: f should smoothly deform the volume
- Identity: If $\forall_i p_i = q_i$, then $\forall_v v = f(v)$
- Interpolation or Approximation: Either $f(p_i) = q_i$ or $| f(p_i) - q_i | < \varepsilon$.

In order to generate real-time deformations, our framework assumes that the handles for the source image are fixed at the time the deformations are generated. We exploit this property and precompute information to facilitate real-time manipulation. If a user alters the source handles, the real-time deformation computation is halted due to the necessary precomputations (we quantify the performance delay in section 5). The intended use of our editor is to manipulate q_i in order to take advantage of the real-time capabilities of our deformation methods.

All of our techniques reduce the deformation of a voxel to the form: $f(v) = \sum \alpha_i q_i$. Here f is the deformation function, α_i are scalar coefficients, and q_i are the displaced handles in the target image. Expressing deformations as a weighted combination of the deformed control handles is the key feature that allows our application to compute deformations in real-time.

A. Thin Plate Splines

We move to the use of thin-plate splines to generate deformations from image S to T. We will proceed with a brief description of the theory behind thin-plate splines [14]. For a more in depth look into thin-plate splines, refer to [14]. A d-dimensional thin-plate spline is the fundamental solution to the biharmonic equation with the form

$$f(v) = U(r) = r^2 \ln r \tag{3}$$

where $v \in \Re^d$ and $r = | v |$. At the root of thin-plate spline theory is the physical notion of bending a thin sheet of metal represented by lofting $U(\{x, y\})$ over the xy-plane. Here the physical lifting is orthogonal to the plane. To apply thin plate splines to the problem of interpolating scattered control points, one treats the lifting of the plate as the actual displacements of the individual components of the control points. We now wish to generate a function $f(x, y, z)$, comprised of scaled translates of our thin-plate spline basis function $\hat{f}$, such that $f(x, y, z)$ minimizes the bending energy given by

$$\iiint_{\Re^3} f_{xx}^2 + f_{yy}^2 + f_{zz}^2 + 2(f_{xy}^2 + f_{xz}^2 + f_{yz}^2) dx\, dy\, | \tag{4}$$

The thin-plate algorithm reduces to a system of linear equations that are directly solved in [14]. We slightly reorganize the approach in [14] to generate a deformation of the form $f(v) = \sum \alpha_i q_i$.

B. Moving Least Squares Deformation

Next, we discuss generating a deformation from S to T using an affine moving least squares approach controlled by control points [15]. Now given a voxel v in S, we want to find the best affine transformation, A_v, which minimizes

$$\sum_i w_i \, | A_v(p_i) - q_i |^2 \tag{5}$$

Here, p_i and q_i are the control points in $\Re^3$ and w_i is either $w_{i_{\text{int}erp}} = \frac{1}{|p_i - v|^{2\alpha}}$ or $w_{i_{approx}} = \frac{1}{|p_i - v|^{2\alpha} + \varepsilon}$ where $\varepsilon > 0$.

With this approach our deformation function becomes $f(\{x, y, z\}) = A_v(\{x, y, z\})$. For brevity, we proceed to a closed form solution for this minimization problem. For a complete derivation of this method, refer to [15]. After manipulation, we can rewrite the minimization problem in equation 5 as

$$\sum_i w_i \, | \hat{p}_i M - \hat{q}_i |^2 \tag{6}$$

Here $p_* = \frac{\sum_i w_i p_i}{\sum_i w_i}$ and $q_* = \frac{\sum_i w_i q_i}{\sum_i w_i}$ are weighted centroids.

After using the classical normal equation solution to determine the minimizing M, we can rewrite our deformation function as $f_v(\{x, y, z\}) = \sum_j \alpha_j q_j$. Here α_j is determined by

$$\alpha_j = \Lambda_j + \frac{w_j (1 - \Lambda_j)}{\sum w_k k} \tag{7}$$

and Λ_j is a scalar that can be determined by

$$\Lambda_j = (x - p_*)(\sum_i \hat{p}_i^T w_i \hat{p}_i)^{-1} w_j \hat{p}_j^T \tag{8}$$

Observe that although the points q_i can change, the points p_i are fixed and allow Λ_j being precomputed. Thus, we can predetermine α_j reducing our deformation function f to a summation of scalar multiples of the points, q_i.

C. Frame-based Moving Least Squares Deformation

We now extend this moving least squares framework to generate deformations by manipulating coordinate frames as opposed to control points. Let the set of coordinate frames in our source image, $\{p_{ix}, p_{iy}, p_{iz}\}$ and their corresponding

matches in $\{q_{ix}, q_{iy}, q_{iz}\}$. Here, $\{p_{ix}, p_{iy}, p_{iz}\}$ and $\{q_{ix}, q_{iy}, q_{iz}\}$ are the local origins, x-vectors, and y-vectors for the respective coordinate frames. Now given a voxel v in our source image, we want to find the best affine transformation, A_v, which minimizes a modified version of equation 5

$$\sum_i w_i \mid A_v(p_i) - q_i \mid^2 + \beta(\mid p_{ix}M - q_{ix} \mid^2 + \mid p_{iy}M - q_{iy} \mid^2) \quad (9)$$

where β is a scalar which regulates the influence of the vector constraints in our new minimization problem. Note that $\beta = 0$ reduces our expression to equation 5.

As before, we define our deformation function $f_v(\{x,y,z\}) = \sum_j A_v(\{x,y,z\})$. Observe that after expanding the quadratic represented by equation 9, we have an expression that is quadratic in *T* and has no new terms involving *T*. This enables us to use the same solution for *T* in terms of M described in [15]. Substituting *T* in equation 9 allows the minimization problem to be expressed as

$$\sum_i w_i \mid \hat{p}_i M - \hat{q}_i \mid^2 + \beta(\mid p_{ix}M - q_{ix} \mid^2 + \mid p_{iy}M - q_{iy} \mid^2) \quad (10)$$

As in the previous moving least squares method, we use the normal equation solution to find the *M* that minimizes equation 10

$$M = \underbrace{(\sum_i \hat{p}_i^T w_i \hat{p}_i + \beta(\hat{p}_{ix}^T w_i \hat{p}_{ix} + \hat{p}_{iy}^T w_i \hat{p}_{iy})^{-1}}_{M_*}$$
$$\sum_j w_j (\hat{p}_j^T \hat{q}_j + \beta(\hat{p}_{jx}^T \hat{q}_{jx} + \hat{p}_{jy}^T \hat{q}_{jy}))$$

With our closed-form solution for *M*, we can now write a simple expression for our deformation function $f_v(\{x,y,z\})$.

$$f_v(\{x,y,z\}) = \sum_j \alpha_j q_j + \Lambda_{jx} q_{jx} + \Lambda_{jy} q_{jy} \quad (11)$$

where Λ_{jx} , Λ_{jy} and α_j are precomputed scalars determined by

$$\Lambda_j = (x - p_*) M_* \hat{p}_j^T$$
$$\Lambda_{jx} = \{1,0,0\} M_* \hat{p}_{jx}^T$$
$$\Lambda_{jy} = \{0,1,0\} M_* \hat{p}_{jy}^T$$
$$\alpha_j = \Lambda_j + \frac{w_j(1-\Lambda_j)}{\sum_k w_k}$$

Note the constant vectors, $\{1,0,0\}$ and $\{0,1,0\}$, which constrains our source handles to be axis aligned.

IV. Visualization and Quality Validation

We will begin with an overview of volume rendering followed by our specific methodology for visualizing the source and target images. We then discuss the methodology of our rendering framework.

A. Volume Rendering

Volumes are typically viewed either by extracting isosurfaces in the form of surface meshes or by directly rendering the volume. Contouring algorithms such as marching cubes [16] or dual-contouring [17] are used to create surfaces from volume data; however, this approach is not well suited for viewing interior information. One of the more widespread class direct volume rendering methods is texture-based methods [4, 5, 6].

In texture-based methods, volume data is commonly represented as a regular grid of values that sample a function (e.g. a scalar field $\tilde{V}: \Re^3 \mapsto \Re$). This data is treated as a texture $\tilde{V}: [0,1]^3 \mapsto [0,1]$ and stored on a graphics card. With this texture information, the standard approach to visualizing the volume requires the generation of a dense sequence of planes parallel to the image plane and intersecting them with the unit cube $[0,1]^3$. The intersections are treated as polygons with the texture coordinates of each vertex being equal to its position (i.e. $tex(\{x,y,z\}) = \{x,y,z\}$). These polygons are processed by a simple vertex shader and the texels of these polygons are processed by a transfer function implemented on a pixel shader.

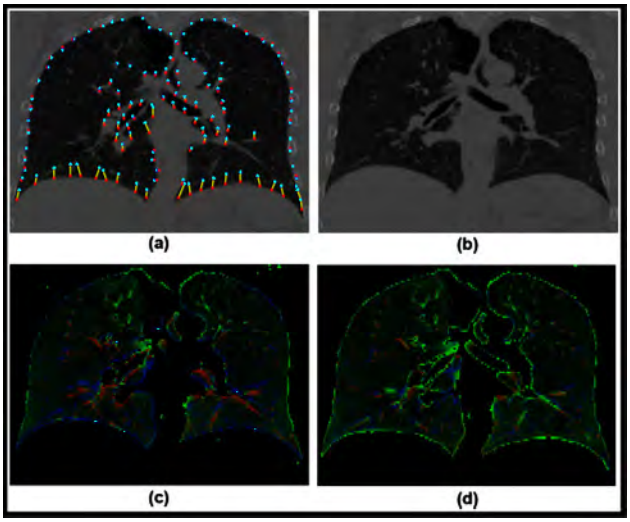

Fig. 6 2D depiction of the quality assessment feature of our application. (a)Source image with control handles and displacements. (b)Target image. (c)Comparison of *S* and *T*. (d) Comparison of *S* and $f^1(T)$ (Note the number of blue or red areas is lessened and major features are better matched than in (c).

Viewing deformed volumes imposes an additional challenge. With present hardware capabilities, real-time calculation of deformed volume sets is not feasible. However, using our feature-based techniques, interactively sampling the deformation on coarser grids is achievable.

B. Rendering Framework

We now discuss our methodologies for the rendering framework. In order to have an effective tool for validating and generating deformed images, a user should be able to:

- View subvolumes around corresponding control handle in order to asses the quality of the displacements (used for generating deformations).
- Visually determine the global quality of the deformed target volume (generated by our framework) with respect to the undeformed source volume.

We accomplish this by synthesizing a texture coordinate space on a uniform grid embedded in the unit cube. The sampled texture coordinates from the grid are encoded as a RGB texture and passed to the GPU. Using a sweeping algorithm (see [18]), we create a set of planes that intersect the cube from front to back. Next, the vertex shader generates texture coordinates equal to the vertex position of the rendered polygons (i.e. $tex(\{x,y,z\}) = \{x,y,z\}$). As the graphics card processes a polygon, the pixel shader fetches the synthesized texture coordinate that corresponds to the incoming fragment. Using this synthesized texture coordinate, the pixel shader then samples the data being visualized.

$$(u_S, v_S, w_S) = tex(\Omega_S, (x,y,z))$$
$$(u_T, v_T, w_T) = tex(\Omega_T, (x,y,z))$$
$$i_S = tex(S, (u_S, v_S, w_S))$$
$$i_T = tex(T, (u_T, v_T, w_T))$$

if $i_S \neq 0 \wedge i_T \neq 0$ *then*
$$\gamma = \min(i_S, i_T)$$
$$col.rgb = (i_S - \gamma, 2\gamma, i_T - \gamma)$$
$$col.a = (i_S + i_T - i_S \cdot i_T)$$
return $col \cdot \beta$
return (0, 0, 0, 0)

Fig. 7 Pseudocode for our quality assessment pixel shader.

C. Local Comparison of Correspondences

Now consider locally comparing the handle correspondences used in our deformation methods. Our goal is to overlay a sub-cube, $Cube_{source}$, of the source image centered at the source handle and a sub-cube, $Cube_{target}$, of the target image centered at the target handle. Assume the dimensions of $Cube_{source}$ and $Cube_{target}$ are identical. For each node in our uniform grid, we store a texture coordinate in our synthesized target image for $Cube_{target}$ (i.e. $tex(\{x,y,z\}) = A_v(\{x,y,z\})$). Here $A_v(\{x,y,z\})$ is a thin plate spline or best affine transformation for q_i as described in section 3. Afterwards, we perform a normal volume rendering pass for $Cube_{source}$ then using our generated target texture coordinate space, we visualize

$Cube_{target}$ as described in the previous paragraph. This overlays the two sub-cubes around the handles, p_i and q_i, in the same cube.

D. Viewing Deformations

Our last goal is to globally determine the quality of the deformed target image in real-time. In order to exactly view the entire deformed volume, our application would need to store and compute the sum of the scaled control handles for each voxel in the deformed image. Real-time performance for this approach is impractical, even for modestly size data sets. To compensate, we generate an approximation of the deformed image using the rendering framework mentioned earlier.

Data Set	Size	#of handles	Setup Times			Manipulation Times			
			MLS	MLS Frame	TP	MLS	MLS Frame	TP	Frame Rate
CT5	256x256x112	200	1.501	1.703	13.22	0.00062	0.00031	0.00031	69.1
Bunny	512x512x360	125	0.781	0.907	5.13	0.00078	0.00032	0.00032	68.5
Brain	256x256x109	216	1.36	1.563	15.50	0.00063	0.00047	0.00047	69.4
CT5	256x256x112	312	1.969	2.297	35.33	0.00063	0.00047	0.00047	68.9
bunny	512x512x360	343	2.172	2.516	44.11	0.00078	0.00047	0.00047	68.3

When comparing the quality of our deformation, note that producing the image $f(S)$ is not a surjective mapping from *S* to *T*. In light of this, we must compare our source image, *S*, with our deformed image $f^{-1}(T)$. We begin by altering the content of the previously mentioned synthesized target image. At each node in our uniform grid, we now store weights corresponding to each control handle. Now whenever a user moves a handle in the target image, we recompute a deformed texture coordinate for each node in our uniform grid. We then update the synthesized target image with these deformed coordinates and render both

volumes as mentioned in the local comparison section. This results in a trilinear approximation to $f^{-1}(T)$ (see Figure 1.2).

Due to the nature of the deformations, trilinear blending yields high-quality approximations when the grid is sampled to a reasonable resolution. In order to maintain real-time calculations with a dense set of sample points, we exploit the fact that $f(v) = \sum \alpha_i q_i$ to speed up the deformation calculation. Whenever a user selects a pair of handles (p_i, q_i) to alter, we store $\hat{f}(v) = \sum_{j \neq i} \alpha_i q_i$ for each sampled vertex. Storing $\hat{f}(v)$ enables our application to modify the synthesized target coordinate space with a simple multiplication and addition for each node in the grid. To further aid, in the time costs of our method, we only recompute the weights in the grid when the source handles are generated. The necessary precomputations of the weights are on the order of seconds for our provided methods (Results are given in the section 5).

E. Quality Assessment

Manually comparing two overlaid volumes can be a tedious process. In light of this, our framework gives aid in quality validation via a transfer function provided by one of the provided pixel shaders. Transfer functions are ran on fragments from the graphics card and return an rgba color tuple to be outputted for viewing. When assessing the quality of matching volumes, a transfer function should be:

- Symmetric (i.e. $h_{T\ to\ S}(\{x,y,z\}) = h_{S\ to\ T}(\{x,y,z\})$)
- Penalize for divergent values

We provide pseudocode for the transfer function used by our framework (see figure 1.4). As can be seen in line 9 of figure 1.4, the color returned by this function is green if there is a match and either red or blue if either the source or target image has greater intensity at the input location. This function also changes the opacity linearly in regards to the magnitude of the intensity difference between the two volumes at a given texel. The rightmost image in figure 4.2 gives a 3D example of this quality assessment.

V. RESULTS

We performed a series of performance tests to assess the performance of different components of our application. These results were taken on a PC with an Intel(R) Xeon 3.2GHz processor with 4GB RAM and a GeForce 8800 GTX graphics card. We used three test images: CT5 (a ct image of human lung), bunny (a ct ct image of the Stanford bunny), and brain (an mri image of a human brain). In all cases, the grid used to synthesize our textures had dimensions 32*x*32*x*32.

All timing results are measured in seconds except for the frame rate which is measured in frames/sec. From our results, the bottle-neck of our software application is processing the weights for our control handles for our different deformation methods. Of the three methods, our thin-plate spline implementations suffers from large setup times as the number of control handles increase. The other two deforming algorithms based on a moving least squares approach have reasonable setup costs. It should be noted that once the weight computation is complete, the time required to alter the deformations is negligible in comparison to the time needed to render a single volume image. For all of the frame rate measurements, the volume encompassed a 900*x*900 pixel^2 screen area.

VI. Conclusion and future results

We have provided an editor for deforming pairs of 3D images. Our editor automatically generates a set of controlling handles on features within a 3D source image. It determines correspondences for these handles in a subsequent target image. Our application then uses these correspondences to generate deformations via several handle-based methods. Further manipulation of these handles induces change in the generated deformation which is reflected in real-time.

The framework also provides visualization methods for real-time fidelity assessment of local handle correspondences and global deformation matching.

As far as limitations, our tool currently does not model non-smooth motion. For example, our editor could not create a deformation that captured the motion of a brick sliding across another brick. This limitation is due to the smoothness property of the deformations generated by this framework. One way to approach this problem in the future is to give the user the ability to paint, or segment, the various portions of the volumes and tag handles to only affect voxels of particular color. This painting feature would allow for discontinuities to exist on the boundaries of different segmented regions. We would also like to address fill-rate limitations of our rendering framework with new methodologies for empty-space culling. There are existing methods that address this problem [19]; however, these methods do not facilitate our visualization framework. We also want to synthesize finer texture coordinate images (i.e. 64^3vand 128^3 grids), however for moderate data, we would need to use improve the setup times for our deformation methods with parallel computing.

A Novel Headset with a Transmissive PPG Sensor for Heart Rate Measurement

Kunsoo Shin[1], Younho Kim[1], Sanggon Bae[1], Kunkook Park[1], Sookwan Kim[1]

[1] Bio & Health Group, Samsung Advanced Institute of Technology, P.O.Box 111, Suwon 440-600, Korea

Abstract — **In this paper, a headset with an ear-clip type, transmissive PPG (Photo-plethysmography) sensor is presented which allows a continuous and real-time monitoring of the heart rate (HR) whilst listening to music during daily activities. Also, the proposed headset is equipped with a tri-axial accelerometer, which enables the measurement of calorie consumption and step counting. During a variety of daily activities (e.g., walking, jogging, and sleeping etc.), a PPG may be contaminated with motion artifacts. To remove these motion artifacts, we designed an adaptive filter based on the accelerometer.**

To evaluate the accuracy of heart rate detection, for 13 subjects the HR from the headset was compared with that detected from the ECG simultaneously recorded with a conventional ECG recorder. As a result, the error rates of the headset are 0.6%, 1.7%, 0.7%, and 5.7% over rest, walking (3km/h), jogging (6 km/h), and running (9km/h), respectively.

From these results, it is likely that the proposed headset shows the performance good enough to be used in the continuous and real-time monitoring of the HR during daily activities. It is expected that the proposed headset is very efficient in the assessment of autonomic nervous activities under various physiological conditions, the exercise monitoring, and the evaluation of physical training performance.

I. Introduction

The skyrocketing healthcare cost in world-wide due to growth in aging population and chronic diseases will continue to put increased pressure on healthcare systems. In this respect, it is needed an innovative paradigm shift in healthcare system, i.e. connected healthcare, which is a cost effective, efficient and high quality healthcare delivery system. Unlike the conventional healthcare system, which has placed emphasis on a physician-operated and hospital centered "diagnosis and treatment" practice, connected healthcare will pursue a proactive, personalized, and preventive health management, such as the prevention and early detection of chronic diseases and the health promotion. This connected healthcare opens the opportunity to reduce healthcare cost and improve the quality of healthcare by avoiding unnecessary hospitalization and tests for the aged and chronically ill people. In connected healthcare, a core technology is one for continuous, real-time, and long-term monitoring of various vital signs, such as ECG, blood pressure, blood glucose level, respiration, heart rate, etc. It is well known that the heart rate is one of the most important vital signs reflecting the individual health status. That is, the heart rate has recently gained interesting interest in wellness applications, including the sport (providing criteria for an assessment of an athlete's performance and a monitoring of exercise load during exercise) and the fitness (providing a guide of a remedy for lifestyle modification). Also, heart rate variability (HRV) has become a popular noninvasive tool for assessing the influences of autonomous nervous system on cardiovascular control system, which enables us to assess a stress level or an emotional status.

In recent, those increase who listen to the music with MP3 player or cellular phone while taking workout. Thus far, a chest-strip type device has been extensively utilized as a device for continuously monitoring the HR during exercise, which allows a user to get the most out of our training by measuring performance, setting new goals and staying motivated [1]. Meanwhile, PPG devices have attracted significant attention in recent years due to their ease of being integrated into wearable accessories, i.e. a headset, a ring, and a wrist watch. The HR can be measured from PPG signal of which a pulsatile component reflects cardiac synchronous changes in the blood volume with each heart beat. In other words, as the heart pumps out the blood around the body, the volumetric changes of the blood vessels modify the absorption, reflection or scattering of the incident lights, such that the resultant reflective/transmittal lights indicate the timing of the cardiovascular events, such as heart rate.

In this paper, we implemented a wearable headset type of the heart rate monitoring device based on PPG sensing technology and investigated its feasibility as a wearable ambulatory device for continuously and on-line monitoring the heart rate.

II. Method

A. Practical Implementation

Sensor Architecture: Figure 1 illustrates a schematic diagram of the headset which consists of three parts: main body, sensing board, and sensor. The sensor part includes a LED (940 nm, Kodenshi), a Photodiode (Kodenshi) and a

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 519–522, 2009
www.springerlink.com

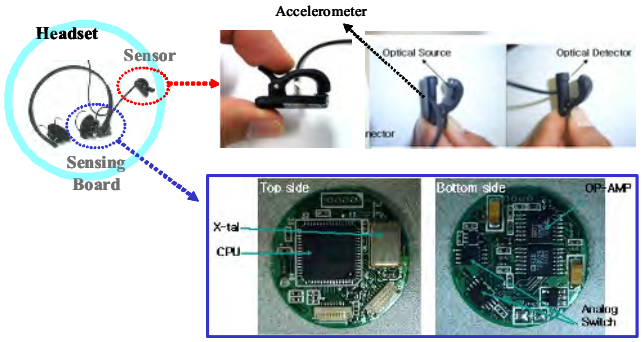

Fig. 1 A schematic diagram of the proposed headset.

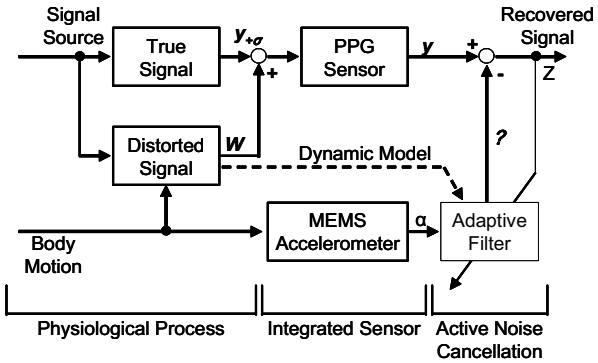

Fig. 3 The block diagram of the proposed ADF.

tri-axial accelerometer (±6g, Kionix). As shown in Fig. 1, by separating the sensor part from the main body, anyone can easily wear it, irrespective of an inter-individual difference in the ear anatomy. Also, the position of the optical sensor does not change significantly when the ear is accelerated because the inertia of the sensor part is very small.

As illustrated in Figure 2, the sensing board consists of a CPU (MSP430), 3 accelerometer inputs (Ax, Ay, Az), a LED driver, I-V converter, 2 sample-and-holder circuits (one is for the ambient light data, the other for the LED), a main amplifier, a high-pass filter (the cutoff frequency is 0.3 Hz), and a low-pass filter (the cutoff frequency is 7 Hz). The CPU controls the LED lighting sequence as well as data acquisition and processing process. The LED driver operates in a pulse mode with a duty cycle of approximately 1/10, i.e., turns the IR LED on and off. It allows to save the power and to remove the influence of ambient light noises. The photodiode current, which is proportional to the amount of light received, is converted into a voltage signal by the I-V converter. And then, the voltage signal is fed into two sample & holder circuits whose timings are synchronized with those when the LED turns on and off. The output signal from a sample-and-holder at the turn-on time of the LED represents ambient light signal. Thus, this ambient light noise can be cancelled by the ambient light removal circuit, in which it was subtracted from the signal at the turn-on time of the LED. After this phase, the continuous PPG signal is finally obtained by filtering with a low-pass filter the quantized signal from the ambient light removal circuit. And then, the resultant signal is fed to the A/D converter port (with 10-bits resolution) which converts it into digital format at the sampling frequency of 64 Hz.

Motion Artifacts cancellation: There is still important motion artifacts, in the PPG signal obtained through a chain of processes mentioned above. Several methods have been proposed to reduce the influence of motion artifacts on a PPG signal [2]. Recently, some studies have addressed that model based techniques showed good performance in optical measurements as compared with other techniques [3]. In this paper, the NLMS (Normalized Lease Mean Squares) method shown in Figure 3 is chosen for real-time processing and computability on mobile CPU. As shown in Figure 3, a reference signal of motion is needed for parametrically modeling the influence of motion artifacts on optical signals. The reference signal used in this model is also recorded with a tri-axial accelerometer. FIR filter parameters are estimated from the motion signals using the normalized least mean square, where the sampling frequency was 64 Hz

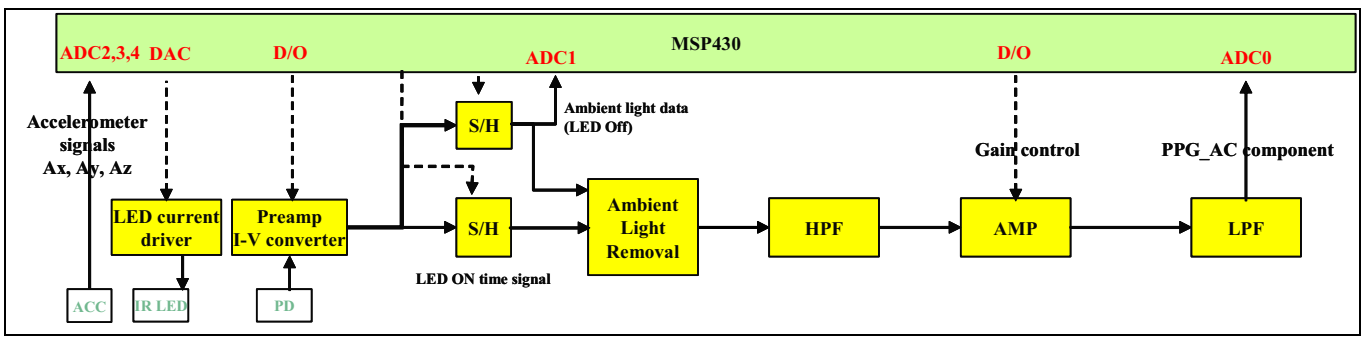

Fig. 2 Functional block diagram of the proposed headset.

and the order of the ADF (Adaptive Filter) was 32. This filtering method allows the efficient removal of only noise components due to movement.

However, the adaptive filtering showed undesirable performance in case the period of a PPG signal is identical to that of the reference signal, which may attribute to the unwanted filtering of the PPG signal with the adaptive filter. To circumvent this problem, an intelligent algorithm is proposed to decide whether or not the ADF will be applied to any segment of PPG signal. Let's define *R(n)* as follows:

$$R(n) = Y(n) / D(n)$$

where

Y(n): the 64-point moving average of the absolute of ADF' output

D(n): the 64-point moving average of the absolute of the PPG data

Then, the ADF will be applied to only segments with *R(n)* being more than a preset threshold (0.5). In the application of this algorithm, on the other hand, it was found that *R(n)* became very small even when the periods of the desired signal and noise signal are different, which results from large noise components relative to the desired PPG signal. To overcome this problem, another parameter (*NW*), called the norm of ADF's coefficients, is introduced, which is calculated as $\sqrt{w_1+w_2+\cdots+w_i}$. Similarly, the ADF filtering will be performed only when the *NW* is below the predetermined threshold.

B. Performance evaluation

Thirteen patients (11 males, 2 females) participated in this study who gave informed written consent after being fully aware of the study protocol and its purpose.

Figure 4 illustrates a typical experimental setup for the feasibility test of the proposed headset as a wearable HR monitoring device. The subjects are first asked to wear the headset and the MP3 player, which is equipped with an ECG measurement module and a BT wireless communication module. And then, they performed exercise test on a treadmill, during which the running speed was increased by 1km/h at an interval of 30 seconds. During each test stage, the PPG signal, 3 accelerometer signals (Ax, Ay, Az), and one-channel ECG signal were continuously recorded, and then transmitted to a host PC via the BT wireless communication module for off-line analysis. To evaluate the performance of the headset as a wearable HR monitor, the HR calculated from the ECG was compared with that obtained from the headset's PPG signal. To facilitate convenient comparison, the signal measured was classified into 4 categories, such as the rest, the walk (from 1km/h to 3km/h), the jogging (from 4km/h to 6km/h) and the run (from 7km/h to 9km/h).

III. Results and Discussion

Figure 5 showed a representative example of a PPG signal, an accelerometer signal (Ax), and an ECG signal recorded with our proposed system. The symbol 'red circle'

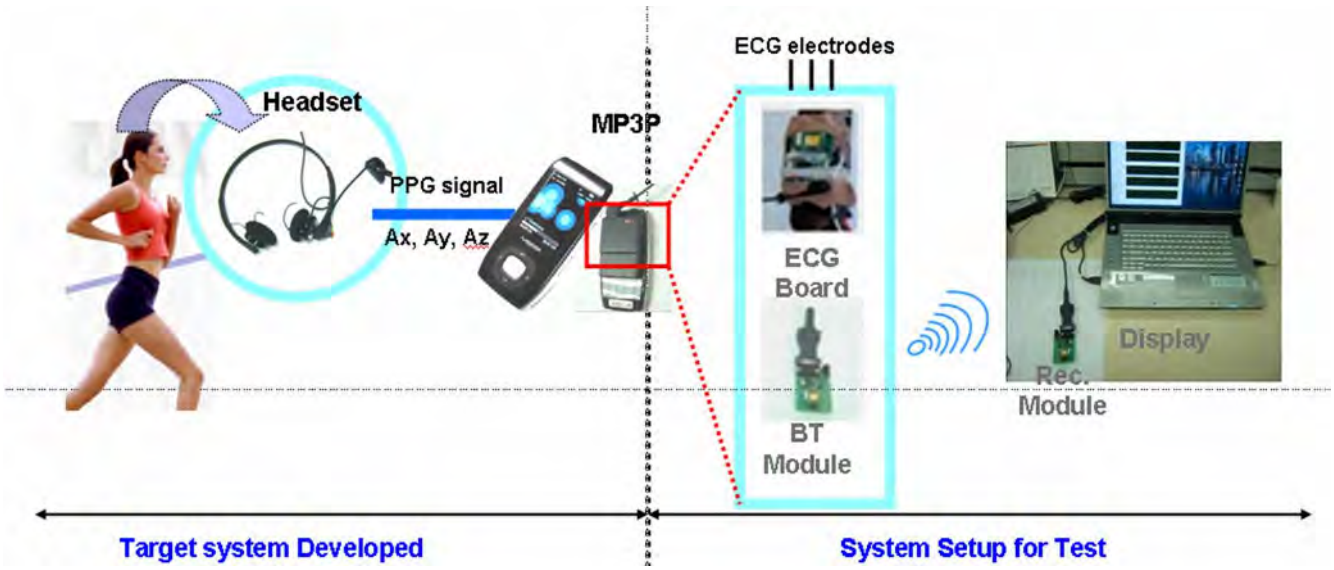

Fig. 4 A typical experimentaö setup of the proposed headset.

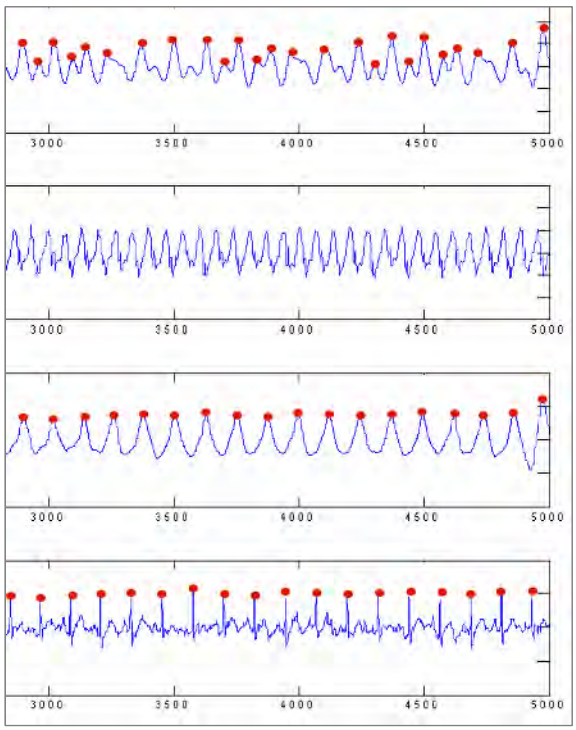

Fig. 5 A representative epochs of various signals recorded with the proposed system.

on traces (a), (c), and (d) in figure 5 represents the R-peak detected. The peak detection algorithm was implemented by a slight modification of an existing peak detection algorithm. In the preprocessed PPG signal (a), which is contaminated with motion artifacts of figure 5(b), the peak-detection algorithm led to erroneous HR measurement. As shown in Figure 5(c), where the motion artifacts were removed with the ADF, the peaks were accurately detected by it. As it were, those peaks accurately corresponded to those on ECG trace (Figure 5(d)).

Figure 6 depicted another example of various signals recorded with the proposed headset. From (c) in figure 6, it was observed that the output of the ADF was largely corrupted. It might attribute to the fact that the period of the PPG signal is identical to that of the reference signal.

To evaluate the accuracy of heart rate detection, for 13 subjects the HR from the headset was compared with that detected from the ECG simultaneously recorded with a conventional ECG recorder. As a result, the error rates of the headset are 0.6%, 1.7%, 0.7%, and 5.7% over rest, walking (3km/h), jogging (6 km/h), and running (9km/h), respectively.

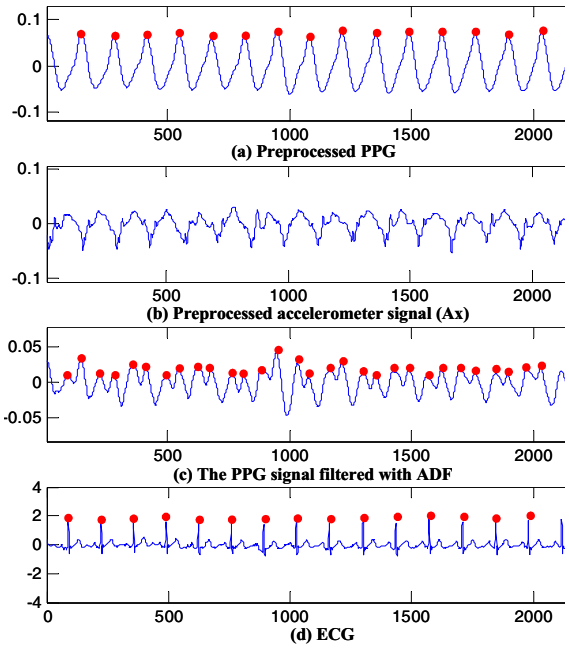

Fig. 6 A representative epochs of various signals recorded with the proposed system.

IV. Conclusions

This paper presented a novel, wearable heart activity monitor (WHAM) which allows the continuous and on-line monitoring of a user's HR. Our results indicated that the headset has enough potential for a wearable, ambulatory HR monitoring device. It is expected that the headset proposed is very efficient in the assessment of autonomic nervous activities under various physiological conditions, the exercise monitoring, and the evaluation of physical training performance

Improvement on Signal Strength Detection of Radio Imaging Method for Biomedical Application

I. Hieda[1] and K.C. Nam[2]

[1] National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba-city, Japan
[2] Korea Electrotechnology Research Institute (KERI), Ahnsan-city, Korea

Abstract — **The authors were applying Radio Imaging Method (RIM) to measurement of the living human body that was originally developed for geological measurement. Small antenna was used to measure electric field intensity changes effectively that was influenced by dielectric material, such as the living body. Experiments were performed with high frequency electric field, such as 50MHz. Water tank was used as phantom of human organ because permittivity of some human organ was as high as that of water. Some problems should be settled that related to the principle and technology. One of the drawbacks was insufficient change of signal strength. When a water tank of 6 x 8 x 25cm was used as a phantom of relatively large human organ, provided signal strength change was approximately 1dB. It only affected lower three bits of 12bit A/D converter instrumented for the experiment. To improve the total resolution, the measurements had been repeated ten to forty times, and the acquired data had been averaged. By improving accuracy of single measurement, the number of trials could be decreased and it was essential for practical systems. In this paper, a new measurement method was introduced. Two plate electrodes of transmission antenna were located side by side, and fed opposed phases to cancel electric field intensity at the receiving antenna that was located 30 cm from the transmission antenna. When dielectric material was located in the measurement field, it broke the balance of electric field, and signal strength change was detected. Because base signal intensity was virtually zero, better resolution was expected than the basic method. The method was tested both by simulation and by experiment. Advantages and disadvantages were discussed based on the results.**

Keywords — **Radio Imaging Method, electric field, biomedical measurement, FDTD, Python.**

I. Introduction

Medical equipment that uses electricity and magnetism, well represented by MRI, contributes to medical care and welfare of the human. On the other hand, high-level and large-scaled medical equipment is one of the factors to push up medical and welfare costs. It becomes financial burden of most of the developed countries. In addition, the developing countries have few benefits of these high-level devices. From the point of view, simple and easy equipment for medical care and health care is demanded. The authors are developing electromagnetic measurement method aimed at medical screenings and welfare applications shown in Figure 1 [1-4]. This is simple, safe and economical method.

Experiments were performed using electromagnetic waves in VHF band. Non-metallic (acrylic) water tank filled with water was measured by the method. The relative permittivity of water at room temperature and pressure was approximately 70 that was as high as some human organs, for example, muscles and internal organs because these tissues contained much moisture than other tissues. The tank filled with water was used as a phantom in the study to imitate portion of human body or some organs.

Early studies of the authors showed signal strength increased when the water moved closer to each of transmission or receiving antenna [1-3]. This suggests that the increments of signal strength were not caused by magnetism but by water permittivity influencing electric field intensity. In the recent paper, the fact was backed by experimental results where electric field antennas were used, and by numerical simulation [5] that was called the Finite-Difference Time-Domain (FDTD) Method [6].

One of the drawbacks of the developing method was insufficient level of signal strength changes. When a water tank of 6 x 8 x 25cm was used as a phantom of relatively large human organ, measured signal strength change was

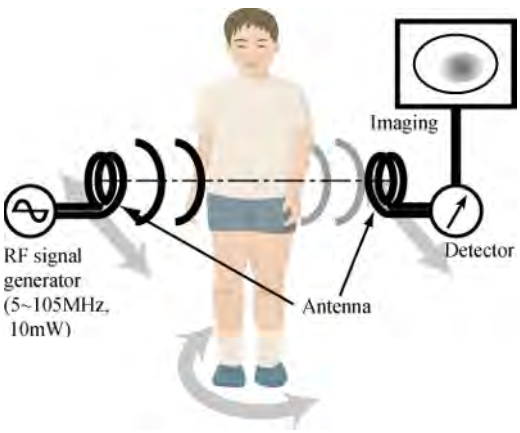

Fig. 1 Conceptual blockdiagram of Radio Imaging Method for medical application.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 523–526, 2009
www.springerlink.com

1dB. It was only acquired as a few effective bits of 12bit A/D converter instrumented for the experiment. At this level of changes, instability of the measurement system could not be ignored. To improve the total resolution, the measurements had been repeated ten to forty times, and the acquired data had been averaged. By improving accuracy of single measurement, the number of trials could be decreased and it was essential for practical systems.

In this paper, a new measurement method was introduced. Two plate electrodes of transmission antennas were placed side by side, and fed opposed phases to cancel electric field intensity at the receiving antenna. When dielectric material was located in the measurement field, it broke the balance of electric field, so that signal strength change was detected. Because base signal intensity was cancelled and it was virtually zero, better resolution was expected than the basic method that had certain level of base signal strength.

II. Methods

A. Experiments

Figure 2 showed overview of the experiments. Transmission and receiving antennas were located 300mm apart. Figure 3 showed two types of antennas. Type A was always used for receiving antenna. Type A and B were used for transmission antenna alternatively.

Two series of measurement were performed for the two types of transmission antenna, respectively. To obtain two-dimensional characteristics, a tall water tank whose dimension was 20 x 60 x 250 mm, shown in Figure 2, was used as phantom and it was moved on a 670 x 200 mm (650 x 140 mm movable area) horizontal plane laid between the antennas. The water tank was driven along paths in the Y-axis direction.

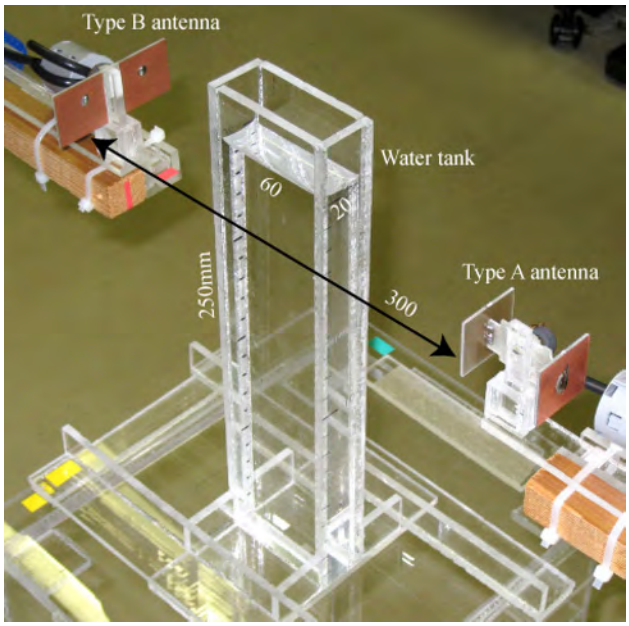

Fig. 2 Overview of the experiment.

Electric field intensity was measured as signal strength by a spectrum analyzer (Anritsu MS2621B) at every 1cm position of the water tank. It was measured forty times per position and the averages were calculated.

In the experiments, 10 mW of power at 50 MHz was fed from RF generator build in the spectrum analyzer to the transmission antenna. Because the antenna did not match the characteristic impedance of the coaxial cable, 50 ohm, the less power was actually transmitted.

B. FDTD Simulation

The Finite-Difference Time-Domain Method (FDTD) was employed to confirm the electromagnetic field changes [6]. The authors used Python script [7,8] that implemented the Uniaxial Perfectly Matched Layer (UPML) Method .for the boundary condition to prevent reflections [6, 7].

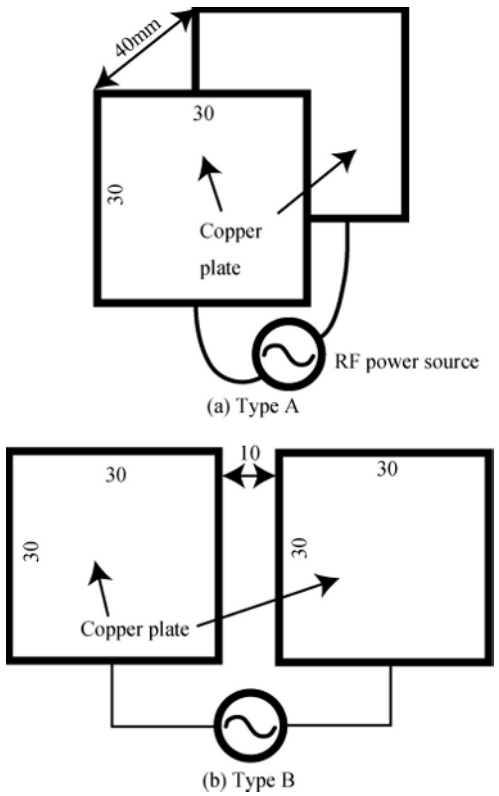

Fig. 3 Schematic diagram of two types of electric field dipole antennas.

The dimension of the simulation space was 860 x 560 x 560 mm and it was meshed in 86 x 56 x 56 square elements so that each square element had 10mm long sides. The simulated water tank had the same dimension as the experiment; however, it had no wall for simplification. The region occupied by the water tank had the relative permittivity of 70. The water tank was moved in the simulation space according to the experimental conditions and electric field intensity was calculated for each water tank position.

Another difference of the conditions between simulation and experiment was the thicknesses of antenna plates. Antennas used for the experiment were made of copper films on printed circuit board that was 0.035mm thick. For the simulation, electrodes were 10mm thick because of the square element dimension. The electric field dipole antenna mainly excited electric field between the two plates; therefore, notable effect caused by thickness of the plates was not expected.

III. Results and Discussion

Figures 4 and 5 showed results of the experiment and simulation, respectively. X- and Y-axes indicated water tank position. The lines where ***x=0*** and ***x=14*** were the water tank paths closest to the receiving and transmission antennas, respectively. In each figure, the upper figure (a) showed results where Type A antenna was used for the transmission antenna, and the lower figure (b) showed results where Type B antenna was used. Type A antenna was always used for the receiving antenna.

In Figure 4, forty measurements were averaged that were performed per water tank position. Z-axis indicated relative signal changes in percentage to base signal strength where no water tank was located in the measurement field.

The simulation results were also relative signal changes in percentage to the electric field intensity without water tank that was shown in Figure 5.

Generally, Figures 4(a) and 5(a) had common characteristics. When water tanks were located on the centerline

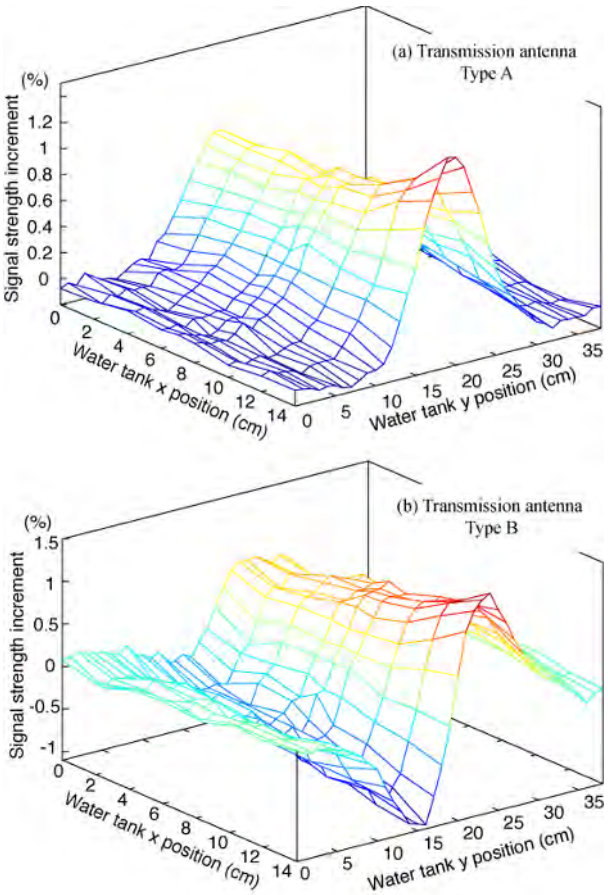

Fig. 4 Measured signal strength changes according to water tank location.

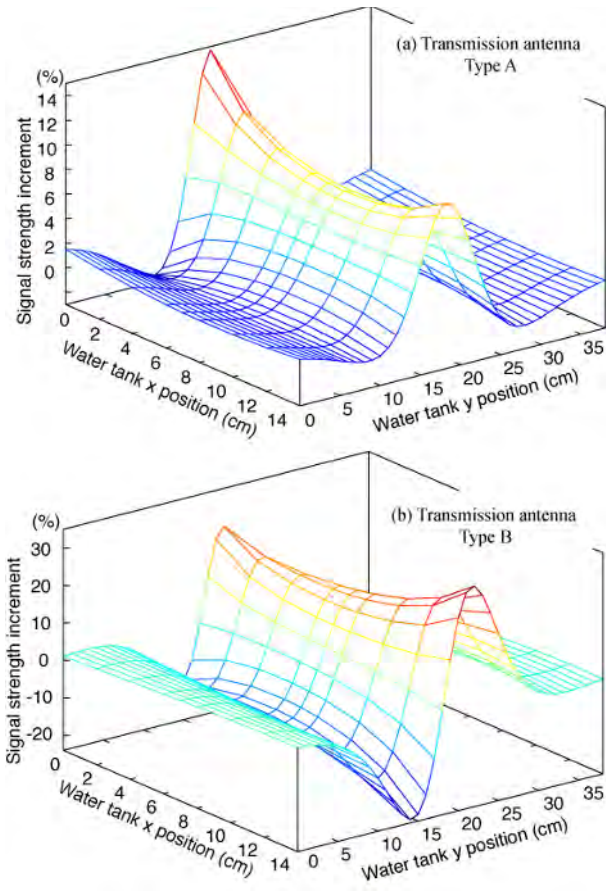

Fig. 5 Simulated signal strength changes according to water tank location.

between transmissions and receiving antennas (***y=18***), signal strength had peaks that formed ridges between the two antennas. The peaks were minimized where water tank was at the center of the centerline (***x=7***, ***y=18***). However, peak heights closest to the antennas didn't have common relative tendency in the two figures.

These qualitative characteristics corresponded to the results of experiments where electric field dipole antennas and loop antennas were used, and to the FDTD simulation that were reported in the authors' previous paper [5].

Figures 4(b) and 5(b), where Type B antenna was used for transmission antenna, corresponded to each other, too. Because two electrodes of Type B antenna were excited 180-degree different phase voltages and the distances from the two electrodes to the receiving antenna were the same, electric field intensity at the receiving antenna was expected to be cancelled when no water tank was located. If the water tank was on the centerline between transmission and receiving antennas (***y=18***), electric field intensity could be cancelled, too. However, Figure 4(b) showed the electric field intensity was not cancelled even if the water tank was centered. When water tank moved a few centimeters forward along Y-axis, the balance was broken more and signal strength increased. On the other hand, the signal strength had minimum points at few centimeters backward along Y-axis from the center. The balance was compensated by the water location.

Interestingly, Figure 5(b) had the same tendency as Figure 4(b). The simulation was expected to have null electric field intensity at receiving point. This result suggests the balance was delicate, and that possible rounding errors and anisotropy of the algorithm caused the unbalance.

The main purpose of the study was to confirm whether the new method provided more significant signal changes than the conventional method. In Figure 4, the maximum changes were 1.2% and 1.5% for (a) and (b), respectively. Because signal strength decreased 1.0% where ***y=15*** in Figure 4(b), total signal change for (b) was 2.5% that was twice as great as (a). However, the improvement was not sufficient to the number of decrease measurement trials.

The simulation results of the conventional method that used Type A antenna had signal changes of 10 to 14 % on the centerline as shown in Figure 5(a). The new method that used Type B antenna provided -20 to +30 % signal changes shown in Figure 5(b) that were significant enough for applications.

In the experiment, unexpected linkages might exist between transmission and receiving antennas that were not affected by water or dielectric materials, for example, magnetic linkage (mutual inductance), radiation from measurement device and coaxial cables. Those linkages pushed up the base signal strength and weakened relatively changes of electric field intensity that the authors were focusing on.

Figures 4(b) and 5(b) had wider waves of signal strength changes than Figures 4(a) and 5(a). This was a drawback of Type B antenna that provided less accuracy than Type A antenna. This was caused by the wider dimension of Type B antenna in the Y-axis direction.

IV. Conclusion

In this paper, a new method to improve signal strength changes was introduced, and results of experiment and simulation were reported and discussed. The improvement of the signal changes was indicated; however, more improvement was necessary for practical usages. The authors plan to upgrade the system to measure some portion of human body, and to develop pilot systems focusing on a certain application field.

Feature Extraction Methods for Tongue Diagnostic System

K.H. Kim, J.-H. Do, Y.J. Jeon, J.-Y. Kim

Korea Institute of Oriental Medicine, Korea

Abstract — **The status of a tongue is the important indicator to diagnose one's health like physiological and clinicopathological changes of inner parts of the body. The method of a tongue diagnosis is not only convenient but also non-invasive and widely used in Oriental medicine. However, a tongue diagnosis is affected by examination circumstances a lot like a light source, patient's posture, and doctor's condition. To develop an automatic tongue diagnosis system for an objective and standardized diagnosis, segmenting a tongue from a facial image and finding many features from the tongue surface are inevitable but difficult since the colors of a tongue, lips, and skin in a mouth are similar and the features have ambiguous boundaries on the tongue surface. The proposed method includes the segmentation of the tongue region to include detecting positions with a local minimum over shading from the structure of a tongue, correcting local minima or detecting edge with color difference and smoothing edges, the decomposition of the color components of the region into hue, saturation and brightness to result in segmenting the regions of tongue coatings and classify them, and the extraction of the red spots and the crack on the tongue surface by computing the distribution of color intensity in a window. Finally, the results show the segmented region to include effective information, excluding a non-tongue region, the accurate diagnosis of coatings and the spots of the tongue surface. It can be used to make a standardized diagnosis for a u-healthcare system.**

Keywords — **Diagnosis, tongue body, segmentation, feature extraction**

I. Introduction

A tongue is an organ that reflects physiological and clinicopathological condition of one's body. Each part of the tongue is related to corresponding internal organs. [1]

Especially, the visual information is used in tongue diagnosis. The color, the form, and the motion of a tongue, tongue substance, and tongue coating are main factors for the diagnosis. The geometrical shape also helps to diagnose one's health, whose method diagnoses the illness by observing the change of the tongue body such as thickness, size, cracks, and teeth-marks. The tongue coating, covered on a tongue like moss is the most important factor, depending on color, degree of wetness, thickness, form, and distributed range to determine a patient's disease and body condition. It is classified by its color – white, yellow, grayish, black, mixed color, and so on.

Even if a tongue diagnosis is convenient and non-invasive, it has the problem of objectification and standardization. The change of the inspection circumstance like a light source affects the result a lot. Moreover, since the diagnosis relies on doctor's experience and knowledge, it is hard to get a standardized result. Recently, many researches are being carried out to solve these problems. [2]-[4]

Since the properties of color and texture are different according to the light condition, it is difficult to divide the tongue area by using a general segmentation method and to decide the optimal parameters to include the entire area automatically. Moreover, since the area near a tongue includes lips and the oral cavity to have the similar color with it and the color and the texture on a tongue have little difference, it is hard to segment a tongue from the facial image with it and to classify tongue coatings, substance and spots. In this study, we put emphasis on the method to extract the tongue area and to classify the tongue coating automatically from the systematic point of view for a tongue diagnosis. A facial image with a tongue was obtained by using the digital tongue diagnosis system (DTDS). The segmentation method optimized on the digital tongue diagnosis to extract the area of the tongue from a facial image by using its feature and to classify the tongue coating by considering statistical color property was proposed. In addition, the primitive method to detect the spot on a tongue was proposed.

II. Proposed methods

A. Tongue diagnosis in Oriental medicine and digital tongue diagnosis system

The tongue diagnosis is the most necessary thing to be researched in order to quantize an OMD's diagnosis. The DTDS to quantize the condition of a tongue should extract a tongue region from a facial image with a tongue above all. Here, the region of a tongue body including tongue substance and coating should be segmented and then the coating and substance regions should be classified.

The system was designed to get a clear facial image using standardized light sources, a digital camera, and color correction. [5] The system was designed to make a darkroom efficiently wherein a face touches the contact surface of the system and uses the strobe light to have the color

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 527–531, 2009
www.springerlink.com

temperature, 5500K, almost similar to sun light in order to standardize the light source.

B. How to acquire facial images

We put facial images including tongue bodies together using the DTDS. A graphic user interface (GUI) of the system shows the facial image in real time and the cross mark, which is at the center of the image, should be located on the part of the tongue when the image is captured. The captured image has the resolution of 1280×960 with RGB 24 bit-BMP format and then images were classified into 5 kinds of non-coated one, white-coated one, yellow-coated one, mixed-coated one with the white-coated and yellow-coated, and non-classified one by OMDs.

C. Segmentation of tongue body

The overall structure of the segmentation method for a tongue diagnosis is illustrated in Fig. 1. The preprocessing is the first step for the segmentation. Due to time consumption from the large-sized image, the down-sampling of the resolution into 533×400 is necessary. Then, edge enhancement [6] is carried out to make the discrimination of the edges larger through making the large value larger and the small value smaller at the edges, which is the last step of the preprocessing.

In segmenting the tongue body, over-segmentation is performed to make the image divided into smaller regions. The used over-segmentation method is the graph-based segmentation method [7]. Using the method, the majority of tongue region with its center area is segmented into one region, but the region can be subdivided due to the reflection and stain on the center area. In addition the region at the boundary regions and tongue coating regions due to different structural and color property is subdivided. In this case, the probability in a fixed area around the center point was measured and then the segmented region was found, namely the largest major region. If like (1) P_A, the probability of the segmented region of A in the fixed area is larger than P_B, that of the segmented region of B in the same area, the major segmented region is decided as A and all regions in the A region and in the fixed area are merged into A. Even if more than 3 regions exist in the fixed area, every region is merged into the region with the largest probability.

$$\left\{ I_{x,y} \in A \middle| P_B < P_A, I_{x,y} \in B \right\} \tag{1}$$

where $I_{x,y}$ means the pixel of (x, y). Also, all the other regions inside the major region are included in the major region.

In this case, since the change of color occurs from the cubic structure of a tongue near its boundary, some areas near its boundary isn't segmented into the tongue because of shading caused from the strobe light. Namely, the intensity is very low at the outer boundary, which is the minimum value near the boundary since the boundary is almost orthogonal to the direction of light incidence. The position of the local minimum is decided as the boundary of the tongue body, which is the step of local minimum detection. The minimum value crossing each side of the tongue in the X direction with a range is found and then using the result, the minimum value crossing the bottom of the tongue in the Y direction is found.

By the way, in the case that the boundary from a merged region is far away from the real boundary, a local minimum for the shading area can't be detected, resulting in the discontinuity of a boundary. To find a real boundary, the discontinuity point with large difference between the current and the next positions of points on edges should be found in each direction, and then the next point with a local minimum is detected at a new point moved to the progressing direction by one pixel from the current point, where the progressing direction is Y direction for left and right boundaries, or X direction for a bottom boundary. This procedure is performed for left, right, and bottom edges, respectively until the next point meets the point that was detected in the previous step, which is local minimum correction.

However, occasionally in the case of a flat tongue with small volume, the shading can't appear at the boundary. To meet the case, the color edge detection to find the position

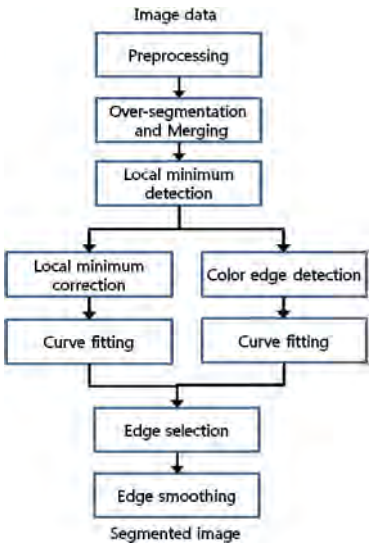

Fig. 1 The overall structure of segmentation for tongue body

that has the largest color-difference is performed from the position of the local minimum value minus a range to the position plus a range as the next step compatible with local minimum correction. In the step, the boundary where makes the difference, d of r (red intensity) largest is found since r is most used at the skin and the tongue, which makes discrimination between skin and a tongue easy.

After the compatible procedures of local minimum correction and color edge detection, curves are drawn in Catmul-Rom spline with sampled points of start, end and a few mid points, which are obtained from the consistent intervals of local minimum correction and color edge detection, respectively. The following procedure is required to select one among the compatible procedures: Firstly, the curve should be checked to have a convex shape due to the shape of a tongue. Secondly, the difference between the curves and the original points should be compared as the step of curve fitting. If the curve is convex, the step with less difference is chosen, which means that the points from the step have soft connection.

After these steps, edge smoothing makes edges smooth with a median filter as the final step. The median filter uses 5 neighboring points and keeps frequency response of edges, excluding its discontinuity.

D. Classification method of tongue coatings

The region of a tongue body consists of tongue substance and coating. The major colors of coating are white and yellow and that of substance is red. To classify white and yellow coating and substance, we select the 2nd order discriminant, assuming that the color distribution of coating and substance is Gaussian conditional density model, where the two dimensional domains are H and S since S is a degree of saturation of a white component, which decides white coating, and the yellow coating and the red-colored substance are classified by H.

Acquisition of the color table to classify tongue coating and substance has three steps as follows; in the first step, the transformation of RGB is performed to resolve color components into hue (H), saturation (S) and brightness (V). Highlights happen on the tongue due to reflection of a light source and since they are saturated, the values of RGB are 255, which are decided as invalid regions.

We use white-, yellow-, and no coated areas segmented by OMDs from 42 images, 8 images and 6 images diagnosed as white, yellow and no coating, respectively, where no coating means substance. In the second one, the distributions of H and S values for all the white-, yellow- and no coated areas are computed, respectively. Statistical data like each mean and covariance for each coating and substance is calculated. In the third one, after low distribution values less than 0.005% are eliminated to reduce noise parts, the values for the distributions are applied to the 2nd order discriminant. In the fourth one, the table for regions in H and S domains to classify coatings and substance are obtained with three 2nd order discriminants.

The coating and substance regions can be classified and segmented when an image is inputted to the table.

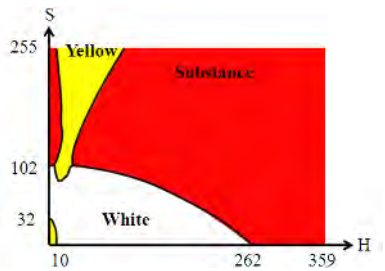

Fig. 2 Table to classify white and yellow coatings and substance

E. Detection of spots

In the previous procedure, the color component of the S domain is resolved. The spot is known as the exposure of tongue substance on the surface covered with coatings. In the first step, the average is measured in a rectangle window in the S domain. In the second one, the area over a threshold is searched since the S value of substance is higher than that of coating. In the third one, white 3×3 points are drawn around the area in order to visualize the spots.

III. Experimental Results

To find the main segmented region, 50×50 pixels were searched around the center, and the location of a local minimum was found in the pixel range of -40 to 40 from each boundary of a region merged from over-segmented regions.

Table 1 The range of color components to classify tongue coating and substance

Types		Mean		Covariance	
		H	S		
Coating	White	12.2	83.6	717.5	-4.7
				-4.7	130.7
	Yellow	18.8	108.8	37.8	55.6
				55.6	252.4
No coating		11.4	116.9	1648.8	-35.8
				-35.8	125.5

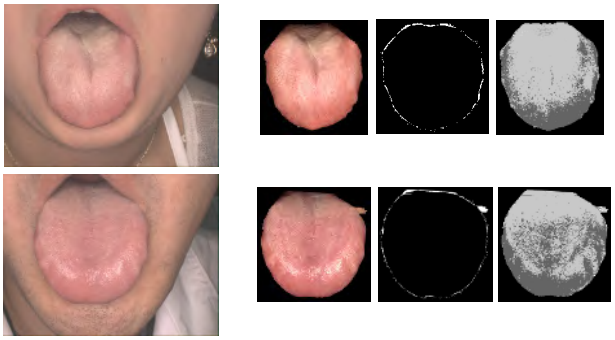

Fig. 3 Original, segmented images, the differences, white-coated images

The threshold to find discontinuous points was 10 pixels, that is, if the distance between the current and the next points at the edges is above 10 pixels, the next point is called the discontinuous point. The search range for local minimum correction or color edge detection narrowed down to -20~20 from the discontinuous point in the boundary processed by the local minimum detection, where color edge detection finds the location to represents the maximum difference of a red value.

For a classification table, we get the means and covariances like Table 1 for Gaussian conditional density models in the H and S domains to produce the 2nd order discriminants, to decide kinds of coatings and substance. Fig. 2 is the table to show the classification region of white and yellow coatings and substance.

Fig. 3 shows the facial images, the segmented results, the differences from reference images and the classified ones, where what a reference image is what an OMD extracted manually and prudently as a tongue body and the classified ones correspond to what were classified by OMDs. The white coated images were not used for obtaining the classification table. It is shown that almost all tongue regions that have different shapes and colors were well-segmented, not affected by either color or status of skin.

The difference rate of the area between a reference image and a segmented image was obtained like (2).

$$r_d = \left| \frac{A_{ref} - A_{seg}}{A_{ref}} \right| \times 100 \qquad (2)$$

where A_{ref} and A_{seg} are the areas of a reference image and a segmented image, respectively. The average difference rate of the selected 40 images was 5.5% and the difference happened at the boundary region slightly like Fig. 3.

Fig. 4 shows the spot detection from S domain image, where a threshold is 10 above the average in the window.

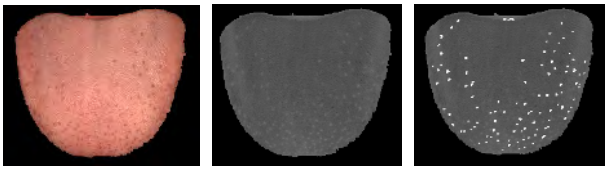

Fig. 4 A segmented, an S domain, and a spot-detected images

IV. Conclusions

In this study, the effective method to segment the tongue area and to classify tongue coatings and substance was proposed for an automatic tongue diagnosis. According to the structural and color properties of a tongue, its boundary were extracted, and using the statistical color property, the tongue substance and coatings were classified.

Preprocessing makes edges more distinct by using the distribution of intensity. After the preprocessing, graph-based over-segmentation with the fixed parameters, region merging, local minimum detection, edge correction to select local minimum correction or color edge detection and edge smoothing to segment the tongue body were performed. Then, the segmented tongue region was classified into kinds of coating and substance areas by resolving color components of HS. As a result, it was possible to segment a tongue body region that is difficult to distinguish from skin inside a mouth and lips. Also, the proposed method could segment the tongue body effectively in spite of the non-uniformity of color, which is caused from tongue coating and reflection of light. The 2nd order discriminants and the table were obtained from statistical data. The tongue body can be divided into white and yellow coatings and substance. Finally, spots could be detected from the difference of S.

Mechanical-Scanned Low-Frequency (28-kHz) Ultrasound to Induce localized Blood-Brain Barrier Disruption

C.Y. Ting[1], C.H. Pan[1] and H.L. Liu[2]

[1]Department of Medical Image and Radiological Sciences, Chang-Gung University, TAIWAN
[2]Department of Electrical Engineering, Chang-Gung University, TAIWAN

Abstract — **Recent technical advances showed that focused ultrasound can induce localized blood-brain barrier disruption, however, usually accompanied with the occurrence of hemorrhage. Low-frequency ultrasound has the nature of not been obstructed by skull and has been widely in the industrial applications, but yet have not been applied for biomedical purpose due to its difficulty in concentrating the ultrasonic energy. The purpose of this study is to first demonstrate the feasibility to employ mechanical-scanned low-frequency (28 kHz) ultrasound in localized BBB disruption, which is believed to be the lowest frequency been applied for this application. To examine this, SD rats were anesthesia IV, and ultrasound contrast agent was administered before ultrasound energy excitation to enhance the BBB disruption effect. Blue dye was also administered before animal sacrifice for gross observation of the affected region, and H&E as well as TUNEL staining were performed to evaluate the ultrasound induced brain tissue damage. Results confirmed that low-frequency can be mechanical-scanned for localized BBB-disruption.**

Keywords — **low-frequency ultrasound, blood-brain barrier(BBB), mechanical scan**

I. Introduction

Blood-brain barrier (BBB) plays an important role in brain. It not only transports nutrients into brain by diffusion, but also limits the passage of many native and exogenous molecules from the circulation into the brain parenchyma. But in some cases, including delivering of potent agents for therapy or neural imaging, BBB has to be disrupted manually to raise its feasibility. By the use of cavitation effect of ultrasound, drug can be directed locally into brain. [1]

Focused ultrasound has been shown to be able to induced localized BBB disruption. According to the literature, by applying the operating frequency ranging form 260 kHz to 3.5 MHz, the concentrated ultrasonic energy can be well generated. However, it was also shown that the frequency exceed 500 kHz can encounter noticeable phase aberration problem and distort the concentrated energy, thereby hamper the energy delivery into the brain [2,3,5]

Another potential issues is that, when intending to deliver drug through BBB in some disease brain trauma or acute stroke, the area need to be treated may be large, whereas limit the treatment efficiency by using the point-like energy to conform the large brain damage area.

The purpose of this study is to propose a new ultrasound BBB-disruption system which utilizes the 28-kHz as the operating frequency. The advantage of the proposed frequency is in two fold: (1) The effect of skull absorption of ultrasound energy is limited and can be almost ignored; (2) The ultrasound energy is non-focused, and can be deposited with a much larger area than operating frequency at this level; (3) The system is easier to be setup. In this report, we aim to examine the feasibility and efficiency of the proposed system on localized BBB disruption. Moreover, we also demonstrate the feasibility to apply the mechanical scanning to improve the capability of enhance the BBB disruption at deeper brain region.

II. Material and methods

A. Experimental setup

Figure 1 shows the experimental setup and the 28-kHz sonication system. One 28-kHz originally applied for industrial purpose machine was employed as the ultrasound energy generator. One single triggering circuit where the synchronized single provided from the functional generator (28-kHz sinusoidal wave was continues generated from the signal generator and gated by the designed circuit) was designed in order to control the sonication parameter including the pulse repetition frequency (PRF) and the burst length. The transducer was mounted on either a stainless-steel made fixed gantry or a in house acrylic -made rotating gentry to provide mechanical scanning. The geometrical center was tuned to align at the unilateral brain of the animal in case the ultrasound either fixed or mechanical-scanned energy can affect the unilateral brain of the animal. At the bottom of the water tank, a 5 cm × 5 cm window was made but sealed by a thin ultrasound-permeable membrane. The animal was carefully placed under the tank the its head was shaved and tightly attached beneath the membrane. Degassed was filled in the water tank to provide good ultrasound coupling to the animal.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 532–535, 2009
www.springerlink.com

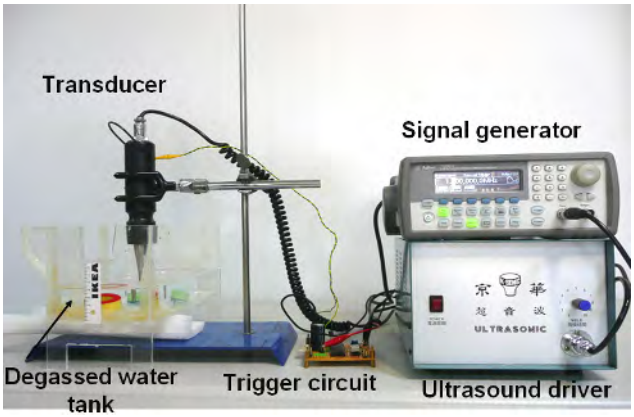

Fig. 1. Experimental setup.

B. Animal preparation

The experiments conducted in this study were approved by the Animal Committee of Chang Gung University and adhered to the experimental animal care guideline. Twenty-eight adult male Sprague-Dawley (SD) rats (each weights 300 ~ 400 g) were anesthesia I.P. by injecting chlorohydrate (30mg/kg). A PE-50 catheter was then inserted into the jugular vein for the following microbubble and blue dye injection. The head of the animal was placed in a plastic holder and set in the treatment position.

C. 28-kHz ultrasound sonications

After setting animal in this low-frequency ultrasound apparatus, Blue Dyes (Evans Blue, 4mg/100g) was injected I.V. to prove the presence of BBB disruption. Approximately 10 seconds before each sonication, ultrasound contrast agent (SonoVue, Bracco UK Ltd.) was poured into I.V. catheter to promote the cavitation effect. After all, the sonications were delivered. The acoustic power of this system is about 1~2W which was measured by ultrasound power meter (Easton®, Model-21601, OHMICO, USA). In order to find the electrical parameter to induce optimal BBB disruption, parameters including sonication time, burst length were tuned. The sonication time in our experiments were given ranging from 2 to 10 min. The burst length was given ranging from 10 to 50 ms under a pulse repetition frequency of 1 Hz.

In order to evaluate the effect of consecutive injection of the microbubble in the effectiveness of microbubble, we conduct ultrasound sonications either (1) by only injecting the microbubble before the sonication start or (2) consecutive microbubble injection for every two minutes.

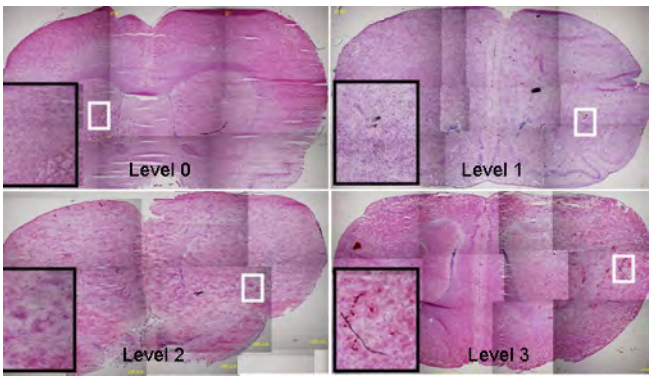
Moreover, in order to evaluate the effectiveness of mechanical scanning for altering the BBB-disruption region, animal experiments by using fixed gentry or applying mechanical scanning were both attempted. For mechanical scanning, the ultrasonic wave can be steered to the target region and concentrate the energy at targeted locations.

D. Frozen Section and Staining

Evans blue was administered before animal sacrifice for gross observation of the affected region.3 to 4 hours later; animals were sacrificed, and were perfused with normal saline. After perfusion, brain tissue was frozen rapidly, and was embedded in OCT (Tissue-Tek, SAKURA, USA). The tissues were sectioned using a Microtome (Model 3050S, Leica, German). The brain sections were first judged with eyes (Observe whether the brain tissue was dyed by Evans Blue). Finally, the slices were preserved and stained with hematoxylin and eosin (H&E) to evaluate the ultrasound induced brain tissue damage [4].

E. Pathologic examinations

The level of cell damage and hemorrhage were classified into four categories as Fig. 2. Level 0 was defined as a little necrosis phenomena. Level 1 was defined as some discontinuous form of bleeding phenomena. Level 2 was defined as some continuous form of bleeding phenomena. Level 3 was defined as some continuous bleeding and tissue injuring phenomena.



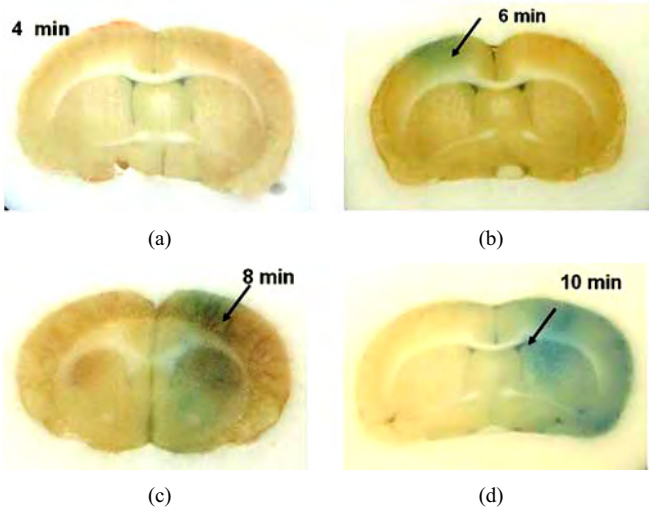


Fig. 2. HE staining sections. (a) Level 0; (b) level 1; (c) level 2; (d) level 3.

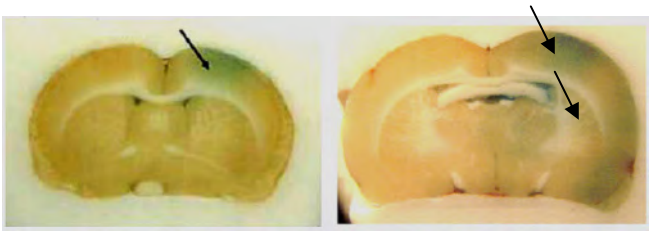
III. Results

A. Comparison between Sonication Time

Figure 3 are examples showing brain sections underwent low-frequency ultrasound exposure and the BBB-disruption effect when varying the sonication time ranging from 4 to 10 min.. BBB was intact when apply 4 min. sonication, whereas the BBB can be locally disrupted when increasing sonication

time to 6 min. The sonication time of 6 min. was regarded as the threshold and as a baseline to disrupt BBB in the following experiments.



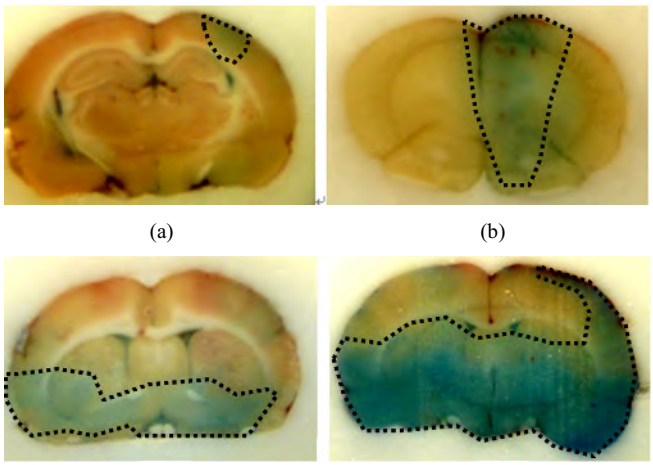
(a) (b)

(c) (d)

Fig. 3. BBB-disruptive section from the 28-kHz ultrasound sonication under different sonication times without applying mechanical scanning: (a) 4 min.; (b) 6 min.; (c) 8 min.; (d) 10 min.

B. Effect of different sonication burst lengths

Next, the effect of the applied burst length of ultrasound sonication was investigated. Figure 4 demonstrates the brain sections underwent different sonication burst length ranging from 10 to 100 ms. It can be found that, as the burst length increase, the BBB disruptive region was also increased. For the burst length of 10 ms, only a small range of BBB-disruption was found, but the BBB-disruptive region was apparently increased when increasing the burst length to 50 ms. When increasing the burst length up to 50 ms, not only the BBB-disruptive region was enlarged but the stained color was darker, showing that the concentration of the blue dye deposited at the sonication region was also increased.



(a) (b)

Fig. 4. Brain sections showing the effect of varying burst length on BBB-disruption. Pulse repetition frequency and the exposure time were controlled to be 1 Hz and 6 min. respectively. (a) burst length = 10 ms; (b) burst length = 50 ms.

C. Effect of mechanical scanning

To increase the potentiality of this low-frequency ultrasound system, we try to focus the ultrasound in a manual way. Through the results of the experiment, we can find out while adopting the same time parameter. The upper and lower row of Fig. 5 demonstrates the difference between the BBB-opening region distribution between sonication without and with mechanical scanning. In transducer-fixed condition, as the burst length increases from 10 to 100 ms, it can be seen that the BBB-disruptive region extend its coverage from the brain surface. However, for mechanical-scanned condition, the BBB-disruptive region appears at deeper region.

(a) (b)

(c) (d)

Fig. 5. Effect of the application of mechanical-scanning on BBB-disruption. (a, b) Sonication with the transducer fixed, burst length = 10 and 100 ms respectively; (c, d) sonication accompanying with mechanical scan. Sonication duration of 6 min. were employed.

D. Histological examination

Figure 6 demonstrates the tissue damage level caused by 28-kHz ultrasound sonication under the sonication time ranging from 4 to 10 min. There was no BBB-disruption effect been observed when the sonication duration of 4 min. was employed. For sonication time equal or larger than 6 min., BBB-disruption can be induced but varies of tissue damage level was also accompanied. Only a few of erythrocyte extravasations was found in the 6 to 8min. case, therefore it was still considered to be a safe sonication parameter. When increasing the sonication time up to 10 min., local microhemorrhage was detected.

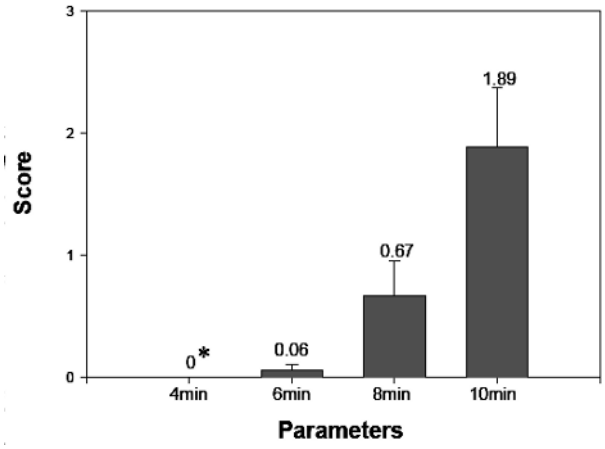


Fig. 6. Tissue damage level analyzed by histological examination at different sonication durations. The soncaiton time was varied from 4 to 10 min. "*" represents no BBB-disruption has been observed under gross observation.

IV. Conclusion

In this paper, we have demonstrated that the 28-kHz in conjunction with the mechanical scan can manipulate the BBB-disruptive region in the animal brain. In our knowledge, it is the first sonication system that employs non-focused ultrasound in this BBB-disruption, and so far the lowest frequency ever been investigated. The feasibility, safety, and efficiency have been confirmed. The designed system may have the potential to explore a wide application benefit from the portability and the improved effective area

Abstract — **The purpose of this study is to demonstrate the feasibility of using ultrasound induced BBB-disruption technology to enhance brain-permeable area in a brain tumor model for the enhancement of brain-tumor drug delivery. In our system setup, either 28-kHz non-focused ultrasound or 400-kHz focused ultrasound was used. To examine this, SD rats (n = 14) with C-6 Cell been intestinally implanted to regarded as brain-tumor model. The animals were treated 10 days after tumor implant. During the treatment, the animal were anesthesia I.P., and ultrasound contrast agent was administered I.V. before ultrasound energy excitation to enhance the BBB disruption effect. Blue dye was also administered before animal sacrifice for gross observation of the affected region, and H&E staining were performed to evaluate the ultrasound induced brain tissue damage. BBB-disruptive regions were compared between controlled and ultrasound-treated animals to see the enhancement of the ultrasound treatment. Results confirmed that ultrasound sonication either 28-kHz or 400-kHz sonication can enhance the BBB-disruption. The pressure threshold of BBB disruption has been confirmed to be 2.25 MPa and 1 MPa in 28 kHz and 400 kHz, respectively. In the 28-kHz sonication case, the BBB-disruptive region surrounding the tumor area can be increased up to 17 fold. Also, tumor-implant animals which underwent localized BBB disruption didn't affect the animal survival, which indicates the ultrasound-induced BBB disruption is secure. The ultrasound-induced BBB disruption may have the potential for brain tumor treatment in the sense of increase the vessel permeability surrounding the brain tumor to increase the local drug concentration near brain tumor.**

I. Introduction

The blood-brain barrier (BBB) plays important roles in protecting the brain. It's not only allows the passage of substances essential to metabolic function by diffusion, but also restricts the passage of various chemical substances. However, we have to enhance the BBB permeability to assist the penetration through the tight junction for therapeutic purpose. Focused ultrasound surgery is an attractive method for performing tissue thermal ablation non-invasively and has become more popular recently. The ultrasound energy has the ability to sharply focused into soft tissues, then induce a localized temperature elevation with the range of 30-55˚C which resulted irreversible tissue necrosis at the target region while surrounding tissues intact. Moreover, acoustic cavitation, which acoustically induced activity of gas-filled cavities, is another mechanism of focused ultrasound to be applied clinically. It has been shown recently that focused ultrasound can also provide a safe operation to conduct temporal and reversible BBB opening in the presence of ultrasound contrast, leading to the potential to perform targeting delivery without intervening tissue damage for brain treatment [1],[2],[4],[8].

Brain tumors affect approximately 170,000 people annually in the United States and each year more than 13,000 of the population die from a primary malignant brain tumor. In USA, Brain tumors are the second leading cause of cancer-related death in children and men aged 20-39 years. Glioblastomas and astrocytomas that account for more than 40% of all central nervous system tumors are the most common brain tumors that affect adults between 45 and 60 years of age. The most common treatment for glioblastomas currently is surgery followed by radiation and chemotherapy. The procedures for initial treatment are beneficial, but tumor cells often don't remove completely. So the poor prognosis is resulting from high recurrent rate. Therefore, developing an adjuvant therapy is necessary. Moreover, many research shows that glioblastoma may not necessary to disrupt the BBB structure in its early developmental stage especially for the tumor peripheral, thus restrict the drug permeability in those tumor regions to reduce the treatment performance of the drugs.

In this paper, we intend to show the ultrasound induced BBB disruption at the tumor peripheral for the purpose of increasing the local drug concentration at tumor location. Two ultrasonic systems which can delivery either planar or focused wave were shown to both capable of inducing localized BBB disruption. Brain tumor animal models were employed in this study. *In-vivo* animal experiments were conduct and the brain tissues were examined histologically to confirm its feasibility and efficiency.

II. Material and Meyhod

A. Low-frequency ultrasound equipment

Figure 1(a) shows the experimental setup and the 28-kHz sonication system. One 28-kHz originally applied for industrial purpose machine was employed as the ultrasound energy generator. One single triggering circuit where the synchronized single provided from the functional generator (28-kHz sinusoidal wave was continues generated from the signal generator and gated by the designed circuit) was designed in order to control the sonication parameter including the pulse repetition frequency (PRF) and the burst length. The transducer was mounted on a stainless-steel made fixed gantry. The beam path of 28-kHz was positioned to align with the unilateral brain of the animal in case. At the bottom of the water tank, a 5 cm × 5 cm window was made but sealed by a thin ultrasound- permeable membrane. The animal was carefully placed under the tank with its head shaved and tightly attached beneath the membrane. Degassed was filled in the water tank to provide good ultrasound coupling to the animal.

B. High-frequency ultrasound equipment

The ultrasonic focal beam was generated by a 400 kHz focused ultrasound transducer (diameter = 60 mm, curvature radius = 80 mm) which put in an acrylic water tank with a three-axis positioning stage. An arbitrary-function generator was used to generate the driving signal that was fed to a radio-frequency power amplifier (100A250A, Amplifier Research, USA). In addition, using a power meter (Model 4421, Bird, USA) to monitor the energy of signal delivered to the transducer. The design of water tank was the same as low-frequency equipment. Its bottom had a square window sealed with a thin film to allow the ultrasound energy went through. The animal was placed under the water tank with its head tightly attached to the thin-film window. The setup of high-frequency equipment was showed in Figure 1(b).

C. Tumor model preparation

Adult male Sprague-Dawley rats (250 - 400g) were purchased from the National Laboratory Animal Breeding and Research Center (Nan-Kang, Taipei, Taiwan). Animals (each weighting from 250 to 400g) were anesthetized by Chlorohydrate (300 mg/kg, IP injection), then removed their uppermost cranial hair with an aid of clippers. After fixing rats on a stereotactic instrument, drill a hole on the skull at the site above striatum which was away from bregma 0.03 mm in axial, 0.32 mm in lateral, 0.56 mm in vertical direction, respectively. The cultured C-6 cell was implanted and

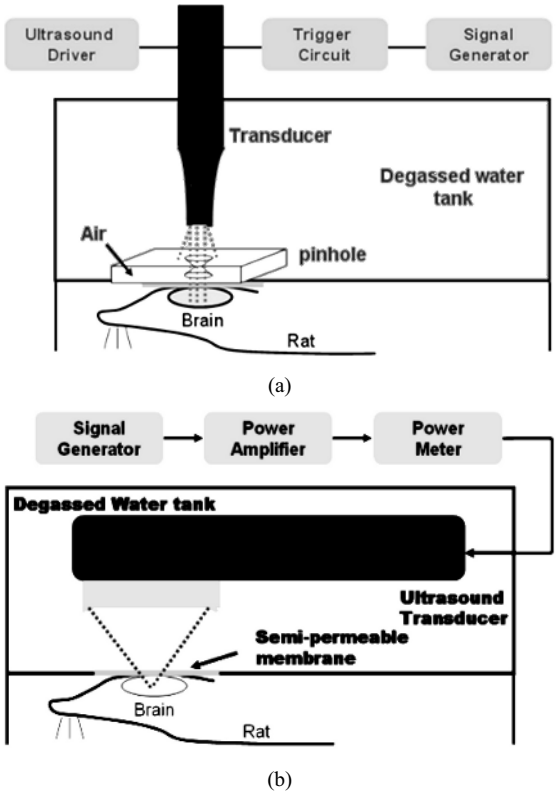

Fig. 1 The schematic diagram of the ultrasound sonication system. (a) low-frequency ultrasound equipment. (b) High-frequency ultrasound equipment.

bone wax was used to seal the hole. The implanted cell concentration was $1X10^5/\mu\iota$, and volume was $5\mu\iota$.

D. Cell culturing and preparation

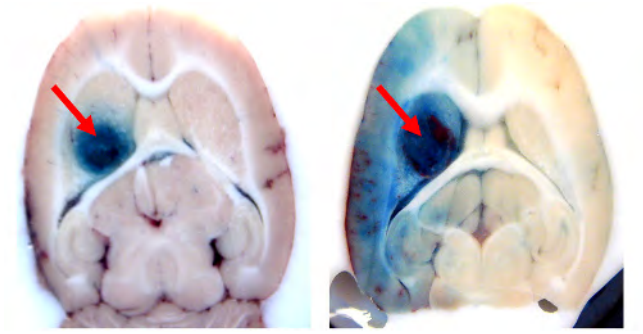
C-6 Cells was necessary to be sub-cultured every 3-4 days and the following list the procedure. First, removed and discard the cultured medium (95%DMEM + 10%FBS+L-Glutamine). Washed cells by PBS and rocked it back and forth to remove all traces of fetal bovine serum. Added trypsin-EDTA to round up the cells from the bottom of the dish followed removed the wash solution. In a few minute, added growth medium to cell suspension. Collected the suspended cells in a centrifuge tube, and removed some dissociating agents by centrifugation with 1500 rpm, 5 minutes. Then, trypsin-containing medium were removed and replaced with fresh medium. The last step is to place the dish on a shelf in a 37°C, humidified CO_2 incubator.

E. Ultrasound sonications

The cultured cells were implanted into animal brain, and conducted the ultrasound experiments 10 days after. When

conducting experiments, animals were anesthetized and removed the hair of their neck. PE-50 catheter was placed in the jugular vein of animal for later contrast agent administration (SonoVue ®, Braco UK Ltd.). The sonication was conducted by either by low-frequency ultrasound (28-kHz) or high-frequency ultrasound (400 kHz). The measured delivered peak pressure in low frequency setup was 2.25MPa with the pulse-width, pulse-repetition frequency and sonication time were set to 10 ms, 1 Hz, and 6 min. respectively; For 400-kHz focused ultrasound, the measured delivered peak pressure was set to 1 MPa, and the pulse-width, pulse-repetition frequency and sonication time were set to 10 ms, 1 Hz, and 30s, respectively. For 400-kHz sonication, magnetic resonance imaging (MRI) were also conducted. 3-T MRI scanner (Trio with Tim, Siemens, Erlangen, Germany) were used after the animal experiments but the time points were controlled no longer than 30 min. MR contrast agent were injected (Magnevist®, Berlex Laboratories, Wayne, NJ) and T1-weighted imaging sequence were performed to detect the BBB-disruptive region. Evans blue was administered before animal sacrifice for gross observation of the affected region.3 to 4 hours later; animals were sacrificed, and were perfused with normal saline.

F. Pathologic examinations



Blue-dye was IV injected into animals to confirm the BBB-disruption, and observed in the process of frozen tissue sectioning by using a Microtome (Model 3050S, Leica, German). The animals were sacrificed about 3-4 hours experiments. The brains were immediately removed and frozen in an OCT compound. (Tissue-Tek, SAKURA, USA).

III. Results

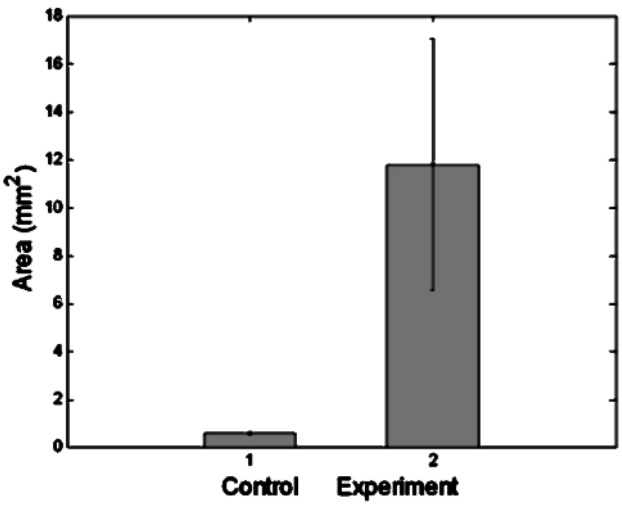
A. Local BBB disruption induced by low-frequency ultrasound

Figure 2 is a typical case showing the comparison of the blue-dye stained region between controlled and ultrasound-sonicated brain. In this comparison, 28-kHz ultrasound was delivered. For control, it can be observed that the implanted tumor can be stain due to the exogenous tissue existed in brain and the BBB structure was destroyed. After the animal brain been sonicated, a noticeable BBB disruptive region increase can be observed, showing that the focused ultrasound sonication can effectively induce a wide local BBB disruption to cover a target such as brain tumor.

Figure 3 analyzes the BBB-disruptive area of the above two groups, and their BBB-disruptive regions (in blue) were measured by using an in-house designed imaging processing tools established in Matlab. From the slice measurement, the measured area in controlled group were 0.598 mm^2 in average, but the sonicated brain appears to have an noticeable increase up to 11.01 mm^2. Compared with the BBB-disruptive region surrounding tumor area, the BBB disruption region induced by low-frequency ultrasound significantly increased up to 17 fold. This confirms the feasibility of using low frequency ultrasound to enhance BBB permeability in a tumor region.

(a) (b)

Fig. 2 The photograph of BBB disruption. (a) disrupted by tumor (b) use ultrasound induced BBB-disruption technology.



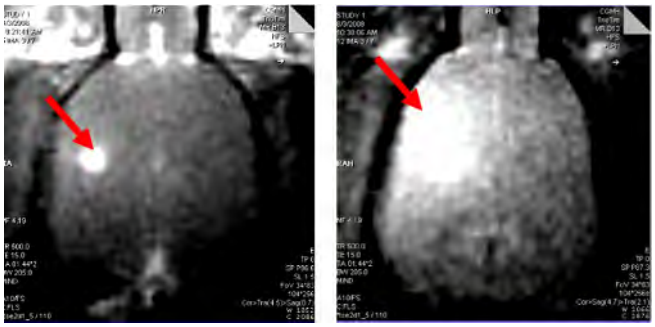


Fig. 3 The BBB-disruptive region of surrounding tumor area and induced by low-frequency ultrasound

B. Localized BBB disruption induced by high-frequency ultrasound

The following shows the feasibility of using focused ultrasound to enhance BBB disruption in the tumor model. Figure 4 shows a typical example to compare the controlled and sonicated brain under the contrast-enhanced T1-weithed MRI. BBB disruption is indicated by localized signal en-

hancement (arrows) due to higher concentration of MR contrast agent penetrated into the BBB-disruptive region. The BBB-disruptive area induced by the tumor and 400 kHz focused ultrasound are 0.06 mm^2 and 0.24 mm^2 respectively. The BBB disruption region induced by high-frequency ultrasound significantly increased up to 4 fold. This confirms the feasibility of using high frequency ultrasound to enhance BBB permeability in a tumor region.

(a) (b)

Fig. 4 Contrast-enhanced axial T1-weighted MR image of BBB-disruption (a) disrupted by tumor (b) disrupted by using ultrasound induced BBB-disruption technology.

C. Safety of ultrasound exposure

In order to confirm the safety of the ultrasound-induced BBB disruption, controlled and experimental animals were placed under observation and the body weights were measured up to 60 days. No specific difference of these two groups were found, and no abnormal behaviors were observed from the experimental group. The body weight of these two groups both shows to have steady increase, representing the tumor implant up to 60 days neither provide significantly health problem, and nor the animal been added the additional ultrasound treatment. The ultrasound sonication is confirmed to have no significant hazard for animals.

IV. Conclusions

Our study demonstrated that the feasibility to noninvasively enhance BBB disruption in brain-tumor model either low- or high-frequency ultrasound exposure. The potentiality of this approach was considered to be potential for brain tumor treatment in the sense of increasing the vessel permeability surrounding the brain tumor as well as to increase the local drug concentration surrounding the brain tumor. We also thought this technology may be benefit during chemotherapy especially for the condition when the high-toxicity drug were administered and the total drug amount may be able to reduce due to the help of increasing local drug deposition.

On Calculating the Time-Varying Elastance Curve of a Radial Artery Using a Miniature Vibration Method

S. Chang[1], J.-J. Wang[1], H.-M. Su[1], C.-P. Liu[2]

[1] Department of Biomedical Engineering, I-Shou University, Taiwan

Abstract — **We examined the time-varying elastance of the radial arterial wall using a minute vibration approach in fifteen volunteers. A sinusoidal displacement of 1.5~2.0 mm with a frequency range from 50 to 100 Hz was used to impose on the superficial radial artery. Meanwhile, a force sensor was used to pick up the contact force exerted by the radial arterial wall. The amplitude of the complex force was found to be negatively proportional to the squared angular frequency imposed on the radial artery. A linear regression line can be obtained using the different frequencies (x-axis) and their force responses (y-axis). The intercept of the regression line with the y-axis denotes the elastance and the slope the effective contact mass. Ten elastance values corresponding to 10 different timings in a cardiac cycle were used to construct a time-varying elastance curve. It was found that the elastance curve fundamentally follows the arterial pressure waveform. In conclusion, we have successfully calculated the arterial elastance values at various cardiac timings by applying the minute vibration method, and the pattern of the elastance curve bears a resemblance to a blood pressure waveform.**

Keywords — **Arterial stiffness, Minute vibration technique, Time-varying elastance, Arterial compliance**

I. Introduction

In addition to aging, several kinds of disease result in vascular hardening, such as the cerebral vessel disease [1], cardiovascular disease [2], diabetes mellitus [3] and renal disease [4]. Thus, it is important to perform an early detection of the arterial stiffness using a reliable method. To date, there have been different technologies for directly or indirectly assessing the arterial stiffness, including the ultrasound echo-tracking (Doppler)[5], analysis of pulse transit time[6], impedance plethysomgraphy [7], photoplethysmography [8], oscillometry [9], tonometry [10], and analysis of pressure waveform [11].

Up to now, there is no reliable way to evaluate the degree of the arterial stiffness (elastance) in the clinical setting. Thus, the purpose of this thesis is to develop a noninvasive apparatus for measuring the arterial wall properties by means of minute vibration technique, and to calculate the time-varying arterial elastance curve.

II. Materials and methods

A measurement system consisting mainly of a micro-vibration generator, a force-sensing device, an analog-to-digital and digital-to-analog converters, and a personal computer was constructed to calculate radial arterial time-varying elastance curve using the minute vibration method.

Characteristics of arterial wall were assumed to be governed by three components, including the inertia, viscosity, and elastance [12]. Furthermore, the force exerted by the inertia component was denoted by the product of mass (M) and acceleration (d^2x/dt^2), the force induced by the viscosity component was equal to the product of blood viscosity (η) and velocity (dx/dt), and the force generated by the elastance component was represented by the product of elastance (E) and displacement (x). According to the concept of force balance, an external force imposed on the arterial wall should equal to the sum of the forces from the three components [12], as follows:

$$F = M\frac{d^2x}{dt^2} + \eta\frac{dx}{dt} + Ex \tag{1}$$

The viscosity term is relatively very small, as compared with the other two force terms. After neglecting the viscosity term, we can obtain

$$F \approx M\frac{d^2x}{dt^2} + Ex \tag{2}$$

If a sinusoidal displacement is imposed on the arterial wall, then relation between the complex contact force and the angular frequency can be represented by

$$F(\omega) = (E - M\omega^2) + j(\eta\omega) \tag{3}$$

From Eq. (3), the real part of the complex contact force is inversely proportional to squared angular frequency (ω^2). Thus, if we make a plot using the real part of the contact force (vertical axis) with respect to ω^2 (horizontal axis). By exciting the arterial wall with a small and different-frequency sinusoidal displacement, a regression line can be obtained. Thus, the intercept of the vertical axis with the regression line corresponds to the wall elastance and the inverse of the slope of the regression line is equivalent to the effective mass of the arterial contact wall.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 540–542, 2009
www.springerlink.com

Eighteen healthy college volunteers (17M and 1F) were included in the study. In the beginning, we asked the volunteers to take a five-minute break to make their hemodynamic condition stable. In the baseline experiment, displacement excitation with different frequencies (40, 45, 50, 55, 60, 80 and 85 Hz) was imposed on the subject's radial artery, and the corresponding contact force signal was recorded. In the pressurized upper arm condition, an air cuff wrapped the upper arm was inflated up to diastolic pressure plus 10 mmHg. The pressurized cuff tended to considerably block the venous return but not the brachial arterial blood flow. This blockage experiment caused blood accumulation not only in the venous vessels but also in the radial artery in the lower arm. Similar to the baseline test, different frequencies were selected to excite the arterial wall, and the corresponding contact force signals were measured for later analysis.

To derive the arterial elastane curve, the elastance values corresponding to ten timing points in one cardiac cycle were calculated, respectively. For a specific timing point, the elastance value was determined to be the intercept of the vertical axis in the force versus ω^2 plot.

III. Result

Typical elastance values (=intercepts) corresponding to the ten timing points in one volunteer in baseline condition are listed in Table 1. It is interesting to note that the elastance value quickly increases in the initial timing points, but gradually decreases in the subsequent timing points. Meanwhile, the values of effective mass of the arterial contact wall, equivalent to the inverse of the slope, are found to be maintained for all the timing points. Fig. 1 shows two time-varying radial elastance curves calculated in the normal and pressurized conditions. Obviously, there is an upward shift in the elastance curve during the upper arm pressurized situation, as compared with that in the baseline condition. In addition, a moderate change in the waveform shape exists between these two radial arterial elastance curves.

Mean ± SD	1.879 ± 0.854	3.017 ± 1.779	62.8 ± 61.5

pressure, the dynamic radial wall elastance varied from 1.422×10^6 to 6.557×10^6 dyne/cm, and the average of maximum elastance became $3.017\times10^6 \pm 1.779\times10^6$ dyne/cm. In the pressurized situation, the average of maximum elastance was increased by 62.8%. But, two of the eighteen subjects showed a decrease in their maximum elastance with the pressurized cuff around the upper arm.

Whereas, in the other results of participants were corresponding with a Psychophysiology theory. It was found in the current result that the elastance curve varied synchronously with the radial blood pressure waveform. Therefore we can estimate the dynamic radial artery elastance with the response to changes in the radial artery.

IV. Discussion

Using the minute vibration method, we have successfully determined 10 values of the radial arterial elstance at 10 different timing points in one cardiac cycle. A full arterial elastance curve is then constructed on the basis of these 10 values. The present elastance, a local index of arterial stiffness, is totally different from that measured from an arterial segment [6-8] or the whole arterial system [13].

The radial artery of interest in the current study is assumed equivalent to a mechanical system, and the elastance is equal to a spring's constant. Although local, the arterial elastance determined by the vibration technique obviously represents an absolute rather than a relative value. Thus, one advantage of the study is capable of calculating a regional and absolute elastance value. Another advantage is the construction of an entire elastance curve over one cardiac cycle.

The drawbacks of the present study include high sensitivity of the measurement location, mechanical instability of the measurement system, and lack of a precise calibration method.

V. Conclusions

We have calculated the arterial elastance values at various cardiac timing points by applying the minute vibration method, and then constructed the whole time-varying arterial elastance curve in a cardiac cycle. It is found that basically the shape of the calculated elastance curve bears a resemblance to the arterial blood pressure waveform.

Abstract — **This paper presents a novel readout circuit with potentiostat for amperometric chemical sensors that has wide output current range and has low power consumption, with its application towards the implantable glucose sensing system. This new design of electrochemical interface circuit operates in current-to-current transfer mode, has low input impedance characteristic and has stable loop gain unaffected by sensor resistance variation. Post layout simulations showed detection of redox current from 50 pA to 50 μA with power consumption from only 390 μW to 745 μW, while experimental verification using on-board prototype provided measurements from 10 nA to 50 μA, with 10 nA as the lowest capability of the semiconductor device analyzer used in the setup. This novel readout circuit was implemented using TSMC 0.35 μm mixed-signal 2P4M 3.3 V CMOS technology with a chip area of 0.1767 mm^2.**

Keywords — **Glucose, Potentiostat, Readout Circuit, Integrated Interface Circuit, Amperometric Chemical Sensor**

I. Introduction

Potentiostat is an electronic interface for amperometric chemical sensors that are capable of detecting many biologically and environmentally significant analytes [1]. Recent works describe this kind of potentiostat for biomedical application, particularly glucose measurement [2-3]. Typical implementation of amperometric chemical sensors uses three electrodes [1-6]; the working electrode (WE), reference electrode (RE), and auxiliary counter electrode (CE).

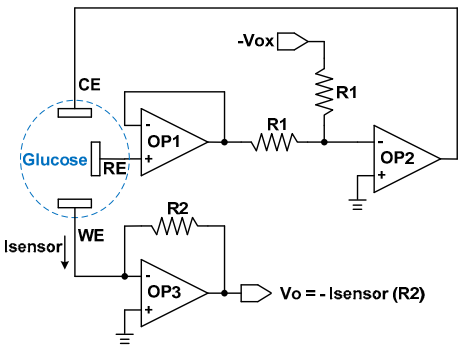

Fig. 1 The standard potentiostat

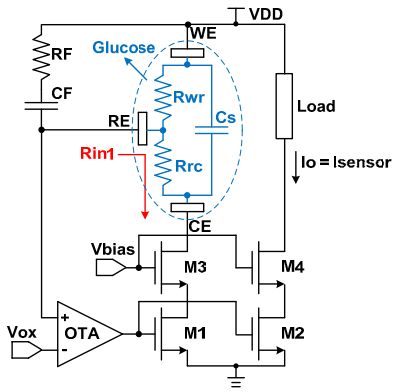

Fig. 2 Readout-1, the original low power potentiostat

The standard potentiostat for amperometric chemical sensors uses three operational amplifiers (OP), as shown in Fig. 1. When the applied reduction-oxidation (redox) potential (Vox) across the RE and WE equals the redox potential of the analyte, a redox current (Isensor) that is proportional to the concentration of the analyte is generated at WE. The Isensor is then transferred into an output voltage (Vo) using resistor R2. Accordingly, by using voltage as output, this circuit limits its output range based on the output swing of OP. Moreover, three OP consumes relatively high power.

With efforts toward miniature implantable glucose sensing systems [2-3], a low-power potentiostat for amperometric chemical sensors [2] is presented in Fig. 2. This circuit needs only one operational transconductance amplifier (OTA) and four MOS transistors. It detects Isensor and mirrors it as output current (Io). This potentiostat improves the output range by operating in current-to-current instead of traditional current-to-voltage transfer mode. However, even with compensation components (RF, CF), its output signal has unwanted oscillations especially when the sensor operates in very small current range.

This paper aims to provide a new design of readout circuit with potentiostat for amperometric chemical sensors that has wide current range including pico-ampere scale, has low power consumption, and has circuit stability not affected by sensor impedance. Availability of such potentiostat makes our research endeavors a step closer in realizing the implantable glucose sensing system.

II. Circuit Design

A. Basic concept of current-mode readout circuit

Electrochemical cells, such as glucose sensors, appear to readout circuit as a current source [3]. This is illustrated in Fig. 3. Therefore, a good readout circuit that operates in current-to-current transfer mode must have very low input impedance characteristic (Rin(readout)) so that it sensitively receives most of the generated sensor current (Isensor). Take also into account that the resistance of electrochemical cells (Rsensor) varies as the concentration of analyte changes [3]. Thus, a reliable readout circuit should be insensitive to the variation in sensor resistance.

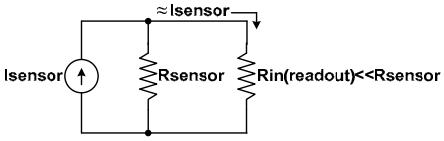

Fig. 3 Glucose sensor appears as current source to readout circuit

B. Readout-1, original low power potentiostat

The original low power potentiostat circuit is illustrated in Fig. 2 and is referred here onwards as Readout-1.

$$R_{in1} \cong g_{m3} \cdot r_{o3} \cdot r_{o1} \tag{1}$$

$$A_1\beta_1(s) \cong A_1(s) \cdot \frac{g_{m1}}{g_{m3}} \cdot R_{sensor} \tag{2}$$

The equivalent input resistance of Readout-1 (R_{in1}) is taken from the drain of NMOS M3 where the sensor is connected and is stated in equation (1). The output resistances (r_{o1}, r_{o3}) of cascode M1 and M3 transistors are inversely related with their drain currents. Consequently, when the sensor current which is also the drain currents of M1 and M3 goes low, the r_{o1} and r_{o3} increase and cause the R_{in1} to be extremely high. This high R_{in1} makes Readout-1 non-ideal as current-to-current readout circuit and insensitive to the sensor current.

Based on equation (2), the loop gain of Readout-1 ($A_1\beta_1(s)$) is directly affected by any change in the sensor resistance (R_{sensor}). This causes the poles of OTA and of sensor to move with R_{sensor} [2], then degrades phase margin, generates oscillations in the output, and becomes unstable.

C. Readout-2, proposed wide current range potentiostat

The proposed novel design of wide current range potentiostat is presented in Fig. 4 and is referred here onwards as Readout-2.

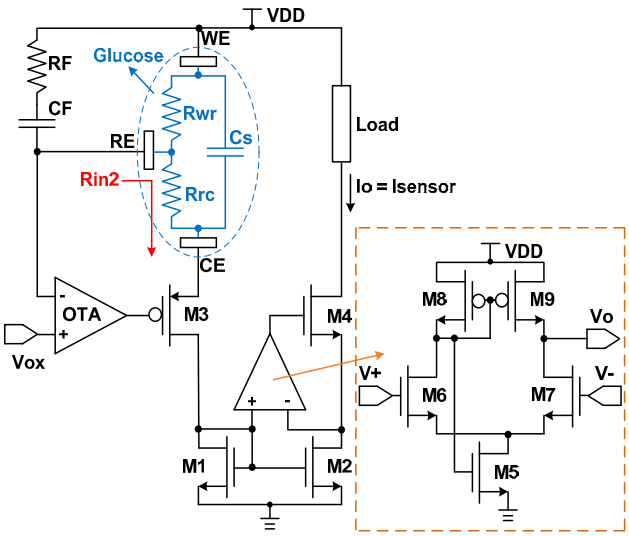

Fig. 4 Readout-2, the proposed wide current range potentiostat

The new readout adopts the structure of potentiostat in Fig. 2 so that it inherits the low power advantage. However, the important low input impedance characteristic is included in the circuit design so that it improves the current sensing range and enhances the stability.

$$R_{in2} \cong \frac{\frac{1}{g_{m1}} + r_{o3}}{1 + g_{m3} \cdot r_{o3}} \cong \frac{1}{g_{m3}} \tag{3}$$

$$A_2\beta_2(s) \cong A_2(s) \cdot \frac{R_{sensor}}{\frac{1}{g_{m3}} + R_{sensor}}, \frac{1}{g_{m3}} << R_{sensor} \tag{4}$$

To establish the low input resistance, the source terminal of MOS is chosen as input point. Then, to maintain the direction of current, the transistor M3 is changed into PMOS. Thus, the source terminal of PMOS M3 serves as input of Readout-2 and from it a very low input resistance (R_{in2}) is derived and is given in equation (3). The low R_{in2} guarantees that Readout-2 is suited for current-to-current transfer interface circuit and is sensitive even when the sensor current is in pico-ampere range.

The loop gain of Readout-2 ($A_2\beta_2(s)$) becomes stable and unaffected by R_{sensor} as specified in equation (4), especially when the input resistance of PMOS M3 ($1/g_{m3}$) is designed to be very small compared with R_{sensor}.

The transistors M1 and M2 serve as current mirror to transfer the sensor current (Isensor) into the output current (Io). The transistors M5 to M9 form the self-bias differential pair.

III. Results and Discussions

A. Set-up of circuit simulation

The post layout performances of Readout-1 and Readout-2 were simulated in HSPICE using the TSMC 0.35 μm mixed-signal 2P4M 3.3V CMOS models.

The amperometric chemical sensor was replaced with Rwr, Rrc and Cs model [2,6], as shown in Fig. 2 and Fig. 4, during circuit simulations.

The redox potential (Vox) was set to 0.4 V.

B. Improvement on feedback stability

Modifying the sensor resistance (Rwr) simulated the change of concentration of analyte. When the Rwr was set to 8 kΩ, 800 kΩ, 8 MΩ and 8 GΩ, that corresponded to generated sensor current of 50 μA, 0.5 μA, 50 nA and 50 pA respectively.

Fig. 5 shows the effect of Rwr variation to circuit loop gain (|L|). Readout-1 had loop gain (|L1|) that variably changes with Rwr while Readout-2 had loop gain (|L2|) that remains stable and unaffected by Rwr. This feature is evident at the lower frequencies.

In Fig. 6, Readout-2 exhibits a stable loop gain (|L|(max)) and a steady phase margin (PM) over the entire Rwr range unlike in the Readout-1. The Rwr used in this part was from 8 kΩ to 8 GΩ.

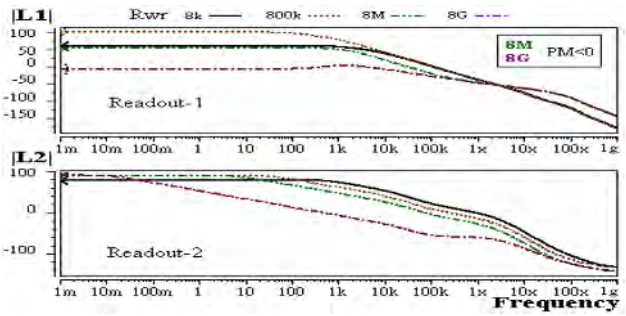

Fig. 5 Bode plot of loop gain |L| at various sensor resistance Rwr

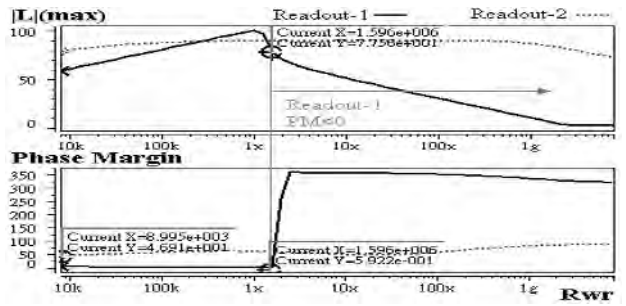

Fig. 6 Characteristics of loop gain |L| (max), phase margin against Rwr

C. Elimination of signal oscillations

The Readout-2 circuit was able to remove the unwanted oscillations in its output signal (Io2) because of improved feedback stability. On the other hand, Readout-1 took longer time to stabilize its output (Io1) as displayed in Fig. 7.

D. Widening of current sensing range

Fig. 8 and Fig. 9 show the agreement of simulation and experimental results regarding the current sensing range of Readout-2. Simulation used 3.3 V while experimental test used 5 V supply. Nevertheless, both results confirmed that Readout-2 can detect current down the nano-ampere range. Post-layout simulation results gave 50 pA to 50 μA range while experimental test provided 10 nA to 50 μA. The 10 nA is the lowest limit of the instrument used.

Fig. 8 also displays the linearity between the input sensor current (Isensor) and mirrored output current (Io) of Readout-2. There was a mismatch between the sensor current and output current. It was attributed to the load device that limited the drain source voltage of transistor M4. In experimental measurement in Fig. 9, when the Isensor was 25 μA, the Io was only 24.55 μA.

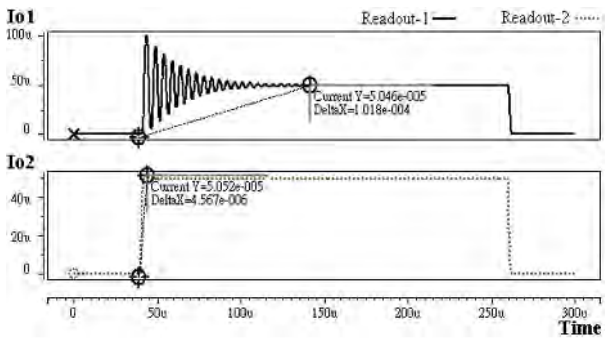

Fig. 7 Transient analysis showing signal oscillations

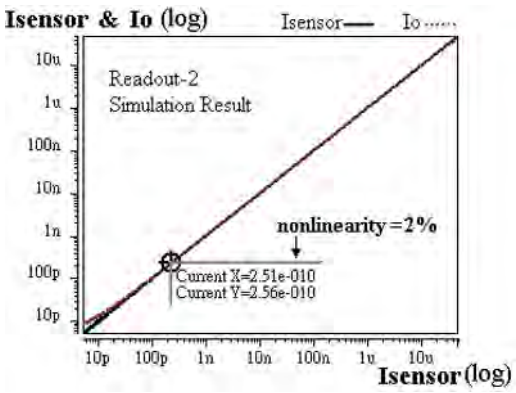

Fig. 8 Post-layout transfer characteristics of Readout-2

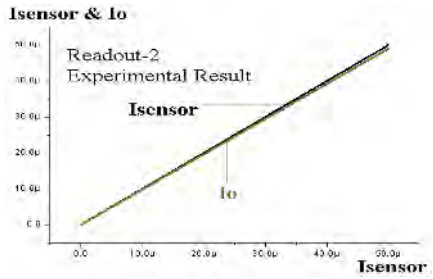

Fig. 9 Experimental transfer characteristics of Readout-2

E. Set-up of experimental test

An on-board module of Readout-2 was built to verify its design and performance. The OTA used the LMC6484AIN because of rail-to-rail output range, the MOS transistors employed the CD4007UBE chip, and the power was set to 5V. The Agilent B1500 Semiconductor Device Analyzer was used to source and sense current down the nano-ampere range, with 10 nA as its lowest limit.

F. Physical layout of the proposed readout circuit

Excluding the pads, the whole layout of Readout-2 circuit presented in Fig. 10 only occupied a chip area of 0.43835 mm by 0.403 mm or 0.1767 mm^2 using the TSMC 0.35 μm mixed-signal 2P4M 3.3 V CMOS technology.

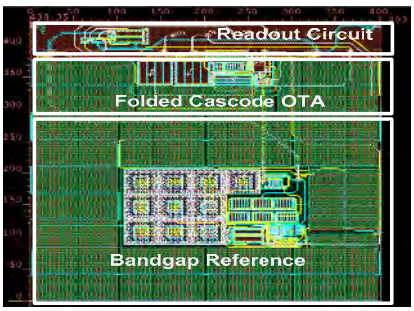

Fig. 10 Physical layout of Readout-2

IV. Conclusions

The proposed Readout-2 with potentiostat for amperometric chemical sensors is able to operate at a wider current range from 50 pA to 50 μA with power consumption from only 390 μW to 745 μW. Availability of this novel design allows us to move closer towards the realization of an implantable glucose sensing system. Table 1 summarizes the performances of Readout-2 as compared to Readout-1. Future work includes the improvement of current mirror to better match the sensor current to the output current.

Table 1 Comparison of original Readout-1 and proposed Readout-2

Characteristics	Readout-1	Readout-2
Sensing range	1 μA to 50 μA	50 pA to 50 μA
Power consumption (Isensor at 50 pA to 50 μA)	390 μW to 720 μW	390 μW to 745 μW
Input resistance (open loop)	924 MΩ	31.6 kΩ
Phase margin (worst case)	PM < 0 when Isensor at nA range	47° when Isensor = 50 μA
Loop gain affected by sensor resistance	Yes	No
Signal with oscillations	Yes	No
Settling time (at 1%)	101.8 μs	4.57 μs
Chip area	0.16 mm^2	0.176 mm^2

Abstract — **Burst-mode driven high intensity focused ultrasound (HIFU) with the presence of ultrasound micro bubbles has been proven to be capable of locally and reversibly increasing the permeability of blood-brain barrier (BBB). However, the use of excessive acoustic pressure usually accompanied with intracerebral hemorrhage, which is considered a deterred side effect, especially when in applications such as drug delivery. The purpose of the current study is to provide a secure protocol using multiple low-pressure sonications, to disrupt localized BBB and preserve sonicated area without producing intracerebral hemorrhage.**

The brains of 10 Sprague-Dawley rats were subjected to 16 sonications, either unilaterally or bilaterally. A 1.5-MHz spherically curved 1-3 composite transducer was used to deliver the burst-mode ultrasonic focal energy into the rat brain after both craniotomy and micro bubble injection. Electric powers from 1 to 10 W were tested and sonication mode was adjusted from single high-pressure sonication (2.45 MPa, 30s ×1) to multiple shoots (1.1 MPa, 30s ×6). The path of sonication could be either a row or a triangle, which depends on the treatment plan. Pathologic examination includes hematoxylin and eosin (H&E) and immuno-histochemistry (IHC) staining. It was used to quantify the damage in accompany with BBB disruption which includes hemorrhage and tissue necrosis. MR imaging was employed to evaluate the BBB disruption and brain tissue hemorrhage *in vivo*. Pathological examinations showed that the average hemorrhage score decreased from 2.3+/- std (severe) to 0.3+/- std (slight) by using the proposed protocol. The finding was confirmed by *In vivo* MRI examinations. Compared with single high-pressure sonication, multiple low-pressure sonication effectively reduced the occurrence of hemorrhage noticed in T2*-weighted images. The efficiency of BBB-disruption increased as observed in contrast-enhanced T1 weighted Turbo-spin-echo sequence. The current study provides an improved sonication protocol which could temporally and locally disrupt the Blood-Brain-Barrier. It therefore demonstrated the possibility of safe drug delivery into restricted brain regions in the future applications.

Keywords — **Focused ultrasound, blood-brain barrier, hemorrhage**

I. Introduction

The blood-brain barrier (BBB) is a specialized structure of blood vessel walls that limits the free transportation and diffusion of molecules from the vasculature to the surrounding neurons. Many methods have been developed to enhance the BBB permeability to assist the penetration through the tight junction for therapeutic purpose, all of which, unfortunately, induce systemic BBB disruption and fail to deliver drug to a specific brain region.

High-intensity focused-ultrasound (HIFU) has been shown with the potential to increase BBB permeability [1, 2]. Hynynen et al showed that BBB can be selectively disrupted with a reduced ultrasound energy exposure[3], which minimized the parenchyma damage through the use of low-power burst mode HIFU sonications and under the presence of an ultrasound contrast agent [4]. However, hemorrhage still persists under the low power used and remains the major adverse effect. Intracerebral hemorrhage can be hazardous, especially in applications such as to deliver therapeutic molecules into brain. Therefore, the safety ultrasound exposure, which only disrupts BBB without any hemorrhage raised widespread interest.

The current study demonstrates a new strategy by using multiple burst sonications instead of high-pressure single-shot sonication to reduce the occurrence of hemorrhage. Animal experiments were conducted, and imaging modalities by both magnetic resonance imaging (MRI) and single-photon emission computed-tomography (SPECT) were employed. The extent of tissue damage was analyzed histologically.

II. Methods

A. Animal preparation

Adult male Sprague-Dawley rats (300–350 g) from the National Laboratory Animal Breeding and Research Center (Nan-Kang, Taipei, Taiwan) were used in the study. The

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 547–550, 2009
www.springerlink.com

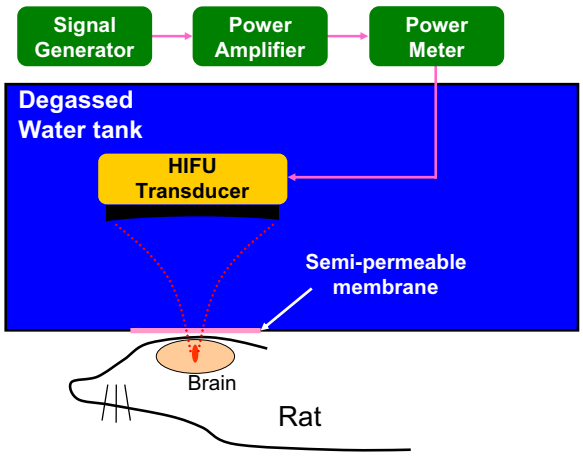

Fig. 1 Experiment setup.

experiments were approved by the Institutional Animal Care and Use Committee of Chang Gung University and adhered to the experimental animal care guideline.

Animals were anesthetized using chlorohydrate (300 mg/kg) through IP injection. Craniotomy was performed before the ultrasound sonication to reduce distortion of the ultrasound focal beam. A cranial window of approximately 7×7 mm^2 was opened with a high-speed drill and a PE-50 catheter was placed in the jugular vein. The skull defects were covered with saline-soaked gauze to prevent dehydration and infection during the process.

B. Ultrasound Sonication

Figure 1 shows the experiment setup. The ultrasonic focal beam was generated by a 1-3 Piezocomposite focused ultrasound transducer (Imasonics, France. Diameter = 60 mm, Curvature radius = 80 mm, Frequency = 1.5 MHz, electric-to-acoustic efficiency = 70%). An arbitary-function generator (33220A, Agilent, USA) was used to generate the driving signal that was fed to a radio-frequency power amplifier (100A250A, Amplifier Research, USA). The energy of signal delivered to the transducer was monitored by a power meter (Model 4421, Bird, USA). An acrylic water tank was used. A window of approximately 4×4 cm^2 was opened at its bottom, which was sealed with a thin film to allow the entry of ultrasound energy. The animal was placed directly under the water tank with its head tightly attached to the thin-film window. The animals were placed below the water tank as figure 1.

Micro-bubbles were injected during the HIFU treatment to enhance the efficiency of BBB opening. SonoVue® (Bracco, Milan, Italy. SF_6 coated with mean diameter = 2.0-5.0 μm) was injected through the catheter 10 seconds prior to the sonications. Each bolus injection contains 10 μl.

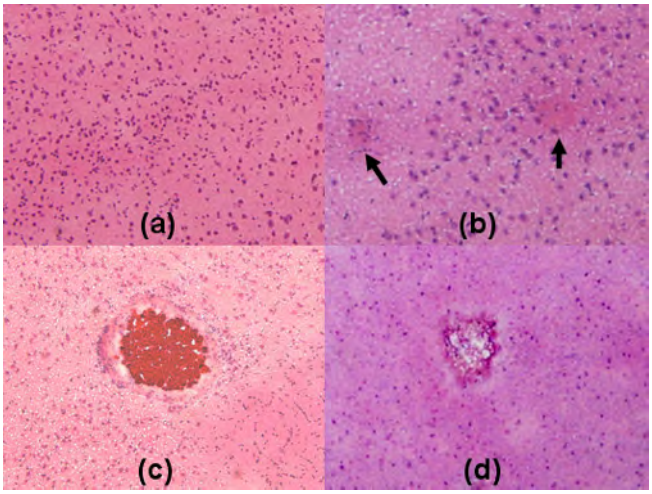
Two experiments were conducted in order to compare the sonication strategy. In the first experiment, the animal sonications were conducted with single-shot focused ultrasound. A relatively high pressure of 2.45 and 3.48 MPa were employed. The sonication was pulsed with a burst length of 10 ms and a repetition frequency of 1 Hz. The duration of each sonication was 30 seconds. In the second experiment, the animal sonications were conducted with six sonications with a small spacing (1 mm) between each targeting point. The peak pressure was 1.1 MPa, 2 and 3 times lower than the acoustic powers used in the first experiment.

C. Pathologic Examinations

Animals were sacrificed approximately 3-4 hours after HIFU sonication. The brains were immediately removed and frozen in an O.C.T. compound (Optimal Cutting Temperature compound, Tissue-Tek®, SAKURA, USA). The tissues were sectioned in Microtome (Model 3050S, Leica, German). The slices were preserved and stained with hematoxylin and eosin (H&E). The results were classified into 4 categories as described in figure 2, which depends on the level of hemorrhage and cell damage. The neuronal cell damage and hemorrhage were evaluated quantitatively by four different grades. The grade 0 was defined as neither tissue damages nor erythrocyte extravasations were observed after sonication. In grade 1, small extravagated erythrocytes were occasionally observed, but H&E staining showed neither neuronal loss nor cell structure changed. In grade 2, there is continuous and extensive hemorrhage, accompanied by neuronal loss, or apoptotic cell death. Grade 3 observed neuronal cell necrotic death, next to the findings in grade 2. It was the most severest damage in tissue.

D. Magnetic resonance imaging (MRI)

After ultrasound sonication, the animals were immediately scanned by MRI. All images were acquired on a 3-T scanner (Trio a Tim system, Magnetom, Siemens, Erlangen, Germany) using the standard wrist coil with an inner diameter of 13 cm. The animals were placed in an acrylic holder and then positioned in the center of the magnet. Images were acquired using a fully flow compensated T2*-weighted 3D Gradient Recalled Echo sequence and dynamic contrast-enhanced (DCE) T1-turbo-spin-echo sequence. An IV bolus (0.125 mmol/kg) of MRI contrast agent (Magnevist®, Berlex Laboratories, Wayne, NJ) was administered through the unilateral jugular vein during the dynamic acquisition of the T1-weighted images.



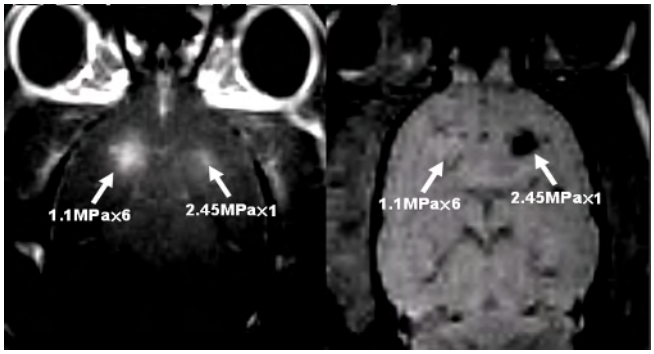


Fig. 2 Four categories of cell necrosis and damage induced by focused ultrasound. (a) level 0: neither tissue damages nor erythrocyte extravasations were observed. (b) level 1: small extravasated erythrocytes were occasionally observed, but H&E staining showed neither neuronal loss nor cell structure changed; (c) level 2: continuous and extensive hemorrhage, accompanied by neuronal loss, or apoptotic cell death; (d)level 3: the most severeest damage in tissue, neuronal cell necrotic death was observed besides findings in level 2.

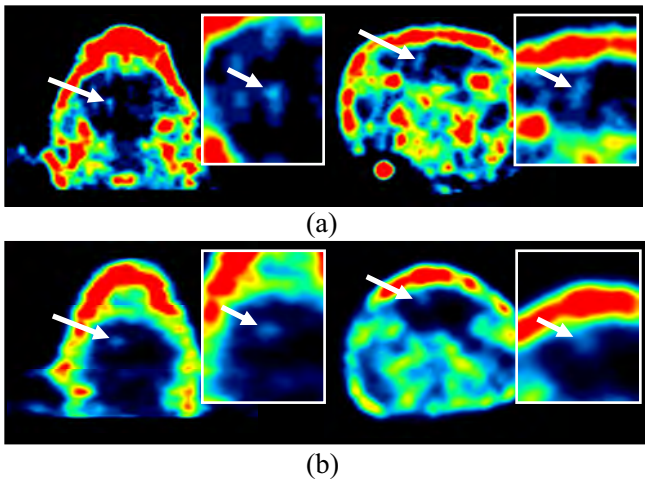
E. Single-proton emission computed tomography (SPECT) imaging

SPECT imaging was acquired to evaluate the potential radiotracer leakage through the disrupted BBB. After HIFU sonication, isotope (^{99m}Tc-DTPA,5 mCi) was intravenously injected and SPECT images of the brain was acquired using a dedicated small animal SPECT/CT scanner (Nano-SPECT®, Bioscan Inc. Washington D.C., resolution = 1.4 mm, voltage = 140keV). Images were reconstructed by OSEM (Ordered Subsets-Expectation Maximization).



III. Results

The area of BBB opening and hemorrhage were confirmed by contrast-enhanced T1-weighted MRI. In normal case, MRI contrast agent cannot pass through the BBB into the brain tissue but it can be observed in image by MRI scanner once BBB been disrupted and the MRI contrast agent leak into brain parenchyma. Figure 3(a) shows that BBB can be disrupted in both power of sonication in the first experiment. The single sonication of 2.45 MPa was targeted at the right brain and the six sonications of 1.1 MPa at left brain. The signal changes by MRI contrast agent were better visualized in experiments of multiple sonications of lower-pressure shot. Figure 3(b) shows that a single 2.45 MPa sonication can cause severe intracerebral hemorrhage

(a) (b)

Fig. 3 MRI (a) contrast –enhanced T1-weighted image to identify the BBB-disruptive region and (b) MR-SWI to identify the intracerebral hemorrhage occurrence.

(a)

(b)

Fig. 4 SPECT images showing the ^{99m}Tc DTPA tracer leaked into parenchyma after sonication with the sonication parameter of (a) single-shot with pressure 2.45 MPa and (b) multi-shot with 1 MPa × 6 points. Left images show the coronal view and right ones show the transverse view of the animal brain.

rather than the multiple 1.1 MPa sonications. This finding indicated that the proposed strategy not only contributes to a higher BBB-disruption efficiency but also reduce or even remove the occurrence of intracerebral hemorrhage. Figure 4 showed one typical SPECT image, which indicated a radiotracer leakage into brain parenchyma through the disrupted BBB under single and multiple sonication protocols. The radio-tracer can be detected in the unilateral sonicated brain, which suggests that a successful BBB disruption by both sonication protocols. No direct imaging from SPECT can indicate the intracerebral hemorrhage such as MR-SWI (Maybe delete this, a negative comment). However, it was noticed that the radio-tracer distribution in the BBB-disruptive region, when using multiple low-pressure bursts,

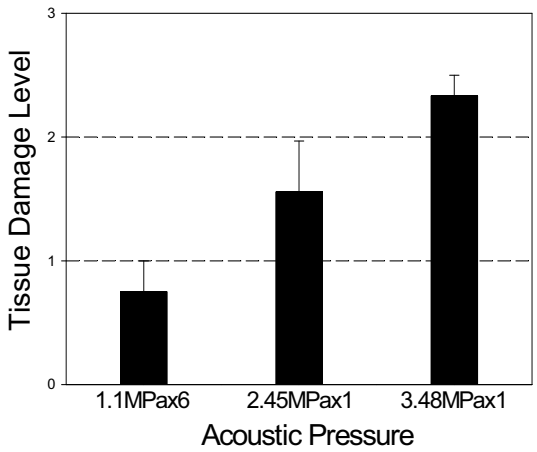


Fig. 5 Quantified grade of tissue damage from low pressure (1.1 MPa) to high pressure (3.48 MPa)

is more uniform when compared to that in single high-pressure burst protocol, which becomes apparent in the coronal view. A high radiation count spot was noticed, when compared to that in the surrounding BBB disruptive region, which suggest hemorrhage because of increased leakage by the radio-tracer.

The level of tissue damage is an issue of importance in HIFU experiment. Figure 5 showed the result from histology examination. The average hemorrhage score decreased from 2.33 +/- std (severe) to 0.75 +/- std (slight) by the proposed protocol. This suggests that the proposed strategy only produce mild erythrocyte extravasations, which can be considered as safe. In contrast, the single high-pressure burst creates BBB-disruption which was accompanied by severe intracerebral hemorrhage and was therefore hazardous.

IV. Conclusions

The current study confirmed that in the proposed strategy (please say explicitely what was proposed) the HIFU energy can lead to reduced level of hemorrhage and at the same time maintain the efficiency of BBB-disruption. Applications such as drug delivery into the brain can therefore be feasible because of increased safety measures.

Abstract — **Schizophrenia is a severe mental illness associated with multiple neuropathological and neurochemical abnormalities. The aim of this study is to examine if patients with schizophrenia exhibit any abnormality in the level of functional connectivity between the neuronal centers responsible for the processing of vestibular information in the left and right side of the head. Signals were recorded simultaneously in response to tilt stimuli by a special hydraulic chair via a pair of electrodes inserted in the left and right ear canals to rest on tympanic membrane. Using the complex Morlet wavelet transform, we compared instantaneous phase synchronization indices on a set of recordings collected from a group of control subjects (n=24) against schizophrenia group (n=11). Our results show differences between groups in the level and duration of synchrony mostly during dynamic rather than static phases of the tilts. Larger study sample is required to verify these findings.**

Keywords — **Schizophrenia, vestibular system, phase synchronization, complex Morlet wavelet**

I. Introduction

Schizophrenia is a serious mental disorder with annual incidence between 0.2 and 0.4 per 1000 and a lifetime risk of about 1%. Schizophrenia is the most disabling among the psychiatric disorders and is characterized by positive symptoms (e.g., delusions, hallucinations), negative symptoms (e.g., apathy, social withdrawal), disorganized symptoms (e.g. disorganized thought, communication, and behavior), and cognitive impairment (e.g., learning, memory, and executive functioning problems).

Schizophrenia is associated with several pathophysiological conditions that involve an extended network of brain structures including cortex, cerebellum, thalamus, hippocampus, and the basal ganglia. In terms of neurochemistry; converging evidence from different studies suggests several neurotransmitter systems are clearly involved. These include dopamine (DA), serotonin, gamma-amino butyric acid (GABA) and glutamate (Glu) systems [1].

The vestibular system is responsible for providing the sense of balance and the information on the motion and position of the head in space. The peripheral part of the vestibular system is located in the inner ear and consists of two sack-like otolith organs (OTO), the utricle and saccule, and three semicircular canals (SCC). The OTO detect linear acceleration and head position while SCC sense direction and speed of angular accelerations (e.g. onset of head rotations). Hair cells within the vestibular apparatus are responsible for generating receptor potentials.

Vestibular nerve fibers that innervate the hair cells project via the VIII cranial nerve to cerebellum and integrative centers in brainstem also known as vestibular nuclei (VN). The four nuclei of the VN are the lateral, the medial**,** the superior, and the inferior vestibular nucleus. There are reciprocal interconnections between the four VN. VN also communicate bilaterally through a commissural system that is predominantly inhibitory. Most of these connections are inhibitory GABA-ergic and provide pathways by which information from pairs of corresponding SCCs and OTOs can be compared. The posterior cerebellum has extensive inhibitory (GABA-ergic) and excitatory (Glu) reciprocal connections with the VN that are involved in regulatory mechanisms for the control of the eye movements, head movements, and posture [2]. Converging evidence from literature, e.g. abnormal posture and proprioception, impaired eye blink conditioning, and impaired adaptation of the vestibular-ocular reflex suggests that some of the symptoms of schizophrenia may be associated with cerebellar anomalies [3]. Recent literature has examined the close links between the vestibular system and emotion processing systems e.g. Parabrachial Nucleus (PBN) with some researchers suggesting a causal relationship [4].

The vestibular system can therefore be regarded as a potential window for exploring the brain function. Measuring the activity of the vestibular system can be providing a quantitative, indirect measure of activity in the brain regions and neural pathways that are frequently compromised in neuropsychiatric disease. Our studies have suggested that vestibular responses acquired by a new method named Electrovestibulography (EVestG) are different in schizophrenia as well as depression and Parkinson's disease.

Affected neurotransmitter pathways in schizophrenia, especially reciprocal pathways that link VN to cerebellum and PBN, may also compromise the VN bilateral commissural connections leading to a change in the index of connectivity between the left and right VN.

Phase synchronization in coupled chaotic systems was introduced by Rosenblum et al. [5]. In area of brain re-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 551–554, 2009
www.springerlink.com

search, patterns of synchronized oscillations have been studied for different frequency bands in EEG signals and it has been pointed out that they reflect various brain states and cognitive processes [6]. Using the same recording set up as EVestG, in order to measure the level of connectivity between the activity of the left and right VN, we have compared averaged dynamic phase synchronization as well as *coherence interval* patterns [7] in the recorded signal from a group of schizophrenia patients with respect to control subjects.

II. Methods

A. Subjects

35 subjects between 20 and 67 years of age, both male and female, took part in this study. 11 participants (7 males, 4 female) aged between 29 and 46 years (Mean= 37.2, SD=5.9 years) met DSM-IV diagnostic criteria for schizophrenia, with disease duration ranging from 15 to 28 years. Symptoms of psychopathology were assessed by a trained clinician using Positive and Negative syndrome Scale (PANSS), a 30-item, 7 point rating instrument. The mean total PANSS score was 53.5 (SD=16.8). A comparison group of 24 healthy, control subjects (12 males, 12 females) aged between 20 and 67 (Mean= 38.9, SD=15.4 years) without a history of neurological or psychiatric illness, also participated. All the participants were screened for cognitive decline using the Mini-Mental State Examination (MMSE). Average score was 29.6 (SD=.7) for control participants and 29.2 (SD=1.3) for schizophrenia group (maximum score of 30). Participants also self-rated their alertness using the Stanford sleepiness test, and all scored below 3 indicative of being alert at the time of testing. A standard hearing test was conducted on all participants to ensure they don't have hearing problems.

No participant demonstrated hearing or balance impairment. All experiments completed under Monash University Human Ethics approval number 2006/604MC.

B. Stimuli

The methodology used in this study is adopted form EVestG recording technique [8]. To avoid neck muscle artifact, the vestibular system was stimulated by passively tilting a participant, with eyes closed, who is seated in a special hydraulic and instrumented chair, housed in an electrically and acoustically shielded chamber. The chair was programmed to move in the defined plane until it made a 45 degrees angle with its original position within 3 seconds. Fig.1 shows the resulted s-shaped position and velocity profiles.

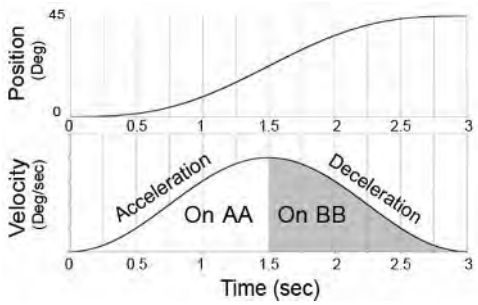

Fig. 1 Smooth position and velocity profiles of hydraulic chair motion. The first 1.5 seconds after onset of the motion is marked as OnAA that corresponds to acceleration. The chair decelerated during OnBB segment until reached steady state.

C. Procedure

A 60 second recording was conducted. The recorded signal was divided into different time segments to investigate dynamic and static phases (i.e. when the tilt chair is moving or when is stationary) for back tilt stimuli. Prior to the tilt (t=0-20 sec) the subject was seated in an upright neutral position to measure background neuronal activity (BG). The transient section of the recorded signal at the onset (On) of the tilt will help to determine the dynamic response (t=20-25 sec). This onset response is made up of an acceleration (OnAA) and deceleration (OnBB) phase and labeled at t=20-21.5 sec and t=21.5-23 sec respectively (see figure 1). The steady state (SS) region labeled at t=30-40 sec.

D. Electrophysiological recordings and Preprocessing

Signals were obtained via a pair of electrodes consist of a wick inserted into the left and right ear canals and positioned to rest on the tympanic membrane. This method of recording was previously used in EVestG and Electrocochleography [9]. Each electrode was referenced to the linked earlobe and signals were amplified using a CED1902 amplifier and digitized by CED1409 A/D converter. The sampling rate was initially 44.1 KHz that is suitable for EVestG analysis but later signals were down sampled to 3 KHz as we did not need very high frequency components for this study. The raw signals were screened in time and frequency domains for muscle and motion artifacts both visually and automatically to find and remove large artifacts. To remove low frequency noise due to the motion and power line artifact, signal was high pass filtered at 5 Hz and notch filtered at harmonics of 50Hz with 3db attenuation factor. Forward and reverse filtering with resultant zero phase shifts was employed in order to preserve the phase information of the signal.

E. Data analysis

Our data analysis method was centered on the dynamic phase synchronization index of the signals recorded from the electrodes in the left and right ear. Phase of the signals, were obtained using the complex Morlet wavelet defined as:

$$\psi(t) = \frac{1}{\sqrt{\pi f_b}} e^{2i\pi f_c t} e^{-\frac{x^2}{f_b}} \quad (1)$$

where f_c is the center frequency of the wavelet and f_b is the bandwidth parameter. For the signal $S(t)$ recorded from an electrode, wavelet coefficients at time t_0 and scale a are defined as:

$$W_S(t_0, a) = \frac{1}{a} \int_{-\infty}^{+\infty} S(t) \psi^*(\frac{t - t_0}{a}) dt \quad (2)$$

where the $\psi^*(\frac{t-t_0}{a})$ is the complex conjugate of the equation (1) above. In the current study, f_c is adjusted at each scale and f_b is set to one. The wavelet coefficients are a complex numbers and can be described as:

$W_S(t_0, a) = A(t_0, a) e^{i\varphi(t_0, a)}$, where $A(t_0, a)$ and $\varphi(t_0, a)$ are amplitude and phase at the moment t_0. The signals $S_r(t)$ and $S_l(t)$ are n:m synchronized if they meet the 'phase locking' condition suggested by Rosenblum et al.[5]:

$$\left|\varphi_{r,l}(t, a, n, m)\right| = \left|n\varphi_r(t, a) - m\varphi_l(t, a)\right| < const. \quad (3)$$

where m and n are integers. In current study, our aim is to study the signals recorded from the same physiological system, so we restricted ourselves to the case of 1:1 phase synchronization:

$$\varphi'_{r,l}(t, a) = \varphi_{r,l}(t, a, 1, 1) \quad (4)$$

When studying the synchronization in noisy dynamical systems we have to take a statistical point of view by analyzing the relative phase angles on the unit circle (i.e. [0, 2π] interval). In this sense, synchronization is understood by appearance of peaks in the relative phase difference histogram [10]. We employed the first Fourier mode of the distribution of relative phase differences to measured 1:1 phase synchronization, $R_{l,r}(t, a)$ [11]:

$$R_{l,r}(t, a) = \left\{ \left\{ \frac{1}{n+1} \sum_{k=-n/2}^{n/2} \sin[\varphi'_{r,l}(t + k\Delta t, a)] \right\}^2 + \cdots \right.$$

$$\left. \left\{ \frac{1}{n+1} \sum_{k=-n/2}^{n/2} \cos[\varphi'_{r,l}(t + k\Delta t, a)] \right\}^2 \right\}^{1/2} \quad (5)$$

Where Δt is the sampling interval (1/3000 Sec.) and n is the length of sliding window (n=300). It is evident that R is restricted to the interval [0,1] and reaches 1 if and only if the condition (3) is met whereas for unsynchronized time series, e.g. uniform distribution of phases, R=0.

III. Results

The recorded signal was wavelet transformed and the phase was calculated as a function of time and frequency. 33 different frequencies between 4 Hz and 100 Hz were analyzed by changing center frequency to desired frequency. The segments of signal during the back tilt stimuli that were analyzed for each subject named as BG, onAA, onBB, On, and SS. Phase synchronization index, R(t,a), was calculated at each frequency. Since we were interested to investigate the total duration of synchronized intervals in the dynamic segments (during or immediately after the tilt) with respect to the BG recording (with the subject seated in a neutral position), a threshold value was calculated based on the mean and standard deviation of each subject's BG segment R value.

During other segments, all the R values that were greater than the threshold were considered significant. The total duration of the significant intervals were computed and averaged across control and schizophrenia groups for each segment. Figure 2 shows the averaged values for synchronized events during On, OnAA, OnBB, and SS phases. There are differences, although not significant across all frequencies, between control and schizophrenia groups. The differences are higher in dynamic phases On, onBB, and onAA with respect to SS and it is appeared that in the frequency range of 6Hz-14Hz the differences are larger between groups. It is also evident that OnBB (deceleration phase) results are better differentiating the groups than OnAA.

Furthermore, the R values during OnAA (acceleration) and OnBB (deceleration) segments were averaged for the frequencies in the selected 6Hz-14Hz range that appeared to be more sensitive to different tilt segments. Figure 3 illustrates the smoothed average synchronization curves. OnBB segment shows better separation between the groups.

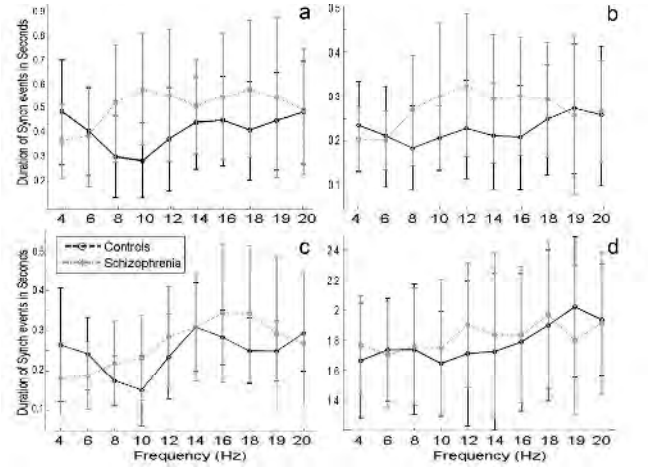

Fig. 2 Averaged duration of synchronization index above the threshold level (Sec.) versus different frequency bands. a) On, b) OnBB, c) onAA, and d) SS response. Error bars show standard deviation.

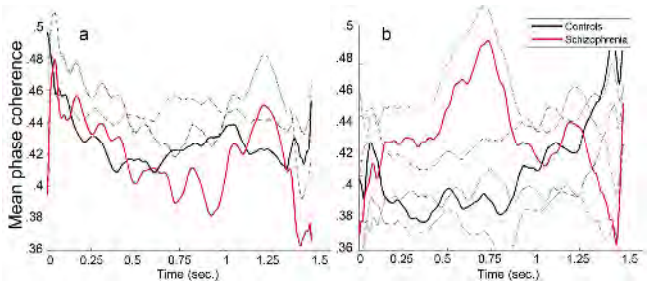

Fig. 3 Smoothed averaged synchronization curves in the frequency range 6Hz to 14Hz during a) OnAA and b) OnBB segments of the tilt. Dotted lines show the overlapping standard error bars.

IV. Conclusions

The results that we observed in the index of phase synchronization revealed some mild differences in the control and schizophrenia group however, differences were consistently higher in the 6Hz-14Hz range. It was also evident that dynamic phases of the tilt were more powerful in terms of separating controls and schizophrenics rather than the SS phase. It is also apparent from the graphs that schizophrenia subjects generally exhibit a slight hyper activity in the level of synchronization between the left and right VN. These evidences can be an indication of the compromised dynamic activity profile of vestibular system in schizophrenia.

The schizophrenia subjects were on different types of medication during the experiments and had different scores on the positive and negative symptoms scale, separation of the responses by the type of medication taken or grouping the patients into different categories of symptoms may improve the results.

Constrained Spatiotemporal ICA and Its Application for fMRI Data Analysis

Tahir Rasheed[1], Young-Koo Lee[1], and Tae-Seong Kim[2]

[1] Department of Computer Engineering, Kyung Hee University, Republic of Korea
[2] Department of Biomedical Engineering, Kyung Hee University, Republic of Korea

Abstract — **In general, Independent Component Analysis (ICA), a blind source separation technique, is used in either spatial or temporal domain. For spatiotemporal data, however, in which the statistical independence criteria of the underlying sources cannot be guaranteed, ICA does not perform well simultaneously in both domains. Thus, spatiotemporal ICA (stICA) has been proposed. However, these conventional ICAs in spatial, temporal, or spatiotemporal mode suffer from a problem of source ambiguity: each source must be identified by users. To extract only the desired sources, recently constrained ICA (cICA) has been proposed in which a priori information of the desired sources are used as constraints in either spatial or temporal domain. In this study, we propose constrained spatiotemporal ICA (constrained-stICA), as an extension of cICA, for better analysis of spatiotemporal data. The proposed algorithm tries to find the maximally independent, yet desired sources in both the spatial and temporal domains. The performance of the proposed algorithm is tested against the conventional ICAs using simulated data. Then, its application to the analysis of spatiotemporal fMRI data indicates improved data analysis against the conventional functional MRI data analysis via SPM.**

Keywords — **Spatiotemporal ICA, Constrained spatiotemporal ICA, Functional MRI**

I. Introduction

Independent component Analysis (ICA), a blind source separation (BSS) method based on higher order statistics, decomposes the linear memory-less mixed observations into their underlying independent sources and the corresponding mixing weights [1, 2]. There are two conventional modalities in which ICA can be used to decompose spatiotemporal data like image sequences into a set of images and a corresponding set of time sequences. Spatial ICA finds underlying independent spatial sources and their corresponding set of time weight sequences. Temporal ICA finds independent temporal sequences and their corresponding set of spatial weights.

With the success of ICA in medical signal processing there is a strong interest in ICA for the analysis of spatiotemporal data (e.g., functional MRI data). Functional MRI (fMRI) is a non-invasive imaging technique to study the spatiotemporal brain functions in both research and clinical areas [7]. In 1998, McKeown *et al.* [6] for the first time introduced ICA for fMRI data analysis, with the assumption that fMRI data is a mixture of spatially independent components. ICA is very successful in the identification of various source signals in fMRI [4] which are considered challenging for the second order techniques such as correlation and regression analysis. So far, most of the applications of ICA for fMRI are based on ICA using the spatial mode (Spatial ICA). However the choice of spatial or temporal ICA is controversial: Comparison and discussion on the underlying assumptions for the use of spatial and temporal ICA is given in [3]. For spatiotemporal data of fMRI, where the underlying sources are not really independent, spatial or temporal ICA tries to find a set of independent sources at the cost of their corresponding unconstrained set of temporal and spatial weights respectively.

Spatiotemporal ICA however, for image sequences data of fMRI where underlying independence assumption is not fulfilled, tries to create a balance by jointly optimizing the two sources [8]. For the high dimensional data, it gives large number of independent components making the subsequent analysis very complicated and subjective. In other words, there exists source ambiguity for ICAs in the conventional spatial, temporal, and spatiotemporal modes.

To find some specific source, constrained ICA (cICA) algorithm incorporates a priori information about the desired source [5]. This algorithm has been applied for fMRI data in [9] with either its spatial or temporal mode.

In this study, considering the nature of spatiotemporal fMRI data, we extend cICA into constrained spatiotemporal ICA (constrained stICA) that finds maximally independent, yet desired temporal and spatial sources. The performance of the algorithm against the conventional ICA is tested using the simulated data. Then it has been applied to fMRI data and its results are compared to those of the conventional fMRI data analysis tool, Statistical Parametric Mapping (SPM).

II. Independent component analysis

Independent component Analysis (ICA) assumes that a linear memory-less observation matrix $\mathbf{X} = (\mathbf{x}_1, ..., \mathbf{x}_n)^t$ can be decomposed into underlying set of independent sources $\mathbf{S} = (\mathbf{s}_1, ..., \mathbf{s}_n)^t$ such that,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 555–558, 2009
www.springerlink.com

$$\mathbf{X} = \mathbf{SA} \quad \text{or} \quad \hat{\mathbf{S}} = \mathbf{XW} \tag{1}$$

where $\mathbf{A}$ is the mixing matrix and $\mathbf{W}$ is the un-mixing matrix.

General implementations of ICA can be found in the literature [1, 2]. If the observation matrix contains image sequence, Equation 1 can be written as $\mathbf{X} = \mathbf{S\Lambda T^t}$ where $\mathbf{S} = (\mathbf{s_1}, ..., \mathbf{s_k})^\mathbf{t}$ represent the independent spatial sources, $\mathbf{T} = (\mathbf{t_1}, ..., \mathbf{t_k})^\mathbf{t}$ the corresponding independent time courses, and $\mathbf{\Lambda}$ the diagonal scaling parameters.

A. Spatial and Temporal ICA

The observation matrix $\mathbf{X}$ can be decomposed into $\mathbf{X} = \mathbf{UDV^t}$ using singular value decomposition (SVD) where $\mathbf{U}$ is an $m \times m$ Eigen image matrix, $\mathbf{V}$ a $n \times n$ matrix of corresponding Eigen sequences, and $\mathbf{D}$ a $m \times n$ diagonal matrix of singular values. By retaining the k singular value we can reduce the rank of the matrix.

$$\mathbf{X} \approx \hat{\mathbf{X}} = \hat{\mathbf{U}}\hat{\mathbf{D}}\hat{\mathbf{V}}. \tag{2}$$

Spatial ICA assumes that the $m \times k$ Eigen image matrix $\hat{\mathbf{U}}$ can be decomposed into the k spatially independent components $\mathbf{S} = (\mathbf{s_1}, ..., \mathbf{s_k})^\mathbf{t}$. The corresponding time courses can be obtained as follows.

$$\hat{\mathbf{X}} = \mathbf{SA_s}\hat{\mathbf{D}}\hat{\mathbf{V}}^\mathbf{t} \quad = \mathbf{ST_s} \tag{3}$$

where the rows of $\mathbf{T_s} = \mathbf{A_s}\hat{\mathbf{D}}\hat{\mathbf{V}}^\mathbf{t}$ contain corresponding time courses. On the other hand, temporal ICA assumes that $n \times k$ Eigen sequence matrix can be decomposed into the k independent temporal components $\mathbf{T} = (\mathbf{t_1}, ..., \mathbf{t_k})^\mathbf{t}$. The corresponding spatial modes can be obtained as follows.

$$\hat{\mathbf{X}} = \hat{\mathbf{U}}\hat{\mathbf{D}}\mathbf{A}^\mathbf{t}_\mathbf{t}\mathbf{T}^\mathbf{t} \quad = \mathbf{S_t}\mathbf{T}^\mathbf{t} \tag{4}$$

where each column of $\mathbf{S_t} = \hat{\mathbf{U}}\hat{\mathbf{D}}\mathbf{A}_\mathbf{t}^\mathbf{t}$ is the spatial mode.

B. Spatiotemporal ICA

The Spatiotemporal ICA (stICA) [8] is based on the assumption that sometimes underlying spatial and temporal sources are not completely independent. In these cases, spatial or temporal ICA will not produce good results in their corresponding temporal and spatial domains respectively. stICA treats the spatial and temporal domains equally by maximizing the following cost function

$$\mathrm{h_{st}}(W_s, \Lambda) = \alpha H(\mathbf{Y}_s) + (1-\alpha) H(\mathbf{Y}_t) \tag{5}$$

where W_s is the spatial un-mixing matrix, Λ scaling matrix, α the relative weighting factor, $H(\mathbf{Y}_t)$ the temporal entropy, $\mathbf{Y_t} = \sigma_t \mathbf{y}_t$ the cdfs of temporal signals, $\mathbf{y_t} = \hat{V}W_t$ extracted temporal signals, $H(\mathbf{Y}_s)$ the spatial entropy, $\mathbf{Y}_s = \sigma_s \mathbf{y}_s$ the cdfs of spatial signals, and $\mathbf{y}_s = \hat{U}W_s$ the extracted spatial signals.

C. Constrained ICA

When a priori information about the desired source is available, we can incorporate this information in the cICA algorithm [9]. These constraints (or references) guide the algorithm in the direction of only desired independent sources during the optimization process. If we let the reference be $\mathbf{r}(t) = (r_1(t), ..., r_k(t))^t$, the closeness constraint for single IC can be written as

$$\mathrm{g}(\mathbf{w}) = \varepsilon(\mathbf{w^t x}, r_i) - \xi \le 0 \tag{6}$$

where ε is some closeness measure. The closeness threshold parameter is denoted by ξ. This algorithm only extracts only the desired subset from the entire sources.

III. Constrained spatiotemporal ICA

In this algorithm, we exploit the salient features of SVD: (i) it decomposes the observed spatiotemporal data into a set of spatial and temporal modes, (ii) both the modes are orthonormal and (iii) the rank reduction can be done by selecting an appropriate number of k vectors. Based on the first property, corresponding underlying sources in the two domains can be found independently if some a priori information about them is available. The a priori information can be incorporated in the process of finding ICs using the cICA. Constrained stICA uses two cascaded cICA stages, one for each domain. A priori information available in either domain is fed to the first cICA stage along with the appropriate mode. The output will be the independent source in that domain plus the approximate information about the corresponding mode. This information along with the other mode is fed to next cICA stage that will give the independent source in that domain. The procedure is summarized in Table 1. The other properties of SVD can be exploited to simplify the cICA algorithm presented in [9]. Both the modes are orthonormal; we can remove the equality constraint from the constrained ICA algorithm. Also the input data is inherently white, which further simplifies the constrained ICA algorithm. With these modifications the constrained ICA algorithm will become:

$$\begin{aligned} &\textit{maximize}: \ J(y) \approx \rho[E\{G(y)\} - E\{G(v)\}]^2 \\ &\textit{Subject to}: g(\mathbf{w}) \le 0 \ \ or \ \ \hat{g}(\mathbf{w}) + b^2 \end{aligned} \tag{7}$$

where J*(y)* denotes the one-unit ICA contrast function introduced by [2], ρ a positive constant, v a zero mean, unit variance Gaussian variable. G(.) is a non-quadratic function as defined in [2], g(**w**) the closeness constraint mentioned in Equation 5, and b the slack variable. Equation 7 is a constrained optimization problem which can be solved through the use of an augmented Lagrangian function. Learning of the weights is achieved through a Newton like learning process.

$$\begin{aligned} C(\mathbf{w}, \mu) &= J(y) + \mu^t \hat{g}(\mathbf{w}) + \frac{1}{2} \| \hat{g}(\mathbf{w}) \|^2 \\ \mathbf{w}_{k+1} &= \mathbf{w}_k - \eta (C'')^{-1} C' \\ \mathbf{w} &\leftarrow \frac{\mathbf{w}}{|\mathbf{w}|} \end{aligned} \tag{8}$$

where C represents the new contrast function to be optimized.

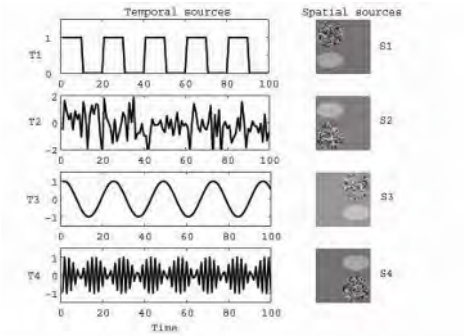
Table 1. Constrained stICA Algorithm

Step 0: The observation matrix X contains the fMRI image sequence.
Step 1: Reduce the dimension of the observation matrix **X** using SVD. Find $\hat{\mathbf{U}}$ and $\hat{\mathbf{V}}$ according to equation 2.
Step 2: Generate reference signal from a priori information
Step 3: Zero mean and normalize the reference signal.
Step 4: Call the constrained ICA stage (equations 8) with $\hat{\mathbf{U}}$ or $\hat{\mathbf{V}}$ (depending upon the domain of reference used, spatial or temporal) and reference as the inputs. Upon convergence the output will be the independent source in the same domain as that of reference.
Step 5: To determine the corresponding independent source, find approximate of this source according to the following equation and used it as the reference for next stage. $\mathbf{r} = \hat{\mathbf{X}}((\hat{\mathbf{V}}\mathbf{w}_t)^t)^{-1}$, $\mathbf{r} = \hat{\mathbf{X}}(\mathbf{T}^t)^{-1}$ *or* $\mathbf{r} = \hat{\mathbf{X}}((\hat{\mathbf{U}}\mathbf{w}_s)^t)^{-1}$, $\mathbf{r} = \hat{\mathbf{X}}(\hat{\mathbf{S}}^t)^{-1}$ where $\mathbf{w}_t$ or $\mathbf{w}_s$ are the un-mixing vector found in step 4 and **T** or **S** is the independent source recovered at step 4.
Step 6: Zero mean and normalize the reference.
Step 7: Call the constrained ICA stage (equation 8) with $\hat{\mathbf{U}}$ or $\hat{\mathbf{V}}$ and reference from step 6 as the inputs. Upon convergence the output will be independent source corresponding to the independent source found in step 4.

IV. Results

The performance of the proposed constrained-stICA algorithm was tested using the simulated data set shown in Figure 1. As evident in the figure neither the temporal nor the spatial sources are independent. The results of spatial ICA and temporal ICA on the mixture of this simulated data set are shown in Figure 2 (only two output sources are shown). Both the spatial and temporal ICA tries to find independent sources at the cost of the sources in the corresponding domain, therefore sources in the corresponding domain get distorted. On the other hand constrained-stICA finds maximally independent sources in two stages with minimal inter domain affect. The results of constrained stICA are shown in Figure 3. It is evident from the Figure 3 that the results are superior to both the temporal and spatial ICA results.

For the fMRI data, a series of 60 FLASH images were acquired at twenty nine axial levels from four healthy persons. After several minutes of dark adaption, we asked each subject to open his eyes for 10 sec and then close for 10 sec



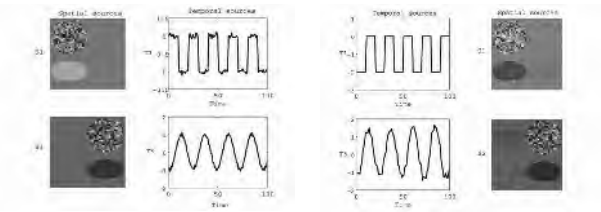


Fig. 1 Simulated temporal and spatial sources.

(a) (b)

Fig. 2 Sources recovered using (a) spatial and (b) temporal ICA and their corresponding sources

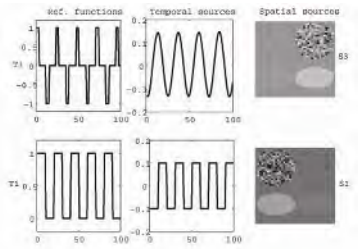

Fig. 3 Temporal (middle column) and spatial sources (right column) recovered with constrained stICA using different reference functions (left column)

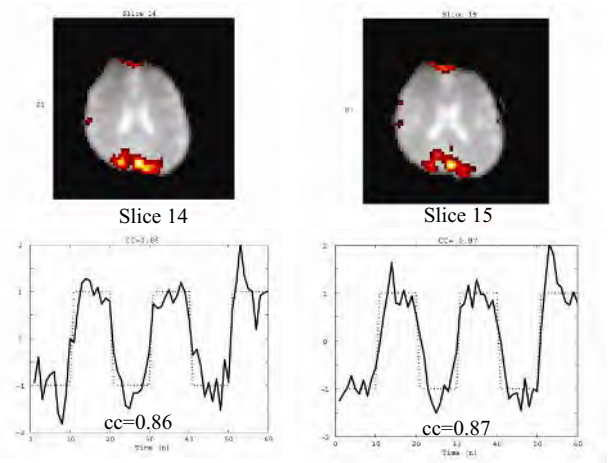

Fig. 4 Z-score maps of the spatial component and their corresponding time courses obtained with constrained-stICA

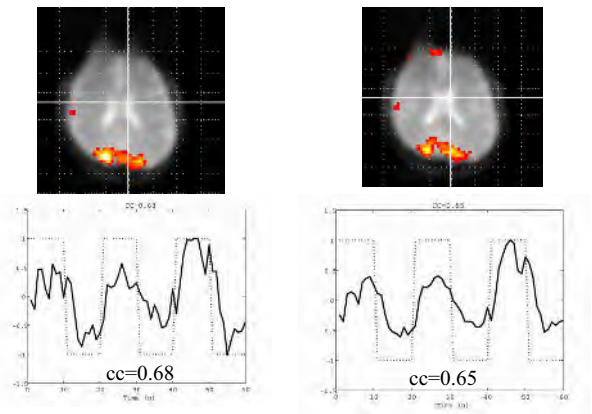

Fig. 5 Z-score maps of the spatial components and their corresponding time courses obtained with SPM

This cycle was repeated for 3 times. The collected data for each individual is normalized and realigned. The data from each individual was processed separately on a single volume basis. Each row of an observation matrix **X** contains an image. The ON-OFF stimulation is used as the initial reference. Independent spatial and temporal components are recovered according to the algorithm in Table 1. Once a component map is recovered, it is converted to the z-map [6] according to the Equation 9.

$$z_{ij} = \frac{s_{ij} - m_i}{\sigma_i} \geq threshold \tag{9}$$

where s_i is the component recovered, m_i the mean, and σ_i the standard deviation of the component.

The functional maps obtained from constrained-stICA are compared with those from SPM. The results for the slice 14 and 15 are presented in Figure 4 and Figure 5. The spatial ICs found by constrained-stICA indicate some frontal activities, missed by SPM,. Also, the recovered time courses have high correlation with the ON-OFF stimulation reference (cc = 0.86 ~ 0.87) compared to SPM (cc = 0.65 ~ 0.68) results. The results indicate that the proposed constrained stICA may be a more effective method for fMRI data analysis.

V. Conclusions

In this study a new algorithm, constrained-stICA is proposed. The method tries to find the desired independent spatial and temporal components by incorporating a priori information. The results of the proposed algorithm on the simulated data and fMRI data are presented.

Abstract — **Glaucoma is a leading cause of blindness worldwide, accounting for 12.3% of the permanently blind according to the World Heath Organization. The disease is particularly prevalent in Asia, with up to 50% of total glaucoma cases found in the region. Although glaucomatous damage is irreversible, studies have shown that early detection can be effective in slowing or halting glaucomatous atrophy. The ratio of the size of the optic cup to the optic disc, also known as the cup-to-disc ratio (CDR), is an important indicator for glaucoma assessment, since glaucomatous progression corresponds to increased excavation of the optic cup. In current clinical practice, the CDR is measured manually and can be subjective, limiting its use in screening for early detection. We describe the ARGALI system which automatically calculates the CDR from non-stereographic retinal fundus photographs, providing a fast, objective and consistent measurement. The ARGALI system consists of a series of steps. As the optic disc occupies only a small region of the entire retinal image, a region of interest is first extracted via pixel intensity analysis. Variational level-set algorithm is next used to segment the optic disc. Optic cup segmentation is more challenging due to the cup's interweavement with blood vessels and surrounding tissues. A multi-modal approach consisting of different methods is used extract the cup. To obtain a smoother contour, ellipse fitting is applied to the extracted cup and disc. A neural network has also been proposed to fuse the results obtained via the various modes. The ARGALI system was tested using images collected from patients at the Singapore Eye Research Institute and achieves an RMS error of 0.05 with a risk assessment accuracy of 95%. The results are promising for ARGALI to be developed into a low cost, objective and efficient screening system for automatic assessment glaucoma risk assessment.**

Keywords — **cup-to-disc ratio, level set, glaucoma**

I. Introduction

Glaucoma is a leading cause of blindness and is characterized by the progressive loss of axons in the optic nerve. From the World Health Organization's Global Data Bank on Blindness[1], glaucoma accounts for 5.1 million out of an estimated 38 million blind people, or about 13.4%, worldwide. It is expected that by 2010, there will as many 60 million glaucoma cases globally. Moreover, due to the close association of glaucoma with age, as the aging population rapidly increases, glaucoma morbidity will rise as well, resulting in increased health care costs and economic burden. In the Tanjong Pagar Study[2] conducted in 1996-97 in Singapore, the age-standardized prevalence of glaucoma was found to be 3.2% in the 40 years and older population. There is no cure for glaucoma, as damage to the ganglion cells is permanent and as yet is irrecoverable. However, with early detection, the advancement of glaucomatous optical neuropathy can be significantly slowed or even halted. Mass screening is thus critical to prevent the further development of glaucomatous damage in a person.

A classic feature of glaucoma is the specific abnormal appearance of the optic nerve head: cupping or excavation of the optic disc, with loss of the neuroretinal rim, typically seen as an enlargement of the optic disc cup to disc ratio (CDR). The cupping of optic nerve head corresponds to increased ganglion cell death, and thus the CDR can be used as a measured of the risk factor for glaucoma. However, a screening test for glaucoma with high accuracy has yet to be developed. In current clinical practice, the CDR is measured manually by an ophthalmologist and is subjective due to differences in intra-observer experiences and training. The reliance on manual efforts restricts the use of the CDR for deployment in mass screening.

Some efforts have been reported in the development of methods for the automatic segmentation of the optic cup and disc from retinal fundus images, with more reports [3,4] on the automatic segmentation of optic disc, but with fewer on [5,6] on optic cup detection due to the cup's interweavement with blood vessel and surrounding tissues. A model-based approach for automated feature extraction in fundus images was previously proposed by Li. H, et al [3]. Optic disc shape detection is done using a modified active shape model (ASM). A disc boundary detection rate of 94% was attained on 100 datasets collected by the authors. No cup and CDR calculation were done in this paper. Automatic segmentation of the papilla in a fundus image based on the C-V model and a shape restraint was proposed by Y. Tang etc [4]. Optic disk detection achieves 94% fully satisfactory image using a database containing 50 color fundus images, including 20 low contrast ones, but no Cup and CDR calculation were done in this paper. The development of a simple diagnostic method for glaucoma using ocular

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 559–562, 2009
www.springerlink.com

fundus pictures was proposed by Naoto Inoue, etc [5], which describes using discriminatory analysis to decide thresholds, and subsequently utilizes these to segment the cup and disc. Although the Cup-to-Disc Ratio (CDR) was measured in this paper, no clear results are given and the image sets used for testing is not clearly described. A method to diagnose glaucoma via optic disk feature extraction via modified deformable model technique was proposed by Xu et al [6]. Disc and cup segmentation were conducted in the paper and the CDR was also calculated. The optic disc center is found by applying the Circular Hough Transformation, and subsequently the disc boundary detection is done through active shape model (ASM) by defining 72 points around the disc following which an energy expression was used to deform the contour.

The ARGALI (Automatic cup-to-disc Ratio measurement system for Glaucoma Analysis using Level-set Image processing) system is developed through inter-disciplinary collaborative efforts between clinician ophthalmologists and computer scientists. It aims to be a novel, state-of-the-art, diagnostic system for glaucoma screening. ARGALI also aims to compliment clinical practices and advance the latest intelligent medical image processing based glaucoma diagnosis algorithm using 2D retinal fundus images which can be obtained through the use of existing, commercially available, low-cost equipment.

In this paper, we present the ARGALI system and report on the experiments and results obtained. Section II provides a description of the various processes involved in ARGALI. Subsequently, in Section III, an experiment is run to determine the performance of ARGALI on a sample of retinal images obtained from the Singapore Eye Research Institute and the results of the experiment are presented. The final section presents the conclusions and future directions.

II. ARGALI

The ARGALI system as shown in Figure 1 is to be developed into a cost effective diagnosis system which will be of clinical significance for glaucoma screening, diagnosis and analysis. Through an innovative fusion of various image processing technologies and clinical experiences, ARGALI is able to automatically calculate the CDR from retinal photographs, providing a fast, objective and consistent measurement with potential for mass screening.

In order to calculate the CDR, the cup and disc boundaries are segmented in ARGALI. As shown in Figure 1, the variational level-set algorithm, which is based on global optimization concepts, is used to segment the disc boundary and extract the optic disc region from the retinal image. Segmentation of the optic cup is more challenging than the optic disc due to the optic cup's interweavement with blood vessel and surrounding tissues. An innovative technique to extract the cup is proposed, in which a multi-modal approach is employed. A color histogram analysis of the image is first carried out, and is subsequently followed by the application of level-set algorithms to segment the cup boundary. The segmented cup is then smoothened using ellipse fitting. Finally, adaptable neural networks are to be trained to fuse the cup-to-disc calculation results from the level-set algorithms as well as the results after different smoothing processes.

The complete process is capable of producing a CDR result in a few seconds which makes the system attractive for screening large numbers rapidly and efficiently. This learning mechanism integrates the knowledge embedded in the clinical practice and provides an optimal CDR for the glaucoma screening, diagnosis and analysis. The complete process can be divided into the following 6 steps. A more detailed description of the processes is described in [7].

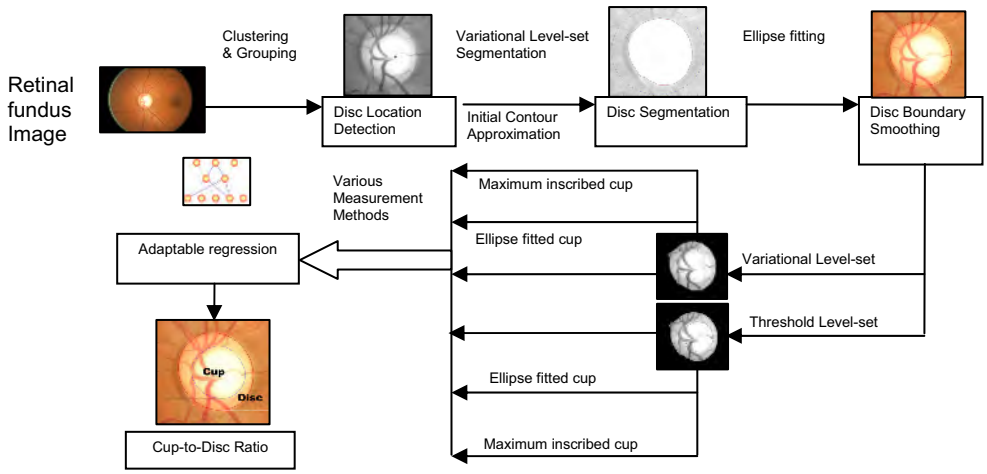

Figure 1.

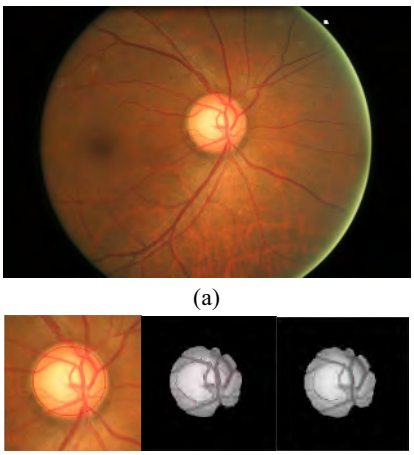
A. Disc Segmentation



For a typical retinal fundus image obtained from the Singapore Eye Research Institute (SERI), the image resolution is approximately 3072 x 2048. However, the size of the optic disc, and cup, typically takes up less than 10% of the entire retinal image. Although the whole image can be analyzed to obtain the cup and the disc, region of interest (ROI) localization would help to significantly reduce the computational requirements and improve the accuracy of segmentation by focusing the efforts on an approximate region. Using the physiological characteristic of the optic disc being of a higher intensity than the surrounding retinal area, histogram-based analysis, whereby the pixels corresponding to the top 0.5% of the cumulative intensity distribution is pre-selected as preliminary feature points. Subsequently, the retinal image is subdivided into 64 regions, and an approximate ROI centre is selected based on the region containing the highest number of pre-selected pixels. Following this, the ROI is defined as a rectangle around the ROI centre with dimensions of twice the typical optic disc diameter, and is used as the initial boundary for the optic disc segmentation.

B. Disc segmentation

The variational level-set algorithm [8] is applied to the fundus image to detect the disc boundary using the optimal color channel as determined by the color histogram analysis and edge analysis in the ARGALI framework. Variational level-set is based on global processing concepts which analyze the entire image in order to find the globally optimum boundary for the disc. Unlike traditional level-set algorithms which need periodic re-initialization to avoid shocks during the level-set process, the variational formulation avoids this by introducing an energy term to keep the evolving level-set function close to a signed distance function, in this way avoiding errors in segmentation due to shocks and discontinuities from the re-initialization process.

C. Boundary smoothing of detected disc

Despite the use of a global optimization technique, the disc boundary detected by level-set in this step may not represent the actual shape of the disc, as the disc boundary can be affected by a remarkable number of blood vessels entering the disc. This can often result in sudden changes in curvature. To avoid this, ellipse fitting [9] is applied to reshape the obtained disc boundary. Ellipse fitting helps to smooth the sudden changes of curvature in the boundary caused by blood vessels and helps to find the ellipse with minimum error to fit the disc boundary.

(a) (b) (c) (d)

Figure 2. (a) Original fundus image, (b) Segmented disc boundary (red line), (c) segmented cup (red line) and (d) ellipse-fitted cup (red line)

D. Cup segmentation

Cup boundary segmentation is more challenging than disc segmentation due to the cup's much intensive interweavement with blood vessels and surrounding tissues. Furthermore, the transition between the cup and the rim is often not as prominent as that at the disc boundary. In this paper we make use of the threshold-initialized level-set function in ARGALI. In threshold-initialization-based level set, the green channel of the extracted optic disc is processed using histogram analysis to determine a threshold value which segments out the pixels corresponding to the top 1/3 of the grayscale intensity was used to define the initial contour in the ROI. Next, the level set formulation discussed earlier was employed to the initial contour to segment the optic cup. Previously, other methods were also compared with level-set for optic cup segmentation, and it was found that use of level-set method provides increased accuracy for cup segmentation [7]

E. Boundary smoothing of detected cup

After the threshold level-set algorithm is applied to obtain the cup boundary, an additional post-processing step using ellipse fitting is employed to eliminate some of the obtained cup boundary's sudden changes in curvature. Ellipse fitting is especially useful when portions of blood vessels in the neuro-retinal rim outside the cup are included within the detected boundary.

F. Learning Network-based Intelligent Fusion

An adaptable multi-layer neural network has also been proposed in the last stage of ARGALI. Using various meth-

ods for cup and disc segmentation, a neural network is to be trained using clinical data, with the clinical ground truth to be set as the target value. The inputs to the neural network correspond to the CDR results obtained from the different individual methods. By training the neural network to optimize the weights of the various inputs, the system hopes to integrate the individual results in an optimal way, integrating the knowledge embedded in the clinical practice to provide an optimal CDR value. This aspect of ARGALI is not explored in the scope of this paper but will be done so in future reports.

III. Experimental results

In our previously reported work [7], we tested some of the component algorithms on a sample of retinal images from normal patients. For this paper, we obtained a sample set of 23 retinal images of patients which have been verified as suffering from glaucoma from the Singapore Eye Research Institute to test the ARGALI system. For the ground truth, we make use of the clinician assessment of the CDR_{clinic}. The image set of 23 glaucoma patients was processed using ARGALI and the calculated CDR using ARGALI is defined as CDR_{clinic}. The results are presented in Figure 3(a). Based on these results, the correlation coefficient was calculated and found to be 0.89, indicating a close correlation between the ARGALI-obtained results and the clinical ground truth.

The error, defined as the difference between the calculated CDR and the clinical ground truth, $Error = CDR_{ARGALI} - CDR_{clinic}$ was also calculated and the results are plotted in Figure 3(b). It can be readily observed from the results in Figure 3(b) that the maximum error for the CDR results obtained by ARGALI is less than 0.1 CDR units, with the root mean square error calculated to be approximately 0.05. Furthermore, using a clinically-derived value of a CDR more than 0.65 to assess a patient as a possible glaucoma case, the ARGALI system was able to correctly identify 95% of the cases, or 21 out of 22. It was observed that one of the patients had been clinically diagnosed as having glaucoma although the clinical CDR is less than 0.65. Despite this, the ARGALI system was still able to determine the CDR relatively close to the clinical value for this patient (CDR_{clinic}=0.55; CDR_{ARGALI}=0.5687).

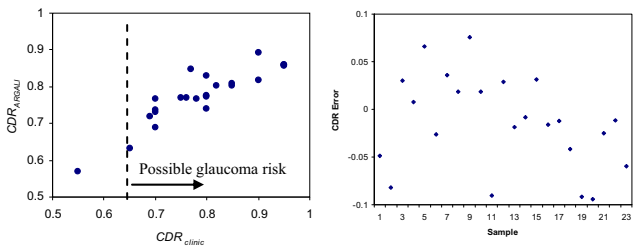


Figure 3. (a) Comparison between CDR_{clinic} and CDR_{clinic}. The correlation coefficient was calculated to be 0.89. Note the patient with a CDR less than 0.65 but still clinically diagnosed as having glaucoma. (b) Error between CDR_{clinic} and CDR_{clinic}. The maximum error is 0.1 CDR units and the RMS error was calculated to be 0.05.

IV. Conclusions

An innovative system integrating existing and new image processing technologies, intelligent fusion technology and clinical experiences is developed and proposed in the paper. The proposed ARGALI system automatically calculates the CDR from retinal photographs, and provides a fast, objective and consistent measurement with potential for screening. The technological novelty and promising experimental results demonstrate ARGALI's potential to be developed into a low cost and efficient glaucoma mass screening system. We will further enhance the performance of the system with more clinical input and validation, as well as to incorporate machine learning aspects into future.

[3]Med Institute Inc, IN, USA

Abstract — **A combination of three techniques – high resolution computed tomography (micro CT) scanning, Archimedes-based volume fraction measurement and serial sectioning or milling – were used to determine the volume fraction as a measurement of trabecular bone quality changes in rabbit distal femur. The objective of this study was to develop the capabilities of micro CT scanning and micro CT image segmentation based on a slice-by-slice global thresholding technique to investigate trabecular microstructural changes in vivo and in vitro. These results were validated within the in vivo and invitro scans at the same time, and validated with the Archimedes-based volume fraction measurements and serial sectioning experiments. A total of six six-month-old New Zealand white rabbits were utilized in this study. The rabbits were scanned twice in vivo seven days a part and all of the left and right femurs (medial and lateral) were scanned in vitro. All micro CT images were obtained at 28 µm (in vivo) or 14 µm (in vitro) nominal resolutions. Specimens from six left and right rabbit distal femurs (medial and lateral) were also measured based on Archimedes' principle and serial milling. These findings have shown that the in vivo and in vitro micro CT scanning are consistently repeatable while the accuracy of the serial milling to Archimedes-based volume fractions and the in vitro micro CT scanning to Archimedes-based were within ± 2.5% estimation respectively.**

Keywords — **micro CT, Archimedes', serial-miling, volume-fraction, trabeculae**

I. Introduction

High resolution micro computed tomography (micro-CT) has been utilized in the study of detailed structure for cancellous bone [1, 2]. The objective of this study was to demonstrate the accurate high-resolution micro-CT images of 3-D trabecular architecture (in vivo and in vitro) to Archimedes' based and serial sectioning technique. A volume fraction comparison was made to ensure the in vivo and in vitro scanning produced accurate results.

II. Materials and Methods

Six New Zealand white rabbits weighing approximately 4 to 5 kg were utilised in this study. The rabbits were scanned twice in vivo seven days apart and all rabbits were then sacrificed and the femurs were scanned again in vitro. The size of the rabbit distal femur and its position of scanning made it possible to obtain 28 µm and 14 µm (nominal resolution) micro-CT (Model ACTIS 200/225 Ffi-HR CT/DR system, BIR Inc., Chicago, IL with built-in X-ray system FXE 225.20, Fein Focus U.S.A.) scans in vivo and in vitro, respectively. The machine is equipped with a 225 KV x-ray source with a focal spot size of 5 µm. In addition, an anesthesia machine (Landmark Model VSA-2100, Hallowell Modeal 2000) was added to the micro-CT scanner such that in vivo scanning could be performed with the animals sedated to minimize unwanted motion.

For the invivo scanning, the rabbit was sedated with a cone mask under anesthesia as shown in Figure 1. The rabbit was completely sedated within 10 and 15 minutes before placing it in an animal holder. The femurs were excised, made into bone cubes and scanned in vitro. The in vitro scan was carried out in a smaller specimen holder. The in vivo scans consisted of 214 slices while the in vitro scans consisted of 428 slices spanning a six-millimetre distance from above the condylar notch to the bottom of the

Fig. 1 A set up of an in vivo micro CT scanning.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 563–565, 2009
www.springerlink.com

medial condyle (region of interest). The in vivo and in vitro images were cropped and rotated for the purpose of image registration. The two sets of data were registered using a custom registration algorithm technique written in MATLAB 7 looking for maximum mutual information to allow direct comparison. The same region of interest from both data sets were extracted and globally threshold slice-by-slice based on Otsu's method of thresholding isolating the bone tissue from the less dense material in the images.

After in vitro scanning, the bone cubes were cleaned using tricholoroethylene in an ultrasonic agitation for an hour followed by rinsing with a waterpik system (model WP-60W) at a pressure control speed of 60psi using about 500ml of water on all sides of the cube. The cleaning process was repeated five times to ensure marrow removal without trabecular damage. Volume fraction measurement was made based on Archimedes' principle.

Then, the cleaned bone cubes were stained black at room temperature by immersion in a 10% (wt) silver nitrate solution, first for 30 minutes in an ultrasound chamber and then for 20 hours. The bone cubes were rinsed and water was drained out and placed into 100% ethanol where they were exposed to 365nm UV light for 120 minutes giving the bone a deep black matted non-reflective colour. The bone cubes were then embedded in a bone embedding media. The serial milling was performed on a custom-made micro milling machine – Ultra-High-Precision Micro Milling with a computer-numeric-controlled (CNC) milling station.

III. Results

The volume fraction measurement is made on left medial (LM), left lateral (LL), right medial (RM) and right lateral (RL) for six rabbits. The volume fraction for lateral condyles between in vivo scans seven days apart (0.401±0.015, 0.397±0.021), between in vitro micro CT (0.352±0.035) and Archimedes (0.365±0.031) and between in vitro micro CT (0.352±0.035) and serial milling (0.369±0.031) were not significantly different. The medial condyles were also not significantly different between in vivo scans seven days apart (0.513±0.010, 0.515±0.011), in vitro micro CT (0.454±0.049), Archimedes(0.460±0.060) and serial milling (0.467±0.050) and it is also illustrated in Figure 2.

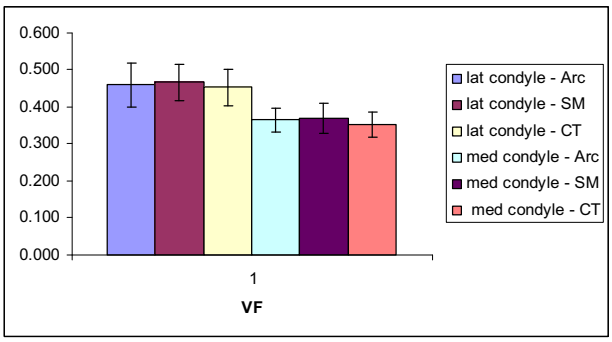

Fig. 2 Average values of volume fraction (VF) for lateral and medial among Archimedes (arc), serial milling (SM) and in vitro micro CT (CT) are shown with standard deviation (n = 11). The coefficient of variation in VF between Arc and SM ranged between 0.10% and 0.22%. The VF for lateral and medial condyles between CT and Arc and between CT and SM were not significantly different (p = 0.294, p = 0.649, p = 0.115, p = 0.118). The y-axis is unitless for VF.

IV. Discussions

Our studies have shown a consistency of in vivo to in vitro micro-CT scans within an acceptable accuracy of 1%. This shows that the micro CT scanning is consistently repeatable. The results between the in vitro micro CT and Archimedes-based volume fractions showed 2.5% underestimation and it is well within 4% [3]. Meanwhile, the results between the serial milling and Archimedes-based data showed 2.5% overestimation and it is well within 5% [4]. The accuracy of the in vitro micro-CT scan is also confirmed by the excellent agreement between our scan data and the Archimedes'-based and serial sectioning data as shown in Figure 3.

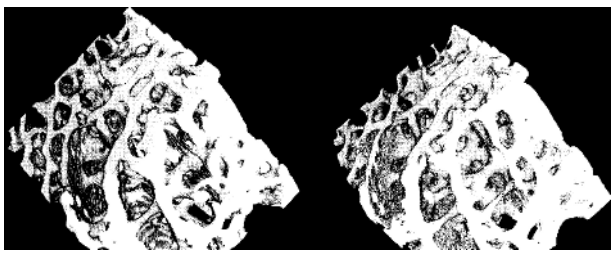

Fig. 3 Three dimensional image stacks of micro-CT (left) and serial sectioning (right)

V. Conclusions

The results in this study have demonstrated the reliability, sensitivity and consistency of in vivo and in vitro micro CT scanning. It indicates that the results of micro CT scanning are statistically comparable to those obtained from density measurement based on Archimedes' principles and serial milling experiments. With this validation, it proved the repeatability of the high resolution micro CT scanning can be used to investigate the trabecular micro structural changes within a living animal that is consistently achievable.

A Force Sensor System for Evaluation of Behavioural Recovery after Spinal Cord Injury in Rats

Y.C. Wei, M.W. Chang, S.Y. Hou, M.S. Young

Department of Electrical Engineering, National Cheng-Kung University, Tainan, Taiwan

Abstract — **In animal model, the feature of spinal cord injury is hindlimbs paralysis, muscle weakness, and a common complaint in humans, so the animal test is necessary for the neurology, pathophysiology study and development of drug therapies. Various methods had been developed and widely used to examine the motor function and behavioural recovery following the spinal cord injury of rats, most of these methods were observed by the observer, then converted the results into the score grade. This study is used to set up the measurement system, use the ground reaction force method to evaluate the hindlimb can support its weight or not and measure the ground reaction force of hindquarter. This system is microcontroller-based , can save the test data to the flash memory, and communication with the PC for save test data to disk and statistical analysis.**

Keywords — **spinal cord injury, behavioural recovery microcontroller-based**

I. Introduction

In the spinal cord injury (SCI), the behavioural response in animal models is relevant to the clinical signs of SCI in human patients. Therefore, it is necessary to have the tools to measure the behavioural function for evaluation the recovery following spinal cord injury in animal models.

According to the type of data collected, these measurement tools include: (1) endpoint measures, (2) kinematic measures, (3) kinetic measurements, (4) electrophysiological measurements [1,2,3], but most of these tools observed by observer. In order to eliminate the influenced by observer, this study is intend to design a quantitative and objective test system for evaluating behavioural recovery focus on hindlimbs and hindquarter of rats.

This system is made up of five force plate and each force plate use two strain gauge as force sensor, when the limbs of rat stand at correct force plate, user touch the any key on the PC, PC will record the test data to the disk for analysis. From the test data, we find the percentage of hindquarter force is decrement when the function of hindlimbs recovery gradually in rat.

II. Methods

A. System Design

This study is used to set up a microcontroller-based system for measure the ground reaction force of hindlimb and hindquarter after spinal cord injury in rats. The system consists of two major parts, one is the test apparatus and the other is control unit. Test apparatus is shown in Fig 1, and block diagram of the control unit is shown in Fig 2.

A general description of the system components and its operation follows.

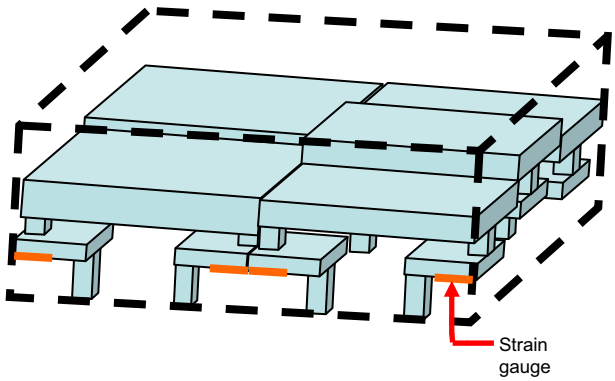

Fig 1. Apparatus of the inclined plane system

www.springerlink.com

1. Test apparatus

The test apparatus is 20cm*8cm*10cm (L*W*H) cuboid and made up of the black acrylic, five plate stick on the bottom to measure the vertical ground reaction force of the forelimbs, hindlimbs and hindquarter. Each force plate use the strain gauge stick on the acrylic, at the rear part the middle force plate is higher than the two sides force plate 0.5 cm. This arrange of force plate can detect the animal stance or not, and can measure the animal ground reaction force of the hindlimbs and hindquarter, when the animal squat.

2. Control unit

a. Hardware

a.1. AVR Microcontroller

The system is based on a ATmega32 microcontroller (ATMEL Corporation), it is a RISC architecture provides fast execution time. The ATmega32 includes four programmable ports, three external interrupt source, three timer/counter, one programmable serial USART, and 32K program memory size, 2K SRAM for data memory. The assignment of the various functions to the ports in theμC is shown in Table 1. The function of AVR microcontroller is read the keypad signal and start the A/D convert, then display the data to the LCD display and send data to PC.

Table 1. Assignment of port function in the μC

Port in microcontroller	Function
Port C	LCD data bus
Port A.0 – port A.1	Touch-button switch
PortA.5,6,7	LCD control bus
Port B.0,1	A/D chip selector
Port B.5,6,7	A/D interface bus
Port D.0,1	RS-232

a.2. Keypad

There are two push-button switch in the controller unit, when pushed by the user, the microcontroller start the A/D converter and display data on LCD display.

a.3. LCD Display

The LCD display is 2*20 characters and included backlight permits easy visualization of the display even in subdued light conditions. It's used to present the ground reaction force of limbs in rat .

a.4. RS-232 voltage lever converter

The input/output signals of the microcontroller are TTL levels. These are not compatible with the RS232 protocol, so need the RS-232 voltage level converter to change the TTL levels match the RS-232 protocol.

a.5. Force sensor

The force sensor is strain gauge, struck on the acrylic, so the rat stance on the acrylic, the strain gauge bended and change the output resister.

a.6. Amplifier and filter circuit

The strain gauge is connected to a bridge circuit, the bridge output is connected to the instrument amplifier and filter circuit. The circuit is used to amplify the force signal to the desired level and filter out the noise.

a.7. A/D converter

The A/D converter is 16 bits resolution and serial data out, used to change the analog signal (output signal of the amplifier and filter circuit) to the digital signal.

b. Software

The program on the AVR microcontroller was written by the C language and coding of the PC for data save and analysis was down in LabView.

B. Operation

When the measurement system is set up, verification is the first step, then take the rat into the acrylic box,and the hindlimbs on the two side force plate, the hindquarter on the middle force plate. If the system connect with PC through the RS-232, the force data can display on the display of the PC continuous, at the time the rat squat steady state, the user touch any key on the PC, the LabView program will save the data in the hard disk. If the system was controlled by the control unit only (No connect with the PC) , when the user press the key on the control unit, the only one test data will showed on the LCD display of the control unit.

III. Results

The prototype of this measurement system had finished, and is testing use the spinal cord injury rats. Fig 3 shows the results of the percentage of the hindquarter, and indicates the percentage of weight of hindquarter is decrement as the time increase. This is the preliminary results, right now, we do more test and verify this system can evaluate the behaviour recovery after spinal cord injury in rats.

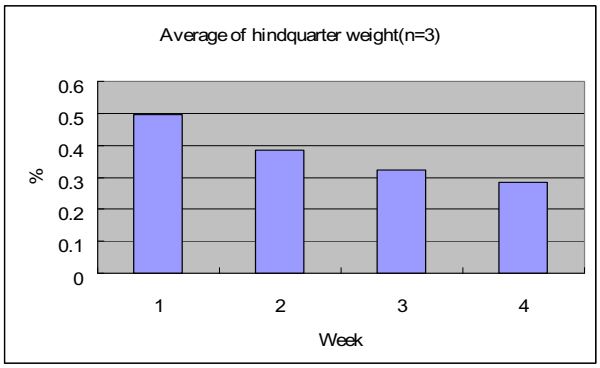

Fig 3. average percentage of hindquarter weight

Abstract — **This paper presents flow results of a magnetic resonance imaging velocimetry system which relies on fluid motion estimation, and uses vorticity map differencing for calibrating its reliability. To validate this new concept, phase contrast magnetic resonance imaging on the right atrium of a healthy subject has been suggested. The study has demonstrated the state of change in blood flow patterns within a cardiac chamber using our implemented system and a well established flow imaging modality. Based on the gold standard imaging technique, flow fields can be used to establish a set of reference data to compare against magnetic resonance fluid motion tracking results. We conclude that our validated technique can be reliable enough for establishing a cardiac based velocimetry system.**

Keywords — **Phase contrast magnetic resonance imaging, Fluid motion tracking, Right atrium**

I. Introduction

Using a velocimetry framework that is different from velocity encoded medical imaging modalities, we implemented MR fluid motion tracking [1] which is based on motion estimation of blood signal shifts that appears as changes in intensity distribution over the entire registered signal image. The speed of the latter technique in terms of processing these images is dependent on the computational platform and the machine that runs it. A strong limitation, however, is the accuracy of the motion predication which is highly affected by the configuration of the algorithm as well as the clarity of signal contrast temporally. And it is the key purpose of this study to validate the output flow fields of MR fluid motion tracking against those produced by phase contrast magnetic resonance images.

For our implementation, we have developed a dual flow imaging and comparison system that enables processing of phase contrast data as well as MR fluid motion tracking of non-velocity encoded MR images. Since velocity flow field is limited in terms of flow analysis, vorticity measurement has been devised to present the strength of rotational blood in the heart chamber. In addition, we have described a concise flow visualisation system which encompasses flow imaging, flow vector presentation, and vorticity mapping, to analysis of vorticity pertaining to the imaged fluid.

Our article is organized as follows: Section II gives an overview of the system implementation for flow results comparison based on two imaging techniques. Section III provides the information on preparing a subject for MRI scanning and data analysis. The results of the two imaging modalities are displayed for selected time frames of a cardiac cycle in section IV. We give a discussion on the reliability of MR fluid motion tracking based on the flow results and in the last section, a conclusion of our implementations and findings.

II. Vorticity visualisation system implementation

A. MR Fluid Motion Tracking

A series of MR images are taken temporally as the fluid is in motion. The velocity of dynamic fluid can be quantified in real time by computing the shift of intensities within the quantised regions of every prior and post images numerically. A velocity flow field can be constructed using a graphical plot as such and other fluid dynamics properties can be derived from the velocity flow measurement. From the results, the characteristics of the fluid flow can be analysed using these properties.

Application of flow based on the use of motion estimation algorithm [2] allows us to produce flow vectors over the region of defined analysis. This technique makes use of images from two subsequent phases to predict flow field. Typically, cine MRI scanning results in a sequence of N phases. Post-processing of data from (N-1) pairs of images gives a series of vector fields for evaluation and analysis.

B. Phase Contrast MRI Velocimetry

Phase contrast MRI works on the concept that hydrogen nuclei from blood that has been exposed to magnetic fields accumulate a phase shift in spin that is proportional to blood velocity in x, y, and z directions [3,4] as shown in Fig. 1.

To quantify a velocity in one spatial dimension, at least two phase images has to be taken for subtraction of flow-induced phase shift from background phases caused by susceptibility-induced non-homogeneities and coil sensitivity changes [5]. Blood velocity can be aliased to an artifi-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 569–573, 2009
www.springerlink.com

cially low value if it exceeds the maximum velocity encoded (VENC) by flow sensitization gradients.

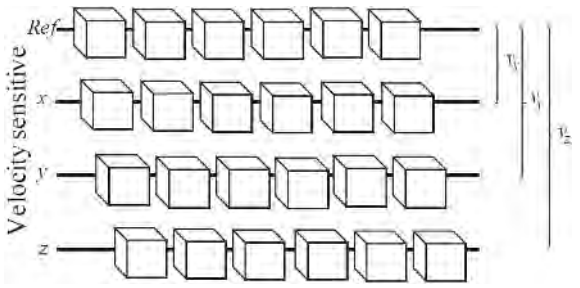

Fig. 1. Phase contrast MRI velocimetry. Velocities v_x, v_y and v_z can be calculated by subtraction of spin phase of measured volumes with that of the reference spaces *Ref*.

C. Visual tools for presentation of flow fields

The magnitude of vorticity ω (in units of s^{-1}) can be indicated by a colour contour map. Reconstruction of such a vorticity map as a colour image display can be achieved by representing vorticity using colours over a spatial grid. The presence of red pixels illustrates counter-clockwise swirling of blood while the blue ones correlate to clockwise swirl. Therefore, the colour and intensity of the image can give an indication of the magnitude of vorticity as well as the direction of rotation over a region.

D. Vorticity Field Differencing

Using Fig. 2, we demonstrate the systematic implementation of vorticity field differencing based on four stages.

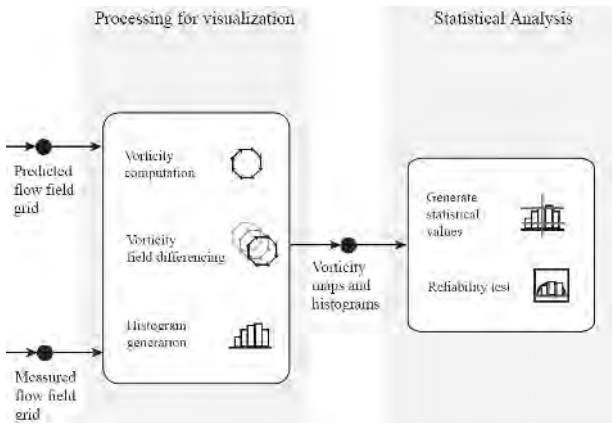

Fig. 2. Reliability test system for MR fluid motion tracking based on vorticity differencing. This system is specially constructed to calibrate the performance of MR fluid motion tracking against the well-established phase contrast MR image velocimetry system.

The first stage starts with scanning of a normal heart with steady-state free precession MR imaging and on a separate occasion, the same scanning using phase contrast MR imaging. During this pre-processing stage, blood motion information is encoded within images in a different manner. The cardiac MR images contain temporal positions of magnetic resonating blood, whereas the phase contrast images have local blood velocities encoded within them. In the visualisation processing stage, both field grids are further processed to give their respective vorticity field, which are then differenced.

III. Methodology

A. Subject for Case Study

In this study, we performed flow imaging on the right atrium of a 22 years old normal subject using phase contrast VENC flow imaging, and then using MR fluid motion tracking. The flow information from these two types of imaging can be used to explain the behaviour of vortices that develop in the right atrium of a heart.

B. Investigation Procedure

A scan is performed at the section of the heart where the atria are positioned. The scan section is taken at a location shown in Fig. 3 whereby the scan is perpendicular to an axis joining the top of the heart to the apex through the septum. Table I is created to configure the flow velocimetry system so that the tracking can be effected.

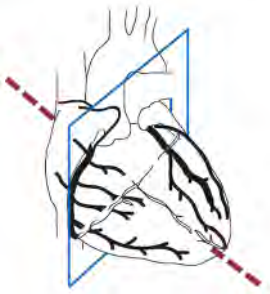

Fig. 3. MRI scan through heart of normal subject. The scanning of the heart is taken at short axis and through two chambers, namely the left and right atria. Therefore this sectional view pertains to the 2-chamber short axis scan.

C. MRI Scan Procedure

The velocity-encloded MR imaging was performed using a Siemens Avanto, 1.5 Tesla, model—syngo MRB15 scan-

ner with Numaris—4, Series No: 26406 software. Cine-MR imaging was performed using one slice in short axis views through the atria. All images were acquired with retrospective gating and 25 phases (from t=1 to 25) for a single slice.

D. Phase Contrast MRI Scan Procedure

For this purpose, velocity-encloded MR imaging was performed using a Siemens Sonata, 1.5 Tesla, model—syngo MR 2004A scanner with Numaris—4, Series No:

Table 1 MR imaging and vorticity measurement properties. The scan properties of standard True FISP and phase contrast MR imaging are presented here. The vorticity flow maps can be determined from them. These parameter values are used to calibrate these flow maps, as well as indicating the sampling vorticity mask size in metric units.

1 - TRUE FISP MRI SCAN		2 - PHASE CONTRAST MRI SCAN		
Symbol	Quantity	1	2	Units
p	Pixel spacing	1.67	1.54	mm/pixel
t_s	Trigger time interval	35.72	29.43	ms
s	Slice thickness	6	6	mm

VORTICITY MEASUREMENT PARAMETERS			
Symbol	Quantity	Value	Units
X	Image width	120	pixel
Y	Image height	150	pixel
W_v	Velocity interrogation window	3x3	pixel

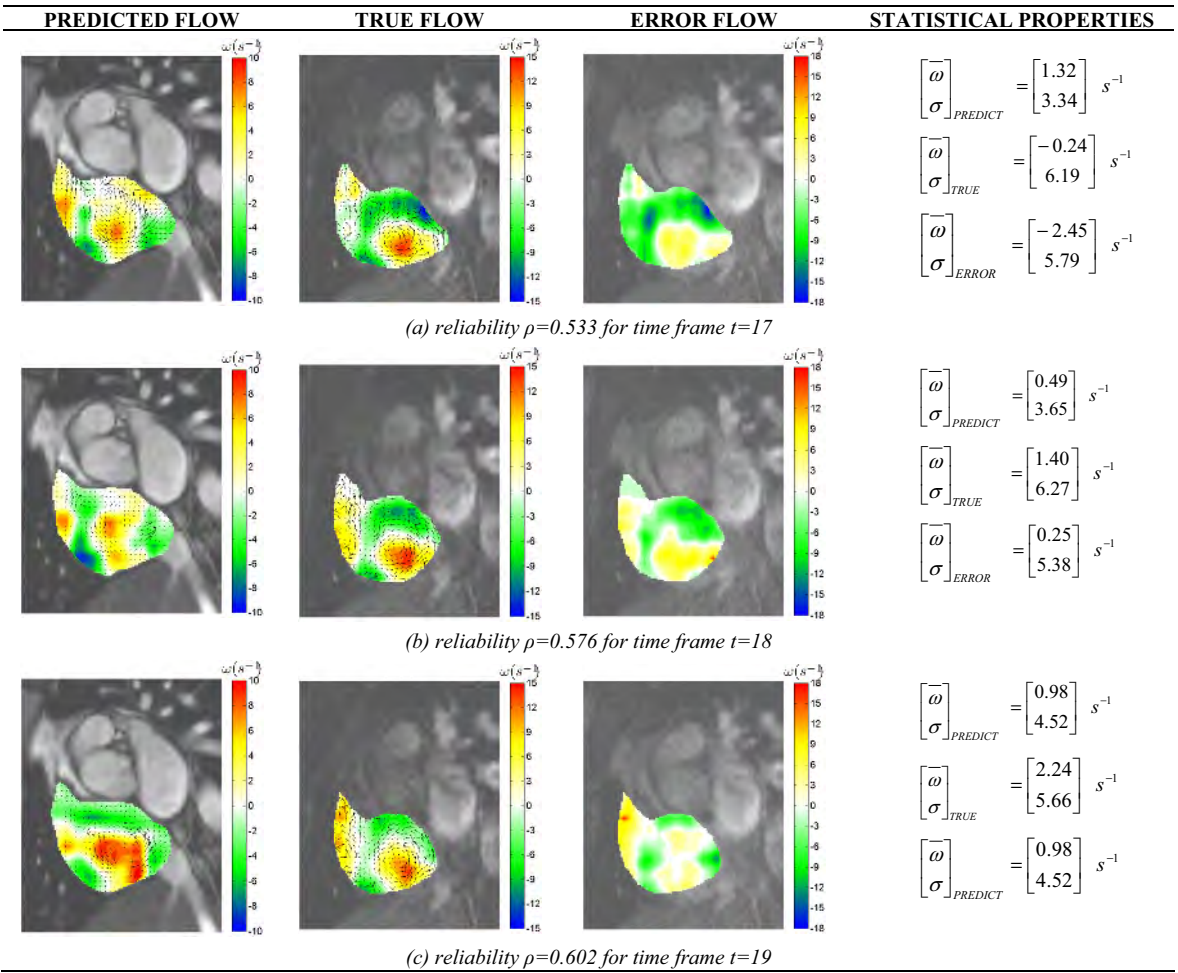

Fig. 4. *Vorticity differencing based on MR fluid motion field and phase contrast MR image field.* Predicted flow fields are verified against the measured ones based on phase contrast MRI velocimetry (taken as true data). Their vorticity map differences can be taken as the deviation of MR fluid motion field from the true flow field. We have performed flow field differencing using time frames t=[17,18,19] out of 25 frames in a cardiac cycle.

21609 software. Cine-MR imaging was performed using one slice in short axis views through the atria. All images were acquired with retrospective gating and 25 phases.

E. Parameters for Data Analysis

The histogram of a vorticity map with vorticity values in the range [0, *L*-1] is a discrete function $h(r_k) = n_k$, where r_k is the kth vorticity value and n_k is the number of pixels in the flow map having vorticity value r_k [6].

Statistical quantification of the blood vorticity map in the right atrium is performed by translating all the scalar values into histogram format. The size of right atrium is different for every phase. Normalization is performed by standardizing the total count of pixels within a segmented region of interest to create an equal integral area under the frequency plot of the flow map. The total counts correspond to the number of pixels representing the atrium per slice.

IV. Results

We varied this parameter from (3×3) to (33×33) pixels with increments of 2 pixels at each interval to chart the reliability of flow measurement using MR fluid motion tracking versus phase contrast MR imaging technique. From Table 1, the width of flow image is 120 pixels, and we have set the interrogation window to a 3 by 3 pixels frame. We observed vorticity flow maps pertaining to time frames t=[17,18,19] out of a maximum of 25 frames in a cardiac cycle for a series of sampling window sizes in Fig. 4.

V. Discussion

In this study using a normal atrium, we assume that the true-score variance σ_{TRUE}^2 is the equivalent of the vorticity variance based on a true map measured by phase contrast MRI. We note that the error variance with the expression σ_{ERROR}^2 is the variance of an error map which is produced by differencing the predicted and true vorticity maps. The reliability of flow field prediction using MR fluid motion tracking ρ is the ratio of true vorticity variance σ_{TRUE}^2 to total measured variance given by $(\sigma_{TRUE}^2 + \sigma_{ERROR}^2)$ [7]:

$$\rho = \sigma_{TRUE}^2 / (\sigma_{TRUE}^2 + \sigma_{ERROR}^2) \quad (1)$$

Implementing an appropriate sampling window size for vorticity measurement can bring the vorticity maps to be as close as possible to the physically measured one.

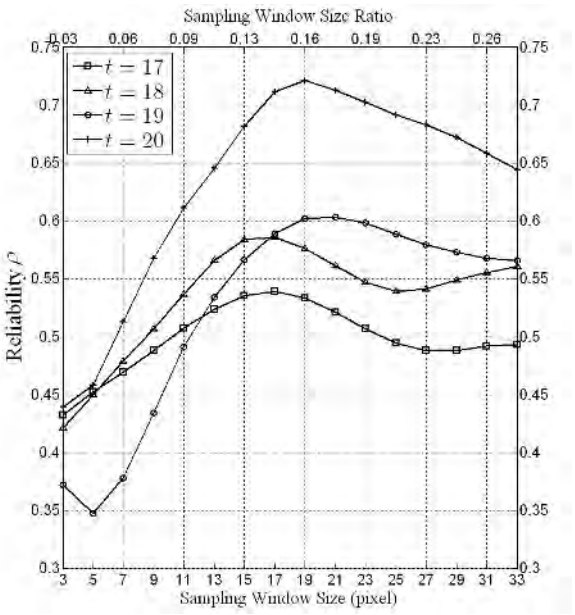

Fig. 5. Reliability study using predicted and true variance. Reliability for the predicted MR fluid motion field data ρ with respect to the phase contrast MRI data (taken as the true data) is computed. The variation of vorticity sampling window size can affect the reliability of computational measurement of the vorticity.

The graph of reliability measurement is shown in Fig. 5 for sampling window dimension of (3×3) to (33×33) pixels. The results are based on 4 cardiac time frames from t=17 to 20 to illustrate variation of measurement reliability.

VI. Conclusion

We have successfully studied one chamber at this stage. The framework developed in this work can be extended to assess flow in the other heart chambers or cardiovascular structures. This study has improved our understanding of blood motion within the heart chamber, which may have implications in the study of blood circulation efficiency.

Considering that the True FISP and phase contrast magnetic resonance imagings are performed on separate occasions with slight dissimilarities in planar imaging configuration, perfect alignments of the right atria region is difficult. Based on this discrepancy, we have to take into account additional error contributed by the imperfect comparison scheme. Therefore, the results suggest that MR fluid motion tracking is reliable enough for cardiac flow assessment.

Abstract — **Background/Aim: Electromagnetic thermotherapy is a new modality for cancer treatment. It applies a high-frequency electrical current to generate a magnetic field and heat up magnetic materials for treating targeted cancers. Using such system, we treat big tumors (more than 1.5 cm in diameter) in a colon cancer bearing murine model.**

Material and Methods: The high-frequency electromagnetic machine has an input of 220V-55A-60Hz. The output frequency and power are 40 kHz and 20 kW, respectively. The magnetic materials are fine needles made of stainless steel. We used agarose gel and porcine liver for thermo-dosimetry *in vitro* and *ex vivo*. During the experiments, IR camera was used to detect the temperature distributions. In an animal model, BALB/C mice were implanted with CT-26 colon cancer cells subcutaneously over their back. After the tumor size grew bigger than 15mm x 15mm, mice were divided into two groups randomly. Group I (n=8) were put in the magnetic field for twenty minutes as a control group. Group II (n=15) were inserted with fine needles into the tumor and magnetic field was used to treat the tumors for twenty minutes.

Results: From IR thermography, the needles in a matrix can achieve better temperature distributions in the targeted area than that from a needle alone. In the animal model, the survival rate achieved 90% in the treated group and no residual tumors over their back at the end of observation (60 days); while in the control group, the survival rate on the 45th day was 0%.

Conclusion: Our experiments showed that using high frequency electromagnetic thermotherapy is very effective to treat big tumors in the animal model, and our method has great potential for future clinical applications.

Keywords — **Thermotherapy, Superparamagnetic, Nanoparticles, Thermography, Matrix**

I. Introduction

Superparamagnetic nanoparticles can enhance localized temperature high enough to ablate focal lesions. Therefore, instead of using systemic hyperthermia, targeting hyperthermia using these superparamagnetic nanoparticles under a high-frequency magnetic field seems promising and warrants extensive investigation [1]. The nanoparticles are heated up by the hysteresis energy loss and eddy-current energy loss under an alternating magnetic field. By this means, magnetic nanoparticles can generate large amounts of heat to kill cancer cells [2]. However, It is very difficult to keep nanoparticles in situ after injection to the target; and they may disperse unevenly in big tumors. Therefore, we try to use magnetic needles as well as nanoparticles which are put in the matrix to make heat distributions better and treat bigger tumors (>15 mm, 1688mg).

II. Materials and Methods

A. Hardware

Machine for electromagnetic field generation: A lab-built instrument including a high-frequency induction machine, a set of coils to provide an alternate magnetic field (AMF) and a thermocouple to provide temperature monitoring was used for this study. Figure 1 is a schematic representation of our developed system.

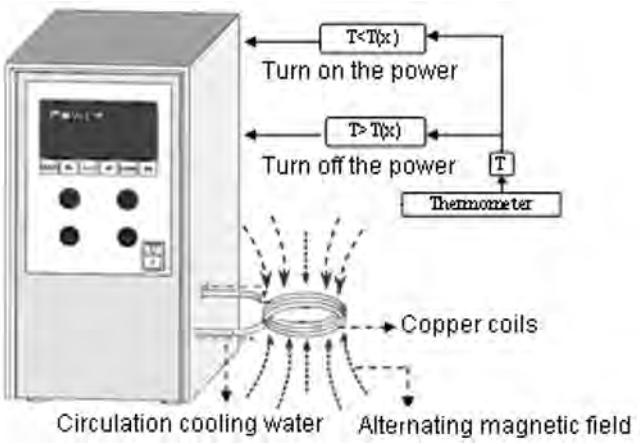

Fig. 1 Schematic representation of the proposed system, including a thermocouple, a lab-built, high-frequency induction machine, copper coils and a feedback temperature control system.

The dimensions of the machine are measured to be 35.5 cm in height and 19.5 cm in width, respectively. The depth of the machine is 42 cm. The diameter of the double coils is 7.5 cm. The operation frequency of the magnetic field is 62.1 kHz. The power consumption is estimated to be 2.2 kW.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 574–577, 2009
www.springerlink.com

Magnetic needles: We used a disposable fine needle (30 G). It is made of stainless steel.

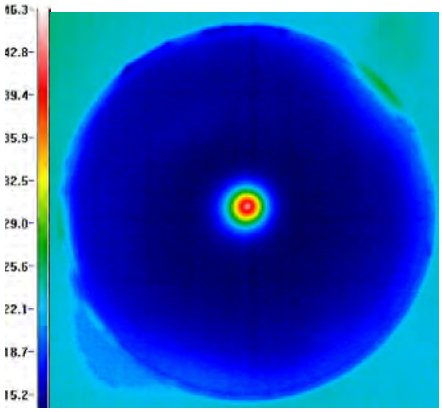
Temperature feedback control system: For monitoring the temperature, a thermocouple which was carefully checked in the AMF to make sure magnetic inertia before employed in our system (R-type, InterTech Technology Inc., Taiwan), then was used to provide a feedback control signal for precise temperature control.

B. Experimental design

In vitro tests: To detect the temperature distribution of our design, needles were inserted to the agarose gel and porcine liver in the matrix. Then, the agarose gel and porcine liver were treated for twenty minutes in the AC magnetic field. After the treating, we used IR camera to detect the agarose gel and porcine liver.

Cancer animal experiments: BALB/c mice, about 6-7 weeks old, were inoculated with CT-26 cells, $1x10^6$, into their back subcutaneously. After two weeks, the tumor grew to about 15mm X 15mm in each mouse. Then, they were divided into control (N=8) and treatment group (N=15). We used 30 G disposable fine needle 1.5 cm to 2.0 cm inserting to the tumors in the matrix. Then, the tumors were treated for twenty minutes in the AC magnetic field and a feedback temperature control was used to keep the temperature between 50°C ~ 55°C. The tumors were treated repeatedly 1 to 2 times in two weeks.

III. Results



A. In vitro tests

The temperature distribution which was generated by inserting needles in the matrix to the agarose gel was found to perform better than that by inserting a single needle. The results are shown in Figure 2 and Figure 3. In Figure 2, the highest temperature in the center of the picture is 48.8°C and the area of the effective temperature (>42°C) is about $1cm^2$. In Figure 3, the highest temperature in the center of the picture is 58.3°C and the area of the effective temperature is measured to be about $16cm^2$.

The results for the porcine liver show the same trend with the agarose gel test. The results are shown in Figure 4 and Figure 5. In Figure 4, porcine liver is inserted with a single needle. The highest temperature in the center of the picture is measured to be 48.6°C and the area of the effective temperature is about $0.7cm^2$. Conversely, when the porcine liver is inserted with needles in the matrix, the temperature is raised up to 83.1°C, and the area of the effective temperature is about $14cm^2$. From these experimental results, it

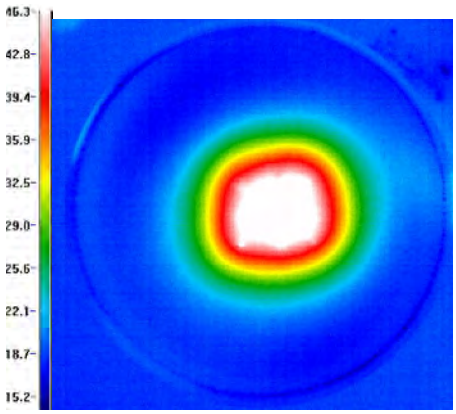

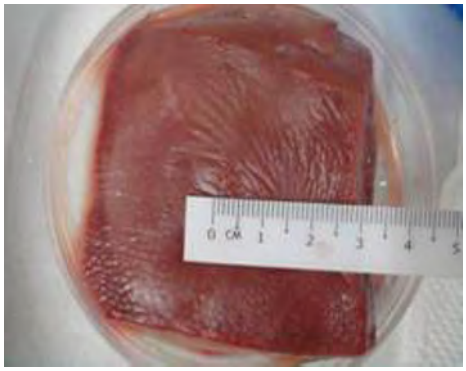

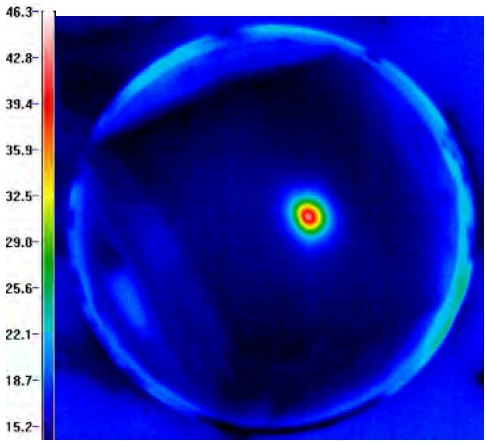

Fig. 3 The IR image which shows the temperature distribution for agarose gel with needles in a matrix. The highest temperature is 58.3°C and the area of the effective temperature is about 16 cm^2. Note that the temperature for the white area is higher than 46 °C

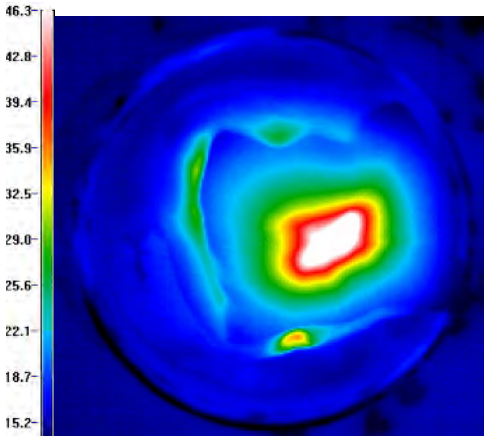
(a)

(b)

Fig. 4 (a) Porcine liver with a single needle. (b) The IR image which shows the temperature distribution. The highest temperature is 48.6°C and the white area temperature is up then 46 °C and the range is about 0.7 cm^2 .



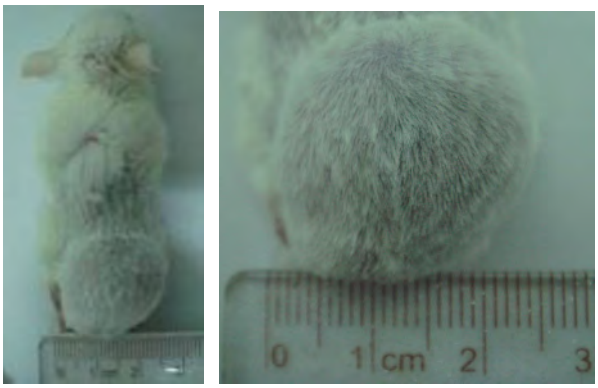


Fig. 5 The IR images for inserting needles in a matrix inside a porcine liver. The highest temperature is 83.1°C and the area of the effective temperature is about 14 cm^2. Note that the temperature of the white area is higher than 46 °C.

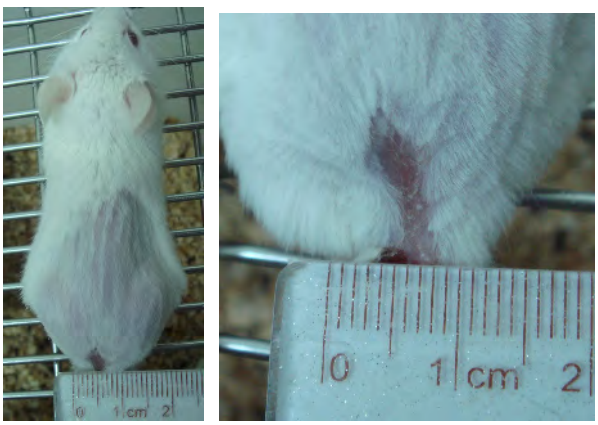
reveals that needles in the matrix are better than a single needle. For this reason, we use the needle matrix to treat the CT-26 tumors in the animal models.



B. Animal experiments

The control group (n=8) mice with tumor died at 11th day. The mouse is shown in Figure 6. The tumor kept growing during the experiment. For the treatment group (n=15), complete regression of CT-26 tumors can be observed in the most of the animals, two of them were dead during the experiment. Figure 7 shows the tumor regression of the treatment group. Figure 8 shows the changes in tumor weight during the observation period. For the control group, the tumor weights increase steadily leading to death and the survival rate at 45th day was 0%. In this animal model, the survival rate achieved 90% in the treated group and no re-

sidual tumor over their back was observation at the end of observation. The comparison is statistically significant.

IV. Conclusions

Fine needles can improve the temperature distribution in the in-vitro tests for hyperthermia cancer therapy. Needles inserted into tumor in the matrix form can induce a localized high temperature in the animal model when placed in an alternating magnetic field. A new feedback temperature control system was successfully integrated into a high-frequency induction machine to create a safer treatment environment. Animal tests showed that focal cancer thermotherapy can eliminate tumors completely in three weeks. We anticipate that the developing system and technology will evolve into a new thermal therapeutic system that can be applied in clinical settings.

[3]Graduate Institute of Electrical and Communications Engineering, Feng Chia University, Taichung, Taiwan, R.O.C.

Abstract — **In this study, a self-organizing neural network system is presented to classify the real-time electrocardiogram (ECG) signal. This system can not only organize continuous analog waveforms but also output useful recognition codes. The system contains a pre-processor and a self-organizing neural network. By using the MIT-BIH electrocardiogram database, the proposed neural network system can be trained to create the waveforms of cardiac diseases and to recognize the ECG waveforms. Also, a novel R point detection method is presented. The exercise ECG signals including 3,614 R points are tested. The proposed R point detection result reaches sensitivity being 99.94%. The self-organizing neural network system was tested using the MIT-BIH ECG database. 18 data for each with five hours durations were segmented to many beat samples. 5 ECG models (without noise) were created. The results of normal and premature ventricular contraction (PVC) samples classifying using MIT-BIH Arrhythmia Database were obtained. We separated the samples into normal and abnormal signals by 15 trained normal models, then we classified the abnormal ones by 44 trained PVC models. The overall accuracy of the classification results is higher than 87%.**

Keywords — **Self-organization neural network, electrocardiogram, model classification, premature ventricular contraction**

I. Introduction

Heart is one of the most important organs in human body. It uses the blood to transport nutrient to each organ, and removes the useless product from human body to balance each elements. The heart is the main center of blood stream, and the electrocardiogram (ECG) is the best indication to observe the cardiac activity. The heart diseases along with different ages and habits are diverse, and the disease symptoms and the conditions are also different. Therefore, it is desirable to realize the human health conditions by reading the outcomes of ECG and find out the disease of either arrhythmia, myocardial infarction, or others.

It has been shown that 90 to 95 percents of patients with acute myocardial infarction have some associated cardiac arrhythmia. Two most common cardiac arrhythmias during an acute myocardial infarction are premature ventricular contractions and sinus tachycardia. The analysis of the electrocardiogram (ECG) signal is the most readily available method for diagnosing cardiac arrhythmias [1]. New techniques of arrhythmia detection using morphology of the waveform have shown promising results in correctly detecting fatal arrhythmias [2-3]. The purpose of this study is to present a self-organizing neural network system to classify the real-time electrocardiogram (ECG) signal. This system can not only organize continuous analog waveforms but also output useful recognition codes. The beat of ventricular premature contraction will be classified on the basis of beat morphology. In previous research, Chiu et al. has proposed an approach for arterial pressure pulse classification using self-organizing neural network [4], and successfully created the normal and abnormal arterial pressure pulse waveform and applied them to the autonomic nerve recognizing. They also had a collaborated project with Taiwan textile research institute (TTRI) to create the exercise ECG models by the similar self-organizing neural network. Based on self-organizing neural network application experiences, we further use the neural network to classify the ECG signal. Many normal and abnormal ECG models are trained and created. We can therefore classify the unknown ECG signal by these well-trained models.

II. Material and methods

A. ECG signal

In this research, the ECG signals from the MIT-BIH Normal Sinus Rhythm Database and the MIT-BIH Arrhythmia Database are adopted. We also acquired the ECG signals from exercise Lead II ECG provided by Taiwan Textile Research Institute. The exercise ECG data contain 3,614 heart beats.

B. Self-organizing neural network

The characteristics of neural network are quite useful. It is able to preserve the original knowledge and learn the new knowledge. However, most neural networks lack of this kind of characteristics, and cause these neural networks being inconvenient to use in practical applications.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 578–581, 2009
www.springerlink.com

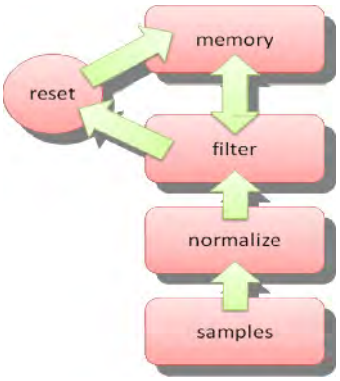

Fig. 1. Block diagram of modified ART neural network

The problem comes to the neural network that it wants to learn the new knowledge without harassing old memory. It is called the stability-plasticity question. In order to make the neural network flexible and being able to learn immediately, Grossberg et al. presented an adaptive resonance theory, ART [5][6][7]. In this research, we slightly modify the ART neural network to be used in classifying the ECG beat signals. The block diagram of underlying algorithm is shown in Fig. 1.

First, we normalize the input sample amplitude to ±1, and resample the input sample to 250 points. Then we process the sample by 1~40Hz band-pass filter. Finally, we calculate the correlation between sample and model in memory. The model is modified if the resulting correlation is higher than our preset threshold. On the other hand, if the resulting correlation is lower than the threshold, the neural network adds the sample into the memory to be a new model. The formula to calculate the correlation is shown as below.

$$R(X,Y)=\frac{\sum(X_i-X_{mean})(Y_i-Y_{mean})}{\sqrt{\sum(X_i-X_{mean})^2\sum(Y_i-Y_{mean})^2}} \tag{1}$$

Where $R(X, Y)$ is the calculated correlation between an incoming sample X and an existed model Y. X_i and Y_i are the i^{th} signal in the sample X and model Y, respectively. X_{mean} and Y_{mean} are the mean values of the sample X and model Y, respectively.

C. Sample definition

In this research, the input sample is defined as an R-R segment. We segment the signal from R point to next consecutive R point. We then resample all the R-R-segment samples to 250 point to make sure that the samples have the same fixed length. The sample definition of an R-R segment is shown in Fig. 2.

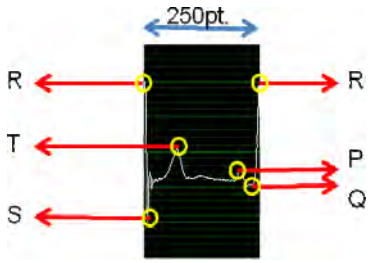

Fig. 2. A sample with a 250-point fixed length

D. A novel R point detection algorithm

According to the result of earlier research, the accuracy of classifying the lead II R point detection in rest position was over 90% using the "So and Chan" method [8]. However, the accuracy of classifying the exercise ECG became lower than 70% by using that method. Therefore, it is inevitable to design a novel detection method in order to segment the ECG signal accurately in real-time. Due to the ECG signal is a time series signal, we are able to make use of the previous QRS segment and predict the following ones. Our proposed novel R point detection algorithm is described as follows.

1. Initialization.

$X(n)$ is incoming ECG series, and the X_n is n^{th} point of the ECG series. R_i is the location index of the i^{th} R point. SR_i is the estimate length of i^{th} RR interval. RR_i is the actual length of i^{th} RR interval. c is the weighted constant. Assume that SR_1 is the scan rate, in our case is 250. At the very beginning 250 points, we can find the first QRS segment and R point location, say R_1, by the following equation.

$$R_1=\text{argmax}[X(n)],\quad 1\le n\le SR_1 \tag{2}$$

2. Iteration

The QRS segment usually appears to be close to periodicity, that is, (i+1th) R point should be located nearby the duration within the range of R_i+SR_i. The range to search the R point can therefore be set by the following equation.

$$\begin{aligned} &R_{i+1}=\text{argmax}[X(n)],\\ &R_i+SR_i-cSR_i\le n\le R_i+SR_i+cSR_i\\ &RR_i=R_i-R_{i-1} \end{aligned} \tag{3}$$

As one knows that the heart rate may fluctuate due to exercise or emotion, the estimate of RR interval, i.e., SR_{i+1}, should be adjusted based on the average value of previous k RR intervals. The following equation show how the SR_i is modified.

$$SR_{i+1}=\frac{RR_i+RR_{i-1}+\cdots+RR_{i-k+1}}{k} \tag{4}$$

3. Validation

The slope examination method similar to the one proposed by So and Chan [10] is applied to validate our proposed R point detection algorithm to avoid misjudging between R and T point. Let S_n be the n^{th} slope in the series $X(n)$. a is a weighted constant. S_n is defined as follows.

$$S_n = (X_{n-2} - X_{n-1}) + a(X_{n-1} - X_n) - a(X_n - X_{n+1}) - (X_{n+1} - X_{n+2}) \quad (5)$$

At most cases, the slope at R point is much higher than that at T point. Therefore, if the slope value detected is smaller that our preset threshold, then the weighted constant c in equation (3) should be adjusted to be smaller. Since the search range becomes smaller, the possibility to obtain R point wrongly will be reduced.

III. Results and Discussion

During the recording of a real-time ECG signal, the ECG signal usually contaminates with noise or motion artifact. The noise or artifact makes the detection accuracy of R points becomes lower without any manipulation.

Table 1. Comparison of sensitivities between "So and Chan" method and the novel R point detection algorithm

Method	true positives	false negatives	false positives	sensitivity
So and Chan	2759	1231	855	61.62%
Novel algorithm	3612	1	2	99.94%

Sensitivity = true positives / (true positives+ false negatives)

Table 1 shows the sensitivity of our proposed R point detection algorithm outperforms previous method in exercise Lead II ECG R-point detection. When detect the ECG signal, So and Chan method should set the detection threshold accurately. If the detection threshold can't change dynamically, the sensitivity using So and Chan method will get even lower. Our proposed R point detection algorithm can change the search range and location dynamically, so the performance of novel algorithm works much better in this study.

The results list in Table 2 are the classification results of signals in MIT-BIH Normal Sinus Rhythm Database using the self-organizing neural network.

Database: MIT-BIH Normal Sinus Rhythm Database
Number of records: 18
Testing signal channel: Signal 1 / 5Hr
Sampling rate: 128 samples/sec.
Filter: none
Training spent time: 560sec.
Classifying spent time: 10sec.

Table 2. Classification results of signals in MIT-BIH Normal Sinus Rhythm Database

Record No.	Samples	Model(s) with noise	Sample-Model ratio	Model(s) without noise
16265	27651	9	0.03%	5
16272	19289	267	1.38%	5

19093	20939	9	0.04%	2
19140	26558	17	0.06%	3
19830	32568	58	0.18%	9
Average	25298.5	54.67	0.22%	4.38

The classification results shown in Table 2 indicate that the self-organizing neural network classifies the input samples into only a few output models. The sample-model ratios are almost lower than 1% of the total input samples. The results point out that the models can be created very effectively and concisely. One can also see from Table 2 that some signals have only one model left after certain noise models are removed from our classification results,. This result indicates that the sample model in the original signal can be very uniform or regular. In some case, signals contain a very low frequency drift. Due to the signal drifting, the correlations between the segmented samples become lower. Therefore, the neural network creates more models than the others recorded signals.

After using the neural network to classify the samples into models, we test the classification results and count the accuracy rate by the following steps. The testing block diagram is shown in Fig. 3.

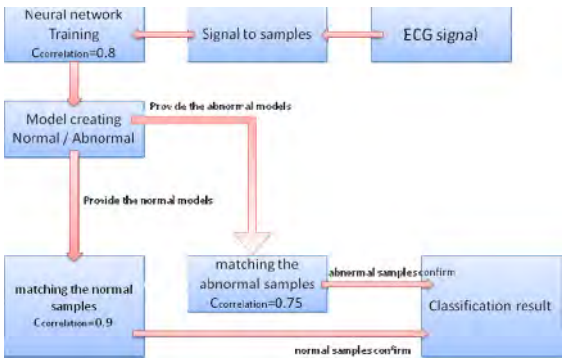

Fig. 3. Block diagram of testing processes

At our experiment, we obtain 15 normal models and 44 typical PVC models. The correlation threshold is set to be 0.9 to match the normal models with testing samples. We set the correction threshold to 0.75 to match the normal models with the remaining test samples. Then we can recognize the abnormal samples using lower correlation threshold with abnormal models, and filter out the samples can't be recognized.

Table 3 indicates the classification results of signals in MIT-BIH Arrhythmia Database. We select the database to be the testing objects because the PVC waveforms usually appear in arrhythmia ECG waveforms.

Database: MIT-BIH Arrhythmia Database
Testing object: Normal / PVC ECG
Testing signal channel: MLII / 5min. data

Table 3. Classification results of signals in MIT-BIH Arrhythmia Database

NO.	+PVC in record	+Normal in record	Normal	Abnormal	$ Correct classification%
105	12	405	391	21	94.48%
106	60	271	227	41	80.96%

233	139	371	267	144	78.62%

+record list:
http://www.physionet.org/physiobank/database/html/mitdbdir/records.htm
#noisy signal
$Correct classification% = (1-(failure classification number/ actual record number))x100%

The normal ECG samples in each record are almost the same. Therefore, we can easily identify the normal ECG samples by the normal models, and then we indentify the fewer remain samples by abnormal models. We can make the classification more efficient by increasing the correct classification rate. The table above shows that the correct classification rates in most cases are higher than 80%. And the average correct classification rate is over 87%. The self-organizing neural network system presented in this study can classify many samples into a few normal/abnormal models effectively and correctly.

IV. Conclusions

A self-organizing neural network system has been presented to classify the real-time ECG signal. The recognized results are useful to find out models of cardiac diseases. By using the signal data in MIT-BIH electrocardiogram database, the proposed neural network system can be trained to create the waveforms of cardiac diseases and to recognize the ECG waveforms. Also, a novel R point detection method has been presented. The proposed R point detection result reaches sensitivity of 99.94%. The results of normal and premature ventricular contraction (PVC) samples classifying with MIT-BIH Arrhythmia Database, we separated the samples into normal and abnormal signals by 15 trained normal models, then we classified the abnormal ones by 44 trained PVC models. The accuracy of the classification results is higher than 87%.

Abstract — **One-third of the lifetime is spent asleep, and the quality of sleep significantly affects health and the quality of life. Many people are unaware that they snore during sleep, and also consider that snoring occurs when the body is too tired, whereas it is actually is an indicator of good health. There is accumulating evidence that snoring is indicative of sleep apnea syndrome, which can decrease blood oxygenation and induce hypertension, right ventricle failure, angina pectoris, and even sudden death. Given the importance of snoring and its relation to blood oxygenation, we built a small oximeter with low power consumption and based on optical penetration, with the acquired physiological data being transferred to a personal computer via a serial interface. In this system the computer measures physiological data of blood oxygen, heart rate, and heart rate variability using Poincaré plots. The stability of the oximeter results was determined using a standard biosignal simulator, with three subjects being monitored: those prone to snoring. This system is noninvasive, makes continuous measurements, and is highly portable, which make it a good choice for monitoring sleep in the home environment.**

Keywords — **Sleep apnea syndrome, oxygen saturation, sleep, snoring**

I. Introduction

Sleep is an important physiological function, with humans spending one-third of their lifetimes asleep, and the quality of sleep significantly affects the quality of life and health. Physiologically, snoring is cased by obstruction of the upper respiratory tract. Sleep apnea during snoring can be a temporary condition or lead to sleep apnea syndrome (SAS) [1–3].

Improvements in living standards, eating habits, and environmental pressures have increased the prevalence of people with chronic disease. However, obstruction of the upper respiratory tract is now experienced by 85–90% of people. Airway obstruction caused by apnea further reduces the oxygen saturation (SaO_2), interfering with sleep and increasing the risk of cardiovascular disease. Moreover, many traffic accidents are due to lethargy and inattention, conditions that are also associated with SAS.

The standard procedure for diagnosing SAS is quite complicated, with several physiological signals being monitored throughout the night, such as the electrooculogram, electroencephalogram, and electromyography, airflow in the mouth and nose cavity, and occurrence of snoring. This process has unfavorable characteristics, such as being cumbersome, costly, and wasteful of medical resources. However, improvements in biomedical photoelectric technology have led to the development of oximeters [4] for the noninvasive method of measuring SaO_2 using optical sensors, which provides convenience and safety advantages.

The aim of this study was to design a small, power-efficient, and inexpensive oximeter that was simple to use. The device used both red light (660 nm) and infrared light (940 nm) produced by two light-emitting diodes (LEDs) to illuminate the body. The reflection and transmission of light energy were determined from the detected light, from which the heart rate and SaO_2 were calculated. In order to reduce medical costs and enable continuous monitoring, the oximeter was linked with a personal computer to provide a system for the real-time analysis of heart-rate variability (HRV). The system can record SaO_2 and HRV changes during sleep, and provide long-term data of snoring for clinical trials.

II. Methods

Heme oxygen containing the hemoglobin share of the total volume is defined as the percentage of oxygen in the blood flow, referred to as SaO_2:

$$SaO_2 = \frac{\mathrm{HbO_2}}{\text{Total hemoglobin}} = \frac{[HbO_2]}{[HbO_2]+[Hb]} \times 100\% \quad (1)$$

where $[HbO_2]$ is the volume of oxygenated hemoglobin, and [Hb] is the volume of deoxygenated hemoglobin in the blood.

Lambert clarified the relationship between the degree and material thickness absorption of optical in 1760, and Beer proposed the relationship between the degree of optical absorption and absorption concentration in 1852. These two observation are combined into the Beer-Lambert law. We define the absorption and concentration along an optical path as exponential functions as follows:

$$I(\lambda) = I_o(\lambda) \times 10^{-\varepsilon \cdot c \cdot d} \quad (2)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 582–585, 2009
www.springerlink.com

where $I(\lambda)$ is the transmission optical intensity, $I_o(\lambda)$ is the incident optical intensity, ε is the absorption coefficient, c is the concentration, and d is the optical path length through the sample.

The absorption factor of a material is affected by the wavelength of the incident light and the temperature. A larger value indicates a higher absorption capacity, which results in measurements of higher sensitivity.

We define the optical density (O.D.) by taking the logarithm of both sides of Equation 2, which corresponds to the absorbance shown in Figure 1:

$$O.D. = \log\left(\frac{I_o(\lambda)}{I(\lambda)}\right) = \varepsilon \cdot c \cdot d = \mathrm{A} \tag{3}$$

where A is the absorbance.

When the optical wavelength and optical path length are fixed, there is a linear relationship between the optical intensity and the concentration of the sample. Therefore, in optical measurement applications, as long as the optical density has been measured with a known light absorption ε and optical path length d, can be obtained under test concentration c. However, the Beer-Lambert law applies only to the absorption of the solution without scattering.

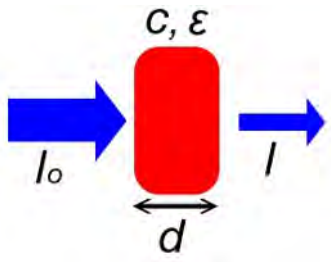

Fig.1 Optical pathway through the material.

Oxygenated and deoxygenated hemoglobin exhibit different absorption properties for different optical wavelengths. Therefore, our system applies light at two wavelengths to the test tissue (usually a finger) to detect changes in optical energy transmittance, and then calculate SaO_2. From results of near-infrared spectroscopy, we chose absorption points either side of 800 nm (i.e., 660 and 940 nm) for the optical source wavelength in a two-wavelength system. Note that these two wavelengths are often used by oximeters available in the marketplace.

We used the small-artery model of the human finger shown in Figure 2. The thickness of the small artery is D during vasoconstriction and $D+\Delta D$ during vasodilation, with change in thickness ΔD being due to stretching and relaxing of blood vessels during the pressure pulse. Assuming that the blood vessels contain only oxygenated and deoxygenated hemoglobin, the Beer-Lambert law can be used to determine the transmission of infrared (940 nm) and red (660 nm) light as follows:

$$I_{IR} = I_{(DC+AC)IR} = I_O \cdot 10^{-\left(\varepsilon_{IR}^{HbO_2} \cdot C_{HbO_2} + \varepsilon_{IR}^{HB} \cdot C_{Hb}\right)D} \cdot 10^{-\left(\varepsilon_{IR}^{HbO_2} \cdot C_{HbO_2} + \varepsilon_{IR}^{HB} \cdot C_{Hb}\right)\Delta D} \tag{4}$$

$$I_R = I_{(DC+AC)R} = I_O \cdot 10^{-\left(\varepsilon_R^{HbO_2} \cdot C_{HbO_2} + \varepsilon_R^{HB} \cdot C_{Hb}\right)D} \cdot 10^{-\left(\varepsilon_R^{HbO_2} \cdot C_{HbO_2} + \varepsilon_R^{HB} \cdot C_{Hb}\right)\Delta D} \tag{5}$$

where ε_{IR}^{Hb} and $\varepsilon_{IR}^{HbO_2}$ are the infrared optical absorption coefficients of Hb and HbO_2, respectively, and ε_R^{Hb} and $\varepsilon_R^{HbO_2}$ are the corresponding red optical absorption coefficients.

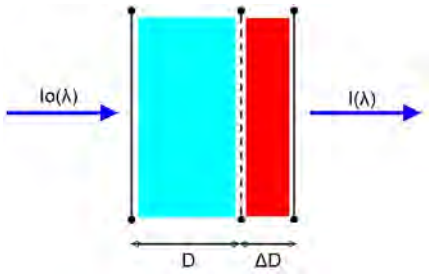

Fig.2 Small-artery model of the human finger.

To simplify the calculation of the SaO_2, we divide both sides of Equations 4 and 5 by $I_{DC(IR)}$ and $I_{DC(R)}$, which after rearranging yields the following definition of the absorbance ratio for red and infrared light:

$$ratio = \frac{R}{IR} = \frac{\log\left(\frac{I_{(DC+AC)R}}{I_{DC,R}}\right)}{\log\left(\frac{I_{(DC+AC)IR}}{I_{DC,IR}}\right)} = \frac{\varepsilon_R^{HbO_2} \cdot c_{HbO_2} + \varepsilon_R^{Hb} \cdot c_{Hb}}{\varepsilon_{IR}^{HbO_2} \cdot c_{HbO_2} + \varepsilon_{IR}^{Hb} \cdot c_{Hb}} \tag{6}$$

Merging Equations 1 and 6 yields the possible theoretical value of SaO_2:

$$SaO_2 = \frac{\varepsilon_{IR}^{Hb} \cdot \frac{R}{IR} - \varepsilon_R^{Hb}}{\left(\varepsilon_{IR}^{Hb} - \varepsilon_{IR}^{HbO_2}\right) \cdot \frac{R}{IR}\left(\varepsilon_R^{Hb} - \varepsilon_R^{HbO_2}\right)} \tag{7}$$

III. System Design

To implement a system using a small oximeter with low power consumption, we selected the MSP430FG439 microcontroller for signal processing. The system was designed to transfer data to a computer using a peripheral interface to allow physiological data analysis and recording. A block diagram of the hardware is shown in Figure 3.

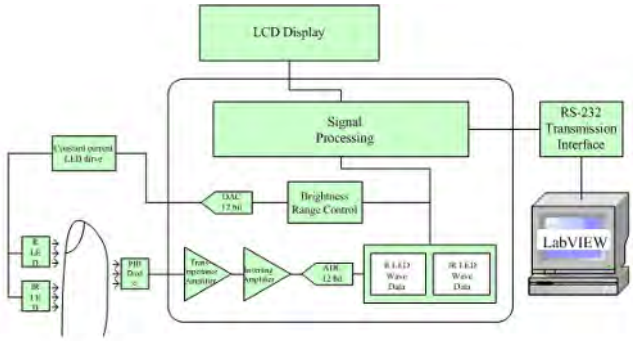

Fig.3 Hardware block diagram.

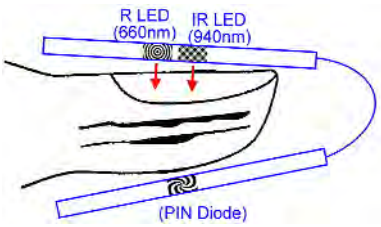

Fig.4 Optical sensor: orientation with finger.

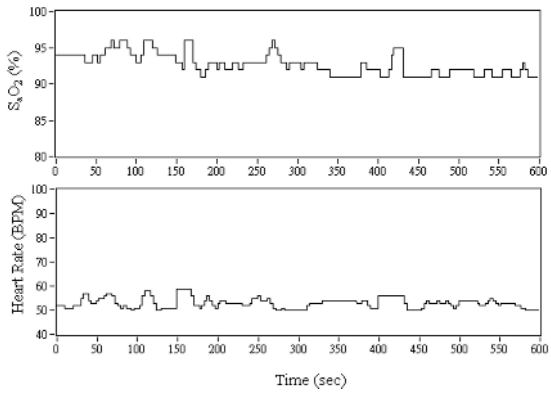
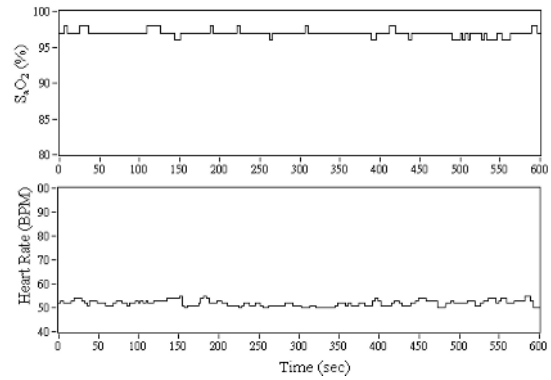
The system's optical sensor uses an oxygen probe (S0010A, MED LINKET) of the optical transmission type, as shown in Figure 4. The optical detector is a light diode that converts light energy into a current signal.



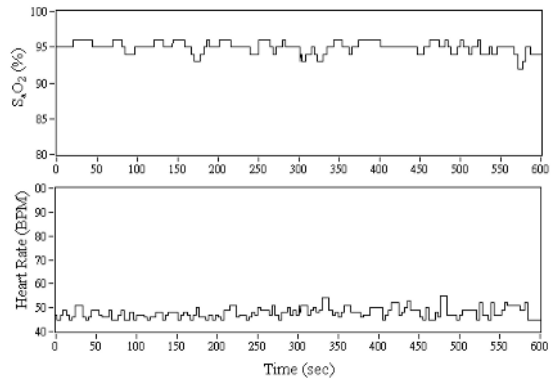
We adopted a time-division pulse modulation method for controlling the timing of the red and infrared LEDs. The MSP430FG439 microprocessor was used to alternately drive the red and infrared light sources and the optical detector. The sensitivity of the optical detector varies with the incident light, and hence the signals for the red and infrared light sources need to be adjusted to the same level.

The signal from the optical detector is sampled and processed by filtering and amplification by the internal operational amplifier in the microprocessor. The system converts the analog signals into digital signals for calculating the SaO_2 and the heart rate, which are finally displayed on an LCD with the data also being sent to a personal computer via a serial interface for recording and analysis using LabVIEW software (National Instruments) [5]. A patient simulator (PS97, BAPCO Instruments) is used to calibrate and verify the SaO_2 value before each sleep experiment.



IV. Results

4.1 Preliminary experiments for monitoring snoring



We explored the impact of snoring on SaO_2, heart rate, and HRV during sleep. Sleep snoring was monitored in three people prone to snoring (mean age=25 years, mean BMI=22.5 kg/m^2). To improve the consistency and objectivity of the experiments, the subjects were asked not to consume food that might affect the central nervous system (e.g., tea, coffee, and alcohol) for 8 hours before participating in the sleep experiment. Moreover, none of the subjects had recently taken any medications. In each experiment, a

(a)

(b)

(c)

Fig.5 Data recorded in three subjects (a, b, and c) in preliminary experiments for monitoring snoring.

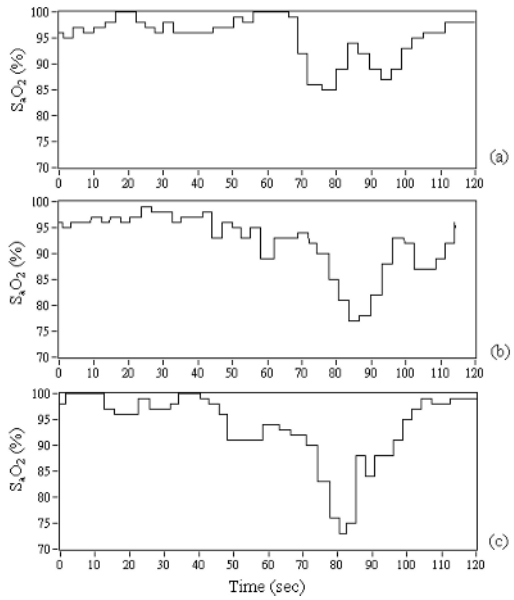


Fig.6 Data recorded in three subjects (a, b, and c) in breath-holding experiments.

staff member monitored the subject throughout the night and recorded significant data for 10 minutes when the subject was snoring. Figure 5 shows the data recorded from the three subjects.

4.2 Human breath-holding experiments

We verified the efficacy of the system in detecting oxygen deficits in the human body induced by breath holding. Changes in SaO_2 were measured using the following experiment (see Figure 6):

1. Seconds 1 to 10: normal breathing.
2. Seconds 10 to 70: stop breathing.
3. Beyond 70 seconds: restore breathing.

V. Discussion and conclusions

In order to explore the impact of sleep snoring on the heart rate and HRV, we have developed an oximeter that is small, portable, has a low power consumption, and can record long-term data. In breath-holding experiments, the device detected a downward trend in SaO_2 as the physiological response to oxygen deficit. In preliminary experiments for monitoring snoring during sleep, no peculiar changes were observed in the SaO_2, heart rate, and HRV in subjects prone to snoring, which indicates that sleep apnea does not necessarily occur during snoring. However, this negative result might be due to the inclusion of only a few patients with clinical sleep disorders.

The described system could be expanded to record snoring sounds, breathing rate, and other important parameters. We believe that this system is suitable for monitoring experiments associated with sleep snoring.

Abstract — **Image processing and visualization of medical data has become an essential support for clinical diagnosis and treatment planning. The available open source libraries such as the Insight Registration and Segmentation Toolkit (ITK) and the Visualization Toolkit (VTK) with custom designed user interface can help rapid development of medical imaging applications. Both ITK and VTK are written in C++ language with the wrappers for Tcl, Python, and Java languages. Numbers of researchers and developers implement their proposed algorithms with some reusable functions available in ITK and VTK. The ITK offers extensive image filtering techniques for segmentation and registration applications without support of data visualization, while VTK mainly supports the visualization. Therefore, several medical software systems have been implemented using the connection of ITK and VTK. However, the successful connection has been reported only implementing in C++, Tcl and Python languages. The connection of ITK and VTK using Java language is still a problem. However, Java has the advantages of being a less complex, free, and easily portable programming language. Hence, the ability to connect the ITK and VTK classes directly using Java will benefit the rapid development of medical applications and teaching medical image analysis.**

In this paper, we present the method that enables the integration of ITK and VTK libraries together in Java. This integrated ITK/VTK offers more flexible handling and benefits of image processing algorithms from ITK together with the 2-D/3-D visualization from VTK. In the last section, examples of the implementation of the integrated ITK/VTK in Java language on the medical imaging samples are presented.

Keywords — **ITK and VTK in Java, image processing, medical imaging applications**

I. Introduction

The ITK [1] and the VTK [2] are the open-source libraries that are widely used in the applications of image processing and scientific visualization. Several researchers and developers implement their proposed algorithms with the reusable and extendable functions available in ITK and VTK to reduce the amount of time in coding and implementation. The ITK library has the advantage of providing support for numerous standard image processing such as linear and nonlinear filters, image transformations and interpolations, segmentation, morphology and level sets etc., while VTK library offers a variety of visualization algorithms like scalar, vector, texture and volumetric techniques and advanced techniques such as polygon reduction, mesh smoothing, contouring and Delaunay triangulation etc [3].

In medical software and application development, the graphical user interface (GUI) is also important. Java language which is free, less complex programming and easily portable has drawn more attention in application development due to the availability of large standard library and several plug-in tools. Both ITK and VTK libraries are written in C++ language with the wrappers for Tcl, Python, and Java languages, hence the researcher and developers are able to implement and develop prototypes in the language that they are more comfortable with. The integration of ITK and VTK libraries has been reported implementing in C++, Tcl and Python languages, for example, VolView [4] and Slicer [5]. The connection of ITK and VTK libraries using Java language is still a problem for numerous developers as the ConnectVTKITK (direct connection between ITK and VTK library) is not wrapped to be used with Java. Moreover, the documents and technical support about the wrappers for ITK and VTK libraries are limited [6].

This paper presents the method that enables the integration of ITK and VTK libraries together in Java programming language. The compiling processes of ITK, VTK and integrated ITK/VTK for Java are explained in the next section. After that the examples of the integrated ITK/VTK implemented in Java programming on the medical imaging samples are demonstrated.

II. Compiling processes of ITK, VTK and integrated ITK/VTK for Java language

The processes of compiling ITK, VTK and integrated ITK/VTK for Java on Windows platform require CMake [7], C++ compiler and Java SDK. We note that CMake version 2.4 and Java SDK version 1.6 are used in our implementation. In the following subsections, we briefly explain the compilation of VTK, ITK and integrated ITK/VTK for Java respectively.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 586–589, 2009
www.springerlink.com

A. Compilation of VTK for Java language

The VTK library written in C++ has its own wrapping facility which is enable to automatically generate Java binding in the same way as the automated wrapping into Tcl as described in [8]. The following steps are carried out for compiling the VTK source code (version 5.0.3 release was used) and generating the Java bindings using the CMake tool. Once the CMake is launched

1. Set the VTK source and the binaries directories
2. Select to build for available C++ compiler
3. Set the following options to ON as the Show Advanced Values option is enable
   - BUILD_SHARED_LIBRARIES to ON
   - ITK_CSWIG_JAVA to ON.
4. Click Configure. There may be some options presented to confirm about the version of Java SDK and click Configure a second time. On the completion, the CMake is automatically closed
5. Open the solution file (VTK.sln) with the C++ compiler and run the Build Solution operation with the Release build configuration. Verify that there are no errors and VTK.jar is built.

Before creating a Java project, the folders that contain compiled VTK library files (DLL files) and VTK.jar must be added to System path.

B. Compilation of ITK for Java language

The ITK can be wrapped using CableSwig or WrapITK [6]. The CableSwig has been developed using a combination of language binding tools such as gccxml[9], CABLE and CSWIG[10]. The WrapITK requires both ITK and CableSwig to have been built firstly. As the WrapITK is still in the development process and mainly supports Python language, hence the wrapping process using CableSwig is recommended. The wrapping can be done by placing CableSwig into the Utilities directory of the ITK source and follow the similar steps as described earlier in compiling the ITK source code and generating the ITK Java bindings.

C. Compilation of integrated ITK/VTK for Java language

The wrapping process for the integrated VTK and ITK is difficult due to the following factors

1. The development of ITK is based on the generic programming (i.e., extensive use of C++ templates), whereas the non-templates are used for VTK.
2. Both ITK and VTK have their own algorithms pipeline.

However, after the thorough study of the ITK and VTK wrapping structures we have proposed the method to wrap the integrated ITK/VTK for Java bindings in the similar way to the integrated ITK/VTK for Tcl language as implemented in 3D Slicer. The project called "vtkDtp" is created by extending the source codes in the vtkITK directory available in the InsightApplications directory. A list of files inside the vtkDtp folder is shown in Fig.1.

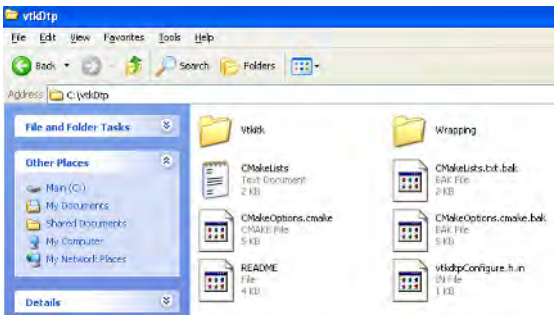

Fig. 1 Files inside the vtkDtp project

The CMakeLists.txt, which is called by CMake tool to compile and build the vtkDtp project, is modified as follows

```
CMAKE_MINIMUM_REQUIRED(VERSION 2.0)
# Set the project name.
#
PROJECT (VTKDTP)
# Load CMake commands that you probably should not modify.
#
INCLUDE (${VTKDTP_SOURCE_DIR}/CMakeOptions.cmake)

# On Visual Studio 8 MS deprecated C. This removes all 1.276E1265
security
# warnings
IF(WIN32)
  IF(NOT BORLAND)
    IF(NOT CYGWIN)
      IF(NOT MINGW)
        IF(NOT
ITK_ENABLE_VISUAL_STUDIO_DEPRECATED_C_WARNINGS)
          ADD_DEFINITIONS(
          -D_CRT_FAR_MAPPINGS_NO_DEPRECATE
          -D_CRT_IS_WCTYPE_NO_DEPRECATE
          -D_CRT_MANAGED_FP_NO_DEPRECATE
          -D_CRT_NONSTDC_NO_DEPRECATE
          -D_CRT_SECURE_NO_DEPRECATE
          -D_CRT_SECURE_NO_DEPRECATE_GLOBALS
          -D_CRT_SETERRORMODE_BEEP_SLEEP_NO_DEPRECATE
          -D_CRT_TIME_FUNCTIONS_NO_DEPRECATE
          -D_CRT_VCCLRIT_NO_DEPRECATE
          -D_SCL_SECURE_NO_DEPRECATE
          )
        ENDIF(NOT
ITK_ENABLE_VISUAL_STUDIO_DEPRECATED_C_WARNINGS)
      ENDIF(NOT MINGW)
    ENDIF(NOT CYGWIN)
  ENDIF(NOT BORLAND)
ENDIF(WIN32)
#
```

```
# Here is where you can list the sub-directories holding your local
# classes. Sorting classes by 'package' type like VTK does (Common,
# Rendering, Filtering, Imaging, IO, etc.) is a good thing and prevents
# numerous dependencies problems.
#

SUBDIRS (
  Vtkitk
)

CONFIGURE_FILE(
  ${VTKDTP_SOURCE_DIR}/vtkdtpConfigure.h.in
  ${VTKDTP_BINARY_DIR}/vtkdtpConfigure.h
)
INCLUDE_DIRECTORIES(${VTKDTP_BINARY_DIR})
```

The subdirectory Vtkitk consists of .cxx and .h files of the integrated VTK/ITK (see inside the Common directory in the vtkITK directory in the InsightApplications directory). Inside the Vtkitk folder also has another CMakeLists.txt, modifying this CMakeLists.txt in the Configure wrappers from Tcl and Python to Java. Next, launch the CMake and set the Cache Values for the project as shown in Fig.2.

Fig. 2 Cache Values Setting for vtkDtp project

Once the vtkDtp project is completely built, the vtkITK.jar can be obtained using the following steps

1. Create folder called “CompileJava”
2. Copy files that have been builded from the VTK project and the vtkDtp project to CompileJava folder. All the files that are copied to CompileJava folder are shown in Fig. 3
3. Use Java JDK tool to pack all the copied file to .jar file. Note that this .jar file contain .class file of VTK and integrated ITK/VTK

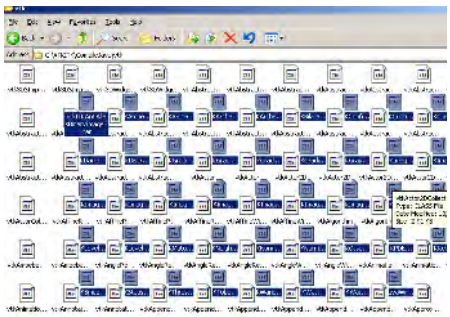

Fig. 3 All the .class file of VTK and integrated ITK/VTK

III. Exerimental Results and Discussion

The following section briefly demonstrates the experimental results of using integrated ITK/VTK in processing and visualizing the input medical images. Fig.4 – Fig.6 illustrate the implemented results using vtkITKOtsuThresholdImageFilter, vtkITKGradientMagnitudeImageFilter, and vtkITKConfidenceConnectedImageFilter classes on the MRI DICOM input respectively.

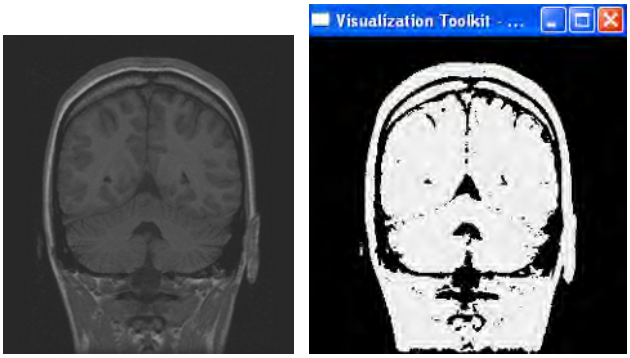

Fig. 4 The implemented result using vtkITKOtsuThresholdImageFilter

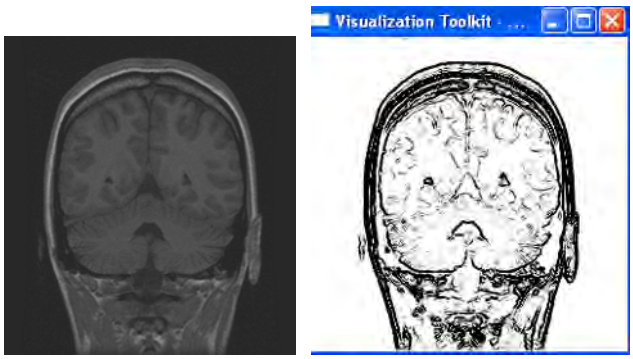

Fig. 5 The implemented result using vtkITKGradientMagnitudeImageFilter

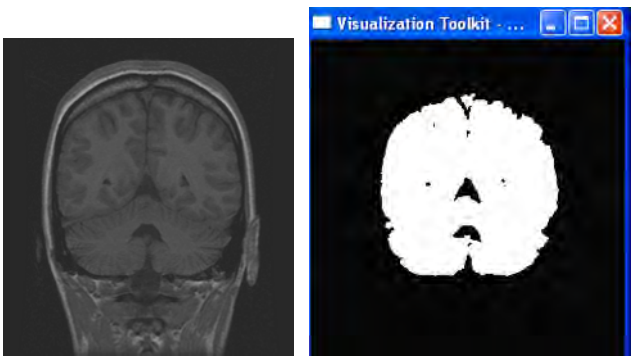

Fig. 6 The implemented result using vtkITKConfidenceConnectedImageFilter

The example of Java code implementing vtkITKGradientMagnitudeImageFilter is as follows

```
package vtkitk_example;
import vtkitk.*;
public class Main {
   static {
      System.loadLibrary("vtkCommonJava");
      System.loadLibrary("vtkFilteringJava");
      System.loadLibrary("vtkIOJava");
      System.loadLibrary("vtkImagingJava");
      System.loadLibrary("vtkGraphicsJava");
      System.loadLibrary("vtkRenderingJava");
      System.loadLibrary("vtkITKJava");
   }
   public Main() {}
   public static void main(String[] args) {
      vtkDICOMImageReader dicomread = new
vtkDICOMImageReader();
       dicomread.SetFileName
("D://DICOM_data/MRI_Series8/I0000437_anon.dcm");
       dicomread.SetDataByteOrderToLittleEndian();

      vtkITKGradientMagnitudeImageFilter Filter = new
vtkITKGradientMagnitudeImageFilter();
      Filter.SetInput(dicomread .GetOutput());
      vtkImageCast cast = new vtkImageCast();
      cast.SetInput(Filter.GetOutput());
      cast.SetOutputScalarTypeToUnsignedChar();

      vtkRenderWindowInteractor renderWindowInteractor= new
vtkRenderWindowInteractor();
      vtkImageViewer viewer = new vtkImageViewer();
      viewer.SetupInteractor(renderWindowInteractor);
      viewer.SetInput(cast.GetOutput());
      viewer.SetColorWindow(255);
      viewer.SetColorLevel(127);
      viewer.Render();
      renderWindowInteractor.Start();
   }
}
```

It can be seen that the proposed method for compiling the integrated ITK/VTK for Java language, has enable the integration of filtering algorithms in the ITK library to the VTK library. There are still numerous filters available in the ITK library that we plan to include in the implementation to make the integrated ITK/VTK library more powerful and available in Java programming language.

IV. Conclusions

In this paper, we present the method that enables the integration of ITK and VTK libraries together in Java language. This integrated ITK/VTK offers more flexible handling the image processing filters in the ITK library into the VTK pipeline. Hence, the rapid development of the applications using the advantages from both VTK and ITK libraries can be achieved.

ECG Feature Extraction by Multi Resolution Wavelet Analysis based Selective Coefficient Method

Saurabh Pal[1] and Madhuchhanda Mitra[2]

[1] Haldia Institute of Technology, West Bengal, India
[2] University of Calcutta,West Bengal,India

Abstract — **One of the major problems in feature extraction methodologies from ECG is to identify the wave and complex boundaries. Here we present a multiresolution wavelet based approach to identify the boundaries. The wavelet reconstruction coefficients are assessed in terms of shape and size to eliminate the interfering components for better detection of wave boundaries. The relevant coefficients are retained that resembles with the original structure of the wave under investigation. The algorithm suggests different set of reconstruction coefficients for different part of the ECG wave which eliminates the scope of probable interaction between adjacent regions and thus correct identification of wave boundaries are ensured. The QRS complex and T wave duration are measured with the algorithm and validated against some arbitrarily chosen ECG records for lead 1 from Physionet PTB diagnostic database. The measured values are compared with the manually determined values and the accuracy for each evaluation is calculated. The test result shows over 95% accuracy for QRS complex and over 92% accuracy for QT interval and T duration.**

Keywords — **ECG, Feature Extruction, Db6 wavelet, Reconstruction Coefficient**

I. Introduction

The new generation of medical treatment has been suported by computerized processes. Signals recorded from t he human body provide valuable information about the activities of its organs. Their characteristic shape, or temporal and spectral properties, can be correlated with a normal or pathological function. In response to dynamical changes in the behaviour of those organs, the signals may exhibit time-varying as well as non-stationary responses. The QRS complex is the most prominent waveform within the electrocardiographic (ECG) signal, with normal duration from 0.06s to 0.1s [1]. It reflects the electrical activity within the heart for total ventricular muscle depolarization. Its shape, duration and time of occurrence provide valuable information about the current state of the heart. Because of its specific shape, the QRS complex serves as an entry point for almost all automated ECG analysis algorithms. The QRS detection is not a simple task, due to the varying morphologies of normal and abnormal complexes and because the ECG signal experiences several different types of disturbances with complex origin. Once the QRS complex has been identified, a more detailed examination of ECG signal can be performed. The detection of the QRS complex is the most important task in automatic ECG signal analysis [2]. The T wave is another important wave in the ECG waveform. It generates due to ventricular depolarization. In some pathological conditions the morphology of the T-wave may change from beat to beat, the simplest and most easily recognizable change being an amplitude change and the time duration change of the wave. The Q-T interval is measured on the horizontal axis from the onset of the Q wave to the end of the T wave. Since the QRS complex represents ventricular depolarization and the T wave represents ventricular repolarization, the Q-T interval denotes the total duration of ventricular systole. The Q-T interval includes the duration of QRS complex, the length of S-T segment and the width of T wave. Accurate measurement is important as QT prolongation is associated with the risk of ventricular tachyarrhythmia and of sudden cardiac death [3].

II. Discrete wavelet transform

A wavelet is a waveform of effectively limited duration that has an average value of zero. Similar to Fourier series analysis, where sinusoids are chosen as the basis function, wavelet analysis is also based on a decomposition of a signal using an orthonormal (typically, although not necessarily) family of basis functions. Unlike a sine wave, a wavelet has its energy concentrated in time. Sinusoids are useful in analyzing periodic and time-invariant phenomena, while wavelets are well suited for the analysis of transient, time-varying signals (well suited for ECG signals). A wavelet expansion is similar in form to the well-known Fourier series expansion, but is defined by a two-parameter family of functions

$$f(t) = \sum_k \sum_j a_{j,k} \psi_{j,k}(t) \qquad (1)$$

where j and k are integers and the function $\psi_{j,k}(t)$ is the wavelet expansion function. The two-parameter expansion

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 590–593, 2009
www.springerlink.com

coefficients $a_{j,k}$ are called the discrete wavelet transform (DWT) coefficients of f(t) and the equation given above is known as the synthesis formula (i.e., inverse transformation). The coefficients are given by

$$a_{j,k} = \int f(t)\psi_{j,k}(t)\,dt\,. \tag{2}$$

The wavelet basis functions are a two-parameter family of functions that are related to a function called the generating or mother wavelet by

$$\psi_{j,k}(t) = 2^{j/2}\psi(2^{j}t - k) \tag{3}$$

where k is the translation and j the dilation or compression parameter. Thus wavelet basis functions are obtained by translation and scaling from a single wavelet. This means that given an approximation of a signal using translations of a mother wavelet up to some chosen scale, we can achieve a better approximation by using expansion signals with half the width and half as wide translation steps. The wavelet transform as such decomposes a signal into two subsignals – detail signal and approximation signal. Detail signal contains the upper half of the frequency components and approximation signal contains the lower half. The decomposition can be further repeated on the approximation signal in order to get the second detail and approximation signal. Thus in discrete wavelet domain, multiresolution analysis can be performed.

III. Simulation and Implementation

Here at first we have taken some arbitrarily chosen ECG text data from physionet PTB diagnostic database [4].As the raw ECG signal may be added with some noise, the wave is first denoised using standard technique. Then decomposion of the function is done upto level eight using Daubechies 6 (Db6) wavelet. Here Db6 wavelet is selected as some detail coefficients from multiresolution decomposition shows better resemblance with QRS complex of the ECG wave [5].

The decomposition result along with the original signal is shown in figure 1. This figure shows that coefficients at level three, four and five shows better resemblance with the QRS complex whereas all others appearing to be noisy with respect to the QRS region having most noises at the upper and lower levels. Thus d3, d4 and d5 coefficients are identified for the detection of QRS complex. The plot of the reconstructed wave comprising of d3, d4 and d5 is shown in figure 2. As from figure 2 it is clear that although the QRS region is properly captured but it is difficult to identify R peak due to the oscillatory nature of the graph. So, by simple manipulation, a function e2 is defined as

$$e2 = d4 \times (d3 + d5)/2^{n}\,, \tag{4}$$

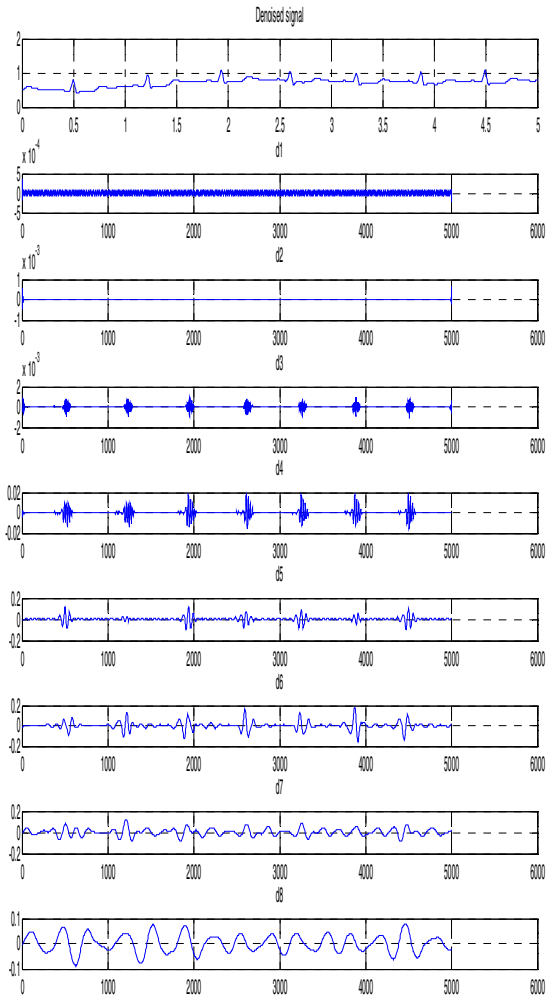

Fig 1: Original signal and multiresolution decomposition using Daubechis 6 wavelet upto level eight

where n is the level of decomposition. Then the modulus of e1 × e2 is done, where

$$e1 = d3 + d4 + d5\,. \tag{5}$$

The corresponding plot is shown in figure 3 along with the original wave. It is seen from plot 3 that the QRS region is not only having sharp peak but is much closely spaced in time also.From this graph the R peak is detected as the highest point. Once the R peak is detected, the Q and S points are to be identified to detect the complete QRS complex. For that decomposition coefficients from d1 to d5 are kept and the reconstructon wave is given by

$$e3 = d1 + d2 + d3 + d4 + d5\,. \tag{6}$$

Then 5 point differentiation on e3 is done to find first two zero slope points on either side of R peak as detected

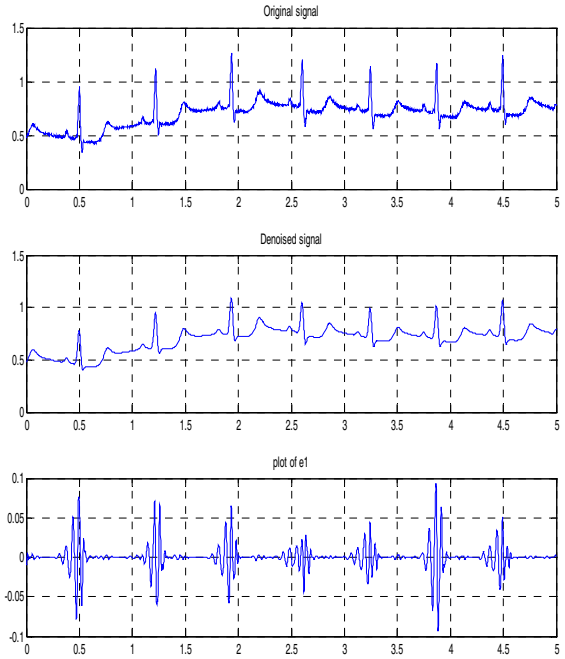

Fig 2: Original signal and polt of e1=d3+d4+d5

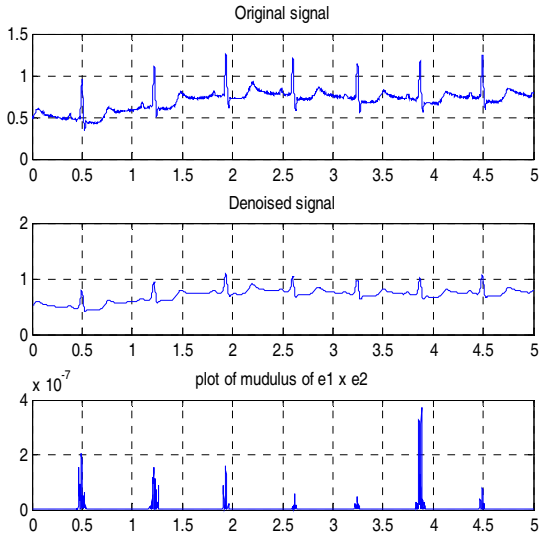

Fig 3: Original signal and plot of modulus of e1 x e2

earlier. The Q point as detected is taken as the J point or zero potential point.

To find out T wave, an inspection has made on the decomposition coefficients and it is seen that T wave is most significant in d4, d5, d6 and d7 coefficients. Hence the reconstructed wave is formed as

$$e4 = d4 + d5 + d6 + d7 \quad (7)$$

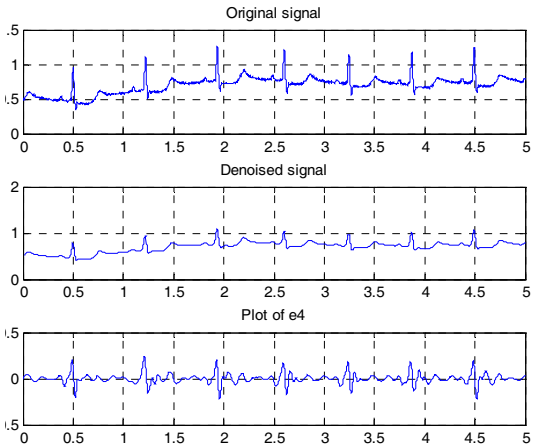

Fig 4: Original signal and plot of e4

Then the T peak is identified as the maxima after the detected S point within a predefined stipulated interval. As the T peak is pointed out, T onset and T offset is found out as the minimum potential crossing points on either side of the T peak. The plot of equation 7 is shown in figure 4. Thus the significant points as Q,R,S and T wave are identified by selective coefficient method.

IV. Result and Analysis

The results are shown in the following figures as per the simulation and implementation discussed in the earlier section. Figure 5 shows the detected QRS complex and T wave for an ECG waveform taken arbitrarily from the physionet database.

Sometimes a serious problem is encountered in automatic ECG feature extraction technique. It is the unpredictable

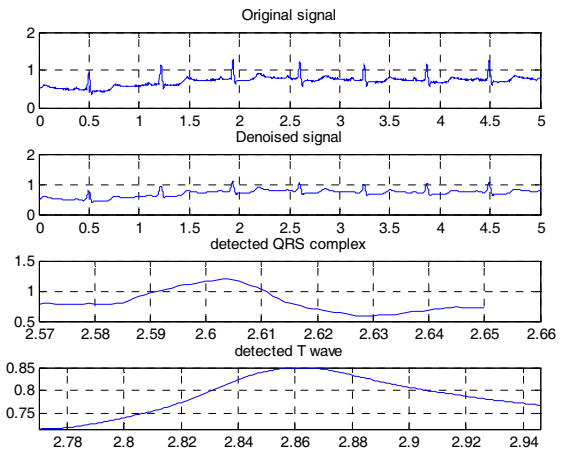

Fig. 5: Plot of Original wave, denoised wave, QRS complex, P wave and NON INVERTED T wave identified by the proposed algorithm.

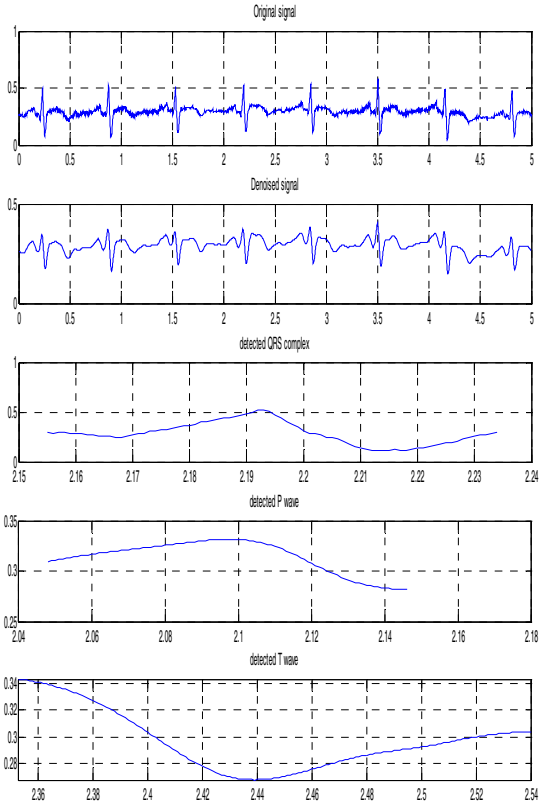

Fig. 6: Plot of Original wave, denoised wave, QRS complex, P wave and INVERTED T wave identified by the proposed algorithm.

shape and slope of T wave specially the inverted T waves. This problem is taken into account here by identifying the type of the T wave at the beginning of the T peak detection algorithm. Here the type of the T wave is detected by comparing the magnitudes within the T wave separated by a predefined interval. An inverted T wave along with corresponding QRS wave is shown in figure 6.

Some arbitrarily chosen data from Physionet PTB diagnostic database are tested by the proposed algorithm and the values of QRS duration, T wave duration and QT internal duration are measured. The results are compared with the manually calculated values for the same database. Some of the results are shown in the following tables.

Table 1: Comparison of QRS duration in automatic and manual mode.

Database	Automatic(sec)	Manual(sec)	Percentage inaccuracy
P61 s210	.079	.077	-2.6
P50 s215	.079	.078	-1.3
P40 s130	.079	.078	-1.3
P42 s 137	.080	.079	-1.3
P32 s106	.057	.059	3.4

Table 2: Comparison of T wave duration in automatic and manual mode.

Database	Automatic(sec)	Manual(sec)	Percentage inaccuracy
P61 s210	.170	.174	2.3
P50 s215	.168	.175	4.0
P40 s130	.173	.177	2.3
P42 s 137	.181	.178	-1.7
P32 s106	.193	.185	-4.3

Table 3: Comparison of QT interval duration in automatic and manual mode.

Database	Automatic(sec)	Manual(sec)	Percentage inaccuracy
P61 s210	.316	.321	1.6
P50 s215	.394	.398	1.0
P40 s130	.394	.383	-2.9
P42 s 137	.300	.314	4.5
P32 s106	.308	.305	-1.0

From the tables it is clear that the proposed algorithm is moderately accurate in terms of the measurement of the durations of QRS complex, T wave and QT interval. Moreover, figure 6 shows that P wave can also be identified by the proposed algorithm.

V. Conclusions

Thus we can hereby conclude that the proposed algorithm based on multiresolution wavelet analysis based selective coefficient method is an easy and accurate one for ECG feature extraction and corresponding analysis. This analysis can further be extended towards automatic disease identification or biometric analysis.

Microarray Image Denoising using Spatial Filtering and Wavelet Transformation

A. Mastrogianni[1], E. Dermatas[1] and A. Bezerianos[2]

[1] Dept. of Electrical Engineering and Computer Technology, University of Patras, HELLAS
[2] Dept. of Medical Physics, School of Medicine, University of Patras, HELLAS

Abstract — **As the aim of using microarray technology is to try to understand fundamental aspects of growth and development as well as to explore the underlying genetic causes of many human diseases, the restoration of the ideal microarray image's properties in a noisy image, is an urgent priority of the image processing procedure. The scope of this work is to describe and evaluate different methodologies for noise reduction in microarray images. In this paper, two basic approaches to microarray image denoising: spatial filtering methods and transform domain filtering methods are presented. The image denoising, with spatial filtering techniques as well as hard and soft thresholding of wavelet coefficients have been tested in microarray images of gene expression profiles of human sarcoma using the Stanford MicroArray Database.**

Keywords — **microarray, image denoising, wavelet, spatial filters**

I. Introduction

Gene expression analysis, using microarrays, targets at the measurement of mRNA abundance as a measure of gene expression activity. In a typical microarray setting, thousands of cDNA clones are robotically spotted onto coated glass slides in a highly condensed array. The output of a single microarray experiment is a digital image [1]. The information extracted from those images comes almost exclusively from the intensities of the spots. Unfortunately, the accuracy of the gene expression depends on the experiment itself, as well as, the image analysis methods.

Due to the nature of the acquisition process, microarray images contain noise, such as dust, fingerprints, small particles, distortions from the optical components and electronic noise, which definitely affect the accuracy of the further data analysis and the validity of the gene mutation prognosis. The noise elimination is a challenging and fundamental problem in microarray analysis and a lot of de-noising methods have already been proposed each one having its advantages and limitations [2, 4].

There are two basic approaches to microarray image denoising: spatial filtering methods and transform domain filtering methods. Spatial filters can be effectively used to remove various types of noise in digital images. Transform domain methods are time consuming and depend on the cut-off frequency and the filter function behavior. Among the most popular transformation methods, wavelet denoising is widely used in microarray analysis [5]. In this paper an overview of various algorithms and analysis is provided and potential future trends in the area of denoising are discussed.

In the next section a presentation of the spatial filtering and wavelet denoising methods is given. In section 3, the microarray database, the experimental results and a number of representative examples are shown. Finally, a short discussion on the results and the on-going work is given.

II. Spatial filtering and wavelet denoising methods

Spatial filters can be classified into non-linear and linear filters. The simplest non-linear filter is the median filter and is effective at reducing impulse noise (i.e. 'Salt&pepper' noise) where the noisy pixels contain no information about their original values. Hsin-Cheng Huang and Thomas C. M. Lee in their work [6] mention a signal and image denoising method using median filter. The linear Wiener filtering method requires the information about the spectra of the noise and the original signal and it performs well only if the underlying signal is smooth. The Wiener filter is the optimal filter for gaussian noise removal in the sense of mean square error.

Wavelet image processing plays a major role in image denoising, especially in the presence of additive Gaussian noise [7]. In medical imaging, wavelet transform were first introduced in 1991 in a journal paper describing an application of noise reduction in MRI images [8]. In 2003, stationary wavelet transform has been used to enhance the quality of microarray images [9], showing superior performance than the discrete wavelet transform and the widely used adaptive Wiener filtering methods.

In this paper we present an overview of microarray image denoising methods, comparing the reconstructed images after using the median filter, the Wiener filter and some of the most commons wavelet families.

All the denoising methods are briefly described in the followed four steps:

- A set of noiseless subarray images are selected from the microarray database.
- Additive 'Salt&pepper' and Gaussian noise are used to distort the selected microarray subarray images.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 594–597, 2009
www.springerlink.com

- The evaluated denoising methods are applied and the restored images are created.
- Objective fidelity criteria (PSNR, SNR) are used to evaluate the robustness of the denoising methods.

In the subarray images the noise had been modeled with either a Gaussian (Fig.1), uniform, or Salt&pepper ('impulse') distribution (Fig.2).

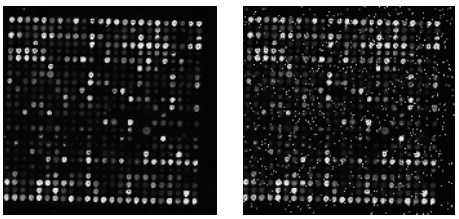

Fig. 1 Microarray image before and after applying Salt&pepper noise of variance 0.04

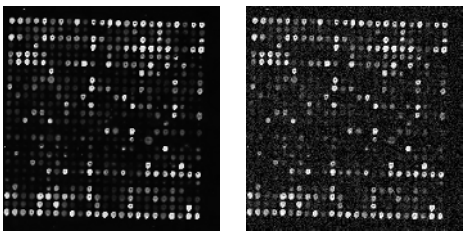

Fig. 2 Microarray image before and after applying Gaussian noise of variance 0.04

Two criteria, the SNR (eq. 1) and the PSNR (eq. 2), are used for quantitating the difference between the noisy microarray and the reconstructed image after applying the denoising method. The higher the PSNR, the better the quality of the reconstructed image.

$$SNR(dB) = 10\log_{10}\left(\frac{P_{signal}}{P_{noise}}\right), \quad (1)$$

where P_{signal} is the power of the signal and P_{noise} is the power of the noise.

$$PSNR(dB) = 10\log_{10}\left(\frac{MAX_I^2}{MSE}\right), \quad (2)$$

where $MSE = \frac{1}{mn}\sum_{i=0}^{m-1}\sum_{j=0}^{n-1}\left\|I(i,j) - K(i,j)\right\|^2$ is the mean square error, I is the $m \times n$ noiseless image and K is the restored image.

III. Experimental results

The implemented denoising methods have been evaluated in 34 microarray images of gene expression profiles of human sarcoma [10], each one containing 32 subarrays. The microarray subarrays are selected according to their level of noise. From the total set of 1088 subarrays included in the Stanford MicroArray Database the less noisy subarrays are selected. In most microarray images extremely noisy background is met but a quite satisfying number of these subarrays (150) had fulfilled our demand for the minimum background noise. The denoising methods were implemented in Matlab computing environment.

In Tables 1 and 2 the mean value of PSNR and SNR of the median and Wiener denoising methods are shown estimated from the evaluation set of 150 subarrays. The median filtering is more effective in case of Salt&pepper noise compared to the PSNR rate achieved in the presence of additive Gaussian noise, as expected. The median filtering is robust in all levels of noise, giving similar PSNR rates in case of Salt&pepper noise. On the contrary, the noise reduction rate using Wiener filtering decreases when the noise level increases in both types of noise.

Table 1: PSNR and SNR for median filtering using four noise levels and two types of noise, in dB.

variance	0.01	0.02	0.03	0.04
		Salt&pepper noise		
PRNR	29.754	29.6907	29.6391	29.54
SNR	9.1173	6.1251	3.9074	3.7803
		Gaussian noise		
PRNR	25.1373	24.4018	23.6430	22.8347
SNR	8.3783	7.7638	7.1149	6.5024

Table 2: PSNR and SNR for Wiener filtering using four noise levels and two types of noise, in dB.

variance	0.01	0.02	0.03	0.04
		Salt&pepper noise		
PSNR	25.3612	23.4316	22.4672	21.8146

The experimental results show that wavelet denoising methods are more effective in the presence of Gaussian additive noise compared to the denoising results derived in case of additive Salt&pepper noise. This figure is valid for both types of thresholding.

In Fig. 3 and 4 two examples of a microarray image denoising processing, using median filter and wavelet bior1.1 transform are given.

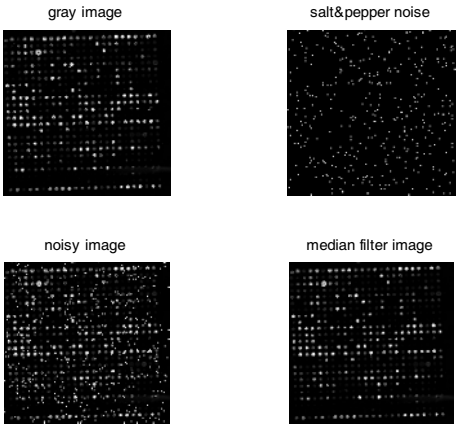

Fig. 3 Example of the median filter denoising method when applying Salt&pepper noise of variance 0.04

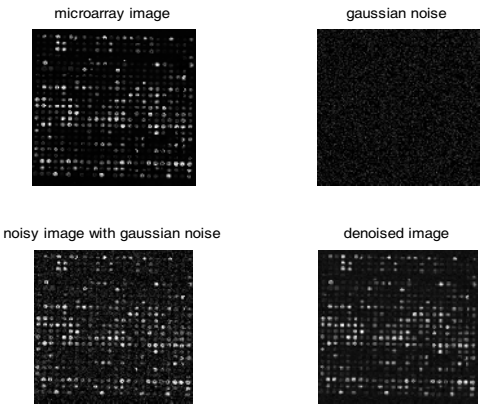

Fig. 4 Example of wavelet bior1.1 denoising method when applying Salt&pepper noise of variance 0.03, soft thresholding and decomposition level of 2

IV. Conclusions

Image denoising is an essential aspect of microarray experiments. The experimental comparison of popular denoising methods in subarray images presented in this paper can be used to implement different denoising methods for different types of noise. The robustness and generalization of the techniques described provide adequate basis to apply the same techniques to nanoarray imaging systems.

Abstract — **There are various blood purifications. Plasma Exchange(PE) is one of the blood purifications. A patient's circulating blood volume is changing during the PE. Hence, the medical workers must treat to stabilize the circulating blood volume. They are the CLIT-LINE monitor (CLM) to obtain the hematocrit (Ht) values, because the circulating blood volume is calculated by Ht values. Ht value reflects the count of red cells in the circulating blood volume, and Ht values are changed by the urination. They recognize the patient's condition by the classifying the change of Ht values. However, the classifying the change of Ht values is depended on the experience of medical workers. This approach is very subjective. Hence, our purpose is the investigation of the possibility about the classifying the change of Ht value using the Self Organized feature Map (SOM). We used the Ht value that was obtained in the Tokushima University Hospital. The Ht data was greatly changed by urination. At first, the Ht data is divided into the consecutive grouped patterns. We used recurrent neural network (RNN) to treat the change of Ht value in each group. RNN is effective to treat the feature of time series signals, and it was known that the weight values of RNN have some information about the feature of signals. The seconds, the weight values obtained in each group are used as input data to SOM. As a result of SOM, Ht data were divided into 4 groups. One of them was a group into which Ht values were greatly changed by urination. It is thought that other groups show the state that has changed little by little during the PE. As a conclusion, it was supposed that the possibility about the classifying the change of Ht value using SOM.**

I. Introduction

There are various blood purifications. Plasma exchange (PE) is one of the blood purifications. A patient's circulating blood volume is changing during the PE. Hence, the medical workers must treat to stabilize the circulating blood volume. With rapid advances in information technology, computer-aided medical treatments are becoming quite common place in hospitals. Several medical treatments have been evolved by relying on the artificial intelligence [1]-[3]. They use the CLIT-LINE monitor (CLM) to obtain the hematocrit (Ht) values, because the circulating blood volume and Ht value are related. The rate of circulating blood volume ($\Delta BV\%$) is very important during the blood purification including the PE. $\Delta BV\%$ is calculated by the two Ht value. One is the Ht value at the beginning of the PE, and another is the present Ht value. Hence, we thought that the many Ht values in a fixed time showed the more detailed condition of the circulating blood volume. If the characteristics of the Ht values in each fixed time are classified, the doctor has the possibility to treat the patient more safety in blood purifications. Hence, our purpose is the investigation of the possibility about the classifying the change of Ht value using the Self Organized feature map (SOM).

We used the recurrent neural network (RNN) to capture the characteristic of Ht values in a fixed time. We used the weight values obtained in a fixed time as the input data for SOM.

II. Analysys data

Currently, CRIT-LINE monitor (CLM) is one of the popular equipments, specifically due to its ability to obtain the Ht value every 20 seconds. At the Tokushima University Hospital where our study was conducted, CLM is used for obtaining Ht values during blood purification [4].

In this study, Ht values were collected from patient during the PE at the Tokushima University Hospital, after obtaining their consent. Durations of each PE treatment was about 100 minutes, and 4 patients were effectively treated with PE under medical supervision. Fig.1 shows the Ht data for patient A.

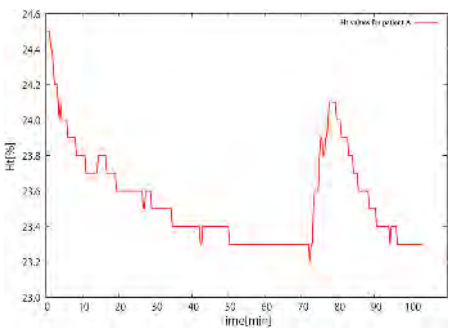

Fig.1 The Ht data for patient A

www.springerlink.com

III. METHOD FOR RNN AND SOM

The structure of RNN is 6 units in the input layer and 6 units in the hidden layer. Ht values of first 5 minutes at the beginning of PE procedure were not used. These Ht values were influenced by the saline. In this study, biological time series signals are Ht values, and they are represented as:

$$x_1, x_2, \cdots, x_i, \cdots x_{last} \tag{1}$$

where, x_i is sampled data at sampling time i and x_{last} is the last Ht value. In this study, we used the 30 Ht values as a fixed time to classify the character of the wave. Otherwise, we divided into the consecutive groups the Ht values. A group is defined as:

$$PG_i : x_i, x_{i+1}, \cdots, x_{i+30-1} \tag{2}$$

where, i represents the sampling time as well as the index of the group. The groups were formed by Ht values in the following manner:

$$\begin{aligned} PG_1 &: x_1, x_2, \cdots, x_{30} \\ PG_2 &: x_{31}, x_{32}, \cdots, x_{60} \\ PG_3 &: x_{61}, x_{62}, \cdots, x_{90} \\ &\vdots \end{aligned} \tag{3}$$

The input/output relation of the RNN in the group i is as follows:

$$\begin{aligned} x_i, x_{i+1}, \cdots, x_{i+5} &\mid x_{i+6} \\ x_{i+1}, x_{i+2}, \cdots, x_{i+6} &\mid x_{i+7} \\ x_{i+2}, x_{i+3}, \cdots, x_{i+7} &\mid x_{i+8} \\ &\vdots \end{aligned} \tag{4}$$

The initial weights of RNN in the each group are same values. The initial weights are small random values. Then, the weights trained in each group are inputted to the SOM.

The training method for SOM is shown as follows. The equation (5) shows the method of update the node in SOM.

$$\mathbf{m}(t+1) = \mathbf{m}(t) + ETA \times (\mathbf{w}(t) - \mathbf{m}(t)) \tag{5}$$

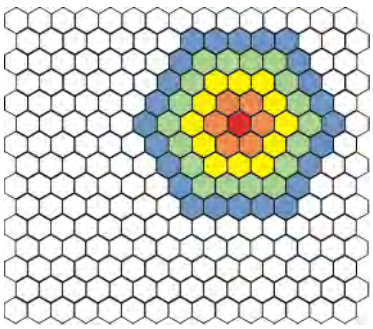

Fig.2 The Self Organized feature Map (SOM)

where, $\mathbf{m}(t)$ is the weights in node fired. $\mathbf{w}(t)$ is the weights of RNN. ETA is the training coefficient. Fig.2 shows the SOM. In this case, the node fired shows the red color, and ETA is 0.1. ETA is 0.05 in the orange nodes. ETA is 0.03 in the yellow nodes. ETA is 0.025 in the green nodes. ETA is 0.02 in the blue nodes.

IV. RESULT

We show the SOMs for each Ht data.

Fig.3 shows the each group for the patient A. Fig.4 shows the node fired. The number in each node fired shows the each group number. The weights of RNN in 1,2,5,6, and 7 groups are fired the same node in the SOM.

Fig.5 shows the each group for the patient B. Fig.6 shows the node fired. The number in each node fired shows the each group number. The weights of RNN in 1 and 2 groups are fired the same node in the SOM. The weight of RNN in 4 and 6 groups are fired the same node in the SOM.

Fig.7 shows the each group for the patient C. Fig.8 shows the node fired. The number in each node fired shows the each group number. The weights of RNN in 1,2,3 and 6 groups are fired the same node in the SOM. The weight of RNN in 4 and 5 groups are fired the same node in the SOM.

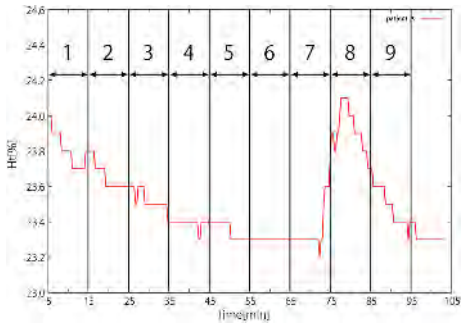

Fig.3 The each group for the patient A

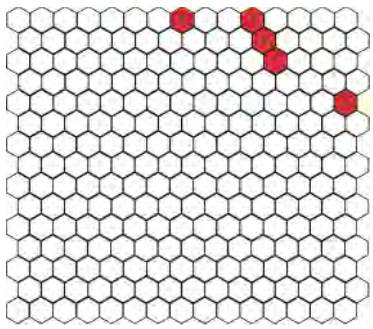

Fig.4 The SOM for patient A

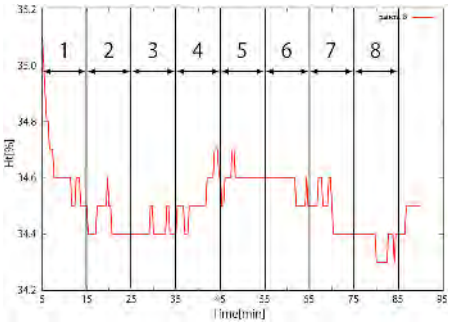

Fig.5 The each group for the patient B

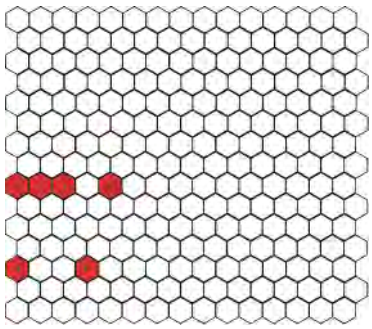

Fig.6 The SOM for the patient B

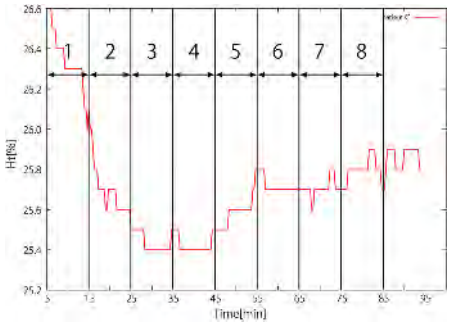

Fig.7 The each group for the patient C

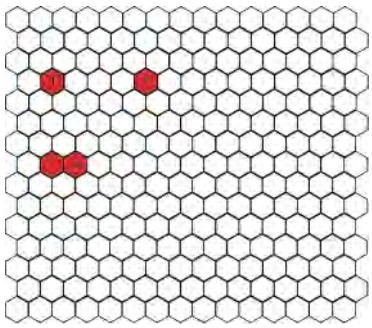

Fig.8 The SOM for the patient C

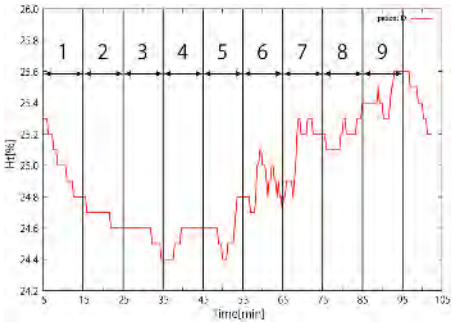

Fig.9 The each group for the patient D

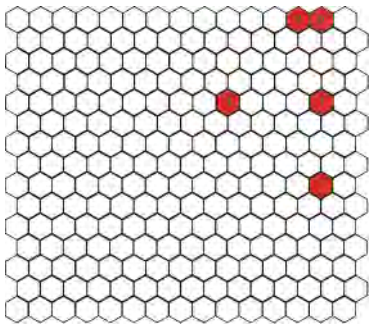

Fig.10 The SOM for the patient D

Fig.9 shows the each group for the patient D. Fig.10 shows the node fired. The number in each node fired shows the each group number. The weights of RNN in 1,2,3 and 6 groups are fired the same node in the SOM. The weight of RNN in 4 and 5 groups are fired the same node in the SOM.

V. Discussion and Conclusion

There was big difference between 8 group and 9 group in Fig.4. The difference was caused by the emiction. The patient A took a leak at the 7 group. The circulating blood volume was changed by this thing. The node fired at the 1 group fired again for the patient A, C and D. It thought that the circulating blood volume returned to the first state.

In this study, we investigated the possibility about the classifying change of Ht values using SOM. Though we investigated the classifying change of Ht values for only 4 patients, we supposed the possibility of the classifying the Ht values using RNN and SOM from the results for 4 patients.

As the future works, we try to investigate the possibility for the many patients and data made by us.

PCG Spectral Pattern Classification: Approach to Cardiac Energy Signature Identification

Abbas K. Abbas[1], Rasha Bassam[2]

[1] RWTH Aachen University, Aachen, Germany
[2] Biomedical Engineering Dept., Aachen University of Applied Sciences, Juelich, Germany

Abstract — **biomedical data clustering play a principal role in automated aided diagnosis in cardiac auscultation. Therefore different Phonocardiography (PCG) signal classifiers have been used to classify blood flow patterns and adopted to use with Computer Aided Diagnosis (CAD) system. The embedded PCG classifier is widely used in Clinical Decision Support System (CDSS) as well. An Automated PCG clustering module was developed as a base for Auscultation Clinical Assisted Diagnosis (AuCAD). Application of the pattern classification as adaptive k-mean in analyzing normal and pathological heart sound was investigated. The patterns of phonocardiogram signals are used to characterize the abnormalities while detecting non-linearity features in order to improve the diagnostic performance of heart sounds. The index for cardiac work as identified energy signature for the heart. In comparison to the linear clustering of PCG spectrum patterns, the results have shown that adaptive k-mean algorithms reveal difference in PCG analysis indicating non-Gaussian or non-linearity scheme. The intensity-based PCG value and the peaks of Short Time Fourier Transform (STFT) spectrum were efficiently determining cardiovascular dysfunctions affecting PCG trends. Mitral regurgitations and valvular dysfunctions associated with blood flow using CED were inspected. ROC performance test for adapted pattern classifier shows a higher stability with normal and abnormal PCG signal related with a mild decline in energy performance index with agglomerative compartment of PCG spectra. CED represents a robust method to distinguishing different pattern associated with cardiac auscultation. Statistical value from the probability density function of PCG data vectors was derived and verified. Cardiac energy detection (CED) has the affinity to alternate the conventional methods in biosignal patterns categorization.**

Keywords — **Phonocardiography, Pattern classification, Acoustic energy, Hemodynamic, Intensity profile**

I. Introduction

PCG Pattern classification, also known as auscultation pattern recognition, was one of the efficient computer-based methods applied to medical decision making system. PCG Pattern recognition generally is interpreted in two ways. The most general definition includes recognition of patterns in any type of PCG dataset and is called uniform PCG pattern classification this discriminate peaks of heart sounds as excitation source for circulation hemodynamic, and other is called adaptive pattern clustering which magnify and observe spectral characteristics associated with PCG waveform turbulences and differentiate them as clinical diagnostic indices. Fig.1 shows how the eight heart sounds, which are correlated to the physiological and pathophysiological events of the cardiac cycle and corresponding, power spectra.

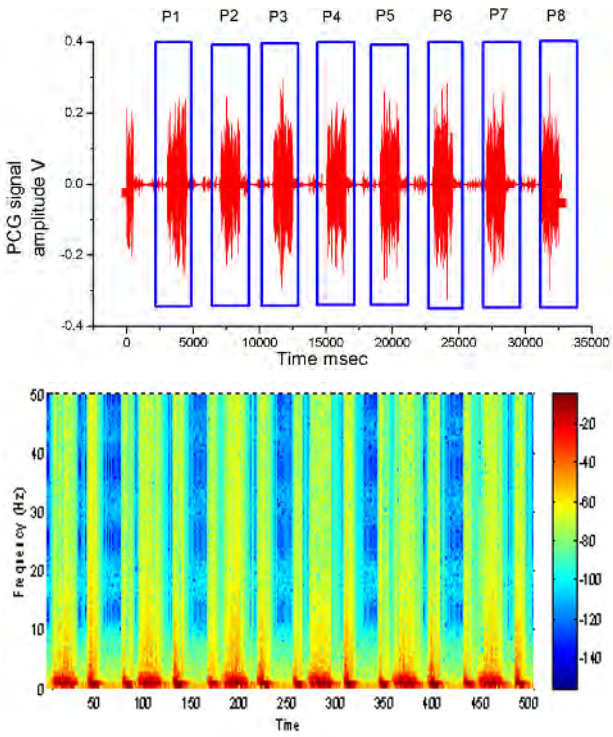

Fig. 1 PCG signal scheme marked with corresponding high intensity spectral peaks.

II. Materials and Methods

The PCG signal was downloaded from Physiobank physiological data bank. Experimental system identification was implemented using MATLAB®. Fig.2 illustrates the experimental setup of PCG signal with k-mean classification algorithm. Spectral estimation was implemented in

www.springerlink.com

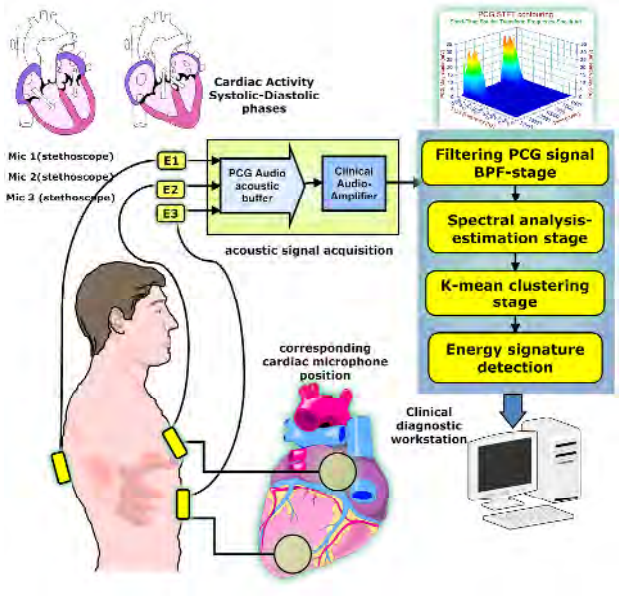

Fig. 2 PCG signal processing system setup based on spectral estimation technique.

computational loop to identify energy signature of cardiovascular activity [1].

III. Cardiac Acoustics Energy

Transducers such as microphones allowed collecting of more accurate acoustical data over a wider range of frequencies. Energy characteristic patterns in PCG data, thus recorded have been associated with conditions affecting hemodynamic patency such as mitral, tricuspid valve insufficiency, angina, malformations and tumors. One common location for recording heart sounds is over mitral valve region, with the sounds recorded referred to as PCG sounds. These sounds are relatively small in amplitude and have a wider range of frequencies than sounds recorded at the chest wall, and also have a close relation to the cardiac circulation [1]. The spectra of these cardiac sounds have been characterized as broad frequency noise with discernible spectral peaks ranging between 8 Hz to more than 23 Hz with a "cut-off"-like frequency of around 13 Hz [2].

IV. Mathematical Method and Computational Implementation

PCG spectra contain vast number of definite harmonics categories that would be useful to be identified as clustering scheme in any data classification algorithms. The majority of these spectra although it belongs to specific valvular pathologies have a distinct energy (intensity) level in STFT plot. This would be attractive point to consider such variation as clustering point; this considerably will orient the classifier algorithm to stable entropy value. The spectral information characteristics of PCG lie within a frequency band of (54-520 Hz) and this band depend on digital stethoscopes interface and resolution of data converters in instrument. This criteria is the basis for pattern classification in which the dependency on frequency (spectral) characteristics. Block diagram for overall spectral classification system is demonstrated in Fig.2 [1]. Several patterns can be derived from the vector input PCG signal, in which they processed with a specific FIR-filter length. The most recognized patterns in PCG are systolic and diastolic and presystolic and post-diastolic peaks of sound (S_1, S_2, S_3, and S_4) which is shown in Fig.1, most of cardiologist prefer the base-diagnosis on two categories of PCG, S_1 and S_2, so that they can discriminate the hemodynamic turbulences in appropriate method[3]. The spectral stamp can be oriented in three schema (supraspectral, infraspectral and mid-spectral) in which are represent the intensity harmonics for PCG waveform, correlation between two intensity peaks of PCG gives a defined index for clustering profile $M_{j\text{-}PCG}$ of PCG signal which in turn apply a segmental cluster for input vector[2]. Systolic and diastolic murmur frequencies are classified according to the frequency band containing the largest power value in the tenth (s) of the systole/diastole corresponding to the found maximum values of SI/DI. If the largest power value is found in one of the two lowest frequency bands (containing frequencies below 125 Hz), the murmur is classified as a low-frequency murmur. If the largest power value is found in one of the eight highest frequency bands (containing frequencies above 250 Hz), the murmur is classified as a high-frequency murmur. If none of the above is the case, the murmur is classified as medium-frequency murmur [5]. The computational steps for PCG energy signature are illustrated below.

1st –step: **PCG Spectral Estimation.**

Spectral Estimation of PCG signal follow the white noise model for identification system parameters in presence of external disturbance.

$$y[n] = (K_{PCG} * g)[n] = \sum_{k=-\infty}^{\infty} K_{PCG}[k]g[n-k]. \quad (1)$$

Extracting the PCG diastolic low frequency components

$$y_{low-PCG(diastolic)}[n] = \sum_{k=-\infty}^{\infty} x_{PCG}[k]g[2n-k] \quad (2)$$

And for PCG systolic high frequency components

$$y_{high-PCG(systolic)}[n] = \sum_{k=-\infty}^{\infty} x_{PCG}[k]h[2n-k] \quad (3)$$

Based on the characteristic features which were derived from PCG-signal, the nature of these signals can be identified using pattern classification techniques. A number of pattern recognition and classification schemes have been implemented for the analysis of heart sounds. Classical pattern recognition techniques include the Gaussian– Bayes classifier and the K-nearest neighbor (k-mean clustering). The Gaussian–Bayes classifier is the most popular parametric technique of supervised pattern recognition. It is considered optimal when the probability density functions (p.d.f) of the patterns in the feature space are known (a pattern is defined as an N-dimensional vector composed of N features)[3,4]. The K-nearest neighbor classifier is a nonparametric approach, which is useful when the p.d.f are difficult to estimate or cannot be predicted [7,5]. The nearest neighbor method is an intuitive approach based on distance measurements, motivated by the fact that patterns belonging to the same class should be close to each other in the feature space. Joo et al [4] illustrated the diagnostic potential of a Gaussian–Bayes classifier for detecting degenerated biocoated prosthetics implanted in the aortic valve [9].

2nd Step: **K-mean Gaussian Clustering**

By applying k-mean clustering for derived PCG spectra, then taking the momentum equation for input vector X_{PCG} to separate the spectral pattern derived from Db-wavelets decomposition algorithm [6].

$$U_{j\,\mathrm{PCG}} = \left(K_{PCG} - \mu_j\right)^T \sum_{j}^{-1} \left(K_{PCG} - \mu_j\right) \tag{4}$$

$$S_{W\,PCG} = \sum_{i=1}^{C} \sum_{x \in X_i} \left(K_{PCG} - m_i\right) \cdot \left(K_{PCG} - m_i\right)^T \tag{5}$$

Where $U_{j\,PCG}$ is the class momentum in *k-space* and it is constructed first to set the separation line for each class, and $S_{W\,PCG\text{-}signal}$ is the segmental pattern derived after integrating the momentum equation (4).

3rd -Step: **Energy signature detection**

The computation of cardiac energy signature based on the following equation.

$$\Psi_{PCG-signal} = \sum_{i=1}^{C} \sum_{x \in X_i} \left| \left(x_{PCG} - m_i\right) \cdot \left(x_{PCG} - m_i\right)^T \right|^2 \tag{6}$$

Through the application of PCG energy equation that was developed by Johnson et al (2003)[10], S1 and S_2 peaks were used as input profile to cardiac energy computation algorithm. The clustered PCG schemes which were identified in the previous step used to correlate result from step two and the result form step three, in order to generate harmonized energy characteristics. In addition to the k-mean clustering, the use of STFT method for detecting intensity-based profile in several mitral valves dysfunction. These findings suggest that there is a potential for these easily-measured tracheal sounds to be used in clinical practice for the diagnosis and monitoring of various respiratory conditions. For such potential clinical applications to be most useful, the relationships between the attributes of these sounds and the underlying anatomy, and ultimately pathophysiology, need to be determined along the computation loop [10, 8].

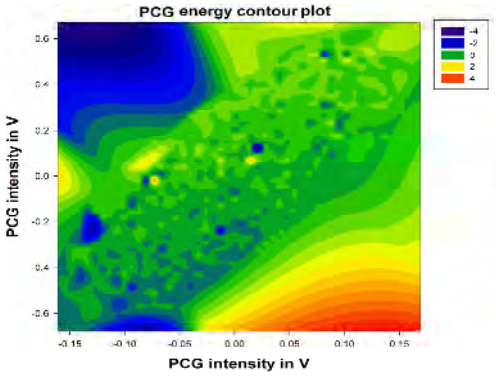

Fig. 3 contouring PCG energy profile that indicated power level of PCG peaks in S_1 and S_2 waveform.

V. PCG SIGNAL INTERPRETATAION

Interpretation of PCG spectral pattern was done through an signal processing toolbox-MATLAB® with spectral generating by Autosignal®; where the vectors of PCG data fed into k-mean-agglomerative cluster kernel and extracted the main classes for $S_1$and S_2 waveform[5]. The computation algorithm presents a stable operation through classification of 11 PCG (8 ♂, 3♀) samples. In Fig.4 the energy index of PCG signal was identified on the basis of correlated amplitude of acquired signal.

In Fig.4, PCG signal classification pattern were identified through k-mean algorithm at which further energy peak definition of PCG power can be localized as energy correla-

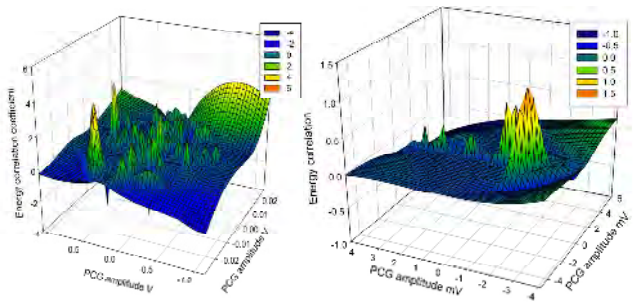

Fig. 4 Energy correlation indices with PCG amplitude, (left) with medium resolution scale (V), the variation index for cardiac hemodynamic (right) with high resolution scale (mV).

tion index versus PCG amplitude which can be noticed in Fig.4, were the correlation index for each PCG was computed in response to intensity amplitude in PCG trace. Hemodynamic parameters of classified PCG signals were illustrated in table.1. X_1, X_2 and X_3 represents the energy value of PCG signal (in watt) after computation of energy signature equation, which indicates for cardiac pathologies.

Table.2 represents estimated paradigm of PCG signal under *k-mean* classification, in which the blood pressure correlation for systolic and diastolic was also computed.

Table 1: Performance index for PCG clustering

Pathology	X1 (watt)	X2 (watt)	X3 (watt)	*K-mean*	*Aggl*	*LMS -Spectral*

VI. Results and discussion

The statistical analysis of cardiac energy signature clustering was achieved based on the 1st and 2nd order regression analysis of the classified PCG. The beat-to-beat interval was also computed from the classified patterns. The number of layers for the k-mean classifier was set to 59 and no of agglomerative classifier was set to 123, and for LMS classifier the layer set to 34 computational layers. Energy cardiac signature was predicted form the (k-mean, agglomerative, LMS) with dynamic computation of spectral pattern for each PCG data batches. The influence of computation layer size will affect on speed and performance of energy signature clustering results.

VII. Conclusions

Cardiac energy signature estimation plays a vital role in quantifying and identifying different hemodynamic pathological cases through pattern classification technique. Well define separation line has been identified and robust S_1 and S_2-spectral patterns. Considerable pathological cases were tested, including different mitral valve regurgitation and systolic hemodynamic abnormalities, stochastic blood flow patterns. A novel method to segment and classified PCG signal into single cycle using spectral pattern decomposition and k-means clustering was achieved. The energy signature identification works well when the heart rate is uniform for the entire sequence of PCG recording. The classification algorithm has shown 91.2% of success. The 29 intensity features of each segmented cycle were reduced to 14 using basic agglomerative clustering. These reduced feature sets were classified by the k-mean clustering into 5 classes. Classification performance for cardiac energy of 95.3% was obtained.

Characteristic of AEP and SEP for Localization of Evoked Potential by Recalling

K. Mukai[1], Y. Kaji[2], F. Shichijou[3], M. Akutagawa[1], Y. Kinouchi[1] and H. Nagashino[1]

Abstract — **After it keeps hearing a periodic auditory stimulus, it might be able to be recalled like actual sound even if there is no stimulus. To clarify brain activity at this time, EEG source localization was performed.**

However, in recalling auditory stimulus experiment, when EEG is ensemble averaged, evoked potential may decrease because subject oneself try to recall auditory stimulus according to same timing as periodic stimulus interval.

If SEP can be used as a trigger to recall acoustic stimulus, ensemble average is expected to be applied to attract EP (evoked potential) by recalling. But, because somatosensory evoked potential (SEP) occurs by electric stimulation, it is necessary for SEP and auditory evoked potential (AEP) to be the summation characteristics in order to analyze the simultaneous evoked potential (here, it is defined as S-AEP) of an electric stimulus and auditory stimulus. However, unexpectedly such a summation characteristics is not shown in a past study.

Therefore, it makes comparative study of AEP and EEG which is reduced SEP from S-AEP. First of all, the correlation coefficient of each scalp electrode was examined about AEP and EEG which is reduced SEP from S-AEP. At this time, 1200 ensemble average was done at each stimulus cycle [1/s], and baseline of EEG was the averaging 100 [ms] before the stimulus. Large evoked potential is observed at 300 [ms] after the stimulus and there were high correlation coefficients (from 0.855437[O2 electrode] to 0.975286[C3 electrode]) in all electrodes between AEP and EEG which is reduced SEP from S-AEP. Moreover, in both EEG the topography of N100 and P200 were corresponding.

The summation characteristics of AEP and SEP were able to be shown from the above mentioned result. According to above results summation characteristics of SEP and AEP were confirmed.

Keywords — **somatosensory evoked potential (sep), auditory evoked potential (AEP)**

I. Introduction

The brain has various functions (recognition, memory, thought, consciousness). In addition, those essential functions are caused by innumerable nerve cells. When these nerve cells are active, the chemical mediator released from nerve cells and an electric potential change occurs. Such a phenomenon expresses the information itself and reflects the function of each the territory field of the brain directly. After it keeps hearing a periodic auditory stimulus, it might be able to be recalled like actual sound even if there is no stimulus. In this case it is seemed that a stimulation pattern is memorized and an autonomous signal source with an oscillation pattern like the periodic stimulation is formed in a brain. It was assume that current dipoles as signal sources in the brain. It will be possible to clarify the state of a brain at that time if it is possible to estimate the position and direction of those dipoles with information of EEG that be provided out of the skull at the time of recalling auditory stimulus. Furthermore, it is also thought that Application to the various brain studies such as the study of an ill diagnosis of the brain and the mechanism elucidation of the brain. By the way, the existence of AEP and SEP is shown by past study [1,3]. However, EP (evoked potential) at the time of the recalling is not yet discovered. Therefore, I want to specify evoked potential at the time of the recalling. However, in recalling auditory stimulus experiment, when EEG is ensemble averaged, EP at the time of the recalling may decrease because subject oneself try to recall auditory stimulus according to same timing as periodic stimulus interval. If SEP can be used as a trigger to recall acoustic stimulus, ensemble average is expected to be applied to attract EP by recalling. But, because somatosensory evoked potential (SEP) occurs by electric stimulation, it is necessary for SEP and auditory evoked potential (AEP) to be the summation characteristics in order to analyze the simultaneous evoked potential (here, it is defined as S-AEP) of an electric stimulus and auditory stimulus. However, unexpectedly such a summation characteristics is not shown in a past study. Therefore, it makes comparative study of AEP and EEG which is reduced SEP from S-AEP.

II. Materials and methods

A. Subject

AEP, SEP and S-AEP measurements were performed in a right-handed normal male (27 years old). He was in good health, taking no medication, and without history of hearing loss or neurological diseases. Informed consent was obtained after the experimental procedures were explained.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 606–609, 2009
www.springerlink.com

B. Measurement methods

In The measurement of SEP, the median nerve was stimulated with an electrical square wave of 0.3 ms duration at 1.0 Hz. In The measurement of AEP 2000 Hz tone pips of 60ms duration with 10 ms rise and fall times were sequentially delivered to the left and right ear by a speakerphone. This auditory stimulus frequency was 1.0 Hz. In The measurement of S-AEP subject is given each stimulus at the same time. The AEP, SEP and S-AEP were measured with EEG measurement system which consists of an array of 18 electrode by 10-20 system (see Fig. 1). Signals from the 16 electrode scraps are amplified for digitizing on A/D converter by using bio amplifier (NEC BIOTOP 6R12 – 4 / I - BF). The reference electrodes were taken on both ear lobe creases. The software on PC analyzes the EEG signal, and displays its result on the monitor. Simultaneously, measured EEG data is stored into the hard disk for localization after the measurement. The EEG signals were measured in sampling rate 500 [Hz] and filtered from 0.05 Hz to 60 Hz and digitized at 500 Hz. Measured EEG is ensemble averaged to decrease artifact. This averaged EEG data was used for localization.

C. Topography

In 5×5 lattice positions of Fig. 2, the electric potential of the parts of white circles where electrodes are not attached to are estimated with a numerical formula from the electric potential of the electrodes in the circumference to the uniformity. And 50×50 points electric potential around these electrodes is calculated in an equation between the assistant of maintaining the same next with the electric potential value of the electrode of 5×5 lattice positions.

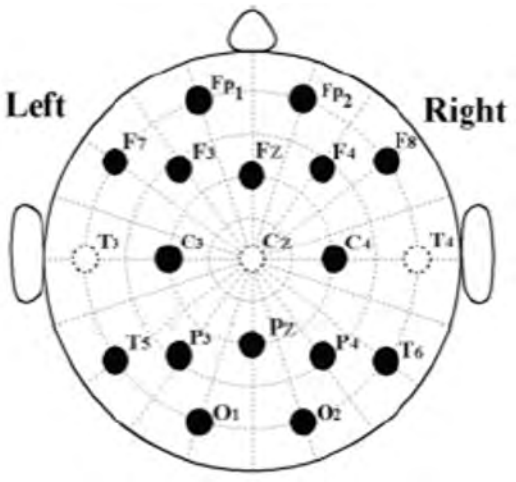

Fig. 1 International standard 10-20 system

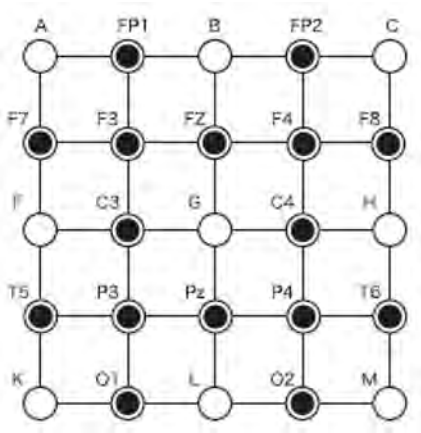

Fig. 2 5×5 lattice positions

The equation in order to calculate the estimate of coordinates except the electrode installation position is as follows;

$$A=\frac{(Fp1+F7)}{k},B=\frac{(Fp1+Fp2)}{2},C=\frac{(Fp2+F8)}{k}$$
$$F=\frac{(F7+F5)}{2},G=\frac{(Fz+C3+C4+Pz)}{4},H=\frac{(F8+T6)}{2} \quad (1)$$
$$K=\frac{(T5+O1)}{k},L=\frac{(O1+O2)}{2},M=\frac{(T6+O2)}{k}$$

But k is different by interpolation function. I applied 4 this time. Interpolation function of k=4 is shown in the next equation by sampling theorem:

$$z=v\cdot\frac{sin(x)}{x}\cdot\frac{sin(y)}{y} \quad (2)$$

III. Result

A. EEG Measurement Result

Fig. 3,4,5 indicate measured EEG that is ensemble averaged AEP, SEP and S-AEP. Furthermore Fig. 6 indicates EEG which is reduced SEP from S-AEP on the front of the head. Horizontal axis is time, and vertical line is EEG value [μ V]. 1200 ensemble average was done at each stimulus cycle [1/s], and baseline of EEG was the averaging 100 [ms] before the stimulus. In AEP data, it seems that the data, the negative peak in the voltage, at time 84[ms] is N100 and the positive peak, minimum in the voltage, at time 158[ms] is P200. Even in Fig. 6 N100 and P200 can identify like evoked potential having been shown with Fig. 3.

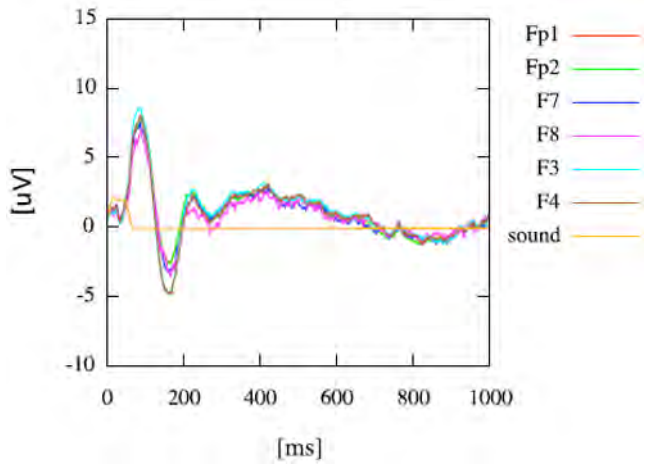

Fig. 3 AEP in the front (1200 ensemble average)

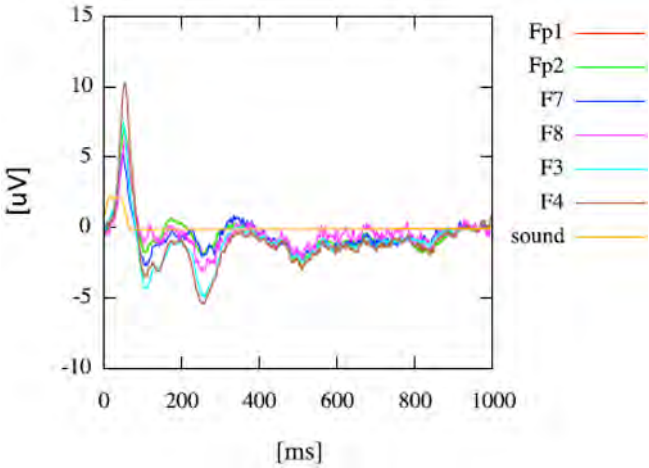

Fig. 4 SEP in the front (1200 ensemble average)

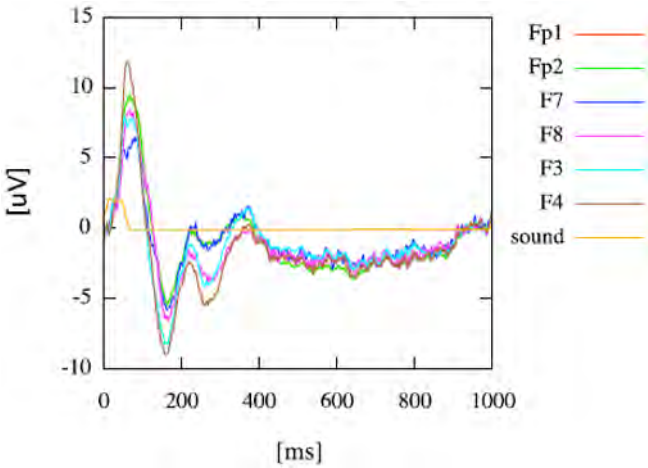

Fig. 5 S-AEP in the front (1200 ensemble average)

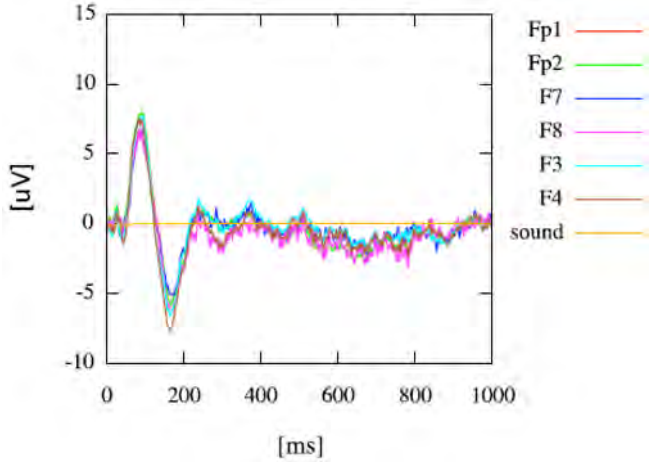

Fig. 6 EEG reduced SEP from S-AEP in the front (1200 ensemble average)

B. Correlation coefficient

Correlation coefficient indicates the strength and direction of a linear relationship between two random variables. A number of different coefficients are used for different situations. The best known is the Pearson product-moment;

$$r_{xy} = \frac{n\sum_{i=1}^{n} x_i y_i - \sum_{i=1}^{n} x_i \sum_{i=1}^{n} y_i}{\sqrt{n\sum_{i=1}^{n} x_i^{\,2} - (\sum_{i=1}^{n} x_i)^2}\sqrt{n\sum_{i=1}^{n} y_i^{\,2} - (\sum_{i=1}^{n} y_i)^2}} \quad (3)$$

Table 1 shows correlation coefficients between AEP and EEG which was reduced SEP from S-AEP in each electrodes at 300 [ms] after the stimulus.). Table 1 indicates that AEP and EEG which is reduced SEP from S-AEP have increasing linear relationship because correlation coefficients of each electrodes were almost +1

Table 1 Correlation Coefficient at 300 [ms] after the stimulus

Pole	Coefficient	Pole	Coefficient
Fp1	0.948320	Fp2	0.947376
F3	0.970904	F4	0.973367
C3	0.975286	C4	0.960479
P3	0.961993	P4	0.935688
O1	0.906088	O2	0.855437
F7	0.968806	F8	0.967107
Fz	0.970577	Pz	0.951431
T5	0.933087	T6	0.906108

Correlation coefficients between AEP and EEG which was reduced SEP from S-AEP in each electrodes.

C. Topography

Fig. 7 represents Topography at N100 (84 [ms]) about each ensemble averaged EEG (AEP, SEP, and S-AEP. EEG which is reduced SEP from S-AEP). Fig. 8 represents Topography at P200 (158[ms]) about each ensemble averaged EEG. Fig. 7 and Fig. 8 indicate that AEP and S-AEP are very similar electric potential distribution.

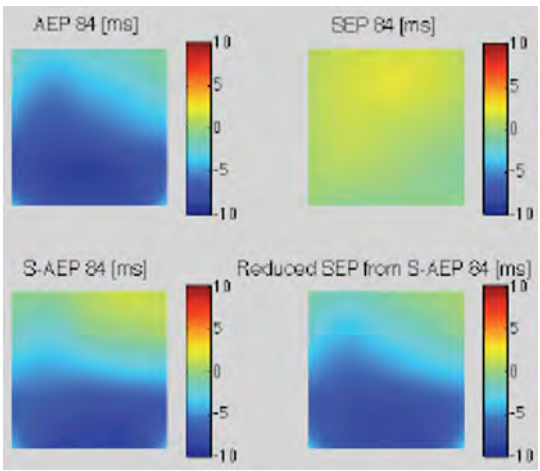

Fig. 7 Topography

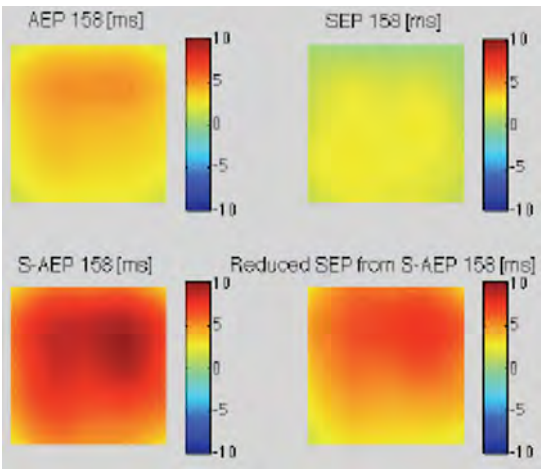

Fig. 8 Topography

IV. Conclusion

It was found that there was strong correlation between AEP and EEG which was reduced SEP from S-AEP by the analysis of EEG data, comparison of Topography, the numerical value of the coefficient of correlation. A linear characteristic of the evoked potential was proved by the above-mentioned result. Therefore, it is thought that application, using SEP as a trigger to recall acoustic stimulus, may be possible for a specific study of the recalling evoked potential as.

Abstract — **Retinal fundus images are commonly used by ophthalmologists to diagnose and monitor the development of eye diseases. One of the key information in the fundus images is to distinguish between the left and right eye. This work is motivated to provide an accurate and automated method to detect the left and right eye based on the retinal images.**

In current clinical practices, a common method to differentiate left and right eye in the retinal images is via the position of the optic nerve head with respect to the macula. This paper introduces a novel method to automatically detect the orientation of the retina in fundus images from the position of the central retinal artery and veins of the physiologic optic nerve head.

Our method first locates the centre of the optic cup using pixel intensity. A 100 x 100 pixel ROI is then formed based on this centriod. Thresholding by pixel intensity and morphology is then used to segment the optic disc from this ROI to obtain an accurate optic disc and its blood vessels within. The pixel intensity in the green channel of this segmented disc along its horizontal axis is projected. The sum of the pixel intensity in the left half of the disc is then compared to the right half. The prevalence of higher green pixel intensity in either half of the optic disc would then indicate if this is a nasal or temporal sector, which would then indicate if this is a left or right eye.

This method is tested on 194 images collected from patients at the Singapore Eye Research Institute and achieves an accuracy of 92.23%. This method is novel and its results are encouraging to provide an accurate and automatic system to make a distinction between left and right eye from retinal images.

Keywords — **Automated, Detection, Retinal, Pixel Intensity**

I. Introduction

Ophthalmologists often have to identify key anatomical structures (optic disk, macular, retinal vessels) in retinal fundus images. Identification of these structures is important and significant as it would provide localization, annotation and measurement of landmark points and features.

In current clinical practices, there are a number of methods to identify left and right eye in colour fundus images.

One commonly used method is by identifying the relative position of the optic nerve head with respect to the macula[4,5]. The side at which the optic disc lies, with reference to the macula, indicates the corresponding side of the eye in the fundus image. The disadvantage of this method lies in the reliance of a clear definition of the macula. In images where the macula cannot be identified, this method of detection will not be useful.

Another way of categorizing is by analysis and tracking of the parabolic course of the central retinal arteries and veins entering and leaving the optic nerve head to the retinal edges[3]. This technique relies heavily on the following the course of the retinal vessels. The disadvantages of this are that the retinal vessels sometimes may not be captured in the fundus image or that the vessels are blocked by exudates.

An alternative method of identification would be via the position of the central retinal arteries and veins of the physiologic optic nerve head. This method is based on the idea that the retinal arteries and veins are usually found near the nasal edge of the physiological cup[1]. This method is less commonly employed as it is sometimes difficult to visually differentiate which side the retinal vessels are near to.

The above mentioned methods are currently manually visually inspected by physicians and can be time consuming. By means of digital image processing techniques, we propose a novel, unbiased and automatic means of identifying left or right eye image based on the last method introduced, via the retinal vessel structure in relation to the physiological cup, to distinguish left and right eye in fundus images for image annotation and context analysis. The details of the proposed algorithm will be presented in Section II; Experimental results are demonstrated in Section III; Section IV gives a conclusion on this paper; and Section V acknowledges the respective organizations involved in this paper.

II. Methodology

To detect the physiological optic disc, we propose a fast method of localization of the optic disc via pixel intensity and forming a ROI to contain the optic disc. The optic disc is then segmented from this ROI by pixel intensity, pixel counts and morphology. The prevalence of the retinal vessels within the left and right half of the optic disc is then compared. This would result in an indication of the nasal and temporal sector and signify a left or right eye.

A. Optic Disc Detection

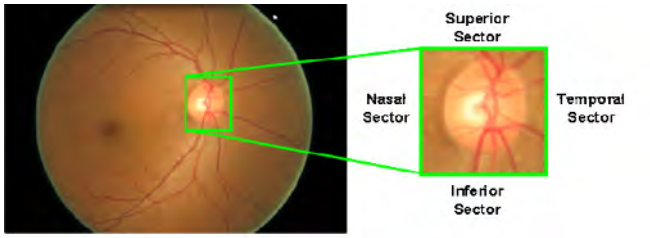

Fig. 1 Retinal Fundus Image. [inset] Optic Disc and its 4 sectors

The optic disc is often the brightest and most distinct feature in a normal patient's retinal colour fundus image. The optic disc can be generally described as a pale-yellow to orange rounded blob, with an embedded optic cup, bright-yellow to white in color, and retinal arteries entering and retinal veins leaving the optic cup.

As shown in Fig. 1, the optic disc, bounded by a green box, has four sectors, Inferior, Superior, Temporal and Nasal. In our approach, we are interested to use retinal vessel information to detect the nasal and temporal sides. This would then reveal if the image is a left or right side. However, segmentation of the optic disc can be tough due to the presence of large number of blood vessels traversing the cup boundary[2], and even more challenging in cases of abnormal retinal images with large areas of exudates[5]. In this paper, we process images in our dataset which are mainly devoid of exudates.

The optic disc detection proposed, an extension of [2], is performed in two steps: patch analysis and disc ROI localization. The fundus image is first divided into 64 8-by-8 patches in its red component channel. Each patch returns the total pixel intensity and a pixel count of the largest mass of threshold blob within itself. An initial patch is selected when it has the highest total pixel intensity among all 64 patches. 'Challenger' patches, patches with the next few highest intensities, are compared against this initial patch. A patch is then selected when it returns the highest threshold pixel count with high pixel intensity. This is done to enhance the accuracy for optic disc detection and obtain a best representation of the optic disc.

The centre of the mass of blob in this selected patch is then used to form a 100x100 pixel candidate area to localize the optic disc. This ROI is set to accurately analyze only the retinal vessels within the optic disc. Pixel intensity is applied to segment the optic disc in this ROI. The threshold for this segmentation is set at the top 2% of highest pixel intensity in the candidate area. A clustering algorithm is then used to fuse nearby blobs and pixels together to form a better representation of the segmented optic disc. The flow of our method is shown in Fig.2.

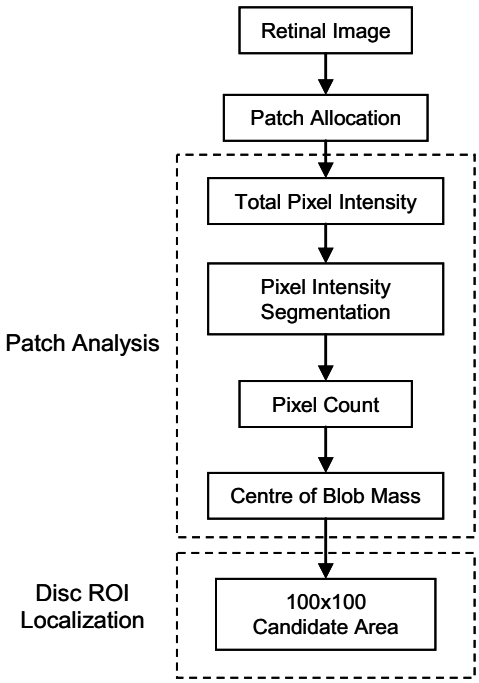

Fig. 2 Optic Disc Detection Workflow

B. Analysis of retinal vessels within optic disc

With the segmented optic disc in the candidate ROI area, we extract the vessel information from the optic disc via its green channel. It is found in our experiments that the central retinal artery and vein are most distinct in this channel. The optic disc is divided into left and right halves. The extracted vessels from the optic disc are then summed up in its columns and projected horizontally across the x-axis. The pixel intensities in each half are compared against each other. The half which indicates lower pixel intensity denotes that it is the temporal sector. If the temporal sector is on the right half, it signifies a right eye, and vice versa.

III. Experimental Results

In this paper, we demonstrate our method on sample 1, a right fundus image, and sample 2, a left fundus image.

Patch allocation and analysis was applied to the sample 1 with results as shown in Fig. 3a. In this sample, majority of the optic disc can be found in the allocated patch. However, as found in our experiments, the optic disc does not necessarily lie fully in the allocated patch as shown in Fig 4a. The

patch which contains the highest total pixel intensity, Fig 4b, may not represent the optic disc at its best. As such, we developed another method to create 'challenger' patches, which takes into account the number of pixels contained in the largest blob after pixel intensity segmentation. As highlighted in the methodology, the threshold is set at the highest 2% of the maximum pixel intensity present in each respective patch. It is important to note that the challenger patches must have a high total pixel intensity before it is compared to the maximum total pixel intensity patch to prevent false detection and unnecessary comparision. After this evaluation, the most suitable patch,Fig 4c, is returned. The centroid of the segmented blob mass, Fig 3c and Fig 4d, is then used as a good centre of origin to create a 100x100 candidate ROI, Fig 5.

Through our experiments, a 100 by 100 pixel ROI is sufficient to contain the optic disc for retinal vessel analysis. The candidate area is first segmented via the red channel as it gives the best outline for the optic disc, Fig. 6. The segmented area is then processed using morphology methods before retinal vessel analysis.

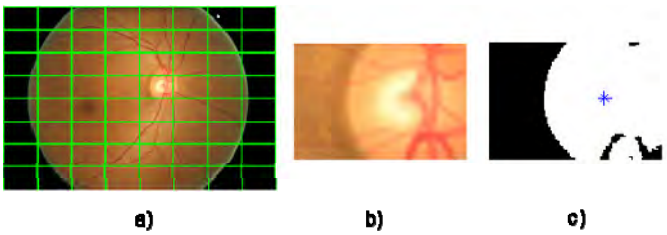

Fig. 3 a) Sample 1 fundus image allocated into patches. b) Selected patch. c) Centre of blob mass after Pixel Intensity Segmentation

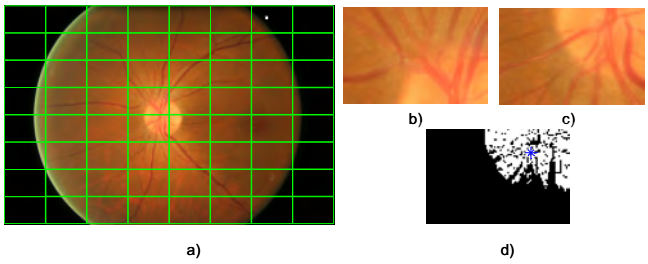

Fig. 4 a) Sample 2 fundus image allocated into patches. b) Max total pixel intensity patch. c) Patch with highest pixel count among high intensity patches. d) Centre of blob mass after Pixel Intensity Segmentation

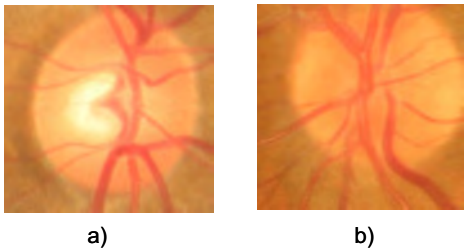

Fig. 5 a) Candidate ROI of sample 1. b) Candidate ROI of sample 2.

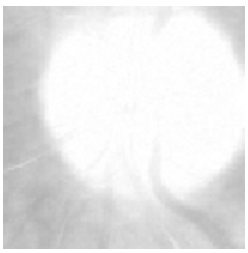

Fig. 6 Red Channel of sample 2 ROI provides a distinct disc boundary.

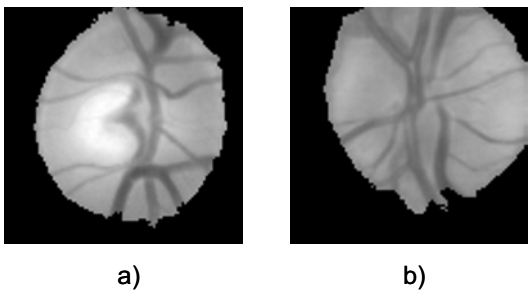

Fig. 7a) Candidate ROI of sample 1. b) Candidate ROI of sample 2.

As shown in Fig. 7, the green channel of this segmented disc provides the clearest information of the retinal vessels. As the retinal vessels are emphasized as the dark regions, they would return a low intensity value. The pixel intensities of the retinal vessels in the optic disc are summed vertically and projected horizontally, Fig 8-9. The optic disc is then divided into left and right halves, and the prevalence of higher pixel intensity in either half would denote the nasal sector of the optic disc. The blue region in Fig 8-9 indicates the temporal sector of the sample images. Sample 1 indicates the temporal sector on the right half, does implying that it is a right eye image. Similarly, sample 2 implies a left eye image. Both results validate our initial claims.

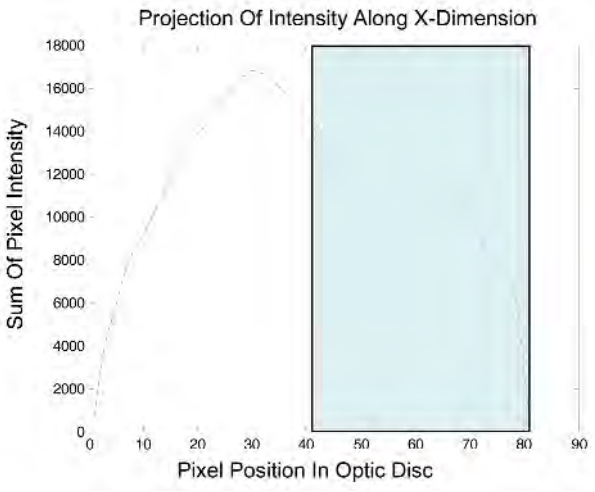

Fig. 8 Projected retinal vessel concentration of Sample 1.

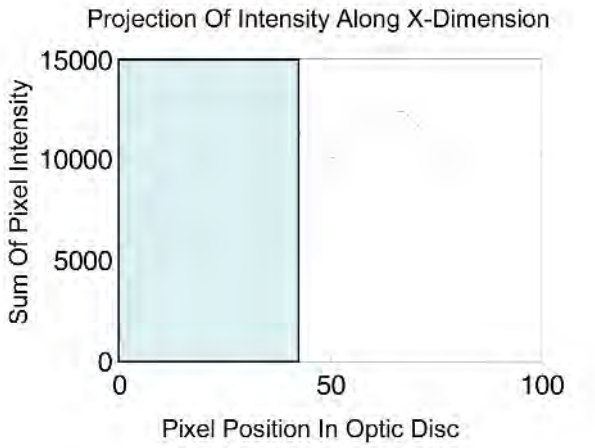

Fig. 9 Projected retinal vessel concentration of Sample 2.

We tested our algorithm on 194 fundus images from the Singapore Malay Eye Study (SiMES)[6]. The SiMES is a research project conducted by Singapore Eye Research Institute(SERI) for determinants of the optic cup to disc ratio in an Asian population. The dataset was first visually inspected and segregated into left and right eyes before the experiments were performed.

As presented in Table 1, our method on 194 images, has achieved a total accuracy of 92.23%. We evaluated our results and found that this approach is highly accurate when the optic disc is accurately detected and segmented.

The failure images were carefully analyzed and we realize that the method is unsuccessful if the optic disc is incorrectly detected and segmented. Retinal images with poorly defined retinal vessels also contribute to inaccurate and unsuccessful detection.

The analysis of the pixel intensity of the retinal vessels confined within the optic disc in the ROI allows the detection to be more robust than analyzing the retinal vessels within the 100x100 ROI area. Our experiments also show that there is no bias for any particular side of the eye.

Table 1 Statistics of Results

Image	# of samples	# correct	Accuracy (%)
Left Eye	97	87	89.69 %
Right Eye	97	92	94.85 %
Total	194	179	92.23 %

IV. Conclusions

In this paper we present a novel method for the fast automatic detection of left and right retinal fundus image. The method is based on using the physiological structure of the retinal vessels in the optic disc. Patch allocation and analysis are performed to provide a fast and accurate means of selecting a candidate ROI for the optic disc. The patch analysis method also consists of a counter check in the form of challenger patches which compete to be selected as the best patch to contain the optic disc. The candidate ROI is subsequently processed to extract the optic disc with its retinal vessels. Retinal vessels are then examined, with their intensity projected along the horizontal axis, giving an indication of the nasal and temporal sector. If the temporal half is on the left, it denotes that the retinal image is a left eye, on the other hand, a right temporal side is a sign that it is a right retinal image.

Our experiments conducted using the 194 images demonstrate an overall accuracy of 92.23%. The results suggest that this is a promising means of detecting left and right fundus images for annotation and subsequent context analysis. We have also established a fast and unbiased method of automatic detection of left and right fundus image. Future work could also be explored to extend this approach to retinal images with exudates.

National University of Singapore

Abstract — **In dentistry, teeth occlusion is the best possible fit between the maxilla (upper teeth) and the mandible (lower teeth). Understanding occlusion is important for diagnosis, prognosis and treatment of occlusal dysfunction and for planning of reconstructive surgery. Teeth occlusion can be determined by a set of occlusal contact points. Due to the complex surface morphology of the maxilla and mandible, identification and localizing this set of contacts, even to the dentist, is not a trivial task. The visualization of occlusal contact points has important significance in providing the dentist a clear picture of the exact locations of these points, which are important in clinical practice when the dentist wishes to recover or maintain a perfect occlusal balance between the maxilla and mandible. This paper presents a method of determining the set of contact points and visualizing them in 3D. We assume that optimal teeth occlusion has been previously obtained. The contacts points are determined by analyzing the difference image between the maxilla and mandible height fields. With a suitable threshold, one can obtain multiple connected contact regions on the difference image. We can further prune the contact points by searching for local minima using an 8-connectivity neighborhood kernel. We then back-project using ray-casting techniques to obtain a pair of contact correspondence for each point. Visualization results are further enhanced by properly positioning the maxilla and mandible models in 3D and joining the contact points by a set of lines.**

Keywords — **occlusal contact points, dental, maxilla, mandible, teeth**

I. Introduction

In dentistry, occlusion is defined as the best possible fit between the maxilla (upper teeth) and mandible (lower teeth). Understanding occlusion is the key to oral function and subsequently the key to restorative oral diagnosis. Critical to the success of determining optimal occlusion is accurate identification and quantification of occlusal contacts.

Conventional approaches of identifying these contacts are determined by an orthodontist or dentist using a color coated, thin plastic sheet known as articulating paper. The patient ``bites'' onto this foil, and the color is then transfered onto patient's tooth surface, thus indicating where teeth have occlusal contacts. Contact information is limited to the width of the foil and requires multiple jaw closures to gather contact information around the around the entire arch [1]. Alternatively, one can use an occlusal registration wax bite. A wax bite can be obtained by inserting a thin sheet of wax into the patient's mouth and having them to bite down on the wax thus leaving a bite mark on both sides of the wax sheet. The dentist can then use the wax bite impression to align both the maxilla and mandible plaster models into its wax bite marks. While wax is commonly used for bite registration, potential problems with wax includes the propensity for wax to warp, bend and/or become brittle, depending on how the wax is handled, stored, and used. A third alternative is to make use of dental impression models which are created separately for the maxilla and mandible using material such as alginate or polyvinylsiloxane (PVS). Once the impression models solidify, they can be mounted on a mechanical articulator which simulates the biting process. The mechanical articulator is accurate, however it is expensive and time consuming in experimental setup. Despite their specific strengths and weaknesses of the three methods that have been discussed earlier, the problem of quantifying the information remains. In the case of a wax bite or silicone impression, transillumination can convert the transparency of the record to digital data. However transillumination is limited because the results are two-dimensional and depend on the orientation of the record to the light source [2].

Having outlined the inconvenience of using conventional methods, this has led to the development of computer-based methods. Advances in 3D digital imaging have allowed the acquisition of more accurate 3D dental data. In this study, we use Minolta Vivid 900 to collect samples of maxilla and mandible of the patients. The scanner allows us to scan the dental impression models quickly and perform occlusal analysis digitally. Due to the fact that, both the maxilla and mandible models are scanned separately at two different instant of time, the relative pose information between the maxilla and mandible that governs the occlusal relationship between them is not captured during the scanning process. An attempt to recover this relative relationship requires occlusal contact registration, which in general is a difficult problem. This requires an optimization over a criterion function that is defined over two separate complex complementary surfaces.

www.springerlink.com

II. Related work

The focus of this paper is to present a method to visualize occlusal contacts; however this can only be done only if optimal occlusions between maxilla and mandible models have been recovered. Using laser scanned models, there are published materials relating to the recovery optimal occlusion. R. Delong [3] recovered occlusion by aligning laser scanned maximum intercuspation occlusal record with the dental models. The results are then compared with the conventional gold standards which are the transillumination records, author concluded that both methods are equivalent. Maruyama [4] describe a method to determine and visualize the occlusal contacts using a virtual semi-adjustable dental articulator. However the occlusion is determined based on a user manually identified fix number of contact points. Without using any occlusal records and user manual identification of contact points, Hiew [5] determined the optimal occlusion of teeth using a two step procedure. The first step coarsely aligns the models using key planar structure which can be detected automatically using a planar clustering algorithm. This is follow by applying a fine alignment which uses a variant of the iterative closest point (ICP) algorithm to obtain optimal occlusion. Visualization of occlusal contact is not extensively studies in this work.

III. Data acquisition

A total of 20 pairs of maxilla and mandible, made of alginate impression, are scanned using Minolta Vivid 900 3D scanner. The scanner has a precision of 0.008 mm and X, Y, Z accuracies of 0.22, 0.16 and 0.10 mm, respectively. Individual views were aligned to each other using the Polygon Editing Tool 2.21 [6]. The aligned views were combined into a single data set representing the object (virtual model), rendered as 3D surfaces. Models are stored in either VRML or STL format. Figure 1 shows the scanned results of the maxilla and mandible.

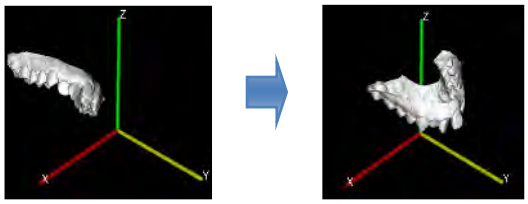
(a) Maxilla (b) Mandible

Fig. 1 Maxilla and mandible scanned using Minolta Vivid 900

IV. Method

A. Searching For Optimal Occlusion

Although mesh representation of the maxilla and mandible is attractive for rendering and display, it is not an efficient and compact representation for the computation of any arbitrary criterion function for searching of optimal occlusion of teeth. We shall first transform the models to a standard canonical coordinate system.



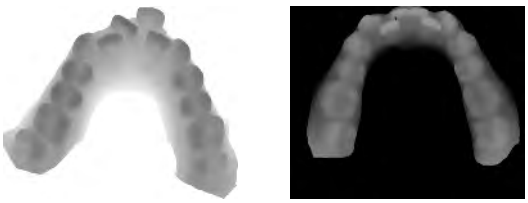


Fig. 2 Canonical transformation of dental models for a more compact and efficient representation

Figure 2 shows one of the models and its world coordinates. Using the principal components of the models, we can adjust the orientation of the models such that the model is parallel to the XY plane. We can then generate a synthetic height field representation of the maxilla and mandible.

(a) Maxilla height field (b) Mandible height field

Fig. 3 Height field representations of the maxilla and mandible

The height fields, also called range images, are generated using a sampling grid of 0.2 mm with linear interpolation by projecting the Z-heights on the XY plane. We transform both the maxilla and mandible such that the Z-heights of the maxilla are always greater than those of the mandible.

Once both models have been transformed in the canonical order, we can search for optimal occlusion. During searching, the mandible is fixed, and only the maxilla is allowed to move in 3D space. A rigid body transformation can be defined by a total of six parameters $\theta = \{t_x, t_y, t_z, r_x, r_y, r_z\}$ which includes both a translation

vector and a rotation matrix. Let $h_u(x,y;\theta)$ and $h_l(x,y)$ be the height fields of the maxilla and mandible generated under transformation θ, respectively.

$$l = \min_{(x,y)}(h_u(x,y;\theta) - h_l(x,y)) \quad (1)$$

$$\hat{\theta} = \max_{\theta} \sum_{(x,y)} e^{-\frac{(h_u(x,y;\theta)-h_l(x,y)-l)^2}{\sigma}} \quad (2)$$

l can be seen as the maximum distance which the maxilla can translate in the Z-axis direction without colliding with the mandible. $\hat{\theta}$ is the optimal solution for optimal occlusion. The summation expression in Equation (2) can be interpreted as a compaction measurement between two complementary surfaces. Optimizing θ will give us the solution to optimal occlusion. Figure 4 shows one of the pair of maxilla and mandibles that are in optimal occlusion determined using the mathematical formulation described in this section.

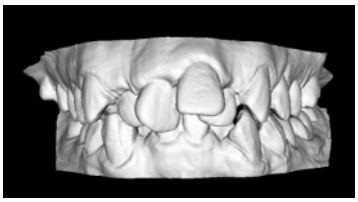

Fig. 4 Maxilla and mandibles in optimal occlusion

B. Identifying Occlusal Contacts

Figure 4 represents one common form of visualizing the maxilla and mandible in optimal occlusion. However if the interest of the dentist is to identify the locations of the contacts, a more effective visualization would be needed. This can be done by first identifying the locations of possible occlusal contacts then displaying them in 3D. In this section, we describe a method of determining the set of occlusal contacts.

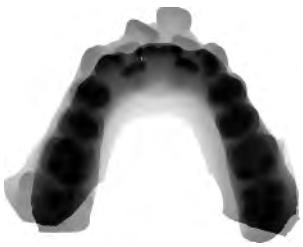

Fig. 5 Height difference image between maxilla and mandible

Given an optimal occlusion parameters $\hat{\theta}$, we can generate corresponding height fields for both maxilla and mandible. The difference between the maxilla and mandible height fields is $h_u(x,y;\hat{\theta}) - h_l(x,y)$.

Let $D = \{d_i \in \Re \mid d_i = h_u(x_i,y_i;\hat{\theta}) - h_l(x_i,y_i)\}$ be the set of height differences. Note that, the lower the values of d_i, the more likely it is that coordinate (x_i,y_i) is an occlusal contact. To determine the locations of occlusal contacts in the image domain, we first sort the values in D, follow by retaining only a certain percentage of the elements in D. In our results, the threshold for this procedure is 2%. We denote this procedure by $T[D_{sort}]$, where T indicates a threshold operation and D_{sort} is the sorted D. The image generated from this procedure identifies the occlusal contact sites in Figure 6 (a).

(a) Occlusal contact sites (b) Superimposed with Fig. 6

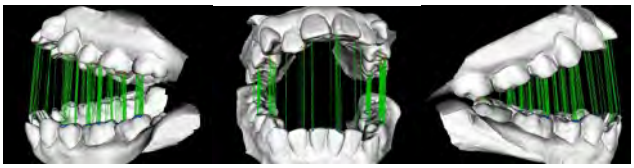

Fig. 6 Height field difference between the maxilla and mandible

Figure 6 (b) also shows an overlay of the contact sites or regions together with the height difference field. Since the contact sites are usually multiply disconnected, we can perform a connected component analysis to identify the number of separate components. In our current example, the components are indicated by different colors in the superimposed image. Contact sites convey region information of the occlusal contacts, it is often desirable to obtain point to point contact information, so that one could display them in 3D. To do so, it is further required to prune down the occlusal contact sites to a finite number of contacting points. In this paper, we make one simple assumption on the occurrence of a true occlusal contact point. We assume that given any point (x_i,y_i) with its corresponding d_i, a point is only a true contact should its value d_i be a local minima in some defined neighborhood. In our experiment, we use the 8-connected neighborhood. Given the true contact points, it is then possible to back project the points to de-

termine their locations on the maxilla and mandible surface model. For each true contact site (x_i, y_i), we have a pair of $h_u(x_i, y_i; \hat{\theta})$ and $h_l(x_i, y_i)$ which defines a 3D line in space. We then determine the intersection of this line with the maxilla and mandible models. The process is similar to ray-casting and the intersection should give two 3D points.

(a) Subject 1

(b) Subject 2

(c) Subject 3

Fig. 7 Visualization of occlusal contact point pairs

For display purposes, we rotate the maxilla and mandible slightly away from the XY plane, so that we can have a full view of teeth. For each contact point pair, we join each of them using green lines as shown in Figure 7. Each column in Figure 7 shows different views of a single human subject. In addition to the model that we use in this paper, we also present another 2 subjects which are shown in Figures 7 (b) and (c).

V. Discussion

We briefly describe the mathematical formulation of optimal occlusion and present a method to visualize the occlusion results. For more details as to how the optimization is being done for Equation (2), readers can refer to one of our earlier works [5]. The main contribution of this paper is to present a fast and efficient method to identify and visualize the occlusal contacts. The algorithm is fast because all processing is done purely in the 2D image domain, and the final output which requires a back-projection to the 3D surface, only involves a small number of points.

In addition to the visualization, it is also possible to measure the number of occlusal contacts, which appear as one of the common measurements in some literature which studies the nature of dental occlusion. We also can obtain a distribution of the number of occlusal contacts over a total of 20 subjects. The weighted average of the number of occlusal contacts is computed as 117.5.

VI. Conclusions

This paper presents a method of obtaining dental occlusion using laser scanned surface models. Instead of using a mesh representation, we use a height field data representation of the maxilla and mandible. Criterion function of arbitrary occlusal configuration can be mathematically formulated using the height fields. Optimal occlusion can now be determined by searching this criterion function. To visualize the occlusal contacts, contacts are first identified using difference of height fields in optimal settings, by applying appropriate thresholds and pruning, we can obtain a sparse number of contact points in the 2D image domain. Points can be back projected using ray-casting techniques to obtain its 3D points on the surface models. One can then visualize the occlusal contact correspondence in virtual 3D. We also quantitatively measure the weight average number of occlusal contacts across a total of 20 human subjects. The weighted average number of occlusal contacts is 117.5.

Modeling Deep Brain Stimulation

Charles T.M. Choi and Yen-Ting Lee

Department of Computer Science and Institute of Biomedical Engineering, National Chiao Tung University, Taiwan R.O.C

Abstract — **The goal of this project was to develop a quantitative understanding about shape of axonal tissue activated (STA) and stimulation site by deep brain stimulation (DBS) in middle brain like thalamus, subthalamic nucleus (STN), and globus pollidus interna (GPi) to make better stimulation effects. The volume of tissue activated (VTA) can be studied using different electrode dimensions.**

Keywords — **Deep brain stimulation, volume tissue activated, VTA, STA.**

I. Introduction

Deep Brain Stimulation (DBS) is a surgical treatment involving the implantation of a medical device which consists of three components: the implanted pulse generator (IPG), the lead with four platinum iridium electrodes, and the extension. All three components are surgically implanted inside the body. It is an effective, proven therapy for the treatment of Parkinson's disease (PD), essential tremor and dystonia. So far, the mechanisms of deep brain stimulation are still not clear, and DBS patient management is primarily based on trial-and-error. We only know that high frequency DBS directly changes brain activity analogous to those achieved by surgical lesion, its effects are reversible (turn on/ off the electrode can inhibit/recover activity in brain) [1].

The fundamental purpose of DBS is to modulate neural activity with extracellular electric fields, but the technology necessary to accurately predict and visualize the neural response to DBS has not been previously available.

The innovation of this paper is to predict the volume of tissue activated [2][3][4] during stimulation using simple FEM DBS electrode-brain tissue model include myelinated axon. Existing DBS system were adapted from cardiac pacing technology ~20 years old. The original design of the Medtronic 3387/3389 DBS electrode was hindered by limited knowledge of the neural stimulation objectives of the device.

But in recent years, we can use new neural engineering design tools, such as computer modeling techniques in this study. We can improve old DBS electrode design.

While DBS is helpful for some patients, there is also some side effects because there is low threshold in surrounding tissue. These may be temporary and related to correct placement and calibration of the stimulator. In this paper we will also study on this issue and try to improve electrode design to fit the tissue which is activated by using virtual channel [4].

II. Method

A. Quantitative measurement of stimulation region

A quantitative measurement is used in this paper: volume of tissue activated (VTA) and shape of tissue activated (STA) are used to predict a 3-dimensional volume of tissue being activated by the electric field. In this paper a 2-dimensional VTA contour will be used to replace the 3-dimensional VTA because it is more straight forward and convey the similar information. A finite element model (FEM) which includes the brain tissue and special DBS electrode contacts is used to address the effects of deep brain stimulation in a homogeneous isotropic medium. The second derivative of the potential distribution (Activating function) generated in the tissue in our model was used as a predictor of the volume of tissue activated (VTA) and shape of tissue activated (STA) [4][5].

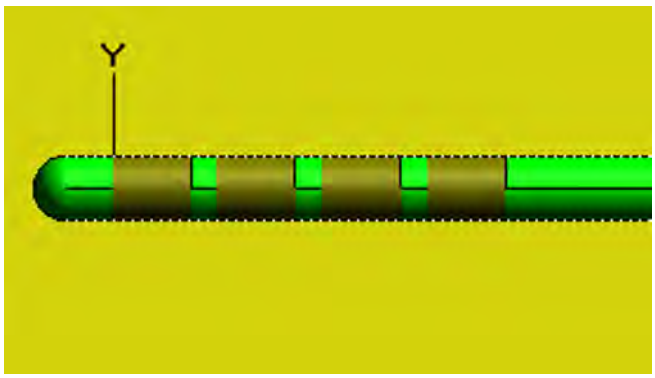

Fig. 1 DBS finite element model (include four contact electrodes and brain tissue). Left to right are electrode 1, electrode 2, electrode 3, and electrode 4.

www.springerlink.com

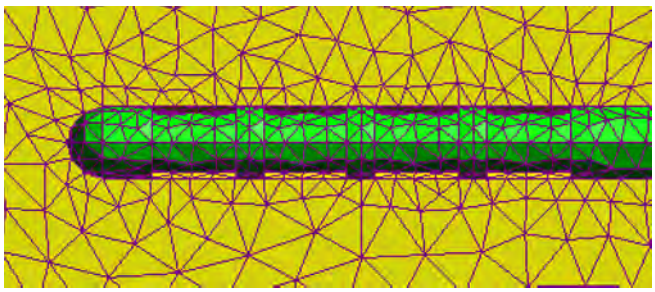

Fig. 2 Finite element meshing model

B. Finite Element model

In our DBS electrode finite element model (Fig. 1, 2), Axisymmetric FEM models of DBS electrodes with approximately 300000 nodes were constructed using Solidwork and ElecNet. The tissue medium was modeled as homogenous and isotropic medium with conductivity $\sigma = 0.3$ S/m. The axisymmetric volume conductor measured 100mm tall by 100 mm wide. Electrode contact dimensions ranged from 0.5mm to 1.5mm in height and 1.27mm in diameter. These dimensions were centered around the Medtronic 3387/3389 quadripolar DBS electrode contact dimensions (1.5mm height, 1.27mm diameter) [6][7]. The electrode lead was modeled as an electrical insulator with the exception of the contact area, which was used for voltage-controlled simulation.

Myelinated axon model [8] is used in conjunction with this FEM model. Under the same power (0.02W), the volume of tissue activated (VTA) was depended on electrode shape (height/diameter) and stimulation site and is relative to the position of electrodes. When we use a DBS electrodes model to simulate STA and VTA, there were also dependent on electrode shape (height/diameter). Stimulation sites were related to the positions of electrode.

C. Simulation Steps

Simulation steps: first, a finite element model is created, then the stimulation waveform is applied to the electrode, and the system is solved using a FEM solver. The result space-dependent voltages are used to calculate activating function thresholds for neural fibers, and the VTA is determined using these thresholds [9][10][11].

III. Result

A. Finite element potential contour and VTA contour

Fig. 3 shows the electrical potential result of DBS finite element model, which contains four-contact platinum electrode and brain tissue. -1V is applied to electrode 2, and others are set to 0V. Fig. 4 shows a VTA contour which shows the volume of tissue being activated.

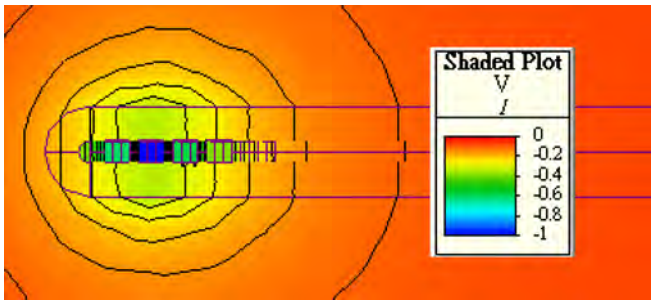

Fig. 3 Finite element potential contour of deep brain electrodes.

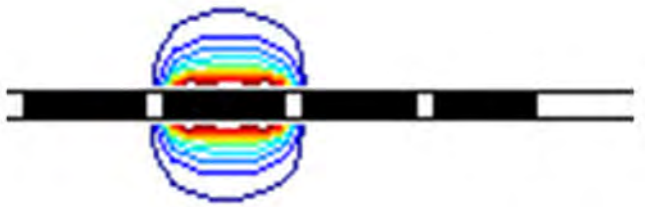

Fig. 4 VTA contour without buffer layer, the region of tissue that would be activated

B. Effect of electrode height, electrode Distance

Fig. 5 shows the relation between electrode height and VTA. When the electrode height is getting larger, VTA is getting longer. It is nearly a direct proportion relationship. The black parts indicate stimulation electrodes in Fig. 5.

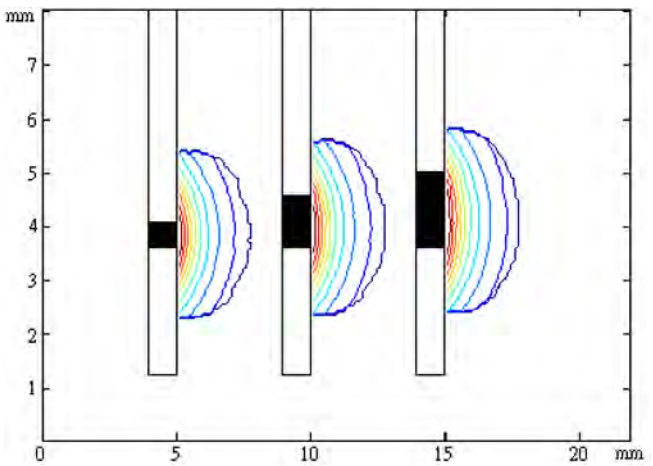

Fig. 5 Relation of electrode height and VTA. VTA contour gets longer with electrode height.

IV. Discussion and conclusion

Volume conduction simulations with typical DBS parameter settings can be used to study VTA and STA for voltage- or current-controlled electrical stimulation [12][13] with various electrode designs. Further, finite element model and neural model for deep brain stimulation can be used in conjunction clinical input parameters and animal models to study the effect of deep brain stimulation and how it is affected by the electric field generated by DBS electrical stimulation.

Abstract — **Metabolic syndrome is not only a major public health problem in the United States and other developed countries but also is associated with increased risk for diabetes and coronary heart disease (CHD). This study presents a easy method for metabolic syndrome detection by measuring the digital volume pulse through the finger photoplethysmography (PPG). The trajectory analysis (TA) has been adopted to produce Poincare plots with the PPG signals. The Poincare plots are two-dimensional graphical representations (scatter plots) of PPG signals. The standard deviation along the longitudinal axis (SD2) in the plots are larger for the subjects with metabolic syndrome than who are without metabolic syndrome. SD2 in the Poincare map of finger plethysmographic singnals is a good indicator to detect metabolic syndrome.**

In this study, we hope to develop a simple detecting indicator of metabolic syndrome, and find a simple way to judge metabolic syndrome through the finger pulse infrared sensor for the non-linear analysis of Poincaré plot. The indicator can remind the user to pay attention to their health, control of eating and living habits to reduce future serious chronic diseases at any time.

Keywords — **Plethysmographic signal, Poincare map, Metabolic syndrome**

I. Introduction

Early detection and more intensive management of the metabolic syndrome in order to reduce the long-term risk of cardiovascular disease and diabetes is now possible[1], according to the International Diabetes Federation (IDF) in a global consensus statement presented for the first time today. The statement includes a new, clinically accessible definition of the metabolic syndrome, representing the views of experts in the fields of diabetes, cardiology, lipidology, public health, epidemiology, genetics, metabolism and nutrition from six continents[2].

Building on earlier definitions put forward by the WHO and NCEP ATP III, the new definition is easy to use in clinical practice. It avoids the need for measurements that may only be available in research settings. For a person to be defined as having the metabolic syndrome, the new definition requires they have central obesity, plus two of the following four additional factors: raised triglycerides, reduced HDL cholesterol, raised blood pressure, or raised fasting plasma glucose level. Gender and, for the first time, ethnicity-specific cut-points for central obesity as measured by waist circumference are included. However, noninvasive measuring instruments are now lack for metabolic syndrome detection in hospitals or at home.

In previous studies we had previously developed photoplethysmograpy (PPG) system using infrared sensors at finger tip for detecting the volume change of blood flow at that finger [3-5]. Being able to detect the changes of blood flow volume indicates the capability of endothelial function and arterial stiffness assessment. This infrared PPG system [6] not only has the capacity to record the digital (finger) amplitude signal according to the change of blood flow volume, in addition, it is also capable to calculate the parameters of digital pulse wave.

II. Materials and Methods

One hundred and forty nine examinees were included from a regular healthy check up from the Minot Christine General Hospital. There were 44 patients with metabolic syndrome and 105 age-matched healthy controls. The participants received blood check up of raised triglycerides, reduced HDL cholesterol, raised blood pressure, or raised fasting plasma glucose level and waist circumference.

A. Instruments and Methods

The system comprises two major parts:

(1) Device for Collection of Infrared Ray Finger Plethysmographic Signals: It includes a penetrating infrared sensor, a signal amplifier circuit and an A/D signal converter. Fig. 1 shows the self-developed non-intruding infrared sensor and signal amplifier circuit with simple structures and low costs. The A/D signal converter used in the system is TX-03A, an analog/digital signal switching interface card with the ISA as its interface. The specifications of the interface card are as follows:

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 622–625, 2009
www.springerlink.com

1. 12-bit resolution;
2. 16 channels;
3. Single electrode;
4. A/D conversion time 60usec/per channel;
5. Input voltage 0-8.5V.

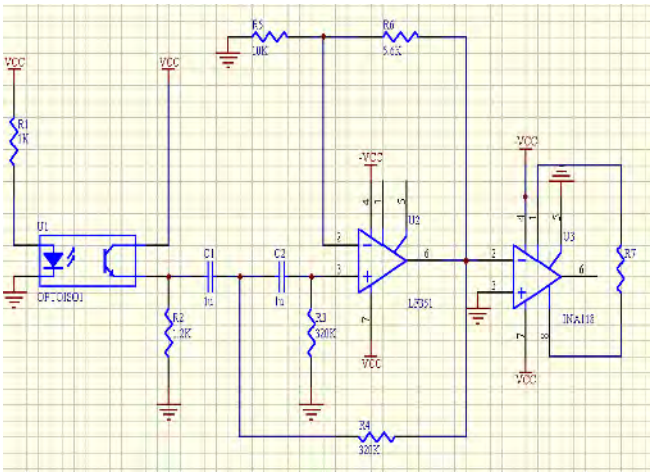

Fig. 1 The self-developed non-intruding infrared sensor and signal amplifier circuit

The hardware comprises (1) a signal collection end and (2) a signal analysis end. At the signal collection end, the signals of the finger capillaries are collected through an infrared sensor with a wavelength of 960nm. The collected signals are then converted to a infrared plethysmographic waveform through a second order differentiating circuit and sent to a low noise amplifier circuit to increase its signal/noise ratio and magnify its power to the level that meets the demand of A/D. The signals are further sent to a buffer circuit for implementing voltage following and impedance matching. The analog volume signals are finally converted to digital signals through the RTX-03A at the signal analysis end.

(2) Poincare Map Interface Analysis:

It can perform Poincare map analysis of plethysmographic signals and Fourier spectrum analysis, and present the different aspect of the plethysmographic strange trajectory. Users may operate the Main Screen to set or adjust parameters to identify the best Poincare maps. The Poincare map interface analysis function of the system has the features of easy operation and excellent expandability.

Signals are sent from the infrared sensor to the hardware circuit for appropriate processing, and then via the signal converter RTX-03A to the software. The software is built in a graphic programming environment created by NI Lab-View8.5. The analog signals collected with a device used to collect the infrared ray finger plethysmographic signals are stored in a file in a real-time manner by RTX-0-3A, driven by an interface controlled data retrieving program. The signals are then read from the file in a real-time manner and form a measure pulse wave diagram. The Poincare map of the STA is presented through the conjunction formed by the trajectory of the sampled signal space of the digital plethysmographic signals and the Poincare plane after the file is read [9]. The input parameter control button is the parameters needed for the input of the STA. Fig.2 shows the Main Screen of the self-developed IRFPS. Fig.2(a) represents original pulsewave from the tester. Fig.2(b) shows poincare map of the pulsewave, and Fig.2(c) is the definition of longitudinal axis,SD1, and the perpendicular direction, SD2.

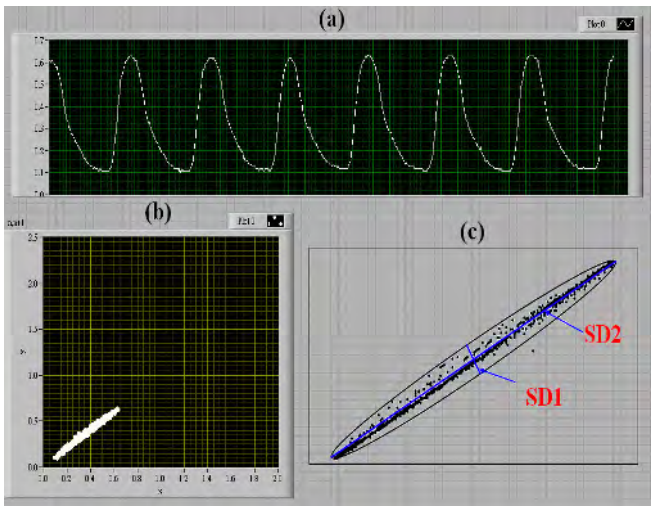

Fig. 2 Main Screen of the self-developed IRFPS

B. Flowchart of STA

The parameters and the actually measured data are read from input and smoothed to draw plethysmographic signals. The signals then undergo a data processing for the drawing of Poincare map conversion used for analysis. The STA follows after the aforementioned steps. Since there are many options for Poincare maps, it depends on the experience of doctors in clinical diagnosis to determine the effective map pattern.

In this study, we address one Poincare map as example for easy description of the study. The value of X/Y-axis of the Poincare map shall be first defined. The value obtained

after the data moves to be the value of X-axis directly. The value gained after the data moves to the parameter delay 1 point is the value of Y-axis. Finally, calculation and storage of the SD1, SD2, SD1*SD2, SD1/SD2, SD2/SD1 will be proceed.

It is the aforementioned observation that motivates us to make the research. We hope that another analysis approach can be provided to doctors and specialists as a reference for their clinical analysis and research to produce an auxiliary effect on diagnoses.

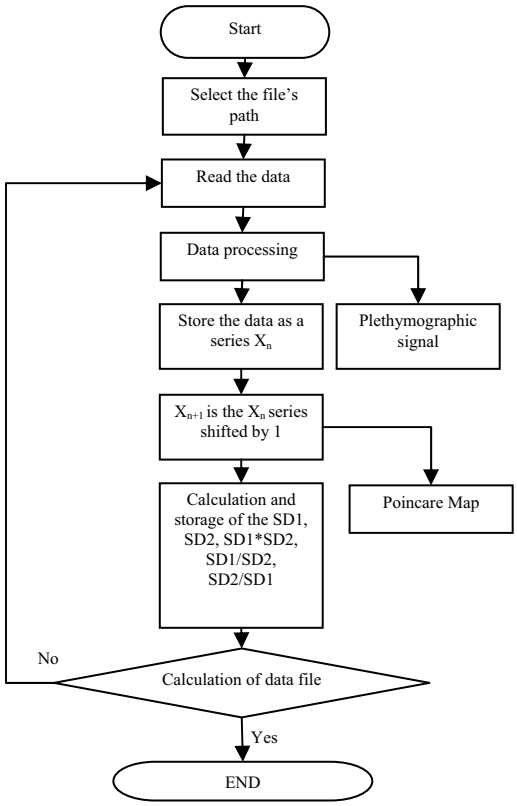

Fig. 3 Flowchart of strange trajectory analysis

III. Results

Among 149 subjects, 44 subjects had metabolic syndrome, and 100 subjects without having the metabolic syndrome. Subjects with metabolic syndrome had significantly higher waistline, weight, systolic and diastolic pressures, blood Glucose, and triacylGlycerol than those without metabolic syndrome, as Table I shown.

However, poincare map shows significant difference of SD2, SD1*SD2 between these two groups. However, there are no significant difference in SD1 and SD2/SD1.

Table I Characteristics of the study population (Mean±SD)

	Metabolic Syndrome N=44	Health N=105	P
Gender(m/f)	13/31	38/67	
Age(years)	61.59±10.74	59.17±11.52	NS

IV. Conclusion

Proposed is a self-developed IRFPS retrieving and the STA system. It is expected that many valuable experiences and clinical information will be produced to identify the type of disease to which the system is applicable and its effective Poincare maps. The trajectory analysis (TA) has been adopted to produce Poincare map with a self-developed infrared ray finger plethysmography system(IRFPS) to present one special strange trajectorie of the plethysmographic signal for metabolic syndrome detection. The proposed system can be used as an alternative diagnostic tool for doctors and specialists in an attempt to facilitate metabolic syndrome clinical diagnosis. In addition, the Poincare map of finger plethysmographic singnals is a good indicator to detect metabolic syndrome.

Diagnosis of Hearing Disorders and Screening using Artificial Neural Networks based on Distortion Product Otoacoustic Emissions

V.P. Jyothiraj[1] and A. Sukesh Kumar[1]

[1]Dept. of Electronics and Communication Engineering, College of Engineering, Trivandrum, India

Abstract — **The auditory system produces low level sound in response to stimulation. Distortion Product Otoacoustic Emissions (DPOAEs) are a series of combination tones generated in the ear when stimulated with two pure tones of frequencies f1 and f2. The most prominent DPOAE is the cubic difference tone at 2f1-f2. The objective of this work is to determine the DPOAE response characteristics from normal and hearing impaired subjects and hearing screening using artificial neural networks (ANN). The data acquisition platform controls the microphone/speaker system which generates the acoustical stimuli for presentation to the ear canal and collects the acoustic responses recorded in the ear canal. Digital signal processing technique involves estimation of weak DPOAE response at the 2f1-f2 frequency, the noise floor and the DPOAE signal to noise ratio (SNR) with f2 at frequencies 1.5, 2, 3, 4, 5 and 6 KHz. The individual pure tone audiometric data are also collected to differentiate ears with normal hearing from impaired ear. DPOAE features and pure tone audiometric data are used to train the ANN classifier. The proposed method is developed and evaluated using a dataset based on 76 hearing subjects. Supervisory learning is used for the training of the classifier. Each hearing subject is classified as normal or abnormal one. The ANN system indicates that the results are comparable to human intervention, with substantial reduction of time and resources. The DPOAE measurement provides detailed frequency specific information on cochlear function; it is a potential tool to find hearing impairment and hearing screening.**

Keywords — **Otoacoustic Emissions, DPOAE, Hearing Screening, Diagnosis, Artificial Neural Networks.**

I. Introduction

Otoacoustic emissions (OAEs) are a low level sound which arises in the ear canal when the tympanic membrane receives vibrations transmitted backwards through middle ear from cochlea as part of the normal hearing process [1], which is discovered by Dr. David Kemp in 1978. The outer hair cell (OHC) system of cochlea is responsible for the generation of OAEs and OHC mobility is the cellular basis of this phenomenon [2] at least for mammals. The generated signal propagates through middle ear and into ear canal, where they can be measured with sensitive microphone placed in the outer ear canal. OAEs are universally present to various degrees in all healthy cochleas, where as they are not generally observed or are greatly reduced in ears with mild hearing losses. This aspect together with the extreme facility to perform the test and the high reproducibility had made the OAEs an increasingly widespread application in diagnosis of hearing impairments.

OAEs are classified according to the type of stimulation to induce them (1) spontaneous otoacoustic emission (SOAEs) (2) evoked otoacoustic emissions (EOAEs). The SOAEs are narrow band and low level signals which are generated without acoustic stimulation, whereas EOAEs occur during or after external acoustic stimulation [3]. There are several subclasses of EOAEs based primarily on the stimuli used to evoke them. These include (i) transient evoked OAEs (TEOAEs) (ii) distortion product OAEs (DPOAEs). TEOAEs are delayed response to acoustic transient stimuli such as clicks or tone burst.

The DPOAEs are inter modulation-distortion response produced by the ear in response to two simultaneous pure tone stimuli referred to as the primary tones f1 and f2 with levels L1 and L2. The primaries are related in frequency separation of f2 from f1 commonly called f2/f1 ratio, i.e., typically 1.22 [4]. The most frequently measured acoustic inter modulation-distortion product is at the frequency 2f1-f2 i.e., the cubic difference tone [4], although the cochlea also produces concurrently DPOAEs at other frequencies (e.g., f2-f1, 2f2-f1, 3f1-2f2) in response to such bitonal stimulation. Indeed, the only emitted distortion component utilized to clinical purpose has been 2f1-f2 because it is the largest DPOAE. The amplitude of a DPOAE depends upon the level of the eliciting stimulus.

The aim of this work is focused (i) to find DPOAE response characteristic of normal and hearing impaired subjects from different age group and (ii) to extract the features from DPOAE measurement data to hearing level for hearing screening using Artificial neural networks. An ANN is computational structure that is inspired by observed processes in natural networks of biological neurons in the human brain. neural net work s have a large number of highly inter connected processing elements that discriminate the ability to learn and generalize from training pattern or data. This work is an extension of author's earlier works [5], [6], [7].

II. Materials and methods

A. DPOAE measurement System

A schematic of computer based DPOAE measurement system is shown in the Fig. 1. , which includes a computer, a probe, data acquisition and Digital signal processing (DSP) system. The DPOAE response is measured via a probe that is sealed in the ear canal using a removable rubber or form ear tip. The probe assembly contains two miniature speakers and a low noise microphone. Each speaker is dedicated to delivering a pure tone, either f1 or f2. The f1 and f2 tones are kept separated from each other until they are inserted into the ear canal to minimize the possibility of instrumentation artifacts interfacing with the measurement of the biological response from the cochlea. The DSP platform is the brain of DPOAE system because it is where signal generation, data acquisition and averaging are controlled. The two primary tones f1 and f2 are digitally synthesized are presented to ear canal through digital to analog converter (DAC) and miniature speaker system to elicit DPOAEs. The responses are collected through miniature microphone, after amplification and filtering it is fed to DSP platform through analog to digital converter (ADC) for further signal processing [8]. The signal detected by the microphone includes the primary tone pair, a series of inter modulation products; biological sounds, such as those associated with breathing, blood flow and muscle movements; and room sounds. The challenge for the DPOAE system is to isolate the desired distortion product from the multitude of other frequencies present within the ear canal. Since only the frequencies in the immediate vicinity of the DP frequency (2f1-f2) have the potential of interfering with the measurement of the DP frequency, it is possible to examine the amplitude of these frequencies when calculating the separation of the DP from the noise. The noise floor level is further reduced by using a low noise environment such as a sound proof room for DPOAE measurement.

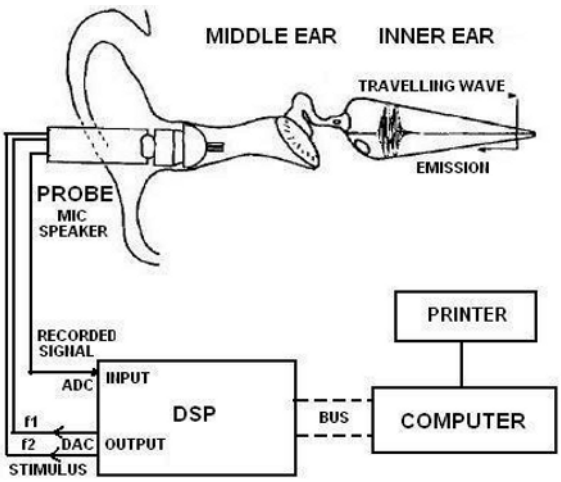

Fig. 1 Schematic of a computer based DPOAE measurement setup

B. DPOAE Acquisition and Analysis

DPOAEs are measured from 76 subjects like normal, hearing impaired, and normal having other diseases. To conduct DPOAE test, two primary tones at frequency f1 and f2 and levels L1 and L2 were presented. The frequency ratio f2/f1 was fixed at 1.22. The stimulus levels were held constant at L1= 65 dBSPL and L2=55dBSPL. These values have been shown to give large amplitude and thus easily detectable.

The recorded DPOAE signal can be formulated as

$$s(n) = \sum_{i=j}^{3} A_i \cos(nw_i + \phi_i) + v(n) \qquad (1)$$

Where $w_i = 2\pi f_i/f_s$ with f_s being the sample rate, and v(n) is the noise. The two sinusoids $A_1 \cos(nw_1+\Phi_1) + A_2 \cos(nw_2+\Phi_2)$ represent the stimulus induced artifact, while $A_3 \cos(nw_3+\Phi_3)$ is the DPOAE component. Because the artifact is about 60 dB larger than the DPOAE, we have $A_1 >> A_3$ and $A_2 >> A_3$. The DPOAE component can be treated as nonrandom signal since the DPOAEs are stable for a long period of time .On the other hand, v(n) is assumed to be uncorrelated Gaussian process with zero mean and variance. In clinical measurement, the signal strength of DPOAEs at f_3 is usually the parameter of interest. Define DPOAE level as $L_{dp}=A_3^2/4$.Since the DPOAEs are tonal; it is possible to obtain L_{dp} by measuring the spectrum of the recorded signal. Conventionally, this is achieved by FFT estimators [9]. The following variables were analyzed**.** (i) the estimated DPOAE level (DP) measured at the 2f1-f2 frequency with f2 at frequencies 1.5,2, 3, 4 ,5 and 6KHz. (ii) the noise level (NF) estimated from the 4 Fourier components nearest to but not including the 2f1-f2 frequency. (iii) the estimated DPOAE signal to noise ratio (SNR) is defined as the difference between estimated DPOAE level and estimated noise level. Fig.2. shows the spectra of ear canal sound pressure detected by microphone.

C. Pure tone audiometric test

In this study, pure tone audiometric data are also collected from the hearing subjects (adults and children)using both air conduction and bone conduction methods in the frequency range1.5 to 6 KHz. Here normal hearing subject is coded as '1', if subject having audiometric mean hearing

level (MHL) less than 30 dB and hearing impaired subject is coded as '0', if MHL greater than or equal to 30dB repetitively. This data are used for ANN training and testing

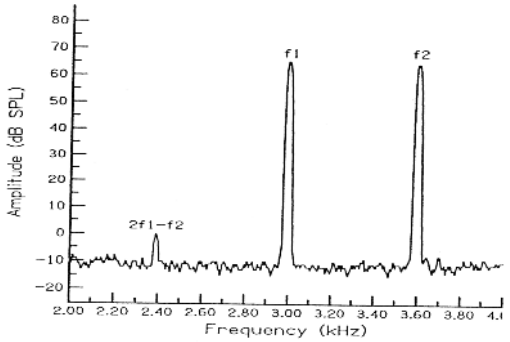

Fig. 2 Spectra of ear canal sound pressure from the ear of a normal hearing adult

D. Artificial Neural Network for Classification

Artificial neural networks are considered to be good classifier due to their adaptive learning, robustness, self organization and generalization capacity. In this work multilayer feed forward network is used for classification (normal or impaired).Fig.3 shows a three layer feed forward network with an input layer, one hidden and an output layer. Where x_i denotes the features vector parameters, 'i' is the number of inputs, k is the number of hidden layers and W_{ik} are the weights between inputs and hidden layers. The number of neurons in the hidden layer is selected by trial and error method. In our case, the final network had 10 inputs, 15 neurons in hidden layer and one neuron in the output layer.

The most popular and well established training algorithm used with the multilayer feed forward network is the back propagation algorithm (BPA), and it is used in this work. The weights were adjusted using Levenberg-Marquardt algorithm during the training procedure. This algorithm has the most rapid convergence properties for network with moderate complexity [10]

The DPOAE features (4Nos), Noise levels (4Nos)of four different f2 frequencies(2 to5KHz), age and sex (1 or 0) of hearing subjects are the input vector for training and pure tone audiometric result (normal and impaired subjects) is the target vector. The network was trained using supervised learning with training set of inputs and targets .This procedure is described by

$$f(x_1,x_2\ldots.x_{10}) = 1 \text{ if } \quad MHL < 30dB$$
$$= 0 \text{ if } \quad MHL \geq 30 \text{ dB} \qquad (2)$$

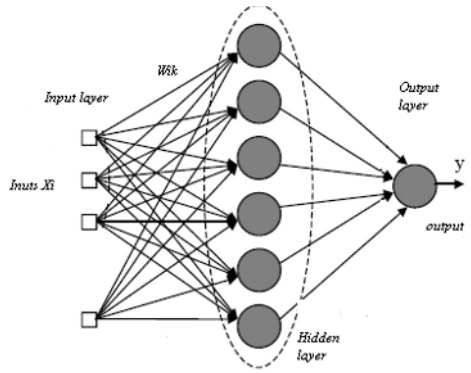

Fig. 3 Schematic representation of a three layer feed forward network

where $f(x_1, x_2,\ldots.x_{10})$ is the discriminate function which have to be determined by the ANN to minimize the mapping error of the features $x_1, x_2,\ldots.x_{10}$ to the targets, the binary values 1 and 0 .These binary value represent the subjects having audiometric MHL in frequency range 2to 5KHz less than 30 dB, and greater than or equal to 30dB respectively. Thus normal hearing subjects are coded '1' and hearing impaired subjects by '0'.

III. Results

The amplitude level of the DPOAE response is depending on the intensity, frequency separation or ratio, and level difference between the tones. The variation of DPOAE level with various stimulus levels for two different frequencies, collected from 6 months old infant with normal hearing is shown in Fig.4. In this graph the emission gradually exceeds the noise floor as the intensity of the primary tones increases. The stimulus increases from 20 to 60 dB, but emission at low intensity levels are difficult to distinguish from the noise floor. At high intensity levels, emissions grow to 15 to 25 dB above noise floor.

Table I gives the DPOAE data of 28 year old female subject with sensorineural hearing loss (left ear) and normal right ear. The result of data analysis shows that the high frequency DP response of the left ear is poorer when compared with that of right ear.

In pure tone analysis behavioral threshold increased significantly with age at and above 3 KHz. The DPOAE amplitude decreased with increasing age at all frequencies. The outcome of analysis for ears is based on 76 subjects for whom both ears are tested; the mean behavioral thresholds are lower in right ear than in left ears for mid frequencies. However the corresponding DPOAE amplitudes did not show any clear difference between right and left ears.

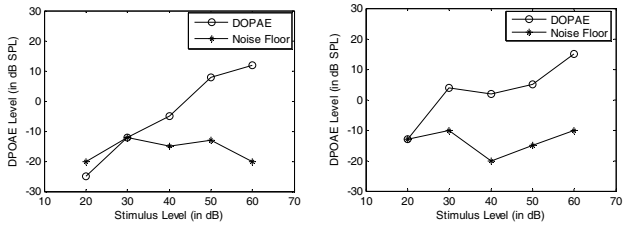

Fig. 4 Variation of DPOAE response level with respect to stimulus level for two different frequencies (a) f2=2KHz and (b) f2=4KHz

Table 1 A sample DPOAE data and Noise floor data

f2 KHz	L1 dB	L2 dB	Left Ear			Right Ear		
			DP dB	NF dB	SNR	DP dB	NF dB	SNR
2	65	55	-4	-17	21	-2	-18	16
3	65	55	-4	-2	16	8	-19	26
4	65	55	-9	-20	11	3	-20	23
5	65	55	-20	-20	0	-3	-20	17

The behavioral thresholds are significantly lower (i.e., better) for women than for men at all frequencies and DPOAE levels are greater for women particularly for frequencies above about 2.5 KHz. DPOAE is a potential tool to find subjects suffering from the noise induced hearing loss, the influence of ototoxic drugs to hearing and cochlear disorders.

An ANN model was trained and applied to classify the normal and pathologic ear using DPOAE response features. For training set 64 normal and 14 pathologic ear data and test set 50 normal and 24 pathologic data were used. The following measures were used to access the performance of classifier i.e. sensitivity, specificity [8] and receiver operating characteristic (ROC) [11]. In this work, ROC points are generated from single trained ANN by systematically varying threshold value for output node Fig.5shows ROC of this ANN model. The ROC, it shows the tradeoff between sensitivity and specificity. The curve closer to left hand border and then the top border of ROC space and away from the 45-degree diagonal of ROC space, i.e. the more accurate the test and approximate area under the curve is more than 80% of ROC space and classifier accuracy is 90.54%.The proposed ANN algorithm is implemented in Matlab.

IV. Conclusions

The ANN classifier transformed a vector of 10 features representing one subjects, into single output. The result

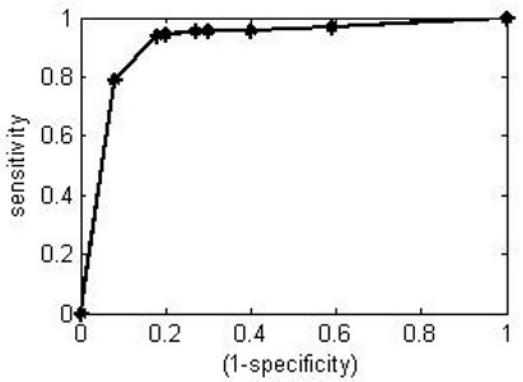

Fig. 5 Receiver operating characteristic of ANN model

concludes that it is possible to classify the hearing subject with the help of 3 layer network driven by BPA. The result shows that the proposed method is effective for classification of hearing subjects with mean accuracy of 90.54%. The ANN system indicates that the results are comparable to human intervention with substantial reduction of time and resources. DPOAE testing is simple, objective and non invasive diagnostic tool in the evaluation of hearing problems and hearing screening.

Detection of Significant Biclusters in Gene Expression Data using Reactive Greedy Randomized Adaptive Search Algorithm

Smitha Dharan[1] and Achuthsankar S. Nair[1]

[1]Centre for Bioinformatics, University of Kerala, Thiruvananthapuram, India

Abstract — **In microarray gene expression data, a bicluster is a subset of genes which exhibit similar expression patterns along a subset of conditions. Each bicluster is represented as a tightly co-regulated submatrix of the gene expression matrix. One of the most popular measures to evaluate the quality of a bicluster is the mean squared residue score. Our approach aims to detect significant biclusters from a large microarray dataset through a metaheuristic algorithm called reactive greedy randomized adaptive search procedure (R-GRASP). The method finds biclusters by starting from small tightly co-regulated bicluster seeds and iteratively adds more genes and conditions to it while keeping the mean squared residue score below a predetermined threshold. In R-GRASP, the parameter that defines the blend of greediness and randomness is self adjustable depending on the quality of solutions found previously. We performed statistical validation of the biclusters obtained through p-value calculation and evaluated the results against the results of basic GRASP and as well as with the classic work of Cheng and Church. The experimental results on the Yeast gene expression data indicate that the Reactive GRASP outperforms the basic GRASP and the Cheng and Church approach.**

Keywords — **Gene expression, Biclustering, Mean squared residue score, Metaheuristics, Greedy randomized adaptive search procedure.**

I. Introduction

DNA microarrays have been extensively used for measuring the expression levels of thousands of genes in a genome simultaneously. Gene expression data is typically arranged as an *m x n* data matrix, with rows corresponding to genes and columns corresponding to experimental conditions. The $(m, n)^{th}$ entry of the gene expression matrix represents the expression level of the gene corresponding to row *m* under the specific condition corresponding to column *n.* Cluster analysis plays an important role in the microarray data analysis through the grouping of genes into subsets with similar expression patterns or similar function. However, clustering has its limitations. Mainly, clustering works on the assumption that related genes behave similarly across all measured conditions. But a general understanding of cellular processes expects subsets of genes to be co-regulated and co-expressed only under certain experimental conditions, but behaves almost independently under other conditions [1]. In order to overcome the above shortcoming of clustering, the concept of biclustering is applied to gene expression data.

Biclustering was first introduced by Hartigan [2] and was named as 'direct clustering'. It performs simultaneous row column clustering. Cheng and Church [3] were the first to apply it to gene expression data. In gene expression data, a bicluster is a subset of genes exhibiting a consistent pattern over a subset of conditions. In [3], Cheng and Church proposed a similarity score called *mean squared residue score* as a measure of coherence of the rows and columns in the bicluster. The lower the score, stronger the coherence exhibited by the bicluster, and better is the quality of the bicluster. However, from a biological point of view, the interest resides in biclusters with subset of genes showing similar behavior and not with similar values. Hence the method aims at finding large and maximal biclusters with mean squared residue score below a certain threshold, δ, and the biclusters thus obtained are called δ-biclusters. The value of δ has to be estimated in advance, and it is different for every dataset [4].

In this work, we address the biclustering problem using a metaheuristic technique called *Reactive Greedy Randomized Adaptive Search Procedure* (R-GRASP) which is a variant of *Greedy Randomized Adaptive Search Procedure* (GRASP) [5, 6]. The algorithm makes use of *mean squared residue score* as the cost function to evaluate the quality of the obtained biclusters. We performed statistical validation of the biclusters obtained through p-value calculation and the results are compared against the classic work of Cheng and Church and also with our own work based on basic GRASP [7].

II. Materials and methods

A. Biclustering

A gene expression matrix is an *m x n* matrix, V, whose rows represent the genes, columns the experimental conditions and an element V_{ij} is a real number that represent the expression level of gene i under experimental condition j. Each row corresponds to the expression levels of a particular gene over all *n* experimental conditions and each column corresponds to the expression levels of *m* genes under a specific experimental condition. Fig. 1(a) shows the profile of a sample gene expression matrix where the experimental

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 631–634, 2009
www.springerlink.com

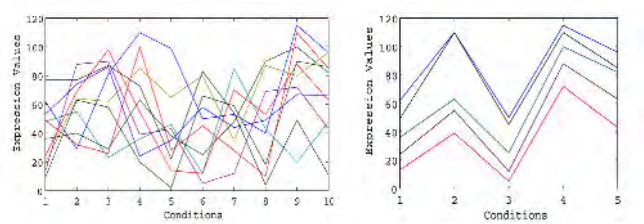
conditions are represented in the x-axis and the gene expression values are represented in the y-axis. It consists of ten genes and ten experimental conditions. Fig. 1(b) shows the profile of an embedded bicluster containing only five genes and five conditions.

Let G = {g_1, g_2 …, g_m} and C = {c_1, c_2,….., c_n} represent a set of genes and a set of experimental conditions involved in a gene expression matrix, respectively. A bicluster is defined to be a subset of genes that exhibit similar behavior under a subset of experimental conditions, and vice versa. Thus, in the gene expression matrix, a bicluster will appear as a sub matrix of it and represented as a pair A = (I, J) or simply as A_{IJ}, where I ⊆ G and J ⊆ C. The rows and columns of the bicluster need not be contiguous as in the expression matrix.

A group of genes are said to be coherent if their level of expression reacts in parallel or correlates across a set of conditions. Similarly, a set of conditions may also have coherent levels of expression across a set of genes. The degree of coherence of a bicluster is measured using the concept of *mean squared residue score, HScore*, which represents the variance of a particular subset of genes under a particular subset of conditions with respect to the coherence. In [3], Cheng and Church defined the mean squared residue score as follows: It is defined for bicluster A_{IJ} as the sum of the squared residues. R (a_{ij}), the residue of an element a_{ij} in the bicluster $A_{IJ,}$ i ∈ I and j ∈ J, is a measure of how well the element fits into that bicluster. It is defined to be:

$$R(a_{ij}) = a_{ij} - a_{Ij} - a_{iJ} + a_{IJ} \tag{1}$$

Now, *HScore* is defined as in (2):



$$HScore = \frac{\sum_{i\in I, j\in J} (R(a_{ij}))^2}{|I| * |J|} \tag{2}$$

where $a_{Ij} = \frac{\sum_{i\in I} a_{ij}}{|I|}$ is the column mean of column j

$a_{iJ} = \frac{\sum_{j\in J} a_{ij}}{|J|}$ is the row mean of row i

$a_{IJ} = \frac{\sum_{i\in I, j\in J} a_{ij}}{|I| * |J|}$ is the mean of bicluster A_{IJ}.

A bicluster is defined to be a δ-bicluster if *HScore (I, J)* ≤ δ, for some δ ≥ 0, where δ is the maximum acceptable mean squared residue. The value of δ has to be estimated in advance, and it is different for every dataset [4]. The *HScore* gives an indication of how the data is correlated in the sub matrix - whether it has some coherence or is random. A matrix of equally spread random values over a range [a, b] has an expected *HScore* of $(b-a)^2/12$ and it is independent of the size of the matrix. A high *HScore* indicates that the data is uncorrelated and a low *HScore* means that there is correlation in the matrix.

(a) (b)

Fig 1. (a) Profile of gene expression data in Table 1. (b) profile of an embedded bicluster.

B. R-GRASP based Biclustering

The bicluster problem is NP-hard as proven by Cheng and Church (2000) [3]. Thus no polynomial time algorithm exists and they might require exponential computation time in the worst-case. In this work, a heuristics based method is adopted for finding the δ-biclusters in reasonable time. The problem is formulated as an optimization problem which aims at minimizing the *HScore*. The algorithm has two major phases. In the first phase, an initial set of seed biclusters are generated. The second is the heuristics based seed growing phase. The R-GRASP metaheuristics, a variant of the GRASP metaheuristics, is used in this phase to refine and enlarge the seeds by adding more rows and columns until their *HScore* reaches a certain predetermined threshold.

Seed generation: A good seed of a possible bicluster is a tightly co-regulated small bicluster whose *HScore* has reached the requirement but the volume may not be maximal. The simplest way to generate quality bicluster seeds is to perform standard one-dimensional k-means clustering on both rows and columns of the expression matrix separately and then combine them to generate different seeds [8, 9]. Finally, the *HScore* of all submatrices are calculated and those having *HScore* less than a threshold value are selected as the seeds.

Seed growing based on R-GRASP: GRASP is a metaheuristic technique, in which each iteration is made up of a construction phase , where a randomized greedy solution is constructed, and a local search phase which starts at the constructed solution. It applies iterative improvement until a locally optimal solution is found. Seed growing is implemented as a two step procedure. Initially, the GRASP iterations are performed over the seed bicluster to enlarge it

column wise and during the second step, another set of GRASP iterations add more rows while keeping the *HScore* below a predetermined threshold.

During the construction phase of each GRASP iteration a set of candidate elements, elements that can be added to the current partial solution without destroying the feasibility are formed. Then a restricted candidate list (RCL) is made from the candidate list according to a greedy evaluation function as shown in (3). The evaluation of the candidate elements by this function leads to the selection of only high quality elements from the candidate list to RCL. i.e. those whose incorporation to the current partial solution results in the smallest incremental costs. The element to be incorporated to the partial solution is randomly selected from those in the RCL. Once the selected element is incorporated to the partial solution, the candidate list is updated and the incremental costs are reevaluated.

$$\text{RCL} \leftarrow \{ s \in \text{C or G} \mid H(\text{Solution} \cup s) \leq \text{Smin} + \alpha(\text{Smax} - \text{Smin})\} \quad \ldots (3)$$

where

$$\text{Smin} \leftarrow \min \{H(\text{Solution} \cup t) \mid \forall\ t \in \text{C or G}\}$$

$$\text{Smax} \leftarrow \max \{H(\text{Solution} \cup t) \mid \forall\ t \in \text{C or G}\}$$

C is the candidate list of conditions
G is the candidate list of genes
H is *HScore*, the cost function to be minimized
α is a threshold parameter, $\alpha \in [0..1]$

The quality of elements in RCL is decided by a threshold parameter $\alpha \in [0..1]$. Since in the case of a minimization problem, $\alpha = 1$ corresponds to pure random construction, as $\alpha \rightarrow 0$; the algorithm behaves more or less like greedy algorithms. Thus the parameter 'α' controls the amount of greediness and randomness in the algorithm. In basic GRASP implementation [7], the same α is used along all iterations and its value is usually determined through experimentation. But in [10], Prais and Ribeiro showed that using a single fixed value for α often hinders finding a high quality solution, which eventually could be found if another value was used. Hence they proposed an extension to GRASP called Reactive GRASP (R-GRASP), in which the parameter α is not fixed, but instead is selected at each iteration from a discrete set of possible values. The solution values used along the previous iterations serve as a guide for the selection process.

During each iteration the value of α is selected from a discrete set of possible values, say $R = \{\alpha_1, \ldots, \alpha_m\}$. Let p_i be the selection probability associated with the choice of α_i, for $i = 1, \ldots, m$. Initially all p_i's are made equal to 1/m. The selection probabilities are periodically reevaluated using information collected during the search. After, each GRASP iteration, with a particular α_i, the difference in the current solution value and the value of the solution obtained in the previous iteration is calculated. Let A_i be the average value of such differences obtained taking $\alpha = \alpha_i$ in the construction phase. The probability distribution is updated after each GRASP iteration by taking $p_i = q_i / \sum_{j=1}^{m} q_j$, with $q_i = 1/A_i$ for $i = 1, \ldots, m$. The value of q_i will be larger for values of $\alpha = \alpha_i$ leading to the best solutions on the average. Larger values of q_i correspond to more suitable values for the parameter α. The probabilities associated with these more appropriate values will then increase when they are reevaluated.

The solution constructed during the construction phase is not necessarily optimal; hence local search is performed over it for further improvements. A first improving local search strategy is adopted for implementation of local search. It considers the neighborhood of the current partial solution and accepts further moves if inclusion of a new row/column improves the current partial solution.

Significance evaluation: The p-values of the biclusters obtained are calculated according to the known classification of genes as follows: suppose prior knowledge classifies m genes into k classes, $C_1, C_2, C_3, \ldots, C_K$. Let B be a bicluster with g genes, out of which g_j belong to class C_j. The *p-value* of B, assuming the most abundant class for B is C_i, is calculated as

$$p(B) = \sum_{k=g_i}^{g} \frac{\binom{|C_i|}{C_k}\binom{m-|C_i|}{C_{g-k}}}{\binom{m}{C_g}} \quad (4)$$

That is, the *p-value* corresponds to the probability of obtaining at least g_i elements of class C_i in a random set of size g.

III. Results

A. Description of the dataset

The proposed biclustering algorithm is implemented in Matlab and tested on the Yeast Saccharomyces Cerevisiae cell cycle expression dataset. The dataset is taken from *http://arep.med.harvard.edu/biclustering* and is based on-Tavazoie et al. [11]. It is a collection of 2884 genes and 17 experimental conditions, having 34 null entries with -1 indicating the missing values. All entries are integers lying in the range 0 to 595. The value of δ is used as an upper limit of allowable dissimilarity among genes and conditions. A higher δ is indicative of diminishing homogenity. Hence in our approach we used a value of 200 for δ.

B. Biclustering using R-GRASP

In R-GRASP, the RCL parameter α is self adjustable based on the quality of solutions found previously. The selection probabilities are calculated accordingly and depending on this, the value of α is selected from a discrete set of possible range [0..1]. In order to ensure the quality of solutions, we have completely eliminated the extreme values. Hence in our implementation of R-GRASP, we have used ten numbers in the range [0.25..0.65]. Since the solution generated by the construction phase is not optimal, local search is performed on these to further improve them.

C. Statistical validation using prior knowledge

For statistical validation, we used the 30 known categories of Yeast genes reported by Tavazoie et al [11]. The p-value of a bicluster signifies how well they match with the known gene annotation. A smaller p-value close to zero is indicative of better match. For a statistical comparison of the biclusters obtained with that of Cheng and church and basic GRASP, the correspondence plot proposed by Tanay et al. [12]. In the plot, the area under the curve shows the approximate degree of statistical significance of the biclusters used to draw the curve [13]. Fig. 2 presents the correspondence plot. It shows the biclusters generated by the R-GRASP tend to be more significant than the basic GRASP and Cheng and Church (CC) approach.

IV. Conclutions

In this paper, the biclustering problem is approached with a bottom up strategy where a tightly co-regulated bicluster seeds consisting of a minimal set of rows and columns are iteratively modified, usually enlarged, until no local improvement is possible anymore. We have proposed a metaheuristic technique- R-GRASP– to enlarge the seeds by adding more rows and columns to increase their size while keeping their mean squared residue below a predetermined threshold. In R-GRASP, the basic parameter that defines the quality of elements in the restricted candidate list is self adjustable depending on the quality of solutions obtained previously. Thus it doesn't require calibration efforts and looks more robust in detecting significant biclusters. We performed statistical validation of the biclusters obtained through p-value calculation and evaluated the results against the results of basic GRASP and as well as with the classic work of Cheng and Church. The results on the Yeast gene expression data indicate that R-GRASP outperforms the others.

Abstract — **As for artificial hearts generally used in short term, thrombus formation is still a serious issue. To realize effective medical treatment for patients with the artificial heart without increase of anticoagulant agent, it is essential to detect and even predict thrombus formations. The purpose of this study is to develop a noninvasive thrombus detection system for artificial hearts.**

Considering the difference from the optical characteristics of both thrombus and blood, we have developed a thrombus detection system with a near-infrared (NIR) laser and a photomultiplier.

This developed system is composed of a light-emitting device with NIR laser (805 nm), a light receiver with photomultiplier for high measurement accuracy, and a thrombus detection algorithm based on probability statistics. This system is generally attached outside the tubing of the extracorporeal circuit.

To confirm the effectiveness of this system, we performed a thrombus detection test by using this system (light intensity of 2 mW and light path of 6 mm) in the mock circulation loop consisting of the reservoir, the Tygon tubing, and a centrifugal blood pump with hydrodynamic bearings. This circulation loop was filled with sheep whole blood including acid-citrate-dextrose solution. When we intentionally generated thrombus by adjusting activated coagulation time with CaCl2, this thrombus detection system continuously detected floating thrombus, which seemed to be generated around the pump impeller and be moved from there. Moreover this system might have indicated prediction associated with a blood condition conductive to thrombus formation before the thrombus formation was supposed to be generated around the impeller.

In conclusion, we have confirmed the developed thrombus detection system has enough performance to detect floating thrombus and may have the possibility to detect early stages of thrombus formation in the artificial hearts.

Keywords — **Thrombus Detection, NIR Laser diode, Photomultiplier, Artificial heart**

I. Introduction

The development of implantable artificial hearts has made great strides over the past few years [1–3]. However, artificial hearts generally used in extracorporeal circulation still has a serious issue of thrombus formation. To realize effective medical treatment for patients with an artificial heart without increase of anticoagulant agent like heparin, it is essential to detect and even predict thrombus formations.

Noninvasive methods of detecting thrombus in the flowing blood using ultrasound or light have been reported by several researchers [4–6]. Although the method with ultrasound has the ability to detect emboli through material which the light can not go through, the medical device with this method imposes the skill on medical staff and also restrict the patients' movements during the measurement. Moreover, the devices are expensive.

The purpose of this research is to develop a noninvasive thrombus detection system with near-Infrared (NIR) laser diode and photomultiplier for artificial hearts.

Since we apply photomultiplier as the photodetector of the thrombus detection system, the thrombus detection system would have higher sensitivity than the existing method with photodiode [5–6]. Therefore, the higher sensitivity impairs the light emitting power of the thrombus detection system. This system realizes safer measurement during long-term use. Moreover, the thrombus detection system with this sensitivity would have ability to make predictions associated with a blood condition conducive to thrombus formation.

II. Materials and Methods

A. Principle of the thrombus detection method

The red blood cells (RBCs) determine the optical characteristic of blood such as absorption and scattering. The Lambert-Beer law based on the concentration of a solution is usually applied to analyze the optical characteristics of liquid. However, it has been reported that whole blood does not obey the Lambert-Beer law, since there are influences of light scattering by the RBC and reflection between RBCs and plasma. According to the Twersky's theory, total optical density (*O.D.*) for whole blood is a sum of the *O.D.* of linear absorbance and the *O.D.* of scattering [7–8]. Total optical density of blood ($O.D._{total}$) is expressed as follows:

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 635–638, 2009
www.springerlink.com

$$\begin{aligned} O.D._{total} &= \log_{10}\left(\frac{I_0}{I}\right) \\ &= O.D._{absorb} + O.D._{scatter} \\ &= kDHct - \log_{10}[(1-q)10^{-b} + q] \end{aligned} \quad (1)$$

where I and I_0 are transmitted and incident light intensities respectively; k is absorption coefficient; Hct is hematocrit; D is optical path length; $b = a*D*Hct*(1-Hct)$; a is a constant (<1) that depends on particle size, wavelength, refractive index of particles, and refractive index of suspending medium for plasma; and q is a constant (<1) that depends on particle size, wavelength, refractive index of particles, refractive index of suspending medium for plasma, and the angle of photo detector aperture.

A thrombus differs from the RBCs in the hemoglobin contents, the particle shapes, the particle sizes, and the reflective index.

If the minute quantities of thrombus are contained in a light path, the optical characteristic of the blood will be changed as compared with the case where RBCs are distributed uniformly.

By using the above characteristics, when the NIR laser is irradiated at the blood flowing inside of a cannula and the intensity of the transmitted (forward-scattered) light is observed, it is possible to detect the floating thrombus in the blood.

B. Measurement system

Figure 1 shows a developed thrombus detection system with NIR laser diode and photomultiplier. The NIR laser used as light source has the wavelength of 805 nm, which is known as the isosbestic point. Since the optical absorption ratio of Hb equals to the ratio of HbO2 at the wavelength of 805 nm, this system can eliminate the influence of the oxidization state of the blood such as the difference between venous and arterial blood, the patient's motion, etc.

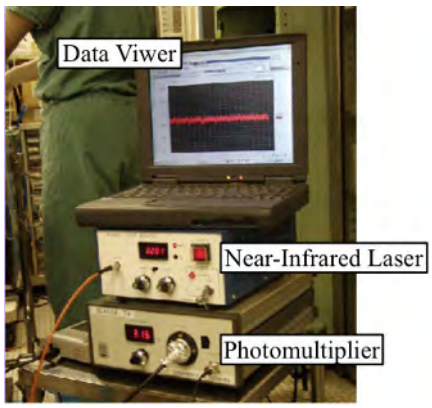

Fig. 1 Photograph of the developed thrombus detection system with a NIR laser and a photomultiplier

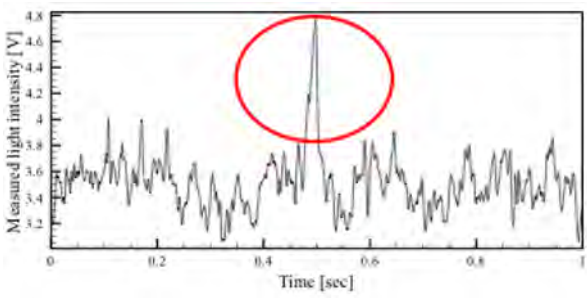

Fig. 2 Light signals of floating thrombus

A photomultiplier with high sensitivity was adopted as the photodetector of the thrombus detection system. Therefore, this system can realize high precision measurement and the noninvasive measurement can be also realized with a low powered laser. The transmitted light signals from the thrombus detection system were recorded by using the computer with 14-bit resolution analog-to-digital converter.

C. Data analysis method

Figure 2 shows transmitted light signals in the case of detecting thrombus by using the developed thrombus detection system. Since the thrombus detection signals are high intensity, the thrombus can be detected by comparison with a threshold value. However, since there are various disturbances such as medications, motions, uneven pulsatile flow of blood and so on, it is too difficult to set the threshold of floating thrombus detection to a constant value, and the credibility of the constant threshold will be low. To solve this problem, it is necessary to develop the method of determining the threshold of the thrombus detection reflecting the ever-changing condition of blood. So, in this research, statistical hypothesis testing is applied to the threshold determination method. As the method of distinguishing the unusual value included in an arbitrary sample (set of data), there is a statistical method called statistical hypothesis testing. The statistical characteristic of the sample $\{x_i\}$ $(i=1, 2, \ldots, n)$ which measured a certain physical value is given by a sample average μ and sample standard deviation σ.

$$\mu = \frac{1}{n}\sum_{i=1}^{n} x_i \quad (2)$$

$$\sigma = \frac{1}{n-1}\sum_{i=1}^{n} (x_i - \mu)^2 \quad (3)$$

This sample x_i shall follow a normal distribution. When a null hypothesis (H_0: $x_k \neq$ unusual value) is made for the *k-th*

data x_k, if the x_k fills a conditional equation (4), this null hypothesis will be rejected with the significant level α.

$$\left|\frac{x_k-\mu}{\sigma}\right| > K_{\frac{\alpha}{2}} \tag{4}$$

$K_{\alpha/2}$ is a constant computed from the significant level α and the standard normal distribution. When sufficient quantity of the measurement data to normal blood is used as a sample, the signals by RBCs follow a normal distribution. On the other hand, when the thrombus is contained in the blood sample of a measurement domain, the abnormal value from which it separates from the distribution of the signal by RBCs based on the difference in the optical characteristic will be outputted. This statistical hypothesis testing is applied to time-series data *y(t)* by which real-time measurement is carried out by the sampling frequency *f* Hz. First, the sample of size *Wf+1* is drawn from the time-series data by using the moving time window of width *W* sec.

$$x_i = \{y((T-W)f), y((T-W)f-1), \cdots, y(T-1), y(T)\} \tag{5}$$
$$i = 1, \quad 2, \quad \cdots, \quad Wf+1$$

The fluctuation of the baseline of *y(t)* by disturbance, such as medication and a pulse, is large. Thus the characteristics of data may not be correctly reflected to the statistics values depending on how to take a moving time window. Then, in order to remove the influence of the baseline fluctuation, the absolute value of the difference of *y(t)* will be used as a sample.

$$D(t) = |y(t) - y(t-1)| \tag{6}$$

At the arbitrary time $t=T$, the deviation $\mu_d(t)$ and standard deviation $\sigma_d(t)$ of the sample $D(t)$ are given as follows:

$$\mu_d(T) = \frac{1}{Wf}\sum_{t=T-Wf}^{T} D(t) = \frac{1}{Wf}\sum_{t=T-Wf}^{T}\{|x(t)-x(t-1)|\} \tag{7}$$

$$\begin{aligned}\sigma_d(T) &= \frac{1}{Wf-1}\sum_{t=T-Wf}^{T}(D(t)-\mu_d(T))^2 \\ &= \frac{1}{Wf-1}\sum_{t=T-Wf}^{T}(|x(t)-x(t-1)|-\mu_d(T))^2\end{aligned} \tag{8}$$

The conditional equation (9) of floating thrombus detection is obtained from equation (4).

$$\left|\frac{D(t)-\mu_d(T)}{\sigma_d(T)}\right| > K_{\frac{\alpha}{2}} \tag{9}$$

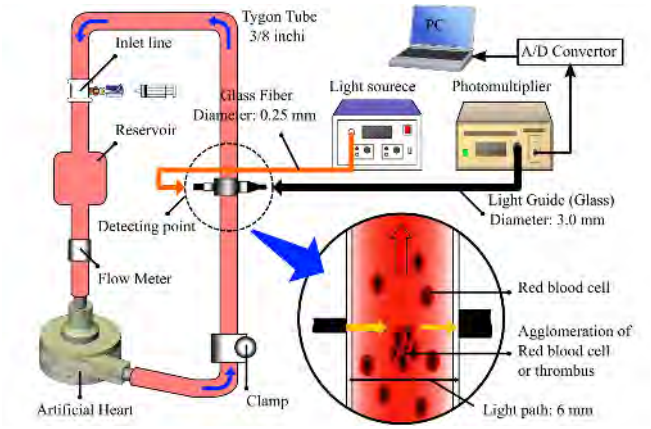

Fig. 3 Mock circulatory loop for the thrombus detection test

If the arbitrary significance level α is determined, it will become possible to solve for the value included in the sample by counting the number of values of *y(t)* that satisfy the conditional equation (9).

We defined the signals separated by this conditional expression (9) as Laser-detected Micro-Embolic Signals (LMES).

D. Thrombus detection test

In order to confirm the validity of the developed system, a thrombus detection test was demonstrated in a mock circulatory loop with sheep blood. The mock circulatory loop was constructed as shown in Figure 3. This mock circulatory loop consisted of a reservoir bag, Tygon tubing, and a centrifugal pump with hydrodynamic bearings (the National Institute of Advanced Science and Technology, Tsukuba, Japan)[9]. The mock circulatory loop was filled with sheep blood as the working fluid. The hematocrit of the blood was approximately 24 %. The thrombus detection system was attached on the surface of the Tygon tubing. The acid-citrate-dextrose solution was previously injected into the sheep blood. The pump flow was set to 5 L/min and the pump speed was set to about 1900 rpm. Then pressure differences across the pump were 100 mmHg. To intentionally generate thrombus formation in the mock circulatory, we adjusted activated coagulation time (ACT) with CaCl2. ACT is an index showing the coagulation property of blood. ACT is shown in the range from 0 sec to 1000 sec, as the time showing that the blood congeals. In this experiment, ACT was used to compare with LMES. The setting conditions of the thrombus detection system were as follows:

- Light emitting power was set at 2mW;
- Light path length between a light-emitting point and a light-receiving point was set at 6 mm;

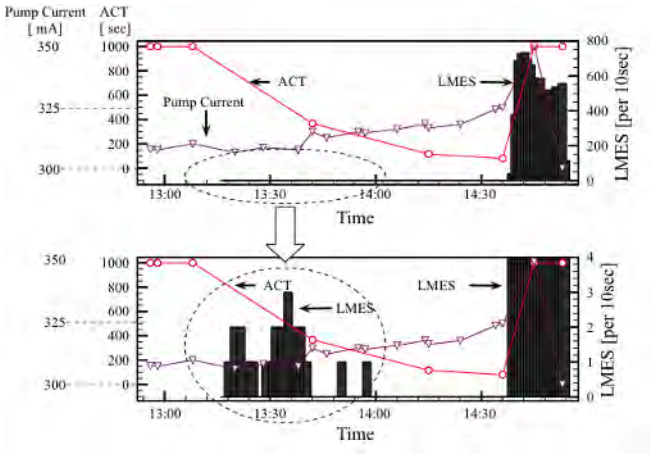

Fig. 4 Result of the thrombus detection test

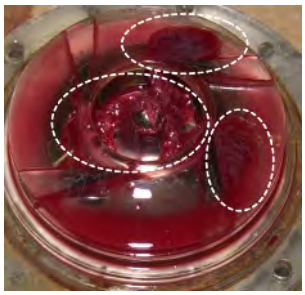

Fig. 5 Thrombus formation around the impeller of the pump in the oval areas

- Sampling frequency was set at 10 kHz;
- Light-trasmitting path was Silica optical fiber (Diameter: 0.25 mm, Length: 3 m);
- Light-receiving path was light guide with glass fiber (Diameter: 3 mm, Length: 2.4 m).

III. Result & Discussion

Figure 4 shows the time-series data which are LMES, ACT, and pump current. The LMES had hardly been detected during ACT of more than 100 sec. After ACT was less than 100, the number of LMES increased from 0 per minute to 80 per minute. And then the number was more than 400 per minute within 1 minute. At the same time, ACT was increased drastically. This would mean that the blood-coagulating factor was used up to generate thrombus in the circulatory loop. After this experiment finished, we checked the impeller and confirmed thrombus formation around this impeller shown in Figure 5. Since there was no thrombus around the reservoir, the Tygon tubing, we think that this thrombus detection system continuously detected floating thrombus, which seemed to originate around the pump impeller and be moved from there. Moreover, this detection system detected a few of the LMES during the period from 13:30 to 14:00. We think that this would indicate prediction associated with a blood condition conducive to thrombus formation before the thrombus formation was supposed to be generated around the impeller because the pump current started increasing after 13:40.

IV. Conclusions

In the present study, we have developed the thrombus detection system with NIR laser and photomultiplier. As a result, we have confirmed the developed thrombus detection system has enough performance to detect floating thrombus and shows the possibility to detect early stages of thrombus formation in the artificial hearts.

Using Saliency Features for Graphcut Segmentation of Perfusion Kidney Images

Dwarikanath Mahapatra and Ying Sun

Department of Electrical and Computer Engineering, National University of Singapore

Abstract — **In this paper we propose a method that uses visual saliency information to segment dynamic kidney perfusion data. Segmenting dynamic data requires the use of temporal information available due to the flow of contrast agent. It is found that although the intensity of the kidney changes due to flow of contrast agent, its saliency profile remains nearly constant. We exploit this characteristic to account for regional information, which we use in a graph cut formulation for segmentation. Our tests on real patient datasets show that our algorithm compares well with other approaches for segmenting dynamic data.**

Keywords — **perfusion MRI, saliency, temporal information, graph cuts.**

I. Introduction

Isolating the kidney from its surrounding organs and tissues is an important step in assessing renal functions. In dynamic perfusion data, intensity at a voxel changes as contrast agent flows through an organ thus providing information on blood flow in different tissues. This temporal information helps in identifying and segmenting organs of interest. Segmentation is a process where image elements representing the same object are grouped together. There have been many useful algorithms for image segmentation such as *snakes* [1], active contours [2] and *geodesic active contours* [3]. Graph cut approaches have also proved to be popular [4].

The graph cut method allows us to find a globally optimal binary segmentation by combining regional and boundary properties in formulating an appropriate energy function. Graph cuts were used by Wu and Leahy in [5] for image segmentation where the image is divided into K optimal parts. Boykov and Jolly use graph cuts to segment an image into object and background and use it for 2D and 3D medical data [6]. Certain points in the image were identified as object and background by the user and information from these 'seed' points are used to classify other points as belonging to the object or the background. Manual selection of seed points allows for imposing hard constraints on the segmentation procedure and at the same time incorporate regional information.

Multidimensional dynamic data presents significant challenges for segmentation techniques. Each volume of data has to be quickly obtained over a short period of time, as a result of which the data sets have relatively low spatial resolution with strong partial volume effects. Many segmentation techniques can easily fail by "leaking" through a large number of weak object boundary segments. Boykov et al. [7] address the difficulties of segmenting dynamic data. In static image data, the regional properties are denoted by intensity histograms for all regions of interest (object and background). Applying these methods to dynamic data poses certain difficulties. Each voxel has an n-dimensional intensity vector instead of a single gray-scale value and it becomes difficult to handle histograms when the dimensionality of data is greater than 4 or 5. To overcome such a difficulty the method in [7] uses temporal Markov model for intensity data. To facilitate calculations it is assumed that the intensity vector is a series of independent observations. However such an assumption does not properly exploit the information present in the time varying intensity data.

We propose a method that uses visual saliency information to facilitate distinguishing between object and background regions. Visual saliency is a concept that states that certain regions in an image are more attractive than their neighbor with respect to low level features. Thus we can say that the saliency value at a voxel (or pixel) is an indicator of its relevance. When the sequence of time series images of a patient are examined it is found that the saliency profile of the kidney region does not change with time even though we see significant intensity change due to flow of contrast agent. This is characteristic of the kidney region and gives us a basis to combine saliency and intensity information. In this paper we propose a method to use this information in a graph cut based formulation to achieve segmentation of the perfusion kidney images.

The rest of the paper is organized as follows: Section II gives a brief description of saliency followed by a short explanation of graph cuts in Section III. Section IV describes saliency and its usefulness in segmenting dynamic image data. Section V describes our experiments and the results and we conclude with Section VI.

II. Saliency

Saliency is a concept which states that there are regions in a scene that are more "attractive" than their neighbors

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 639–642, 2009
www.springerlink.com

and hence draw attention. Attention can be due to bottom-up cues or top-down influences. A saliency map of an image is a representation of the salient regions of the image. Saliency at a given location is determined primarily by the contrast between this location and its surroundings. The image formed on the fovea of the eye is the central object on which a person is focusing his attention resulting in a clear and sharp image. Regions surrounding the central object have a less clear representation on the retina. To simulate this biological mechanism, an image is represented as a Gaussian pyramid comprising of layers of subsampled and low-pass filtered images. The central representation of the image on the fovea is equivalent to the image at higher spatial scales, and the surrounding regions are obtained from the lower spatial scales. The contrast is thus the difference between these scales. Details of the method can be found in [8]

III. Proposed segmentation framework

A. Graph cuts

Graph cuts are a powerful optimization tool for binary labeling problems because of their ability to obtain a global minimum with a single cut of a graph. The pixels of an image, *P*, are represented as nodes in a graph and in case of binary segmentation problems there are two additional nodes called the source (object) node and the sink (background) node. Pairs of neighboring nodes are connected by a set of edges whose weights are determined by neighborhood information. It is the ability to incorporate both regional and boundary properties that makes graph cut optimization techniques very powerful. An example of the graph used for segmentation is shown in Fig. 1. Consider a neighborhood system in *P* which is represented by a set *N* of all unordered pairs *{p,q}* of neighboring pixels in *P*. Let *L* be the set of labels *{0,1}*, corresponding to kidney and background, respectively. Labeling is a mapping from *P* to *L* and we shall denote the set of labels by $\boldsymbol{f}=\{f_p : p \in P, f_p \in L\}$. Segmentation is achieved by minimizing an energy function that combines region and boundary properties of segments. This function is defined as follows

$$E(f) = \sum_{p \in P} D(f_p) + \sum_{\{p,q\} \in N} V(f_p, f_q) \quad (1)$$

where $D(f_p)$ measures how much assigning a label f_p to pixel *p* disagrees with the pixel intensity i_p. $V(f_p,f_q)$ which represents the penalty of the discontinuity between pixels p and q, incorporates neighborhood information. We shall now explain each of the terms in Eqn. 1.

B. Data Penalty term - $D(f_p)$

The data penalty or the regional term reflects how the intensity of pixel *p* fits into a given intensity model. We selected certain number of points belonging to the object and the background. Information from these points was used to build a model characteristic of the particular region (object or background). It was observed that the saliency profile of the kidney region remains the same even in the face of intensity change due to contrast enhancement and this information proves to be an effective tool to differentiate between kidney and the background. Using the selected seed points, our objective is to formulate a cost function that can clearly distinguish between object and background. A saliency based approach has also been used to register the perfusion image sequences [9].

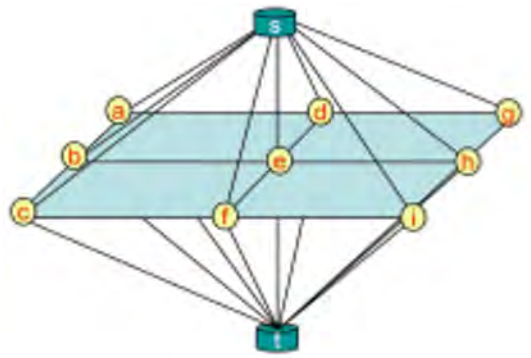

Fig 1. Graph used in image segmentation.

From the seed points belonging to the kidney region we observed that although the intensity of these points changes significantly due to flow of contrast agent, the saliency values remain very nearly the same. We thus define the data penalty term as follows

$$D(f_p) = \frac{\left(\sum_{j=1}^{n}(|\vec{s}_p - \vec{s}_j|) + \in\right) \times \left(\sum_{k=1}^{n}(|\vec{i}_p - \vec{i}_k|) + \in\right)}{n \times n}, \quad (2)$$

where s_p is the saliency value at pixel p and s_j is the saliency value of the j^{th} seed point corresponding to the object (or background), n is the number of seed points chosen for object)or background) . Similarly i_p and i_k are, respectively, the intensity values at pixel *p* and intensity of k^{th} seed point of object (or background). Since the intensity and saliency values of a pixel are vectors the magnitude in eqn. 2 denotes the ℓ_1 norm. Eqn. 2 is thus the product of the saliency and intensity costs.

When pixels belonging to the kidney region are plugged in with the values of the object seed points, the data penalty value is lower and the same is true when background pixels are plugged in with the corresponding parameters of background seed points. To prevent the entire data penalty term from going to zero due to any one value we introduce a small constant ε

C. Neighborhood term - $V(f_p, f_q)$

This term incorporates boundary properties of the image into the segmentation framework. It is a penalty for a discontinuity between p and q. V is large when pixels p and q are similar and V is close to zero when the two are very different. The penalty V can also decrease as a function of the distance between p and q. The penalty may be based on local intensity gradient, gradient direction or other criteria. For our experiments we set the neighborhood term as

$$V(f_p, f_q) = \exp\left(-\frac{(I_p - I_q)^2}{2\sigma^2}\right) \times \frac{1}{dist(p,q)} \quad (3)$$

where *dist(p,q)* is the Euclidean distance between p and q

This function penalizes a lot for discontinuities between pixels of similar intensities i.e. when $|I_p - I_q| < \sigma$. However if pixels are very different, i.e. $|I_p - I_q| > \sigma$, then the penalty is small.

IV. Experimental results

We tested our algorithm on 7 real patient datasets consisting of contrast-enhanced dynamic perfusion MR images of the kidney. The acquired volumes comprised of 40 slices and for each patient 41 volumes were acquired at different time instances.

For each dataset certain points were identified as belonging to the kidney and the background. These seed points have two uses. They provided us with information that is characteristic to the kidney and background, and helps in distinguishing one from the other. Intensity and saliency values of the corresponding points are used in determining the penalty value of each pixel from Eqn. 2 for each label. Besides, the seed points impose hard constraints for the segmentation process. Intensity values of neighboring pixels are used to determine the value of the smoothness term of the energy function given in Eqn. 3.

(a) (b) (c) (d) (e)

Fig 2. Segmentation results: (a)-(c) kidney at different stages of perfusion. (d) kidney segmented by method in [7]. (e) kidney segmented using our approach.

(a) (b) (c) (d) (e)

Fig 3. Segmentation results using an average image: (a)-(c) kidney at different stages of perfusion; (d) kidney segmented by method in [7]; (e) kidney segmented using our approach.

The neighborhood term is useful when the surrounding organs have intensity characteristics that are different from the organ of interest. In many of the datasets, the pre-contrast slices make it difficult to distinguish the kidney from neighboring organs. In such a scenario use of saliency information effectively uses the temporal information increasing the effectiveness of the smoothness term.

In Fig. 2 we show the results of our segmentation algorithm when applied to MR images of the kidney and the results obtained by the method in [7]. The method in [7] assumes Markovian property of the intensity values, i.e. the intensity of a pixel is dependent only on the intensity value at the previous time instant. Fig. 2 (a)-(c) shows slices corresponding to different stages of contrast enhancement and Fig. 2(d)-(e) show, respectively, the results by the approach in [7] and by our method. The segmented region in Fig. 2 (d) includes parts of the liver as well which is not seen by results using our method. This is a typical case of low contrast images for which the method in [7] is not very effective. On the other hand, our approach produces segmentation results that are as good as the one assuming Markovian relationship between intensity values at different time points.

The method in [7] uses negative log likelihood to determine the data penalty values which requires a model histogram for both the object and background. A robust model is possible only when we have a large number of seed points else the segmentation is inaccurate. The use of our penalty term gives accurate segmentation results even when the number of seed points are very few.

An average image of all acquired images shows the kidney having greater intensity. However this is not good enough for segmentation. Certain regions in the image can have noisy characteristics, i.e. regions where there is no flow of contrast agent seem bright, due to noise in the image acquisition process. Thus, in such a scenario use of intensity information alone will be misleading. Using saliency information helps us to avoid such pitfalls. The saliency maps that we get are robust to noise thus ensuring the accuracy of the data penalty values. In Fig 3 we show the results while using an average image. The inaccuracies are expected because of the sole use of intensity information in segmentation.

V. Conclusions

We have proposed a method that can exploit the temporal information present in dynamic contrast enhanced images for efficient segmentation. The saliency information that we use is an effective way to distinguish between the kidney and background in case of dynamic data. We tested our algorithm on real patient datasets and the results obtained were comparable to other methods (e.g. [7]) that deal with segmentation of dynamic data using graph cuts. In some cases where the data is noisy our method outperforms the above mentioned method. From our experiments we also conclude that using the average of the acquired images does not give good results and our approach is especially effective for noisy images.

Acknowledgment

We would like to thank Dr. Vivian Lee of the New York University Langone Medical Center for providing us with the datasets. The work was supported by NUS grant R-263-000-470-112.

Low Power Electrocardiogram QRS Detection in Real-Time

E. Zoghlami Ayari, R. Tielert and N. Wehn

Microelectronic Systems Design Research Group, Department of Electrical Engineering, University of Kaiserslautern, Germany

Abstract — **A real-time capable, low complexity QRS detection method based on the temporal cross-correlation is presented. Applying a high-resolution QRS template, the new method enables an acceptable under-sampling of the recorded ECG signal. High performance (100%) and standard deviations within the tolerance limits indicate that our method achieves a reliable and accurate QRS detection while reducing the overall energy consumption in the ECG system compared to the use of the classical temporal cross-correlation method.**

Keywords — **Low Power, low complexity, QRS detection, real-time, cross-correlation.**

I. Introduction

The QRS-complex is the dominant waveform within the electrocardiogram (ECG) that corresponds to the depolarization of the ventricles. Its duration, amplitude, and morphology provide much information about the current state of the heart. It is hence useful in diagnosing many cardiac disease states, but also in analyzing the psychological and physiological state of the body, e.g. stress and tiredness. Therefore, QRS detection is a prerequisite procedure in automated ECG signal processing and analysis. The necessity of an accurate and reliable QRS detection algorithm is of great importance. Numerous techniques have been developed for QRS detection. A good review of different techniques for QRS detection can be found in [1].

Energy saving is one of the most crucial requirements to be fulfilled while designing wearable, wireless, and battery-powered ECG systems. Energy in those systems is consumed by three main parts: signal acquisition and conditioning, data communication to a central node, and computational analysis of the signal for features extraction. Most of the existing QRS detection techniques use high sampling rates up to 1kHz [2]-[4], which increases the energy consumption of the analog to digital converter in the signal acquisition and conditioning part of the system.

A wide range of prototyped portable wireless ECG systems can be found in the literature. A mobile-based data acquisition system for real-time health monitoring is developed in [5]. The acquired data are transferred wirelessly in the unlicensed 2.4GHz ISM band to a local PC, or laptop, for storage and further processing. A platform of an ECG sensor conceived for heart patients with needs for home based monitoring is presented in [6]. After digitization, a continuous stream of ECG data are transmitted over IEEE 802.11 and displayed on a PC. The drawback of these systems is the high energy burden on the communication unity due to the transmission of the full signal at a minimum sampling frequency of 200Hz. This energy burden is alleviated in [7] using an on-system integrated wavelet data compression before transmission. However, even though the communication energy is reduced, the energy consumption in the sensing part of the system is still large because of the high sampling rate varying between 150 and 1200Hz.

With aspect of the computational energy consumption, the implementation of a QRS detection algorithm in such an environment requires besides accuracy and stability, low computational load. Whereas different QRS detection techniques show very high detection performance, their shortcoming is the high computational complexity [8], [9].

We propose in this work a low power real-time detection method of QRS-complexes in the ECG signal, which overcomes these limitations and minimizes all of the three parts of the energy consumption in the system. The detection method employs a self-adapting algorithm based on the cross correlation technique, and features the beneficial property of an acceptable under-sampling of the signal. A pre-defined high resolution template is cross-correlated with a dynamically adjustable data set of few samples estimating the location of the QRS complex. The time window of the sampling points is continuously improved after the extraction of the fiducial point.

This paper is organized as follows. Section 2 elaborates on the details of our proposed low power QRS detection method. Section 3 presents the detection results and delineation accuracy of the method. Finally, section 4 concludes the paper.

II. Methods

A. Background

Our QRS detection method is implemented for an ECG system which is dedicated for Ambient Assisted Training, i.e. assisted bicycle training, to optimize the training by monitoring the heart beats of the cyclists [10]. Therefore, normal beats are selected for the evaluation of our method. In this AmI system cyclists and bikes are equipped with a

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 643–646, 2009
www.springerlink.com

multiplicity of sensors such as an ECG sensor. The bikes are connected to each other and to a coach unit that executes the application, via a wireless network. Each cyclist has his own performance profile and training plan. Two scenarios are suggested, individual training and group training. In the individual training, the training ride has to be controlled in such a way that each cyclist meets his training plan as far as possible. The system enables intervention by the coach during the training, e.g. in cases of too high heart rates of the cyclists, or heart rates below a given threshold value for the obtained pedal power. The scenario of the group training concerns the optimization of the overall performance of the group. The bicycle group is controlled using the stored performance data as well as the actual sensor data, and the condition of the cyclists, so that a given distance must be passed in minimal time by one member of the group.

B. Low Power cross-correlation method for beat detection

The cross-correlation (CC) indicates the strength and direction of a linear relationship between two signals as a function of a time-lag applied to one of them. The CC computes the sum of the products of corresponding pairs of points of the two signals within a specified time window. The CC coefficient measures the degree of similarity between the two signals. The best known is the Pearson product-moment correlation coefficient r_{xy}, which is obtained by dividing the covariance of the two variables by the product of their standard deviations and is defined as:

$$r_{xy}(l) = \frac{\sum_{n=1}^{N}\left(x(n)-\bar{x}\right)\left(y(n+l)-\bar{y}\right)}{\sqrt{\sum_{n=1}^{N}\left(x(n)-\bar{x}\right)^2}\sqrt{\sum_{n=1}^{N}\left(y(n+l)-\bar{y}\right)^2}} \quad (1)$$

where $x(n)$ and $y(n)$ are the values of the two signals to be studied, respectively, at the nth sampling instant; $\bar{x}$ and $\bar{y}$ are their average values; l is the lag between the two signals, and N is the total number of samples.

In ECG signal processing, CC is by far the most widely used alignment technique for ECG records [11]. The ECG signal is matched to a predefined or averaged template. A CC coefficient sequence $r_{xy}(l)$ is computed between the template beat and the time-shifted ECG signal in a temporal window, and the position of the highest value is returned. If this value is greater than a predefined threshold, the lag corresponding to this value is chosen as the alignment point. Many works have successfully reported the use of CC as a means of automated beat detection. In [12] the CC was used for extrasystole rejection and location of fiducial points. Govrin et al. [13] adapted the algorithm in [12] to locate both the P waves and QRS-complexes using CC. In [14] the multi-component based CC approach is introduced, as opposed to a single template CC based approach, for an accurate beat detection. However, the use of the classical temporal CC in signal processing implies the need for the same total number of sampling points in both the analyzed beat and the reference template. Consequently, the ECG signal and the template have to be digitized at the same sampling rate. As the sampling frequency has to be at least higher than the Nyquist frequency, 200 samples are typically required for the QRS alignment at a sampling frequency of 1kHz [11]. This results in a high sensing energy consumption in the system. Moreover, the CC coefficient is typically computed at each sampling instant lag within the time window by shifting the incoming beat one sample point at a time. Thus, 200 computations of the CC coefficient are needed for the above mentioned case to detect the fiducial point, which increases the computational cost.

In order to overcome the drawbacks of the classical CC method regarding to energy consumption, we propose a new low power method based on the cross-correlation for beat detection. The idea of the method is to store the requisite information of the beat to be examined in a high-resolution template, and to reduce the sampling frequency in the recorded signal. The CC coefficient sequence is then computed between the under-sampled beat and a transformed template, which has the same total number of samples as the examined beat. The transformed template is performed in function of the examined beat, the stored high-resolution template, and an estimated lag. Fig. 1 illustrates an example of the low power CC method.

After sampling the ECG signal $y(n)$ within the specified time interval at a lower sampling rate f_S than the typical sampling frequency F_S (>200Hz), an appropriate transformed template is generated. For this aim, time values t_y of the sampled data are shifted by the estimated lag (l=320ms in Fig. 1) building time values of the transformed template t_{x*}, and corresponding data are extracted from the high-resolution template forming the transformed template's data $x*(n)$. If a t_{x*} value doesn't belong to the time range $t_x(n)$, a value of 0 is associated to the corresponding $x*$. Otherwise, an interpolation calculation is made to extract the appropriate data x_{Interp} from the high-resolution template.

$$t_{x*} = t_y - l \quad (2)$$

$$x*[ty-l] = \begin{cases} x_{Interp}[ty-l], & if\,(ty-l) \in t_x[ms] \\ 0 & \end{cases} \quad (3)$$

Our method allows for an acceptable under-sampling of the signal, since the used high-resolution template includes all the waveform information. Consequently, not only the signal sensing energy in our method is reduced by a factor of F_S/f_S compared to the classical cross-correlation method, but also the computational energy by the same factor, since the computational complexity of the algorithm is directly proportional to the energy consumed for its computation.

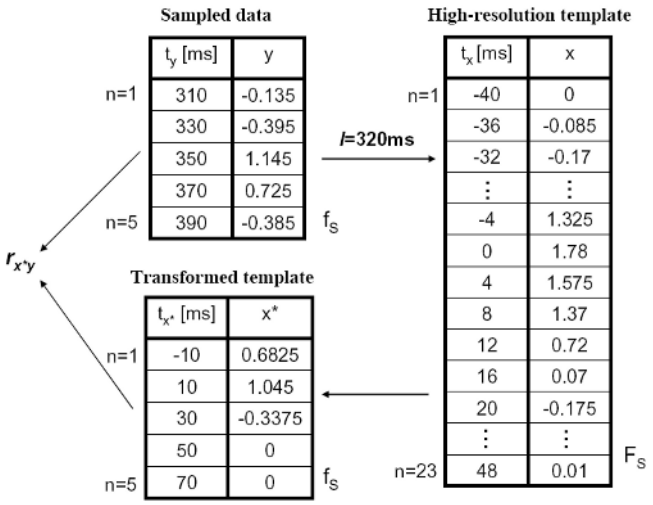

Fig. 1 Example of the Low Power Cross-Correlation

C. Online QRS detection procedure

The Online QRS detection procedure based on our proposed method consists of three stages.

In the *calibration and training stage* a representative high-resolution template of the QRS-complex is manually extracted by an expert from the ECG signal to be analyzed. The ECG signal is sampled at a high frequency of F_S. The QRS template details accurate marker positions of the respective QRS-complex onset and offset. This stage is only once processed for each cyclist on static conditions.

In the *initialization stage* a time period of 2s of the recorded ECG signal is stored, so that at least two consecutive heart beats are available. The goal of this stage is to localize the QRS-complex in the recorded signal, and to obtain an initial time information about the RR-interval. A maximum search is performed in this signal section providing an estimate of the sweep range center of the initial lag to be used for the cross-correlation computation between the QRS template and the signal part around the maximum. An accurate R-peak position is then determined corresponding to the lag with the maximum CC coefficient value. This signal section is sampled at a frequency higher than 200 Hz, so that the result of the maximum search supplies a good estimate of the R-peak position. The time period between the two last extracted R peaks provides an estimate of the QRS sample window center in the next stage.

During the *analysis stage* acquired data from the ECG sensor are online processed for QRS detection and delineation. Positions of the QRS-complexes are dynamically predicted using the last RR-interval. The signal is sampled only in time windows centered around the time corresponding to the last detected R-peak plus the last measured RR-interval. The low power cross correlation is computed within these time windows, where the initial lag corresponds to the first time value of the estimated time window. The lag is not constantly incremented by a sample period, but is increased by a larger step while a low threshold value of the CC coefficient is not attained. After achieving this value, the lag begins to increase by a fine step (sample period). This yields also to a reduction of the algorithm's complexity and thus of the computational energy. The position of the R-peak is chosen as the lag $l_{R\text{-}peak}$ providing the highest value of the CC coefficient computed in the time window. Onset and offset of the QRS-complex are automatically generated from the characteristic lag and the stored QRS template:

$$Onset/Offset[ms] = Onset/Offset_{template} + l_{R-peak} \quad (4)$$

The estimated time windows are continuously adjusted by the algorithm depending on the extracted time position of the R-peak relative to the beginning and end of the actual correlation interval. Information about time distances between the R-peak and the correlation interval's extremities are gained in the training stage according to the time periods between the R-peak and P- and T-waves offset and onset, respectively. Finally, only the online extracted QRS-complex features are transmitted wirelessly to the coach unit. For a heart rate of 60bpm, this reduces the communication energy by a factor of approximately 70 compared to a transmission of the full ECG signal measured at the minimum sample frequency of 200Hz.

III. Results

The proposed algorithm has been first evaluated by a collection of ten ECG recordings from the MIT-BIH Normal Sinus Rhythm Database [15]. The selection of these records was to allow for a comparison with a recent work [4] applying normal ECG beats to a modified "So and Chan" QRS detection method. The comparison results were assessed by the sensitivity metric defined as the ratio between the true positives (TP) and the sum of the true positives and false negatives (FN), where TP denotes the number of the true detected beats, and FN is the number of missed detections.

Table 1 shows that our method outperforms the modified "So and Chan" QRS detection algorithm in [4].

Our QRS detection method has been further tested on approximately 3000 cycles of different ECG recordings sampled at 250 Hz from the standard annotated PhysioNet QT Database [16] to evaluate the accuracy of the QRS boundaries detection. Table 2 lists the mean (me) and standard deviation (SD) of the errors between our QRS detector's annotations and the available manual annotations provided by expert cardiologists. It can be seen that the obtained standard deviations are within the tolerance limits recommended for an automated algorithm.

IV. Conclusions

A low complexity with reduced energy consumption electrocardiogram QRS detection method in real-time based on the CC has been presented. This method features the beneficial property of an acceptable under-sampling of the signal owing to the use of a high-resolution reference template, which includes the complete signal section information. Therefore, applying this method enables a reduction of the overall energy consumption of the ECG system without compromising its accuracy. High performance (100%) of the method in detecting cardiac cycles, and standard deviations of the extracted features within the tolerance limits are achieved, thus demonstrating the beneficial use of our method including power efficiency, accuracy and simplicity in the detection of QRS-complexes in the ECG signal. The method is, in addition, not restricted on the QRS detection but can be extended to the detection of all the heart waves, and generally to the biosignal processing.

Analytical Decision Making from Clinical Data- Diagnosis and Classification of Epilepsy Risk Levels from EEG Signals-A Case Study

V.K. Sudhaman[1], Dr. (Mrs.) R. Sukanesh[2], R. HariKumar[3]

[1]U.G Students, ECE, Bannari Amman Institute of Technology, Sathyamangalam
[2]Professor ECE, Thiagarajar college of Engineering, Madurai
[3]Professor ECE, Bannari Amman Institute of Technology, Sathyamangalam

Abstract — **Making decision under certainty is a perennial part of human predicament. In this research, we review the potential of fuzzy modeling technology as a tool for constructing customized decision making function for medical diagnosis, such as classification of epilepsy risk levels. We investigate the optimization of fuzzy outputs in the classification of epilepsy risk levels from EEG (Electroencephalogram) signals using soft decision as post classifier. The fuzzy techniques are applied as a first level classifier to classify the risk levels of epilepsy based on extracted parameters like energy, variance, peaks, sharp and spike waves, duration, events and covariance from the EEG signals of the patient. Soft Decision Trees are identified as post classifiers on the classified data to obtain the optimized risk level that characterizes the patient's epilepsy risk level. The Performance Index (PI) and Quality Value (QV) are calculated for the above methods. A group of ten patients with known epilepsy findings are used in this study. High PI such as 97.87 % was obtained at QV's of 23.31, SDT optimization when compared to the value of 40% and 6.25 through fuzzy techniques respectively. The performance of SDT is lucidly presented in this work. SDT results are validated with standard Multi Layer Perceptrons (MLP) neural networks.**

Keywords — **EEG Signals, Epilepsy risk levels, Fuzzy techniques, Soft Decision trees, MLP Neural networks**

I. Introduction

Epilepsy is a chronic disease characterized from recurrent seizures that cause sudden but revertible changes in the brain functions. Classification of epilepsy risk levels, according to international standard is difficult because individual laboratory findings and symptoms are often inconclusive [1]. Approximately 1% of the people in the world suffer from epilepsy. The electroencephalogram (EEG) signal is used for the purpose of epileptic detection as it is a condition related to the brain's activity. This paper presents the application of Soft Decision Trees (SDT) towards optimization of fuzzy outputs in the classification of epilepsy risk levels. We also present a comparison of SDT and MLP Neural network methods based on their Performance Indices(PI) and Quality Values(QV).

II. Materials and Methods

The EEG data used in the study were acquired from ten epileptic patients who had been under the evaluation and treatment in the Neurology department of Sri Ramakrishna Hospital, Combiatore, India. A paper record of 16 channel EEG data is acquired from a clinical EEG monitoring system through 10-20 international electrode placing method. With an EEG signal free of artifacts, a reasonably accurate detection of epilepsy is possible; however, difficulties arise with artifacts [2]. With the help of neurologist, we had selected artifact free EEG records with distinct features. These records were scanned by Umax 6696 scanner with a resolution of 600dpi. Figure 1 enumerates the overall epilepsy risk level (Fuzzy-SDT/Neural network) classifier system. The motto of this research is to classify the epilepsy risk level of a patient from EEG signal parameters [3],[4],[5].

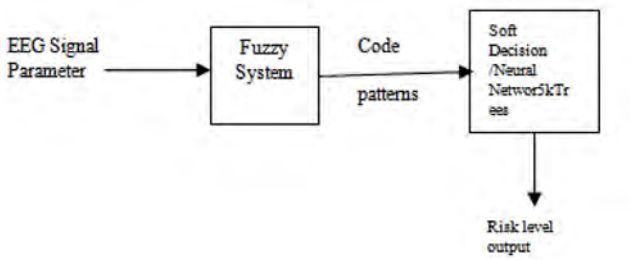

Figure 1. Fuzzy and Soft Decision Tree/ Neural Network Classification

1. The energy in each two-second epoch is given by

$$E = \sum_{i=1}^{n} x_i^2 \qquad (1)$$

Where x_i is signal sample value and n is number of samples. The scaled energy is taken by dividing the energy term by 1000.

2. The total number of positive and negative peaks exceeding a threshold is found.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 647–651, 2009
www.springerlink.com

3. Spikes are detected when the zero crossing duration of predominantly high amplitude peaks in the EEG waveform lies between 20 and 70 ms and sharp waves are detected when the duration lies between 70 and 200ms.
4. The total numbers of spike and sharp waves in an epoch are recorded as events.
5. The variance is computed as σ given by

$$\sigma^2 = \frac{\sum_{i=1}^{n} (x_i - \mu)^2}{n} \quad (2)$$

Where $\mu = \frac{\sum_{i=1}^{n} x_i}{n}$ is the average amplitude of the epoch.

6. The average duration is given by

$$D = \frac{\sum_{i=1}^{p} t_i}{p} \quad (3)$$

Where t_i is one peak to peak duration and p is the number of such durations.

7. Covariance of Duration. The variation of the average duration is defined by

$$CD = \frac{\sum_{i=1}^{p} (D - t_i)^2}{pD^2} \quad (4)$$

A. Fuzzy Membership functions

The energy is compared with the other six input features to give six outputs. Each input feature is classified into five fuzzy linguistic levels viz., very low, low, medium, high and very high [6]. The triangular membership functions are used for the linguistic levels of energy, peaks, variance events, spike and sharp waves, average duration and covariance of duration. The output risk level is classified into five linguistic levels namely normal, low, medium, high and very high. Rules are framed in the format.

IF Energy is low AND Variance is low THEN Output Risk Level is low

B. Estimation of Risk Level in Fuzzy Outputs

The output of a fuzzy logic represents a wide space of risk levels. This is because there are sixteen different channels for input to the system at three epochs. This gives a total of forty-eight input output pairs. Since we deal with known cases of epileptic patients, it is necessary to find the exact level of risk the patient. A specific coding method processes the output fuzzy values as individual code. Since working on definite alphabets is easier than processing numbers with large decimal accuracy, we encode the outputs as a string of alphabets. The alphabetical representation of the five classifications of the outputs is as shown below.

Normal U, Low W, Medium X, High Y, Very High Z

A sample output of the fuzzy system with actual patient readings is shown in figure. 2 for eight channels over three epochs. It can be seen that the Channel 1 shows medium risk levels while channel 8 shows very high risk levels. Also, the risk level classification varies between adjacent epochs. The Performance of the Fuzzy method is defined as follows [7]

$$PI = \frac{PC - MC - FA}{PC} \times 100 \quad (5)$$

Where PC – Perfect Classification, MC – Missed Classification, FA – False Alarm, PI= [(0.5-0.2-0.1)/0.5] *100 =40%.

Epoch 1	Epoch 2	Epoch 3
YYYYXX	ZYYWYY	YYYXYZ
YYYXYY	ZZYZZZ	YYYXYZ
YYYYYY	ZZYZZZ	ZYYYZZ
ZYYYZZ	ZZYZYY	YYYXXZ
YYYYYY	YYYXYY	YYYYYZ
YYYYYY	YYYXYY	YYYXYY
YYYYYY	YYYYYY	YYYYYY
ZZYZYZ	ZZYZZZ	ZZYZZZ

Figure 2. Fuzzy Logic Output

The perfect classification represents when the physicians and fuzzy classifier agrees with the epilepsy risk level. Missed classification represents a true negative of fuzzy classifier in reference to the physician and shows High level as Low level. The performance for Fuzzy classifier is as low as 40%. Soft Decision Tree (SDT) optimization technique (post classifier) [8] is utilized to optimize risk level and is given below.

III. Soft Decision Trees (Max-Min) for Optimization of Fuzzy Outputs

Our objective is to merge the epilepsy risk level representation, with approximate reasoning capabilities, and symbolic decision trees while preserving advantages of both: uncertainty handling and gradual processing of the former with the comprehensibility, popularity, and ease of application of the later.

A. Algorithm for SDT Optimization

From a processing point of view, these types of trees are highly recommended [9] [10]. The generic representation of SDT optimization is explained, let W= [P_{ij}] be the co – occurrence matrix with (i,j) elements which represents fuzzy based epilepsy risk level patterns of single epoch. There are 48 (16x3) epochs are available. Now the optimization is a two stage process through SDT, which is explained as below,

1. Deduce the 16x3 matrix epilepsy risk level into 16x1 viz row wise optimization through three types of optimization viz, a) Aggregation method, b) Maximum pattern in the particular row, and c) Minimum element in that particular row.
2. Deduce the 16x1 matrix into one optimum epilepsy risk level through SDT optimization with four levels. Here also we have two decision methods at node level which are Max-min &Min-max combination. Therefore effectively we have six methods of SDT post classifier.

Stage I: The aggregation method converts the column elements of i,j element into a single row element as R_I= 0.4 (P_{ij}(max)+ 0.3(P_{ij}(mid)+ P_{ij}(min)) and the other two methods are self explained in nature. Now the row of three elements is converted into single element. This is repeated for all the 16 rows and the matrix is reduced into 16x1 matrix.

Stage II: Group (16x1) elements as the leaf nodes of the tree. The next level of tree is named as B with eight decision nodes, which is followed by C level with four soft decision nodes. Further level is designated as D level with two nodes and the final level is the E level with single node which is the root of the tree. Perform the following decisions at the each node of the tree as in the case of Aggregation followed by **Max-min method.**

Let R_I , R_{I+1} be the ith and i+1 th leaf to be decided at next level B_I , as

1. B_i=max (R_I,R_{I+1}),& B_{i+1}=min (R_{I+2},R_{I+3}) and at next C_J level, 2. C_i=min (B_I,B_{I+1}) & C_{i+1}=max (B_{I+2},B_{I+3}) and at next D_I level, 3. D_i=max (C_I,C_{I+1}) & D_{i+1}=min (C_{I+2},C_{I+3}) and at next E level, 4. E_I =0.6(D_I) + 0.4 (D_{I+1}).

In the case of **Min –max** procedure the following decisions are taken at the nodes of B, C, D, and E levels

1. B_i=min (R_I,R_{I+1}),& B_{i+1}=max (R_{I+2},R_{I+3}) and at next C_J level, 2. C_i=max (B_I,B_{I+1}) & C_{i+1}=min (B_{I+2},B_{I+3}) and at next D_I level, 3. D_i=min (C_I,C_{I+1}) & D_{i+1}=max (C_{I+2},C_{I+3}) and at next E level, 4. E_I =0.4(D_I) + 0.6 (D_{I+1}).

The obtained singleton results are immensely helpful in devising the therapeutic procedure of the epileptic patients. The pertinent explanation about MLP Neural network is given below.

B. Multi layer Perceptrons (MLP) Neural Network for Risk Level Optimization

Multilayer perceptrons (MLPs) are feed forward neural networks trained with the standard back propagation algorithm. They are supervised networks so they required a desired response to be trained [11]. Most NN applications involve MLPs. They are very powerful pattern classifiers. They have been shown to approximate the performance of optimal statistical classifiers in difficult problems. They can efficiently use the information contained in the input data. The advantage of using this network resides in its simplicity and the fact that it is well suited for online implementation [12]. The Levenberg-Marquardt (LM) algorithm is the standard training method for minimization of MSE (Mean Square Error) criteria, due to its rapid convergence properties and robustness. This error back propagation algorithm is used to calculate the weights updates in each layer of the network. The results of the MLP back propagation neural models trained with the Levenberg-Marquardt (LM) learning algorithm are shown in table I. The gain or learning rate η (0.3), momentum α (0.5), and training epochs are tabulated for each model [13]. The average confidence score for each MLP Network architecture is tabulated in the table. I

Table I. Estimation of MSE in Various MLP Network Architectures

Architecture	**Training Epochs**	**Mean Square Error (MSE) Index**		**Confidence score**
		Training	**Testing**	**C_i=exp(-λε_i^2)**
16-16-1	**38**	**0**	**7.31E-03**	**0.9927**
16-3-1	6	0	2.19E-02	0.9783
8-8-1	283	0	9.13E-03	0.9909
8-4-1	6	0	5.1E-02	0.9503
4-4-1	**9**	**0**	**2.83E-08**	**0.9999**
2-4-2	**8**	**0**	**0**	**1**
1-1-1	4538	1.08E-08	1.2E-08	0.9999

IV. Results and Discussions

To study the relative performance of these Fuzzy techniques STD systems (6 Types), and MLP (2 types), we measure two parameters, the Performance Index and the Quality Value. These parameters are calculated for a group of ten patients and compared.

A. Performance Index

A sample of Performance Index for a known epilepsy data set at average value is shown in table II. It is evident that the STD optimization with [Agg & Max-min] method as well as [Agg &Min-max] method gives a better performance than the fuzzy techniques because of its lower false alarms and missed classifications. The MLP (4-4-1) outperforms the both the methods due to no missed classifications and insignificant false alarm rate.

Table II. Performance Index

Methods	Weighted delay (s)	False-alarm rate/set	Performance Index %	Quality value
Fuzzy logic	4	0.2	40	6.25
Agg&max-min	2.095	1.04	95.88	22.68
Agg&min-max	2.058	1.66	95.88	22.43
Max&max-min	1.9832	2.92	95.88	21.99
Max&min-max	1.942	3.74	95.66	21.66
Min&max-min	2.175	1.25	93.33	21.64
Min&min-max	2.112	1.875	94.1	21.64
MLP Neural Network (16-16-1)	1.92	4.58	96.29	22.05
MLP Neural Network (4-4-1)	1.98	0.624	99.34	24.43

B. Quality Value

The quality value is determined by three factors. Classification rate, Classification delay, and False Alarm rate. The quality value Q_V is defined as [5]

$$Q_V = \frac{C}{\left(R_{fa} + 0.2\right) * \left(T_{dly} * P_{dct} + 6 * P_{msd}\right)} \quad (6)$$

Where, C is the scaling constant, R_{fa} is the number of false alarm per set, T_{dly} is the average delay of the on set classification in seconds, P_{dct} is the percentage of perfect classification and P_{msd} is the percentage of perfect risk level missed. Table III shows the Comparison of the fuzzy, STD optimization techniques, and MLP neural networks. It is observed from table III, that STD (Agg& max-min) and (Agg& min-max) methods are performing well with the higher performance index and quality values. It is compromised to select STD (Agg& min-max) method even though it has low quality value than its predecessors. The SDT results are validated with the standard MLP (16-16-1) and MLP (4-4-1) neural networks, and are also depicted in the table III. Since MLP neural network models are supervised learning in nature and therefore it provides better optimized solution than other two methods.

Table III. Results of Classifiers taken as Average of all ten Patients

Methods	Perfect Classification	Missed Classification	False Alarm	Performance Index
Fuzzy logic	50	20	10	40
Agg&max-min	96.03	2.91	1.04	95.88
Agg&min-max	96.04	2.29	1.66	95.88
Max&max-min	96.04	1.04	2.92	95.88
Max&min-max	95.83	0.416	3.74	95.66
Min&max-min	93.75	4.998	1.25	93.33
Min&min-max	94.37	3.75	1.875	94.1
MLP (16-16-1)	96.42	-	4.58	96.29
MLP(4-4-1)	99.37	-	0.624	99.36

The cost associated with the learning is additional burden with neural networks so that we may select SDT method as a mid path solution to this problem.

V. Conclusion

In this paper, we consider generic classification of the epilepsy risk level of epileptic patients from EEG signals. Since, the fuzzy outputs are highly nonlinear in nature with dynamic probability functions. We have chosen STD based optimization technique to optimize the risk level by incorporating the above goals. Off the six types of STD methods Agg &min-max method performs well with high PI, Quality value and with moderate time delay. Further research is in the direction to compare the STD with unsupervised RBF neural networks model to solve this open end problem.

Magnetic field transducers based on the phase characteristics of GMI sensors and aimed at biomedical applications

E. Costa Silva[1], L.A.P. Gusmão[2], C.R. Hall Barbosa[1], E. Costa Monteiro[1]

[1]Post Graduation Program in Metrology, Pontifícia Universidade Católica do Rio de Janeiro, Brazil
[2]Electrical Engineering Department, Pontifícia Universidade Católica do Rio de Janeiro, Brazil

Abstract — **For the last four years the Laboratory of Biometrology of PUC-Rio has been working in the development of magnetic field transducers to be used in biomedical applications – especially in the three-dimensional localization of needles inserted in the human body and in the measurment of arterial pulse waves. While previous investigations were based on the behavior of the magnitude of the impedance of Giant Magnetoimpedance (GMI) ribbon-shaped sensors, this manuscript presents the preliminary results of a new research that considers the changes in the phase characteristics of GMI sensors due to varying low-intensity magnetic fields. In spite of being less explored in the literature, the work carried out so far indicates that the sensitivity of the phase can lead to more promising results than the ones already obtained with transducers based on the variation of the impedance magnitude. By means of examples showing that the sensitivity of the phase is affected by parameters (amplitude, frequency and DC level) of the AC biasing current that flows throught the sensor, this manuscript discusses how an ideal stimulation condition was derived in order to obtain more sensitive transducers. It is also examined the influence of the ribbon length in the sensitivity. A new conditioning electronic circuit – responsible for the excitation and measurement of the GMI sensor, and designed to work in the 100kHz to 5Mhz range – has been developed and is presented in the manuscript. Simulation studies of the complete transducer, including the conditioning circuit and based on data obtained from measured curves, have shown that an improvement of 10 to 100 times can be expected when compared to the sensitivity of previous magnitude-based transducers.**

I. Introduction

A. Historical context

The department of Metrology for Quality and Innovation (Post-MQI) of PUC-Rio, through the research line in Biometrology and in partnership with the department of Physics of the Federal University of Pernambuco (UFPE), is carrying out studies seeking the implementation of prototypes of magnetometers based in the Giant Magnetoimpedance (GMI) phenomenon [1-2].

The importance of GMI in the world's scientific scenery has been increasing, and several laboratories are accomplishing promising researches in several application areas. A recent example was the concession of the 2007 Nobel Award in Physics to the researchers Albert Fert and Peter Grünberg, who discovered the giant magneto-resistance, GMR [3,4].

The Giant Magnetoimpedance effect started to be studied intensely in the decade of 90. The first results obtained in such studies were interpreted as a variation of the Giant Magnetoresistance effect (GMR), whose experimental behavior is examined with the application of a continuous current and in the presence of a continuous magnetic field. The GMR effect only considers the variation of the resistance, and the phenomenon is explained by the electrons motion change when we act on their spin through the orientation of a magnetization [3]. However, experiments accomplished with samples of amorphous ferromagnetic alloys, using alternating current, have shown a variation of the resistive part as well as of the reactive part with respect both to the external magnetic field and to the frequency of the applied current. Thence comes the name GMI.

B. GMI effect

We focus on a particular case of GMI named Longitudinal Magnetoimpedance (LMI). The phenomenon of LMI is induced through the application of an alternating current (I) along the length of a ribbon (or wire), which is submitted to an external magnetic field ($\vec{H}$) parallel to it. The potential difference (V) is then measured between the extremities of the ribbon, as shown in Figure 1.

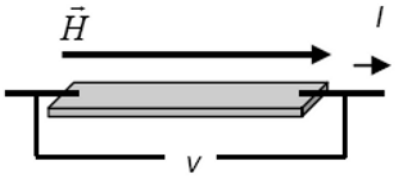

Fig. 1: Typical GMI measurement.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 652–656, 2009
www.springerlink.com

Using the phasorial description of the AC tension and current, as well as arbitrating the phase of the current (ϕ_I) as zero, the impedance of the sample can be calculated as:

$$Z=\frac{|V|e^{j\phi_V}}{|I|e^{j\phi_I}}=\frac{|V|}{|I|}e^{j\phi}=|Z|e^{j\phi} \quad (1)$$

Thus, the complex impedance (Z) is defined by two components, a real one and imaginary one:

$$Z=R+jX, \quad (2)$$

where

$$R=|Z|\cos\phi \text{ and } X=|Z|\sin\phi \quad (3)$$

The GMI effect is actually a result of the skin depth dependency with the magnetic permeability, which varies not only with the external magnetic field that is applied to the sample, but also with the frequency and intensity of the current that passes through it. Then, generically, in agreement with the literature [5-6], we can define:

$$Z=(1-i)\frac{L}{2\omega\sigma\delta}\frac{1}{1-e^{-(1-i)/2\delta}}, \text{ and} \quad (4)$$

$$\delta=\frac{c}{2\pi}\sqrt{\frac{1}{2\omega\mu\sigma}}, \quad (5)$$

where L is the length and t is thickness of the ribbon, ω is the frequency of the current and σ is the conductivity of the material.

A. Previous Works

The Laboratory of Biometrology of PUC-Rio has developed, in the recent past, some magnetic field transducers for biomedical applications, all based on the magnitude characteristics of the GMI phenomenon.

As a matter of fact, most of the studies accomplished in the field of GMI has been based in the magnitude characteristics of the samples, being rare those that consider its phase characteristics. Even the most used figure for determination of the GMI percentile variation - as a function of the applied magnetic field - takes into account just the magnitude [5-6]:

$$GMI(\%)=\left[\frac{|Z(H)|-|Z(H_{max})|}{|Z(H_{max})|}\right]10^2, \quad (6)$$

As examples of transducers developed at PUC-Rio, which are based on the magnitude variation of the GMI effect and uses GMI ribbons as sensor elements, it can be mentioned the transducer for localization of needles inserted in the human body shown in Fig. 2 (which sensitivity was 12V/Oe), and the transducer for measurement of arterial pulse waves shown in Fig. 3 (which sensitivity was 1mV/Pa) [1-2, 7-8].

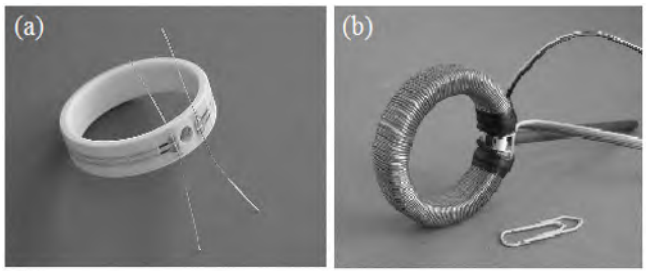

Fig. 2: (a) Partial ring shaped prototype with GMI ribbons fastened; (b) Complete prototype with the excitation coils.

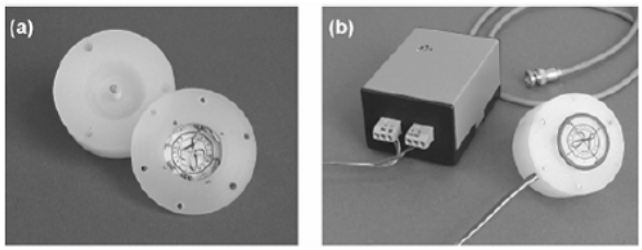

Fig. 3: (a) Opened prototype without the electronic circuit; (b) Complete prototype.

This paper presents the improvements introduced in the foregoing transducers when the phase characteristics of GMI samples started to be considered in place of its magnitude.

II. Experimental Research

A. Phase and Magnitude Characterization

Some initial studies have examined the effect of the frequency and DC level of the excitation current on the sensitivity of the ribbons. All those parameters, as well as the length of the ribbon, affect the magnitude and phase sensitivity in a significant and different way.

Such studies lead to the conclusion that the ribbons presented a maximum sensitivity for DC currents around 80mA, independently of their length or of the AC current frequency. Measurements were accomplished with DC currents of 0mA, 20mA, 40mA, 60mA and 80mA. Due to technical limitations, and to the difficulties imposed by its microelectronic implementation, the sensitivity for higher current values was not tested, but the results should continue to get better.

All of the measurements were made in $Co_{70}Fe_5Si_{15}B_{10}$ ribbon-shaped alloys with an average thickness of 60 mm and an average width of 1.5 mm. The AC current magnitude was kept in 15 mA_p, because it has been previously seen that such variable did not affect the GMI ribbon behavior significantly.

Figures 4 and 5 exemplify, respectively, the magnitude characterization results obtained with 15 cm and 3 cm long ribbons (using an 80 mA DC current), where Z_0 is the value of the magnitude in the case of a null external magnetic field parallel to the ribbon length.

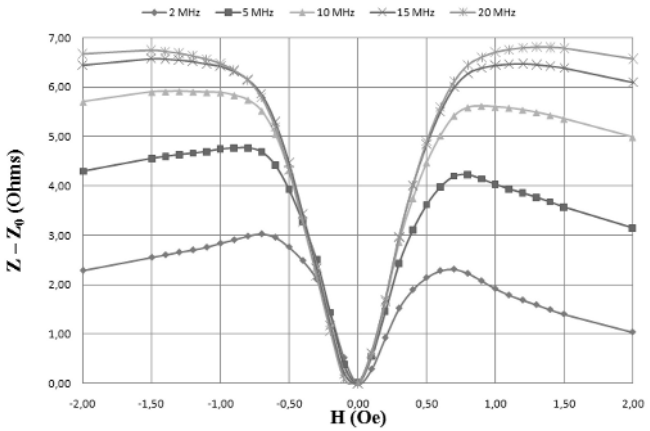

Fig. 4: Magnitude of the impedance of a 15 cm long GMI ribbon submitted to an 80 mA DC current.

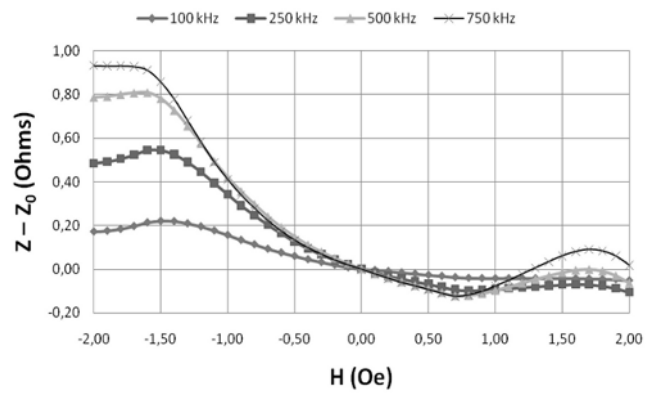

Fig. 5: Magnitude of the impedance of a 3 cm GMI ribbon submitted to an 80 mA DC current.

The best magnitude sensitivity obtained with the 15cm long ribbon was 12.9Ω/Oe at 80mA and 20MHz, while for a 3 cm long ribbon was 0.9Ω/Oe at 80mA and 10MHz.

In spite of the largest value of the sensitivity happening for the highest frequency value tested, it has been noticed that, starting with 10MHz, the sensitivity begins to saturate.

Figures 6 and 7 show, respectively, the results of phase characterization of 15 cm and 3 cm long ribbons, when driven by an 80 mA DC current. θ_0 is the value of the phase in the case of a null external magnetic field parallel to the ribbon length.

The best phase sensitivity obtained with the 15cm long ribbon was 17°/Oe at 80mA and 10MHz, and for a 3 cm long ribbon was 9°/Oe at 80mA and 100kHz.

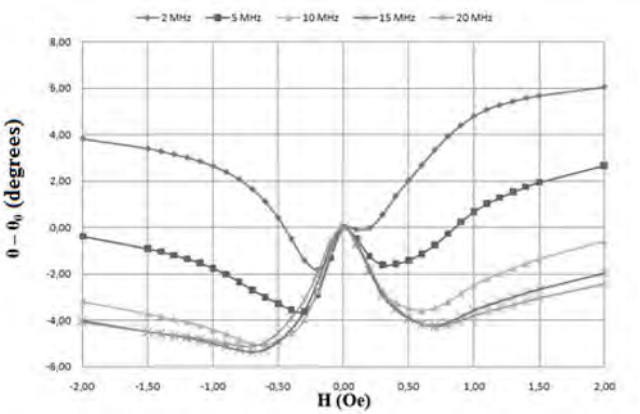

Fig. 6: Phase of the impedance of a 15 cm long GMI ribbon submitted to an 80 mA DC current.

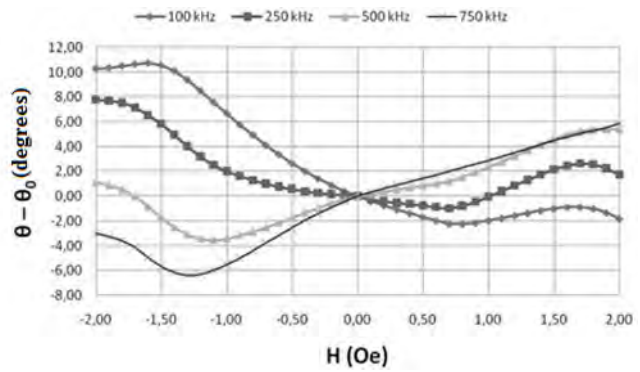

Fig. 7: Phase of the impedance of a 3 cm long GMI ribbon submitted to an 80 mA DC current.

For a fair comparison between the performance of the ribbons with different lengths, the sensitivity value of the 3cm ribbon should be multiplied by five. If this is done, the magnitude sensitivity of the 15 cm long ribbon will be about 2.9 times better than the tripled one, while the phase sensitivity of the cascaded 3 cm ribbons will be about 2.6 times

better than the large one. In other words, the phase sensitivity is improved for smaller lengths of ribbons, while the magnitude sensitivity is reduced as the lenght also reduces. This is clearly an advantage for biomedical applications, where, in general, it is very convenient to work with the smallest possible sensor elements, in order to have a better spatial resolution.

Still, the highest magnitude sensitivities happen for high frequencies (over 2MHz), while a maximum phase sensitivity is obtained in a relatively low frequency (100kHz). Those low frequencies facilitate the implementation of the electronic conditioning circuits, and constitute another advantage of using the phase characteristics of the GMI effect.

B. Electronic circuit

The block diagram of the proposed phase detection and conditioning circuit, to be used in the implementation of the new transducers, is presented in Figure 8.

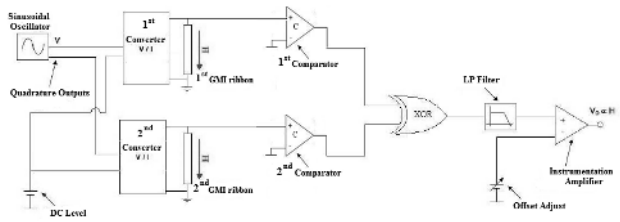

Fig. 8: Conditioning and phase reading electronic circuit.

The idealized circuit is capable of conditioning the ribbon, supplying the AC current (with the appropriate frequency and magnitude) and the specified DC level. It also delivers a voltage output which is proportional to the phase variation of the ribbons ($\Delta\theta$).

Since its final objective is to measure small magnetic fields - to detect small phase variations - the above circuit has to be implemented with fast components (in particular the XOR gate). For this reason, an ECL family XOR - typical propagation delay of 260ps - has been adopted.

The electronic circuit of the arterial pulse waves transducer is similar to the one here presented (fig. 8), except for small alterations. Thus, it won't be shown here for the sake of brevity.

C. Simulations Results

Some simulation studies of the complete transducer circuit have been carried out with the help of a SPICE program. To accomplish this, the GMI ribbons were modeled as a resistance in series with an inductance. The results shown in Table 1 were obtained by the transducers based on the GMI phase characteristics.

Table 1 Transducers Sensitivity

Transducer	Sensitivity
Magnetic Bodies Detection	459 V/Oe
Arterial Pulse Waves Measurement	13.5 mV/Pa

III. Conclusions

The new transducers, based on the GMI phase characteristics, present a significant increase in sensitivity when compared with those based on the magnitude characteristics, approximately 38 times for the Magnetic Bodies Detector and 13 times for the Arterial Pulse Waves Measurement [1-2]. These results indicate, doubtless, that the phase characteristics of the GMI effect deserves to be more studied, especially when it deals with the development of transducers.

It may be also pointed out that the effects of the ribbon length variation should continue to be analyzed, since they can make possible the miniaturization of the sensor elements, especially when using an electronics based in the phase detection.

Abstract — **Visuospatial working memory is one of the important cognitive processes and makes it possible to maintain and manipulate the visual information stored in brain systems. In this study, effects of task difficulty and two-week training of visuospatial working memory task on brain activity and its neural mechanisms were investigated.**

We used visuospatial working memory task with 10 or 30 visual targets displayed on a screen. Each target was a numbered white square and subjects were instructed to click the targets sequentially. Brain activity during performance of the task was measured with functional magnetic resonance imaging (fMRI), before and after two weeks task training. Four subjects practiced the task with 30 visual targets 15 times a day for two weeks, and another four subjects were not practiced.

Statistical probability mapping revealed high activity in prefrontal cortex during performance of the task, especially in Brodmann area 10 and 46, which are commonly related to working memory processes. Higher and larger activation was observed for the task with 30 targets than that with 10 targets before training. After training, activated level and area of BA10 and 46 was increased and expanded in tasks with 10.

Keywords — **Visuospatial working memory, fMRI, Brodmann area 10, Brodmann area 46.**

I. Introduction

Recent advances in information technology have provided artificial and digital information environment. Under such environment, we must select necessary information from a lot of digital visual information resources by reading them and saving shortly in our memory.

Working memory (WM) is one of the important functions for such visual information selection, and is thought to be a mechanism of maintenance and the processing of an active memory [1-4]. After Baddeley and Hitch proposed a fundamental framework for the WM [1], many studies on verbal and spatial WM have been presented [2-4]. Neuroimaging studies have shown that the prefrontal cortex is involved in human WM including the central executive system and memory buffers [5-7], and WM is mediated by frontal cortical regions differing in the types of information maintained (e.g., verbal or spatial) [5, 8]. Recent studies have examined the effects of practice, development and aging on cortex activity related to WM [7, 9-12].

In this study, brain activity during visuospatial WM task was investigated to determine how and which cortical regions are involved in the human information processing in the task. Effects of task difficulty (depending on numbers of visual targets displayed) and training (two-week practice) on the brain activity were examined. Preliminary results have already reported [13], but some experimental conditions were improved in this report. The results may give a clue towards understanding the brain function and its relation to the working memory.

II. Methods

A. Subjects

Eight healthy male students (age range, 19-25 years) participated in this study. All subjects were right-handed. A written informed consent was obtained from all subjects.

Subjects were divided into two groups with or without practice: four subjects with practice (group 1), and four subjects without practice (group 2).

B. Visuospatial working memory task and brain activation measurement

We used the same visuospatial working memory (VSWM) tasks, stimulation protocols, and brain imaging methodology that used in our previous report [13].

VSWM tasks with 10 and 30 visual targets (T10 and T30 tasks) were used. The visual target is a numbered white square displayed on black background as shown in Fig.1. Subjects were instructed to sequentially point and to click a visual target by using computer mouse. When subject correctly clicked a target, the target disappeared and next numbered target would appear at another random position of the screen.

www.springerlink.com

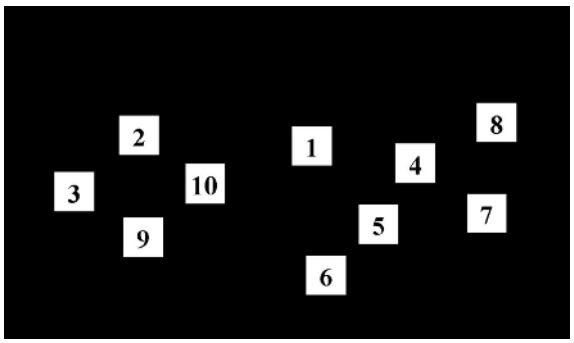

Fig. 1 Stimulus image (T10).

Brain activation during tasks was measured with functional MRI at each end of the two-week the T30 task training. First functional MRI measurement was performed before the training (experiment 1), and second measurement was performed after the training (experiment 2). Subjects in group 1 practiced the T30 task 15 times a day for two weeks after experiment 1. Subjects reported on the score of T30 every day. Subjects in group 2 did no task for two weeks.

Imaging was performed with a 1.5T HITACHI STRATIS MRI scanner equipped with a quadrature RF head coil. Boxcar design which consists of 3 blocks of rest (50 seconds) and task (50 seconds) was employed in this study. Further details are provided in our previous report [13].

C. Statistical analysis

Statistical analysis was performed with SPM99. Functional data sets were realigned and corrected for motion using the first image as the reference, and were normalized to the Talairach space using the EPI template image in SPM99. The normalized data sets were smoothed using an isotropic Gaussian kernel (full width half maximum [FWHM] = 10 mm). For the statistical parametric mapping analysis (SPM), a canonical hemodynamic response function within SPM99 was employed as a basis function. SPM projection maps were generated using the general linear model (GLM) within SPM99.

As for the experiment 1, the brain activation of the 8 subjects conducting T10 task was compared to the brain activation of the same 8 subjects conducting T30 task. Furthermore, for each task, T10 and T30, the brain activation of the experiment 1 and the experiment 2 were compared. Group SPMs were generated using a random-effects model within SPM99 with the individual contrast map. The resulting SPM {t} map was transformed to the unit normal distribution SPM {Z} and threshold at a significance level of $p<0.05$ corrected for multiple comparison, using the theory of Gaussian fields as implemented in SPM99.

III. Results and Discussion

A. Effects of task difficulty (Experiment 1)

Brain activity of T10 and T30 task in experiment 1 are shown in Table 1 and Figure 2. Table 1 shows the analytical result of eight subjects in experiment 1. Figure 2 is a front view of brain areas and the significantly activated areas were displayed with a color code ranging from yellow (high-level) to red (low-level).

Significant activation was observed in right inferior frontal gyrus for both T10 and T30 task. Right inferior frontal gyrus has reported to relate to processing of spatial WM [14] and spatial attention [15], although its role or function is still controversial. Moreover, the Brodmann area 10 (BA10) was significantly activated for both T10 and T30 tasks. BA10 has reported to be the most higher-order functional area in prefrontal cortex [16]. Significant high activity in these areas indicates that both T10 and T30 tasks required spatial processing and attention. In fact, during T10 and T30 tasks, subjects were required to perform visual searching, memorizing of spatial location and spatial motor tasks, in order to click and delete targets sequentially as fast as possible.

However, the highest activity was observed in occipital lobe for both T10 and T30 task, as shown in Table 1. This activation area was large and found in occipital lobe and the cerebellum (this area is not shown in Figure 2). These were because of the visual searching and motor task (computer mouse pointing and clicking).

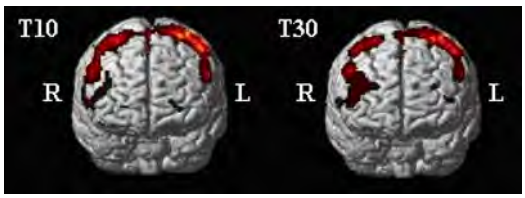

Fig. 2 Significantly activated areas in experiment 1.

Significant high activity was observed in left and right superior frontal gyrus including BA10 for T10 task. In contrast, high activity was observed in left and right middle frontal gyrus for T30 task. This activated area was large and included BA46. Maintenance and manipulation of more visual information in T30 than T10 would lead to the higher and larger activity in T30. Previous study demonstrated that superior frontal gyrus related to visual-spatial WM [17]. It is confirmed that WM task of spatial location activated right middle frontal gyrus and WM task of visual form activated left and right middle frontal gyrus [18]. BA9 and BA46 has considered to be the neural basis of the central executive system in human information processing [5-7], and its activation has confirmed by spatial and verbal task [19]. More visual targets displaying in T30 task would have required the more visual information processing especially on form (numbers on squares) and spatial location.

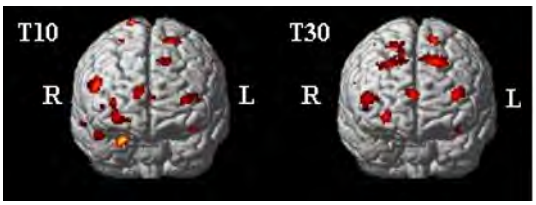

Fig. 3 Areas where their activation level increased after practice weeks in group 1 (with two-week practice).

B. Effects of two-week practice

Practice period of two weeks were determined by referring to the previous other studies [9, 12]. Mean of T10 task score (numbers of correctly clicked targets during fMRI measurement) increased after two weeks practice in group 1 (with two-week practice), from 47.7 ± 5.5 to 53.3 ± 3.3 and that of T30 task score increased from 26.5 ± 1.8 to 28.3 ± 2.5. In group 2 (without practice), the score mean of T10 also increased from 43 ± 3.7 to 45.4 ± 3.0, but that of T30 did not changed (from 25 ± 2.5 to 24.8 ± 2.3). The larger increase of the score in T10 implied the effect of two-week practice. The practice may not be enough to rise the scores of more difficult task T30.

The activated areas in group 1 (with two-week practice) were shown in Table 2 and Figure 3. Those in group 2 (without practice) were shown in Table 3 and Figure 4. Theses results were obtained by the exclusive masking of SPM99. This masking will remove all voxels of the activated areas in the experiment 1 from those in the experiment 2. Masking does not affect p-values of the contrast. In both groups, significant increasing of activity was observed

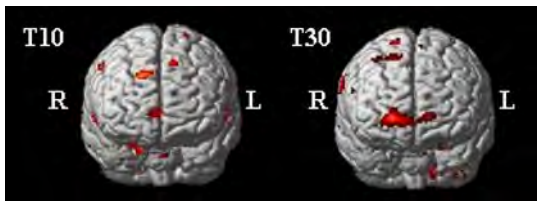

Fig. 4 Areas where their activation level increased after practice weeks in group 2 (without practice).

in the frontal lobe and in the cerebellum. Especially for T10 task in group 1, a lot of activation increased areas were observed, and this would be effects of two-week practice. The activation increase was observed in right middle frontal gyrus and right superior frontal gyrus. In particular, activation in BA46 and 10 increased for T10 task after practice in group 1, but not in group 2. These changes imply that subjects were able to maintain more WM capacities after the practice. In fact their scores actually increased for T10 as mentioned above. The results of activation increase in frontal lobe agreed with previous research [9]. Although no significant increase of activity in BA10 and 46 in group 2, the scores actually increased a little as shown above, so that the reproducibility of task-related brain activity is necessary to be examined in the future.

Moreover, activation increased in the left and right temporal lobe. However, these areas activated in group 1 and group 2. Therefore, it will not be an effect of the practice. We thought the influence of the individual variation.

IV. Conclusions

Effects of task difficulty (number of visual targets) and two-week practice by using visuospatial working memory task were examined. Higher and larger brain activity was observed during the task with more visual targets. Significant activation was observed in BA10 for both T10 and T30 task, and BA46 for T30 task. Results indicate that T30 task required a lot of working memory capacity for the information processing. After two-week practice, the activated area has expanded in the frontal lobe. Effects of practice was observed especially in BA46 and 10 where related to the working memory.

Retrieval of MR Kidney Images by Incorporating Shape Information in Histogram of Low Level Features

D. Mahapatra[1], S. Roy[2] and Y. Sun[1]

[1]Department of Electrical and Computer Engineering, National University of Singapore, Singapore
[2]Institute for Infocomm Research, Singapore

Abstract — **Retrieval of medical images from databases is important in the wake of increasing medical image data. Intensity histograms and its variants have proved to be useful features for image retrieval. But in the presence of intensity change due to contrast enhancement in perfusion images, histogram based techniques are not very useful. We propose to use shape context information for retrieval of dynamic perfusion images. Our tests on renal perfusion MR images show that shape context information is a useful approach for the retrieval of such images.**

Keywords — **retrieval, perfusion MR, histogram, shape context, kidney**

I. Introduction

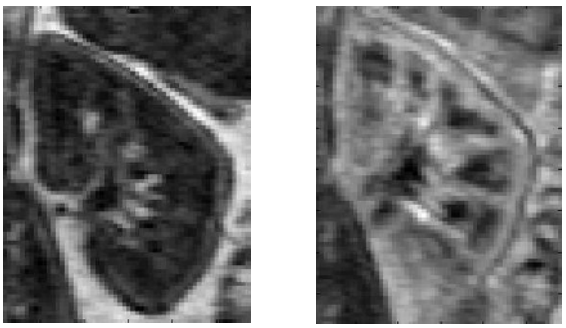
Recent advances in imaging technology have increased the amount of medical data generated and subsequently, automated search and retrieval of images from medical databases has become a very important issue. Traditional medical images are indexed and retrieved using texts only. However the semantic gaps in describing complicated image contents verbally limit the ability of such an approach and affect the performance of content-based image retrieval (CBIR) systems.

Low-level features from the image are used to represent the information content in an image. Although not powerful enough, low-level features are the only information available that can be automatically extracted from images. Low-level features that have been used for image retrieval include color moments [1], color histogram, color correlogram [2] and Gabor wavelet texture feature [3]. These features can be roughly classified into three categories: color, texture or shape. Except for color moment, other features have high dimensionality or the feature extraction algorithm is difficult to implement.

Different features capture different aspects of the semantic contents of images; therefore their combination could be expected to give better results, e.g. color and texture information have been characterized in one feature representation. Yu *et al.* in [4] proposed the color texture moment feature (CTM) to represent image content and Li in [5] derived texture moments from CTM.

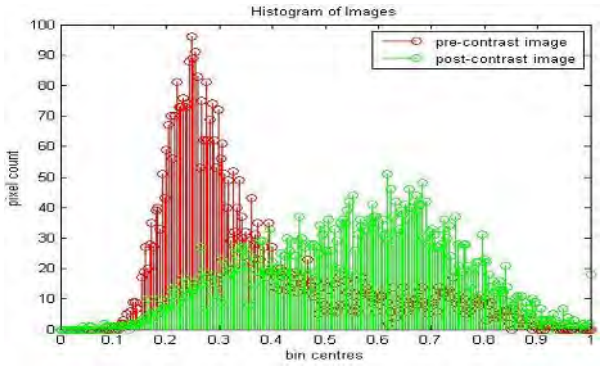
Intensity histograms have also been widely used for retrieval applications. However they give a global representation of intensity distributions in an image and incorporating spatial context into the histogram provides a more powerful descriptor [6]. However the spatial histogram cannot capture the similarity information when dealing with contrast enhanced images where there are significant intensity changes.

In dynamic perfusion MRI, the patient body is scanned at regular intervals immediately after the injection of a contrast agent. As the contrast agent flows into the veins and subsequently the kidneys, there is an increase in intensity of the corresponding regions. In such a situation using histograms for image matching tasks does not prove to be very useful. Referring to Fig.1 we see that the histogram for the two images is vastly different. For the post-contrast stage image, where the intensity is higher, the pixels are grouped into higher bins compared to the pre-contrast image. We propose the use of shape context information for retrieval of dynamic renal MR images. Shape context information was proposed by Belongie et al. [7] for digit classification and trademark retrieval among other tasks. The shape context at a reference point captures the distribution of the remaining points relative to it, thus offering a globally discriminative characterization. Such a metric enables us to include shape information into a histogram formulation scheme. We test our proposed metric to retrieve images that best match a given query image



The rest of the paper is organized as follows. Section II discusses the proposed approach. Section III gives details of our experiments and the results are presented in Section IV. Finally we conclude with section V.

II. Our approach



A. Shape Contexts

An object in an image is treated as set of points and the shape is captured by a subset of these points. Practically, a shape is represented by a discrete set of points sampled from the internal or external contours on the object and these can be obtained from the location of edge pixels as

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 661–664, 2009
www.springerlink.com

(a) (b)

(c)

Fig. 1 Image Histogram: Pre- and post-contrast images with their respective intensity histograms.

found by an edge detector. They need not correspond to key-points like maxima of curvature or inflection points.

Let us consider two shapes P and Q. for each point p_i on the first shape the best matching point, q_j, has to be found on the second shape. This is akin to a correspondence problem and matching becomes easier by using a rich local descriptor. Descriptors that use information from a window of pixels reduce ambiguity in matching. The shape context acts as a rich local descriptor. A set of vectors originating from a sample point to all other points on the shape expresses the configuration of the entire shape relative to the reference point. As the dimension of the vector gets larger more information is captured and representation becomes more exact.

For a point p_i on the shape, a coarse histogram h_i of the *relative coordinates* of the remaining points is generated. This histogram is defined to be the shape context of p_i. The bins of the histogram are uniform in log-polar space, making the descriptor more sensitive to positions of nearby sample points than those to points that are further away. The cost of matching two points p_i and q_j is given by

$$C(p_i, q_j) = \frac{1}{2}\sum_{k=1}^{K}\frac{[h_i(k) - h_j(k)]^2}{h_i(k) + h_j(k)}, \quad (1)$$

where $h_i(k)$ *and* $h_j(k)$ denote the K-bin normalized histogram at p_i and q_j respectively. The cost can also include an additional term based on local appearance similarity at p_i and q_j.

The total cost of matching given by $\Sigma\, C(p_i,q_j)$ has to be minimized in order to get the optimal matching. This is done using a bipartite matching algorithm.

B. Using Shape Contexts for Image Retrieval

The shape context information serves as the feature using which a similarity score between images can be determined. The shape context of the target image is compared with that of the query images using a similarity metric that we describe later.

Using the shape context information we can also identify the most similar slice from the acquired 3D volumes. This is achieved by comparing the shape context measure for all slices in a particular 3D volume.

We also compare the performance of the shape context based method with that of a spatial context based histogram method. To incorporate spatial context into a histogram we make use of the algorithm in [6].

C. Similarity Measure

The measure of similarity between query and target images is defined in the following manner

$$D(p,q) = \sqrt{\sum_{\forall i}\left(p(i) - q(i)\right)^2}, \quad (2)$$

where p and q are the corresponding histograms.

Performance Evaluation: the error of a retrieval task is measured as the sum of actual distances of returns ranked higher than the relevant slice. The performance of retrieval is measured as the average error of all retrieval tasks.

III. Experiments

Our dataset comprised of 5 real patient datasets. For each patient, 41 volumes were acquired at different sampling instances and each volume consisted of 40 slices. The sampling instances corresponded to various stages of contrast enhancement. Regions of interest corresponding to the kidney were cropped from the full abdominal scan of the patients. Our experiments consisted of finding the most rele-

vant images as well as the most similar slice in the scanned volume.

Matching Image:. This task involved identifying the image which is most similar to a template image. To determine the shape context information of an image the locations of the boundary are detected using a canny edge detector to determine the distribution of the relative coordinates.

The shape context information is in the form of a $p \times b$ histogram where p is the number of edge points and b is the number of bins into which the coordinates relative to the current pixel are binned. Distribution of relative coordinates helps to capture shape information even in the face of distortions.

The cost of matching two points as given by Eqn. 1 returns a $p \times q$ matrix, where p and q are the number of points in each edge image. The i^{th} row of the matrix thus gives the matching cost of the i^{th} edge point with all the edge points of the second image. However, to evaluate the effectiveness of the shape context information we need to have a single value. We use Eqn. 3 to get the matching score for two images.

$$score = \sum_{i=1}^{p} \sum_{j=1}^{q} C\left(p_i, q_j\right) \Big/ pq, \qquad (3)$$

where $C(p_i,q_j)$ is obtained from Eqn. 1.

Retrieving Slice: In this set of experiments, we focus on identifying the slice in a 3D image volume that is most similar to a given target slice. Here again we used the score in Eqn. 3 to compare the shape context information between two images.

IV. Results

For the image matching task, we took corresponding slices of different acquired volumes and chose 2 of them as reference. The images were then compared using shape context information. For the image matching task, we had to determine the edge coordinates of the kidney. However for contrast enhanced images it is not an easy task to get an accurate shape contour. Due to the high intensity, the Canny edge detector identifies edges within the kidney cortex as well. To overcome this obstacle we applied connected component analysis to extract the kidney by neglecting the artifacts inside the cortex region. Fig. 2 illustrates the scenario. Although the edge image after pre-processing does not exactly resemble the edge image of pre-contrast images, it is good enough for accurate image matching and in this lies the strength of the shape context based approach. The accuracy of the retrieval task was *73* % using our approach and

(c) (d)

Fig. 4 Results for matching slices. (a) reference slice; (b)-(d) matched slices returned in decreasing order of similarity.

60 % using a histogram based approach and a typical case of matched images is shown in Fig. 3.

For the task involving matching slices within the image volume, slices of volumes from the post-contrast stage were subjected to connected component extraction. Fig. 4 shows typical examples of a reference slice and returned matches. The accuracy using shape context information was 85% compared to an accuracy of 61 % using intensity histograms. However it is important to note that the intensity histogram is not an appropriate approach to capture shape information.

V. Conclusion

We proposed the use of shape context information for retrieval of contrast enhanced perfusion images of the kidney. Shape context information helps in identifying the kidney due to change in shape and size of the kidney and also in the face of intensity change due to contrast enhancement, a scenario not addressed by histogram based approaches. The shape of the kidney was identified using connected components. Performance of our approach is comparable to other histogram based techniques for image retrieval. Using shape context information for retrieving appropriate slices shows good performance.

Performance Comparison of Bone Segmentation on Dental CT Images

P. Yampri, S. Sotthivirat, D. Gansawat, K. Koonsanit, W. Narkbuakaew,
W. Areeprayolkij, W. Sinthupinyo

National Electronics and Computer Technology Center, Phahon Yothin Rd, Klong Luang, Pathumthani 12120, Thailand

Abstract — **Computed tomography (CT) images used in the dental application mainly consist of bone and soft tissue regions. Segmentation of bones from the soft tissues can help clinicians to assess the quality of the patient's jawbone more easily. Moreover, the identifiable bone region can help creating the better results of 3D surface/volume rendering. In the dental CT images, the bone regions are usually surrounded by other regions which are in a larger area and darker colors. The application of Local Entropy Equalization is usually suitable for the images with the mentioned characteristics. It has been reported that different thresholding techniques, namely Otsu and Kittler, are used to segment the bone regions. In this paper, we present the experimental studies for bone segmentation of CT images in the dental application using three different techniques based on i) Otsu's thresholding, ii) Kittler's thresholding, and iii) Local Entropy thresholding. The performances of these three different techniques on the bone segmentation and 3D rendering, which are applied on several CT datasets, are compared and presented. The experimental results show that segmentation of bones using the Local Entropy thresholding technique provides better quality than the Otsu's and Kittler's methods.**

Keywords — **bone segmentation, autometic thresholding**

I. Introduction

Segmentation is a process for dividing a digital image into multiple sets of pixels. It helps selecting the interested region such as a bone boundary in a medical image. In general, the dental CT images include bone and soft tissues. In the case analyses jawbone of patient. If patient has a metal material in his mouth. Such crown with amalgams, the intensity of the image around the location of these materials will be distributed. Thus, this effect is called the metal artifacts. The bone region is difficult to select when the metal artifacts are presented in the data. The result of the manual process may appear the value which is higher or lower than the bone region. Thus, the approximation process for fitting bone is necessary. The thresholding technique is appropriate for using because it is a simple to apply an approximate with volume of CT image data. This paper proposes the case study of an automatic thresholding technique for detecting true bone boundary. It consists of three techniques: Otsu thresholding[1], Kittler thresholding [2] and Local Entropy thresholding[3]. The thresholding technique include creates a histogram of CT images and calculates threshold value from weighting a histogram. However, these concepts are generally used in an automatic threshold technique. In this paper, we compared the performance on bone segmentation of these three thresholding techniques. The result is using the Local Entropy thresholding techniques provides the best results.

II. Segmentation

In CT images, soft tissues and bone regions can be identified through the so-called CT numbers which are in the Hounsfield units (HU). As show in Fig 1

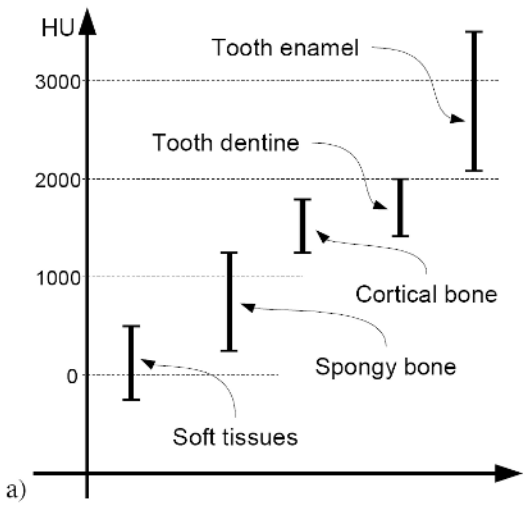

Fig. 1 Typical ranges of different tissues in Hounsfield units

In the case of dental applications we need to perform segmentation of teeth and jawbones. The cortical bone (compact) has the density in range of 1200 to 1800 HU, while the spongy bone the density in the range of 200 to 1200 HU. Teeth consist of two main tissues: enamel and dentine. Enamel is the hardest tissue in human body and has the density in the range of 2100 to 4000 HU. Dentin has the CT number similar to the cortical bone in the range of 1400

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 665–668, 2009
www.springerlink.com

to 2000 HU. Human soft tissues usually have the density in the range of -200 to 400 HU. Since the CT number of soft tissues and the cortical bone are not overlapping, it is simple to separate them by thresholding or adaptive thresholding. However, spongy bone might be difficult to separate.

III. Threshold techniques

This topic represents the case study of the thresholding techniques for segmenting bone region in CT image. which consist of otsu's thresholding, kittler's thresholding and local entropy thresholding.

A. Otsu's thresholding

In this method, the weight sum between the background and foreground variance (σ_W^2) is computed as follows:

$$\sigma_W^2 = q_1(t)\sigma_1^2(t) + q_2(t)\sigma_2^2(t) \tag{1}$$

where $\sigma_1^2(t)$ is the background variance, which is computed from the value of gray level between at 1 and *t*. as follows:

$$\sigma_1^2(t) = \frac{\sum_{i=1}^{t} [i-\mu_1(t)]^2 P(i)}{q_1(t)} \tag{2}$$

a $\sigma_2^2(t)$ is the foreground variance, which is computed from the gray level between *t+1* and maximum gray level intensity (*l*). as follows:

$$\sigma_2^2(t) = \frac{\sum_{i=t+1}^{l} [i-\mu_2(t)]^2 P(i)}{q_2(t)} \tag{3}$$

where the weights

$$q_1(t) = \sum_{i=1}^{t} P(i) \quad \text{and} \quad q_2(t) = \sum_{i=t+1}^{l} P(i)$$

$$\mu_1(t) = \frac{\sum_{i=1}^{t} iP(i)}{q_1(t)} \quad \text{and} \quad \mu_2(t) = \frac{\sum_{i=t+1}^{l} iP(i)}{q_2(t)}$$

$P(i)$ is the probability of the intensities between i = 1,..*l* and *l* is the maximum gray value.

$$P(i) = \frac{number\{(r,c) \mid image(r,c) = i\}}{(R \times C)} \tag{4}$$

where r = the r[th] row , c = the c[th] column,
R and C values are the number of row and column

The optimal threshold value is selected by searching for the smallest weighted sum. The minimum value of variance must be computed from every intensity value to achieve the minimum value of the weighted sum. This provides the optimal threshold value.

B. Kittler's thresholding

This technique calculates the parameters similar to otsu's thresholding. However, the weighted sum of variance (*H*) is defined as follow:

$$H = \frac{1+log2\pi}{2} - q_1 log(q_1) - q_2 log(q_2) + \frac{1}{2}\left(q_1 log(\sigma_1^2) + q_2 log(\sigma_2^2)\right) \tag{5}$$

This technique finds the threshold value by searching for the minimum value of variance.

C. Local Entropy thresholding

This method represents on the Co-occurrence matrix. The co-occurrence matrix looks like a 2D histogram. This matrix can be created by the equation below.

$$t_{ij} = \sum_{m=1}^{M} \sum_{n=1}^{N} \delta_{mn} \tag{6}$$

where: t_{ij} is the $(i,j)^{th}$ element .
M and N are the number of rows and columns.

$$\delta_{mn} = \begin{cases} 1 \ if \begin{cases} f(m,n) = i \ and \ f(m+1,n) = j \ \ and/or \\ f(m,n) = i \ and \ f(m,n+1) = j \end{cases} \\ 0; \ otherwise \end{cases}$$

We transform an input image to a co-occurrence matrix, which is divided into four quadrants with a threshold value in Fig.2. There four quadrants are defined A, B, C and D. We can calculate variance of each quadrant from these equations.

$$\left.\begin{aligned} P_A^t &= \sum_{i=0}^{t}\sum_{j=0}^{t} p_{ij}, \quad P_B^t = \sum_{i=0}^{t}\sum_{j=t+1}^{L-1} p_{ij}, \\ P_C^t &= \sum_{i=t+1}^{L-1}\sum_{j=0}^{t} p_{ij}, \quad P_D^t = \sum_{i=t+1}^{L-1}\sum_{j=t+1}^{L-1} p_{ij} \end{aligned}\right\} \tag{7}$$

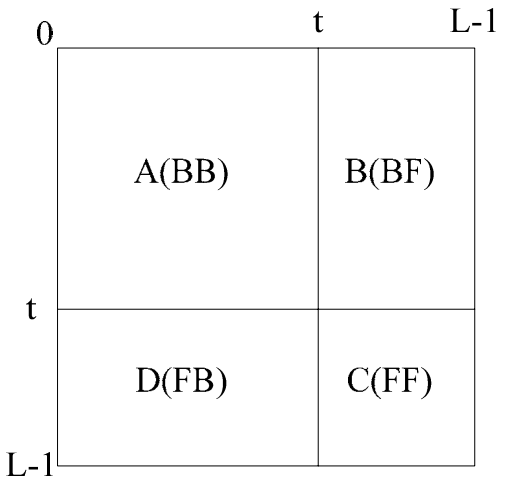

Fig. 2 Co-occurrence matrix

where p_{ij} the probability at element (*i,j*)

p^t_A, p^t_B, p^t_C and p^t_D the probability at quadrant.

$$p^t_{ij|A} = \frac{p_{ij}}{P^t_A},\ p^t_{ij|B} = \frac{p_{ij}}{P^t_B},\ p^t_{ij|C} = \frac{p_{ij}}{P^t_C},\ p^t_{ij|D} = \frac{p_{ij}}{P^t_D} \quad (8)$$

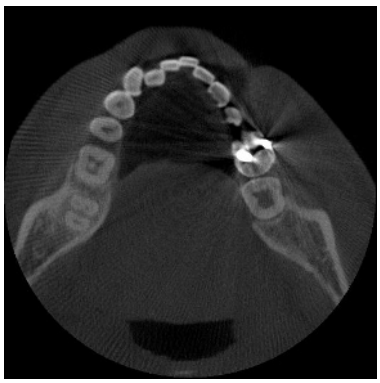
The pixels that have the gray value above the threshold are a foreground. Likewise, the pixels that have the gray value below the threshold are the background. Thus, quadrants A and C are the transition for the background and the foreground we can calculate the local entropy as follows:

$$H_{BB}(t) = -\sum_{i=0}^{t}\sum_{j=0}^{t} p^t_{ij|A} log p^t_{ij|A} \quad (9)$$

$$H_{FF}(t) = -\sum_{i=t+1}^{L-1}\sum_{j=t+1}^{L-1} p^t_{ij|C} log p^t_{ij|C} \quad (10)$$

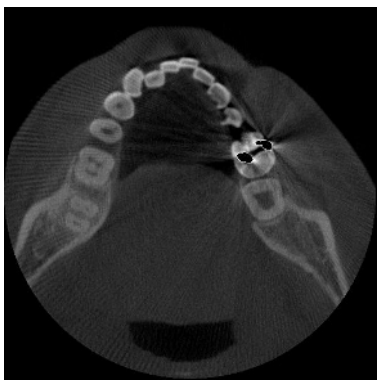
where $H_{BB}(t)$ is the local entropy value of quadrant A and $H_{FF}(t)$ is the local entropy value of quadrants C. can be calculate total local entropy as follows:

$$H_{LE}(t) = H_{BB}(t) + H_{FF}(t) \quad (11)$$



The optimal threshold value can be derived be searching for the minimum value of the total local entropy $(H_{LE}(t))$.

IV. Experiment result

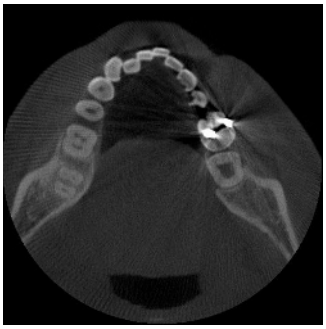


The experimental studies are divided into three parts.

A. Otsu's thresholding

With otsu's thresholding, the bone region cannot be segmented. Only the metal area can be segmented. Thus, automatic thresholding using otsu's thresholding is not suitable for segmentation in CT image.

a.) Original image



b.) Segment Image

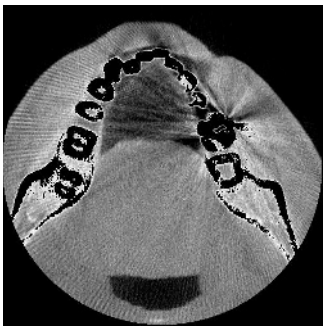


Fig. 3 result of otsu's thresholding

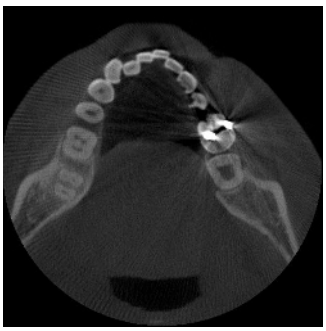
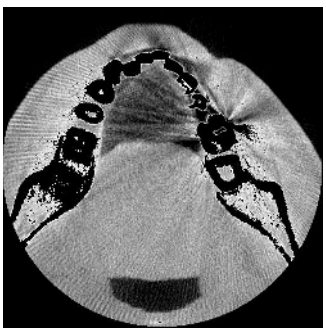
B. Kittler's thresholding

In the Kittler's thresholding technique, only some part of the bone region can be segmented as show in the black area of Fig.4. Both Otsu and kittler thresholding techniques are base on bi model histogram, which is not appropriate for CT images.



a.) Original image



b.) Segment Image

Fig. 4 result of kittler threshold

a.) Original image

b.) Segment Image

Fig. 5 result of Local Entropy threshold

C. Local Entropy thresholding

Unlike the previous two techniques, that are based on bimodal histogram of the image. Local entropy thresholding uses the co-occurrence matrix to calculate the threshold value, it provides better segmentation. The results are show in fig.5.

Table 1 represents the Experimental result to finding threshold value form jawbone. Which it have metal for fit jawbone of each CT-scan machine.

Scan machine	local En-tropy(HU)	Kittler (HU)	Otsu (HU)
Hitachi	1166	1390	3079
ICAT	1359	1500	3095

V. Discussion and conclusion

In this study we have compared three different techniques for segmenting the bone region. Otsu and Kittler thresholding find the threshold values based on the bimodal histogram; however, it is not always true in CT images. The results show that Otsu's thresholding can only segment the metal area. Although the Kittler's thresholding provides better results the Otsu's thresholding, it can partly segment the bone region. With local entropy, the co-occurrence matrix computes the 2D histogram, which is better then 1D histogram as Otsu and kittler methods. The results show that this technique can provide better results than the other.

Multi Scale Assessment of Bone Architecture and Quality from CT Images

T. Kalpalatha Reddy[1], Dr. N. Kumaravel[2]

[1]SKR Engineering College/ ECE, Anna University, Chennai, India
[2]College of Engineering,Guindy / ECE, Anna University, Chennai, India.

Abstract — **The purpose of this study was to develop a methodology for Quantitatively assessing bone Quality and anisotropy based one Texture analysis using curve lets. The curve let approach has the capability to simultaneously examine the images at low and high resolutions to gain information on both global and detailed local features of the bone image. It also allowed us to examine the texture energy at 13 orientations to gain insight about the details of anisotropy. Both histomorphometry and the texture analysis detected significant differences in the trabecular bone of the mandible between the control and abnormal groups. However the texture energy value at all orientations were significantly correlated. Texture analysis was able to assess anisotropy, which could not be extracted from histromorphometric parameters. we conclude that texture analysis is an effective tool for assessing 2-D Jaw Bone images that yields information regarding the Quantity of Bone as well as the orientation of the trabecular structure that can augment our ability to discriminate between normal and pathological bone tissue. The approach consists of two steps: automatic extraction of the most discriminative texture features from regions of interest and compare the features to discriminate between normal and pathological bone tissue. The discriminate power of several curvelet based texture descriptors are investigated.**

Keywords — **Multi – resolution analysis, Texture features curve lets: Computed Tomography**

I. Introduction

Quantitative measures of bone strength, which is dependent on mass, material and architecture, are necessary to investigate factors affecting bone strength.Histomorphometric analysis of trabecular bone has been used to quantity bone mass as well as the rate of bone formation resorption [8]. However, these measures were only designed to assess surface cellular activity, not the quantification of trabecular and cortical bone architecture. Multiple approaches have been utilized in characterizing the structure of trabecular bone from two dimensional images, particularly in describing orientation disparity or anisotropy. Mean intercept length was defined as the ratio between the total line length (in a linear grid) divided by the number of intersections, which when calculated as a function of direction gave information about the anisotropy of a bone sample [8] The MIL method however failed to recognize a visible anisotropy in a simulated images whose pattern had an isotropic interface between the bone and marrow Phases. Volume based methods including the volume orientation (vo) method and star volume distribution (svd) provided measure of trabecular bone around a point in the trabecula and were able to recognize anisotropy when MIL based methods failed, but they only recognized the anisotropy when the correct phase was chosen to avoid the isotropic interface [9].

Our aim is to determine whether a method can be found to characterize and classify the normal and abnormal bone structures and use this to monitor the progression of changes in the bone. The assessment of bone structure / bone quality in live patients is very difficult. Modern clinical methods of assessing bone quality such as QCT, single photon absortionometry, Dual energy radiography depend largely on measurement of bone mineral density. However it has long been acknowledged that the role of bone structure is important in the determination of bone quality and bone mineral density [8].While clinical methods such as the ultrasonic assessment of bone are believed to contain structural information [10], it is not yet known that what contribution this makes to the measured parameters. Other methods used to o obtain structural information are bone biopsies [8],CT imaging [9] [though the high resolutions is necessary to visualize trabecular bone structure require high dosage levels of X – rays], and magnetic resonance imaging [11].MRI is a promising technique but its expense means that any attempt to propose it as a routine method of assessing bone disease must justify its ability over other methods.

Further image analysis has been applied to most of these to extract quantitative information, including histomorphometry[8] and fractal geometry[9],although it has been suggested that the latter method is prone to artifacts. This was a preliminary study designed to test the proposed methods and evaluate their effectiveness in discriminating between different types of bone pathologies.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 669–672, 2009
www.springerlink.com

The differences in structure between normal and abnormal bone are often apparent to the unaided eye, but extracting the information contained in images of bone & Quantifying this for classification purpose is not trivial. This study set out to investigate whether changes in bone structure due to disease can be identified by mathematical methods.

In the last decade wavelet theory has been widely used for Texture classification process [2]. A comparative study by Randon & Husoy shows that various filtering approaches yield different results for different images [9] Wavelets are good at catching Zero dimensional or point singularities but two dimensional piecewise smooth signals resembling images have one – dimensional singularities [2]. Multiresolution analysis allows for the preservation of an image according to certain levels of resolution or blurring. Broadly speaking, multiresolution analysis allows for the zooming in and out in the underlying texture structure.

By decomposing the image into a series of high pass and low pass bands, the wavelet transform extracts directional details that capture horizontal, vertical and diagonal activity. However, these three linear directions are limitating and might not capture enough directional information in noisy images, such as medical CT scans which do not have strong horizontal vertical and diagonal elements. To overcome the weakness of wavelets in higher dimensions, Candes & Donoho pioneered a new system of representations named curvelet transform which is designed to handle curve discontinuities well. Here the idea is to partitioning the curves into collections of ridge fragments and then handle each fragment using ridge let transform .Curve lets are proven to be particularly effective at detecting image activity along curves instead of radial directions. Instead of capturing structure along radial lines, the curvelet transform captures this structural activity along radial 'wedges' in the frequency domain.

In this paper the curvelet transform is applied on a set of CT bone images and curvelet statistical features such as mean, variance, energy, entropy and curvelet co-occurrence features are extracted from each of the curvelet sub bands.

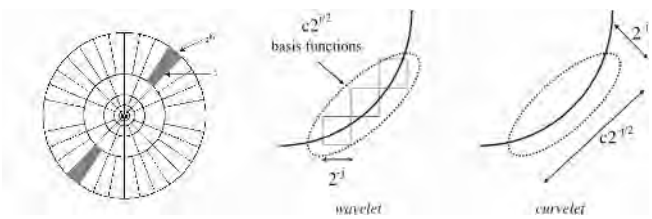

Fig. 1 Curvelet transform

The structural activity extracted from the curvelet transform of the image can be analyzed statistically to generate texture features used in the classifier to create classification rules. Common statistical measures used in texture classification in image processing are mean, standard deviation, energy, entropy, contrast, homogeneity, variance, correlation, max probability ,cluster tendency, cluster shade etc. However since these statistics are being applied to the curvelet transform, which extracts contrast pixel pairs in radial 'wedges', not all of these statistical measures are appropriate. This article introduces the use of several combinations of those descriptors and presents a comprehensive analysis determining the optimal texture descriptors for the curvelet transform as applied to CT scans.

II. Methodology

The texture classification algorithm proposed in this article consists of four main steps: Segmentation of regions of interest, application of the discrete curvelet transform, extraction of texture features and creation of a classifier.

Our tests were conducted on 3D dental CT data extracted from 30 patients consist of 190 2D DICOM consecutive slices for each patient and each of size 512 x 512 having 16-bit grey level resolution. Curvelets, like wavelets are extremely sensitive to contrast in the grey level intensity. Every slice is preprocessed by Gaussian filter and histogram equalization was done for contrast enhancement. The original dental images contain the bone and the background. In order to effectively use curvelet based texture descriptors, it was necessary to eliminate all back ground pixels to avoid mistaking the edge between the artificial background and the tissue as a texture feature. Each slice was therefore further cropped and only square 32 x 32 sub images fully contained in the interior of the anterior & posterior bone region were generated.

The texture features used in the algorithm are derived from the DCT, introduced by Candes & Donoho in [4] .The transform consists of four steps, application of a 2-dimensional Fast Fourier transform of the image, formation of a product of scale and angle windows, wrapping this product around the origin, and application of a 2 - dimensional inverse Fast Fourier transform. The approximate scales and orientations are supported by a generic 'wedge'.

The discrete curvelet transform can be calculated to various resolution or scales and angles. Two parameters are involved in the digital implementation of the curvelet transform: number of resolutions and number of angles at the coarsest level. For our images of 32 x 32, maximum resolution extraction was three levels of resolutions and 16 angles were found to be ideal.

Several features were calculated on the curvelet Coefficients. The most common statistics calculated on wavelet are mean and standard deviation obtained from the histogram of detail matrices. One of the goals of this research was to identify the most effective texture descriptors for medical images. Features such as mean and standard deviation are calculated from histogram of each of these curvelet sub-bands and are stored in the database. In addition to this co-occurrence matrices were also calculated at each detail and level of resolution. Curvelet transform is able to capture multidirectional features, as apposed to the wavelet transform which focuses mainly on horizontal, vertical and diagonal features which are not dominant in medical CT scan images

A co-occurrence matrix captures the spatial dependence of contrast values depending on different directions and distances specified. From the co-occurrence matrix the features such as contrast, cluster shade, cluster-tendency, homogeneity, max-probability are calculated and are stored in the feature data base. For computational efficiency the detail sub bands were binned for the co-occurrence matrix to reduce the size of the matrix

Comparison between the bone texture variables in disease affected and control patients were performed by using the non-parametric regression analysis due to the low number of patients. A value of $r<0.03$ was considered as statistically significant. The results were expressed as mean ± S.D

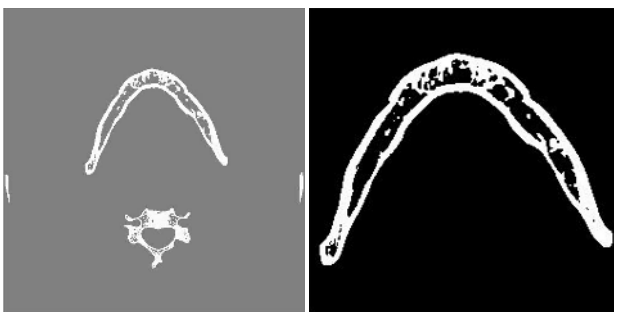

Fig. 2 The Original Jaw bone sample and extracted bone image

Table 1. Statistical Analysis of Significant Parameters

Parameter	Anterior Mandible		Posterior Mandible	
	Normal	Abnormal	Normal	Abnormal
Energy	0.2(0.03)	0.35(0.05)	0.21(0.04)	0.23(0.07)
Entropy	1.83(0.1)	1.31(0.17)	1.74(0.12)	1.71(0.23)
Variance	3.7(1.1)	1.96(0.98)	3.6(1.19)	2.9(0.74)
Mean	3.46(0.39)	2.0(0.34)	3.26(0.398)	2.9(0.56)
Kurtosis	3.78(1.11)	8.49(2.81)	3.94(1.16)	5.04(2.54)
Contrast	14.0(6.15)	4.5(2.8)	11.56(2.95)	10.7(3.3)
Homogeneity	4908(2229)	2302(1215)	2526(2987)	1113(1075)
Cluster Tendency	191.7(122.1)	147.4(60.3)	120.3(57.38)	74.85(56.6)
Maximum propobility	0.048(0.008)	0.426(0.024)	0.09(0.009)	0.142(0.04)

III. Discussion

We developed original methods for the analysis and characterization of bone texture based on numerical processing of Dental CT images. The results of this study indicate that curvelet – based texture analysis is an effective tool that could quantify bone architecture as well as bone density in two dimensional slices. This study set out to investigate whether changes in bone structure due to disease can be identified by mathematical methods. The texture analysis not only detected deficits in the amount of bone following a disuse protocol but the orientations in which the deficit occurred. The most promising structure parameters for CT images are contrast, maximum probability, homogeneity, cluster tendency, energy and variance. The discriminating powers of several resolution levels as well as various feature reduction techniques were analyzed.

A comprehensive analysis was carried out to determine the optional texture descriptors for the curvelet Transform as applied to CT scans. The multi directional features in curve lets prove to be very effective in the texture classification of the more organic textures in medical images. The results indicate that using curvelet based texture descriptors significantly improves the classification of normal and abnormal bone obtained from different patients.

An Evolutionary Heuristic Approach for Functional Modules Identification from Composite Biological Data

I.A. Maraziotis, A. Dragomir and A. Bezerianos

Department of Medical Physics, Medical School, University of Patras, 26500 Rio, Greece

Abstract — **Modular structures are key features of the complex biological networks which control the functioning and dynamics of the living cell. In order to unravel this intricate modularity we propose an algorithm having evolutionary features that unveils and optimizes sub-networks within a weighted graph of protein interactions. The graph is enriched by integrating information from gene expression profiles. Functional modules are retrieved by expanding a kernel protein set that originates from 'seed' proteins and validated through biological and topological criteria. The modules obtained are further refined using a framework based on binary particle swarm optimization.**

Keywords — **protein-protein interaction, functional modules, protein interaction network, data integration, particle swarm optimization.**

I. Introduction

Functional modules within protein interaction networks are characterized by the defining property that their members interact to achieve a common biological process, while from the topology point of view, they share more interactions among themselves than with members of other modules [1-2]. The determination of small-scale functional modules, such as protein complexes from large-scale interaction networks is therefore crucial in understanding the relation between the function and organization of a network. With experimental data probing protein interactions available from yeast two hybrid experiments or via immunoprecipitation [3-4], and protein complexes identified from mass spectrometry [5], computational methods are strongly required to fill in the knowledge gap.

Towards this goal, several algorithms ranging from hierarchical clustering [6] to methods considering local topology-based concepts [7] and graph alignment for determining probabilistic motifs [8] have recently been applied for detecting modules in protein interaction networks. These approaches represent the protein network as an unweighted graph, where nodes correspond to proteins and edges to interactions among them. Algorithms based solely on topological aspects manage to capture several features of complex networks. Nevertheless they might prove insufficient when applied at protein interaction networks that include special characteristics like inter-module crosstalk. Additionally, since protein-protein interaction data (PPI) is error-prone and therefore the models derived might be unconfident and misleading, additional measures need to be taken [9].

Various methods have been applied to overcome this. Pereira et al. [10] weighted an interaction based on the number of experiments that support it. Others weighted the distance between two proteins with the minimum shortest path between them [6],[11]. Even though these approaches assign some kind of confidence score to a certain interaction, still they fail to allocate a possible functional association in a pair of proteins. A straightforward solution was to enrich the PPI interactions with information from the corresponding protein-producing genes. The underlying concept is that genes with similar expression profiles are under the same transcriptional control and therefore functionally associated [12]. Despite the inherent noise embedded in expression data, it provides significant information about genes under more perturbations in comparison to PPI data [13]. However, few studies have so far considered gene expression data for weighting the protein interactions graph [14].

Our study introduces a new method for integrating gene expression data and PPI data in order to determine functional modules. Specifically, given a graph describing a set of experimentally determined protein interactions, we assign a weight to each one of these interactions. This weight originates from clustering the gene expression profiles of the corresponding proteins. Subsequently we present a new algorithm for the determination of functional modules within the original PPI graph starting from a kernel protein group that originates from a 'seed' protein. In the final stage, the candidate functional modules are refined within a framework based on Discrete Particle Swarm Optimization, which selects the optimal modules structure by minimizing a fitness function based on the connectivity degree of graph nodes and the weighted density of the graph.

II. Methods

In this section we will describe the procedure we follow to add weights to the interactions of the protein graph as well as the proposed algorithmic approach we have applied to extract functional modules from a given 'seed' protein.

www.springerlink.com

A. Assigning weights to Interactions

The weight is based on the GO similarity of the neighbours of proteins sharing the interaction at translational (protein) level and of the gene neighbours (in terms of similar expression profiles) of the corresponding genes at (transcriptional) gene level.

Each one of the proteins p_i and p_j that form a protein interaction u_{ij} is connected to another number of proteins (nodes of the protein graph) called neighbours of the proteins, symbolised as N_i and N_j respectively. Given the fact that each p_i and p_j are neighbours (since they share an interaction) they could have some other common nodes among N_i and N_j; we will symbolize the set of common neighbours as C_{ij} while the sets of the non-common neighbours will be denoted as D_i and D_j respectively. Therefore for the neighbours of the 2 proteins we have:

$$\left|\mathrm{D_i}\right|+\left|\mathrm{D_j}\right|+\left|C_{\mathrm{ij}}\right|=\left|N_{\mathrm{i}}\cup N_{\mathrm{j}}\right| \tag{1}$$

Of course the set C_{ij} could be empty and each one of the proteins forming the interaction is part of the neighborhood set of the other protein. Next step is to check common GO functionality concerning the neighbors of the two proteins based on the sets D_i and D_j (we do not check for functionality on N_{ij} since they are the same proteins for each one the interacting proteins). Specifically, we are considering the set with the minimum number of pairs like:

$$T_{ij}=\min\left(D_i,D_j\right) \tag{2}$$

We check each one of the members in T_{ij} against all of the members in the other set (e.g. that is D_i or D_j, pending on which of the two has the largest number of members) which we will call maximal set (MS), for GO similarity. When we are referring to GO similarity, we mean that the 2 genes having as products the corresponding proteins, share a common GO term. Every time we find a member in T_{ij} having a similar term in MS then we insert this member in the set of similar functionality members named S_{ij}.

The reason for considering the neighborhood set with the minimum number of neighbors instead of the maximum (2) is that there are many proteins that have a very large number of neighbors (these proteins are also known as hubs proteins). The most important reason for this is that a hub protein is a protein involved in many different functions within the cell. Therefore, if we consider the neighbors of such a protein to be compared against some other non-hub protein, then the weight would be degenerated losing information while it shouldn't, since we are interested in the relation between two specific proteins. In other words we are not interested if a specific gene/protein is involved in a large number of cell functions but if a protein is working together even in a fraction of the functions that its hub protein is involved.

Finally the weight for the specific interaction between proteins p_i and p_j is given by:

$$\beta_{ij}^{PPI}=\frac{\left|C_{ij}\right|+\left|S_{ij}\right|}{\left|C_{ij}\right|+\left|T_{ij}\right|} \tag{3}$$

This is the weight of the interaction resulting from the protein level. In an exact similar manner we establish the weight of the gene level. The neighbors of the corresponding gene whose protein product we study each time is determined by a constant number of genes that have the highest degree of similarity with the one under study, concerning their gene expression profiles. As we can derive from (3) the range of the two weights is normalized so as to range from zero to one, namely:

$$0\le\beta_{ij}^{PPI},\beta_{ij}^{GE}\le 1 \tag{4}$$

We now integrate the two weight types to a single weight as:

$$\mathrm{B}_{ij}=n\cdot\beta_{ij}^{PPI}+\left(1-n\right)\cdot\beta_{ij}^{GE} \tag{5}$$

Where n, is a constant ranging from 0 to 1 and determines the importance we impose on the PPI weight, while β_{ij}^{GE} corresponds to gene expression neighbors of the same interaction. In this study we have set the value of n equal to 0.6. The integrated weight B_{ij}, also ranges between 0 and 1 since both of the weights in the right hand side of (5) also have the same range.

B. DMSP

In a recent study we introduced a new method (DMSP – detect modules from seed proteins) for integrating gene expression data and protein-protein interactions in order to determine functional modules [15]. The algorithm operates in two phases as follows: firstly it accepts a 'seed' protein and selects a subset of its most promising neighbors, subsequently expanding this initial kernel to accept more proteins. This expansion is based on certain assumptions, concerning the number of neighbors for the specific protein as well as the weights of these connections.

In the first stage of the algorithm only a certain number of the neighbors of the 'seed' protein are selected. These adjacent nodes are sorted in descending degree of significance and this subset of nodes – proteins is named kernel.

The two criteria (commonly used in graph theory) by which the original kernel is selected are the density of the kernel and the weighted internal and external degrees of it. The objective for selecting the kernel of the seed node is two-fold. Firstly we check that the number of edges of a kernel node within the rest of the kernel is larger or at least equal to the number of the edges that a node has outside the group. At the same time and after we have confirmed that a selected node fulfils the first condition, we request that the same node has smaller weighted internal degree than its corresponding weighted external degree. Nodes that fail to pass the above criteria are discarded, while those that do, are sorted based on the level that each one of them manages to do so.

The second stage of the algorithm receives as input the selected kernel of the 'seed' protein and iteratively adds adjacent nodes based again on two criteria. The first criterion the algorithm checks is the same as the first one of the initial stage of the algorithm. After this criterion has been checked then we select a node to be added to the neighborhood, if it satisfies the condition of having a smaller or equal weight than the weighed internal degree of the kernel node.

C. Evolutionary DMSP

The final step of the algorithm we are proposing is the optimization of the extracted functional modules. In order to accomplish this, we have used a binary discrete version the algorithm particle swarm optimization (PSO). PSO is an algorithm that simulates the social behaviour of organisms, such as birds in a flock [16]. This behaviour can be described as an automatically and iteratively updated system. In PSO, each single candidate solution can be considered as a particle in the search space. Each particle has a position in the search space (which is a possible solution to a given problem) and makes use of its own memory and knowledge gained by the swarm as a whole to find the best solution. All of the particles have fitness values, which are evaluated by a fitness function to be optimized. During movement, each particle adjusts its position by changing its velocity according to its own experience and according to the experience of a neighbouring particle, thus making use of the best position encountered by itself and its neighbour. While there are various different neighbouring schemes for different problems, in this study each one of the particles follows the best position acquired by the flock. Particles move through the problem space by following a current of optimum particles. The process is then iterated a fixed number of times or until a predetermined minimum error is achieved [16].

The procedure of integrating the binary version of PSO (BPSO) and DMSP is the following: initially, we create a predetermined number of particles. The position of each particle is represented by: $X_i = \left(X_{i1}, X_{i2}, \ldots, X_{iN}\right)$ where N is the number of proteins in the module, extracted by DMSP in the 1st stage. Therefore the module is represented by the various particles as a binary string randomly generated; the bit value *{0}* and *{1}* represent a non-selected and selected node/protein, respectively.

The velocity for each one of the particle is given by:

$$v_{ij}\left(t+1\right) = W_I \cdot v_{ij}\left(t\right) + c_1 \cdot \left(B_{ij}^{i} - x_i\left(t\right)\right) + c_2 \cdot \left(B_G^{ij} - x_i\left(t\right)\right) \quad (6)$$

where W_I is known as inertia weight, and c_1, c_2 are called learning or acceleration factors. All of these variables are randomly selected parameters of BPSO ranging between 0 and 1. B^i_{ij} is the best position of the i-th particle and B_G is the best position acquired by the whole swarm.

In every iteration of the algorithm the position of each particle (i.e. the newly formed module based on the one extracted by DMSP) is changed towards an optimum solution which will represent the optimized functional module. In other words the algorithm initiates with a module having an initial number M of proteins and searches for the best subset of these proteins in terms of topological coherency among its members. The fitness function we use for the BPSO is the following:

$$F\left(X_i\right) = D_w\left(G\right) - \frac{1}{N}\sum_{i=1}^{N}\theta\left(G, u_i\right) \quad (7)$$

The fitness function (FF) is built so as to improve, after the end of BPSO, the extracted by DSMP functional module based on topological characteristics of the module within the protein graph. Specifically the FF uses the density $D_w(G)$ of a graph G(V, E), which is generally measured by the proportion of the number of edges in the graph to the number of all possible edges, which is equal to |V|(|V|-1) for an undirected graph. Due to the fact that we work on a weighted graph we are using weighted density of a graph or sub-graph $D_w(G)$, which is the sum of the weights of actual edges over the edges among all nodes in G:

The degree $\theta(G, u_i)$ of a node u_i that is member of a subgraph G of a graph Γ is given as the number of edges of a specific node with the rest of the members of the subgraph, over the total number of edges of the specific node to all other nodes of the graph Γ.

III. Results

Based on MIPS database (http://mips.gsf.de/proj/ppi/) we have created a protein graph of known interactions for yeast. Specifically the protein graph consisted of 4176 proteins and was composed of several smaller isolated subgraphs and nodes (137) consisting of 1 to 5 proteins, and one main sub-graph consisting of 3964 proteins and 11200 interactions among them. For weighting the PPI graph we have used gene expression cell cycle data (http://cellcycle-www.stanford.edu). On the large component we have applied the evolutionary DSMP algorithm.

Table 1 presents some (due to space limitations) of the obtained results. The first column corresponds to the protein given as input 'seed' protein to the algorithm. The second column indicates the protein complex that the algorithm managed to detect, on the third column we provide the number of members detected from the corresponding complex and the true number of members of the complex, in the parentheses there is the number of members of the extracted functional module. Finally the last column gives the p-value which is a commonly used metric for validating results and represents the probability of observing the co-occurence of certain proteins in a protein complex and a detected functional module by chance, based on binomial distribution. The smaller this value is the more remote is the probability of having detected a specific protein complex by chance.

Describing briefly one of the entries in Table 1, we can comment that by entering 'APC11' as a seed protein to the algorithm we have obtained a module of 14 proteins corresponding to the Anaphase promoting complex (APC) which is composed of 11 members. The p-value (<1e-14), signifies that the proposed algorithm (based on the weighted graph we created) managed to adequately detect the protein complex whose member is the provided 'seed' protein.

IV. Conclusions

The technology advances of the last decade triggered an exponential growth in the amount of molecular biology data and created a paradigm shift, from a reductionist view to a systems-oriented one. Therefore the frontier of research moved towards integrated approaches comprising computational analysis and mining large sets of different data types.

The concept of data integration has already been examined by works like [9], which validated the view that protein-protein interaction data are flooded with false interactions and therefore additional sources of data are to be considered in order to provide a more complete and valid models of interaction networks.

In the current study we consider an algorithm that identifies functional modules from weighted graphs derived from PPI by expanding a kernel protein set which originates from 'seed' proteins used as starting point. The functional modules that are obtained are further optimized using an approach based on a particle swarm optimization method. We prove based on data of *Saccharomyces cerevisiae* that our method provides modules with functional and topological consistency.

Table 1 Results obtained using the evolutionary DMSP algorithm

Seed	Complex	Members	p-value
TAF5	SAGA	14/16 (22)	<1e-14
APC11	APC	11/11 (14)	<1e-14
SEC27	COPI	7/8 (10)	<1e-14

An Empirical Approach for Objective Pain Measurement using Dermal and Cardiac Parameters

Shankar K.[1], Dr. Subbiah Bharathi V.[2], Jackson Daniel[1]

[1]Senior Lecturer, Dept. of EIE, National Engineering College, Kovilpatti, Tamilnadu, India
[2]Professor, Dept. of CSE, DMI College of Engineering, Chennai, Tamilnadu, India

Abstract — **As the exact pain measurement is an important prerequisite for pain management, this work aims to measure Pain objectively. As the physiological parameters have significant relationship with pain, we intend to measure ECG, HR, BP and GSR with the equal amount of pain being induced on all the subjects. For this purpose, we have designed an apparatus called Pain Inducer which consists of five discs mounted on a central slot to induce the pain. The experiments (Pre Pain, During Pain and Post pain experiments) were conducted inside the controlled laboratory environment. The parameters have been acquired and analyzed by an instrument called physiograph (RMS Polyrite-D). We have chosen 50 male volunteers of age between 20 and 22 years, for this purpose. The subjects were with normal appetite (food habits) and residing in a confined locality. It is found that both the cardiac parameters and somatic resistance showed significant changes between the 'pain' and 'no pain' conditions. However more experimental studies with additional physiological parameters on large number of subjects in actual clinical setup are required to validate this method. Also, a generalized pain measurement system for all kinds of pain is another challenge to be addressed. Further work on this area may improve the utility of this method in clinical practices for measuring pain objectively. It leads to reduced administration of painkillers.**

Keywords — **GSR, Objective Measurement, Pain, Pain inducer, Physiograph.**

I. Introduction

The onset of the 21st century is an incredibly exciting time in pain research [1]. Information from recent studies in basic pain research is virtually exploding and has revealed numerous novel targets in pain research. The pain offers challenges to both, physician and sufferer [2]. For the sufferer, it is a hurt. He faces huge challenges in getting relieved from pain. For the physician, it offers great challenges in terms of curing sufferer's pain. As the pain is a worldwide clinical problem that causes great suffering for the individual and costs for society, the assessment and evaluation of perceived pain is necessary for diagnosis, choice of treatment, and for the evaluation of treatment efficacy. In order to cure pain, a physician must know the quantity of sufferer's pain exactly. Otherwise, the physician may prescribe a wrong dosage of pain killers; it may lead to adverse effects [3, 4].

Presently, subjective methods (Visual Analog Scale, Verbal Analog Scale, Color Analog Scale, Face Pain Scale, Questionnaire method and Behavioral measures) are being used to assess the pain [5]. As there is no specific standard, we have no accurate terminology for the physician to interpret it. There is an increasing demand for pain measurement especially for infants, mute and people at unexplainable situations. Therefore, it is essential to measure the pain objectively and we need some quantitative indicator of pain.

Though there are many quantitative indicators of pain in the literature [6], we aim to check a response of Galvanic Skin Response (GSR) and Cardiac parameters for the pain. And we checked which one of these parameters could be used as a valid pain indicator.

The term 'pain' in this paper is limited to only for mechanically stimulated pain and not the actual pain. The mechanical pain is induced using 'Pain Inducer' (Fig. 1) designed and fabricated by the 'Pain Experiment Group' (PEG). The parameters of all subjects were measured and analyzed by using a digital physiograph – RMS Polyrite D. The experiments were done in a controlled laboratory set up, not in clinical set up.

II. Methodology

A. Pain Inducer

The pain inducer resembles the "TOWERS OF HANOI" [7]. It consists of discs of diameter of 5cm provided with a central slot. So that weights can be added and the amount of pain can be increased. The base disc is supported with a central rod of 15cm in length. The base of the pain inducer consists of a perfect cube of area 1 X 1 cm. One of the edges of the cube was supposed to be placed on the inner side of the subject's middle finger.

Pain caused (induced):

Pain (pressure) = Force/Area

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 678–681, 2009
www.springerlink.com

Fig. 1 Pain Inducer setup

Since the cube is of unit area, Area = 1 sq.cm

Therefore, Pain (pressure) = force = mass x gravity

Since gravity is a universal constant, Pain (pressure) is proportional to the applied mass.

By using the pain inducer setup together with the additional discs of 150 grams each, we induce the pain on the subjects. In this setup we could add the weights up to 950 grams. So this pain inducer could cause the pain which is equal to 950 grams / sq.cm.

B. Experiments

The experimental studies in this work involve two types namely (i) Pain-Dermal (PD) and (ii) Pain-Cardiac (PC) experiments. The experiments were conducted in three stages namely 'Pre Pain', 'Pain' and 'Post Pain'. For conducting these experiments, we selected 50 male volunteers of age group between 20 and 22 years. All these 50 volunteers were with normal appetite and healthy. The volunteers were from confined locality also.

Before involving the volunteers in the experiments, the PEG explained all about the experiments including the pain to be induced on them, duration etc. The experiments were conducted only after getting the consent from the volunteers. By conducting these experiments we acquired the dermal and cardiac parameters. Of these parameters the Blood Pressure (BP) alone was measured by using a separate Auto BP module (RMS Phoebus 401 N), simultaneously with other needed parameters.

During the experiments, we followed standard instructions for placing the electrodes on volunteers at desired area of body [8].

III. Results

Experimental studies have been performed to find the effect of certain physiological parameters like GSR, ECG, Heart rate, R-R interval, and Blood pressure when pain was induced on the subjects.

The effect of the pain was analyzed individually related to the noted physiological parameters like blood pressure, Electro cardiogram, and Galvanic Skin response of all the subjects.

A. PD Experiments

The consolidated readings of the average values of Skin resistance (in Kilo Ohms) for each of the subjects are shown in. Table 1.

From these tabulated readings, we come to know that out of fifteen subjects; only one subject has been an exception whereas the rest of the subjects showed a decrease in resistivity, when pain stimuli was induced on them.

The Galvanic skin response introduces an objective element [9], but does not dispose all the problems. But the skin resistivity is a variable and often an unstable phenomenon. Some individuals react too sluggishly; further certain psychic components are involved in GSR analysis. [10].

Table 1 Results of Pain – GSR Analysis

S.No.	Subject	Pre-Pain	During Pain	Post-Pain
1	selva	115.54	93.5	99.87
2	krishnakumar	155.48	110.52	111.42
3	karthikeyan	93.16	51.09	65.77
4	vivek	147.77	143.91	103.37
5	raju	255.75	232.52	242.73
6	kailash	81.38	79.8	102.28
7	p.karthik	87.56	76.09	80.32

15	boopathy	122.66	87.83	112.92

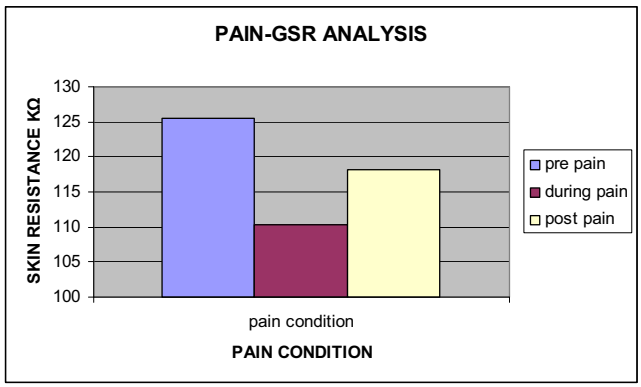

Fig. 2 Average results of Pain – GSR Analysis

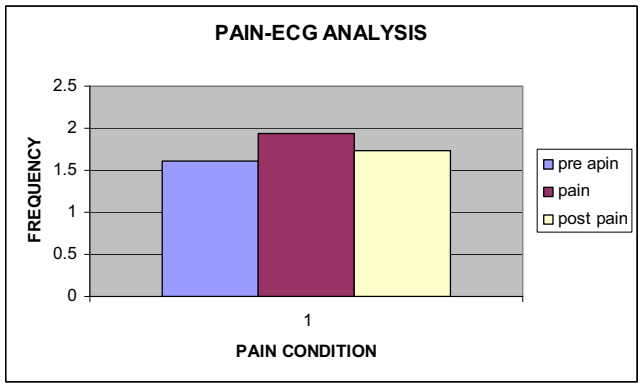

Fig. 3 Average results of Pain – ECG Analysis

On an average, there was a decrease in skin resistance of about 15 kΩ from pre pain to during pain condition and there was an increase in skin resistance of around 8 kΩ when the subject reacts from during pain condition to post pain condition as indicated in Fig. 2.

B. PC Experiments

The influence of pain on the Electro Cardiogram was analyzed in three different time durations of two minutes, each pertaining to the pre pain, during pain and the post pain conditions as in the case of PD experiments.

The Fast Fourier Transform (FFT) analysis was carried out on the recorded readings of the ECG data of all the subjects as shown in the Table 2.

Table 2 Results of Pain – ECG Analysis

S.No.	Subject	Pre-Pain	During Pain	Post-Pain
1	selva	1.311	1.47	1.311
2	krishnakumar	2.95	3.27	3.11
3	karthikeyan	0.98	1.147	0.9
4	vivek	0.98	1.147	0.98
5	raju	0.98	1.147	0.98
6	kailash	1.147	1.47	1.311
7	p.karthik	1.311	1.47	1.311
8	bijoy	1.311	1.47	1.311
9	sakthivel	1.63	1.8	1.47
10	praveen	0.87	0.87	0.87
11	jone	4.42	4.75	4.58
12	sundar	2.26	2.7	2.62
13	mujibur	1.147	1.148	1.147
14	nagarajan	1.51	1.55	1.63
15	boopathy	1.311	3.6	2.45

From this tabulation, we can come to a conclusion that, there has been a sturdy increase of the frequency component of the ECG data of all the subjects when subjected to the pain stimuli, compared with the pre pain and the post pain conditions.

Exceptionally two subjects did not show any significant change in the readings taken during the pre pain, during pain and post pain conditions. And the frequency increased to 4 Hz in one subject, whereas in rest of the subjects the value of frequency was less than 1.8 Hz.

On an average there was a steady increase in the frequency of the ECG wave (Fig. 3) when the subjects were given pain stimuli.

In the Pain – Blood pressure analysis, the blood pressure readings (both systolic and diastolic) were sought out from all the subjects and the values were manually entered for the three stages of experiment.

From the Table 3, we can draw to a conclusion that, there is a significant increase in both the systolic and the diastolic blood pressure values of all the subjects. On an average, there has been an increase of 5 mmHg of blood pressure from the pre pain condition to the during pain condition and also there has been a decrease in blood pressure of about 7mmHg from the during pain to the post pain condition (Fig. 4).

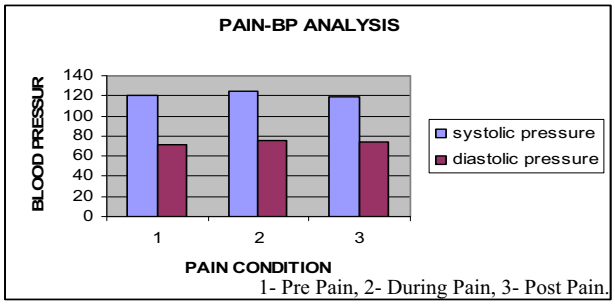

Fig. 4 Average Results of Pain and BP

IV. Conclusion

The specific but future goal of this project is to measure Pain objectively, for which we have taken the cardiac and the dermal parameters to analyze the pain. These results show a clear relation between Pain and GSR also between Pain and other Cardiac parameters like ECG, Blood Pressure and Heart Rate Variability. There is a prominent increase in the value of the R-R interval, which is abruptly seen in the results of HRV analysis.

In the Pain – HRV analysis, the recorded ECG recordings are analyzed both in time and frequency domains. As the cardiac parameters are supposed to be fluctuating under the normal circumstances, for any disturbances, we conclude that there is a scope for measuring pain objectively with a larger reliability on dermal changes.

But it requires a lot of experimental studies with other physiological parameters on many numbers of subjects and could be made to consider this as a method for Objective Pain Measurement. The further work in this area may improve the utility of this method in clinical practices for measuring pain objectively for pain killer management. The future work in this context involves in designing a system to measure all types of pain objectively and guide the physicians in proper administration of painkillers. Further improvements can be made in the reported work by

- Conducting experiments in a clinical setup with actual pain rather than in a laboratory setup with induced pain, and establishing relation between pain and certain other physiological parameters.

- Analyzing the pain responses of larger group of subjects consisting of male and female of different ages may help to determine the precise range of physiological change.

Acknowledgement

The authors thank the students – Mr.Selvamurugan, Mr.Karthik and Mr.Krishnakumar for their help in conducting the experiments.

Abstract — **This paper proposes a system to support diagnosis for quantitative evaluation of motility function based on finger tapping movements using probabilistic neural networks (PNNs). Finger tapping movements are measured using magnetic sensors and evaluated by computing 11 indices. These indices are standardized based on those of normal subjects, and are then input to PNNs to assess motility function. The subject's motor ability is probabilistically discriminated to determine whether it is normal or not using a classifier combined with the output of multiple PNNs based on bagging and entropy. This paper reports on evaluation and discrimination experiments performed on finger tapping movements in 33 PD patients and 32 normal elderly subjects. The results showed that the patients could be classified correctly in terms of their impairment status with a high degree of accuracy (average rate:** 93.1 ± 3.69 **%) using 12 LLGMNs, which was about 5% higher than the results obtained using a single LLGMN.**

Keywords — **Finger tapping movements, magnetic sensors, neural networks, pattern discrimination, diagnosis support**

I. Introduction

To identify neurological disorders such as Parkinson's disease (PD) and quantify motility function by measuring patients' physical movements, various assessment methods have been discussed, including tremor and reaction movements [1] and finger tapping movements [2]. In particular, finger tapping movements have already been widely investigated, and a method to analyze tapping rhythm as well as a method to quantify tapping amplification and velocity [3],[4] have been reported. However, the above evaluations have been performed only for basic analysis such as verification of the feature quantities of PD patients. To realize a diagnosis support system for use in the routine assessment of PD in clinical environments, the features of finger movement need to be extracted numerically for quantitative classification and evaluation.

The classification and evaluation of a subject's movement and symptom severity are equivalent to clustering on measured data distribution. So far, several nonlinear classification methods have been proposed by assuming probabilistic distribution of measured data, and probabilistic neural networks (PNNs) have recently attracted widespread attention [5]. However, the authors are unaware of any reports detailing the use of PNNs to classify motility disturbance.

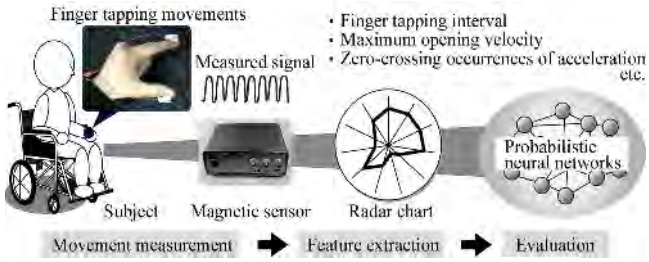

Fig. 1 Concept of the proposed diagnosis support system for finger tapping movements

In this paper, we propose a diagnosis support system employing multiple probabilistic neural networks. The system utilizes a magnetic sensor to measure finger tapping movement and extract its features (such as velocity and rhythm) based on medical knowledge, and then displays the feature indices for doctors' reference on a monitor. Further, the relationships between symptoms and movement features are embedded into the neural networks through learning, and can be used to evaluate motility function by combining outputs of multiple neural networks based on the ensemble learning method of bagging [6]. Since the outcomes of the neural networks indicate probabilities, doctors can intuitively understand the features of finger tapping movements and make quantitative evaluation from the indices or radar chart on the display.

II. Diagnosis Support System for Finger Tapping Movements

The diagnosis support system is shown in Fig. 1. The details of each process are explained in the subsections below.

A. Movement measurement [4]

The magnetic sensor developed by Kandori et al. [3] is utilized to measure finger tapping movements. This sensor

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 682–686, 2009
www.springerlink.com

can output a voltage corresponding to changes in distance between the detection coil and the oscillation coil by means of electromagnetic induction. First, the two coils are attached to the distal parts of the user's fingers, and finger tapping movements are measured. The distances between the two fingertips (the *fingertip distances*) are then obtained from the output voltage by a calibration model expressed as

$$d(t) = \alpha V^{-1/3}(t) - \varepsilon \,, \tag{1}$$

where $d(t)$ denotes the fingertip distance, $V(t)$ is the measured voltage of the sensors at a given time t, and α and ε are constants computed from calibration [4]. In the calibration process, α and ε are estimated using the linear least-square method for n values of measured output voltages and fingertip distances for each subject. Further, the velocity $v(t)$ and acceleration $a(t)$ can be calculated from the fingertip distance $d(t)$ using differentiation filters.

B. Feature extraction

This paper defines eleven indices for the evaluation of finger tapping movements as follows: (1) *total tapping distance*; (2) *average maximum amplitude of finger taps*; (3) *coefficient of variation* (*CV*) *of maximum amplitude*; (4) *average finger tapping interval*; (5) *CV of finger tapping interval*; (6) *average maximum opening velocity*; (7) *CV of maximum opening velocity*; (8) *average maximum closing velocity*; (9) *CV of maximum closing velocity*; (10) *average zero-crossing occurrences of acceleration*; and (11) *spectral variability of finger taps.*

First, the integration of the absolute value of velocity $v(t)$ through the measurement time is signified as the total tapping distance (Index 1). As feature quantities of the i^{th} tapping, the maximum and minimum amplitude points (dp_i, dq_i) between the interval [T_i, T_{i+1}] are calculated from the measured fingertip distance $d(t)$, and the average (Index 2) and CV (Index 3) of maximum amplitudes $ma_i = dp_i - dq_i$ are computed. Here, T_i (i = 1,2,…,I) is the instant of finger contact, and I is the number of contacts between fingertips. Further, the finger tapping interval It_i, which is the time interval between two consecutive contacts, is applied as $It_i = T_{i+1} - T_i$, and the positive and negative maximum velocity points are defined as the maximum opening velocity vo_i and the maximum closing velocity vc_i, respectively. The averages and CVs of the finger tapping interval, maximum opening velocity and maximum closing velocity are then computed from all the values of It_i, vo_i, and vc_i (Indices 4–9), respectively.

In addition, zc_i, which denotes the number of zero crossings of the acceleration waveform $a(t)$, is calculated from each interval between T_i and T_{i+1}, and the zero-crossing occurrences of acceleration zc_i are defined as the evaluation values of multimodal movements (Index 10). Finally, the time-series finger tapping interval It_i is resampled at f_a Hz by applying the linear interpolation method, and the power spectral density of the data is then estimated using the fast Fourier transform (FFT). The value of the integrated power spectrum from f_b to f_c Hz is defined as the spectral variability of finger taps (Index (11)).

The evaluation indices calculated for the subject are normalized based on the indices of normal subjects to enable comparison of the differences in movement. In this paper, the standard normally distributed variables x_j are converted to the mean and standard deviations of the tapping data from those of the normal subjects using Eq. 2.

$$x_j = (z_j - \mu_j)/\sigma_j \tag{2}$$

Here, j corresponds to the index number, z_j is the computed value in each index, and μ_j and σ_j describe the average and standard deviations of each index in the group of normal elderly subjects respectively. j = 1 represents the total tapping distance, j = 2,…, 9 signify the averages and CVs of maximum amplitude, finger tapping interval, maximum opening velocity and maximum closing velocity, and j = 10 and 11 denote the average zero-crossing occurrences of acceleration and the spectral variability of finger taps. Additionally, the input vector $\boldsymbol{x} = [x_1, x_2, ..., x_{11}]^{\mathrm{T}}$ is defined for the discrimination of finger tapping movements.

C. Evaluation using probabilistic neural network ensembles

The extracted features are discriminated to enable evaluation of motility function. In this paper, a log-linearized Gaussian mixture network (LLGMN) [5] is used as the PNN, and each index is evaluated using the ensemble learning method based on bagging [6] for the LLGMN.

LLGMN [5]*:* The LLGMN is based on the Gaussian mixture model (GMM) and the log-linear model of the probability density function (pdf), and the *a posteriori* probability is estimated based on the GMM by learning. By applying the log-linear model to a product of the mixture coefficient and the mixture component of the GMM, a semi-parametric model of the pdf is incorporated into a three-layer feed-forward PNN. Through learning, the LLGMN distinguishes movement patterns with individual differences, thereby enabling precise pattern recognition for bioelectric signals such as EMG and EEG [5].

Combination rules for LLGMNs: The combination strategy for multiple LLGMNs is shown in Fig. 2. This method consists of the C LLGMN classifiers, corresponding to the number of input vectors, $\boldsymbol{x}_1, \boldsymbol{x}_2, \ldots, \boldsymbol{x}_C$. Each LLGMN out-

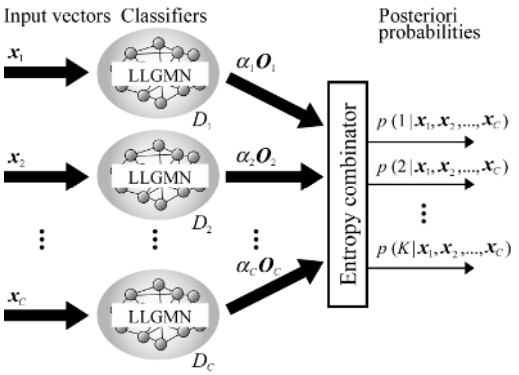

Fig. 2 Combination strategy for LLGMNs

puts the *a posteriori* probability of each learned class, which are then combined based on the ensemble learning method of bagging and entropy. First, each input vector $\boldsymbol{x}_c$ (c = 1,2,…,C) is input to the cth LLGMN, and the *a posteriori* probability vector $\boldsymbol{O}_c$ is calculated by the LLGMN. Here, $\boldsymbol{O}_c$ is defined by Eq. 3 using the *a posteriori* probability $p(k \mid \boldsymbol{x}_c)$ at given value $\boldsymbol{x}_c$:

$$\begin{aligned}\boldsymbol{O}_c &= \left[{}^{(3)}O_1, {}^{(3)}O_2, \ldots, {}^{(3)}O_K\right]^{\mathrm{T}} \\ &= \left[p(1 \mid \boldsymbol{x}_c), p(2 \mid \boldsymbol{x}_c), \ldots, p(K \mid \boldsymbol{x}_c)\right]^{\mathrm{T}}.\end{aligned} \tag{3}$$

The entropy combinator receives the output of each LLGMN weighted by coefficient α_c, and outputs the *a posteriori* probabilities of all classes. Each element of the entropy combinator's input vector $\boldsymbol{y}_c$ is given by

$$y_k(\boldsymbol{x}_c) = \alpha_c p(k \mid \boldsymbol{x}_c), \tag{4}$$

where coefficient α_c $(0 < \alpha_c < 1)$, which denotes the degree of effect of the cth LLGMN's output, is defined as

$$\begin{aligned}\alpha_c &= 1 - H(\boldsymbol{x}_c) \\ &= 1 + \frac{1}{\log K}\left(\sum_{k=1}^{K} p(k \mid \boldsymbol{x}_c) \log p(k \mid \boldsymbol{x}_c)\right).\end{aligned} \tag{5}$$

Here, $H(\boldsymbol{x}_c)$ signifies the entropy of the output of the LLGMN, and denotes the ambiguity of the *a posteriori* probabilities. When these probabilities are ambiguous, the entropy $H(\boldsymbol{x}_c)$ becomes large and α_c approaches 0.

In the entropy combinator, the *a posteriori* probabilities of all classes are calculated by

$$Y_k = p(k \mid \boldsymbol{x}_1, \boldsymbol{x}_2, \ldots, \boldsymbol{x}_C) = \frac{\sum_{c'=1}^{C} y_k(\boldsymbol{x}_c)}{\sum_{k'=1}^{K}\sum_{c'=1}^{C} y_{k'}(\boldsymbol{x}'_{c'})}. \tag{6}$$

In the above method, each pdf for input vector $\boldsymbol{x}_c$ can be estimated and combined, and the networks can be used to calculate the *a posteriori* probability of class k for any given measured data.

For the discrimination of measured data, the entropy of all classes defined by Eq. 7 is used:

$$E = -\sum_{k=1}^{K} Y_k \log Y_k. \tag{7}$$

If E is smaller than discrimination determination threshold value E_d, the class with the highest *a posteriori* probability becomes the result of discrimination. Otherwise, if E exceeds E_d, discrimination is suspended as an obscure class.

Evaluation of finger tapping movements: First, input vector $\boldsymbol{x}_c$ is created from measured finger tapping movements for their evaluation. $\boldsymbol{x}(t_{all}) \in \Re^{11}$ and $\boldsymbol{x}(t_d) \in \Re^{11}$, which are the feature vectors, are computed for the overall measurement time t_{all} and the time interval $[t_d^{st}, t_d^{ed}]$ respectively. Then, the jth elements $x_j(t_d)$ of $\boldsymbol{x}(t_d)$ (d = 1,2,…,D) are used to make the new vector, defined as $\boldsymbol{x}'_j = [x_j(t_1), x_j(t_2), \ldots, x_j(t_D)]^{\mathrm{T}} \in \Re^D$ (j = 1,2,…,11).

The system next measures the finger tapping movements of the patient and those of normal subjects. The feature vectors $\boldsymbol{x}'_j$ and $\boldsymbol{x}(t_{all})$ calculated from these movements are then input to each LLGMN as teacher vectors, and the LLGMNs are trained to estimate the *a posteriori* probabilities of each movement. Thus, the number of LLGMNs is C = 11+1 = 12. After training, the system can calculate similarities between patterns in the subject's movements and trained movements as *a posteriori* probabilities by inputting the newly measured vectors to the LLGMNs.

III. Experiments

A. Method

The subjects were 33 patients with PD (average age: 69.4 ± 8.1, male: 16, female: 17) and 32 normal elderly subjects (average age: 68.2 ± 5.0, male: 16, female: 16). Coils were attached to the distal parts of the thumb and index finger, and the magnetic sensor was calibrated using three calibration values of 20, 30 and 90 mm. The movement of each hand was measured for 60 s in compliance with instructions to move the fingers as far apart and as quickly as possible. The severities of PD in the patients were evaluated by a neuro-physician based on the finger tapping test of the Unified Parkinson's Disease Rating Scale (UPDRS). The calculated indices were standardized on the

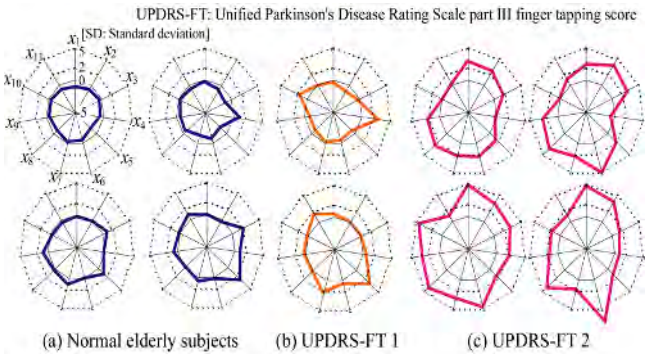

Fig. 3 Examples of radar chart representation of the results of the evaluated indices [4]

basis of the values obtained from the normal elderly subjects. The sampling frequency was 100 Hz. Each index was computed for the overall measurement time t_{all} = 60 and at four pre-specified time intervals of t_1 =[0,30], t_2 = [10,40], t_3 = [20,50] and t_4 = [30,60] and input to the LLGMNs. The measured finger tapping movements were then put into two classes in terms of whether they were normal or not; k = 1: normal elderly; k = 2: PD; K = 2. In addition, fifteen samples of each class were used as teacher vectors for learning.

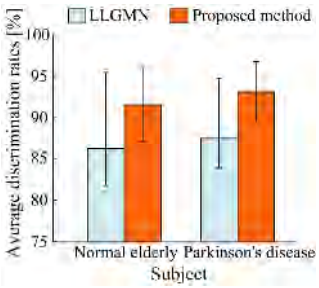

Fig. 4 Discrimination rates of finger tapping movements

B. Results

Radar chart representation of the results of the indices is shown in Fig. 3; (a) to (c) illustrate the charts for normal elderly subjects, PD patients with UPDRS-FT 1 and those with UPDRS-FT 2 respectively. The solid lines describe the average value of each index in the group of normal elderly subjects, and the dotted lines show double and quintuple the standard deviation (2SD, 5SD). The classification results of the finger tapping movements for all subjects are outlined in Fig. 4. This shows the mean values and standard deviations of the discrimination rates for 50 kinds of training set and for the test set, where the initial weight coefficients were changed randomly 10 times in each trial. The average discrimination rates of the normal elderly subjects using a single LLGMN with the proposed method were 86.2 ± 9.24% and 91.6 ± 4.51%, and those of the PD patients were 87.5 ± 7.25% and 93.1 ± 3.69% respectively. Further, each LLGMN's output $y_2(\boldsymbol{x}_c)$ (c = 1,2,…,12), which represents the *a posteriori* probability for PD patients, for all subjects is illustrated in Fig. 5. The subjects shown in this figure are the same as those in Fig. 3.

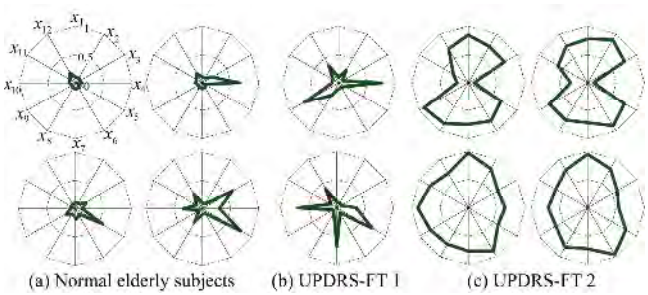

Fig. 5 *A posteriori* probabilities of Parkinson's disease in each index

C. Discussion

From the experimental results, plotting radar charts showing the indices of movements computed and standardized using the basic values obtained from normal elderly subjects revealed that data from normal elderly subjects lie near the average, while those in PD patients' charts become larger according to the severity of their condition. Further, the results of discrimination demonstrated that the patients could be classified correctly in terms of their impairment status using 12 LLGMNs with a degree of accuracy about 5% higher than results obtained using a single LLGMN. Moreover, representing the *a posteriori* probabilities as radar charts confirmed that the values for PD patients become large, and such charts enable quantitative evaluation and description of subjects' motility function. These results indicate that the proposed method is capable of detecting the disease and supporting PD diagnosis.

IV. Conclusions

This paper proposes a diagnosis support system that can quantitatively evaluate motility function for finger tapping movements. From the experiments performed, the finger tapping movements of PD patients were discriminated at a rate of 93.1 ± 3.69 %, demonstrating that the proposed system is effective in the support of diagnosis using finger movements. In future research, we plan to improve the proposed

method to enable diagnosis of the severity of the disease, as well as investigating the effects of aging with an increased number of subjects.

Increasing User Functionality of an Auditory P3 Brain-Computer Interface for Functional Electrical Stimulation Application

A.S.J Bentley[1], C.M. Andrew[1] and L.R. John[1]

[1]MRC/UCT Medical Imaging Research Unit, University of Cape Town, Faculty of Health Sciences, South Africa

Abstract — **A brain-computer interface (BCI) provides a hands-free means of controlling electrical devices by using signals derived directly from brain activity. Its aim is to provide an additional voluntary channel of output. A P3 BCI utilizes the fact that various stimuli may provide a detection response in the brain's electrical activity to act as a control signal. The aim of this research is to explore different stimulus paradigms in an attempt to develop an accurate, efficient and readily applicable P3 BCI for real task applications. The increased amplitude of a target P3 determines the extent to which it may be detected and thus its efficiency as a signal controller in a P3 BCI. Six different experimental paradigms were explored for feasibility and sustainable applicability. Principal component analysis (PCA) and independent component analysis (ICA) were used to pre-process the data to increase computational efficiency before a linear support vector machine (SVM) was used for categorization. The experimental procedures for single trial detection produced excellent results for visual and auditory stimuli. Visual proved slightly superior overall, but the auditory paradigms were sufficient for real applications. Increasing user functionality decreased the accuracy of the results. It should be noted that accuracies of over 90% were obtained in some instances. Salient results suggest increasing the number of varying stimuli causes minimal differences in speed categorization. The added benefit of a three-stimulus paradigm as opposed to the traditional paradigm is highlighted by its increased user functionality for applications such as functional electrical stimulation (FES). Additionally auditory BCIs do not require the user to avert their visual attention away from the task at hand and are thus more practical in a real environment. Coupled with the proposed three-stimulus procedure, the P3 BCI's capability is vastly improved for people suffering from neurological disorders.**

Keywords — **BCI, FES, P3, auditory, visual**

I. Introduction

Functional electrical stimulation (FES) presents a neuroprosthetic technique that uses changes in potential to activate nerves innervating muscles associated with motor movement [1]. "Neuroprostheses operate through a command interface that measures some modality over which voluntary control is maintained, and translates this to a specific operation of the prosthesis." [2] Devices are developed to restore or improve functionality of an impaired nervous system affected by paralysis [1]. A brain-computer interface (BCI) provides a hands-free means of controlling FES devices. Many patients require the use of their extremities for the intended application and thus it isn't possible to use these in operating a command system. Therefore measured electrical activity in the brain presents a possible control system for FES devices. A BCI is a direct communication pathway between a brain and a reactive device and can operate via mutual interaction between both interfaces [3]. A major aim and incentive of BCIs has been to help users suffering from conditions which inhibit physical control, but which leave intellectual capabilities unhindered. Simplified, BCIs "determine the intent of the user" from various electrophysiological signals in the brain and convert these into responses that enable a device to be controlled [4]. Most BCIs are operated via a visual stimulus or motor imagery [2]. Unfortunately this often distracts the user's attention from the task at hand. Additionally many neurological disorders may lead to loss of vision, especially in the case of patients suffering from a complete locked-in state (CLIS) – voluntary muscular control is lost [5]. Therefore an *auditory* BCI is adopted as the preferred interface between FES and the user.

Although visual stimulus BCIs have proven more accurate than auditory BCIs, their applicability in a clinical setting is limited. A study conducted by Nijboer et al. concluded "that with sufficient training time an auditory BCI may be as efficient as a visual BCI" [6]. Hill et al. suggested that auditory event-related potentials (ERPs) could be used as part of a single trial BCI [7].

Various physiological signals may be used as the control signal for an auditory BCI. However, the associated recorded EEG integrity is affected by passive or active movement of extremities. The P3 presents a robust solution to combating the effects of signal distortion. P3 BCIs provide a means of obtaining cognitive information and communication without relying on peripheral nerves and muscles. For this reason they have widespread use in people with disabilities.

A. P3 (or P300)

It is an ERP component of EEG and indicates a subject's recognition of useful information according to a task. The P3 is one of the most common features of an ERP [8].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 687–690, 2009
www.springerlink.com

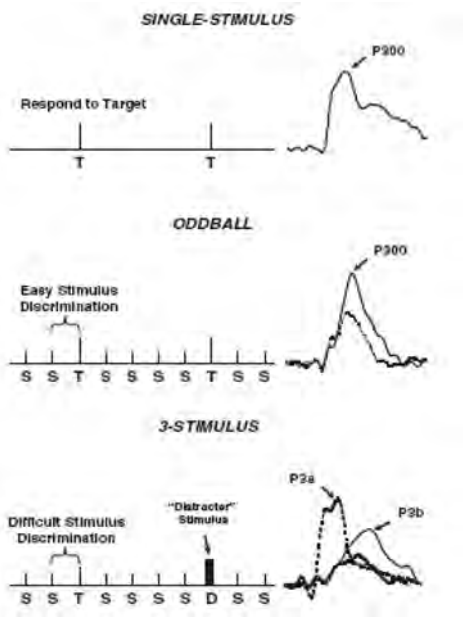

Fig. 1 Schematic illustration of P3 (or P300) waveform [9].

Figure 1 illustrates the three traditional paradigms associated with P3 generation. The target elicits a large positive potential that increases in amplitude and propagates from the frontal to the parietal electrodes of an EEG "and has a peak latency of 300 ms for auditory and 400 ms for visual stimuli in young adults" [9]. Extensive P3 theory is discussed in [9].

A traditional P3 experimental paradigm only allows the user to distinguish between two stimuli – that is, binary selectivity – via a process of weighted probability, whereby the stimulus with the least probability is seen as the target producing a comparable increase in amplitude of the P3. In everyday activity we are confronted with multiple decisions, thus increasing the number of stimuli for P3 production indirectly improves decision making capabilities of an auditory P3 BCI. An attempt must also be made to assess the efficiency with which the proposed system is able to distinguish the target stimulus amongst two other stimuli with the same probability.

B. Principal and Independent Component Analysis

BCI systems employing measurement of cortical areas associated with motor movement are limited by the reliability of the signal for FES applications [5]. The corollary indicates that "using signals outside of motor areas make them less susceptible to disturbance from active or passive movement of limbs" [2].

Most current FES-BCI systems use visual input as a control signal. The reality is that in real-life situations this is not feasible. The pre-processing technique presented by Bentley et al. creates a means of increasing the accuracy and response time of FES-BCI systems for economically viable solutions [5].

P3 waveforms are extracted from EEG signals more often than not by principal component analysis (PCA) or independent component analysis (ICA). *PCA presents an attractive method of data reduction and ICA a means of source extraction* [10]. Importantly PCA is able to compress high resolution data into a format for ICA to extract the required information – increasing computational efficiency. Xu et al. used algorithms based on ICA (with PCA preprocessing) for P3 detection on a 64-channel system by means of anatomical and psychological knowledge of P3 spatio-temporal progression [11].

II. Method

Traditional P3 paradigms consist generally of a two-stimulus experimental technique, whereby decreasing the probability of one stimulus alternately increases the probability of it being distinguished from the other stimuli. These changes in the P3 waveform enable BCIs to differentiate between them. EEG recordings from electrical activity in the brain act as the control method for BCIs. These signals can be generated most effectively by mental imagery and external stimuli produced by vision or hearing. Most of these waveforms (apart from the P3) carry with them complications associated with artifact production and signal echo distortion created by motor movement generated in the motor area of the cortex.

Advantages of auditory stimuli over visual and mental imagery are discussed in Hill et al. [7]. This method of signal control also does not require the extensive training that mental imagery techniques require and the resultant device is not as user specific. It allows the user to focus their attention on the task at hand.

A method using a combination of PCA and ICA techniques discussed in [5] is utilized to pre-process and extract the waveform – the computational efficiency of which is of the utmost importance if it is to be used for FES. The data is spatio-temporally manipulated in the single trial scenario to highlight and enhance the P3 waveforms for classification.

A. Experimental Paradigms

The aim of this research was to investigate increasing user functionality of alternative paradigms associated with the P3.

Materials: It was determined that the use of regular earphones should be utilised for the auditory stimulus so as to replicate a real environment. Electrical noise generated was taken into consideration due to the proximity of the earphones to the high resolution 128-channel Geodesic Sensor Net (GSN).

It was determined that five experiments of 180 trials were to be conducted on 15 subjects (right-handed males between the ages of 21 and 30) using the high resolution system.

The paradigms included visual and auditory stimuli, a requirement for a button to be pushed in certain instances, and a traditional P3 approach. The use of three stimuli of equal probability is assessed for classification accuracy and efficacy so as to simulate multiple decision processes in actual scenarios. It was decided to utilize three different stimuli in an attempt to add extra selective functionality for the user (as opposed to the traditional paradigm utilizing only two differing stimuli).

The five experiments included:

1. presenting the subject with an auditory target stimulus amongst two other stimuli;
2. the same procedure as experiment 1 except that a button is pushed to indicate a target and a separate button is pushed to indicate a non-target;
3. presenting the subject with a visual stimulus amongst two other stimuli;
4. the same procedure as experiment 3 except that a button is pushed to indicate a target and a separate button is pushed to indicate a non-target; and
5. a traditional P3 experiment consisting separately of auditory (indicated by a * in Table 1) and visual stimuli in the single-stimulus paradigm illustrated in Figure 1.

In each case the subject was presented with the target prior to testing to familiarize themselves with the stimulus. All experiments required the subject to focus on a cross-hair and were positioned 0.5 m from the screen.

Auditory stimuli varied only by frequency (volume and time were kept constant throughout). The predetermined sinusoidal tones had frequencies of 500, 1500, and 3500 Hz, which presented the least level of discomfort. These were chosen after subjects indicated from a variety of frequencies which three provided the best discernible differences from a selective range.

Visual stimuli consisted of three arrows of equal size and positioning which only varied by orientation – left, right, and up. The target in each case was randomly selected for cross-validation averaging. In paradigms 1 and 3 the subjects were required to count the number of targets and in instances 2, 4 and 5 they were required to push a button. The paradigms were established according to the ERP technique discussed in [12] and sampled at 200Hz.

B. Processing and Classification

Eye artifacts and bad channels were removed from the recordings and the raw data was 0.1 to 8 Hz band-pass filtered (spectrum analysis reveals that the principal energy of the P3 is in the 1 to 8 Hz band [11], but using high-pass filtering above 0.1Hz tends to attenuate the P3 waveform). A combination of PCA and ICA was used to formulate an independent component (IC) matrix from the training data. This matrix acted as an "unmixing" matrix (W) for single trial data. The ICs of each single trial epoch are then spatio-temporally manipulated to highlight the qualities associated with P3 detection. This method is discussed in [5] and presents an effective and relatively fast classification technique (Figure 2).

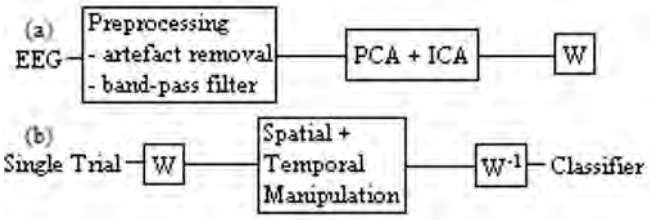

Fig. 2 Algorithm for P3 detection: (a) training and (b) testing phase [5].

A linear support vector machine (SVM) is then used to classify a moving average of the data from 0 to 650ms for a single trial epoch. Thornton's separability index was used to determine the optimal features for classification. A generic subset of features was chosen. The most prominent feature combination was used on all the data in contrast with calculating the index for each test (increased accuracies can be obtained by calculating individual indices).

III. Results

An average of 10 separate cross-validation sets was used to determine the prediction accuracies. It should be noted that certain subjects, presented with the 1500 Hz auditory stimulus, highlighted that identifying the target proved more difficult than in the cases where the higher or lower frequencies were the target. Additionally confusion developed for certain subjects in the visual stimulus paradigm when asked to push a button located on the left when a "right" arrow was displayed and vice versa.

Table 1 Prediction accuracy percentages of cross-validation tests

Subject	Test 1	Test 2	Test 3	Test 4	Test 5
1	68.1	67.2	71.4	74.5	85.0*
2	72.1	71.7	77.3	77.6	83.2
3	72.8	73.1	76.4	78.4	81.5*
4	78.1	75.1	79.1	78.0	81.0
5	65.3	69.6	70.2	68.8	86.2*
6	69.7	68.4	67.5	70.1	90.1
7	72.5	60.2	71.9	77.2	82.3*
8	62.4	68.2	61.3	69.3	77.3
9	73.8	75.4	77.8	76.9	87.7*
10	69.7	70.2	72.3	75.1	87.0
11	58.3	61.4	61.5	62.0	81.6*
12	67.4	66.8	69.9	70.7	78.5
13	73.1	69.9	73.4	71.3	82.2*
14	73.6	71.0	74.5	79.6	91.0
15	70	75.2	74.7	76.1	88.6
Average	*69.8*	*69.6*	*71.9*	*73.7*	*84.2*

Classification accuracies of between 82 and 88% were obtained for auditory P3 single trial traditional paradigms (visual paradigms resulted in accuracies between 77 and 91%). For the four new experimental paradigms (i.e. two stimuli and one target) average accuracies of 70% and 73% were obtained for auditory and visual cases respectively. The results were enhanced by acceptable sensitivity (82%) and specificity (76%) scores for FES compatibility [13].

IV. Conclusions

By using the nominated three-stimulus paradigm, classification accuracies are obtained that may prove acceptable in a clinical environment for FES applications. Greater preprocessing capabilities and classification techniques need to be developed so as to enhance P3 waveform characterization to combat the proportional decrease in P3 differentiation. The traditional P3 paradigm proved superior due to the nature of P3 generation i.e. its increase in amplitude with decreased probability. Visual paradigms proved slightly superior in performance to auditory classification paradigms [4]. However, accuracies obtained from some auditory experiments allow for potential FES implementation [13] and indicated that the traditional button response to stimuli did not prove superior. The speed with which the algorithm may detect single trial P3s is sufficient for the intended application; although the accuracies obtained using the proposed paradigms need to be improved. The lower accuracies result from increased target probability and hence increased task difficulty compared to the traditional paradigm [14].

An Electroencephalogram Signal based Triggering Circuit for controlling Hand Grasp in Neuroprosthetics

G. Karthikeyan[1], Debdoot Sheet[2] and M. Manjunatha[2]

[1]Department of Biomedical Engineering, SSN College of Engineering, Chennai, INDIA.

Abstract — **Quadriplegia is a serious problem in the case of patients with neurological disorders. Functional Electrical Stimulation (FES) has been a very good rehabilitation technique to treat this condition and help the patient to lead a near-normal life by aiding him/her to move the limbs of the upper and lower extremities with less difficulty. Various techniques have been proposed to trigger the FES system. In this paper, we describe the design of a novel circuit used to trigger a FES device by a person's EEG signals i.e., by his thoughts. The total project was divided into three modules. The first module was to design a proper interface between the electrodes placed on the scalp and the electronic system which was to be used as a trigger. The second module was to amplify the signal to a sufficient level such that the strength of the signal is high enough to drive the third module which served as the classifier part. The classifier part of the circuit was built out of commercially available IC's and external discrete components. Though there was some tolerance errors induced due to the external components, the error was at a minimal rate when compared with the actual signal considered. The circuit was powered by a 9V battery and the only input to it was the thought waves through EEG signals from the subject/patient considered. The circuit is low power efficient with a wide operational range of ±3V to ±18V.**

Keywords — **Circuit synthesis, Electroencephalography, Electronic equipment, Filters, Instrument amplifiers, Integrated circuits, Logic design.**

I. Introduction

Quadriplegia is a medical condition in which one half of the body is completely paralyzed, greatly reducing mobility of the affected person. In the case of upper extremity paralysis (which is the condition dealt with in this study), the affected person suffers from an inability to move his/her hands, resulting in severe inability to grasp objects and perform normal tasks. The two reasons for occurrence of Quadriplegia are Congenital and Result of a stroke or illness. Though there is little development as of now for treatment of the congenital type of Quadriplegia, recent developments in the field of Functional Electrical Stimulation (FES) have lead to ease in the treatment of the second kind of patients. The treatment of stroke induced Quadriplegia is made possible by a FES system due to the fact that though the Upper Motor Neurons (Connecting the brain with the spinal cord) are damaged, the Lower Motor Neurons (Connecting the spinal cord with the limbs) are healthy. As a result of this, any stimulation given to the nerves connecting the affected limb with the spinal cord stimulates the muscles of the limb and facilitates motion. Recent developments in the acquisition and analysis of Electroencephalogram (EEG) signals have shown that EEG signals are unique for each person and for each thought activity. This property of the EEG has been found to be suitable for usage in Brain- Computer Interface (BCI) applications [1]. Most of the BCI applications use variations in EEG patterns to classify a person's thoughts and make an external device act according to the patterns recognized by the machine [2]. The EEG based trigger circuit developed in this project acts using the same principle as that of a Brain-Computer Interface, detecting patterns in EEG signals using a circuit tailor- made for stimulation of the FES device.

II. Functional electric stimulation: an overview

A Functional Electrical Stimulator is a neuroprosthetic device, the main function of which is to activate the inactive and weak nerves of the upper/lower extremities of the body. Usage of a FES is fruitful in a way that the affected nerves are rejuvenated by continual usage of the device and this helps in restoring movement to the patient. The affected portion of the patient is stimulated whenever movement is required by the patient.

Most of the early FES devices were based upon pure analog designs which rendered the usage and accuracy of usage of the FES device an unpredictable one. But, recent developments in digital technologies and usage of microcontrollers have rendered the usage of FES systems a reliable method of rehabilitation. The schematic of the device used here is shown in Fig. 1 and is controlled using a microcontroller and the output waveform of the circuit is shaped in such a manner that the patient feels negligible fatigue of muscles.

Bio-potentials as a command for FES. Numerous works have been done to study the feasibility of using EEG signals for control of FES. A significant result with regards to this

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 691–693, 2009
www.springerlink.com

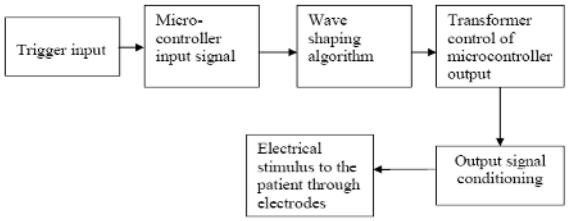

Fig. 1 Block setup of FES

was given by Juul et al (2000) [3] stating that there is a remarkable change in the EEG patterns during preparation of hand or leg movements. This experiment used different kinds of movement trainings to record the Movement Related Potentials (MRPs) for different kinds of movement attempts. Seven recording sites were used according to the 10–20 electrode placement system. The promising results shown by this study prompted us to use C_3 and C_4 recording sites for tapping the Beta waves of the EEG which are the control signals to be used in triggering the FES.

III. Idea of the Circuit

The basic idea of the circuit is divided into two parts- The first part would amplify the circuit to the required level and the second part would classify the amplified signals for triggering of the circuit. The block set up of the total circuit is given is Fig.2 and Fig.3.

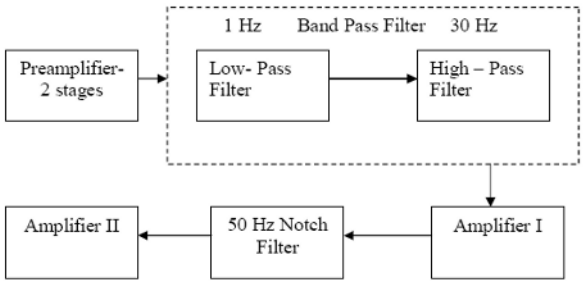

Fig. 2 Amplifier and Preprocessing set up of the circuit

The second portion of the circuit is involved in choosing and classifying the frequencies of interest which would facilitate triggering of the FES device.

The output/ Gain calculation of the amplification portion of the circuit is shown in Table 1.

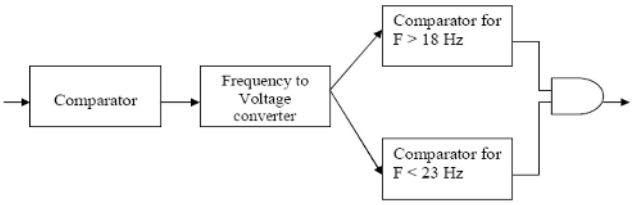

Fig. 3 Classification portion of the circuit

Table 1 Gain of the various stages of the amplification portion of the circuit

Stage	Gain
Preamplifier - I	2.08
Preamplifier - II	74.46
Non-Inverting Amplifier - I	24.33
Non-Inverting Amplifier – II	7.76
Net Gain of circuit in Fig. 2	29358

Voltage dectection and FES triggering using comparators and AND gates: A very critical component of the circuit is the Frequency to Voltage (F–V) converter which is used to convert the various frequencies present in the EEG signal into proportional voltages.

The output of an F–V converter is a voltage signal which would make this portion of the circuit act as a classification precursor stage. The output of the F–V converter is given into two comparators with one comparator being sensitive to voltages corresponding to frequencies greater than F_1 and another comparator being sensitive to frequencies lesser than F_2. The outputs of these comparators are treated as logic levels of 1's and 0's. These logic levels are given as inputs to the AND gate and this AND gate responds to the logic level inputs and gives out an output which is given as a trigger signal to the FES device and the algorithm for the output and input of the comparators and AND gate is as seen in Table 2. The output of the AND gate, is a logic level of 1 or 0 and would be suitable for use as an input to the trigger switch of the FES device.

Table 2 Logic levels of the comparators and AND gate for triggering the FES

Input to AND gate from Comparator 1	Input to AND gate from Comparator 2	Output to the AND gate
0 ($F<F_1$)	0 ($F\geq F_2$)	0
0 ($F<F_1$)	1 ($F<F_2$)	0
1 ($F\geq F_1$)	0 ($F\geq F_2$)	0
1 ($F\geq F_1$)	1 ($F<F_2$)	1

IV. Conclusions

The concept and design of the circuit is in such a manner that it would help quadriplegic and with some fine-tuning, paraplegic patients with foot drop to lead a near- normal life. Though the circuit would help in bringing a near-normal lifestyle back into the life of the patients, it is extremely difficult for any machine to bring a normal life back to the patient at least with present day technology.

The best thing which can be done to improve the lifestyle of disabled people is using rehabilitation techniques such as FES and neural engineering methodologies.

The major drawback with the circuit described above or for that matter any kind of Brain-Computer Interface technologies is the fact that they require cooperation from the patient's side and ultimately however strong the technology developed is, for the technology to be successful, cooperation from the patient side is very much essential.

A Novel Channel Selection Method Based on Partial KL Information Measure for EMG-based Motion Classification

T. Shibanoki[1], K. Shima[1], T. Tsuji[1], A. Otsuka[2] and T. Chin[3]

[1]Graduate School of Engineering, Hiroshima University, Higashi-Hiroshima, Japan

[3]Hyogo Rehabilitation Center Hospital, Kobe, Japan

Abstract — **To control machines using electromyograms (EMGs), subjects' intentions have to be correctly estimated and classified. However, the accuracy of classification is greatly influenced by individual physical abilities and measuring positions, making it necessary to select optimal channel positions for each subject. This paper proposes a novel online channel selection method using probabilistic neural networks (PNNs). In this method, measured data are regarded as probability variables, and data dimensions are evaluated by a partial KL information measure that is newly defined as a metric of effective dimensions. In the experiments, channels were selected using this method, and EMGs measured from the forearm were classified. The results showed that the number of channels is reduced with 33.33 ± 11.8%, and the average classification rate using the selected channels is almost the same as that using all channels. This demonstrates that the method is capable of selecting effective channels for classification.**

Keywords — **Kullback-Leibler information, partial Wilks' lambda, variable selection method, pattern classification, electromyogram**

I. Introduction

Since electromyograms (EMGs) reflect human intentions and motions, these signals can be used to control various machines estimating these intentions and motions. Recently, neural networks (NNs) to classify EMG patterns have been widely studied, as such networks can represent any nonlinear mapping by learning [1], [2]. In addition, Tsuji *et al*. proposed the Log-Linearized Gaussian Mixture Network (LLGMN) and confirmed its effectiveness in biological signal classification [3].

The number of channels and the measuring positions for EMGs are very important because the accuracy of EMG classification is greatly influenced by the amount of information in measured signals. In the case of EMG classification, effective channel selection methods have been proposed [4], [5] by evaluating all combinations of EMG electrodes. With a very large number of channels, however, computation takes a long time, meaning that real-time applications for human-machine interfaces cannot be achieved. To select effective channels for each subject, it is necessary to evaluate users' EMG patterns and the impact of each channel on the EMG classification with less computational time.

This paper proposes a novel variable selection method based on Kullback-Leibler (KL) information and its application to channel selection for EMG measurement. In this method, measured signals are regarded as probability variables, and their probabilistic density function (pdf) is estimated using probabilistic neural network (PNN) learning based on Kullback-Leibler (KL) information. In addition, a partial KL information measure based on a partial Wilks' lambda is newly defined as a metric of effective dimensions for classification, and dimensions that are not effective are eliminated. As a result, effective channels for each user can be selected using this method without evaluating all channel combinations.

II. Partial KL information measure

A novel metric of dimensions for pattern classification, called the partial KL information measure, is newly defined. Using the partial KL information measure, the most ineffective dimensions can be eliminated.

A. Partial Wilks' lambda [6]

Wilks' lambda is a test statistic used in multivariate analysis of variance. There are N_k samples in the kth class, and each sample x is a vector with L dimensions ($\boldsymbol{x} \in \Re^L$). $\boldsymbol{x}_n^{(k)}$ ($n = 1,2,\ldots,N_k$) denotes the vector of the nth sample in the kth class. Wilks' lambda is defined as follows:

$$\Lambda = |W| / |T|, \tag{1}$$

where $|\cdot|$ denotes the determinant of the matrix, W is the within-class sum of squares,

$$W = \sum_{k=1}^{K} \sum_{n=1}^{N_k} (\boldsymbol{x}_n^{(k)} - \bar{\boldsymbol{x}}^{(k)})(\boldsymbol{x}_n^{(k)} - \bar{\boldsymbol{x}}^{(k)})^{\mathrm{T}}, \tag{2}$$

and T is the total sum of squares,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 694–698, 2009
www.springerlink.com

$$T = \sum_{k=1}^{K}\sum_{n=1}^{N_k}(\boldsymbol{x}_n^{(k)} - \bar{\boldsymbol{x}})(\boldsymbol{x}_n^{(k)} - \bar{\boldsymbol{x}})^{\mathrm{T}}, \quad (3)$$

where $\bar{\boldsymbol{x}}^{(k)}$ is the centroid of class k, and $\bar{\boldsymbol{x}}$ is the overall centroid. K is the number of classes, and $(\cdot)^{\mathrm{T}}$ denotes the transpose of the matrix. The smaller the Wilks' lambda, the more classes are separated.

To identify important dimensions for discrimination, a partial Wilks' lambda is then introduced:

$$\Lambda(x_i^* \mid \boldsymbol{x}_{[i]}^*) = \Lambda(\boldsymbol{x}_{[i]}^*, x_i^*) / \Lambda(\boldsymbol{x}_{[i]}^*), \quad (4)$$

where x_i^* is the data set of ith element of $\boldsymbol{x}$, and $\boldsymbol{x}_{[i]}^*$ is the set of vectors that are eliminated in the ith dimension from $\boldsymbol{x}$. Here,

$$F_i = \frac{N-K-(L-1)}{K-1} \cdot \frac{1-\Lambda(x_i^* \mid \boldsymbol{x}_{[i]}^*)}{\Lambda(x_i^* \mid \boldsymbol{x}_{[i]}^*)} \quad (5)$$

performs the same role as the F-statistic in one-way analysis of variance, where N is the number of samples in all classes ($N = \sum_{k=1}^{K} N_k$). This follows an F distribution with K - 1 and N - K - (L - 1) degrees of freedom [7]. In the backward elimination method, the smallest of all the Fi values is eliminated if it is lower than the critical value of Fout. This process is repeated on the remaining dimensions until the smallest F_i value is higher than F_{out}.

However, the partial Wilks' lambda cannot respond to non-Gaussian data since it is based only on data variance. Therefore, it might be difficult to correctly classify the EMG, which is not always Gaussian, for human-machine interfaces after evaluating the dimensions using the Wilks' lambda. To solve these problems, a new metric of effective dimensions referred to as partial KL information is proposed.

B. Partial Kullback-Leibler (KL) information

To classify non-Gaussian and/or non-linear data, it is common to regard them as probability variables and estimate their pdf. It is considered possible to evaluate the dimensions using the estimated distribution.

The KL information represents the difference between two probability distributions [8]. Let $\boldsymbol{x}_n^{(k)}$ be the vector of the nth sample in the kth class, and the probabilities of the kth class in true probability distribution and estimated distribution are $\Pr\{\boldsymbol{x} = \boldsymbol{x}^{(k)}\} = P_k$ and Q_k, respectively. The KL information is calculated by

$$I(\boldsymbol{P}, \boldsymbol{Q}) = \sum_{k=1}^{K} P_k \log \frac{P_k}{Q_k}$$

$$= \sum_{k=1}^{K} P_k \log P_k - \sum_{k=1}^{K} P_k \log Q_k, \quad (6)$$

where $\boldsymbol{P} = [P_1, P_2, \ldots, P_K]^{\mathrm{T}}$ and $\boldsymbol{Q} = [Q_1, Q_2, \ldots, Q_K]^{\mathrm{T}}$, respectively, and the first term on the right side is reduced to a constant; therefore, if the second term becomes the minimum, the KL information becomes the minimum. This means that the estimated distribution is close to the true distribution.

Based on the above concept, this paper defines the partial KL information to evaluate dimensions:

$$I_i = \sum_{n=1}^{N} I_n(\boldsymbol{P}, \boldsymbol{Q}) / \sum_{n=1}^{N} I_n(\boldsymbol{P}_{[i]}, \boldsymbol{Q}_{[i]}), \quad (7)$$

$I_n(\boldsymbol{P}_{[i]}, \boldsymbol{Q}_{[i]})$ is the KL information for the nth sample $\boldsymbol{x}_n$, and is obtained using the probability variable $\boldsymbol{x}_{[i]}^*$ in which the ith element of each variable included is eliminated. If $I_n(\boldsymbol{P}, \boldsymbol{Q}) \equiv I_n(\boldsymbol{P}_{[i]}, \boldsymbol{Q}_{[i]})$, this means that true distribution can be estimated without the dimension x_i.

III. Partial KL Information-Based Variable Selection Using PNN

A novel variable selection method using the partial KL information measure is newly proposed for pattern classification. In this method, KL information is calculated through PNN learning, and redundant dimensions are eliminated one by one.

A. Variable selection using the LLGMN

The LLGMN is based on the GMM and the log-linear model of pdf [3]. By applying the log-linear model to a product of a mixture coefficient and the mixture component of the GMM, the semiparametric pdf model is incorporated into a three-layer feedforward NN. This network can calculate the *a posteriori* probability $Y_k(n)$ for the input pattern $\boldsymbol{x}(n)$ after learning [3].

A simple backpropagation algorithm is feasible when the teacher vector $\boldsymbol{T}(n)$ for the nth input vector $\boldsymbol{x}(n)$ is given. As the energy function J for the network,

$$J = -\sum_{n=1}^{N}\sum_{k=1}^{K} T_k(n) \log Y_k(n) \quad (8)$$

is used, and learning is performed to minimize the KL information for true distribution. This means that a learned network can approximate the data distribution.

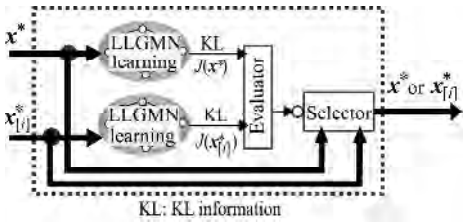

Fig. 1. Variable selector

The variable selection procedure for two input vector sets $\boldsymbol{x}^*$ and $\boldsymbol{x}^*_{[i]}$ is shown in Fig. 1. First, the KL information $J(\boldsymbol{x}^*)$ and $J(\boldsymbol{x}^*_{[i]})$ of two input vector sets are calculated through LLGMN learning. Next, each set of KL information is input to the evaluator. The evaluator outputs the partial KL information calculated based on Eq. (7), where

$$E_i = J(\boldsymbol{x}^*) \ / J(\boldsymbol{x}^*_{[i]}). \tag{9}$$

Based on E_i, two inputs are evaluated, and the more effective one is selected through the selector. The ith dimension for which E_i (i = 1,2,…,L) has the largest value is eliminated by the selector, and ineffective dimensions are then eliminated one by one through repetition of this procedure.

B. Channel selection for EMG classification

Using the partial KL information-based variable selection method, we applied the technique to channel selection for EMG classification. The structure of the channel selection method is shown in Fig. 2.

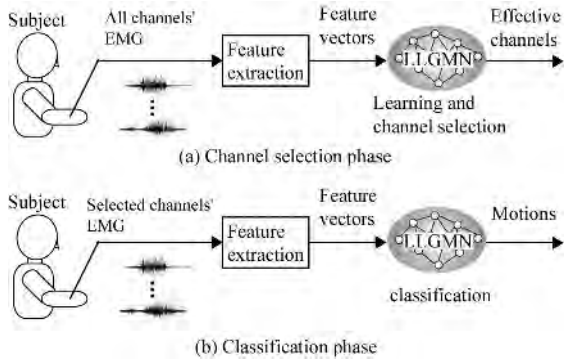

Fig. 2. Structure of the proposed channel selection method

- Feature extraction

First, EMG signals measured from L pairs of electrodes are digitized by an A/D converter (sampling frequency: 1 [kHz]), and are rectified and filtered out through a second- order Butterworth filter (cut-off frequency: 1 [Hz]). These sampled signals are defined as $EMG_l(n)$ (l = 1,2,..., L). Next, the $EMG_l(n)$ values are normalized to make the sum of L channels equal to 1:

$$x_l(n) = \frac{EMG_l(n) - \overline{EMG}_l^{st}}{\sum_{l'=1}^{L} EMG_{l'}(n) - \overline{EMG}_{l'}^{st}} \quad (l = 1,2,..., L) \ , \tag{10}$$

where $\overline{EMG}_l^{st}$ is the mean value of $EMG_l(n)$ while relaxing the muscles. This feature vector $\boldsymbol{x}(n) \in \Re^L$ is input to the LLGMN for channel selection.

- Channel selection

For EMG classification, the effective dimension of the feature vector (i.e., the EMG measurement position) is selected through LLGMN learning. In the channel selection algorithm, ineffective channels are eliminated based on the partial KL information when the termination condition is fulfilled. The algorithm details are as follows:

1. EMG signals are measured from L pairs of electrodes of K motions for LLGMN learning, and the feature vector $\boldsymbol{x}(n)$ is calculated using Eq. (10).
2. The data sets $\boldsymbol{x}^*$, $\boldsymbol{x}^*_{[1]}$, ..., $\boldsymbol{x}^*_{[L]}$ are prepared, and each set is learned by the individual LLGMN.
3. $J(\boldsymbol{x}^*)$ and $J(\boldsymbol{x}^*_{[i]})$ are calculated using Eq. (8), and the partial KL information measure E_i (i = 1,2,…,L) is obtained from Eq. (9).
4. Using each obtained value of E_i, the most ineffective channel is selected. Since the learned network with less partial KL information can approximate the true distribution, therefore, dimension j (for which the partial KL information E_j is the largest) is eliminated. Here, if $E_j \le E_\theta$ (where E_θ is the critical value for the termination condition), the dimension x_j is not eliminated, and the elimination process ends. Meanwhile, if $E_j > E_\theta$, the dimension x_j is eliminated. Then, let $\boldsymbol{x}^* = \boldsymbol{x}^*_{[j]}$ and $L = L - 1$, and return to Step 2.

IV. Channel Selection Experiments

To verify the effectiveness of the proposed channel selection method, we performed EMG-based motion classification experiments.

A. Experimental conditions

The subjects were five normal volunteers (including one person who had experienced EMG control), and six electrodes were attached to each subject's right forearm (see Fig. 3). The subjects performed four motions (K = 4; hand grasping, hand opening, wrist flexion and extension) for a few seconds, and

repeated each motion 10 times. The sampling frequency was 1 [kHz]. One set of the measured data was used for learning and channel selection (learning data), and the other sets were used only for classification (evaluation data). The limit value $E_\theta = 0.8$ was used for channel selection, the number of learning data was $N = 80$, and the number of evaluation data was 4,000 (20 and 1,000 for each motion respectively).

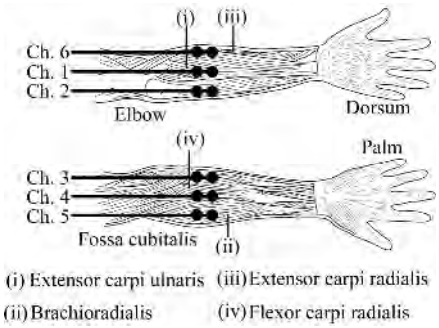

Fig. 3. Electrode positions

B. Results and discussion

Figure 4 shows the relationship between classification rates and KL information when the number of channels for classification is changed. The figure outlines the results of reducing the number of channels using learning data measured from Subject A. In this experiment, the initial weights of the LLGMN were changed 10 times, learning deviations wereand classification were performed in each trial, and the average classification rates and standard obtained. Since the KL information from these results was almost near zero with three to six channels, it is confirmed that the accuracy of classification was high. At this point, three channels were selected by the termination condition of the proposed method (Ch. 2, Ch. 3 and Ch. 6), and the average classification rate was 100%.

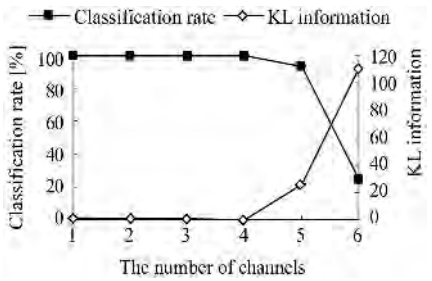

Fig. 4. Relationships between classification rates and KL information (Subject A). Note that the standard deviations are less than 0.27% for the classification rate and 0.06% for the KL information.

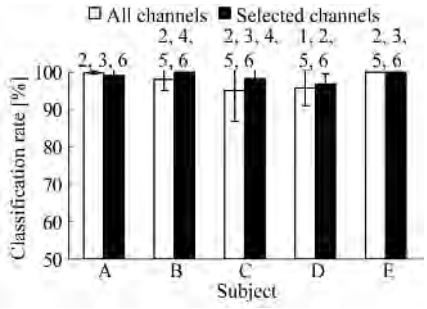

Fig. 5. Classification rates using all channels and selected channels

Next, the average classification rates of the evaluation data using the channels selected with the learning data are shown in Fig. 5. This figure shows the classification results of using all channels' and selected channels' EMG for all subjects. It can be seen that motion could be classified using only the selected channels. The number of channels is reduced with $33.3 \pm 11.8\%$. The classification rates of Subject A, which were calculated using three channels of all combinations from six channels' EMG (i.e. the number of combinations was 6C3 = 20) are shown in Table 1. In this table, the gray zone highlights the outcomes using the proposed method. These results show that the second-highest classification rate was obtained by the proposed method, meaning that semi-optimal channel combination could be selected from all combinations. In the experiments on the other subjects, optimal or semi-optimal channel combinations could also be selected with the highest or second-highest classification rate. These results lead us to the conclusion that effective channel could be selected using the partial KL information measure without evaluating all possible channel combinations.

Table 1. Classification rates using three channels of combinations from all channels (Subject A)

Selected channels	2, 5 ,6	2, 3, 6	2, 3, 4	2, 4, 5	1, 2 ,3
Classification rate [%]	99.16	98.99	97.52	96.96	95.58
Standard deviation	1.75	2.19	4.4	5.27	7.91
Selected channels	1, 3, 5	1, 4, 5	1, 5, 6	1, 2, 4	3, 4, 5
Classification rate [%]	94.97	94.76	94.13	94.06	92.34
Standard deviation	5.16	6.08	5.64	8.6	7.8
Selected channels	1, 2, 5	2, 3, 5	1, 3, 4	1, 3, 6	3, 5, 6
Classification rate [%]	92.24	91.47	90.83	90.78	90.09
Standard deviation	8.96	5.24	8.37	8.08	7.86
Selected channels	1, 4, 6	4, 5, 6	1, 2, 6	3 ,4, 6	2, 4, 6
Classification rate [%]	84.14	81.97	80.91	77.56	75.94
Standard deviation	13.31	19.48	12.5	16.93	17.55

V. Conclusion

This paper proposes a variable selection method using a new metric to select effective dimensions called the partial

KL information measure. In order to confirm its effectiveness, the method was applied to channel selection for EMG classification. In experiments on forearm motion classification, effective channels for classification could be selected for each subject. In future research, we plan to enhance the channel selection method by considering cross-talk EMG and applying the method to training systems for human-machine interfaces using EMG.

Acknowledgment

We would like to cordially acknowledge and express our appreciation to Mr. M. Shigeto for his assistance in the implementation of this research. This work is partially supported by the 21st Century COE Program of JSPS (the Japan Society for the Promotion of Science) on Hyper Human Technology toward the 21st Century Industrial Revolution.

A Mobile Phone for People Suffering From The Locked In Syndrome

D. Thiagarajan[1], Anupama.V. Iyengar[2]

[1] Sri Sairam Engineering college/Electrical and Electronics Department, Anna university, Chennai, India
[2] Sri Sairam Engineering college/Electrical and Electronics Department, Anna university, Chennai, India

Abstract — **In this paper we have Proposed an idea to design a mobile phone for people suffering from locked-in syndrome using existing technologies. Using this mobile people can code SMS message, compose ring tones, browse and select menu in a commercially available mobile using his/her thoughts.**

Keywords — **Brain computer interfacing, Pattern classification, locked-in syndrome, mobile phone**

I. Introduction

A Brain computer interface (BCI) is a real time communication system designed to allow a user to voluntarily send message or commands without sending them through the brain's natural output pathways [1]. All BCIs have at least four components: Signal acquisition, signal processing, pattern recognition with classification, and external device control.

Locked-In syndrome is a condition, in which a patient is aware and awake, but cannot move or communicate due to complete paralysis of nearly all voluntary muscles in the body. It is the result of a brain stem lesion in which the ventral part of the Pons is damaged.

Applications of BCI systems comprise the restoration of movements, communication and environmental control [2]. However, recently BCI systems have been also used in other research areas such as in the field of virtual reality (VR) [3, 4]

II. Mobile model

Data acquisition: Electrodes are placed on the scalp in the C3, C4 region of the brain according to 10-20 international system.

Signal Processing: The Mu rhythm is amplified filtered and is converted into a digital signal and is transmitted to a mobile phone via a blue tooth.

Pattern recognition: There are many pattern recognition softwares based on MAT LAB, Neural networks, Fuzzy ART map, statistical algorithms like the Bayesian classifier etc and [5] are available commercially. A software compatible with mobile Operating System and is which coded in java can be installed in the mobile phone for classification of signals. We used Java Implementation of Naïve Credal Classifier (JNCC2) open source software for simulation purpose. In real time this software or any software similar to this can be installed in the mobile. The software classifies the signal as left side or right side signal and moves a cursor to the left or right in the mobile screen to navigate and select various options, vertical movements are also possible from classification output. The Figure 1 shows the overall design of the mobile.

The Figure 2 shows the mobile screen, the cursor is represented as arrows in four directions, depending upon the user's imagined direction, the cursor moves horizontally or vertically to select the desired options.

For example if the user chooses 'Message' options by moving the cursor towards it by thought, the message option expands as shown in Figure 3

The message screen consists of three parts. It has a virtual keypad from which the user can select the alphabets from the nine clusters (three alphabets per cluster), the 'dictionary mode' inbuilt in the mobile would coin meaningful words automatically. The user has to keep the cursor on a cluster of alphabets for certain duration for it to get selected. The screen has space for writing the message and a space showing a list of all possible words in that letter combination.

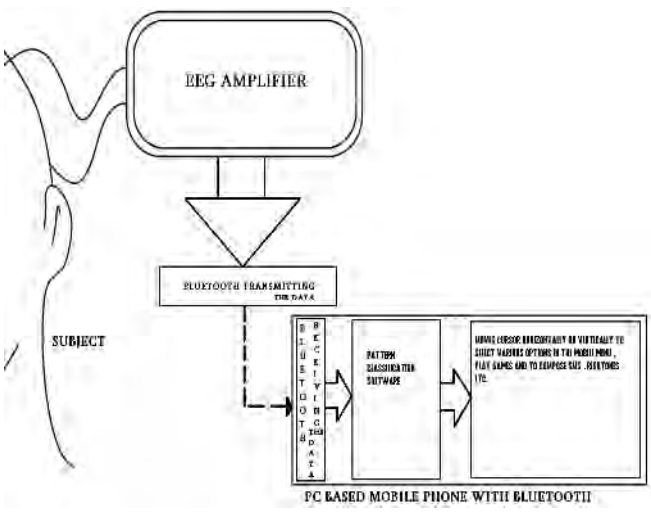

Fig. 1

www.springerlink.com

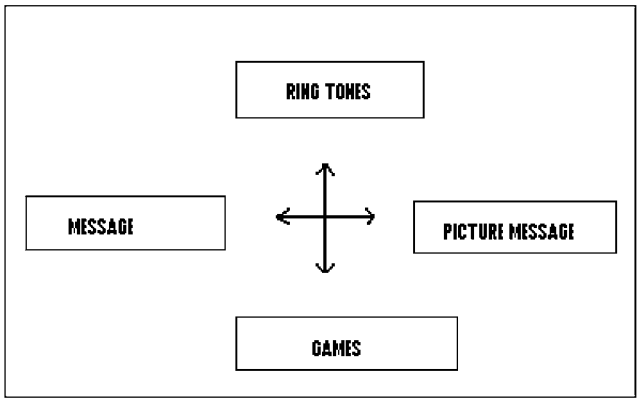

Fig. 2

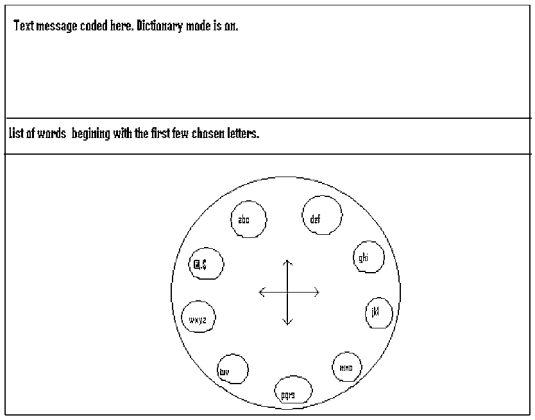

Fig. 3

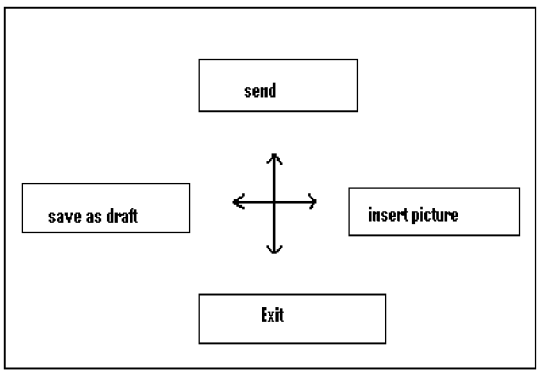

Fig. 4

If the user wants to edit the message he has to select a specific symbol say '@' symbol for a particular duration and if he wishes to navigate back to the main menu, he has to select a specific symbol say '/' for a particular duration of time. The time duration for deletion of message and for navigating backwards to the main menu is different from the duration set for normal selection of words so that a user may use these symbols as text too.

If the user finishes coding the message he has to choose a specific symbol say '#' so that the screen now shows a new screen as shown in Figure 4.

Thus the user can use various options available in a commercial mobile. The picture message options contain some readymade picture templates to display various emotions. The ring tone option consists of symbolic musical notes and the user can select the symbols to compose a tone.

III. Conclusions

BCI is a revolution in technology and would soon find its application in our day to day life. It is in our hands to use it for the betterment of mankind.

Generating Different Views of Clinical Guidelines Using Ontology Based Semantic Annotation

Rajendra Singh Sisodia, Puranjoy Bhattacharya and V. Pallavi

Philips Research Asia, Bangalore, India - 560045

Abstract — **Clinical guidelines comprise collection of medical information related to clinical goals and are used by people having diverse information needs. Commonly users are only interested in information pertinent to their respective goals. Current clinical guidelines are largely textual in form and lack suitable mechanisms for extracting information relevant to different users. This paper proposes a method to extract information from clinical guidelines using a view based approach. Our view generation approach has four steps namely *annotation, view description, view extraction* and *view presentation*. As a case study, we have illustrated the proposed method using the CVD (Cardio-vascular diseases) risk management guideline published by WHO by creating views for different clinical care settings.**

Keywords — **Clinical guideline, View generation, Information extraction.**

I. Introduction

Clinical guidelines are evidence based documents prepared by regulating bodies with the aim of guiding decisions and criteria regarding diagnosis, treatment and management in specific areas of health care. Mostly, it is designed as a multipurpose medical document, which serves different purposes for different users. The principle users include physicians, medical specialists, nurses, medical officers, government health departments, universities and health care industries. All these users have different scopes and purposes. Commonly users are only interested in information pertinent to their respective goals.

Current clinical guidelines are largely textual in form usually written in as a series of paragraphs and lack suitable mechanisms for extracting information relevant to different users. The medical bodies responsible for the publication of guidelines pay more attention to the development of guideline rather than to implementation of guidelines for routine use in clinical settings. There are specific situations when the same information required by different users needs to be adapted for their intended goals. For e.g. a specialist is concerned with only those guidelines that relate to his/her area of specialization. So he/she has to read fewer guidelines and seek finer details in the guideline. However a general practitioner, who treats a range of diseases of multiple domains, will not need the finer details of the diseases as he/she is not a specialist, but will need the macro level details from a large number of guidelines. For these two categories of users, the usage of guideline information for their goals remains the same but differ in terms of details, granularities and entry/exit stage criteria.

If the guideline is not properly indexed getting relevant information becomes a time consuming and tedious task to practitioners for their clinical practices on need basis. In different usage context, the data and control flow within clinical guideline is sequential as defined by the order or textual paragraphs. Hence implementation of any decision support system [[1]] based on clinical guideline is very tedious and prone to error. To address these limitations of the clinical guidelines, this paper proposes a method to extract information from clinical guidelines using a view based approach. Svatek et al. [[2]] developed a document–centric mark–up tool called Stepper, to decompose a clinical guideline formalization process into multiple user–definable steps corresponding to interactive XML transformations. However, this paper does not generate different views of a clinical guideline.

The organization of the paper is as follows. In section II, we present our view based approach and highlight the key steps. Section III discusses our case study for WHO CVD guideline [[3]] for hypertension. We finally conclude and present the future work in section IV.

II. View based approach for information extraction

A view is defined as a collection of information extracted from a guideline and tailored for viewing to the needs of the respective user. Thus, a view could be thought of as a guideline in the user's perspective. It illustrates only the information that the user actually wants to see and omits other details. Views can be of many forms depending on the needs of the users. It could be a list of precautions, or a list of recommendations or the fine details about a particular condition of the disease or any combination of knowledge in guidelines depending on the user's interest.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 701–705, 2009
www.springerlink.com

A. Potential Views

In a guideline some views can be predefined based on some particular aspects of treatment which are frequently encountered in the health care. We discuss some of these predefined views and take one as a case study to illustrate our proposed approach.

Disease Condition Specific View: A medical treatment is a sequence of action steps based on a list of evidence. Each action step needs some evidence for execution. Thus the treatment often involves branching of a flow of steps. A view can be defined based on major branches or the special conditions of treatment so that information in other branches not concerning a particular patient can be omitted from the view.

Temporal View: Medical treatment, especially for chronic disease is not done in a single encounter, but is episodic in nature. In many cases, physicians may ask their patients to revisit them after a few days. In this case a view can be described as a set of information related to a particular visit, so that the physician while treating for a particular visit need not look at instructions meant for other visits. The disease management of the guideline in this view looks at the steps needed by practitioner in temporal order.

Resource based View: The healthcare infrastructure, especially in developing and under-developed countries, varies considerably in terms of resource availability. The resource can be lack of facilities, availability of specialized physicians, etc. There can be financial restraint on access to proper medical treatment by patient who may not be able to afford the specialized care and all the recommended medicines. In such cases, it is desirable to have a guideline view based on healthcare resources. For example, in a low resources scenario, the practitioner does not need to look at steps meant for specialized physicians. The assessment and treatment phase should be structured so that guideline recommendations of a are suitable for variable resource settings.

B. View based Approach

In this section we propose our method to extract information from clinical guidelines using a view based approach. Our approach has four steps as shown in Fig. 1 namely annotation, view description, view extraction and view presentation. They are described in the following

C. Semantic Annotation

The first step in our approach is to annotate the textual document of clinical guideline with semantic tags. This step is usually manual and provides additional meta information to be added with the textual clinical guideline thus allowing the process for generating views. The main issues during this step are (i) defining tags for annotation (ii) granularity of annotation (iii) mechanism to annotate.

The selection of tags is influenced by the information of the text to annotate. They should act as keywords and be sufficiently representative of the information they annotate. In trying to keep our tags generic to satisfy the requirements of a variety of users, we restrict ourselves to aspects of common usage of guidelines; in a sense these are kinds of things that users of guidelines try to look for, or relate to in the course of relevant healthcare services. Typical examples include time (such as episodic, stage within each episode, trend), resources (low, medium, high), disease categorization (chronic, acute, risk category, symptoms, observations), workflow (observation, assessment, treatment, referral) etc. The terms to be used for tagging the guideline are assumed from ontology for standardization purposes.

Annotation granularity implies granularity of textual information annotated within the scope of a given tag. Annotation at word level is too granular for any meaningful annotation as the context of the information may get lost whereas annotation at the paragraph level is too broad to generate any useful view. A sentence or phrase level annotation is a good balance between these extremes to capture the context of the information as well as to generate a view, and this has been adopted for the current approach. Annotating mechanism implies the rules and process of annotation. Main issues are (i) whether all text in a guideline should be annotated or some part of the guideline such as background information can be omitted? (ii) whether tags will have nested or overlapping scope? (iii) how tool support can facilitate efficient and effective semi-automated tagging mechanism and reduce the tagging errors? Figure 2 shows our approach for defining tags.

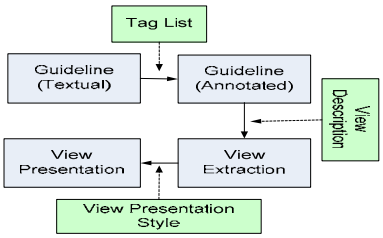

Figure 1: Semantic Annotation Based View Generation

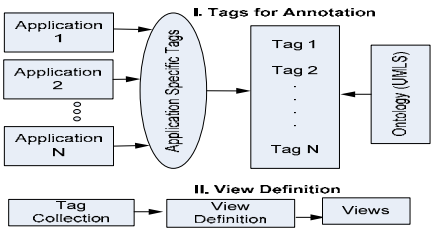

Figure 2: Tag Description

Each tag has a set of attributes to provide more semantic information. In XML, these attributes act as qualifier and can be used for meta information for generating views, organization and presentation.

D. View Description

The second step is to define views according to which the information is extracted. A view is a high level description of logical set of information that a user wants to see in the guideline to fulfill a specific goal. The goal can be different from the medical goals of clinical guidelines. In an ideal case, the logical set of information is a set of continuous or disparate piece of information within a guideline that is sufficient and complete for a user specific goal presented in a logical manner. Operationally, in our approach, a view is a sequence of tagged segments, where each segment satisfies a Boolean function or regular expression of tags.

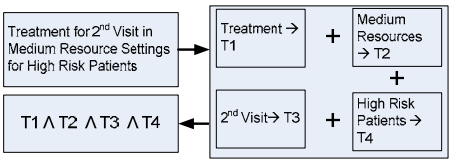

Figure 3: View Description as Boolean Function

Figure 3 describes a specific view for a user who wants to view treatment for second visit of a high risk patient for medium resource settings. The view comprises four aspects *(i)* workflow (treatment**)** *(ii*) resources*,(iii)* episodic (2nd Visit) *(iv*) patient condition assessment (high risk). The annotation tags (T1, T2, T3 and T4) correspond to these aspects to describe the view.

MediumResourceView := <Assessment>$^+$ <Treatment>$^+$
Assessment := <Condition>$^+$<Observation>$^+$
Condition := (<ConditionCriteria><Evaluation>*)$^+$
Observation :=(< ObservationCriteria><Evaluation>*)$^+$
ConditionCriteria := <EpisodicCriteria>$^+$ <RiskCriteria>$^+$
< ResourceSettingCareCriteria>$^+$
ResourceSettingCareCriteria:= 'MEDIUM RESOURCE'
EpisodicCritera := 'SECONDVISIT'
RiskCriteria := 'HIGH'
Evaluation := 'No' |'Yes' |'TRUE' |'FALSE'
Treatment := <Action>|<Advice>
……

Figure 4 : View Description as Regular Expression

The alternative way of describing a view is using a regular expression such as Backus-Naur Form (BNF). In this form (see Fig. 4), the definition of a view is expressed in terms of a set of tags with quantifiers to express the number of their occurrences. The tags composition is recursive in nature and expressed as a function of tags and attributes. We define view using XML schema and XML document type definition (DTD). XML schema is a description of a type of XML document, typically expressed in terms of constraints on the structure and content above and beyond the basic syntactical constraints imposed by XML itself. An example in this form for the same view is as follows

E. View extraction

Once a clinical guideline is annotated with a set of tags and the guideline is annotated by selected subset of tags as discussed in Section C. To illustrate the application of our view generation approach for a specific view: view for low/medium resource settings from specialist settings, we annotated corresponding text with tags to define criteria and context for (i) entry and exit boundary conditions (ii) observation, assessment and treatment for each care settings (iii) tags to qualify the episodic information and patient condition trends. Table 1 shows the annotated text according to our approach. Nested tags define the context and boundary of information. For example, <assessment> tag subsumes <condition> tags to illustrate that within assessment phase, multiple conditions need to be evaluated. For richer semantic information, each tag has set of attributes and their values to add meta information to qualify the tags. For e.g., the <condition> tag <Condition Evaluation= "Observation" Result="No/Yes" Scope=ALL" define attributes to qualify tags to define the evaluation criterion, scope for various care settings and expected results.

Views are defined for the document using a subset of tags structured according to a schema, the next step is to extract the information from the annotated document according to the view. Since we have an annotated document in XML representation, any XML parser [[4]] can provide annotated information for any tags. For a view, we iterate the annotated document to extract information for each tag defined in the view according to the XML schema of the view.

F. View Presentation

The information extracted for the view during view presentation phase is reorganized so that the extracted information is logically relevant. In ideal case, the information extracted in sequential manner from the annotated guideline should be logically relevant as structuring of guidelines is influenced by clinical workflow. For operational purpose we have combined the view extraction and view presentation phase. The XSL [[5]] is used to extract and present the view information. XSL provides a mechanism to select attributes on an XML document using the programming constructs. In any phase of our view generation, we do not modify the content of the guideline and preserve all the

information as it is. The modification in the guideline information during view extraction and presentation is the syntactic change in terms of reorganization of the information rather than any semantic one.

III. Case study

We have applied our proposed approach on WHO CVD Risk Management guideline [3] specifically designed for low and medium resource settings. As a case study we have selected only the high and medium risk assessment and treatment procedure. We omitted details of complicated scenarios of hypertension that are secondary or arises out of complications. The Table 1 shows the annotated guideline for one of the scenario mentioned in the WHO hypertension guideline designed for full specialist care setting. This setting encompasses[1] other care settings with limited resources in terms of facilities and availability of trained personnel. We will discuss how two other views can be generated.

Table 1: Annotated Guideline with Semantic Tags

<Action> <Advice scope= "High_Risk/Medium_Risk" Trend=No Improvements If established CVD and total cholesterol is >5mmol/L (193mg/dl) start statins (if available and affordable) <Advice> <Action>

[1] The third scenario is a superset of the remaining scenarios handling all the complicated cases of CVD which were recommended as referrals in first two care settings.

The view description for medium resource setting is defined in Fig. 4. The view is composed with set of tags with specific value. For e.g., ResourceSettingCareCriteria:= 'MEDIUM RESOURCE' assigns a specific value to the tag and detail the tag composition. The view description schema imposes structural criteria in terms of set of tags and their attributes. e.g., <Assessment>+ <Treatment>+, which are further refined iteratively in terms of their own composition, and ends. The view extraction and view presentation are combined as a single step in the case study. A view specific XSL script is used to extract the relevant tags from the XML complaint annotated document and is transformed into a readable document. In the view extraction step, we define selection and filtering of tags from the complete annotated guideline based on the view description. The view extraction extracts macro level annotated texts encoded within the participant's tags. The specific text within the extracted tags is filtered out during the view extraction stage based on the filtering criteria derived from the attributes and their values. The view presentation step presents the extracted text according to the presentation rules specified in the view presentation style sheet. Table 2 shows the view extracted from the annotated Table 1 for medium resource setting for medium risk CVD patient across multiple episodes.

IV. Conclusions

In this paper we discussed a view generation approach to extract and present information according to user specific needs. We discussed a four step approach to enrich the clinical guideline with semantic tags, mechanism to define views and extract and present them to a user. Our case study illustrates that our approach can be used to generate different views for accessing information from a clinical guidelines. With tool support, many of the steps can be automated thus enabling wide spread use of clinical guidelines for standard care among various clinical care settings.

Acknowledgment

We would like to thank Gopal Banarwal for his initial investigation on view generation for clinical guidelines.

A High-Voltage Discharging System for Extracorporeal Shock-Wave Therapy

I. Manousakas [1], S.M. Liang [2], L.R. Wan [3]

[1] Department of Biomedical Engineering, I-Shou University, Taiwan
[2]Department of Computer Application, Far East University of Technology, Taiwan
[3]Department of Aeronautics and Astronautics, National Cheng Kung University, Taiwan

Abstract — **Extracorporeal Shock wave therapy has applied by medical doctors on lithotripsy and orthopedics in replacing traditional surgery [1]. For generating shock waves, a high-voltage system of electrical mechanism is necessary to provide [2], and is designed with particular features in this study [3]. In order to build a high-voltage system for an extracorporeal shock wave therapy, some electrical circuits was specially designed and assembled by a charging capacitor system and a discharge control system. The components of the high-voltage system include a power supply, high-voltage resistors, capacitors, a spark gap, a triggering module, and two electrodes. Because the high-voltage power supply is the most decisive device, some electrical components were designed to be protected due to the electromagnetic interference associated with the high- voltage power supply. The high-voltage system can be applied to electromagnetic [4], electrohydraulic and piezolectric shock wave generators that produce shock waves. The details of materials and design methods used will be described. Control procedures for the designed shock wave therapy machine will be explained as flow charts. Schematic diagrams for all designed circuits and dimensions will be illustrated. Each single control procedure for the high-voltage system was validated by a time sequence and profiles of signals captured from an oscilloscope. It is noted that electromagnetic interferences associated with the high-voltage system have been reduced by 99% [5-7] by using well-shielded and optical devices such as optical fibers and infrared modules for controlling signals. Moreover, the mechanical and electrical properties of our designed shock wave generator have been measured. Finally, the positive peak pressure, negative peak pressure, and shock wave intensity were measured by using the pressure sensor of a PVDF membrane hydrophone [8].**

Keywords — **High-voltage, electrohydraulic, Shock wave.**

I. High-voltage system

In order to build an extracorporeal shock wave lithotriptor, a high-voltage system is needed. An important component of a shock wave generator is its electrical circuit. Basically the circuit was assembled by the charging capacitor system and the discharge control system. The components of a high-voltage system include a power supply, high-voltage resistors and capacitors, a spark gap, a triggering module, and two electrodes. Because the high-voltage power supply is the most decisive device, it must have to be used carefully. Thus, a circuit diagram was suggested in the application note of the high-voltage power supply from the Lambda EMI Company. To match practical conditions of our ESWL/ESWT machine, we modified the suggested circuit and added some electrical components to protect the high-voltage power supply. The modified circuit was as shown in Fig. 1.

The principal components of the circuit are a high-voltage power supply model 202A with variable voltage between 0 and 30 kV, a triggered spark gap model GP-12B, a trigger module model TM-11A with 15-30kV output voltage, and several capacitors with different capacitances. The designed circuit of high-voltage power supply as shown in Fig. 1 was used to charge the main capacitor C_2 through a high-voltage resistor R_1. The capacitor C_2 is set to discharge across the underwater spark gap by a triggered spark gap. The trigger spark gap acts as a switch and is held in an off position by a pressurized nitrogen atmosphere which inhibits electrical breakdown. It is turned on when a high-voltage pulse, delivered to a central electrode, ionizes the gas allowing conduction to take place across the spark gap. As a safety reason, the vacuum relay will be kept closed when the high-voltage supply is switched off or any power failure happens so that the capacitor C_2 discharges through the high-voltage resistor R_1 and R_2. Note that capacitor C_1 plays a role as a firewall of high-voltage power supply in this circuit. Power supply will charge the capacitor C_1, and the capacitor C_2 will be charged by the capacitor C_1 right

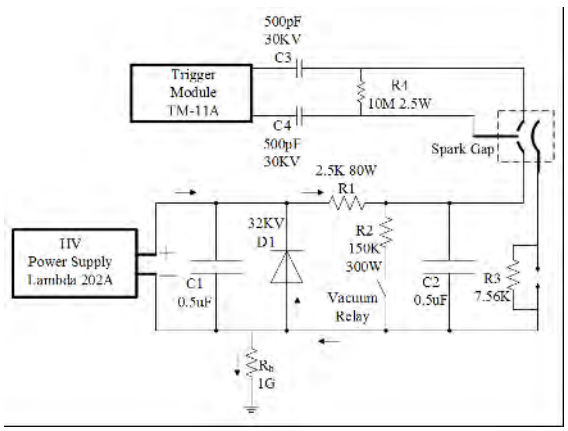

Fig. 1 The high-voltage circuit of our designed ESWL/ESWT machine.

www.springerlink.com

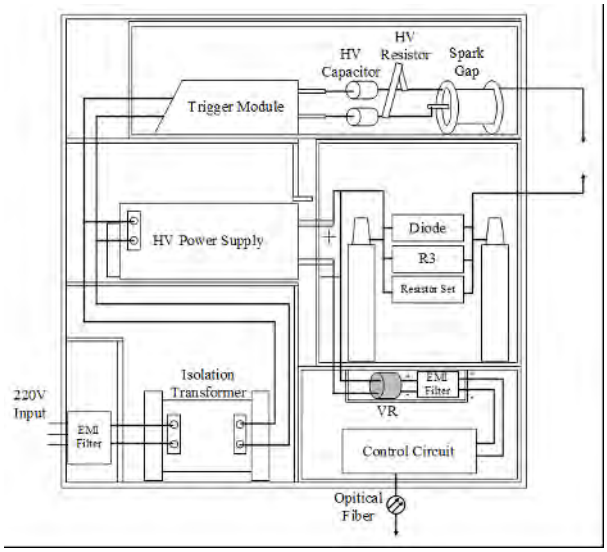

Fig. 2 The settings of a high-voltage system.

after. With this firewall in the front of the high-voltage power supply, any power accident will be blocked by the capacitor C_1 first. Therefore, the high-voltage power supply will be safe. Moreover, the resistor R_3 plays as a damper of discharging. While we trigger the spark gap, an electrical arc will be produced between the two electrodes. At the same time, EMI and signal noise are radiated. With the use of the resistor R_3, most of EMI and noise will be absorbed. This is so-called a soften discharge. Sometimes if a triggered arc failed to discharge between the electrodes, the resistor R_3 will absorb the energy.

To assemble all the high-voltage devices into a high-voltage system, a steel case with several small rooms is needed in order to reduce the electromagnetic radiation. After estimating the size of all the high-voltage devices, a case with the required rooms was designed. For the safety reason, all the small rooms were set with bakelite to prevent any electric shock accident. The designed settings were illustrated in a front view as shown in Fig. 2. The sketch of Fig. 2 also shows the connected wires. The actual circuit can be referred to the circuit diagram in Fig. 1. It is worthwhile to mention that all the separated rooms have their own covers to prevent the electromagnetic radiation. When the covers are closed, most of EMI is blocked by the well-grounded steel case

II. Control System

A. Design of the control circuit

From our experiences, we found that the EMI mainly came from both power and wires or air. To overcome the

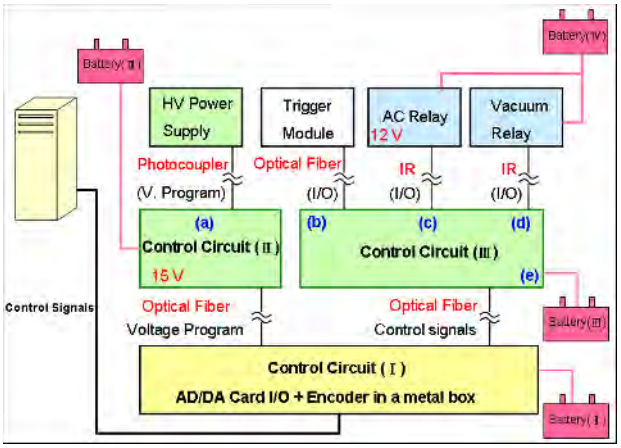

Fig. 3 A sketch of controls.

EMI problem, we insulated the high-voltage device from low-voltage devices for safety. In Fig. 3, a computer was connected to a box, the control circuit (I). This circuit is basically an encoder for controlling signals. These signals were controlled without encoding. A wire looks like an antenna. Connected wires can interfere each other by receiving unnecessary electronic magnetic disturbances. Control signals were encouraged to be transmitted by encoding and decoding processes, resulting in more stable and more safety. Furthermore, the encoded signals can be transmitted through a light transmitting unit without a wire connecting from the control circuit (II) with the control circuit (III). The safety of avoiding electric shock (surge) was guaranteed by separating them completely. Moreover, due to the fact that signals transmitted to the high-voltage power supply should not be interfered by other signals, we separated the control circuit (II) from the control circuit (III) as an independent unit, as shown in Fig. 3.

B. Optical devices applied

Signal transmission by using an optical method could completely avoid the EMI coming from connected wires. Many light transmitting modules were applied in our control system except for signals power. We introduce the main methods we applied in this study.

Optical fiber module: This module consisted of an optical transmitter and an optical receiver. These light transmitting units were manufactured by the EDISON OPTO CORPORATION, and could transmit signals at a high speed of 16 Mbps. Generally speaking, signals were transmitted by a light-transmitter and a light-receiver would receive signals through an optical fiber. The completed control circuit was installed in a metal box as shown in Fig. 4.

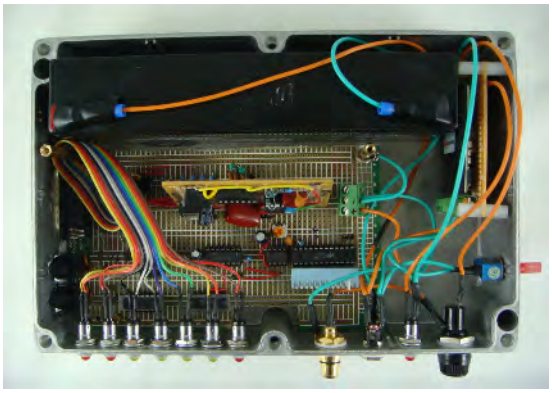

Fig. 4 The assembled control-circuit (II) of high-voltage power supply

Infrared module: The AC relay and the vacuum relay were controlled by control-circuit (III) through an infrared module. Infrared modules were commonly applied in our life. We transmitted the on/off signals with the infrared method and more complicated signals with the optical-fiber method. Here we use two channels of infrared transmission for the AC relay and vacuum relay which were made in a metal box, as shown in Fig. 5. Because the deflection might happen to interfere with each other, an opaque tube was added to limit the infrared passage in the tube. The two tubes shown in Fig. 5 were installed for light limitation.

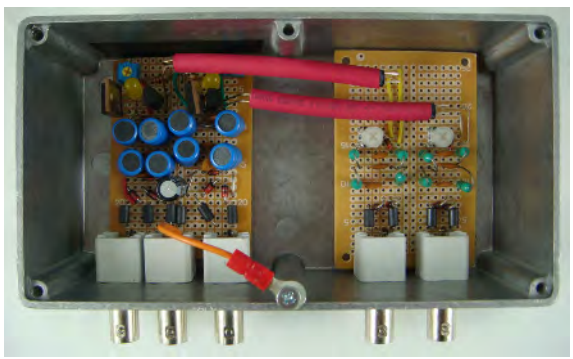

Fig. 5 The infrared signals limited in an opaque tube.

III. Result

A. Result of high-voltage system

According to the design Fig. 2 and 3 we mentioned before a high-voltage system was set up and constructed as shown in Fig. 6. In order to shielding from EMI radiation the room for the high-voltage system was also added with metal covers as their shelter.

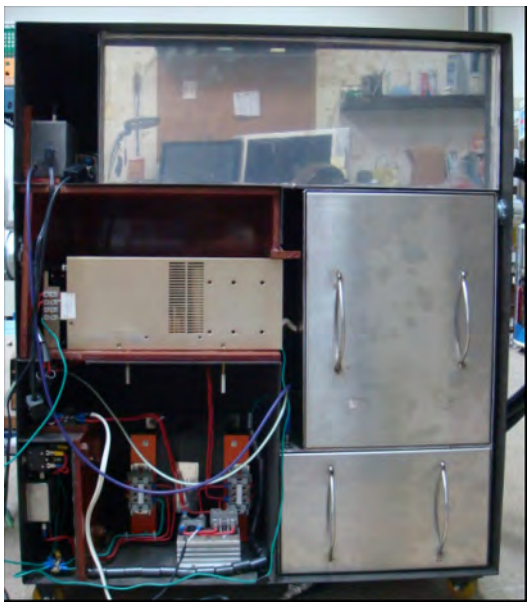

Fig. 6 The high-voltage devices were covered by metal shelters.

B. Results of EMI reducing

The results were measured by using an optical fiber. And the infrared technique was applied in communicating with ACR and VR. All rooms were covered with a metal shelter. Most of high-voltage wires were covered with ferrite cores, too. Fig. 7 shows that the signal without optical device applied and the EMI is about 233V. As shown in Fig. 8 for confirming the result of EMI elimination, resulted pictures of an oscilloscope were captured for several times while the trigger module was triggered. The measured EMI was reduced from about 200V to 2V. The reduction in EMI is approximately 99% by using the present method.

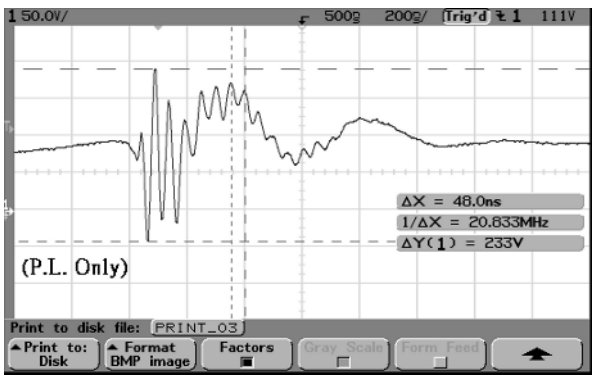

Fig. 7 A signal of EMI before using optical devices.

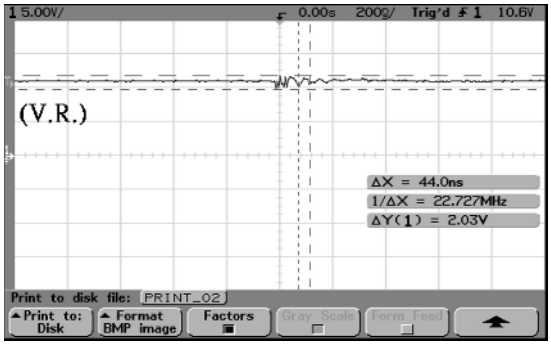

Fig. 8 The resulted signal after using optical devices.

C. Results of output pressure

The focused pressures from our developed ESWL machine were measured by using the pressure sensor of a PVDF membrane hydrophone and a PCB pressure sensor. The profile of the output pressure with its standard deviation was measured at the operation voltage from 10kV to 15kV as shown in Fig. 9. The output pressures were measured by a PVDF membrane hydrophone and each standard deviation were calculated with ten pressure values. Also, the energy density of intensity was calculated from the pressure data as shown in Fig. 10.

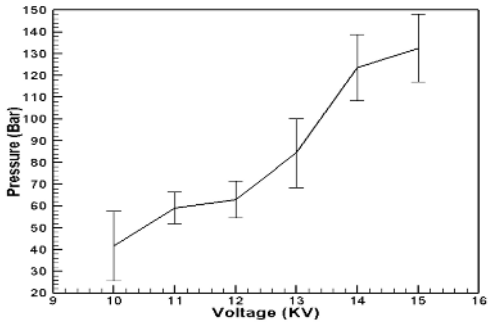

Fig. 9 The measured output pressure from 10kV to 15kV

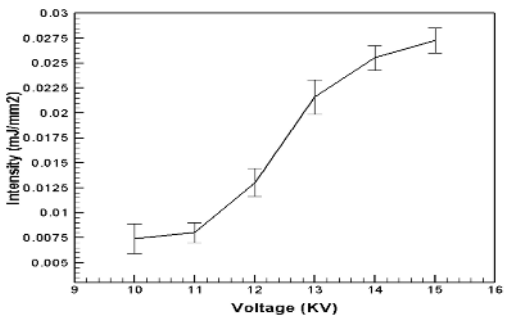

Fig. 10 The profile of intensity from 10kV to 15 kV

IV. Conclusions

The circuit of our high-voltage system has been designed and wired with the aids of the manuals of HVPS. The final test verifies the successful design of our high-voltage circuit. The EMI effects of independent power source, shielding with metal covers and ferrite cores were eliminated, which were found to no longer exist from the captured figures on an oscilloscope. The techniques of using optical module, infrared, encoding and decoding were applied in the controlling system. Circuits and software have been built to communicate signals with the high-voltage device. The test operations of the high-voltage system have successfully passed. The inputted signals would not be interfered by the emitted EMI. All output signals performed clearly and were coincident with expected waveforms. The output pressures at the second focus were measured by a PVDF hydrophone, and the intensity was calculated from the waveform of the output pressures.

Development of the Robot Arm Control System Using Forearm SEMG

Yusuke Wakita[1], Noboru Takizawa[1] , Kentaro Nagata[2]and Kazushige Magatani[1]

[1] Department of Electrical and Electronic Engineering , Tokai university, Japan
[2] Kanagawa rehabilitation center, Japan

Abstract — **SEMG has many benefits. For example, measurement of SEMG is easy and non-invasive, and especially a characteristic pattern of SEMG is obtained for each body movement. In this research, our objective is the development of a new man-machine interface that is able to control carious equipments by using a characteristic pattern of forearm SEMG. In this paper, we will describe about our developed interface that is controlled by forearm SEMG.**

Keywords — **SEMG, man-machine interface**

I. Introduction

SEMG (Surface Eloctromyogram) is one of the bio-electric signals that is generated from the muscle. There are many kinds of muscles in a human body, and used muscles are different for each body movement. Therefore, body motions can be estimated by analyzing generated SEMG patterns. Our objective of this study is the development of the method that makes perfect estimation of the hand movements possible using SEMG and applying this method to the man-machine interface. In our developed SEMG system, SEMG signals of suitable channels SEMG signals which are measured from a right and left forearm of a subject are used to detect hand motions. And a robot arm is controlled as the results of detecting hand motions.

II. SEMG system

Fig.1 shows a block diagram of our developed SEMG system. In our system, two multi-electrodes that include 48 channels silver electrodes are used to measure left and right forearm SEMG patterns. Measured forearm SEMG signals from a multi-electrode are amplified, filtered and analog to digital converted. In digitization, sampling frequency is 3[kHz], and bit resolution is 16bits. Digitized SEMG data are analyzed in a personal computer.

A block diagram of one channel SEMG amplifier is shown in Fig.2. As shown in this figure, SEMG is amplified about 4400 times and a band width is limited from 10 to 1.5[kHz]. In addition, a SEMG amplifier includes a hum filter which eliminates 50[Hz] in order to be able to use the system in unshielded place. Developed 48 channels SEMG amplifier is also shown in Fig.3.

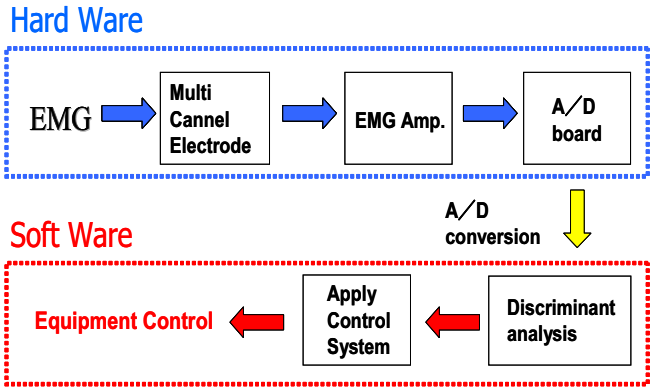

Fig. 1 A block diagram of the SEMG system

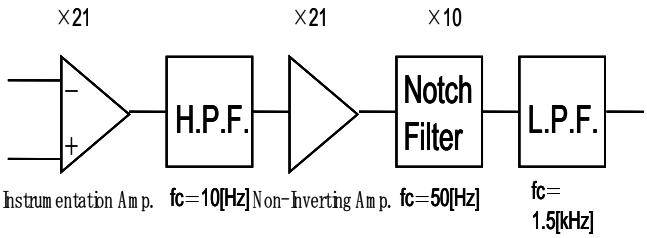

Fig. 2 A block diagram of 1 channel SEMG amplifier

Fig. 3 48 channels SEMG amplifier

A structure of 48 channels surface multi-channel electrode is shown in Fig.4. This multi-channel electrode is composed of 48 silver electrodes (12 x 4). Each electrode is

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 710–713, 2009
www.springerlink.com

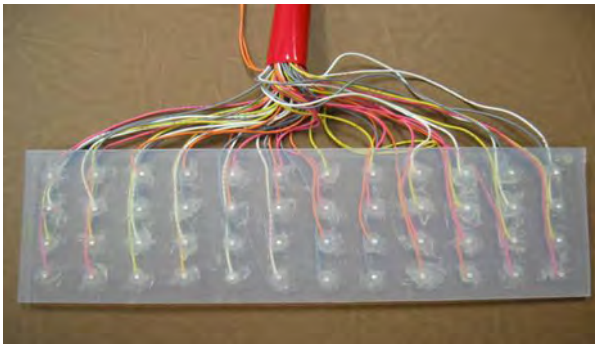

Fig. 4 A multi-channel electrodes

1[mm] in diameter. To fit a forearm bodyline, flexible silicone rubber is used as a base of 48 silver electrodes. A thickness of this silicone rubber is 2[mm].

III. Motion detection

In our system, hand motion detection is done using the method of canonical discriminate analysis. An integrated value while 300[ms] of absolute value of SEMG is used as a SEMG feature extraction. Therefore, each channel's SEMG feature extraction Xi (i = 1, 2, 3, ... , 48) is shown as following formula.

$$X_i = c\sum_{i=1}^{Ti} |x_i(t)|$$

Where C is a constant value for normalization, $xi(t)$ is sampled SEMG value for each channel. Ti is a integration period and this value is set as 300[ms]. As mentioned earlier, sampling frequency of our SEMG system is 3[kHz]. Therefore, one SEMG feature extraction is calculated using 900 data of sampled SEMG.

If we control some equipment using SEMG, the number of using electrodes is important. Of course, using small number of electrode is better. In our system, suitable channels and position of electrodes are estimated by Monte Carlo Method. At first, 48 channels SEMG patterns of a subject are recorded for each hand motion. Next, from 1 to 12 channels electrode sets are evaluated in our system. Positions of electrode are generated randomly for each set in a computer. And recognition rate of each hand motion is calculated for each set by using recorded SEMG patterns. Positions of electrode are generated 1000 times randomly for each set. From results of these trials the suitable number of electrode and suitable positions of electrode are decided for each subject. A flow chart of this deciding process is shown in Fig.5. In our system, canonical discriminate analysis is used for classification of hand motion as mentioned earlier.

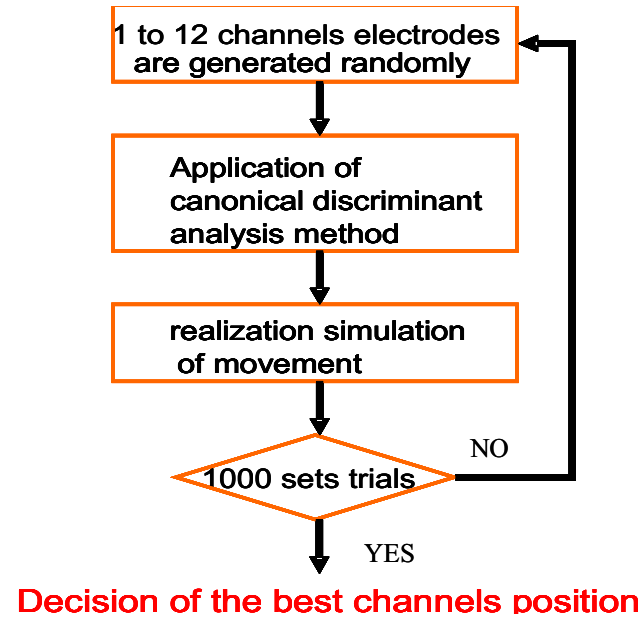

Fig. 5 An algorithm of deciding process for electrode

An example of distribution of classified basic 13 motions of a hand and figures on canonical space are shown in Fig.6. As shown in this figure, all clusters are separated each other. In the case of recognition, the Euclid distance between measured point and mean position of each cluster is calculated, and the motion for the shortest distance is estimated as the real motion.

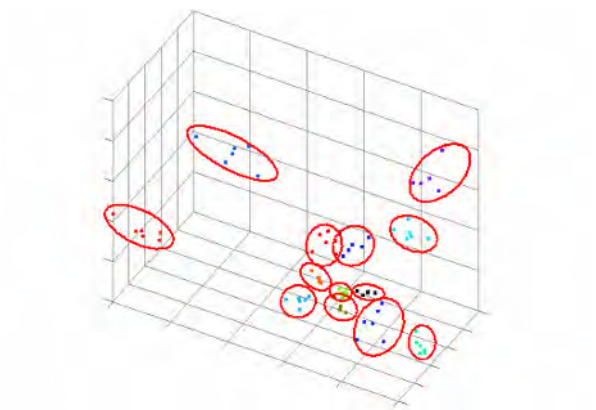

Fig. 6 An example of distribution of hand motion in canonical space

IV. Experiment

At first, the developed system was evaluated for real time motion recognition. In this experiment, basic 8 hand motions and 5 finger motions were tested. Three normal male sub-

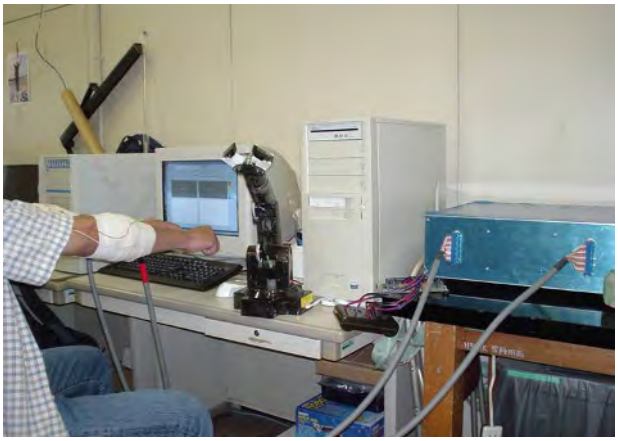

Fig. 7 A scenery of the experiment

jects were studied with our system. Two multi-channel electrodes were attached to subject's right and left forearm. A picture of experiment scenery is shown in Fig.7.

A. Pre-Process

Every subject registered their hand motions to the system and suitable number and position of electrodes were calculated. Then all subjects move their hand 10 times for each 13 hand motions. An example of mean values of the recognition rate is shown in Table 1. This table shows recognition rates of the right hand of one subject for 13 hand motions. As shown in Table 1, for all hand motions, recognition rates were more than 90[%]. In this case, our system selected 6 channels of electrodes as suitable number of electrode. In case of other subject and left hand, recognition rate were also more than 90[%] for all motions. These results indicate that our recognition method worked well.

Table 1 Result of the real time recognition

Motion	Recognition rate [%]
Wrist Flexion	100
Wrist Extension	100
Grasp	90
Release	100
Pronation	100
Supination	80
Radial Deviation	80
Ulnar Deviation	90
Flexion of Thumb Finger	100
Flexion of Index Finger	90
Flexion of Middle Finger	100
Flexion of Ring Finger	100
Flexion of Little Finger	90
Average	94.62

B. Real time recognition using a robot hand

After selecting suitable electrode positions, the number of electrodes, and calculating canonical space, our EMG system are identify hand motions on real time. After these pre processing, a robot arm was tested with our EMG system. One is a robot arm and another is a radio controlled vehicle (tank). Fig.8 shows the toy robot arm which was used in our experiment. This robot arm can operate 10 kinds of motion as shown in Table 2.

Three normal male subjects were tested with this robot arm control system. Their recognition rate was more than 92[%] in all hand motions and he knew this SEMG system very well. They could control the robot arm accurately, and they could transport a small box from one place to another by using this arm. In this experiment, robot arm grasped a box, lifted up it, turned body and release a box on another place.

Fig. 8 Robot arm

Table 2 Correspondence between a robot motion and hand motion

Movement of robot arm	Movement of SEMG
Grasp	Right arm grasp
Release	Right arm release
Counterclockwise of wrist	Right arm pronation
Clockwise of wrist	Right arm supination
Elbow (Up)	Right arm radial deviation
Elbow (Down)	Right arm ulnar deviation
Counterclockwise of base	Right arm wrist flexion
Clockwise of base	Right arm wrist extension
Shoulder (Up)	Left arm wrist flexion
Shoulder (Down)	Left arm wrist flexion

V. Conclusion

In this paper, we talked about our developed SEMG system which can control some equipments using hand motion recognition by SEMG. In our system, suitable electrode positions and number of electrodes are selected from analyzing results of 48 multi-channel SEMG patterns for each subject. The hand motion detection was done using the method of canonical discriminate analysis. In this study, 13 basic hand and finger motions were detected. Recognition rates of this experiment were more than 90[%]. We think this recognition rate is very high and our system works well.

All subjects controlled a robot arm accurately using SEMG patterns which were generated left and right forearm. In this experiment, subjects could transport a small box from one place to another by using this arm. From this experiment, we see that if subjects are experienced for the system, our developed system can control a complex system well.

From these results of our experiment, we have concluded that our new man-machine interface which used SEMG worked perfect and will be a valuable interface in future.

Tissue Classification from Brain Perfusion MR Images Using Expectation-Maximization Algorithm Initialized by Hierarchical Clustering on Whitened Data

Y.T. Wu [1,2,3], Y.C. Chou[1,2], C.F. Lu[1,2] , S.R. Huang[1,2] and W.Y. Guo[4]

[4] Department of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan, ROC

Abstract — **Classification of different perfusion compartments in the brain is important to the profound analysis of brain perfusion. We presents a method based on a mixture of multivariate Gaussians (MoMG) and the expectation-maximization (EM) algorithm initialized by the results of hierarchical clustering (HC) on the whitened data to automatically dissect various perfusion compartments from dynamic susceptibility contrast (DSC) MR images so that each compartment comprises pixels of similar signal-time curves. Monte Carlo simulations have been designed and executed to assess the performance of the proposed method under various signal-to-noise ratios (SNRs). The results of simulations showed that using EM initialized by HC on whitened data produce the best accuracy of segmentation. Five healthy volunteers participated in this study for the validation of this method. The averaged ratios of gray matter to white matter for relative cerebral blood volume (rCBV), relative cerebral blood flow (rCBF) and mean transition time (MTT) derived from 5 normal subjects were 2.196±0.097, 2.259±0.119, and 0.968±0.023 which are in good agreement with those reported in the literature. The proposed method can subserve the diagnosis and assessment of various diseases involving the changes of cerebral blood distribution.**

Keywords — **MR perfusion, expectation-maximization algorithm, hierarchical clustering, whitening, segmentation.**

I. Introduction

Dynamic-susceptibility-contrast (DSC) MR imaging is a widely used tool to record the signal changes embodying different blood supply patterns after intravenous injection of a bolus of contrast agent. With the bolus profile of arterial compartment identified, cerebral hemodynamic parameters, namely, relative cerebral blood volume (rCBV), relative cerebral blood flow (rCBF) and mean transit time (MTT) can be computed based on indicator dilution theory [1].

In order to facilitate the analysis of brain perfusion, we classify the brain tissues into different components based on their specific bolus transit profiles. In this study, a method based on a mixture of multivariate Gaussians (MoMG) and the expectation-maximization (EM) algorithm initialized by the results of hierarchical clustering (HC) on the whitened data is presented to automatically dissect various perfusion compartments. Since the dimension of dynamic MR data is usually far larger than the number of tissue types, we first apply the principal component analysis (PCA) [2] to reduce the data dimension, and the reduced data were further whitened so that the covariance matrix of the whitened data is an identity matrix. The distribution of the whitened data associated with each tissue type is assumed to be a multivariate Gaussian function, and the overall distribution of the whitened data is assumed to be a mixture of multivariate Gaussians (MoMG) [3]. Hierarchical clustering (HC), a multilevel classification method without the need of random initial guess, was applied on the whitened data to segment out each tissue cluster via a hierarchical cluster tree based on a minimum variance algorithm, namely the Ward's method [4]. The results were used to initialize the mean vectors, covariance matrices of the MoMG, and the proportion of each class in the subsequent EM estimation. The number of classes in MoMG model, namely tissue types, is determined by minimizing the information criterion of the minimum description length (MDL) [5]. After comparing values of the resultant posterior probabilities at each pixel, the tissue type that produces the maximal probability will determine the pixel label [6]. To assess the performance of the proposed method, Monte Carlo simulations have been designed and conducted under various noise levels.

II. Material and method

A. Subjects and data recording

Five healthy volunteers aged from 18 to 47 (3 males and 2 females) with body weights between 49 and 70 kg participated in this study. Written informed consent was obtained from each subject before this study. A multi-slice gradient-echo EPI pulse sequence on a 1.5 Tesla scanner (Signa® CV/*i*, GE Medical Systems, Milwaukee,WI, USA) was used to acquire dynamic perfusion images. Imaging used transaxial imaging, TE/TR = 60/1000 ms, flip angle = 90 degree,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 714–717, 2009
www.springerlink.com

FOV = 24 cm × 24 cm, matrix = 128×128, slice thickness/gap = 5/5 mm for 7 slices, one acquisition, and 100 images per slice location. Twenty ml of Gd-DTPA-BMA (Omnisacn®, 0.5 mmol/ml, Nycomed Imaging, Oslo, Norway) followed by 20 ml of normal saline were delivered administratively using a power injector (Spectris®, Medrad, Indianola, PA, USA) at a flow rate of 3-4 ml/sec in the antecubital vein. Temporal resolution is one second. Since only dynamic images which have stable baselines and discernibly temporal signal changes are of interest, the first three and last twenty-seven images were removed from a total of 100 images, with seventy images retained per slice location for analysis. All routines were implemented using MATLAB (MathWorks, Inc., Natick, MA) code and carried out on a 2 G-Hz Pentium-based personal computer.

B. Data pre-processing and Dimension reduction using PCA and data whitening

Brain regions were extracted from perfusion images by first setting all pixel values larger than the threshold derived from Otsu's method [7] to one and all values smaller than this threshold to zero. An erosion operation with a 3x3 structure element was applied to the resultant binary mask removing pixels corresponding to skull and scalp areas. This was followed by a dilation operation with a 5x5 structure element filling holes in the brain region. Only the remaining pixels within the extracted brain region were subjected to further classification processing. Assume that the brain region for each image comprises of N pixels, the observation of 70 temporal images can be represented by a $70\times N$ matrix, i.e., each row is an image and each column contains signal intensities of a pixel across 70 time points. To facilitate the subsequent segmentation process, we further reduced the dimension of each data set by PCA [2] to retain most of the data information.

The whitening process is the same as PCA, except that the zero-mean data were transformed by the orthogonal matrix so that the covariance matrix of the whitened data is an identity matrix [2]. In this study, the first *t*-th eigenvectors were selected to form the orthogonal matrix where t was chosen to be between 5 and 12 to condense the data size from $70\times N$ to $t\times N$ so that the sum of the associated eigenvalues interpreted at least 99% of the data variance. The transformed data with reduced dimension resulted from PCA or whitening process were used in the subsequent hierarchical clustering.

C. Initialization: HC on the PCA data or whitened data

Let the compressed data, which were obtained from either PCA or whitening process, be denoted by a matrix $\mathbf{X}$ with size $t\times N$ and each $t\times 1$ column vector in $\mathbf{X}$ be referred to as a feature vector. The objective of HC is to carry out grouping in the data set $\mathbf{X}$ based on a created cluster tree with multilevel hierarchy, where any two nearer clusters at one level are merged into one cluster at the next higher level. The algorithm of HC consists of three major parts: (1) find the dissimilarity between every pair of feature vectors in the data set; (2) group the feature vectors into a binary and hierarchical cluster tree; and (3) determine what level or scale of clustering by cutting the hierarchical cluster tree. Many algorithms are available in regard to the calculation of dissimilarity and the creation of cluster tree [4]. In this work, we employed the Ward's hierarchical clustering method, one of the agglomerative algorithms, for constructing a hierarchical tree. The clustering results on the condensed data $\mathbf{X}$ were used to initialize the mean vectors, covariance matrices of the MoMG, and the proportion of each class for the subsequent EM estimation.

D. Tissue segmentation by the MoMG model with EM algorithm and calculation of rCBV, rCBF and MTT

The tissue segmentation was carried out by EM algorithm by fitting the overall distribution of the whiten data, x_n ($t\times 1$), n = 1, … N, to a mixture of multivariate Gaussian distributions. The EM algorithm is often used for estimation problems in which some of the data are "missing". In this application, the missing data is knowledge of the tissue labels. This algorithm consists of two alternating iterative steps, namely, E-step and M-step. The E-step is to compute the posterior probabilities of tissue classes $p(i\,|\,x_n,\theta^{j-1})$ based on the estimation from previous *(j-1)th* iteration

$$p(i\,|\,x_n,\theta^{j-1})=\frac{\pi_i^{j-1}g_{x_n}[\mu_i^{j-1},\Sigma_i^{j-1}]}{\sum_{l=1}^{K}\pi_l^{j-1}g_{x_n}[u_l^{j-1},\Sigma_l^{j-1}]} \tag{1}$$

where *i=1, ... N* represent labels of tissue classes, $g_{x_n}[\mu_i,\Sigma_i]$ represents the multivariate Gaussian density with the mean vector μ_i and covariance matrix Σ_i of tissue class *i*, π_i denotes the proportion of each class *i* and θ^{j-1} denotes the parameters $\{\mu_i^{j-1}, \Sigma_i^{j-1}, \pi_i^{j-1}\}$ at the *(j-1) th* iteration. The M-step consists of estimating parameters θ^j as follows

$$\mu_i^j = \frac{\sum_{n=1}^{N} p(i \mid x_n, \theta^{j-1}) x_n}{\sum_{n=1}^{N} p(i \mid x_n, \theta^{j-1})},$$
$$\Sigma_i^j = \frac{\sum_{n=1}^{N} p(i \mid x_n, \theta^{j-1}) x_n x_n^T}{\sum_{n=1}^{N} p(i \mid x_n, \theta^{j-1})}, \quad (2)$$
$$\pi_i^j = \frac{1}{N} \sum_{n=1}^{N} p(i \mid x_n, \theta^{j-1})$$

The number of classes K is determined by information criterion of minimum description length (MDL) [4]:

$$\mathrm{MDL}(K) = -\log\left\{ \prod_{n=1}^{N} \sum_{i=1}^{K} \pi_i g_{x_n}[\mu_i, \Sigma_i] \right\} + \lambda J \log(N) \quad (3)$$

where the term $\prod_{n=1}^{N} \sum_{i=1}^{K} \pi_i g_{x_n}[\mu_i, \Sigma_i]$ is the maximum likelihood of $p(x_n \mid \mu_i, \Sigma_i, \pi_i)$ with parameters $\{\mu_i, \Sigma_i, \pi_i\}$ estimated by the EM algorithm, $J = (t \times t + 3 \times t + 2) \times K/2 - 1$ (i.e., tK parameters of μ_i, $(t+1)tK/2$ parameters of Σ_i, and $K-1$ parameters of π_i), and λ is a scalar factor. The tissue label at each pixel was determined by the maximal value of $p(i \mid x_n, \theta^{j-1})$ at that pixel and therefore each tissue type was classified. Once all tissues of interest are identified, the averaged concentration time curves of each tissue type are computed and the AIF is modeled from the averaged concentration time curve of artery to compute the rCBV, rCBF, and MTT maps [8].

E. Monte Carlo Simulation

We conducted the Monte Carlo simulations to assess the performance of the EM-MoMG method. The mean vector and covariance matrice for each cluster were initialized by the following approaches: 1) HC on the whitened data, 2) HC on the PCA data, 3) random selection of columns from the PCA data, and 4) selection of every Kth column (K is the number of cluster) from the PCA data. Sets of simulated dynamic images were first created so that each data set consisted of four to nine hypothetical clusters. The number of pixels and intensity distribution of each hypothetical cluster were generated based on the region of interest (ROI) on one of the raw data sets so that the statistics of the simulated dynamic images can emulate the actual ones. For example, in the case of seven hypothetical tissue clusters, the selected ROIs on the raw data represented artery (Artery 461 pixels), gray matter (GM, 1785 pixels), white matter (WM, 1663 pixels), vein and sinus (vein+sinus, 606 pixels), sinus (104 pixels), cerebrospinal fluid (CSF), choroid plexus (cp, 402 pixels), and artifact (418 pixels), respectively. The ROIs were either merged or split to produce less or more hypothetical clusters. Pixels within each hypothetical tissue area were assumed to be spatially independent, and their intensities across time were assumed to be multivariate Gaussian-distributed. The averaged intensity-time curves, each of which was a 70×1 vector, and covariance matrices of intensities across time, each of which has dimension 70×70, within ROIs on the raw data were employed as the hypothetical parameters for the MoMG model to create a set of noise-free simulated dynamic images using random number generators. Sets of noise-free simulated dynamic images with different numbers of hypothetical clusters were generated in a similar manner. In addition, Gaussian noise was added to each set of noise-free simulated dynamic images to produce the signal-to-noise-ratio (SNR) levels with values of 40 and 70. For each number of hypothetical clusters and SNR level, a Monte Carlo simulation of 1000 runs was performed. Accordingly, the total number of simulated image sets was 6 (number of hypothetical clusters) $\times 3$ (SNR levels) $\times 1000 = 18000$. Each set of simulated dynamic images was rearranged into a $70 \times N$ matrix before classification, where N ($N = 5439$ in the simulation) was the number of pixels representing brain area. Next, PCA and whitening process were applied to condense the $70 \times N$ matrix into two $5 \times N$ matrices in which sum of the 5 largest eigenvalues interpreted 99% of the data variance. The EM-MoMG estimation was initialized by four different initials with number of tissue classes being tested from 3 to 10. After comparing values of posterior probabilities $p(i \mid x_n, \theta)$ at each pixel, the cluster resulting in the maximal probability was identified and the pixel was labeled accordingly. The classification rate for each cluster, denoted by r_i, was defined by the observed proportion of agreements, namely $r_i = f_i / n_i$, where f_i was the number of agreements for the i th cluster and n_i was the total number of pixels in the i th class. The classification rate for a set of simulated dynamic images, denoted by R, was computed by $R = \sum_{i=1}^{K} 100 \times r_i / K$ (percentage), where K is the number of clusters.

III. Results

The results of Monte Carlo are summarized as follows 1) The EM-MoMG method initialized by the results of HC on the whitened data outperformed the other three initializations. Not only the averaged classification rates were much higher, which were between $99.0 \pm 0.39\%$ and $93.6 \pm 1.42\%$ under the noise-free with 4 hypothetical tissue clusters and SNR=40 with 9 hypothetical tissue clusters,

respectively, but also the standard deviations were much smaller (always less than 1.42%), implying accurate and reliable segmentations; 2) The mean classification rates from all methods decreased slightly as the SNR decreased from the noise-free condition to 40. In the case of the proposed EM-MoMG method with whitened+HC initial, the largest decrease and increase of the mean classification rate and standard deviation were merely 0.5% and 0.07%, respectively, namely, from 94.1 ± 1.35% (noise free) to 93.6 ± 1.42% (SNR = 40) in the case of 9 hypothetical tissue clusters; 3) The performances of all methods degraded as the number of hypothetical tissue clusters increased. In the worst case of SNR = 40, although the results obtained from the EM-MoMG method with whitened+HC initial decreased from 98.9 ± 0.40% to 93.6 ± 1.42%, they were far superior to other results in terms of higher classification rates with much smaller standard deviations.

Five normal subjects' data were processed and their perfusion images were segmented into different compartments based on the rule of minimizing MDL. Figure 1 illustrates the segmentation image and its corresponding mean concentration-time curves of one normal subject. Figure 2 illustrates the hemodynamic parametric maps derived from the averaged concentration-time curve of artery.

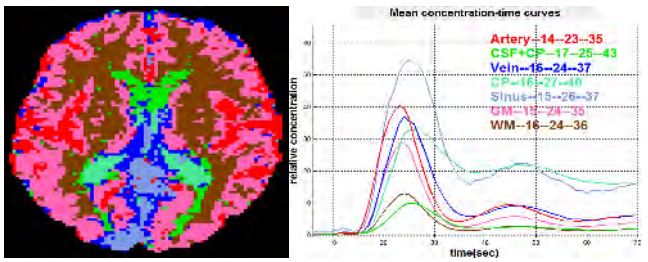

Fig.1 Segmentation results. Left is the composite color-coded image. Right is the corresponding mean concentration-time curves. Seven compartments, namely arteries (red), cerebrospinal fluid +choroid plexus (green), vein (blue), choroid plexus (cyan), sinus (light blue), gray matter (pink) and white matter (brown), were segmented from the whitened dimension-reduced data by EM-MoMG method. The three numbers following each name of tissue type in left-to-right order in the plot stand for the starting time, peak time and ending time of the first pass of contrast.

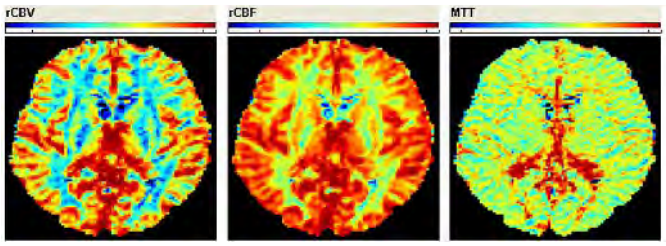

Fig.2 Hemodynamic parametric maps. From left to right are rCBV, rCBF and MTT, respectively.

The average ratios of gray matter(GM) to white matter(WM) for rCBV, rCBF and MTT were 2.196±0.097, 2.259±0.119 and 0.968±0.023, respectively, which are in good agreement with those reported in the literature[9] and it demonstrates the accuracy and feasibility of our proposed method.

IV. Conclusions

The study presents an EM-MoMG method initialized by the HC on the whitened data. This method features several advantages for central hemodynamics studies and clinical applications. First, an AIF can be modeled consistently on the same slice location for the calculation of hemodynamic parametric maps. Second, various tissue compartments on perfusion images can be classified systematically. Third, the bolus transit profiles of these tissues can be well separated.

Abstract — **This study aims to recover the somatosensory evoked potentials (SSEPs) from the smearing electroencephalography (EEG) recordings using independent component analysis (ICA) in conjunction with the proposed time-frequency SSEP template (TF-SSEP). The SSEPs induced from patients with the impaired motor functions exhibit longer latency and lower amplitude than the normal SSEPs and are inevitably contaminated by artifacts and environmental noise. Although ICA has been demonstrated as a novel technique to segregate the EEG into independent sources, the selection of task-related components needs to be further elaborated. The TF-SSEP template, generated by the Morelet wavelet transformation of the averaged SSEPs from three normal subjects, was used to automatically extract the SSEP-related features. The performance of the TF-SSEP template was further validated using EEGs through the left and right peroneal nerve stimulation of four stroke patients. After ICA decomposition, the sources were selected for reconstruction if their correlation coefficients with the TF-SSEP template were higher than the predetermined threshold. On the other hand, the unselected sources were considered as the event-unrelated components or artifacts. Among all patients, the topography maps at four peak times, namely P40, N45, P60 and N75, showed higher contrast in the vicinity of the foot-associated motor area, and the resolved SSEPs demonstrated uncontaminated waveforms in comparison with the conventionally averaging method. This indicated that the proposed method can remarkably suppress artifacts and effectively extracted the SSEP-related features.**

I. Introduction

Evoked potentials are the electrical activities generated by the nervous system in response to external sensory stimuli. Cortical somatosensory evoked potential (SSEP), recorded by electroencephalography (EEG) system, has been applied to assess the functional integrity of the nervous system or to assist in the diagnosis of certain neuropathologic states [1]. Specifically, the morphological characteristics, i.e. latency and amplitude, of SSEP following stimulation of the lower limbs have been used to evaluate the rehabilitation treatment of stroke patients. In comparison with the EEG background rhythm, the evoked potential is much smaller, especially in stroke patients with impaired motor function [2]. The conventional method employs the average of hundreds of trials to increase the signal-to-noise ratio which, however, can only reduce the disturbances of random noise and un-phase-lock brain oscillations. Accordingly, the development of advanced techniques to extract such minute signals is of potentially importance.

EEG recordings are overlapping activities contributed from individual neurons inside the brain as well as the artifacts produced outside the brain [3]. Independent component analysis (ICA) [4-5] is one of the most effective blind-source-separations to separate independent sources from mixing signals, which in turn enables us to resolve features of interest from EEG. ICA has been successfully applied to remove non-physiological artifacts from EEG data [4,5], to segregate Rolandic beta rhythm from magnetoencephalographic (MEG) measurements of right index finger lifting [6], to extract task-related features from motor imagery EEG and flash visual evoked EEG in the study of the brain-computer interface [7,8], to discriminate the concurrent abnormal patterns from EEGs of Creutzfeldt-Jacob disease [9], and to segment spatiotemporal hemodynamics from perfusion magnetic resonance brain images [10].

After ICA decomposition, the signal-to-noise ratio is enhanced by selecting the task-related components for reconstruction, i.e. eliminating the artifact-related or task- unrelated components of the signals. Accordingly, the key step of such ICA-based approaches is the identification of the independent components (ICs) of interest. In this study, we propose a time-frequency-based approach to automatically select the SSEP-related components. We first created a time-frequency (TF) map of the SSEP induced by peroneal nerve stimulation using the Morlet wavelet transformation [11]. The resultant TF-SSEP map was employed as a template to match the TF maps calculated from the EEG independent components of stroke patients. The reconstructed

SSEP waveforms obtained from the selected components demonstrated that ICA in conjunction with TF-SSEP template was a robust method to effectively remove the contamination of artifacts.

II. Material and Method

A. EEG recordings

Seven participants (all males), 3 normal subjects and 4 patients with chronic stroke, were recruited for this study. The normal EEG data sets were employed to establish the standard template which consisted of the time-frequency features, i.e. TF-SSEP. The conventional averaging technique and the waveform reconstruction using the separated ICs selected by the TF-SSEP template were applied on the EEGs for performance assessment.

Surface stimulations of the right and left peroneal nerves were performed on the dorsum of the ankle using constant current square wave pulses of 1 ms duration with a stimulation rate of 3 Hz. The stimulus current was set to produce the minimal twitch of the extensor digitorum brevis muscle. Each nerve was stimulated with one session consisting of 1000 stimuli. The EEGs through the peroneal nerve stimulations were acquired using a 32-channel SymAmp EEG system (digitized at 1000 Hz) with Ag/AgCl surface electrodes, placed based on the configuration of the extended international 10-20 system (Fig. 1(A)). The referential montage was applied in the whole head recordings (bandpass filtered between 1 to 450 Hz), and the SSEPs were furthermore calculated from the bipolar derivation, Cpz-Fz.

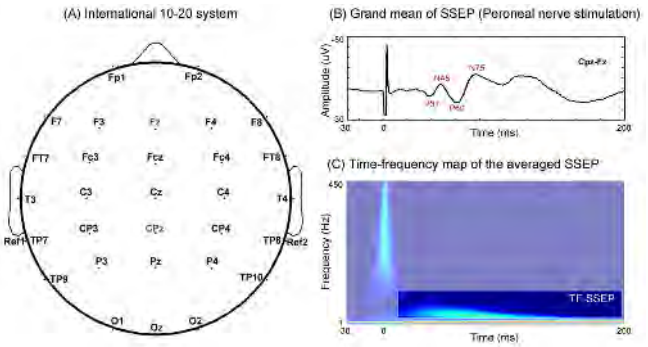

Fig. 1 . (A) The whole scalp of each subject was covered with 32 EEG electrodes placed onto anatomical locations according to the extended international 10-20 system, where Fp, F, C, P, O, and T represent the abbreviations of frontal polar, frontal, central, parietal, occipital, and temporal, respectively. (B) The grand mean of SSEP (gmSSEP) computed from the EEGs through peroneal nerve stimulation, in which P37, N45, P60 and N75 are the four main peak times of interests. (C) The TF map of SSEP produced by the transformation using Morlet wavelet. The darker blue area indicates the feature of interest.

B. Blind source separation by FastICA

ICA is a statistical method that has been developed to extract independent signals from a linear mixture of sources. Let $\underset{m\times n}{X}$ denote the measured data with m and n being the number of channels and the number of data samples, respectively. In the context of ICA, **X** is assumed to be linear combinations of k unknown independent components and can be expressed as

$$\underset{m\times n}{\mathbf{X}} = \underset{m\times k}{\mathbf{A}} \cdot \underset{k\times n}{\mathbf{S}} \tag{1}$$

where **S** contains k independent sources with the same data length as **X**, and **A** is a constant mixing matrix with the k_{th} column representing the spatial weights corresponding to the k_{th} component of **S**. Given the measurement **X**, ICA techniques attempt to recover both the mixing matrix **A** and the independent sources **S**. In the present study, all calculations were performed using the FastICA algorithm [12,13]. The FastICA technique first removes means of the row vectors in the **X** matrix and then uses a whitening procedure, implemented by principal component analysis [13], to transform the covariance matrix of the zero-mean data into an identity matrix. In the next step, FastICA searches for a rotation matrix to further transform the whitened data into a set of components which are as mutually independent as possible. In combination with the previous whitening process, the matrix **X** is transformed into a matrix S via an un-mixing matrix W, i.e.,

$$\underset{k\times n}{\mathbf{S}} = \underset{k\times m}{\mathbf{W}}\ \underset{m\times n}{\mathbf{X}} \tag{2}$$

so that rows of **S** are mutually independent. In this study, the pre-processed epochs were concatenated and arranged across m channels (m=30) and n sampled points (n=231*1000) into a $m\times n$ matrix **X**. The i_{th} row contains the observed signal from the i_{th} EEG channel, and the j_{th} column vector contains the observed samples at the j_{th} time point across all channels. FastICA was applied on the pre-processed and concatenated signals to resolve **W** and **S**. After estimating the un-mixing matrix **W**, we can recover the temporal waveforms of each independent source by applying the inverse matrix of **W** on both sides of equation (2) to yield

$$\underset{m\times n}{\mathbf{X}} = \underset{m\times k}{\mathbf{W}^{-1}} \cdot \underset{k\times n}{\mathbf{S}} \tag{3}$$

where $\mathbf{W}^{-1}$ is the best estimation of the mixing matrix **A** in equation (1). In this study, **S** represents the time sequences of activation sources, i.e. temporal waveforms of ICs, and **A** stands for the weighting of sources recorded

from electrodes. Since **W** is the estimated un-mixing matrix, each column in $\mathbf{W}^{-1}$ represents a spatial map describing the weightings of the corresponding temporal component at each EEG channel. These spatial maps will hereinafter be referred to as IC spatial maps. To determine the number of sources, we simply used the number of channels as the number of sources, as suggested by previous studies [4-10].

C. Criterion for discrimination of ICs

To discriminate the SSEP-related from artifact-related ICs, the TF-SSEP was generated to select ICs. We computed the grand mean of SSEP (Fig. 1 (B)) by averaging the normal SSEPs across all trials and three subjects, which was then transformed into the TF map by using the Morlet wavelet. The window consisted of temporal features within 20 ms to 200 ms after stimulus and frequency information from 10 to 50 Hz (see dark blue area in Fig. 1(C)) was used as the TF-SSEP template

In the present study, the selection criterion for ICs was validated using normal EEGs prior to the processing of EEGs from stroke patients. After ICA decomposition, the correlation coefficients between the templates and ICs were computed. In order to select the SSEP-related ICs, a cutoff value was required. The lower the cutoff value, the more ICs were selected. Since the values of correlation ranged from -1 to 1, we examined cutoff values between -0.5 and 1. The cutoff value, or threshold, for IC selections using the TF-SSEP was determined to be 0.65 so that the correlation coefficients between the reconstructed SSEP (rSSEPs) and the averaged SSEP was as high as 0.9.

III. Results

Figure 2 shows the artifact-suppressed results from the EEGs induced by the right PNS ((A)-(D)) and left PNS ((E)-(H)) of the stroke patients (PT1-4). The averaged SSEPs without using ICA and the rSSEPs using TF-SSEP templates are denoted by green and red waveforms, respectively. It should be noted that the ripple artifacts, which constantly appeared in each trial, cannot be suppressed by the conventional averaging technique (see green spikes and ripples in (B)(C)(D) and (F)(G)(H)). However, as in the normal cases (IC2 in Fig. 4(A)), such contaminations have been successfully separated from the ICA, which in turn can be substantially reduced in the reconstructed results (red curves). The corresponding topographies calculated at the four peak times, labeled 1 (P37), 2 (N45), 3 (P60), and 4 (N80), are displayed in the second and third rows in the upper and lower panels.

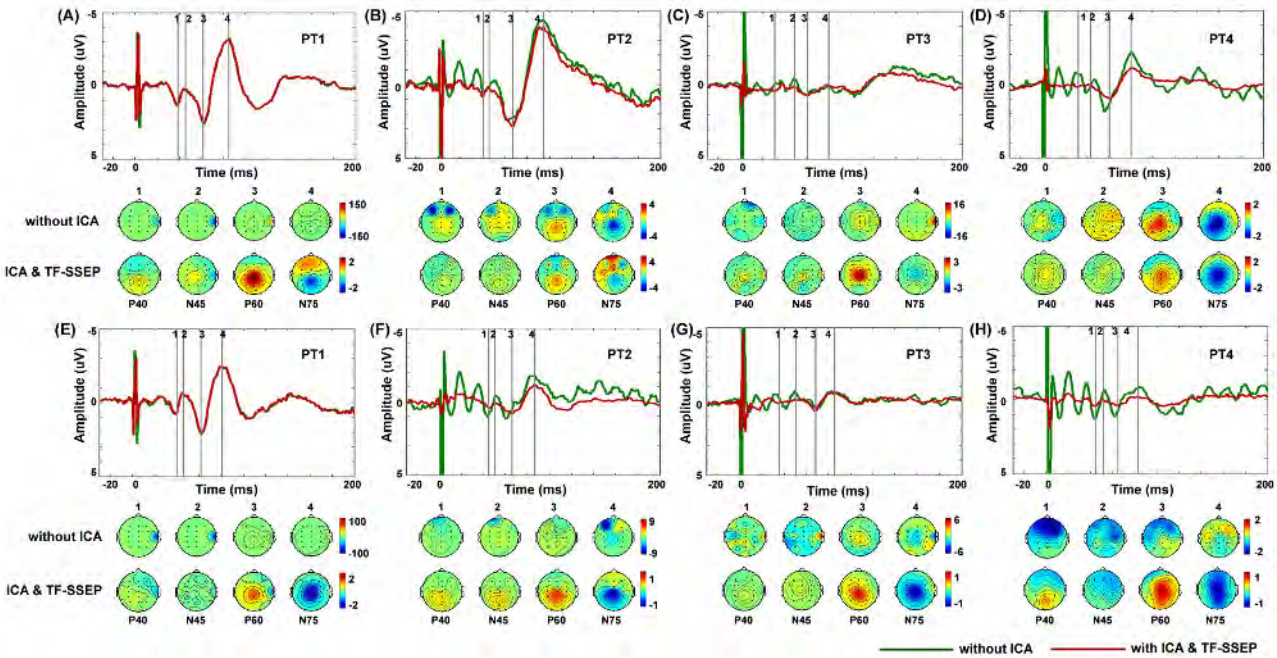

Fig. 2 . The results from the EEGs induced by the right PNS ((A)-(D)) and left PNS ((E)-(H)) of the stroke patients (PT1-4). The green and red curves represent the SSEPs obtained from conventional averaging, and the reconstructed SSEPs using the TF-SSEP templates, respectively. The corresponding topographical maps at P37, N45, P60, and N80 are displayed below the plots of reconstructed SSEPs.

IV. Conclusions

It is worth noting that the signal-to-noise ratio of SSEPs of stroke patients could be much worse than that of the normal, which made the averaging method have difficulty to extract reliable SSEPs from the smearing background (green curves in Figs. 5(B)(C)(D) and (F)(G)(H)). Accordingly, the EEG has seldom been used to investigate reorganization of motor system after stroke in human, although motor recovery assessed by the functional neuroimaging has become an intriguing field over the last decade [14]. Our results demonstrated that the SSEPs embedded in the EEGs of stroke patients can be successfully resolved by ICA with the TF-SSEP template, which sheds the light for the future study of reorganization of motor system for stroke patients.

Abstract — **Multiple system atrophy (MSA) is a well-known neurodegenerative disorders that present parkinsonism syndrome and autonomic dysfunction. Patients with MSA who have the combination of parkinsonism and cerebellar ataxia are referred to as MSA-C. Brain diffusion-weighted imaging (DWI) offers the potential for objective criteria in the diagnosis of MSA. We aim to develop an automatic method to segment out the abnormal whole brain area in MSA-C patients based on the 13-direction DWI raw data. The whole brain DWI raw data of fifteen normal subjects and nine MSA-C patients were analyzed. In this study, we proposed a novel method to perform tissue segmentation directly based on the directional information of the DWI images, rather than using the parametric images, such as fractional anisotropy (FA) and apparent diffusion coefficient (ADC) as in the previous literatures. Specifically, a hierarchical clustering (HC) technique was first applied on the down-sampled data to initialize the model parameters for each tissue cluster followed by automatic segmentation using the expectation maximization (EM) algorithm. Our results demonstrate that the HC-EM is effective in multi-tissue classification, namely, the cerebrospinal fluid, gray matter, and several areas of white matters, on the DWI raw data. The segmented patterns and the corresponding intensities of thirteen directions of the cerebellum in MSA-C patients showed the decrease of the anisotropy, which were evidently different from the results in normal subjects.**

Keywords — **Multiple system atrophy, diffusion- weighted imaging, hierarchical clustering, expectation maximization algorithm**

I. Introduction

Brain tissue segmentation plays an important role in both structural and functional studies. However, most of the methods in segmentation issues were based on the difference of image intensity in MR structural data, and can be limited due to the field in-homogeneity, partial-volume effect, etc. Diffusion weighted images (DWI), on the other hand, can provide complementary information of tissue contrast to the structural MRI for facilitating the tissue segmentation. In a previous study, Liu et al. have demonstrated that tissue segmentation results based on the parametric images was superior to that in structural MR images [1], but the features of directions of neural fibers have been lost in the parametric images and thus only limited information was utilized.

In this study, we propose a novel method to segment the brain tissue directly on the 13-direction DWI raw data in MSA-C patients so that the direction information can be fully taken into account. To initialize the segmentation for each tissue cluster, the hierarchical clustering (HC) based on a minimum variance algorithm (the Ward's method) [2] was first applied on the down-sampled data. By the assumptions that each tissue type is a multivariate Gaussian function and the overall distribution of the raw data is a mixture of multivariate Gaussians (MoMG) [3], we initialized the parameters of the MoMG and the proportion of each class using the segmented results from HC. Finally, the tissue classifications on the higher dimensional data were given by the expectation maximization (EM) algorithm. Data from fifteen normal subjects and nine MSA-C patients were analyzed. The results illustrated that HC-EM is effective in multi-tissue classification. The segmented patterns and the corresponding intensities of thirteen directions of the cerebellum in MSA-C patients were evidently different from the results in normal subjects.

II. Material and method

A. Subjects and Data Recording

Fifteen normal subjects (9 male and 6 female; range of age, 23-89 years) and nine MSA-C patients (5 male and 4

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 722–725, 2009
www.springerlink.com

female; range of age, 32-67 years; disease duration, 1-8 years) participated in this study. Written informed consent was obtained from each volunteer before this study. For the DWI settings, A multi-slice gradient-echo EPI pulse sequence on a 1.5 Tesla GE Echo speed scanner system (Signa® CV/i, GE Medical Systems, Milwaukee, WI, USA) was used with the following settings. Sequence: maximum gradient amplitudes: 40 mT/M; square FOV: 240×240 mm; matrix = 128×128; 3 mm slice thickness; no interslice distance; TE: 69.70 ms; TR: 15000 ms; b value: 1000 s/mm^2. DWI images along thirteen non-collinear directions were collected. Whole brain data for about 50 slices, one acquisition, and fourteen images per slice location (one T2 structural image and thirteen directional DWI images).

B. Data Pre-processing

The brain regions were extracted from the diffusion-weighted images slice by slice. We first set all pixel values lower than 15% of the maximum intensity to zero and followed by the erosion (3×3 structure element) and dilation (5×5 structure element) operation. With total $v = \sum_i v_i$ pixels (without air background), v_i stands for the pixels of brain areas on *ith* slice, the observation of 13 directional images can be represented by a $13 \times v$ matrix, i.e., each row is whole brain area and each column contains signal intensities of a pixel across 13 different directions.

In this study, we assume that there are *N* major tissue types presented on DWI images and the overall distribution of the raw data is a MoMG. The raw DWI data with dimension $13 \times v$ was first reduced its dimension to $N \times v$ by whitening process, which is mathematically similar to principal component analysis (PCA). By the limitation of memory capacity, we use the down-sampled data, $N \times v'$ with $v' \le v$, in the following HC step, after such approximate segment by HC, the second step, EM algorithm, would optimize the parameters on the original raw data to carry out the tissue segmentation.

C. Hierarchical Clustering

HC is a means to carry out grouping in a data set based on a created cluster tree with multilevel hierarchy, where clusters at one level are joined as clusters at the next higher level. HC consists of three major parts: (1) find the dissimilarity between every pair of feature vectors in the data set; (2) group the feature vectors into a binary and hierarchical cluster tree; (3) determine what level or scale of clustering by cutting the hierarchical tree. Many algorithms are available in regard to the calculation of dissimilarity and the creation of cluster tree [4]. In this study, we adopted the Euclidean distance to calculate the dissimilarity, which was defined by

$$d_{rs}^2 = (x_r - x_s)^T (x_r - x_s). \tag{1}$$

where d_{rs}^2 is the Euclidean distance between two featured column vectors x_r and x_s. In order to construct the cluster tree, we employed the Ward's method to measure the distance between two clusters which was defined by

$$d^2(p,q) = n_p n_q \frac{\left\| \bar{x}_p - \bar{x}_q \right\|_2^2}{(n_p + n_q)} \tag{2}$$

where $d^2(p,q)$ is the distance between two clusters of featured vectors, n_p and n_q are the numbers of featured vectors in cluster *p* and *q*, respectively, $\| \ \|_2$ is the Euclidean distance, $\bar{x}_p$ and $\bar{x}_q$ and are the centroids of clusters *p* and *q*, respectively, which are defined by

$$\bar{x}_p = \frac{1}{n_p} \sum_{i=1}^{n} x_{pi} \ \text{ and } \ \bar{x}_q = \frac{1}{n_q} \sum_{j=1}^{m} x_{qj} \tag{3}$$

where x_{pi} is the *i*th featured vector in cluster *p* and x_{qj} is the *j*th objects in cluster *q*.

D. Expectation Maximization Algorithm

Let each point in the whiten data be denoted by $x_n (N \times 1)$, $n = 1, \ldots v$. The tissue segmentation was carried out by EM algorithm which fit the overall distribution of the whiten data to a mixture of multivariate Gaussian distributions consisting of two alternating iterative steps, namely, E-step and M-step. The E-step is to compute the posterior probabilities of tissue classes $p(i | x_n, \theta^{j-1})$ based on the estimation from previous *(j-1)th* iteration

$$p(i | x_n, \theta^{j-1}) = \frac{\pi_i^{j-1} g_{x_n}[\mu_i^{j-1}, \Sigma_i^{j-1}]}{\sum_{l=1}^{N} \pi_l^{j-1} g_{x_n}[\mu_l^{j-1}, \Sigma_l^{j-1}]} \tag{4}$$

where *i=1, ... N* represent labels of tissue classes, $g_{x_n}[\mu_i, \Sigma_i]$ represents the multivariate Gaussian density with the mean vector μ_i and covariance matrix Σ_i of tissue class *i,* π_i denotes the proportion of each class *i,* and θ^{j-1} denotes the parameters $\{ \mu_i^{j-1}, \Sigma_i^{j-1}, \pi_i^{j-1} \}$ at the *(j-1)th*

iteration. The M-step consists of estimating parameters θ^j as follows

$$\mu_i^j = \frac{\sum_{n=1}^{v} p(i \mid x_n, \theta^{j-1}) x_n}{\sum_{n=1}^{v} p(i \mid x_n, \theta^{j-1})},$$
$$\Sigma_i^j = \frac{\sum_{n=1}^{v} p(i \mid x_n, \theta^{j-1}) x_n x_n^T}{\sum_{n=1}^{v} p(i \mid x_n, \theta^{j-1})} - \mu_i^j (\mu_i^j)^T, \quad (5)$$
$$\pi_i^j = \frac{1}{v} \sum_{n=1}^{v} p(i \mid x_n, \theta^{j-1})$$

The number of classes N is determined by information criterion of minimum description length (MDL) [3]. The tissue label at each pixel was determined by the maximal value of $p(i \mid x_n, \theta^{j-1})$ at that pixel and therefore each tissue type was classified.

III. Results

A. Normal Subjects

Each DWI raw data set covers whole brain areas (including cerebellum and cerebrum) and Figure 1 displays the fourteen images on a particular slice position for a normal subject.

The final segmentation result based on HC-EM algorithm was depicted by a color-coded composite image (right-lower image in Figure 2). Compared with the segmentation result on structural MR T2 image obtained from Otsu approach (left-lower image in Figure 2), a well-known automatic thresholding method [5], the gray matter (GM, colored in green) classified was obviously over-segmented on the posterior region (white arrows in Figure 2), whereas the GM and cerebrospinal fluid (CSF, colored in brown) were satisfactorily segmented out by our method. These segmentation results show that the intensity-based classification approach, such as Otsu thresholding, would highly depend on the intensity homogeneity of image data and our method could alleviate this disadvantage by taking the directional information into account from 13 directional DWI images. Moreover, the HC-EM algorithm could further divided the anisotropic-white-matter area (colored in red, blue, pink and yellow), into four different clusters according to their different directional primitives. The color map of 1st eigenvectors was calculated to validate our result [6].

Figure 3 shows the corresponding mean signal-direction curves of whole brain areas. The mean signal-direction curves illustrate the variant directional properties of each cluster. For example, the curves of GM (green) and CSF (brown) are less fluctuated than that of other tissues, suggesting the diffusion of these two clusters is less dependent on direction, i.e., isotropic diffusion. Moreover, the mean directional signal intensity between GM and CSF are quite different and therefore classified into different clusters by the EM algorithm.

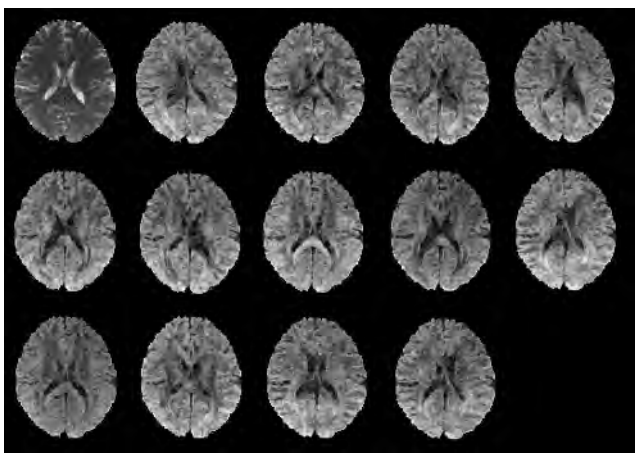

Fig. 1. The 14 images on a slice location consisted of T2 weighted image (upper leftmost one) and 13 directional DWI images.

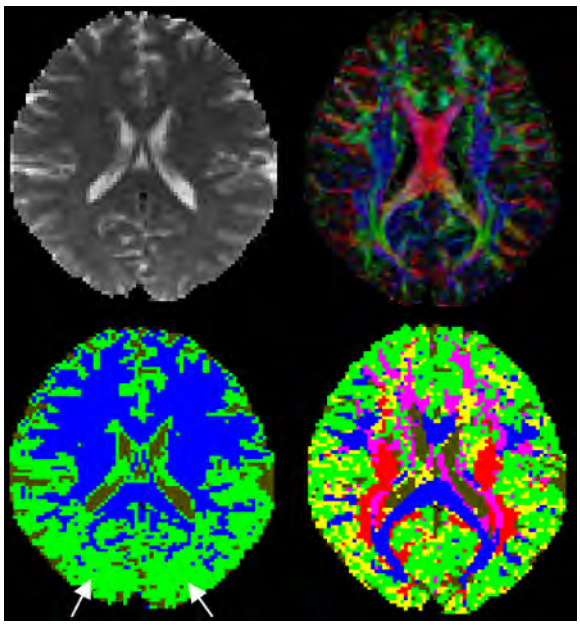

Fig. 2. The structural MR T2 image (upper left), the color map of 1st eigenvectors (upper right), the segmentation result by Otsu thresholding on T2 image (lower left) and the final segmentation result for each tissue type represented by a color-coded composite map by HC-EM algorithm on DWI raw data (lower right). Gray matter is labeled by green, cerebrospinal fluid by orange and white matter is depicted by red, blue, pink and yellow. The white arrows point out the over-segmented area of GM by Otsu method on structural T2 image.

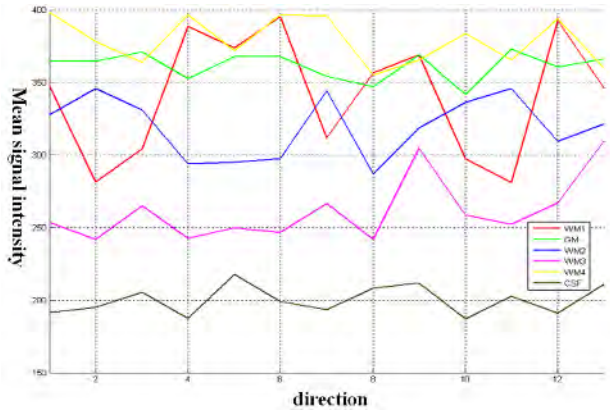

Fig. 3. The mean signal–direction curves of whole brain areas resulted from the HC-EM algorithm.

B. MSA-C patients

In order to show the abnormality in the MSA-C patients, we focused on the slices of the cerebellum areas. Figure 4 illustrates the results of tissue classification using the HC-EM method from a normal subject (left column) and a MSA-C patient (right column). The T2 images on the upper row in Figure 4 exhibited the evident atrophy of cerebellum with large area of high-intensity CSF in the MSA-C patient. In the clustering results on the lowest row, the parenchyma of normal cerebellum were segmented into three major different areas (blue, red and yellow) with averaged intensity ranging from 400 to 500 (Figure 5, left). In contrast, the clustering result in the MSA-C patient only showed one area (blue) in the parenchyma of cerebellum and three different low-intensity CSF areas (Figure 5, right).

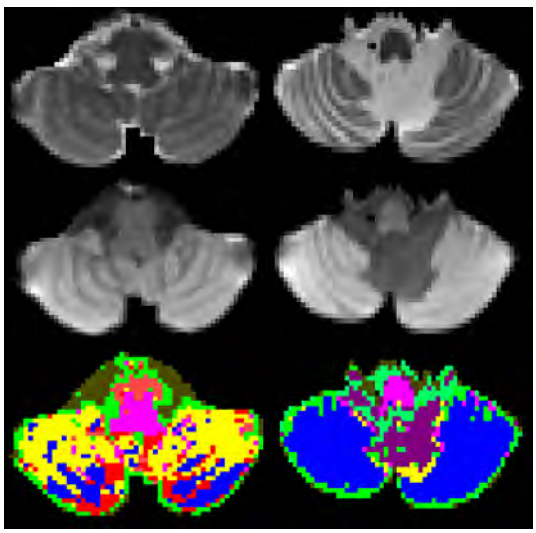

Fig. 4. The left column shows a particular slice of the cerebellum images from a normal subject, and the right column from a MSA-C patient. The upper row presents the T2 images; the middle row presents the averaged images of T2 and 13 directional DWIs; the lower row shows the clustering results using the HC-EM method.

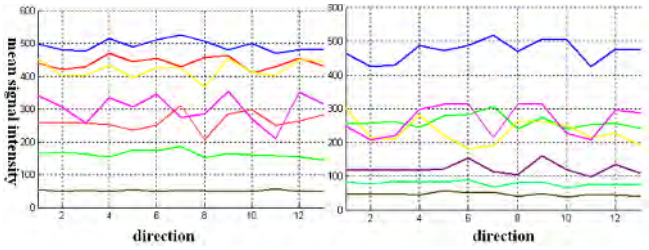

Fig. 5. The signal–direction curves corresponding to the results in Fig. 4 in the normal subject (left) and MSA-C patient (right).

Our results demonstrated that the complexity of the anisotropy in the cerebellum of the MSA-C patient was decreased compared with that of the normal subject. Figure 5 shows the signal-direction curves corresponding to Figure 4 of segmented clusters for the normal subject (left) and MSA-C patient (right).

IV. Conclusions

This study presents a novel HC-EM method for the extraction of different directional dependence tissues from brain diffusion-weighted images. This method features several advantages for using directional information and could be an effective tool for diagnosis of MSA-C.

Abstract — **Small-world network is a highly clustered system but with small mean path length between networks which allow the information transferred with high efficiency. The human brain can be considered as a sparse, complex network modeled by the small-world properties. Once the brain network was disrupted by disease, the small-world properties would be altered to manifest that the information integration was inefficiency and the network was loosely organized. The aim of this study is to investigate the difference of small-world properties of brain functional network derived from resting-state functional magnetic resonance imaging (fMRI) between the healthy subjects and the patients with Bipolar disorder (BD). The functional MRI data was acquired from 5 healthy subjects and 5 patients with Bipolar disorder. All images of each subject were parcellated into 90 cortical and sub-cortical regions which were defined as the nodes of the network. The functional relations between the 90 regions were estimated by the frequency-based mutual information followed by thresholding to construct a set of undirected graphs. Small-world properties, such as the degree and strength of the connectivity, clustering coefficient of connections, mean path length among brain regions, global efficiency and local efficiency, are examined between any pair of functional areas. Our findings indicated that, in comparison with the control subjects, the BD patients presented smaller values of the degree, the strength of the connectivity and the clustering coefficient of connections, whereas larger values of mean path length among brain regions. This suggested the reduced global and local efficiency of the small-world properties for BD patients. In addition, the small-world properties of BD patients were altered significantly in some regions in the frontal lobes and limbic system which were in good agreement with the dysfunction connectivity reported by the previous literatures in the study of bipolar disorder.**

Keywords — **Small-world network, functional connectivity, Bipolar disorder, frequency-based mutual information.**

I. Introduction

A remarkable network between a random network and a regular network is called 'small-word', which is characterized by high cliquishness and short mean path length [1]. The human brain can be considered as a sparse, complex network modeled by the small-world properties, which support rapid integration of information across segregated sensory brain regions, confer resilience against pathological attack, and allow the information transferred between different brain regions with high efficiency. Once the brain network was disrupted by disease, the small-world properties would be altered to manifest that the information integration was inefficiency and the network was loosely organized.

Bipolar disorder (BD) is a category of mood disorders defined by the presence of one or more episodes of abnormally elevated mood. Findings from structural magnetic resonance imaging (MRI) studies suggest that some abnormalities, such as prefrontal sub-region decreased volumes; amygdala and stiatal enlargement and midline cerebellum atrophy. From functional imaging technologies, such as positron emission tomography (PET), single photon emission computed tomography (SPECT) and functional magnetic resonance imaging (fMRI), which are obtained at rest or during cognitive tasks to study specific neural networks, including anterior limbic regions that may underlie bipolar disorder [2,3,4].

These data suggest that activation of 'limbic' prefrontal areas may disrupt of 'cognitive' prefrontal regions. Functional imaging studies support the notion that abnormalities in anterior limbic networks, in which structural and spectroscopic abnormalities have also been reported, appear to underlie the expression of bipolar disorder. The aim of this study is to investigate the difference of small-world properties of brain functional network derived from resting-state

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 726–729, 2009
www.springerlink.com

functional magnetic resonance imaging between the healthy subjects and the patients with Bipolar disorder.

II. Materials and Methods

A. Data acquisition and preprocessing

The study included 5 patients with bipolar disorder who were recruited from Taipei Veterans General Hospital. Confirmation of the diagnosis for all patients was made by clinical psychiatrists, using the Diagnostic and Statistical Manual of Mental Disorders (DSM). All the five healthy subjects had no history of psychiatric illness. All subjects gave voluntary and informed consent according to the standards set by Taipei Veterans General Hospital.

Imaging was performed on a 1.5 Tesla GE scanner in Taipei Veterans General Hospital. Blood oxygenation level dependent (BOLD) images of the whole brain using an echo planar imaging (EPI) sequence were acquired in 20 axial slices (TR=2000ms, TE=40ms, flip angle=90°, FOV=24cm; 5mm thickness and 1 mm gap). For each subject, the fMRI scanning lasted about 400 seconds. Structural images were obtained using a rapid acquisition gradient echo 3D T1-weighted sequence for each subject (TR=2045ms, TE=9.6ms, flip angle=90°, FOV=24cm). All the preprocessing was carried out using statistical parametric mapping (SPM5). The 200 volumes were first corrected for the acquisition time delay among different slices, and then the all images were realigned to the first volume for head-motion correction. Then, correct differences in image acquisition time between slices. The third step is co-registration: all fMRI images register to the anatomy T1 weighting imaging. The fMRI images were further spatially normalized to the T1 template image.

B. Anatomy parcellation

The registered fMRI data were segmented into 90 regions (45 for each hemisphere, Table1) using the Individual Brain Atlases using Statistical Parametric Mapping Software (IBASPM). For each subject, the representative time series of each individual region was then obtained by simply averaging the fMRI time series over all voxels in this region.

C. Frequency-based mutual information

We applied frequency-based mutual information to each regional time series and estimated the pair-wise inter-regional relations in the specific frequency band (0.01~0.08Hz). We consider the observations of the time series of p points in the brain as finite realizations of a multivariate stationary stochastic process:

$$X(t)=\{X_1(t),X_2(t),...,X_p(t)\},t\in Z \quad (1)$$

We apply the discrete Fourier transform (DFT) to a finite realization of Eq. (1), we have a new set of values

$$Y(\omega_k)=\{Y_1(\omega_k),Y_2(\omega_k),...,Y_p(\omega_k)\} \quad (2)$$

at each $\omega_k(k:1,...,n)$ Fourier frequency. The mutual information between any pair of subsets a, b of Y at frequency ω_k is [5,6]

$$MI_{a,b}(\omega_k)=-1/2\log\left(\left|f_{X_a,X_b}(\omega_k)\right|/\left|f_{X_a}(\omega_k)\right|\left|f_{X_b}(\omega_k)\right|\right) \quad (3)$$

where , $f_{X_a}(\omega_k)$ $f_{X_b}(\omega_k)$and $f_{X_a,X_b}(\omega_k)$are the Hermitian positive definite, (cross-)spectral density matrices of the original processes Xa(t), Xb(t) and {Xa(t), Xb(t)} Symbol $|\ |$ denotes the determinant.

D. Small-world properties

Small-world properties have been described for graphs defined by nodes (brain regions) and undirected edges (functional connectivity). A 90× 90 binary graph can be constructed by applying a threshold T to the frequency-based mutual information. The maximum threshold must assure that each network is fully connected with N= 90 nodes. The minimum threshold must ensure that the brain networks have a lower global efficiency and a larger local efficiency compared to random networks with relatively the same distribution of the degrees of connectivity. The key metrics are the degree and strength of the connectivity, clustering coefficient of connections ,mean path length among brain regions, global efficiency and local efficiency, all defined for each of the i=1,2,3,. . . ,n nodes in the network (Table 1) [7].

Table 1 Small-world indices

Index	Meaning	Formula
K_p	Degree of connectivity	$K_P=\frac{1}{N}\sum_{i\in G}K_i$
E_{corr}	Strength of connectivity	$E_{corr}=\frac{1}{N}\sum_{i\in G}\left(\frac{1}{K_i}\sum_{j\in G_i}\lvert MI(i,j)\rvert\right)$
C_p	Clustering coefficient	$C_P=\frac{1}{N}\sum_{i\in G}\frac{E_i}{K_i(K_i-1)/2}$
L_p	Mean path length	$L_P=\frac{1}{N}\sum_{i\in G}\frac{1}{N-1}\sum_{i\neq j\in G}\min\{L_{i,j}\}$
E_{global}	Global efficiency	$E_{global}=\frac{1}{N(N-1)}\sum_{i\neq j\in G}\frac{1}{L_{i,j}}$
E_{local}	Local efficiency	$E_{local}=\frac{1}{N}\sum_{i\in G}\left(\frac{1}{N_{G_i}(N_{G_i}-1)}\sum_{j,k\in G_i}\frac{1}{L_{j,k}}\right)$

III. Results

The two 90×90 mean functional connectivity matrices shown in Fig.1 were calculated by averaging the frequency-based mutual information matrices of all subjects within the group. The distributions of all the small world properties as a function of threshold from 0.34 to 0.56 within each group are shown in Fig.2. The degree (Kp) evaluates the level of sparseness of a network in Fig.2(A). The strength of the functional connectivity (E_{corr}) of the brain network is shown in Fig.2(B). The cluster coefficient (C_p) measures the extent of a local cluster of the network is shown in Fig2.(C). The mean path length (L_p) measures of the extent of average connectivity of the network is shown in Fig.2(D). The global efficiency (E_{global}) is a measure of the global efficiency of parallel information transfer in the network in Fig.2 (E). The local efficiency (E_{local}) is a measure of the fault tolerance of the network in Fig.2(F). The region analysis for the degree, strength of connectivity, cluster coefficient and mean path length are shown in Fig.3, in which the blue bars and red bars represent healthy subjects and BD patients respectively.

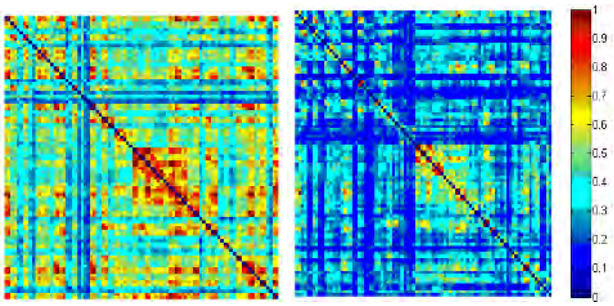

Fig. 1. The mean functional connectivity matrices. Each figure shows 90×90 square matrix, where x and y axes represent the 90 brain regions, and each pixel value indicates the strength of connectivity between each pair of brain regions. The diagonal from upper left to lower right is self-relation, and is set zero. The functional connectivity was stronger in healthy subjects (left) compared with BD patients (right).

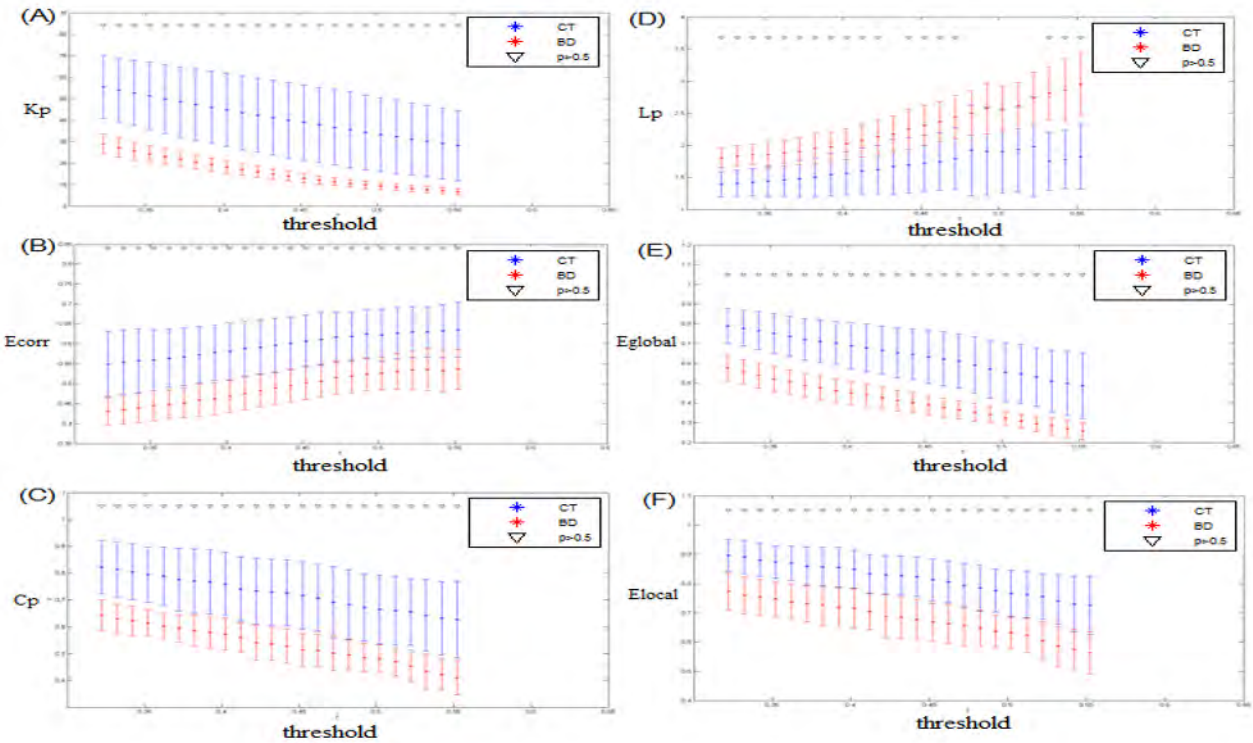

Fig.2. The distributions of all small-world properties. (A) The degree of connectivity (K_p). (B) The strength of connectivity (E_{corr}). (C) The cluster coefficient (C_p). (D) The mean path length (L_p). (E) The global efficiency (E_{global}) (F) The local efficiency (E_{local}). The blue star and red star represent healthy group and BD group, respectively. The black triangle represents the significantly difference between healthy subjects and BD patients.

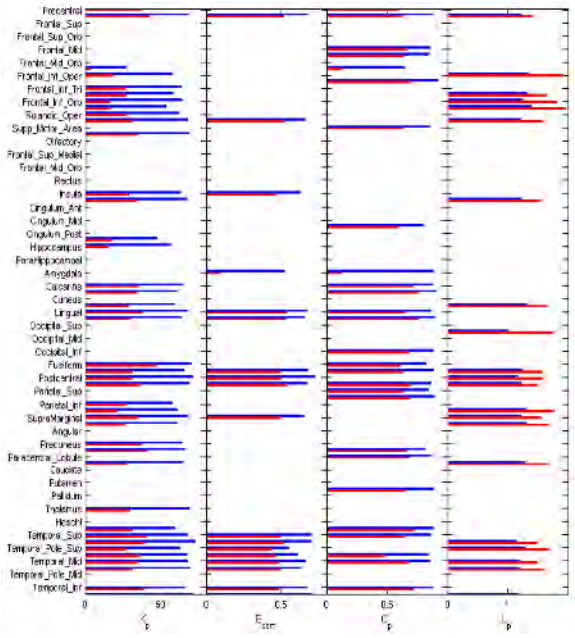

Fig.3 Regional small world properties. The vertical axis is 45 brain regions (both right and left hemispheres), and the horizontal axes are the degree (K_p)., the strength (E_{corr}), the cluster coefficients (C_p) and mean path length (L_p) from left to right in order. Bars indicate the brain region is significantly altered in the relative measurement, and the length of the bar indicates the mean value of the relative measurement between two groups. The blue bars and red bars represent the healthy group and BD group respectively.

IV. Discussion

With an increase in the threshold, the degree (Fig.2(A)) decreases; whereas the strength of the connectivity (Fig.2(B)) increases because increasing the threshold corresponds to eliminate the weaker connections that are more likely to be noisy. Over the whole range of thresholds the degree and strength of connectivity are significantly lower in the BD group. This means the lower connectivity between brain regions in BD patients.

As shown in Fig.2(C) and (D), the higher threshold, the lower cluster coefficient but longer mean path length. The relative lower cliquishness and longer mean path length were presented in BD patients. These results show that the network in BD patients is disrupted.

For all thresholds, both global and local efficiency in Fig.2(E,F) are significantly higher in healthy subjects than BD patients. These results reveal that the information transferred between different brain regions with low efficiency when the brain network was attacked by disease.

We used a two-sample two-tailed t-test to evaluate statistical differences in the four small-world properties between two groups in 90 brain regions at each selected threshold shown in Fig.3. The small-world properties are significantly altered in many brain regions in the frontal, parietal temporal lobes and in limbic system. The similar results in regional analysis show that the brain network in BD patients is sparse and weak connective so that the degree and strength of connectivity are lower. From the lower cliquishness and larger mean path length in BD group indicate the network is loosely organized. Summarize above evidences, the brain network is inefficient in BD patients compared with healthy subjects. Since all thresholds were similar in their trends with respect to the differences in their small-world properties between the BD patients and the healthy subjects, we have chosen to report only one typical threshold (T = 0.34, the top of the threshold range).

V. Conclusion

Our results support the concept that the small-world properties would be altered to manifest that the information integration was inefficiency and the network was loosely organized. These results were in good agreement with the dysfunction connectivity reported by the previous literatures in the study of bipolar disorder. This approach may also be able to be used in other psychiatric disorders such as major depression disease, which can also be taken as a disconnection syndrome and in which abnormal functional connectivity plays a role.

Abstract— **Multiple system atrophy-cerebellar (MSA-C) is a degenerative neurological disease of brain. In this study, we used three-dimensional (3D) fractal dimension (FD) method to investigate the structural complexity change of human cerebellum white matter (CBWM) and gray matter (CBGM) for MSA-C disease diagnosis. Twenty patients and twenty-three normal subjects as the control group participated in this study. The T-1 weighted magnetic resonance (MR) images were processed and 3D CBGM and 3D CBGM were analyzed by the FD method. Results demonstrated that the FD values of patients' CBWM and CBGM decreased significantly, and that their CBWM FD values decreased more significant than that of CBGM. Results also showed that the 3D FD method was superior to the conventional volumetric method in terms of better reliability, accuracy, and sensitivity.**

Keywords—**MSA-C, Fractal dimension**

I. Introduction

MSA is a form of sporadic spinocerebellar degeneration characterized by varying degrees of parkinsonism, cerebellar ataxia, and autonomic dysfunction. This disease can be categorized into two subtypes according to dominant clinical features: MSA-C (cerebellar) and MSA-P (parkinsonism). [1,2]. MSA-C is the most common subtype of MSA and also termed as Olivopontocerebellar atrophy (OPCA) [3,4]. In Taiwan, MSA-C is more common than MSA-P. Gait ataxia is the most typically early symptom of this disease and others clinical features consist of dysarthria, unintentional movement, parkinsonian and other extrapyramidal symptoms [5]. Many investigators have reported that the factors of MSA-C are the loss of neurons in the ventral portion of the pons, inferior olives and cerebellar cortex. The fundamental lesions are located in the arcuate, pontine, inferior olivary, pontobulbar nuclei and cerebellar cortex [6].

Magnetic resonance imaging (MRI) is a widely used tool for brain pathology and diagnosis to evaluate demyelinating lesions within the brain and spinal cord, such as MSA [7], motor function impairment [8], epilepsy [9] and tumor detection. The abnormal change of cerebral tissue structure including atrophy, lesions and degeneration could potentially be regarded as disease-diagnosis parameters. Accordingly, the quantification of complexity of the morphological change of cerebral tissue is significant for disease diagnosis.

The FD analysis method applied for cerebrum atrophy diagnosis has been increasing recently. It is an efficiently computational tool for describing the structural complexity and especially suitable for measuring complexity. A fractal is an irregular object in which part of the compartment resemble to the overall shape. Mathematically, FD can condense all the structural details into a single numeric value that summarizes the irregularity of the object, leading to a quantitative measure of morphological complexity [10]. Because the FD analysis is based on the logarithmic scale, small changes in the FD value correspond to large differences in the shape complexity. Smith et al. verified that a difference of 0.1 of FD value representing a doubling of complexity [11].They suggested that the FD analysis would be a useful tool for pathological study. Practically, the FD can serve as an index for quantifying structural complexity of the neural system during the stages of development, degeneration, reorganization, or evolution, because in these processes the FD may be dynamically changing. The conventional volumetric analysis has the defects of less sensitivity and accuracy and often difficult for quantifying the grade of atrophy in the brain and the cerebellum during disease duration. To alleviate this problem, many studies have adopted box-counting method to measure FD of brain structures because of its easy implementation and applicability for objects with or without self-similarity.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 730–733, 2009
www.springerlink.com

The aim of this study was to employ 3D FD analysis for investigating the atrophy aliment of GM and WM structures of MSA-C patients. The effectiveness of 3D FD analysis method as an index in quantifying the complexity alteration of CBWM and CBGM in MSA-C patients was assessed.

II. Material and Method

A. Material

Twenty patients (7 males and 13 females, age range 32-77 years), and 23 healthy subjects (10 males and 13 females, age range 32-57 years) were recruited to participate in this study in the Department of Radiology, Taipei Veterans General Hospital (Taiwan) from 2005 to 2007. Written informed consent was obtained from each volunteer before this study. MSA-C, MSA-P and PD were diagnosed according to established guidelines [12]. The patients' illness duration range was from one to 19 years, 17 patients were below 5 years, two patients were above 10 years and the other one patient was in the period between 5 to 9 years.

The axial magnetic resonance (MR) human brain images covering the entire cerebrum and cerebellum were performed on a 1.5-T Vision Siemens scanner (Erlangen, Germany) using a circularly polarized head coil, with the following parameters: 1.5mm axial slices; echo time=5.5ms; repetition time=14.4ms; flip angle 200; field of view 25cm; matrix size=256×256 and the in-plane resolution 1mm×1mm.

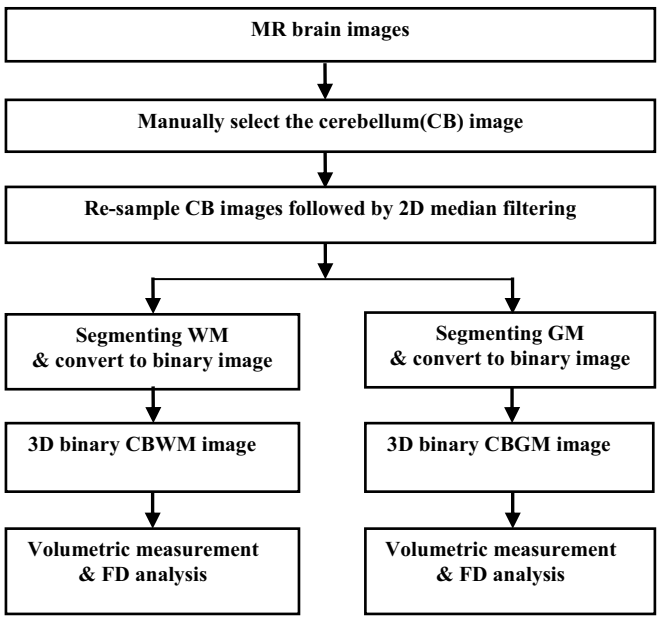

Fig.1 Flow chart of image processing and measuring steps.

B. Method

The processing of MR images and FD measurement consisted of five steps and the flowchart was depicted in Fig.1. It should be noted that the volumes of reconstructed 3D CBWM and CBGM were computed based on the total numbers of pixels within the objects and their units were mm^3. The fractal dimension (FD) is a quantitative indicator of object complexity which condenses all the details into a single numeric value. Let N(r) denote the minimal number of cubes of size r covering the fractal object. The FD of a fractal is defined in the power law relationship [13] $N(r) \propto r^{-FD}$. In this study, the FD analysis was implemented by the box-counting method derived from HarFA software (http://www.fch.vutbr.cz/lectures/imagesci).

The MATLAB 7.0 software was used for the implementation.

There are three steps in the FD measuring procedure: (1) counting the number of boxes to encompass the whole 3-D fractal object in Euclidean space, (2) repeating step (1) with different box sizes, (3) performing the linear regression analysis within the proper range of box sizes to estimate the FD value.

In this study, the FDs of CBWM and CBGM of the normal and patients groups were compared using the t-test for assessing the CBWM and CBGM structural complexity of MSA-C disease. The significant differences were detected at $p<0.01$.

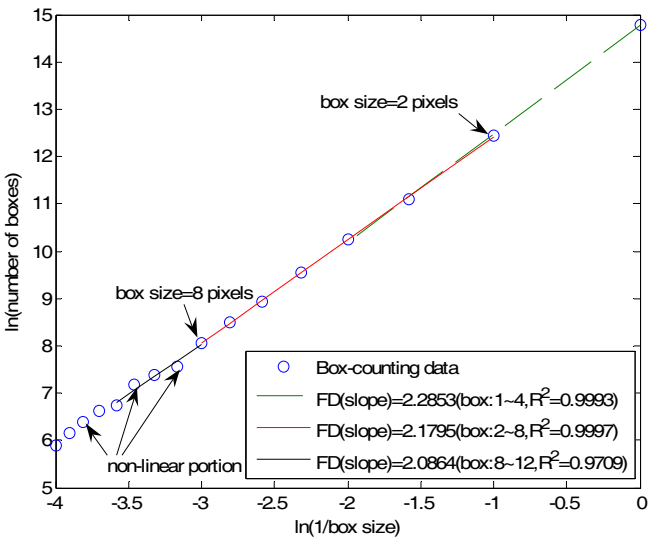

Fig.2 Linear regression analysis to calculate the FD value of CBWM from one patient.

III. Results

Figure 3 displays the MR brain images, CBWM segmented results, and the 3D reconstructed CBWMs from a normal subject and a MSA-C patient, respectively. Compared Fig. 3(c) to Fig. 3(f), the patient's CBWM presented a smaller volume and less folding patterns. The statistical results of FDs analysis and volumes of CBWM and CBGM of all participators were summarized in Table 1. It is worthy to note that the standard deviations of the FDs are much smaller compared with that of the volumes, no matter in control group or patients group. This suggests better reliability of the FD method than the volumetric method. No significant difference was detected between genders of control group (p=0.1592 for CBWM and p=0.6231 for CBGM) and MSA-C patients (p=0.6664 for CBWM and p=0.5562 for CBGM) for both while calculating the FD values of CBEM and CBGM.

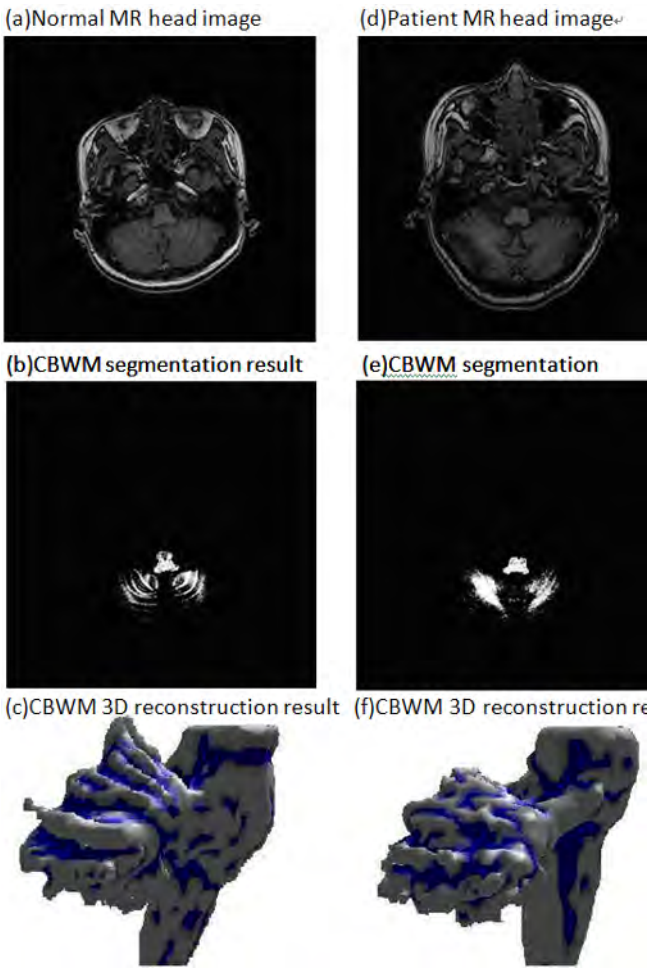

Fig.3 Results of image segmentation and 3D reconstruction for WM from one normal (a-c) and one patient (d-f) subject.

Figures 4(a) and 4(b) displays the statistical results of MSA-C and normal in which the MSA-C patients presented significantly lower CBWM FD values than the normal (p=5.4335e-008,(a)) and the CBGM FD values of MSA-C patients were also lower than the normal (p=6.1139e-005,(b)). The volumes of the cerebellum, including pons and brain stems for the normal subjects, were 172.89±17.05cm^3, and that for MSA-c patients were significant smaller, which were 140.36±26.62cm^3. In addition, the mean value of CBWM volume of the patients was 34.80cm3 which was smaller than that of the control group CBWM (47.48cm^3). The mean value of CBGM volume for patients was 105.57cm^3 which was also smaller that that (125.41cm^3) for the normal subjects. Results were also summarized in Table 1.

Table 1 Statistical results of FDs and volumes of all participators

Groups	MSA-C	Control group	*P*
Age	32~77	30~57	-
Number	20	23	-
Duration(Y)	5.0(1~20)	-	-
FD			
CBWM FD	2.155±0.096	2.267±0.037	<0.01
CBGM FD	2.4999±0.059	2.528±0.027	<0.01
Volume(cm^3)			
CBWM	34.80±8.54	47.48±6.0	<0.01
CBGM	105.57±23.30	125.41±12.73	<0.01
CB	140.36±26.62	172.89±17.05	<0.01

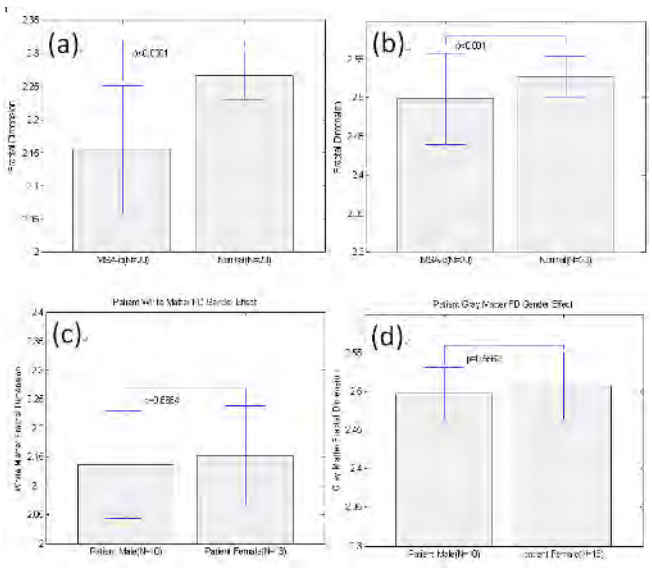

Fig.4 FD comparison between MSA-C and control group

IV. Discussion

Since the 3D cerebellum of MSA-C patients exhibited less folding pattern and smaller volume size, the structures of cerebellum of MSA-C patients were less complicated, and, therefore, smaller FD values. In this study the result confirmed that the FD values of CBWM and CBGM volumetric general structure were decreased in MSA-C patients, and we found that the FD value of CBWM decreased more significant than that of CBGM (p=5.4335e-008 for CBWM; p=6.1139e-005 for CBGM FD values). This suggested that the atrophy phenomena may occurred more seriously in the CBWM region. It is noted that most of the previous studies in brain atrophy disease used the FD analysis to analyze the complexity of surface boundary between WM and GM, and seldom analyze the structural complexity of CBWM and CBGM. In this study, the morphological changes of the CBGM and CBWM of MSA-C patients (Fig.3(c), (f)) have been effectively quantified by FD method. Similar observations have been reported by Specht et al. who applied the VBM analysis to detected WM and GM loss of MSA-C patients and reported that GM degenerated significantly in the cerebellar hemisphere and vermis, and WM degenerated in the pons, middle cerebellar peduncles, mesencephalon and frontotemporal areas.

Although the volumes and FD values of CBWM and CBGM were both smaller for MSA-C patients comparing with the control group, the FD method is superior to the conventionally volumetric method in terms of better reliability, sensitivity, and less gender effect. It can be seen in Table 1 that the percentages of standard deviation of FD values for CBWM and CBGM in the control groups were 2.0% and 1.0%, respectively, which were much smaller than that of volumes (15% and 10.5%, respectively). Volumetric measurement with large variations would make the statistical inference less reliable in comparison with the FD method. In addition, the logarithm-scale based FD measurement is more sensitive to structural change: a small difference in FD value may have a significant impact on the brain structures and their alteration, specifically, a difference of 0.1 of the FD value equivalent to a double of complexity (Smith et al,1989). Zhang et al. have verified that the FD analysis is more sensitive for characterizing WM structural features than the volumetric measurement and capable of describing complexity and variability of WM (Zhang et al., 2007). Moreover, there was no gender effect when the FD values of CBGM and CBWM were evaluated, no matter in the controls or MSA-C patients (Figs. 4(a)(b)(c) and(d)). However, there was a gender effect in evaluating the CBWM volume which could bias the results of volumetric method.

V. Conclusion

We have employed a 3D FD analysis method, which is more accurate and sensitive than the conventional volumetric method, to quantify the atrophy of CBWM and CBGM for MSA-C patients.. Our results showed that the FD of CBWM decreased faster than that of CBGM for the MSA-C patients, suggesting the CBWM degeneration would be the dominate atrophy phenomenon of the disease.

Abstract — **n this study, we propose a novel method to detect the intimal layers of the near and far wall of the common carotid artery (CCA) in dynamic B-mode images using dual dynamic programming (DDP). The lumen diameter (LD) can then be measured along a section during a certain time period (1 to 2 seconds.) In addition, the intima-media thickness (IMT) can be measured via detecting the intima and adventitia of the far wall using the same procedure but embedding different anatomic knowledge in DDP. All automatic detection results have been visually confirmed by professional physicians.**

Keywords — **IMT, CCA, dual dynamic programming, lumen diameter**

I. Introduction

Common carotid artery intima-media thickness (**CCA-IMT**) measurements have been confirmed to be an earlymarker of atherosclerosis [1] and have been associated with a higher risk of stroke [2] and myocardial infarction [3]. Recently, it has been shown that an increased CCA-IMT is cross-sectionally associated with a higher risk of brain infarction [4]. The non-invasive sonographic examination has demonstrated its potential in early predicting cardiovascular diseases. The IMT is an important index in modern medicine and can be measured either manually [4] or automatically [5]–[18].

The automatic methods have the potential in reproducing results and eliminating the strong variations in the manual tracings of different observers. Moreover, the processing time can be considerably reduced. The motivation of this study is to develop a confidential system which can identify the intima and adventitia of CCA automatically even under strong speckle noises using dynamic B-mode sonographic images. This system can identify not only the IMT of the far wall and but also the lumen diameter during both systolic and diastolic cycles. Via this system, the dynamic process of CCA can be represented by some parameters such as IMT variation and lumen diameter variation.

The carotid artery stiffness (CS) is one of the important factors for predicting cardio-vascular (CV) events [7]. The factor CS can be measured via measuring the systolic and diastolic carotid diameter on the distal wall of the CCA, 1 to 2 cm beneath the bifurcation with high-precision sonographic modality. Firstly, carotid distensibility (CDist) is estimated through the variations in arterial cross-sectional area and blood pressure (BP) during systole based on the assumption of a circular lumen. CDist is calculated as $\text{CDist}= \Delta A / A \cdot \Delta P$, where A is diastolic lumen area and ΔA is the maximum area change during a systolic-diastolic cycle, and ΔP is the local blood pressure change measured by applanation tonometer. The CDist can be converted to CS by giving $CS = (CDist)^{-1/2}$ [7].

Traditionally, CS is estimated by measuring the lumen diameters in systolic and diastolic states, i.e., only two points. This study provides a new technique in detecting the lumen diameter changes along a section of CCA, which is in general different from previously published works. We propose a novel dual dynamic programming combined with some anatomic knowledge into the algorithm which makes the detection more robust against the speckle noises.

This paper is organized as follows: In section II we firstly introduce how ultrasonic images are obtained. The difficulties of this study are discussed. Afterwards, the feature extraction is stated in details. In section III the results of lumen diameter and IMT detection are demonstrated. We finally issue our conclusion in section IV.

II. Materials, problems, and methods

A. Image acquisition

An Esaote MyLab ultrasound machine with a high resolution transducer was used for the acquisition of the sonographic image sequences. The CCA was examined by turning the neck of the study subject slightly to the left side. The transducer was positioned at the lateral side of the neck without compression on the inner jugular vein. The lumen was then maximized in the longitudinal plane with an optimal image of the near the far vessel wall of the CCA. Thus, both near and far wall of CCA can be observed and the video image sequences were saved on a recorder for off-line proc-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 734–737, 2009
www.springerlink.com

ess. All image sequences used in the paper were made in the Department of Prevention, Rehabilitation and Sports Medicine, TU Muenchen, University Hospital, Germany.

B. Problem statement

Figure 1 shows a typical image made by our sonographic modality. The *first* problem is the impact of speckle noises. It is very common that there are speckle noises in the artery lumen. In general, the noises on the near-wall side are stronger than the noises on the far-wall side. It makes the detection of near wall intima much more difficult, comparing to the detection of far wall intima. *Secondly*, some diseases such as atherosclerotic plaques change the structure of IM complex or the intimal layer. Some changes result in strong echoes such as calcification. When the intima is damaged, there are nearly no echoes on the damaged part so that results in an echo hole. All of these problems make the intima detection complex. *Finally*, the target we are processing is moving during the image sequence since it is made by dynamic B-mode sonography. Therefore we have to face the tracking problem. Fortunately, the target we are tracking does not change its shape in a large scale. Moreover, there is no overlapping or shadow problems, which might happen very often in the camera videos. In order to conquer problems listed above, we propose the novel scheme as follows.

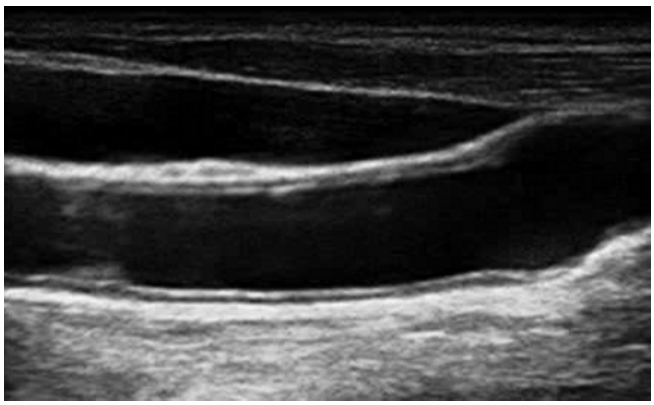

Fig. 1: A typical sonographic image (Esaote MyLab).

C. Image features

The dynamic B-mode image sequences are recorded and converted to several static images saved in BMP format. A graphic user interface (GUI) is designed for the user to select region of interest (ROI) to analyze. The user has only to select a rectangle area which is large enough covering the possible area during a complete systolic and diastolic cycle, when the lumen diameter will be measured. Similarly, the user has to select a smaller rectangle area to cover the intima and adventitia layers on the target to be detected. However, since the IMT does not change too much, the rectangle area is much smaller than the one measuring the lumen diameter.

The image features are extracted only on the selected ROI for the purpose of reducing the computation time. Several operators are used for feature extraction. The first one is MacLeod operator [8]:

$$f_M(x,y) = \exp(-\frac{x^2+y^2}{d_c^2})[\exp(-(\frac{d_{xy}+d_{pk}}{d_{pk}})^2) - \exp(-(\frac{d_{xy}-d_{pk}}{d_{pk}})^2)] \quad (1)$$

where

d_c constant determining rate of radial decay,

d_{pk} distance from axis to peaks in positive and negative weights,

$d_{xy} = x\sin\theta - y\cos\theta$, perpendicular distance of point (x, y) from axis of edge (at orientation θ to horizontal).

The MacLeod operator is in general to detect the gradient in different orientations. In this study, the size of MacLeod operators used in IMT and lumen diameter detection must be different and there are totally four orientations are applied.

One MacLeod operator is insufficient for the intima-adventitia detection since there causes noise layer in the IM-complex [9]. We therefore apply an enhancement operator to degenerate the noise layer in the IM-complex resulted from the MacLeod operator:

$$f_{IMT(far)} = \begin{bmatrix} 0 & \cdots & -1 & \cdots & 0 \\ & & \vdots & & \\ \vdots & & 0 & & \vdots \\ & & \vdots & & \\ 0 & \cdots & 1 & \cdots & 0 \end{bmatrix}, \quad (2)$$

where the size of the operator is determined by the pixelsize and anatomical knowledge. For instance, the IMT of a normal adult is 0.5mm. Therefore, the mask size should not be larger than 11×11. This operator is applied only for IMT detection of the far wall.

Another operator is applied for lumen diameter (LD) detection. The goal of this operator is to inhibit the gradient resulted from the adventitial layer. This is because the adventitia might cause a larger gradient than the intima does. However, the lumen diameter is determined by the intima but not by the adventitia. We thus define the following operator:

$$f_{LD(far)} = \begin{bmatrix} 0 & \cdots & -1 & \cdots & 0 \\ & & \vdots & & \\ \vdots & & 0 & & \vdots \\ & & 1 & & \\ & & \vdots & & \\ 0 & & 0.5 & & 0 \end{bmatrix}, \quad (3)$$

Again, the size of the operator is not fixed. It depends on the pixelsize and the anatomical knowledge. The goal of this operator is to reduce the impact of the gradient resulted from the adventitia. The operator for the near wall LD detection is simply reversed. With this construction, we simply reduce the noise impact and make the lumen diameter detection much easier, the IMT determination as well.

The resultant image feature is the composition of gradient images made by different operators:

$$h' = | I * f_M | + I * f_x, \quad (4)$$

where I is the original sub-image (ROI), f_x is $f_{IMT(far)}$ for IMT determination (far wall) and f_x is $f_{LD(far)}$ for LD determination (far wall). After two terms are summarized, *h'* might have negative values. Therefore, *h'* is shifted to have 0 as the smallest value and then divided by the largest value so that the final h is $0 \le h \le 1$.

D. Dual dynamic programming (DDP)

Structure: An image grid is denoted as $I(x, y)$ of size $M \times N$, where M and N are the number of rows and columns, respectively. Let $g(x, y)$ be the normalized image feature of $I(x, y)$ with $0 \le g(x, y) \le 1$. Suppose the dual curves run from left to right on $I(x, y)$ with two y-coordinates y_1 and y_2 in each column, $1 \le y_1, y_2 \le M$. The node pair is considered instead of the single node as that was done in the traditional dynamic programming. We assume that the dual curves have minimal and maximal distance between each other. Therefore, the anatomical relation is embedded into the dual dynamic programming structure. The details of DDP are described in [10]. The dual dynamic programming is applied on the image feature grid $h(x,y)$ instead of $I(x, y)$ denoted above in this section.

III. Results

Figure 2 shows a typical dynamic B-mode CCA image in one of our image sequence. There are total 84 images in this sequence. The GUI allows the user to select a ROI as shown in the rectangle area. All image features and DDP are executed on the selected ROI.

Fig. 2: The user can select a ROI for LD measurement.

Figure 3 shows the detection results. The parameter settings are: $\omega_1, \omega_2 = 0.1, d_{\min} = 55, d_{\max} = 85, k = 1$, where (ω_1, ω_2) are used to set the stiffness of the curves, $(d_{\min}, d_{\max})$ are the minimal and maximal distance between these two curves, and k denotes how far the neighboring nodes can jump and thus it represents the roughness of the curve. Details of the parameter description are in [10].

The section length of LD analysis is about 1.94 cm (pixelsize=0.0106 cm.) In Fig. 4, the ripple shows there are three systolic-diastolic cycles in this sequence. The middle

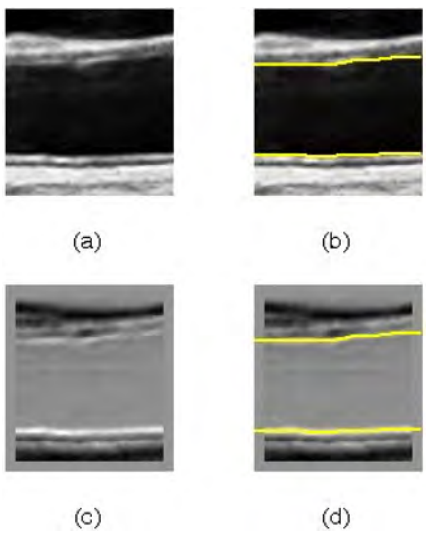

Fig. 3: (a) The selected ROI original sub-image; (b) ROI with detected intimal layers (near and far wall); (c) the feature image; (d) feature image with results.

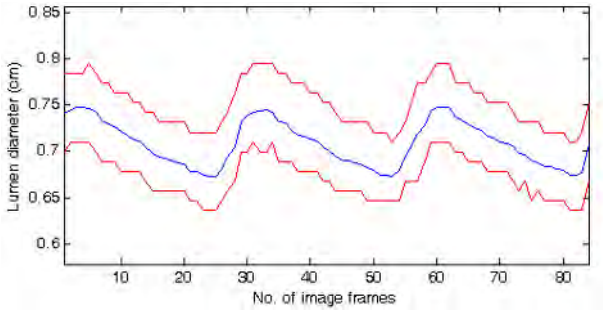

Fig. 4: The detected LD changes along a section. This sequence has 84 images and it lasts more than 2 seconds.

(blue) curve shows the average LD along this section and the upper and lower curves are the maximal and minimal LD changes along this section during the whole cycles, respectively. From the result, we observe that the averaged LD changes from 0.67 cm to 0.75 cm. The ripples of the upper and lower curves might reveal some important information for CV events and it needs a further study to confirm. However, this study provides a practical tool for physicians to analyze the LD along a section of CCA wall for further studies such as finding another factor or information for predicting the CV events.

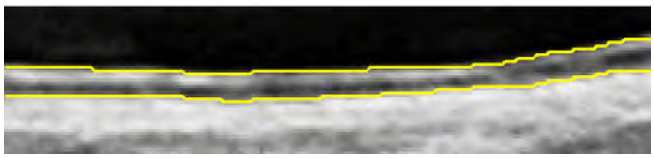

Fig. 5: One detection result of intima-media thickness. There are total 84 images of this analysis.

Figure 5 shows one of the IMT analysis. The length of this section is about 2.18 cm (206 pixels.) From the analysis one can observe the IMT changes along the systolic and diastolic cycles.

IV. Discussion and Conclusion

In section II we have stated three kinds of problem. In this study, we have proposed a novel method in detecting IMT and LD via a dual dynamic programming with a proposed image feature extraction scheme. Through a series of experiments we demonstrate the function and novelty of this proposed scheme which is able to against the speckle noises in the artery lumen. Although the experiment shown in this paper does not include echo holes or calcification, however, we have made some other experiments which reveal that this algorithm is able to solve these kinds of problem. Due to the page limitation, we are not able to demonstrate all experiments we have made.

This system is practical for physicians making further clinical studies such as finding new factors in CV events.

Acoustic Imaging of Heart Using Microphone Arrays

H. Kajbaf[1] and H. Ghassemian[1]

[1] Electrical and Computer Engineering Department, Tarbiat Modares University, Tehran, Iran

Abstract — **In this paper a novel method for acoustic imaging of heart is proposed. Heart is assumed to be a spread acoustic source which generates sound from its different locations. A simultaneous multisensor recording is used to record the heart sound from human chest wall. By using beamforming techniques the recorded data are combined to form a two or three dimensional representation of heart sound distribution. This map shows the acoustic energy of heart in different locations. Simulations with different array arrangements are done to verify the performance of this system. The heart sound is segmented without any need for other biosignals using an unsupervised method. This procedure is used to separate first and second heart sound. The segmented signal is used in beamforming algorithm. This results in a time-space map of heart sound for different intervals of heart activity. A setup is designed and implemented to record heart sound from human chest. Data are saved on a personal computer for signal processing in order to form a two or three dimensional image. This noninvasive and inexpensive imaging method offers new aspects, which with further studies, can help physicians in more precise diagnosing of heart diseases.**

Keywords — **Microphone array, acoustic imaging, near-field beamforming, heart sounds.**

I. Introduction

Initial diagnosis of heart diseases by listening to heart sound has been a very common method for a long time [1]. Physicians usually listen to the patient's heart sound in different auscultatory areas. Heart sound has different characteristics in different places on the body. This fact recommends an idea that if an electronically recorded heart sound or phonocardiograph (PCG) from different locations in front and at the back of the human chest is used, by combining these data, we can have an acoustic map of the heart.

For this purpose, we need an array of microphones which records the sound simultaneously and sends it to a processing unit. By using an array processing method we can have a spatial filter which helps us to localize the sound source. The configuration of the array and the location of microphones play an important role in array processing. In this research, we investigate different microphone arrangements to find which one is more efficient for heart sound localization.

II. Simulations

Sound is a mechanical wave which propagates through a medium with a speed which depends mainly on the material of medium and ambient conditions. It is generated by a source, travels through a medium and we can sense it with a sensor which is usually a microphone. Heart is a spread sound source which generates sound from its different parts. This source can be estimated with some point sources which generate sound separately [2]. If we estimate each point's signal energy by combining these data, we will have a map which represents the distribution of heart sound through the thorax. As a result, an image is formed that can be named as an acoustic image of heart.

A. Delay-and-sum beamformer

Beamforming is one the most common solutions for sound localization. In this research a delay-and-sum beamformer is used to localize the source. It has been shown that an imaging resolution for human chest cannot be better than approximately 2 cm [3]. So the beamformer scans the total area of the chest by focusing on each point in 1 cm steps. It estimates each point's signal energy and assigns a number between 0 and 1 to that point due to the maximum and minimum of energy in that region.

B. Sound propagation model in human chest

The acoustic properties of human chest are partly known because of its complexity. The speed of sound is varying from 23 m/s to 1500 m/s in human chest [4]. According to some literatures, sound travels as slow as 10m/s in the thorax [5]. Sound speed in chest wall and heart tissue is about 1500 m/s. The large air ways transmit sound with 222 to 312 m/s. Parenchymal sound speed is estimated to be between 23 and 60 m/s depending on air content. Damping is just about 0.5 to 1.0 decibel per centimeter at 400 Hz [3, 4].

Normal heart sound ranges in frequency from 20 to 150 Hz. Other sounds caused by structural abnormality or pathology, have the frequency up to 1200 Hz [4].

In order to verify our algorithm we conducted the simulations on the basis of these assumptions for different sound speeds and different array arrangements. A delay-and-damp model is used in these simulations [6]. In this model the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 738–741, 2009
www.springerlink.com

propagating wave is delayed and damped in its way from source to sensors. The delays are according to different times of arrival and are basis criteria in array processing. As mentioned above, damping factor in human chest is relatively low, but by considering it, we can make the model more precise. This model is presented in equation (1) [6]:

$$s\left(t-|x-y|/c\right)=d.|x-y|.r\left(y,t\right)/|x-y|^2 \qquad (1)$$

In this equation s is the recorded signal at each microphone, x is the location of each microphone, y is the location of source in any coordinate system and $r(y,t)$ is source signal. Assuming constant characteristic through the medium, c and d represent speed of sound and damping factor respectively.

C. Array arrangement

Array arrangement plays an important role in array processing. Here, we have a spread sound source which is in the near-field of the array. Our aim is to find a proper arrangement to fit the geometry of human body and at the same time localize the source with least error possible. The simulations are done in two dimensional and three dimensional arrangements. The 2-D arrangement is used for 2-D maps and the 3-D arrangement for the 3-D maps. Several arrangements are tested in each category. Figure 1 shows three typical array arrangements.

A single source of sound is located in a medium with a sound propagation speed of 10, 40 and 344 m/s. 10 m/s is the least propagation sound speed, 40 m/s is an average speed in human body [3] and 344 m/s is the speed of sound in air at room temperature.

The location of the source is changed in 1 cm step size and the error in detecting the location of source is measured as the distance between the detected source and the real source. The total error of each arrangement is defined as the average of these errors. The total error and the standard deviation of the error of each arrangement are shown in tables 1, 2 and 3. The region of interest is set to match the typical human body size. Signal source is a 500 Hz sine as well as a recorded heart sound.

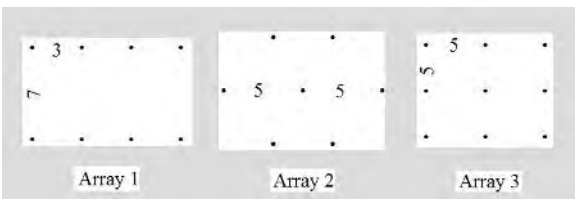

Fig. 1 Array arrangements (distances between microphones are in cm)

Table 1 Total error and standard deviation of the error (speed of sound is 10 m/s)

Array arrangement	Total error (cm)	Error standard deviation (cm)
1	0.02	0.27
2	0.002	0.05
3	0.0	0.0

Table 2 Total error and standard deviation of the error (speed of sound is 40 m/s)

Array arrangement	Total error (cm)	Error standard deviation (cm)
1	0.36	1.57
2	0.35	0.36
3	0.0	0.0

Table 3 Total error and standard deviation of the error (speed of sound is 344 m/s)

Array arrangement	Total error (cm)	Error standard deviation (cm)
1	3.65	2.34
2	4.57	2.60
3	2.31	1.15

The result of simulations for 3-by-3 array at the speed of 40 m/s is presented in figure 2. This array has the least total error and standard deviation of the error among other simulated arrays. It can be seen that the algorithm separated two sources distinctly. In these images points with higher energy are darker and points with lower energy are brighter. Figure 3 shows a three dimensional image. A three dimensional array is used in this case. The array is consist of two 3-by-3 arrays, one in front and one at the back of the chest. So, 18 microphones are used in this array. Because of overlapped voxels, one percent of the points are presented in this image. A side lob can be seen in the image, but it not in the region of interest, so it can be neglected.

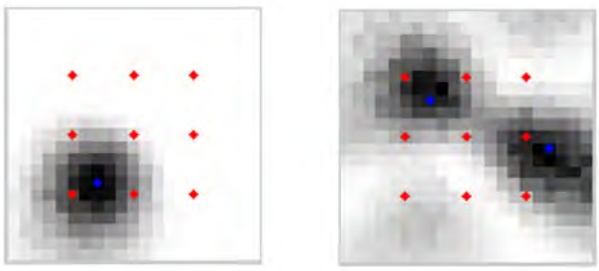

Fig. 2 Localization of one (left) and two (right) acoustic sources (red points indicate microphones location and blue points indicate sources)

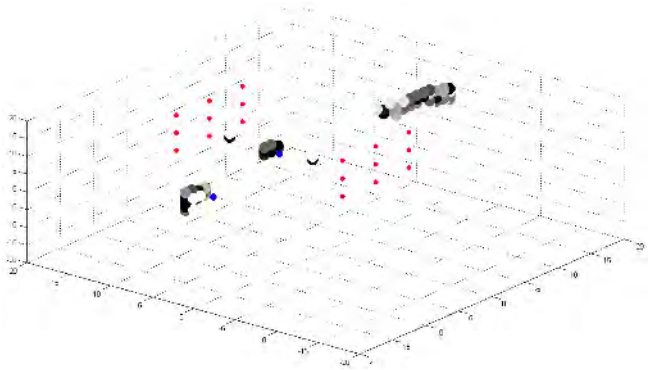

Fig. 3 Three dimensional localization of two acoustic sources (red points indicate microphones location and blue points indicate sources)

III. Segmentation

Heart sound is generated from different places in heart in different intervals [2]. The place of source is different during first heart sound (S1) and second heart sound (S2) so if we separate the sources in time domain, it can help a lot in the problem of source separation and generating the map. We used a heart sound segmentation method presented in [7]. This method doesn't need any extra biological signal (e.g. ECG) as a time guide. More over it overcomes the problem of asynchrony between these extra signals and the phonocardiograph as sometimes occur in certain diseases.

In this method a Morlet bank is used because of its similarity to heart sound. The energy profile of the signal is calculated using this wavelet. Peaks in the energy profile derived from the time-scale representation, are identified and are used to obtain segments containing any activity. Then the singular value decomposition (SVD) of the signal is calculated to determine which segment has a fundamental activity. Due to the following characteristics of PCG the segmented signal is labeled either as S1 or S2: (1) sequential repetition of fundamental activities, (2) the duration of time interval between S1 and S2 (systole) is longer than the duration of time interval between S2 and S1 (diastole), and (3) the heart rate is less than or equal to 160 beat per second. Figure 4 illustrates a PCG signal and its segmented energy profile. These labeled signals are used separately in the beamformer to form time-space maps. More details can be read in [7].

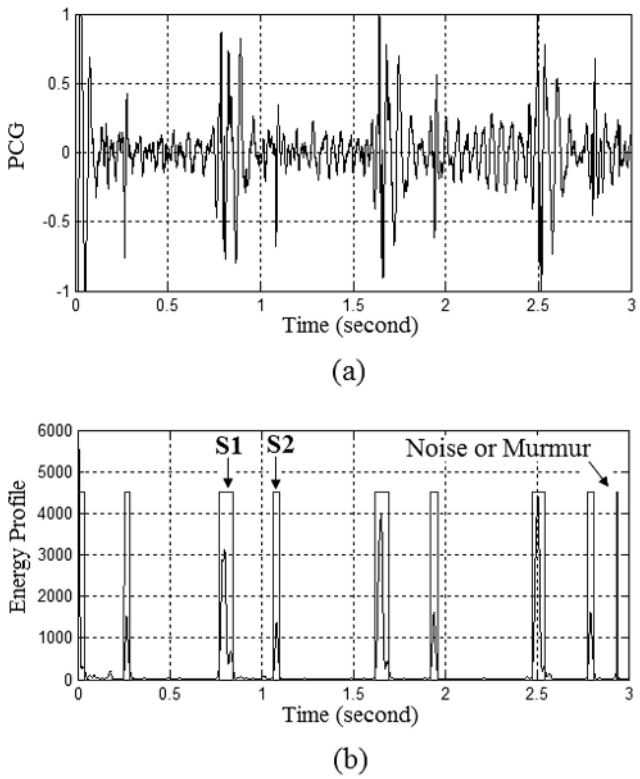

Fig. 4 An example of PCG and its corresponding energy profile. (a) PCG (b) Energy profile

IV. Experimental tests

An experimental setup is prepared for acoustic imaging of heart. It consists of software and hardware units. Software unit process the acquired data to form the acoustic map. Beamforming, segmentation and data presentation are performed in this unit.

Hardware has three major parts: microphone array is made up of Panasonic electret condenser microphones WM-52B, preprocessing unit which amplifies and filters microphone signal in order to enhance sound signal to noise ratio and data acquisition card (DAQ) which is an Advantech PCI-1713 card playing the role of interfacing with a Pentium IV platform PC.

Noise plays an essential role in experiments. In order to eliminate it, firstly we used a low pass filter in the preprocessing circuit with cut-off frequency of 1200 Hz. In software unit the frequencies below 20 Hz are damped with a high pass filter. Some noises such as electricity lines 50 Hz and its higher harmonics and environmental noises such as computer fan noise are inevitable. These noises occur in frequency band that heart sound has information in it and we cannot eliminate them with regular filters. In order to overcome this problem an extra microphone is used to collect noise and subtract it form the main signals adaptively. This method helps enhancing SNR and therefore signal's quality.

Fig. 5 Heart acoustic map for first (left) and second (right) heart sound (red points indicate microphone location)

Experiments are done on a human subject. He is asked to stop breathing at lung resting volume for 3 seconds in order to eliminate breathing sound and heart sound is recorded during this time. According to [3] sound speed in this physiologic condition is near 30 m/s and is closer to the propagation average speed which is 40 m/s. On the other hand overestimation of sound speed causes less artifact and deviation than underestimation [3]. So, experimental tests are done assuming 40 m/s as the propagation speed.

The signals are recorded and saved on a PC, they are segmented using the described method and beamforming is done. Finally a two or three dimensional image is presented on the screen. Figure 5 shows a two dimensional image of heart. It can be seen that heart sound is generated from different locations in different time intervals.

V. Conclusions

The results of this research show that a new imaging method can be introduced and might be helpful. Few clinical researches are done in this field, so there is a need for more investigations to indicate the abilities of this method in diagnosing heart diseases. The most important characteristic of this method is its noninvasive and nondestructive manner. So in future, we may see improvements in acoustic based instruments for heart disease diagnosis.

Some suggestions for improvement of this method are as follow: using more accurate microphones to improve the quality of recorded sound, a more precise estimation of the speed of sound in human chest and designing more complicated array arrangements to eliminate side lobes and to improve the focusing of the array.

Statistical Variations of Ultrasound Backscattering From the Blood under Steady Flow

Chih-Chung Huang[1], Yi-Hsun Lin[2], and Shyh-Hau Wang[2]

[1)] Department of Electronic Engineering, Fu Jen Catholic University, Taiwan
[2)] Department of Biomedical Engineering, Chung Yuan Christian University, Taiwan

Abstract — **Our previous studies have demonstrated that the statistical distributions of ultrasonic backscattered signals were able to characterize hemodynamic properties of flowing blood associated with red cell aggregation and coagulation. Yet very little is still known about the phenomenon of spatial variation of "black hole" (BH) in the laminar flow with signal statistics of the flowing blood. To further explore this issue, measurements were performed from the porcine blood (with hematocrits of 20 and 50%) circulating in a mock flow loop under various steady laminar flows at mean flow velocities ranged from 1.5 to 12.2 cm/s using a 10 MHz focused ultrasonic transducer. Results showed that the BH phenomenon was apparent for the 50% blood flowing at a low velocity. The BH phenomenon tended to be decreased with the increase of flow velocity and was hardly observed in the 20% blood. The probability density function (PDF) of signals backscattered from flowing blood tended to distribute as pre-Rayleigh statistics with the corresponding mean Nakagami parameter is less than 1. The scaling parameters and Nakagami parameters are respectively decreasing and increasing respectively to the increase of flow velocity. Moreover, larger scaling parameters and smaller Nakagami parameters were obtained respectively from 50% and 20% bloods. The spatial distribution of red cell aggregation and shear rate in the flow tube is a predominant factor leading to the statistical variations of ultrasonic backscattering in the flowing blood and that the formation of BH phenomenon tended to decrease the Nakagami parameter.**

Keywords — **Ultrasonic backscattering, Black hole phenomenon, Nakagami model**

I. Introduction

Several individual red blood cells (RBCs) could aggregate together to form a rouleau depending on blood flow conditions. The red cell aggregation is a reversible physiological process that may increase viscosity and resistance of the flowing blood and further promote blood coagulation [1]. Recently, properties of red cell aggregation associated several factors with blood flows have been studied using ultrasound techniques due to their real-time and noninvasive capabilities [2]. The variation of scatterer size in the flowing blood owing to red cell aggregation may be sensitively detected by ultrasonic backscattering due to that it is scatterer size dependent. Consequently, several previous studies have found that ultrasonic backscattering, corresponding to the formation of RBC aggregation, is affected by the shear rate, hematocrit, and fibrinogen concentration in the flowing blood [2]. An interesting phenonmenon, called "black hole" (BH) phenomenon, was found to form a hypoechoic hole near the center stream of the flow conduit surrounded by a hyperechoic zone discerned by the cross sectional B-mode images, which is presumably resultant from the smaller aggregates at the center stream due to very low shear rate and a maximum aggregation at a certain shear rate [3].

The BH was initially observed by Yuan and Shung [4] in the blood under steady flow and recently that of under pulsatile flow [5]. Many studies indicated that the BH phenomenon is affected by flow velocity, pulsatile condition, entrance length, and hematocrit of the blood. Shehada *et al*. had observed the formation of BH phenomenon from the flowing blood of mean flow velocities ranging from 1.3 to 5.3 cm/s circulated in a rigid tube with a large diameter of 2.54 cm [3]. In addition, a 7 MHz B-mode system was used to image the porcine whole blood at a 28% hematocrit for different entrance lengths circulated in a rigid tube under steady flow conditions, in which results demonstrated that a smaller zone of BH in the center stream was obtained in accordance with the increase of the inlet length of tube [6]. Qin et al. found that the BH was more pronounced corresponding to higher kinetics of RBC aggregation using a 10 MHz Doppler system to measure blood circulated in a 1.27 cm diameter tube under steady flow conditions [7]. Furthermore, the BH phenomenon was investigated with porcine whole blood of different hematocrits under pulsatile flow conditions circulated in a rigid tube of 0.95 cm diameter measured by an ultrasonic scanner with a 7.5 MHz linear array [8]. The results indicated that the formation of BH occurred at hematocrits of blood over 23% and that becomes prominent as that the hematocrit is increased further. Results of these just mentioned investigations showed that the formation of BH phenomenon is related to red cell aggregation in the flowing whole blood.

In this study, the spatial variations of flowing blood including the association of BH phenomenon was explored to better elucidate the relationship between RBC aggregation and backscattering signals statistical behavior. Measurements were carried out on porcine whole blood of 20 and

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 742–745, 2009
www.springerlink.com

50% hematocrits flowing in a rigid tube of 0.954 cm diameter under various steady laminar flows at mean flow velocities ranged from 1.5 to 12.2 cm/s. The statistical Nakagami parameter and the spatial distribution of backscattering strengths across the whole section of flow tubing were measured and calculated corresponding to different blood properties and flow conditions. The experimental results were analyzed to empirically explore the relationship between BH phenomenon and signal statistics for flowing blood.

II. Materials and Methods

Fresh porcine blood, containing 15% acid citrate dextrose (ACD) anticoagulation solution, was collected from a local slaughterhouse. The impurities of blood, such as hair or fatty tissue, were filtered out using a sponge and that the collected blood was discarded whenever any coagulation was observed. The whole blood was centrifuged at a 2500 rpm for 15 min to separate RBCs from the plasma and other cells. The separated RBCs were subsequently washed twice with saline buffer solution. Whole blood of 20 and 50% hematocrits were obtained by reconstituting the packed RBCs with certain volumes of plasma. The subsequent experiments were performed within 24 h after that the blood sample was collected.

The mock flow phantom, shown in Figure 1, was arranged and calibrated. The flow model comprised a peristaltic pump (Model 7518-00, Masterflex, Cole-Parmer, IL, USA), two reservoirs, and a magnetic stirrer (Cole-Parmer, IL, USA). The blood sample in the conduit was circulated for approximately 20 min before that each data acquisition of an experiment was carried out to eliminate those possible air bubbles and to allow thermal equilibrium with the ambient temperature of 25±1°C. A portion of flow tube was immersed in the degassed water contained in a plexiglass tank to facilitate the transmission and reception of ultrasound waves. The polyurethane flow tube is with an inner diameter of 0.954 cm and thickness of 0.159 cm.

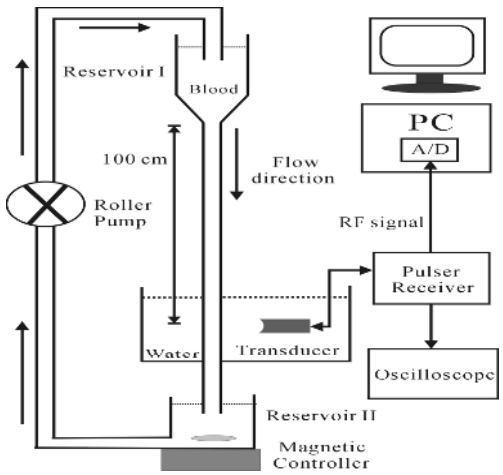

Figure 1, Experimental arrangement.

Prior to each experiment, the flow was calibrated by timing certain flow volumes with respect to the settings on the pump. The mean flow velocities, including 1.5, 3.8, and 12.2 cm/s, were prepared for this study. The inlet length of the tube between the top reservoir and the site of ultrasonic transducer was sufficient (100 cm) to allow a fully developed laminar flow. A wideband 10 MHz focused transducer (A311R, Panametrics, Waltham, Massachusetts, USA) was applied in these measurements. A pulser/receiver (5072PR, Panametrics, Waltham, Massachusetts, USA) was used to drive the transducer for transmitting and receiving ultrasound signals at pulse repetition frequency (PRF) of 100 Hz. The clock signals synchronized with PRF were used to trigger the data acquisition of backscattered echoes at a maximum sampling frequency of 100 MHz by a 14-bit analog-to-digital converter (PCI-5122, National Instruments, Austin, Texas, USA). For all measurements, the sample volume of each collected signal was arranged to be located near the focal zone of the transducer, which was positioned perpendicularly to the flow direction.

A total of 1000 A-lines of radio frequency (RF) backscattered signals were acquired, in which each A-line corresponded to a gated window of 12 μs (assuming the speed of sound in blood is 1540 m/s, and then the length of sample volume is approximately 0.924 cm). The diffraction effect of transducer was subsequently compensated using the axial beam profile of the transducer been measured. The envelopes of those diffraction-compensated backscattered signals for calculating the Nakagami parameter, scaling parameter, and the distribution of backscattering strengths across the flow tube were estimated using Hilbert transform. The M-mode images were obtained for conveniently visualizing the spatial variation of backscattering from flowing whole blood. A total of five porcine blood samples from different animal subjects were used for this study.

The ultrasonic signals backscattered from tissues would result various distributions of PDF, including pre-Rayleigh, Rayleigh, and post-Rayleigh distributions, depending on scatterer concentrations in the sample volume. It thus is feasible to differentiate properties of blood by modeling the PDFs of backscattered envelopes from the blood. The PDFs of the Nakagami distribution (*f*) calculated from the envelope (*R*) of backscattered signals is given by [9],

$$f(R) = \frac{2m^m R^{2m-1}}{\Gamma(m)\Omega^m} e^{\left(-\frac{m}{\Omega}R^2\right)} U(R), \tag{3}$$

where $\Gamma(\cdot)$ and $U(\cdot)$ are respectively the gamma function and unit step function. Both the Nakagami parameter (m) and scaling parameter (Ω) associated with the Nakagami distribution can be calculated as follows:

$$m = \frac{[E(R^2)]^2}{E[(R^2 - E(R^2))^2]}, \tag{4}$$

and

$$\Omega = E(R^2), \tag{5}$$

in which $E(\cdot)$ is the statistical mean. The scaling parameter may directly refer to the average power of the backscattered envelope. In accordance with the resolution cell of the ultrasonic transducer that contains a large number of randomly distributed scatterers, the envelope statistics of the ultrasonic backscattered signals tends to be Rayleigh distributed in which m approached to 1. For that the resolution cell contains scatterers that have randomly varying scattering cross sections with a comparatively high degree of variance, the backscattered envelope tends to be pre-Rayleigh distributed with m less than 1. Further, that the scatterers are located periodically, the corresponding envelope statistics tend to be post-Rayleigh distributed with m larger than 1 [9].

III. Results

Figure 2 is a set of typical M-mode images acquired from flowing whole blood of a 50% hematocrit under different flow velocities ranging from 1.5 to 12.2 cm/s. A tiny hypoechoic region (or black hole) in the center stream of the flow tube surrounded by bright rings was observed associated with flow velocities of 1.5 and 3.8 cm/s shown in Figures 2(a) and (b), respectively. Figure 3 demonstrates respectively the corresponding amplitudes of the backscattered signal envelopes to Figure 2 as a function of radial position in the tube, in which the spatial variation of ultrasonic backscattering from flowing blood could be better delineated. The associated result of Nakagami parameter as a function of flow velocity is in Figure 4, in which the mean Nakagami parameter increased from approximately 0.26 to 0.46 as the flow velocity increased from 1.5 to 12.2 cm/s at a hematocrit of 50 %. As the flow velocity was increased, the corresponding Nakagami parameter tended to increase accordingly.

IV. Discussion and conclusions

Several studies have been undertaken to better comprehend the origin of BH phenomenon [6-7]. As mentioned before, it has been hypothesized that BH phenomenon in the laminar flow was caused partially by the formation of red cell aggregation under the influence of shear rate in the flowing tube. Another study suggested that the very low shear rates around the center of the tube tend to inhibit the

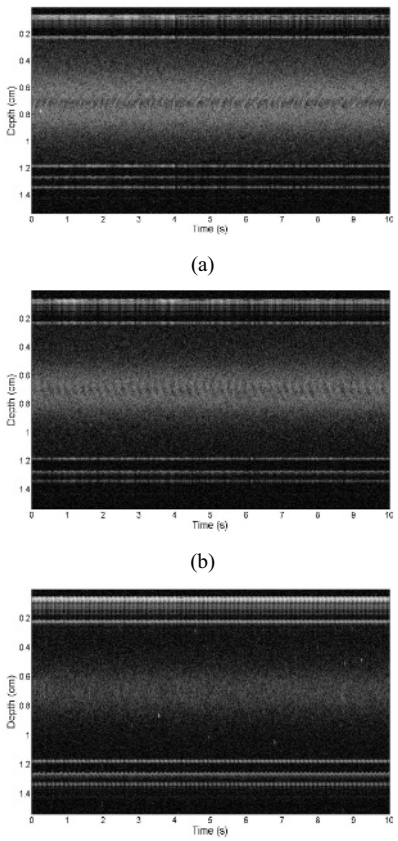

Figure 2, Typical M-mode images associated with whole blood of 50% hematocrit under different flow velocities: (a)1.5 cm/s, (b)3.8 cm/s, and (c)12.2 cm/s.

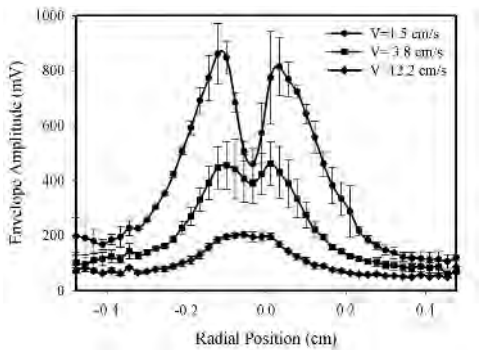

Figure 3, Envelope amplitudes of signals backscattered from a 50% hematocrit blood as a function of radial position in the flowing tube corresponding to different flow velocities.

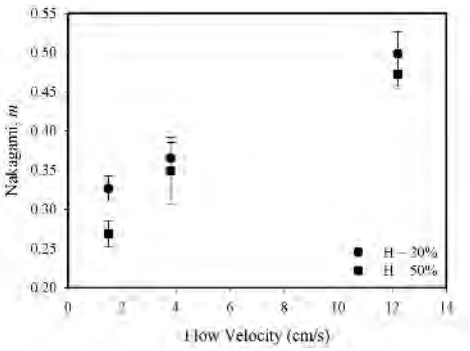

Figure 4, Nakagami parameter of blood of different hematocrits as a function of flow velocity.

formation of large rouleaux whereas higher shear rates in the surrounding region are favorable for the formation of aggregates to produce the BH [8]. However, very little is known about the effect of BH phenomenon on the signal statistics for flowing blood. For this reason, the relationship between blood backscattering behavior and signal statistics should be further established to characterize blood properties with respect to various blood flow conditions.

In general, the BH phenomenon is more likely to appear accordingly to such conditions as the blood flow of lower velocity, the blood of higher hematocrit (over 23%), and a sufficient large flow tube [5]. In this study, the BH phenomenon was able to be created as that the whole blood flowed at very low flow velocities (1.5 to 12.2 cm/s) and circulated in a large tube (diameter of 0.954 cm). The BH in the center stream of the flow tube was observed for blood flowed at velocities of 1.5 and 3.8 cm/s, as shown in Figures 2(a) and (b). As the flow velocity was further increased, the BH phenomenon was diminished. This result well agrees with pervious studies for that the BH phenomenon appeared at a very low velocity [3].

According to results in our pervious study [9], the Nakagami parameter increased from 0.45 to 0.78 as the flow velocities increased from 10 to 60 cm/s. The Nakagami parameter of a blood of 20% hematocrit increased from approximately 0.33 to 0.47 with the increase of flow velocity from 1.5 to 12.2 cm/s, that led PDFs of signal envelopes to pre-Rayleigh distribution. These results imply a correlation could exist between Nakagami parameter and flow velocity. The Nakagami parameter seems to increase with the flow velocity due to the effect of red cell aggregation that varies the size of scatterers in the flowing blood. On the other hand, the PDFs of signal envelopes (50% hematocrit) still exhibited pre-Rayleigh distribution despite the occurrence of BH phenomenon for blood of lower flow velocities from 1.5 and 3.8 cm/s.

In summary, the effects of BH phenomenon in the flowing blood on the backscattering signal statistical behavior using the Nakagami statistical model were investigated. The BH phenomenon was observed obviously associated with the blood of higher hematocrit and that flows at a lower velocity. The experimental results indicated that the Nakagami parameter was smaller than 1 for flowing whole blood due to ultrasonic backscattering of flowing whole blood is spatial variation in the flow tube, resulting in the PDF of the signal envelope being close to pre-Rayleigh distribution. The tendency of decreasing degree of BH phenomenon with respect to the increase of flow velocity is consistent with results obtained from Nakagami parameters.

Abstract — **Acoustic microscopy offers unique advantages in the investigation of the mechanical properties of biological materials. Ultrasound contrast agents (microbubbles) provide unique acoustic scattering signatures for novel imaging and, in combination with ligands, facilitate molecular imaging capabilities. The potential role and application of microbubble contrast agents at ultra-high frequencies (> 100 MHz) remains an open question. We examine microbubble contrast agents at 200 MHz, 400 MHz and 1.0 GHz in the vicinity of endothelial cells. Visualization of individual microbubbles is demonstrated at 1.0 GHz.**

I. INTRODUCTION

During the previous decades, on-going research has described the vascular endothelium as an active endocrine, paracrine and autocrine organ, indispensable for the maintenance of vascular homeostasis. Anomalies of the homeostatic state, induced by various stimuli, may cause localized alterations or endothelial dysfunctions, whereby disturbances to molecular and mechanical functions result as direct consequences. The dramatic change of endothelial interaction with blood leukocytes occurring during inflammation provides an example of such an endothelial dysfunction [1]. Furthermore, abnormalities of endothelial function occur in cardiovascular diseases such as atherosclerosis, hypertension, heart failure and organ transplant rejection [2, 3].

The existing techniques for the direct, real-time and non-invasive evaluation of endothelial function *in vivo* have substantial limitations. Acoustically active targeted microbubbles have been applied as a means to non-invasively assess the functional status of the endothelium. Microbubble contrast agents represent an entirely novel family of materials that previously have been used for tissue delineation and perfusion. Their usefulness depends on the compressibility of the interior gas and its associated sound scattering properties which differ from the near-incompressibility of tissue and cells.

Scanning acoustic microscopy (SAM) was employed for the purposes of the current study to examine these acoustic properties at ultra-high frequencies (> 100 MHz).

II. TIME-RESOLVED ACOUSTIC MICROSCOPY

Acoustic microscopy is a significant and promising technique. It depends on the elastic response of the material to waves; and therefore, provides information on local changes in mechanical properties without any physical contact with the specimen. Furthermore, scanning acoustic microscopy (SAM) shows extraordinary advantages such as excellent spatial resolution and minimal invasiveness due to higher sound frequencies, which do not cause damage or disturb the cells [4].

Microbubbles reflect incident ultrasound waves in their response to the alternating compression and rarefaction cycles by changing diameter. This is because their gas content is much more compressible than cells or their surroundings. These oscillations are non-linear for sufficiently high pressure amplitudes. Consequently, this non-linear response alters the character of the reflected signals and hence the

www.springerlink.com

degree of difficulty of differentiating the received signals is significantly increased.

III. MATERIALS AND METHODS

A. Cell culture

Murine endothelial cells were readily transformed in a single step by the polyomavirus oncogene encoding middle-sized tumor antigen. These cells, bEnd.3 [5], form tumors (hemangiomas) in mice which are lethal in newborn animals [6]. The bEnd.3 cells rapidly proliferate in culture and have an elongated spindle shape (Figs. 2 & 3).

The bEnd.3 cells (obtained from W. Risau, Max Planck Institute) were maintained in Dulbecco's modified Eagle's medium (DMEM) with L-Glutamine (Promochem, 30-2002) containing 10% heat-inactivated fetal bovine serum (Invitrogen) supplemented by 50 i.u./mL of penicillin and 50 µg/mL of streptomycin (Invitrogen).

The cells were dissociated into suspensions of single cells with 0.05% trypsin, seeded at a density of 1-2x10^5 cells/cm^2. The cells were then incubated in a humidified atmosphere of 95% air, 5% CO_2 at a temperature of 37°C. The culture medium was replaced once every 24 hours.

Prior to the experiments, the cells were transferred from culture dishes to Lab-Tek®II (Nunc, GmbH & Co, Wiesbaden, Germany) chambered coverglasses and were then maintained at a temperature of 37°C for 24 to 72 hours. Before conducting high-frequency measurements, the culture medium was replaced by another medium containing 90% DMEM with L-Glutamine supplemented with 10% Fetal Bovine Serum, 40 mM Hepes (Invitrogen), 50 i.u./mL penicillin and 50 µg/mL streptomycin.

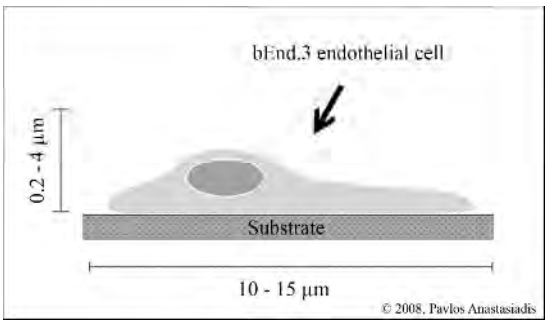

Fig. 2. b.End3 endothelials cells.

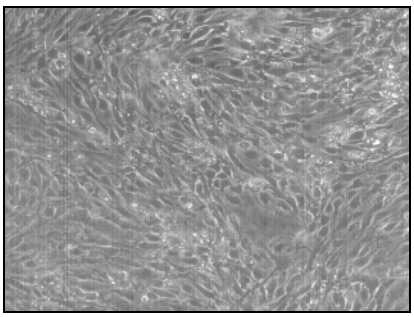

Fig. 3Phase-contrast image of bEnd.3 endothelial cells.

B. Microbubble contrast agents

For the purposes of this study, positively charged lipid-based perfluorocarbon-filled (PFC) microbubbles (Fig. 4) and liquid perfluorohexane emulsion were applied.

The microbubble samples were washed twice in degassed aqueous saline by centrifugation (10^3 rpm for 5 min) to remove the lipids not incorporated in the microbubble shell. The microbubble solution was added along with the degassed saline into a 3 cc syringe equipped with a 3-way luer-lock valve, sealed off with parafilm and subsequently centrifuged. The thin layer of microbubbles that was formed after centrifugation was removed. In the final step, the microbubbles were dispersed onto the adhered bEnd.3 cells.

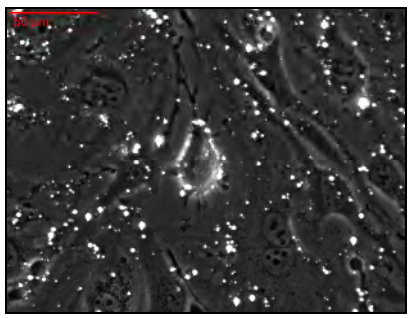

Fig. 4Phase-contrast image of b.End3 cells with microbubbles.

The population of microbubbles used in the study, as determined by an automatic laboratory cell counting apparatus (Casy®, Innovatis Casy Technology, Reutlingen, Germany), was found to be 21.92×10^7 for the PFC-microbubbles per 1 ml solution with a mean diameter of 4.19±1.2 µm, while it appeared to be 11.23×10^7 for the emulsion solution per 1 ml with an average diameter of 4.11±1.2 µm.

C. SAM measurements

Prior to conducting acoustic measurements, the positively charged microbubbles were dispersed into the cell sample chambers as described in the section above. Due to electrostatic forces, they were attracted to either the net negatively charged extracellular matrix (ECM) on the substrate or to the cell surface. Although no systematic quantification

was undertaken, it was observed that most of the microbubble contrast agents remained attached to the extracellular matrix. This might be explained based on electrostatic interactions or simply due to the fact that the substrate corresponds to a substantially larger flat area as opposed to the curved cell surfaces of the sample.

Acoustic measurements were conducted by employing the SASAM scanning acoustic microscope (SASAM, Fraunhofer IBMT, Germany) at frequencies of 200 MHz, 400 MHz and 1.0 GHz. Technical details and applications of SASAM can be found elsewhere [7-9].

IV. RESULTS

A. SAM at 1.0 GHz

Individual bEnd.3 cells were acquired at a frequency of 1.0 GHz at the initial focus position (Z=0) and at different defocused positions above and below the focus position Z (Fig. 5). Microbubbuble contrast agents can be clearly visualized independently of the area of attraction on either the extracellular matrix or the cell surface.

Furthermore, the RF-signals of microbubble A attracted to the ECM and of microbubble B attached to the cell surface (Fig. 6), were compared by plotting the respective power spectra. The power spectra comparison reveals that although a significant overlapping can be observed, there are significant differences at higher frequencies. This discrepancy could be due to the fact that microbubble A is attached to a rigid surface (substrate) as opposed to microbubble B which sits on an elastic surface (cell).

The attenuation of sound in the gigahertz frequency range is high. At the same time, the difference in acoustical impedance between cells and the surrounding medium remains relatively small. The introduction of microbubble contrast agents substantially enhances the amount of backscatter and thus allows for imaging despite the fact that the 1.0 GHz frequency is significantly different from the linear, monopole frequency of the microbubble.

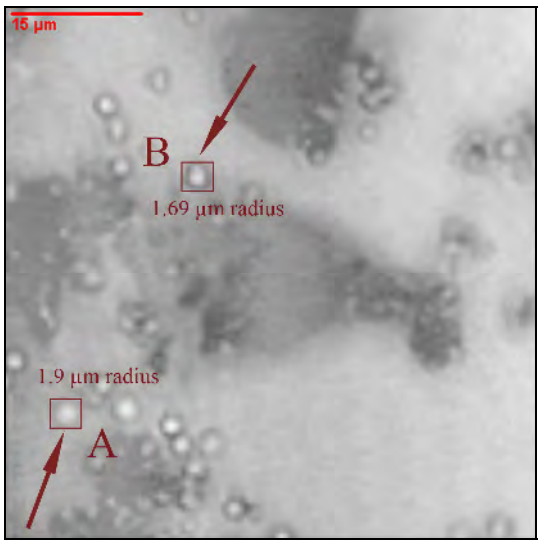

Fig. 6 Visualization of bEnd.3 cells and microbubble contrast agents at 1.0 GHz. The visualization window is 60 µm × 60 µm and the scale bar corresponds to 15 µm.

B. SAM at 400 MHz

Furthermore, bEnd.3 endothelial cells with electrostatically attracted microbubble contrast agents on either the ECM or

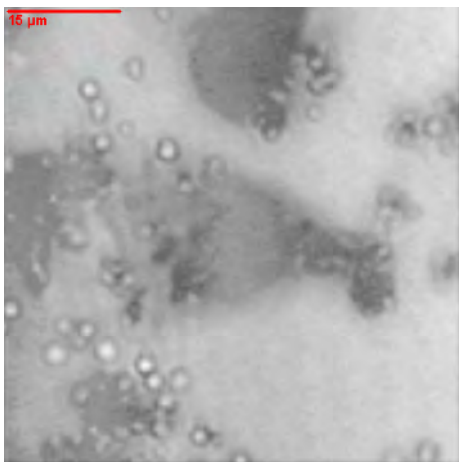

Fig. 5Acoustic microscopy image of bEnd.3 endothelial cells and microbubble contrast agents. The visualization window is 60 µm × 60 µm and the scale bar corresponds to 15 µm.

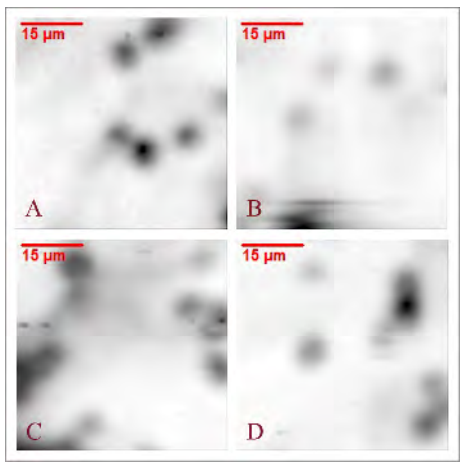

Fig. 7Acoustic microscopy image of bEnd.3 endothelial cells and microbubble contrast agents at 400 MHz. The visualization window is 50 µm × 50 µm and the scale bar corresponds to 15 µm.

the cell surface were imaged ultrasonically at the frequency of 400 MHz (Fig. 7). Although individual microbubbles could be visualized alongside individual cells, the resolution is less than that obtained at 1.0 GHz. This is due to the fact that the resolution at this specific frequency range is approximately 4 μm as opposed to 1.5 μm at 1.0 GHz.

C. SAM at 200 MHz

Visualization of the microbubbles and cells at 200 MHz is limited due to the significant decrease in spatial resolution. However, in Fig. 8 we can discern a cell and microbubbles in the dark region. The cell appears as the darkest semicircular area in the lower left portion. We hypothesize that the regions appear dark due to the defocused position of the acoustic lens.

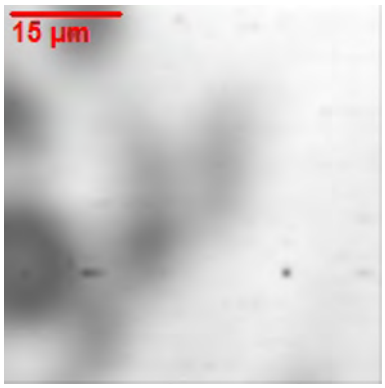

Fig. 8Acoustic image of bEnd.3 endothelial cells and microbubbles obtained at 200 MHz. The visualization window has dimensions 50 μm × 50 μm and the scale bar corresponds to 15 μm.

V. CONCLUSION

Scanning acoustic microscopy equipped with time-resolved analysis provides unique opportunities for real-time monitoring of physiological processes and the assessment of mechanical properties of cells. Furthermore, the combination of SAM and targeted microbubble contrast agents offers the potential to bridge the understanding between the macroscopic factors of cells and their manifestation at the molecular level.

The interaction between microbubbles and ultrasound has been recognized to be fundamental for novel applications in the biomedical field. Nonetheless, the behavior of microbubble contrast agents at ultra-high frequencies remains to be more thoroughly understood.

Abstract — **Research on biofilms has benefited from the development of powerful new techniques to investigate their structure, function and morphology. Conjugated lectins combined with microbubbles and high-frequency ultrasound provides unique possibilities to obtain quantitative information on biofilm properties. High-frequency time-resolved scanning acoustic microscopy (SAM) offers a novel means to obtain the structural and material properties of biofilms. Noninvasive measurements were conducted by employing a high-frequency time-resolved scanning acoustic microscope operating at a center frequency of 100 MHz. Fluorescently labeled lectins were used in combination with targeted microbubbles, epifluorescence microscopy and time-resolved SAM for visualization and characterization of carbohydrate-containing extracellular polymeric substances (EPS) in the biofilms of *Pseudomonas aeruginosa*. In addition, ultrasonic reflectivity and transmission experiments were performed on biofilms alone and biofilms with targeted ultrasound contrast agents (UCA) in a water tank at frequencies ranging from 1 to 15 MHz. This data provides measurements of the reflection and transmission coefficients, over a broad frequency spectrum for a range of biofilm growth stages in both the presence and absence of targeted UCA.**

Keywords — **Biofilms, Pseudomonas aeruginosa, High-Frequency Ultrasound, Acoustic Microscopy, Mechanical properties.**

I. Introduction

In natural environments, many bacteria form surface-attached communities known as biofilms [1, 2]. Microbial biofilms are a complex community of sessile bacteria whose behavior is highly differentiated yet coordinated, and are profoundly different from their planktonic counterparts [1, 3]. These three-dimensional heterogeneous assemblages of microbial cells and exopolymeric substances afford bacteria with a protective degree of stability, a primitive circulatory system and a framework for the development of cooperative and specialized cell functions [4, 5]. Notorious for their high level of resistance against all forms of antagonistic chemical treatment; the role of biofilms are of medical interest due to their association with a variety of persistent infections [3, 6, 7].

Numerous methods are available for assessing the formation of biofilms, but their application is often limited by low sensitivity, time intensive intrusive sampling. Rapid, sensitive, and non-intrusive methods are needed for advances in real time monitoring of biofilm research.

Fluorescently labeled lectins, in combination with fluorescencent or confocal laser scanning microscopy, have been used in biofilm research to visualize, localize and biochemically characterize polysaccharides, monitor changes in polysaccharide composition, and to detect cell-cell interactions [8-10]. Despite these successes, the biotechnical and medical potential of using such lectins to identify and localize the presence or absence of a pathogenic biofilm in-situ has not been fully investigated.

The opportunistic pathogen, *Pseudomonas aeruginosa,* often associated with chronic airway infections synthesizes two lectins, LecA and LecB that play an important role in clinical infections [11]. The current study investigates the potential of employing fluorescently labeled lectins in combination with targeted microbubbles and high-frequency time-resolved scanning acoustic microscopy to identify and localize the presence of a *Pseudomonas aeruginosa* biofilm in-situ.

II. Time-resolved acoustic microscopy

Ultrasound imaging is widely used for a range of medical applications. Scanning ultra high-frequency time-resolved acoustic microscopy, in particular, is an emerging and promising technique. A short burst of ultrasound is emitted from a transducer and directed into tissue. Echoes are produced as a result of the interaction of sound with tissue, and some of these are reflected back to the transducer. By timing the period elapsed between the emission of the pulse and the reception of the echo, the system provides information on local changes in mechanical properties without any

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 750–753, 2009
www.springerlink.com

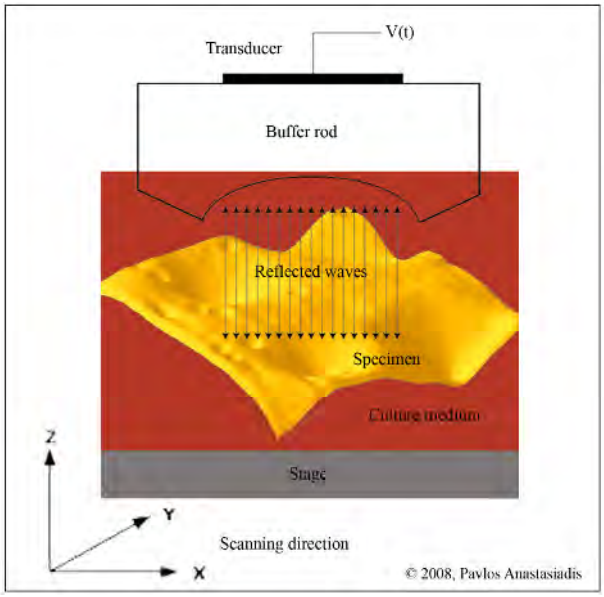

Fig. 1 Scanning acoustic microscope principle.

physical contact with the specimen. Echoes are generated when the propagating ultrasound wave encounters an object with different acoustic impedance. When the sample is significantly smaller than the acoustic wavelength, echo is generated through scattering. This is the origin of the echoes within the biofilm. Finally, if the acoustic wave encounters an interface that is relatively large with respect to the wavelength, then reflection occurs. This is the situation for the substrate/biofilm interface.

Furthermore, microbubble contrast agents scatter incident ultrasound waves in their response to the alternating compression and rarefaction cycles. Their gas content is much more compressible than cells or their surroundings such that they oscillate about their equilibrium radii. This difference in acoustical impedance and compressibility allows for an enhanced ultrasonic image.

III. Materials and Methods

A. Pseudomonas aeruginosa biofilm growth

The bacterial species and strain used in this study was *Pseudomonas aeruginosa* PAO1 (provided by Tung T. Hoang, Department of Microbiology, University of Hawaii at Manoa, Honolulu, USA). A bacterial culture was prepared by inoculating one colony of 1.5 ml *Pseudomonas aeruginosa* strain PAO1 thawed from frozen stock to 100 ml Trypsin Soy Broth growth medium (TSB, T8907, Sigma-Aldrich, St. Louis, USA). The TSB growth medium was diluted in ultrapure water (Alfa Aesar, Ward Hill, MA, USA) and filtrated through a 22 μm filter. Subsequently, the mixture was incubated overnight for twelve hours and kept on the incubator shaker at 37 °C atmosphere and 160 RPM. After the overnight incubation, the culture of *Pseudomonas aeruginosa* was standardized to an optical density at 600 nm (OD_{600}) of 0.05 relative to the TSB growth medium by employing a spectrophotometer (Beckman Coulter, Inc., Fullerton, CA, USA).

Pseudomonas aeruginosa biofilm assays were conducted by adding three microliters of standardized culture in each of the pre-treated cover slips. Cover slips were previously treated with various acids and solutions to enhance hydrophilicity and make them charge neutral to improve biofilm attachment. The cover slips were then kept inside an incubator shaker at 37 °C and 160 RPM continuously for periods of 12, 24, 48, 72 and 96 hours respectively before harvesting the biofilms and image them by confocal scanning laser microscopy and ultrasonically.

B. Microbubble contrast agents and visualization

For the purposes of this study, lipid-encapsulated perfluorocarbon microbubble contrast agents with a mean diameter of 2.5 μm were employed (Targeson, LLC, Charlottesville, VA, USA).

The mircorbubble samples were washed twice in degassed aqueous saline by centrifugation (10^3 rpm for 5 min) to remove the lipids not incorporated in the microbubble shell. The concentration that was used throughout the study was $1\text{-}3\times10^8$ microbubble contrast agents per milliliter.

Prior to ultrasonic and confocal scanning laser microscopy imaging, the microbubble contrast agents were conjugated with 20μL Streptavidin AlexaFluor 568 (Invitrogen).

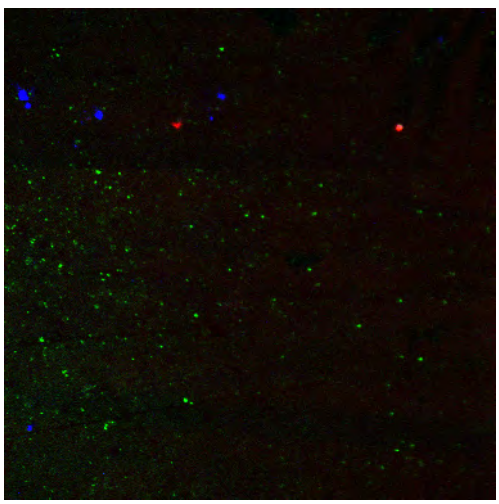

Fig. 2 Confocal scanning laser microscopy image of LecA after 48 hours.

The solution was incubated on ice for 30 minutes. After this time, the excess streptavidin was washed from the microbubbles by adding degassed phosphate buffered saline (PBS) to a 3mL lock-luer syringe attached to a one-way stopcock until a total volume of 2.0 mL within the syringe was reached.

Wheat Germ Agglutinate (WGA) AlexaFluor 488 and Concanavalin A (ConA) AlexaFluor 488 were both used as lectin proteins as both bind different polysaccharides. This is important because *Pseudomonas aeruginosa* biofilms have a tendency to switch polysaccharide makeup of their biofilm production. By using two different lectins that bind to polysaccharides, the chances of biofilm labeling are increased.

The final fluorescent label used was a DAPI, a nucleic acid dye that can be added to TSB media and taken up by the *P. aeruginosa* bacteria. The addition of this nucleic acid dye helps differentiate actual bacteria cells from the polysaccharide matrix of the biofilm.

C. Ultra high-frequency acoustic microscopy

For the purposes of this study a scanning high-frequency time-resolved acoustic microscope with a center frequency of 100 MHz (SASAM, Fraunhofer IBMT, St. Ingbert, Germany) was employed. The transducer mechanically scans laterally over a region of interest, and forms a 2D image using echoes from a series of adjacent transducer beam locations (Fig. 1). The lateral resolution of the system lies in the range of 10-15 μm. At a given beam location, the received ultrasound echo is converted into a brightness scale that is subsequently displayed as one line on the image. The growth medium was refreshed before conducting ultra high-frequency measurements.

D. High-frequency ultrasound measurements

The longitudinal wave data is obtained by the ultrasonic broadband substitution method [12]. This technique provides a means of determining both the attenuation and phase velocity profiles, simultaneously, over a range of frequencies. Briefly, a broadband pulse is generated by a ceramic acoustic transducer (Olympus NDT, Waltham, MA) that is electronically excited by a pulser/receiver (PR5900, Olympus NDT, Waltham, MA). In a water tank, the pulse is either received by another similar ceramic transducer aligned along the wave propagation direction, or received by the same transducer via an aluminum reflecting block. The received signal is digitized by a digital oscilloscope of 500 MHz bandwidth and 5-GHz sampling rate (Waverunner 6051A, Lecroy, Chestnut Ridge, NY). The sample is then inserted between the two transducers (or the single transducer and the reflecting block), allowing the sound beam to propagate, normally, through the sample. The waveform transmitted through the sample is then digitized by the oscilloscope. A complex spectrum is obtained from the sample waveform data, which are then divided by the spectrum from the water, with no sample present. This ratio allows for the determination of the sample's longitudinal phase velocity and attenuation, concurrently. A range of broadband transducers were used to cover the medical relevant ultrasonic frequency range of 1 to 15 MHz.

Biofilms were grown on substrates consisting of 0.003 inch thick TPX polymer films (K-Mac Plastics, Wyoming, MI, USA) and placed in the water bath for insonification, as described above. TPX has an acoustical impedance very similar to that of water and causes virtually no perturbation of ballistic pulse as it travels through the sample/substrate; hence reflection or transmission data can be analyzed without regard to film interference. In order to infer bio-film mechanical properties, acoustic microbubbles are used, which have a high echogeneity where biofilms do not. The micro-bubbles, therefore, act as the necessary coupling agent between the sound and the biofilm. Biofilms with and without attached microbubbles were characterized ultrasonically, in the manner explained above, to quantify the degree of micro-bubble attachment to the films. This quantification can be inferred from the inspection of either the reflected (backscatter) wave amplitude, or conversely by the transmitted (forward scatter) wave amplitude, which is shown over a broad range of frequencies.

IV. Discussion

Microscopy is a highly valuable approach to biofilm investigations, and especially confocal scanning laser microscopy can provide accurate 3D reconstructions. Nonetheless, this technique cannot be used to visualize unstained material or any other matrix which was not specifically treated [13]. Acoustic microscopy provides a non-invasive method which can be applied repeatedly on the same sample after subjecting it to different treatments or materials without the need of any staining or fixing procedure.

Time-resolved acoustic microcopy, in particular, provides a non-invasive visualization method in the field of medicine and biology. Moreover, SAM enables the real-time monitoring of physiological processes in living samples. The observation of changes in the mechanical properties by employing ultrasound with targeted microbubbles in general and ultra high-frequency combined with targeted microbubbles in particular offers the potential to provide new insights at the molecular level and to further assist understanding the complexity of biofilm pathways.

While other studies have focused only on morphology and thickness, this work examines the avenue of ultrasound molecular imaging by employing targeted microbubble contrast agents. Furthermore, it has been shown that high-frequency ultrasound signals can be sensitive to both tissue structure and cells undergoing apoptosis [14]. Thus, examining ultrasound signals reflected from different biofilm types or during growth, after therapy or treatment, may bear useful information and assist advancing considerably the understanding of biofilms.

A Comparative Study for Disease Identification from Heart Auscultation using FFT, Cepstrum and DCT Correlation Coefficients

Swanirbhar Majumder [1], Saurabh Pal[2] and Pranab Kishore Dutta [1]

[1] North Eastern Regional Institute of Science and Technology, Arunachal Pradesh, India
[2] Haldia Institute of Technology, West Bengal, India

Abstract — **We present a comparative study for correlation coefficients of three different, but popular transforms of audio signals i.e. Fast Fourier Transform (FFT), Cepstrum and Discrete Cosine Transform (DCT). But this study is done keeping into mind an important application, the heart sound analysis or heart auscultation analysis which manually is done by doctors for disease identification. We present a very simple automated software based approach for first detecting whether the heart is normal or abnormal and then identifying the disease if within the range of diseases for which it has been trained. Here our application has been trained for only three heart diseases, Mitral Regurgitation, Mitral Stenosis, and Splits. Further training might enable our application for identifying other diseases as well. We get better the detection accuracy with the increase of training data. We have taken the help of FBS (Frontiers in Bioscience) online data base for heart sounds for this purpose, and have used their .wav format of heart sound files for our analysis. But along with these we also found out that though Cepstrum is a very important transform for speaker recognition and other audio based application, but here in case of heart sound analysis it is not very user friendly for analysis.**

Keywords — **FFT, Cepstrum, DCT, Mitral Regurgitation, Mitral Stenosis, Splits**

I. Introduction

The heart sounds are generated by mechanical vibration of heart and cardiovascular where they provide abundant information about them while the measurement is noninvasive and low cost. Heart sounds and murmurs are the important parameter used in diagnosing the heart condition and it can be captured by using phonocardiogram or heart auscultation [3]. Classically the sounds made by a healthy heart are conceived as being a nearly periodic signal consisting of four components. These four parts are referred to as the first, second, third and fourth heart sounds as in Fig 1. The first two heart sounds give rise to the familiar 'lub-dup' beating sound of the heart and tend to dominate the Phono-CardioGraphic (PCG) signals [4].

First Heart Sound, S1 is the effect of closing the tricuspid and mitral valve at the beginning of ventricle systolic. There are four components of the first heart sounds. The first component is the effect of ventricular contraction and blood movement towards atrio-ventricular valve. This occurs at beginning of ventricle systolic. The second component is the effect of atrioventricle closure. The third component is reflected the opening of semi lunar valve and the beginning of blood ejection. The fourth and last component represents the maximum blood ejection from ventricle to aorta. Second Heart Sound, S2 represents the vibrations as a result from closure of semi lunar valve at the end of ventricle systolic. Since there are two component of semi lunar valve, the second heart sound is a combination of two components. The aortic valve closed earlier than the closing of pulmonary valve. Third Heart Sound, S3 results from vibration setting by early filling of ventricle during ventricle diastole. Lastly the fourth Heart Sound, S4 is caused by rapid filling of ventricle with blood during atrium systole. It also marked the end of ventricle diastole [8].

Each beat is separated by an interval of the order of around one second, with each heart sound having duration of roughly 50ms. The interval between beats varies even in a patient at rest because of respiration. Similarly the exact nature of each beat varies from beat to beat. The result is a signal which is non-periodic, even though it has a repetitive character.

The heart murmurs occur as the additional components in the PCG signal, most often arising in the interval between the first and second heart sound. Heart murmurs are the result of turbulent blood flow, which produces a series of many vibrations. The murmur signal is often of much smaller amplitude than either of the heart sounds. Many murmurs are described as "whooshing" sounds and are believed to be derived from flow noise. The heart murmurs will produce the abnormal heart sounds. There are four main factor of producing murmurs, firstly high rates of flow through normal and abnormal valves, then forward flow through a constricted or irregular valve or into dilated vessels, next backward flow through an incompetent valve, septal defect, or patient ductus arteriosus and lastly decreased viscosity, which causes increased turbulent and contributes to the production and intensity of murmurs

II. Different techniques

The different techniques we employ are FFT (fast Fourier transform), Cepstrum and DCT (discrete cosine transform). Fourier transform belongs to the family of linear transforms widely used in digital signal processing based on decomposing signal into sinusoids (sine and cosine waves). Usually in DSP we use the Discrete Fourier Transform (DFT), a special kind of Fourier transform used to deal with aperiodic discrete signal. Actually there are an infinite number of ways how signal can be decomposed but sinusoids are selected because of their sinusoidal fidelity that means that sinusoidal input to the linear system will produce sinusoidal output, only the amplitude and phase may change, frequency and shape remain the same. Discrete Fourier Transform changes an Ns point input signal into two Ns/2 +1 point output signals. The output signals representing the amplitudes of the sine and cosine components scaled in a special way as in equations (1) and (2).

$$C_K[i] = \cos(2K\pi/N_S) \quad (1)$$

$$S_K[i] = \sin(2K\pi/N_S) \quad (2)$$

where C_K are Ns/2+1 cosine functions and SK are Ns/2+1 sine functions, index K runs from zero to Ns/2. These functions are called basis functions. Actually zero samples in resulting signals are amplitudes for zero frequency waves, first samples for waves which make one complete cycle in Ns points, second for waves which make two cycles and so on. Signal represented in such a way is called to be in frequency domain and obtained coefficients are called spectral coefficients or spectrum. Frequency domain contains exactly the same information as the time domain and every discrete signal can be moved back to the time domain, using operation called Inverse Discrete Fourier Transform (IDFT). Because of this fact, the DFT is also called forward DFT. The amplitudes for cosine waves are also called real part (denoted as Re [K]) and for sine waves are called imaginary part (denoted as Im[K]). This representation of frequency domain is called rectangular notation. Alternatively, the frequency domain can be expressed in the polar notation. In this form, real and imaginary parts are replaced by magnitudes (denoted as Mag[K]) and phases (denoted as Phase[K]) respectively. The equations (3) and (4) are used for conversion from rectangular notation to the polar notation [7].

$$Mag[K] = \sqrt{(Re[K]^2 + Img[K]^2)} \quad (3)$$

$$Phase[K] = \tan^{-1}\left(\frac{Img[K]}{Re[K]}\right) \quad (4)$$

There are two main reasons why DFT became so popular in digital signal processing. First is Fast Fourier Transform (FFT) algorithm, developed by Cooley and Tukey in 1965, which opened a new era in DSP because of the efficiency of the FFT algorithm. The second reason is the convolution theorem, which states that convolution in time domain is a multiplication in frequency domain and vice versa. This makes possible to use high-speed convolution algorithm, which convolves two signals by passing them through the Fast Fourier Transform, multiplying and using Inverse Fourier Transform computing convolved signal. Here we use the fast Fourier transform to calculate the frequency components of heart sounds.

The Cepstrum [5] is representation of the signal normally having two components that are resolved into two additive parts. It is computed by taking the inverse DFT of the logarithm of the magnitude spectrum of the frame as in equation (5).

$$\text{Cepstrum (frame)}=\text{IDFT}(\log(|\text{DFT(frame)}|)) \quad \textbf{(5)}$$

The process of moving to the frequency domain provides the operation changing from the convolution to the multiplication. Then by taking logarithm, the operation is moving from the multiplication to the addition. That is desired division into additive components. Then it can be applied linear operator inverse DFT, knowing that the transform will operate individually on these two parts and knowing what Fourier transform will do with each part.

The most common DCT definition of a 1-D sequence of length *N* for $\boldsymbol{u} = 0, 1, 2\ldots N$ is:

$$C(u) = \alpha(u)\sum_{x=0}^{N-1} f(x)\cos\left[\frac{\pi(2x+1)u}{2N}\right] \quad \textbf{(6)}$$

Similarly the inverse transformation is defined for $\boldsymbol{x} = 0, 1, 2\ldots N$ is:

$$f(x) = \sum_{u=0}^{N-1} \alpha(u)C(u)\cos\left[\frac{\pi(2x+1)u}{2N}\right] \quad \textbf{(7)}$$

In both equations α(u) is defined as:

$$\alpha(u) = \begin{cases} \sqrt{\frac{1}{N}} \text{ for } u = 0 \\ \sqrt{\frac{2}{N}} \text{ for } u \neq 0 \end{cases} \quad \textbf{(8)}$$

Thus for $\boldsymbol{u} = 0$ we have the DC coefficient and other than that all others are the AC coefficients.

III. SIMULATION AND IMPLEMENTATION

Here we first get the samples of the test samples of normal heart sounds, and the test samples for the three diseases we are analyzing Mitral Regurgitation, Mitral Stenosis, and Splits. Then we go for the first step of detection of the four heart sounds S1, S2, S3, and S4 after undergoing discrete fourier transform on them. Thus based on their values we can detect the condition of heart i.e whether normal or abnormal as well as the heart rate value [2].

Then we take the all the test samples (normal and diseased) and find the FFT (Fast Fourier Transform) of the each one of them. On getting the Fourier coefficients, we get the value of correlation coefficient of each test sample with every other test sample and plot the graphs for normal & the three diseases. This method is replicated for the Cepstrum coefficients as well as the DCT (Discrete Cosine Transform).

Then we go for the analysis of those plots and decide on the specific correlation coefficient values which we can set as threshold for detection. All these operations were built in MATLAB® Release 2008a.

IV. RESULT ANALYSIS

Here firstly for the FFT coefficients we plot 12 test samples of which first three are normal, followed by three each of mitral regurgitation, mitral stenosis and split respectively. Thus figure 2, 3, 4 and 5 give the respective correlation coefficients for the FFT coefficients with each other for normal, mitral regurgitation, mitral stenosis and splits, respectively. Here we see that for each figure the correlation coefficients for the same type of heart sounds are above 0.7, while with others it is less. The analysis is plotted in Table I below for correlation of FFT coefficients.

Correlation coefficients of Cepstrum could not give the same amount of demarcation as provided by FFT coefficients.

Table 1: Analysis of Correlation coefficients of test samples for FFT coefficients

Test Sample	Coefficient	Analysis
Normal	Greater than 0.3	Normal Heart
Mitral Regurgitation	Less than 0.2	Normal Heart
	0.2 to 0.5	Mitral Stenosis
	Greater than 0.65	Mitral Regurgitation
Mitral Stenosis	Less than 0.3	Normal Heart Sound
	0.4 to 0.55	Mitral Regurgitation
	0.5 to 0.6	Splits
	Greater than 0.7	Mitral Stenosis
Splits	Less than 0.3	Normal Heart
	0.25 to 0.4	Mitral Regurgitation
	0.5 to 0.6	Mitral Stenosis
	Greater than 0.7	Splits

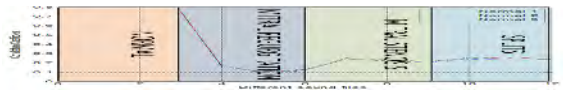

Fig 2: Correlation of FFT coefficients of Normal heart sounds

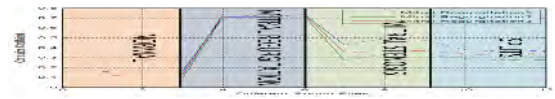

Fig 3: Correlation of FFT coefficients of Mitral Regurgitation heart sounds

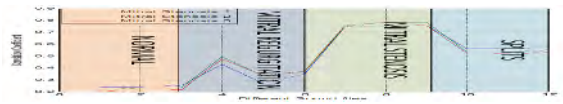

Fig 4: Correlation of FFT coefficients of Mitral Stenosis heart sounds

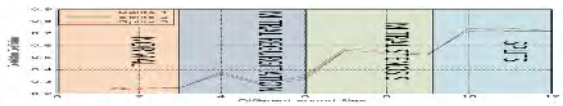

Fig 5: Correlation of FFT coefficients of Splits heart sounds

Though figures 6, 7, 8 and 9 do provide some details but there are some overlapping test sample data which cause conflict in decision making. Any way a partial analysis has been discussed about these plots in Table II based on the correlation of the Cepstrum coefficients with each other. The most alarming problem here is caused by the splits and normal Cepstrum coefficients data as here the splits Cepstrum coefficients give higher correlation with the normal Cepstrum coefficients this leading to erroneous result. Moreover the mitral stenosis based correlation of Cepstrum coefficients does not help in any type of analysis due to their random nature.

Correlation coefficients of DCT coefficients work in a similar pattern as that of FFT coefficients but the range of FFT coefficient was wider than this. Any way it still satisfies our need which can be seen from the figures 10, 11, 12 and 13. The analysis of this is given in Table III, which we can see is of similar type as in case of Table I for analysis of FFT coefficient correlation analysis.

Table 2: Analysis of Correlation coefficients of test samples for Cepstrum coefficients

Test Sample	Coefficient	Analysis
Normal	Greater than 0.87	Normal Heart
	0.7 to 0.85	Splits
	Less than 0.7	Mitral diseases
Mitral Regurgitation	Less than 0.8	May be anything
	Greater than 0.8	Mitral Regurgitation
Mitral Stenosis	Anything	No proper Analysis
Splits	Less than 0.2	Mitral Regurgitation
	0.6 to 0.7	Splits
	0.7 to 0.9	Normal Heart

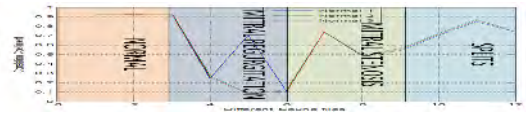

Fig 6: Correlation of Cepstrum coefficients of Normal heart sounds

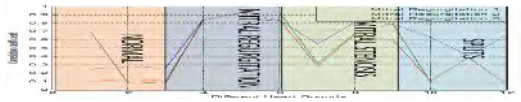

Fig 7: Correlation of Cepstrum coefficients of Mitral Regurgitation heart sounds

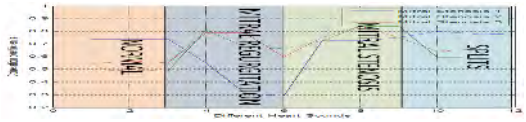

Fig 8: Correlation of Cepstrum coefficients of Mitral Stenosis heart sounds

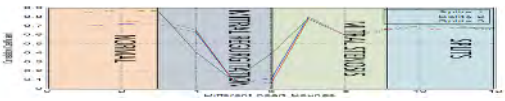

Fig 9: Correlation of Cepstrum coefficients of Splits heart sounds

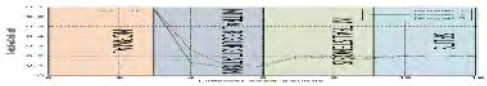

Fig 10: Correlation of DCT coefficients of Normal heart sounds

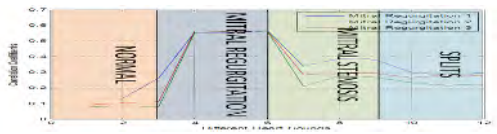

Fig 11: Correlation of DCT coefficients of Mitral Regurgitation heart sounds

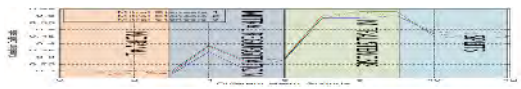

Fig 12: Correlation of DCT coefficients of Mitral Stenosis heart sounds

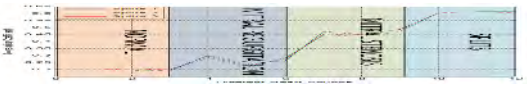

Fig 13: Correlation of DCT coefficients of Splits heart sounds

Table 3: Analysis of Correlation coefficients of test samples for DCT coefficients

Test Sample	Coefficient	Analysis
Normal	Greater than 0.25	Normal Heart
Mitral Regurgitation	Less than 0.2	Normal Heart
	0.2 to 0.4	Mitral Stenosis/Splits
	Greater than 0.5	Mitral Regurgitation
Mitral Stenosis	Less than 0.2	Normal Heart Sound
	0.3 to 0.4	Mitral Regurgitation
	0.4 to 0.5	Splits
	Greater than 0.57	Mitral Stenosis
Splits	Less than 0.2	Normal Heart
	0.25 to 0.3	Mitral Regurgitation
	0.4 to 0.5	Mitral Stenosis
	Greater than 0.6	Splits

V. CONCLUSIONS

Thus we can hereby conclude after analyzing the correlation coefficients of the FFT, Cepstrum and DCT coefficients of different normal and abn006Frmal heart sounds that DCT and FFT give best results for disease identification based on this method.

Multi Resolution Analysis of Pediatric ECG Signal

Srinivas Kachibhotla[1], Shamla Mathur[2]

[1] Govt.Institute of Electronics, Secunderabad, India (kbhotla_s@yahoo.com)
[2] College of Engg, Department of ECE, Osmania University, Hyderabad, India

Abstract — **This paper investigates the use of Multiresolution technique using Wavelet Transform for analysis of pediatric ECG signals. Wavelets are useful to describe signals at different levels of resolution. By means of multiresolution analysis, a signal can be decomposed into a set of signals (or scales), each scale containing only structures of a given size. The multiresolution approach allows a better understanding of the data values how they are distributed in a signal, and how the signal can be separated from the noise. The main advantage related to wavelet transforms is that they are localized both in the frequency and time domains. This paper presents a useful method based on the wavelet transform, for feature extraction of the Pediatric electrocardiograph (ECG) signals. The ECG signal is first denoised by a soft threshold and then each PQRST cycle is decomposed into a coefficients vector by the bioorthogonal wavelet function.**

Keywords — **The ECG Signal, PQRST cycle, Wavelet Transform, Frequency resolution, Depolarization**

I. Introduction

In signal analysis, there are a number of different functions one can perform on that signal in order to translate it into different forms that are more suitable for different applications. The most popular function is the Fourier transform that converts a signal from time versus amplitude to frequency versus amplitude. This transform is useful for many applications, but it is not based in time. To overcome this problem, mathematicians came up with the short term Fourier transform which can convert a signal to frequency versus time. Unfortunately, this transform also has its shortcomings mostly that it cannot get decent resolutions for both high and low frequencies at the same time. So how can a signal be converted and manipulated while keeping resolution across the entire signal and still be based in time? This is where wavelets come into play. Wavelets are finite windows through which the signal can be viewed. In order to move the window about the length of the signal, the wavelets can be translated about time in addition to being compressed and widened [1].

The Wavelet Transform (WT) is designed to address the problem of non-stationary ECG signals. It is derived from a single generating function called the mother wavelet by translation and dilation operations. The main advantage of the WT is that it has a varying window size, being broad at low frequencies and narrow at high frequencies, thus leading to an optimal time-frequency resolution in all frequency ranges.The WT of a signal is the decomposition of the signal over a set of functions obtained after dilation and translation of an analyzing wavelet [2].

The DWT represents a 1-Decomposition signal s(t) in terms of shifted versions of a low pass scaling function $\varphi(t)$ and shifted and dilated versions of a prototype band pass wavelet function $\psi(t)$.

$$\Psi_{j,k}(t) = 2^{(-j/2)}\, \psi\,(2^{-j}\, t - k) \qquad (1)$$

$$\varphi_{j,k}(t) = 2^{-j}\, \varphi\,(2^{-j}\, t - k) \qquad (2)$$

where: j controls the dilation or translation,
k denotes the position of the wavelet function

Discrete Wavelet Transform is also referred to as decomposition by wavelet filter banks. There are two kinds of data: the sparse data and the detailed data. These coefficients are extracted from the original set of number by using two kinds of filters, high pass (details) and low pass (approximations) The two filters are applied the filtered data from the high pass filter is stored as coefficients for later reconstruction of the signal. The filtered data from the low pass filter is now treated as the original data and the low and high pass filters are then applied to this data. This is repeated until the filtered data from the low pass filter outputs only one number. This is because DWT uses two filters, a low pass filter (LPF) and a high pass filter (HPF) to decompose the signal into different scales. The output coefficients of the LPF are called approximations while the output coefficients of the HPF are called details.The DWT can be calculated at different resolutions using Mallat-algorithm to utilize successive lowpass and highpass filters to compute DWT[8].

The procedure of DWT decomposition of a input signal x[n] is schematically shown in the Figure.1 above. Each stage consists of two digital filters and two down samplers by 2 to produce the digitized signal. The first filter, g[n] is the discrete mother wavelet, which is high-pass filter, and the second, h[n] is low-pass filter. As shown in Fig.2 above the down sampled outputs of first high pass filters and low-pass filters provide the detail, D_1 and the approximation, A_1. The first approximation, A_1 is decomposed again and this process is continued.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 758–760, 2009
www.springerlink.com

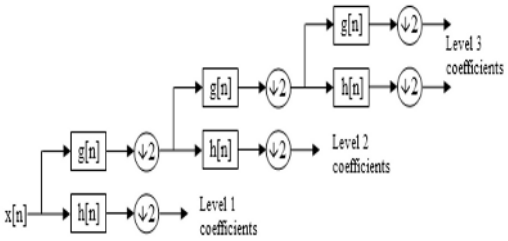

Fig .1 Decomposition of DWT

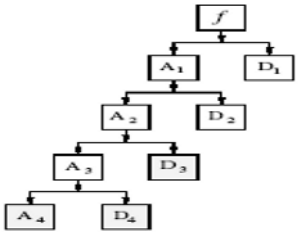

Fig.2 Four level DWT Decomposition

The decomposition of the signal into different frequency bands is simply obtained by successive highpass and lowpass filtering of the time domain signal. The signal decomposition can mathematically be expressed as follows:

$$y_{hi}[k] = \Sigma\, x[n].g[2k-n] \quad (3)$$

$$y_{lo}[k] = \Sigma\, x[n].h[2k-n] \quad (4)$$

II. ECG SIGNAL

The ECG signal, measured with an electrocardiograph, is a biomedical electrical signal occurring on the surface of the body due to the contraction and relaxation of the heart. This signal represents an extremely important measure for physicians, as it provides important information about a patient's cardiac condition and general health [3].Sinus or sinoatrial rhythm is the heart's normal mechanism, the driving impulses arising regularly in the sinus node and driving the heart at a rate between 60 and 100 beats per minute, this does not imply that rates outside this range are abnormal [4].As the heart undergoes depolarization and repolarization, the electrical currents that are generated spread not only within the heart, but also throughout the body. This electrical activity generated by the heart can be measured by an array of electrodes placed on the body surface. The recorded tracing is called an electrocardiogram (ECG, or EKG) [5].

III. RESULTS AND ANALYSIS

The ECG data for the analysis is taken from the MIT-BIH (Massachusetts Institute of Technology-Beth Israel Hospital Arrhythmia Laboratory) ECG arrhythmia database The ECG is of 2 years baby suffering from sepsis. The original Pediatric ECG was shown in Fig.3. We selected Pediatric signal here it is contaminated by noise of artifact and also to prove that bioorthogonal wavelet function which is used for our analysis best suited even under the noisy environment. Initially the signal is denoised as shown in Fig.4 using soft threshold scheme [6].

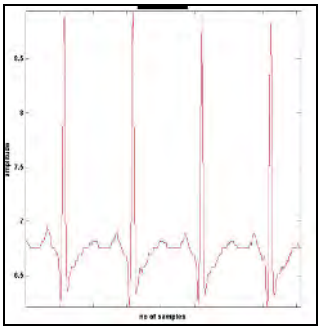

Fig.3 Original pediatric ECG

In the present work 'bior 1.1' wavelet has been used as the mother wavelet. For achieving good time-frequency localization the preprocessed Pediatric ECG signal is decomposed by using the DWT up to the fourth level. The 4-level wavelet decomposition structure is shown in Fig.5 and the resultant uncorrelated five subsets of coefficients are used for further processing. Most of the energy of the ECG signal lies between 0.5 Hz and 40 Hz [7]. It is observed that this energy of the wavelet coefficients is concentrated in the lower sub-bands. The detail information of levels 1 and 2 are discarded, as the frequencies covered by these levels were higher than frequency content of the ECG.

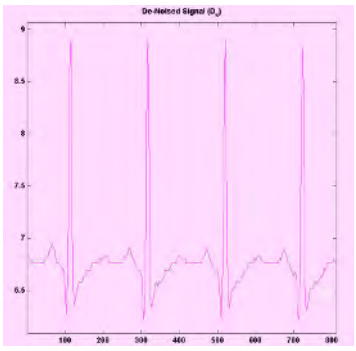

Fig.4 Denoised Pediatric ECG

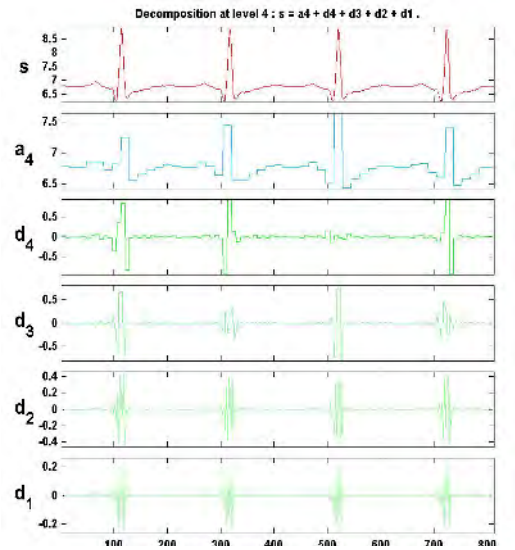

Fig.5.Decomposed Pediatric ECG at Level 4

There are eleven characteristic points in one ECG period.(maximum amplitude of R wave, beginning and maximum amplitude of Q wave, maximum amplitude and end of S wave and beginning ,maximum amplitude and end of P and T waves. Selectable parameters are type of wavelet, order of wavelet and number of decomposition levels.

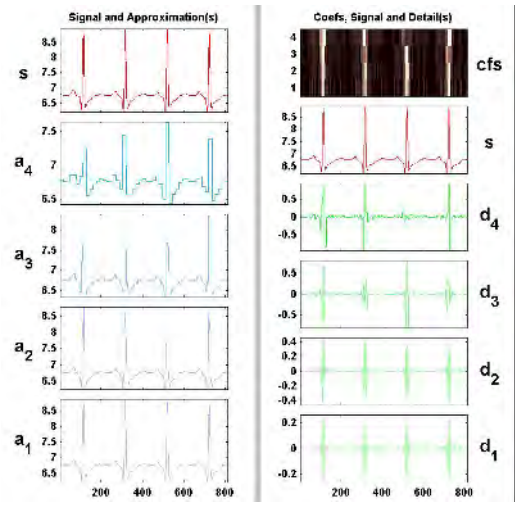

Fig.6 Decomposed signal with approximation and details separately

The characteristic points are found on decomposition of the signal by DWT. Fig.5 shows the original pediatric signal at the top of the plot. Below the signal, the details of all four levels and average value of the fourth level is shown for better illustration. Adding all the details plus remaining signal approximations reconstructs the original signal.Fig.6 shows the all approximations and details at all levels and along with plot of coefficient vectors. R_{max} is found as zero crossing on all details. It is more pronounced in the level1 and level 2 approximations. Q_{peak}, $S_{peak,}$ and S_{offset} also clearly visible and found in a lower levels of details. Finally P and T waves onsets, peaks, offsets are detected in approximations by denosing individual components. Similarly Q and S wave parameters are detected on fourth detail. Unlike the adult ECG features the Pediatric ECG features found in approximation component because of the heart rate of Pediatrics is nearly 120 beats/min.

IV. Conclusions

Selecting a Wavelet function is depends on signal characteristics. In this paper we applied bio-orthogonal wavelet functions which have high reconstructing ability. Bio-orthogonal wavelets are useful when the filters in decomposition require to be asymmetric and our results proved that it is best suited for ECG signal even under the noisy environment and most complicated pediatric signal denoising and feature selection

3D CT Craniometric Study of Thai Skulls Revelance to Sex Determination Using ogistic Regression Analysis

S. Rooppakhun[1,2], S. Piyasin[2] and K. Sitthiseripratip[3]

[1] School of Mechanical Engineering, Institute of Engineering, Suranaree University of Technology, Thailand
[2] Department of Mechanical Engineering, Faculty of Engineering, Khon Kaen University, Khon Kaen, Thailand
[3] Medical Rapid Prototyping Laboratory, National Metal and Material Technology Center, Pathumthani, Thailand

Abstract— **This study aimed to evaluate the sexual dimorphism in the Thai dry skull based on three-dimensional computed tomography (3D CT) data, and to develop practical a logistic regression model for the sex determination. A total of 21 cranial measurements were investigated from 56-male and 35-female skulls of known sex and race. 3D CT craniometry with identified landmarks and calculated measurements were performed using medical image processing software (MIMICS, Materialise N.V., Leuven, Belgium). According to craniometry, the results indicated that the dimensions of male skull were larger than that of a female. Of 4 cranial measurements displayed non-significant ($p < 0.05$) sexual dimorphism (maximum frontal breadth, anterior interorbitale breadth, nasal breadth, and palatal length). The logit response model was as follows: ln (odds) = Z = 79.759 – 0.392(NA-BA) – 0.200(ZM_l - ZM_r) – 0.520(NA-PR) +0.332(OR-STA). These had the overall accuracy of 92.3% and the accuracy of 92.85%, 91.42% among males and females, respectively (using cut off point for P = 0.5). Using a logistic regression analysis, 3D CT craniometry can be used to determination of sex among Thai.**

Keywords— **Three-dimensional, Craniometry, Thai, Sex determination, Logistic regression analysis.**

I. Introduction

The determination of sex from human skeleton remains is a critical component in forensic anthropological investigation. Normally, the determination of sex has been invented either using a metrical or non-metrical assessment, followed by uni- and multivariate statistical analyses [1, 2]. The accuracy of the sex determination varies considerably between different osteological elements (such as the tibia, femur, humerus, mandible and cranium, etc.), and also between different human populations are reported [1-6].

Normally, the instruments used to measure the skull were osteo metric board, the Mollison's craniophore, and the spreading and sliding calipers [7]. Although, these direct measuring devices can provide accurate and reproducible three-dimensional (3D) surface measurements. But several limitations include the time required for collecting data, as well as storing and reconstructing these data for 3D purpose is reported [7, 10]. With regard to the Thais skull studies, there are almost cranioscopy and craniometry by using either conventional or 3D coordination method. The sexual dimorphism differences in mean and index between genders were reported [12-15].

Currently, the introduced 3D CT software which enables 3D reconstruction and assesses craniofacial morphology is become widely used [8, 9]. Since, it can give much information including complete measurement details which possible to derive linear landmarks, inter-landmark distances, and the special angular measurements. Also these can store in the template file and recall for fast retrieval during subsequent landmark identification which are comparable with the large collection of traditional anthropological data available [10, 11]. In this study, we examined the sexual dimorphism in the skull of Thais based on 3D CT analysis, and developed a logistic regression model for the sexual determination.

II. Meterial and method

A. The reconstructed data acquisition

A CT data base of Thai dry skulls collected in the north-east of Thailand from Department of Anatomy, Medicine, Srinagarind Hospital collections were used. The samples were 56 males and 35 females with age ranging from 26 to 80 years at the time of death. A prepared set of four skulls was created using prepared acrylic box of in each CT scan following a strict protocol axially at 120 kV and 100 mA as shown in Fig 1. The slice thickness was 1.5 mm and the

Fig.1 A prepared set of four skulls for each CT-scanning

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 761–764, 2009
www.springerlink.com

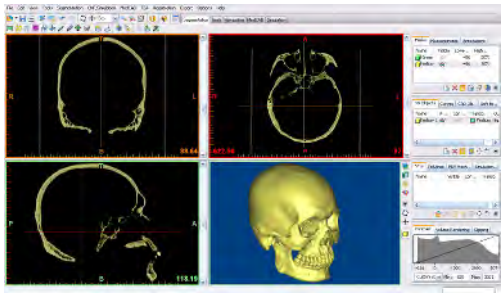

Fig.2 The 3D reconstructed model that can be shown in coronal, axial, and sagittal views

reconstruction interval was 1.0 mm. All CT data set were recorded using DICOM 3.0 format into CD-ROM, and subsequently imported to commercial image-processing package (MIMICS, Materialise N.V.) which saved into *.mcs files (MIMICS project files). Using *segmentation* module, the data were reconstructed into 3D image which manipulated by extract the boundaries of the each skull from the CT data set as shown in Fig 2.

B. 3D CT craniometric analysis

Using *Measure & Analyze* module, the craniometric analysis was performed. The anatomical landmarks were identified into the 3D image which precisely verified their positions on multi-planar layout views as shown in Fig 3. A

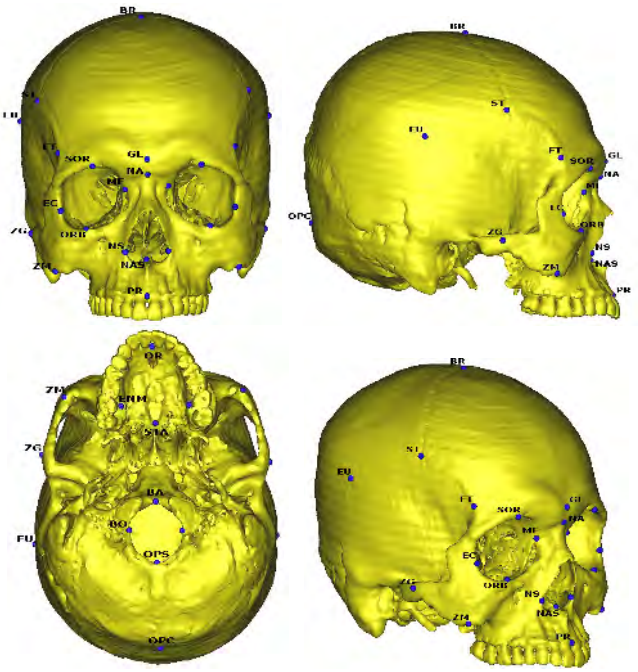

Fig. 3 The anatomical landmarks used in study

total of 21 cranial measurements were calculated and stored into *.xls files (Excel XP^{TM}). Because inter-landmark distances were calculated between the coordinates of the skeletal structure in 3D space, thus the error of magnification or head positioning was avoided.

C. Statistical data analysis

For the descriptive statistics, 3D craniometrical measurement was reported. P-value, difference of mean, and 95% CI of the difference were reported. A 2-tailed p-value of less than 0.05 was examined statistically significant. A binary logistic regression analysis using forward stepwise method was applied to determine logistic response model with the best prediction of gender. Measurements with high colinearity were not excluded in the model fitting process. Statistical data analyses were performed using the SPSS 13.0 software program (SPSS^{TM}, Inc)

III. Results & Discussion

In Table 1, the mean, standard deviation (SD), and standard error of mean (S.E.) of the measurements in both sexes are presented. The analysis of variance (e.g., mean difference, 95% CI diff, and p-value) is used to compare mean measurement values. Examination of the results indicates that males are larger in all dimensions. Of the 21 measurements compared, 17 are shown significantly different ($p < 0.05$); the 4 non-significant measurements are maximum frontal breadth, anterior interorbitale breadth, nasal breadth, and palatal length. And also, the 4 measurements expressing the greatest dimorphism ($p << 0.001$) are nasion-basion length, maximum cranial length, basion-bregma height, and bizygometic breadth.

Using logistic regression analysis, a forward conditional method is used to fit the best discrimination between genders. The logit response function was then calculated and revealed that 4 of 21 from the cranial measurement were significantly predictors ($p < 0.05$). The coefficient (b), standard error, and significant values of each measurement are reported in Table 2. The logit response model was as follows: $\ln(\text{odds}) = Z = 79.759 - 0.392(\text{NA-BA}) - 0.200(ZM_l - ZM_r) - 0.520(\text{NA-PR}) + 0.332(\text{OR-STA})$. From the following logit response function of Z (Table 2), the probability of being a

male (P) can be calculated through $e^z / (1+e^z)$ ($e = 2.718$). So the probability of being a female is then 1–P. These had the overall accuracy of 94.6% and the accuracy of 93.9%, 95.7% among males and females, respectively.

With regard to sexual determination from the skull, using a stepwise discriminant function analysis, Steyn [4] presented the equations for the sexual dimorphism in the crania and mandible of 91 South African Whites (44 males and 47 females). The average accuracy in correct sex classification ranged from 80% (bizygomatic breadth) to 86 % (cranium). The dimension from the complete cranium provided the best accuracy and the bizygometic were the most dimorphic of measurements. Franklin et. al., [2] presented the function from 322 indigenous South African crania (182 males and 150 females). The facial width (bizygometic breadth) was the strongest discriminating morphometric variable, and cranial length, basi-bregmatic height is the next most significant features. The overall accuracy of sex determination varied between 77 to 80%, with 78% of a single measurement (bizygometic breadth), and 75 to76% of the separate functions (calvaria and face). Dayal et al., [1] proposed the function using discriminant function analysis for sexual assessment in black South Africans skull. The three measurement (bigonial breadth, mandibular ramus height, and total mandibular length) using stepwise analysis from the six mandibular measurements had shown the sex classification rate of 85%. An average accuracy of 80.8%, 80.0 % was obtained for stepwise analysis using cranial and all significantly difference measurements, respectively.

For the study of Thai skull, Sangvichien et.al, [13] presented logistic model which consisted of four craniometry measurements(e.g., nasion-basion length, maximum breadth of the cranium, facial height, and bizygometic breadth) via the forward method. The overall accuracy of correct sex classification was 88.8%, and 82.9%, 92.1% among females and males, respectively. However, Boonkaew [1] recommended that the sexual classification from Krogman's cranioscopy were the best method with an overall accuracy of 91.1%, and 82.9% for females, and 95.5% for males. In comparison to this, our study yielded higher accuracies than the previous study. We attributed our good results to a number of factors. First, most of the previous studies rely on manual measurements using conventionally technique or directly measurement, while we used 3D CT system for indentified landmark and extracted measurements. Second, we established the function from difference sample.

IV. Conclusions

Using 3D CT craniometry, the skulls of Thais have been shown to be sexually dimorphic. Logit response model has also been derived from various combinations of these measureents. The authors suggest that these functions cloud be applied to the Thai population for assessing the skeleton gender.

Abstract — **In order to find EMG indices that can be used for quantification of rigidity in PD, EMG signal of arm flexor and extensor was recorded for the group of patients consists of 16 persons and group of controls consists of 8 persons. This was repeated in two situations of rest and voluntary contraction. Using statistical methods, correlation of indices and rigidity aspect of qualitative method for evaluation of disease was checked. Although mean values of all indices were different in the groups of controls and patients, no significant statistical difference was seen in most of them between two groups. This could be the result of big variances. Also, the average of maximum amplitudes of rectified signal in rest has the highest correlation with the rigidity examined with the qualitative method. EMG indices of Extensor muscles have the priority for the objective evaluation of Parkinson's disease. This verifies the fact that in Parkinson disease, extensor muscles are more affected than flexor ones.**

Keywords — **EMG, Rigidity, Parkinson's disease, quantification.**

I. Introduction

These Parkinson's disease (PD) is a neurodegenerative disease which is caused by degeneration of cells in a part of brain called substantia nigra[1-3]. PD leads to a range of syndromes which can be divided in three main groups of motion deficits, sensory deficits and emotional deficits. Motion deficits caused by PD are:

1- Tremor at rest which is an involuntary rhythmic movement with a frequency of 6-7 Hz, mostly obvious in hands [1, 2].
2- Rigidity of limbs which is presence in all range of motion and does not decrease with repetition [2].
3- Slowness of motion which leads to problems associated with everyday tasks and is directly related to the passive rigidity of limbs [1].

By the time, subjective method called Unified Parkinson's Disease Rating System, UPDRS is implemented for the evaluation of disease and its level. The method has a qualitative rigidity measure which groups patients from 0 to 4. Zero indicates no unmoral rigidity and four indicates high rigidity and freeze. In some cases surface EMG is performed.

Most of research done on EMG has been goaled at detection between patients and controls [4-7]. Lokhania and co-workers [5] studied the relation of EMG and Movement aspects of UPDRS. Anyhow, no good relation was found.

In the present study, the aim was to consider more indices out of EMGs for more cases. Furthermore, local amplification which was used in this research was considered a way to decrease signal to noise ratio.

II. Material and methos

Data acquisition was performed Using EMG device indexed NOSSX230, manufactured by Biometrics, UK. The device was consisted of skin probes, eight-channel switcher and an amplifier which was connectable to a pc via USB port. Each probe had two skin electrodes and a built in preamplifier with gain of 1000 and band pass of 20-450Hz. Local amplification was considered to minimize noise, because desired signals of about 1 mv. were amplified only [8].Data was monitored and saved using Data Link software which came with the device. The software also had processing items which was used to extract research indices out of EMG data saved.

EMGs of flexor m. m. biceps and lateral head of triceps brachii were simultaneously acquired with two probes in both situations of rest and voluntary contraction. The procedure was performed for 16 parkinsonian referees to neurology clinic of Rasoul hospital, Tehran, Iran and 8 controls. Parkinsonians were 13 male and 3 females with mean age of 57.93 years old and controls were 6 males and 2 females with mean age of 42.37.

As a protocol, for the rest situation, the patient was asked to put his/her arm on a support, with no voluntary contraction and no remarkable mental activity. In contraction mode, patient was asked to flex and extend his/her arm after the "start" command.

In addition to EMG tests, UPDRS rigidity score was measured by the neurologist co-worker for each individual case for later use on. The procedure was the same as what neurologists always do to qualify the patient's rigidity: passive movement of flexion and extension was done

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 765–768, 2009
www.springerlink.com

on upper limbs of patient to find how rigid they are. Rigidity was measured in two situations of with and without reinforcement. In reinforcement protocol, patient was asked to perform a movement in mirror lime which was examined.

Using Data Link software the following indices [9,10] were calculated out of EMG data saved:

1- Average amplitudes of rectified resting EMG for 5 ms, ARa
2- Maximal amplitudes of rectified resting EMG for 5 ms, Arm
3- Surface integral of rectified resting EMG for 5 ms, Sint
4- Root mean square of resting EMG for 5 ms, RMS
5- Average EMG amplitude on a section with most marked changes in muscle activity under voluntary contraction ,AVCa)
6- Phasic Activation coefficient, PhAC where $PhAC = (AVCa-ARa)/AVCa$

Indices number 3 and 4 have not been studied in previous researches. In particular index number 3 which indicated the mechanical work was considered to be an important index.

Spss-13 software was used for statistic means [11]. Mann-Whitney test was performed to find the significances of differences between control/patients groups and spearman's correlation test was performed to check the correlation of each index and UPDRS levels.

III. Results

Mean values for almost each index were different in groups of control and patients (table1).

Statistic tests showed different significances in different indices (Fig1-3). ARm for both of flexor and extensor had significant difference ($p<0.05$). Other indices including ARa, SInt, RMS and AVCa had significances just for the extensor muscle. PhAc of the extensors in group of patients had negative std. The reason was the negative values of the index in two cases.

Totally, no good correlation ratio was found between indices and UPDRS levels (Fig 3-7). Looking at table1 It can be inferred that high stds in indices has lead to this problem.

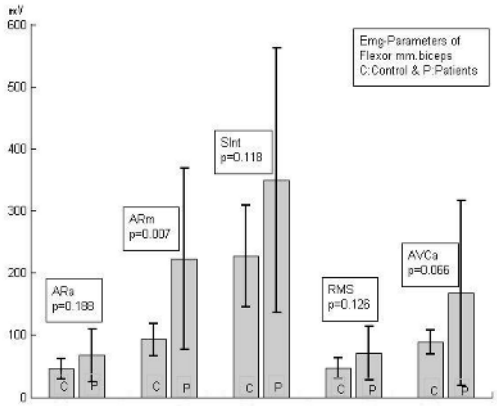

Fig. 1 P-value of Mann-Whitney test for flexor indices

Table1. Mean and std for research indices. UPDRS-R was measured with reinforcement.

	Control				Patients			
	Flexor		Extensor		Flexor		Extensor	
	Mean	Std	Mean	Std	Mean	Std	Mean	Std
ARa	45.38	16.142	43.50	13.959	67.44	42.258	83.31	48.397

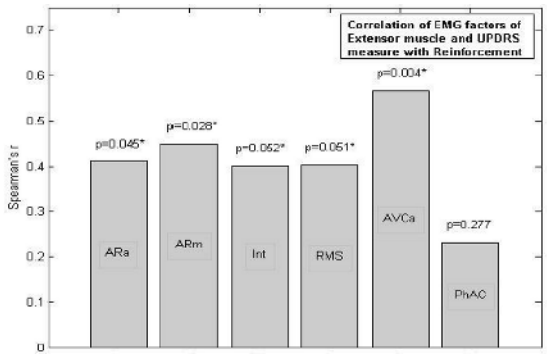

Fig. 7 Correlation ratios of extensor indices and UPDRS measured with reinforcement

IV. Discussion

In the present research, EMG signals of flexor and extensor of the arm was recorded in two groups of controls and parkinsonians. The procedure was done in two situations of rest and voluntary contraction. Statistic tests were performed to find relation between quantified indices of EMG and UPDRS levels measured.

Statistically, indices related to triceps brachii had higher significances than those of m. m. biceps. This finding showed that extensors are more affected by PD than flexors and was reported previously.

Although, indices had different mean values in groups of control and PDs, except for the ARm, there were no good significances in indices of m. m. biceps. This can be addressed to high stds of indices which is a known characteristic of EMG signal.

The highest linear regression ratio to UPDRS was found between ARm and UPDRS measured in reinforced situation (r= 0.528). Totally, regression ratios with UPDRS in reinforced situation were higher than none reinforced situation.

Use of local amplification which leads to decrease in signal to noise ratio was considered in current research. This was previously considered by Flament and co-workers [6]. In the former research the amplification ratio was 10 whilst in present study the ratio was 1000.

Mean values of ARa and ARm measured from m. m. biceps of both control and patients groups in present study were higher than what was previously calculated [5]. Any how in both researches increase in mean values of these two indices for patients than controls were obvious. This had been addressed to damage in relaxation mechanism of PDs [5].

PhAc index of m. m. biceps calculated in this study was closed to what had been reported before [5]. There were no significances related to this index in both researches. In two cases PhAc was calculated negative which was result of higher activity at rest than contraction and was reported in former study [5].

To find a more reliable relation between quantified indices and UPDRS rigidity level, it is suggested to exam more cases and to use more than one neurologist on a case. The later suggestion was previously implemented by Patric and co-workers [12].

V. Conclusion

It can be concluded that direct measurement of rigidity like what had been previously done [12, 14] may better characterize the level of rigidity in PD than what can be done using EMG.

A Test for the Assessment of Reaction Time for Narcotic Rehabilitation Patients

S.G. Patil[1], T.J. Gale[1] and C.R. Clive[1]

[1] School Of Engineering, University Of Tasmania, Hobart, Australia

Abstract — **Reaction Time Testing has been successfully used in various areas of research and is potentially a good assessment technique for narcotic rehabilitation patients. However, the number of reaction time samples required from each subject for accurate assessment can be a hindrance in using this test. Therefore in this study we proposed to study the effect of sample size on accuracy and the inter-person differences with normal subjects with a reaction time test of our design. Five normal subjects were tested repeatedly. No significant difference among the mean reaction times of the 5 subjects were found indicating that the test was reliable and the mean of all 5 correlated well with literature values. The test is reliable with normal patients and will be trialed as an assessment tool for use in research with narcotic rehabilitation patients.**

Keywords — **Reaction time test, Narcotic rehabilitation, opioid assessment**

I. Introduction

Reaction time tests have been used in various areas of research including recovery from Althesin anaesthesia, spatial attention after brain damage, etc [1]. We have previously proposed reaction time testing in the assessment of opioid dependent patients [2]. Symptoms of opioid intoxication are the typical symptoms of sedation, including slurred speech, delay in reaction to stimuli and drowsiness.

The test proposed was reaction time to a visual stimulus. Here we describe the test we have designed to evaluate the use of reaction time in the assessment of the levels of intoxication of narcotic dependent patients participating in narcotic replacement program.

In general there are three types of reaction time test. Simple, Recognition and Choice. The simple reaction time test is one reaction to one stimulus, while the recognition reaction time test is either reacting or not reacting depending on the stimulus. The choice reaction test on the other hand has equal numbers of stimuli and responses. In our study we propose to use a simple reaction time test [3].

The number of reaction time samples needed to be acquired as one test set is an important parameter that determines the power of the test in resolving inter and intra person differences. Professional psychologists doing Choice reaction time tests typically employ about 20 people doing 100-200 reaction times each per treatment. [4] recommends an adequate period of practice, and then collection of 300 reaction times per person. This number may not be feasible with narcotic rehabilitation patients as it is very easy for them to feel uncomfortable with such a monotonous test taking such a long time.

For about 120 years, the accepted figures for mean Simple reaction times for college-age individuals have been about 190 ms for light stimuli and about 160 ms for sound stimuli [5, 6]. In addition it was also shown that visual stimuli that are longer in duration elicit faster reaction times [7].

In the present study our aim is to conduct pilot experiments on normal university-age individuals and investigate the effect of sample size on accuracy and the inter-person differences in reaction times using a simple reaction time test of our own design. These results will subsequently help us design tests for assessment of patients undergoing narcotic replacement programs.

II. Method

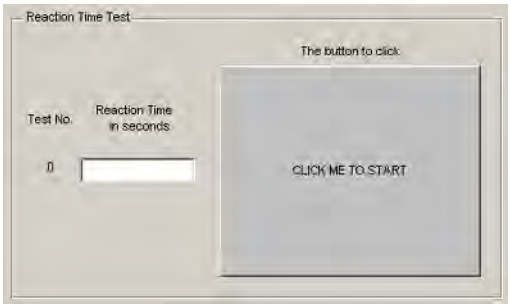
A. Research Participants

Five subjects were used in this study. The subjects were invited from the School of Engineering, University of Tasmania, who volunteered to participate after being briefed about the aims and procedure of the test. The subject ages were 20, 22, 26, 24 and 29. The subjects were considered as a control group as no obvious signs of abnormality were observed. The subjects were also informed about the test 24hrs before the test was conducted so that they were mentally aware and prepared for the test. The subjects were given a demonstration on how the test works. On the given day the subjects were asked to do their normal daily activity as per routine. The test was conducted on each subject one after the other till all 5 subjects were tested. This procedure was repeated 5 times. Each test lasted approximately 3-5 minutes and after that a gap of 5 minutes to reset the test and prepare the next subject for the test. In between test periods each patient was allowed to do their routine work. Most of them just went back to their desk and continued working until their turn to be tested.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 769–773, 2009
www.springerlink.com

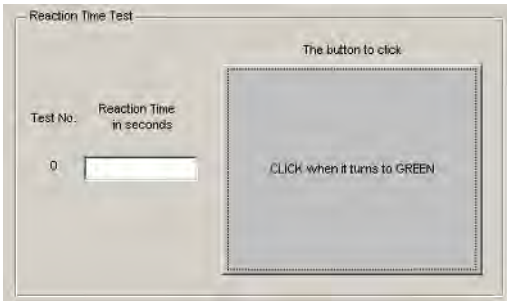
B. Test Design

The test was developed in Matlab R2006b (Mathworks, USA). A stimulus was displayed on the background of a grey screen of a 15" SVGA monitor placed at a distance of 80 cm from the eyes. Screen resolution was 1280 X 1024 pixels. A single target, a bright green fluorescent filled square with dimensions 7 cm (height) by 4.5 cm (width) was used as the visual stimulus. The target transforms to green color from grey color at random time intervals during the test. The time between the color change to the clicking of the left mouse button is recorded as the reaction time. The reaction time in milliseconds was displayed in a text box besides the target. The test number increments with each response from the user. The software was designed to record 60 reaction times in one set.



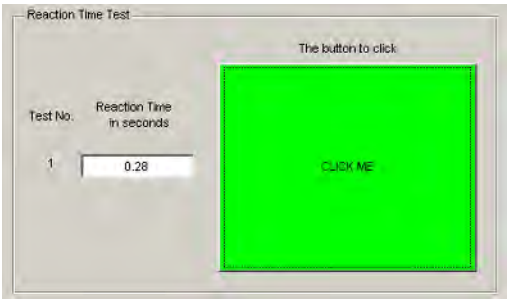
C. Test Procedure

The subjects sat on a chair in a lit room and instructed to look at the monitor and click the left mouse button as soon as, but not before, the stimulus turned green. The computer mouse was kept at the same height used by the subjects in their workplace. To more closely simulate normal conditions, fixation was not required but, to ensure that the participants did not divert their gaze constantly, the background of the monitor was turned to grey, similar as the background of the stimulus when not green. The test was interrupted if the participant slumbered, or distracted, or volunteered to stop, although this was seldom needed.



Prior to the initiation of the test, the subjects were shown examples of the working of the test system. Next, they performed a training session of one trial in which targets appeared in random intervals 10 times. Following the trials the participants were asked to do the real test. A few minutes rest was given after each test of 60 responses, during which the subjects were allowed to do whatever they liked but were asked not to eat or drink anything except water.

Fig 1 shows a step wise illustration of one reaction time test. Initially the computer screen as well as the test software is grey in color. The stimulus button or the target to be clicked is clearly seen in rectangular shape with "click me to start" written on it.



Once the user clicks the left mouse button the test starts. After clicking the target changes the message on it to "CLICK when it turns green". Once the target turns color to green the user has to respond by clicking the left mouse button. The time taken from the target turning green to the user clicking the mouse is considered the reaction time. The time is displayed in the text window besides the target in seconds.

(d)

Fig 1. An illustration of the reaction time test. (a) The screen when the trial starts (b) The screen when the grey button is clicked (c) The buttons turn to fluorescent green (d) The target turns back to grey and repeats (a)(b)(c)

D. Data Collection and Analysis

The test was designed to save the reaction times in a text file. The data obtained was averaged to obtain the mean value for each subject. To test the reproducibility of the technique, the results for each subject were compared using statistical tools in MS Excel. The Mean ± SD of each test and for all tests for each subject were plotted and compared. T-test was used to find any significant differences in inter and intra subject reaction times. A moving average representation of intra-subject data was used to see the trend of reaction times over the course of the test

The data was assumed to be normally distributed and confidence interval of the mean was calculated. The following expression was used to calculate the upper and lower 95% confidence limits

Upper 95% Limit=x+(y*1.96)

Lower 95% Limit=x-(y*1.96)

Where, 'x' is equal to the sample mean, 'y' is equal to the standard error of the sample, and 1.96 is the .975 quantile of the normal distribution.

III. Results

The reproducibility test showed that the reaction time for all subjects agreed well with a mean percentage SD of 10.7%. The intraclass correlation coefficient (correlation of the 5 test sets) for 95% confidence level was r = 0.922 ($p <$ 0.001), which showed a high reproducibility.

The Mean ± SD obtained from all data from the 5 subjects was 0.42± 0.1. The individual Mean ± SD obtained in the 5 subjects is shown in Fig 2. No significant differences were observed between the subjects S1, S2, S4 and S5, however a significant difference ($p<$ 0.01) was observed between S3 and each of the others.

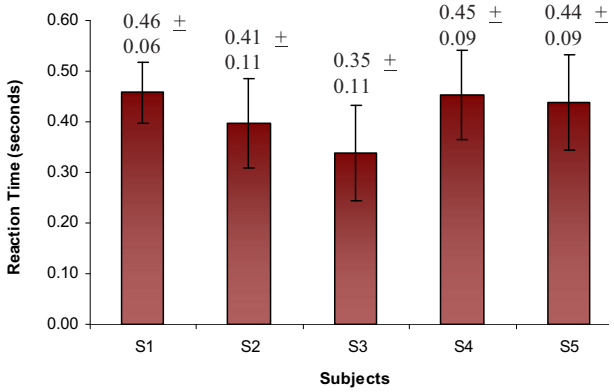

Fig. 2. The Mean ± SD of the 5 subjects participated in the test.

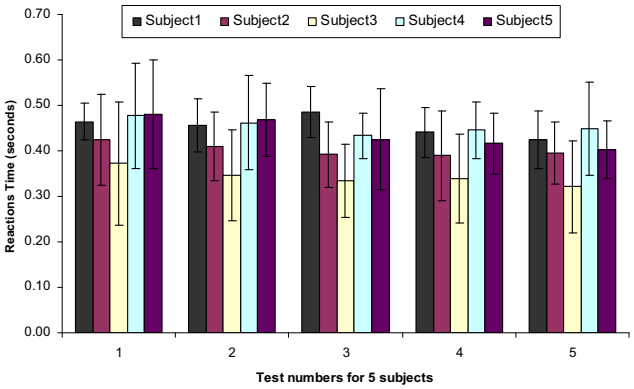

Fig 3 The Mean ± SD of each test for every individual subject.

The Mean ± SD of each test set conducted for each subject is shown in Fig 3. The error lines indicate the variance observed in each test. Fig 4 shows a trend plot (50 point running average) of reaction time in ms against the number of times each subject were tested. The reaction times decrease from test 1 to test 5 for all subjects. Fig 5 shows a typical example of reaction times conducted on one subject (S1). The plot contains of all the data from the 5 test sets carried out by S1. The plot indicates the variance of the data from mean. The variance remained similar for other subjects too. The range of variance observed in Fig 5, between the reaction times, matches with values obtained by [8]. The range of reaction time values found in that study was from 420 ms to 630 ms.

Fig 6 shows a plot of confidence interval versus the number of reaction time taken from all the subjects. Reduction of confidence level can be observed as the number of the samples increases.

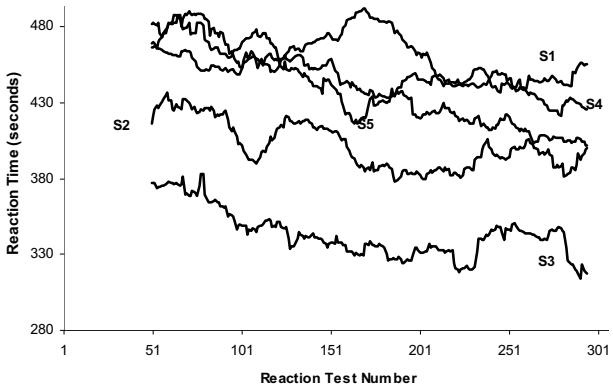

Fig 4. Figure indicates a decreasing trend of reaction time as the test progressed from test set 1 to test set 5 for each subject

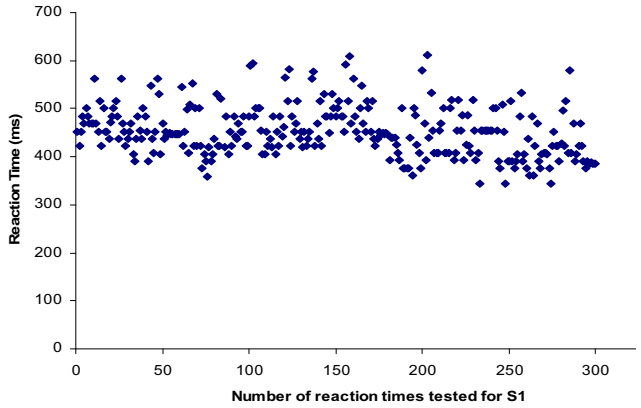

Fig. 5. The graph indicates a typical response of reaction times v/s the number of times tested for subject S1.

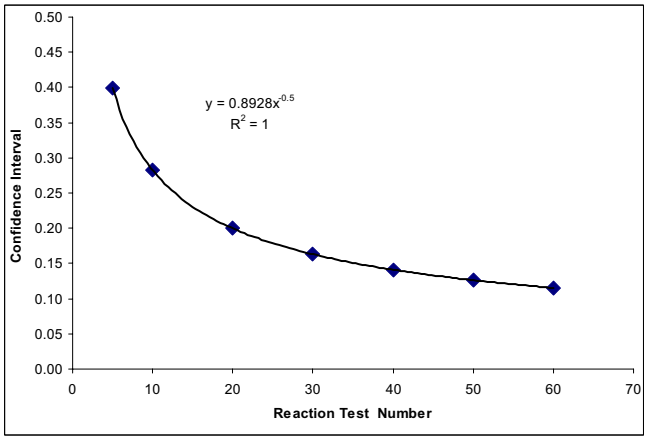

Fig 6. The confidence Interval plot v/s the test number.

IV. Discussion

The means of the 5 subjects were similar except for one subject (S3), all other results being within the range of 0.41s to 0.46s. The difference for S3 can be attributed to the alertness or freshness of the subject. But to confirm this point more samples need to be taken in future. The highest mean reaction time was recorded by S1 (the only female and youngest participant) (0.46 $\pm$ 0.06) which agrees with the result found in few studies in the past [9]. However, one sample is not enough and further test should be carried out according to ages to investigate if sex and age, and their combination can form a significant difference in reaction time test. Studies have shown that age has significant effect on the reaction times. [10] also reported that this age effect was more marked for choice reaction time tasks, and [9] concurred.

System learning capabilities of subjects were also seen during the test. A decreasing trend in reaction time was observed in all the subjects during the first three test sets showing that as the subjects progressed through the test their understanding of the test improved (Fig 4). The difference was noticeable with the maximum difference between the start of the test to the end being 18% however the difference was not statistically significant. The last two sets were mixed with either higher or lower reaction time, however were not significantly different.

Fig 6 shows the confidence interval when more than 40 samples are taken does not change significantly. Considering the above a 40 set test is recommended as a suitably powerful test to discriminate changes in reaction time, without requiring an excessively large number of samples. We plan to use this in future testing of intoxicated narcotic rehabilitation patients.

V. Conclusion

It can be concluded that the reaction time test is reproducible and reliable. Our future work is to use the test with narcotic rehabilitation patients to determine the change in reaction time under methadone intoxication.

Abstract — **Cancer metastasis is the main attribute to cancer-related deaths and early detection is one of the most effective means to treat the disease. Spreading of cancer to distant sites is achieved usually through the circulatory system and the number of circulating tumor cells (CTCs) in peripheral blood is strongly associated to cancer development. Thus detecting CTCs in blood samples will be helpful in identifying susceptible subjects. Here, we propose a label-free technique to isolate these cancerous cells from blood. Using cancer cells spiked in blood samples, isolation efficiency of at least 80% were obtained with high isolation purity. The microdevice also preserved the integrity of the isolated cells to allow further studies to be done on these cells. These results showed a potential effective microdevice for CTCs studies and possible clinical application.**

Keywords — **Cell Isolation, Microfluidics, Circulating Tumor Cells, Cancer Metastasis, Computational Fluid Dynamics (CFD)**

I. Introduction

Early detection is important to effectively treat cancer [1] and advancement in imaging techniques have resulted in faster and more accurate diagnosis. Despite the improving diagnostic aids, cancer remains a leading cause of death globally [2]. This is mostly due to the lack of tell-tale signs until the very late stages of the disease when the cancer has metastasized. Metastasis remains the detrimental part of the disease with tumor cells spreading to distant sites through the body's circulatory system [3,4]. Therefore, analyzing the blood specimens of potential patients is important. Evidence from clinical studies has also showed that the density of cancer cells in blood is directly correlated to disease progression [5,6]. Thus, there is much interest to enrich and enumerate these cells from blood.

Immuno-magnetic separation using various cancer biomarkers followed by immunocytochemistry detection is a leading technique to enumerate circulating tumor cells (CTCs) in peripheral blood [7,8]. However, the sensitivity of the tests varies from different cancer types and is dependent on the biomarkers used [9]. Furthermore, the procedure is tedious involving many complicated steps from sample preparation to immunofluorescence staining of the sample. In the process, viability of the cells are lost, which hold important information about the condition of CTCs whilst in circulation [10]. Having viable cells will also allow further analysis on the CTC subpopulations that might shed insights to the metastatic process.

Here, we present a microdevice that aims to isolate cancer cells from blood using the distinctive difference in biorheology of blood constituents [11,12] and cancer cells [13,14]. Previously, we have reported upon the device to effectively trap breast cancer cells with the ability to maintain the viability of these cells [15]. In this investigation, simulation studies were performed to ensure minimal disturbance to isolated cells that aimed to preserve the condition of the cells during isolation. In addition, we showed that the microdevice was effective for cancer cell types of breast and colon origin. We obtained high isolation purity of the cancer cells in the microdevice which minimizes false positive results and showed that the conditions of isolated cells are preserved. No functional modifications were required in the microdevice. Separation and detection can also be completed in a single step.

II. Methods

A. Microdevice Layout and Fabrication

Numerous crescent structures with gaps are created in the microdevice that aimed to provide effective traps for cancer cells in the sample mixture (Fig. 1a and Fig. 1c). Each trap is positioned with pitch of 50μm which effectively prevents clogging in the device. The gaps of 5 μm in each of the traps ensure that mostly cancer cells are isolated, and allowing other blood constituents to pass through due to their ability to traverse very small constrictions. In this way, white blood cells (WBCs) of comparable size to cancer cells are effectively removed as well. In retrieval of the isolated cells, the inverted isolation structures provide favorable paths that minimized mechanical damage due to physical interactions. For each device, there are a total of 900 cell trap structures.

www.springerlink.com

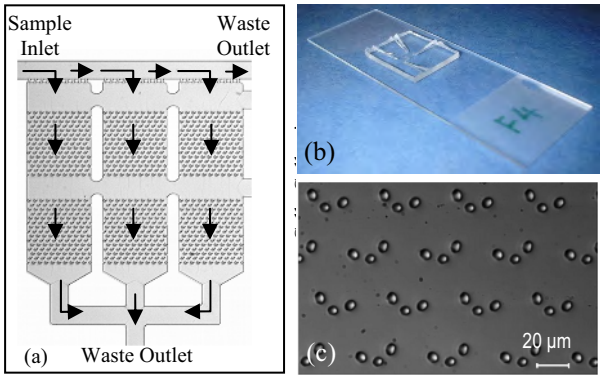

Fig. 1 Microdevice for isolating cancer cells in blood. (a) Device layout. (b) Fabricated microdevice. (c) Crescent isolation structures.

The microdevice was fabricated using soft lithography[16]. An 8 inch silicon substrate was spin coated at 3200 rpm for 45 seconds with SU8-2025 (Microchem Corporation) to get the thickness of 20 μm. Then it undergone an ultraviolet exposure of 120 mJ/cm^2 followed by development. A final hard bake of the master mold ensured better adhesion of the photoresist to the substrate. Polydimethylsiloxane (PDMS, Sylgard 184, Dow Corning) was mixed according to manufacturer's recommendation and poured over the mold. Curing of the PDMS was done in an oven preset at 80°C for 2 hours. Upon careful removal of the patterned PDMS, fluidic ports were created using flat tip needles. The microdevice is completed after subjecting the PDMS pattern structure and a glass slide to oxygen plasma and bonding them together (Fig. 1b).

B. Computational Fluid Dynamics (CFD) Studies

In order to optimize the design of the microfluidic device and visualize the flow profile in the microdevice, 3D computational analyses were simulated on commercial software Fluent (Ansys Inc., Lebanon, NH, USA). Mesh density of approximately 57000 were used in each study with mesh independence ascertained. The flow path as well as the shear stresses of the cells during isolation is of interest so as to maximize isolation efficiency and minimize mechanical damage on cells during isolation.

C. Sample and Apparatus Preparation

Human adenocarcinomas (MDA-MB-231 and HT-29) of breast and colon origin were used in the experiments. Both cell lines were cultured using Dubelcco's Modified Eagle Medium (DMEM) supplement with 10% fetal bovine serum (FBS) and 1% penicillin G / streptomycin / amphotericin. For all apparatus including the microdevices, tubes and fluidic connectors, they were thoroughly sterilized with 70% ethanol prior to experimentation. Sterile phosphate buffered saline (PBS 1×) was then used to remove the ethanol traces and made ready the device for sample injection.

For isolation efficiency characterization, suspended cancer cells were added to PBS 1× at 100 cells per milliliter. By counting the number of escaped and trapped cells over a period of 20 minutes, the efficiency of cell isolation could be obtained. To ascertain the purity of capture, cancer cells were added into whole blood donated from healthy donors at the concentration of 100 cells per milliliter. Isolated cells in the microdevice were stained for EpCAM (Santa Cruz Biotech), CD45 (Santa Cruz Biotech) and DAPI to distinguish between cancer cells and WBCs. For cell viability experiments, isolated cells were retrieved and reseeded back for culture. Their proliferative rate was compared with normal cultures which acted as controls in the experiment.

III. Results and Discussion

The clinical significance of enumerating CTCs is reported to gauge cancer disease progression and also a good measurement for treatment efficacy [17,18]. Having viable CTCs will also help to address issues pertaining to the conditions of CTC in circulation such as their viability, origin and proliferative status [10]. Thus, there is interest to isolate, count the density of cancer cells in blood mixture and preserve the conditions of cells after isolation.

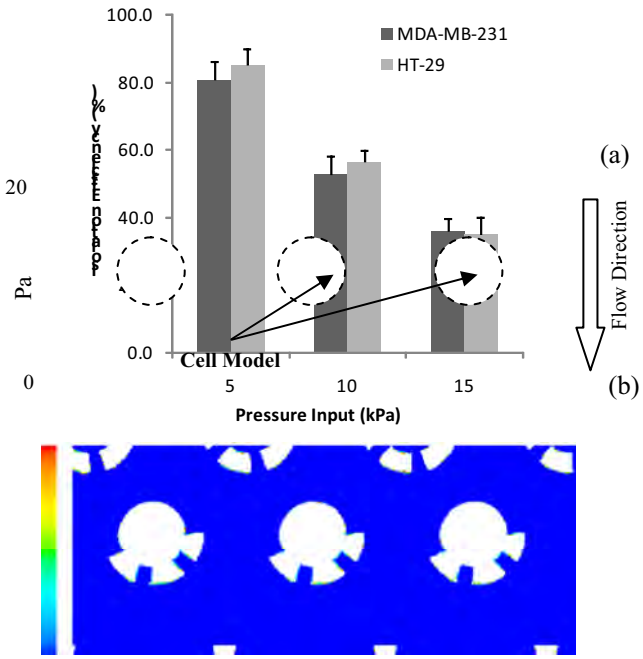

Fig. 2 Microdevice characteristics. (a) Isolation efficiency. (b) CFD studies of shear stress on isolated cells.

Table 1 Isolation purity at different input conditions

Cell Type	5kPa	10kPa	15kPa
MDA-MB-231	85.3%	91.5%	85.3%
HT-29	90.6%	92.0%	87.4%

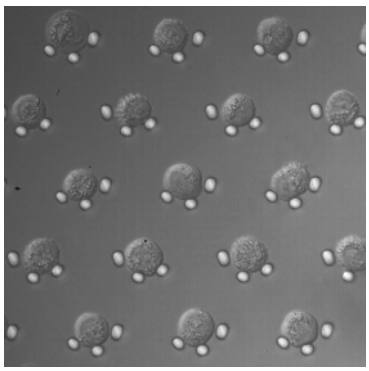

Fig. 3 Isolated HT-29 cells in the microdevice

A pressure driven flow controlled by pressure regulators were used to deliver sample mixtures into the microdevice. Using pressure regulators provided the advantage of precise flow control and allowed real time changes to be made. Isolation via deformability and size of the different cells in the mixture allowed higher capture purity as cancer cells are much stiffer compared to blood constituents which can easily traverse capillaries of 4 μm and smaller. The efficiency of capture is thus likely also to be a determinant of the pressure difference applied in the flow as insufficient pressure applied will retain most WBCs while too much pressure damages the isolated cancer cells and displaces them out of the traps.

Figure 2a showed the investigation of the isolation efficacy over various pressure differential inputs. A general decreasing trend was observed as pressure input was increased for both MDA-MB-231 and HT-29 cancer cell lines. Higher pressure differentials attributed to faster sample processing time but at a reduced isolation efficiency which was not desired. Higher pressure differentials also increased the risk of mechanical damage to isolated cells as the shear forces become excessive due to the flow. Using lower pressure conditions allowed higher isolation efficiencies but at the expense of longer sample processing which might not make the device practical for processing large sample volumes. For our microdevice, at least 80% efficiency was obtained with a pressure setting of 5 kPa for both MDA-MB-231 and HT-29. Our microdevice matches other leading techniques in terms of the enriched cancer cells from blood which can range from 20% to 90% [7,9,19]. Fig 2b showed a simulation study of the shear stresses around an isolated cell at the pressure input of 5kPa. An estimate of the average shear around the isolated cells was still within physiological conditions, highlighting that cells were unlikely to be affected or damaged by the input flow. The proposed optimal condition to operate the device is thus at 5 kPa to attain high isolation efficiency and minimize damage to isolated cells.

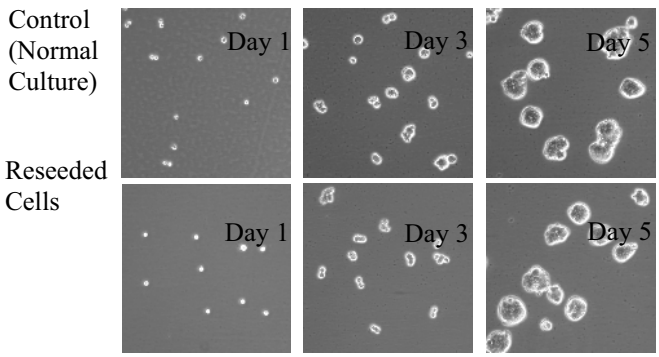

Fig. 4 Cell viability between normal cultures (control) and retrieved HT-29 over a period of 5 days.

To ascertain that the cell isolation was specific only to cancer cells in the blood mixture, immunocytochemistry was performed on the isolated cells in the microdevice for EpCAM, CD45 and DAPI. It is reported that EpCAM is overexpressed in the cancer cells and CD45 is specific for WBCs [20,21]. Thus immunofluorescence staining provided a visual means to quantify the isolated purity over the pressure conditions used. Table 1 summarizes the results of the staining experiments in the microdevice showing a high capture purity of cancer cells from the blood mixture for the range of input pressure used. The high capture purity ensured minimal false positive results giving an accurate assessment of the condition. The uniform arrays of isolation structures also allowed enumeration of isolated cells to be easily processed with image processing software or be counted by visual means under the microscope. As shown in figure 3, most cell traps stores only a single cell and experimental observations saw no more than 3 cells in any isolation structure.

In ensuring the conditions of isolated cells were minimally affected during isolation, the viability and proliferation rate of these cells were studied. Isolated cells were retrieved by reversing the pressure conditions allowing cells to flow to the cell collection port. These cells were reseeded. Figure 4 depicts a typical 5-day culture comparing to normal culture which acted as control. There was no significant difference between the reseeded sample and control, highlighting minimal effects to the cells during isolation. The mechanism to allow retrieval of isolated cells also allows further studies to be undertaken on real clinical samples in subsequent work to better understand the disease.

IV. Conclusions

We had demonstrated a microdevice with an efficient enumeration of viable cancerous cells from blood which has potential in CTCs applications. Neither functional modifications nor complex enrichment processes were required. Separation of cancerous cells from blood utilized their difference in size and cell deformability as cancer cells are stiffer than blood constituents and usually much larger in size. Isolation purity was high which minimized false positive results. Thus a secondary detection mechanism such as immunocytochemistry might not be necessary. The ease of control and handling this microdevice presents an effective means for CTC studies and for evaluation of the cancer status.

In-situ Optical Oxygen Sensing for Bio-artificial Liver Bioreactors

V. Nock[1], R.J. Blaikie[1] and T. David[2]

[1] MacDiarmid Institute for Advanced Materials and Nanotechnology, University of Canterbury, Christchurch, New Zealand
[2] Centre for Bioengineering, University of Canterbury, Christchurch, New Zealand

Abstract — **In this paper we present the characterization and application of integrated oxygen sensors to laterally-resolved dissolved oxygen (DO) measurement within a Bio-artificial Liver (BAL) bioreactor device. Sensor patterns were integrated into the PDMS-based bioreactor and calibrated for detection of DO concentration. The intensity signal ratio I_0/I_{100} of the sensor films was optimized to 6.1 by reducing sensor film thickness to 0.6 µm and remained constant for nearly two weeks while covered with type I collagen. Calibration of DO measurement showed linear Stern–Volmer behavior that was constant for flow rates from 0.5 to 2 mL/min. The calibrated sensors were subsequently used to demonstrate detection of transverse oxygen gradients produced by combining multiple flow streams inside the bioreactor. The device has potential applications in shear-dependent cell culture and drug assays with simultaneous monitoring of oxygen tension.**

Keywords — **Laminar flow, bioreactor, PtOEPK/PS sensor, dissolved oxygen, transverse gradient.**

I. Introduction

In a physiological environment, such as in mammalian organs, cellular oxygen is a parameter regulated to within the normoxic range. Values in excess of this range can lead to terminal damage to the cells or, in case of insufficient oxygen supply, to metabolic demise [1]. In contrast, variations within this range have been found to play a significant role in the gradient-induced distribution of functional zones throughout an organ. A prominent example exhibiting oxygen-induced modulation is the mammalian liver, where oxygen gradients (from periportal blood, 84-91µmol/L, to perivenous blood, 42-49µmol/L) have been shown to result in zonal gene expression in hepatocytes [2].

With important biomedical applications, such as liver cell assays and Bio-artificial Liver (BAL) devices, relying on the in-vitro culture of hepatocytes, it is therefore of great interest to study, control and eventually harness the effect of oxygen concentration gradients on cell function. In a BAL bioreactor measurement and control of the dissolved oxygen (DO) level is essential to re-create optimal conditions for in-vivo like liver cell function [3]. Several studies have investigated the relationship between medium flow, oxygen transport and hepatocyte metabolic function [4-7], indicating the importance of DO gradients to liver-specific function of hepatocytes in culture. However, most current experimental approaches featuring parallel-plate reactor geometries are lacking robust control over oxygen graduation. While high-resolution oxidative microgradients have been demonstrated for general, static cell-culture, such graduation relies on potentially hazardous chemical reactions [8].

Previously, we have shown how channel geometry alone can be used to control the fluid shear stress and oxygen gradient experienced by cells cultured within a flow-through bioreactor chamber. A novel analytical model was introduced which can be used to determine the bioreactor shape for a desired oxygen gradient along the reactor length [9]. The model requires only a single inlet stream with an initial oxygen concentration and was validated for the example of linear and constant gradients using computational fluid dynamics [10]. In a further step towards experimental verification, in-situ oxygen sensing was integrated into a prototype of the gradient-producing device. A novel layer-by-layer fabrication process for the integration of platinum(II) octaethylporphyrin ketone (PtOEPK) oxygen sensors, suspended in a microporous polystyrene (PS) matrix, into polydimethylsiloxane (PDMS) based microfluidic devices was developed and sensors were calibrated for detection of DO [11]. In this paper we show how the device can be modified by use of further inlets to yield an additional transverse graduation of DO levels.

II. Fabrication and Experimental

The bioreactor device and the integrated and external gas exchangers were fabricated using micro-lithography and replica-molding in PDMS (Sylgard 184, Dow Corning). Details of the fabrication process and integration of the oxygen sensor layer (PtOEPK, Frontier Scientific; PS, Sigma Aldrich) via soft-lithography are described in [11]. Figure 1 shows a photograph of the complete device with external tubing and two modular gas exchangers attached. The gas exchangers were used to provide a defined oxygen concentration at the bioreactor inlet. Figure 1(b) shows a close-up of the gas exchanger; channels for liquid and gas are separated by a 30 µm thick, gas-permeable PDMS membrane, allowing for bubble-free oxygenation of the liquid. Figure 1(c) indicates the three separate flow streams, with their respective oxygen concentration, converging on the bioreactor chamber. De-ionized (DI) water could be oxy-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 778–781, 2009
www.springerlink.com

genated to within a range of 0 to 34 ppm O_2, with 34 ppm being the saturation level for pure oxygen and 8.6 ppm for air (~2_1% O_2) in the gas exchanger.

Oxygen measurements were performed using a standard fluorescence microscope in combination with a digital camera for image acquisition. The change of PtOEPK fluorescent dye intensity in presence of molecular oxygen was analyzed using the image processing module of Matlab and a pre-recorded Stern-Volmer calibration curve, as shown in [11]. A dual syringe pump was used to provide pressure-driven flow for single, dual and triple flow streams. During measurements the device was placed on a microscope stage warmer and held at a constant temperature of 37°C, corresponding to cell-culture conditions. For long-term oxygen measurement experiments a layer of 0.01% (w/v) type I collagen (rat tail, Sigma Aldrich) was deposited onto the PtOEPK/PS film and incubated at room temperature for a duration of 8 hrs. The purpose of this layer is to promote adhesion in subsequent cell culture.

III. Results and Discussion

Observations in vivo have identified oxygen concentration as a major tool to induce metabolic zonation in continuously perfused bioreactors. Concentration gradients parallel to the direction of perfusion can be realized by the use of an integrated gas supply layer [3,4,7] or via the modification of the reactor geometry [10]. Figure 1(c) shows an example of the latter, where the bioreactor shape is designed to provide a nearly constant oxygen concentration along its length. While longitudinal gradient control is of great interest, flow characteristics at the micro scale can be harnessed to implement additional oxygen graduation in the transverse direction.

Due to laminar flow conditions in the bioreactor, and the absence of convective mixing at low Reynolds numbers, diffusion is the predominant transverse transport mechanism. Two or more streams entering the device create a moving interface between the flow streams characterized by the width of the diffusive layer, which, in turn, can be adjusted via the flow rate [12]. Figure 2 shows a schematic of the bioreactor dimensions and corresponding visualization of the oxygen concentration inside the reactor for two inlet streams of water with different DO levels and a flow rate of

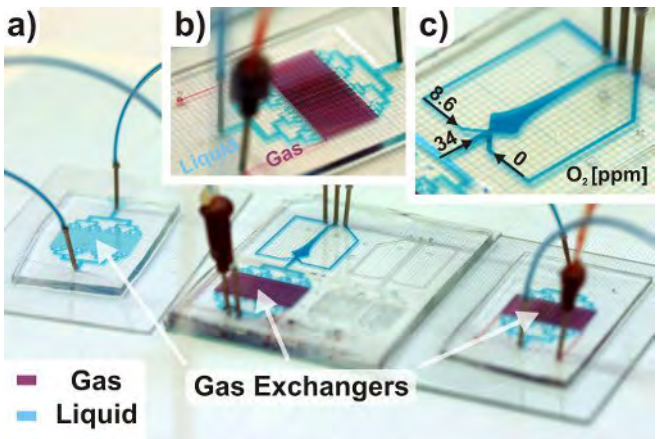

Fig. 1 a) Photograph of the device with two modular gas exchangers. b) Close-up of a single gas exchanger indicating the separate layers for liquid (blue) and gas (red) separated by a thin PDMS membrane. c) Close-up of the central, tapered bioreactor combining three separate flows of water with an oxygen concentration of 8.6, 34 and 0 ppm O_2, respectively. Channels containing liquid were filled with blue (light grey) dye-colored water and those containing gas with red (dark) for illustration purposes.

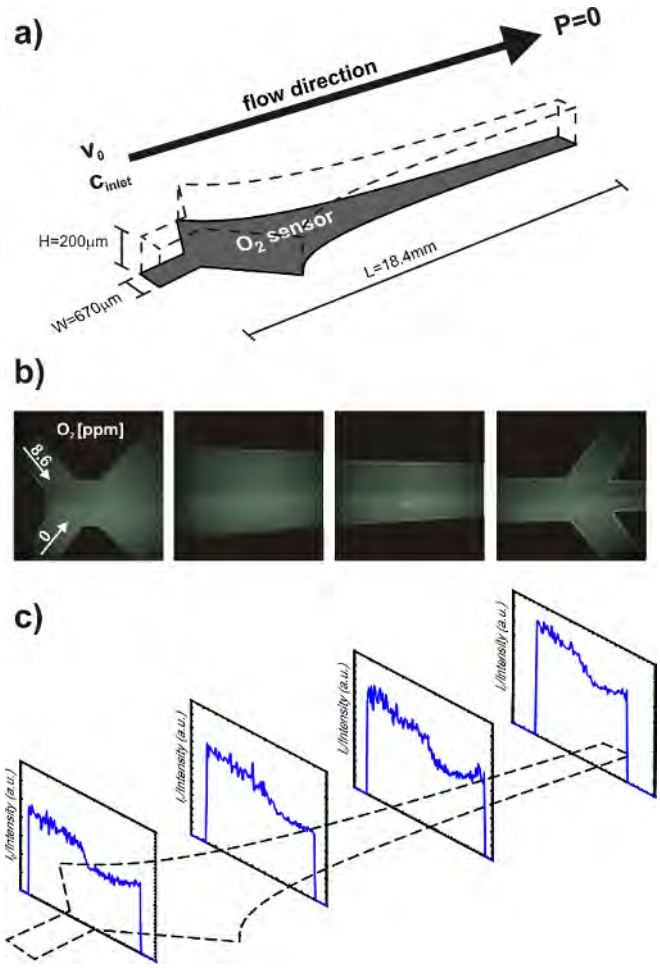

Fig. 2 Illustration of the oxygen measurement process for dual flow conditions: a) Schematic of the bioreactor chamber showing dimensions and flow direction, b) fluorescent intensity images for four positions along the reactor length and two parallel flow streams (8.6 and 0 ppm O_2), and c) plots corresponding to the intensity images overlaid onto the reactor footprint.

0.1 mL/min each. As can be seen from the fluorescence images in Figure 2(b), the difference in intensity of the polymer sensor layer at the bottom surface of the bioreactor indicates the difference in oxygen concentration between the streams. Upon contact the two streams form a stable interface, which remains sharply defined along the reactor length, from the two inlets (left) to the outlet (right). This observation is further supported by plotting the relative intensity I_0/I, where I_0 is the unquenched sensor intensity for 0 ppm O_2, across channel width for the individual intensity images, as shown in Figure 2(c).

The change in sensor signal intensity observed in Figure 2(b) is directly related to the DO concentration of the stream via reversible quenching of the electronic states in the PtOEPK fluorescent dye molecule by O_2. This relationship between intensity and concentration is described by the Stern-Volmer equation

$$\frac{I_0}{I} = 1 + K_{SV}^{S}[O_2] \qquad (1)$$

where K_{SV}^{S} is the Stern-Volmer constant and $[O_2]$ is the oxygen concentration in solution. During fabrication it was observed that the intensity signal ratio I_0/I_{100} of the sensor layer could be optimized to 6.1 by reducing sensor film thickness to 0.6 µm during spin-coating. As shown in Figure 3, this ratio reduced by only 8% over a duration of two weeks while covered with a layer of cell adhesion-promoting collagen to demonstrate its suitability for cell culture.

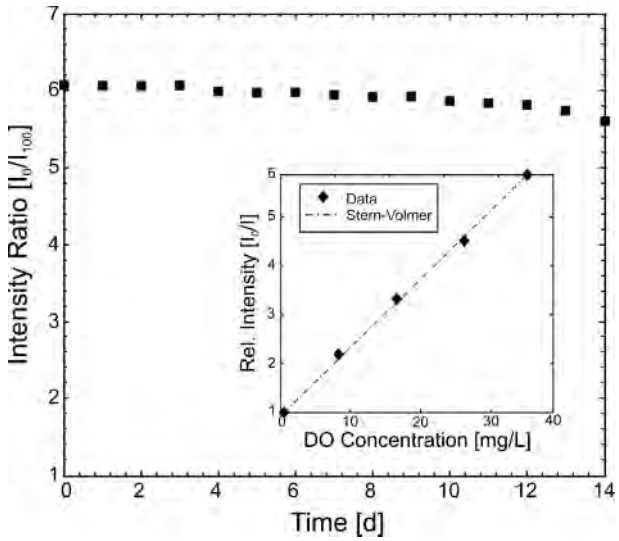

Fig. 3 Plot of the sensor intensity ratio I_0/I_{100} as a function of time in days for a PtOEPK/PS film covered by type I collagen. The inset shows the Stern-Volmer calibration curve for measurement of DO concentration using the same sensor film.

By recording a calibration curve for defined oxygen concentrations, sensor intensity can be translated into corresponding oxygen concentration values. The inset in Figure 3 shows the measured relationship between the relative intensity and five different DO concentrations, as used for calibration. The plot indicates linear Stern–Volmer behavior, which was constant for flow rates from 0.5 to 2 mL/min.

Figure 4 shows the application of the oxygen measurement method by plotting the transverse oxygen concentration profile as a function of the width of the bioreactor. The profiles plotted in Figure 4(a) correspond to the inlet and outlet of the example shown in Figure 2. Dashed lines in the

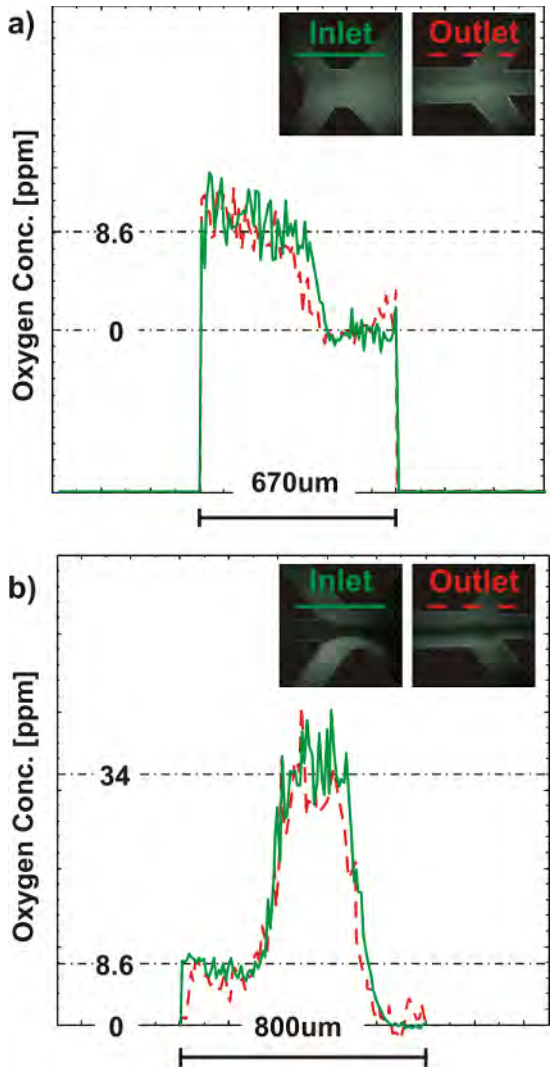

Fig. 4 Plot of the transverse oxygen concentration versus bioreactor width at the inlet (solid) and outlet (dash): a) For two parallel laminar flow streams of 8.6 and 0 ppm O_2, and b) for three streams of 34, 8.6 and 0 ppm O_2. In both cases DI water was used as medium.

graph indicate the 0 and 8.6 ppm DO levels. In Figure 4(b) a third central flow stream was added to the two existing ones via a third inlet connected to an additional gas exchanger. The DO level of this stream was produced by flowing industrial-grade oxygen through the exchanger and represents the upper limit of the attainable range (34 ppm). Custom values in between can be realized by use of an appropriate mixture of nitrogen and oxygen in the gas exchanger.

A further characteristic of parallel laminar flow streams is the development of a diffusive boundary layer between streams of different oxygen concentration. Depending on the flow rate and residence time, oxygen from the oxygen-rich stream diffuses into those with a lower initial DO level. In the transverse concentration plot of Figure 4(a) for example, this is illustrated by a flattening of the initially stepwise transition from inlet to outlet. If undesirable, this effect can be reduced by increasing the flow rate, whereas otherwise it provides a convenient means to determine the diffusion constant of oxygen in the respective medium used for perfusion [13].

The combination of multiple laminar streams with varying DO levels, such as demonstrated here, has the potential for oxygen-dependent treatment of cells without the need for physically separated bioreactors. A similar setup has previously been used to selectively treat cellular microdomains with chemicals [14,15]. However, oxygen concentration, a further parameter with significant effect on cell behavior, was not controlled or monitored for the individual streams used. In contrast, our device enables similar experiments to be performed while simultaneously controlling the DO level of the individual flow stream, thereby increasing the validity of in-vitro experiments.

Concerning BAL devices, the concept of transverse oxygen gradients has the potential, to further understanding of the effect of autocrine signaling on cell metabolic functions and zonation. One such example is the inverse relationship between hormone gradients and those for oxygen, as observed in the liver [2]. Using parallel laminar flow streams, dynamic and simultaneous observation of the effect of different oxygen concentrations on cells located downstream will be possible in a single bioreactor, while at the same time keeping stream-to-stream cross-talk to a minimum.

IV. Conclusions

We have shown the generation and detection of transverse gradients of DO inside a PDMS-based microfluidic device. The oxygen concentration of individual flow streams was controlled, visualized and measured using a polymer-based oxygen sensor layer. Multiple streams were combined in a single bioreactor chamber demonstrating stable inter-stream interfaces. The presented chip provides a novel tool for the parallelization of DO concentration-dependent assays, BAL and tissue engineering applications.

Quantitative and Indirect Qualitative Analysis Approach for Nanodiamond Using SEM Images and Raman Response

Niranjana S., B.S. Satyanarayana, U.C. Niranjan and Shounak De

Manipal Institute of Technology, Manipal, Karnataka, INDIA,576 104.

Abstract — **In the era of nanotechnology, one of the material which seems to be in the forefront, in terms of its application in medical domain is nanocarbon. Various forms of nanocarbon including, carbon nanotubes, nanostructured graphite, nanodiamond, nanowalls, nanocluster carbon, diamond like carbon (DLC) and tetrahedral amorphous carbon(taC) are being studied, for different biomedical applications includes Vacuum based X-ray source, Tribology coating for joints or surgical, Micro/Nano Elcecto Mechanical System (MEMS /NEMS) and Biosensor. Study of nanodiamond grown with Hot Filament Chemical Vapor Deposition(HFCVD) process with various CH4/H2 condition indicates various morphological and compositional properties. The surface based morphology are studied with SEM images provides visual information's. Studied compositional variation using nondestructive and instantaneous approach using Raman response. Reported the mechanism of deposition and the influence of the deposition parameters in terms on the morphology and composition. Designed an insitu applicable software approach for SEM images analysis. The images are initially segmented for enhancing the cluster regions on the substrate and each individual clusters are labeled. Generated histogram using the area estimated for each cluster and analysed it quantitatively. The Raman and SEM based analysis evaluates cluster dimensions, distribution and provides quantitative and indirect qualitative information for evaluating the nanodiamond.**

Keywords — **Nanodiamond,Quantitative analysis, SEM images, Raman Response,**

I. Introduction

Recently miniaturized products have become increasingly dominant in every aspect of life. As per ITRS (International Technology Roadmap for Semiconductor) novel, self aligned nanomaterials which are being developed are the building blocks of future nanoelectronic devices [1-8]. Among the many nanomaterials, nanocarbon is one of the most studied material for nanotechnology applications, in its various manifestations. The various forms of nanocarbon being studied include nanodiamond, Single-walled / Multi-walled carbon nanotubes (SWNT/MWNT), fullerenes (C_{60}), Nanohorns, Nanowalls, Nanowires, Nanofibers, nanocluster or nanostructured carbon. Growing areas of technology were these nanocarbon find applications include Nanoelectronics, Vacuum nanoelectronics, Sensors, Biomedical applications, Novel energy sources, Interconnects in ICs, Novel light, strong and even conducting Composite materials and Flexible electronics [1-8]

Presented here nanodiamond grown using Hot Filament Chemical Vapor Deposition (HFCVD) process under various CH4/H2 condition and its SEM and Raman response based analysis. The morphological information's derived from SEM includes nanostructure distribution ,size and thereby furnishes details for quantitative analysis. The study also provides understanding of the quality of the film. The uniformity of size or distribution of the structure indirectly qualifies the thin films. However the uniform distributed films are more preferred for applications like sensors. Raman Spectroscopic approach of characterization is one of the nondestructive and instantaneous technique used for characterization of nanocarbon in nanotechnology. Raman response as unique signature for nanostructure, is interesting for understanding bonding and dimensional details[9-12].

II. Exeriment

Hot Filament CVD

The heavily n-doped silicon substrate surface was pretreated by polishing to increase diamond nucleation. The nanodiamond deposited using Hot Filament Chemical Vapour deposition[HFCVD]at 1% methane to hydrogen ratio(CH4/ H2) atmosphere for two hours. The filament temperature during the deposition was ranging between 2200 ~ 2300^{o}C and the substrate temperature was between 725 ^{o}C to 925 ^{o}C. Grown nanocrystaline diamond thin films with the variation of methane to hydrogen(CH4/ H2)ratio from 0.5 % to 3 %. Further study was made using the Scanning Electron Microscope(SEM) images, Raman response of the thin films. Typical thickness of the films grown was 500nm.

Further developed , the MATLAB based automated morphology analysis tool for nanostructure size based analysis.

III. Result and Discussion

A. Sem Based Analysis

The morphological and dimensional features of various nanocarbons including nanodiamond, carbon nanotube, carbon based nanocluster and nanowalls were studied using Scanning Electron Microscopic images (SEM). Shown in figure1, is the typical SEM images of the nanodiamond considered for the study. The surface morphological study for various sized nanostructures are possible with visual inspection. However automated approach of morphological study is essential for in situ applications. In this approach from the SEM image the nanostructure dimension is estimated. The indirect quality analysis of nanodiamond films are achieved with the histogram plot.

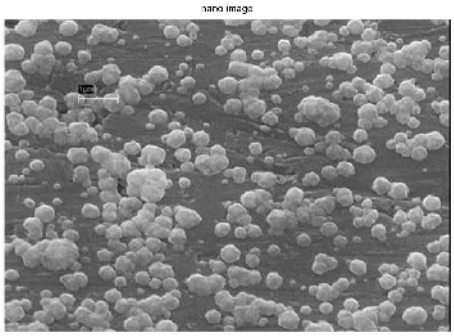

Fig. 1 The original SEM image of Nanodiamond

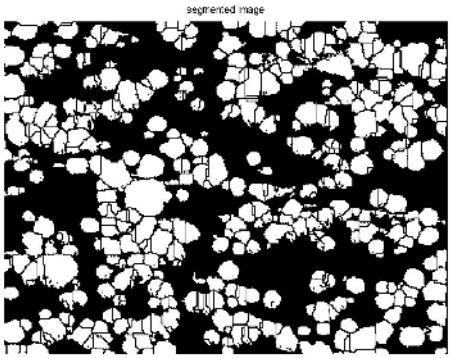

Fig. 2 The segmented SEM image after enhancement

The image based analysis approach includes following steps. Initially the grey image is preprocessed for noise pixel elimination and to enhance the quality.The enhanced binary image is then segmented to get region of interest. Shown in figure2, the image after Watershed segmentation. Estimated area of each nanodimond structure using software and finally plotted the area based histogram for further analysis of the film.

Shown in figure 3, the area histogram plot of nanodimond film plotted considering area along the x axis and count of, nanodiamond structures along y axis. The plot indicates the size distribution of nanodiamond structure around the film surface as well provides the median size or size range

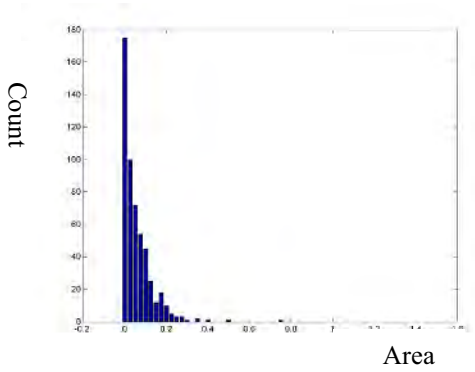

Fig. 3 Histogram plot for the nanodimension indicates Area of structures (along X axis in μm^2, Count (along Y axis)

B. Raman Response Analysis

Raman response of wide variety of nanostructures including carbon nanotube,nanodiamond,nanowall and nanocluste are shown in figure 4. It clearly shows different signature for each individual nanomaterial, promising usage of Raman Response for instantaneous and nondestructive way of nanomaterial understanding approach. In case of Raman studies of nanocarbon, the visible Raman spectrum shows

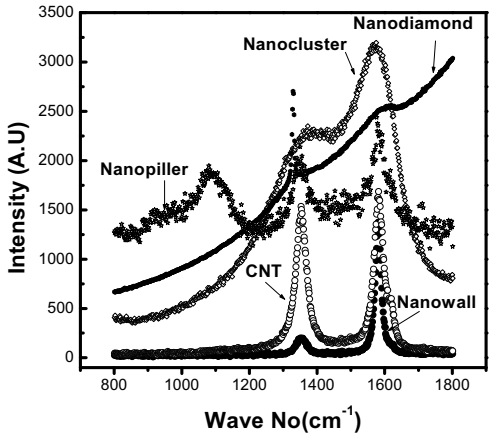

Fig. 4 Raman response of various nanocarbon thin films

two prominent features and some minor modulations. The prominent features are G Peak (Graphite peak around 1580cm^{-1}), and D Peak(Disorder peak around 1330 cm^{-1}) In the case of nanostructured carbon nanowalls we see relatively the narrowest G peak around 1580cm^{-1}, showing the well formed nanowalls. The carbon nanotubes show both the G and D peaks like the nanowalls, but area broader. This shows that the materials have more amorphous phase materials and also clusters with varying dimensions besides the carbon nanotubes. From the Raman response of room temperature grown nanocluster carbon it may be observed that G and D peak are even broader than nanotubes. This indicates that the clusters with vastly varying dimensions and amorphous phase materials.

Especially in case of nanodiamond, the visible Raman spectrum shows two prominent features. The nanodiamond film exhibits a narrow diamond peak around 1332cm^{-1} and a broad peak around 1580cm^{-1}(G peak) showing the presence of graphite like and amorphous phase materials around the grain boundaries. Raman can be used to identify a wide range of material parameters or properties including, if it is amorphous, nanocrystalline or crystalline, the size of the cluster, the nature of bonding: graphite like (sp^2 bonding or π bonding)or diamond like (sp^3 bonding or σ bonds)and the ratio between the two (sp^2/sp^3) types of bonding. Analyzed nanodiamond for understanding its property by using curve fitting approach. Shown in figure 5, curve fitted nanodiamond Raman response. Extracted features from curve fitting includes:D-Peak, G-Peak, Id-Ig Ratio, D peak – G peak Ratio, G-area, D-areas and some statistical values.

Further an effort was made to look at possibility of correlation between the nanocarbon dimension estimated from SEM images to field assisted electron emission properties of theses films finding the FN slope from field emission response and the dimension/size of nanocarbon. The influence of temperature variation also studied between 725 ^{o}C to 975^{o}C for a constant CH4/H2 ratio. Observed the shift of the G peak position towards smaller wave number, with an incremental change of temperature, resulting a more sp3 phase nanodiamond. Based on the experimental data between temperature range 800 ^{o}C -850^{o}C suggests the region of uniform cluster size and distribution.

Shown in figure 6 and figure 7 are some relationship shown with Raman derived parameter Id/Ig. The Figure 6 indicates possibility of some dimension and Id/Ig ratio relation. Similarly shown in figure.7 a plot of process parameter(CH4/H2) ratio dependence along with Raman derived ratio. The results are clearly indicates possibility of usage of Raman response for nanodiamond analysis.

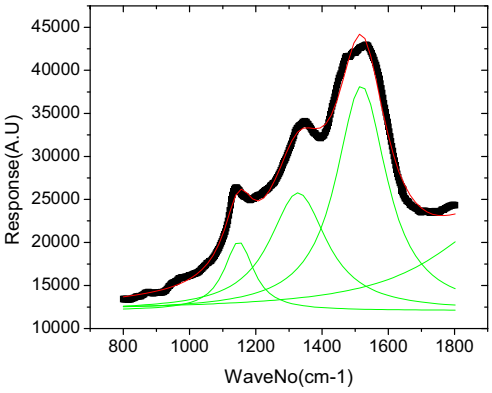

Fig. 5 Curve fitted Raman Response for a nanodiamond film

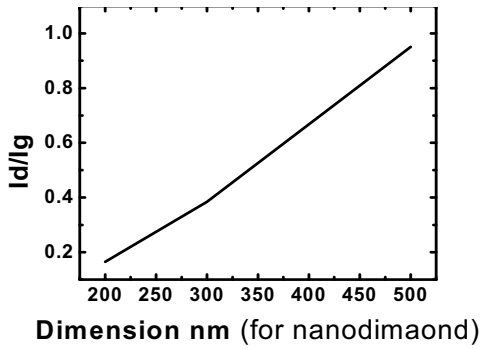

Fig. 6 Size variation of Nanodiamond size with Id/Ig ratio calculated from Raman response.

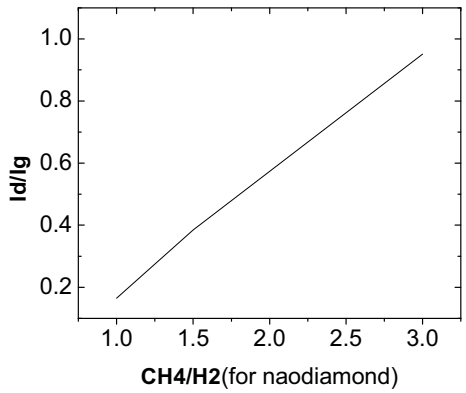

Fig. 7 CH4/H2 ratio variation and Id/Ig ratio for nanodiamond films grown under various conditionsonse.

IV. Conclusion

The study promises the possibility of correlation between dimensions (size) derived from SEM images of nanodiamond and parameters derived from Raman response. Also suggested automated SEM image analysis approach for analysis of nanodiamond SEM image for quantitative analysis. Further the derived parameters from the Raman response are used to evaluate or classify the nanocarbons indirectly with the extracted parameters. However the Raman signature of nanodimond material needs further detailed study to explain conductive or other electronic properties .The work promises the importance of Raman study for qualitative analysis of nonmaterial.

Non-invasive Acquisition of Blood Pulse Using Magnetic Disturbance Technique

Chee Teck Phua[1], Gaëlle Lissorgues[2], Bruno Mercier[2]

[1]School of Engineering (Electronics), Nanyang Polytechnic, Singapore
[2]ESIEE – ESYCOM , University Paris Est, France

Abstract — **Blood pulse is an important human physiological signal commonly used for the understanding of the individual physical health. Current methods of non-invasive blood pulse sensing require direct contact or access to the human skin. As such, the performances of these devices tend to vary with time and are subjective to human body fluids (e.g. blood, perspiration and skin-oil) and environmental contaminants (e.g. mud, water, etc). This paper proposes a novel method of non-invasive acquisition of blood pulse using the disturbance created by blood flowing through a localized magnetic field. The proposed system employs a magnetic sensor and a small permanent magnet placed on the artery (major blood vessel) of the limbs. The magnetic field generated by the permanent magnet acts both as the biasing field for the sensor and also the uniform magnetic flux for blood disturbance. As such, the system is able to operate at room temperature, reliable for continuous long term acquisition, compact (small size) and convenient for daily usage. The heart rate obtained from the proposed system when measured through non-conductive opaque fabric, is found to be highly correlated to commercially available cardiac monitoring system such as ECG and pulse-oximetry.**

Keywords — **blood pulse, magnetic biasing, non-invasive, magnetic disturbance**

I. Introduction

A. Context of the study

With the advancement of bioelectronics, portable health monitoring devices are getting popular because they are able to provide continuous monitoring of an individual's health condition with ease of use and comfort. Portable health monitoring devices are increasingly required at places such as home, ambulance and hospital, and at situations including military training and sports.

Pulse rate is a measurement of the number of times the heart beats per minute. The heart pushes blood through the arteries, which expand and contract allowing blood to flow.

Heart or pulse rate is an important parameter subject to continuous monitoring because they are representative in assessing the physical health condition of an individual. Healthcare institutes such as the hospitals and elderly care centers can use this information to monitor the health conditions of their patients. This is particularly important for patients with cardiac arrhythmia whose heart rate variability needs to be monitored closely for early detection of cardiac complications.

Furthermore, pulse rate information of individuals subjected to mentally or physically stressful conditions may be utilized to trigger alert for immediate attention when large changes in heart rate variability indicate potentially fatal events such as heat stroke, cardiac disorder and mental break down. Finally, it can be also important to monitor pulse rate of personnel working in dangerous environments such as deep sea condition (divers), high temperature (fire-fighters), and deep underground (coal miners).

B. State of the art

Current methods of heart or pulse rate acquisition can be classified into electrical [1-2], optical [3,7], microwave [4], acoustic [5,8,11], mechanical [6,9] or magnetic [10,12,13] means. The use of electrical probes to measure heart rate was discovered in 1872. Such a method normally requires good electrical contact with the human skin and the performance is subjective to human body fluids (e.g. blood, perspiration, skin-oil) and environmental contaminants (e.g. mud, water, etc). In most deployment, reference electrodes are usually required to ensure such a system is less susceptible to electrical noise [2]. Recent research [1] had also reported a new method of ECG acquisition using contact free capacitive sensing. However, this method is highly subjective to noise and motion artefact.

Examples of commercially available heart rate acquisition systems include ECG monitoring devices, pulse rate monitoring watches and chest strips. All of these devices require electrical contact between the probes and the human skin.

The use of optical sensors in pulse oximetry [3,7] is getting popular due to its compact nature and the ability to concurrently acquire SpO_2 concentration in blood. The basic operating principle of such a system requires a light source and a sensor where the reflected light content is measured to determine the blood pulse and SpO_2 concentration in blood. Typically, such a system is worn on the tip of the fingers or toes where optical transmittance of the human skin is important to ensure signal quality.

Microwave radar [4] has also been reported for non-invasive detection of heart rate. However, such methods are

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 786–789, 2009
www.springerlink.com

highly subjective to motion artifacts created due to movement of the subject.

Acoustic method of acquiring heart rate on the human chest was available through the invention of the stethoscope since 1816. Over the years, this method, which has progressed with electronics and innovative signal acquisition systems, is widely reported [5,8,11].

Biomagnetic signal from the heart was detected in 1963 by Baule and McFee. The basic principle involves the mapping of the magnetic field around the thorax while the heart magnetic vector is acquired and is commonly known as magnetocardiogram (MCG). Such a method requires highly sensitive magnetic sensors such as SQUID (Superconducting QUantum Interference Device) and is currently not readily deployed for clinical use as ECG proves to be more reliable, convenient and less expensive.

Another way to measure the blood pulse is based on Hall Effect [10,13]. Such system applies a uni- or bi-directional magnetic field on the human body to create polarization of blood molecules. Electrodes are placed on the human skin near the applied magnetic field to pick up the potential difference created by the induced magnetic signal.

Mechanical methods to acquire heart or pulse rate varies from the use of pressure cuff to piezo-electric materials worn over the limbs or body [6,9]. Such mechanical methods to acquire heart or pulse rate requires the application of localized pressure on the human subject and are not well suited for continuous signal acquisition.

The limitations of each of the above methods to acquire heart or pulse rate motivated the research on a simple and yet reliable magnetic means to acquire blood pulse. Such a method will support the acquisition of blood pulse without the need for a good electrical or optical contact and can be used over a prolonged period of time on the limbs. One of the objectives in developing a non-invasive magnetic based blood pulse acquisition system is to use commercially available magnetic sensors in place of SQUID or electrodes. This will allow the system to operate at room temperature, to be reliable, compact (small size), cheaper, and more convenient for daily usage.

II. Experimental set-up

The experiment on blood pulse acquisition utilizes the concept of placing a magnetic field in the vicinity of the major artery where the blood flowing through the magnetic field will disturb the magnetic field, thus creating a magnetic disturbance. Such a magnetic disturbance is acquired using a magnetic based sensor operating at room temperature as shown in Figure 1. In this experiment, the variation of magnetic field is termed Modulated Magnetic Signature of Blood (MMSB).

The relative position between the magnet (1), sensor (2) and the artery (major blood vessel) was varied and the final set-up for measurement is shown in Figure 2 where the sensor output was sufficiently amplified and then connected to an oscilloscope. The configurations of the sensor on the limbs are illustrated in Figure 3.

To achieve the objective of small size for portability and operation at room temperature, the uniform magnetic field is created by the use of a button-sized permanent magnet (3mm diameter) with magnetic strength of 1000 Gauss. The magnet is placed over the major arteries on the limbs with a magnetic sensor placed in close proximity. The measurements will depend on several aspects: the distance between the sensor and the magnet (approximately 15mm) providing a uniform magnetic field that ensures proper biasing, the magnet strength that does not saturate the sensor, and the appropriate penetration of the magnetic field into the skin tissues.

The magnetic sensor has typical performance characteristics as shown in Figure 4. Magnetic biasing is illustrated in Figure 4 where the sensitivity of the sensor is improved by operating it in the linear region. As such, the sensor is able to amplify any minute changes to the magnetic field due to the flow of pulsatile blood in the uniform magnetic field.

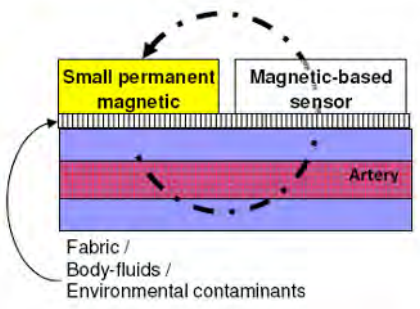

Figure 1. Cross-sectional view of the experimental setup to acquire MMSB

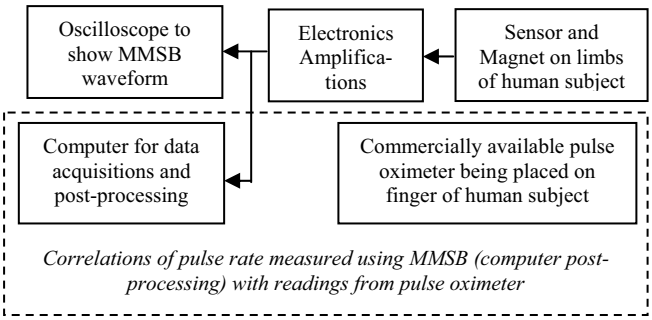

Figure 2. Block diagram of experimental setup to acquire MMSB with correlation of results using commercially available pluse oximeter.

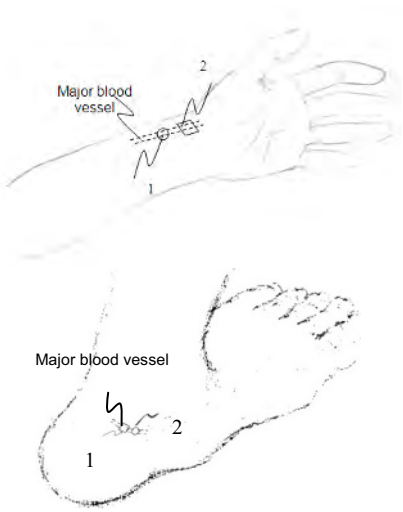

Figure 3. Illustrations of the relative position of the magnet(1), sensor(2) and a major blood vessel

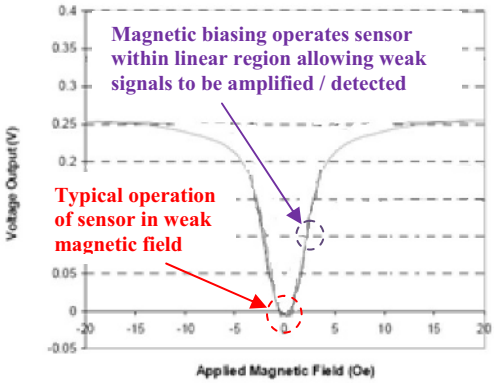

Figure 4. Typical sensor response with illustration of magnetic biasing to increase its sensitivity

III. Results and Discussions

The experimental setup to acquire MMSB on the wrist was done in a laboratory condition where subjects are in a sitting position and their arms are well rested on the table. The magnet is secured on the wrist using a non-magnetic adhesive tape while the sensor is positioned on the artery, near to the magnet. Similar experimental setup to acquire MMSB on the heel was performed on subjects in a sitting position with their heels rested on the floor.

The signal acquired from the sensor on each subject is repeated on at least two separate measurements and found to be repeatable. In addition, these experiments have also been repeated on fifty different subjects and the pulse rates measured are found to be within ±5% of the readings obtained from a pulse oximeter.

A typical waveform acquired from the sensor in this setup is shown in Figure 5 where it can be observed that it is highly periodic and has the pulse width of the subject's heart rate. The waveform obtained is also observed to have high correlations to the MCG reported in [10] as illustrated in Figure 6.

In addition, on the basis of magnetic disturbance of the pulsatile blood flow on a uniform magnetic field, MMSB can also be used to describe the activities of the heart as illustrated in Figure 7. For example, an increase in the measured magnetic disturbance can only be created by an increase in blood flow due to the compression of the heart ventricles. As the ventricles compress to their maximum, the peak of the waveform is reached. Without further force from the heart on the blood flow in the artery, the blood flow rate will reduce as shown in the decreased in amplitude of the waveform. With the relaxation of the ventricles, a back-flow of blood is present in the artery. Finally, the atrium will simultaneously compress, resulting in a small forward flow of blood as shown in the second peak detected in MMSB.

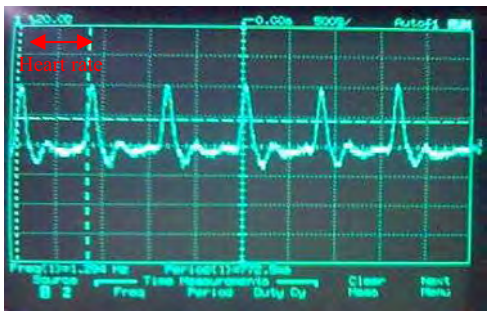

Figure 5. Waveform captured from the sensor output using oscilloscope

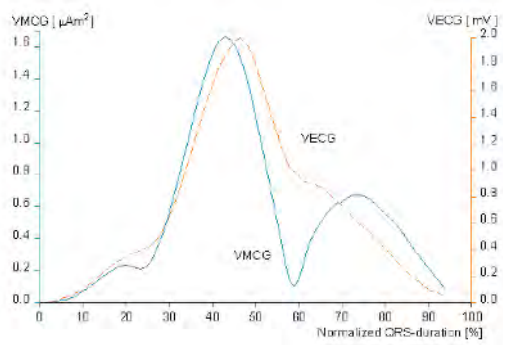

Figure 6. Simultaneous plots of the magnitude curves of the EHV (dashed curve) and the MHV (solid curve) during the QRS complex [10]

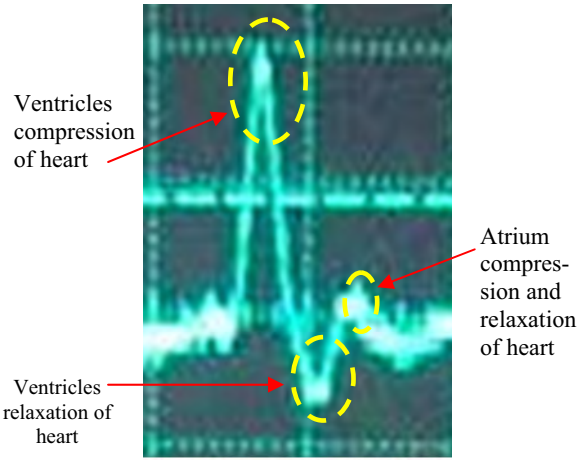

Figure 7. Illustration of MMSB and the activities related to the heart

IV. Conclusions

This experiment demonstrated the concept of magnetic disturbance (MMSB) by the pulsatile blood flowing in a uniform magnetic field. Such magnetic disturbance can be acquired by the use of a button sized permanent magnet and a commercially available magnetic sensor. The waveform obtained is highly correlated to the activities of the heart. It is conclusive that MMSB exists and has the advantage of being contact surface independent which is lacking in existing methods of heart or pulse rate acquisition systems.

Further work will focus on the modelling of the magnetic modulation using blood, to optimise the system sensitivity. This should lead to a reduction in the overall size of the sensing module (i.e. sensor and magnet).

Abstract — **Micro Electrode Arrays (MEAs) offer an elegant way to probe the neuronal activity distributed over large populations of neurons either in vitro or in vivo. They also give the possibility to deliver specific electrical stimulations to neuronal networks. This paper will present the fabrication of different kinds of 3D electrode arrays based on silicon micromachining: dense 3D arrays with high aspect ratios (up to 1024 probes with a pitch of 50µm and 80µm of height) and 3D probes enabling recording within the depth of the tissues. Stimulation is also possible with these systems, and we have developed a specific MEA to deliver a focal stimulation in the tissue. The 3D-shaped microelectrodes are necessary to achieve better contacts with the neural tissue, the tip of each needle being the recording site. Indeed, we will detail a new technology based on the Deep Reactive Ion etching technique (DRIE) which offers the possibility to manufacture various shapes of electrodes on silicon. Second, alternative geometries with several contacts on each needle will be described, leading to really 3D probes scanning within the depth of the tissues. Such geometry is based on the combination of DRIE and standard etching techniques. Experiments currently performed have shown that both kind of MEAs present a noise level around 10µV, in the same range as available commercial MEAs. In vitro applications will be presented concerning the study of the whole spinal cord of embryonic mousse and we conceived a new configuration to reach a focal stimulation for in vitro and in vivo applications.**

Keywords — **Micro Electrode Arrays, microfabrication, DRIE**

I. Introduction

Although neuroscience has already progressed in the knowledge of the neuronal system with the development of medical imagery (like CT scanner, MRI and nuclear medicine), all those imagery systems only give a global vision of neurons operation. Then Micro Electrode Arrays (MEAs) offer an elegant way to get the recording of large neuronal networks and follow the cellular information, providing a means to record the activity of many cells simultaneously over large networks. Such techniques are using arrays of microelectrodes placed in contact with the neural tissue to probe neuronal electrical activity at several sites simultaneously. In order to be as close to neurons as possible, microelectrodes for in vitro systems are usually shaped as 3D needles, at the tip of which is the recording site.

II. MEA fabrication

A. Standard MEAs

Classically the isotropic etching [1,2], which is a very simple process, is used to etch silicon or glass substrates to fabricate 3D electrodes, Figure 1. Either wet etching (fluorhydric acid, KOH) or dry etching (plasma) is possible.

The major problem of the isotropic etching is due to a large under etch above the protection layer. In isotropic etching, the substrate is etched at the same speed in all directions. The under etch is problematic when you want to fabricate a narrow structure. To obtain a micro needle after isotropic etching we protect the substrate with circular protective layers. Theses circles correspond to the requested diameter of the micro needle.

However, the drawback of such isotropic etching is a dimensioning constraint: the electrode height vs. the electrode pitch. Indeed, the electrode pitch cannot be smaller than twice the electrode height. For example, electrodes with 80 µm of height impose the pitch to be higher than 160 µm. The fabrication of very dense 3D electrode arrays with high aspect ratios is therefore impossible with the standard technique.

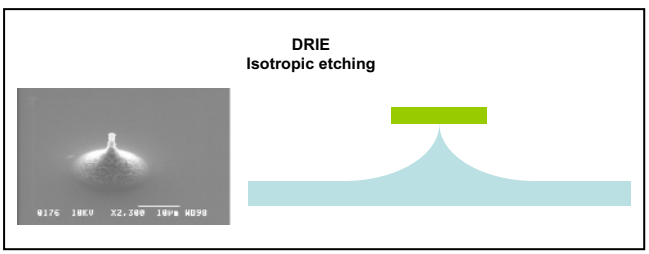

Fig.1. Classical 3D MEAs Process

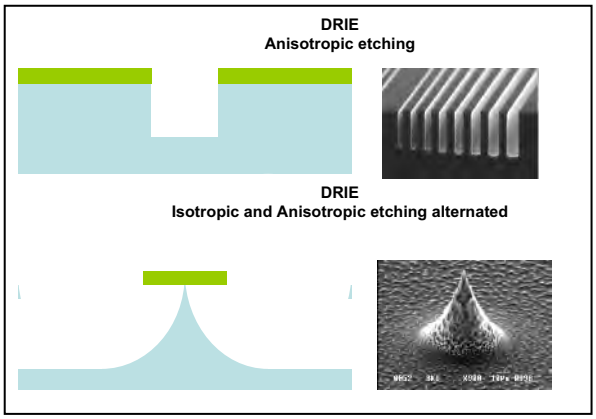
B. Dense MEAs

The DRIE (Deep Reactive Ion Etching) is an anisotropic etching process and a classical process used to obtain vertical side walls is the Bosch process [3].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 790–793, 2009
www.springerlink.com

To get high aspect ratios, a repetitive alternation of etching and insulation steps, see figure 2. This process is composed by two steps performed subsequently: deposition and etching. The sidewall passivation is obtained by teflon-film deposition on the silicon surface and avoids a lateral etching. In plasma etching the ions are oriented vertically to the substrate and etch in priority the bottom of the structures. Consequently the ions firstly etch the teflon-like layer at the bottom before they etch the silicon and leave teflon-like protection on the side walls.



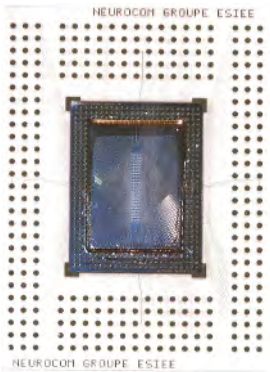


Fig.2. DRIE process adapted to dense MEA fabrication

To prevent the previous limitation of isotropic etching to achieve micro needles, we developed a new technology based on the DRIE technique [4]. We combine anisotropic etching and isotropic etching to give us the opportunity to reduce the diameter of the base micro needle.

a)

b)

Fig.3. An example of a 256 electrode array a) and its position on the whole spinal cord of embryonic mouse b)

We obtained dense MEAs with 64, 256 or 1024 electrodes [5] having a height of 80µm and a pitch of 50 µm, figure 3. This process also offers the possibility to manufacture various shapes of electrodes on silicon, as shown on figure 4.

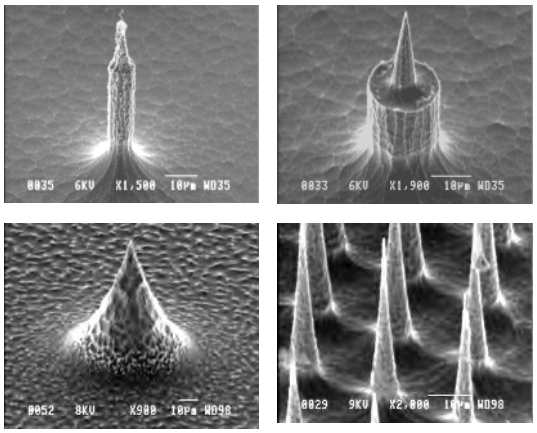

Fig.4. Various shapes of 3D electrodes processed by DRIE

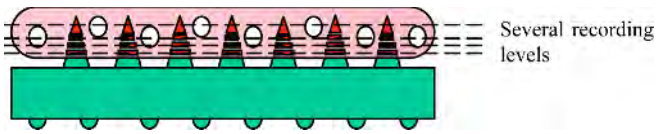
C. 3D needles used in MEAs

The neuronal activity is not distributed on one level but in 3D within the volume of the tissues, i.e. at different depths, as illustrated on figure 5. To achieve a 3D recording, we have fabricated a comb with 4 shafts on which there are 4 electrodes.



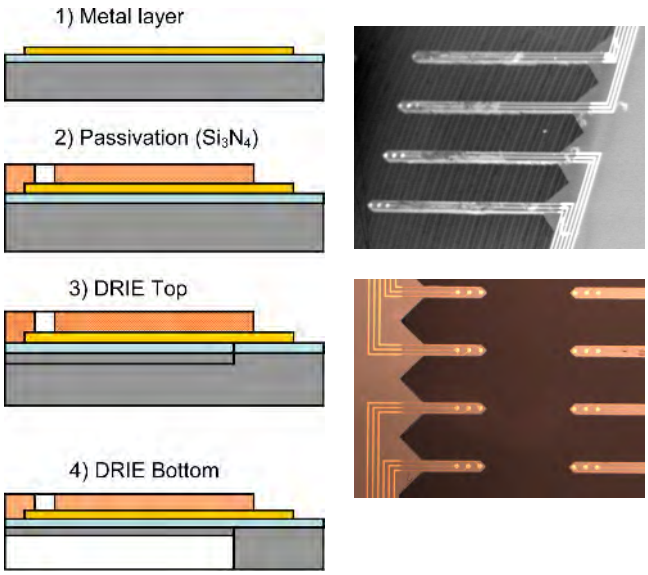


Fig.5. Principle of 3D recording

The fabrication process is again based on DRIE used to release long silicon needles with several recording sites on each, as shown on figure 6 [6].

To manufacture this comb shaft, we started with an oxidation step of a silicon wafer (500 nm). A metallic gold or platinum layer is sputtered to fabricate the micro electrodes. Such noble metal is necessary to prevent degradation of metal in contact with tissues and physiological liquids. A PECVD (Plasma Enhanced Chemical Vapor Depostion) silicon nitride layer is deposited to insulate the leads on the comb shaft from the liquid environment. Top side DRIE is done to define the comb shafts and a second bottom side DRIE to release the structures.

a) process steps b) SEM & top photography

Fig.6. Fabrication process of 3D needles a) and examples of fabricated samples b)

The prototypes are mounted on a PCB support and connected to a specific acquisition system. The first tests have shown that noise level is around 10 µV.

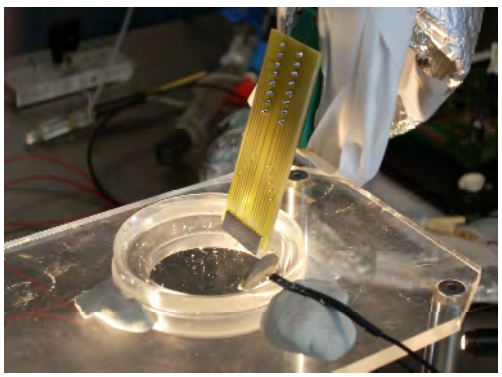

Fig.7. Comb Shaft Mounted on PCB for testing

D. Optimized design for stimulation

Different studies showed that the activation of single neurons may impact the activity of large populations at the networks level [7, 8]. Therefore the precise activation of small groups of neurons is required during stimulation with MEAs. Indeed, each electrode of such array should act as an independent "stimulation pixel", only influencing cells in its close vicinity. Thus an optimized design was elaborated to obtain a more efficient stimulation, which means focal stimulation [9]. The basic idea was to add a ground surface surrounding the electrodes (either a plane or a grid), allowing the whole current delivered by the stimulation electrode to return back directly through this ground surface, figure 8. The induced change in the fabrication technology of the MEA was the addition of one masking level on which a second metallic (Pt) layer is deposited above the passivation layer. The Pt layers can be patterned with a liftoff process. The ground surface was designed as a grid instead of a plane in order to ensure enough transparency of the MEA.

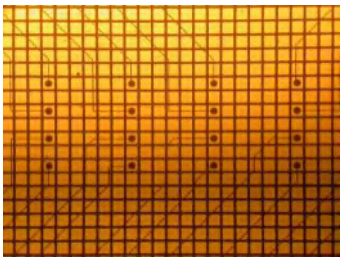

Fig.8. Part of a 4×15 MEA with a grid-like ground surface surrounding all the electrodes

III. In Vitro Measurements

All the presented electrode arrays have been tested by the CNIC laboratory on the whole spinal cord of embryonic mouse, figure 9, and showed performances corresponding to commercially available MEAs. They indeed present a noise level around 10µV.

An example of the improvement obtained during stimulation with the ground surface configuration is illustrated on figure 10.

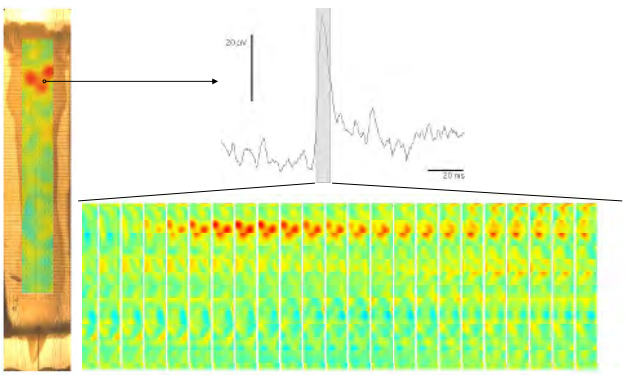

Fig.9. Map of Mouse spinal cord activities (LFP)

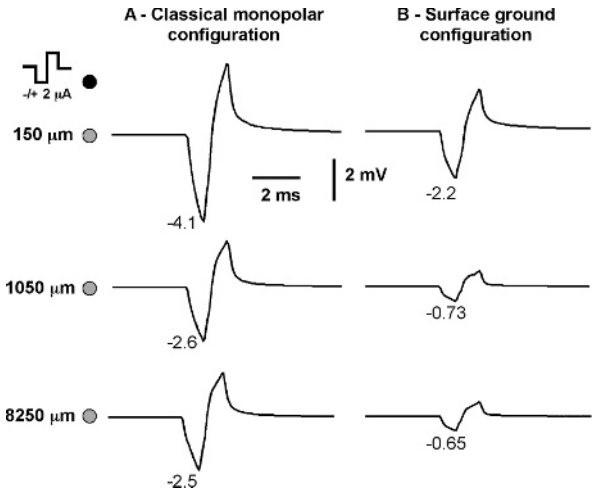

Fig.10. Comparison of field focality between a classical monopolar configuration (A) and the proposed ground surface configuration (B). The potential field is recorded in response to a biphasic stimulation on 3 electrodes located at 3 different distances from the stimulation electrode (150, 1050, and 8250 µm).

IV. Conclusion

In conclusion, we presented the fabrication of different kinds of MEA: very dense 3D microelectrode arrays with high aspect ratios using a specific DRIE process, or real 3D needles to access the volume of the tissues and scan within their depth. We also proposed a new electrode configuration that appears to ensure a good compromise between potential field focality and isotropy, which moreover requires few additional steps in the fabrication process. Such a prototype was micro-fabricated showing that the field focality could be improved.

Abstract — **In realizing Lab-on-a-Chip systems, micro pumps play an essential role in manipulating small, precise volumes of solution and driving them through the various components of the micro chip. The current study proposes a micro pump comprising four major components, namely a lower glass substrate containing a copper micro coil, a microchannel, an upper glass cover plate, and a PDMS-based magnetic diaphragm. A Co-Ni magnet is electroplated on the PDMS diaphragm with sufficient thickness to produce a magnetic force of the intensity required to achieve the required diaphragm deflection. When a current is passed through the micro coil, an electromagnetic force is established between the coil and the magnet on the diaphragm. The resulting deflection of the PDMS diaphragm creates an acoustic impedance mismatch within the microchannel, which results in a net flow. The performance of the micro pump is characterized experimentally. A deflection of 30 μm is obtained by supplying the micro coil with an input current of 0.6A, and results in a flow rate of 1.5 μl/sec when the PDMS membrane is driven by an actuating frequency of 240 Hz.**

Keywords — **electroplating, impedance pump, magnetic diaphragm, micro coil, micro pump**

I. Introduction

The rapid advances achieved in micro-electro-mechanical systems (MEMS) techniques over the past decade have enabled the development of a wide variety of microfluidic devices for use in the industrial, chemical, biological and medical fields. Typically, these devices are designed to perform specific functions such as sample injection, cell sorting and counting, polymerase chain reaction (PCR), species mixing, and so forth. As the characteristic size of such devices has reduced, researchers have demonstrated the feasibility of integrating two or more micro devices on a single chip to construct so-called micro-total-analysis systems (μ-TAS) capable of performing a complete biochemical assay of solutions. In realizing such systems, micro pumps play an essential role in manipulating small, precise volumes of solution and driving them through the various components of the micro chips.

Broadly speaking, micro pumps can be classified as either mechanical or non-mechanical, depending upon their mode of actuation. Non-mechanical micro pumps are typically actuated using electrohydrodynamic, magnetohydrodynamic or electroosmotic techniques. However, such devices are not fully compatible with many biological systems and suffer a number of practical problems such as electrolytic bubble formation (in the magnetohydrodynamic type) [1] or a solution-dependent flow response (electroosmotic type) [2]. Mechanical micro pumps can be classified as either reciprocating (i.e. diaphragm-based) or peristaltic. Most commercially-available mechanical micro pumps tend to be of the former type since they are generally more easily controlled, more reliable and more effective than their peristaltic counterparts. Furthermore, reciprocating micro pumps resolve many of the problems associated with non-mechanical pumps and are easily integrated with other micro devices to construct large-scale microfluidic networks. Gong *et al.* [3] developed reciprocating micro pumps incorporating a pressure chamber and a system of mechanically-operated inlet and outlet passive check valves. While the results showed that the pump successfully drove fluids, the use of mechanical valves rendered the pump prone to clogging and to leakage at high driving pressures. In an attempt to resolve these problems, researchers have proposed a variety of valveless micro pump schemes based on peristaltic effects [4,5] or the use of reciprocating diaphragms and integrated nozzles/diffusers [6,7]. Some researchers have also presented impedance-based micro pumps comprising an elastic section connected at either end to a rigid body. In such pumps, the elastic section is compressed asymmetrically to create an acoustic impedance mismatch within the microchannel, which prompts a net flow through the pump. Rinderknecht *et al.* [8] proposed a novel valveless, substrate-free impedance-based micro pump driven by an electromagnetic actuating force. The performance of the pump was found to be highly sensitive to the waveform, offset, amplitude and duty cycle of the excitation force. Wen *et al.* [9] presented a planar valveless micro impedance pump in which a PZT actuator was used to drive a thin Ni diaphragm at its resonance frequency of 34.7 kHz. The resulting large-scale displacements of the diaphragm created a significant driving pressure, and yielded a substantial net flow. In their study, the pump was composed of an elastic section con-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 794–798, 2009
www.springerlink.com

nected at the ends to rigid sections and a mismatch in acoustic impedance was used to drive fluid flow. By independently compressing the elastic section periodically with the PZT actuator at one asymmetric position from the ends, traveling waves emitted from the compression combined with reflected waves at the impedance-mismatched positions and generated a typically pulsatile flow. It was also found that a flow reversal happened in some range of actuating frequency. However, the device required a high actuating voltage and therefore consumed an excessive power.

Reviewing the literature, it is found that many alterative actuation mechanisms have been proposed for micro pumps, including piezoelectric [9], thermopneumatic [10], electrostatic [11], electromagnetic [12] and others [13]. Of these various methods, electromagnetic actuation has a number of major advantages, including an extended working range, a rapid response time and a low actuating voltage. These characteristics render electromagnetic actuation an appealing choice for applications in which large diaphragm deflections and a straightforward structural integration is required. Among them, Lee *et al.* [12] developed a micro pump comprising a micro coil and a permanent magnet mounted on a PDMS diaphragm. When a current was passed through the micro coil, an electromagnetic force is established between the coil and the magnet. The resulting deflection of the PDMS diaphragm created an acoustic impedance mismatch within the microchannel, which resulted in a net flow.

Accordingly, the current study develops an impedance-based micro pump utilizing an electromagnetic actuation technique. The major components of the device include a lower glass substrate containing an electroplated planar copper micro coil, a glass microchannel, a glass cover plate and a PDMS diaphragm with a magnet diaphragm electroplated on its upper surface. In the pumping operation, fluid is driven through the pump by applying a current to the micro coil such that an electromagnetic force is established between the coil and the magnet causing a resulting deflection of the PDMS diaphragm. The performance of the pump is evaluated experimentally. It is shown that the maximum diaphragm deflection is approximately 30 μm and is attained using an actuating current of 0.6 A. Under these operating conditions, a flow rate of 1.5 μl/sec can be achieved by driving the diaphragm at a frequency of 240 Hz.

II. Design

As shown in Fig. 1, the micro pump comprises four basic layers, namely a lower glass substrate containing a planar micro coil, a microfluidic channel, a glass cover plate, and a PDMS diaphragm with a magnet electroplated on its upper surface. The pump body has overall dimensions of 26 mm × 15 mm × 2.5 mm (length × width × height), while the microchannel measures 11.35 mm × 4 mm × 50 μm (length × width × height). The flow rate of the impedance pump is determined by the volume change induced in the microchannel each time the diaphragm deflects and the frequency at which the diaphragm is actuated [9]. Therefore, in theory, the flow rate can be enhanced by increasing the stroke volume of the diaphragm (i.e. increasing its displacement) or increasing the excitation frequency.

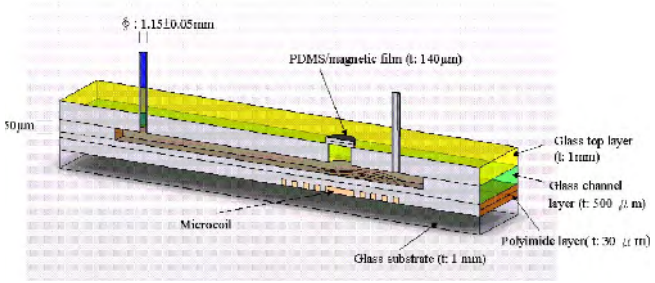

Fig. 1 Schematic illustrations of valveless micro impedance pump

III. Fabication

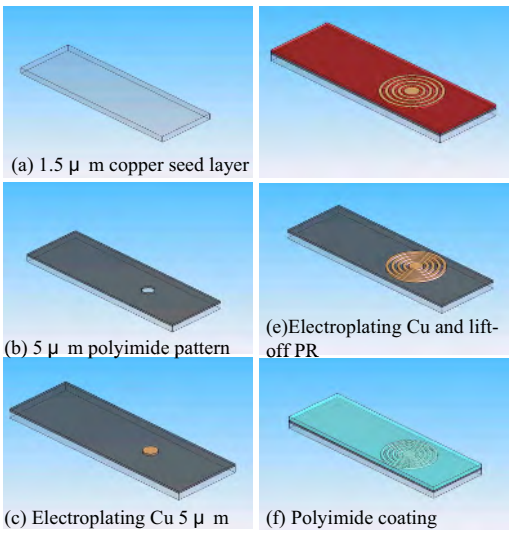

Fig. 2 Major steps in micro coil fabrication process.

The micro pump developed in this study was fabricated using photolithography, vacuum evaporation, electroplating and wet etching microfabrication techniques. The fabrication process involved the following basic procedures: (1) electroplating the micro coil on the lower glass substrate (Fig. 2), (2) etching the microchannel configuration into a second glass substrate, (3) bonding the lower glass substrate

and the etched substrate, (4) fabricating the PDMS diaphragm, (5) electroplating the magnet of Co-Ni alloy on the PDMS diaphragm, (6) attaching the PDMS diaphragm to an upper glass substrate, and (7) bonding the upper and lower substrate layers to form a sealed microchannel (Fig. 3).

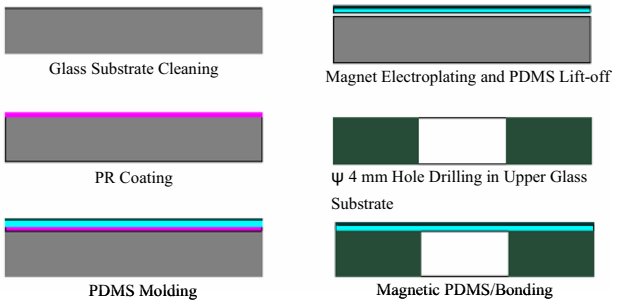

Fig. 3 Major steps in upper plate fabrication process.

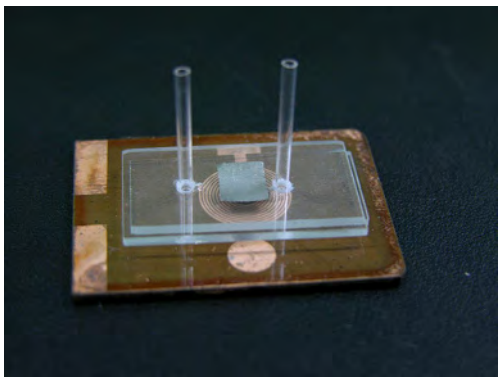

Fig. 4 Photograph of completed micro pump.

IV. Results and Discussion

The flux density characteristics of the micro coil were measured using a Tesla meter (TM-401, KANETEC, Japan). In the characterization tests, the coil was supplied with an input current of 0.2, 0.4 and 0.6 A, respectively, and the variation of the flux density was measured in the vertical direction along the central axis. The experimental results are presented in Fig. 5. Figure 6 presents the experimental results for the rate of change in the magnetic flux density along the vertical centerline of the micro coil. As discussed previously, to optimize the performance of the electromagnetic actuator, the magnet should be positioned at a height corresponding to the maximum rate of change of the magnetic flux. From an inspection of Fig. 6, it is found that the magnet should therefore be positioned 500 μm above the micro coil.

The displacement characteristics of the diaphragm were evaluated experimentally using a laser displacement meter (LC-2400A + 2430, Keyence, Japan) powered by a PR8323 power supply (ABM, Taiwan). The displacement was measured at the central area of the diaphragm, i.e. the position of maximum deflection, at micro coil currents in the range 0.1-0.5 A. The experimental results for the variation of the diaphragm displacement with the input current are presented in Fig. 7.

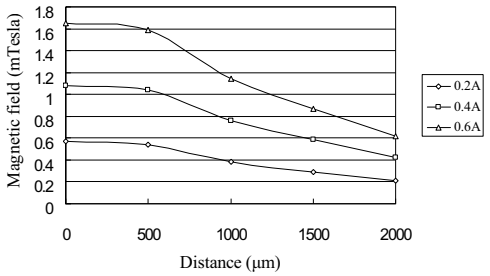

Fig. 5 Experimental results for flux density produced by micro coil.

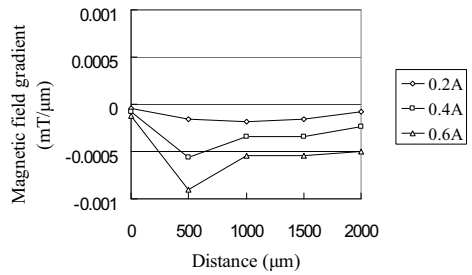

Fig. 6 Experimental results for rate of change of flux density with vertical distance from micro coil

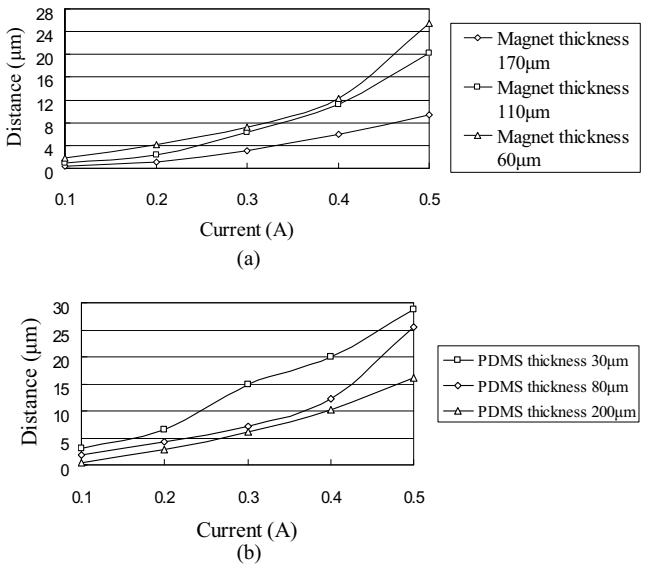

Fig. 7 Experimental results for maximum diaphragm deflection for input current ranging from 0.1 A to 0.5 A. at (a) different magnet diaphragm thicknesses and (b) different PDMS diaphragm thicknesses.

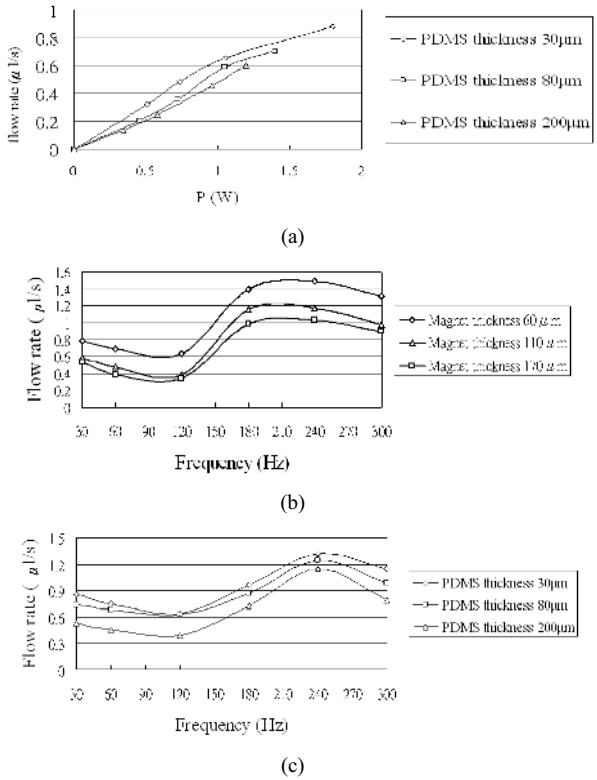

Fig. 8 Experimental results for flow rate given (a) input power ranging from 0 W to 1.8 W at different PDMS thicknesses, (b) actuation frequency raging from 30 Hz to 300 Hz at different magnet diaphragm thicknesses and (c) the same frequency range at different PDMS diaphragm thickensses.

The flow rate characteristics of the micro pump were evaluated by monitoring the difference in the levels of two water columns contained within capillary tubes connected to the inlet and outlet sides of the pump, respectively (see Fig. 4). Figure 8(a) illustrates the variation in the flow rate with different input powers. The results indicate that the flow rate increases linearly with an increasing input power on the coil. From inspection, the maximum operational flow rate (i.e. the flow rate at a coil power of 1.8 W) is found to be around 0.9 μl/s as the PDMS diaphragm thickness is 30 μm and the actuation frequency is 30 Hz. Maintaining a constant coil current of 0.6 A, the flow rate was evaluated for excitation frequencies ranging from 30~300 Hz at different magnet diaphragm and PDMS diaphragm thicknesses. The corresponding results are presented in Fig. 8(b) and (c), and indicate that the maximum flow rate is obtained at a frequency of 240 Hz.

V. Conclusions

This study has designed and fabricated a novel micro valveless impedance pump. The experimental results have shown that the actuator mechanism, comprising a micro coil, a PDMS diaphragm and an electroplated magnet, provides a large diaphragm deflection and a low power consumption. The micro pump is fabricated using MEMS techniques, has a planar structure and can therefore be readily integrated with other microfluidic devices to create a Lab-on-a-Chip device. It has been shown that the maximum diaphragm deflection is approximately 30 μm and is attained using an actuating current of 0.6 A. The corresponding flow rate is found to be 1.5 μl/sec at an actuating frequency of 240 Hz. Overall, the experimental results indicate that the micro pump presented in this study represents an ideal solution for microfluidic systems in which miniaturized pumps are required.

Sample Concentration and Auto-location With Radiate Microstructure Chip for Peptide Analysis by MALDI-MS

Shun-Yuan Chen, Chih-Sheng Yu, Jun-Sheng Wang, Chih-Cheng Huang, Yi-Chiuen Hu

[1] Instrument Technology Research Center, National Applied Research Laboratories, Taiwan

Abstract — **A new micro-scale radiate chip was demostrated for matrix assisted laser desoption/ionization mass (MALDI-MS) sample concentration and auto-location. While mass spectrometry is nowadays an important tool for analyzing and characterizing large biomolecules of varying complexity, sample preparation has become a key point within the whole experiment, and sample concentration is a most often used procedure to improve MALDI sensitivity. Here we demonstrated another simple method in concentrating samples for MALDI mass spectrometry analysis by using a micro-scale structure chip. Samples applied around the chip could auto-located to the center and deposited on the central zone after air dried. It showed that all the samples applied on the chip were concentrated and confined precisely to the central zone, even up to 30 micro liters. Sample spots formed on our chip were much smaller than those on an unmodified plate with the same total volume. With standard MALDI/MS sample preparation procedure, we found that matrix samples were precisely concentrated in our chip and significant enhanced results were obtained by MALDI/MS.**

Keywords — **MALDI, mass spectrometry, concentrate, chip, auto-location.**

I. Introduction

While mass spectrometry is nowadays an important tool for analyzing and characterizing large biomolecules of varying complexity, sample preparation has become a key point within the whole experiment. Sample concentration is the most often used procedure to improve the sensitivity of matrix assisted laser desorption/ionization mass (MALDI/MS). Different kinds of methods have been reported and used, like nano-material added, plate surface modified, hydrophobic surface deposition, and so on. Different kinds of functional plates were made by using the concepts of nanotechnologies with unreveal materials that could precisely control the deposition of sample on the surface. The dried spots would be precisely restricted within the less than 300um diameter central zone after vacuum sublimation. With appropriate modification on the surface, the plate could even isolate and purify specific proteins.

Another continuing challenge in MALDI MS is the spread of matrix and sample cocrystalline structures required for effective ionization. Typically, in MALDI MS, the analyte is distributed unevenly throughout the sample spot, or "sweet spot". To search for these sweet spots is time consuming for high-throughput or automated processes. Hence, the ability to concentrate and localize samples is advantageous, especially for low concentration of analyte.

Different methods, like chemical treatment and nanotechnology have been developed to change the surface hydrophobic characters. Although these methods may have good performance, but the processes of manufacture are minute and complicate. Here we demonstrated a new method for peptide sample preparation. Micro-scale radiate chip was manufactured by photolithography process, and could apply directly to the MALDI/MS. Added sample could auto-located to the center of the chips and deposited on the central zone after dried. After analysis by mass spectrometer, the results showed that our chip really had better performance in sample concentration and deposition than conventional MALDI/MS plate.

II. Materials and methods

A. Reagents and Materials

All test materials were reagent grade or better. A-cyano-4-hytdroxycinnamic acid (CHCA) matrix was purchased from Waters Corporation. Acetonitrile (ACN), ethanol, 0.1% trifluoroacetic acid, ammonium citrate, and human albumin were purchased from Sigma-Aldrich. The peptides adrenocorticotropic hormone (ACTH) fragment were used as reference standard and purchased from Bruker Corporation, ACTH (18-39)_[M+H]+_mono with a molecular weight of 2465.199 Da and ACTH(7-38)_mono with 3657.929 Da.

B. Methods

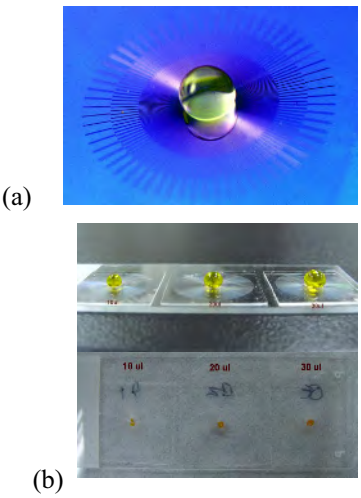
Sample preparation

CHCA matrix working solution was prepared as followed. 5 mg/ml CHCA was dissolved in the solution of 90:10 acetonitrile : 0.1%TFA. Peptides were dissolved in distilled water to a final concentration of 1 mg/ml. Human albumin was dissolved to 5mg/ml solution before use.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 799–801, 2009
www.springerlink.com

Micro-scale chip fabrication

The radiate microstructure chip was manufactured by photolithography process, and was deposited with C4F8 in Plasma-thermo Parallel Plate Plasma Etcher. Finally, chips was adhered to the stage of the ABI Vayager mass spectrometer.



The MALDI/MS experimental process

First, we applied 1 micro litter peptide sample on the plate or chip, and added another 1 micro litter matrix solution immediately without mixing. The mixture solution was dried down in ambient conditions for about few minutes. Finally, the analyte/matrix mixture had been analysis by the mass spectrometer. The time is a function of an ion's mass-to-charge (m/z) ration, enabling an ion's mass to be derived from its TOF.

III. Results

Radiate Microstructure Chip

The chip manufactured by photolithography was illustrated as figure 1. All lines were radiates from the central circle zone which has different diameter. After applied appropriate volume of samples around the chip, the sample droplet would run into the center without any external force and deposited on the central zone. Here we demonstrated 5 mg/ml albumin as sample, and separately added 10, 20, 30 microliter to each chip. The sample droplets were confined to the central zone by the radiated lines. After about four hours, all samples were dried and concentrated into the central zone.

Cocrystalline on the central zone

In order to analyze by the mass spectrometer, sample mixed with organic matrix needed to apply to the stainless plate for electricity conduction. For this reason, we used the silicon chip as substrate. After applied 2 microliter peptide/matrix mixed sample on the chip, cocrystalline was formed in a short time and concentrated on the central zone. Figure 2a showed that peptide/matrix mixed droplet applied on the silicon chip and the observation of cocrystalline from the microscopy. After cocrystalline was formed, chips were analyzed by ABI voyager MALDI/MS. Figure 2b are the peptide mass maps from 1 pmole ACTH with different central zone size. Each zone size all has a significant signal from MALDI/MS.

(b)

Fig. 2 (a) The appearance of radiate microstructure chip used for MALDI and the peptide/matrix cocrystalline observed by optical microscopy. (b) The peptide mass map of ACTH(7-38)_mono (3657 Da) based on the radiate microstructure chip.

Matrix optimization

In order to find out the optimum condition in our chip, different concentrations of CHCA in matrix were used. We applied 1ul of 1mg/ml ACTH on the chip, and then added another 1ul of matrix immediately. Figure 3 showed the ACTH peptide mass map separately with 10mg/ml, 2mg/ml, 1mg/ml, 0.5mg/ml, 0.1mg/ml CHCA as matrix. It looks that even with low concentration of matrix, the signal from MADLI/MS was still significantly.

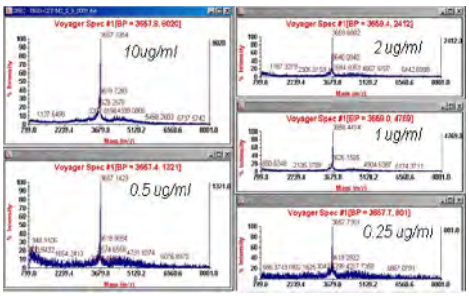

Fig.3 The effects of different CHCA concentration on ACTH peptide mass analysis.

Sample Concentrate on Microstructure Chip

To verify the effect of concentrate on our chip, the original ABI stainless sample plate was used as the control. We used different concentration of ACTH as sample, which was applied separately to the ABI plate and on our chip. Then added equal volume of matrix immediately and waited till dried. All experimental conditions, like laser pulse intensity, were the same. After collected from mass spectrometer, the data were showed as figure 4. It looks that the sensitivity and signal intensity have remarkable performance on our chip than original stainless plate.

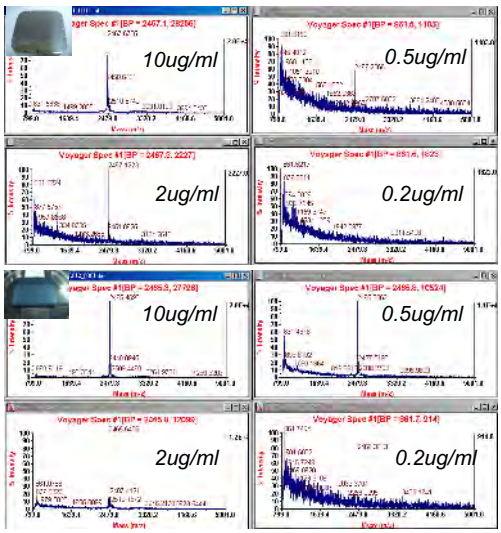

Fig.4 The comparison of ACTH peptide mass maps between conventional mass stage (upper) and radiate microstructure chip (below).

IV. CONCLUSIONS

Silicon-based substrate used for the MALDI/MS has been reported by A. Kraj et al. They developed porous silicon to improve the sensitivity of low molecular weight sample. Here we demonstrated the on-chip concentration with our chip. The radiate silicon chip could concentrate and auto-deposit sample, and used for MALDI/MS is just one of our applications. The results from our experiments showed that to use the microstructure silicon chip as the substrate for mass spectrometer was a feasible way. With appropriate design for the radiate lines, sample/matrix would centralize and cocrystallize to the central zone of our chip. And analyzed by the mass spectrometer, the sensitivity and intensity of our chip showed better than original stainless plate.

The sensitivity and speed of MALDI-MS analysis have led to its being used for the majority of protein and oligonucleotide analysis in high-throughput proteomics and genomics projects. Our chip provides a novel direction to concentration and deposition in MALDI/MS sample preparation, and make the automated process to be more feasible.

Abstract — **The development of a seed-mediated growth method for synthesis of iron oxide nanoparticles with tunable size distribution and magnetic properties is reported. The detailed investigation of the size distribution of seed as well as iron oxide nanoparticles during the growth process has been carried out using transmission electron microscopy (TEM). It was observed that the distribution of size gradually becomes narrow with time via the intra-particle ripening process and Oswald ripening process. The monodispersed iron oxide nanoparticles with sizes between 5 - 10 nm were fabricated using this method by varying the experimental parameters. The magnetic nanoparticles showed well-defined superparamagnetic and blocking temperature due to the size effects in consistent with the TEM images. The thermogravimetric analyses exhibited the size-dependent weight loss of the magnetic nanoparticles. The in vitro cytotoxicity tests were also performed in order to determine the cell viability as a function of size and concentration of the magnetic nanoparticles. The as-prepared iron oxide nanoparticles showed biocompatibility and nontoxicity against the normal as well as cancerous cell lines.**

I. Introduction

The magnetic nanoparticles have been researched extensively for magnetic resonance image, drug targeting, magnetic separation and catalytic applications. [1-3] The size effect of particles have the influence on their electrical, magnetic and chemical properties. Hence, it is really important to obtain monodispersity-distribution size during the fabrication of the nanoparticles to increase the sensitivity of these particles for the various applications such as cell image. Generally, the synthesis of magnetic nanoparticles, using methods such as chemical coprecipitation [4] and hydrothermal treatment [5-7], produces broad size distribution of particles. Hence, the development of novel methods have been the focus of recent research to fabricate uniform and highly monodispersed nanocrystals by thermal decomposition method.

Herein, we report the development of a seed-mediated growth method for the synthesis of iron oxide nanoparticles with tunable size distribution and magnetic properties. A simple method has been illustrated to fabricate the monodispersed iron oxide nanoparticles from 5 to 10 nm with varying the experimental parameters. It was observed that the seed-mediated growth method for iron oxide nanoparticles is advantageous since it is a non-injection or heating-up method with easily controllable growth process. The iron oxide nanoparticles were characterized by X-ray diffraction (XRD) and thermogravimetric analysis (TGA). The synthesis of iron oxide nanoparticles was found to be reproducible with the tunable properties. The *in vitro* cell viability analysis were also performed for these iron oxide nanoparticles in order to determine their cytotoxic effects.

II. Materials and methods

A. Experimental section

Synthesis of iron oxide nanoparticle seeds. The seeds were prepared by following a procedure reported in literature. [8] Briefly, The mixture of the $Fe(acac)_3$ (2 mmol), oleic acid (6 mmol), oleylamine (6 mmol), 1,2-tetradecanediol (10 mmol) and 20 mL of phenyl ether were magnetically stirred in a three-net-round flask under nitrogen atmosphere. The mixture was slowly heated at 265 °C to reflux for 30 min, then followed by cooling under room temperature. The iron oxide nanoparticles were washed using ethanol and collected in solid form after centrifugation at 9000 rpm. The product was further washed several times by hexane to remove the residual solvent. Finally, 5.4 nm iron oxide nanoparticles were obtained after drying in the oven, which were redispersed into hexane. The different size iron oxide nanoparticles in growth solution was synthesized. The synthesis of iron oxide nanoparticles of different sizes involved an initial formation of iron oxide nanoparticles as seeds and subsequent growth of the particles in the presence seeds at high temperature. The concentration of growth solutions prepared by adjusting the concentration of

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 802–805, 2009
www.springerlink.com

$Fe(acac)_3$ and phenyl ether/ benzyl ether were 0.028, 0.056, 0.084, 0.112 M. The mixture of 0.08 g seeds and 20 mL growth solution in the presence of 1,2-tetradecanediol, oleic acid and oleylamine was heated to 265 °C at a rate of 4 °C/min under nitrogen atmosphere and then was kept at this temperature for 30 to 90 min for complete growth of nanoparticles. After the growth of the nanoparticles, the reaction mixture was cooled down to room temperature followed by the addition of ethanol. The brown precipitate thus formed was redispersed into hexane.

B. Cytotoxicity assay

Considering the increasing applications of the magnetic nanoparticles in the biomedical fields, the in vitro cell viability studies were performed in presence of the magnetite nanoparticles synthesized by the above method. The normal breast epithelial cell (H184B5F5/M10) and the three type of breast cancer cells (SKBR3, MB157 and T47D) were used for cytotoxicity tests. These cells (2000 cells per 90 μL) with 10 μL of different concentrations of nanoparticles (in 0.l, 1, 10, 100 μg/mL) were seeded into different wells and were incubated for 72 h followed by the addition of 20 mL of MTS (3 - (4,5-dimethylthiazol-2-yl) -5 - (3-carboxymeth oxyphenyl) -2-(4-sulfophenyl)- 2 H- tetrazolium, inner salt) in each well. The optical density (OD) of the resultant solutions were determined (λ= 490 nm) by using microplate absorbance reader (SpectraMAX 340pc, Molecular Devices, CA).

III. Results and Discussion

Figure 1 shows the standard deviation (σ) of nanoparticles size distribution after refluxing for different time scales. In the beginning, the σ value increases with increasing refluxing time owing to the result of size difference between the small nuclei and the growth particles. The maximum value has been observed between 30 and 60 min and then it begins to drop and deviates from the original trend. As a result the amount of small particles decreases and the distribution of particle size start to focus. The rapidly decreasing σ value in high concentration solution shows the small particles dissolves easily due to the relatively large critical radius. By controlling the reaction time and various concentrations of growth solution, it was possible to produce monodispersed nanoparticles with particle sizes of 6.8, 7.6, 8.2 and 8.3 nm. The TEM images of the particles along with the seed are shown in Figure 2. The figure 2 (F) is the table of calculated average size of the particles by using corresponding TEM images of the samples.

Figure 3 shows the concentration-dependent seed growth after reacting for 90 min in different solvents such as benzyl ether and phenyl ether. The boiling temperature of benzyl ether is higher than that of phenyl ether, so the system in benzyl ether product the high temperature condition than in phenyl ether. It was observed that the size of as prepared seeds in benzyl ether is larger than in phenyl ether, because the amount of monomers induced by thermal energy increases with temperature. The growth curve finally reached the saturation value due to the high concentration of solvents. The maximum value was observed at around 8.2 and 10.2 nm for phenyl ether and benzyl ether, respectively. Although the higher concentration causes faster seed growth, some part of monomers also form small particles and grow over the level of critical radius to compete with as-prepared seeds. Hence, the final particle concentration is contributed partial from primary nucleation of the particles, so that the particle size is limited. Thus, by tuning the parameters such as temperature and concentration, the series of monodis-

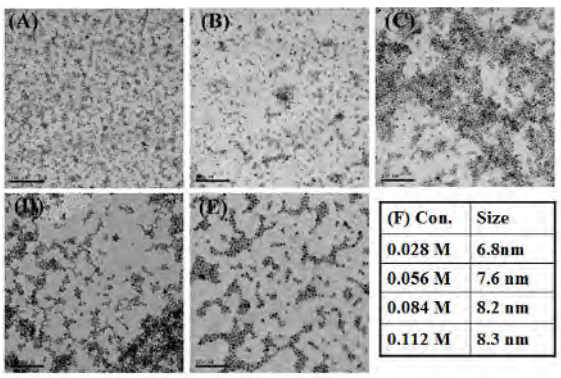

Fig. 2 TEM images of seed solution (A) and iron oxide nanoparticles after growth in different concentrations of growth solution such as (B) 0.028 M, (C) 0.056 M, (D) 0.084 M, (E) 0.112 M and (F) Final particle size of iron oxide nanoparticles in different concentrations of growth solution.

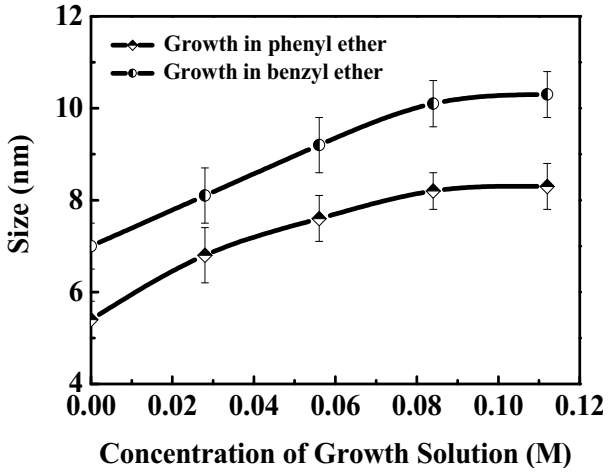

Fig. 3 The concentration-dependent seed growth in phenyl ether and benzyl ether.

persed nanoparticles in the range of 5.4 to 10.2 nm are synthesized successfully.

Figure 4 shows the XRD patterns of iron oxide nanocrystals of 5.4, 6.8, 7.6, 8.2 nm and the standard Fe_3O_4 and αFe_2O_3. The peak positions and relative intensities of nanoparticles agree well with XRD patterns of standard Fe3O4, which confirms the well-known inverse spinel structure of the magnetite materials. The average size of the iron oxide nanoparticles are deduced from Sherrer's equation as shown in Table 1, which is consistent with the result obtained from the transmission electron microscopy (TEM) analysis.

The weight loss in TG analysis for 5.4, 6.8 and 7.6 nm iron oxide nanoparticles are shown in Figure 5. The TGA curve displays a weight loss from room temperature to 250°C and a sudden drop between 250 ~ 350°C and 550 ~

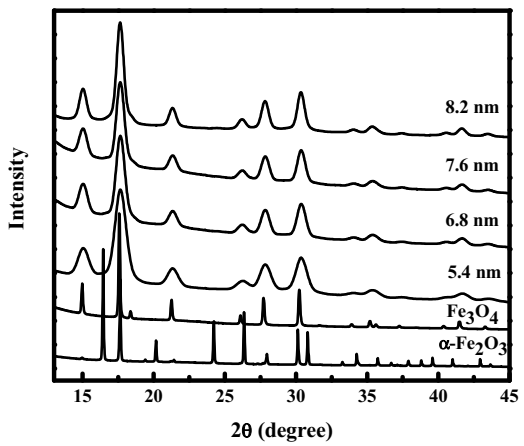

Fig. 4 XRD patterns of iron oxide nanocrystals of 5.4, 6.8, 7.6, 8.2 nm sizes and the Fe_3O_4 and α-Fe_2O_3 standard.

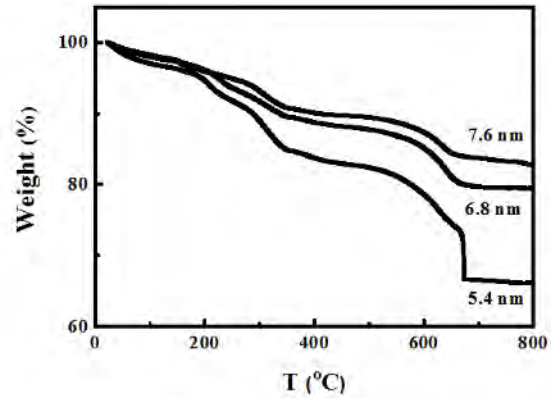

Fig. 5 TG analysis for 5.4, 6.8 and 7.6 nm iron oxide nanoparticles

650°C, respectively. The weight loss in the low temperature region results from the evaporation of free oleic acid and the solvent, phenyl ether. However, the weight loss at relative high temperatures can be attributed to the decomposition of oleic acid bound tightly to the surface of nanoparticles. These results suggest the two dissociation regions of oleic acid, owing to the two kinds of interactions between iron oxide nanoparticles and oleic acid. The decomposition at higher temperatures can be attributed to the chemical bonding between Fe^{2+}/Fe^{3+} and carbonyl group of ligand. Since the smaller nanoparticles provide more binding sites on the surface for surfactant than larger ones, the amount of weight loss is related to the particle size due to higher surface area to volume ratio of nanoparticles. Thus TG analyses offer the important quantitative analysis for different particle sizes of magnetic nanoparticles.

For the biomedical applications of iron oxide nanoparticles such as magnetic resonance imaging, it is necessary to modify the hydrophilic ligand on the nanoparticles surface to promote the suspension of nanoparticles in aqueous media. In the present studies, we have modified the nanoparticles surface by replacing the oleate species using the tetramethyl- ammonium 11-aminoundecanoate ligand to promote hydrophilicity. [8] The carboxylate group of the

ligand binds to the surface iron and exposes the hydrophilic amino group to aqueous media. For analyzing the biocompatibility, the hydrophilic nanoparticles of size 5.4 nm and 7.6 nm in the concentrations range of 0.1, 1, 10 and 100 μM were treated with the normal breast epithelial cells (H184B5F5/M10) and the three types of breast cancer cells (SKBR3, MB157 and T47D) for 72 h. Figure 6 shows the cell viability results for normal as well as breast cancer cells using 5.4 nm and 7.4 nm nanoparticles. The cytotoxicity studies revealed that there is no obvious change in cell viability in the studied concentration range of magnetic nanoparticles, although the 100 μM nanoparticle concentration is considered to be far higher than the normal use. Thus, the as-prepared nanoparticles showed biocompatibility and nontoxicity against the normal as well as cancerous cell lines.

IV. Conclusions

In summary, we have synthesized the iron oxide nanoparticles with monodispereity using the seed-mediated method combined with thermal decomposition. The size evolution has been demonstrated by understanding the growth process for the formation of monodispersed nanoparticles. It is also possible to control the distribution and size of the particles by tuning the temperature and the concentration of growth solution. Under the high concentration condition, the nucleation and growth process compete with each other to consume the monomers, whereas the temperature can affect the degree of dissociation of precursor for the further growth of nanoparticles. Hence, we modified these factors to get the monodispersed iron oxide nanoparticles with standard deviation ($\sigma < 1$). The TG analyses showed that the surface of nanoparticles were occupied by different amount of ligands via physical absorption and chemical binding, which changes with particle size, owing to the surface area to volume ratio. The as-prepared iron oxide nanoparticles showed biocompatibility and nontoxicity against the normal as well as cancerous cell lines.

Abstract — **The ultraviolet (UV) rays from sun are generally divided in three types such as UVA (315~400 nm), UVB (280~315 nm) and UVC (100~280 nm). Among these, the UVC rays with the highest energy get absorbed completely as they pass through the atmospheric layer. The UVA and UVB rays which penetrate through the atmospheric layer pose a threat for the humankind due to its carcinogenic nature to human skin. Hence it is necessary to develop the cosmetics which absorb the UV rays to prevent the damage of the skin. Generally, the Tinosorb M (2,2'Methyl-enbis[6-(2H benzotriazol-2-yl)-4-(1,1,3, 3-tetra-methylbutyl) phenol]) is mixed in the cosmetics which absorb UVB rays. But almost 97% of the UV rays consist of UVA rays which are mainly responsible for the damage of skin. Recently, the sun-screening cosmetics containing the nanoparticles such as ZnO and TiO_2 nanoparticles or nanorods have attracted great attention for protecting skin from UVA by reducing the amount of UVB penetrating into the skin due to the reflection and scattering. Therefore, it is necessary to investigate the risk factors involved in the usage of these nanoparticles in cosmetics. The present studies involve the characterization of cosmetics containing TiO_2 and ZnO nanoparticles and its comparison with the commercial samples. The absorbance measurements in the range of UVA were performed in order to determine the absorption efficiency of nanoparticles extracted from the cosmetics samples. The transmission electron microscopic analysis revealed the morphology of the nanoparticles. The in vitro cell viability tests were performed as a function of particles size in order to determine the cytotoxicity of the nanoparticles.**

Keywords — **sun-screening cosmetics, zinc oxide, titanium oxide, nanoparticles and cytotoxicity analysis.**

I. Introduction

The nanoscience and nanotechnology have already been offered the new industrial and health related applications of nanoparticles for the commercial product such as cosmetics, food additive and medicine reagent, because it is attributed to the unique properties for nanoparticles in comparison with the their relative bulky materials. [1-4] The sun-screening cosmetics containing the additive of nanoparticles are useful way to protect the human skin from the exposure to the UVA by the result of scattering and reflection physical properties. The nanoparticles such as zinc oxide, titanium oxide etc. with smaller size than the wavelength of light provide the excellent scattering and absorption ability in the range of UVA, but there are many uncertain risk factors formed such as the penetration of nanoparticles for skin and the exposure of nanoparticles to the lung. [5-7] Hence, it is necessarily for scientist to investigate the properties of manufactured commercial product.

In the present studies, the properties of commercial product of sun-screening cosmetics containing the nanoparticles has been investigated, including of the determination of their percentage content and the identification of nanomaterials, by using extraction method to separate the part of nanoparticles from sun-screening cosmetics. We offer and confirms the exact the nanoparticles component for further quantitatively/qualitative analysis and bio-analysis such as cytotoxicity assay. The cytotoxicity analyses of different commercially available nanoparticles are performed with different cell lines including S-G (transformed oral keratinocyte), OMF (oral mucosa fibroblast) and WI-38 (lung fibroblast) to investigate the particles size effect on cell viability.

II. Materials and Methods

A. Experimental section

The sun-screening cosmetics were purchased from the five companies. (SH, ES, KA, LA and CL) Nano-scaled commercially available TiO_2 nanoparticles (AFDC; 161 nm spherical irregular particles and M212; 20 nm width/ 50 nm length nanorods) were purchased from Top Rhyme International Company. Acetone (>99.5%, Sigma-Aldrich), ethanol (99%, Riedel-deHean) and n-hexane (99%, Riedel-deHean) were used as purchased without further purification.

The 1.5 g sun-screening cosmetics was dispersed into 50 mL solvent such as ethanol, hexane or acetone followed by sonification for 20 min. Supernatant was removed using centrifugation at the rate of 9,000 rpm and then white powder was collected and dried in the oven at 70^{o}C for 10 min. Repeating the above steps several times to complete re-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 806–809, 2009
www.springerlink.com

moval of the organic species from the sample. Finally, the pure white powders were obtained which was characterized by XRD (X-ray powder diffraction; PANalytical X' Pert PRO), UV/visible spectroscopy, SEM (scanning electron microscope; Tecnai-G2-F20) and TEM (transmission electron microscope; JEOL JSM-1200EX II).

B. Cytotoxicity assay-MTS assay

Three normal cell lines were employed in this study including S-G (transformed oral keratinocyte), OMF (oral mucosa fibroblast) and WI-38 (lung fibroblast). S-G and OMF were cultured in Dulbecco's modified Eagle' medium (DMEM, Gibco, Grand Island, NY, USA). WI-38 was cultured in Minimum essential medium (MEM, Gibco, Grand Island, NY, USA). All mediums supplemented with 10% (v/v) FBS (Hyclone, CA, USA), 2mM glutamine (Gibco, Grand Island, NY, USA), 100 units/mL penicillin (Gibco, Grand Island, NY, USA), and 100 mg/mL streptomycin (Gibco, Grand Island, NY, USA). All cell lines were incubated in a 37°C humidified atmosphere (95% air and 5% CO_2).

In the first day, 2000 cells were seeded to each well in 96-well plate and incubated overnight at 37 °C in 5% CO_2.In the second day, replaced the medium with variant amounts of titanium dioxide which was suspended in 200 µL growth medium. The doses of titanium dioxide (AFDC and M212) were followed: 13000, 300, 80.3, 20.8, 5.2 and 1.3 µg/mL. After 72 hrs incubation, 20 µl MTS was added into each well and incubated for one to three hours. The cell viabilities were determined by the absorbance of OD_{490nm} which were measured by ELISA reader.

III. Results and Discussion

The morphology of the nanoparticles extracted from the sun-screening cosmetics was analyzed using TEM. The images of TEM are shown in figure 1(a) ~ 1(e). The morphology image of the nanoparticles exhibits the irregular spherical shape for the SH and ES cosmetics, the mixture shape of irregular spherical, long rod and short rod for KA cosmetics and only rod shape for LA cosmetics. The morphology of the CL nanoparticles reveals that the shape of the uniformly distributed core-shell structures, which is quite different from others. The TEM images show all the nanoparticles were of the nano-scale size except the figure 1(e) and the morphology of nanoparticles are different due to the nature properties of materials such as the preference orientation for crystallization growth. The nano-scale size of particles satisfies the scattering requirements for the wavelength of UV (100 nm ~ 400 nm) and absorption peak found

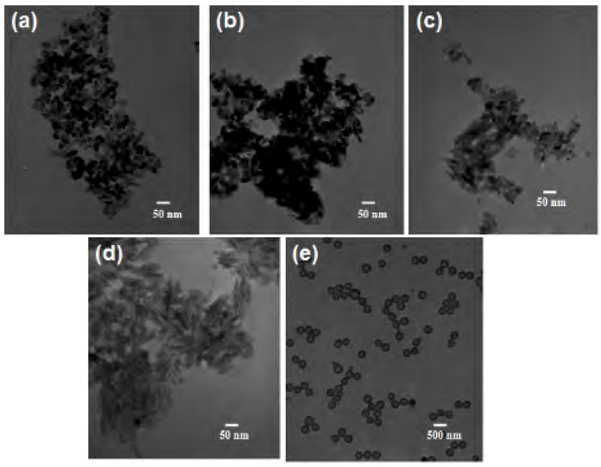

Fig. 1 The TEM images of nanoparticles extracted from the commercial products of (a) SH, (b) ES, (c) KA, (d) LA and (e) CL companies.

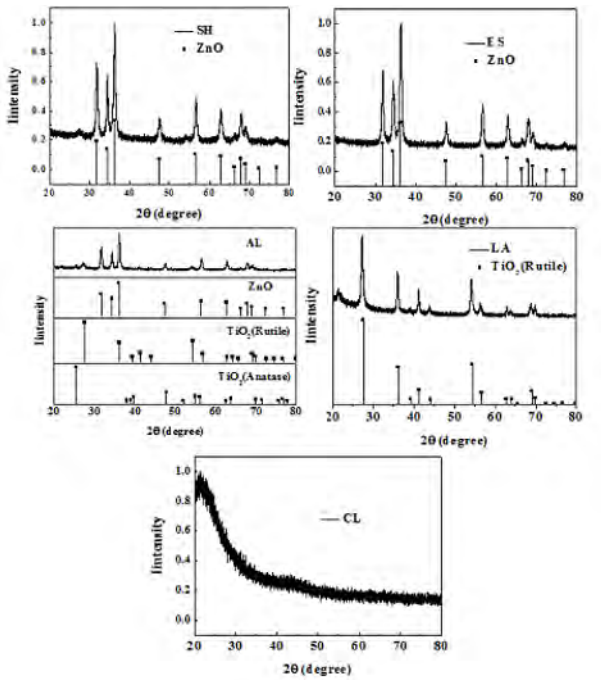

Fig. 2 XRD patterns of nanoparticles and standard of zinc oxide and titanium oxide in the form of rutile and anatase

in the range of UVA, as the nanoparticles size is smaller than the wavelength of incident light and the absorption position of energy shifts to UV range due to size effect. Hence, The TEM images also support that the size of nanoparticles are responsible for the physical sun-screening. Figure 2 reveals the several characterization peaks for the nanoparticles. The XRD peaks of SH nanoparticles are agreed well with the standard zinc oxide pattern and the

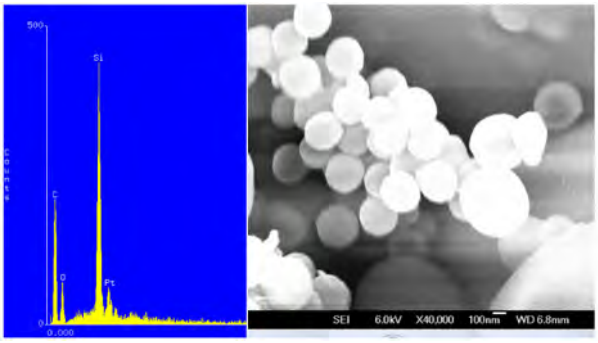

Fig. 3 SEM-EDS and SEM image of nanoparticles extracted from the commercial product of CL company.

same is found for ES nanoparticles, so these contains zinc oxide nanopartcles as the physical sun-screen component. Because the XRD pattern of AL nanoparticles consists of the standard pattern of zinc oxide and titanium oxide in the rutile and anatase forms, the AL nanoparticles being composed of three type nanoparticles, which are responsible for more absorption positions in the range of UVA and UVB than only single material. The XRD peaks for LA nanoparticles appear only the characterization of titanium oxide in the form of rutile. Finally, the crystalline of CL nanoparticles is amorphous, because there is no any peak appeared in the XRD pattern of CL nanoparticles. In figure 3, SEM image revealed the surface morphology of CL nanoparticles, which was found in form of smooth spphere and SEM-EDS analysis show all of its composition is silica. Low refractive indexed non-crystalline components of CL sun-screen make it transparent and high reflection due to the bulk material. In the table 1, it displays the of nanoparticles size for five products calculated by using the Scherrer equation. The zinc oxide nanoparticles sizes are consisted with the TEM image around 20 nm for the SH, ES and AL nanopaticles. However, the titanium oxide in the anatase form for AL cosmetics shows the larger size than others due to the length of nanorod. For titanium oxide in the rutile form, it appears the

Table 1 Nanomaterials size are deduced using scherrer equation.

	SH	ES	AL	LA	CL
ZnO	16.0 nm	16.6 nm	22.8 nm	-	-
TiO_2 (Rutile)	-	-	12.2 nm	16.9 nm	-
TiO_2 (Anatase)	-	-	41.3 nm	-	-

Table 2 Weight percentage of solid component of cosmetics

	SH	ES	AL	LA	CL
Powder (wt%)	20%	16.6%	16%	5.2%	5.5%
Others (wt%)	80%	83.4%	84%	94.8%	94.5%

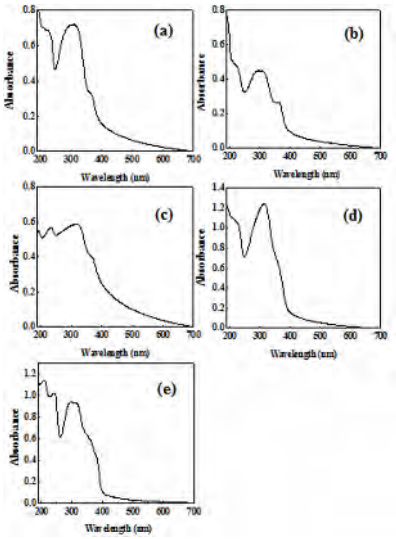

Fig. 4 UV/vis spectroscopy of (a) SH, (b) ES, (c) AL, (d) LA and (e) CL cosmetics with anal sized in the range of 200 ~ 700 nm

size is as same as zinc oxide nanoparticles, so it also forms irregular sphere by comparison with the TEM image. There is no specific peak found in XRD pattern for the CL core-shell nanoparticles, so the particles size is only calculated by the TEM or SEM image.

Table 2 show the percentage of content for cosmetics such as the powder and other organic species. Present of 20 wt%, 16.6 wt%, 16 wt%, 5.2 wt% and 5.5 wt% powders were found for the sun-screen cosmetics of SH, ES and AL cosmetics after the extraction procedure. It shows the large amount of powder used as content of cosmetics during the manufacture procedure. Previously, there is no any investigation that includes bio-analysis such as cytotoxicity for these cosmetics. Exposure of such fine particles to human skin or lung is very dangerous. Though the nature of titanium oxide and zinc oxide did not show any toxicity for humankind, the unexpected effects occurred as the particles size decreases to the nano-scale. Base on the data of TEM image and XRD pattern, the major materials of nanoparticles used as sun-screen agent in cosmetics are titanium oxide and zinc oxide and their sizes localize around 20 nm.

The UV/visible spectroscopy are measured for five cosmetics shown in Figure 4. The wavelength range of UVA lies between 315 ~ 400 nm. The absorption peaks for titanium oxide and zinc oxide nanoparticles are found to be at 280 nm and 375 nm, respectively. Therefore, they all appear the characteristic peaks in the range of UV . [7] The characteristic peak for titanium oxide nanoparticles localize at the UVB range with high intensity, but the absorption peak of zinc oxide nanoparticles exhibit in UVA range with low intensity. For the sun-screening in the UVA range, the zinc

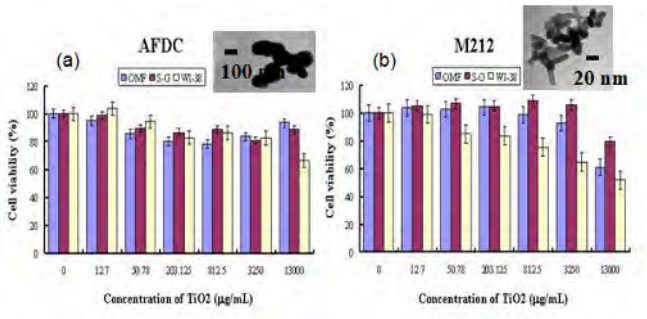

Fig. 5 Cytotoxicity analysis of commercially available titanium oxide with diameter of (a) 161.1 nm and (b) ~20 nm width / 50 nm length nanorod. (The inserts are TEM image of nanoparticles)

oxide nanoparticles is more useful for human skin than titanium oxide nanoparticles, but the intensity is relative low by comparison with each characterization absorption peak. The background for each nanoparticles in figure 4 (a) to 4 (d) is relative higher than the larger particles in figure 4 (e) due to scattering effect by the influence of closed package nanoparticles than larger nanoparticles.

Figure 5 shows the result of cytotoxicity assay of OMF, S-G and WI-38 cell lines incubating in two type nanomaterials as AFDC (161.1 nm nanoparticles) and M212 (20 nm/ 50 nm nanorods). The result reveals that oral keratinocye and fibroblast cells have higher tolerance to the various concentrations of titanium oxide nanoparticles than lung fibroblast, because the cell viability decreases until 13000 μg/mL. For cell lines exposed to M212 nano-materials, the cell viablitity of WI-38 starts to decrease at 50.78 μg/mL. In comparison, the AFDC nano-materials appears less toxic than M212 in cell lines due to the size effect. The mechanisms of the TiO2 to inhibit cell viability remain unknown.

IV. Conclusions

By the analysis of TEM image and XRD pattern, the results reveal that the material of nanoparticles extracted from sun-screening cosmetics is composed of zinc oxide, titanium oxide or mixture of both for the cosmetics of SH, ES, AL and LA companies, but the silica is component for product of CL company by the SEM-EDS. The percentage of content on nanoparticles are 20wt% for SH company, 16.6wt% for ES company, 16wt% for AL company, 5.2wt% for LA company and 5.5wt% for CL company. The datum show quite large amount of nanoparticles used in the sunscreen cosmetics, so the cell in skin and lung will be dangerous to expose to the nanoparticles by the way of contact with flying nanoparticles. The nanoparticles all show the characterization absorption in the range of UV, but only the absorption peak of zinc oxide nanoparticles localize at the range of UVA, and the peak position for titanium oxide nanoparticles place in the range UVB. Hence, the zinc oxide nanoparticles is excellent for sun-screening cosmetics to protect the skin of human kind form the major part of UV, which is UVA. By the cytotoxicity analysis for five cell lines, the high wt% nanoparticles do not benefit the growth environment for the cell and the nano-scale materials suppress the growth of cell due to the size effect.

Design and Analysis of MEMS based Cantilever Sensor for the Detection of Cardiac Markers in Acute Myocardial Infarction

Sree Vidhya[1] & Lazar Mathew[2]

[1] Healthcare Practice, Frost & Sullivan (P).Ltd, Chennai, India
[2] School of Biotechnology, Chemical & Biomedical Engineering, VIT University, Vellore, India.

Abstract — **Piezo-resistive actuation of a microcantilever induced by biomolecular binding such as DNA hybridization and antibody-antigen binding is an important principle useful in biosensing applications. As the magnitude of the forces exerted is small, increasing the sensitivity of the microcantilever becomes critical. In this paper, we are considering to achieve this by geometric variation of the cantilever. The sensitivity of the cantilever was improved so that the device can sense the presence of antigen even if the magnitude of surface-stresses over the microcantilever was very small. We consider a 'T-shaped' cantilever that eliminates the disadvantages while improving the sensitivity simultaneously. Simulations for validation have been performed using Intellisuite software (a MEMS design and simulation package). The simulations reveal that the T-shaped microcantilever is almost as sensitive as a thin cantilever and has relatively very low buckling effect. Simulations also reveal that with an increase in thickness of the cantilever, there is a proportional decrease in the sensitivity.**

Keywords — **Microcantilever, Acute Myocardial Infarction, Cardiac Troponins, Piezo resistive, Thermo Electro Mechanical Analysis**

I. Introduction

This paper presents an analytical modeling of a piezoresistive cantilever used as MEMS based biosensor for the detection of cardiac markers in Acute Myocardial Infarction (AMI).Diagnosis of Myocardial Infarction was achieved by the nanomechanical deflection of the microcantilever due to adsorption of the Troponin I complex. The deflection of the microcantilever was measured in terms of the piezoresistive changes by implanting boron at the anchor point where there is maximum strain due to the adsorption of the analyte molecules. The biochemical interactions between the Cardiac Troponin I (cTnI) complex and the immobilized antibodies would cause change in resistance of the piezoresistor integrated at the anchor point. A 'T' shaped microcantilever design was proposed for the study.

The distal end of the device was coated with gold. The sensitivity of the cantilever was improved so that the device can sense the presence of antigen even if the magnitude of surface-stresses over the microcantilever was very small.

To obtain an application specific optimum design parameter and predict the cantilever performance, Thermo Electro Mechanical (TEM) Analysis using Intellisuite (a MEMS design and simulation package) was performed. The miniaturization of the cantilever-based biosensor leads to significant advantages in the absolute device sensitivity. Precise measurement of the deflection at the end of the cantilever was achieved through this arrangement. Measurement of antigens up to picogram levels can be done using this technique.

II. Materials & methods

A. Theoretical Considerations

The fact that there is no standard procedure to determine the electromechanical parameters of piezo-resistive structures is apparent. In this paper, two different approaches have been used to study the characteristics of the T-shaped microcantilever and to predict its performance during the biomolecular binding process. The first approach uses theoretical relationship between differential surface stress and tip displacement during the biomolecular binding process at the upper surface of the cantilever. In the second approach, FEM simulations by *Intellisuite Software* have been performed on the T-shaped microcantilever.

Piezoelectric materials strain when exposed to voltage and, conversely, electrical charge accumulates on opposing surfaces and produces voltage when strained by an external force. This is due to the permanent dipole nature of these materials. When the biomolecular interaction occurs on the top of the cantilever, the change in the radius of curvature, R and the cantilever deflection z_{max} can be related to the differential surface stress, Δs, by

$$1/R = 6(1 - \nu)\, \Delta s/Et2$$

$$\text{and } z_{max} = 3l\, 2(1 - \nu)\, \Delta s/Et2$$

Where ν is Poisson's ratio, E is Young's modulus for the substrate, t is the thickness of the MC, and l is the cantilever length.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 810–812, 2009
www.springerlink.com

B. Microcantilever Design

Silicon is the substrate material used. To use silicon as a substrate material, it has to be pure silicon in a single-crystal form. The Czochralski method appears to be the most popular method among several methods that have been developed for producing pure silicon crystal. A popular method of designating planes and orientations is the Miller indices. These indices are effectively used to designate planes of materials in cubic crystal families. For simulation purposes, we have considered the design parameters given in table 1.

Table 1 Design Parameters

Length of the cantilever	250 µm
Length of the T-arm	100 µm
Width	50 µm
Cantilever thickness	1 µm

Keeping these parameters into consideration a T-shaped microcantilever was designed using IntelliFAB designer. Sequential steps led to the design of the microcantilever model as shown in figure 1.

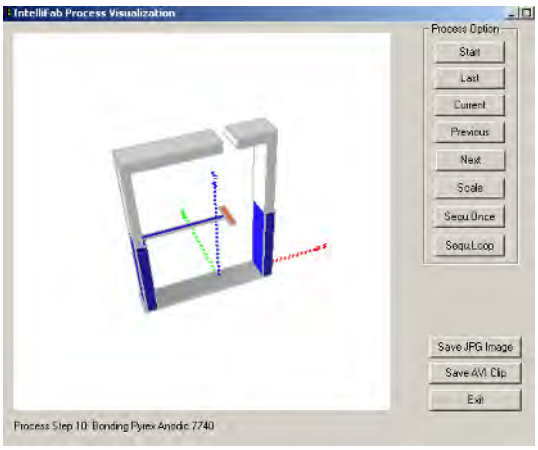

Fig. 1 Cross section of the T-shape micro cantilever design

C. Thermo-electro Mechanical Analysis

Thermo-electro mechanical (TEM) analysis using Intellisuite was chosen as the simulation tool in this study because of its unique capabilities in MEMS design, simulation, and modeling. It has a fully integrated MEMS design environment. The first step (pre-processing) in using TEM analysis module is constructing a model of the structure to be analyzed. The input of a topological description of the structures and geometric features is required in TEM. This is represented in 3D form, using the IntelliFAB designer which gives the virtual prototype of the model. The primary objective of the model is to realistically replicate the important parameters and features of the real model.

Once the geometric model has been created, a meshing procedure is used to define and break the model up into small elements. In general TEM model is defined by a mesh network, which is made up of the geometric arrangement of elements and nodes. Nodes represent points at which features such as displacements are calculated. Elements are bound by set of nodes, and define localized mass and stiffness properties of the model. Elements are also defined by mesh numbers which allow reference to be made to the corresponding deflections or stresses at specific model locations. A fine meshed model of the T-shaped microcantilever used in the analysis is shown in figure 2.

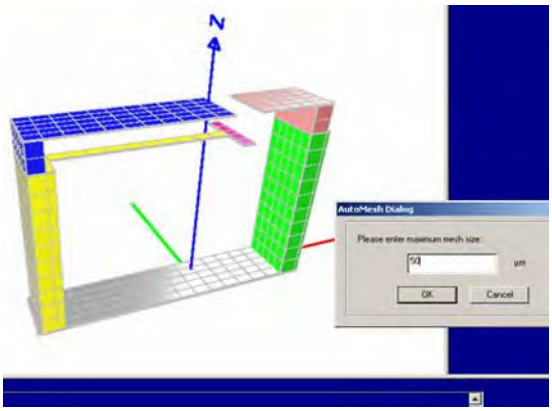

Fig. 2 Intellisuite Auto Mesh With 50 X 50 µ M

III. Simulations and Results

Simulations were performed in order to validate the claim that the T-shaped microcantilever leads to significant advantages in the absolute device sensitivity. Microcantilever with 250µm length x 100µm length of the T-arm x 50µm width x 1µm thickness was used for simulations using INTELLISUITE: material - silicon; Young's Modulus 200GPa; Poisson's ratio 0.22 and mass density of 2.3g cm^{-3}. The effect of the surface stress created by the troponincomplex interactions on the gold coated surface of the cantilever can be effectively simulated by substituting it with a line force (amounting to $15.2x10^{-17}$ MPa) on the edges of the T-arm. Sensitivity has been meas-

ured in terms of the maximum displacement and surface stress undergone by any point on the cantilever as shown in figure 3 & 4.

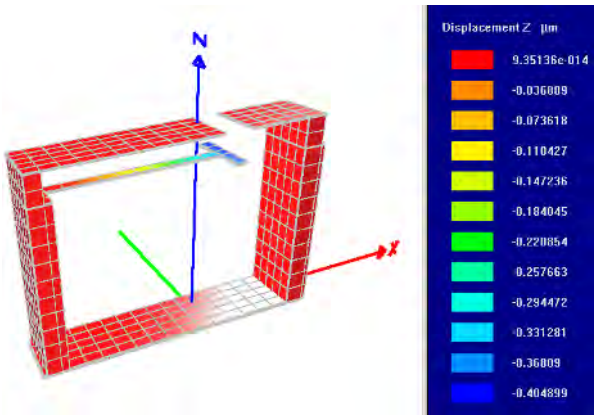

Fig.3 Displacement along Z - axis

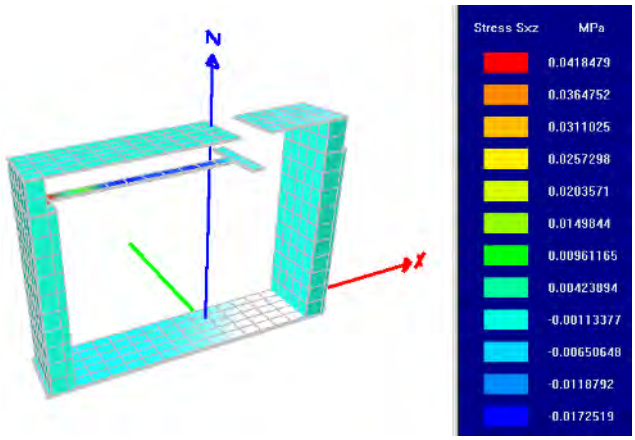

Fig.4 Stress at the anchoring region along Z - axis

IV. Conclusion

Thus a T-shaped microcantilever was designed, analyzed and simulated successfully. Stresses were generated at the anchoring region of the cantilever where Boron was implanted. These stresses were detected by employing piezo-resistive detection method. However, analyses based on the concentration of sample solution may be needed for further research.

Abstract — **In this paper a bio-sensing module by integrating a micro-array probes device and a semiconductor amplifier respectively on two flexible substrates is proposed, which utilizes semiconductor processes. The amplifier is formed of bottom-gate thin film transistors (TFT). As such, the signal obtained by the bio-sensing probes can be amplified nearby to improve the signal-to-noise ratio and impedance matching. This module is formed on the flexible substrate such that the bio-probe device can be disposed to conform to the profile of a living body's portion to improve the electrical contact property.**

Keywords — **Bio-sensing probe, thin film transistor amplifier, flexible substrate, signal-to-noise ratio**

I. Introduction

Conventional micro array biological probes are produced on a hard silicon wafer substrate [1-7]. This kind of product is not only heavy and frangible but also high temperature processes needed. Moreover, the conventional micro array biological probes fail to be designed and disposed relying on the profile of a living body's portion, and adversely affecting contact between the biological probes and living body. Besides, after a signal detected from the conventional micro array biological probes, the signal is picked up to process signal-to-noise ratio and impedance matching. Additional devices for signal processing are required.

This research provides a micro array bio-probe device integrated with TFT amplifier formed of bottom-gate thin film transistors [8-9], which utilizes a micro-electro-mechanical process and a semiconductor process to integrate micro array bio-probes and an amplifier, formed of bottom-gate TFTs on a flexible substrate. As such, the signal obtained by the probes can be amplified nearby to improve the signal-to-noise ratio and impedance matching. The micro array bio-probes are formed on the flexible substrate such that the present bio-probe device can be disposed to conform to the profile of a living body's portion so as to improve the electrical contact property.

The organization of this paper is as follows: the first section is introduction. The second one is the fabrication steps of semiconductor amplifier and bio-sensing probe device. The next are microprobe fabrication test and discussion. The last part is the conclusion.

II. Device Fabrication Steps

As in Fig. 1, the bio-sensing probe has a tip end to facilitate thrusting into the living body to decrease the contact impedance. This research can vary the density, occupied area and sharpness of the tip ends of the probes to change the contact impedance so as to meet different needs. In addition this product can be designed for roll-to-roll types to facilitate mass-production.

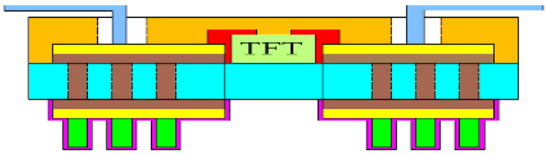

Fig. 1 The side view of the proposed module for micro array bio-sensing probe device integrated with a semiconductor amplifier.

A. Semiconductor Amplifier Design

Step 1: Using mask #1 and Photolithography And Etching Processes (PAEP), some through holes are formed on the flexible substrate for signal conduction between both surfaces. Then remove the Photo Resist (PR). The next is by E-gun evaporator (a low temperature process) to deposit a layer of TiN (0.1 μm) on each side of substrate as seed for electroplating copper (100 μm). The result is in Fig. 2.

Fig. 2 The result of design step 1.

Step 2: By E-gun evaporator deposit an insulating layer of S_iO_2 or Si_3N_4 (2 μm) on the lower surface of substrate. By using mask #1 and PAEP to make vias on those holes made in Step 1 through the insulating layer deposited. Then evaporating a layer of amorphous silicon layer (to be for the four active regions of thin-film-transistors, 2 μm) and using

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 813–816, 2009
www.springerlink.com

mask #2 with PAEP to left four island regions for making MOS transistor. These regions are going to make two pairs of amplifiers, the left-hand side two regions are for making two N-MOS transistors, and the other two regions are going to make a CMOS transistor amplifier. Finally remove the PR, and anneal the amorphous silicon for re-crystallization by Nd-YAG laser. The result is in Fig. 3.

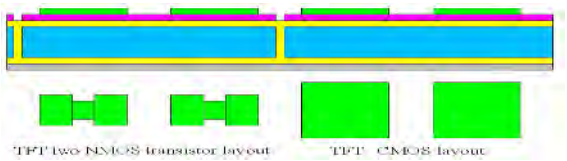

Fig. 3 The result of design step 3.

Step 3: Evaporate layers of S_iO_2 (2μm) and amorphous S_i (2 μm) respectively, and with mask #3 and PAEP to make the gate electrodes of transistors and wirings connecting to the vias. Finally remove the PR, and the result is in Fig. 4.

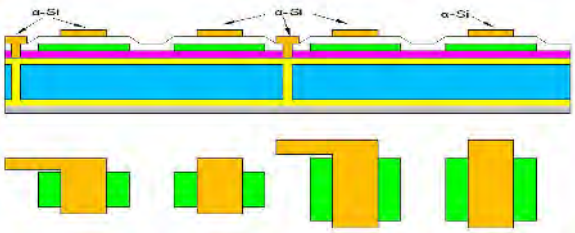

Fig. 4 The result of design step 3.

Step4: Using mask #4 and the PAEP to etch S_iO_2 away at the sources, drains and wirings on the left three N-MOS transistors for phosphorous (N+ donor type) ion implantation. Finally remove the PR, and the result is in Fig. 5.

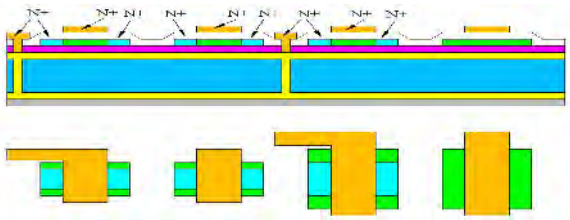

Fig. 5 The result of design step 4.

Step 5: By using mask #5 with the PAEP to etch some regions of S_iO_2 away at the sources, drains and wirings on the right hand side P-MOS transistors for boron (P+ acceptor type) ion implantation. Finally remove the PR, and the result is in Fig. 6.

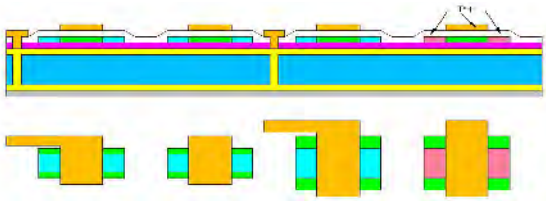

Fig. 6 The result of design step 5.

Step6: Evaporate a layer of Si_3N_4 or SiO_2 (2μm), and with mask #6 and PAEP to make the contact holes for all the electrodes of MOS transistors and wirings. Finally remove the PR, and the result is in Fig. 7.

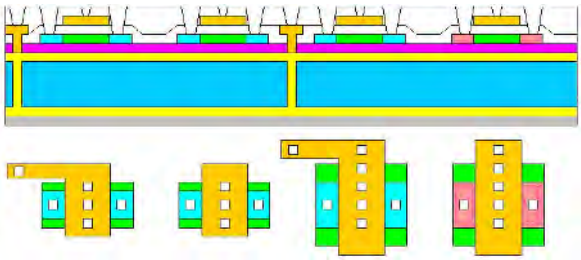

Fig. 7 The result of design step 6.

Step 7: Evaporate a layer of aluminium (2 μm) and with mask #7 and PAEP to make the contact metallization for all the electrodes of MOS transistors and wirings. Finally remove the PR, and the result is in Fig. 8.

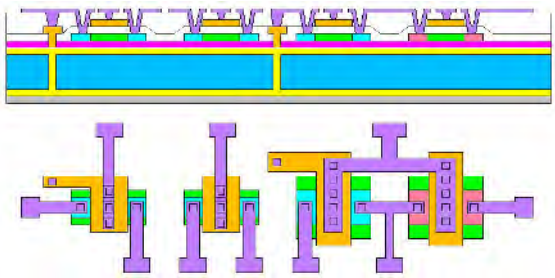

Fig. 8 The result of design step 7.

Step 8: By E-gun evaporator deposit a layer of S_iO_2 or Si_3N_4 (2 μm) for insulation and passivation, using mask #8 with PAEP to make the pad holes for wire bonds. Then electroless plating two layers of nickel and gold. Finally remove PR, and the result is in Fig.9, it is ready for making bumps to connect to the outer circuit by solder screening and the reflow processes. The four transistors are connected as two sets of amplifiers in Fig. 10; they can be used for impedance matching and increasing signal-to-noise ratio.

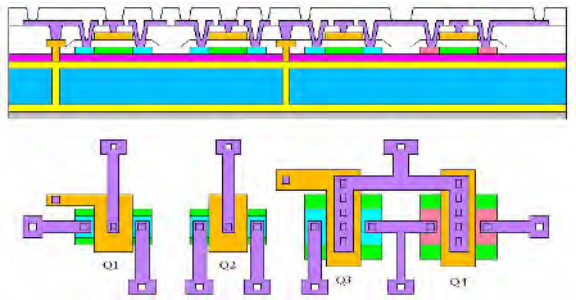

Fig. 9 The result of design step 8.

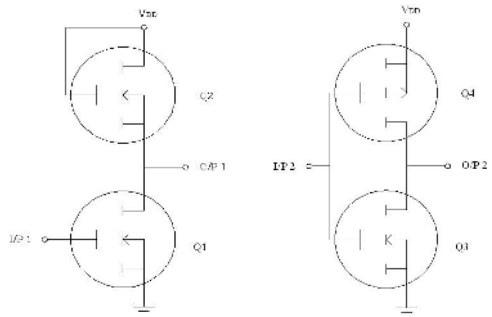

Fig. 10 Four MOS transistors are connected as two pairs of amplifiers

B. Micro Array Bio-Probe Design

Step 1: The conducting vias of the micro array bio-sensing probe is formed by using Nd:YAG laser ablation. Make SU-8 thick photo-resist (500 μm) on each side by using mask #9. The result is in Fig.11.

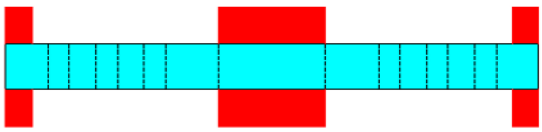

Fig. 11 The result of design step1.

Step 2: Evaporate copper and TiN on each side with thickness 100 μm. Stripe SU-8 photo-resist away. The result is in Fig.12.

Fig. 12 The result of design step 2

Step 3: Forming a layer of Lift-Off-Resist (LOR) with thickness as 500 μm on the back side with mask #10. Make SU-8 PR (500 μm) on back side with mask #3 in Fig. 13.

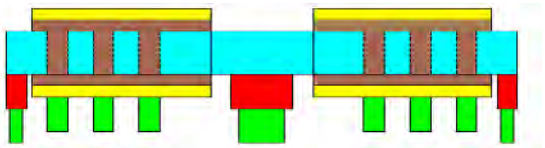

Fig. 13 The result of design step3.

Step 4: By E-gun evaporator deposit a layer of TiN (2 μm). The result is in Fig. 14.

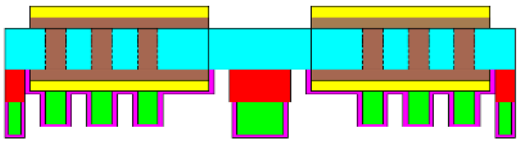

Fig. 14 The result of design step 4.

Step 5: Stripe LOR PR away, then the micro array bio-sensing probe can be formed. The result is in Fig. 15.

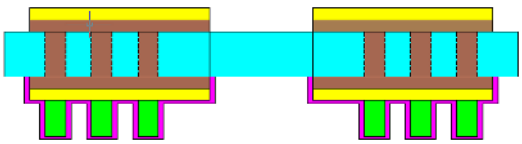

Fig. 15 The result of design step 5.

Step 6: Wire-bonding for electrical signal connection. The result is in Fig. 1.

III. Test and Discussions

The top view and the fabrication result after packaging is shown in Figs.16.and 17. The next step is impedance test [10]. The center line is soldered with the probes while the outer shielding ones connected to the ground of the probe. Then the pig skin in Fig.18 is applied for testing with the equivalent circuit model in Fig.19. The results of pig skin impedance measurements for two cases are shown in Table 1. It can be seen that the resistance obtained by case A is about 330 times larger than that of case B for the same kind of pig skin. The reason is that area of case A is larger, the insertion force may not large enough to penetrate the real skin, and thus the resistance is so much larger. The result of case B is more reasonable.

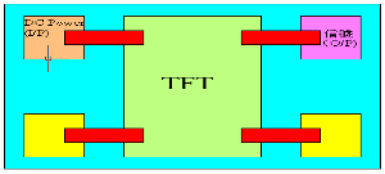

Fig. 16 The top view of the design result.

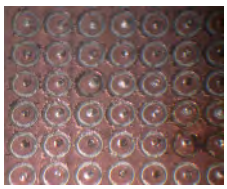

Fig. 17 The result of fabrication.

Fig. 18 The pig skin under test.

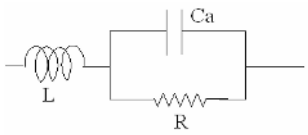

Fig. 19 The equivalent circuit model of pig skin.

Table 1 The results of pig skin impedance measurements for two cases.

Case / Sample	A	B
Length, Width, Thickness (cm)	14 , 14, 0.5	12 , 12, 0.3
Area (cm^2)	196	144
R (Resistance)	11.5261 MΩ	34.9063 KΩ
L (Inductance)	255.366 nH	1.37497 μH
Ca (Capacitance)	8.39747 pF	12.1078 pF

IV. Conclusions

This research employs the MEMS process to integrate TFT amplifiers and micro array biological probes on the flexible substrate. It becomes possible to dispose the bio-sensing probe in conformity with the profile of the living body's portion by forming the bio-probe on the flexible substrate. As such, the contact effect between the biological probes and living body becomes better. On the other hand, the TFT amplifier is also produced on the flexible substrate such that a signal detected from the biological probes can be amplified through a short path. The signal-to-noise ratio and impedance matching are improved.

Abstract — **Present medical practitioners apply combination drug therapy for faster and effective treatment of diseases. Every individual's reaction to certain drugs or drug combinations is different. Mix and match of drugs is common but they can have adverse complications in the body or sometimes be useful in accelerating the treatment. The uncertainty is very high due to non-linearity of drug interactions. Hence optimization is required, so that the effect of the therapy is useful.**

The present paper discusses a microfluidic-based sensor system that can carry out simultaneous investigations of cell outcomes, exposed to a combination of drugs. It consists of a PDMS based microfluidic-chip that can generate serial combinations of two compounds in a single step and a bioreactor to house the chip, designed to provide favourable conditions for cell growth. The results confirm that the chip can be used for long and short term monitoring of various cell types.

Keywords — **Drug mix, drug interaction, microfluidics, PDMS**

I. Introduction

The fields of biotechnology and microfluidics have witnessed tremendous developments in the past decade. Initially coined by Manz *et. al.* in the early nineties [1] where the concept of "miniaturized total chemical analysis system" or μTAS was first introduced. Since then these systems have been explored for their innumerable advantages, like low volume consumption of reagents and samples, high resolution and sensitivity, economical and short analysis time. Many microfluidic devices that uses combinatorial chemistry to synthesize compounds and/or for culturing cells have been previously reported in literature [2, 3].

In today's age, where infectious diseases are growing rapidly, there is an urgent requirement of effective and long term solutions. Combination drug therapy is often useful, but sometimes one drug may reduce the therapeutic effect of other or even have adverse effects in the body due to drug interactions. One of the reasons for this may be due to the non-linearity of drug interactions with other drugs or herbs which is often difficult to predict for an individual. Hence it is necessary to understand the effects of combination of drugs and/or herbs on various cell types.

In this paper the authors describes a system to monitor and track combinatory drug effects in order to provide a more effective means of accessing drug-drug effects on cell outcomes using various cell types (adhesion and suspension). It consists of a polydimethylsiloxane (PDMS) based microchip for drug mixing and cell culturing and a bioreactor to provide favourable environmental conditions for cell growth in the chip. The results obtained, demonstrates the system to have a strong potential in high-throughput drug-drug analysis on cells.

II. Design Principle

The microchip was aimed at mixing several fluids together to enable rapid mixing ratios to be carried out. As a proof of concept, this work focused on using only two fluids into serial concentration steps of 20% for simplicity. Since microscale flow is laminar (Reynolds number of the order of unity), flow can be controlled more readily, giving:

$$\mathrm{Re} = \frac{\rho V D}{\mu} \tag{1}$$

where, ρ is fluid density, V is fluid velocity, D is characteristic length, and μ is absolute dynamic fluid viscosity [4]. Typical velocity profiles are parabolic in pressure driven flows. Flow can be described by the Stokes equation for incompressible fluids with non-slip boundary conditions. For rectangular channels, height h and width w, pressure drop Δp over length L is related to volumetric flow rate Q by:

$$Q = \frac{w h^3 \Delta p}{12 \mu L}\left[1 - O(h/w)\right] \tag{2}$$

where, the approximate form $O(h/w) = \frac{6(2^5)}{\pi^5}\frac{h}{w}$ gives less then

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 817–820, 2009
www.springerlink.com

10% error for $h/w \leq 0.7$ [5]. These parameters were used as guidelines to ensure stable laminar flow in the microchannels designed.

The macrowells of the chip were designed at a higher dimension that does not fall in the micro range (~4 mm, see figure 1), to ensure mixing to occur, because the fluid flow is no longer laminar after it enters the wells from the microchannels.

The rationale for microfluidic chip Design I (Figure 1a) entails that the daughter channels have equal cross-sections and were positioned symmetrically with respect to the parent channel upstream. In this respect, each of the channels would receive the same amount of fluid and the flow rate is effectively halved.

The principle of chip Design II (Figure 1b) was based on the distance traveled by a fixed amount of fluid from the parent channel to the daughter channel, for a particular period of time. Each well was filled by each of the opposite two channels from inlets A and B respectively.

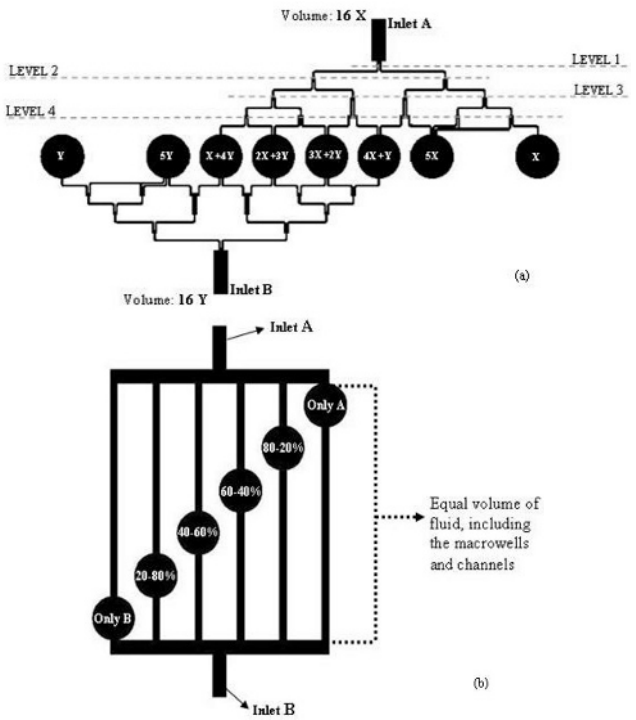

Fig. 1 (a) The layout of design I with the ratio of the fluid mixes denoted as xX + yY ($x \neq y$, X = Y). Volumes of 16X and 16Y enters from inlet A and B respectively. The rectangular microchannel has width of 200 μm except the inlets. (b) The layout for design II with annotations. The percentage mixtures are indicated on the macro-wells as A-B% of fluid volume from inlet A and B respectively. The macrowells measures 4 mm in diameter. Vertical channels are 1mm by 30 mm (excluding wells), horizontal channels are 2mm by 31.5 mm and inlets are 5 mm by 2 mm.

III. Methods and materials

The microchip was fabricated by standard photolithography on four inch silicon wafer (JA Associates, Singapore) and soft lithography on PDMS (Slygard 184 kit, Dow Corning) using SU-8 photoresist (Microchem, USA). This process is well documented in many books and journals and has been used for over a decade for developing PDMS based microchips for biomedical applications [4, 6]. The choice of material was primarily because of its biocompatibility and ease of use and makes the microchip useful for all types of optical detection methods [7]. The final device is shown in figure 2.

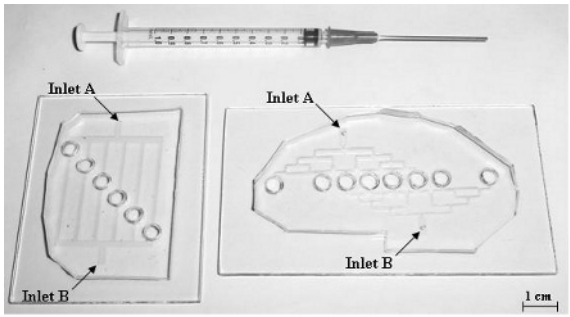

Fig. 2 Final microchips compared to a standard 1 ml syringe. From left to right – Design II and I. The inlets and the wells were punched using 18 gauge blunt needle and 4 mm cork borer respectively. Dimensions: (width × height × thickness) 10 × 6 × 0.6 cm and 6 × 7.5 × 0.6 cm for design I and II respectively.

The depth of the microchannels for both the designs was 150 μm and volume of each well was approximately 50 μl each. For design II, the total volume of each vertical channel is 4.5 mm^3. It is matched with 4.5 μl of fluid in each well. For fluid injection two tubes from both the inlets were connected to standard 1 ml syringes.

The microchips were tested for their performance using water soluble dye, tryphan blue which was simultaneously injected along with DI water from both the inlets of the microchip using syringes and syringe pumps. The concentration was inspected by spectrophotometric studies at 590 nm wavelength (Analytical Instrument Systems Inc., Model DT 1000 CE) as the source and USB2000 (Ocean Optics Inc.) as the detector. The experimental set-up is shown in Figure 3. A control test was done by manually preparing the desired concentrations using the dye and water.

A bioreactor system was designed to house the chip and provide favorable environmental conditions for cell growth and monitoring. The block diagram of the bioreactor is shown in figure 4**.** It consists of a box incubator to house the microchip, integrated with plate heaters and temperature sensors, programmed to maintain the internal temperature at

37 °C using a microcontroller circuitry (ATmega16 chip and AVR® SKT500).

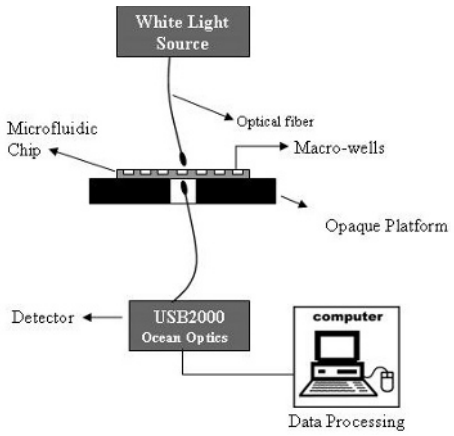

Fig. 3 Experimental setup to perform spectrometric studies on microchip

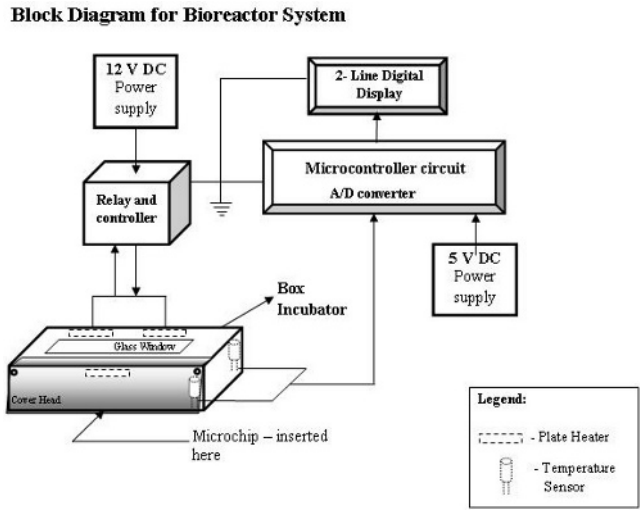

Fig. 4 Block diagram illustrating the components of the bioreactor system. The microchip can be inserted in the box incubator behind the cover-head.

A. Case studies using suspension cells

As one of the prospective application of the diverse microchip, it was used to investigate long term growth of cultures of *Escherichia coli* (*E. coli* strain MC 1061) in the chip wells using Luria-Bertani (LB) broth (Sigma-Aldrich, Singapore) [8]. The chip was incubated in the bioreactor for 18 hours and monitored by optical density (OD) measurement at 600 nm wavelength using the same setup shown in figure 3. The growth curve for bacteria was obtained by plotting absorbance (OD value) versus time.

B. Case studies using adhesion cells

This experiment was performed to check the viability of the microchip and its material for growth and adhesion of mammalian cells. Mouse neuroblastoma or Neuro-2A (N2A) cells were sub-cultured and planted in the wells of the chip and in standard flasks as control to compare the growth. Adhesion was compared by taking images from the test and control after 24 hours of incubation at 37 °C.

IV. Results and Discussion

The result of the dye experiment performed to test the integrity of the microchip is shown in figure 5. The graph was obtained by plotting the averaged absorbance values at 590 nm wavelength versus the concentration of dye in each well of the microchips.

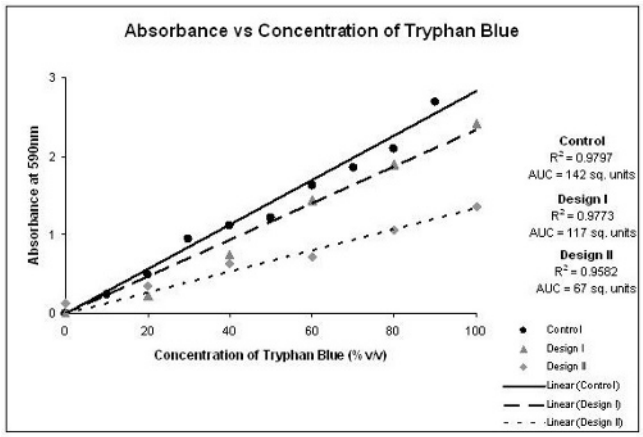

Fig. 5 The graph showing comparison between the microchip results with those of the control (solid line). All the test result data points exhibits an average linear deviation of ± 5 %)

The results obtained were compared with the control for accuracy using R^2 value (coefficient of determination) and area under curve (AUC). R^2 value was used to determine the proportion of variability in a data set [9], whilst AUC was used to establish coherence with the control. The results obtained from the microchip having design I exhibits a near linear graph as compared to design II, also inferred from its high R^2 value of 0.9773. It also reveals that design I presents a high coherence with the control set, with a small AUC difference of 25 square units compared to design II. Hence the design I was the preferred choice for further investigations.

The bacterial growth curve obtained by measuring the OD at 600 nm wavelength in intervals of 3 hours is shown

in figure 6. The growth curve closely matches the standard bacterial growth curves [10] and suggests that the system can be used to monitor long term batch cultures of bacteria.

Mammalian N2A cells that were allowed to incubate for 24 hours before images were taken directly from the chip wells under the microscope, were compared with those taken from the control flasks. The comparison is presented in figure 7 and it clearly suggests good adhesion of the cells onto the bottom of the chip wells as seen also in those taken from the flasks and that the chip wells can sustain mammalian cell for long term monitoring.

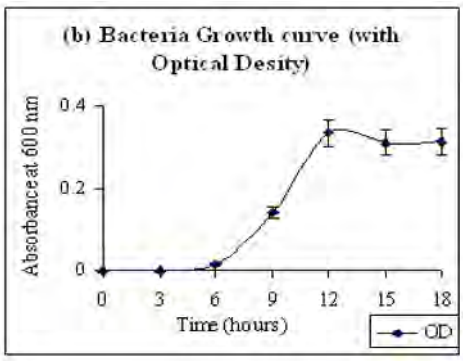

Fig. 6 Growth curve obtained by plotting OD against time with ± 10% error. The error represents average liner deviation of OD.

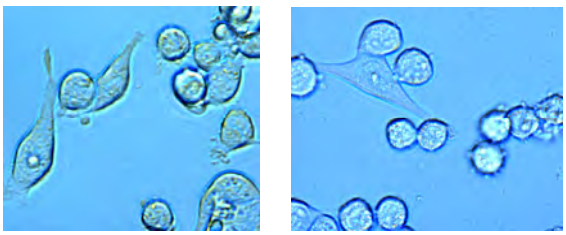

Fig 7. Images show N2A cells at 400 times magnification. The left image was taken from the chip well (test) after 24 hrs of incubation and the right image was taken at the same time from the flask (control).

V. Conclusion

A microfluidic-based sensor system was designed and tested. Case studies were performed by sub-culturing different cell lines into the system and monitored over time. The two microchips designs that were tested with dye solution for accuracy suggested that performance of design I, based on symmetry was superior in terms of reproducibility and accuracy based on the results obtained. This microfluidic platform helped integrate the process of mixing, pipetting and cell screening to perform simultaneous drug-drug investigations on cells *in-vitro*. This in turn results in reduced manpower, time and reagents giving higher accuracy in a single step, compared to conventional mixing techniques.

Microscale mixing problems are not encountered as the mixing occurred in macroscale. Incorporating drugs from the inlets of the microchip would expose the cells directly to various drug-drug combinations that can be monitored over time under microscope or by doing spectrometric studies.

Abstract — **The "Matrix-assisted Layer-by-Layer (LbL)" encapsulation technique is one approach to encapsulate biomolecules within hydrogel microcapsules. However, performing "matrix-assisted LbL" encapsulation usually results in low encapsulation efficiency of water soluble biomolecules as these biomolecules leach out into the aqueous phase during the LbL process. To achieve high encapsulation efficiency, the idea of LbL in organic solvents, termed as Reverse-Phase (RP)-LbL, is extended into the "matrix-assisted LbL" encapsulation technique. In this work, agarose microbeads are conferred stability in an organic solvent by fabrication of agarose-based colloidosomes. Next, non-ionized polyelectrolytes (non-ionized poly(allylamine) and non-ionized poly(acrylic acid)) are used to coat the surface of these colloidosomes in organic phase to prevent leakage of preloaded biomolecules from the interior of the colloidosomes. This can allow encapsulation of water soluble biomolecules in agarose microcapsules with high efficiency.**

Keywords — **Layer-by-Layer, colloidosome, hydrogel, polymer capsules, polyelectrolytes**

I. Introduction

Microcapsules, with micrometer dimensions, possess a large surface area to volume ratio and therefore allow efficient diffusion of material into or out of the microcapsules. These allow microcapsules to serve as excellent carriers of biomolecules for many fields. For example, in therapeutics [1,2], micro-bioreactors [3], and bioanalytical applications [4,5]. Hence, different methods to fabricate microcapsules that can encapsulate biomolecules have been developed including colloidosomes [6] and the templated Layer-by-Layer (LbL) polyelectrolyte self-assembly technique [7].

Colloidosomes are capsules formed from self assembled microparticles at an interface. For example, liquid/liquid such as oil/water [8]. However, the requirement of harsh conditions for fixation of the microparticles, such as using a chemical cross-linking reagent or sintering at a temperature of 100 °C [9,10], limits their application for encapsulation of biomolecules.

Another approach to encapsulate biomolecules is via the "Matrix-assisted LbL" polyelectrolyte self-assembly technique. Using this technique, water soluble biomolecules have been encapsulated within hydrogel matrix spheres [11]. The hydrogel spheres contain almost 98% water and can provide both physiological environment for the encapsulated biomolecules and mechanical support for maintaining the shape of the microcapsules. However, low encapsulation efficiency of the pre-loaded biomolecules is usually obtained as the water soluble biomolecules leach out from the spheres during the aqueous LbL process.

As existing hydrogel microcapsules encapsulation methods do not allow high encapsulation efficiency, we extend the idea of LbL in organic phase, termed as Reverse-Phase LbL (RP-LbL) [12], into "matrix assisted LbL" encapsulation technique to allow high encapsulation efficiency of water soluble biomolecules.

II. Experimental section

A. Materials

1-butanol anhydrous 99.8%, mineral oil and N-(3-dimethylaminopropyl)-N'-ethylcarbodiimide hydrochloride (EDC) were purchased from Sigma. Poly(allylamine) (PA) MW 65,000 Da and poly(acrylic acid) (PAA) MW 450,000 Da were purchased from Aldrich. Span® 80, Rhodamine 123 and N-hydroxysuccinimide (NHS) were purchased from Fluka. Carboxylate-polystyrene (carboxylate-PS) microparticles with diameter of 1.0 μm and fluorescent labeled carboxylate-PS microparticles with diameter of 1.0 μm were purchased from Polysciences Inc. PS microparticles with diameter of 20 μm were purchased from microParticles GmbH. Ethanol was purchased from Fisher Scientific. Low melting agarose was purchased Promega. PBS was purchased from 1st BASE. All materials were used as received. Double distilled water (d.d. H_2O) used was distilled using a Fistreem™ Cyclone™ machine.

B. Preparation of Colloidosomes

500 μl of carboxylate-PS microparticles suspension as purchased was aliquoted and centrifuged (4,000 rpm, 6 minutes) and the supernatant was subsequently removed. Ethanol was

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 821–824, 2009
www.springerlink.com

added and the microparticles were sonicated for 30 minutes to remove any existing surfactants. After sonication, the microparticles were centrifuged (2,000 rpm, 3 minutes) and the supernatant subsequently removed. This sonication procedure was repeated for a total of 3 times. The microparticles were dried, weighted and d.d. H_2O was added to make a suspension of 20 % w/v microparticles. The carboxylate-PS microparticles were subsequently used for fabrication of colloidosomes.

All necessary reagents were pre-warmed and kept at a temperature of 45 °C. A molten solution of 4% w/v low-melting agarose was prepared then mixed with the carboxylate-PS microparticles (20% w/v) to prepare a mixture with a final concentration of 2% w/v carboxylate-PS microparticles in 2% w/v agarose. The agarose/carboxylate-PS mixture was added to prewarmed mineral oil containing 0.1% Span 80 and stirred vigorously for 15 minutes to form water-in-oil (w/o) emulsion droplets. The emulsion droplets were then cooled to 25 °C while stirring for another 10 minutes to allow solidification of the molten agarose core and formation of colloidosomes. The colloidosomes were further stabilized by placing at -20 °C for 5 minutes.

C. Preparation of Agarose Microbeads

Agarose microbeads were prepared with similar procedures as mentioned in the preparation of colloidosomes except no carboxylate-PS microparticles were used in the fabrication step.

D. Self assembly of Non-ionized Polyelectrolytes (niPolyelectrolytes) onto Colloidosomes by Reverse-Phase LbL (RP-LbL)

The RP-LbL coating process was entirely performed in 1-butanol with non-ionized poly(allylamine) (niPA) and non-ionized PAA (niPAA) as niPolyelectrolytes. niPA was prepared by drying the PA solution and dissolving with an appropriate amount of 1-butanol to obtain a concentration of 1 mg/mL. niPAA was prepared by dissolving PAA in 1-butanol to a concentration of 5 mg/mL. To transfer the colloidosomes from mineral oil to 1-butanol, an equal amount of ethanol was shaken with the colloidosomes in mineral oil and centrifuged (1,000 rpm, 2 minutes). The mineral oil and ethanol were then discarded and the colloidosomes were then further washed 2 times with 1-butanol using centrifugation (1,000 rpm, 2 minutes) and redispersion. 1.5 mL of niPA in 1-butanol was used as the initial layer followed by 1.5 mL of niPAA in 1-butanol as the subsequent layer. Each niPolyelectrolyte was coated for 15 minutes with gentle vortexing and excess niPolyelectrolyte was washed away via centrifugation (1,000 rpm, 2 minutes) and redispersion 3 times with 1.5 mL of 1-butanol before coating of the next layer.

E. Self assembly of Non-ionized Polyelectrolytes (niPolyelectrolytes) onto PS microparticles by Reverse-Phase LbL (RP-LbL)

The RP-LbL coating process of niPolyelectrolytes onto PS microparticles is similar to the coating process mentioned in self assembly of niPolyelectrolytes onto colloidosomes except PS microparticles were used in place of colloidosomes.

F. Preparation of Fluorescence niPolyelectrolyte

PAA-Rhodamine 123 conjugate was synthesized with a conjugation ratio of 1:10 (Rhodamine 123 molecules:PAA monomer) using EDC/NHS, purified by dialysis (MWCO of 8,000 Da) and dried at 50 °C. The dry niPAA-Rhodamine 123 was dissolved to a concentration of 0.5 mg/mL in 1-butanol.

III. Results & Discussion

A. Coating of Non-ionized Polyelectrolytes (niPolyelectrolytes) onto PS microparticles by Reverse-Phase LbL (RP-LbL)

To study the RP-LbL coating of niPolyelectrolytes, a fluorescent-labeled niPolyelectrolyte (niPAA-Rhodamine 123) was used in combination with niPAA to coat 20 μm PS microparticles. niPA was coated as the odd layers while niPAA/niPAA-Rhodamine 123 was coated as the even layers.

Figure 1 shows the fluorescence intensity of PS microparticles as a function of the number of coated layers. The fluorescence intensity of PS microparticles after each layer coating was quantified by capturing the fluorescence image

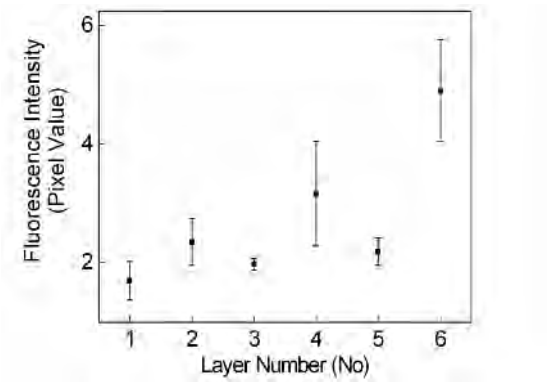

Fig. 1 Fluorescence intensity (pixel value) of PS microparticles against layer number coated onto the microparticles via RP-LbL technique. PAA-Rhodamine 123 was used during coating of even layers as proof of multilayer deposition.

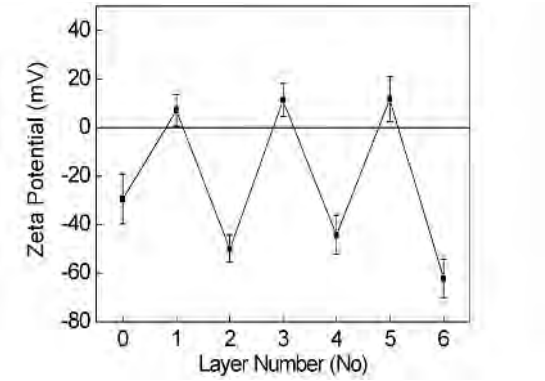

Fig. 2 Zeta potential as a function of layer number (No) for coating of niPolyelectrolytes onto PS microparticles in 1-butanol. Multilayer deposition is demonstrated by the alternating signs of the zeta potential.

of the microparticles and measuring the pixel values of each image using ImageJ. It was noted that the fluorescence intensity of the microparticles increases after each bi-layer coating and this increase in fluorescence intensity is contributed from the accumulation of niPAA-Rhodamine 123 onto the microparticles after each even coating. This result demonstrates that niPA and niPAA can be stepwisecoated onto PS microparticles by RP-LbL.

As further evidence for RP-LbL coating of niPolyelectrolytes onto the PS microparticles, the zeta-potential of the microparticles after each layer coating was measured. All measurements were performed after transferring the PS microparticles from 1-butanol to 0.01x PBS. Figure 2 shows the zeta potential of the PS microparticles after coating of each niPolyelectrolyte layer. The alternating magnitudes of the zeta potential from initially -30 mV (zeta potential of "bare" PS microparticles) to +7, +11 and +12 mV for deposition of niPA layers and -50, -44 and -62 mV for niPAA layers supports evidence for coating of niPolyelectrolytes onto PS microparticles in 1-butanol.

B. Stability & Morphology of Colloidosomes

To improve the mechanical stability of microcapsules and provide a good matrix material to entrap biomolecules, fabrication of microcapsules was done through the use of agarose microbeads – a hydrogel template. Unfortunately, being hydrophilic in nature, the beads are not stable in anhydrous 1-butanol but begin to aggregate (Figure 3A). Hence, microparticles were included into the emulsification phase of agarose microbeads fabrication to produce hydrogel-based colloidosomes [8]. Addition of microparticles was performed to confer dispersion stability to the agarose microbeads in 1-butanol and allow reverse phase (RP)-LbL deposition of polymers. Colloidosomes in 1-butanol were found to be able

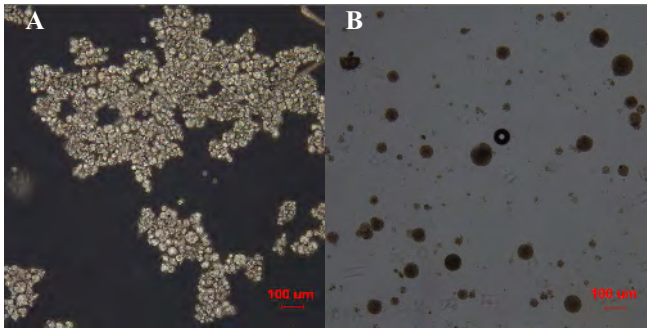

Fig. 3 Optical images of A) Agarose microbeads aggregated in 1-butanol and B) fabricated colloidosomes in 1-butanol. Colloidosomes are stably dispersed and show no aggregation.

to retain their spherical shape (Figure 3B) and colloidosomes fabricated using fluorescent labeled carboxylate-PS beads exhibited a denser population of microparticles lining on the surface of the colloidosomes (Figure 4).

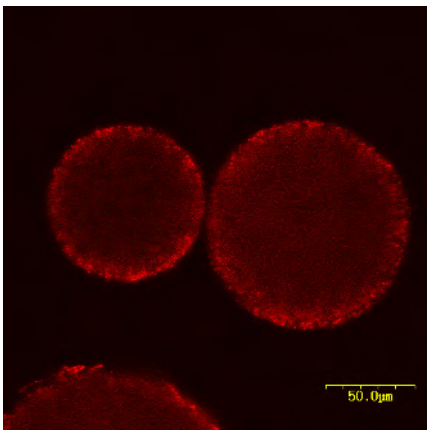

Fig. 4 Confocal Image of colloidosomes fabricated with fluorescent labeled carboxylate PS microparticles. A fluorescence ring can be observed around each colloidosome.

In summary, the inclusion of microparticles for the formation of colloidosomes does allow for the stable dispersion of agarose microbeads in 1-butanol. This stability allows RP-LbL coating of niPolyelectrolytes onto the agarose microbeads for high encapsulation efficiency of water soluble biomolecules.

C. Coating of Non-ionized Polyelectrolytes (niPolyelectrolytes) onto Colloidosomes by Reverse-Phase LbL (RP-LbL)

Encapsulation of preloaded water soluble biomolecules within hydrogel microcapsules with high efficiency requires little or no loss of biomolecules to occur during the LbL

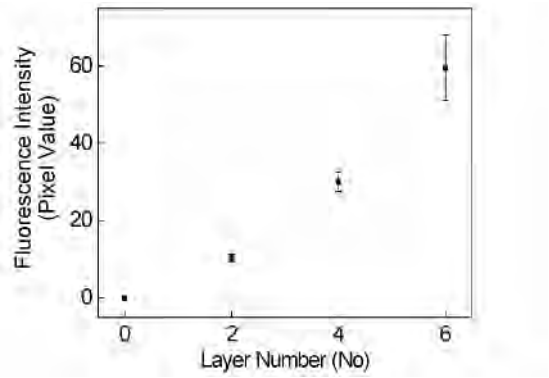

Fig. 5 Fluorescence intensity (pixel value) of colloidosomes against layer number coated onto the colloidosomes via RP-LbL technique. PAA-Rhodamine 123 was used during coating of even layers as proof of multilayer deposition.

coating process. To allow minimal loss of biomolecules, a suitable "coating system" onto the colloidosomes is needed and performing RP-LbL coating of niPolyelectrolytes onto colloidosomes is one suitable approach.

The study of the coating of niPolyelectrolytes onto colloidosomes via RP-LbL was done by using niPAA-Rhodamine 123 as discussed in coating of niPolyelectrolytes onto PS microparticles. Similarly, niPA was coated as the odd layer and niPAA/niPAA-Rhodamine 123 was coated as the even layers. The fluorescence intensity of colloidosomes was also quantified in a similar fashion. Figure 5 shows the fluorescence intensity of the colloidosomes increasing after each bi-layer coating. This increase in fluorescence intensity is due to an accumulation of niPAA-Rhodamine 123 after each bi-layer coating and shows that niPA and niPAA can be coated onto agarose-based colloidosomes by RP-LbL.

IV. Conclusions

niPA and niPAA have been identified as non-ionized polymers that can perform RP-LbL coating of niPolyelectrolytes onto colloidosomes. By coupling this "organic phase coating system" with hydrogel-based colloidosomes, the high encapsulation efficiency of water soluble biomolecules within agarose hydrogel templates has been made possible. We believe that our technology can significantly contribute to the development of microcapsule based bioreactors and bioanalytical system.

Abstract — **In the perioperative area, the period before and after surgery, it is essential to measure diagnostic parameters such as oxygen saturation, hemoglobin (Hb) concentration and pulse. The Hb concentration in human blood is an important parameter to evaluate the physiological condition. By determining the Hb concentration it is possible to observe imminent postoperative bleeding and autologous retransfusions. Currently, invasive methods are used to measure the Hb concentration. For this purpose blood is taken and analyzed. The disadvantage of this method is the delay between the blood collection and its analysis, which doesn't permit a real-time patient monitoring in critical situations. A non-invasive method allows pain free online patient monitoring with minimum risk of infection and facilitates real time data monitoring allowing immediate clinical reaction to the measured data.**

Keywords — **hemoglobin, non-invasive, photoplethysmography**

I. Introduction

In the perioperative area, the period before and after surgery, it is essential to measure diagnostic parameters such as oxygen saturation, hemoglobin (Hb) concentration and pulse[1]. The Hb concentration in human blood is an important parameter to evaluate the physiological condition. By determining the Hb concentration it is possible to observe imminent postoperative bleeding and autologous retransfusions. Currently, invasive methods are used to measure the Hb concentration. For this purpose blood is taken and analyzed. The disadvantage of this method is the delay between the blood collection and its analysis, which does not a permit a real-time patient monitoring in critical situations. A non-invasive method allows pain free online patient monitoring with minimum risk of infection and facilitates real time data monitoring allowing immediate clinical reaction to the measured data. The absorption of whole blood in the visible and near infrared range is dominated by the different hemoglobin derivatives and the blood plasma that consists mainly of water.[2] It is well known that pulsatile changes of blood volume in tissue can be observed by measuring the transmission or reflection of light through it. This diagnostic method is called photo-plethysmography (PPG) The newly developed optical sensor system uses three wavelengths for the measurement of the Hb concentration, oxygenation and pulse. This non-invasive multi-spectral measurement method is based on radiation of near monochromatic light, emitted by light emitting diodes (LED) in the range of 600*nm* to 1400*nm*, through an area of skin on the finger. The sensor assembled in this investigation is fully integrated into a wearable finger clip and allows full wireless operation through on board miniature wireless enabled microcontroller.

II. Measurement method

The new developed sensor device allows a non-invasive continuous measurement of hemoglobin concentration, oxygen saturation and pulse which is based on a multi-spectral measurement method. Thereby the area of skin on the finger is transilluminated by monochromatic light which is emitted by LEDs in the range from 600nm-1400nm.

The arteries contain more blood during the systolic phase of the heart than during the diastolic phase, due to an increased diameter of the arteries during the systolic phase. This effect occurs only in arteries but not in veins.[3]

For this reason the absorbance of light in tissues with arteries increases during systole because the amount of hemoglobin (absorber) is higher and the light passes through a longer optical path length d in the arteries. These intensity changes are the so called PPG-waves.[4] The time varying part allows the distinction between the absorbance due to venous blood (DC part) and that due to the pulsatile component of the total absorbance (AC part). Figure 1 shows the absorption model for light penetrating tissue to sufficient depth to encounter arterial blood. Upon interaction with the tissue the transmitted light is detected non-invasively by photo diodes. Suitable wavelengths were selected for the analyses of relative hemoglobin concentration change and SpO_2 measurement. During the measurement of hemoglobin the absorption should not be dependent on the oxygen saturation. That means that the measurement is only practicable at so called isobestic points where the extinction coefficients of HHb and HbO_2 are identical. One such point is

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 825–828, 2009
www.springerlink.com

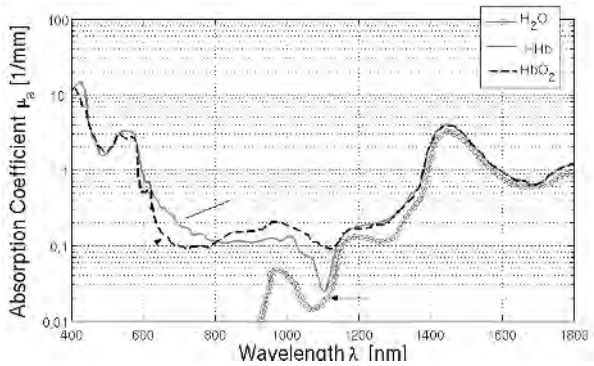

Figure 1: Absorption Spectra of Hemoglobin and Water

known to exist around a wavelength of 810nm.[5] According to the assumption that red blood cells are mainly filled with water, the absorption coefficient of blood is similar to a solution consisting HHb, HbO_2 and water (H_2O) and the absorption of HHb and Hb02 is indistinguishable to the absorption of H_2O above 1200nm, it is necessary to select a wavelength value in this region above the diagnostic window.[6] (Figure 2)

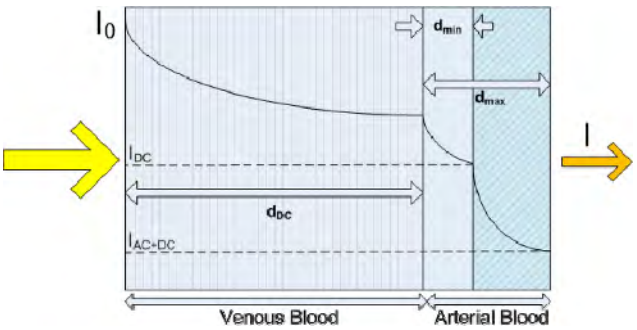

Figure 2: Model of Tissue Layer

Finally the determination of hemoglobin concentration will be performed at the wavelengths λ_1 = 810nm and λ_2 = 1300nm. The AC/DC Values of both wavelengths leads to the quotient H (equation 1):

$$H = \frac{\frac{I_{AC-DC\,810nm}}{I_{DC\,810nm}}}{\frac{I_{AC-DC\,1300nm}}{I_{DC\,1300nm}}} = \ln(10)\frac{\varepsilon_{Hb}\left(\lambda_{810nm}\right)c_{Hb}}{\mu_{H20}\left(\lambda_{1300nm}\right)64500g/l} \quad (1)$$

This theoretical equation results in incorrect values in practise but the fact f(H) is true.[7] Thus, the hemoglobin sensor needs calibration using an external blood stream model including real blood.

III. Sensor Device

The sensor system being developed consists of hardware modules including appropriate light sources and receivers, a microcontroller and a wireless interface. A key component of the sensor system is the low power microcontroller MSP430F1611.[8]

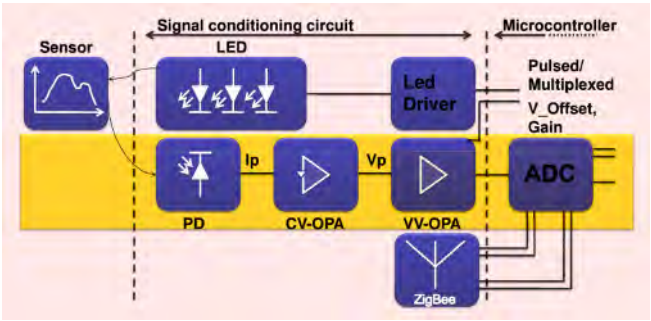

Figure 3: Functional Diagram Sensor Device

This enables software controlled and time multiplexed operation of the light sources and receiver channels. The mean value is calculated and the dark current subtracted in software, and the data is transmitted via serial RS232 or wireless interface. With application software programmed in LabView it is possible to handle the data on a Laptop or PC. The light sources, three LEDs, with centre wavelengths of λ_1= 670nm, λ_2= 810nm and λ_3= 1300nm are installed in the upper part of the clip. The pulsed LED currents are controlled by the microcontroller that allows a change of the light source intensity. To detect the transmission signals of the LEDs a silicon photodiode with a spectral range of 400nm-1100nm was used. For measuring at 1300nm an additional Indium Gallium Arsenide (InGaAs) photodiode with a spectral of 1000nm-1700nm is selected.
Figure 4 shows a photo of the sensor device.

Figure 4: Sensor Head with Photodiodes and Light Sources

IV. Blood Stream Model

The human circulatory system is a fast regulatory transport system. This closed circuit consist of parallel and serially connected blood vessels for which the heart acts as a circulation pump. The mandatory blood circulation is maintained by the contraction of the muscular cardiac wall. The heart is made up of a left and right cardiac half, each of them being a muscular hollow organ. In functional and morphologic terms the circulatory system consists of two serial sections. The heart also can be considered as two serial pumps. The right cardiac side absorbs the deoxygenated blood from the body and transports it to the lungs (lung circuit), where it is re-oxygenated. The oxygenated blood arrives at the left cardiac side, wherefrom the dispensation to various organs takes place (body circuit). The oxygenated blood in the body circuit is pumped from the left ventricle to the aorta and main arteries whose sub branches lead to the tissue and organs. Following the next stage of branching into arteriole and capillary, the oxygen and nutrients and the ingestion of carbon monoxide and intermediate catabolic products are distributed to the tissue and organs of the body. Finally the capillaries terminate into venules and veins which transport the deoxygenated blood back to the right atrium. Figure 5 shows the measuring point for the developed hemoglobin sensor which is located on the finger terminal element.

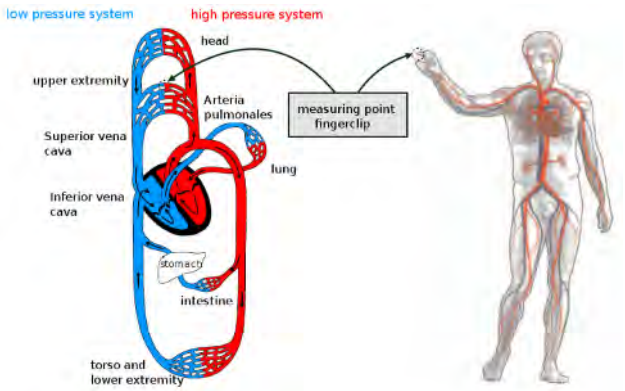

Figure 5: Measuring Point on Circulatory System

Based on human circulatory system a bloodstream model has been designed which is necessary for validation of the measurement method of hemoglobin concentration and the

newly developed optical sensor system. With the help of the model a controlled variation of the blood parameter, hemoglobin concentration and oxygenation are feasible. Thereby both parameters can be changed separately or simultaneously on circulating blood is not representative of the typical physiological state. Therefore a setup for optical measurement on circlulating blood is necessary. By using a circulation system based on a roller pump the blood is circulated through the closed circuit and a pulsatile blood volume is generated. The schematic diagram of the system is shown in Fig. 6.

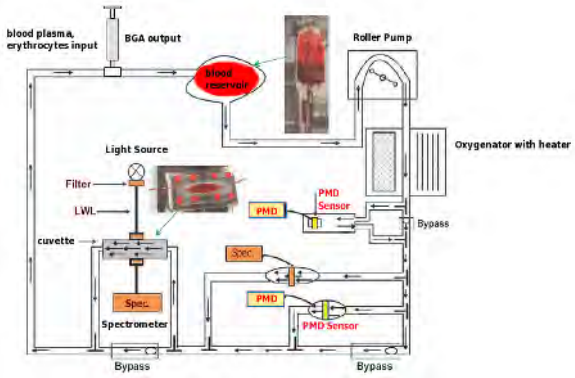

Figure 6: Functional Diagram of the Blood Stream Model

Using this system measurement allowing the accurate assessment of the pulsatile blood portion (AC/DC signal ratio) is possible. The input point is at the same time the blood sample extraction point which will be needed for the reference point measurement. The blood gassing takes place in the oxygenator which allows the precisely controlled introduction of oxygen or carbon monoxide and a separate heated water circuit allows the elevation of the blood temperature to 36°C -37°C

V. Results

Initial measurements of the transmission signals on the finger terminal element have shown variations in light absorption due to the arterial pulse at all three wavelengths. The signal at 1300nm is especially weak and requires further effort in signal processing. However, the signal quality is sufficient to allow analysis of the signals and to calculate the relative attenuation coefficient of the arterial blood. In case of the signal components at 1300nm an evaluation of the relative portions of hemoglobin and water in blood are feasible.[9] On the basis of this measurement technique a pulsed signal for the calculation of the relative attenuation coefficient is required. Decreases of the signal amplitude and therefore the signal to noise ratio caused by vasoconstriction at the extremities is a potential problem. Small signal amplitudes can give rise to inaccurate results.[10] Figure 7 shows the signal at 1300nm and 810nm when light is transmitted through the finger.

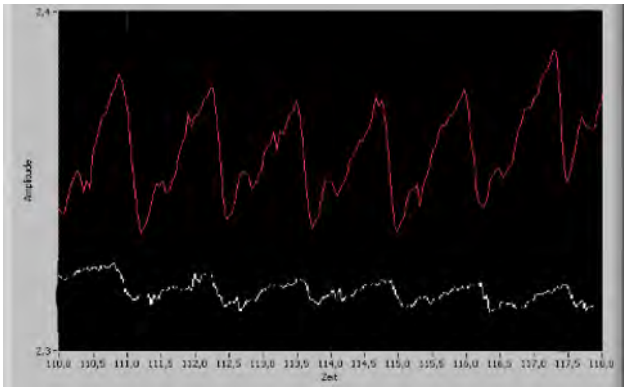

Figure 7: PPG Wave at 810nm and 1300nm

The developed sensor device is suitable for non-invasive continuous online monitoring of one ore biological parameter. The advantage of this measuring technique is independent of blood samples and this allows a minimum risk of infection and it makes possible to react immediately on the measured data.

VI. Conclusions

In this paper a non invasive device for measuring hemoglobin concentration based on multi wavelength light absorption has been reported. The newly developed sensor device is able to measure PPG signals at three independent wavelengths continuously. Future work involves validation of the sensor measurement based on further measurements using an experimental blood stream model and optimisation of the sensor device.

Abstract — **An overview of publications (1991 – 2007) on amperometric sensors for hydrogen peroxide (H_2O_2) is presented, with emphasis on carbon electrodes modified with multivalent-metal oxides as electro-catalysts and applications in biosensors.**

Keywords — **Hydrogen peroxide; amperometric sensors; amperometric biosensors; metal oxides; electrocatalyst; carbon electrodes.**

I. Introduction

The development of methods for the detection and quantification of hydrogen peroxide (H_2O_2) in environmental and biological samples is invaluable, particularly as it will also find applications in the indirect determination of several substances of clinical, dietary, and environmental importance [1-4]. H_2O_2 is a by-product of several biochemical reactions and, as a result, it is ubiquitous in the natural biological systems. It has been described as quantitatively the most dominant peroxide in brain cells [4]. Formed via various routes such as superoxide dismutase-catalyzed disproportionation of the superoxide ion [5] and oxidiase enzymes-catalyzed oxidation of biomolecules with oxygen [4,6-8], it is eliminated from the body by the action of catalase and peroxidase enzymes. Peroxidases rely on molecular reducing agents like ascorbates and glutathion [9,10]. Thus, while H_2O_2 by itself is an intesting analyte, the above listed enzymatic reactions in general, and the oxidase catalyzed systems in particular serve as selective biochemical recognition reactions linking H_2O_2 with a number of biomolecules of clinical and dietary interest such as amines, uric acid, glucose, glutamate, lactate, cholesterol, and alcohols [11-15]. Therefore, the development of H_2O_2-detection methods is a catch-all strategy in bioanalytical chemistry.

H_2O_2 can be assayed using various chemical and instrumental methods such as volumetric redox titration [16], spectrophotometry [17], chemiluminometry [18], fluorimetry [19], amperometry/ voltammety and potentiometry [20,21]. *In vivo* and *in vitro*-H_2O_2 determination methods based on indirect spectrophotometric and fluorimetric detections were reviewed by Tarpey and co-workers [22]. Brief reviews on amperometric/ voltammetric sensors for H_2O_2 are widely available [23-27]. Amperometric sensors are interesting since they are suitable for designing portable and multiplex chemical sensor devices with background and interference correction capability. Such H_2O_2 sensors transduce the concentration of H_2O_2 into an electrical current signal via a direct or an indirect electrochemical reduction (cathodic) or oxidation (anodic) of H_2O_2. It is also easy to tailor amperometric sensors in order to suit different real samples by using materials with selective recognition and signal amplification properties towards the analyte of interest [28,29]. Multivalent metal oxides are interesting materials because of the wide spectrum of structure-properties they exhibit. We give an over view of amperometric H_2O_2 sensors in which these oxides function as electrochemical recognition and signal amplification componets. Biosensors developed on sensors for some clinical analytes are also highlighted.

II. Chemically modified electrodes in context

In biomedical analysis, of particular interest is the development of selective amperometric biosensors for in-*vivo* and *in-vitro* applications. Such sensors must be able to function at physiologic pH conditions in the highly complex matrix of undiluted body fluids. For instance, a successful blood serum diagnostics could be anticipated only if the biosensor is developed on an H_2O_2 sensor that responds insignificantly to other common electroactive components at the respective serum concentrations; i.e., less than 1 mM uric acid, ascorbic acid, and acetaminophen; few mM xanthine; 20-40 μM hypoxanthine, Fe, and Cu species [30,31]. Amperometric methods and biosensors based on the detection of H_2O_2 at classic metal electrodes (Pt, Hg, Au) or carbon (C) require very high operating potentials (> 600 or

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 829–833, 2009
www.springerlink.com

< -600 mV and even outside the range ± 1000 in case of C). Consequently, they are prone to interference [23,24,26] besides surface-fouling complications [26,32]. These limitations could be addressed by different strategies [23,26,33], among which is to lower the operating potential itself by using electrocatalyst-modified electrodes [24]. Chemically modified electrodes have been excellently discussed else where [28,29], and carbon electrodes are the most attractive for modification studies [25,34,35].

Carbon paste (CPE) or thick film (screen printed) carbon electrodes (SPCE) modified with MnO_2 [36], Prussian blue [37], metallophthalocyanins [38], Rh and Ru [24], hexacyanoferrates [39] exhibited significantly reduced operating potentials and improved selectivity. Different enzymes (purified or as-is in tissues) have also been utilized in H_2O_2 biosensors and bi-enzymatic oxidase-biosensors [40,41]. As readily available and robust catalytic materials are preferred, the authors are particularly interested in multivalent metal oxides, which are thermodynamically stable and sparingly soluble under ordinary conditions [42] could yield stable and commercially cheap sensors.

III. Multi-valent metal oxide-modified electrodes

The earliest (1990s) H_2O_2 sensors with electrodes-modified with electrocatalytically active oxides of multivalent metals were based on Mn and Ir oxide films electrochemically deposited on GCE surfaces [43,44], and a Co(II,III) oxide-bulk modified CPE [45]. Since then, amperometric sensors for H_2O_2 based on commercially available powders of MnO_2, Fe_3O_4, CuO, and oxides of platinum metals incorporated into bulk-modified carbon paste and screen printed carbon electrode have been reported [27,46-54]. GCEs modified with electrodeposited films of Ni and Co hydroxides were also reported recently [55,56]. Some Pervoskyte-type oxides, namely $La_{0.6}Ca_{0.4}MnO_3$ and $La_{0.6}Ca_{0.4}CoO_3$ were also tested [57,58]. Zirconia doped with vanadium was also shown to be promising [59]. Polyoxometallates (POMs) [60], especially heteropolytungstates and heteropolymolybdates or their doped and composite versions, are electroctalytic towards H_2O_2 but sensors based on POM-modified electrodes worked only at very low pH conditions [61,62].

Table 1 compiles the multivalent-metal oxide-modified carbon electrodes studied at physiological conditions. Operating potentials, detection limits, and linearity ranges varied markedly with the type of the oxide. The operating potentials of the sensors operated anodically may be compared as follows: nano Co_3O_4 = $La_{0.6}Ca_{0.4}MnO_3$ (+750 mV) > nano MnO_2 > RhO_2 = PdO ≈ RuO_2 (+480 mV) ≈ IrO_2 (+400 mV) ≥ MnO_2 > nano cryptomelane type Mn oxide (+300 mV). Those which were operated cathodically may be ordered according to decreasing operating potential: $VZrO_2$ (-400 mV) = CuO/ Cu_2O ≥ FeO (-200 mV) ≈ Fe_3O_4 ≈ SnO_2 (-170 mV) ≥ PtO_2 (-100 mV).

[§]Assume microparticles if not specified; "nano" - nanoparticles; **"|"**: bulk-modified, "||": surface-modified; GCE, CPE, and SPCE: glassy, paste, screen printed carbon electrodes; NaMM: sodium montmorillonite; DHP: dihexadecyl hydrogen phosphate; *m*- prefix: monoclinic; ******operating potentials vs. Ag|AgCl or Hg|Hg_2Cl_2 reference; superscripts: a: anodic, c: cathodic; FIA: flow injection analysis; RDE: rotating disc electrode; CV and DPV: cyclic and differential pulse voltammetry; DL: detection limit.

Operated either under hydrodynamic (rotation, stirring, and flowing injection) or voltammetric modes, response times of the sensors were generally described as fast (seconds), but flow rates and voltammetric scan rates obviously determined sample throughput rates. The lowest detection limit (0.4 nM) was reported for nano Co_3O_4-film-modified GCE (rotating disc set-up). However, this was found at high operating potential (+750 mV). The widest linearity range (5 orders) was reported for electrodeposited films of Co_3O_4 and MnO_2. With respect to operational and storage stability, no practical limitations were reported.

SPCEs modified with oxides of Fe and Sn were reported as selective against ascorbic acid, uric acid, acetaminophen,

and xanthine species, possibly because of their low operating potentials. Ascorbic acid, nucleic acid species, and dopamine interfered with MnO_2, RuO_2, and RhO_2-modified electrodes, probably because they were operated at relatively high anodic potentials. Generally, sugars and amino acid species were reported as non-interfering substances. Such data was unavailable for the other oxides.

MnO_2, Fe_3O_4, FeO, RuO_2, RhO_2, IrO_2, PdO_2, and PtO_2 bulk-modified SPCEs have been tested successfully by developing model biosensors using glucose oxidase [48-50,68-70]. A similar demonstration of CuO was also reported [69] using CPEs double bulk-modified with the oxide and glucose oxidase. MnO_2 has seen further applications in which biosensors for sarcosine [71], glutamate [72], and β-ODAP [73] were developed and tested for the determination of these analytes in food samples. In-tissue implantation study with MnO_2-based glucose biosensors was also reported [74]. RuO_2 was tested in a fish quality biosensor [75].

IV. Concluding remarks

A brief account sensors for H_2O_2 with multivalent metal oxide-modified electrodes was presented. Oxides of twelve multivalent metals: Mn, Fe, Co, Ni, Pt, Rh, Pd, Ru, Ir, V/Zr, Cu, and Sn have been identified. Overall, the analytical characteristics of the sensors largely appeared promising.

Abstract — **This paper reports a new approach to enable patch-clamp recording from living cells in arrays of droplets placed on a microstructured silicon surface. Single cells were positioned on the lateral patch sites by using dielectrophoresis (DEP) electrical force. This approach simplifies the complex packaging process involved when pressure-driven fluidics are used to guide cells through microchannels towards the patching sites. It also enables direct access to the droplets for fluid exchange, opening the way for the gold standard patch-clamp technique to become compatible with the industry standards of high-throughput liquid handling platforms. The microchips contained two 20µm deep chambers etched in silicon and passivated by silicon oxide, holding the reagent droplets, and separated by a 250µm-long buried microchannel with an aperture of around 1µm in diameter. Simulations of a four-electrode configuration showed that negative DEP could advantageously eliminate the need of any bulk fluid movement and enable single cell positioning in droplets.**

Working DEP parameters (voltage, frequency) were identified using gold microprobes as external electrodes, dipped in the cell droplets. Single cell positioning at the keyhole was achieved at a speed of about 4µm/s for an optimum cell concentration.

Keywords — **patch-clamp, microchip, droplet, microfluidics, dielectrophoresis**

I. Introduction

Patch-clamp is the golden standard technique when studying ion channels in living cells. Contrary to optical assays relying on fluorescence, it enables a direct measurement of the ion transport through the membrane pores of the cells. These ion channels play a fundamental role in cell signaling and are involved in many diseases including epilepsy, cardiac arrhythmia, high blood pressure, and diabetes. Moreover ion channels can be affected by drugs targeted at other mechanisms, which lead the U.S. Food and Drug Administration (FDA) to propose new regulations to study such potential side effects [1]. Conventional patch-clamping uses glass micropipettes terminated by micron-sized apertures to electrically isolate a *patch* of cell membrane (electrical sealing) and record the ionic current flowing through the ion channels it contains. To position the pipettes on the cell and obtain a good seal in the order of gigaohms (Gigaseal) through gentle suction, a skilled scientist uses micromanipulators under a microscope. This technique achieves high precision, but is laborious, and hence, low-throughput.

In an attempt to transform patch-clamp into a high-throughput assay, research groups have been developing microfabricated chips containing arrays of patch apertures to replace the glass micropipettes, either in a planar [2] or lateral[3,4] configuration. In an opposing fashion to the conventional technique in which the micropipette is brought to the cell, the chip-based systems rely on pressure-driven flow of the bulk fluid to position the cell on the patch aperture. The same means are used to gently suck the cell further to obtain the gigaseal. Even though means to achieve pressure-driven actuation on chip have been proposed, a truly integrated system is far from reaching the capabilities of high-throughput assays liquid handling platforms. In addition, fluidic channels opened to air can greatly ease fluidic exchanges [4].

Following a trend put forward by DNA chips and liquid handling machines, droplets have been proposed as bioreactors for cell-based assays [5]. They constitute a completely open-access architecture without any capping, greatly simplifying fluidic integration (Figure 1). Furthermore they use very little volumes of precious samples, such as cells or primary cells, or drug candidates. However surface droplets cannot sustain pressure gradients to position the cells to the patch apertures and obtain a good seal.

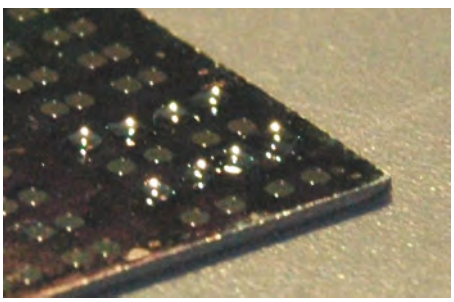

Fig. 1: Silicon microchip for lateral patch-clamping in an array of droplets, without any fluidic channels. Droplets of 0.25µl of cell suspension were manually dispensed onto the microchip

www.springerlink.com

Dielectrophoresis (DEP), the electric force arising from the interaction of a particle's polarization and the spatial gradient of the electric field, has been widely used to handle living cells be it in microfluidic flow, or by trapping them in electric field potential wells for example[6,7]. DEP has the advantage of eliminating any bulk movement of the fluid, associated with pressure-driven flow. By carefully designing the geometry of the system, single cells can be captured or directed to specific areas of microsystem, while no measured effects on the cells owing to field exposure have been reported[8].

In this paper, we report a new approach to enable patch-clamp recording from living cells in arrays of droplets placed on a microstructured silicon surface. The patch microapertures (or "keyholes") were fabricated following a technique developed by our group, creating integrated round glass microcapillaries on silicon chips, which has been demonstrated to produce a high success rate of Gigaseals [3]. Using simulations, we studied how negative DEP obtained *via* a four-electrode configuration can control cells in two dimensions and move single cells to the keyhole without liquid flow. This concept is demonstrated by achieving the positioning of single cells to the keyholes at a speed of about 4µm/s.

II. Material and methods

A. Microchip design and fabrication:

The patch micro-apertures were fabricated using a previously reported technique [3] (Figure 2). Briefly, lithographically-defined narrow trenches (2x250x3.5µm cross-section) were etched into a p-type silicon wafer using deep reactive ion etching (RIE). Phosphosilicate glass (PSG) was deposited via plasma enhanced chemical vapour deposition (PECVD) forming a trapped void (''keyhole'') inside the trench, which was rounded after a thermal reflow 1150°C for 30 min.

A second lithography followed by a combination of directional dry etching steps was carried out to create 1mm wide round chambers at both ends of the keyholes and open up the buried capillary. In a final DRIE step the chambers were deepened to 20µm to enable easy access of the cells to the keyhole. The whole surface was finally passivated by silicon oxide.

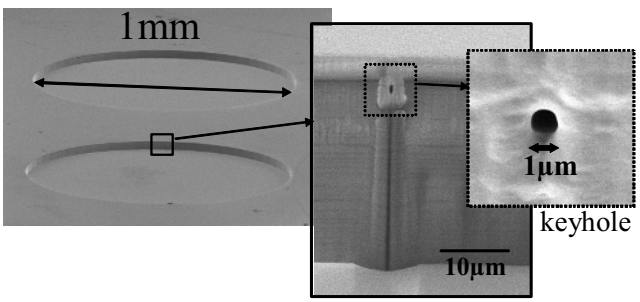

Fig. 2: Scanning Electron Microscope images of a chip, with 2 chambers of 1mm in diameter separated by a 250µm long buried microchannel (or "keyhole").

B. Dielectrophoresis design and simulations:

A 3D model of the microchip was designed in which 4 microelectrodes were placed 2 by 2 on both sides of the keyhole (Figure 2a). The square electrodes shown in Figure 2 represent planar or 3D electrodes that can be microfabricated on the surface of the chip. For ease of computing dimensions were reduced compared to the actual chip. Simulations were performed using depSolver, an Open Source code[9].

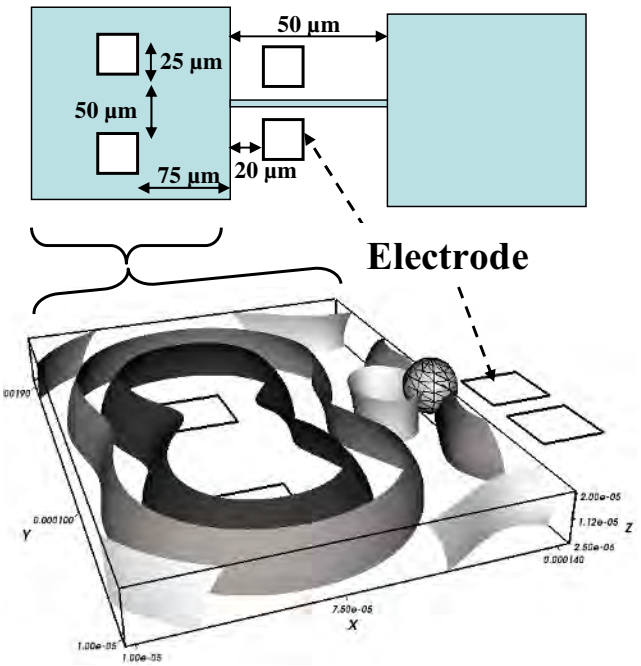

Fig. 3: 3-dimensional simulation of DEP, applied through 4 electrodes (2 right electrodes at the potential +V, left electrodes at –V).
a. Model design used for the simulation. b. Results showing isosurfaces of the DEP force, from dark (intense force) to white (weak).
The sphere represents a particle trapped at the keyhole.

C. DEP application on cells, using external electrodes:

Jurkat T-lymphocytes (ATCC) were maintained following the supplier's protocol. They were harvested and resuspended in Phosphate Buffer Solution (PBS) fresh for every experiment.

Chips were washed with isopropanol (IPA) and water and dried under nitrogen. 0.25µl of the cell suspension solution at the desired concentration were manually dispensed as droplets in the chambers on the chips. The solution formed delimited droplets as seen in Figure 1 above. To prevent evaporation, the droplets were covered with a few microlitres of mineral oil (Sigma-Aldrich, cat#M5904) depending the number of droplets used.

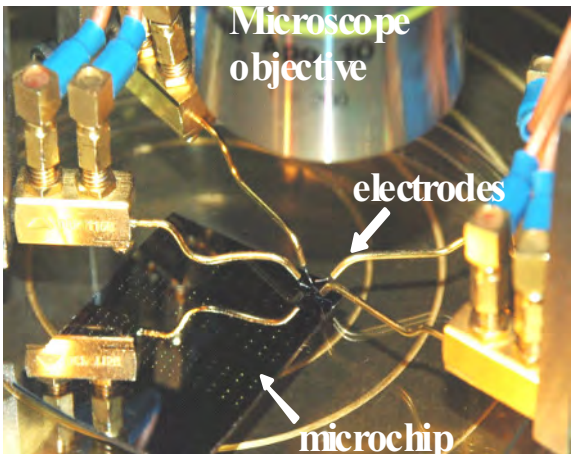

Fig. 4: experimental set-up showing the microchip supporting cell suspension droplets covered in oil. The 4 external gold electrodes are immersed inside 1 droplet on two sides of the keyhole, in a similar configuration as shown in Figure 3.

The chip supporting the droplets in oil were positioned in a probestation (MicrochamberTM alessis REL-6100), which contained 4 micromanipulators, connecting 4 fine-tipped gold microprobes to the electrical circuit. The probes were elongated to allow for liquid contacts. Using the microscope incorporated in the probestation set-up, the tips of the electrical probes were carefully positioned inside the cell suspension droplet in the desired configuration (Figure 4). The use of external electrodes enabled the study of a wide range of configurations and geometries. Voltage (0.2-5MHz, 0.5-20Vpp) was applied to external microprobes to obtain DEP. Movement of the cells was recorded using a digital camera connected to the microscope under a 10X objective.

III. Results and Discussion

A. Dielectrophoresis simulation:

Figure 3 above shows the results of the simulation of the negative DEP force arising from a non-uniform electric field applied from 4 electrodes, placed 2 by 2 on both sides of the keyhole. The isosurfaces presented confirm that the electric field is more intense at the edges of the electrodes. Therefore the minimum of the electric field was located in the middle of the 4 electrodes. Similar configurations had been studied previously, for example for trapping cells moved inside a microchannel by bulk fluid flow[10] and show similar results. Under negative DEP, the cells would be effectively repelled from the electrodes towards the minimum of the electric field. By tuning the distances between each electrode, specific configurations could be found that placed the minimum of the electric field nearest to the entrance of the keyhole (Fig 3.b.).

B. Moving cells in droplets via dielectrophoresis:

In order to confirm the results from the simulations and refine further the configuration of the electrodes onto the microchip, external microelectrodes were used to apply the DEP voltage. The microprobe set-up was flexible so as to allow studying various geometries and configurations without the time-consuming efforts of design and microfabrication of integrated electrodes onto the chip surface. Jurkat cells at relatively high concentrations (around 2 millions cells/ml) were manually dispensed on the microchip in small droplets of 0.25µl, and subjected to DEP voltage. Results from one such experiment are shown in Figure 5 below.

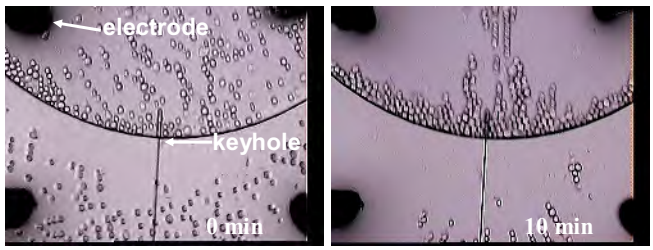

Fig 5: Movement of a high concentration of Jurkat cells under negative DEP towards the keyhole (1MHz, $6V_{RMS}$, in PBS)

The 4 electrodes at the 4 corners of the pictures were placed around the keyhole. The 2 electrodes on top were placed inside the chamber, while the 2 at the bottom were positioned outside the chamber, but still in the cell suspension droplet, that overflowed to keep electrical contact with

the solution. At the beginning of the experiment, cells were distributed throughout the surface. When the DEP voltage was applied, the cells were repelled from the electrodes and moved towards the minimum of the electric field in the center of the 4 electrodes, as was predicted by simulations. Cells accumulated at the border of the chamber because the DEP force was not strong enough to overcome the 20µm deep edge.

C. Single cell positioning:

Patch-clamp recordings are performed on a patch of the cell membrane of a single cell, positioned at the micropipette aperture. Therefore high concentrations of cells between the electrodes such as those used in Figure 5 above, where clusters of cells are connected together at the keyhole, were not suitable for enabling a patch-clamp configuration of interest. A usable concentration would be lower. On the other hand, a concentration where single cells are seldom present in between the electrodes is also damaging. For each configuration of the electrodes, the cell concentration can be optimized so that a single cell will be directed to the keyhole by the DEP force. Figure 5 presents a series of pictures taken during the journey of one cell to the keyhole at a speed of about 4µm/s.

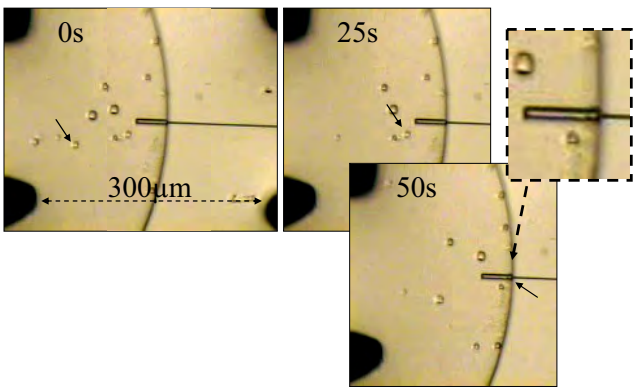

Fig 6: Movement and positioning of a single cell (arrow) to the keyhole ($8V_{RMS}$ at 1MHz). Droplets of 0.5µl containing around 250 cells were manually dispensed

IV. Conclusions

This paper presents a new approach to enable single cell positioning in arrays of droplets placed on a microstructured silicon surface, in order to achieve chip-based lateral patch-clamp experiment. Droplets are completely open-access and will greatly ease fluidic interfaces. Single cells were positioned on the lateral patch sites by using dielectrophoresis, without the requirement of any bulk fluidic movement, which could eliminate the need for pressure driven fluidics limiting the throughput of these assays. The integration of the electrodes onto the microstructured surface will enable greater control on the cell movement.

Label-free Detection of Proteins with Surface-functionalized Silicon Nanowires

R.E. Chee, J.H. Chua, A. Agarwal, S.M. Wong, G.J. Zhang

Institute of Microelectronics, Agency for Science, Technology and Research, 11 Science Park Road, Singapore 117685.

Abstract — **Semiconducting silicon nanowires (SiNWs) have shown great potential for the electrical detection of human disease biomarkers. The technique for label-free detection using SiNWs allows for fast, efficient and inexpensive detection of biomarkers, unlike current time-consuming methodologies such as fluorescence ELISA or western blot. We demonstrate a proof-of-principle protein detection using biotinylated SiNWs for the detection of ultralow concentrations of streptavidin with a maximum sensitivity of up to 10 fM. Real-time detection of human cardiac troponin T using antibody-functionalized SiNWs is also presented. The possibility of large scale integration paves the way towards the simultaneous detection of a large number of protein biomarkers within a single chip and is of importance to the development of diagnostic tools as well as point-of-care applications.**

Keywords — **silicon nanowire sensor, protein detection.**

I. Introduction

Silicon nanowires (SiNWs) have demonstrated significant potential in its capability for ultrasensitive detection of bio-molecular moieties such as DNAs[1-5], proteins[6,7] and viruses[8]. The biologically gated device owes its sensitive nature to the surface area to volume ratio that the one-dimensional structure confers: unprecedented ultra-sensitivity to biological as well as chemical species. A top-down approach as opposed to nanowire growth techniques elsewhere demonstrated was utilized for which individually addressable silicon nanowires were fabricated[2-5, 7], since reproducible nanowire structures could be mass manufactured and later integrated with external CMOS circuitry for direct electrical readout. The basis of operation of the nanowire device depends on the charge characteristics of the bio-moiety in question. In this case, proteins with various pIs were utilized; surface charges inherent in the protein molecule result in the SiNW operating in either the accumulation or depletion mode depending on the polarity of the charges attached to the target biomolecule.

We investigate the variation of the conductances of the nanowire device where various concentrations of streptavidin and avidin are utilized for covalent attachment, since the pI of streptavidin and avidin are substantially different from the pH of the buffer solution and thus would facilitate the identification of the change between baseline conductances and the conductance after wires have been exposed to a particular protein. These biotinylated wires offer significant advantage over traditional protein identification techniques such as the Western blot or fluorescence ELISA which are both time-consuming and labor-intensive. Furthermore, the bio-FET approach eliminates the need for a fluorescent label, demonstrating high specificity and sensitivity together with rapid response rates, paving the way towards the development of low-cost, sensitive and rapid diagnostic as well as point of care applications which potentially may necessitate the sensing of biomolecules in concentrations of down to 10 fM levels. In addition, the individually addressable array allows for the simultaneous detection of different species in solution, alluding to the devices' capability for multiple detection schemes on a single platform. We also demonstrate the real-time detection of human cardiac troponin-T (cTnT), a significant biomarker for the indication of myocardial tissue necrosis[9-11], which demonstrates the practicable development of biosensors for the identification of patients suffering from acute myocardial infarction.

II. Materials and methods

A. Materials.

EZ-Link™ Sulfo-NHS-LC-Biotin, avidin, and streptavidin were purchased from Pierce Biotechnology, Inc. (Rockford, IL). Mouse anti-human cardiac troponin T and human troponin T were purchased from HyTest Ltd. (Turku, Finland). All other chemicals were purchased from Sigma-Aldrich, Inc. Proteins were used without further purification and diluted to the required concentrations with assay buffer.

B. SiNW device design and fabrication.

SiNW devices were fabricated on a 145-nm buried oxide layer silicon-on-insulator (SOI) substrate that was n-doped on purchase. Deep ultraviolet lithography techniques were used to pattern and etch fins that were later doped and thermally oxidized to form the individual nanowires. Contact metal definition and Si_3N_4/SiO_2 passivation of metal lines were performed and the nanowires released by dry etching of the passivation layers followed by wet etching of the remaining SiO_2 on the device array surfaces. Scanning electron microscopy (SEM) and transmission electron

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 838–841, 2009
www.springerlink.com

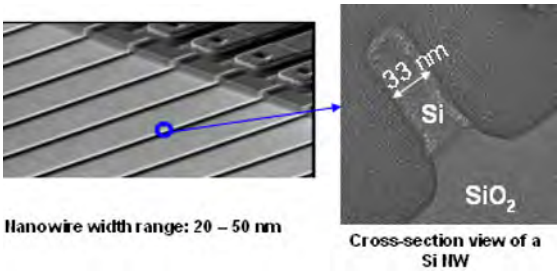

Figure 1. (a) SEM micrograph of SiNW array. (b) TEM image showing the cross-sectional profile of an individual nanowire.

microscopy (TEM) were performed to monitor the uniformity and quality of the resultant devices. Figures 1a and 1b show a SEM micrograph and TEM image of the SiNW array structure, from which the high uniformity of the wire dimension and spacing can be observed.

C. Surface functionalization.

Surface functionalization of the SiNW array chips was carried out using a conventional silane chemistry that has been well documented in the literature[12]. The chips were immersed in a solution of 2% 3-aminopropyltriethoxysilane (APTES) in a 95%/5% mixture of ethanol and deionised water for 2 hrs, resulting in the formation of an amine-terminated surface. A 20 µl aliquot of 10 µg/ml biotin in 1xPBS was applied to the SiNW device clusters and left to incubate in a humidity-controlled environment at room temperature overnight, allowing the N-terminus of the biotin molecules to bind to the amine-terminated SiNW surface. Unbound biotin molecules remaining in the solution aliquot were removed by washing with 1xPBS for 10 minutes, followed by washing in deionised water for 5 minutes. The freshly prepared chips were immediately used for electrical detection experiments, although storage in a 4^0C environment was observed to be possible for short periods of time (< 12 hours) without degradation of the quality of the SiNW devices.

D. Electrical characterization and biomolecular detection.

Electrical characterization of the SiNW devices was carried out with an Alessi REL-6100 probe station (Cascade Microtech, Beaverton, OR). Data was measured and recorded with a HP-4156A parameter analyzer. A controlled voltage of 0.5V was applied across the drain and source electrodes of each individual SiNW device via a two-probe system that referenced one end of the device to ground. The current through the SiNW device was then measured and used to compute the resistance of the SiNW device.

The detection of protein biomolecular species was achieved by measuring the resistance of the SiNW devices at three stages: before chemical functionalization (denoted R_1), after immobilization of biotin probe molecules on the SiNW device surface (denoted R_2), and after the binding of streptavidin or avidin target molecules to the probe-immobilized surface (denoted R_3). The percentage change between R_2 and R_3 was computed and used as the indicator for the binding event.

III. Results and Discussion

A. Theoretical considerations.

Proteins, which consist of long-chain amino acid sequences joined and folded in a specific manner, demonstrate an amphoteric nature in solution due to zwitterion formation between the amine and carboxyl functional groups on the protein molecule. In a solution with a pH less than its iso-electronic point (pI), a protein molecule carries a net positive charge due to the net protonation of its functional groups. Conversely, in a solution with a pH greater than its pI, a protein molecule carries a net negative charge due to the overall deprotonation of its functional groups.

As the SiNW devices used in our experiments are n-doped, the presence of a negative surface charge on the device causes depletion to occur in the SiNW bulk, reducing the effective cross-sectional area for conductance of the SiNW device and thus increasing the resistance of the device. Conversely, the presence of positive surface charge on the SiNW device causes carrier accumulation in the device, increasing its conductance and decreasing its resistance. A positive or negative charge layer on the surface of the devices arise from the charge on the target proteins bound to the antibody-functionalized SiNW surface; thus, by measuring the magnitude and direction of resistance change in the SiNW devices, it is possible to determine with high specificity the type and concentration of biomolecular species present in the analyte solution.

As the strength and specificity of the binding between biotin and the avidin family of proteins is well documented, these biomolecular species were selected for the demonstration of the sensing capabilities of the SiNW devices. The highly specific binding between the antibody and the target molecule ensures that the charge carried by the target molecule is brought sufficiently close to the SiNW surface to affect the resistance changes described above; the presence of a different target protein that does not bind to the biotinylated surface should result in little or no change in SiNW resistance.

B. Streptavidin detection.

Streptavidin (pI = 5.5) has an isoelectronic point that is less than the pH of the assay buffer used, and thus carries a net negative charge in solution. After the immobilization of biotin probe molecules onto the SiNW surface, a 20 µl aliquot of 0.01x PBS solution was applied to the SiNWs and the resistances (R2) of 15 wires on each chip were measured. The buffer solution was then washed away and the dried SiNW chips incubated for ~1hr with a 20 µl aliquot of streptavidin solution in 0.01x PBS solution applied to the SiNWs. Excess streptavidin solution was washed away with 0.01x PBS (3x5min) and deionised water (1x5min) and the chip dried in a stream of dry N_2 gas. Solutions of streptavidin with concentrations of 1 nM, 10 pM, 10 fM and 1fM were used on different devices to investigate the concentration dependence of SiNW device response. The SiNW devices were immersed in a second 20 µl aliquot of 0.01x PBS solution and the resistance (R_3) measured. A box diagram of the responses are given in Figure 2.

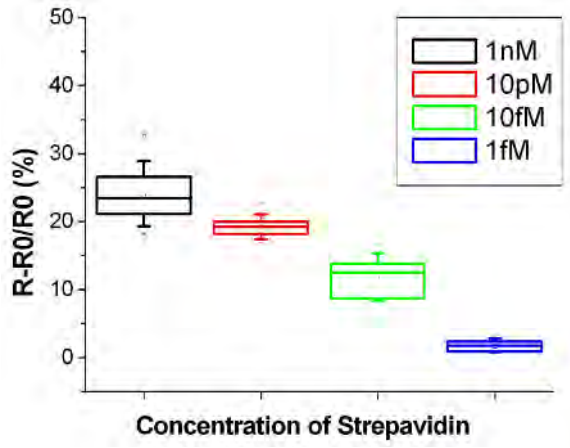

Figure 2. Box diagram of percentage change in resistance of SiNW device with different concentrations of streptavidin solution.

C. Avidin detection.

Avidin (pI = 10.5) has an isoelectronic point that is greater than the pH of the assay buffer used, and thus carries a net positive charge in solution. A 1 nM in 0.01x PBS avidin solution was used to bind avidin target molecules to the SiNW device in the same manner as described above in the section on streptavidin detection. In accordance with theory, a decrease in SiNW resistance was observed from R_2 to R_3 upon binding of avidin. A box diagram of the avidin response plotted with 1 nM streptavidin response for comparison is given in Figure 3.

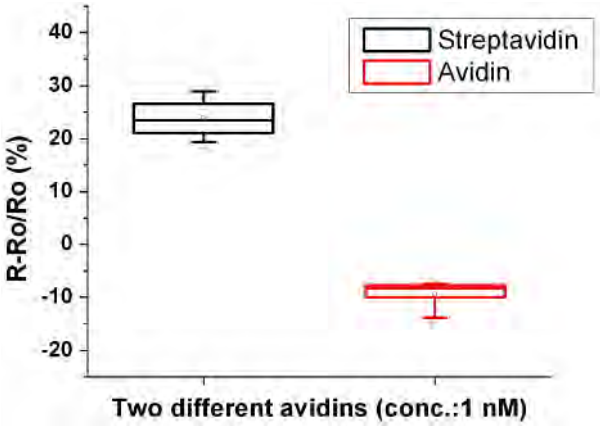

Figure 3. Box diagram comparing the percentage resistance changes of SiNW devices when used to detect 1 nM streptavidin and 1 nM avidin.

D. Detection of human cardiac troponin-T.

In order to demonstrate the applicability of the SiNW array biosensor for medical point-of-care applications, a detection experiment with 1 ng/ml human cardiac troponin-T (cTnT) was performed. Human cTnT is regarded as one of the most cardiac-specific biomarkers and is highly indicative of acute myocardial infarction in heart disease patients. The rapid, real-time and label-free detection of cTnT with the SiNW array biosensor will pave the way for the development of an electrical biosensor for medical point-of-care applications.

A SiNW array device was functionalized with anti-cTnT capture probes in the manner described in section 2.3. Glutaraldehyde, a bifunctional linker, was used to bind the anti-cTnT probe molecules to the amine-terminated SiNW surface as cTnT is unable to directly bind to the amino

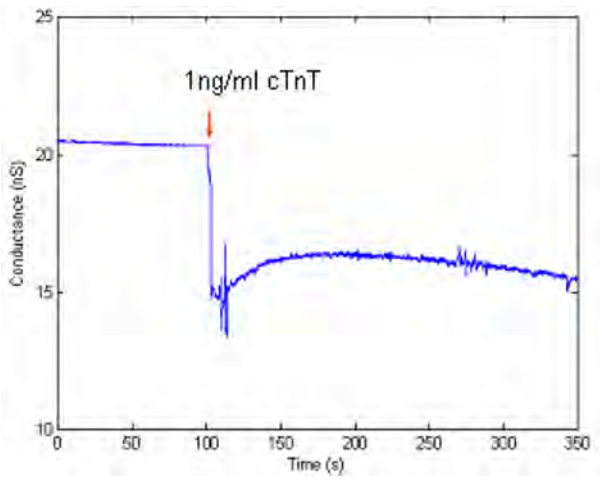

Figure 4. Graph of conductance against time for the real-time detection of 1 ng/ml cTnT in 0.01x PBS.

groups on the silicon surface[13]. Detection was performed by monitoring the baseline current through a SiNW device immersed in 0.01x PBS solution, followed by the addition of an aliquot of 1 ng/ml solution of cTnT in 0.01x PBS. A graph of the conductance against time of the SiNW device is given in Figure 4, and it may be clearly seen that a large and rapid response is obtained upon addition of the cTnT solution. The SiNW conductance decreases and stabilizes quickly to a new, lower baseline level, demonstrating that the binding and detection event has occurred in accordance with theory.

IV. Conclusions

We have demonstrated the sensing capabilities of the silicon nanowires for various proteins, as well as investigated the real-time sensing features of human cardiac troponin-T. The ability to identify ultra-low concentrations of streptavidin in the femtomolar regime attests the sensitive nature of the SiNWs, a feature inherently due to the miniature dimensions of the sensing platform itself. Further work is being carried out to determine the detection limit of troponin-T, but is expected to be comparable to that of streptavidin. The individually addressable nature of the SiNWs alludes to the multiplexing capabilities of the device since each SiNW could be selectively functionalized using a robotic spotter to specifically bind to a specific bio-marker of interest, leading to multiple confirmatory diagnostic investigations on a single platform.

Abstract — **By attaching different biomolecule probes to surface-modified microspheres, a large number of complementary targets labeled with fluorophores can be interrogated simultaneously using the bead-based microarray format. In this work, a new bead-based DNA microarray was fabricated on a porous polymer film with well-ordered array of pores. The well-ordered porous polymer film was prepared using the non-lithographic breath figure method. Different biotinylated DNA probes were conjugated to avidin-modified polystyrene (PS) microspheres. The DNA microarray was fabricated by randomly dispersing DNA probe-conjugated PS microspheres into the pores on the polymer film. Multiplexing detection of DNA was performed using target DNAs labeled with ATTO dyes using a fluorescence microscope imaging system. The Bead-based DNA microarray was constructed for detection of four serotypes of Dengue virus. This technique was demonstrated to be a simple and cost-effective method for rapid detection of DNA targets.**

I. Introduction

DNA microarray technology has been well-known for its tremendous power to conduct parallel analyses of nucleic acids in a single experiment. It has been an extremely important tool in biomedical research and also in diagnostic, treatment and monitoring applications [1]. In a traditional microarray, various DNA probes are immobilized in an array of microscopic spots on a planar substrate [2], such as nylon membrane, glass slide or compact disc. Each type of probes can be spatially addressed, enabling high throughput. However, planar microarrays are restricted by the diffusion-limited kinetics; therefore the amount of probes that can be immobilized on the planar substrate and the amount of targets that can be hybridized on the planar microarray are limited, resulting in low single-to-noise (S/N) ratio.

Instead of using planar surface, bead-based microarrays are applying the non-planar bead surface as the substrate to immobilized probes. The immobilization reaction can take place in a solution with shaking or votexing, resulting in high reaction efficiency. Also, the high surface-to-volume ratio of beads allows a larger amount of probes to be immobilized. Moreover, beads can be fabricated with magnetic, electrical or spectral properties, with various functional groups and of different sizes. Therefore, bead-based microarray format is becoming increasingly popular in nucleic acid analysis.

Various bead-based DNA microarrays have been developed. The most famous are the bead suspension array using flow cytometry [3] for detection and fiber-optic bead-based microarrays [4] from Illumina (San Diego, CA, USA). Facilities such as flow cytometry and the imaging system compatible for the use of optical fibers are needed for these techniques. Other work has been reported on the construction of bead-based DNA microarrays on a platform with patterns fabricated using lithographic methods [5]. However, the need of clean room facilities increases the cost.

Herein, we present a novel technique for the fabrication of bead-based DNA microarrays. This technique applied well-ordered porous polymer films with micrometer-sized pores to serve as the microarray platform. Beads were deposited and confined in the surface pores of the porous films. The porous polymer films were fabricated by the breath figure method, a low-cost non-lithographic technique. Fluorescent microscope equipped with charge-coupled device (CCD) camera was used for the signal detection. In the whole construction of the bead-based DNA microarrays on porous film, only common laboratory facilities were used, resulting in a very simple and cost-effective method. The bead-based DNA microarray was demonstrated for rapid detection of dengue virus.

II. Experimental section

A. Materials

Polystyrene-block-poly(ethylene-ran-butylene)-block-polystyrene (PSEBS, 31wt% styrene) and all solvents were obtained from Sigma-Aldrich. Polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP, M_n^{PS}= 20.0kg/mol, M_n^{P4VP}= 19.0 kg/mol, M_w/M_n=1.09) was purchased from Polymer Source Inc.

SuperAvidin™ coated polystyrene (PS) microspheres, mean diameter 9.9 μm (1% w/v aqueous suspension; binding capacity: 0.036 μg biotin-FITC/ mg microspheres) were purchased from Bangs Laboratories, Inc.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 842–845, 2009
www.springerlink.com

The 25-mer DNA probes were designed according to the sequences of the four serotypes of dengue viruses. Dengue Probes (DP), DP1, DP2, DP3 & DP4 were the capture probes for the Type 1, Type 2, Type 3 & Type 4 dengue viruses, respectively. Their genome positions (GenBank accession No.) are as follows: DP1: 10,550-10,574 (M87512); DP2: 10,557-10,581 (M20558); DP3: 10,530-10,554 (M93130); and DP4: 10,483-10,507 (M14931). All of the four DNA probes were purchased with their 5' end functionalized with biotin. Dengue targets (DT), DT1, & DT2 were the perfect match targets for DP1 & DP2, respectively. All the targets were biotinylated at their 5' end. All the DNA probes and target were purchased from Proligo (Singapore). The sequences of the DNA probes and targets used in the bead-based DNA microarray were listed in Table 1.

Table 1 Sequences of the probes and targets used in the bead-based DNA microarray

Name	Probe sequence
biotin-DP1	biotin-5'-GGGAAGCTGTATCCTGGTGGTAAGG-3'
biotin-DP2	biotin-5'-ATGAAGCTGTAGTCTCACTGGAAGG-3'
biotin-DP3	biotin-5'-AGGGAAGCTGTACCTCCTTGCAAAG-3'
biotin-DP4	biotin-5'-GAGGAAGCTGTACTCCTGGTGGAAG-3'
biotin-DT1	biotin-5'-CCTTACCACCAGGATACAGCTTCCC-3'
biotin-DT2	biotin-5'-CCTTCCAGTGAGACTACAGCTTCAT-3'

Streptavidin labeled ATTO dyes, streptavidin–ATTO 488, streptavidin–ATTO (1mg/ml in 1 x PBS buffer; Molecular Weight = 60.0 k Da) were purchased from Jena Bioscience.

Buffers were prepared as TTL buffer (100 mM Tris-HCl, pH 8.0; 0.1% Tween 20; and 1 M NaCl), TT buffer (250 mM Tris-HCl, pH 8.0; and 0.1% Tween 20) and TTE buffer (250 mM Tris-HCl, pH 8.0; 0.1% Tween 20; and 20 mM EDTA). Hybridization mixture contained 300 M NaCl, 0.5% sodium dodecyl sulfate (SDS) and 30% formamide.

B. Preparation of the polymer porous films

The polymer porous films were prepared by the breath figure method. A mixture of PS-b-P4VP and PSEBS (1/1, w/w) was dissolved in a mixture of toluene and benzene (7/3, v/v) to form a 5~30 mg/ml polymer solution. Equal amount of the solutions were cast onto clean glass substrates (15×15 mm) in a sealed 300 L chamber at room temperature, and then the chamber was immediately vacuumized to an appropriate vacuum level of -50 kPa within about 30 seconds. At the same time, the humidity in the chamber was maintained at 80-85 r.h.%. After dried, porous polymer films were obtained.

C. Patterning of microbeads on the polymer porous films

A glass slide covered with porous polymer films was inserted into a suspension of 9.9 μm polystyrene microbeads in a vial. The vial was then shaken on a shaker to allow beads to settle in the pores by gravity. The settling time is about two hours. After the microbeads were dispensed into the arrayed pores, the surface of the porous films was washed with water to remove the excess beads. The film was then dried at room temperature.

D. Preparation of probe beads and dengue detection

A hundred microliters of avidin-PS beads were washed three times using TTL buffer and resuspended in 20 μl TTL buffer. According to the binding capacity, 0.04 nmol of biotinylated probes was added. Probes were immobilized onto the bead surface via the biotin-avidin coupling by gentle mixing at room temperature for 2 hrs. After probe immobilization, beads were rinsed twice using TT buffer and resuspended in TTE buffer at 80 ^{o}C for 10 min to remove any unstable biotin-avdin coupling. Beads were washed again and resuspended in 100 μl hybridization mixutre.

Twenty microliters of beads conjugated with each type of probes (PS-DP1, PS-DP2, PS-DP3 & PS-DP4) were mixed and diluted to 0.1 wt % using hybridization mixture. Porous film was immersed in the bead suspension in a vial and shaked for 2 hrs. Excess beads were rinsed away.

One microliter 100 μM biotin-DT1 or biotin-DT2 was mixed with 9 μl 1 mg/ml avidin-ATTO 488 or avidin-ATTO550, respectively. The mixture was diluted to 100 μl using TTL buffer and incubated at room temperature for 2 hrs. Twenty microliters of of ATTO-labeled targets from each mixture were mixed and diluted to 800 μl in hybridization mixture. The bead-based DNA microarray on porous film was immersed in the the target solution and incubated at 37 ^{o}C for 1 hr. Array was rinsed with hybridization buffer to remove excess targets thereafter.

III. Results and Discussion

The construction of the bead-based DNA microarray is shown schematically in Figure 1. Firstly, porous polymer films with well-ordered honeycomb structure could be formed when a polymer solution was drop-cast onto a glass slide in a vacuum chamber with moist atmosphere. The vacuum caused a rapid evaporation of the volatile solvent (e.g. toluene and benzene) and subsequently a rapid cooling of the solution, and then sub-micrometer or micrometer sized water droplets were formed on the surface of the cold solution [6]. Convection currents induced by temperature gradients and

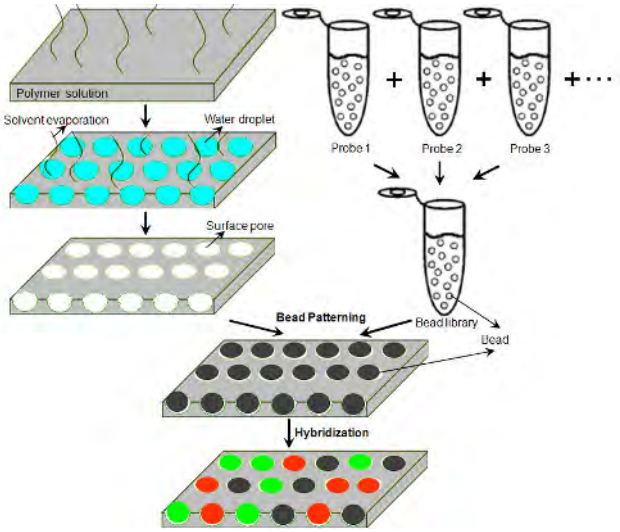

Fig. 1 Schematic design of the bead-based DNA microarray on porous film

capillary forces between the water droplets favored a regular stacking of the water droplets with a narrow size distribution [7]. After the solvent evaporated completely, a polymer film was formed with the water droplets in the film. After the water droplets evaporated, a porous film with well ordered pore structure was formed. Polystyrene (PS) beads with avidin on their surface were mixed with the four types of the dengue probes in separate tubes. An amount of each type of beads, PS-DP1, PS-DP2, PS-DP3 & PS-DP4 was pooled and mixed. The porous film was immersed in the diluted bead mixture to allow settling of beads into the surface pores to form one-bead-in-one-pore pattern. To detect dengue virus, the ATTO-labeled targets were applied on the array to hybridize with the DNA probes immobilized on the bead-based microarray on the porous films.

In order to prepare the porous polymer films for the preparation of the bead-based DNA microarrays, a polymer blend of PS-b-P4VP and PSEBS was dissolved in a solution of mixed toluene and benzene. PSEBS is an elastomer and

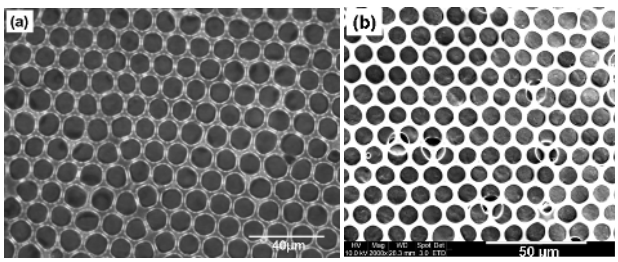

Fig. 2 (a) Optical and (b) SEM images of PS-b-P4VP/PSEBS porous films by the breath figure method. The polymer concentration of preparing the polymer porous films was 15 mg/ml. The relative humidity is 82 r.h.% and the vacuum level is -50 kPa.

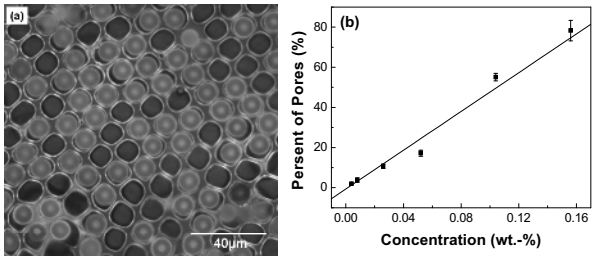

Fig. 3 (a) Optical image of beads-based patterns on the polymer porous films (54%). (b) Bead occupancy as a function of the bead concentration.

the PS-b-P4VP/PSEBS blend polymer has good mechanical properties. Then the porous films with long-range honeycomb structure were prepared in a vacuum chamber with a moist atmosphere. Figure 2 exhibits optical and SEM images of porous polymer films made of a blend of PS-*b*-P4VP and PSEBS. The porous films show two-dimensional and periodical structures with hexagonal array of pores in a long-range order. The pore sizes are on the microscale. The pore sizes of the films were altered by controlling the air humidity and vacuum level in the vacuum chamber. Herein, the pore diameter is 10~12 μm when the vacuum level is about -50 kPa, a polymer concentration is 15 mg/ml and a relative humidity is about 82 r.h.%.

The porous polymer films can be used to pattern beads. Figure 3a exhibits the photograph of beads-based pattern on the porous polymer films. The beads were embedded within the holes on the porous films in a one-bead-in-one-pore format. Figure 3b shows that the bead occupancy on the porous films increased as the bead concentration increased.

DNA probes were immobilized on the bead surface via the biotin-avidin coupling. Equal amount of the four types of probe immobilized beads, PS-DP1, PS-DP2, PS-DP3 & PS-DP4 beads, were pooled and diluted to 0.1 wt % bead suspend in hybridization mixture. A porous film with pore density of 8.38×10^9 pores/m^2 was immersed in the bead suspension in a vial with gentle shaking. The probe beads were settled down in the surface pores to form bead-based DNA microarray on the porous film. Figure 4 shows (a) the

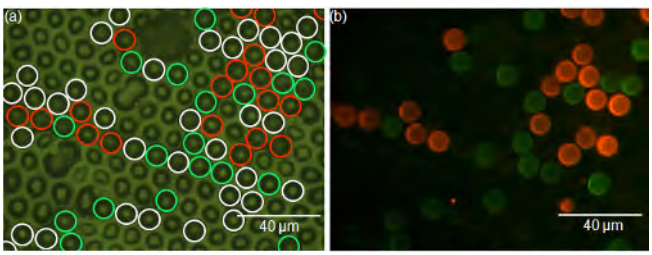

Fig. 4 (a) bright field and (b) fluorescence microscope image of beads-based DNA microarray on the polymer porous films (bead occupancy 50%).

bright field and the fluorescent (b) image of the bead-based DNA microarray after hybridization with ATTO488–DT1 & ATTO550-DT2. On an area of 1.79×10^4 μm^2 on the porous film, shown in the Figure 4, there were 19 replicates for both the detection of DT1 (green beads) and DT2 (red beads). The rest 35 beads (white circled in Figure 4a) were the beads attached with DP3 and DP4. The replicates helped prevent the false-positive or false negative signals. The detection condition could be optimized for even faster analysis and the bead-based DNA microarray could be constructed for the detection of other diseases.

IV. Conclusions

A novel bead-based DNA microarray was constructed on a well-ordered porous polymer film. The porous polymer films were fabricated by the one-step breath figure templating method, a low-cost non-lithographic method. Beads immobilized with DNA probes were patterned on the porous film. The pore size was complementary to the bead size; therefore beads were secured in the pores. These bead-based DNA microarrays were used for the detection of dengue virus. This technique was demonstrated to be a simple and cost-effective method for rapid and high-throughput detection of DNA targets.

Other molecules, such as proteins, peptides or other small molecules can also be immobilized on the bead surface to form a bead-based microarray on porous film. Future work is designed to apply the well-ordered porous films to construct various bead-based microarrays or even cell microarrays.

Monolithic CMOS Current-Mode Instrumentation Amplifiers for ECG Signals

S.P. Almazan, L.I. Alunan, F.R. Gomez, J.M. Jarillas, M.T. Gusad and M. Rosales

Microelectronics and Microprocessors Laboratory, Department of Electrical and Electronics Engineering,
University of the Philippines, Diliman, Quezon City, Philippines

Abstract — **In this paper, four monolithic current-mode instrumentation amplifier (in-amp) topologies are implemented in 0.25um CMOS process, with positive second-generation current conveyors (CCII+) as building blocks. The in-amp topologies are designed to handle biomedical signals, specifically that of the Electrocardiogram (ECG). Four types of CCII+ are characterized and realized using a rail-to-rail op-amp and different types of current mirrors. The *Op-Amp with Simple Current Mirror* exhibits the highest current swing and the lowest power consumption, and is thus chosen as the optimum CCII+ block to be used in all four in-amps. All current-mode in-amps are implemented using a standard 0.25um CMOS process and yield excellent common-mode rejection ratio (CMRR) greater than 150dB for a differential gain of 100. All four in-amps consumes less than 2.5mW of power for a single voltage supply of 2.5V. However, the *2-Current Conveyor with Op-Amp at the Output (2-CC with Op-Amp)* has adjustable output reference voltage and provides the lowest output impedance among the four in-amps.**

Keywords — **Instrumentation Amplifiers, Current-Mode, Rail-to-Rail Op-Amps, Current Conveyors, ECG**

I. Introduction

The measurement of low-energy bio-potential signals such as the ECG makes the in-amp a significant signal-conditioning block for biomedical systems. With the use of in-amps, it is possible to accurately amplify these weak electric body signals even in the presence of high-amplitude common-mode noise that may tend to corrupt the desired signal. Having this critical application, in-amps are particularly designed to achieve high CMRR to correctly extract and amplify low-amplitude differential signals, and to block unwanted noise potentials that are usually common to the in-amp inputs [1], [2].

Recent works have explored alternative ways to implement in-amps using the current-mode approach to overcome the requirement for matched resistors [3]. One approach is through the use of current conveyors.

Vital parameters for characterization and analysis of in-amps include CMRR, input and output impedance, input and output swing, and power consumption. A simulated ECG signal with common-mode noise is used in simulating these different in-amp circuits to determine which in-amp configuration could best extract these biomedical signals.

II. Current conveyors

A positive second-generation current conveyor (CCII+) is a 3-terminal device with a representation shown in Fig. 1.

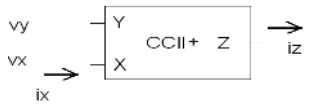

Fig. 1 CCII+ black-box reperesentation

Current conveyor performance relies on its ability to act as a voltage buffer between inputs, and to convey current between two ports that have extremely different impedance levels. To realize this, a CMOS CCII+ can be implemented by a high gain op-amp with a class AB output buffer stage, and connected with a negative-feedback loop, followed by a current mirror [4], as shown in Fig. 2.

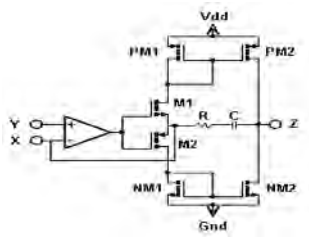

Fig. 2 CCII+ block with series-RC compensation

A. Op-amp block

To implement a CCII+, the *Complementary Differential Pair with NMOS Cascode Load (ComdiffCasc-PN) with Push-Pull Inverter Output Stage* [5] shown in Fig. 3, is the topology used as the op-amp block.

The op-amp has rail-to-rail swing at both the input and output and has fewer stages than the other rail-to-rail op-amp configurations in [4], which makes it more stable. Also, its push-pull output stage further improves the differential gain and provides higher output voltage swing.

Setting all the transistor lengths (L) to 1.2um, the initial op-amp transistor widths (W) may be solved using the current equation, given in Eq. 1, for a MOSFET in saturation.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 846–850, 2009
www.springerlink.com

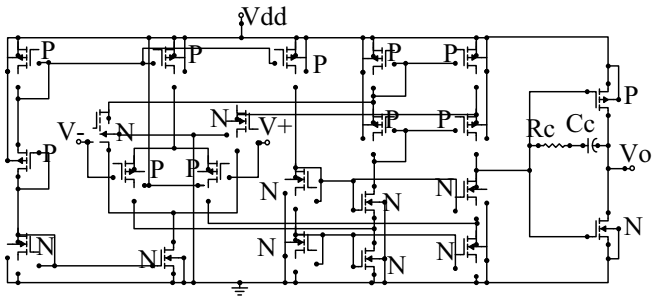

Fig. 3 *ComdiffCasc-PN* with push-pull inverter output stage

The reason for choosing the 1.2um transistor length, instead of the minimum length of 0.25um, is that short-channel effects are more significant at channel lengths less than 1um. Furthermore, submicron lengths for differential input pairs tend to introduce large offset voltage [6]. The tail current (I_{bias}) is set to be 20uA to minimize the total current and to meet the power consumption limits.

$$I_D = \frac{k'}{2}\frac{W}{L}\left(V_{GS} - V_T\right)^2 \tag{1}$$

A width of 5um/20um is used for NMOS/PMOS transistors with $I_{bias}/2$ current. Plugging these values into the schematic produced an op-amp differential voltage gain of less than 10,000, which is below the target gain of at least $1x10^6$. The transistor widths are then resized to increase the gain. A series of simulations aimed at characterizing the op-amp were carried out. The effects of varying the width of each transistor on the op-amp parameters such as differential gain, common-mode gain, 3-dB bandwidth, unity-gain bandwidth and phase margin were studied and plotted. Finally, transistor sizes were assumed to be multiples of 6, to aid in the layout implementation. The compensation resistor (R_C) and capacitor (C_C) used were 10KΩ and 500fF, respectively.

Due to parasitics introduced by metal layers, the total output resistance in the layout simulations increased, as compared to schematic simulations – thus increasing the differential gain. However, slight mismatches in the layout and the lack of symmetry in routing also increased the common-mode gain, hence decreasing the CMRR.

Furthermore, these parasitics introduce more poles, thus decreasing the bandwidth of the op-amp. It was also observed that the phase margin of the layout implementation is 20º lower than that of schematic simulations. As such, it is suggested that the phase margin be set at a relatively high value early in the schematic design stage to ensure stability in the layout stage.

B. Current conveyor block

The designed rail-to-rail op-amp is then connected to an output buffer stage before being paired with four types of current mirrors, which are: *Simple Current Mirror, Cascode Current Mirror, High-Swing Cascode Current Mirror* and *Wilson Current Mirror.* The requirements for the current mirrors to be used for the CCII+ are high output impedance, wide output voltage swing, small input bias voltage, and good high frequency response [7].

Even though the *Op-Amp with Simple Current Mirror* displayed the lowest output impedance among the four CCII+ implementations, it provided the highest current swing and had the least layout area and power consumption (having the least number of transistors) among all designs.

The positive input signal swing is determined by the state of transistor M1 while the negative input signal swing is determined by M2, as shown in Fig. 2. To have a functional output buffer stage, transistors M1 and M2 in Fig. 2 must remain saturated [7]. Therefore, the positive and negative input signal swing is restricted by Eq. 2-3.

$$V_{IN}^{+} = V_{DD} - V_T - V_{DSAT} - V_{DSAT1} \tag{2}$$

$$V_{IN}^{-} = V_{DSAT2} + V_T + V_{DSAT} \tag{3}$$

To minimize the voltage drop across the mirrors, the width of the transistors comprising the current mirrors is increased. This decreases the required V_{GS} for saturation. Hence, decreasing the input bias voltage requirements of the current mirrors increases the input swing at node X in Fig. 2. For uniformity and ease of layout, the widths of all the NMOS and PMOS transistors for the simple current mirrors are set to be 48um and 192um respectively.

III. Current-mode instrumentation amplifiers

Initial simulations on the *Improved 2-Current Conveyor (Improved 2-CC)* in-amp, shown in Fig. 4, verified the functionality of the *Op-Amp with Simple Current Mirror*. The in-amp produced a very high CMRR. However, it was observed from the in-amp's gain plot that the differential gain varies with the differential input voltage by ±10%. This gain irregularity is explained by the current error of the CCII+ (difference in current at the Z and X terminals). Ideally, the current at the output node Z of the conveyor follows the current at the input X but based on simulations, the current error increases as differential input is increased.

Stability was compromised due to the multiple stages employed in the CCII+ implementation. A series-RC compensation was placed between the buffer stage output and the current conveyor output node Z for all the CCII+

blocks used in all the in-amp circuits. The compensating resistor was set to 1KΩ while the compensating capacitor was limited to 2pF due to lay-out area considerations.

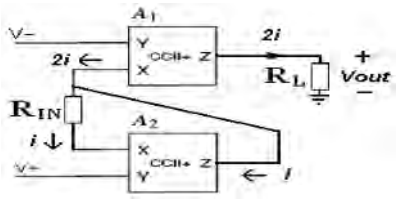

Fig. 4 Improved 2-CC schematic design [8]

The *2-Current Conveyor (2-CC)* is the most basic current-mode implementation of the in-amp. Any voltage difference applied between the in-amp inputs V+ and V- will also be reflected across $R_{IN,}$ forcing a current through it.

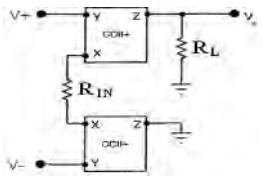

Fig. 5 2-CC schematic design [3]

By the operation of the CCII+, this same current will be conveyed and will then flow through $R_{L.}$ It can be derived that the differential voltage gain of this topology is

$$A_{VD} = \frac{V_{OUT}}{(V-)-(V+)} = \frac{R_L}{R_{IN}} \tag{4}$$

The resistors chosen for this circuit were 50KΩ for R_L (as in the other topologies) and 500Ω for R_{IN} to achieve a gain of 100. A large value of R_L was needed to make the output voltage swing approach the supply rail despite the low current being passed at the output.

The configuration in Fig. 6 is an improvement to the *2-CC* in-amp. As seen, an op-amp is added as an output stage to decrease the output impedance of the in-amp circuit. This op-amp, $A_{3,}$ is chosen to be tied at the output of the conveyor A_2 to produce a positive gain. As in the previous topology, the differential gain is given in Eq. 4.

The cascaded op-amp A_3 is the same op-amp used in the CCII+ implementation, with the same sizing and biasing. However, it was necessary to increase the compensation of the op-amp to make the *2-Current Conveyor with Op-Amp at the Output (2-CC with Op-Amp)* stable. The op-amp's C_C was increased from 500fF to 2pF, while R_C was increased from 10KΩ to 20KΩ.

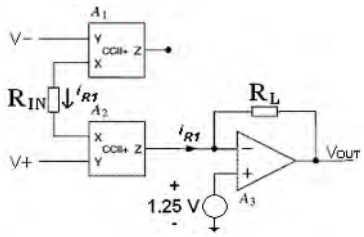

Fig. 6 2-CC with op-amp at the output schematic design [4]

The positive terminal of A_3 must be biased to at least V_{DSAT}, instead of just being grounded. This is to ensure that the output current mirrors of the conveyor A_2 have enough drain-source bias to maintain saturation, and thus enables the conveyor A_2 to properly mirror current $\boldsymbol{i}_{R1}$. In this design, a 1.25V-bias serves two purposes – aside from ensuring that conveyor A_2 effectively mirrors the current $\boldsymbol{i}_{R1,}$ it also raises the in-amp's output reference voltage to 1.25V, placing the output reference exactly between the rails. The 1.25V could be derived from the 2.5 V_{DD} through voltage dividers.

The *Improved 2-CC*, shown in Fig. 4, is typified by a feedback loop from the unloaded output of A_2 to the X terminal of A_1. Effectively, the voltages V- and V+ are imposed on the opposite ends of R_{IN} and determines the value of the current *i*. This same current is forced to flow into the Z terminal of A_2. Therefore, the total current leaving the X and Z terminals of A_1 is 2*i*. A_{VD} can be calculated to be,

$$A_{VD} = \frac{V_{OUT}}{(V-)-(V+)} = 2\frac{R_L}{R_{IN}} \tag{5}$$

The *3-Current Conveyor (3-CC)* topology consists of three CCII+'s and two resistors, with current conveyors B and C cascaded. As seen in Fig. 7, the current entering R_L is twice the current entering R_{IN}, so A_{VD} can be shown in Eq. 5.

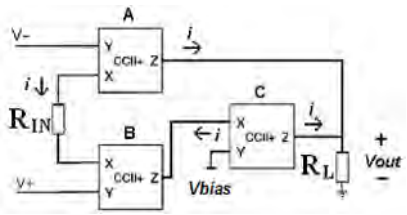

Fig. 7 3-CC schematic design [9]

The CCII+ labeled as C, has V_{BIAS} at its Y terminal instead of being directly grounded. Again, this is to ensure that there is enough V_{DS} at the output current mirrors of conveyor B. As done previously, V_{BIAS} was set to 1.25V.

IV. Representation of the ECG Signal

A representation of an ECG waveform using a piece-wise linear voltage source file is employed to verify the capability of the in-amps to accurately amplify ECG signals amidst common-mode noise. The model used in plotting the signal is adapted from related literature on biomedical signals. In addition, the simulated ECG signal was made to last for only 3 periods, so that simulations would not take much time.

Common-mode noise was added to the ECG signal, as a cascade of 100mV-sinusoids at 60, 120, 180 and 240Hz. A 1.25V DC voltage source was also used as a commode-mode input voltage to maintain correct biasing of the in-amp.

V. Results and Analysis

All the current-mode in-amp topologies achieved the fixed differential gain of 100, a superior CMRR of at least 150dB, and very high input impedance in the GΩ-range. However, the in-amps failed to provide a rail-to-rail input voltage signal swing because of the input signal constraints of the current conveyors. Hence, to allow the uV-range signal level of the ECG as input to the in-amps, the 1.25V DC input common-mode voltage was necessary.

Table 1 Parameters of *2-CC with Op-Amp* vs. INA326

Parameters	*2-CC with Op-Amp*	INA326
Differential gain	102.92	0.1 to 10000
Common-mode gain	4.16E-7	1.995E-04
CMRR	167.87dB	114 dB
Output voltage swing	6.14mV to 2.46V	Vss+10mV to
Input offset voltage	-3.24 uV	100uV
Supply current	798.51uA	2.4mA
Power consumption	1.99mW	Current*(±2.7 to ±5.5)
R_{IN}^+, R_{IN}^-	794GΩ, 792GΩ	100GΩ, 100GΩ
R_{OUT}	58.49Ω	--
3-dB bandwidth	1.26MHz	1KHz
PSRR @ 60Hz	85.68dB	110dB
Settling time	639.28ns	0.95ms
Slew rate	1.9V/us	Filter limited

No significant difference is observed between the *2-CC* and the *Improved 2-CC* in-amps. Both topologies consume less power because they have fewer components compared to the other two topologies. The only difference between them is that the *2-CC* has a greater tendency to suffer crosstalk due to the unused output of one of its conveyor blocks. The *3-CC* in-amp, on the other hand, also produces the same performance despite the additional conveyor. Simulations have shown that aside from failing to produce an evident improvement in results, the third conveyor also degrades the bandwidth of the circuit and consumes more power.

The *2-CC with Op-Amp* in-amp provides the smallest output impedance because of the addition of an op-amp as an output stage. Furthermore, this topology has an easily adjustable output reference voltage.

Shown in Table 1 is the comparison between the achieved parameters of the *2-CC with Op-Amp* and the specifications of the INA326, which is also a current-mode in-amp.

Meanwhile, shown in Fig. 8 is the output plot obtained as the *2-CC with Op-Amp* is applied with the simulated ECG signal and common-mode noise. Clearly, it can be seen that the in-amp has indeed rejected the common-mode signals incorporated in the simulated ECG signal.

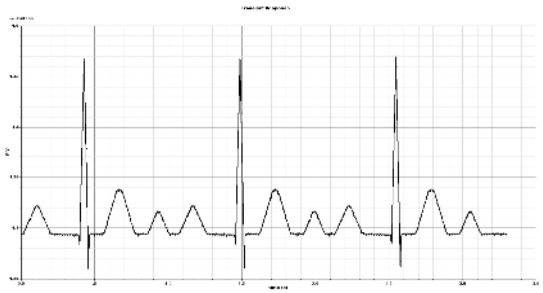

Fig. 8 Output of 2-*CC with Op-Amp* with input ECG signal and noise

VI. Conclusion

In-amp designs should always take into account the trade-off between CMRR and stability. Simulations showed that a decrease in the common-mode gain increases the CMRR, thus compromising stability. Generally, cascading more stages to improve certain parameters, such as CMRR, worsens the stability of a system.

All the current-mode in-amp topologies achieve impressively high CMRR. Hence, any of the implemented current-mode circuits is an outstanding differential amplifier and thus, a potential ECG system block. However, the *2-CC with Op-Amp* provides the lowest output impedance that is essential for connecting the in-amp into a larger system. It also has the advantage of being able to adjust its output reference voltage, allowing it to handle both negative and positive signals with respect to the reference voltage.

Abstract— **In this work, we present a microfluidic device with a 16 parallel electrode array and microchamber for cell separation by using travelling wave dielectophoretic force. The dielectrophoretic PDMS chamber was fabricated using standard microfabrication techniques. The Cr/Au parallel electrode array of 100 µm wide and 300 nm thick was patterned on a glass slide by sputtering through microshadow mask. In order to test twDEP devices, two different size of polystyrene microspheres suspension in deionized water were used as the tested cells. Each type of polystyrene was tested in both the separated and mixed solution. Cells response to the electric field in various mechanisms depending on the applied voltage and frequency of AC signals. For 4.5 µm polystyrene, cells were forced to locate in the center between electrode array and move along the channel and the traveling wave dielectrophoresis occur, when the applied voltage was 10 V and the frequency of the applied signals is in the range of 50 kHz-700 kHz. For 10 µm polystyrene the twDEP occurs when the applied voltage was 7 V and frequency was in the range 30 kHz-1MHz. For the mixed solution containing equal amount of 4.5 and 10 µm microspheres, the big microspheres were moved under twDEP force when the applied voltage was 7 V and the frequency was in the range 25 kHz-1MHz while the small microspheres were attached to the electrodes. Therefore, the twDEP device can separate the microspheres with different sizes and it can be further applied for cells separation and manipulation.**

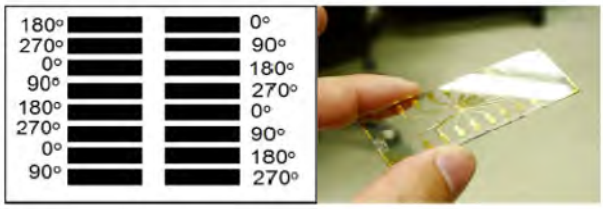
Keywords— **Traveling wave dielectrophoresis, cell separation, lab-on-a-chip.**

I. Introduction

Recently, there have been growing interests in using the MEMS technology for biological and medical applications. The use of electrokinetic effects for manipulating microparticles has been shown to be efficient for biological applications. The examples of electrokinetic phenomena include dielectrophoresis, electrorotaion and traveling wave dielec-trophoresis [1-5]. Dielectrophoresis (DEP) is an electrokinetic movement of neutral particles induced by polarization in non-uniform electric field [6]. The time averaged dielectrophoretic force on a dielectric sphere in non-uniform electric fields is represented by

$$F = 2\pi\varepsilon_0\varepsilon_m r^3[\mathrm{Re}(f_{CM})\nabla|E|^2 + (-\frac{2\pi}{\lambda})\mathrm{Im}(f_{CM})E^2]$$

Where ε_0 is the vacuum dielectric constant, r the particle radius, f_{CM} is a Clausius-Mossotti factor, and ε_p^* and ε_m^* are the relative complex permittivity of the particle and the medium, respectively. The positive and negative DEP force is determined by the real part of a Clausius-Mossotti factor. When the dielectric constant of particle is larger than that of medium, the first term is positive; the dielectrophoresis is positive and the particle moves towards the locations with the greatest electric field. In contrast, if the dielectric constant of particle is less than that of medium, the first term is negative, the dielectrophoresis is negative and the particle is repelled from the locations with the greatest electric field [7, 8]. Traveling wave dielectrophoresis (twDEP) is a traveling wave electric field which can be produced when a 90°-phase shift signal sequence is applied to a parallel electrode array. twDEP occurs when the real part of the force equation is much less than the imaginary part [9]. Since the strength of the force depends strongly on the medium, the particle's electrical properties, the particle's shape and size, and the frequency of the electric field, varying of any parameter allows the manipulation of particles with great selectivity which can be applied in many applications.



In this work we present a design and fabrication of twDEP device for separation of cells with difference size. The characterization of chip was studied by observing the movement of microparticles under different conditions of applied twDEP.

II. Experimental Study

A. Dielectrophoretic devices

The dielectrophoretic chamber was fabricated using standard microfabrication techniques. A Silicon wafer was cleaned in piranha solution (mixture of 1: 4 of 50% H_2O_2 and

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 851–854, 2009

97% H_2SO_4) at 120 °C for 10 minutes, then carefully rinsed several times in deionized water and dried with a gentle stream of air. After that the silicon wafer was dehydrated by heating at 150-200 °C for 10 minutes. SU-8 photoresist was spin-coated on the silicon wafer using a spin coater (Laurell technologies corp. model WS–400A–6NPP), then soft baked to remove all the solvent in the layer. The photoresist coated wafers were exposed using MJB4 mask aligner (SUSS microtec), then post-baked in order to selectively cross-link the exposed portions of the film. The sample was left in the desiccators to cool down slowly at room temperature for more than 13 hours. Finally, samples were developed and cleaned with deionized water and isopropyl alcohol, and then it was gently dried with air. Spin speed, exposure time, baked time, and developing time were optimized to achieve a smooth surface on mold. The chamber was made from Poly (dimethylsiloxane) (PDMS) by solvent casting and drilling. PDMS was prepared by mixing the precursors sylgard with a curing agent at a ratio of 10:1 by volume. The prepolymer mixture was degassed at 20-50 mTorr at room temperature in desiccators pumped with a mechanical vacuum pump for 10 minutes to remove any air bubbles in the mixture. PDMS mixtures were gradually poured onto the SU8 master mold to the height over the depth of designed chamber. After the PDMS is cured at 100 °C for 30 minutes on a mold, the molded polymer samples are peeled off.

(a) (b)

Fig. 2. The photograph of twDEP chip (a) experimental set up (b)

The mask for fabricating electrode was designed to have 8 parallels bar shape by using L-Edit software as shown in Fig.1. The Cr/Au electrode array of 100 μm wide and 300 nm thick was patterned on glass slide by DC sputtering through microshadow masking. The chromium and gold were sputtering under argon plasma. The sputtering pressure, sputtering current, and time for chromium are $3x10^{-3}$ mbar, 0.2 A, and 2 minutes, respectively. Next, gold was sputtered under the argon pressure of $3x10^{-3}$ mbar and the sputtering current of 0.2 A for 10 minutes. The sputtering was conducted at room temperature. The chamber and electrodes were treated under oxygen plasma (Harrick scientific corp. model PDC –32 G) before being attached to each other.

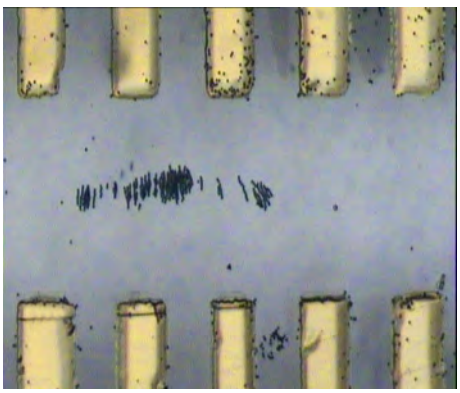

Fig.3 The 4.5 μm microsphere were attached to the center between electrodes array when the applied voltage and frequency to the electrode array was 10 V and 500 kHz

B. Separation test

In order to test the twDEP devices, polystyrene microspheres suspended in water were used as the tested cells. Polystyrene microspheres of 4.5 μm mean diameter and a density of 4.99×10^8 particles per milliliter were purchased from Polysciences, Inc, Warrington, PA, USA. While the 10 μm polystyrene microspheres was purchase from Sigma Aldrich company, USA. The polystyrene solution was dilute 1000 times in deionized water. A 10 milliliter polystyrene solution was dropped in the chamber. The chamber was then closed on top by glass slide. The electrodes were energized with four square wave signals. The cells movements under electric fields were observed by using microscope CX41 (Olympus). Cells respond to the electric field in various mechanisms depending on the frequency of applied AC signals. The experimental setups are shown in Fig.2.

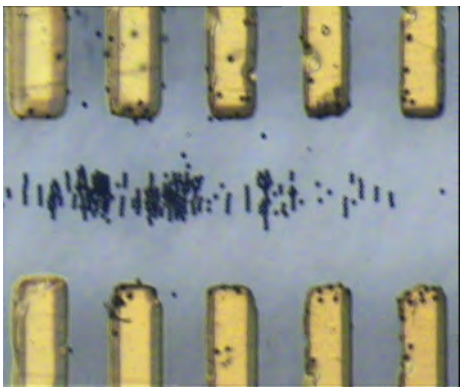

Fig.4 The 10 μm microsphere were attached to the center between electrodes array when the applied voltage and frequency to the electrode array was 7 V and 250 kHz

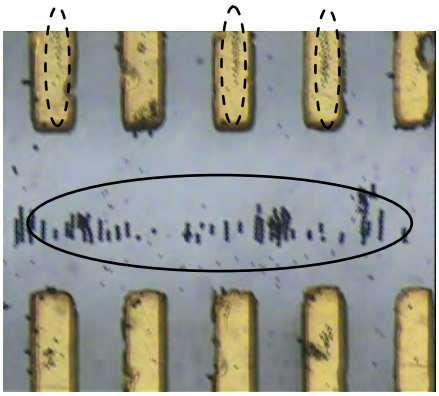

Fig.5 The mixd of two type of microsphere were in the applied voltagae and frequency of 7 V and 25 kHz. The big microsphere were attached to the center between electrodes array (solid line) while the small microspheres were attached to the electrodes (dotted line)

III. Result and Discussion

Two types of cells were tested separately to find the optimum conditions that traveling wave dielectrophoretic occur. For the 4.5 μm microsphere, when the applied voltage and frequency to the electrode array was 10 V and 50 Hz, cells were moved over to the electrode edges in a vertical circular motion and moved faster when the frequency or voltage was increased. When the frequency of the applied signals were more than 350 Hz, cells started moving slowly and tried to move to the center of electrode array. As the frequency of the applied signals was in the range of 50 kHz-700 kHz, cells were attached to the center between electrode arrays and moved slowly along the channel as shown in Fig.3. When the frequency of the applied signals was more than 700 kHz, cells started moving out of the center between electrodes. Therefore, that indicates that the 4.5 μm cells are subjected to the effects of a traveling dielectrophoresis force when the applied voltage was 10 V and the frequency was in the range 50 kHz-700 kHz. These results are consistent with the theory that twDEP occurs when the frequency of applied AC fields is in the range where dielectrophoresis (DEP) is negative so when cells experience twDEP force they were repelled from the electrode rather than being trapped by positive DEP. When applied the proper voltage and frequency to the 10 μm microspheres, the big cells show similar behavior to the small cells. In this case, the twDEP occurs when the applied voltage was 7 V and frequency was in the range of 30 kHz-1MHz, as shown in Fig. 4. For the mixed solution containing equal amounts of 4.5 and 10 μm microspheres, the big cells start moving to the center between the electrode arrays when the frequency reaches 5 kHz. When the frequency was 25 kHz-1MHz, the big cells were attached to the center between electrodes, and moved under twDEP force while the small microspheres were attached to the electrodes as shown in Fig.5. The threshold frequency that the big and small cells have started separating were recorded when the big cells started moving to the center between electrode arrays and the small cells were attached to the electrodes. The threshold frequency at each applied voltage is shown in Fig. 6. It can be seen that at the high applied voltage cells separated at the high applied frequency. However, the best separating condition for the 4.5 and 10 μm microspheres was at the applied voltage and frequency equal to 7 V and 25 kHz-1 MHz, respectively. This result can be further applied in biological and medical application such as motion control and cell selectivity.

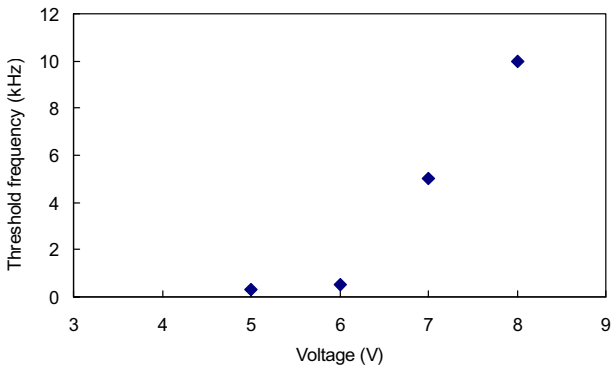

Fig. 6 The relationship between the applied voltage and threshold frequency for cells separation

IV. Conclusions

The traveling wave dielectrophoretic microfluidic devices were successfully fabricated. When energized the electrodes with four square wave signals, cells response to the electric field in various mechanisms depending on the amplitude and frequency of applied AC signals. Cells with different size were subjected to traveling wave dielectrophoresis in the different voltage and frequency range. And the results for the mixed of two type of cells show that at the proper applied voltage and frequency, two cells can be separated. Furthermore, this twDEP separation approach could be applied to the flow system and integrated with other devices for using in biological and medical application.

A Novel pH Sensor Based on the Swelling of A Hydrogel Membrane

K.F. Chou, Y.C. Lin, H.Y. Chen, S.Y. Huang and Z.Y. Lin

Department of Biomedical Engineering, Yuanpei University, Hsin Chu, Taiwan

Abstract — **A novel pH sensor consists of the pH sensitive hydrogel and conductive polymer layer was developed. The monomers of hydroxyl ethyl methacrylate were polymerized and modified by UV radiation to become the pH sensitive hydrogel. The pH sensitive functional group of poly(HEMA) was created by UV treatment. The sensing principle of the device was based on the piezoresistive effect induced by the swelling behavior of the hydrogel varied with pH value of testing solution on the conductive polymer. The correlation between the sensitivity of the device and UV radiation dosages was investigated. The stree-strain relationship of the polymer membranes and output characteristic of pH sensor were measured, and the computer-aid analysis based on the hyperelastic–viscous model of hydrogel was achieved by using the fine element method. The optimization aspect of pH sensor also was found from the simulating process.**

Keywords — **hydroxyl ethyl methacrylate, pH sensitive, sensor.**

I. Introduction

For past years, a lot of papers on pH sensor based on hydrogel had been published[1-9]. The operating principle of the pH sensors with hydrogel substrate all are based on the bending of flexible matrix induced by the swelling effect of gel. The deformation of geometry structure could be transfer into the change of capacitance or resistance. These similar principles were applied in the design of various sensors. Herber et al.[2] developed a hydrogel biosensor for monitoring the partial pressure of CO_2 in the stomach. Han et al.[1] combinated the pressure transducer and pH sensitive gel to develop a biosensor applied into the measurement of the concentration of glucose in blood. On the other hand, Trinh et al.[9] investigated the effect of polymerization condition on the sensitivity and response time, and predicted the characteristics of the sensor by using Mooney-Rivlin model and finite element method.

Most researchers chose PVA-PAA copolymer as the pH sensitive materials. In our previous study[10,11], the swelling degree of poly(HEMA) exposed by gamma ray in buffer solutions changed with the pH value of buffer. Besides, the pH sensitive behavior could be modified by irradiation dosages. However, in this study, we modified the poly(HEMA) with ultraviolet irradiation but not gamma ray in order to keep the mechanical properties of hydrogel thin film.

II. Material and Method

A. Sensing principle

The sensing device was composed of the pH sensitive hydrogel layer(poly(HEMA)), resistance Ag gel layer and SiO_2 substrate. The operating principle of the sensor was showed as Fig. 1. The swelling of the polymer film induced by absorbing testing solution, and the swelling degree changed with the pH value of solution. The resistance layer under the hydrogel deformed with the swelling of sensitive layer such that resistance changed. The relationship between the resistance variation and strain are linear as formula (1). The resistance layer connected with a Wheatstone bridge. The voltage output of Wheatstone bridge could be measured as the change of the resistance of Ag gel.

$$\frac{\Delta R}{R} = \varepsilon \tag{1}$$

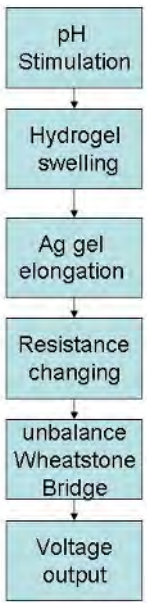

Fig. 1 Operating principle of pH sensor

B. Materials

All chemical reagents were purchased from Tokyo Kasei Kogyo Co. Ltd. and were used as received. Water was dis-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 855–858, 2009
www.springerlink.com

tilled and deionized at 18 M resistance. Aqueous solutions (10 wt%) of ammonium persulfate(APS) and sodium metabisulfite (SMBS) were used together as initiators and were made prior to every use. All chemicals were used as received unless otherwise stated. Ethylene demethacrylate (EDMA) were used as crosslinking agent.

C. Polymerization of poly(HEMA)

The monomer mixture was comprised of monomers (HEMA), crosslinking agent (ethylene dimethacrylate, EDMA), and solvent (D. I. water). HEMA monomer diluted with water (HEMA : water = 60 : 40). Next, EDMA, ammonium persulphate and sodium metabisulphite was added into the solution and mixed by ultrasonic machine for 5 min. The polymerization of these monomer mixtures are initiated by APS and SMBS concentrations were 0.5 wt% and 0.2 wt% of the total monomer, respectively. Prepolymerization occurred at 65℃for half hour. Then the prepolymers were spin coated on resistance layer to form the polymer thin film with thickness of 300 μm. After prepolymerization, the specimens were exposed on 360nm UV radiation for 2hr (dosages of 72J/cm^2).

D. Characteristic analysis of the sensitive layer

The chemical structure of poly(HEMA) was determined by FTIR. The hydrogel samples were immersed in various pH buffer solutions. Their weight changes were measured with an electronic balance. The swelling degree of hydrogel was calculated from the result. The definition of swelling degree (SR) listed as equation (2). W_t means the weight of thin film at time t, W_0 is the initial weight.

$$SR = \frac{W_t - W_0}{W_0} \tag{2}$$

E. Fabrication of Sensing Chip

The fabrication process of sensing chip was shown as Fig. 2. The process was divided into three steps (a) two square SiO_2 plates were made up through a PMMA mold, and Ag gel layer was spin coated on SiO_2 substrate. (b) Au conducting electrode was fabricated by sputtering coater, and remove the bump by using acetone. Poly(HEMA) sensitive layer was filled by the principle of siphon effect. (c) The second Ag gel layer was coated on the hydrogel layer.

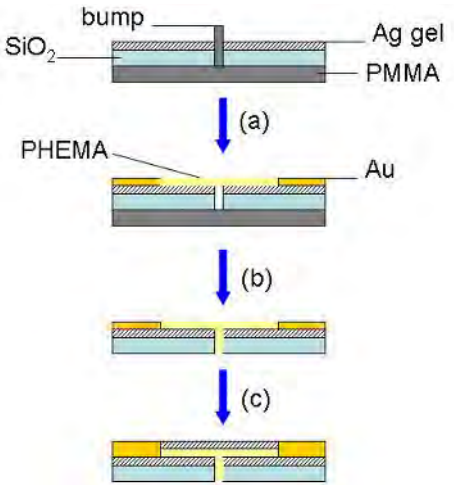

Fig. 2 Fabrication of pH sensor

F. pH measurement system

The infrastructure of pH measurement system was shown as Fig. 3. The pH sensor contains a sensing chip and Wheatstone bridge. In the signal condition part, The output signal are amplified and filtered through AD620 IC. Then, the voltage output converted to digital signal with NI 6024E DAQ. Finally, the curve of pH value versus time is displayed by the panel of virtual instrument.

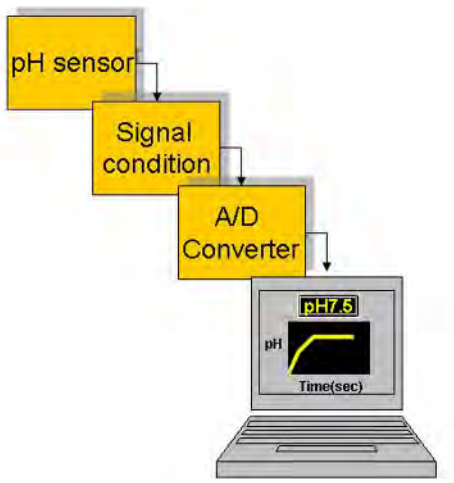

Fig. 3 pH measurement system

III. Results and Discussion

A. Characteristic analysis of the sensitive layer

The effect of UV radiation on the chemical structure of poly(HEMA) was analyzed by FTIR. The spectrum was shown as Fig. 4. Poly(HEMA) thin film exposed on 360nm UV radiation of 72 J/cm^2 presents two significant shift and adsorption at 1244cm^{-1} and 3500cm^{-1}, respectively. The adsorb band at 1244cm^{-1} corresponds to the acrylate group and crosslink structure of EDMA. That implies that UV radiation energy would destroy the crosslink structure and create weak basic groups. On the other hand, the decreasing of restrict force was due to the breaking of crosslink structure. Therefore, the absorption peak of hydrophilic groups was enhanced. This inference was verified by the swelling experimental. Fig. 5 presents the result of the experimental. The swelling degree of poly(HEMA) immersed in acidic solution was higher than base solution, the swelling ratio exponential decays with pH value of buffers.

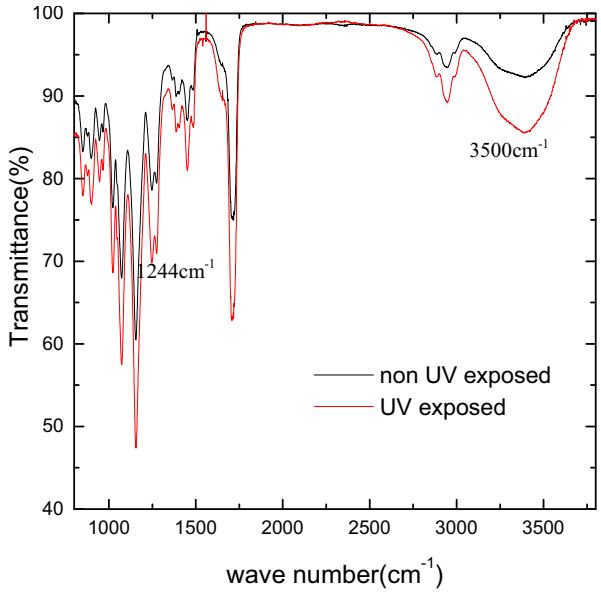

Fig. 4 FTIR spectrum of P(HEMA)

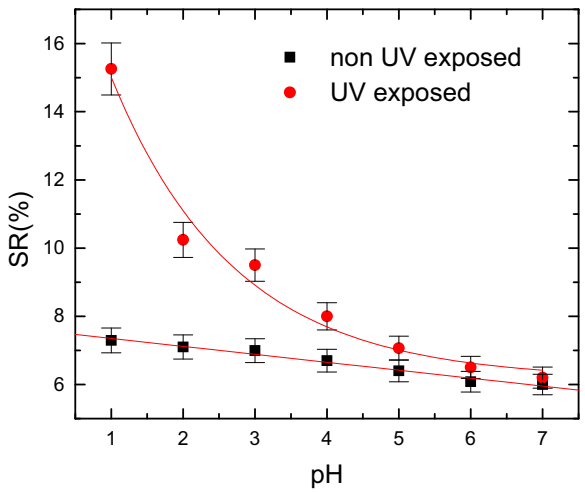

Fig. 5 Plot of swelling degree of P(HEMA) versus pH value of buffers

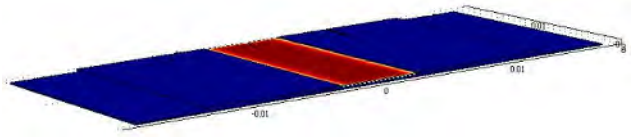

Fig. 6 Stress distribution applied in the P(HEMA) thin film

The Young's modulus of poly(HEMA) was obtained by tensile testing, the value is 0.73MPa. The swelling stress distribution was simulated with Comsol Multiphysics software, shown as Fig. 6. The deformation was limited along axis y and z.

B. Output Characteristic of the resistance Ag gel layer

The plot of resistance of Ag gel layer versus pH value of buffer solutions was shown as Fig. 7. The trend of data could be divided into two stages. The resistance of Ag gel increases with the increasing pH value of buffers in the range of pH1~pH4. However, the trend reverses at pH4. The resistance decreases with the increasing pH value of buffers in the range of pH4~pH7. The characteristic of Ag gel was matched with the swelling behavior of sensitive

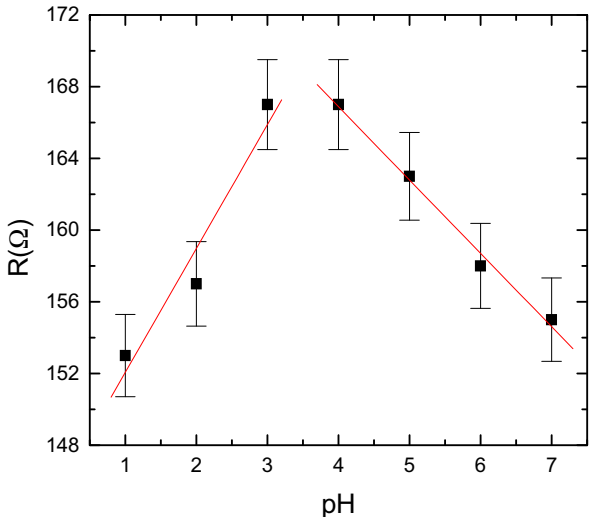

Fig. 7 Plot of resistance of Ag gel versus pH value of buffers

layer as the value of pH>4. Nevertheless, it might be that the moist raises the conductivity of Ag gel, such that the opposite trend was happened as the value of pH<4. This unexpected result should be improved by hydrophobic surface modification of Ag gel.

IV. CONCLUSIONS

This study developed a novel pH sensor based on the swelling of pH sensitive Poly(HEMA). Poly(HEMA) was modified with exposure of UV radiation. A weak basic group was created by the breaking of crosslink structure, such that the swelling degree of Poly(HEMA) exponential decay with the pH value of buffers. Ag gel was made as the resistance layer covered the hydrogel layer. The output characteristic of Ag gel presents two stages. The strain dominated the characteristic of Ag gel in the range of pH4~pH7, so the resistance of Ag gel decreases with the pH value. However, the moist dominated the conductivity of resistance layer in the range of pH1~pH4, such that resistance increases with the pH value of testing solution.

Abstract — **Polymerase Chain Reaction (PCR) technology has been widely used in molecular biology, forensic analysis, evolutionary and medical diagnostic. PCR requirement for point of care application is shorten reaction time and reduces PCR reagent. If the PCR chip can be done by droplet basis, then the analysis system which minimal amount of fluid will be possible. In this report, we describe the simulation and experimental study of a parallel–plate electrowetting on dielectric (EWOD) based PCR device. The EWOD device is applied to control PCR reagent and sample for a polymerase chain reaction (PCR) system. The EWOD-based PCR system consists of 3.4 mm wide, 15.1 mm long serpentine-shape microheater integrated underneath to maintain temperature at each stage and 370 μm deep microchannel. DNA was driven by moving droplet through each square electrode (dimension 1x1 mm^2) that maintains temperature at denaturation, annealing, and extension region. The fluid dynamics of the device have been modeled by Coventorware®, a commercially available MEMS simulation software, to show temperature distribution on each electrode. In experiment, this work studied contact angle reduction of different droplet because this result can be studied possibility of transporting of PCR reagent for a droplet based PCR.**

Keywords — **Polymerase Chain Reaction (PCR), Electrowetting on Dielectric (EWOD), Droplet, Finite Element Analysis.**

I. Introduction.

The polymerase chain reaction (PCR) is a powerful technique used to make copied DNA sequences of interest through repetitive temperature cycling. For the first report introduce in 1983, PCR has been widely used in molecular biology, medical diagnostic, forensic analysis, evolutionary and medical diagnostic [1]. The temperatures used in PCR are typically 90 - 94°C for denaturation, 50 - 70°C for annealing, and 70 - 75°C for extension. The double-stranded helix of nucleotides, carrying the genetic information, is separated during denaturation, reacts with chemical primers during annealing, and becomes a complete double-stranded DNA helix structure during extension. After about 30-40 thermal cycles, the target is copied into billions copies.

The objective is to design a better PCR device are shorten reaction time and reduces PCR reagent. Currently, most developed PCR system is based on continuous flow system. If the PCR chip can be done by droplet basis, then analysis system with minimal amount of fluid will be possible. In 2003, Zhang et al. reported a theoretical performance of the droplet-based PCR system is better than the continuous flow in terms of performance, simple to design and ease of integration with sample preparation or product detection [2].

Electrowetting is a well known method for moving droplet. The concept of electrowetting process is to alter the wetting properties of a surface by applied electric field. The energy stored in this field can be formulated as equivalent interfacial tension, and thus, related to the large change of contact angle for liquid droplet due to external electric field [3-7].

In 2005, a droplet-based micro oscillating-flow PCR chip was designed and fabricated but this device requires mechanisms to move the sample in the system [8]. Therefore, our research work demonstrates the simulation and experiment of a parallel-plate EWOD device that moves fluid droplets through surface tension effects in microchannel without the use of mechanism to move the sample.

In this work, we show that to achieve a successful device, the shapes of reaction chambers along with the microheaters. In microchannel, PCR was designed by using silicone oil to cover the droplet to prevent evaporation and help reducing voltage to transport droplet [9,10].

II. A droplet based PCR design.

We propose a droplet based PCR by EWOD technique to focus on minimizing reagent consumption and without the use of mechanical mechanism to move the sample in the system. The PCR has a single microchannel because of simplicity and more convenient integration of DNA amplification with product detection. As illustrated in Fig. 1, our design consists of a microchannel and three microheaters.

The main channel is single, straight microchannel with three independent temperature zones for denaturation, annealing and extension zones. Three microheaters maintained at 95ºC, 70ºC, and 60ºC for three temperature zones of single microchannel. A droplet is introduced in the reservoir and is

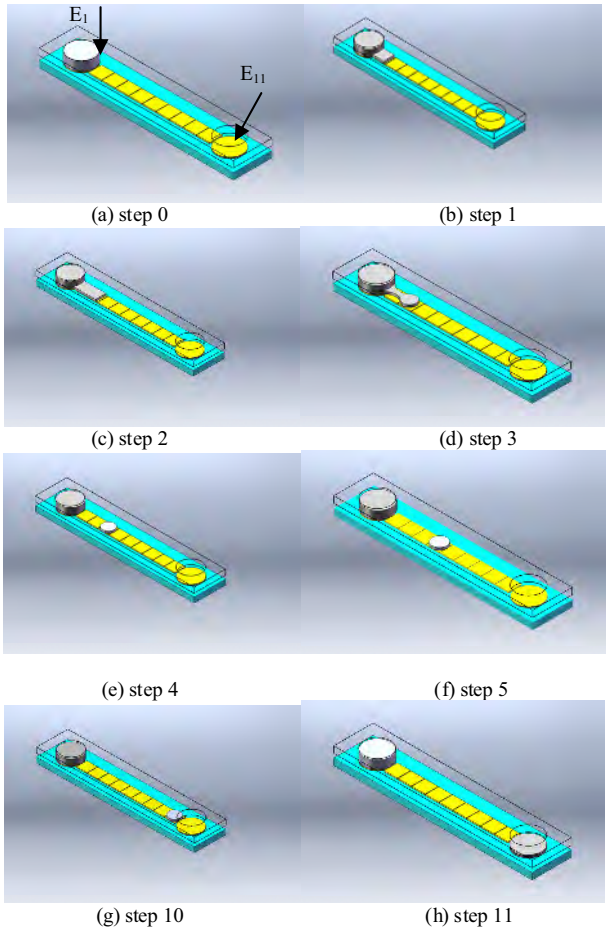

Fig. 2. Schematic of device with voltage pattern used.

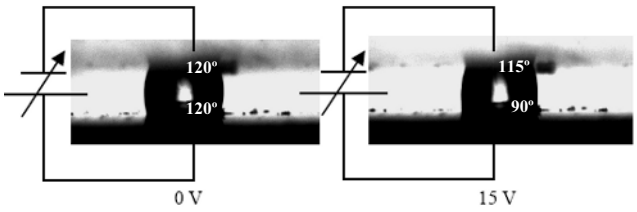
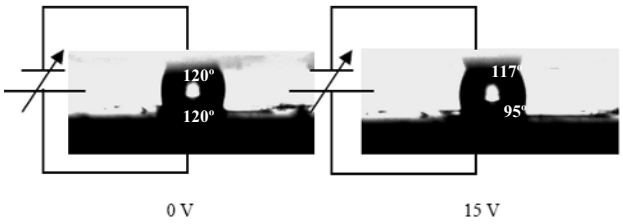
moved back and forth along the microchannel by concept of EWOD device. The number of thermal cycles consists of 30-40 cycles in depend on application. Finally the droplet is pushed out of the chip from the outlet hole for analysis.



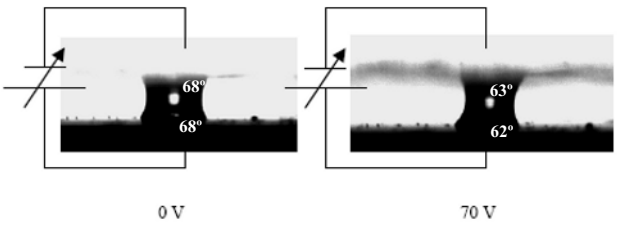
The droplet can be moved in fully controlled manner by applying voltage corresponding to a voltage control scheme shown in Table 1 and Fig 2.

III. Fabrication of EWOD Device.



The EWOD device is fabricated with environmental silicone oil and air in microchannel. Initially, 100 nm thick Au electrode is deposited on a glass substrate.A set of device consists of a single linear array of nine control electrodes are fabricated. The first dielectric layer, 100 nm thick silicon dioxide layer is deposited by sputtering technique. Then, a 20 nm Teflon® AF 1601 (Dupont, USA) layer is spin-coated on the silicondioxide layer. This Teflon® AF layer acts as the dielectric layer as well. The entire area of

cover glass is coated with a transparent and conductive ITO film (indium tin oxide, < 15 Ω/square) by sputtering technique as a ground electrode. Then, a 20 nm Teflon® AF layer is also spin-coated on the ITO covered top cover glass to make the surface hydrophobic. Polydimethylsiloxane (PDMS) microchannel used to define the gap between the top and bottom plates in the parallel-plate channel. The droplet was placed and squeezed in microchannel.



In experiment, the 0.9 µl droplet was dropped on the one electrode of EWOD device (bottom glass, 100 nm SiO_2 and 20 nm Teflon® AF). Contact angle have been determined by image analysis of side views of the droplet using contact angle measurement system (Rame’-hart instrument co. model 200). The contact angle reduction droplet were measured. The reversibility of EWOD actuation is critical to guarantee reliable transportation of droplets.

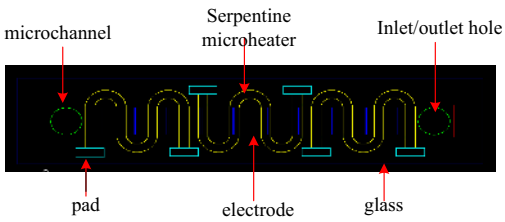
(a)

(b)

(c)

Fig. 3 Relationship between voltage drop across the dielectric layer and contact angle. (a) Images of de-ionize droplet (b) Images of 0.1 M KCl droplet (c) Images of PCR reagent droplet.

Fig. 3 shows contact angle reduction of droplet at 15 V for de-ionized water, 0.1 M KCl solution and 70 V for PCR reagent. A significant contact angle occurs from 120º/120º to 115º/90º on the top wall/bottom wall for de-ionized water is observed shown in Fig. 3(a). The de-ionized water droplet evaporates at 200 V. The KCl 0.1 M droplet, contact angle change from 120º/120º to 117º/95º on the top wall/bottom wall shown in Fig. 3(b) but the droplet evaporates at 20 V.



For the droplet of PCR reagent, a significant contact angle change happened at 70 V shown in Fig. 3(c). The characteristic of the PCR droplet is different from de-ionized water and 0.1 M KCl because the contact angle changes from 68º/68º to 63º/62º and droplet evaporates at 200 V.

In microchannel, silicone oil is used to surround the droplet to prevent evaporation. In the experiment, cover glass was coated with silicone oil for contact angle reduction measurement compared with PCR microchip that use air environment. From experimental result, silicone oil helps increase contact angle reduction.

From the result, contact angles of the droplet reduce 3º/2º, 4º/5º and 1º/3º on the top all/bottom wall for de-ionize water, 0.1 M KCl and PCR reagent respectively. The deionized water droplet can be applied by voltage higher than 500 V without evaporation. The droplet of 0.1 M KCl and PCR reagent evaporates in silicone oil at 200 V and 450 V respectively.

IV. Thermal Analysis of a Droplet Based PCR.

A droplet based PCR is first designed using L-edit, commercial 2D layout design software. The 3D EWOD PCR structure is then constructed in CoventorWare® from the 2D layout and predefined PCR fabrication process as shown in Fig. 4 (a) and (b). The 3D structure is then meshed with suitable meshing parameters and simulated for electrothermal behaviors by Etherm module of CoventorWare®

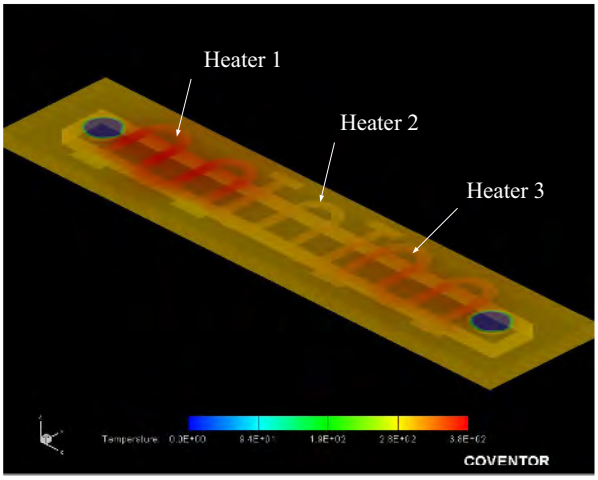

Fig. 5 Temperature distribution of microheaters (with microchannel, inlet and outlet).

In simulation, the PCR were set surface boundary condition into six pad layer for analyzer. To solve temperature distribution of PCR, we vary voltage for each heater. To assess voltage corresponding with temperature in PCR. Heater 1, 2 and 3 are area of denaturation, annealing and extension process. The appropriate voltages for each heater for the required temperatures are 1.19, 0.35, and 0.90 V, respectively as shown in Fig. 5 and Table 2.

Table 2 Temperature vs. applied voltage of three microheaters of a EWOD droplet based PCR.

Heater 1		Heater 2		Heater 3	
Voltage (V)	Temp (°C)	Voltage (V)	Temp (°C)	Voltage (V)	Temp (°C)
1.50	150.35	0.50	78.31	1.00	82.14
1.00	85.34	0.80	75.86	0.90	75.56
1.25	85.63	0.35	60.89	0.50	40.82
1.20	95.92	0.35	58.56	0.60	46.87
1.18	93.6	0.35	61.18	0.80	64.23
1.19	94.9	0.35	61.71	0.90	74.08

Table 3 Temperature vs. applied voltage of three microheaters of a EWOD droplet based PCR that filling channel with silicone oil.

Heater 1		Heater 2		Heater 3	
Voltage (V)	Temp (°C)	Voltage (V)	Temp (°C)	Voltage (V)	Temp (°C)
1.19	93.91	0.35	60.52	0.90	71.82

Table 2 shows temperature vs. applied voltage of microheter of EWOD droplet based PCR system in which microchannel filled with silicone oil. Three microheaters were assessed voltage 1.19, 0.35, and 0.90 V respectively. It can be seen that temperatures of microheaters corresponds to temperature zones of EWOD droplet based PCR slightly lower than in air environment. This result confirms using silicone oil in microchannel slightly change of temperature distribution.

V. Conclusions

A novel EWOD droplet based PCR has been designed, simulated and set up experiment. The EWOD droplet based PCR system consists of two parts, EWOD microchannel and microheater. In addition, contact angle reduction of different droplets by EWOD and silicone oil were studied. The result supports the silicone oil can be used to fill in microchannel to prevent evaporation and reduce contact angle. From simulation result, three microheaters varies applied voltage of 1.29, 0.35 and 0.90 V. The temperature distribution of microheaters correspond to temperature zone of EWOD droplet based PCR both air and silicone oil environment are investigated.

Abstract — **A novel signal amplification mechanism for impedimetric biosensors is proposed. The proposed mechanism is based on humidity sensing properties of BST composite film and eliminates the need for application of bioactive labels for signal enhancement in amplified impedimetric biosensors. It suggests a good alternative to conventional impedimetric biosensors by improving the detection limit without adding any extra complexity to the system. It is direct and label-free, and can be employed for detection of a wide range of analytes. The sensing capability of the system was exemplified for detection of anti-BSA protein and a low detection limit of 10 ng/ml was obtained.**

Keywords — **Electrochemical Sensor, Impedimetric Immunosensor, Impedance Spectroscopy, Surface Modification, Barium Strontium Titanate.**

I. Introduction

A biosensor is an analytical device which integrates a biological sensing element with a transducer to produce a signal which is proportional to concentration of a specific analyte or a group of analytes. If antibodies or antibody fragments are applied as the biological element the device is termed immunosensor [1, 2]. Immunosensors have been the subject of an increasing interest during the past few years. That is mainly because of their high selectivity and specificity, short response time, relatively low cost, potential for miniaturization, portability, and ease of use [3, 4].

Immunosensors, as of most of other biosensing devices, involve formation of a biorecognition complex upon the bio-reactions. Formation of the biorecognition complex induces changes in physical properties of the surrounding environment which could be translated to a meaningful electrical signal using various techniques. If impedance features of the system are used for transduction of the immune-reaction, the device will be termed impedimetric immunosensor. Impedimetric immunosensors are attracting increasing interest since they are direct and label free and have many advantages with respect to speed, low driving voltage, simple operation, and the potential for miniaturization and large scale production [5, 6]. However, they still suffer from several drawbacks. One of the major problems of these immunosensors is the relatively small change of the impedance spectra upon direct binding of the analytes to the functionalized electrodes, especially when the analyte concentration is low and the surface coverage of the antigen-antibody complex is far from saturation [7]. This results in low detection limit and low signal to noise ratio. To overcome this problem, the concept of amplified impedimetric immunosensors was introduced. In general, this approach involves the application of enzyme-labels to perform biocatalytic reactions upon the antibody-antigen reactions to amplify the signal [7]. Application of enzyme-labels which could precipitate insoluble products on the sensing interface to increase the interfacial impedance has been reported [7]. Although these signal amplification mechanisms improve the sensitivity of the device, however, they involve application of labels which is not desirable as it increases the cost and complexity of the system.

In this study, a novel label-free signal amplification mechanism for impedimetric immunosensors was proposed, and a prototype immunosensor was fabricated to demonstrate the sensing capability of this sensing mechanism. This method can improve the detection limit by amplifying the generated signal. It also eliminates the need for using harmful redox probes [8], such as $[Fe(CN)_6]^{4-/3-}$, for Faradaic impedance measurements. It is based on humidity sensing properties of Barium Strontium Titanate (BST).

BST is a ferroelectric material with perovskite structure. When water molecules interact with BST grains, the electrical properties of the BST change. As humidity increases, the capacitance of the BST film increases and its resistance decreases. This property has been used for humidity sensing applications [9]. BST can also dissociate the water molecules into H^+ and OH^- ions due to its high polarity [10].

II. Experimental procedures

A. Fabrication of the BST composite film

A modified sol-gel process [11] was applied for fabrication of BST composite films using commercial nano-size

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 863–866, 2009
www.springerlink.com

BST powder (average grain size: 50 nm, PI-KEM Ltd). The method involved dispersion of BST nano-size powders into BST sol-gel precursor using ball mill technique to form a uniform slurry. The slurry was then deposited onto the platinum coated silicon wafer using the spin-coating technique. Using this method, uniform and crack-free BST composite films with thickness of around 3 μm were synthesized. A part of the BST film was etched off using diluted HF solution to expose the platinum substrate as an electrode.

B. Surface Modification of the BST composite film

BST composite films were functionalized with poly(TMS-*r*-NHSMA) to be able to bind to bio-receptors covalently. A detailed description of the polymer-modification process is reported in [11]. BST composite films were soaked in Nitrogen bubbling DI water for 10 minutes to remove the soluble ions or contaminations, and were dried at room temperature. Clean BST films were treated with phosphoric acid to gain more OH function groups for better polymer modification. Films were immersed into 9.5 % phosphoric acid aqueous solution for 10 minutes and dried at 60 °C for 8 hours, then washed in constant Argon bubbling water for 30 minutes and dried at 60 °C under vacuum condition for 6 hours. Then, the acid modified BST films were immersed in poly(TMS-*r*-NHSMA) methanol solution (8.8 mg/ml) for 10 minutes and dried at 200 °C for 16 hours.

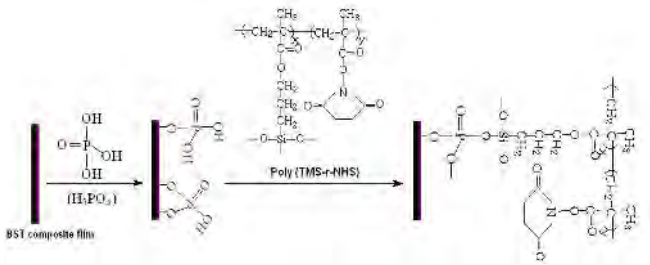

Fig. 1 BST surface modification using phosphoric acid and poly(TMS-r-NHSMA)

C. Immobilization of the biomolecules

To immobilize the Bovine Serum Albumin (BSA) molecules on the surface, polymer modified samples were soaked in BSA solution for 16 hours at 4 °C. The BSA solution was prepared by dissolving BSA in Phosphate Buffer Solution (PBS). Then, the excess protein molecules were removed by rinsing the samples with PBS. The same procedure was applied for immobilization of the anti-BSA molecules.

D. Electrical Characterization

To measure the impedance value, a measurement setup was developed to hold the sample and facilitate the connection between sample's electrodes and electrical probes of the impedance analyzer. The measurement setup consisted of two separate parts: a gold top electrode which was fabricated using e-beam evaporation on a glass substrate, and a platform made of poly-dimethylsiloxane (PDMS) for holding the sample and the top electrode. After fixing the sample on the platform, 10 μl of DI water was dropped onto the sample surface using micropipette. Then, the drop of water was covered by the gold top electrode to form a capacitor structure for impedance measurement. The electrical impedance measurement was carried out using a Solartron SI1260 impedance /gain-phase analyzer in conjunction with SI1296 interface (Solartron Group Ltd, Farnborough England). The impedance spectroscopy was performed over the frequency range of 1 Hz – 1 MHz using ac voltage amplitude of 50 mV. A detailed description of the device structure and the measurement procedure is provided in [11].

III. Results and Discussion

A. Characteristic curve of the immunosensor

Several samples with similar treatment procedure and background impedances were chosen. The samples were first immobilized with BSA solution with concentration of 1 mg/ml, and then were reacted with different concentrations of anti-BSA. Impedance spectroscopy was carried out and differences between impedances of the anti-BSA immobilized samples and impedance of a reference sample were calculated. An interpolated curve of the impedance changes for various anti-BSA concentrations is plotted in Figure 2. As it is shown, higher concentrations of anti-BSA result in higher impedance values. This can be applied for quantifi-

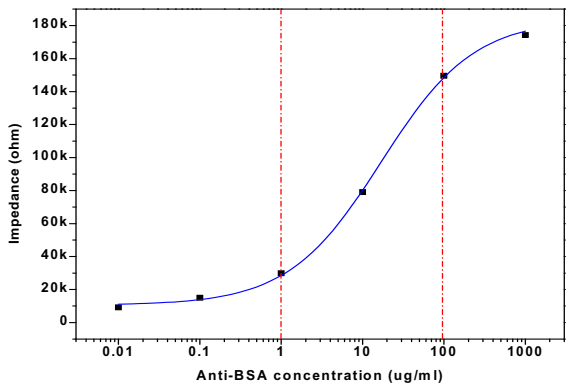

Fig. 2 Characteristic Curve of the immunosensor

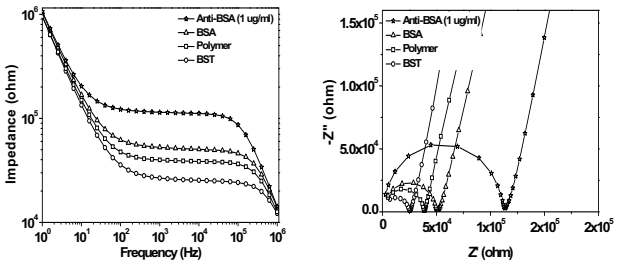

cation of anti-BSA concentration in a solution by calculating the impedance changes upon anti-BSA immobilization and using this characteristics curve.

As it is shown in Figure 2, the relationship is almost linear for anti-BSA concentrations in the range of 1 - 100 μg/ml. The curve tends to saturate at high anti-BSA concentrations. This might be due to the full coverage of all bioreceptors with complimentary analytes (which impedes the binding of further spices). A low detection limit of 10 ng/ml could also be identified, which might be due to the protein association/dissociation constraints at low concentrations.

B. Discussion on sensing mechanism

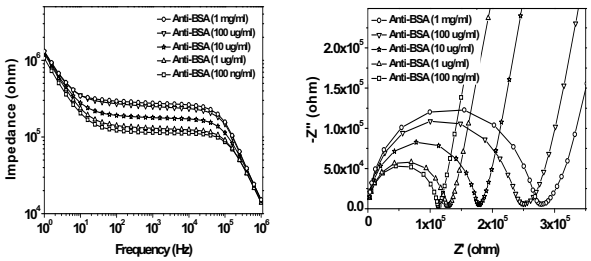

Figure 3 plots the impedance spectra of the bare BST composite film, the poly(TMS-*r*-NHSMA) modified BST composite film, the BSA immobilized film, and the anti-BSA immobilized film (after being immobilized with BSA and reacting with 1 μg/ml anti-BSA solution). After being modified with poly(TMS-*r*-NHSMA), the BST composite film showed higher interfacial resistance. This indicates that the poly(TMS-*r*-NHSMA) could obstruct the charge transfer in the system. After immobilization of BSA molecules, even a further increase in the impedance value was observed which indicates that BSA molecules could further block the surface. A similar behavior was also observed after immobilization of anti-BSA molecules.

An equivalent circuit model was set up to simulate the electrical behavior of the system and obtain a better understanding of the sensing mechanism. The proposed circuit model is illustrated in Figure 5 and includes the ohmic resistance of the water, R_s; resistance of the BST layer, R_m; capacitance of the BST layer, C_m; Warburg impedance (due to diffusion of ions from bulk water to the electrode/water interface), Z_w; the double layer capacitance at the electrode/electrolyte interface, C_{dl}; and charge transfer resistance at the electrode/electrolyte interface, R_{ct}. R_s and Z_w depend on bulk properties of the water and diffusion of dissociated ions, respectively. C_{dl} and R_{ct} represent the impedance features of the electrode/water interface, while R_m and C_m represent the electric properties of the BST layer.

(a) Bode plot (b) Nyquist plot

Fig. 3 Impedance spectra of bare BST film, poly(TMS-r-NHS) modified BST film, BSA immobilized film, and anti-BSA immobilized film

(a) Bode plot (b) Nyquist plot

Fig. 4 Impedance spectra for various concentrations of anti-BSA

Impedance data was fitted to the proposed circuit model and corresponding parameters were extracted. R_s, R_{ct} and R_m increased, and C_{dl} and C_m deceased as the anti-BSA concentration increased from 10 ng/ml to 1 mg/ml. When protein molecules bind to the surface, they will block the surface and reduce the charge transfer at the interface. This results in an increase in the interfacial impedance of the system. The thickness of the interfacial layer also increases which causes a decrease in the capacitance of the double layer and hence an increase in the interfacial impedance of the system. Impedance of the DI water also increases since the dissociation rate of DI water molecules, and hence the amount of charge carriers, decreases. Moreover, the impedance of the BST composite film increases upon prevention of the DI water from penetrating into the BST structure. This is due to the fact that the BST film is a humidity sensor and shows higher impedance values for lower water contents [9].

Figure 6 illustrates the calculated impedances of the DI water, the BST composite film, and the electrode/electrolyte interface. As it is shown, the blockage of the surface after the biorecognition reaction increases the impedance values of all three layers. However, the change in impedance of the BST layer is dominant and can be considered as a significant enhancement to the interfacial impedance changes which is applied in conventional impedimetric biosensors.

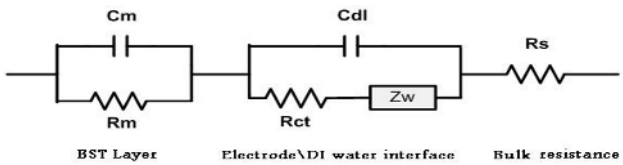

Fig. 5 An equivalent circuit model for analyzing the impedance data, including: R_s, ohmic resistance of the DI water; Z_w, Warburg impedance; C_{dl}, double layer capacitance; R_{ct}, charge transfer resistance; R_m, the BST composite film resistance; and C_m, the BST composite film capacitance

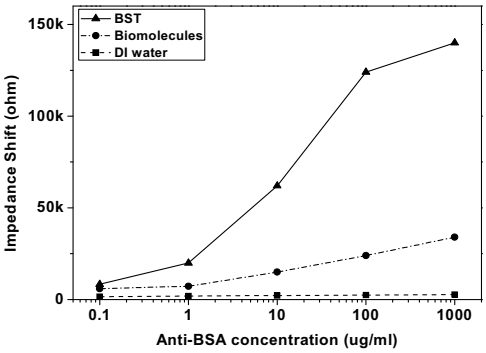

Fig. 6 Impedance changes of the DI water, the BST composite film, and the electrode/electrolyte interface after immobilization of various concentrations of anti-BSA

Thus, the generated signal of the system has been greatly amplified by using this structure.

C. Optimization of the polymer concentration

The effect of polymer concentration on sensing characteristics of the immunosensor was investigated. Several immunosensors with various polymer concentrations were fabricated and the sensitivity of them was measured. The sensitivity was defined as the amount of change in impedance value of the system per decade change in anti-BSA concentration in linear range of the characteristic curve. Figure 7 plots the calculated sensitivity values for various polymer concentrations.

As it is shown, the sensitivity reaches its optimum value at polymer concentration of 8.8 mg/ml. A possible reason for low sensitivity at lower polymer concentrations might be the lack of enough bioreceptors to detect their complementary species. This results in low sensitivity and low device performance. Low sensitivity at high polymer concentrations might be due to two possible factors: 1- difficulty in controlling the modification process which results in different background signals because of cross-sample and sample-to-sample variations, and 2- full blockage of the surface at high polymer concentrations which nullifies the signal amplification mechanism. Further investigations are needed to confirm these possible reasons.

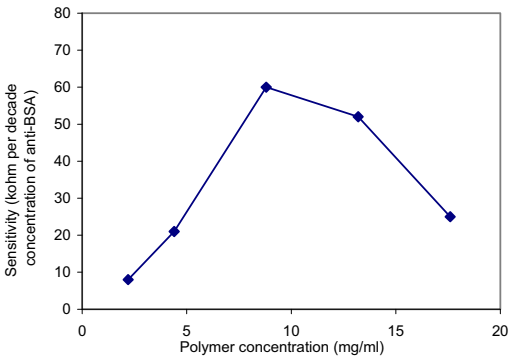

Fig. 7 Sensitivity of the immunosensor for various polymer concentrations

IV. Conclusions

A novel label-free impedimetric immunosensor with a signal amplification mechanism based on humidity sensing properties of BST composite film was introduced. The sensing capability of the fabricated device was illustrated for detection of anti-BSA as a test analyte. The primary results proved that the device could be applied for detection of desired analytes. It suggests a good alternative to conventional impedimetric immunosensors by utilizing a signal amplification mechanism without using any bioactive labels. Moreover, it eliminates the need for using harmful redox reagents for Faradaic impedance measurements.

Abstract — **Generally, there are many significant changes in physical and chemical characteristics such as electronic, magnetic, and optical properties when material size decreases to nanoscale[1]. For example, gold nanoclusters (GNCs) consist of several to tens of atoms which exhibit discrete, electronic states and size-dependent fluorescence. Also, the surface of plasmon resonance peak disappears in these smaller GNCs (< 2nm) [2]. In fact, the preparatory method for colorful fluorescent gold quantum dots was the original theory (which was reported by Dickson group whom) that utilized the dendrimer PAMAM to synthesize and stabilize gold nanodots[3].**

Most nanoparticles were synthesized in organic phase which was not suitable for probe design of cellular imaging. Converting those hydrophobic particles to water phase would be necessary. However, the fluorescent quantum yield will always decrease with the phase transformation. Therefore, the following study should consider how to enhance the fluorescent quantum yield for the use in fluorophore to bio-application, like cellular imaging .

In this study, we focus on how to enhance the fluorescent quantum yield with UV, gel electrophoresis and heat. These physical ways will change the nanoparticles structure or result in the purification of the nanoparticles to disperse. Furthermore, we discuss the appearance of the fluorescence nanoparticles like aging.

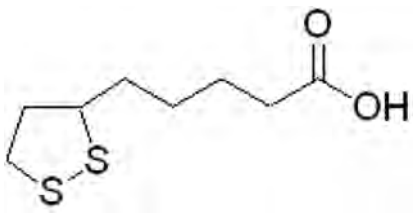
Keywords — **gold nanoclusters (GNCs), fluorescence enhance, aging, UV and heating, EDC**

I. Introduction

Wilcoxon observed that the gold nanocluster (< 5 nm) which composed of only a few gold atoms exhibited fluorescence properties in 1998. When we decrease the size of those nanocluster decreases to smaller than 2 nm, a surface plasma effect (SPR) will disappear[2]. These evidences prove the optical and electronic properties of nanocluster which are different from bulk metals.

Monolayer-protected metal clusters (MPCs) in particular have gained much attention as prototype systems to study size-dependent evolution of the electronic structures of metal clusters. One of the recent topics in unique properties of the MPCs is it's photoluminescence (PL). The PL quantum yields of gold MPCs are enhanced by several orders from bulk gold. These PL quantum yield variation can be qualitatively viewed as a consequence of quantization of the electronic levels of the metal cores. But some research reports also indicate the fluorescence property may be the result of the interaction of electron from ligand and the surface of metal, a process we call that "Ligand-Metal Change Transfer" (LMCT).

Based on the MPCs, most studies have been using ligand which includes thiol. The reason is that the thiol ligand has a stronger force (covalent bond) with the surface of GNCs than static electricity.



Keeping these in mind, we study lipoic acid (LA) (scheme1.) which also has thiol ligand to cover the surface of the nanocluster and analyze the PL characteristic. Furthermore, we study how to use different kinds of ways to enhance the PL quantum yields.

II. Materials and methods

The protocol of the nanoparticles followed according to Peng in 2003[4]. First, we reduce the $AuCl_3$. Second, we used surfactant to protect the nanoparticles and dissolve them in organic solution (~6 nm). Last, we etch the nanoparticles to be smaller nanoclusters (~2 nm), but the GNCs is not PL at present.

And then, we conjugated the lipoic acid (LA) to the surface of GNCs. Base on LMCT, the interaction between thiol and the surface electron of GNCs produced fluorescence property. However, the reaction is not completed, with the PL presented weakly. In order to improve the reaction, we

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 867–869, 2009
www.springerlink.com

Scheme1 : lipoic acid

irradiate the UV (365 nm) and heat to 70℃, and the reaction of conjugation becomes more complete. Therefore, we increase the fluorescence characteristic and enhance the PL quantum yields.

III. Results and Discussion

Based on Peng (2003), we synthesized 6 nm gold nano-particles. Also, we add over precursor to etch nanoparticles to become smaller nanoclusters (~2 nm). Fig.1 is the UV-vis absorption spectra shows that gold nanoparticles (~6 nm) have a distinct absorption peak at 520 nm (black wire). When we add the over precursor, the original nanoparticles are etch down to become smaller (~2 nm). As the size is smaller than 2 nm, the surface plasma effect disappeared and the peak on the UV-vis absorption spectra disappeared as well (red wire).

Furthermore, we add lipoic acid (LA) to a solution of gold nanoclusters, and mix it for five minutes. We can observe that the red fluorescence from the solution, but fluorescence is presented weakly. Fig.2 is the fluorescence emission spectra, and there is a peak at 580 nm (black wire). In the following experiment, we paid more attention to the fluorescence enhancement by irradiating UV (365 nm) and heating the GNCs up to 70℃. We can observe that the peak at 580 nm is raised in Fig.2.

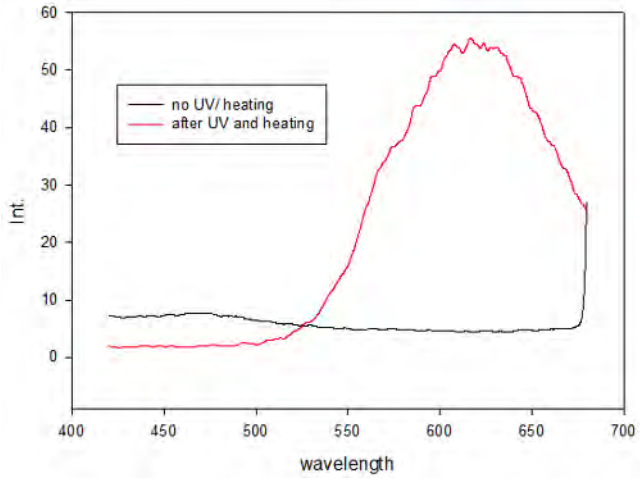


Fig.2 The fluorescence emission spectra of GNCs: a) The black wire is smaller gold nanoclusters b) and the red wire is irradiating UV (365 nm) and heating the GNCs up to 70℃

Another experiment is to add EDC to the solution and mix them for a few minutes. Following this, we found that the fluorescence has a further enhancement (Fig.3).

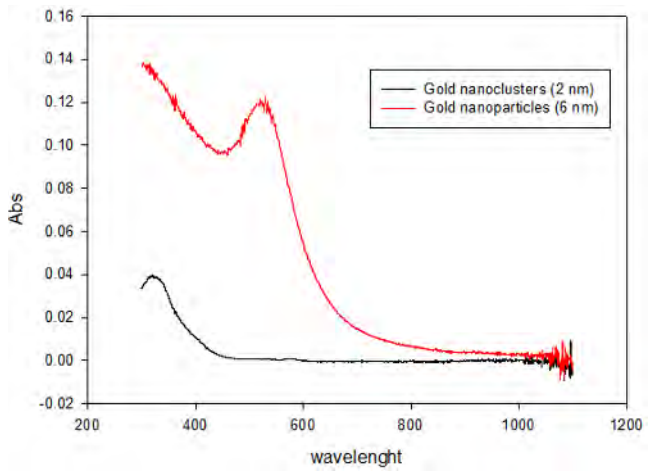

Fig.1 The UV-vis absorption spectra : a) The black wire is gold nano-particles (~6 nm); b) the red wire is smaller gold nano-clusters (~2 nm).

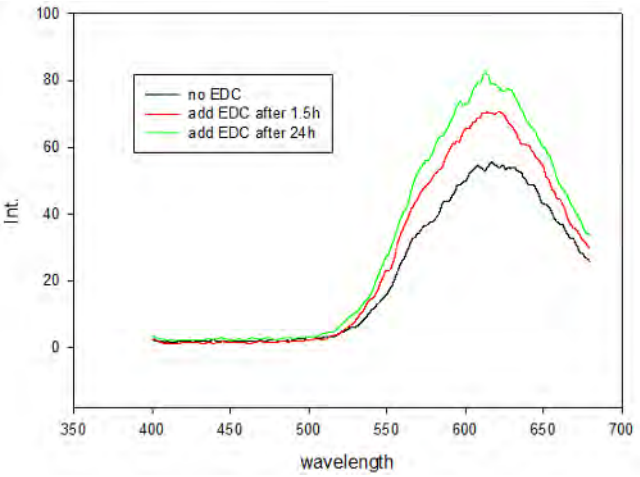

Fig.3 The fluorescence emission spectra of GNCs: a) The black wire is the smaller GNCs; b) the red wire is added EDC and mixed 1.5h; c) the green wire is added EDC and mixed 24h.

After synthesizing GNCs with fluorescence characteristic step by step, GNCs's fluorescence can be maintained for one month at room temperature. After one month, the fluorescence of the GNCs does not decrease but instead increase. We call the phenomenon "aging". Fig.3 is the fluorescence emission spectra, and we can observe the peak at 580 nm increased progressively as time passes.

IV. Conclusion

We conjugated lipoic acid (LA) with thiol ligand to the surface of GNCs using monolayer-protected metal clusters (MPCs). Therefore, we focused more on systems that have a fluorescent characteristic. Furthermore, we developed the way to enhance fluorescence by irradiating UV (365 nm) and heating the GNCs up to 70℃. Finally, we conjugated EDC to the surface of GNCs, and it strengthened the fluorescence signal again.

Follow the above-mentioned, our work provides a new way to get a new clusters with a fluorescent characteristic, and we can enhance its fluorescence signal by UV, heat and EDC, and it is extremely stable. Therefore, we suggest these small metal clusters can work as fluorescent probes to develop biological nanosensors, molecule imaging probe, and optoelectronic nanodevices

We focused on how to develop the molecule imaging probe. The outcome is that GNCs with fluorescence are smaller than quantum dots, and they have better photostability than organic fluorophores at room temperature.

Abstract — **Gold nanoparticle (GNP) is one of the most stable and popular nanoparticles, which receives considerable attention due to their applications in biomedical imaging and diagnostic tests. However, its cytotoxicity has not been fully investigated. Here we report the effects on biocompatibility of water-soluble GNPs with different sizes and concentrations to human bone marrow mesenchymal stem cells (hBMSCs) and human hepatoma carcinoma cells (HuH-7). Cytotoxicity was analyzed at different time points using MTT assay after co-culturing with different concentrations of GNPs. Both cells incubated with 71.1 μg/mL 15- and 30-nm GNPs exhibited more than 80 % cell survival. However, cell viability decreased to less than 60% after incubated with 31.6 μg/mL 5-nm GNPs for 5 days. GNP 15 nm in size was chosen for the following experiments. According to Annexin V and propidium iodide (PI) analysis, the percentage of necrotic cells increased gradually with the concentration of GNPs increased. Approximately 1.5 fold increase in the level of reactive oxygen species (ROS) was found, suggesting that necrosis might be triggered by ROS production after GNPs were endocytosed by cells. Alkaline phosphatase activity and calcium deposition of hBMSCs during osteogenic differentiation were inhibited slightly by co-culturing with GNPs. A similar observation was made in adipogenic hBMSCs, in which the accumulation of triacylglycerides was repressed by the addition of GNPs. In conclusion, despite 15- and 30-nm GNPs had little toxicity to hBMSCs and HuH-7 cells, they still had some influence on both osteogenic and adipogenic capabilities of hBMSCs.**

Keywords — **gold nanoparticle, biocompatibility, differentiation, HuH-7, mesenchymal stem cell**

I. Introduction

In the past 30 years, nanomaterials have received considerable attention because of their great potential in nanobiotechnology and drug delivery. Most of the research is focused on nanoparticles. For example, quantum dots are colloidal semi-conductor nanocrystals with unique light emitting optical properties that make them can be used as fluorescent probes for long-term cell targeting and imaging [1,2]. Dextran-coated iron oxide nanoparticles have superparamagnetic core which can be used in magnetic resonance imaging and magnetic biosensors [3]. Gold nanoparticles (GNPs) exhibit scattering light when excited due to surface plasmon resonance [4]. In fact, GNPs are widely used in biomedical imaging and diagnostic tests because they have many advantages over other types of nanoparticles. Besides their characteristics of optical properties, GNPs are chemically inert, easy to prepare and highly stable once synthesized [5]. Conjugation chemistry to biomolecules is simple and well developed in GNPs. Despite the wide application of GNPs, there is a serious lack of information concerning the impact of manufactured GNPs on human health and environment. Because nanoparticles can pass through biological membranes, they can affect the physiology of any cell in human body. This consideration is important for stem cells, where the effect of GNPS on their potential for self-renewal and differentiation is unknown. Here, we report the effect of GNPs on human cells. In addition, the influence on osteogenesis and adipogenesis of human bone marrow mesenchymal stem cells by GNPs treatment was explored.

II. Materials and methods

A. Preparation of GNPs

GNPs were synthesized as described by Turkevich *et al*. [6]. A solution of 1 mM $HAuCl_4$ (Alfa Aesar, MA, USA) was heated to boiling while stirring. After boiling was commenced, 38.8 mM sodium citrate (Mallinckrodt Baker, NJ, USA) solution was added slowly to the $HAuCl_4$ boiling solution. The solution changed color from yellow to dark red within 10 min. The solution was slowly cooled down to room temperature (RT). The resulting particles were coated with negatively charged citrate and were well-suspended. The GNPs solution was stored at 4°C for further use. GNPs of 5, 15 and 30 nm in size were prepared using different ratios of $HAuCl_4$ and sodium citrate solutions.

B. Cell culture

Human hepatoma carcinoma cells (HuH-7, Japanese Collection of Research Bioresources, Japan) were cultured Dulbecco's minimal essential medium (Gibco/BRL, Invitrogen, CA, USA) supplemented with 10 % fetal bovine serum (FBS, Biological Industries, Israel). Human bone marrow

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 870–873, 2009
www.springerlink.com

mesenchymal stem cells (SV40T- and hTERT-immortalized cells, hBMSCs) were grown in Alpha-minimum essential medium (α-MEM, Gibco/BRL, Invitrogen, CA, USA) containing 10 % lot selected FBS (Hyclone, Utah, USA). Both cells were maintained at 37°C under atmosphere with 5 % CO_2.

C. Cytotoxicity assay

To determine the cytotoxicity of GNPs to HuH-7 cells and hBMSCs, cells (5000 cells/well) were inoculated on a 96-well microplate and allowed to adhere for 24 h. Then, different concentrations of GNPs solution with same volume were added into each well. Cell viability was measured using MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide) assay after 24, 72 and 120 h incubation. Medium was removed and cells were rinsed with Dulbecco's phosphate buffered saline (PBS, Sigma, MO, USA) twice. The cells were then incubated with MTT solution (0.5 mg/ml) at 37 °C for 4 h. The purple formazan formed in each well was dissolved in 0.1 ml of DMSO for 40 min. The absorbance at 570 nm was monitored using an ELISA reader (Multiskan Spectrum, Thermo Fisher Scientific, Inc., MA, USA).

D. Assessment of necrosis and apoptosis

Annexin V/ Propidium iodide (PI) staining method is commonly used to differentiate necrotic and apoptotic cells. Here, phosphatidylserine externalization and nuclei were stained by the Annexin V-FITC Apoptosis Detection Kit (Sigma, MO, USA). One million HuH-7 cells and hBMSCs were plated on a 60-mm dish. Various concentrations of GNPs15 nm were added to each dish and incubated for 24 h. Cells were trypsinized and resuspended in 1 x binding buffer (0.01 M HEPES, pH 7.4; 140 mM NaCl; 25 mM $CaCl_2$), then incubated with staining solution (Annexin V-FITC : PI = 1 : 2) in darkness for 20 min at RT. Immediately after annexin V/PI staining, the sample was analyzed with Becton Dickinson FACSCalibur flow cytometer (BD Biosciences, NJ, USA).

E. Measurement of ROS formation

Reactive oxygen species (ROS) formation was detected using 2',7'-dichlorofluorescin diacetate (DCFDA, Sigma, MO, USA). Cells (10^6 cells/dish) were seeded a 60-mm dish. Various concentrations of GNPs15 nm were added to each dish. After 24 h incubation, cells were washed with PBS and DCFDA (20 μM) was added into each dish. Cells were washed twice with PBS after 1 h, and lysed by sonication. DCF (2',7'-dichlorofluorescein) fluorescence in cell lysate was analyzed by an ELISA reader (Fluoroskan Ascent FL, Thermo Fisher Scientific, Inc., MA, USA) (ext: 488 nm). The protein amount in each sample was determined by bicinchoninic acid protein assay (Sigma, MO, USA).

F. Differentiation of hBMSCs

To observe the effect of GNPs on osteogenic differentiation of hBMSCs, cells (500 cells/well) were grown on a 96-well microplate and incubated in the osteogenic medium (α-MEM containing 2% FBS, 10 μM β-glycerophosphate, 10^{-7} M dexamethasone and 50 μM ascorbic acid 2-phosphate) containing different concentrations of GNPs 15 nm for 28 days. Fresh medium containing GNPs was replaced every 3 days. Alkaline phosphatase (ALP) activity and calcium deposition of hBMSCs were assessed every week. ALP activity was assayed based on the conversion of *p*-nitrophenyl phosphate (*p*-NPP) into *p*-nitrophenol (*p*-NP) in the presence of ALP. Culture supernant (100 μl) was mixed with 100 μl of 6.7 mM *p*-NPP (Sigma, MO, USA), followed by incubation at 37°C for 30 min. After stopping the reaction with 50 μl of 3 N NaOH, the absorbance at 405 nm of *p*-NP was measured with an ELISA reader. Calcium deposition is a late marker for osteogenic differentiation, which can be stained with Alizarin red S. Cells in each well were stained with 50 μl of 5% (W/V) Alizarin red S. To quantify the amount of mineralization, 50 μl of 5% (W/V) cetylpyridinium chloride (Sigma, MO, USA) was added into each well to dissolve calcium deposition at RT for 3 h. The absorbance at 550 nm was read by an ELISA reader.

To observe the effect of GNPs on adipogenic differentiation, hBMSCs (2×10^4 cells/well) were grown on a 24-well plate for 6 days. Then, the medium was changed into adipogenic medium (α-MEM containing 2% FBS, 0.5 mM 3-isobutyl-1-methylxanthine, 10^{-6} M dexamethasone, 60 μM indomethacin and 5 μg/ml insulin) containing different concentrations of GNPs 15 nm and the medium was replaced every 3 to 4 days. Adipogenesis was assessed by Oil Red-O stain. To quantify the amount of triacylglyceride, 50 μl of isopropanol was added into each well to dissolve Oil Red-O at RT for 10 min. The absorbance at 510 nm was read by an ELISA reader.

III. Results and Discussion

A. Effect of GNPs on cell survival

The results of cell survival of HuH-7 cells and hBMSCs treated with various concentrations (0-75.05 μg/mL) of GNPs with different sizes are shown in Table 1. Cytotoxicity of GNPs was determined by MTT assay that measures

the metabolic activity of survival cells. The LD_{20} value is where the concentration of GNPs that resulted in a 20% reduction in cell survival compared to the untreated control. It is found that cytotoxicity decreased as the size of GNPs increased in HuH-7 cells. GNPs 5 nm in size resulted in less than 80 % cell survival even at low concentrations at day 1. On day 3, the percentages of cell survival for GNPs 15 and 30 nm were higher than 80%, indicating these GNPs had little toxicity to HuH-7 cells. Similar observation was made in hBMSCs, where cell viability increased as the size of GNPs increased. Cytotoxicity of GNPS to HuH-7 cells was higher than that to hBMSCs. Culture media were replaced with fresh media containing GNPs on day 3 (after MTT assay). GNPs endocytosed by cells with GNPs replenished in the fresh medium could lead to increase in total concentration of GNPs, which might be the reason why the LD_{20} values decreased on day 5. To investigate the mechanism of cell death and the effects on hBMSCs differentiation, GNPs 15 nm was chosen for the following experiments.

Table 1 LD_{20} dose of GNPs to human cells

Cell types	Size of GNPs (nm)	LD_{20} (μg/mL)		
		Day 1	Day 3	Day 5
HuH-7	5	0.06	0.70	7.90
	15	14.10	- *	52.21
	30	73.30	-	0.75
hBMSCs	5	16.00	9.31	15.80
	15	45.49	57.70	24.44
	30	-	-	37.53

*The percentage of cell survival was higher than 80% within the range of the concentrations of GNPs tested.

Table 2 Percentages of live, apoptotic, and necrotic cells treated with GNPs

Cell types	Cells gated (%)	GNPs (μg/mL)					
		0	3.56	7.11	17.78	35.55	71.1
HuH-7	Live	99.4±0.1	60.4±2.9	71.5±1.0	78.8±1.3	79.2±4.1	75.4±4.2
	Apoptosis	0±0	0.4±0.2	2.5±0	1.6±0.2	2.2±0.1	3.1±0. 6
	Necrosis	0.6±0.1	39.2±3.0	26.0±0.9	19.6±1.5	18.6±4.2	21.5±4.7
hBMSCs	Live	98.8±0.1	78.2±2.9	83.7±0.4	81.5±0.6	82.3±0.3	86.0±0.3
	Apoptosis	0±0	4.9±0.6	3.9±0.4	3.4±0.6	5.3±0.8	3.4±0.9
	Necrosis	1.2±0.1	17.0±2.3	12.5±0	15.1±0	12.5±1.1	10.6±1.2

B. Apoptosis versus necrosis caused by GNPs

To determine apoptosis and necrosis in HuH-7 cells and hBMSCs treated by GNPs, cells were stained with a combination of Annexin V and PI and subjected to analysis by flow cytometry. As shown in Table 2, both cells treated with 15-nm GNPs were found that the percentage of live cells decreased as the concentration of GNPs increased. Significant increase in necrotic population was observed after treated with GNPs. In contrast, there was no significant increase in apoptotic cells was seen. Our results indicate that GNPs induce cell death in HuH-7 cells and hBMSCs via necrotic process.

C. Effect of GNPs on ROS production

ROS production from HuH-7 cells and hBMSCs was observed (Fig. 1). It was found that the fluorescence intensity increased significantly after treated with GNPs. The level of ROS increased 1.5 fold of the non-treated control. The result suggests GNPs may result in cell death elicited from excessive ROS formation.

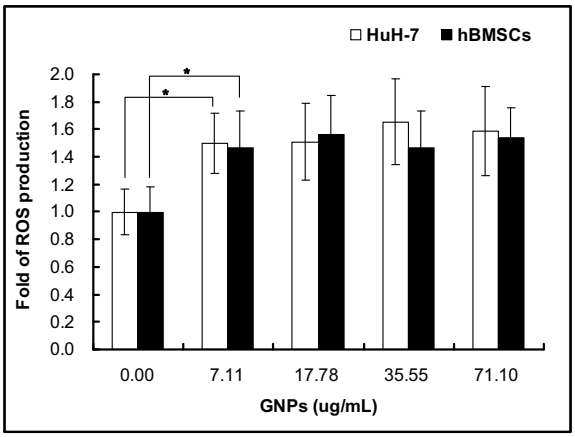

Fig. 1 The effect of GNPs on ROS generation

D. Effect of GNPs on hBMSCs differentiation

Human bone marrow MSCs were subjected to osteogenic induction while treated with GNPs. The osteogenic medium containing GNPs was replaced every 3 days. ALP activity and calcium deposition of MSCs were assessed every week. It was observed that both ALP activity and calcium deposition were significantly inhibited by the addition of GNPs compared with control. ALP activity did not seem to be repressed at early stage of osteogenesis but apparent inhibition was seen at day 14 when GNPs ≧14.78 μg/ml was applied (Fig. 2). Calcium deposition was suppressed at day 28 (Fig. 3). No correlation was found between the decrease of osteogenic differentiation and the concentration of GNPs. Our results suggest that GNPs influence the late stage of hBMSCs osteogenic differentiation.

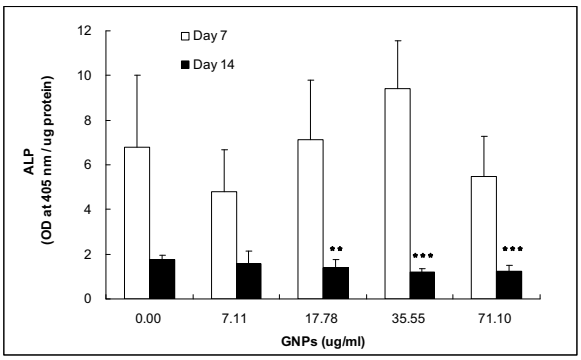

Fig. 2 The effect of GNPs on ALP activity of hBMSCs

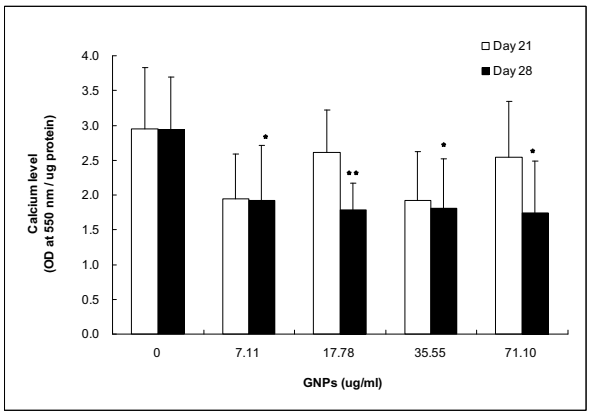

Fig. 3 The effect of GNPs on mineralization of hBMSCs

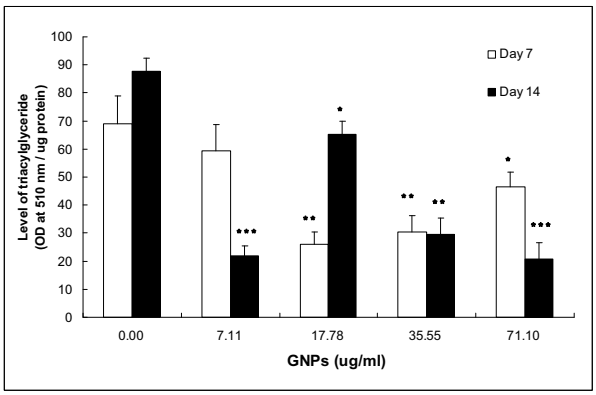

Fig. 4 The effect of GNPs on adipogenesis of hBMSCs

The influence of GNPs on hBMSCs adipogenic differentiation was also studied. It was found that the level of triacylglyceride accumulation decreased as the concentration of GNPs increased during the 14-day period of adipogenesis (Fig. 4). The above results indicate that the addition of GNPs inhibited hBMSCs differentiation despite that hBMSCs showed better tolerance for these nanoparticles.

IV. Conclusions

Our results showed that low concentration of GNPs exhibited more than 80% cell survival in HuH-7 cells and hBMSCs. Cell survival decreased as the size of GNPs increased. GNPs induce cell death via necrotic process, which might be elicited from excessive ROS formation. The addition of GNPs inhibited hBMSCs differentiation despite that hBMSCs showed better tolerance for these nanoparticles. The molecular mechanisms of GNPs toxicity to hBMSCs remain to be explored further.

Gold Nanorods Modified with Chitosan As Photothermal Agents

Chia-Wei Chang, Chung-Hao Wang and Ching-An Peng

Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan

Abstract — **Gold nanorods (GNRs) are one of the nanomaterials, which could absorb near-infrared (NIR) light and convert to heat for the application on photothermal therapy. According to literature, Cetyltrimethylammonium bromide (CTAB) is one of the widely used surfactant for the synthesis of GRNs. However, due to cell toxicity of CTAB, it is necessary to modify the surface of gold nanorods for cell-related studies. In this study, thiolated chitosan was employed to replace CTAB on gold nanorods due to its biocompatibility. The absorption spectra ranged from visible to NIR wavelength were tuned by changing the aspect ratio of chitosan-tagged GNRs. We further conjugated chitosan/GNRs with disiloganglioside (GD2) monoclonal antibody which can lead to the functionalized nanomaterials endocytosed into stNB-V1 neuroblastoma cells. After exposure with NIR laser at 808 nm, photothermal destruction of stNB-V1 cells was clearly demonstrated by calcein AM staining.**

Keywords — **gold nanorods, photothermal, neuroblastoma, GD2**

I. Introduction

The use of nanoparticles in medicine is one of the important directions that nanotechnology is taking at this time. Their applications in drug delivery [1], cancer cell diagnostics, and therapeutics [2] have been investigated. Recently, photothermal therapy using the absorption properties of antibody-conjugated gold nanoshells [3] and gold nanospheres [4] has been demonstrated to selectively kill cancer cells.

Gold nanorods (GNRs) have unique optical properties due to their shape [5]. Based on the tissue is friendly penetrated by Near-IR, the optical properties of GNRs are expected to offer a plethora of applications in the bioscience field.

To use long-wavelength (650-900 nm) in laser irradiation that penetrates tissue for in vivo photothermal treatment, the absorption band of the nanoparticles has to be in the NIR region. The synthesis of gold nanorods with various aspect ratios, which enable tunable absorption wavelength in the NIR region is quite simple and well-established. The appropriate size of the nanorods is quite small and is potentially useful in applications such as drug delivery, gene therapy, and recently the noncytotoxicity of gold nanoparticles in human cells has been studied in detail [6].

Neuroblastoma, a neoplasm derived from the sympathetic nervous system, is a common and highly malignant solid tumor of pediatric age [7]. To date, conventional therapy for neuroblastoma includes chemotherapy, radiotherapy and surgical debulking. Despite of aggressive treatment regimens, the overall survival rate of patients with advanced stage neuroblastoma who are older than 1 year at diagnosis has not been prolonged in a satisfactory manner, even if they are treated with high-dose chemotherapy followed by autologous hematopoietic stem cell transplantation [8]. Moreover, anti-neoplastic agents, used in conventional cancer treatments, lack specificity to tumour cells and consequently result in high systemic and organ toxicity [9]. Since the conventional treatments are inefficient, the need of developing novel therapeutic modalities and new selective anticancer drugs with less cytotoxic side effects is indispensable. Several promising approaches have recently emerged to circumvent such treatment failures. For example, it has shown that high-dose, pulse therapy with 13-*cis*-retinoic acid given after intensive chemoradiotherapy significantly improved survival in high-risk neuroblastoma [10]. Anti-GD2 monoclonal antibody immunotherapy has also been shown to dramatically reduce the metastatic spread of neuroblastoma and prolong survival in a dose-dependent manner in a mouse model [11]. Another novel form of therapy for neuroblastoma that has recently been investigated is the targeted delivery of antisense oligonucleotides encapsulated within liposomes. These liposomes were then externally coupled to a monoclonal antibody specific for the neuroectodermal antigen disiloganglioside GD2 resulting in creation of anti-GD2-targeted liposomes. Since disialoganglioside GD2 is expressed on neuroblastoma but is absent in normal tissues [12]. Due to its specific expression on tumor surfaces, GD2 is an attractive targeting ligand for neuroblastoma therapy. In this study, chitosan was covalently grafted with thioglycolic acid (TGA) thiolated chitosan whith was harnessed to replace CTAB originally used to stabilize the suspension of gold nanorods. The biocompatible chitosan-modified gold nanorods (CGNRs) were further functionalized with monoclonal antibody disialoganglioside (anti-GD2) in order to specifically target neuroblastoma (NB) cells which express abundant GD2 on cell surface. The specific binding of anti-GD2 conjugated CGNRs (GCGNRs) against GD2-positive NB cell lines in vitro and the ensuing ingestion of fluorescent

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 874–877, 2009
www.springerlink.com

labeled GCGNRs were investigated. After GCGNRs nanohybrids are molecularly targeted to neuroblastoma cells and then endocytosed inside the cells, 808nm near-infrared laser system with appropriate intensity and irradiation time was harnessed to excite the energy absorber GNRs, leading to photothermal ablation of NB cells.

II. Materials and methods

A. Materials

Cetyltrimethylammonium bromide (CTAB, Sigma), Chloroauric acid ($HAuCl_4$, Acros), sodium borohydride ($NaBH_4$, Alfa Aesar), ascorbic acid (Sigma), silver nitrate ($AgNO_3$, Showa), 1-Ethyl-3-[3-dimethylaminopropyl] carbodiimide hydrochloride (EDC, Acros), N-hydroxysuccinimide (NHS, Acros), Thioglycolic acid (TGA, Sigma), chitosan (chit5K, MW=5000), rhodamine B (Arcos), mouse anti-human Disialoganglioside GD2 monoclonal antibody (Chemicon international, Inc.), calcein AM (Invitrogen).

B. Instruments

UV-Vis-NIR Spectrometer (JASCO MODEL V-570), ZETASIZER (Malvern Zetasizer 3000 HS), confocal microscope (Leica TCS SP5, Wetzlar), 808-nm laser source (Opto Power Corporation, Tucson, AZ) equipped with , a 15 watt fiber-coupled laser integrated unit, microscopy (Nikon TE2000-U), and transmission electron microscopy (Hitachi H7000).

C. Preparation of gold nanorods

The synthesis of gold nanorods was made according to the seed-mediated method [16], with some modification. First, the gold seed particles were prepared by adding an aqueous of 1mL 0.0005M $HAuCl_4 \cdot 3H_2O$ to 1mL 0.2M CTAB solution. And, then 0.12 mL 0.01M ice-cold $NaBH_4$ was added with gentle mixing, which resulted in the formation of brownish yellow solution. The gold nanorod growth solution was prepared by adding 5mL 0.001M $HAuCl_4 \cdot 3H_2O$ to 5 mL 0.2M CTAB solution. Then, 0.26 mL 0.004M $AgNO_3$, 67 μL 0.0079M ascorbic acid was added respectively. The solution color changed from dark yellow to colorless, while adding the ascorbic acid. Finally, 0.12 μL gold seed solution was added to the above solution. In order to remove the excessive CTAB, the gold nanorod solution was kept in a refrigerator and followed by centrifugation at 3000 rpm for 10 mins.

D. Synthesis of thiolated chitosan

Chit5K dissolved into deionized water was reacted with TGA in the presence of EDC dissolved in 0.1M MES buffer for 24 h at room temperature. The molar ratio of chit5K/EDC/TGA was 1:10:20. The product was dialyzed (3.5 kDa cutoff) against deionized water. The solution containing thiolated chitosan remained in the dialysis tube was freeze-dried and stored for later use.

E. Preparation of chitosan modified gold nanorods

500μl of an appropriate concentration of gold nanorod solution and 5μL ca. 6mg/ml of chit5K-TGA were mixed at room temperature for 2 days. The solution was centrifuged to remove excess chit5K-MAA.

F. Preparation of anti-GD2 conjugated CGNRs

1 μg anti-GD2 were reaction with 5mg EDC and 3mg NHS for 1hr and then adding 500μl ca. 2nM CGNRs further reacted for 3hr at 4 ℃. After the reaction, the mixture was washed with deionized water, and resuspended in MES buffer (PH=6.1) for further use.

G. Endocytosis of anti-GD2 conjugated CGNRs

Neuroblastoma cell line stNB-V1 obtained from Academia Sinica (Taipei, Taiwan) was cultured in DMEM/F12 medium supplemented with 10% FBS. All the cultivation was performed at 37 °C in humidified air containing 5% CO_2. Cells (1×10^6 cells) were plated on T-25 flask for 24 h. Prior to anti-GD2 conjugated CGNRs (GCGNRs) challenge, stNB-V1 and cells NIH 3T3 were separately detached from the T-25 flask by tripsinization and inoculated onto a coverslip-bottomed Petri dishes (MatTek, MA, USA). In each dish, 100 μl of rhodamine B labeled GCGNRs was added.

Neuroblastoma cell line stNB-V1 cells and NIH 3T3 cells were imaged by a confocal spectral microscope (Leica TCS SP5, Wetzlar, Germany).

H. Photothermolysis by NIR

For the laser irradiation experiment, a continuous-wave fiber-coupled laser integrated unit with wavelength 808nm was used. Before the photothermal experiment, neuroblastoma cell line stNB-V1 cells and fibroblast NIH 3T3 cells were cultured in 24-well tissue cultured plate for 24h, then incubation with GCGNRs for 6 hrs. Then, the culture plates were washed thrice with PBS solution prior to the two types of cells exposed to laser source with intensity tuned at

6W/cm^2. After laser irradiation, cells were stained with calcein AM to examine viability under microscopy.

III. Results and Discussion

The surface plasmon absorption of gold nanorods have two bands: a strong long-wavelength band ca. 800nm due to the longitudinal oscillation of electrons and a weak short-wavelength band around 520 nm due to the transverse electronic oscillation. Fig.1 shows the observed optical absorption of GNRs and CGNRs. When thiolated chitosan replace CTAB, the absorbance band shows a little red shift. The optical absorption can be changed by simply adjusting the aspect ratio of gold nanorods.

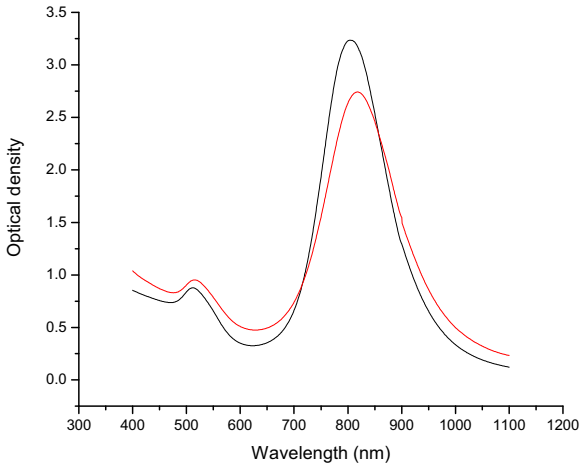

Fig. 1 Absorbance of gold nanorods (-GNRs) and thiolated chitosan modified gold nanorods (CGNRs)

The average size of GNRs and CGNRs were 66 and 84.9 nm, respectively, measured by DLS method and the transmission electron microscopy (TEM) image of the GNRs with an aspect ratio of 3.9 shown in Fig. 2.

GNRs and CGNRs were both positive charges with zeta potential measured to be 28.7 and 26.6 mV, respectively. This is because both of CTAB and chitosan are positively charged substances at neutral pH medium.

The degree of thiolation was determined by qualitative analysis of amount of thiol groups on the modified chitosan with Ellman's reagent. First, 5 mg of thiolated chitosan was dissolved in 2.5 ml of demineralized water. 250µl of 0.5 M phosphate buffer pH 8.0 and 500µl of Ellman's reagent dissolved in 10 ml of 0.5 M phosphate buffer (pH 8.0) were

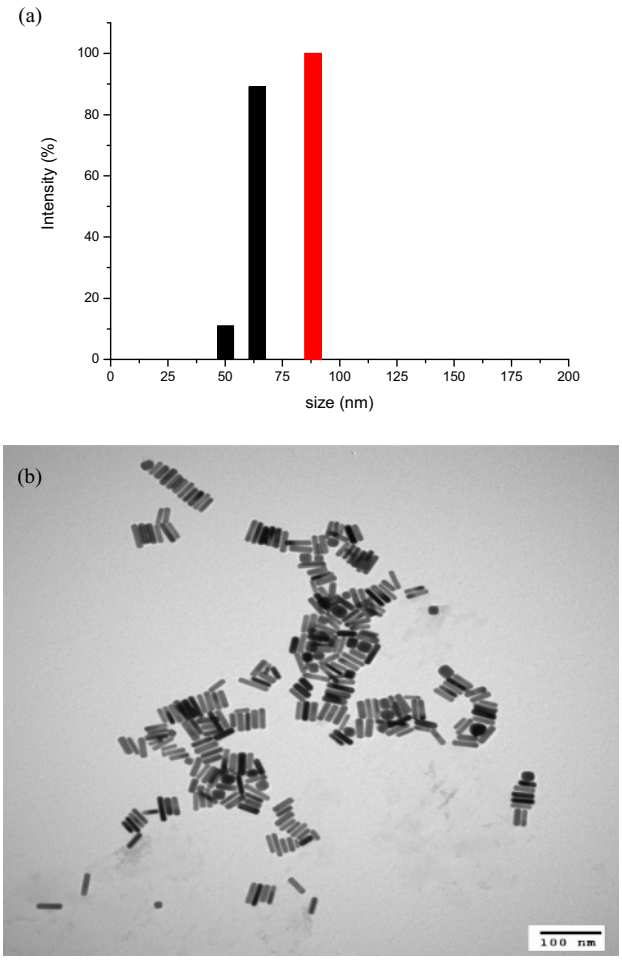

Fig. 2 (a) Size distribution of gold nanorods (-GNRs, shown by two black bars) and thiolated chitosan modified gold nanorods (CGNRs, shown by a red bar), (b) TEM image of GNRs

added. The reaction was allowed to proceed for 2 h at room temperature. Afterwards, the precipitated polymer was removed by centrifugation (18000×g; 5 min) and 1 ml of the supernatant fluid was transferred to a 1 mL cuvette. The absorbance was immediately measured at a wavelength of 412 nm with a UV-VIS spectrometer.

As shown in Fig3, the absorbance of thiolated chitosan was larger than pristine chit-5K at 412nm. This implies that chit-5K was successfully conjugated with TGA. As the molecular weights of chitosan were increased, the absorption values of chitX-TGA/chitX were increasing accordingly. (here X stands for 5K, 12K, 50K).

We used rhodamine B to label GCGNRs, and cultured with stNB-V1 cells and NIH 3T3 cells. The GCGNRs were targeted toward the cell membrane of neuroblastoma stNB-V1 cells which express the high-intensity of GD2. stNB-V1

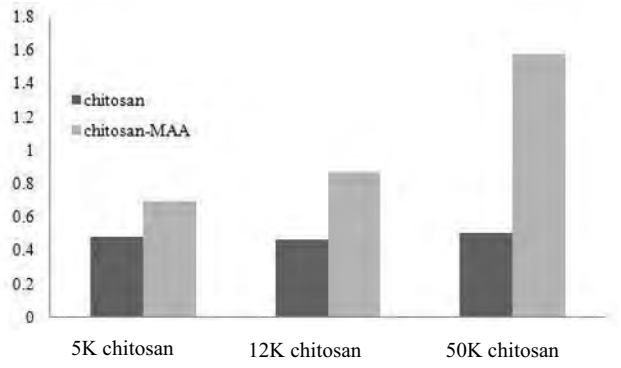

Fig. 3 Thiolated groups of different molecular weight of chitosan determined by Ellman's reagent

cells were observed to be associated with rhodamine B labeled CGNRs in large quantity, in comparison with NIH 3T3 cells after 6 h incubation using confocal microscope. This indicates the anti-GD2 specially interacted with disialoganglioside GD2 abundantly expressed on the extracellular membrane of neuroblastoma cell line stNB-V1.

After cell uptake of GCGNRs, cells remained viable indicating the bioacceptability of GNRs due to the existence of thiolated chitosan on GNRs. To demonstrate the photothermolysis efficacy of GNRs bound with anti-GD2, stNB-V1 and NIH 3T3 cells were exposed with 808 nm, 6W/cm^2 NIR laser separately for 15 min. As shown in Fig 4. stNB-V1 cells went to necrosis while NIH 3T3 cells survived.

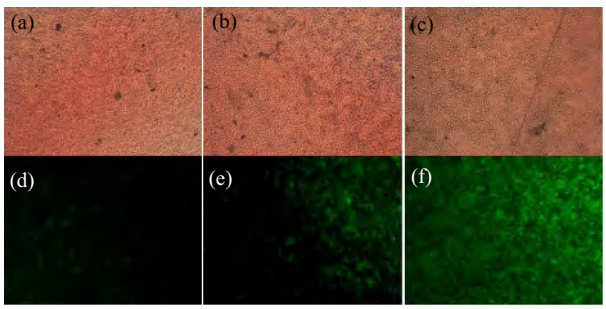

Fig. 4 Images of stNB-V1 cells by laser-beaming range of inside, boundary and outside (a-c). Fluorescent expression of laser-beaming range of inside, boundary and outside under (d-f).

IV. Conclusion

Gold nanorods are better for application in thermal therapy due to the ability to accurately control the absorption maximum to the required wavelength by modulating the aspect ratio with the silver ion concentration added during the gold nanorod growth process. In this study, chit5K-TGA was harnessed to replace CTAB (which is toxic to cells) due to its biocompatibility. CGNRs were further conjugated with anti-GD2 for specific binding to neuroblastoma cells. It was demonstrated that, within NIR laser irradiation zone, cells were not able to be stained in green by calcein AM. In other words, cells were killed via photothermolysis with the aid of internalized or surface bound GNRs. By contrast, cells remained alive (shown green after stained with calcein AM) outside the NIR laser irradiation zone, The above results suggest that CGNR can be used as an efficient photothermal agent for cancer cell therapy.

QDs Capped with Enterovirus As Imaging Probes for Drug Screening

Chung-Hao Wang, Ching-An Peng

Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan

Abstract — **The increasing threats of viral diseases have gained worldwide attention in recent years. Quite a few infectious diseases are still lack of effective prevention or treatment. The pace of developing antiviral agents could be expedited by the availability of quick and efficient drug screening platforms. Enterovirus 71 (EV71) is a highly infectious major causative agent of hand, foot, and mouth disease (HFMD) which could lead to severe neurological complications. There is currently no effective therapy against EV71. In this study, quantum dot (QD), an emerging probe for biological imaging and medical diagnostics, was employed to form complexes with virus and used as fluorescent imaging probes for exploring potential antiviral therapeutics. Inorganic CdSe/ZnS QDs synthesized in organic phase were encapsulated by amphiphilic alginate to attain biocompatible water-soluble QDs via phase transfer. To construct a QD-virus imaging modality capable of providing meaningful information, preservation of viral infectivity after tagging EV71 with QDs is of utmost importance. In order to form colloidal complexes of QD-virus, electrostatic repulsion force generated from both negatively-charged EV71 and QDs was neutralized by various concentrations of cationic polybrene. Results showed that BHK-21 cells infected with EV71 incorporated with QDs exhibited bright fluorescence intracellularly within 30 min. To demonstrate the potency of QD-virus complexes as bioprobes for screening antiviral agents, BHK-21 cells were incubated for one hour with allophycocyanin (APC), C-phycocyanin (CPC) purified from blue-green algae and then infected with QD-virus complexes. Based on the developed cell-based imaging assay, APC and CPC with concentration of 31.25 μg/mL led to extremely weak intracellular fluorescence post-infection of QD/virus complexes for 60 min. That is, the efficacy of anti-enteroviral activity of the algae extract was clearly illustrated by the inorganic-organic hybrid platform constructed in current study.**

Keywords — **Quantum dots, Enterovirus 71, Amphiphilic alginate, Polybrene, Drug screening**

I. Introduction

Enterovirus 71 (EV71) belongs to the family Picornaviridae under the genus Enterovirus and is a human enterovirus A species. It is a positive single-stranded RNA virus with a non-enveloped capsid and a genome size of 7411 nucleotides. It has caused significant mortality worldwide in recent years. EV71-infected children could develop severe neurological complications that lead to rapid clinical deterioration and death. EV71 is one of the main etiological agents of hand, foot, and mouth disease (HFMD). With the emergence of EV71 in Asia as a major causative agent of HFMD fatalities in recent years and the ineffectiveness of anti-enteroviral therapy, there is a need to find a specific antiviral therapy.

In view of the drawbacks of using fluorescent dyes [1, 2], colloidal semiconductor quantum dots (QDs) were investigated in this study to explore the potency of tagging QDs to viral particles. Thanks to excellent photostability, broad adsorption spectra, and narrow emission spectra, QDs have attracted great interests in many areas of research, from molecular and cellular biology to molecular imaging and medical diagnostics [3]. Tri-n-octylphosphine oxide (TOPO)-coated QD suspended in organic solvent was first converted into water-soluble QD employing synthesized amphiphilic alginate surfactants. Complexes between QDs and dengue virus, both possessing a net negative surface charge, will be formed by colloidal clustering, facilitated by positively charged polycationic compound - polybrene. In order to test if QD-virus complexes can be harnessed as diagnostic probes for fast screening potential anti-dengue viral drug candidates, allophycocyanin (APC, a protein-bound pigment) and C-phycocyanin (CPC) purified from a blue-green microalga *Spirulina platensis* was used as the model agent since it has been reported to exhibit anti-EV71 activities [4]. Our results showed that the intensity of green QD images within BHK-21 cells was decreased along with the dosage increase of allophycocyanin up to 125 μg/mL provided one hour prior to the addition of QD-virus complexes. It was clearly illustrated that allophycocyanin possesses anti-enteroviral activity and this can be determined within half an hour after target cells incubated with enteroviruses incorporated with amphiphilic alginate coated QD in the presence of 50 μg/mL polybrene.

II. Materials and methods

A. Synthesis of CdSe/ZnS QDs

To prepare semiconductor CdSe/ZnS QDs, a mixture of 25.7 mg of cadmium oxide (CdO, Sigma, USA), 3.88 g of Tri-n-octylphosphine oxide (TOPO, Sigma), and 2.41 g of hexadecylamine (HDA, Acros, Belgium) was heated to 300-320℃ under a dry nitrogen atmosphere. After the formation

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 878–881, 2009
www.springerlink.com

of a CdO-HDA complex as indicated by the change of color from reddish to colorless, the temperature of the solution was cooled down to 260℃ and waited for injection. A stock solution with 31.58 mg of Selenium powder (Se, Sigma-Aldrich) dissolved in 5 mL of tri-n-butylphosphine (TBP, Showa, Japan) was quickly injected into the solution under rigorous stirring to nucleate CdSe nanocrystals. After injection, the core solution was grown at 260℃ for approximately 5 s when the color of the mixture turned from colorless to slightly red. The temperature was then cooled to 200℃ for shell growth. The shell solution containing 379.4 mg zinc stearate (J.T. Baker, Netherlands) and 12.8 mg sulfur powder (S, Sigma) dissolved in 5 mL of TBP was heated to 110℃ for 30 min and then cooled to room temperature for injection. The shell solution was added dropwise into the core solution under stirring over a period of 15 min. After addition of shell solution, the core-shell solution was cooled down to 120℃ to anneal for 2 h. The core-shell solution was cooled to room temperature afterwards. The CdSe/ZnS nanocrystals were precipitated by anhydrous methanol (Tedia, USA) and then stored in chloroform (Tedia) for further use.

B. Preparation of amphiphilic alginate surfactant

Sodium alginate solution (Sigma) mixed with 2% weight percent sodium periodate (Acros) in a dark, cold chamber (4℃) for 24h. Exclusion of light was essential for the prevention of side reaction. To obtain oxidized 2,3-dialdehydic alginate, the reaction mixture was extensively dialyzed against distilled water and subsequently freeze-dried. Two milligrams of octylamine (Acros) dissolved in 8 mL methanol was reacted with 0.276 mg 2,3-dialdehydic alginate dissolved in 10 mL phosphate buffer saline (PBS) solution containing 0.1 g sodium cyanoborohydride ($NaCNBH_3$, Acros). The reductive amination proceeded for 12 h with rigorous stirring at room temperature. The reaction mixture was dialyzed and subsequently freeze-dried to obtain the amphiphilic alginate surfactant.

C. QDs encapsulated with amphiphilic alginate

0.4 mg of CdSe/ZnS suspended in 5 mL of chloroform was added with 2 mg of alginate surfactant. The mixture was sonicated in a bath for 10 min, and then the chloroform was removed by a rotary evaporator (Eyela, Japan) at room temperature. At the end of the operation, the mixture was resuspended with PBS solution and filtered through a 0.22-m syringe filter (Millipore, USA) to remove aggregates. The filtrate was freeze-dried to obtain the amphiphilic alginate coated quantum dots in the powder form.

D. Particle size and Zeta potential analysis

QDs encapsulated by amphiphilic alginate (AA-QDs) were thoroughly dispersed in aqueous solution by a sonicator (200 W, 40 kHz; Branson Ultrasonics Corporation, CT, USA) for 10 min and then passed through a 0.22-μm syringe filter to collect non-aggregated AA-QDs which were analyzed for mean particle size and size distribution by the dynamic light scattering (Zetasizer Nano ZS, Malvern Instruments, UK) equipped with a diode-pumped solid-state laser operating at 633 nm wavelength as a light source. (Dispersion Technology Software 5.02, Malvern Instruments, UK). The surface electric charge of AA-QDs, dengue virus, and QD-virus complexes was measured separately by the zeta potentiometer (Zetasizer Nano-ZS, Malvern Instruments, UK) via determining the electrophoretic mobility.

E. Absorption and photoluminescence spectra of AA-QDs

A UV–vis spectrophotometer (Jasco Model V-570, Japan) and a photoluminescence spectrophotometer (Jasco Model FP-6000, Japan) were used to characterize AA-QDs. UV-visible absorption spectrum of QDs was scanned in the wavelength range of 300-700 nm. The photoluminescence of the particles was measured in the wavelength range of 400-700 nm. The spectra were obtained with the data pitch at 5 nm and the scanning speed of 500 nm per min. All samples were placed in quartz cuvettes (1-cm path length) and the optical measurements were carried out using PBS as the reference for AA-QDs.

F. Inhibition of QD/virus infection by algae extracts

AA-QDs suspended in 1 mL DMEM medium were added into 1 mL enterovirus 71-containing medium with multiplicity of infection (MOI) of 0.1, 0.5, and 1.0, respectively. After gentle shaking of the mixed media, polybrene (1,5-dimethyl-1,5-diazaundecamethylene polymethobromide, MW = 5,000 – 10,000, Sigma-Aldrich) stock solution was pipetted into the mixture to reach a final concentration of 10 and 50 μg/mL, respectively. Then, the mixed solution was incubated at 4°C for 1 hour to prevent dengue virus from losing infectivity. After the process of incorporating virus with AA-QDs, 5×10^4 BHK-21 cells in the exponential growth phase were replaced with the QD/virus-containing medium. After treating BHK-21 cells with the QD-virus complexes for various periods of time (30, 60, and 120 min), the cell culture dish was washed with PBS three times and observed under Spectral Confocal and Multiphoton System (Leica TCS SP5, Wetzlar, Germany) with the settings of objective lens 63×, pinhole 1.0, smart gain 380 mV, and 405-nm laser ND 3. The fluorescent intensity of

QDs revealed within the observed BHK-21 cells was quantitatively analyzed by the MetaMorph® imaging software (Version 7.5, Molecular Devices, USA). To determine the efficacy of APC and CPC on preventing enteroviral infection, these algal extracts were added into cell culture plates with various concentrations for pre-selected periods of time prior to the inception of viral infection.

III. Results and Discussion

Colloidal nanocrystal QDs consisting of an inorganic core/shell structure (e.g., CdSe/ZnS) surrounded by a layer of organic ligands (i.e., TOPO) can be converted into hydrophilic nanoparticles by several approaches (Bruchez et al., 1998; Chan and Nie, 1998; Dubertret et al., 2002; Mulder et al., 2006; Pinaud etal., 2004; Zhelev et al., 2006). The commonly used strategy is based on the exchange of the original organic layer with hydrophilic ligands, however the physical properties (i.e., quantum yield) are usually deteriorated through such surface modification. In this study, we demonstrated the first time that amphiphilic alginate can encapsulate CdSe/ZnS by intercalating alginate surfactant's hydrophobic pendant moieties (i.e., octyl chains) into the hydrophobic surfactant layer (i.e., TOPO) on the QD surface, thereby resulting in the phase transfer of hydrophobic QDs from organic solvents to aqueous solution via hydrophilic backbone (i.e., alginate). The average size of water-soluble QDs encapsulated by alginate surfactants was determined to be 23.1 nm in the range of 18.1 to 28.7 nm shown in Fig. 1. As long as the number of pendant groups is sufficient high, the linkage of amphiphilic alginate to the QD surface could be very stable and thereby lead to the physical properties of QD intact. The absorption and emission spectra of QD encapsulated with amphiphilic alginate given in Fig. 2 reveal higher absorbance between 525 and 550 nm and strong photoluminescence with the emission wavelength peaked at 534 nm after excited by UV-light. The inset image in Fig. 2 illustrates the bright green color of AA-QD in aqueous solution.

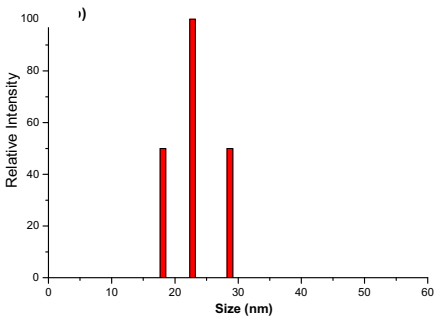

Fig. 1 Particle size distribution of AA-QDs by dynamic light scattering.

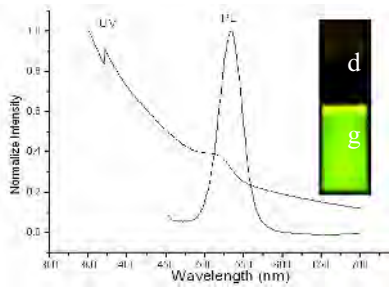

Fig. 2 Photoluminescence and UV/Vis spectra of AA-QDs. Ultraviolet-visible absorption spectrum of AA-QDs was detected in the range of 300-700 nm. The photoluminescence of AA-QDs was measured in the range of 400-700 nm with an excitation wavelength of 390 nm. The photoluminescence with the emission wavelength peaked at 534 nm indicating bright green fluorescence of AA-QDs in aqueous solution shown in the inset photograph.

Fig. 3A showed the photomicrographical images of BHK-21 cells incubated with AA-QDs at various time periods. In Fig. 3A (a)-(b), when the AA-QDs (zeta potential measurement of -7.18 mV) added in cell culture dish without polybrene respectively for 30 and 60 min, AA-QDs were not detected under fluorescent microscopy after remained AA-QDs was washed off with PBS. This is due to electrical repulsion between alginate macromolecule and cell surface which are both negatively charged. However, after 120 min co-culture of AA-QDs and cells without the addition of polybrene, green dots representing QDs were able to be pinpointed within cellular domain (Fig. 3A(c)). It is surmised that, given a longer incubation time (i.e., 120 min), sufficient amount of proteins (ingredients from fetal bovine serum) adsorbed onto the surface of negatively charged AA-QDs triggered nonspecific cell binding and ensuing endocytosis. While, in Fig. 3A(d)-(f), AA-QDs were started to be detected in the intracellular space 60 min post-incubation, in the presence of 10 μg/mL polybrene. This is probably because the electrostatic neutralization effect of polycationic polybrene led to nonspecific adsorption of negatively-charged AA-QDs on negatively charged cell membrane. It is noteworthy that polybrene is a cationic polymer and has been reported to act by neutralizing negative charges on the surface of cells and virions to promote virus attachment and enhance viral transduction rate. Once the concentration of polybrene increased to 50 μg/mL, AA-QDs were able to enter the cell ports within a short period of time and expressed green fluorescence in BHK-21 cells after 30 min of treatment. The QDs encapsulated with amphiphilic alignate surfactants were employed to form colloidal clusters with dengue viruses (zeta potential measurement of -6.04 mV) in the presence of cationic polybrene. To determine the suitable viral concentration for the development of quick and efficient cell-based fluorescent imaging drug screening plat-

form, various MOIs (multiplicity of infection) were employed ranging from 0.1 to 1. As shown in Fig. 3B (a)-(f), green fluorescent intensity expressed within BHK-21 cells due to the entrance of QD-virus was augmented in proportion to the increment of MOI (from 0.1 to 0.5). To confirm the QD/virus complexes were indeed internalized into BHK-21 cells rather than absorbed on cell surface.

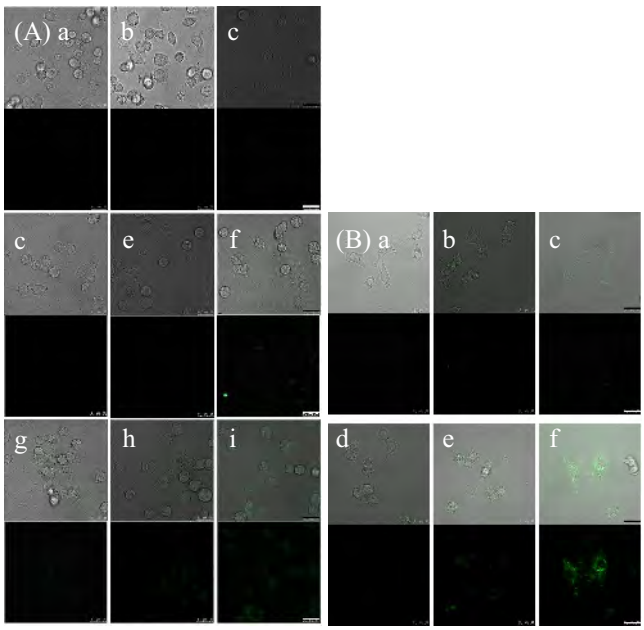

Fig. 3 (A) Photomicrographical images of BHK-21 cells exposed separately to AA-QDs with and without polybrene for various periods of time. (a)-(c) images of BHK-21 cells incubated with QDs without polybrene for 30, 60, and 120 min, respectively. QD was not detected intracellularly under fluorescent confocal microscopy until 120 min post-incubation; (d)-(f) images of BHK-21 cells incubated with QDs in the presence of 10 μg/mL polybrene. QD was not detected intracellularly under fluorescent confocal microscopy until 60 min post-incubation. (g)-(i) images of BHK-21 cells incubated with QDs in the presence of 50 μg/mL polybrene. QD was clearly detected intracellularly under fluorescent confocal microscopy after 30 min post-incubation. (B) Photomicrographical images of BHK-21 cells exposed separately to QD/virus complexes of different MOIs with 10 μg/mL polybrene for various periods of time. (a)-(c) images of BHK-21 cells incubated with QD/virus complexes of MOI being 0.1 for 30, 60, and 120 min, respectively; (d)-(f) images of BHK-21 cells incubated with QD/virus complexes of MOI being 0.5 for 30, 60, and 120 min, respectively. MOI=0.5 and scale bar=25 μm.

As shown in Fig. 4 (a)-(d), (e)-(g) the intensity of green images within BHK-21 cells was decreased along with the dosage increase of APC and CPC provided one hour prior to the addition of QD-virus complexes which were constructed in the presence of 50 μg/mL polybrene for 60 min. It should be noted that cells incubated with QD-virus complexes for only 60 min can give a fairly clear fluorescent intensity decrease with the concentration of APC and CPC up to 125 μg/mL. For cells treated with CPC higher or equal to 31.25 μg/mL for one hour then challenged with QD-virus complexes for 60 min, the diminish of green fluorescence is even astonishing prominent. Compared to other anti-viral agent screening assays, the cell-based QD/virus imaging modality exploited in this study indeed has fast and efficient features for screening antiviral therapeutics.

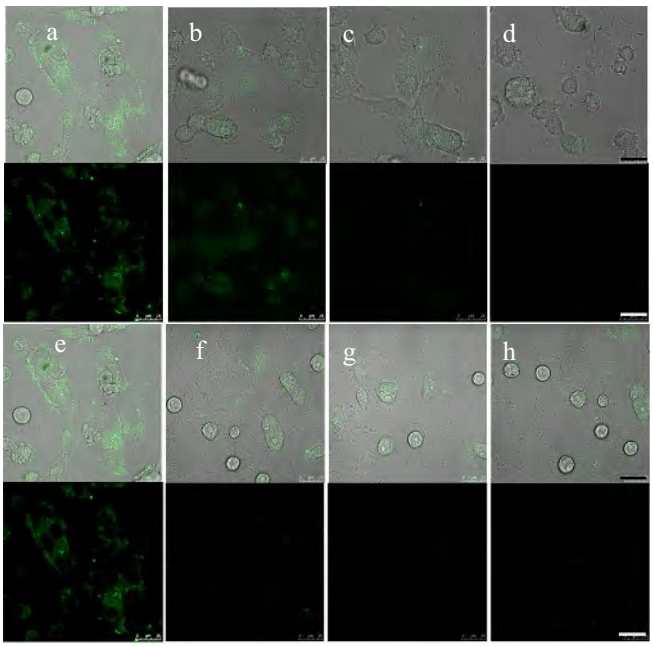

Fig. 4 Photomicrographical images of BHK-21 cells treated with and without allophycocyanin for one hour, then exposed to QD/virus complexes with 50 μg/mL polybrene for various periods of time. (a)-(d) images of BHK-21 cells incubated with QD/virus complexes for 60 min, after cells pre-treated with APC of 0, 6.25, 31.25, and 125 μg/mL, respectively. (e)-(h) images of BHK-21 cells incubated with QD/virus complexes for 60 min, after cells pre-treated with CPC of 0, 6.25, 31.25, and 125 μg/mL, respectively.

Elucidation of Driving Force of Neutrophile in Liquid by Cytokine Concentration Gradient

M. Tamagawa[1] and K. Matsumura[1]

[1] Kyushu Institute of Technology, Fukuoka, Japan

Abstract — **This paper describes the effects of gradient of cytokine concentration on chemotaxis of neutrophile by observing the motion in liquid with adding cytokine concentration. The aim of this investigation is to control of neutrophile motion in liquid by concentration gradient for drug delivery systems**

Keywords — **Neutrophile, Marangoni effect, Concentration gradient, Chemotaxis**

I. Introduction

Inflammation reaction is very important role as immune response in human body. In this reaction, once the inflammation occurred, the cytokine (chemokine) is delivered from the inflammation place, then neutrophile aggregate at the place to cure. The neutrophile moves the place that has large gradient of cytokine concentration. This is so called chemotaxis of neutrophile, but the driving force of this motion in liquid is not elucidated yet.

In the previous investigations, the motion of neutrophile has been considered to be amebic swimming in liquids as same as amebic motion on solids. Generally, the particulate in liquid on the gradient of concentration has the force by Marangoni effects. So the netrophile has the driving force of the motion in liquids by both amebic motion and Marangoni effects (Fig.1).This mechanism has possibilities to be applied to the drug delivery systems. Once the chemokine or concentration is generated at the affected part, the capsule with chemotactic function moves to this place automatically.

In the previous experiments, the effects of gradient of cytokine concentration on chemotaxis of neutrophile were investigated by observing the motion in liquid with adding cytokine concentration. Then the motion of neutrophile in the physiological salt was taken by CCD camera on microscope. Using PTV measurements, the average velocity of neutrophile was obtained with changing the cytokine concentration.

In this paper, the model of membrane for sensing is discussed by comparing with inorganic particulate model in water. Then the cytokine with fluorescent material (FITC) is observed in the microscope and the motion of neutrophile are analyzed.

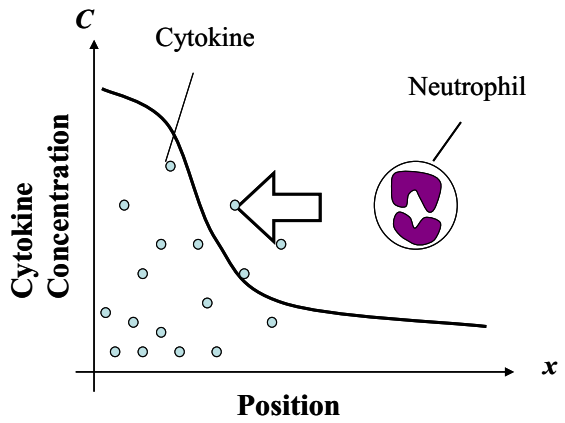

Fig. 1 Concept of chemotaxis using concentration Marangoni effect

II. Driving Force by Surface Tension Gradient

Suppose that the particulate sphere in liquid under the surface tension gradient as shown in Fig.2. The driving force F of particulate in liquid by the surface tension is obtained from the following equation,

$$F = -\nabla G(x) = -4\pi R^2 \left(\frac{d\sigma}{dx} \right)$$

where G indicates kinematic potential. And surface tension on the sphere is generally defined as follows;

$$\sigma = \sigma\left(C(x), T(x)\right)$$

where C and T indicates concentration and temperature.

Then the gradient of surface tension is expressed as follows if the temperature is constant,

$$\left(\frac{d\sigma}{dx} \right) = \left(\frac{\partial \sigma}{\partial C} \right)_T \left(\frac{dC}{dx} \right)$$

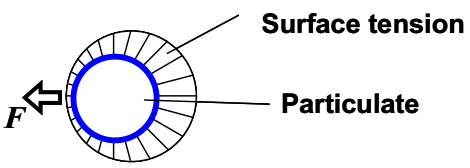

Fig. 2 Driving force by surface tension gradient

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 882–883, 2009
www.springerlink.com

From this relation the driving force of particulate is dependent on the concentration gradient. Our supposition is that the driving force of neutrophlie is caused by the concentration gradient, so called Marangoni effect.

III. Observation of Concentration Diffusion and Neutrophile Motion by Fluorescence

To prove the neutrophile motion by concentration gradient, the experimental observation was done using the simple system as shown in Fig. 3. In this system, after dropping the cytokine IL-8 at the side of liquid area of neutrophile suspension, the concentration of cytokine diffused to the suspension liquid. The motion of neutrophile is taken by the video movie at the center of the liquid area in Fig.3. The cytokine with fluorescent material (FTTC) is observed as intensity level in CCD image. Figure 4 shows diffusion process of cytokine and motion of neutrophile. It is also found that the high intensity region can be observed around the neutrophile. So it is considered that the cytokine with fluorescence is attached to the

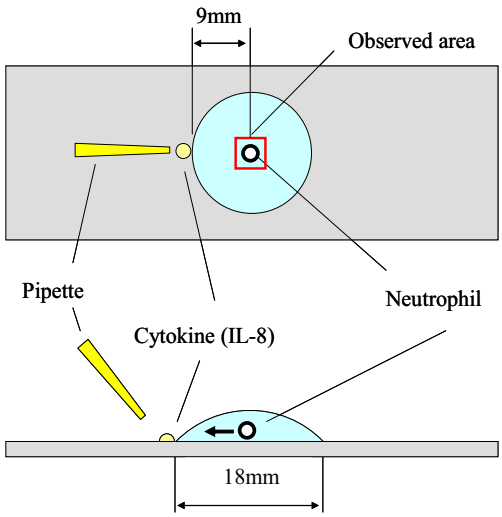

Fig. 3 Observation of neutrophile motion by concentration

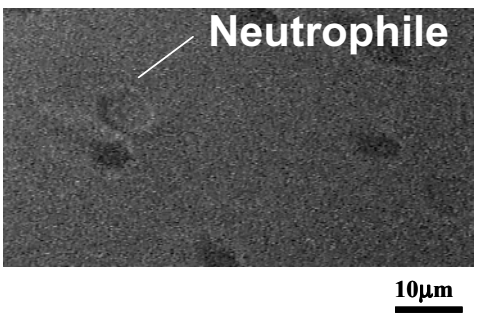

Fig. 4 Observation of neutrophile motion

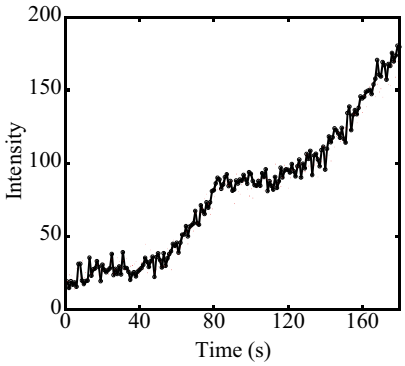

Fig.5 Intensity history at the front of neutrophile

membrane of neutrophile. In Fig.4, the intensity of the point indicated by arrow is measured by CCD image. Figure 5 shows intensity history on this point. From this result, the concentration is increasing suddenly at 50 (s). From this time, the neutrophile begins to move from left to right. These results mean that the surface tension between the membrane and the liquid is different. So the important mechanism of the driving force is hidden in the structure of the membrane of the neutrophile.

Conclusions

From the experiments, the diffusion process of concentration is different between on the membrane and around the membrane. The difference of diffusion process corresponds to the surface tension difference, which leads to driving force by Marangroi effect.

Development of a Biochip Using Antibody-covered Gold Nano-particles to Detect Antibiotics Resistance of Specific Bacteria

Jung-Tang Huang[1], Meng-Ting Chang[1], Guo-Chen Wang[1], Hua-Wei Yu[1] and Jeen Lin[1]

[1] Institute of Mechatronic Engineering, National Taipei University of Technology

Abstract — **Detection of bacteria's drug resistance at an early stage not only helps doctors in choosing the appropriate antibiotics, but also prevents antibiotic abuses. The purpose of this research is to develop a simple and efficient method for detecting bacteria and detecting bacteria's drug resistance, which can replace the traditional method. This research used MEMS technology to construct a biochip for detecting the concentration of bacteria in the sample solution. The experiments could be separated into three distinct parts: design of dieclectrophoresis (DEP) electrodes of biochip, the collection and measurement of bacteria, and the detection of bacteria's drug resistance. The detection method primarily used the effect of DEP force to ensure that the bacteria in the solution can be collected within the range of electrodes, increase the validity and accuracy of the detection. Also, this research explored the effect of antibody-covered gold nanoparticles mixed with bacteria in the solution for the detection of bacteria concentration.**

In this experiment, the electrodes of the biochip were fabricated on the glass by a thermal evaporator to deposit a layer of aluminum and then by wet enchant to etch the Al to construct the comb-like electrode pattern which was composed of 7 fingers and surrounded with thick PR to accommodate several μl sample. The width of each finger was 500 μm, and the gap between fingers was 5 μm. The detection based on impedance change among the electrodes.

In this study, the bacteria sample was *Salmonella*, and the results showed that the sensitivity of the biochip could reach to 10^6 CFU/ml. In the experiment of bacteria's drug resistance, the initial concentration of bacteria of 10^5 CFU/ml could be detected after about 2 hrs of bacterial growth period with and without adding ampicillin. The total detection time of this method could be completed within 4 hrs.

Keywords — **nano-gold particles, Bio-chip, antibiotics resistance**

I. Introduction

The impedance change method is one of the most common electrochemical methods for rapid detection of bacteria. It is based on measurement of changes in impedance due to the different concentration of bacteria or the growth of bacteria. This method has been applied to detect different bacteria with appropriate antibodies. DEP force was used to ensure that the bacteria in the solution can be collected within the range of electrodes [1]. Using the specific antibody-covered gold nanoparticles can make sure the selectivity of this method [2-5]. Combining these methods, the biochip can detect the concentration of bacteria and the bacteria's drug resistance.

The purpose of this research is to develop a simple, efficient method for testing bacteria and detecting bacteria's antibiotics resistance, which can replace the traditional method. In order to the target, interdigitated microelectrodes were integrated within the biochip to measure the impedance. Our recent study [6] indicated that impedance change from the concentration of bacteria cloud be measured and the sensitivity could reach to 105 CFU/ml. In this study, the detection of bacteria's antibiotics resistance was explored.

II. Materials and Methods

A. Fabrication of DEP electrodes

The electrodes were fabricated by depositing a layer of aluminum on the glass by a thermal evaporator and then by wet enchant to etch the Al to construct the electrode pattern. The shape of these parallel electrodes was comb-like. Each electrode finger was 10 mm in length and 500 μm in width. The gap between two fingers was 5 μm. The 6 gaps were formed by 7 electrodes. These parallel electrodes were surrounded by a thick photoresist or silicone to form a closed chamber, which has area of 3 mm × 10 mm. (a capacity of 5-10 μl)

B. DEPIM equipment and test setup

The fluidic samples were dropped into the chamber of the chip by a micropipette. The nanoparticles in the system were observed and recorded by using a microscope (Discovery) and a digital camera (Nikon DXM1200). The AC signals were generated by a function generator (TTi, TGA1244), had a frequency ranging from 100 kHz to 800 kHz and a magnitude ranging from 10 to 20 V. The waveforms of the AC signals and the voltage on the chip were monitored by the digital oscilloscope (HP54610B). An equivalent circuit for the DEPIM experiment is shown in Fig. 1 [6-9].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 884–887, 2009
www.springerlink.com

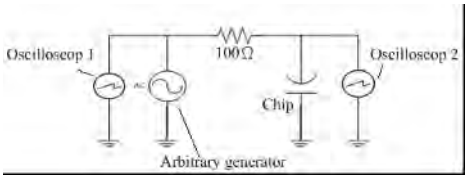

Fig. 1 Schematic diagram of experimental setup

We modeled the impedance of the electrodes on the chip as a capacitive reactance $\frac{1}{\omega C_s}$ serially connected with a resistance R_s. Let a resistor R = 100 ohm to share the supply voltage V_{s_1}. We defined the voltage across the electrodes as V_{s_2}.

$$Vs = \frac{Vs_2}{Vs_1} = \frac{Rs - j\frac{1}{\omega C_s}}{(R + Rs) - j\frac{1}{\omega C_s}} = \frac{\sqrt{Rs^2 + (\frac{1}{\omega C_s})^2}}{\sqrt{(100 + \mathrm{Rs})^2 + (\frac{1}{\omega \mathrm{C}_s})^2}} \quad (8)$$

$$\psi = \tan^{-1}\frac{1}{\omega C_s(100 + R_s)} - \tan^{-1}\frac{1}{\omega R_s C_s} \quad (9)$$

Simultaneously solving the above two equations according to the measured signal from the oscilloscope,

$$Z_{control} = \sqrt{Rc^2 + (\frac{1}{\omega C_c})^2} \quad (10)$$

$$Z_{sample} = \sqrt{Rs^2 + (\frac{1}{\omega C_s})^2} \quad (11)$$

Where Z_{sample} was the magnitude of impedance for the control sample which DI water mixed with antibody-covered gold nano-particles. The Z_{sample} was the magnitude of impedance for a sample which bacteria was coated by antibody-covered gold nano-particles. Then the normalized impedance change, NIC (%), was defined by following formula [10]:

$$\mathrm{NIC}(\%) = \frac{(Z_{sample} - Z_{control})}{Z_{control}} \quad (12)$$

III. Results

Before the drug resistance experiment, it was necessary to know the growth curve measurement from aspect of biotechnology. Measuring T_d (doubling time) of bacteria ensured the repeatability. In the drug resistance experiment, we explored the influence of ampicillin on bacteria growth.

A. Growth curve and Doubling time

The growth of bacteria could divide into four different phases: lag phase, log phase, stationary phase, and death phase. Generally, bacteria were transposed into specific culture medium, they would not grow instantly, which is called "lag phase". In this phase, bacteria did not conduct binary fission. In the log phase, bacteria began to split off, and the total number of bacteria increased geometrically. When the nutrition of culture medium was poor, bacteria did not fission anymore. This phase was called "stationary phase". Finally, bacteria were going dead and the total number of bacteria was decreased. This study just considered the first two phases, lag phase and log phase. Different bacteria had different growth curve. In these experiments, the sample of bacteria was *Salmonella***.**

The experiments were executed in 800 KHz, 10V, and the conductivities of samples were all about 0.005 S/m. As shown in Fig. 2, the lag phase of *Salmonella* was observed from 0 to 1.5 hours and the log phase was from 1.5 to 3 hours. The data showed that the higher concentration of *Salmonella* would get the lower NIC (%) and the magnitude of NIC (%) decreased rapidly in the log phase.

Repeating the same experiment three times, the growth curve of *Salmonella* could be obtained, as shown in Fig .3. Utilizing Interpolation, the doubling time could be obtained. Table 1 indicated the doubling time of *Salmonella*, which was 20 to 25 minutes.

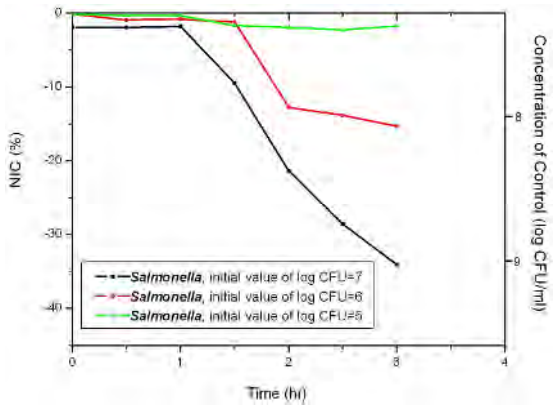

Fig. 2 The growth curve of *Salmonella*, which had different initial concentration about 5, 6 and 7 log CFU/ml

Table 1 Doubling time of Salmonella

	First measurement	Second measurement	Third measurement
log CFU/ml = 7, T_d (mins)	20	23	25
log CFU/ml = 6, T_d (mins)	22	22	24

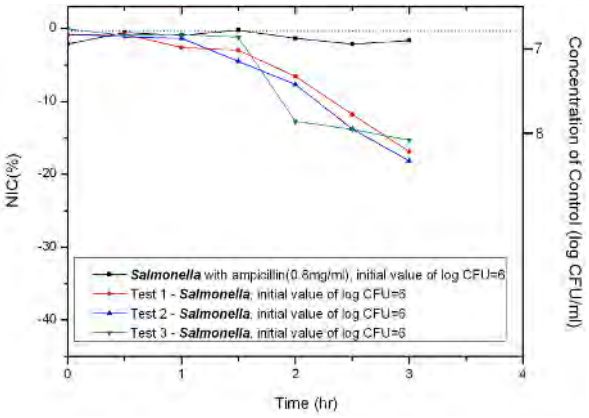

Fig. 3 The growth curve of *Salmonella* with/without ampicillin from 0 to 3 hours

We compared the doubling time that measured by traditional method with ours, and resulted that their doubling time were almost the same. Then, the viability of *Salmonella* could be verified.

B. Growth curve of Salmonella with/without Ampicillin

Measure the changes of the growth curve of *Salmonella* with initial concentration of 6 log CFU/ml. In the same parameters, we added antibiotic, ampicillin with the concentration about 0.8 mg/ml. As a result, we found that the samples with or without ampicillin had different changes of NIC (%), as shown in Fig. 3. The change of NIC (%) of sample without ampicillin was about 20%, and the sample with ampicillin had not large change.

Figure 4 showed that the growth curve of three kinds of initial concentration of *Salmonella* adding with the anti-

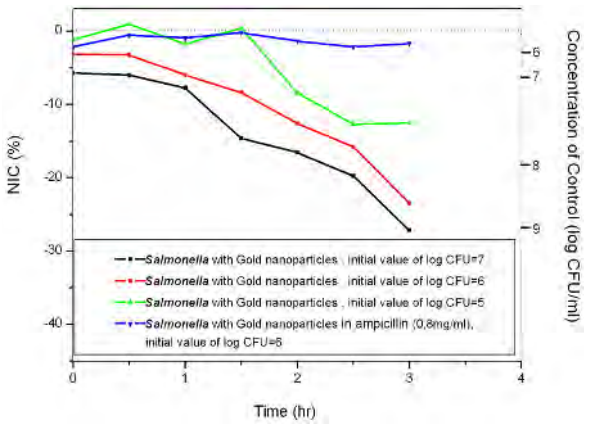

Fig. 4 The growth curve of *Salmonella* mixed with gold nanoparticles with/without ampicillin from 0 to 3 hours. The initial concentration was 5, 6, 7 log CFU/ml.

body-covered gold nanoparticles. Comparing Fig. 4 with Fig. 2 and 3 would know that the sample with gold nanoparticles had the larger change than without gold nanoparticles and therefore the sensitivity could get larger. The deviation between *Salmonella* with and without gold nanoparticles was about 5 to 10 % NIC (%).

As shown in Fig. 5 to 7, observing the *Salmonella* by microscope could found that the number of *Salmonella* with initial concentration of 6 log CFU/ml had different growth situations in the sample with/without ampicillin. The number of *Salmonella* with ampicillin was almost the same with initial, but the number of *Salmonella* without ampicillin had a lot of growing. These observed results were the same as NIC changes.

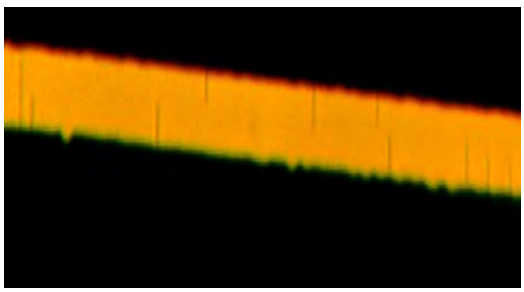

Fig. 5 When the electrode is energized, we observed the initial concentration 6 log CFU/ml by microscope

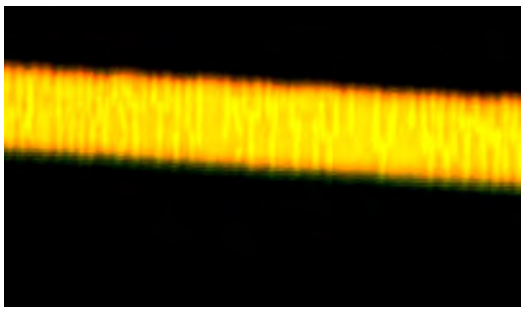

Fig. 6 After 3 hours, the sample without ampicillin was growing up obviously

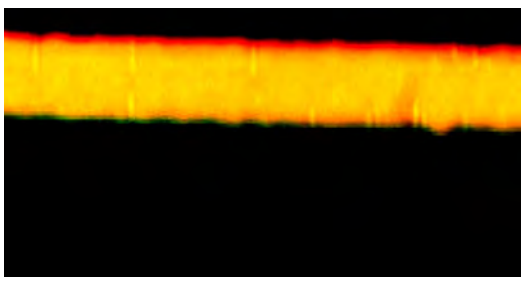

Fig. 7 After 3 hours, the sample with ampicillin *was almost the same as initial*

IV. Conclusions

In this study, impedance biochip based on interdigitated microelectrodes was developed. And this biochip combined with antibody-covered gold nano-particles has been successfully employed to detect the bacteria's drug resistance.

This biochip was used to detect as low as 10^5 CFU/ml of *Salmonella* with antibody-covered gold nanoparticles. The results showed that the initial concentration of bacteria of 10^5 CFU/ml could be detected with and without adding ampicillin after about 2 hrs that because of lag phase. The total detection time of this method could be completed within 4 hrs, which indicated the detection time of bacteria's drug resistance was faster than existing method with the total detection time about 72 hours. If the sensitivity of the biochip could be increased, the detection time would be faster.

Photothermal Ablation of Stem-Cell Like Glioblastoma Using Carbon Nanotubes Functionalized with Anti-CD133

Chung-Hao Wang, Yao-Jhang Huang and Ching-An Peng

Department of Chemical Engineering, National Taiwan University, Taipei, Taiwan

Abstract — **Despite aggressive multimodality therapy, most glioblastoma-bearing patients relapse and survival rate remains poor. Exploration of alternative therapeutic modalities is needed. Biologically modified materials with intrinsic optical properties, such as multi-walled carbon nanotubes (MWNTs) and gold nanoparticles, have been recently extensively explored for their potential use in biomedical applications. MWNTs revealing strong optical absorbance in the near-infrared region warrant their merits in photothermal therapy. In order to specific target CD133 over-expressed on the surface of glioblastoma cell line GBM S_1R_1, anti-CD133 monoclonal antibody was employed by conjugated to acidified MWNTs pre-modified with N-hydroxysuccinimide (NHS). In order to visualize anti-CD133 tagged MWNTs ingested by GBM S_1R_1 cells, fluorescent dye rhadoamine B was labeled onto MWNTs conjugated with anti-CD133. In comparison with DAOY cells, with negative CD133 expression, confocal images and flow cytometric analysis were showed. After CD133-grafted MWNTs were added into cell culture, GBM S_1R_1 glioblastoma cells and DAOY cells were irradiated separately with 808 nm near-infrared (NIR) laser for 15 minutes under intensity of 6 W/cm^2. Our results showed prominent photothermal damage of GBM S_1R_1 cells, while less necrosis of CD133-negative DAOY cells.**

Keywords — **Multi-walled carbon nanotubes, glioblastoma, CD133, Near-infrared laser**

I. Introduction

Glioblastoma (GBM) is the most common primary brain tumor in adults, without efficient known therapy. Treatment with chemotherapy has been hampered by the apparent resistance of GBM in vivo to various agents and challenges in delivering agents to the tumor cells. This is also due partly to the infiltrating growth pattern of the tumor and the relative resistance of GBM to cytotoxic agents in vitro. The lack of progress in such treatments reflects the need for rapid assays to study the effect of cytotoxic agents on GBM in vitro. It appears now that a new approach for such an assay can be based on the existence of a small fraction of the GBM that can be identified as cancer stem-like cells.

CD133 is a cell surface marker expressed on the progenitors of hematopoietic and endothelial cell lineages. Moreover, several studies have identified CD133 as a marker of brain tumor-initiating cells. In malignant brain tumors, CD133 has been suggested to be a cancer stem cell marker (Singh S. K. et al, 2003 and 2004) since only CD133 positive cells from brain tumor biopsy material were able to initiate brain cancer in a mouse model. Prominin-1 (PROM-1), also called CD133, is a protein with several isoforms of unknown physiological or pathological function, and is localized both in the cytoplasm and at the cell surface [1, 2].

Recently, molecular targeting and photothermal therapy have shown great potential for cancer therapy. Among a plethora of nanomaterials designed and synthesized for biomedical applications, carbon nanotube (CNT) owing to its unique features has been demonstrated to be an alternative option for localized hyperthermia treatment in comparison with nanogold-based materials [3, 4]. There is an increasing interest in exploring all of these properties that CNT possesses for applications ranging from sensors for the detection of genetic or other molecular abnormalities, to substrates for the growth of cells for tissue regeneration, and as delivery systems for a variety of diagnostic or therapeutic agents. For thermal destruction of cancer cells using CNT, Kam et al. (2005) showed CNTs functionalized with folic acid internalized by HeLa cells overexpressed with folate receptors led to cell death under 808-nm near-infrared light exposure. Gannon et al. (2007) [5] further demonstrated that CNTs targeted to cancer cells allowed noninvasive radiofrequency field treatment to produce lethal thermal injury to the malignant cells.

II. Materials and methods

A. Carboxylation of MWNT

In a typical experiment, 10 mg of MWNTs were added to a 20 mL of a mixture of sulfuric acid and nitric acid in a composition of 3/1 by volume. The mixture was sonicated in a bath for 10 min at room temperature. The mixture was then refluxed at 80 ℃ for 48 h. At the end of the reaction, the mixture was washed with deionized water for 5 times. The carboxylated MWNTs were freeze-dried and collected in the powder form. Comparing MWNT and carboxylated MWNT were used by UV/Vis spectrophotometer (Jasco

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 888–891, 2009
www.springerlink.com

Model V-570, Japan) and X-ray powder diffraction XRD (PANalytical ; X' Pert PRO).

B. Carboxylated MWNT conjugated with anti-CD133 and rhodamine B

10 mg of the carboxylated MWNTs dissolved into DMF were reacted with 4 mg of EDC in the presence of 6 mg of NHS for 1 h at room temperature. After centrifugation for 10 min at 7,690 × g, the modified MWNTs were collected from the bottom layer. Five mL of deionized water were used to suspend MWNTs under sonication for 30 min. Then, 0.5 g of anti-CD133 were added into 10 g of the MWNT-containing tube and reacted for 2 h. For fluorescence observation, 2 g of rhodamine B dissolved in DMF were further used to conjugate anti-CD133 via carbodiimide chemistry at 4 for 8 h. After the reaction, the mixture was washed with deionized water for 3 times to remove excrescent rhodamine B.

C. Endocytosis of anti-CD133-MWNT

Glioblastoma cell line GBM S_1RGlioblastoma cell line GBM S_1R_1 and DAOY obtained from institute of clinical medicine in National Yang-Ming University were cultured in α-MEM medium supplemented with 10% FBS, non-essential amino acids solution, sodium pyruvate, L-glutamine. All the cultivation was performed at 37°C in humidified air containing 5% CO_2. Cells (1×10^6 cells) were plated on T-25 flask for 24 h. Prior to MWNT challenge, GBM S_1R_1 and DAOY cells were separately detached from the T-25 flask by trypsinization and inoculated onto a coverslip-bottomed Petri dishes (MatTek, MA, USA). In each dish, 2.5 g of rhodamine B labeled anti-CD133-MWNTs (CDMWNT) was added. Glioblastoma cell line GBM S_1R_1 cells were imaged by a confocal spectral microscope imaging system (Leica TCS SP5, Wetzlar, Germany). For nucleus staining, 20 g DAPI was added to each dish and allowed to incubate for 1 hr at room temperature before taking confocal images.

D. 808-nm laser irradiation

First, 1×10^5 cells of GBM S_1R_1 cells were cultured in 24-well tissue cultured plate for 24 h. GBM S_1R_1 cells with CDMWNT treatment were exposed to an 808-nm laser source (Opto Power Corporation, Tucson, AZ), a 15 watt fiber-coupled laser integrated unit . Note that all cells were washed with excess MWNTs in the solution removed and placed in fresh solutions after incubation in MWNT solutions and before any of the *in vitro* laser radiation experiments described in this work. The laser beam was delivered to the target through a 1.5m long, 600 μm single core fiber with a numerical aperture of 0.37, followed by a 25-mm focal length fused-silica biconvex lens. The focused spot size was 1.2 cm. After the treatment of laser, cells were stained by 2.5 μM calcein-AM. Cell death was determined by calcein-AM dying cells to determine cell viability.

E. Flow Cytometry.

After the mixed with different ratio of GBM S_1R_1 and DAOY cells and treated by CDMWNT at 6 hr, the mixed cell population were beamed at 15 min by 808-nm NIR laser. Afterwards, the cells were stained by calcein-AM. Finally, the fluorescent intensities of the mixed cells were determined by flow cytometry (Partec CyFlow, Muster, Germany).

III. Results and Discussion

We could obtain the information of that MWNT absorbed the energy of 808-nm laser irradiation according to the peak of 808-nm wavelength and the high intensity about 4.22 in Fig. 1 by UV/Vis. After 808-nm laser beaming, MWNT would enhance the environmental temperature. According to Fig. 2 detected by XRD, the diffraction peaks at 25.9° and 53.6° were assigned to the graphite crystallographic planes (002) and (004) of MWNT and carboxylated MWNT respectively. We could observe that intensity of the planes (002) in the carboxylated MWNT weaken in contrast to MWNT. As shown in Fig. 2, MWNT had the carboxyl group by the mixed solution of a mixture of sulfuric acid and nitric acid in a composition of 3/1 by volume. The carboxylated MWNT was bound with anti-CD133 using NHS to crosslink the carboxylated group of MWNT and the amino group of anti-CD133. The CDMWNT were added into 24-well tissue cultured plate with 0.8 mL medium.

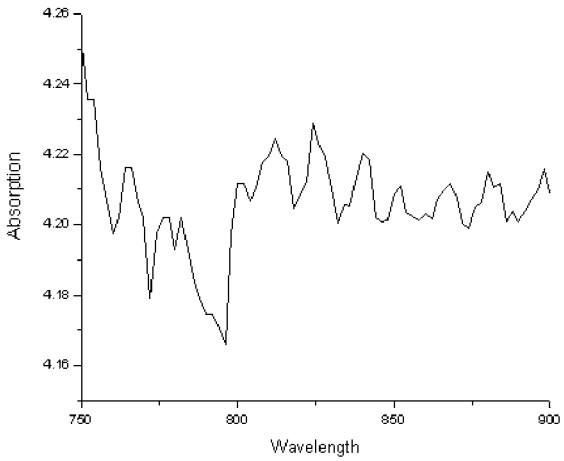

Fig. 1 UV/Vis absorption spectrum of MWNT irradiating by NIR

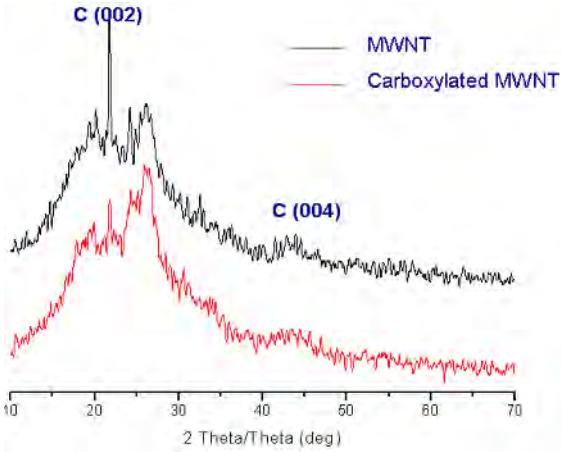

Fig. 2 XRD patterns of MWNT and carboxylated MWNT.

As shown in Fig. 3, after 20 mg, 10 mg, 5 mg of normal MWNT in 2 mL DI water were beamed by 808-nm laser in 12 min, the temperature of solution reached 54 and remained steady.

This situation indicate the anti-CD133 develop the ligand function, make the interaction with the expression of CD133 in the interior of glioblastoma cell line GBM S_1R_1. Monoclonal antibodies CD133 were able to bind to and be internalized by GBM S_1R_1 cells with high affinity. Fig. 4A were showed that the rhodamine B labeled VDMWNTs were targeted toward the cell membrane of glioblastoma GBM S_1R_1 cells to express the high-intensity CD133 receptor. Comparing with DAOY cells in Fig. 4C, GBM S_1R_1 cells could internalize more CDMWNT into cell inside than DAOY cells did. Therefore, anti-CD133 labeled MWNT could selectively target on GBM S_1R_1 cells expressed with the CD133 receptors.

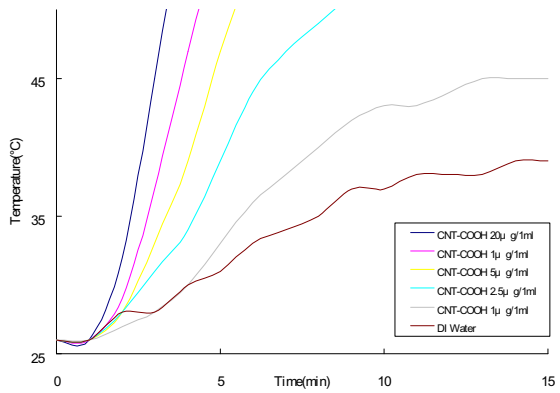

Fig. 3 Temperature curve for the medium with different amount of MWNT.

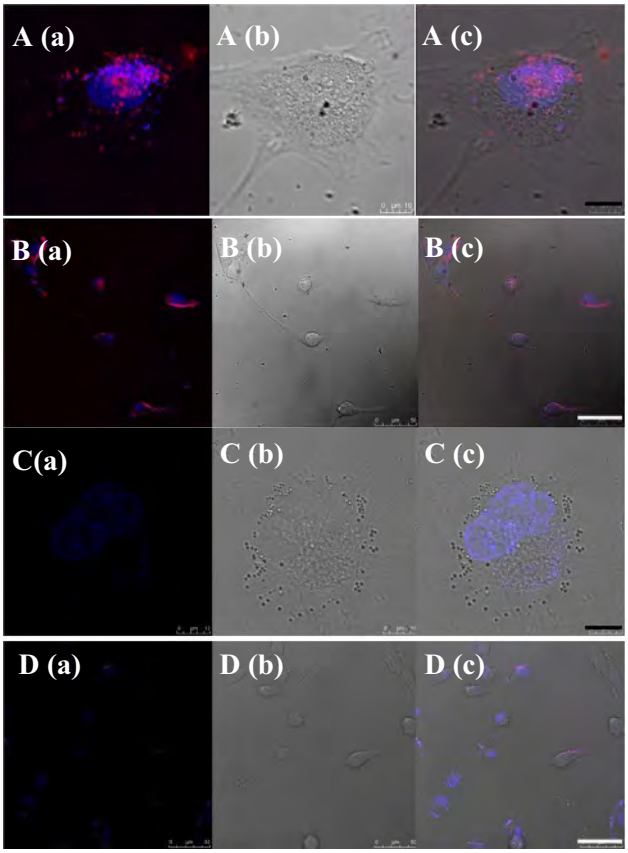

Fig. 4 Confocal images after GBM S_1R_1 cells (A), (B), and DAOY cells (C), (D) were cultured with MWNT-anti-CD133- rhodamine B at 6 hrs in (a) fluorescence with rhodamine B and DAPI, (b) bright view, (c) overlay of (a) and (b) (Block scale bar = 10 μm; white scale bar = 50 μm)

Adding calcein-AM to cells can observe cell death after irradiated with NIR laser. Calcein-AM in common was used to detect the cell viability to make us definitely differentiate the death and living of GBM S_1R_1 and DAOY cells. After dying with calcein-AM then use 496 nm blue light to irradiate the cell, if the cells were alive, it would emit 516 nm green light. If the cells were dead, it would not emit any light. After incubation of CDMWNT for 6 hr, the images of DAOY in the laser-beaming range, boundary and outside were taken and showed in Fig. 5 B (a)-(c). The inside cells appeared darkly to compare cells outside. As shown to the cells dyed calcein-AM in Fig. 5 B (d)-(f), DAOY cells with CDMWNT had the apparent boundary of death and living. GBM S_1R_1 cells with CDMWNT were dead nearly in the region of laser beam. Nonetheless, GBM S_1R_1 cells treated with CDMWNT and beamed with 808-nm laser were observed that the cells would nearly die in Fig. 5 A (d) and wouldn't die in Fig. 5 A (f). In Figure 5 C (d)-(e), the one-by-one ratio mixture of GBM S_1R_1 and DAOY cells wouldn't die absolutely after 808 nm NIR

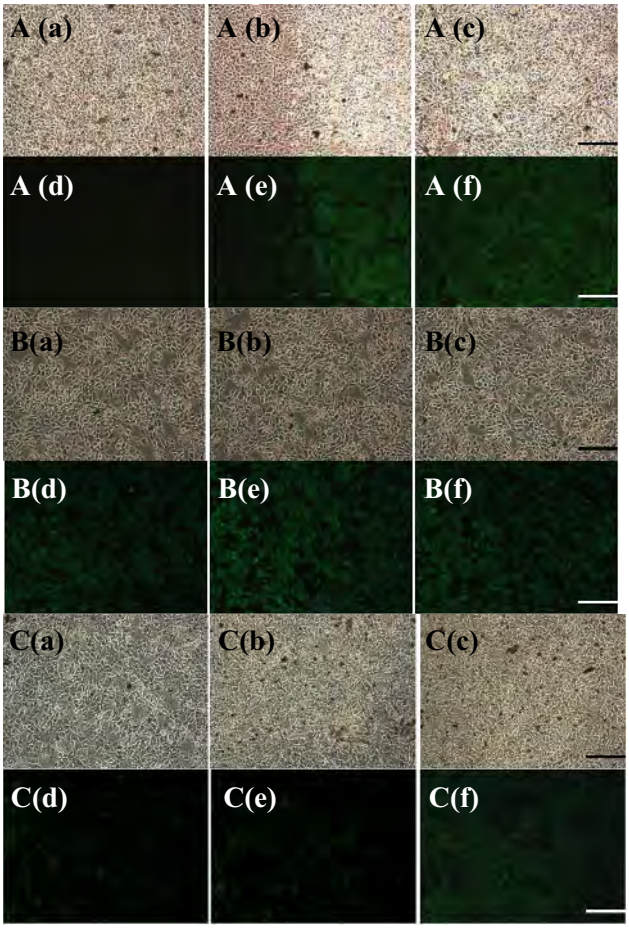

Fig. 5 Photothermal therapy of (A) GBM S_1R_1, (B) DAOY, (C) mixture with GBM S_1R_1 and DAOY cells, ratio was 1 to 1, beamed 808-nm laser. After the incubation with CDMWNT in GBM S_1R_1, DAOY, mixture cells at 6 hr, using 808-nm laser to beam the cells at 15 min. Then, the cells calcein-AM dyed. After dying, Fig. 5 (a-c) were the bright view photos in the wells of laser beaming inside, boundary, and outside. And Fig. 5 (d-f) were the fluorescent photos to dye by calcein-AM in the wells of laser beaming inside, boundary, and outside. (Scale bar = 100 μm.)

beamed. Furthermore, we would make the ratio 1:3 and 3:1 mixture of GBM S_1R_1 and DAOY cells, and use 808 nm NIR to beam. Fig. 6 were showed by flow cytometry that different ratio mixture of GBM S_1R_1 and DAOY cells could be obtained oppositely fluorescent intensity of calcein AM. When the sample including more GBM S_1R_1 cells in Fig. 6 (a) after 808 nm NIR beamed, the fluorescent intensity of lived cell would weaken as compared with Fig. 6 (b). Taken all together, it appears that anti-CD133-tagged MWNTs can specifically target onto GBM S_1R_1 cells, internalized into cells, and photo-theraml ablated by NIR irradiation.

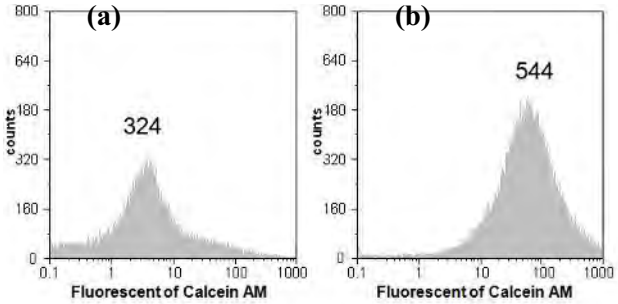

Fig. 6 Flow cytometry of different ratio of mixture with GBM S_1R_1 and DAOY cells beamed 808-nm laser. The ratio of GBM S_1R_1 and DAOY cells were (a) 3 to1 , (b) 1 to 3.

A Design of Smart Dust to Study the Hippocampus

Anupama V. Iyengar[1], D. Thiagarajan[2]

[1] Sri Sairam Engineering college/Electrical and Electronics Department, Anna university, Chennai, India
[2] Sri Sairam Engineering college/Electrical and Electronics Department, Anna university, Chennai, India

Abstract — **In this paper we have designed a smart dust, which is capable of sensing the neural activity of a human Hippocampus.**

Keywords — **Hippocampus, Nano Generator, Nano Sensor, Volume conduction**

I. Introduction

Hippocampus plays a vital role in the memory formation [4], behavioral inhibition etc. Diseases affecting the brain like the Alzheimer's disease, Amnesia etc involve damage of the hippocampus. Therefore monitoring this region of the brain would deepen our knowledge about the nature of diseases related to it and can save many lives. It would also provide a wealth of information about the memory formation, a phenomenon which still baffles the scientists.

II. Smart dust design

The chip is implanted in any sub-field of the hippocampus, say CA3. The chip is self powered and hence it is devoid of a bulky power supply. The chip consists of a nano sensor, which senses the neuron potential. It is amplified, filtered and is then transmitted to any external interface, like the commercially available motes, MICA2DOT [2] and MICA2 [2]. The neural activity can thus be observed in the computer or through the internet. The design of the power supply has been done by us. The chip uses the property of volume conduction [3] with X- shaped antennas [3] as in other invasive motes used commercially.

The overall design of monitoring the hippocampus is Shown in Figure 1

The smart dust consists of the following parts:

1. Power supply (Nano generator)
2. Nano sensor
3. Amplifier, filter and modulator
4. X- shaped antenna

The Figure 2 shows the overall block diagram of smart dust

Power supply construction and working: The power supply to the chip comes from a nano generator. A set of piezoelectric nano wires are placed in-between the poles of a magnet as shown in the figure 3. The piezoelectric wires contact the neurons and starts vibrating when they receive electrical input from the action potentials of the neurons. When the crystals starts vibrating they cut the magnetic flux between the two poles of the magnet and electrical power is generated by the principle of electro-magnetic induction. We simulated this design using MATLAB.

Nano Sensor: The nano sensor consists of a set of hundreds of gold nano wires which senses the action potentials of hundreds of neuron inside the hippocampus.

Amplifier/filter/modulator: The signal is amplified, high pass filtered, modulated, multiplexed and is sent to the antenna.

X-Shaped Antenna: The x shape antenna forms the exterior parts of the chip and is used for data communication.

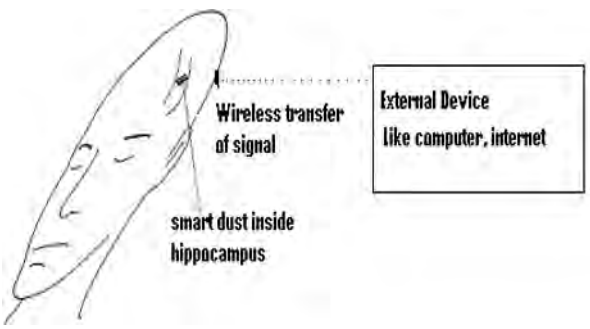

Fig. 1

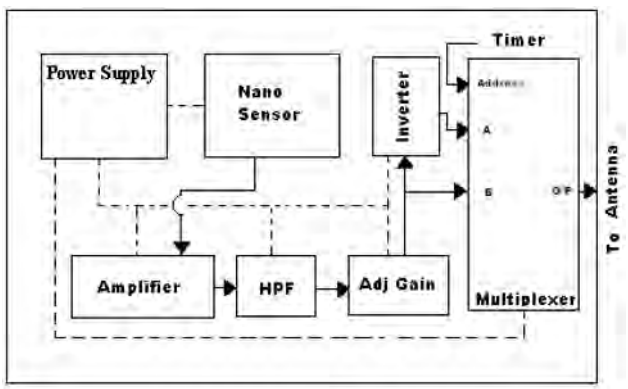

Fig. 2

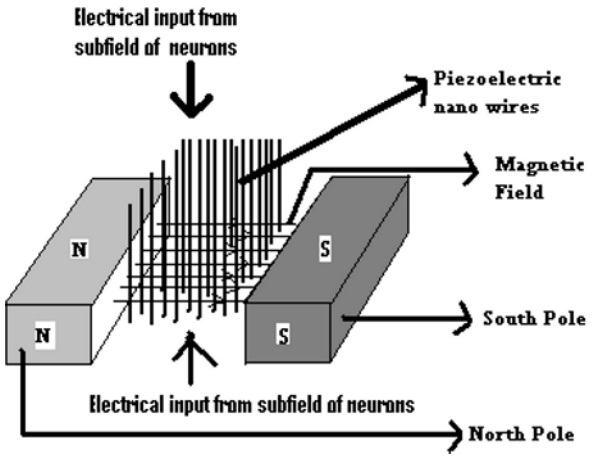

Fig. 3

This type of antenna design has many advantages. It provides a large separation of two antenna surfaces; it occupies little space of the chip and doesn't require a supporting mechanism. Since the chip body acts as an insulator between the antenna, it blocks the formation of shorting current paths and forces the current to take longer paths.

Volume Conduction: The signal is transmitted by the property of *volume conduction. In this system the ionic fluid within the human body passes information between inside and outside the body.* This system has the advantages over Radio Frequency transmission because of lowered frequency operation, the shielding effect of ionic fluid in the body is no longer a problem, instead it is now employed as the information carrier. The volume conduction circuit is simpler than the RF circuit, allowing aggressive size reduction. The system does not require signal conversion to/from RF and is therefore, highly energy efficient. The signal is received by any external interface placed on the scalp like the commercially available motes MICA2DOT and MICA2 and the signal can be observed in a computer or internet.

III. Conclusions

Monitoring hippocampus would answer many unsolved mysteries about the memory formation, behavioral science and cognitive neuro science. We must strive to utilize this technology for the betterment of mankind.

Determination of Affinity Constant from Microfluidic Binding Assay

D. Tan[1], P. Roy[2]

[1] Graduate Programme in Bioengineering, National University of Singapore, Singapore
[2] Division of Bioengineering, National University of Singapore, Singapore

Abstract — **We present a method of determining the affinity constant of a receptor-ligand pair using equilibrium binding in a microfluidic channel. This technique involves the immobilization of the receptor to the microchannel surface and perfusion of the ligand at a fixed flow rate. The ligand concentration in the eluent is monitored in real time. The break-through time of the ligand is then determined and compared with that of an appropriate, non-binding, reference molecule. The difference in break-through time can then be used in a mathematical model we have developed to determine the affinity constant of the receptor-ligand pair. Using this method, we have determined the equilibrium dissociation constant, K_D, of a rat anti-insulin immunoglobulin and a fluorescein-conjugated human insulin. Fluorescein-conjugated aprotinin was used as the non-binding reference molecule. Our experiments yielded a K_D value of 0.76 μM for this anti-insulin IgG and insulin-FITC pair.**

Keywords — **Receptor-ligand, equilibrium binding, microfluidic, equilibrium constant, mathematical model.**

I. Introduction

Molecules in solution that undergo specific binding are described as receptor-ligand pairs. Since these binding events do not result in covalent bond formation, but rely rather upon the formation of hydrogen bonds, van der Waal's forces and other noncovalent interactions, they are reversible and in the absence of perturbation and mass change, result in an equilibrium bound state. This state comprises the free receptor, free ligand and the receptor-ligand complex co-existing at concentrations characteristic of the system. These concentrations can be expressed as a single parameter – the equilibrium dissociation constant, K_D – which is a useful means of characterizing the receptor-ligand system. The K_D of a receptor-ligand pair is the concentration of free ligand in the system when half of the receptor binding sites have been occupied [1]. K_D is the inverse of the equilibrium affinity constant.

Consider a monovalent receptor, R, undergoing a binding event with the ligand, L:

$$R + L \underset{k_{-1}}{\overset{k}{\rightleftharpoons}} RL \qquad (1)$$

At equilibrium, the forward rate of reaction is equal to the reverse rate of reaction. Defining the forward and reverse reaction rate constants as k and k_{-1} respectively, the equilibrium dissociation constant, $\frac{k_{-1}}{k}$ (K_D) can be expressed as follows:

$$K_D = \frac{[R][L]}{[RL]} \qquad (2)$$

As such, the equilibrium dissociation constant of a system can be determined if the concentration of free ligand, free receptor and receptor-ligand complexes can be measured.

Conventional systems for determining K_D include dialysis, immunoprecipitation or solid-phase binding assays [1-3] wherein the system is allowed to reach equilibrium, after which the free components are separated from the complexes. Where dialysis and immunoprecipitation allow the binding event to occur completely in solution, the solid-phase assays typically involve immobilisation of the receptor on a solid surface, as is employed in enzyme-linked immunosorbent assays [2,3]. In the latter case, the ligand would have to diffuse from the bulk solution to the reaction surface, whereupon they would bind to the immobilized receptors. Subsequently, the concentration of either of the free molecules, or that of the complex may be determined.

To facilitate this determination, either the receptor or the ligand might be labeled with an enzyme or a fluorescent probe. Unlike enzyme probes, which require the addition and enzymatic modification of a substrate to yield a detectable product, a fluorescent probe allows direct measurement of concentration. Mass conservation would then allow the concentration of the other components, and subsequently, the K_D to be calculated.

However, these assays require the use of quantities of receptor or ligand which may be prohibitive in the case where either or both may not be readily available. Adaptation of the solid-phase assay for 96-well plates reduces the necessary reaction volume to 100 μL per microwell and increases the surface area to volume ratio, so improving the efficacy of the system. However, this improvement can be taken a step further by adapting the assay for a microfluidic system [4,5].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 894–897, 2009
www.springerlink.com

Microfluidic channels are capillary tubes, typically made of optically transparent material, with at least two of their dimensions being less than a millimeter. A microchannel of 35 μm (H) x 240 μm (W) x 4 cm (L) would have a volume more than 297 times less than that in a microwell. This considerably reduces the volume of reagent needed for each assay. Typically, the receptor molecules are immobilized onto the surface of the microchannel and the ligand in solution is perfused through the microchannel, during which binding occurs. Parameters such as flow rate and perfusion time can then be selected to ensure sufficient time for systems with fast-binding kinetics to attain equilibrium.

Using a fluorescence-labeled ligand, the bound fraction can easily be quantitated by measuring the fluorescence intensity retained in the microchannels. Alternatively, one could monitor the eluent fluorescence intensity and exploit changes in the breakthrough time to calculate K_D.

In the absence of a receptor, the ligand resident time in the microchannel should be dictated only by the flow rate used. The resultant elution profile is a dispersion-induced sigmoid. In contrast, when the receptor is immobilized on the surface of the microchannel walls, binding of the ligand to the receptors increases the residence time, so delaying the breakthrough time. This delay is a function of the system K_D value.

A model was developed to describe the relationship between the shift in breakthrough time, $\Delta T_{50\%}$, immoblised receptor surface concentration (R_T), antigen concentration (L_0) and K_D [6].

Here, we report the use of a polydimethyl siloxane (PDMS) microchannel system to determine the K_D of FITC-conjugated recombinant human insulin and a monoclonal rat anti-insulin immunoglobulin (IgG). FITC-conjugated aprotinin was used as a reference.

II. Materials and Methods

A. Labeling of proteins with fluorescein.

Recombinant, human, insulin (Sigma-Aldrich, USA) and bovine lung aprotinin (Fluka Biochemika, Switzerland), each at 10 mg/mL were prepared in 0.1 M sodium bicarbonate buffer (pH 8.3). Fluorescein isothiocyanate (FITC) succinimidyl ester (Molecular Probes, USA) at 10 mg/mL in dimethylsulfoxide was then added to each protein solution at a FITC to protein molar ratio of 5:1. The reaction mixes were then incubated at room temperature for one hour with gentle agitation at 165 rpm on an orbital shaker. Unreacted FITC was then removed from each reaction mix by ultrafiltration (Vivaspin 500, 3 kDa MWCO, Sartorious, Germany). The protein solutions were then diluted to 500 μL using phosphate-buffered saline supplemented with 0.05% (w/v) sodium azide (PBSA) and the protein concentration of each solution was measured using the bicinchoninic acid assay (Pierce, USA).

B. Conjugation of anti-insulin IgG with biotin.

To immobilize the anti-insulin immunoglobulin (IgG) onto the avidin-coated microchannel surface, it was conjugated with the amine-reactive biotin ester, NHS-PEO-Biotin (Pierce, Rockford, IL). This biotin derivative was selected because it includes a poly(ethylene glycol) (PEO) linker of 29Å between the biotin moiety and the conjugation site [7]. This long and flexible spacer would extend the IgG further into the bulk flow, so minimizing the effects of steric hindrance on the antigen-antibody binding event. Furthermore, the PEO segment would improve the solubility of the biotin succinimidyl ester in aqueous solutions, so allowing the IgG to be conjugated under conditions that would not jeopardize its structure and function. To prepare the reaction mix, 92 μL of D6C4 anti-rodent insulin IgG (Hytest, Finland) at 1.1 mg/mL was added to 8 μL of biotin succinimidyl ester at 0.5 mg/mL (biotin to protein molar ratio of 10:1). The mixture was then incubated at room temperature for one hour, with gentle agitation at 165 rpm on an orbital shaker. The reaction mix was then diluted to 1, 000 μL with PBSA and the unreacted biotin was removed from the mix by ultrafiltration at 12, 000 rcf for 20 min using two Vivaspin 500 ultrafiltration units (50 kDa MWCO, Vivascience, Sartorious, Germany). Each retentate was then diluted to 500 μL and filtered again. This is repeated one more time to ensure complete removal of the unreacted biotin. The final retentates were diluted to a total volume of 400 μL using PBSA. The concentration of the biotinylated IgG was then determined using absorbance at 280 nm.

C. Microchannel fabrication.

Microchannels with a width of 240 μm, a height of 35 μm and a length of 3.7 cm were micromolded from a template using Sylgard 184 (polydimethyl siloxane, PDMS, Dow Corning, USA) at a ratio of 10 parts of PDMS base to one part of cross-linker. A one-millimeter diameter perforation of the PDMS at one end of each microchannel was made to form the outlets. A 4 mm layer of PDMS was separately prepared and both pieces of PDMS were exposed to reactive air plasma for 5 minutes before being bonded together to seal the microchannels. A 1 mm diameter perforation was then made through both layers of PDMS to form the inlets. A piece of PDMS was used to fabricate a flow cell with a PEEK tube from the outlet passing through it and placed in contact with a fiber optic cable via a T-junction.

Another PEEK tube, at the inlet, was carefully perforated and aligned with the microchannel to eliminate impinging flow.

D. Microchannel surface blocking and IgG immobilization.

Immediately after sealing, avidin (Sigma-Alrich, USA) in PBSA at 1 μM was perfused into each microchannel at 5 μL/min for 60 min. The avidin solution was then left in the microchannels for a further one hour at room temperature. The resident blocking buffer was then removed by perfusing the microchannel with PBSA at 10 μL/min for 6.5 hrs to ensure thorough removal of unadsorbed avidin. Biotinylated IgG at 600 nM was then perfused into the microchannels at 1 μL/min for 60 min, and left to incubate in the microchannels for a further 60 min. The microchannels were then re-perfused with 600 nM biotinylated IgG at 1 μL/min for 1 hr, followed by a PBSA wash (1hr at 10 μL/min) to remove IgG that had not bound to the surface-adsorbed avidin. The value of R_T was determined to be 10 pmoles/cm^2 [7].

E. Microchannel binding assay.

Excitation of the eluent in the flow cell was maintained at 490 nm from a LED source (Instech, USA). Fluorescence from the eluent was filtered at 520 nm using a monochromator (DongWoo Optron, Korea) and detected using a photon multiplier tube. The data was then acquired by a PC using the counting board software (Hamamatsu, Japan).

Each microchannel was perfused with wash buffer (polyethylene glycol in PBSA) at 0.20 mL/hr for 30 min before being used for each assay. The reference molecule was then perfused into the microchannel at 0.02 mL/hr and the increase in fluorescence intensity of the eluent was monitored until no further increase was observed. The reference protein was then washed from the microchannel by perfusing wash buffer at 0.20 mL/hr and monitoring the decrease in fluorescence intensity until no further decrease was observed. The sample solution was then perfused into the microchannel at 0.02 mL/hr and monitored as before, for the fluorescence signal.

III. Results and Discussion

The microfluidic competition assay works by entraining the ligand and competitor in laminar flow through a microchannel whose surfaces contain the immobilized receptor. The mathematical model that we have developed [6], incorporates the basic physics describing the microchannel transport and equilibrium binding of receptor and ligand. Although the theory is generally applicable, the results presented here correspond to straight microchannels of rectangular cross section where the Taylor-Aris dispersion theory remains valid [8] ($U \leq 0.39$ cm/s). All experiments were designed to adhere to the conditions prescribed by the theoretical model in order to achieve the best possible agreement.

Aprotinin, with a molecular weight of 6.5 kDa, displays an almost identical elution profile to that of human insulin at 5.8 kDa, likely due to their similar diffusivities. For this reason, aprotinin was used as the reference for elucidating the transport characteristics of the ligand, in the absence of receptor binding. In the presence of surface-immobilised antibody, the model predicts a right-shift of the elution profile, indicating an increased residence time.

Each elution profile has the characteristic sigmoidal shape whose maximum slope is a function of the solute dispersion coefficient [9]. Since dispersion distorts the profile, so making determination of breakthrough time difficult, the time at which the eluent concentration is 50% of that of the inlet was used instead. Any difference between the ligand and reference breakthrough times is then expressed as $\Delta T_{50\%}$, which is the difference between the ligand and reference breakthrough times at 50% of the respective inlet concentrations.

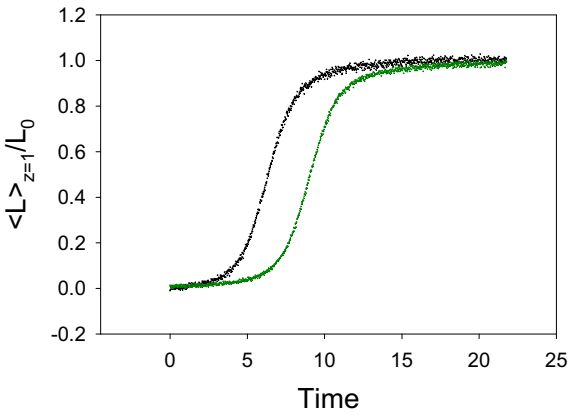

Fig. 1 Average concentration at the outlet ($<L>_{z=1}$) normalized with the inlet concentration (L_0) as a function of dimensionless time, obtained during measurement of K_D corresponding to $\Delta T_{50\%}$=2.7 with aprotinin-FITC (black dots) as the reference and insulin-FITC (green dots) as the ligand.

Figure 1 shows the experimental data for FITC-conjugated human insulin binding to rat monoclonal anti-insulin IgG immobilized in the microchannel. The reference used is FITC-conjugated aprotinin, which has a similar diffusivity. The breakthrough curve for insulin is shifted to the right of the aprotinin curve as expected from the theoretical results. In order to minimize the variation between different micro-

channels, each assay comprising a reference perfusion as well as a ligand perfusion was performed in the same microchannel. Our measured value for $\Delta T_{50\%}$ was 2.7±1.3.

Mathematical simulation of insulin and aprotinin transport phenomena in microchannels coated with anti-insulin IgG demonstrates this trend and also demonstrates how $\Delta T_{50\%}$ changes with L_0/K_D (constant R_T) (Fig. 2). It is seen that an increase in affinity constant increases $\Delta T_{50\%}$ because more binding takes place at the leading front, so depleting the bulk flow to a greater extent.

Our experimentally determined $\Delta T_{50\%}$ allows us to estimate K_D from a plot of $\Delta T_{50\%}$ vs K_D for a fixed L_0 = 2 μM. The value of K_D was found to be 0.76 μM. Further confirmation of this K_D may be achieved by experiments with other L_0 values in the linear part of the binding curve.

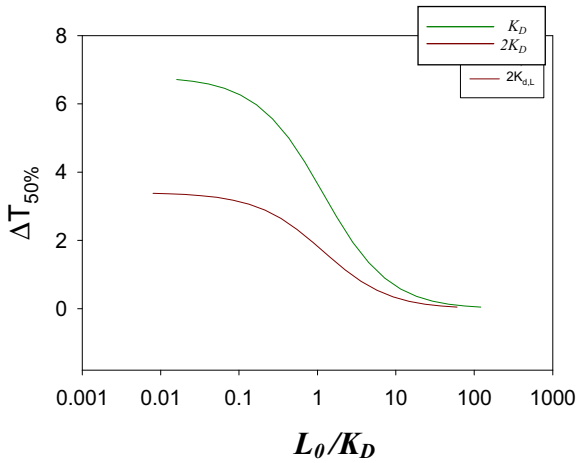

Fig. 2 Binding curves obtained from the numerical simulation showing the change of $\Delta T_{50\%}$ with $L_0/K_{d,L}$ for two different affinity constants.

IV. Conclusions

We have developed a microfluidics-based method of determining the equilibrium dissociation constant of any receptor-ligand pair. This method relies upon determination of the difference in breakthrough times between that of a reference molecule and that of the ligand. The proposed method has the following advantages: 1) uses less reagents than standard ELISA, 2) allows a larger selection of detection techniques, 3) is relatively quicker and, 4) has better mass transfer characteristics than assays in well plates. Furthermore, the theoretical results presented here may also be extended to the study of equilibrium binding (or systems with fast binding kinetics) between the immobilized receptor and competing molecules in solution. This would allow us to develop the system for use in quantitative competition assays. The advances in immobilization methods and linker designs together with low cost microfabrication, makes this a viable and promising technique for large scale adoption.

Acknowledgment

The authors would like to thank Song Ying for assistance with the experimental protocols and Chaitanya Kantak for helping with microchannel fabrication. This study was funded by NUS-FRC research grant R397000015112/101.

Abstract — **Nanoscale biomolecular motor driven transport systems are the bioinspired alternative for Nanorobotics. With the increasing knowledge within the mechanisms of motor binding and regulation, the appropriate motor components can be modified for micro/nano cargo transportation such as biomolecules, quantum dots, organic molecules, microbeads etc. Our group has already demonstrated transport of such molecules and motor binding tendencies to organic and inorganic drug molecules and regulation is strongly anticipated. Present study explores In-vitro transportation of 5-aminosalicylic acid (5-ASA) by actin myosin motor system. 5-aminosalicylic acid is an anti-inflammatory drug used to treat inflammation of the digestive tract (Crohn's disease) and mild to moderate ulcerative colitis. In this appraoch, binding of 5-ASA to actin filament is achieved by streptavidin-biotin crosslinking. Here, succinimido group of NHS-Biotin will be attached to free amine group present on 5-ASA forming drug-biotin conjugate. Biotinylation of F-actin was attained by capping negative end with biotinylated gelsolin which inturn convert F-actin into biotinylated F-actin. Attachment of drug with actin filament was attained by reacting drug-biotin conjugate with streptavidin. Biotinylated actin filaments were reacted with drug-biotin-streptavidin complex to achieve drug-biotin-streptavidin-actin complex. As streptavidin has four biotin specific sites, two sites will attach to drug-biotin conjugated and remaining two will be available for biotinylated actin filaments. Confirmation and quantitation of attachment of drug was done by UV-vis-spectroscopy, Transmission Electron Microscope, Atomic Force Microscopy and High Performance Liquid Chromatography. Transportation of drug attached to actin filaments was directed by applying a weak electric field. Velocity of actin filaments attached to drug was calculated by tracking program developed in MATLAB. Present study provides insight into the actin-myosin based molecular motor system for drug transportation.**

Keywords — **Actin, 5-Aminosalicylic acid, Biotin, Gelsolin, Streptavidin.**

I. Introduction

Molecular motor protein systems play vital role in actively transporting or moving other molecules or proteins within cellular system. Research during the past several decades has provided a wealth of understanding about nanoscale motor proteins, which generate force and motion in biological systems by hydrolyzing adenosine triphosphate (ATP) as a fuel (1, 2). Examples of these types of proteins are the kinesin motor proteins and actinomyosin motor system. Actin can transport cargo using myosin as a track to run on. Actomyosin motor protein system is an ideal candidate for hybrid nanomechanical systems due to their small dimension and high fuel efficiency (3). The most challenging aspect of using actomyosin motor protein system for drug transportation is to attach a particular drug to actin filaments and then studying their motility on myosin tracks (4). Herein, we present a successful protocol for attaching drug to actin filaments by using biotin-streptavidin conjugate. The binding of biotin to streptavidin (a 60-kDa tetrameric protein) is the strongest noncovalent interaction known (KA~1014M-1) (5). 5-aminosalicylic acid an anti-inflammatory drug used in Crohn's disease was attached to actin filaments. 5-ASA has amine group which forms bond with succinimido group of NHS-Biotin making drug biotinylated. Biotinylated drug inturn will bind to biotinylated actin filaments through streptavidin crosslinking. Drug attached to actin filaments was viewed under flurescence microscope where fluorescence of drug crystals confirms attachment of actin filaments to drug. Velocity of actin filaments carrying drug on myosin tracks was calculated by MATLB software.

II. Materials and Methods

Actin, Myosin of rabbit skeletal muscle, Phalloidin-Tetramethylrhodamine-B-isothio cyanate (Rh-Ph; fluorescent dye) was procured from Sigma-Aldrich. Sulfo-NHS Biotin and Streptavidin were procured from Pierce, USA. 5-Aminosylsalic Acid (5-ASA) was procured from Universal labs. Dimethyl formamide (DMF) was procured from Sigma- Aldrich. All other chemicals used were of molecular and analytical grade unless otherwise stated. All the buffers and solutions were prepared in double distilled deionised (18 MΩ) autoclaved water.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 902–905, 2009
www.springerlink.com

A. Polymerization and labeling of actin

G-Actin was polymerized in polymerizing buffer (2 mM $MgCl_2$, 50 mM KCl, 0.25 mM ATP, 0.5 mM DTT, 1 mM EGTA, 0.1 mM $CaCl_2$, 10 mM Imidazole, pH 7.5) prepared in AB buffer (25 mM Imidazole, 25 mM KCl, 1 mM DTT, 1 mM EGTA, 4 mM $MgCl_2$). 25 µg of actin was dissolved in 50 µl of polymerization buffer and incubated for a period of around 4 hrs at room temperature (RT). 500 µl stock solution of Rh-Ph (10 µg/µl) was prepared in methanol. 10 µl of Rh-Ph (10 µg/µl) was transferred in a vial and dried with dry nitrogen stream till the pellet was formed. The pellet was dissolved in 2 µl of ethanol, 290 µl AB buffer and 10 µl of F-actin, stepwise. This was incubated for a time period of 12-16 hrs at 4°C.

B. Biotinylation of actin filaments

0.1mg/ml of gelsolin was dissolved in M buffer (40 mM HEPES, 75mM KCl, 2 mM EGTA, 2 mM $MgCl_2$ pH 7.4). NHS-Biotin (4 µg/ml at a concentration of 0.1 mM) was prepared in Di Methyl Sulfoixide (DMSO). NHS-biotin was mixed with gelsolin at a ratio of 10:1. Mixture was incubated for 2 hours. Biotinylated gelsolin was separated from unbound gelsolin by dialyzing (membrane size: 10,000 MW cutoff) the mixture against M-buffer for 24 hrs at 4°C. 50 µl biotinylated gelsolin was mixed with 50 µl of F-actin (25 µg/ 50 µl), gently mixed and kept for 2 minutes. Biotinylated gelsolin will bind to the minus end of F-actin which will inturn leads to Biotinylation of F- actin.

C. Attachment of 5-ASA with actin filaments by biotin-streptavidin cross linking

10 mg stock solution of 5-ASA was prepared in 1 ml Dimethylformamide (DMF). Stock solution of biotin was prepared by keeping the concentration at 4µg / ml in distill water. For biotinylation of 5-ASA, 20 µl of the biotin (4µg / ml) was taken in 920 µl of distill water. 20 µl of 5-ASA was added to the above suspension and was incubated for 30 minutes. This leads to biotinylation of 5-ASA. To this suspension 20 µl of biotinylated actin was added followed by 20 µl of streptavidin solution (1 mg / ml). Suspension was incubated for 30 minutes.

D. Characterization and quantitation of 5-ASA attached to actin filaments

Quantitative analysis of 5-ASA was done by UV-vis Spectrophotometer (Hitachi U-2800) operating between the ranges of 200 nm to 650 nm. Baseline correction was carried out by water. The morphologies of attached drug to actin filaments were characterized by using Transmission Electron Microscope (Hitachi H- 7500) operating at 80 kV. The samples were prepared by placing a drop of suspension on carbon coated TEM grids (300 mesh, 3 mm, purchased from TAAB Laboratories, England) and viewed under transmission electron microscope. Image analysis of attachment of actin filaments to drug was done by Matlab software. Irfanview software was used to extracts the image frames

E. In Vitro Motility Assay

The micro reaction cell was prepared on 0.1% nitrocellulose coated thin glass slide (25 x 75 x 0.14 mm) Bagga et al., (2005). 100 µl of myosin (40 µg/ml in AB buffer containing 0.6 M KCl) was infused and incubated for 60 sec. 100 µl of AB/BSA solution (0.5 mg/ml of BSA in AB buffer) was infused followed by 100 µl of 5-ASA suspension with actin after incubation for 60 sec. 100 µl of AB/BSA, AB/BSA/GOC (0.3 mg/ml of glucose, 0.1 mg/ml of glucose oxidase and 0.018 mg/ml of catalase in AB/BSA solution), and AB/BSA/GOC/ATP (2 mM of ATP in AB/BSA/GOC solution) was infused subsequently and movement of actin filaments attached wih drugs was recorded on Axiovert 200, USA, Bagga et al.,(2005). Fluorescence images with resolution of 320 x 240 pixels were recorded by 'Camatasia Recorder' at 15 frames per seconds. Irfanview software was used to extracts the image frames from the recorded motility of actin filament in avi format. Images were processed for calculating velocity of individual drug attached with actin filaments by custom built programme in Matlab software.

III. Results

A. Attachment of 5-ASA with actin filaments by biotin-streptavidin cross linkin

G-actin was polymerized to F-actin in polymerization buffer. Length of F-actin filaments as measured were found to be in the range of 1.5 – 5 µm. Attachment of drug for Crohn's disease to actin filaments was achieved by streptavidin-biotin conjugate. As streptavidin biotin linkage is the strongest non covalent linkage hence attachment of drug to actin filaments will be more stable therefore, actin filament can carry 5-ASA on myosin tracks. Attachment of 5-ASA was confirmed by fluorescence microscope and transmission electron microscope (TEM). Figure 1 shows the attachment of 5-ASA to actin filaments.

Figure 1A & 1B represents 5-ASA on actin filaments and actin filaments without drug respectively. Drug molecules are seen as a dots on actin filaments as compare to actin

filaments without drug. Drug crystals were also observed in fluorescence microscope. When drug crystals were viewed with white light on microscope no fluorescence was observed while fluorescent crystal of drug was observed under fluorescent lamp. Flourescence confirming that actin filaments are attached to drug. This is because actin filaments are rhodamine phalloidin labelled which in turn will give fluorescence to drug (Frigure 1C & 1D).

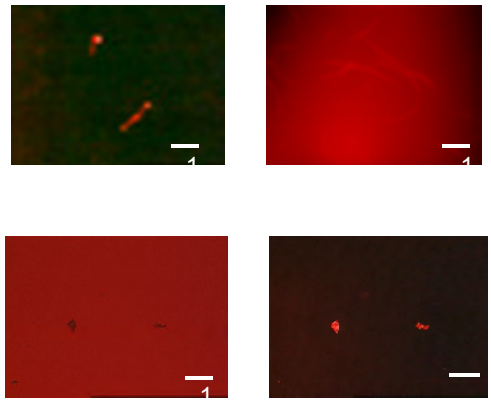

Figure1: Fluorescent images of actin filaments and drug crystals. 1 A & B represents fluorescent image of actin filament with 5-ASA molecule and without drug molecule respectively. 1 C & D shows 5-ASA crystals without fluorescence and with fluorescence which is due to attachment of Rh-PH labeled actin filaments.

Confirmation of drug attachment to actin filament was also done by transmission electron microscope. Similar drug molecules were observed on actin filaments as seen under fluorescent microscope. Actin filaments without drug were observed without any molecules as shown in figure 2A & B.

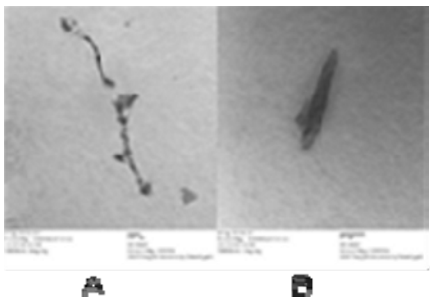

Figure2: TEM images of actin filaments. 3A represents 5-ASA molecules on actin filaments while 3B shows actin filaments without 5-ASA molecules.

Quantitation of attachment of 5-ASA to biotinylated actin filaments was determined UV-VIS spectroscopy. Concentration of biotinylated drug was calculated by using the specific extinction coefficient of 5-ASA at 236 nm as shown below:

Absorbance of 5-ASA at (λmax= 236nm),
$A_{236} = 0.964$
Concentration of drug (c) = 0.1 mM

Molar extinction coefficient of 5-ASA at λmax,
$\varepsilon 236 = A\ 236 / c\ L = 9.64\ (mM\ cm)^{-1}$
Amount of drug attached to biotin (c_1) =

$$\frac{\text{Absorbance of biotinylated drug at 236 nm A'236}}{\varepsilon 236 \text{ X L}}$$

Amount of 5-ASA attached to biotin = 0.07mM

It was calculated that 70 % of 5-ASA drug was biotinylated during incubation. Similarly, we calculated the amount of biotinylated 5-ASA attached to streptavidin and actin filaments was calculated and it was found that >50% of biotinylated 5-ASA attaches to actin filaments through streptavidin cross linking. Absorbance spectra of biotinylated 5-ASA and 5-ASA attached to actin filaments are shown in figure 3 A & B.

B. In Vitro Motility Assay

Sliding velocity measurement is another attempt to confirm non covalent attachment of actin to 5-ASA. Maximum velocity of single bundle of actin filament only on myosin heads was calculated and found to be 4.0-6.0 μm/s (4). The average velocity calculated was found to be 3.59 μm/s. Direction of motile actin

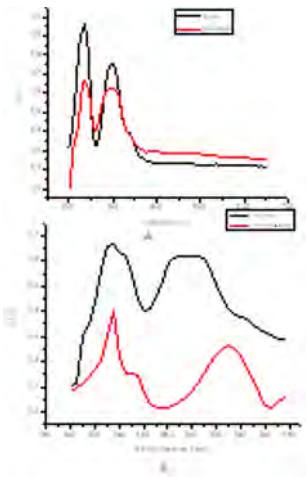

Figure 3: UV-VIS spectra of 5-ASA, biotinylated 5-ASA (A) and biotinylated 5-ASA & actin attached 5-ASA (B). filaments attached to drug was tracked by determining the centroid of actin-drug complex in each frame. After superimposing consecutive frames the path followed by the actin filaments was obtained as shown in figure 4.

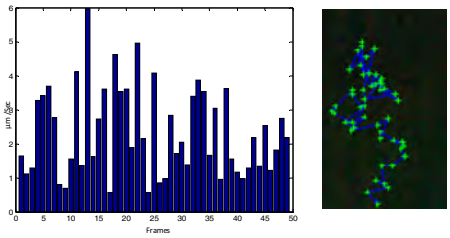

Figure 4: Histogram for velocity of drug attached actin filaments calculated by processing each frame in Matlab (A).The track of motile actin filaments attached to 5-ASA (B).

IV. Discussion & Conclusion

Development of Nano-Robotic devices based on molecular motors (Actin-Myosin) is long anticipated. Attachment of actin to limited cargoes is the pre-requisite to realize such devices. Attachment of actin filaments to drugs by streptavidin-biotin cross linking has not been reported yet. In the present study, we have reported a new methodology to directly attach 5-ASA to actin filaments which is beneficial as load on actin filaments will be reduced. If drug is coating on certain cargoes and then attached t actin filaments then the velocity of actin filament will be reduced as load on filament will be increased. We have calculated the velocity of drug attached actin filaments as 3.59 μm/s which is good enough to carry drug in desired direction. It has been reported that when a polystyrene bead is attached to actin filaments then the velocity reduces to 0.99 μm/s (7). If we will coat drug on these polystyrene beads and then attach them to actin filaments then actin filament will not be able to carry drug. Confirmation of drug attached to actin filament was concluded by fluorescence microscope data where smooth surface of actin filaments get distorted when drug molecules attaches to it as shown in figure 1A & B. Similar structural distortion in actin filaments was also observed in TEM images (figure 2A & B). Quantitation of drug was analyzed by UV-VIS spectroscopy, it was calculated that approximately 50% of the drug in the solution is attached to actin filaments via streptavidin- biotin cross linking. Therefore efficiency of attachment of 5-ASA with this method is not only stable but also efficient.

In the present work, a simple, cheapest and less time consuming method of attachment of drug to single bundle of actin filaments has been reported using biotin and streptavidin as a cross linker. Attached drug can be exploited for transportation for realizing nano-robotic devices in future.

Abstract — **Limb salvage surgery has replaced amputation as the treatment of choice for sarcomas of the extremities. However, complications such as prosthesis loosening and fracture of bone or prosthesis continue to occur due to poorly aligned prosthesis or unconsidered bone deformities. These can be minimized by detailed implantation planning: intervention, resection, selection, and alignment decisions considering anatomical variations. Previous works employed interactive identification of anatomical landmarks, and prosthesis position planning by superimposing prosthesis drawing on radiographic image, which is cumbersome and error-prone. We present an automated methodology for mega endoprosthesis implantation planning in a 3D computer graphics environment. First, a virtual anatomical model is reconstructed by stacking and segmenting CT scan images. A neighborhood configuration based 3D visualization algorithm has been developed for fast rendering of the volumetric data, enabling a quick understanding of anatomical structures. Key skeletal landmarks used for implantation are automatically localized using curvature analysis of the 3D model and knowledge based rules. Anatomical details (mainly dimensions and reference axes) are extracted based on the landmarks and used in resection planning. A decision support method has been developed for segregating prosthesis components into three sets: 'most suitable', 'probably suitable', and 'not suitable' for a particular patient. The geometrical landmarks of the prosthesis components are mapped with respect to the anatomical landmarks of the patient's model to derive alignment relationships. 3D curved medial axes of both (prosthesis and anatomical models) are used for reference and alignment. A set of selection and positional accuracy measures have been developed to evaluate the anatomical conformity of the prosthesis. The computer-aided methodology is illustrated for tumour knee endoprosthetic replacement. It is shown to reduce the time required for implantation planning and improve the quality of outcome. The 3D environment is also more intuitive and easy-to-use than the traditional approach relying on 2D images.**

Keywords — **tumour knee replacement, virtual 3D reconstruction, prosthesis selection, prosthesis alignment, anatomical understanding**

I. Introduction

Virtual surgery planning is an interdisciplinary contribution of medical and computational knowledge to health sector. The goals of preoperative planning tools are threefold. (i) enable a surgeon to understand the patient's anatomy and the surgical challenges it poses, (ii) help in the development of customized prostheses, alignment of prosthesis components, and evaluation of post-surgical outcomes and (iii) present the data in a way that enables fast and accurate decisions.

Limb salvage surgery (prosthetic replacement after excision of tumour affected bone region) has replaced amputation (excision of lower part of the limb) as the treatment of choice for sarcomas of the extremities (e.g. knee) [1]. However, complications such as prosthesis loosening and fracture of bone or prosthesis continue to occur [2,3]. This can be reduced by detailed implantation planning (intervention, resection, selection, and alignment), which should be carried out bearing in mind that the anatomy of each person is unique [4,5]. A typical prosthesis set, used in massive replacement of distal femur portion of the knee due to primary bone tumour, composes of femoral condyle (FC), space fillers (SF), femoral fork (FK), tibial tray (TT), tibial poly (TP), femoral and tibial stem (FS and TS), and articulation and locking elements (Fig. 1).

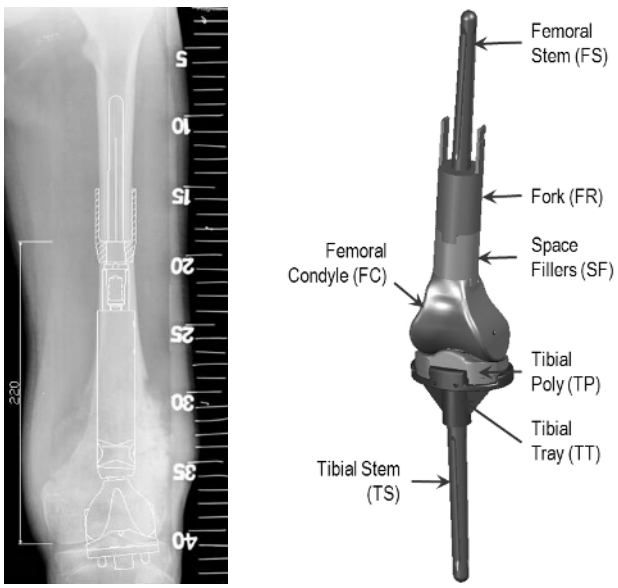

Fig. 1 Endoprosthesis used for reconstructing distal femur/knee after excision of tumour (a) prosthesis design verification using radiographic image (b) typical components of the prosthesis

www.springerlink.com

Previous work employed interactive identification of anatomical landmarks and prosthesis positioning by superimposing 2D prosthesis drawing on radiographic image (Fig. 1a). This approach is cumbersome and error-prone, especially for complex anatomical situations, such as total reconstruction of the knee joint [5,6,7]. This can be eliminated by using patient specific 3D computerized anatomical models [4,8]. Even though significant research has been carried out on arthritis knee surgery, 3D solutions for planning are rare especially in tumour knee replacement (TKR). In our knowledge, there is no reported literature on virtual surgery planning of TKR, despite an increasing demand from fields such as computer- and robotic-assisted surgery. In this work, we focus on using 3D computer graphics and geometric reasoning algorithms to aid surgeons in planning tumour knee replacement.

II. Materials and Methods

A. Reconstruction of 3D Anatomical Models

The reconstruction steps of 3D anatomical models start with the imported axial CT images in DICOM (Digital Imaging and Communications in Medicine) format [8]. These images are first processed with filters to reduce the noise while preserving the edge information in the form of intensity gradient. Global thresholding of bony tissue, based on a range of HU values, is carried out in line with local adaptive thresholding, which segments by analyzing 26 neighbors (N_{26}). Next, 3D region growing algorithm is initiated to group the bone data from the thresholded regions. Due to the similarities (overlap) in bone and surrounding tissues, classification only based on thresholding is not feasible. 3D morphological operators (both manual and automatic) are used to close the discontinuities in outer (periosteal) and inner (endosteal) contours. These segmented data are rendered in two modes: direct or volume rendering using transfer functions and surface rendering by fitting triangles using surface tiling.

B. Identification of Anatomical Landmarks

Anatomical landmarks are distinct regions or points on bones with uniqueness in shape characteristics in their vicinity. Manual location of landmarks and related measurements consume time, require a high level of expertise, and may lack in accuracy. Geometrically invariant measures such as curvatures, concavity, and convexity are useful in identifying landmarks on a 3D anatomical model.

We have developed a methodology for automatic localization and identification of anatomical landmarks on a 3D bone model [9]. The model surface is segmented into different regions based on Gaussian and mean curvature gradients, which are then classified as peak, ridge, pit and ravine. These anatomical landmarks are constrained in a spatial relationship that is the same for all the knee models. In order to encode these constraints in a network diagram, we characterize the edges pairs by the positional adjacency of a landmark relative to its neighboring landmarks. Skeletal landmarks are automatically identified by an iterative process using a spatial adjacency relationship matrix formed by these relations between the features. Figure 5 shows the anatomical landmarks on distal femur and proximal tibia which are most distal point of medial and lateral condyles (MC_F and LC_F), medial and lateral epicondyles (ME_F and LE_F), medial and lateral peak of anterior patella tracking edges (MP_F and LP_F), medial and lateral peak on tibial condylar plateau (MP_T and LP_T), tibial tuberosity (TT_T), medial and lateral intercondylar tubercles (MI_T and LI_T), and apex process of fibula (HF).

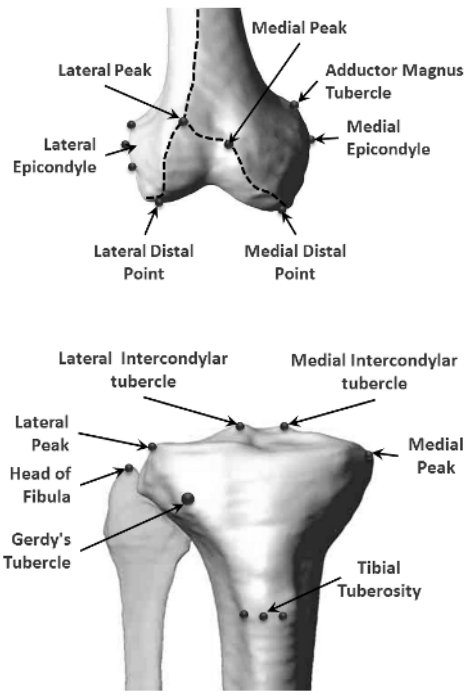

Fig. 2 Anatomical landmarks (a) on distal femur (b) on proximal tibia

C. Assessing Anatomical Parameters

Primary anatomical parameters are extracted using the associated landmarks. These include medio-lateral length

(ML), anterio-posterior length (AP), and inner and outer diameters (d and D) of femur (ML_F, AP_F, d_F, and D_F) and tibia (ML_T, AP_T, D_T, and d_T) bone respectively. Others include femur valgus (V) angle, femur bone curvature (RC_F), and resection length (RL) decided by the surgeon according to spread of disease.

D. Prosthesis Components Selection

Prosthesis components selection is driven by the extracted anatomical details and a decision based methodology. The standard modular prosthesis components are classified into three major categories: *small* (S), *medium* (M), and *Large* (L) according to their sizes (ranges are decided by one of our internal studies on knee morphometry). These components are indexed in terms of their geometric characteristics and design driven parameters to create a database. Critical components (tibial tray, femoral condyle, and tibial poly) are selected independently based on anatomical parameters. Other components (FK, SF, FS, and TS) are selected based on both dimensions and influence of previously selected components. As per this strategy, we found the best selection flow is TT-FC-TP-FK-SF-TS-FS. Remaining components are chosen based on sizes of the mating components.

The selection is performed in two steps: First, the components which are undersized and oversized are eliminated, then the dimensions of components are mapped with the corresponding measured anatomical parameters to form *fuzzy-based-decision-tree* based on the pre-defined rules compiled from surgeons' experience. The TT and FC are first selected based on AP_T and ML_F respectively. The TP is selected based on ML_{FC} and AP_{TT}. The remaining components are selected based on the dimensions of these three. FK is chosen based on D_F and influenced by D_{FC}. FE is chosen based on RL and RCL. Based on d_F and d_T, FS and TS are selected. Each branch of the decision tree is assigned a weight to evaluate its suitability. The choice of prosthesis components are classified with a qualitative tag as: *'most suitable'*, *'probably suitable'*, and *'not suitable'*.

E. Prosthesis Positioning

Positioning of prosthesis components with 3D anatomical model is carried out with reference to anatomical landmarks and reference axes. A set of reference axes of both anatomical (A_A) and prosthesis (A_P) model are generated by computing medial axis. Major reference axes include longitudinal axes of the femur (A_F) and tibia (A_T) bone, and axis of FS (A_{FS}) and TS (A_{TS}). Registering components with corresponding bone is carried out in two steps. First, matching reference axes such as A_F with A_{FS} and A_T with A_{TS}. This is repeated for the entire set A_A and A_P. Next, point to point registration (iterative closest point) with anatomical landmarks on bone model and geometric landmarks on prosthesis components. This include surface matching on both prepared tibial and femoral bone surface with FK and TT respectively. Space fillers are chosen from the 'most suitable' prosthesis components set accordingly after aligning FC, FK, and FS in femoral side, TT, TP, and TS in tibial side. The orientation of the bone is not changed during positioning.

F. Anatomical Suitability Evaluation

Modular prosthetic components may require a little compromise in confirming anatomical shape and size which affects the functional outcome of the joint. A set of anatomical suitability metrics were evolved to evaluate the selected prosthesis components considering their suitability with respect to patient's anatomy (Fig. 3). These measures are: *geometric error* (E_G) (dimensional difference between the resected bone and selected prosthesis components), *curvature error* (E_C) (difference between the measured bone curvature and the obtained curvature after implanting prosthesis with curved stem, with and without osteotomy), *re-*

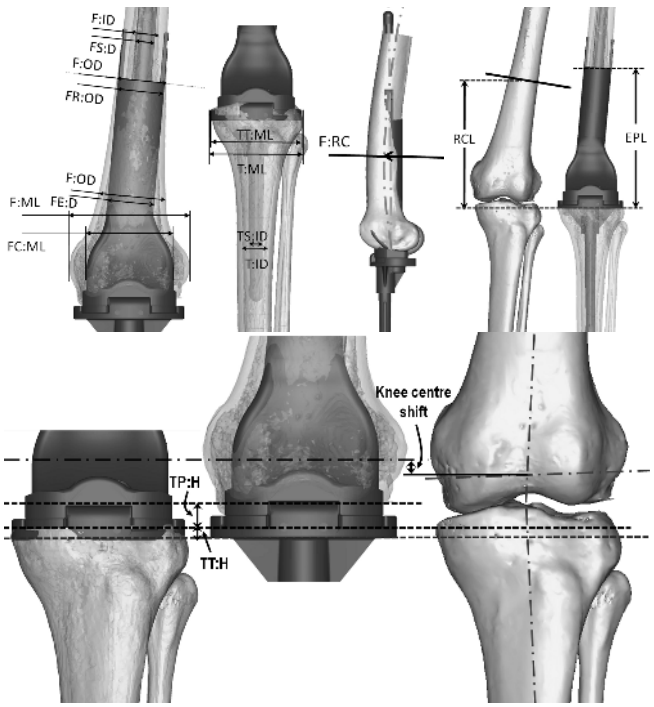

Fig. 3 Anatomical suitability metrics based on (a) geometry (b) bone curvature (c) reconstruction length (a) knee shift

construction length error (E_{RL}) (difference between actual RCL and effective length of the prosthesis (EPL), given by the distance between tibial component's bottom and femoral component's top surface) and *knee centre shift error* (E_{CS}) (difference between the natural knee's articulation centre and the artificial implant's articulation centre after implantation). These metrics are important in deciding whether standard modular prosthesis can be used or customized version is required for the patient.

III. Results

In this study, distal femur knee replacement for a patient (35/M) has been taken as an example to illustrate the methodology. 3D model of the knee joint is reconstructed from 468 CT axial slices in DICOM format (Fig. 4).

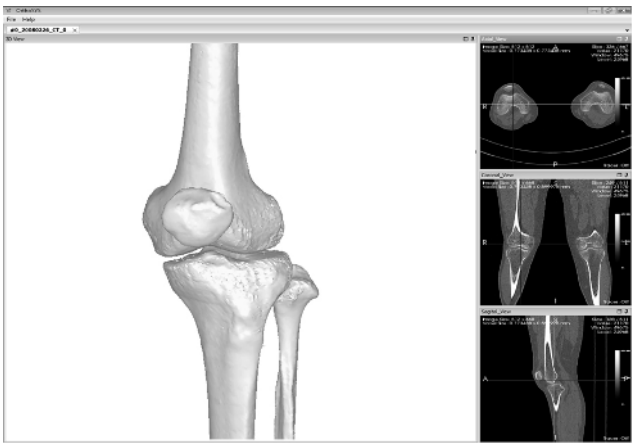

Fig. 4 Reconstructed 3D anatomical model of the knee

Anatomical landmarks and parameters extracted and prosthesis is selected based on these data. In femur (ML:64mm, AP:60mm, D:28-25mm, d:16-13mm, VA: 4.6^0, RL:120mm), tibia (ML:70mm, AP:58mm, d:14mm). The 'most suitable' set is large TT, FC, and TP. Generated reference axes along with landmarks are used in positioning of prosthesis and aligning knee into pre-operative posture (Fig.5). The final suitability metrics are E_G:6mm, E_C:4mm, E_{RL}:3mm, and E_{CS}:4.5mm. The measured metrics are within the limits, which does not affect the gait of the limb.

IV. Conclusions

The implantation planning of knee prosthesis after excision of primary tumour is discussed. The aligned endo-

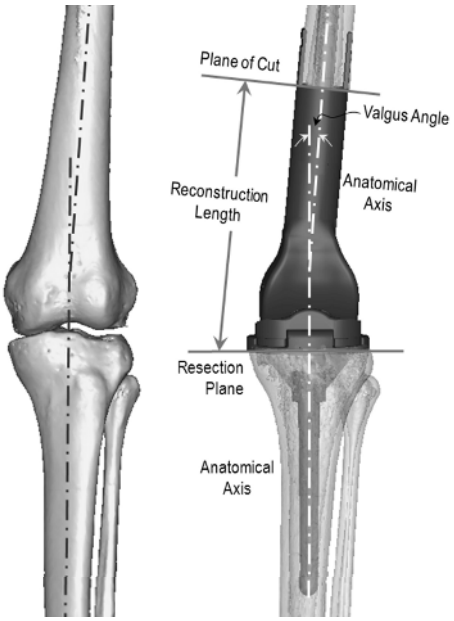

Fig. 5 Aligned distal femur prosthesis in 3D anatomical model

prosthesis is rendered with 3D bone model for visual verification. The suitability metrics indicate a numerical measure to the surgeons to give more attention to error-prone steps during surgical procedure. Integrating 3D geometric reasoning algorithms for anatomical understanding with decision methods makes the system intelligent and independent.

Color Medical Image Vector Quantization Coding Using K-Means: Retinal Image

Agung W. Setiawan[1], Andriyan B. Suksmono[2] and Tati R. Mengko[1]

[1]Biomedical Engineering, School of Electrical Engineering & Informatics ITB, Bandung, Indonesia
[2]Telecommunication Engineering, School of Electrical Engineering & Informatics ITB, Bandung, Indonesia

Abstract — **Retinal images play an important role in supporting medical diagnosis. Digital retinal image usually are represented in such a large data volume that takes a considerable amount of time to be accessed and displayed. Digital medical image compression therefore become crucial in medical image transfer and storage in electronic database server. This research is concerned with the development of a color medical image coding scheme using vector quantization. K-means is clustering technique that is applied to create codebook in vector quantization (VQ) coding. This research investigates the performance of each of these clustering technique in four color models: RGB, 4:4:4 YUV, 4:2:0 YUV and HSV. The VQ coding scheme is conducted separately to image components in each channel of the color models. Reconstructed color image is obtained by combining the VQ decoding result of each image components. The VQ coding performance relies on the quality of the utilized codebook. The VQ codebook used in this research was developed from retinal image. The retinal image was processed as a set of four quarter-images. This special treatment is required to cope with the large computational load of the VQ codebook generation, while ensuring the incorporation of the color and texture diversity of the training set in the resulted codebook. The RGB 444 color mode (coding of the red, green, and blue channels by the size of 4×4) produces the best subjective and objective quality of image coding. However, the optimum color models for tele-ophthalmology and electronic medical records are the YUV 4:2:0 and RGB 848 for retinal image.**

Keywords — **Color Medical Image, Retinal Image, Vector Quantization, K-Means.**

I. Introduction

Image is one of the medical data needed in diagnosis. Types of medical image are gray image – for example is Xray image and color image – such as retinal image. These medical images are saved into a medical record database sever. Image compression/coding will be needed to reduce the storage capacity in the server. Without image compression, the size of the images saved in a server will be large. For example, the normal size for a 1600 × 1216 pixels retinal image is 5,701 MB. Therefore, clients will need a lot of time to access such a large file in tele-diagnosis. Meanwhile, the access time also depends on the network bandwidth used. As we know, most of Indonesia rural areas use Public Switched Telephone Networks which have narrow bandwidth capacities.

Tele-diagnosis with asymmetric coding has an advantage, such as the decoding computation in client side is simpler that in the sever side. Thus, vector quantization coding is used in this research because of its lossy-to-lossless capability in sending images in Region of Interest (RoI).

The research aims are to develop a color medical image coding based on vector quantization, to search for an optimal size of codeword in retinal images and to decide a suitable model of color image for quantization vector coding.

One of the most important steps in vector quantization coding is to make a coding book. In this research, coding book is made by K-means algorithm. K-means is an unsupervised learning algorithm which is widely used for data classification. The procedure of its data classification is simple and easy for clustering.

Vector quantization method is commonly used for digital data compression, such as digital image and sound compression. For image compression, vector quantization is computed in adjacent correspondence image pixels. It is likely that the adjacent pixels of pixel P will have the same value as pixel P.

II. Vector quantization

One of the most important steps in vector quantization coding is to make a coding book. In this research, coding

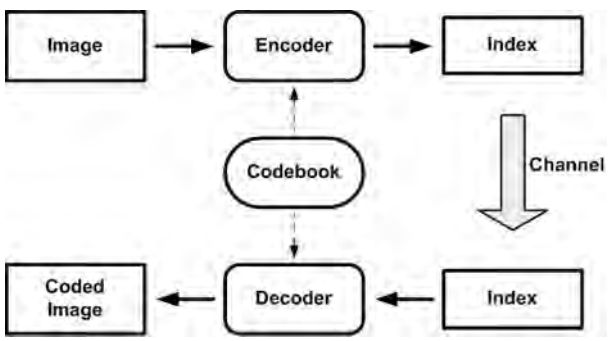

Fig. 1 Vector quantization coding scheme.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 911–914, 2009
www.springerlink.com

book is made by K-means algorithm. K-means is an unsupervised learning algorithm which is widely used for data classification. The procedure of its data classification is simple and easy for clustering.

Vector quantization method is commonly used for digital data compression, such as digital image and sound compression. For image compression, vector quantization is computed in adjacent correspondence image pixels. It is likely that the adjacent pixels of pixel P will have the same value as pixel P.

A vector quantizer consists of two parts, encoder and decoder. The function of encoder is to get the input vector and to result the codeword which gives minimum distortion. The most minimum distortion is determined by Euclidian distance between input vector and every codeword in the codebook. Then, this codeword index is saved in a digital data storage or sent through the communication channel. The function of decoder is to change the codeword index received into the codeword form the codebook.

In vector quantization, image coding is done by dividing an image into small blocks of pixels, until it is fit with the codeword dimension, like 2×2, 4×4, etc. The input image in encoder side is divided into small blocks of pixels. The chosen codeword should have the least distance between input vectors. After the codeword has been found, the encoder will result the numbers of codeword index. Then, these process will be repeated until all of the small pixels blocks have their own index numbers.

The encoder reconstructs the image based on the index numbers obtained. A look–up table is needed to produce reconstruction vectors from index numbers. The image encoding – by vector quantization method – is lossy, since it is unsimiliar between the input image and the reconstructed image. These differences are occured because the small blocks of pixels is changed into the codeword which has the least distance with that small pixel block.

III. System Design

The codebook is made by using four retinal images 1600 × 1216 pixels which are cropped until its quarter size. Then, each of these cropped images is combined to be an image in its original size, 1600 × 1216 pixels. This step is effective to decrease the computation load in codebook compilation. Four images chosen are varied in patterns because it is important to obtain a codebook with various values, so that it can be used for various types of retinal images. The tested images can be shown in Figure 2.

There are five color models to be coded, RGB, YUV RGB, YUV 4:4:4, YUV 4:2:0 and HSV. All of those color models have three channels. Codebook is made in each

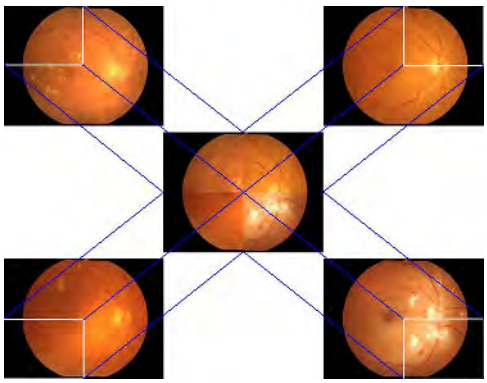

Fig. 2 Retinal image training.

image channels before it is classified by K-means algorithm, which need channels to be extracted. The block diagram is shown in Figure 3.

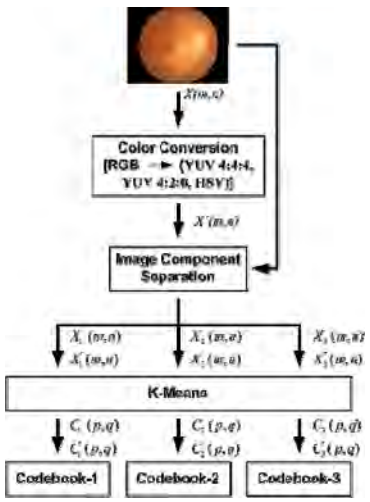

Fig. 3 Codebook generation block diagram.

Coding scheme for RGB, YUV 4:4:4, and YUV 4:2:0 is shown in Figure 6 below. Channel 1 is R & Y channel, channel 2 is G & U channel, and channel 3 is B & V channel. Two types used in this coding are :

1. Input image (RGB) splits directly into channel R, channel G and channel B.
2. Input image (RGB) is changed into color model YUV 4:4:4 and YUV 4:2:0. The converted image then splits into channel Y, channel U and channel V images.

Each of the images channels is coded by using the codebook, and results the index for every channel. To get a coded image, encoding is done by using the same codebook.

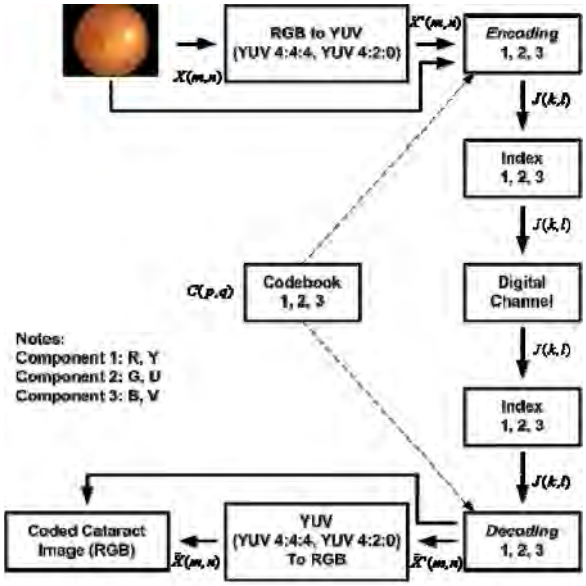

Fig. 4 RGB & YUV image coding scheme.

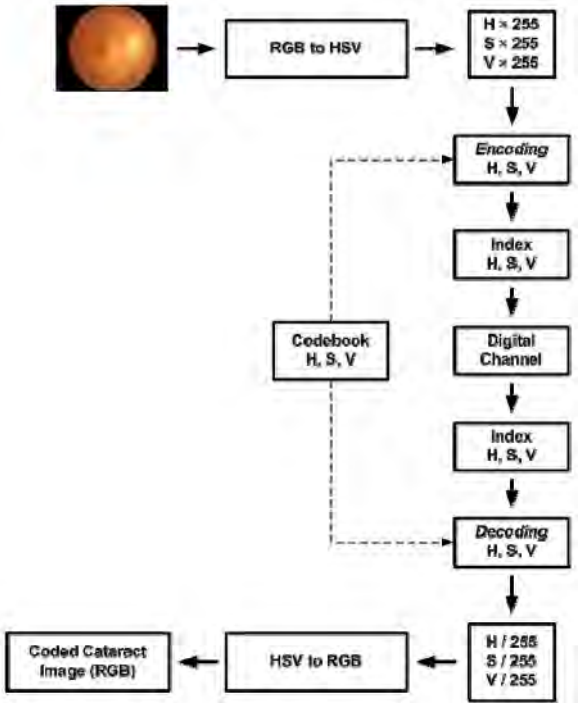

Fig. 5 HSV image coding scheme.

For HSV model, a converted image from RGB has an interval [0,1], so that it must be multiplied by 255 to get an image with interval [0,255]. Therefore, the codebook compilation, encoding process and decoding process will be easier to be done. Otherwise, the computation load will be abundant if the interval is not in [0,255], *out of memory* and the codebook cannot be obtained. Figure 5 shows the coding scheme of HSV model. Before the decoded image is converted into RGB, it is divided by 255 to restore its original interval [0,1].

IV. Experimental Results

We use 10 RGB retinal images of 1600 × 1216 pixels. We tested the system to assess the effectivity of the developed algorithms. Parameter used here is PSNR (Peak Signal-to-Noise Ratio), from RGB coded images with various size of codeword in each color models. PSNR formula for a color image with three channels:

$$\text{PSNR}=10\log_{10}\left(\frac{255^2}{\frac{MSE(1)+MSE(2)+MSE(3)}{3}}\right) \quad (1)$$

Time to produce a codebook of retinal images with 4x4 codeword dimensions is also used as a parameter in this research. This codebook is arranged by classification methods, like K-means. The average PSNR value for retinal images with K-means is in the interval 36,75 – 42,26 dB and can be seen in Figure 6.

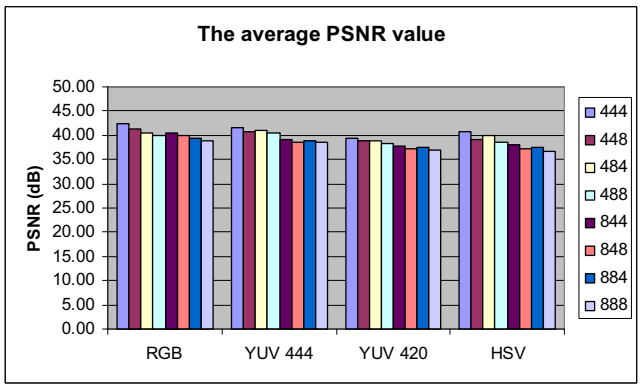

Fig. 6 The average PSNR value.

Tabel 1 gives the size of codebook file and retinal images index with codeword dimension 4×4 and 8×8. It can be shown that all of the channels of RGB, YUV 4:4:4 and HSV have the same size in codebook file and index. The size of codebook file in YUV 4:2:0 is the same as the other channels, but its index file size is different from the other color models. In retinal images, the size of index file in

channel Y is the same as the other color models', but the size of index file in channel U and V for 4×4 dimension codeword is 31 KB and for 8×8 dimension codeword is 9 KB. In

An objective (PSNR values) and subjetive assessment shows that the image quality is not very different/almost similiar with the image quality in other models. The size of index file in channel U and V is small, so that it will be easier to transfer the retinal images in tele-ophthalmology system. Moreover, this advantage will reduce the capacity required for saving the file in electronic medical records server.

Based on the experimental results, an RGB retinal image with combination 848 (red channel is coded in 8×8, green channel is coded in 4×4, and blue channel is coded in 8×8), objectively and subjectively – has a good quality and the coded image can be read. This combination will reduce the size of the codebook and index which will be sent or saved.

Table 1 Size of codebook file and retinal images index

Color Model		Codeword 4 × 4 (KB)		Codeword 8 × 8 (KB)	
		Codebook	Index	Codebook	Index
RGB	R	5	120	17	31
	G	5	120	17	31
	B	5	120	17	31
YUV 4:4:4	Y	5	120	17	31
	U	5	120	17	31
	V	5	120	17	31
YUV 4:2:0	Y	5	120	17	31
	U	5	**31**	17	**9**
	V	5	**31**	17	**9**
HSV	H	5	120	17	31
	S	5	120	17	31
	V	5	120	17	31

V. Conclusions

According to the research results, it can be concluded that :

1. Color model RGB with 444 combination (red, green and blue channel are coded in 4×4) subjectively and objectively (PSNR value) – yields the best quality in retinal and cataract coded images. In tele-ophthalmology application and electronic medical records, YUV 4:2:0 is the most optimal color model for retinal and cataract images since it can reduce the size of the codebook and index which will be sent or saved.
2. A retinal image with RGB 8×8-combination (red channel is coded in 8×8, green channel is 4×4 and blue channel is coded 8×8) subjectively and objectively – has a relatively good quality and its coded image can be read. This combination can reduce the size of the codebook and index which will be sent or saved.

Development of the ECG Detector by Easy Contact for Helping Efficient Rescue Operation

Takahiro Asaoka and Kazushige Magatani

Department of Electrical and Electronic Engineering, Tokai University, Japan

Abstract — **When a large-scale disaster occurred, it is expected that much damage occurs. In recent years, various rescue robots are developed as second anti-disaster measures mainly. The realization of a quick rescue operation is expected by these rescue robots. To save life of more victims, it is important that rescuers divide a victim by triage. Effective rescue operations can be realized by it. However, well trained person for the triage can do correct judgment, but it is difficult for other people. Therefore, if rescuers gather bio-signals of the victim when they find or save the victim, they can get a clear criterion. From this, it is thought that many rescuers can evaluate the condition of the victim correctly using bio-signals of the victim. So, we developed the device to detect an electrocardiogram by easy contact in this study. The electrocardiogram is one of the important vital signs in the bio-signal of the human. If we can detect an electrocardiogram, we can diagnose the change of the condition of the person. At the time of the disaster, the diagnosis of the irregular pulse is effective in particular. It is possible to diagnose the irregular pulse by only one detected electrocardiogram. However, the measurement of electrocardiogram at the time of the disaster is difficult, because 12 lead electrocardiogram which is the most general method needs ten electrodes. Therefore we avoid the method to need many electrodes in this way, we aimed for the detection of the electrocardiogram with as few electrodes as possible to be able to measure it at the stricken area. In addition, for the realization of a more effective measurement, I aim at the development of the induction method that is able to detect a electrocardiogram by electrodes which do not touch skin directly.**

Keywords — **ECG (Electrocardiogram), Capacitive coupling, Easy contact**

I. Introduction

As the scale of the disaster becomes big, this widespread damage becomes terrible. And, rescue persons increase together with victims. As this result, there is also possibility that rescue persons receive a serious injury or lose thier life by a second disaster. In order to avoid these situations, robots that engage in rescue operations are being researched and developed. By the introduction of various rescue robots, a quick rescue operation is enabled safely by the people of small number. In addition, the rescue person performs triage after the rescue of the victim. The triage is to choose a priority of the treatment by the state of the victim, but it is necessary training to be able to judge accurately. It is difficult to judge appropriate for other people for that reason. Therefore we developed the device which could detect a bio-signal by easy contact. We think that the detection result of this device helps triage. In addition, if rescue robots have this function, the rescue person can also decide a priority of the help of the victim by this function in the rescue operation. Especially, it is useful in the case of the help of the victim who became burying alive. The survival rate of the victim decreases remarkably after passing 72 hours from buried alive. So, it is desirable to grasp the condition of the victim easily by using this function. Therefore, our goal is the development of a system which can be installed on a rescue robot, measure the victim's vital signs and send these data to medical doctors. In this paper, we describe developed measuring methods for ECG (Electrocardiogram) by using capacitive coupling. In our method, only touching victim's skin with electrodes, a correct victim's ECG is obtained.

II. Methodology

ECG is a bio-signal which is a voltage gap to be lead in two different positions of the heart, and indicates electrical activity of the heart. ECG serves for diagnosis and cure for heart diseases. The heart rate and the existence of the arrhythmia which is helpful on a disaster are obtained by ECG. They are able to be diagnosed from the time relation of each wave of ECG. Therefore, it is possible to estimate them from only one of induction methods of ECG.

There are two leading methods for ECG if we classify them widely. One is the limb leading by bipolar, the other is the precordial leading by unipolar. These leading methods have each merit. However, at the disaster area, we have to select leading method in accordance with the situation. Therefore, we developed the system which can choose either leading method by the situation.

In general, many electrodes are necessary for measuring typical ECG. And to avoid artifacts, the resistance between electrodes and human body surface is fixed on the low resistance value. In other to keep this condition, conductive paste is used between electrodes and body surface. However, it is difficult to measure ECG using these methods at the disaster area. Therefore, new ECG measuring method

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 915–918, 2009
www.springerlink.com

which needs only two or three electrodes without conductive paste was developed. Using this method we can detect arrhythmia from measured ECG easily.

In our method, ECG is led by capacitive coupling between body and electrode. This principle is explained as following. At first action potential occurs by the heartbeat. By this electric potential, an electric field is formed, and this affects the body surface. This electric field and the electrode form a capacitor. This capacitive coupling between a body surface and the electrode derives ECG signal from a body to the electrode. So, we can obtain ECG without direct touching of electrodes to the body surface. For example, even if electrodes are touched to the victim's clothes, ECG of victim will be able to be measured. Fig.1 shows an equivalent circuit of this principle.

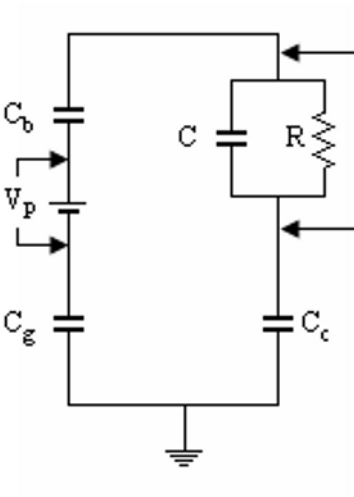

Fig. 1 The equivalent circuit of capacitive coupling.

Where, V_p is the action potential of the heart. V_{out} is the output voltage. C_b is the capacitance between human body and ECG detector. C_g is the capacitance between human body and ground. C_c is the capacitance between ECG detector and ground. C and R are the capacitance and the resistance of the first op-amp respectively. From this figure, a equation of V_{out}/V_p is shown as following.

$$\frac{V_{out}}{V_p} = \frac{1}{\frac{1}{j\omega C_b R} + \frac{C}{C_b} + \frac{1}{j\omega C_g R} + \frac{C}{C_g} + \frac{1}{j\omega C_c R} + \frac{C}{C_c} + 1}$$

III. Detecting device

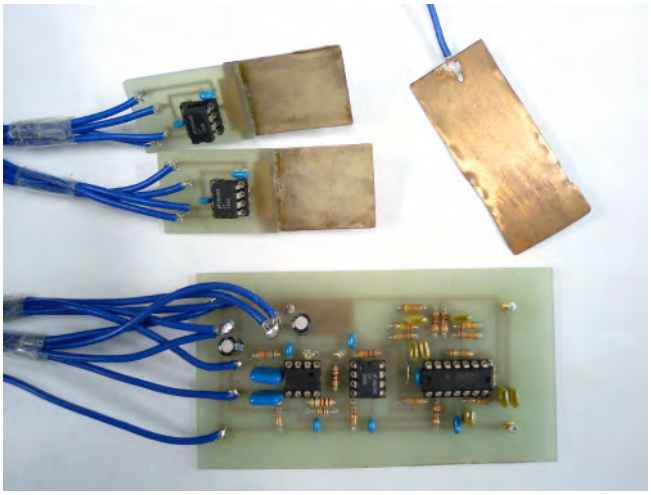

Fig. 2 The ECG electrodes and amplifier.

Fig.2 shows a picture of developed ECG measurement system. As shown in this figure, this system uses three electrodes. One is for the common and others are for leading ECG. In our system, normal detected ECG is measured by using three electrodes. And, capacitive coupled ECG is measured by using only two electrodes. Materials of each electrode are copper sheets. Because of high impedance between a capacitive coupling electrode and body, a voltage follower amplifier is installed on electrode. And low impedance output of a voltage follower is send to the ECG amplifier. The block diagram of our ECG measurement system is shown in Fig.3. As shown in this figure, signals from electrodes are differential amplified by an instrumentation amplifier. Noises in amplified ECG are reduced using filters. B.E.F. removes hum noise.

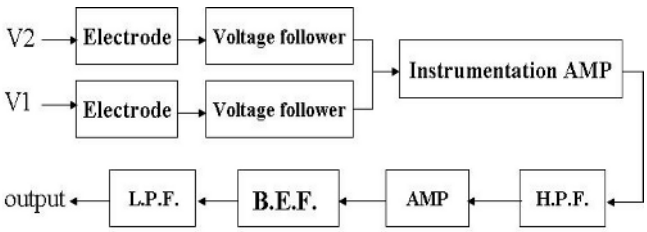

Fig. 3 Block diagram of ECG amplifier.

IV. Experiment and Result

(1) Detection by each lead method

Fig. 4 The ECG wave of the limb lead.

Fig. 5 The ECG wave of the precordial lead with three electrode.

Fig. 6 The ECG wave of the precordial lead with two electrodes.

ECG was experimentally measured about three normal subjects by using each lead method. The detection method of the ECG is mentioned earlier. In all leading methods, ECG was able to detect. As an example, detection results for one subject are showed the following. The result of ECG waveform by limb leading is shown in Fig.4, and Fig.5 shows the ECG for precordial leading. These results were measured by using three electrodes. In these experiments, two electrodes were used for bipolar leading of ECG and one electrode was used for common. A result of ECG for unipolar leading is also shown in Fig.6. This result was acquired by capacitive coupling. As shown in these figure, an amplitude of unipolar leading (Fig.6) is smaller than bipolar leading (Fig.5). In addition, as shown in Fig.5, there are many distortions with ECG waveform. However, measuring ECG using two electrodes is easier than using three electrodes for our objective.

(2) ECG detection through the clothes

Fig. 7 The ECG from the surface of a T-shirt.

Fig. 8 The ECG from the surface of a T-shirt by capacitive coupling.

ECG through the clothes was experimentally measured about one subject by using precordial leading. Fig.7 shows the ECG waveform that is acquired from the surface of a T-shirt by using three electrodes. Fig.8 shows the ECG waveform that is acquired from the surface of a T-shirt by using two electrodes. This result was acquired by capacitive coupling. These results were obtained by higher amplitude than previous experiment result. From these results (especially in Fig.8), a lot of noises are generated in ECG detection through the clothes. So, we think that it is hard to stabilize ECG pattern by using a developed amplifier. So, we are considering about optimal amplitude and filtering of ECG amplifier. And I think that a more accurate filter is necessary to suppress the noises.

V. Conclusion

In this paper, we described about the developed device for measuring vital signs of suffered person under the disaster. ECG measuring system by using capacitive coupling type electrodes was developed. This system can detect ECG by easy contact through textiles. However, the output of this detecting method is unstable, and includes a lot of noises. Therefore, we have concluded that if these problems are improved, our developed system will be useful to rescue sufferers.

A Navigation System for the Visually Impaired Using Colored Guide Line and RFID Tags

Tatsuya Seto[1], Yuriko Shiidu[1], Kenji Yanashima[2] and Kazushige Magatani[1]

[1]Department of Electrical and Electronic Engineering, Tokai University, Hiratsuka, Japan
[2]National Rehabilitation Center for the Disabled, Hiratsuka, Japan

Abstract — **There are approximately 300,000 visually impaired persons in Japan. A navigation system using GPS and point blocks are examples of famous supporting systems for independent activities of the visually impaired. However, these support systems are usually useless in the indoor space (e.g. underground shopping mall, hospital, etc.) and cost a lot of money to spread. Most of the visually impaired in Japan are old and they probably cannot use complex support systems. Therefore, our objective is the development of a simple and inexpensive navigation system for the visually impaired which can use in the indoor space. Our developed instrument consists of a navigation system and a map information system. These systems are installed on a white cane. Our navigation system can follow a colored guideline that is set on the floor. In this system, a color sensor installed on the tip of a white cane senses the colored guideline, and the system informs the visually impaired that he/she is walking along the guideline by vibration. The color recognition system is controlled by a one-chip microprocessor and this system can discriminate 6 colored guidelines. RFID tags and a receiver for these tags are used in the map information system. The RFID tags are set on the colored guideline. An antenna for RFID tags and the RFID tag receiver are also installed on a white cane. The receiver receives tag information and notifies map information to the user by mp3 formatted pre-recorded voice. Three normal subjects who were blindfolded with an eye mask were tested with this system. All of them were able to walk along the guideline. The performance of the map information system was good. Therefore, our system will be extremely valuable in supporting the activities of the visually impaired.**

Keywords — **white cane, RFID tags, colored guideline, color sensor, visually impaired.**

I. Introduction

A white cane is a typical supporting device for the visually impaired. They use a white cane while walking for the detection of obstacles around them. In their known area, they can walk independently using a white cane. However, they cannot walk without help of others in their unknown area, even if they use a white cane. Because, a white cane is a detecting device for obstacles and not navigation device that gives them a route to the destination. Therefore, a navigation system that supports independent activities of the visually impaired is required.

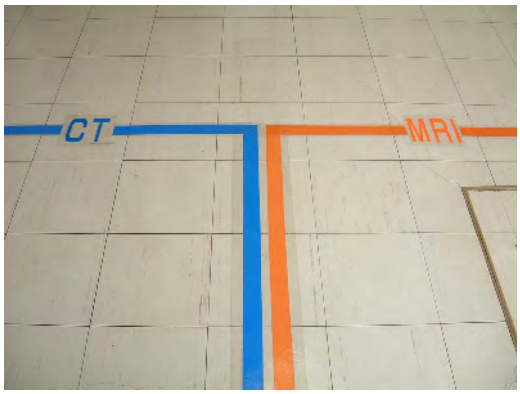

Fig. 1 Example of colored navigation lines

Many navigation systems for the visually impaired are developing. For example, a navigation system using GPS that supports the independent walking of the visually impaired is being developed. However, most of them are for outdoor space and not for indoor. Our objective of this study is a development of the navigation system which can be used in the indoor space and supports independent activities of the visually impaired without help of others.

In Japan, navigation line system is used for the normal person. This system is composed of some colored tapes that set on along the walking route. These colored lines are called colored navigation line. Each color is assigned for each destination. If we walk along one of these navigation lines, we can arrive the destination that corresponds the color of line easily. Fig.1 shows an example of the navigation line system.

II. Methodology

A. Conception

Fig.2 shows the conception of our system. This system is composed of colored navigation lines, RFID tags and an intelligent white cane. A navigation line is set on the floor along the walking route to the destination. If there are many

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 919–922, 2009
www.springerlink.com

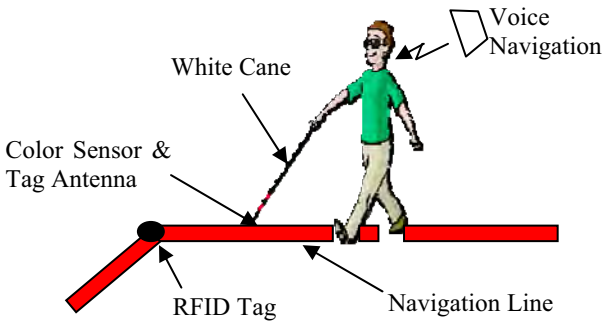

Fig. 2 A conception of the navigation system

destinations, different color is assigned for each route. At the each landmark point of the walking route, an RFID tag that indicates area code is set on a navigation line. An intelligent white cane includes a RGB color sensor, a transceiver for RFID tags, a vibrator and a voice processor. These devices included in a white cane are controlled by one chip microprocessor. A color sensor installed on the tip of a white cane senses the color of a navigation line. A visually impaired user swings the white cane left to right or right to left in order to find a target navigation line. If this sensor catches the target color, the white cane informs the visually impaired that he/she is walking along the correct navigation line by vibration. The white cane also makes communication with a RFID tag at the landmark point of walking route. If the white cane finds a RFID tag, a voice processor notifies area information that corresponds to the received area code by pre-recorded voice. Therefore, a user of this system can obtain the area information and reach the destination, only walking along the selected navigation line by using an intelligent white cane.

B. Color sensing system

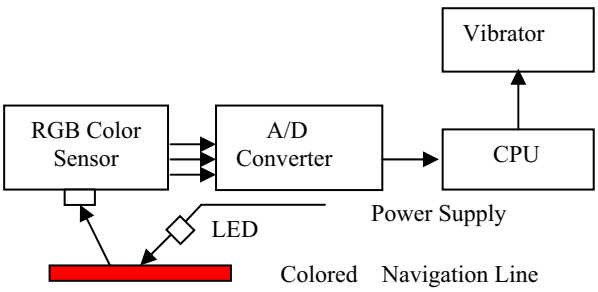

Fig. 3 A block diagram of the color detecting system

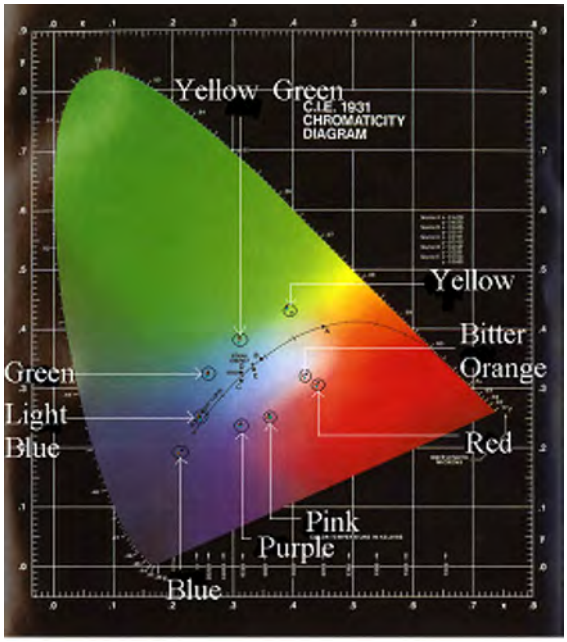

Fig. 4 xy-Chromaticity diagram

A block diagram of a colored line sensing system is shown in Fig.3. In this system a RGB color sensor installed on the tip of a white cane senses the floor color. RGB outputs of this sensor are amplified and noise reduced by a low pass filter. Then these signals are analog to digital converted by 8bit resolution, and then analyzed by a CPU (one chip microprocessor). Intensity of RGB signals change as the circumferential brightness, even if the sensed color is same. However, the ratio of RGB signals dose not change under same color sensing. In our system, digitized RGB signals are transformed to the Yxy notation. A point of one color in x-y coordinate of Yxy notation is located a same point at any condition. Therefore, the system evaluates a line color correctly at any condition by using Yxy notation. The x-y coordinate of Yxy notation is shown in Fig.4.

If a sensed color is the target color, a CPU turns on a vibrator to notify that the user is on the right route. This system can discriminate 6 or more colors of the navigation line.

C. RFID tag system

A block diagram of RFID tag information system is shown in Fig.5. In the navigation route, there are some landmark points where the system has to notify a user of the area information. For example, a corner to turn left or right, an entrance to the elevator, stairs are typical landmark points for the visually impaired. In our previous navigation

system, optical beacons that were set on the ceiling and a receiver for the beacons were used for this objective. From experiments, it is confirmed that the performance of the optical beacon system was good. However, an optical beacon consumes electric power continuously to emit the area code as infrared signals. And a user has to have a receiver for the beacon in addition to a white cane. Therefore, RFID tags are used in our new system. It is not necessary to have own power source for typical RFID tag. The dimension of RFID tag is 8.5cm x 5cm, and the frequency characteristic is 135kHz. The power of RFID tag is supplied from the transceiver that can make communication with RFID tag as radio frequency wave. And RFID tag system can be installed in a white cane. These are the benefit for using RFID tags.

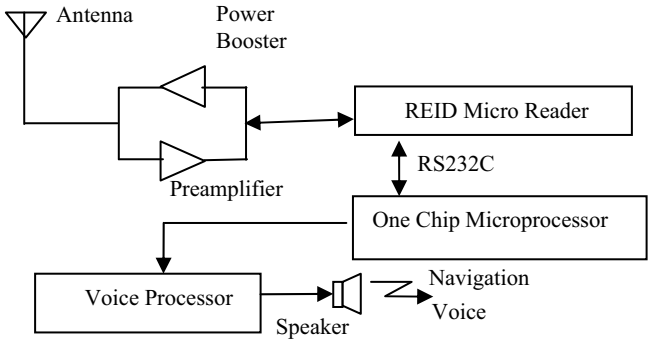

Fig. 5 A block diagram of a RFID tag transceiver and a voice processor

Both receiving sensitivity and output power of ordinary RFID Micro Reader (transceiver) are too small for our system. So, a preamplifier for the receiver and a power booster for the transmitter are developed and equipped in our system. An antenna for the transceiver is also installed on the tip of a white cane. By using this system, communicable distance between an RFID tag and a white cane is about 50cm. Fig.6 shows an RFID tag that is used in our system.

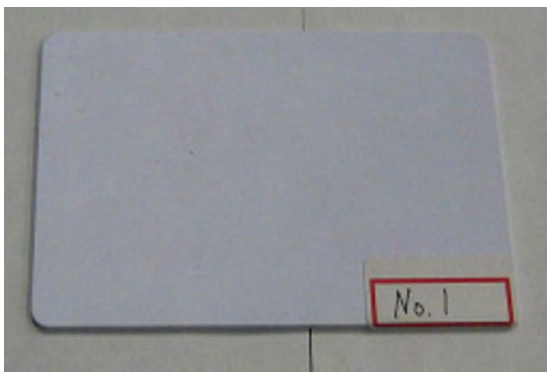

Fig. 6 An example of used RFID tag

The voice processing unit is also necessary for RFID tag system. At a landmark point, it is necessary to notify area information by voice. In our system, a CPU selects and outputs the pre-recorded phrase that corresponds with a received area code. Pre-recorded phrase is encoded in mp3 format and saved in the memory of one chip microprocessor.

III. Experiment

There normal subjects who were blindfolded with an eye mask were tested with our developed system. Two experiment routes were set on the floor and RFID tags were also set at the landmark point of these route. One navigation route was red and another was blue. Start point of both navigation lines were same. A destination of red navigation line is a door to the laboratory and blue is the toilet. Fig.7 shows the schema of experiment route. As shown in this figure, a subject had to turn left to follow red route at the crossing. And a subject had to turn right to follow blue route. RFID tags were set on the navigation lines at the crossing and the destinations. In this experiment, the distance form start point to the destination was about 15m in all routes.

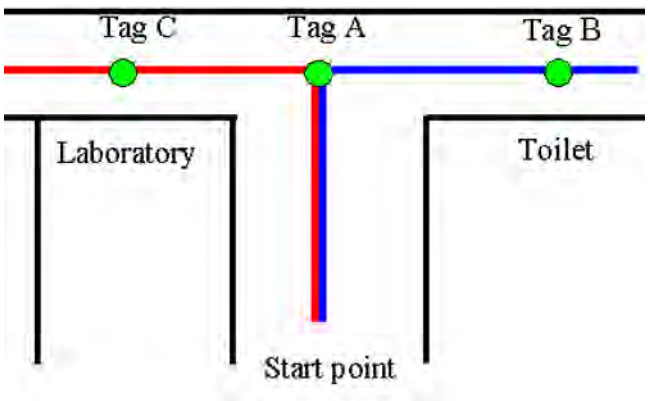

Fig. 7 The schema of experiment route

All subjects could walk along the navigation line correctly, and all colored lines were continuously detected stably. In all cases of this experiment, an intelligent white cane found RFID tag and notify the subject of turning information, and all subjects turned right or left and reached to the destination. Therefore, we think that our navigation system for the visually impaired worked perfect. Fig.8 shows one subject under experiment.

Fig. 8 A subject of the experiment

IV. Conclusion

We described about our developed new navigation system for the visually impaired. A user of this system can obtain the area information and reach the destination, only walking along the selected navigation line by using an intelligent white cane.

We think that our developing method to navigate a visually impaired person using navigation lines worked well. However, previous system was too heavy and huge. So, we developed a new system. These problems were improved in a new system. Therefore, we concluded that our navigation system will be a valuable one for the visually impaired.

A Development of the Equipment Control System Using SEMG

Noboru Takizawa[1], Yusuke Wakita[1], Kentaro Nagata[2], Kazushige Magatani[1]

[1]Department of Electrical and Electronic Engineering TOKAI University, Japan
[2]Kanagawa Rehabilitation Center, Japan

Abstract — **SEMG(Surface Electromyogram) is one of the bio-electric signals that is generated from the muscle. There are many kinds of muscles in a human body, and used muscles are different for each body movement. Therefore, any kind of body motions can be detected by analyzing generated SEMG patterns. Our objectives of this study are the development of a method that makes perfect detection of the hand motions possible using SEMG patterns and applying the method to the man-machine interface. In this paper, four channels SEMG signals which were measured from a right forearm of the subject were used to detect right hand motions. And a radio controlled vehicle was controlled as the results of detecting hand motions.**

In our system, suitable electrode positions are selected from analyzing results of 48 multi-channel SEMG patterns for each subject. Measured SEMG signals from electrodes are amplified, filtered and analog to digital converted. Digitized SEMG data are analyzed in a personal computer. The hand motion detection is done using the method of canonical discriminate analysis. In this study, five basic hand movements (wrist flexion, wrist extension, grasp, pronation, supination) were detected and used to control a vehicle. Three subjects were studied with our system. They were male and had not used our system before experiment. After few minutes training, they tried to control a radio controlled vehicle. In spite of first operation, they could control a vehicle almost perfectly and average recognition rate of hand movements were more than 90% for all subjects. From these results of our experiment, we have concluded that our new man-machine interface worked perfect and will be a valuable interface in future.

Keywords — **EMG, Movement identification, Machinery control.**

I. Introduction

SEMG (Surface EMG) is one of the bio-electric signals that are generated from the muscle. There are many kind of muscle in a human body, and used muscles are different for each body movement. Therefore, any kind of body motions can be detected by analyzing generated SEMG patterns. Our objectives of this study are the development of a method that makes perfect detection of the hand motions possible using SEMG patterns, and applying this developed method to the man-machine interface.

In this study, our target machine that is controlled by SEMG is a radio controlled toy vehicle on market. This vehicle and a remodeled radio controller are shown in Fig.1. A user of this vehicle can control five actions (turn left, turn right, go forward, go back, firing) using radio controller. In this study these five actions are controlled by subject's hand movements.

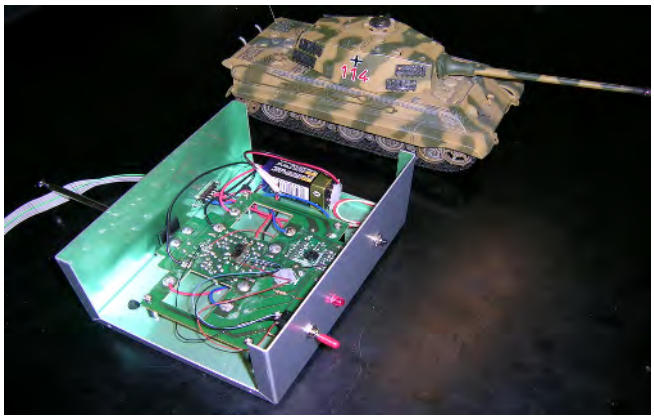

Fig. 1 The vehicle and a remodeled radio controller

II. Methodology

In our system, we tried to use four channels SEMG that were measured a right forearm in order to control a radio control vehicle. It is very important for this objective to select suitable electrode positions. So, we developed a SEMG amplifier and the method that made perfect hand motion detection possible. Fig.2 shows a block diagram of

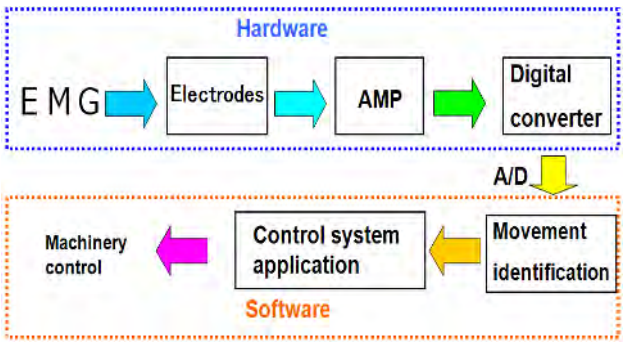

Fig. 2 A block diagram of one channel SEMG amplifier

www.springerlink.com

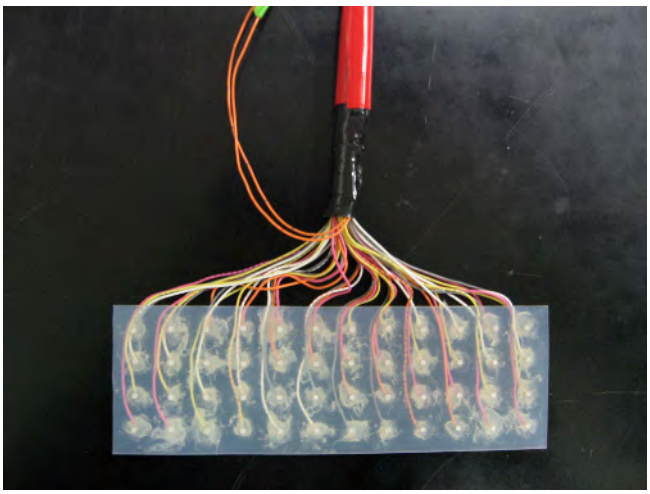

Fig. 3 A multi-channel electrode

one channel SEMG amplifier. As shown in this figure, SEMG measured from a right forearm using an Ag electrode is amplified, noise reduced by a low pass filter and analog to digital converted. And then digitized data is inputted to a personal computer and analyzed in it.

In order to select suitable electrode positions, 48 channels forearm SEMG for each hand motion are measured. A multi-channel electrode that includes 48 channels Ag electrodes is developed for this purpose. Fig.3 shows the multi-channel electrode. As shown in Fig.3, 48 channels Ag electrodes are set on a silicon rubber sheet. This electrode is wrapped around the forearm and 48 channels SEMG are measured form each Ag electrode. Fig.4 shows a 96 channels SEMG amplifier that includes low pass filters. We can

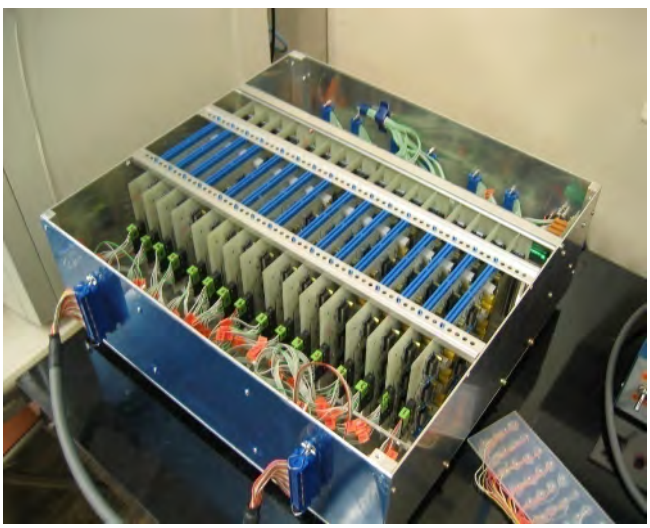

Fig. 4 A SEMG amplifier that include 96 channels

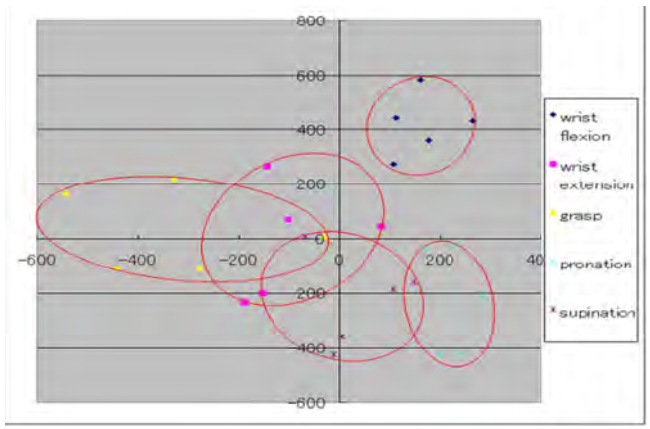

Fig. 5 An example of distribution map

measure 2 forearms SEMG at the same time using this amplifier.

In our system, suitable electrode positions are decided by Monte Carlo method. As mentioned earlier, 48 channels forearm SEMG for each hand motion are measured and digitized at first. 1000 sets of four channel electrodes are generated randomly. And recognition rate of hand motions are calculated and evaluated by canonical discriminate analysis for each electrode set. And finally, the electrode set that achieves highest average recognition rate is selected as the suitable electrode set [1]. Fig.5 shows the an example of distribution map for each hand motion on canonical space. As shown in this figure, cluster of each hand motion are separated each other on canonical space. After deciding electrode set, hand motion analysis is done using selected four channel electrode positions. Fig.6 also shows four channels Ag electrode set that is developed for our objective.

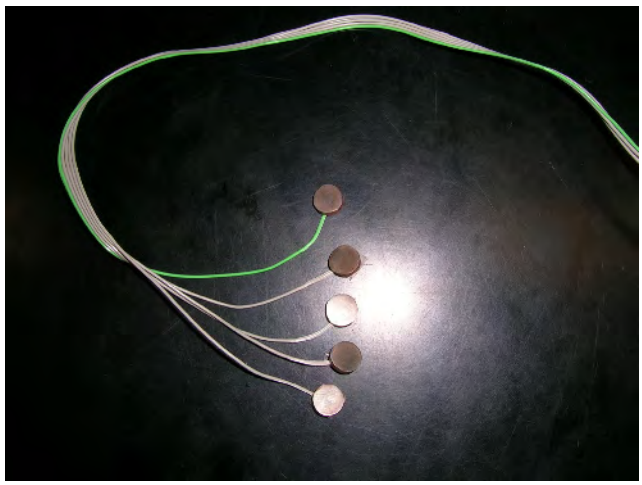

Fig. 6 Four channels Ag electrode

III. Experiment and results

At first, three normal male adult subjects were studied with our SEMG control system. All subjects set a multi-channel electrode on a right forearm and measured 48 channels SEMG for each hand motions. Suitable four channel electrode positions were decided by Monte Carlo method as mentioned earlier. After selecting electrode positions, four channel electrodes (shown in Fig.6) were set on a correct position of right forearm, and real time hand motion recognition test was done. Table 1 shows the correspondence between a hand motion and a motion of a radio controlled vehicle. All subjects moved hand 40 times for each hand motion. And recognition rates of each hand motion were calculated. The result of this experiment is shown in Table 2. As shown in this table, recognition rates for each hand motion are more than 95 % in all subjects. After, this experiment, all subjects tried to control a vehicle by SEMG. In this experiment, all subjects could control the vehicle almost perfect.

Supination	95
Average	99

Subject(c)

Movement	Recognition [%]
Wrist flexion	100
Wrist extension	100
Grasp	96.67
Pronation	96.67
Supination	100
Average	98.67

IV. Conclusion

In this paper, we described about our developed man-machine interface using SEMG. In this system, by using four channels SEMG a radio controlled toy vehicle are controlled. SEMG generated by hand motions are measured and evaluated, and acted hand motion are estimated by measured SEMG. Vehicle's actions are corresponded with estimated hand motions. Therefore, a radio controlled vehicle is able to be controlled by SEMG for each hand motion in our system.

Electrode positions for hand recognition are selected using Monte Carlo method. As using this method, we can obtain suitable set of electrode positions. From our experiment results, recognition rates of hand motions were more than 95% using this method. These results show that our developed method works perfect. In this paper, we described experiment results about three adult subjects. After those experiments, many children were also tested with our system. In spite of the first experience of our system for all children, most of them could control a vehicle perfect. However, our system is too huge to control a small interface. And in real time control by using SEMG, there are

some problems about control timing. Therefore, we concluded that if these problems are improved, our developed system will be a valuable one for the man-machine interface using SEMG.

Abstract — **Generally, voluntary muscles are able to be moved freely, if we want to move them consciously. In addition, EMG is generated in a muscle according to contraction of it. If we want control some equipment like an artificial hand by using EMG, a beginner cannot control it without concentration on the motion of equipment. However, if he/she is practiced in operation of the equipment as a result of training, he/she can control it without concentration. In other words, a skilled person has obtained some abilities from training, and these abilities will change brain functions. Making the change of brain function as a result of training clear by using f-MRI is our objective of this study. In our study, 6 channels EMG which are generated from right forearm are measured and basic hand motions are recognized by using them. In our experiment, a subject in a gantry of MRI moves his/her right hand, and generated 6 channels EMG are amplified, filtered and digitized. Digitized EMG data is analyzed and then a recognition result is indicated to a subject as an animation of the recognized hand motion by a LCD projector. A subject trains himself/herself in order to improve the recognition rate. F-MRI is measured while training continuously. In this paper, we will talk about our measurement system and the results of experiment.**

Keywords — **fMRI, EMG, artificial hand, training,**

I. Introduction

Generally, voluntary muscles are able to be moved freely, if we want to move them consciously. In addition, EMG is generated in a muscle according to contraction of it. Therefore, body motions can be estimated by analyzing generated EMG patterns, and the results of estimation are used as the control source for some equipment. If we want to control some equipment like an artificial hand by using EMG, a beginner cannot control it without concentration on the motion of equipment. However, if he/she is practiced in operation of the equipment as a result of training, he/she can control it well without concentration. In other words, a skilled person has obtained some abilities from training, and these abilities will change brain functions. Making the change of brain function as a result of training clear by using f-MRI is our objective of this study.

In our study, 6 channels EMG which are generated from right forearm are measured and basic hand motions (wrist flexion, wrist extension, grasp and release) are recognized by using them. In our experiment, a subject in a gantry of MRI moves his/her right hand, and generated 6 channels EMG are analyzed in a personal computer. The result of recognition is indicated to a subject as an animation of the recognized hand motion by a LCD projector. Therefore, a subject can check the recognition result immediately. All subjects of this experiment are beginners of the EMG recognition and train themselves in order to improve the recognition rate. F-MRI is measured while training continuously. And then, the changes of brain function as a result of training are analyzed by using these f-MRI data.

II. Experiment method

Fig.1 shows a simplified block diagram of our measurement system. As shown in Fig.1, Magnetom-Vision 1.5T(SIEMENS) is used as the f-MRI. 6 channels EMG are measured from right forearm of a subject in a gantry of MRI. Wires of electrodes are shielded and extended to the EMG amplifiers which are set on the outside of the MRI room. A LCD projector in the MRI room projects a result of hand motion recognition to the permeable screen which is set in front of a gantry of MRI. A subject can see the recognition result as an animation of hand motion through a mirror which is set in front of subject's eyes.

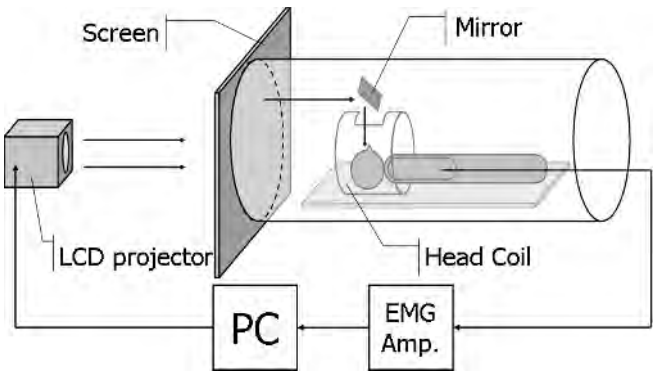

Fig. 1 The Measurement System

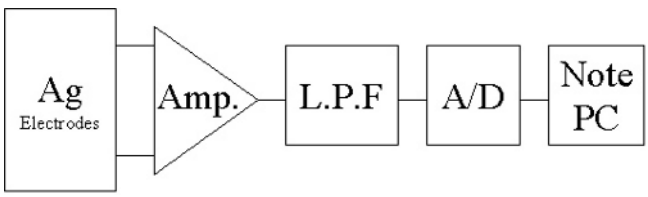
Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 927–930, 2009
www.springerlink.com

A block diagram of one channel EMG amplifier is shown in Fig.2. As shown in this figure, SEMG is amplified about 4400 times and a band width is limited from 10 to 1kHz. In addition, a EMG amplifier includes a hum filter which eliminates 50Hz. In digitization of EMG, sampling frequency is 2kHz, and bit resolution is 16bits. Digitized EMG data are analyzed in a personal computer.

Hand motion detection is done using the method of canonical discriminate analysis. An integrated value for 300ms of absolute value of EMG is used as the EMG feature extraction. In our system, suitable position of electrodes is estimated by Monte Carlo method [1], [2]. At first, 48 channels EMG pattern of a subject is recorded for each hand motion. Next, positions of 6 channels electrode are generated 1000times randomly. From results of these trials the suitable position of electrodes is decided. Using this Monte Carlo method, even if we use only 4 channels of EMG, recognition rate of basic 8 hand motions (wrist flexion, wrist extension, grasp, release, radial deviation, ulnar deviation, pronation, and supination) are more than 96%. A 48 channels multi-electrode is shown in Fig.3 (a) and a 48 channels EMG amplifier using detection of suitable position of electrodes is also shown in Fig.3(b).



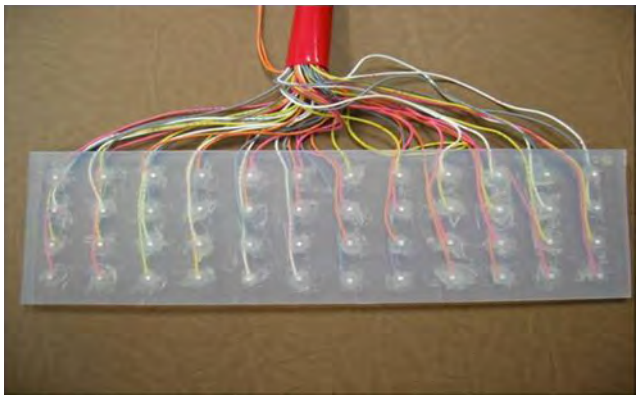


Fig. 2 Machine constitution

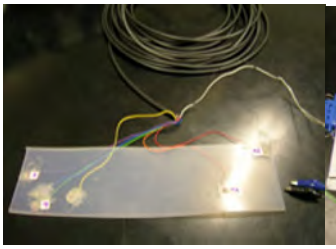
A structure of the surface 6 channel multi-electrodes is shown in Fig.4 (a). This multi-channel electrode is composed of 6 silver electrodes. Each electrode is 1mm in diameter. To fit a forearm bodyline, flexible silicone rubber is use as a base of 6 silver electrodes A thickness of this silicone rubber is 2mm. Positions of silver electrodes are set as the results of Monte Carlo method for each subject, as mentioned earlier. The 6 channel EMG amplifier is shown in Fig.4 (b). A 6 channel active low pass filter and a regulated power supply are also shown in Fig.4 (c) and (d). In our system, sometimes ordinary Ag-AgCl electrodes are used. In this case, positions of electrodes are decided as the anatomical position of muscles. Fig.4 (e) shows the shielded Ag-AgCl electrodes. Fig.5 shows the attached multi-electrode on the subject's forearm.

It is well known that many electric noises are generated by MRI. At first, electromagnetic noise from MRI was measured and analyzed. In this experiment, electrodes were

(a) A 48 channels multi-electrode



(b) A 48 channels EMG amplifier

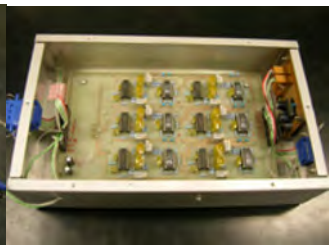


Fig. 3 A suitable position of electrodes detecting system

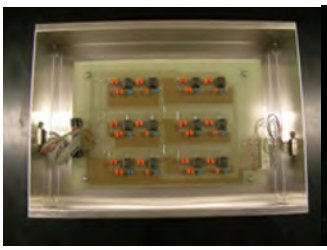
not attached on a subject's forearm. Each electrode was terminated with 10k ohm respectively, and MRI was measured. Generated noise under MRI measuring was recorded and analyzed. An example of power spectrum for recorded noise is shown in Fig.6. As shown in this figure, 3 peaks of power are observed, and frequencies of all peaks are more than 1kHz. Therefore, noise reduced EMG is obtained by using low pass filter whose cutoff frequency is set under 1kHz. Because of this result, in our system, maximum frequency of amplified EMG signal is limited under 1kHz as mentioned earlier.



Next, two beginners of the EMG recognition were tested with our system. Multi-channel EMG patterns of all subjects were measured and suitable positions of electrodes were decided before experiment. In this experiment, a subject in a gantry of MRI moved their hand. Because the motion of electrodes and wires of electrodes in accordance with

hand motions will generate electric noise, basic 4 hand motions (wrist flexion, wrist extension, grasp and release) which do not cause motion artifact are selected as recognized motions.

An example of distribution of classified basic motions of a hand in canonical space is shown in Fig.7 (same colored dot means same motion). As shown in this figure, all clusters are separated each other and we can recognize each hand motion.

Fig.8 shows an example of f-MRI result under EMG recognition test. The subject was a beginner of the EMG rec-

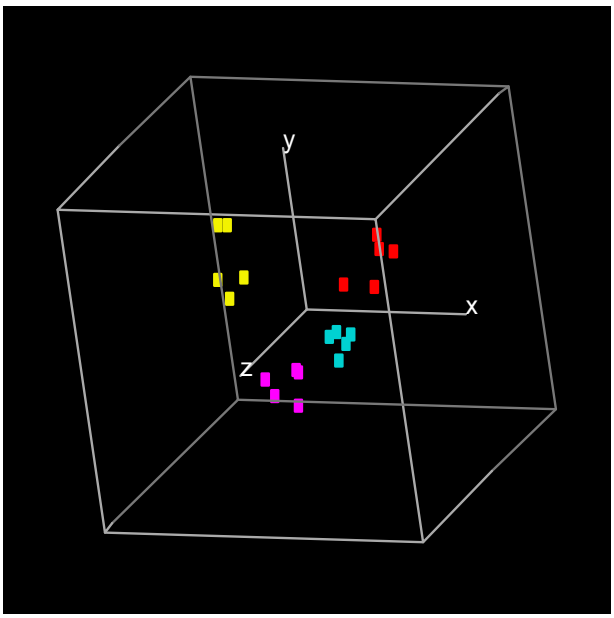

Fig. 7 Distribution result of classified basic motions of hand

ognition, and it was hard for the subject to control EMG pattern. Many activated places are observed in Fig.8. We think that because of inexperience in EMG recognition is the main cause for multi-activation of the brain.

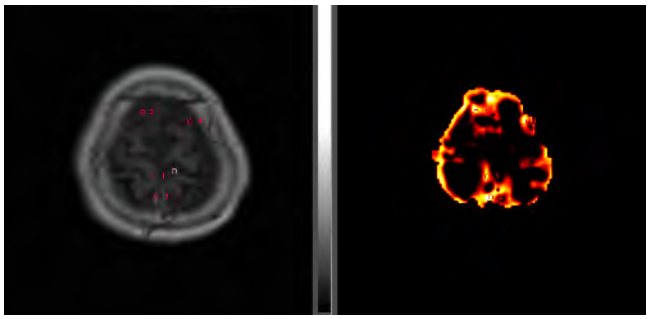

Fig. 8 An example of f-MRI result under EMG recognition test

Fig.9 express signal strengths which can measure at the time of simultaneous acquisition of f-MRI and EMG. As shown in this figure, we can observe activations in a various area of brain that include motor are.

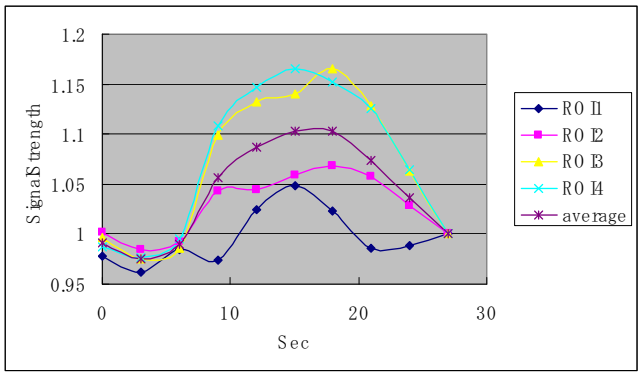

Fig. 9 Signal strength when of f-MRI and EMG simultaneous measured

III. Conclusions

We can use EMG as the control source for some equipment. For example, an artificial hand is controllable using EMG. However, a beginner cannot control it without concentration and skilled person can control it without concentration. A skilled person has obtained some abilities, and these abilities will change brain functions. In order to observe these changes of brain functions, we developed

EMG measurement system which can measure 6 channels EMG and f-MRI simultaneously using canonical discriminate analysis, 4 basic hand motions were recognized from forearm EMG and f-MRI was measured simultaneously. From the results of this experiment, we can see that many places of the brain were activated for a beginner of the EMG recognition. We think that because of inexperience in EMG recognition is the main cause for multi-activation. We would like to trace the change of brain activation in subject's training stage in figure.

Abstract — **When a disaster occurs, there is a possibility that a lot of suffering person results. There is also possibility that a rescue person encounters disaster in order to rescue suffering persons. Therefore, there are many researches about rescue robots for the disaster. These robots can find sufferers and rescue them. However, they cannot evaluate sufferer's condition. If we can measure sufferer's vital sign at the disaster area, measured data will be useful for triage. So, we are investigating a measured system which is installed on a rescue robot and can measure the vital sign at the disaster area easily. SPO2 (Arterial blood oxygen saturation degree) is one of the important vital sign of a human. We can evaluate sufferer's state using SPO2. For example, normal level of SPO2 is more than 96%, and under 90% of SPO2 means that he/she is in the fatal condition. SPO2 is able to be measured by using a pulse oxymetry method easily. Therefore, we are developing the easy measuring method of SPO2 of sufferers at the disaster area which is based on pulse oxymetry. Oxy or de-oxy hemoglobin makes change the color of red blood cell. Infrared ray is absorbed in de-oxy hemoglobin and red ray is absorbed in oxy hemoglobin. Therefore, SPO2 can be measured, if light characteristics of blood can be measured. In our method, pulse signal is obtained as the reflection of applied light to the skin. And red ray and infrared ray are used to obtain two kind of pulse. And then, SPO2 is calculated using the amplitude of these two pulses. We developed and assessed a SPO2 measurement system which can measure SPO2 by only easy touching to the skin. Four subjects were studied with our system. In all cases, our developed system was able to measure SPO2 correctly.**

Keywords — **SPO_2, Easy touching, Vital sign, Hemoglobin, Pulse oxymetry.**

I. Introduction

A disaster like a big earthquake usually brings many destroyed buildings and many sufferers are generated in the disaster area. There is also possibility that a rescue person receives a serious injury or loses his/her life by a second disaster. In order to avoid these situations, robots that engage in rescue operations are being researched and developed. By employment of various types of rescue robots, rescuers can search a sufferer under debris, remove obstacles, make a route to him/her, and rescue him/her. However, they cannot measure the sufferer's condition. We think that if they can measure sufferer's vital signs (for example a body temperature, pulses, and so on) at the disaster area, it will be possible to evaluate a sufferer's condition and to realize the effective rescue ability.

So, we developed the device which detected bio-signals. This device helps triage by detecting a bio-signal after rescue with a victim. In addition, if this device is installed in a rescue robot, the rescuer can decide a priority of the help of the victim by bio-signals from this device in the rescue operation. Therefore, our goal is the development of a system which can be installed on a rescue robot, measure the sufferer's vital signs and send these data to medical doctors. In this paper, we describe developed measuring methods for SPO2 using pulse oximetry. In our method, only touching sufferer's skin with a sensor, a correct sufferer's SPO2 is obtained.

II. Methodology

A. SPO2 Detection

SPO2 is an index to show a ratio of oxygen in the body, and is also the thing which expressed the ratio of the oxidation hemoglobin of all hemoglobin by % notation. It is possible to calculate a SPO2 by using 2 types of pulse waves which are measured by infrared rays and red rays respectively. Most of the pulse oxy meter which is a general SPO2 detector is a penetrative type. But, it is difficult to detect SPO2 using penetrative method at disaster areas. So, we developed SPO2 measurement system by using pulse detection of reflection type.

B. Pulse Detection

The pulse is one of the most important vital sign of a human, and it is generated continuously while our life is lasting. The pulse is generated by blood flow that is caused by beats of the heart. In other word, we can observe the pulse as a change of artery diameter from the result of a beat of the heart.

Hemoglobin in the blood absorbs infrared ray. Therefore, if we irradiate infrared ray to a blood vessel, absorption rate of infrared ray will change as increase and decrease of a blood flow. The absorption and reflection of infrared ray inside the blood can be used to detect the pulse. It is possible

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 931–934, 2009
www.springerlink.com

to detect the pulse by measuring the blood flow of the capillary which is distributing to the skin of human body with infrared ray. In other words, change of reflection rate of infrared ray irradiated a skin of human expresses the pulse.

Then, as two characteristics of infrared ray, infrared ray has permeability to all the substances including the skin, and has a characteristic of absorption toward blood. In our method, the pulse is measured using these characteristics. Infrared ray from an infrared LED is irradiated to the skin. Even if there is one of clothes between the LED and the skin, infrared ray can permeate the clothes completely and reaches the skin surface. A part of this infrared ray is absorbed or penetrates vessels, and the rest is reflected. We can observe the pulse as the intensity change of this reflection.

By the way, red ray is also absorbed into blood. However, infrared ray is mainly absorbed into de-oxy-hemoglobin and red ray is mainly absorbed into oxy-hemoglobin. These characteristics are used to calculate SPO2 in our system. So, we developed a unified sensor which has two types of a pulse sensor. One uses infrared ray (900nm) and the other uses red ray (660nm). Both sensors consist of a LED and a photo sensor. The unified sensor is touched to the human body. It emits infrared and red ray at the same time from each LED, and each photo diodes detect the each reflected ray as electric current.

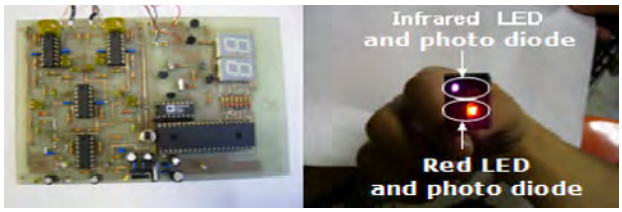

Fig. 1 SPO2 detecting system device and an unified sensor

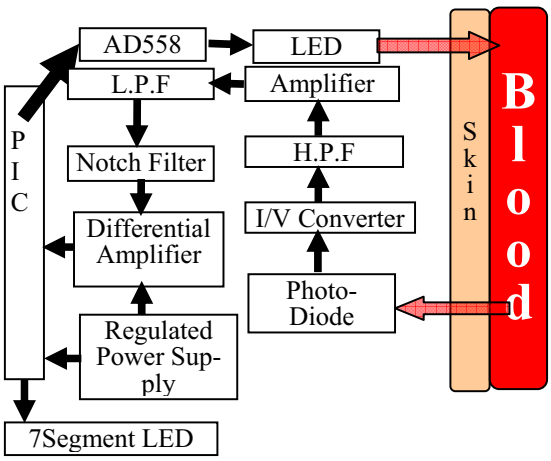

Fig. 2 Block diagram of SPO2 measuring system

Fig.1 shows the view of our system and sensor. Electric current from a photo diode is converted to voltage and then amplified and filtered for noise reduction. Direct contact with human skin of the sensor is the best condition to detect a pulse. However, in many cases at the disaster area, it is difficult to touch a sensor to a skin directly, and there are sufferer's cloths between the sensor and a skin. For such cases, in our measurement system, the brightness of a LED and the amplitude of a photo detector are able to control in order to set their level optimal. These controls of the system are conducted by a one-chip microprocessor (PIC16F877). In our system, intensity of LED is changeable by using a 8bit Digital to Analog converter (AD558). This D/A converter can change the output voltage of a power supply for LED according as a input of the converter. This voltage varies in a range from 0 to 10V by the signal changes in a range from 0 to 255. A block diagram of the system is shown in Fig.2

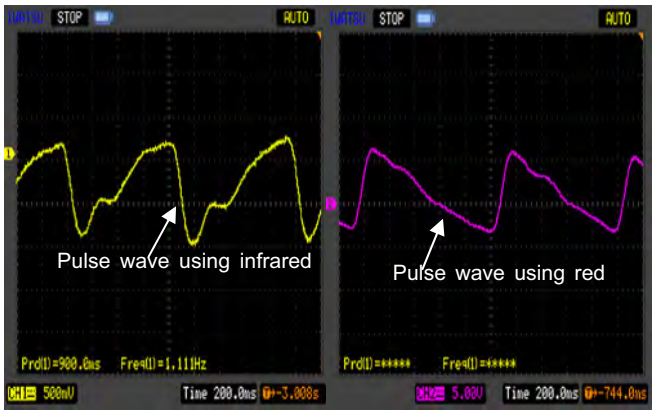

Fig. 3 2 types of measured pulse

Fig.3 shows 2types of measured pulse wave. The pulse by using infrared ray is shown as yellow line and by using red ray is shown as pink line.

C. Calculation of SPO2

It is possible to calculate SPO2 by using these pulse waves. SPO2 expresses the percentage rate of oxy-hemoglobin in blood. This value is one of the most important vital sign of a human. SPO2 reflects the body condition strongly. The body condition for each SPO2 rate is shown in Table I. It is said that about 95% and more of SPO2 is normal level in human. Some medical treatments will need in the condition from 90% to 94% of SPO2. Then, 89% and under-values of SPO2 mean fatal condition, and a correct medical treatment is necessary as soon as possible.

Table 1 Symptom Relation of SPO_2

Oxygen Saturation Blood (%)	Condition	Symptom of body
99 - 95	No damage	Good health
94 - 90	Minor damage	Minor symptom
89 - 75	Middle damage	Cyanosis
74 -	Serious damage	Damage to tissue Cellular death

Hemoglobin is in the red blood cell. And oxy or de-oxy hemoglobin makes the color of red blood cell change. Using this light characteristic of red blood cell, SPO2 can be obtained. In actuality, SPO2 is obtained as a ratio of a magnitude of the pulse for infrared ray and a magnitude of the pulse for red ray. To calculate this value, following formulas were used.

$$\Delta A = \log (I / (I - \Delta I))$$
$$\Delta B = \log (L / (L - \Delta L))$$
$$\Phi = \Delta A / \Delta B$$
$$SPO2 = (Ia/(Ia+La)) \times \Phi \times 100 \quad (1)$$

Where, *I* means the maximum amplitude of infrared pulse signal, and L means the maximum amplitude of red pulse signal. *ΔI* and *ΔL* mean the minimum amplitude respectively. *ΔA* and *ΔB* mean the difference between maximum and minimum amplitude of each signals. And φ is the absorbing light constant. *Ia* and *La* mean the average of pulse wave respectively. SPO2 is calculated by formula (1).

D. Experiment of pulse detection

Fig. 4 The pulse wave through one clothes

Usually, SPO2 is measured from a tip of finger. However, at the disaster area a SPO2 sensor is not always set on a tip of finger. In addition, a sensor is not always set on a skin directly. So, we tried to measure pulse wave from some body places expect a tip of finger, and tried to measure through clothes. In all cases, we could detect pulse wave using our developed system. An example of measured pulse wave (through clothes) is show in Fig.4.

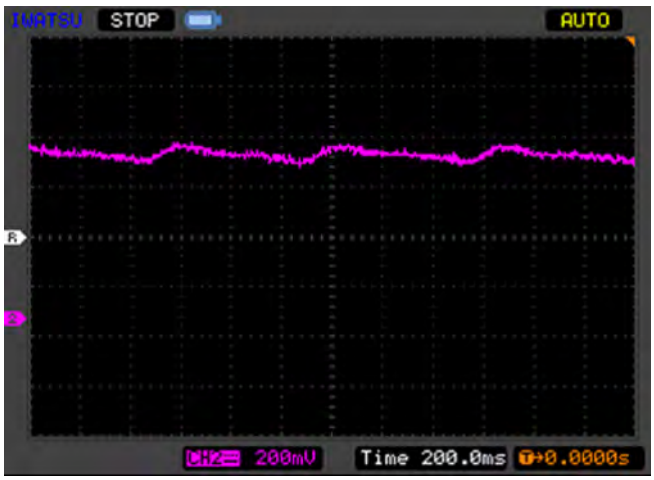

Fig. 5 The pulse wave through two clothes

An example of pulse wave that was measured through two pieces of clothes is shown in Fig.5. In this figure, pulse wave was measured as same as Fig.4. As shown in these figures, it is difficult to measure pulse wave through the clothes. However, if a gain of signed amplifier and brightness of LED is optimal, we can obtain pulse wave through the clothes.

E. Experiment of SPO2 detection

The SPO2 was experimentally measured by using our developed system. Fig.6 shows externals of the comparison experiment. In the experiment, a pulse oxy mater on the market (OLV-3100 Nihon Kohden Ltd.) was also used as a reference. This device's sensor is the penetrating type, but our sensor is the reflection type. In this figure, indicated number by 7segments means calculated SPO2 value. In Fig.6 (Experiment 1), a subject attached the sensor of a pulse oxy mater to the forefinger of the light hand, and the sensor of our device to the forefinger of the left hand respectively. As shown in Fig.6, if brightness of LEDs at set to suitable level, obtained SPO2 value will be correct. However, sometimes errors occurred in our system. Error range of the SPO2 which was measured by our developed system was about from -4% to +4%. We think that a cause of this error is mainly crosstalk between two kinds of light (infra-

red and red ray). We think that it is necessary to develop a new type unified sensor which is able to cancel this cross talk.

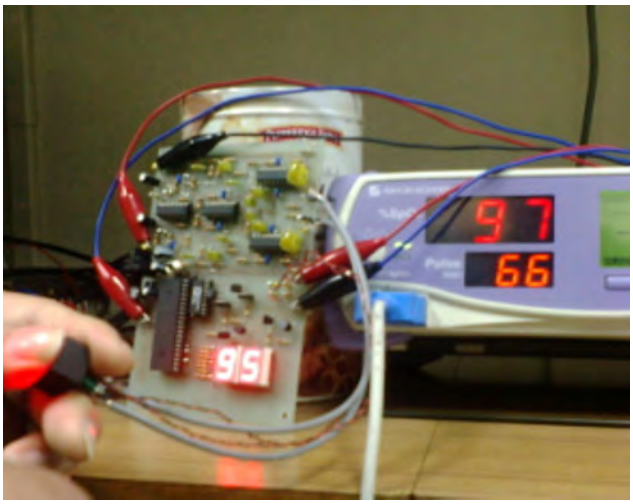

Fig. 6 Experiment 1 and this result

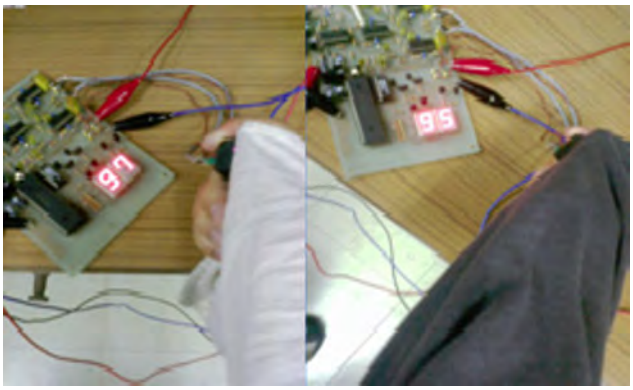

Fig. 7 Experiment 2 and this result

Fig.7 is an experiment result of acquisition on the clothes. From this fig.7, it has been understood to be able to acquire the pulse wave from clothes.

III. Conclusions

In this paper, SPO2 measuring system by using infrared and red ray was developed. This system can detect a pulse on subject's cloths and on many parts of body. And SPO2 value was calculated using measured pulse. This value had some error. Main cause of this error will be crosstalk between photo sensors. Therefore, we have concluded that if these problems are improved, our developed system will be useful to rescue sufferers. And, to install it in the rescue robot, the circuit is miniaturized.

A Estimation Method for Muscular Strength During Recognition of Hand Motion

Takemi Nakano[1], Kentaro Nagata[2], Masahumi Yamada[2] and Kazusige Magatani[1]

[1]TOKAI University, JAPAN
[2]Kanagawa RehabilitationInstitute, JAPAN

Abstract — **In this study, we describe the estimation method for muscular strength during recognition of hand motion based on surface electromyogram (SEMG). Although the muscular strength can consider the various evaluation methods, a grasp force is applied as an index to evaluate the muscular strength. Today, SEMG, which is measured from skin surface, is widely used as a control signal for many devices. Because, SEMG is one of the most important biological signal in which the human motion intention is directly reflected. And various devices using SEMG are reported by lots of researchers. Those devices which use SEMG as a control signal, we call them SEMG system. In SEMG system, to achieve high accuracy recognition is an important requirement. Therefore, conventionally SEMG system mainly focused on how to achieve this objective. Although it is also important to estimate muscular strength of motions, most of them cannot detect power of muscle. The ability to estimate muscular strength is a very important factor to control the SEMG systems. Thus, our objective of this study is to develop the estimation method for muscular strength, and reflecting the result of measured power to the controlled object. Since it was known that SEMG is formed by physiological variations in the state of muscle fiber membranes, it is thought that it can be related with grasp force. We applied to the least-squares method to construct a relationship between SEMG and grasp force. In order to construct an effective evaluation model, four SEMG measurement locations in consideration of individual difference were decided by the Monte Carlo method.**

From the experimental result, the performance of our method using two normal subjects shows that the recognition rate of four motions was perfect and the error rate of the grasp force estimation at that time was less than 5 %.

Keywords — **SEMG, The grip presumption, Operation recognition**

I. Introduction

Electromyography (EMG), is obtained by measuring the electrical signal associated with the activation of the muscle. EMG can be used for a lot of studies (e.g., clinical, biomedical, basic physiological, and biomechanical studies). Recently, in order to describe the neuromuscular activation of muscles within functional movements, kinesiological electromyography deserves attention and is established as an evaluation tool for various applied research. In order to apply it simply, the surface electromyogram (SEMG) which is measured from the skin surface, is widely used as a control source for human interface such as myoelectric prosthetic hands. The SEMG related system has many practical applications in various fields such as human interfaces. Human interfaces are reported by many researchers, and we call them "SEMG interfaces". Our study also aims to develop the SEMG interfaces like myoelectric prosthetic hands. As for a SEMG interface, it is desirable to operate it with the same feeling as the sensations of real body movements In order to achieve this objective, accurate recognition of motions, which is an essential requirement and estimation of muscular strength are both important factors. However, conventional SEMG interfaces have mainly focused on how to achieve the accuracy using sophisticated signal-processing techniques which are represented by a neural network model and a nonlinear one. We think the ability to estimate muscular strength is also an important factor in controlling it. And furthermore, in consideration of simplicity and ease of use in using the SEMG interface, construction of a simple discriminant model with a small number of measurement electrodes has been one of a SEMG interface's main requirement.

In this study, our objective is to develop an estimation method for muscular strength while maintaining the accuracy of hand motion recognition and to reflect the result of the measured power on the controlled object. In order to achieve this purpose, we directed our attention to measuring sufficient amounts of information for SEMG. This is because, the disadvantages of SEMGs are that they have a large detection area and therefore, have more potential for cross talk from adjacent muscles. Each subject's SEMG greatly differed depending on the individual's tissue characteristics, physiological cross talk and so on. Therefore, it is a problem subjects. We think that there is a suitable measurement location for every subject, and it is more effective for solving individual differences than employing strong discriminant simple linear models, and the selection method of optimal electrode configuration for using them effectively. The selection method has been one of our main objectives. As for the number of measurement electrodes, our current work shows "four electrodes"are satisfactory to our objective. In order to perform the selection of an optimal measurement electrode configuration , a 96ch multielec-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 935–937, 2009
www.springerlink.com

trode is required to be able to measure an individual's differences for SEMG.

II. Materials and Methods

A. 96ch Multi electrode and SEMG measurement system

The multi electrode is one of the features and the key of our system. This is used in order to detect an individual difference of a measuring SEMG while it is being used by the subject moving their hand. This multi electrode was attached to the forearm and an optimal electrode configuration was selected from it. The structure of this multi electrode is shown in Fig.1. To fit a forearm, we use a flexible silicone gum as the base of 96 silver electrodes. And we also designed the SEMG amplifier, which amplifies an SEMG signal about 3,000 times and the frequency band is limited from 10 Hz to 1,000 Hz. The amplified SEMG signals are sampled by a 16-bit A/D converter at a rate of 2,000 Hz.

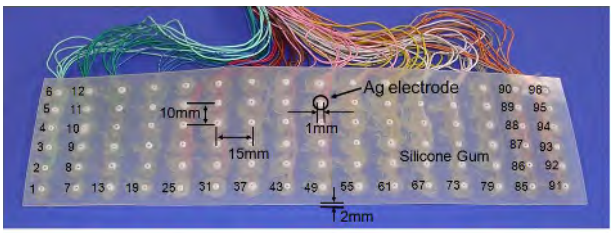

Fig. 1 Structure of 96-channles surface multi electrode. By the side of each electrode is shown the placement number from 1 to 96

B. Grasp force measurement system

In order to estimate a grasp force based on an SEMG signal, it is necessary to determine the relationship between the SEMG characteristic of grasp and a real grasp force for every individual. In the case of most measurement equipment for grasp force, the measured value is indicated by a needle that moves over a dial gauge, and as a result the acquired grasp data cannot be stored into a personal computer (PC). To analyze the relationship using a PC, we developed a grasp force measurement system that provides a real time grasp force measurement and the output data is stored on a PC with the SEMG simultaneously.

A potentiometer is attached to the axis of rotation of the indicator, and translates the indicated value on the dynamometer into a resistance value. The resistance is converted to voltage using a resistance-to-voltage converter which we made. And the analog output voltage is converted to digital for PC input. Most dynamometers indicate only the maximum grasp force, but our equipment directly indicates the change of grasp. Fig.2 shows measuring equipment for grasp force and the resistance-to-voltage converter.

Fig. 2 Grasp force measuring equipment for PC input and the resistance-to-voltage converter

C. Grasp force estimation method

It is well known that there is a close relationship between the muscular force and the EMG signal. However, we used subject-specific models to reduce problems due to intra-subject variation. Thus, our system applies a personal EMG/force relationship depending on the individual's muscle characteristics.

Now, the relationship is written by

$$y_m = \alpha + \beta X_m + \varepsilon_m \tag{1}$$

where y_m is the grasp force data which is performed as the response variable, and X_m is the features of SEGM which is performed as the predictor variables. X_m is the mean value of selected four SEMG. The term ε_m is the residual and it is written by

$$\varepsilon_m = y_m - \hat{y}_m \tag{2}$$

And a SSE is denoted by

$$SSE = \sum_{l=1}^{m} \varepsilon_m^2 \tag{3}$$

The usual method of estimation for the regression model is ordinary least squares. The coefficients α and β are determined by the condition that the sum of the square residuals is as small as possible. Thus, partial differentiation is applied to equation (12), it becomes

$$\begin{aligned} \frac{\partial(SSE)}{\partial\alpha} &= -2\sum_{l=1}^{m}(y_l - \alpha - \beta X_l) = 0 \\ \frac{\partial(SSE)}{\partial\beta} &= -2\sum_{l=1}^{m} X_l(y_l - \alpha - \beta X_l) = 0 \end{aligned} \tag{4}$$

Finally, the regression coefficients are given by

$$\hat{\beta} = \frac{\sum_{l=1}^{m}(X_l - \overline{X})(y_l - \overline{y})}{\sum_{l=1}^{m}(X_l - \overline{X})^2} \qquad (5)$$
$$\hat{\alpha} = \overline{y} - \hat{\beta}\overline{X}$$

where $\overline{X}$ is the mean of the X values and $\overline{y}$ is the mean of the y values. The result of the relationship between the SEMG and the grasp force is shown in Fig.3.

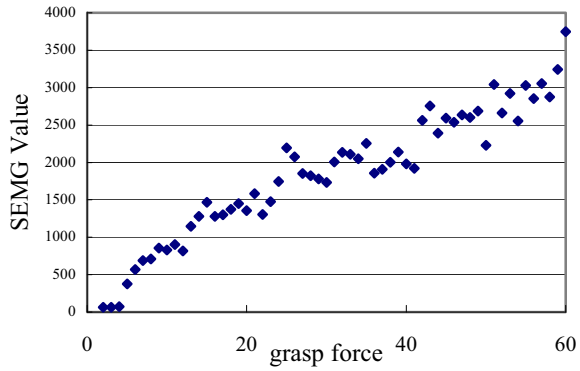

Fig.3 Relationship between the SEMG signals and measured Graspforce

III. Experimental Results and Discussion

We tested two normal subjects to evaluate our system. Requested motions were set to four types which were composed of three motions and one state (Grasp, Release, Pronation, and Rest state). The neutral state is relaxed and there is no motion. This is the initial state and recognition of the three motions is started after this state. The recognition was performed by every 300 ms, and once a grasp motion is recognized, our system moves to the grasp force estimation mode. While a grasp motion is recognized, our system keeps evaluating the grasp force. As for the motions, each subject received training to get used to the control of our system. However, we didn't instruct the subject how to operate the system. Instead, they performed in their own way according to their individual's characteristics.

The experiment was set up as follows:

1 Registration of the SEMG characteristic of the four motions for every subject. This data was used as "predefined data"for the both modeling
2 Selection of best configuration of four measurement electrodes
3 Construction of estimation model and comparison with a real measured grasp data

According to this procedure, the estimation experiment was performed. Fig.4 shows the comparison results of grasp force data between the estimated value and the real measured one. From Fig.4, the estimated value of the grasp force is a good approximation to the real one.

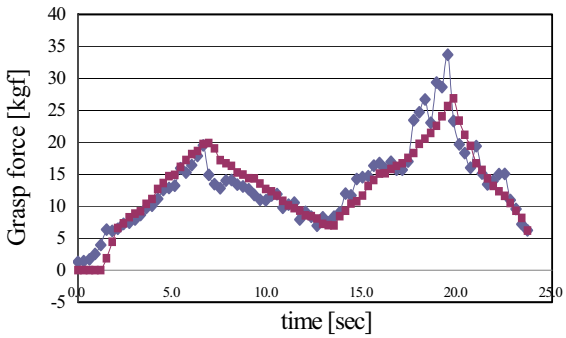

Fig. 4 The grasp force data of estimated value and real measurement value

IV. Conclusion

We have presented an estimation method for muscular strength while maintaining the accuracy of hand motion recognition, and experimental results shows the recognition of four motions were perfect and the grasp force estimated results fit well with the real measured.

The Navigation System for the Visually Impaired Using GPS

Tomoyuki Kanno[1], Kenji Yanashima[2] and Kazushige Magatani[1]

[1]Department of Electrical Engineering, Tokai University, Japan
[2]National Rehabilitation Center for the Disabled, Japan

Abstract — **It is possible for the visually impaired to walk their known area independently by using a white cane. However, in their unknown area, they cannot walk without help of others even if they can use a white cane very well. In such cases, not only a visually impaired person but he/she who assists them receives many stress in dairy activity. Therefore, many types of independent walking assist system for the visually impaired are developing. Our objective of this study is the development of an auto navigation system for the visually impaired which assists independent walking of them. This system measures the position of a visually impaired person (a user) by using GPS (Global Positioning System) and navigates him/her to the destination like as a car navigation system. In our system, a location data is stored in the map database and a position of user are analyzed and optimal route for a user to the destination is calculated. Our system guides a user to the destination along this route, and notifies the user of this route and some information for the safety walking by artificial voice. Three normal subjects were tested with our navigation system. All subjects were blind folded by an eye mask and equipped a navigation system. As a result, our system worked well and all subjects were able to walk to the destination following guidance voice. So, we are developing a new navigation system which is installed on a cellular phone. In Japan, there are some cellular phones that include GPS. And most of application programs for cellular phone are written by JAVA. Therefore, GPS included in a cellular phone will be used and every functions of the navigation system will be written by JAVA. In this paper, we also reports about this new navigation system.**

Keywords — **Visually impaired, GPS, Navigation**

I. Introduction

The objective of this study is the development of the auto navigation system that supports the independent walking of the visually impaired. This system calculates a suitable route to the destination and notifies the user of this route and some information for the safety walking. Fig.1 shows the conception of our navigation system. In our system, the destination is inputted at first. The system obtains the user's position by using GPS and calculates a suitable route to the destination by using map information of the system database. And then, the system guides the user along this route. The voice guidance is used for the notification of a route and some information to user. The action of our system likes a car navigation system. However, there are many different points from a car navigation system. For example, the suitable route is the shortest route in a car navigation system. However, in our system, the suitable route is not the shortest route and is the most safety route for the visually impaired. Therefore, a safety level of each roads are stored in the map database and these information are used in order to calculate a suitable route. And it is important to notify the user of turning and landmark information. In our system, these information is announced by pre recorded voice.

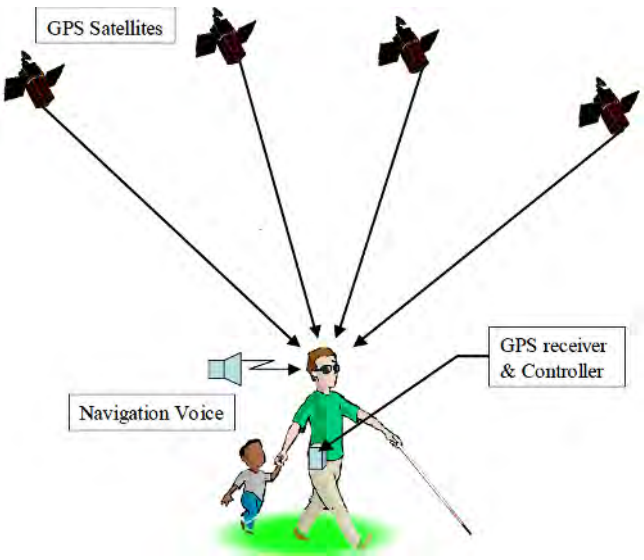

Fig. 1 Navigation system using GPS

II. Methodology

A. GPS

GPS(Global Positioning System) is one of the famous positioning system using satellites. We can obtain the latitude longitude and altitude of the measured position every one second easily. High accuracy data of positioning is able to obtain by using DGPS. In our previous system, DGPS was used in order to measure correct position. However, now we can use GPS without SA, and typical error range of

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 938–941, 2009
www.springerlink.com

GPS is less than 5m. Therefore, normal GPS is used in our system.

B. Map database

As mentioned earlier, our system has a map database. This database consists of three layers. Latitude and longitude sets of each crossing and landmark are stored in the first layer. Link information between each crossing and landmark are stored in the second layer. And safety levels of each road that is defined the way between one crossing and another are stored in the third layer. In our system, the most likelihood user's position is determined base on GPS and this database information by using map matching method [1]. And the third layer of the database is used in order to obtain a suitable route as following. An example of visualized map information based on a map database is shown in Fig.2.

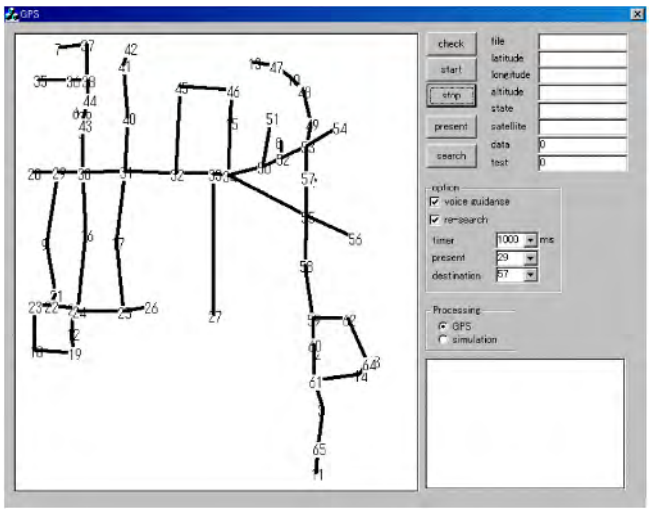

Fig. 2 Digital map

C. Suitable route

Our map database has the safety information of the rode as mentioned earlier. Generally, a rode has many kind of condition and safety. For example, even if the straight road, a rough conditioned rode is not good for the visually impaired. And a road that has stairs or has heavy traffic is not good also. So, the safety levels of each rode for the visually impaired are defined and these levels are stored in the map database. The calculation of a suitable route is based on Dijkstra's method. Generally, the every road distances are used and the suitable route is determined as the shortest distance to the destination in Dijkstra's method. In our system, logical distance of the road is determined as the product of the physical distance and the safety level. Therefore, the logical distance of bad condition road is longer than the physical distance in our system. These logical distances of each road is used for the suitable route calculation. Fig.3 shows a result of the suitable route calculation. In this figure, the system calculated the route form point 1 to point 9. The shortest route is shown in Fig.3. However, in this database the road condition was set as route 34 to 33 was danger for the visually impaired. So, the calculation result is shown in Fig.4. This result is not shortest route, however the road 34 to 33 is avoided.

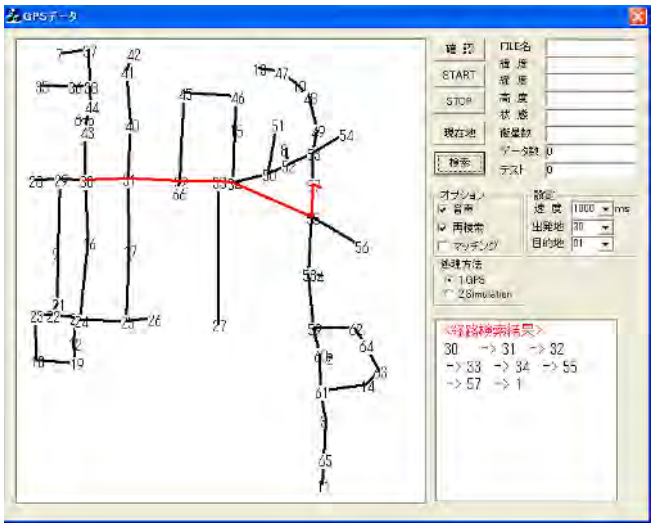

Fig. 3 Shortest route

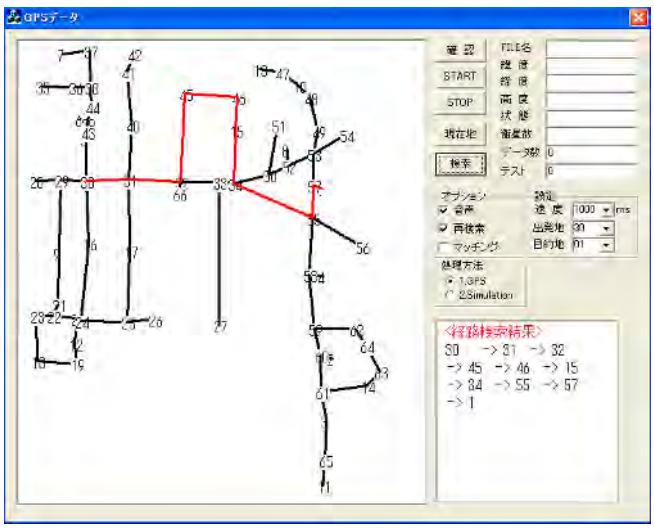

Fig. 4 Suitable route

D. Voice notification

As mentioned earlier, voice processing system is used in order to notify the user to some information of the crossing and the landmark. In our system, the processing of voice guidance is separated into two stages. When an user enters into the landmark point, the system has to notify him/her of the landmark information by pre-recorded voice. In order to avoid miss hearing of this information, voice processing system is separated into two stages. At first stage, when an user enters into the area that is 7.5m away from the landmark, the system notify of the entering to the important area by beep sound. At second stage, after the first stage when an user reach the area that is 5m away from the landmark, the voice notification is started. In our system, first beep sound means "voice guidance point comes soon", and after this warning, the voice guidance is started. The conception of this method is shown in Fig.5.

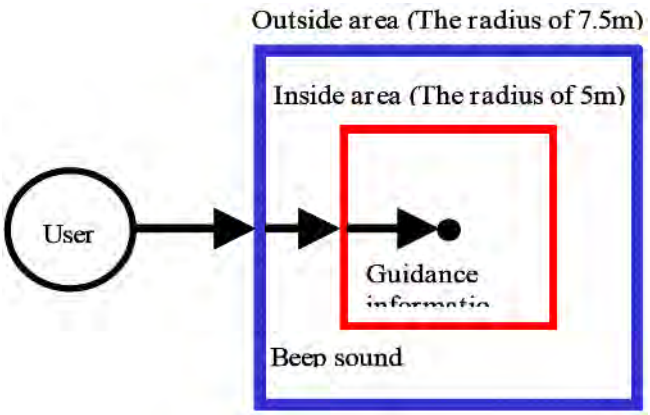

Fig. 5 Voice guidance area

III. Experiment&Results

Five normal subject was tested with our new navigation system. All subjects were blindfolded by an eye mask and equipped the system. The navigation route was set as the point 30 to point 57 and all subjects walked following the guidance voice. A green line of Fig.5 shows that walked on the calculated suitable route. From this experiment, the following characteristics became clear.

(1)All subjects could walk to the destination following the guidance voice.

(2)There are some areas where GPS did not work. Therefore, some system that estimates the position of the user is need.

(3)In some points, voice processing system did not work because of accuracy of GPS.

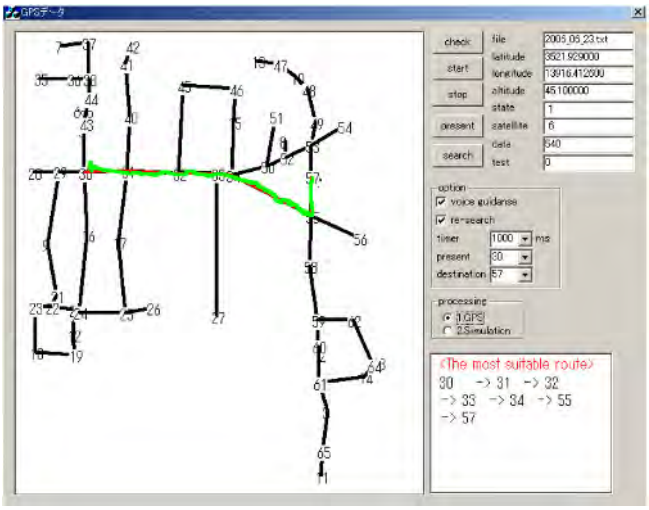

Fig. 6 A result of experiment

IV. Conclusion

In this paper, we described about our developed navigation system for the visually impaired. In this system, suitable route from start point to the destination is calculated by using user's position that is obtained using GPS and a digital map database. In our system, area information is announced by artificial voice at the landmark. Developed navigation system was tested for normal subject. The subject equipped our system and walked along generated suitable route. From this experiments, some problems of our system become clear. However, we think that these problems will be improved near future. And our navigation system will be a very valuable one to support activities of the

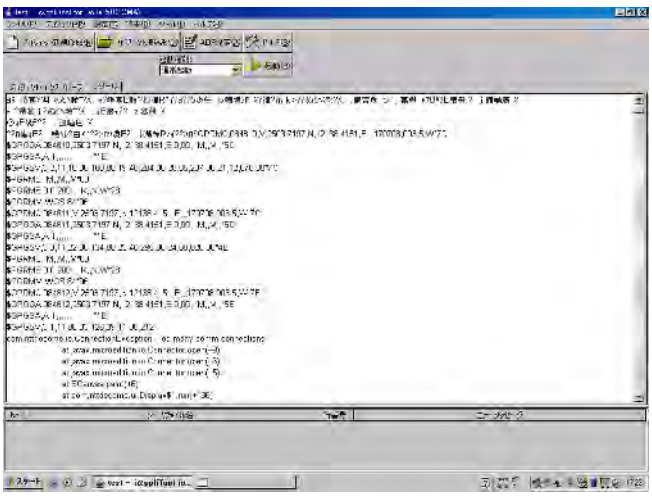

Fig. 7 Location data catched by cellular phone

visually impaired. This study, we propose a navigation system on cellular phone. Cellular phone has high performance processor, high density memory and GPS receiver. It is possible to make more small navigation system for visually impaired. We make an application program written by JAVA language. We test this program, and get location data. Infuture, we will make navigation program on cellular phone.

Investigation of Similarities among Human Joints through the Coding System of Human Joint Properties—Part 1

S.C. Chen[1], S.T. Hsu[2], C.L. Liu[2] and C.H. Yu[3]

[1]Department of Physical Medicine and Rehabilitation, Taipei Medical University and Hospital, Taipei, Taiwan
[2]Department of Mechanical Engineering, National Taiwan University, Taipei, Taiwan
[3]Department of Physical Therapy and Assistive Technology, National Yang-Ming University, Taipei, Taiwan

Abstract — **Properties of human joints are essential for orthopedic practice, physical therapy, designing related motion assistive devices, etc. Few studies, however, have ever tried to collect and arrange this knowledge, making researchers need to look up references tiresomely. In view of the above, Hsu et al. [1] proposed a coding system of human joint properties, trying to make reference consulting more convenient and efficient. This coding system includes eight properties of 41 kinds of human joints. The eight properties are locations of joints, numbers of bones involved in joints, functions of joints, shapes of joint surfaces, arthrokinematics of joints, directions of rotation of joints, directions of translation of joints, and numbers of axes of joints. Our work, taking one step ahead, adds one property—the weight bearing of joints—into the original coding system, so as to make the coding system more suitable for medical use. For our newly added property, simple digits are assigned as codes to symbolize the behavior of the 41 kinds of joints. This new property is then joined into the original coding system, and a new coding system with the nine properties is established as a result. In conclusion, this new coding system not only serves as a concise approach to investigating human joint properties, but relatively meets the needs of medical science. We expect that researchers can make further comprehensive studies with this new coding system. Certainly, to upgrade and improve this new classification system, we need specialists' and experts' feedbacks.**

Keywords — **Coding system, weight bearing, property of human joint, human joint.**

I. Introduction

The concern with properties of human joints, which are the essence of orthopedic practice, physical therapy, as well as designing motion assistive devices, has been growing recently. Pertinent studies have focused on properties of such specific joints as the shoulder joint [2], elbow joint [3], wrist joint [4], hip joint [5], and so forth [6, 7], making the related knowledge well developed and human joint properties well understood.

Germane information is so plentiful while works trying to organize it are so rare that reference consulting has been an arduous task. To solve this problem, Hsu et al. [1] collected and arranged this copious knowledge, and proposed a coding system containing eight properties of the 41 kinds of human joints. The eight properties are locations of joints, numbers of bones involved in joints, functions of joints, shapes of joint surfaces, arthrokinematics of joints, directions of rotation of joints, directions of translation of joints, and numbers of axes of joints.

In our work, we attempt to add one more property—the weight bearing of joints, an indispensible factor in the field of rehabilitation—into the original coding system, expecting to enable this system to be more favorable for medical use.

II. Coding procedure for weight bearing

A. Weight bearing of human joints

Weight bearing of joints can be defined as a capability of tissues to bear the compressive force imposed by the weight of the body located above them without being injured or damaged [8]. Besides, joints situated in the lower extremity or in the axial body are generally belonging to weight-bearing joints [8]. Given this point, we categorize the 41 kinds of joints considered in [1] into two groups: weight-bearing joints and non-weight-bearing joints. And those in the lower extremity or axial body are weight-bearing, while others are not. This classification is given in Table 1.

Table 1 Classification of joints according to the property of weight bearing

Weight-bearing joints	Non-weight-bearing joints
Cervical spine, lumbar spine, lumbosacral j't, thoracic spine, atlantoaxial j't, atlanto-occipital j't, symphysis pubis j't, intermetatarsal j't, patellofemoral j't, sacroiliac j't, tarsometatarsal j't, proximal tibiofibular j't, distal tibiofibular j't, subtalar j't, interphalangeal j't (foot), tibiofemoral j't, metatarsophalangeal j't, hip j't, transverse tarsal j't, talocrural j't	Temporomandibular j't, suture j't of the skull, sternocostal j't, intrasternal j't, costotransverse j't, costovertebral j't, 2nd, 3rd carpometacarpal j't, intermetacarpal j't, acromioclavicular j't, humeroulnar j't, interphalangeal j't (hand), proximal radioulnar j't, distal radioulnar j't, metacarpophalangeal j't, 1st, 4th, 5th carpometacarpal j't, sternoclavicular j't, humeroradial j't, glenohumeral j't, scapulocostal j't, radiocarpal j't, midcarpal j't

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 942–945, 2009
www.springerlink.com

B. Coding rule of the property of weight bearing

Since we are to code the joints and combine the coding result with the ones in [1], the coding rule of the property of weight bearing is required. We define the coding rule as follows: If a joint is a weight-bearing joint, it is coded by 1; if not, it is coded by 0. For instance, the cervical spine in the left column of Table 1 is weight bearing, and thus the code of this property of the cervical spine is 1; on the other hand, the temporomandibular joint in the right column possesses no weight-bearing ability, and thus its code is 0.

C. Codes of weight bearing of joints

Based on the definition given above, all the 41 kinds of joints are then coded. The coding result is given in Table 2, in which the order of the 41 kinds of joints is arranged by their locations: from superior to inferior and from proximal to distal.

Table 2 Codes of weight bearing of joints

Joint	Code of weight bearing
Suture j't of the skull	0
Temporomandibular j't	0
Atlanto-occipital j't	1
Atlantoaxial j't	1
Cervical spine	1
Thoracic spine	1
Lumbar spine	1
Lumbosacral j't	1

	7	Combination of 1, 2 and 3
	a	Dependent trans. alone a medial-lateral axis
	b	Dependent trans. along an anterior-posterior axis
	c	Dependent trans. along a vertical axis
Number of axes	0	Nonaxial joint
	1	Uniaxial joint
	2	Biaxial joint
	3	Triaxial joint
	s	(Unable to be classified)

IV. Discussion

A coding system containing nine joint properties is proposed in this work. For each property, all the 41 kinds of joints are assigned appropriate codes; namely, the joints are expressed by a series of nine digits indicating their nine properties, allowing researchers to learn their needed information through readily consulting the table. Once the code of a certain property is learned, Table 2 and Table 4 can serve as "decoders" to decipher the code, and knowledge of the required properties is then obtained. The coding system, thus, presents an efficient approach to acquiring or gathering pertinent materials.

A. Applications of the coding system

The advantage given above further enables researches to learn these properties simultaneously, for they do not have to consult to different references individually for an individual need anymore. Instead, all the nine properties of these 41 joints can be readily obtained at one time by referring to this system. Thus, a systematical classification of joints, or even an investigation of similarities among joints, is made to be possible. Take the property of the number of axes for example. We can classify the joints according to this property by simply sorting their codes of this property with the help of suitable software. The result classifies all the joints into five groups, as the five ones indicated in the row of Number of Axes in Table 4; joints in the same group possess the similarity regarding the property.

In the same way, similarities among different joints for two or more properties can also be disclosed as well. For instance, if we are interested in finding out all the diarthrotic joints which are also saddle joints, we can focus our attention on the codes of function and shape of surfaces. By searching for the joints with the code of function being 3 (indicating the diarthrotic joint), and the code of shape of surfaces being 5 (indicating the saddle joint), three kinds of joints satisfying this requirement are found; they are the sternoclavicular joint, midcarpal joint, and 1st, 4th and 5th carpometacarpal joint. Other similarities among joints for various combinations of properties can be determined through the same method.

Properties of human joints are the crucial foundation of such pertinent medical fields as orthopedic practice, physical therapy, and designing related motion assistive devices. In addition to these, human joint properties, especially those concerning movement, are also related to the mechanism design for humanoid robots in the mechanical field [9]. It could be beneficial to apply this coding system to this mechanical field. For example, researchers can code the kinematic pairs, which are considered as joints of a kinematic chain [10], according to their pertinent properties. With the two sets of coding systems, relationship between human joints and kinematic pairs will be revealed. Moreover, the equivalent kinematic pairs of human joints, allowing corresponding movements to those of human joints, can also be determined.

B. Interdependence among the properties

The coding system proposed in this study considers nine different properties, six of which are interdependent upon at least one another, and three interdependent cases exist.

The first interdependence occurs among the function, the direction of rotation, direction of translation, and the number of axes. If a joint rotates around one, two, or three axes, its number of axis was one, two, or three. If a joint rotating around no axis allows translations, its number of axis was 0. If a joint allows neither rotation nor translation, then its function is synarthrotic and is coded by "s" in Table 3. The interdependence is denoted by ID1 in Table 5.

The second interdependence occurs among the function and the shape of surfaces. If the code of the function is 1 or 2, the code of the shape of surfaces must be 0; only when the code of the function is 3 can the code of the shape of surfaces be 1 to 6. It agrees with the fact that only diarthrotic joints can be classified according to their shapes [11]. The interdependence is denoted by ID2 in Table 5.

The third interdependence occurs among the function and the arthrokinematics. If the code of the function is 1, the code of the shape of surfaces must be 0; only when the code of the function is 2 or 3 can the code of the shape of surfaces be 1 to 7. It indicates that the synarthrotic joint allows no movement between bones. The interdependence is denoted by ID3 in Table 5.

Except the three sorts of interdependences, other properties are independent of each other.

Table 5 Interdependence among the properties

	Location	Number of bones	Function	Shape of surfaces	Arthrokinematics	Direction of rotation	Direction of translation	Number of axes	Weight bearing
Location	--								
Number of bones		--							
Function			--	ID2	ID3	ID1	ID1	ID1	
Shape of surfaces			ID2	--					
Arthrokinematics			ID3		--				
Direction of rotation			ID1			--	ID1	ID1	
Direction of translation			ID1			ID1	--	ID1	
Number of axes			ID1			ID1	ID1	--	
Weight bearing									--

V. Conclusions

This work proposed a coding system containing nine properties of human joints. The system serves as a concise approach to investigating joint properties, and also meets the needs of medical science. Besides, with this system, comprehensive inspection of information about joints and other interdisciplinary applications are attainable. In the future, feedbacks from specialists and experts are needed, so as to enhance this new classification system.

Abstract — **In rehabilitation engineering and assistive technology, precedent researches have focused on a single characteristic or property of a single joint, while little attention was paid to similarities among joints. This work attempts to investigate similarities among human joints by referring to the coding system of human joint properties proposed in Part 1. To investigate the similarities, eight out of the nine properties in this coding system (except the locations of joints) are divided into five cases. In Case 1, we consider the numbers of bones involved in joints and shapes of joint surfaces. In Case 2, we consider the directions of rotation, directions of translation, and numbers of axes of joints. In Cases 3, 4 and 5, the functions of joints, arthrokinematics of joints, and weight bearing of joints are considered respectively. Similarities among the 41 kinds of joints in this coding system are hereby investigated by sorting the joints' codes in each case. As results, the 41 kinds of joints are classified into 12, 13, 3, 6 and 2 groups in Case 1 to Case 5 in sequence. Regarding the properties discussed in each case, joints in the same group possess similar properties. However, four groups in Case 1, four groups in Case 2, and one group in Case 4 each have only one kind of joint, which is unique, having no similarities with other joints in the properties considered. In conclusion, similarities among human joints are discovered systematically by referring to the coding system proposed in Part 1. These similarities offer an innovative and utile reference for assistive technology device designs and other pertinent research. Similarities beyond these five cases can be further investigated with the same method.**

Keywords — **Similarity among human joints, coding system, property of human joint, sorting, human joint.**

I. Introduction

In the field of rehabilitation engineering and assistive technology, numerous attempts have been successfully made to discover properties of human joints; knowledge of joint properties has been widely understood. These properties are indispensable to pertinent researches in such medicine fields as physical medicine, rehabilitation, assistive technology devices, and so forth. Take continuous passive motion (CPM) for example. It was proved that CPM has a great effect on recovering the range of motion of joints [1, 2], and a considerable number of designs for CPM devices have been proposed for various joints based on their various properties [3, 4]. Besides, many types of artificial joints have also been proposed for different human joints [5, 6]. Another research field related to human joint properties is the mechanism design for humanoid robots. In its designing process, the degrees of freedom (DOFs) of human joints have to be considered, so that the DOFs of humanoid robot joints can approximate to that of human joints [7]. Though properties of human joints are extensively applied in these pertinent fields, most studies have focused on a single property of a single joint; properties of joints have been investigated individually before a designing process begins. Similarity among joints, deserving consideration, has unfortunately hitherto been neglected [8]. If similarities among joints are taken into consideration, one advantage is that, for instance, designers can simply change one existing design of a similar joint to complete a new design fitting their needs. Developing a design in this way thus takes much less time than beginning a completely new one from scratch. On these grounds, the purpose of this paper is to investigate the similarities among human joints.

To achieve this purpose, we attempt to apply the coding system proposed in the first part of our work. One reason for using coding systems, according to Groover [9], is design retrieval—a mechanism for determining whether a similar part exists; if so, an uncomplicated change in an existing part can be made. This is our expectation. Therefore, the coding system is utilized in this part of our work as an approach to investigating similarities among joints.

II. Determination of Cases and Research Method

The coding system proposed in Part 1 considers nine properties, eight of which are of our interests (except the locations). They are categorized into five cases.

In Case 1, the number of bones involved and the shape of surfaces are considered. The two properties are both pertinent to anatomical structures of joints. In Case 2, the direction of rotation, direction of translation, and the number of axes are considered. The three properties are related to the direction of motion allowed at joints. In Case 3, the func-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 946–949, 2009
www.springerlink.com

tion of joints is considered. This property has to do with range of motion at joints. In Case 4, we consider the arthrokinematics of joints, which refers to relative movements occurring between joint surfaces. In Case 5, the weight bearing of joints is considered, which is an essential factor widely considered in physical therapy.

The similarities of joints are then investigated based on these five cases. In each case, codes of the considered properties are sorted incrementally by Microsoft Excel®. Similarities among joints can then be determined by the sorting results.

III. Sorting Procedure and Results

For Case 1, the codes of the number of bones involved and the shape of surfaces are to be sorted. We select the codes of the number of bones as the primary codes for sorting, the codes of the shape of surfaces as the secondary codes. And the sorting result is given in Table 1. The result remains constant if we switch "the codes of the number of bones involved" and "the codes of the shape of surfaces" to secondary codes and primary codes respectively.

It is learned from Table 1, from the top, that a group of 16 kinds of joints has similarities concerning the two properties; another group containing two kinds of joints has similarities; still another group containing five ones has similarities, and so on. Altogether, there are 12 groups of joints, among which four groups possess only one kind of joint. Joints in these four groups are unique, sharing no similarities with others in the properties considered.

For Case 2, as given in Table 2, the codes of the direction of rotation, direction of translation, and the number of axes are to be sorted. The codes of the direction of rotation is chosen as the primary codes for sorting, the codes of the direction of translation as the secondary, and the codes of the number of axes as the third. Similarly, the order of sorting has no influence on the result.

As a result of Case 2, joints are classified into 13 groups; those in the same group possess same properties considered in this case. Among the 13 groups, four groups possess only one kind of joint.

Table 1 Similarity among joints and the sorting result regarding the number of bones and shape of surfaces

Distal tibiofibular j't	4	1	2	0	3	**c**	**c**	**1**	1	

With the identical sorting procedure, joints can be sorted for Cases 3, 4 and 5, and similarities among joints in these cases are then obtained. The results are directly presented in Table 3 to Table 5. Each table gives the codes of the joints belonging to a group as well as the number of the joints sharing the similarity.

Table 3 Similarity among joints regarding the function

Joints	Code	Number of joints
Suture j't of the skull, sternocostal j't, intrasternal j't, 2nd, 3rd carpometacarpal j't, symphysis pubis j't	1	5
Cervical spine, thoracic spine, lumbar spine, lumbosacral j't, costovertebral j't, costotransverse j't, intermetacarpal j't, sacroiliac j't, patellofemoral j't, proximal tibiofibular j't, distal tibiofibular j't, transverse tarsal j't, tarsometatarsal j't, intermetatarsal j't	2	14

IV. Discussion

Five cases of similarities are discovered in this work through the coding system proposed in Part 1. Researchers can determine any other case of similarities based on their needs through the same method. Since the coding system provides us with nine properties of joints, a combination of up to 2^9-1= 511 cases can then be investigated.

The similarities determined in this work may be applied to practical use. Take the atlantoaxial joint, humeroradial joint, and the tibiofemoral joint in Table 2 for example. As indicated in this table, all the three joints possess the same direction of rotation, same direction of translation, and (therefore) the same number of axes. Even if almost all the other codes are different, it could be possible to make a pertinent adjustment in an existing device related to the movement of, for instance, the atlantoaxial joint to produce a fitting device applicable to the humeroradial joint or the tibiofemoral joint.

In this work, joints are sorted by their codes with the help of packaged software. Programs searching the codes or expert systems that help users find out the appointed codes are worth developing. With them, joints possessing the required codes of the appointed properties can therefore be discovered with more efficiency, thus reducing the time for discovering the similarities among joints.

V. Conclusions

In this part of our work, similarities among joints are discovered systematically by sorting their codes proposed in Part 1. The similarities can serve as an innovative and utile reference for assistive technology device designs and other pertinent studies. Similarities beyond these five cases can also be determined with the same method.

Circadian Rhythm Monitoring in HomeCare Systems

M. Cerny, M. Penhaker

VSB – Technical University Ostrava, Faculty of Electrical Engineering and Computer Science, Biomedical Engineering Laboratory, Ostrava, Czech Republic

Abstract — **HomeCare system is designed, developed and realized in our laboratory and special Test flat. It is compact remote monitoring system of base life functions primarily. But not only standard biosignals like ECG and others can give us information about changes in state of health of monitored man. One of the possible monitored values can be circadian rhythm.**

The monitoring of the circadian rhythm of people in HomeCare systems is very usable. Each man has own rhythm. This rhythm is periodical for elderly people. In case the life cycle is changed, we can deduce some heath problem will occur.

This article shows our designed a tested technical solutions for circadian rhythm monitoring single elderly man in his flat and methods of interpretation.

Keywords — **ZigBee, HomeCare, Day Activity**

I. Introduction

Elderly people living alone in their own flats have similar day activities. Their own one day cycle is similar for the most of days. There are not so many abnormalities. The personal characteristic circadian rhythm could be calculated from several measured circadian cycles. If any deviation from the characteristic circadian rhythm is detected, it could signify a health problem.

The typical example of day life cycles abnormality could be the typical case of early fall detection during night hours. Old alone living man must regularly visit toilet between second and third hour in the morning. One day he wakes up and goes to the toilet. But he doesn't come back to his bed. The movement monitoring system has found out that he reached the toilet and went away from the toilet. The last found man's position was at the corridor. Another movement had not been detected in other rooms in his flat for a set up time. It could be the sign that he has fallen down. Afterwards the movement monitoring system goes to alarm state. Thanks to the early fall detection his broken leg could be sooner restored to health.

There are two categories of the circadian rhythms deviations. The first type is "short-term" deviation. This type of deviation was described in previous example. It is detection of urgent and accidental changes of circadian rhythm. This detection helps to recognize urgent health problems and accidents.

The second category is "long-term deviation". It means that the evolution of the circadian rhythm is recognized. This evolution could not be strictly pathologic. The degree of pathology has to classify the doctor. Afterwards, this knowledge could be applied to the adaptive and self learning system, which will classify these rhythm changes automatically. The typical example of long term deviation can be the change in the frequency of toilet room visiting.

Of these reasons the monitoring of the personal activity circadian rhythms has information validity in the HomeCare projects.

There are discussed technical solutions for movement monitoring, first. Than there is discussed designed autonomous movement monitoring system.

II. Movement monitoring

The first designed and realized method of the movement monitoring uses standard PIR sensors. These sensors were modified. The communication was realized by ZigBee technology. The measured data were represented in PC by visualization software which was developed in Labview.

This method has some advantages: The hardware is powered by only one CR battery. No wires are required for data transmission. The sensor can work for a long time.

The disadvantage is: The bigger pet could be detected instead of person. In the case that more people will be in the flat, there are misdetections too. These misdetections will influence circadian cycle monitoring. The information about the position is not exact. The area of presence is only found out.

The second designed solution uses the Location Engine solution from Texas Instruments. This engine is included in their single on chip ZigBee chip named CC2431.

The location algorithm used in the CC2431 Location Engine is based on Received Signal Strength Indicator (RSSI) values. The RSSI value will decrease when the distance increases.

Four reference nodes were placed in the flat. The flat user was equipped with special watches, where was mounted the ZigBee chip with location engine.

The advantage of this solution is that the information about position of monitored person is as exact as possible. It

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 950–953, 2009
www.springerlink.com

isn't possible to detect incorrectly other person or pet in the flat.

This solution has one important disadvantage: The user has to wear an active ZigBee device. This fact could be unacceptable for some elderly people. But the ZigBee chip could be a part of continuously measuring device for ECG measurement which is used in HomeCare system. Thanks to this solution the movement monitoring could be more tolerable for some people.

A. Technical solution discussion

The definitive determination of the human position in the flat can not be done with only one of the introduced movement monitoring technologies. The combination of proposed two technologies has to be used for definitive person's position determination. The additional usage of the optoelectronic bars in the doors will be optimal. Afterwards, the person in the flat can be successfully located. The circadian rhythm could be constructed from these determined person's position data.

III. The Circadian Rhythm Interpretation

The interpretation of the measured data is an important part of this project. It was necessary to define some condition for the data interpretation, respective circadian rhythm construction. There are conditions which are related to long and short term activities representation. From circadian rhythm has to be recognizable person's movement between monitored rooms in his flat. The short time activities have to be recognizable too. The circadian rhythm shall be processed in the microprocessors by the reason of planned movement system autonomy.

A. The mathematical description

The information about human's position in the flat is different for day hours and night hours. In the day hours is active location engine, so measured data are more precise that in the nigh hours, when only the PIR sensor based measurement is active. Actual position of human in the flat could be defined as vector P (eq.1):

$$P = f(x, y, t)$$
$$\textit{where}$$
$$x, y \textit{ are coordinates of persons's position} \quad (1)$$
$$t \textit{ is time}$$

It could be represented by following picture. The displayed flat layout concerns to our HomeCare Testing Flat

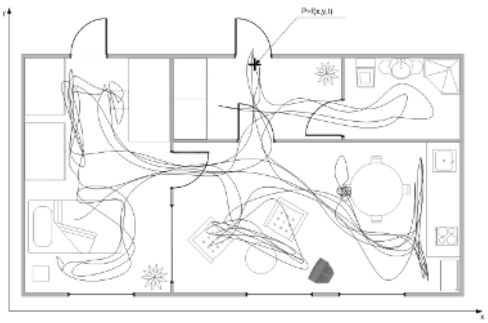

Fig. 1. The movement monitoring during day hours

Information about human's position in the flat is not so exact during night hours due to method of movement monitoring. The PIR based monitoring system purveys only information about area of supposed person's presence. The coordinates of person's position in the P vector are replaced by coordinates of the middle of PIR sensor detection area (see Fig. 2.).

Because the information about person's position given by PIR sensors could be influenced by many errors (misdetection due to for example pets) the additional system of optoelectronic bars controls the validity information.

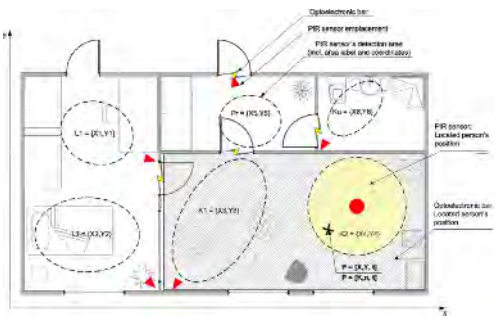

Fig. 2. The movement monitoring during night hours

B. The chronological succession of person's presence in the flat

The simplest method how to represent measured data is the chronological succession of person's presence in the monitored areas of the flat. The circadian rhythm which corresponds to the information about person's movement activity in the flat could be represented by:

$$C = \sum_{t=0}^{24} K[t] \qquad K[t] \in \mathbf{C},\ t \in \mathbf{R}^{+}$$

where (2)

K is a code for monitored area in the flat

The K code for monitored area of the flat could be represented by RGB code. This coding is very useful for next representation of measured data. For each room of flat has been defined own color. Each color is described by the RGB code.

The RGB code definition for each are must be carefully defined. From the RGB coding has to easily be recognizable connections between coded areas. Each room of the flat has one of the RGB code part in maximal values are zeros. The distance from beginning of coordinates system is took into consideration. In the figure 3 is displayed suitable RGB coding for our testing flat. RGB coding is suitable for larger flats too, it is because of number of possible combinations.

Fig. 3. RGB codes for each room of flat and the position vector p

When RGB coding is used the circadian rhythm could be displayed as “chronological succession of RGB codes” .

C. The position matrix

Actual position of monitored person it flat is defined by vector P (eq.1.). When the monitored flat will be represented by matrix, which has the same dimensions as the monitored flat (in the cm) afterwards matrix elements could represent person’s presence in the monitored flat.

$$a_{i,j} = \begin{cases} 0 & \text{for } i \neq x,\ j \neq y \\ 1 & \text{for } i = x,\ j = y \end{cases}$$

where (3)

$a_{i,j}$ *is matrix element*

x, y *are coordinates of person's position*

The actual position of the person in the flat will be represented by one non-zero matrix element in the position matrix. The circadian rhythm *C* could be afterwards represented by the position matrix (eq.4.). This matrix has to be three dimensional matrix, where each two dimensional matrix *M(t)* concerns to one moment (see Fig. 4.).

$$C = \sum_{t=0}^{24} M[t] \qquad \text{where } t \in \mathbf{R}^{+}$$

$$M[t] = \sum_{i=0}^{x_{max}} \sum_{i=0}^{y_{max}} a_{i,j}[t] \qquad (4)$$

$$\text{where } a_{i,j}[t] = \begin{cases} 0 \text{ for } i \neq x_t,\ j \neq y_t \\ 1 \text{ for } i = x_t,\ j = y_t \end{cases}$$

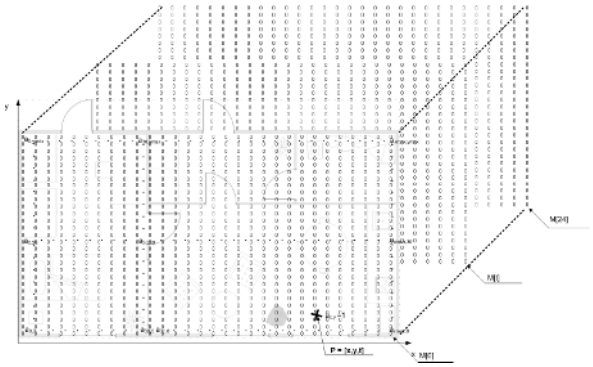

Fig. 4. The position matrix

The position matrix is not suitable for next data processing, and it is not useful for data processing in the microcontrollers, what is one of the conditions defined in the beginnings chapter IV.

D. The position vector

The actual position of the monitored person could be defined as a position vector. This vector is a distance coordinates beginnings and the measured actual position.

The module of this vector could be counted for each measured person’s position (eq. 5.).

$$|\vec{p}| = \sqrt{p_x^2 + p_y^2} \qquad (5)$$

E. The colored vector of position

In the consequence of defined conditions and proposed possibilities of circadian rhythm interpretation it seems to

be most effective to combine "The chronological succession of RGB codes" and "The colored vector of position".

Afterwards can be constructed colored vector of position (Fig. 6.). The x axis is the time axis, the y axis has values of $|\vec{p}|$. The RGB code has been added to each recorded value of position, to we can see, where (in which room) the user was found out. The added RGB code is necessary, because the exact person's position can not be exactly recognized from position vector modulus.

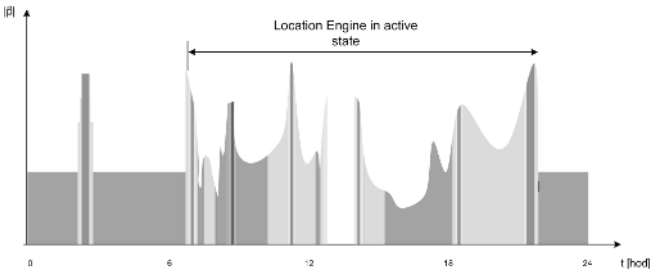

Fig. 5. Colored vector of position (simulation)

This type of interpretation of circadian rhythm concerns to all conditions defined above. The color of vector is very usable for processing of long-term deviations. Personal characteristic long term circadian rhythm can be constructed from the colored vector of position. The values of modulus of position vector are usable for short term deviations detections and classification.

IV. Conclusion

The proposed HomeCare system has been particularly realized and tested in our special HomeCare Testing Flat. The realized measuring devices have been based on Bluetooth technology. The new measuring devices using ZigBee are in progress now and they will be tested in the near future.

The circadian rhythm monitoring system is an important part of our HomeCare system and it is tested in our Testing flat too. The autonomous movement monitoring system was designed and it is in the realization now. The method of the circadian rhythm construction has been specified. The analyze system has to be designed.

The goals of this work could be used in HomeCare systems or in the other circadian rhythms monitoring projects.

Effects of Muscle Vibration on Independent Finger Movements

B.-S. Yang[1,2] and S.-J. Chen[1]

[1]Department of Mechanical Engineering, National Chiao Tung University, Hsinchu, Taiwan
[2]Brain Research Center, National Chiao Tung University, Hsinchu, Taiwan

Abstract — **Previous studies had demonstrated that small amplitude muscle vibration (MV) could increase the motor pathway excitability of the vibrated hand muscle and inhibit the excitability motor pathways of neighboring muscles in healthy individuals. The purpose of this study is to examine whether the vibration-induced neurophysiological changes reflect in the voluntary control of finger movements. We tested the hypothesis that MV to individual hand muscle (abductor pollicis brevis, APB; first dorsal interosseus, FDI; or abductor digiti minimi, ADM) affects the control of finger abduction/adduction. Each fingertip position was captured using a motion capture system during four experiment conditions: no MV, MV to APB, MV to FDI, and MV to ADM. Two consecutive 10-s trials in each condition were tested for each finger. We calculated individuation index (Iind) and index of selective activation (ISA) to compare finger independency with and without MV. The results indicated that muscle vibration could enhance the independency of finger movements.**

Keywords — **Muscle Vibration, Finger independency, Muscle selectivity**

I. Introduction

Lack of finger independency and muscle selectivity is a major contributor to hand dysfunction post stroke [1-4]. Rosenkranz and Rothwell [5] reported that for healthy adults, small amplitude (<0.5mm) muscle vibration to specific hand muscle (abductor pollicis brevis, APB, first dorsal interossei, FDI or abductor minimi digiti muscle, ADM) could increase the motor-evoked potential (MEP) of the vibrated muscle and inhibit or provide no change to the MEPs in other same-hand muscles. Our previous study showed that this vibration-induced neurophysiological modulations might also occur in stroke [6]. The purpose of this study was to explore whether the vibration-modulated neurophyiological changes reflect in the voluntary control of finger movements. We specifically tested the hypothesis that muscle vibration to specific hand muscle affects the individuation of finger movements in healthy adults. If muscle vibration can improve independent finger movement, it may be a useful tool for stoke hand rehabilitation.

II. Materials and methods

A. Subjects

Six healthy subjects (aged 20-25 yrs) without musculoskeletal or motor deficits in upper limbs were studied. The test procedure of this study was approved by the Institutional Review Board of Chang Gung Memorial Hospital. Every subject provided a written consent prior to the experiment.

B. Electromyography (EMG)

Surface EMG recordings were made from the abductor pollicis brevis (APB), the first dorsal interosseus (FDI), and abductor digiti minimi (ADM) using AMT-4 system (Bortec, Alberta, Canada). Signals were sampled at 2 kHz and the raw EMG was filtered with a band-pass of 30 Hz to 1 kHz to analysis afterwards.

C. Muscle Vibration (MV)

Muscle vibration was given to the target muscle using an electromagnetic vibrator (Ling Dynamics System Ltd, United Kingdom) with a 7mm diameter custom-made probe. The vibration frequency was set at 80 Hz and the amplitude was adjusted to just below the threshold for perceiving an illusory movement for each subject [7]. The vibration started 0.5 second before the instructed movement of the finger and lasted till 0.5 second after the end of the movement.

D. Experiment Design

Each subject was comfortably seated beside a table with the forearm and palm of the dominant upper limb positioned on the custom-made device. The shoulder was 30° abduction. Each finger was loosely spread apart to avoid obstructing instructed finger by other fingers during abduction/adduction movements. During experiments, we put some talcum powder on the table to minimize the friction between the fingers and the table. Six-camera motion capture system (Smart-D, BTS Bioengineering, Italy) was used to capture the fingertip movements at 250 Hz.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 954–956, 2009
www.springerlink.com

Abduction/adduction movements were tested without and with MV. Subjects were asked to move one finger abduction/adduction cyclically following a metronome timer (40 bpm, 0.67 Hz). Between two closest audio cues metronome, subjects needed to complete one abduction/adduction movement. The instruction for subjects was "move one finger with comfortable range of motion and try to keep the other fingers stationary." Subjects were able to see their finger movements during the test. Before each experiments condition, subjects could practice until they understood the instruction and adapted to the desired movement frequency.

Four conditions were tested: (1) without MV; (2) MV to APB; (3) MV to FDI; (4) MV to ADM of the dominant hand. For each condition, we recorded two consecutive 10s trials for each instructed finger (in the order of thumb, index, middle, ring, and little finger). The sequence of MV conditions was randomized across subjects.

E. Individuation Index (Iind)

An individuation index (Eq. 1), established by Lang and Schieber [3], was employed to quantify the independency of the control of each finger. Motion data were low-pass filtered with cutoff frequency of 10 Hz and the traveled distance of each finger tip was then calculated. The average path distance was defined as the total distance a fingertip traveled in a 10-s trial divided by the number of completed abduction/adduction cycle. The Individuation Index is defined as:

$$H_j = 1 - \frac{\sum_{i=1}^{n} |D_{ij}| - 1}{n-1} \quad (1)$$

Where H_j is the individuation index the j^{th} finger, D_{ij} is the normalized path distance of the i^{th} finger during the j^{th} instructed movement, and n is the number of fingers (here n = 5). For each finger, two Iind values of the same condition would average to get one Iind value. The Iind is unity for an ideal independent movement when the instructed finger moves without any movements in uninstructed fingers.

F. Index of selective activation (ISA)

ISA, adopted from a previous study [3], was used to quantify the selectivity of muscle activation between with and without MV. EMG data were band-pass filtered (30Hz to 1 kHz), rectified, and low-pass filtered with cut-off at 30 Hz. EMG signals of each muscle were then normalized to the highest maximum EMG value recorded from the same muscle within the same test condition. The normalized EMG data were further integrated over a 10-s period. The integrated EMG value was then divided to the cycle number of the instructed finger to obtain an average activation value (A_{ag}, described below). The ISA is defined as:

$$ISA = 1 - [(A_1 / A_{ag} + A_2 / A_{ag} + A_3 / A_{ag} + A_4 / A_{ag}) / 4] \quad (2)$$

Where A_{ag} is the average activation of agonist muscle during the instructed movement, and $A_{1,2,3,4}$ are the average activations of the same muscle during the other four instructed movements. For example, when instructed thumb to move, the A_{ag} is the average activation value of the APB muscle, and $A_{1,2,3,4}$ are average activation values of APB during the instructed movements in the other tested fingers under the same MV condition. Means of two ISA values under the same test condition were used to compare the effects of MV.

III. Results

Fig. 1 shows the individuation index of each finger during no MV versus three different MV conditions. The individuation index of one subject during MV to ADM was not included because some kinematic data were missing.

Regardless MV location, the Iind for the thumb and index finger did not change as compared with no MV condition. The most pronounced effects of MV on Iind were found in ring finger movements. During MV to APB or FDI, the ring finger performed significantly more independent finger movements than those with no MV ($p<0.05$, paired *t*-test). During MV to ADM, the ring finger moved less independently ($p>0.05$, paired *t*-test).

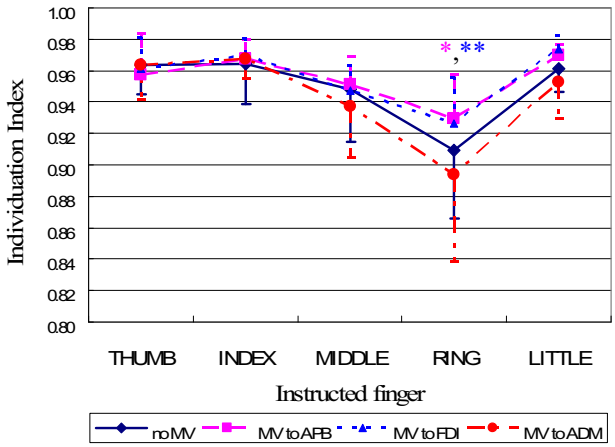

Fig. 1 Group means (error bar: standard deviation) of individuation indices of each instructed finger between different MV conditions when performed abduction/adduction movements. Paired t tests comparing MV with no MV conditions: *: $p<0.05$, MV to APB; **: $p<0.05$, MV to FDI.

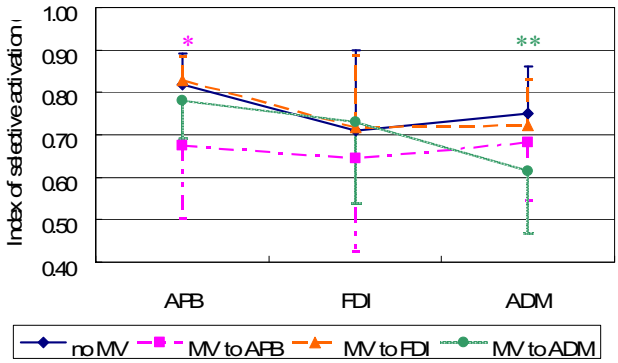

Fig. 2 Group means (error bar: standard deviation) of indices of selective activation for four conditions (no MV and MV to three muscles) when performed abduction/adduction movements Paired *t*-test comparing MV with no MV conditions: *: $p<0.05$, MV to APB; **: $p<0.05$, MV to ADM.

Fig. 2 shows the indices of selective activation of three muscles in four MV conditions. During MV to APB, ISA for APB was significantly smaller than that without MV ($p<0.05$, paired *t*-test). In addition, ISA for ADM was significantly reduced by the MV to ADM as compared to that without MV ($p<0.05$, paired *t*-test).

IV. Discussion

Individual muscle vibration to three hand muscles (APB, FDI or ADM) could affect the independency of finger movements in the same hand, especially the ring finger. Although the vibration-induced improvement in independent control of finger movements is not significant in healthy individuals, we expect to see more pronounced changes in the voluntary control of finger movements modulated by vibration in individuals with less finger independency, such as individuals with neurological disorder [3].

Previous study showed that individual muscle vibration to rested hand could enhance corticomotor excitability of selective motor pathway and inhibit the excitability of motor pathways of other muscles in the same hand in intact or neurological-injured individuals [5, 6]. In this study, we further demonstrated that muscle vibration could modulate voluntary control of finger movements, although the patterns of modulations and disease related effects still need to be studied.

V. Conclusion

Muscle vibration could modify the voluntary control of individual finger movements and the selectivity of hand muscle activation.

Modelling Orthodontal Braces for Non-invasive Delivery of Anaesthetics in Dentistry

S. Ravichandran

Faculty, Temasek Engineering School, Temasek Polytechnic, Singapore

Abstract — **It is known that oral and maxillofacial surgeons in collaboration with orthodontist often perform corrective dental procedures and these procedures are carried out after providing local anesthesia adjacent to the site of the lesion. As most of the minor surgical procedures in dentistry do not require general anesthesia, they are carried out with the help of local anesthesia. Local anesthesia is induced when propagation of action potential is to be inhibited from the source of stimulation, such as a tooth, to the sensory areas of the brain. Local anaesthetics work by blocking the entry of sodium ions into their channels, thereby preventing the transient increase in permeability of the nerve membrane to sodium ions for generating an action potential. When a local anaesthetic is injected into soft tissues, it exerts a pharmacological action on the blood vessels in the area. All local anesthetics possess a degree of vasoactivity which may vary depending on the selection of the drug. Development of orthodontal braces for containing the drug for local anaesthetic procedure is one of the emerging areas in biomedical engineering and our research work focuses on the development of one such tool designed for administering anaesthesia non-invasively before dental procedures. Based on the qualitative studies on the nature of the current suitable for the transfer of drug, we have developed the drug delivery system which augments with the orthodontal braces for the delivery of small doses of anaesthetic drug to the target site with the aid of pulse electrical stimulation.**

Keywords — **Orthodontal braces, Local anaesthetic, Non-invasively, Corrective dental procedures**

I. Introduction

A. Anesthesia in Clinical Dentistry

General anesthesia used for major surgical procedures leads to an induced state of unconsciousness, accompanied by partial or complete loss of protective reflexes and also includes the inability to maintain an airway independently and respond purposefully to physical stimulation or verbal command [2]. However, not all dental surgery requires the use of general anesthesia. Some surgical procedures in dentistry are carried out with the help of local anesthesia. It is known that local anesthetics block the entry of sodium ions into their channels, thereby preventing the transient increase in permeability of the nerve membrane to sodium ions for generating an action potential to occur [4, 8, 28, 29].

B. Classification of Local Anesthetics

Local anesthetics can be broadly classified as esters, amides and quinoline. Structurally, local anesthetics have specific fundamental features in common, which include a lipophilic group, joined by an amide or ester linkage to a carbon chain which, in turn, is joined to a hydrophilic group. Most local anesthetics are classified by these amide or ester linkages [8].

C. Neuromodulation of Pain

Pain stimuli receptors are distributed throughout the tissues of the body. These naked nerve endings with no specialist receptor on stimulation initiate a train of action potential [19]. The 'C fibre' receptors are sensitive to many kinds of stimuli including chemicals released from damaged tissue and hence, are also called polymodal receptors [7]. On excitation, a train of action potential travels back to the central nervous system through afferent neurons where processing of the sensory input is completed. The gate control theory of pain, proposed decades ago by Melzack and Wall postulates that information from the vibration and touch receptors located in the skin transmits nerve impulses through A-ß nerve fibers to stimulate inhibitory interneuron in the spinal cord. This in turn acts to reduce the amount of pain signal transmitted by A-delta and C fibers from the skin to second-order neurons that cross the midline of the spinal cord before ascending to the brain [10, 11, 13]. Local anesthetics block the sensation of pain by interfering with the propagation of peripheral nerve impulses. It has been found in the electrophysiological research studies that local anesthetics do not significantly alter the normal resting potential of the nerve membrane but they rather impair certain dynamic responses to nerve stimulation [19,21]. Local anesthetics interfere with Na^+ permeability of the nerve, and its blocking action is characterized by a progressive reduction in the rate and extent of depolarization in the nerve. When depolarization is inhibited, it result in the absence of action potenitial generated from the receptor which in turn results in the absence of nerve conduction leading to the inhibition of transmission of sensory information to the Central Nervous System (CNS) [6].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 957–960, 2009
www.springerlink.com

D. Drug Uptake and Biological Interactions

Local anesthetic injected into soft tissues exerts a pharmacological action on the blood vessels in the target area. All local anesthetics possess a degree of vasoactivity which may vary depending on the selection of the drug. A significant effect of vasodilation is an increase in the rate of absorption of the local anesthetic into the blood, which eventually decreases the duration of pain control, while increasing the anesthetic blood level. These effects are also related to the vascularity of the injection site [8]. Local anesthetics cause vasodilatation, which leads to rapid diffusion away from the site of action and results in a very short duration of action when these drugs are administered alone intraorally. This diffusion is reduced to a good extent by adding a vasoconstrictor with the anesthetic [8]. In clinical practice, epinephrine is usually mixed with anesthetic, like Xylocaine, to increase the duration of action of the drug at the target site.

E. Dosing For Safety

High drug levels in the blood can occur due to the result of the single unintended intravascular administration. Table 1 suggests the recommended maximum doses of some of the local anesthetics with vasoconstrictor [5, 27, 29].

Table 1. Recommended doses of local anesthetics

Drug	Maximum Dose
Articaine (4%)	7 mg/kg (up to 500 mg) 5 mg/kg in children
Lidocaine (2%)	7 mg/kg (up to 500 mg)

Lidocaine is a relatively common local anesthetic. It has been studied thoroughly for many years, and has well known effects and side effects. Lidocaine has been used on both adults and children for more than five decades and thus Xylocaine is the drug of choice in our applications [1, 9].

F. Pharmocotherapy

Pharmocotherapy involves the use of electrical fields or acoustic waves for transferring selected chemicals/drugs inside the body. Electrical fields and acoustic waves have been widely used in the delivery of certain ions or drugs inside the body and these processes are more commonly known as iontophoresis and phonophoresis. Iontophoresis has been widely used in the delivery of drugs such as hydrocortisone and methyl salicylic acid for analgesia and anti-inflammatory effect [14, 15]. Phonotherapy is also another effective way of delivering certain drugs through the skin and has been used widely in certain clinical conditions.

G. Phonophoresis

Phonophoresis is the movement of drugs through the skin into the subcutaneous tissues under the influence of ultrasound as ultrasonic vibration has been known to accelerate the movement of drug through the skin. Phonophoresis relies on perturbation of the tissue causing more rapid movement of particles, thus encouraging absorption of the drug. The effects of phonophoresis are those of drug employed combined with the effects of ultrasound [7]. Recent studies using ultrasound applicators for the delivery of selected drugs have shown that this area of noninvasive drug delivery is promising in antithrombotic applications too [22, 23, 26].

H. Iontophoresis

Iontophoresis is a drug delivery method that uses low-level direct current in the milliampere (mA) range to transport drugs and other water-soluble salts through the skin. It is a process of migration of ionized molecules across biological membranes under the influence of mild electric current. Drugs in the form of ions can be transported through the skin or mucus membrane with the aid of small current to the deeper layers of the biological structure [12, 14, 15, 20]. In dentistry, studies have been reported on the use of Lignocaine iontophoresis in small doses for tooth extraction in children [3].

II. Limitations of Iontophoresis in Dentistry

Intolerance to electrical stimulation is one of the major limiting factors in low frequency electro-stimulation. The tolerance to the stimulus has been well investigated in our research program and has been qualitatively documented using Perception Response System (PRS) where the sensation is graded under four perception labels. PRS used in different electro-stimulation studies were found useful in evaluating the tolerance to the electrical currents used in iontophoresis. Recording on this scale involve patient's interaction to classify perception on qualitative basis which is decided on the skin response to the stimulation parameters used in therapy. This qualitative assessment allows the user to choose the right stimulation parameters for treatment which can be selected based on patient's perception to the stimulation. This system thus provides a more reliable guideline in the assessment of stimulation parameters used in the present studies [16, 17, 18].

III. Xylocaine drug delivery system for dentistry

Based on the qualitative studies on the nature of the current suitable for iontophoresis, we have developed the drug delivery system for dentistry to deliver small doses of Xylocaine to the target site with the aid of pulse electrical stimulation. This system, named as "Orthodontal Brace based Drug Delivery System" (OBDDS), is designed around the orthodontal brace and consists of some essential sub modules, such as electrode embedded drug holding cell, and the microcontroller based control system. The control system consists of electrical pulse generator, and interfacing circuit for energizing the electrodes in the drug holding cell. The system architecture of the drug delivery system designed and developed around an orthodontal brace for our application is further discussed.

A. Drug holding cell

The drug holding cell is located at various points of the orthodontal brace and is capable of holding adequate amount of drug for transdermal application. The drug holding cell can be removed and replaced for every application. This drug holding cell is made out of biocompatible polymer and does not cause any adverse reaction.

B. Stimulating electrodes

Use of sensor embedded electrodes have been in practice in our earlier research studies in transdermal delivery of hydrophilic drugs to the target site [24, 25] and based on our earlier experience in designing such electrodes, we have designed the electrodes for this application in dentistry. Wired electrodes were embedded in the drug holding cell and these electrodes are capable of providing the electrical fields for the transfer of drugs from the drug holding cell to the biological tissue under the electrodes. These electrodes are connected to the electronic circuit, providing electrical pulses to stimulate the target site.

C. Control system

This system is programmed for supporting the interface for generating mid frequency pulses ranging from 2 kHz to 10 kHz.

D. Qualitative Studies Based on Perception

Based on the earlier experiments with low frequency currents, we have documented the perception to the pulse current in the frequency range from 2 kHz to 10 kHz. As per the Perception Response Index Scale (PRIS), the tolerance to the currents in the frequency band (2 kHz to 10 kHz) was reported less irritating. It was also observed that the effect of the anesthetic delivery using this method was not any less inferior when compared to the earlier iontophoretic drug delivery protocol. Thus, this developed system is definitely more promising in terms of patient tolerance and usefulness in dentistry.

E. Results and Discussion

It is observed that anesthetized state maintained by quantized delivery of the anesthetic deposited in the target site using a hypodermic needle is usually longer than other methods. This is due to the higher quantity of the medication injected into the target site and also the composition of the anesthetic combined with a vasoconstrictor. With the use of the OBDDS, the duration of the anesthetized state is maintained by quantized delivery of the anesthetic to the target area and is decided only by capillary circulation aided by the electrical pulses. This limits the amount of the anesthesia contained in the target area and thus prevents overdosing which can occur in the conventional method using hypodermic needles.

IV. Conclusion

Avoiding a needle prick for producing anesthesia is a fact appreciated by people who have a strong aversion for injections. Thus, this system will not put off those patients who have a fear for needle pricks and will be useful for dentist to perform minor surgical procedures. However, for major surgical procedures, this method can be a useful prelude to provide the initial dosing non-invasively, before providing larger doses of anesthetics through injections after the initial numbness has set in. Another advantage of this method over the conventional method is that very little drug is required to produce a local analgesic effect. The newly developed OBDDS for providing anesthesia in dental application is definitely a promising tool for pedagogical researchers and professionals in dentistry.

Abstract — **Acute post-stroke rehabilitation protocols include passive mobilisation as a means to prevent contractures, but this technique could also help preserve neuromuscular activation patterns through proprioceptive information. This paper presents SHADE, an active orthosis that provides repetitive passive motion to a flaccid ankle by using shape memory alloy wire actuators. SHADE was studied to assess the promoted passive range of motion (PROM), acceptability and cortical effects. PROM and tolerability was assessed on 3 acute post-stroke patients (58±5y/o) by means of optoelectronic cinematic analysis. EEG/MEG instrumentation was utilised to evaluate sensorimotor cortical involvement during passive mobilization induced by SHADE in 7 healthy subjects (30.3±6.9y/o). These data were compared with voluntary movement (VM). SHADE produced good mobilisation across the available PROM (typically, from 5° plantarflexion to 15° dosiflexion). Acceptability in patients was also good. Suitable functional sources were identified for the primary sensorimotor areas. Cortico-muscular coherence was high not only in primary motor but also in primary somatosensory cortex. The cerebral involvement in these regions during the use of SHADE was similar to VM and significantly different from rest. This suggests that passive stimulation with SHADE could have clinical implications in supporting recovery of active functionality in stroke patients.**

Keywords — **Stroke, rehabilitation, orthotics, shape memory alloys, MEG.**

I. Introduction

Ankle rehabilitation techniques are very widespread in the clinical practice, as they are strongly indicated in the treatment of several different neuromuscular diseases. For instance, the distal lower extremities are very often affected by stroke events. After stroke, a rehabilitation program should be performed as soon as the patient's conditions are sufficiently good. Moving the limbs passively can improve circulation, maintain joint flexibility and normal muscle tone, while the patient is unable to exercise actively [1]. Contracture prevention due to passive stretching in the acute phase after CNS injury is also reported [2]. AHA/ASA endorsed guidelines for 2005 [3] indicate that a strong difference in the final treatment outcomes derives from the sheer time spent on physical rehabilitation. This could be improved using robotic devices without much impact on hospital task scheduling.

Passive mobilization [4] may also contrast deafferentation and learned non-use, i.e. directly address impairment of the cortical pathways involved in active limb control. The way this happens is not clear. There is evidence, however, that functional recovery occurs while changes in sensorimotor activation take place in the cerebral cortex.

A simple, user-friendly and safe device for use in the first few weeks after the acute event, during or following manual treatment by a therapist, could lead to great benefits for the patient by preventing the insurgence of severe sequelae and would help limit health service costs. In order to be a reli-

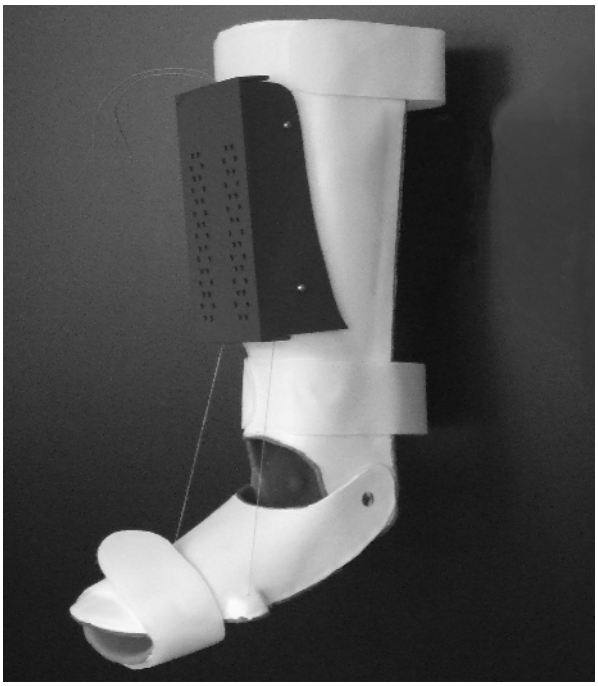

Fig. 1 The SHADE orthosis. Actuators are mounted frontally inside the vented shin housing. Inextensible threads connect them to the foot shell.

www.springerlink.com

able device for rehabilitation purposes, this orthosis should comply with a number of clinical and functional requirements, i.e. it should be capable of promoting cyclic mobilization of the ankle joint across at least a range of -5° to 10° (negative is plantarflexion), have suitable repetition times in a physiological range, be thermally and electrically safe for the patient, light-weight and compact to wear. Such a device was designed as a prototype: SHADE (Fig.1).

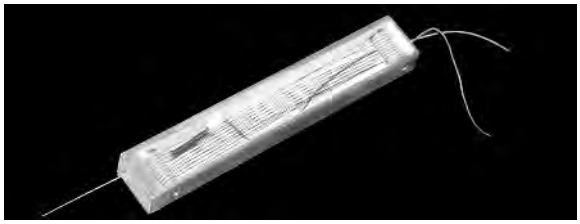

Fig. 2 Actuator mounting 2.5m of NiTi wire between 2 arrays of pulleys.

II. Material and methods

A. Shape memory actuators

Shape memory alloys (typically NiTi alloys) are metal compounds with the unique characteristic of being very deformable at room temperature and fully recovering deformation up to 8% when heated. This behavior is due to a reversible phase transformation occurring in the solid state, from martensite (stable at lower temperatures, more deformable) to austenite (stable at higher temperatures, stiffer). Shape recovery occurs if the alloy is heated above a certain transformation temperature, namely A_f, while on cooling down the material transforms again into martensite below M_f. During shape recovery, these alloys produce force and thus can be utilised to carry out work. For this application, a shape memory NiTi 250µm-diameter commercial wire stabilised for actuation was utilised (M_f= 274K and A_f = 351K) to ensure lasting performance for SHADE and industrial reproducibility. The actuator was designed as a 150mm×20mm×15mm insulated aluminium cartridge wherein 250cm of 0.25mm-diameter NiTi commercial wire is led back-and-forth between two arrays of ten mini-pulleys (Fig. 2). Heating is provided by Joule's effect, while cooling is left to natural convection. Preliminary tests have demonstrated that this actuator can lift 12N through 8cm when activated at 20W for 7s.

B. Orthosis design

A prototype of SHADE was assembled with two thermoplastic shells modelled on a prototype human lower limb of average size. These are hinged together at the ankle and strapped by Velcro® bands on the frontal aspect of the shin and on the foot. Two cartridge actuators are fixed on the front of the upper shell with inextensible threads connecting each NiTi wire to the foot shell. This configuration provides a theoretical maximum angular displacement of 28.67° with maximum force per actuator of around 10N with a foot weighing 12-17N. A dedicated software home-written in LabView (National Instruments, Austin, TX, USA) controls an array of electronic relays (NI9481, National Instruments) that switch on and off a dc-generator providing sufficient power to get shape recovery. All the electric connections and the thermal shielding are suitable to guarantee patients' safety. The performance of the SHADE prototype was tested measuring the angular displacement by means of electrogoniometer SIM-HES-EG 042 (Signo Motus, Messina, Italy). The current pattern was a 7s-step of 1.4A (0.7A per cartridge) and 30s allowed for cooling. The results of these tests showed that the angular displacement is very stable with weight (26.25°±1.5°, mean ± st.dev.), while curves tend to drift towards lower angles (decreasing dorsiflexion) on increasing weights.

C. Pre-clinical assessment

A group of 3 patients (A1, A2, A3) was enrolled to assess the efficacy of SHADE in producing ankle dorsiflexion in accordance with the clinical requirements and to prove short-term tolerability. The selection criteria were: flaccid or slightly spastic (≤1 on the Ashworth Scale) hemiparesis involving the ankle as a consequence of first stroke, no major skin or articular pathologies, no severe cognitive impairment, able to answer questions. The patients' characteristics are presented in Table 1.

Patients were treated according to ethical principles, as approved by the hospital ethical committee, and gave informed consent. They underwent general clinical assessment prior to the start of the treatment. Then they used SHADE in single trials to measure the instantaneous range of motion by means of eight optoelectronic cameras sampling at 100Hz (Elite Gait Eliclinic - BTS, Garbagnate Milanese, Italy). Six IR reflective markers were positioned on the *condyli tibiales*, the *malleoli*, *metatarsi I* and *V*, identifying the ankle angle as the one extending between the central

Table 1 Patients' characteristics (AROM: active range of motion)

	Age	Sex	Time after stroke	Affected side	AROM
A1	63	F	4 y	left	full
A2	53	M	3 y	left	none
A3	58	M	3 mo	left	none

Table 2 EEG left side derivations and mapped areas

EEG derivation	Mapped area
T7-A1	left secondary sensory (S2)
Cpz-C1	left primary sensory (S1)
C1-FC1	left primary motor (M1)
FC1-FZ	left supplementary motor (SMA)

axes of shin and foot. The patients, wearing SHADE, were asked to try and lift the tip of their foot without any cues about to what extent or at what speed the task had to be carried out; irrespective of the results of this active trial, SHADE was then used to elicit passive dorsiflexion twice.

D. Cortical involvement during passive mobilization

EEG and MEG activities were collected bilaterally on 7 healthy subjects (aged 30.3±6.9; 5 male) during rest (REST) and dorsiflexion as produced by voluntary movement (VM) and passive mobilization through the SHADE orthosis (O-PM). Only data from the left hemisphere were analysed. EEG derivations (according to the international 10/20 system) were used as markers of different cortical areas (Table 2). Brain magnetic fields were recorded from a scalp area of 180cm^2 by means of a 28-channel MEG system (Vacuumschmeltze GmbH, Hanau, Germany), centered 2.5cm posteriorly relative to Cz (i.e. in correspondence of Rolandic areas devoted to the lower limb control). Primary sensory and motor areas were then discriminated by Functional Source Separation [5]. The effects of maintaining attention/distraction attitudes during O-PM were also considered. Power spectral density modulation was used to quantify involvement of sensorimotor areas in the different conditions focusing mainly on the α (8-13Hz), β (14-32Hz) and γ bands (33-90Hz).

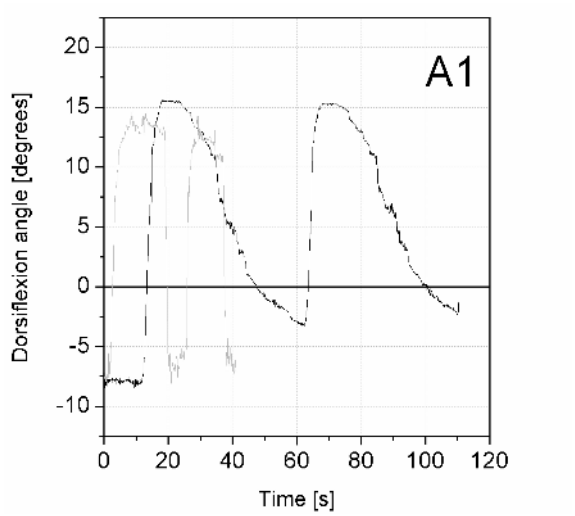

Fig. 3 Results of optoelectronic tracking of ankle motion during the use of SHADE. The black lines represent passive exercise by SHADE; the grey line represent the active ankle motion. Range of motion produced by SHADE is patient-dependent. For patient A1 it is possible to appreciate that dorsiflexion speed (positive slope) is similar to the one spontaneously chosen by the patient. Plantarflexion (negative slope) is limited to 30s by the input current waveform.

III. Results

A. Clinical outcomes

Optoelectronic movement analysis on each patient revealed that SHADE is capable of producing an appropriate range of motion for rehabilitation purposes (Fig. 3). In particular, with patient A3 it elicited motion from -4.5° to +19°, adding up to a total angular displacement of 23.5°, not too far from the theoretical limit. Patient A1 is particularly interesting, as she was able to produce active movements of her own. The speed of passive dorsiflexion, closely matches the one of natural spontaneous motion. Reset speeds and angles are not matched, however. Acceptability was good for all the patients and movement was deemed natural.

B. Cortical correlate of passive movement

Suitable functional sources for S1 (FS_{S1}) and M1 (FS_{M1}) were identified in all subjects. FS_{M1} was correctly found to be more frontal than FS_{S1} (p=0.023). Interestingly, FS_{S1} showed high coherence with ankle muscular activity.

In the β band (Fig. 4), S1 activity during VM and O-PM were both different from the activity during REST (respectively, p=0.015 and p=0.054), while M1 reacted significantly with respect to REST only in VM (p=0.014). Centro-parietal sensory involvement during O-PM was also evident from EEG data (p=0.002, Cpz-C1).

In the γ_1 band (33-60Hz) significant source effect indicated higher power in the primary motor area than in the primary sensory area in all conditions (p=0.04). The same happened also in γ_2 (33-60Hz), with p=0.017. Slightly higher sensory-motor coherence was also observed in γ_2 during attention than no-attention in O-PM (p=0.119).

IV. Discussion

Technical tests were conceived so that the weights and lever arm produced plantarflexion moments in the range of those typical of foot weights (e.g. 15N foot weight × 10cm

lever arm). It is important to notice that with all the tested weights (producing moments 80% to 110% of the reference one) the clinical requirements are always met. Also the clinical tests showed that SHADE can produce dorsiflexion beyond the minimum requirements. The dorsiflexion speed resulted appropriate to generate a natural movement. The reset speed is, on the other hand, much lower than the spontaneous one. This depends on the cooling rate which is rather low, as convection is strongly hindered by the actuator housing walls (albeit they are vented). It was decided that an adjustable reset time of 30s would be allowed during cyclic clinical working. This time is long enough to reach plantarflexion almost completely by means of the sheer foot weight without any forced convection. The chosen reset time, even though it is unnatural, could be suitable for physical rehabilitation because it allows the ankle to remain stretched for as long as 70% of each cycle, which is hoped to avert the development of contractures.

Whereas the applicability of passive mobilisation to maintaining tissue properties and articular suppleness is well referenced in daily clinical practice, any evidence that it affects cortical structures could suggest it might be of some utility in preserving motion planning and control abilities as well. This is certainly hard to tell from a study on healthy control subjects but it was felt to be a good start to prepare a thorough and more to-the-point analysis of post-stroke cases. The experience gained on the chosen acquisition protocol (very scant as to the number of EEG markers and limited MEG-scanned area) suggests that while this MEG paradigm is suitable to study primary motor and sensory cortices, EEG derivations should be increased to monitor more precisely the supplementary, pre-motor and secondary motor areas, whose involvement was not clearly evidenced in this study even during VM but could be of peculiar interest. Furthermore the reconstruction of data from the ipsilateral/contralesional hemisphere (or the right hemisphere in healthy controls) could be included, since cortical remapping and recovery processes can affect both sides in post-stroke patients. On the whole, however, this set-up was able to show significant effects correlating, in particular, somatosensory activation to the use of SHADE, in ways similar to what happens with voluntary movement. If that were true also for post-stroke patients (which will have to be proved), there would be a possibility that passive mobilisation play a role in stimulating appropriate cortical circuitry associated with the execution of ankle motor tasks. For this reason repetitive and prolonged passive mobilisation might be effective in contrasting deafferentation and learned non-use, especially during the post-acute flaccid phase when the patient is unable to carry out active dorsiflexion. The observed slight effect of attention on γ_2 suggests that, through cognitive elaboration of afferent information, patient's awareness might enhance outcomes on cortical stimulation. More subjects are needed to improve significance of these data, however, particularly because constancy of attention levels is difficult to achieve during rather lengthy acquisition sessions.

In sum, it is hoped that the immobilisation-disuse vicious cycle initiated by stroke and the ensuing paresis could be interrupted by a threefold effect of passive mobilisation with SHADE: preserving soft tissue properties; preventing sensorial deprivation and promoting movement rehearsing; modulating remapping by offering constant afferent input.

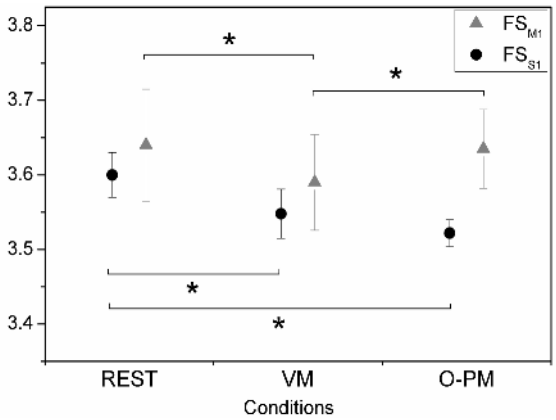

Fig. 4 Power spectral density in the β band in different experimental conditions. VM and O-PM are similar conditions for FS_{S1}.

V. Conclusions

A prototype of SHADE was built and tested, showing good performance even beyond the clinical requirements. Preclinical tests demonstrated that SHADE produces dorsiflexion across a sufficient range of motion from -4.5° up to 19°. During cyclic motion posterior calf muscles remain lengthened for around 70% of the time, ensuring suitable stretch. Acceptability by the patients was very good, but further trials are needed to verify this in longer sessions.

SHADE was proved to stimulate somatosensory cortical areas in a way similar to voluntary ankle motion in healthy subjects. Future work will address the efficacy of passive stimulation in the functional recovery of stroke survivors.

A Behavior Mining Method by Visual Features and Activity Sequences in Institution-based Care

J.H. Huang, C.C. Hsia and C.C. Chuang

ICT-Enabled Healthcare Project, Industrial Technology Research Institute – South, Tainan, Taiwan, R.O.C

Abstract — **This paper proposed a behavior mining method through discriminative visual feature extraction from disabled elder caring. Nursing activities for bed-ridden residents were manually annotated from video data which was collected and provided by a care center. The variation grid sequences are extracted as discriminative features from the difference blobs of successive image frames. The sequential association rules are trained based on the grid sequences for each nursing activity category. A similarity measure between test video segment and related rules is proposed for nursing activity recognition. Through empirical evaluation on annotated video dataset, the proposed approach is very promising for nursing activity discrimination through the sequences of visual features.**

Keywords — **Nursing activity, Behavior mining, Image sequence, Bed-ridden, Institution-based care.**

I. Introduction

With the rapid increasing trends of aging population and chronic diseased or disabled elders, long-term healthcare becomes more and more important. However, the limitation of human resources, including nurses and caregivers, results in caring quality degradation. In the past decade, more efforts have been made to adopt information and communication technology for clinical nursing assist, like nurse call [1], patient monitoring [2], and information system [3] etc.

A lot of healthcare technologies are developed for detecting and monitoring status or behavior of disabled elders. With nursing labor shortage, the lack of professional supervision and possible burn out due to difficulties of nursing care were threats to the caregivers, especially to foreign nursing labor. To reduce the negligence, a reminding system by detecting and recording regular nursing activities is helpful.

Video surveillance system for healthcare is usually used to increase overall security and safety, monitor continuously, and store visual evidence for investigations. Object tracking [4] and fall incident detection [5-6] are hot topics in the last years. However, the complicated environment and light effects are still limited the application.

From the observation of activity of bed-ridden residents, caregivers, and the interaction between them, it can retrieve certain meaningful information from visual features. In this paper, a behavior mining method for nursing activity is proposed. Briefly, the proposed method is composed of two main phases: 1) construction of sequential association rules and 2) discrimination unknown nursing activities with those rules. In next section, we descript the video data which was collected from a care center and introduce the proposed method for behavior mining. Then empirical evaluation of the proposed method is presented. Finally, conclusion is stated in the last part.

(a) (b)

Fig. 1 The view of IP-cameras

II. Material and Method

Video data were collected in the care center using snapshot capturer system with IP-cameras. Two elder subjects participated in. One is 68 years old, recovering from stroke on both sides, especially the left side, and the other is 73 years old, has a stroke on left side and hypertension. The IP-cameras were mounted on the walls. Figure 1 shows the snapshots for the two subjects, (a) for the former and (b) for the latter. The marked regions represent the bed areas.

The snapshot capturer system captures a 320x240 JPEG image from each IP-camera every three to four seconds. The consecutive image sequences of two weeks were collected. The data of the first and second week were used as training and testing set, respectively. Six types of nursing activities were annotated manually and the numbers of annotated activities in training and testing data set are shown in Table 1. “Diaper” means that the caregiver checks is the diaper wet or dirty, and change it. “On Bed” and “Off Bed” means that the caregiver helps residents to get onto and out off the bed. “Reposition” means that the caregiver repositions the residents regularly to reduce pressure sores. “Vital Signs”

means that measuring vital signs of the residents, like heart rate, blood pressure, and body temperature. "Food" means that the food and medicine are given to the residents through their nasogastric tube.

Figure 2 depicts the flowchart of the proposed method including training and predicting phases. In visual preprocessing, the changed pixels are extracted for each pixel when the difference between two successive images is larger than a threshold α. The Erosion filter is used to remove random noisy pixels, and the remained changed pixels are clustered into blobs. Only the area of the bed is used for nursing activity modeling and recognition. The bed area is divided into $M \times N$ grids and the variation grid sequence is extracted as the visual features for video segment V_j with $K+1$ image frames.

$$D_k^{(j)} = \left\{ g_{m,n}^{(j)} \mid grid^{(j)}(k,m,n) = 1 \right\} \tag{2}$$

and

$$1 \le k \le K, \quad 1 \le n \le N, \quad 1 \le m \le M \tag{3}$$

$$F_j = \Big\{ \big\{ g_{1,1}, g_{2,1}, g_{3,1}, g_{1,2}, g_{2,2}, g_{3,2}, g_{1,3}, g_{2,3}, g_{3,3}, g_{1,4}, g_{2,4}, g_{3,4}, g_{1,5} \big\}, \big\{ g_{1,1}, g_{2,1}, g_{1,2}, g_{2,2}, g_{1,3}, g_{2,3}, g_{1,4}, g_{2,4}, g_{1,5}, g_{2,5} \big\}, \big\{ g_{1,1}, g_{1,2}, g_{1,3}, g_{2,3}, g_{1,4}, g_{1,5} \big\} \Big\}$$

Fig. 3 Example of visual feature extraction

The function $grid^{(j)}(k,m,n)$ represents if the grid in location (m,n) contains blobs (equals to 1) or not (equals to 0). Figure 3 gives an example of part of "On Bed" activity for subject (b). The activity contains four image frames. The area of the bed is segmented into 4×5 grids, and red grid denotes that the grid contains blobs. The visual feature is show in the bottom of Fig. 3. Symbolization is a useful method for mining sequences. The same visual features are encoded with the same symbol. An activity can be regarded as a transaction and a transaction contains several symbols viewed as items. The activity-transaction table is established for training and predicting.

A. Training Phase

Input: An activity-transaction table D and minimum support *minsup*
Output: Frequent itemsets F
Algorithm: Gen_FreItems

1. $F_1 =$ scan for each item and get the frequent 1-itemsets;
2. $k = 2$;
3. **while** $F_{k-1} \neq \phi$ **do**
4. **for** $\forall p, q \in F_{k-1}$ **do**
5. **if** $p_1 = q_1 \,\&\, p_2 = q_2 \,\&\, ... \,\&\, p_{k-1} = q_{k-1}$ **then**
6. $r =$ concatenate $\{p_1, p_2, ..., p_{k-1}, p_k, q_k\}$;
7. $C_k = r \cup C_k$;
8. **end if**
9. **end for**
10. $F_k = \{X \mid \sup(X) \ge minsup, X \subseteq C_k\}$;
11. $k = k + 1$
12. **end while**

Fig. 4 Algorithm for generating sequential association rules

From the activity-transaction table, we make use of Apriori-like association mining method [7] to discover the frequent itemsets that sufficiently exceed the presetting minimum support *minsup* , as shown in Fig. 4. These generated frequent itemsets can be viewed as association rules directly since temporal continuities are inherent in them. The difference with Apriori algorithm is the concept of sequence. Keep the order of itemsets in transaction and calculate the support, the number of transactions satisfying the itemsets is measured in each pass. After candidate itemset generation and activity-transaction table scanning, the sequential association rules of each activity are performed.

B. Predicting Phase

For an unknown video segment, the nursing activity is decided based on the similarity to each pre-trained activity rule sets. First, the transaction items of unknown video segment and activity rule sets are be converted into original visual features, which contain $M \times N$ binary attributes. The similarity measure is to accumulate the support of matched rule sets in each activity category. The algorithm by utilizing is shown in Fig. 5. The procedure dist is to get score between two transaction items. The higher score represents more similar. If the number of different visual features is smaller or equals to one, the score is assigned the minimum distance of all the permutations of unmatched visual features of transaction items. Ignore it if the number of different visual features is larger than one. We check if the transaction of unknown video segment contains the rule or not

Input: An unknown activity-transaction $\{a_1, a_2, ..., a_m\}$, an activity rule sets $\{R_1, R_2, ..., R_n\}$ and corresponding support $\{s_1, s_2, ..., s_n\}$

Output: Accumulated support value V

Algorithm: Get_AccSupport

1. **for** $\forall R_i \subset \{R_1, R_2, ..., R_n\}$ **do**
2. let matched number be $M = 0$;
3. **for** $\forall r \subset R_i$ do
4. get corresponding $a \in \{a_1, a_2, ..., a_m\}$
5. **if** dist$(r, a) \le threshold$ **then**
6. $M = M + 1$;
7. **end if**
8. **end for**
9. **if** $M = \text{size}(R_i)$ then
10. $V = V + S_i$
11. **end if**
12. **end for**

Fig. 5 The support accumulation of matched rule sets

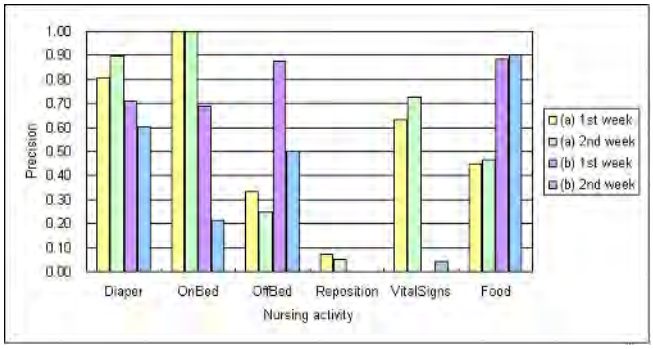

Fig. 6 The precisions of our method

by above method. According to the accumulated support, what activity category does unknown video segment belong to is decided.

III. Results and Discussion

Precision rate is used to evaluate the performance of proposed nursing activity recognition method and is calculated as:

$$\text{Precision} = \frac{\#\text{ of correctly recognized activities}}{\#\text{ of recognized activities}} \quad (4)$$

Figure 6 shows the results for nursing activity recognition. Compared to the chance level, 0.17, the average precision rate of the proposed method is 0.5.

Except for "Diaper" activity, the lower precision of activity "Reposition", the higher part equals to the lower part in the other four. Through the observations on the frequencies and the sequential association rules of activities, we can explain the result of above experiment. First, from the Table 1, the frequencies of activity "Diaper", "Vital Signs", "Food" is larger than the others. The reliability of rules is highly related to the visual features, but the predicting results are not precise in activities "Vital Signs" and "Food". The confusion matrix is shown in Fig. 7. The two activities are not discriminable by rules. The motions of caregiver in "Vital Signs" and "Food" nursing activities are similar to each other. The caregiver always stands near the bedrail and actions on the left-top side of subject. The rules of those two activities are ambiguous. In other words, the sequential association rules are insufficient for discriminating "Vital Signs" and "Food". But duration is an important factor between them. In statistics, the average time spend in vital signs measure is one minute and in feeding is three minutes. Therefore we can use the factor of duration to improve our method. Second, the experimental data are two weeks and number of each activity is not equal, especially "On Bed",

	Diaper	OnBed	OffBed	Reposition	VitalSigns	Food
Diaper	85	1	8	2	4	0
OnBed	0	6	1	0	0	0
OffBed	0	4	2	0	1	0
Reposition	9	3	14	2	4	1
VitalSigns	5	0	0	0	28	8
Food	7	0	0	0	56	53

(a)

	Diaper	OnBed	OffBed	Reposition	VitalSigns	Food
Diaper	69	0	12	0	1	23
OnBed	1	14	1	0	1	13
OffBed	0	1	21	0	4	4
Reposition	0	1	4	0	1	0
VitalSigns	0	0	0	0	1	42
Food	2	1	5	0	1	76

(b)

Fig. 7 Confusion matrices of subject (a) and (b)

"Off Bed" of subject (a) and "Reposition" of subject (b). Nursing activities is not always on schedule. Some nursing activities are taken for the subject if the caregivers think that is helpful for him. Third, the lower precision of "Reposition" is due to the rule sets. For the "Reposition" of subject (a), there are lower support and fewer rules be found. And for the subject (b), the number of training data is just two. Overall, the experiment of "Reposition" is to be no effect.

IV. Conclusions

In this paper, the sequential association rules are mined from visual features and used to discriminate unknown activities. The experimental results show that the proposed method is promising for nursing activity discrimination through the visual features. The goal of nursing activity discrimination is not only alert with daily scheduled nursing activity but also supervise the procedure of nursing activity is being done completely. According the mechanism, reduce the negligence of caregivers, strengthen manpower training, and raised the quality of health care.

Acknowledgment

The experimental data of this paper is provided by a care center in Tainan City, Taiwan, and the dataset were annotated by Professor C. J. Hou, Y.T. Chen and their students, in Southern Taiwan University. We appreciate them for the support of this work.

Chronic Disease Recurrence Prediction Model for Diabetes Mellitus Patients' Long-Term Caring

Chia-Ming Tung[1], Yu-Hsien Chiu[1], Chi-Chun Shia[1]

[1]ICT-Enabled Healthcare Program, Industrial Technology Research Institute – South, Tainan, Taiwan (R.O.C.)

Abstract — **Recurrence and complication prevention is crucial in caring chronic patients. This paper presents a chronic disease recurrence prediction model in long-term caring for diabetes patients. A nursing information system is developed and applied in an institution-based health care center. Values of blood sugar, vital signs, BMI and nursing records of diabetes patients are collected during the daily nursing procedure. Since data are recorded in different time with variable sampling period, a flexible time series analysis method is presented for exploiting seasonal variation and cyclical fluctuation between diabetes and daily-recorded signals. Expert knowledge for chronic disease is built based on domain specific language to extract chronic disease care knowledge from nursing records. Finally, a health surveillance system is developed by integrating multi-modal daily caring information for long-term caring of chronic patients. Several experiments with statistical testing are conducted and the results compare the performance of the proposed method. The expected outcome will build a prediction model to early warning before diabetes will be recurrence.**

Keywords — **chronic disease, diabetes, long-term healthcare, institution-based health care center, nursing information system**

I. Introduction

Taiwan becomes aging society in 1996. 10.33% of population is elder in Taiwan at August 2008 [2]. Elder healthcare is the most important social welfare in the aging society. Taiwan government planned many long-term projects to healthcare. In Taiwan's society, most of the elder live in their home. The elder may have chronic diseases, although not every family could afford enough human resource or knowledge to care the elder. An alternative way is care them at foundational healthcare center for a centralized caring.

Diabetes mellitus is one of the common diseases in elderly human. It is the top four of ten leading causes of death in 2006 [1], and other diseases erupt at the same time, like Cardiovascular disease, Hypertension, Visual disturbance et al. At this time, the best control over diabetes mellitus is to monitor the blood sugar value. The values of blood sugar before or after the meals are measured, and it is now the standard procedure in foundational healthcare center. If patient's status was instable, the blood sugar values are measured once or twice a day. Other signals are also been monitored for diabetes mellitus patients, like vital signs, body mass index (BMI), nursing record, medicine and so on. In healthcare center, nurse or caregiver may not have time to review these measured data. If computer assist tools can help caregiver to monitor these data, caregiver may use these signals to prevent some diseases.

Information and communication technology (ICT) may help caregiver to analysis the nursing record. Jimmy Lin and Dina Demner-Fushman have developed a statistical and knowledge-based automatic medical knowledge extraction [3, 4].

ICT can help caregiver to store and analyze the nursing record. However, ICT can not replace the human resource in healthcare. It can assist human to make the right decision if the knowledge base was built. Back-end database can store interactive result among doctor, nurse or caregiver and patient [5]. Olga Medvedeva, Tamara Knox and Jody Paul present how ICT were utilized to develop assistive software for decision-making in treatment of diabetes [5]. In doctor's view, diabetes mellitus type II is simple to diagnose but difficult to treatment. They develop a web-based application that can help doctor to access data and provide recommendation for patient with better treatment. Software can automatically learn and be applied to medical data diagnosis. The learning algorithm is built and well tuned, the software can automatically learn and diagnosis. The diagnosis result can be verified by human professors [7]. When learning the knowledge, the data type should be considered. Nursing data can be numerals, text, video or sound. Integration of these multi-modal data is helpful [6].

This study prepares to predict the blood sugar value of diabetes mellitus patient. A nursing information system is been applied in a foundational healthcare center for collect the nursing record. Nursing records are collected and analysis by using multiple regression analysis. Two groups' data are categorized to find its own prediction model. Knowledge base was been used to store the predict model.

The prediction models can help caregiver to predict the patient's value of blood sugar. Caregivers don't measure patients' value of blood sugar everyday. Only measure in schedule time or patients' status is not good. The healthcare center can reduce times to measure patients' value of blood sugar. It can use this assist tools to reduce the operation cost, too.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 970–973, 2009
www.springerlink.com

II. Materials and Methods

Blood sugar values, vital signs, BMI, text nursing record, and values of SpO_2 are collected and recorded by a nursing information system. These data are measured with different time period. Vital signs, text nursing records are measured and collected everyday. Blood sugar values are measured independently for different patients from twice a week, or once a month. Patient's weight is measured every two-month, and height is measured every half year. The BMI is calculated and recorded every two months. The flowchart of this research is showed in Fig. 1.

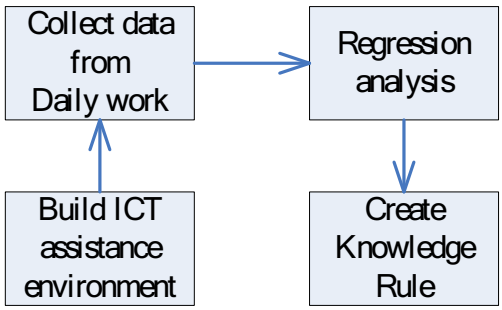

Fig. 1 Research Flow

- ***Build ICT assistance environment***

  Nursing information system (NIS) was deployed into the foundational long-term healthcare center. The NIS system was based on windows application. Design strategy is easy use for caregiver when operating the NIS system. Both mouse and keyboard can be used when input the data.

- ***Collect from daily work***

  Vital signs, values of blood sugar, values of SpO_2, BMI and text nursing record were input into the system. Vital signs and text nursing record were measured everyday for every patient. Values of blood sugar and values of SpO_2 were measured if necessary. BMI was recorded every two months.

  In the other hand, for the cost issue, only diabetes mellitus patients and new entrance patient were measure the blood sugar values.

- ***Regression analysis***

  To understand the relationship among all data, this study used multiple regression analysis to analyze all kinds of data and find out which kinds of data will infect the values of blood sugar.

- ***Create knowledge Rule***

  The prediction model is built based on the results of the multiple regression analysis. Knowledge base can be store in database. Feature, this knowledge could use in expert system like JBOSS Drools.

III. Results

- ***Build ICT assistance environment***

  NIS prototype system was developed and provide user to use and modify the operation flow for ease of use. This study deploys 1 database server and 5 client's user interface in care stations and supervisor's PCs.

- ***Collect from daily work***

  All patients' vital signs were measured every day. The values of blood sugar were not measured for every patient. In the healthcare center, only new patient entrance or the diabetes mellitus patients need to measure the values of blood sugar.

  If the new entrance patient's blood sugar value was normal, the care-giver never tracks the values of blood sugar for this patient.

  The value of blood sugar is measured every Wednesday and Sunday. Some patients ever got the diabetes mellitus before, after treatment the patient was fully recovered from diabetes mellitus. Ever they never need any medicine for treat the diabetes mellitus but doctor still require the caregiver to track these patients values of blood sugar. They only measure value of blood sugar every month.

  Patient's height is measured every 6 months and weight is measure every 2 month. So BMI is calculated every two months.

Table 1 nursing data measure standard

Name	Below	High
Body Temperature	36	37.5
Pulse	60	90
Breath	12	20
Systolic Pressure (SP)	100	130
Diastolic Pressure (DP)	60	85
SpO2	90	100
BMI	18.5	24
Value of Blood Sugar	60 *	100 **
	80 *	120 **

*: Before meal; **: After meal

Table 1 show the measure standard of all nursing records.

This study categorized the diabetes mellitus into two groups. Group 1, patients got both diabetes mellitus and hypertension. Group 2 has diabetes mellitus only or more than two diseases except hypertension. This study didn't use diabetes mellitus type I and type II to separate the diabetes mellitus patients.

- ***Regression analysis***

Both group 1 and group 2 use the same condition. The dependent variable is the value of blood sugar; independent variables are body temperature, pulse, breath, systolic pressure, diastolic pressure, SpO2 and BMI.

Stepwise multiple regression analysis was used to analyze the relationship among value of blood sugar and other data.

Group 1 has 354 numbers of data that selects all data from database when care-giver measures the value of blood sugar and record into database. Group 1's prediction model is below:

$$Y= -0.135_{Breath}+0.155_{BMI}+0.153_{SpO2} \quad (1)$$

Fig.2 showed the Group 1 has not close normal distribute.

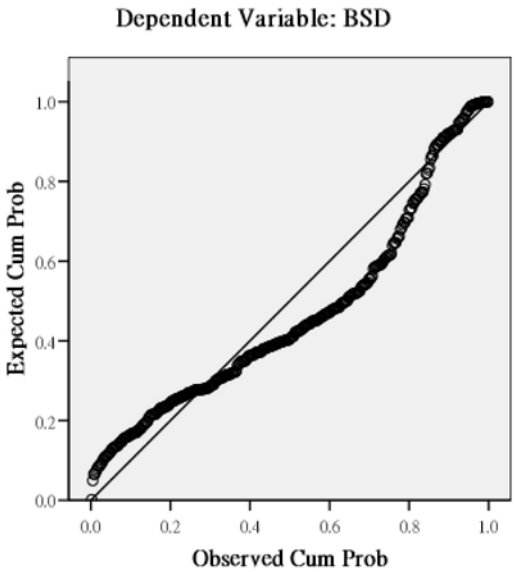

Fig. 2 Normal P-P plot of Regression Standardized Residual for Group 1

Group 2 has 340 numbers of data that selects all data from database when care-giver measures the value of blood sugar and record into database. Group 2's predicting model is below:

$$Y= -0.341_{BMI}+0.259_{SP}-0.205_{DP}+0.120_{Pulse} \quad (2)$$

Fig.3 showed the observed probability was much closed to normal distributes.

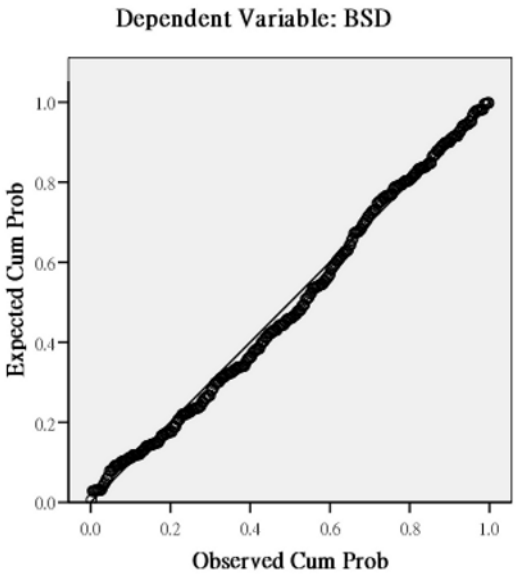

Fig. 3 Normal P-P plot of Regression Standardized Residual for Group 2

- ***Create knowledge Rule***

Two prediction models will be stored in the knowledge base. Excel format is good to store the knowledge rules. The expert system needs the rules and facts to inference the result.

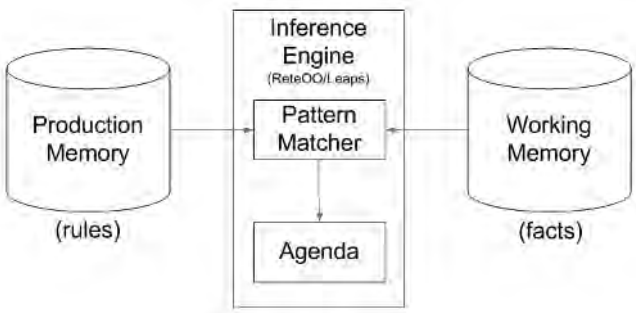

Fig. 4 Expert System common framework

Fig. 4 shows the basic expert system's framework. Rules will be creates by this study's prediction model. Facts will be the data that caregiver

measure with patients. JBOSS Drools is a kind of expert system. In this system, the knowledge rule will be store in Drools or decision table. Decision table can be used excel format. The expert system still be continue to develop. The prediction models will be transfer to domain rule language at that time.

IV. Discussion

Model 1 can predict the value of blood sugar with the patients have both diabetes mellitus and hypertension. Model 2 can predict the value of blood sugar with the patients have diabetes mellitus and other diseases except hypertension. In real condition, some other can cause the value of blood sugar to raise or descent. Like food is the other main reason can influence the value of blood sugar. When family go to healthcare center to visit the elder lived in center. They may take food for the elder. This will break the nutrition plan. The value of blood sugar becomes more difficult to control.

V. Conclusions

The study provides these models to predict the value of blood sugar. If care-giver need, they can measure the value by the standard procedure. Base on these prediction models, the healthcare center can know the patient' value of blood sugar without measure for save the operating cost. But ICT just provide the assist tools, not for replace the human resource. Human determine and experience are the most important than ICT assist tools. For patients' safety, human resource should be the main consideration.

This study just uses numerals to analysis the value of blood sugar. Feature, the multimodal data analysis need to be creates for more correct prediction rate. The more prediction rate, the ICT assist more helpful for care-giver.

Abstract — **The foot-pressure while walking represents the status of the geometrical balance of the human's musculoskeletal system. The foot-pressure in unbalanced anatomical position causes physiological disorders to the human body and accumulates stress to the musculoskeletal system. Repetitious abnormal impacts become the direct cause of vertebrae disease. The purpose of this study is to evaluate the correlation between the degree of scoliosis and the foot-pressure distribution in twenty males who have no clinical history of vertebral disease. The F-scan system(Tekscan Inc., USA, 850Hz sampling frequency) was used to measure the foot-pressure. The sole was divided into 7 regions of interest(ROI), and an analysis was performed for these ROIs. The degree of scoliosis was expressed as the angle, calculated with X-ray image, which showed lumbar vertebra number 5 to thoracic vertebra number 7. This angle was used to evaluate the correlations with the result of the foot-pressure analysis. Measurement of foot-pressure on the subjects was executed using the same protocol. The correlation between the measured foot-pressure and the degree of scoliosis was evaluated under a 0.05 level of significance. The results of the evaluation revealed the tendency that, as the degree of scoliosis increases, a difference in foot-pressure also increases. The variables used for analysis showed high correlations. The obtained results will be used to determine the occurrence of vertebra and lower limb disease and to present a qualitative evaluation basis for the rehabilitation of patients with lower limb disease.**

Keywords — **Foot-pressure, F-scan System, Scoliosis**

I. Introduction

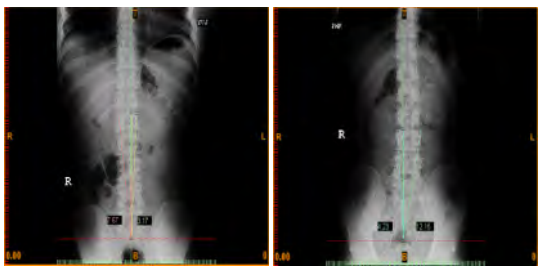
Gait is the most common motion of a human being and is learned involuntarily[1]. Gait cycle is a step made by two legs with a line drawn between the on-stance phase and swing period. Normal gait is the repetition of the movement process from the time when one heel reaches the ground to the time for the other heel to reach the ground. Foot-pressure distribution is made by the anatomical and functional status or state of the shoes and road surface while walking[2]. As the standard to reflect the balance of the human body, foot-pressure is one measurement point which is interesting in the clinical and research field of kinematics[3]. The pressure of particular sections of the sole can be observed by measuring foot pressure[4]. The gait pattern by with incorrect posture brings about physiological troubles, fatigues muscles and joints, and is the immediate cause of vertebral disorder because repetitive and abnormal impact is transmitted to the backbone[5].

Typical methods to measure foot-pressure, use a force plate, pressure plate or put pressure sensors in shoes. But methods using a force plate and pressure plate have measuring limits for the pressure of each part of the sole, and are not able to provide variable information about foot pressure[3]. The method of putting pressure sensors in shoes is useful to get information about the change in foot pressure while walking, and it is the primary method of measurement used since the 1990s. As concern about foot health is increasing, the measurement of foot pressure is studied for distribution analysis for patients with leg pain, diabetes, rheumatoid arthritis, and so on[6].

This study was performed to evaluate the relationship between foot pressure distribution and scoliosis. The same protocol for the experiment was given to all subjects and the foot pressure data was acquired and utilized to analyze the relationship between foot pressure distribution and scoliosis.

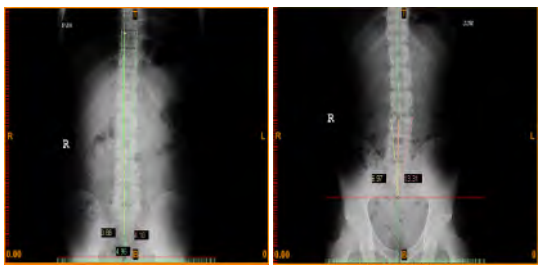
II. Material and Method

In this study, a F-scan®VersaTek System(Tekscan Inc., USA) was used to measure foot-pressure distribution data and a Research Foot ver 5.23(Tekscan Inc., USA) was used to analyze the data. Subjects were twenty year-old males who had no clinical history of vertebral disease and similar body conditions to minimize variation in measurement. Table 1 is characteristics of the subjects and Figure 1 is the X-ray image of the subjects, showing scoliosis direction and degree. In Figure 1, the scoliosis degree of (a) is 2.25 degrees to the right for the 12th thoracic vertebrae and (b) is 3.96 degrees to the left direction for the 2nd lumbar vertebra. The scoliosis degree of (c) is 1.61 degrees to the left for the 7th thoracic vertebrae and (d) is 3.32 degrees to the left for the 2nd lumbar vertebra.



In this study, the F-scan®VersaTek System(Tekscan Inc., USA) was used to measure foot-pressure distribution and consists of sensor assembly, PC interface device and signal process board. Pressure sensor assembly is similar to general foot form, and it is possible to control the size, since

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 974–978, 2009
www.springerlink.com



it made of thin material which is easy to shape. The sensor resolution for the foot-pressure measurement was 5mm × 5mm with the array form. The sensor has a cable about 10m long to allow for the free movement of the subjects. The Interface device attaches at ankle. The interface device consists of light material to minimize its affect on foot-pressure when a subject walks. The signal processing board sends the measured foot-pressure signal to a PC and acquires data for 850Hz sampling frequency. Figure 2 shows the foot-pressure measurement system and measuring method.

Table 1 Characteristic of Subjects

Subject	Age(yr)	Stature(cm)	Weight(kg)
1	25	177	84.5
2	26	181	84
3	25	179	84
4	23	180	68

(a) (b)

(c) (d)

Fig. 1 Analysis of Scoliosis using X-ray Image

Before the measuring foot-pressure, sensors were adjusted to fit a subject's foot size. Because the sensitivity of the sensor is influenced by shoes and friction on the road, the best sensitivity is obtained from bare feet. Consequently, foot-pressure was measured by adhering a sensor to the subject's bare foot. Data acquisition was collected separately about both the right and left foot. The reliability of data was assured by using the same measurement protocol and signal processing. For image mapping of the foot, the weight of the subject was entered in to Research Foot ver 5.23 and the subject stood on the foot that the sensor was attached to without moving for 5 seconds to allow for calibration. Following this, all subjects practiced their most natural and comfortable walks at a predesignated space. After the subject is judged to have a adapted himself to the changed environment, he performed ten free walks along a line which was drawn in the experiment space. Of all the acquired data, the first and last data entries were not used. Foot pressure distributions appeared in the same regions by using the mask image. Region of interest were divided into two-sections of prosole(M1, M2), three-sections of midsole(M3, M4, M5) and two-sections of backsole(M6, M7). Figure 3 shows the ROI.

Fig. 2 Measurement Hardware of Foot-Pressure and Measurement Picture

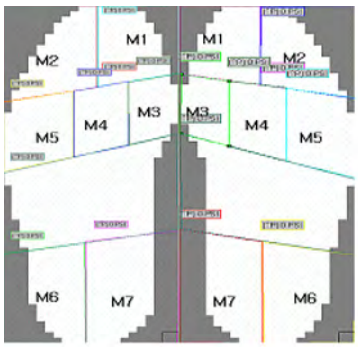


Fig. 3 Demarcation of ROI

III. Discussion & Results

The subjects of this study were healthy people who had never had any spinal disease. Foot pressure data was acquired from form left and right foot for 10 times and the total number was 20. 4~6 pieces of data without errors was

used for analysis of foot pressure. From this data some essential information was found(moving distance, axis point, inclination, direction). The result is Table 2.

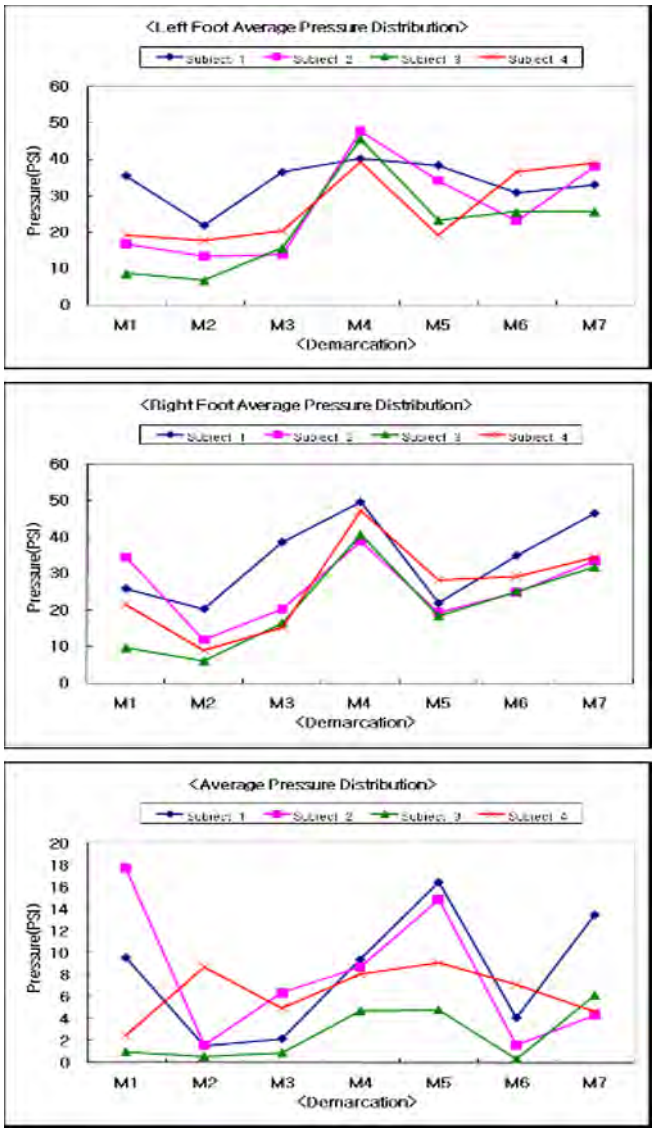

Fig. 4 Average Pressure Distribution; Left Foot(Top), Right Foot(Middle), Difference Pressure(Bottom)

Table 2 Basic Information of Mobility Route in Foot-Pressure

Subject	Distance		Slope		Direction
	Left	Right	Left	Right	
1	194.6±4.2	189.8±3.3	17.16	30.27	inner
2	172.0±5.0	179.5±1.5	27.56	48.38	inner
3	157.0±8.0	174.0±2.0	8.76	7.92	inner
4	162.0±9.6	163.5±9.1	26.38	16.04	inner

Figure 4 and 5 shows the pressure distribution average and maximum pressure. The maximum value showed that there was no difference at the M4 region, but the M5 region has the greatest difference. The area showed the contact status of the sole and the ground. There is a similar value for both the left and right foot while walking, but area of contact subjects who mainly use their mid-outsole and pro-sole when they walk is wider the than area of subjects who mainly use their midsole and backsole. Table 3 shows all the variable that were used for analysis. The vertebra formed "S" shape when viewed from at side and was when viewed from the front. The heavy scoliosis appeared as a sproportion of the body and occurred due to a difference in foot-pressure. In this study foot-pressure was measured during free walks, and the correlation between scoliosis and foot pressure was found by analysis of the variables.

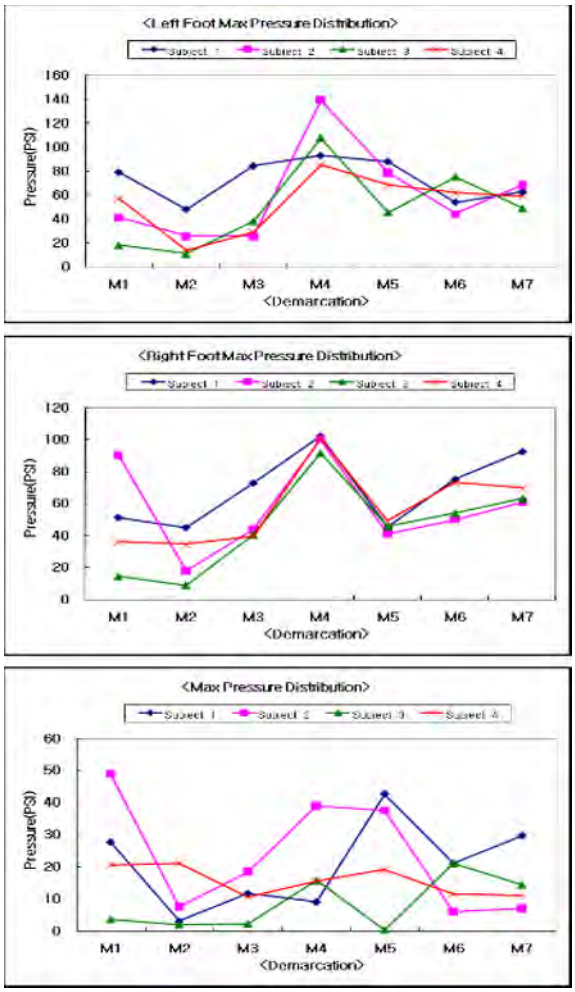

Fig. 5 Max Pressure Distribution; Left Foot(Top), Right Foot(Middle), Difference Pressure(Bottom)

Table 3 Result of Analysis of Foot-Pressure and Scoliosis

Subject	Slope	Area (mm^2)	Average/Max Pressure(PSI)							Scoliosis (°)
			M1	M2	M3	M4	M5	M6	M7	
1	13.11	275.58	9.6/27.7	1.5/3.0	2.17/11.7	9.42/9.0	16.5/42.7	4.1/21.0	13.5/29.7	2.25(R)
2	20.82	322.38	17.8/49.0	1.63/7.5	6.4/18.5	8.75/39.0	14.9/37.5	1.6/6.0	4.4/7.0	3.96(L)

4	10.34	222.5	2.5/20.5	8.8/21.0	5.0/10.5	8.1/15.5	9.1/19.0	7.1/11.5	4.6/11.0	3.32(L)

Table 4 Result of Correlation Analysis

	Slope	Average Pressure of Demarcation						
		M1	M2	M3	M4	M5	M6	M7
Correlation	.754*	.678*	.247	.563	.444	.410	-.058	-.359
Sig.(2-tailed)	.012	.070	.491	.090	.199	.239	.873	.309
N	10	10	10	10	10	10	10	10
	Different Area	**Max Pressure of Demarcation**						
		M1	**M2**	**M3**	**M4**	**5**	**M6**	**M7**
Correlation	.594	.692*	.218	-.534	-.227	-.594	-.268	-.583
Sig.(2-tailed)	.070	.027	.546	.112	.529	.070	.455	.077
N	10	10	10	10	10	10	10	10

In result, Table 3 shows that as the degree of scoliosis increases, the difference in foot-pressure also increases. Table 4 is the result of analysis of the correlation about all variables used. It was performed by Pearson analysis under the significance 0.05. In the results of the analysis, slope means the numerical value of the mobility route in foot pressure. It showed that as the degree of scoliosis increases, the change in the mobility route is expanded. The significance of the difference area of foot pressure left/right is 0.035. It means scoliosis occurred to the disproportion of the body. Significance of average pressure and maximum pressure distribution in M4(midsole), M6(back-outsloe), M2(a little toe) region was low, and in the case of M4, because all of subjects were used without scoliosis. In the case of M2, it is believed that the significance is low because individual differences appeared because one of the subjects used a little toe when they walked. In the case of M6, the low significance is considered to be due to a foot-pressure distribution difference appearing on the backsole area because of an ankle angle difference while walking. The significance of another area is high and foot-pressure distribution appeared by left/right load difference depending on the degree of scoliosis.

IV. Conclusions

In the study, foot pressure was measured to analyze the correlation between scoliosis and foot pressure. Center mobility route in foot pressure, average and maximum pressure in each ROI, area of on stance phase and degree of scoliosis were used as variables in the analysis. The analysis showed that the directivity of the center mobility route on foot-pressure was similar for all subjects and was not related to scoliosis. In addition, the tendency of the mobility route directivity and length among subjects had no relationship to scoliosis. The numerical values of variables were the proportional relationship with the degree of scoliosis. A high significance level was shown with the exception of three variables(M2,M4,M6) sixteen variables. It was considered that the method using foot pressure and the degree of scoliosis while walking can be used to diagnose the disease from an unbalance in the body. With these result, this study is considered to distinguish vertebral and lower limb disease, and is expected to act as a qualitative evaluation basis for rehabilitation of patients with lower limb disease.

Abstract — **The sensing of biological signals is very actual theme. Especially bioelectrical signals are commonly measured for the evaluating a health status of a man. This article is focused on the analysis and design of sensing electrodes by the use of unconventional materials for a long term bioelectric activity measurement with advanced capabilities in a transmission of signal, time-impedance stability and low half cell voltage. The advantages of this matter are in development also the electrodes to build up the sensing element for electrochemical matter detection. The possibility of glucose and cholesterol detection in cheap production process seems to be possible.**

The principle of electrodes is conducting polymers which can be built-up on a textile or other non primary conducting materials.

Keywords — **Biopotential Electrode, Conducting Polymer,**

I. Introduction

Nowadays the sensing of bioelectrical signals with high sensitiveness and long term parameter stability are much needed. Part of them are measured invasively and most of them especially in common medical profession non – invasively. In a long term measurement of bioelectrical activity there should be a problem with standard types of electrodes which has a time variable parameters. [1] [8] [9]

A. Biopotential electrodes

Electrodes (second class leader) have to make a quality conductive connection of these two types' line wires regarding to the fact that the tissue (first class leader) is a conductor of a different type that leads electricity by available ions. That is why the electrodes are supplemented with conductive gels that generate electrolyte to transmit passage electrode – skin. The electrolyte creates surrounding body fluids to undersurface electrodes. [1] [3]

Biopotential electrodes are active sensors – source of an electrical current, source of signal.

General requirements are: high-quality conductive connection skin- instrument, nontoxic and nonirritating for skin, chemical stability, sterility for invasive use, disinfection potentiality.

The biopotential electrode can be as an electrochemical half cell. In contrast of a chemical cell the polarity isn't constant. There are proceeding reducing oxidative reactions. At the electrochemical cell the half cell potential is the goal and instead at biopotential electrodes this is unwanted necessity. During a measurement on a human there is potential difference between electrodes and skin which we would like to measure. Regarding to ignorance and inability to measure the half cell voltage of electrodes exactly the irremovable error is added during measurement. That is why the evaluation of biosignals is not processed absolutely, but also is compared signal from more places and frequency analysis is provided. [2]

II. Methods

Conducting polymers are composed of long repeated constitutional group of chain. Common polymers like polyetylen or polyvinylchloride are non-conducting and they are usually use as an insulating material. However there has been a group of polymers which is chemically conducting.

From that reason of long term monitoring and sensing of biological data there is necessary to find out new materials and conception of sensing to obtain validate data. In this case the conducting materials like textile, polymers and conducting rubber is a way how to realize it. [3] [4]

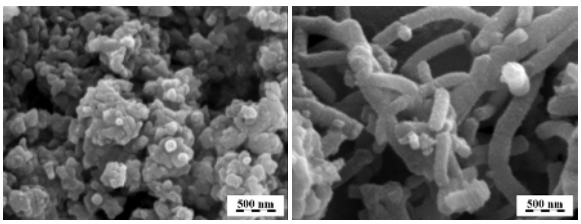

Fig. 1 During polymeration in strong acid environment rising granulation (left). In reduced acidity rising polyaniline nano tubes (right) [6]

Conductive polymers are forming system conjugate dual structures, i.e. in their structure regularly diversify simple and dual bindings Fig.1.

Except conjugation there is another necessary presumption seat electrical conductivity present bearers bullet that the mediating his transport through chains. They are rising which is in an analogy with classical semiconductor given a name geed - up. However substantial discrepancy is between geed - up organic and inorganic semiconductors. In

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 979–983, 2009
www.springerlink.com

polymers it is for example higher concentration than in inorganic semiconductors. [5]

Table 1 Changes of conductivity during the storage of PANI hydrochloride powder. [4]

Storage time	Conductivity (S cm–1)	
Title	Standard polyaniline	Polyaniline prepared in excess 1 M HCl
3 days	3.20 ±0.04	9.94 ± 0.27
4 months	2.59 ±0.06	12.70 ± 0.34
16 months	1.53±0.03	6.91 ± 0.14
19 months	1.63±0.02	6.87 ± 0.41

Electric conductivity of those group of polymers is at the level 0,01 – 30 $S.cm^{-1}$, i.e. it is compare with conductivity inorganic solid - state materials, as is for example germanium Table 1. Conductivity is then manifold lower in comparison with metals, as is copper or silver, overleaf is but heaps order higher, than it is customary near common polymers. [3] [5]

III. Implementation analysis

The sensor design is a part of the process called implementation analysis. This is set from the implementation layers:

- Knowledge model
- Sensitivity analysis
- Sensor design
- Tests

At the beginning there is necessary to collect the knowledge model. This contains the information about what type of sensor is designed on, what sort of measured variables is measured and the explicit expression of models. Knowledge model is very important for other implementation layers.

The layer of sensitivity analysis consists in an assessment of their relevant changing factors. In the layer of sensor designed is made a list of existing sensors or rules of relevant factors to design new one.

The test layer verifies the quality of the chosen or designed sensor concerning required factors. Also there is a possibility to adjust the knowledge model and sensitivity analysis entry conditions to improve the sensor characteristics.

IV. Knowledge model

Knowledge model specify of physician-expert requirement for measuring the specific biosignals. In our case it is bioelectric signal measure none invasively on the skin. The input information's are: 0,1 – 50mV voltage range, 0 – 1000 Hz frequency range, 40 – 100% humidity range, 2,1 – 7,8 pH range, -40 – 50 °C temperature range etc..

From the physician requirements are not specified the information about accuracy and resolution of bioelectrical signal. These properties have to be linguistic expression and they are input of sensitivity analysis.

V. Sensitivity analysis

Sensitivity analysis establishes an important parameter for sensor selection or new design. In the sensitivity analysis we got layers up from linguistic expression and also from principles of physical measurement. The result is sensitivity level influence of an assigned value. It means that the sensitivity of input/output transmission has the desired value.

Biosignals desired value is deterministic. Most of them are time variable in spite of all regulated fixed factors. That is why it is necessary to reflect some of the criterions like: sensitivity, error, range, resolution, accuracy, time response and others.

In the dependence on a sensor type we can also distinguish from proper and mediate biosignals types, measurement methods and sensor utilization in medical diagnostics.

General requirements on bio-sensors are:

- Explicit input/output sensitivity
- Preferably linear dependence
- Maximal sensitivity
- Acceptable transfer function modality
- Time stability of sensor
- Minimal parasitic dependence
- Minimal measured object stress
- Maximal reliability
- Minimal energy consumption
- Simple construction and maintaining

Sensitivity analysis is mostly done by expert access. Outgoing list then specifies an important respect of sensor selection/design as: speed of response, material, dimension, cable length, impedance and other related aspect for example sensor placement, case making, atc..

A. Deterministic method of sensitivity analysis

Deterministic method is based on partial derivation of input particular parameters implied function.

There can be set a partial derivation in an analytical way for more simple models. For a complex one it can be done by numerical approximation.

By system's analyzing and synthesis there are used mathematical models which are taken to be well known. In reality the real system can not be identified accurately. It is not possible to solve most of tasks without model's simplification. The sensitivity knowledge on parameters change should be necessary piece of every task of identification, analysis, synthesis and also optimization.

Mathematical model is assigned to a certain variable to parameter vector **g.** The variable can be temperature, electrical potential, pH, impedance etc. The parameters are material, response, accuracy, resolution, etc. In certain conditions of continuity assignment can be make out matrix function **S.** This function is sensitivity function. [11]

Vector of parameters is defined by:

$$\mathrm{g}(\mathrm{a}):\mathrm{R}^{m}\times\mathrm{R}^{n}\rightarrow\mathrm{R}^{m} \tag{1}$$

$$\mathrm{g}=\left\{\mathrm{g}_{1}(\mathrm{a}),\mathrm{g}_{2}(\mathrm{a}),\mathrm{g}_{3}(\mathrm{a}),\ldots,\mathrm{g}_{\mathrm{m}}(\mathrm{a})\right\} \tag{2}$$

Sensitivity function is generally defined as Jacobian:

$$S_{i,j}=\frac{\partial g_{i}(\mathrm{a})}{\partial a_{j}}\quad i=1,2,\ldots,m\ and\ j=1,2,\ldots,n \tag{3}$$

The S function is except a parameters also generally dependent on time, frequency, input quantity, etc.. That is why S function is not matrix coefficient but sensitivity function.

For sensitivity function there stand the same rules as for partial derivations. Sensitivity functions in time realm are actually time behaviors of a function. They can be easily simulated by sensitivity models. The functional can be defined to sensitivity functions. They characterize the sensitivity globally by one number that is called sensitivity rate.

VI. Sensors design

A great problem occurs at the ECG measurement. The medical instrument should be transportable and that's why the electrodes has to be part to not to manipulation illimitability. The problem rises how to create the electrodes which can by only put on the skin and not to be stick by conducting stick or gel (dry electrode). As a result it is clear that the designed electrode should be no metal or gel one. For the construction of this kind of electrode the same principles were used as in common electrode. Also the interface skin - electrolyte (gel) – metal. Instead the electrolyte there was used material referred to conducting polymer. It is a mixed conductor. There is neither first-order conductor nor second-order one.

From that reason the polyamide is suitable for making dry bioponetial electrode. Their conductivity is 4 $S.cm^{-1}$ is sufficient because they are settled in thin film form with thickness 100nm.

The production of this type of electrode takes apx. 15 minutes and there is also the need of another 12 hours for desiccation. The production is very cheap and easy to attach for a single use. The price of one polymer electrode realization is apx. 0.25 EUR. For the electrodes manufacturing we can use them with an advantage that there isn't registered any toxic or irritable character.

We can qualify it as a harmless electrode. Another advantage is that the utilization of the material can be manufactured electrode on any matter to resisted acidic medium. Textile materials are easy to use and that is why the electrodes on Velcro fastener were made. Velcro both side fastener is covered by polyaniline. [6], [7]

VII. Results presentation

The testing layer serves for verifying of designed procedures and also for function testing. This can also improve obtaining of valid information about measured value.

During the testing on three leads ECG there was found out that manufactured electrodes are well usability. The measurement were done by ECG being short (pectoral) bipolar placement gained by bioamplifier G.BSamp, 16 channels from G.tec medical engineering GmbH and digitalized by A/D card NI DAQPad-6052E. The results were measured with common attached electrodes on computer at the same time. The measured results were mathematically compared and results were presumable and plausible.

Electrodes were mounted on flexible t-shirt made on elastics fiber. Adherence pressure was too small to well connect skin with electrode and that is why the great interference voltage arose. Consequently there was added the elastic belt on thoraxes to improve adherence pressure of the electrodes.

For impedance characteristics measurement Eval AD5933 module was used. The measurement of impedance was done in frequency range 700 Hz to 15 kHz. The testing voltage was 2 V.

Impedance characteristics measured on AG/AgCl electrode with the gel RED Dot 2570 and Polyaminil covered

textile. Both were measured on six samples each. Results evaluation was compared by value of standard deviation σ (4). The range of σ were between 0,006 to 0,015 Ω.

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}\left(X_i - \bar{X}\right)^2} \qquad (4)$$

where:
X_i - difference between Ag/AGCl and Polyaminil txtile
N - number of values of impedance record (N=14300)

During the tests we designed the electrodes for measuring the glycaemia. The electrodes are silicon (roller) or plastic PVC (wafer) ground. On the Fig. 2. On the matter is 100 nm thin polyamynil thin film. This can be use with the advance of easy and cheap construction of glycaemia strip.

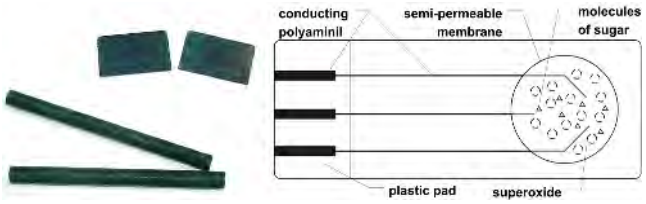

Fig. 2 Semi finished material as silicon (roller) or plastic PVC (wafer for glycemia sensor) ground electrodes covered by polymer and glycemia sensor strip design with polyaniline conducting way

For the biopotential measuring also from plant we designed the process of covering the plant by conducting polymer. The differences between normal matter and plant is in final step of stabilization of the allied substances. In normal process of stabilisation there is used the acid with 5 -7 pH which is absolutely scathing for the plant. That is why we modify the final procedure of stabilizing and we were able to use acid with 2 pH for making the polymer conducting as in dead matter.

VIII. Discussion

We are able to mention that polyamides are suitable material for biopotential electrodes construction from acquired results of our experiments. But there is a need to concentrate on parameters´ measuring and monitoring in long term firmness - both an electro technical and a mechanical. From the point of view the tissue feature that changes its acidity and pH, there can be changes in electrical features of biopotential electrodes in specific circumstances. That is why it is also important to concentrate on materials mechanical resistance.

Also a wide range of sensor design methods can be discussed. Except deterministic method we can use also statistical, graphical and others based on fuzzy, neural network and chaos theory. This has to be verified because probably none of them are multi-purpose for all physical variables.

IX. Conclusions

In the present time the health telemetry systems create an integral part of our everyday lives. The sensors are the primary part of these systems and also the improvement on design, new materials, constructions and sensor disposition are actual nowadays. Our research and tests enabled us to find out that electrochemical allied substances seem to be appropriate for the future applications.

Fall Detection Unit for Elderly

Arun Kumar, Fazlur Rahman, Tracey Lee

Singapore Polytechnic, Singapore

Abstract — **A fall in case of an elderly person can result in quite serious injuries because of his/her fragile bone structure. In-fact, in one of the recent medical studies on "The Presentation of Elderly People at an Emergency Department in Singapore", published in the Singapore Medical Journal, falls were found to be the second most common cause. Our team has designed and developed a small sized, portable sensor unit that can detect a fall and subsequently send a help request message to the care-giver or a central monitoring station. This unit, which is based on a microcontroller and 3-axis accelerometer, can easily be worn on the waist belt without being obtrusive in a user's normal activities. A number of power saving features have been included in the unit. The signal processing software on microcontroller has been developed to differentiate between the normal movements e.g. sitting, lying down and the movements resulting from a fall. Two different kinds of wireless communication methods, RF and GSM, have been developed and tested in these units. RF communication is useful when a number of persons need to be monitored within a small area using a central monitoring station e.g. in an elderly home. GSM communication has been developed keeping in view the elderly persons staying alone. The GSM based sensor unit is able to send a SMS directly to the caregiver in case a fall is detected. An additional feature, which allows the user to request for help whenever required, has also been incorporated into the unit.**

Keywords — **Fall detection, elderly care, assistive technology, accelerometers, microcontroller based device.**

I. Introduction

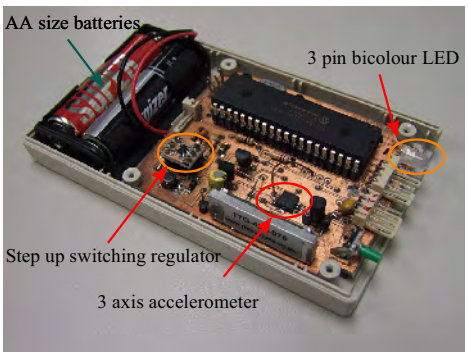
This paper describes a hardware device that has been developed to monitor the well-being of elderly persons living alone in home and also for the residents of an old-age home. Generally they are not in the prime of their health; hence keeping a check on their general wellbeing is necessary. Presently most of the monitoring is done by caregivers, nurses or volunteers stationed at the location. If certain parts of these monitoring can be automated, caregivers and others can be relieved of some of their duties and the elderly can lead a more independent life. In the case of the elderly one of the major causes of worry is a fall, because most of the time a fall in their case results in a serious injury because of their fragile bone structure. In fact, in one of the recent medical studies on "The Presentation of Elderly People at an Emergency Department in Singapore", published in Singapore Medical Journal, falls was found to be the second most common cause of injuries [1].

The system developed by our team, is capable of detecting a fall in a user and it can subsequently inform the care giver. The sensor unit is small in size; battery operated with a number of power saving features and can be worn by the user in an unobtrusive manner. The unit is able to communicate wirelessly with a central monitoring station and/or the hand phone of care taking person using RF/GSM communication.

II. System setup

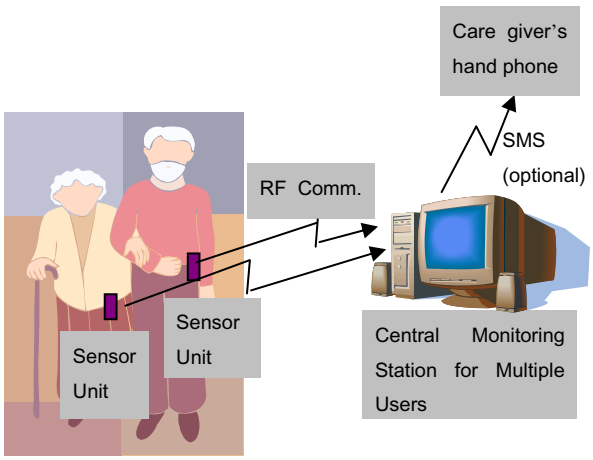
Two different prototypes of the sensor units were designed, developed and tested, with both of them based on a PIC18f4520 microcontroller and 3D accelerometer (Table 1). These prototypes have been described below. Microchip PIC18F4520 was selected because it has low power consumption, is low cost, has powerful development system and can be easily programmed using ICD2 Debugger [2-3].

Table 1: Characteristics of two developed prototypes



Unit	Sensor Unit Hardware	Sensor Unit Software	Receiver
1	PIC18f4520 microcontroller based unit with a number of power saving features +accelerometer	Program developed to detect fall and transmit the message using RF transmitter.	Computer based GUI program designed - to show data from multiple users. - with option to send out a help request SMS using GSM modem.
2	PIC18f4520 microcontroller based unit + accelerometer	Program developed to detect fall and to interact with a GSM modem to transmit the message using SMS.	Caretaking person's hand phone

Prototype I



Prototype 1 is based on a microcontroller board which has been designed and developed by our team, with PIC18f4520 microcontroller chip (Figure 1a) [4]. The sen-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 984–986, 2009
www.springerlink.com

sor unit (microcontroller board with accelerometers) is programmed to filter and process the accelerometer signal and detect a fall. Three volts battery based supply is used to power up the sensor unit. A wireless (RF-433MHz) transmitter is used to transmit the fall detect signal to a receiver unit.

(a)

(b)

Figure 1: (a) Sensor unit (b) Set up for prototype I

A sensitivity switch is also provided on board to adjust the sensitivity of the unit according to the normal movement pattern of a person. For example, if the person tends to have more abrupt movements normally, the sensitivity of the unit may be lowered to reduce the false alarms. If the person in general has slow movements, the sensitivity can be set to high. In the designed unit, we have allowed the connections for the In Circuit Debugger (ICD), to facilitate programming the device and for debugging. Also the wired connection is retained, as we also may need it to debug the wireless serial link. Finally, we eschewed the use of a connector for the on/off switch and used a PCB mounted switch instead. Also, we have used ST LIS3AL02 3-axis accelerometers to reduce the parts count and also for more efficient usage of space in the unit. We used a specialized boost circuit incorporating the LM2731. This part can provide the voltage even when the combined cell voltages have dropped to 2.2 V. We have opted for a through hole and surface mount (SM) configuration and mounted the SM LM2731 on a special socket. This is in order to avail ourselves of new voltage control technologies as this is currently an active area of development, with the rising price of electrical energy. Some power saving features has been included to make the battery life time longer. The unit does not send the data continuously; instead it sends the data only when the fall is detected. The processor has been programmed in the sleep mode and allows the timer to wake it up during normal operation for saving energy. A LED on the sensor unit has also been programmed to light up whenever the unit recognizes a fall, in order to show the user that a message for his/her help is being sent out. The setup is as shown in figure 1b.

The receiver unit is computer based with a RF receiver (Figure 2), and running the virtual instrumentation (VI) program [5-6].

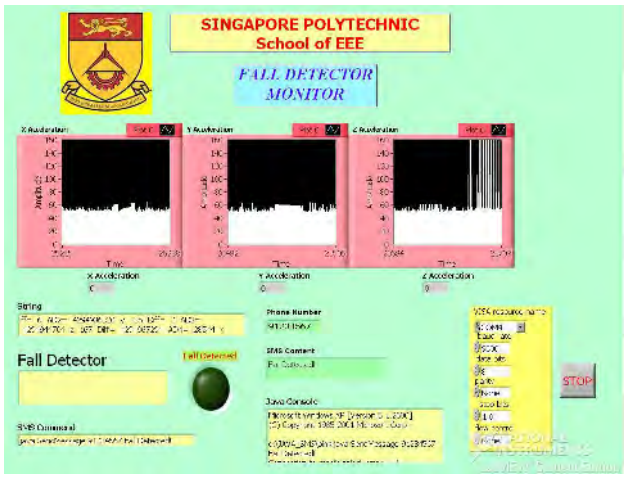


Figure 2: Receiver unit's user interface

The receiver unit is capable of monitoring multiple users at the same time. It is useful when a number of persons need to monitored from a central station e.g. old-age home. Since the range of RF receiver is limited, multiple RF receivers are used around the premises. These multiple receivers are connected to the same monitoring station. The limited range of multiple RF receivers around the old-age home is used in

detecting the location of the elderly. Based on the RF receiver which is receiving the data, we can have some information about the location of the elderly. An option has been provided in the receiver to forward the 'fall detected' message to the caregiver's hand phone, using a GPRS modem, whenever a fall is detected in any one of the users. In this case there is a single modem connected to the receiver unit.

Prototype 2

In this setup, the microcontroller board used is the same as in prototype 1, but instead of the RF transmitter a GSM modem is attached to the microcontroller board (Figure 3). GSM modem is connected to the serial output of prototyped circuit board and a set of *AT commands* are used by the microcontroller board to operate the modem. The microcontroller board is programmed to send a 'help request' SMS whenever it detects a fall. A single unit can also be programmed to send help request to multiple care giving persons, in case required.

Figure 3: Prototype 2

This setup has the advantage that it can be used as a stand-alone unit. It does not require any computer based receiver as used in prototype 1. Prototype 1 is more appropriate in old-age homes, where a number of users need to be monitored centrally. Prototype2 on the other hand is useful for the elderly staying alone at home.

In this setup, the receiver unit is the care giver's hand phone, capable of receiving SMS. The text of the message, e.g. 'Fall Detected', can be set up in the microcontroller program.

III. Conclusions

Two prototypes of small sized fall detection units have been designed, implemented and tested successfully. These units are low cost solutions to detecting falls in elderly and in providing information to the caregivers, resulting in timely aid for the elderly in case of a fall. The system will also be useful in monitoring the dementia patients that get up from bed during night, and also the patients suffering from frequent urination to keep check on number of times they go to toilet. The design of this product proved to be very enlightening for our design group, the electronic and mechanical design re-emphasized the importance of user interface design. The power saving and wireless aspects of the design gave us the experience for future similar ventures.

Abstract — **Often, people travelling in ships, trains, aircraft, and cars tend to experience motion sickness. It has been reported that even users of virtual environments and entertainment systems experience motion sickness. This visually induced motion sickness (VIMS) is known to be caused by sensory conflict, which is the disagreement between vergence and visual accommodation while observing stereoscopic images. VIMS can be measured by psychological and physiological methods. The simulator sickness questionnaire (SSQ) is a well-known method that is used herein for verifying the occurrence of VIMS. We also quantitatively measure the sway of the centre of gravity of the human body before and during exposure to several types of movies. During the measurement, subjects are instructed to maintain the Romberg posture for the first 60 s and a wide stance (with midlines of the heels 20 cm apart) for the next 60 s. The centre of gravity is projected on a plane that is parallel to the ground. The body sway is recorded as a stabilogram on the plane. According to previous research, a stochastic process is regarded as a mathematical model that generates stabilograms. We propose a method to obtain stochastic differential equations (SDEs) as a mathematical model of the body sway on the basis of the stabilogram. While there are several minimal points of the temporally averaged potential function involved in the SDEs, the stereoscopic images decrease the gradient of the potential function. We have succeeded in estimating the decrease in the gradient of the potential function by using an index called sparse density.**

I. Introduction

The human standing posture is maintained by the body's balance function, which is an involuntary physiological adjustment mechanism called the 'righting reflex' [1]. In order to maintain the standing posture when locomotion is absent, the righting reflex, centred in the nucleus ruber, is essential. Sensory receptors such as visual inputs, auditory and vestibular functions and proprioceptive inputs from the skin, muscles and joints are the inputs to the body's balance function [2]. The evaluation of this function is indispensable for diagnosing equilibrium disturbances such as cerebellar degenerations, basal ganglia disorders, or Parkinson's disease in patients [3].

Stabilometry has been employed to evaluate this equilibrial function both qualitatively and quantitatively. A projection of a subject's centre of gravity onto a detection stand is measured as an average of the centre of pressure of both feet (COP). The COP is traced for each time step, and the time series of the projections is traced on an xy-plane. By connecting the temporally vicinal points, a stabilogram is composed, as shown in Figure 1. Several parameters such as the area of sway (A), total locus length (L) and locus length per unit area (L/A) have been proposed to quantitize the instability involved in the standing posture, and such parameters are widely used in clinical studies. It has been revealed that the last parameter particularly depends on the fine variations involved in posture control [1]. This index is then regarded as a gauge to evaluate the function of proprioceptive control of standing in human beings. However, it is difficult to clinically diagnose disorders of the sense of balance function and to identify the declines in equilibrial function by utilizing the abovementioned indices and measuring patterns in the stabilogram. Large interindividual differences might make it difficult to understand the results in comparison.

Mathematically, the sway in the COP is described by a stochastic process [4]-[6]. We examined the adequacy of using a stochastic differential equation and investigated the most adequate one for our research. G(x), the distribution of the observed points x, has the following correspondence with V(x), the (temporal averaged) potential function, in the stochastic differential equation (SDE) as a mathematical model of the sway:

$$V(\vec{x}) = -\frac{1}{2}\ln G(\vec{x}) + const. \qquad (1)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 987–991, 2009

The nonlinear property of SDEs is important [7]. There were several minimal points of the potential. In the vicinity of these points, the SDE shows local stable movement with a high-frequency component. We can therefore expect a high density of observed COP in this area on the stabilogram.

The analysis of stabilograms is useful not only for medical diagnosis but also for explaining the control of upright standing for two-legged robots and for preventing falls in elderly people [8]. Recent studies suggest that maintaining postural stability is one of the major goals of animals, [9] and that they experience sickness symptoms in circumstances where they have not acquired strategies to maintain their balance [10]. Riccio and Stoffregen argued that motion sickness is not caused by sensory conflict, but by postural instability, although the most widely known theory of motion sickness is based on the concept of sensory conflict [10]-[12]. Stoffregen and Smart (1999) report that the onset of motion sickness may be preceded by significant increases in postural sway [13].

The equilibrium function in humans deteriorates when observing 3-dimensional (3-D) movies [14]. It has been considered that this visually induced motion sickness (VIMS) is caused by the disagreement between vergence and visual accommodation while observing 3-D images [15]. Thus, stereoscopic images have been devised to reduce this disagreement [16]-[17].

VIMS can be measured by psychological and physiological methods, and the simulator sickness questionnaire (SSQ) is a well-known physiological method for measuring the extent of motion sickness [18]. The SSQ is used herein for verifying the occurrence of VIMS. The physiological methods measures autonomic nervous activity: heart rate variability, blood pressure, electrogastrography, and galvanic skin reaction [19]-[21]. It has been reported that a wide stance (with midlines of the heels at 17 cm or 30 cm apart) significantly increases total locus length in stabilograms of the high SSQ score group, while the low score group is less affected by such a stance [22].

This study proposes a methodology to measure the effect of 3-D images on the equilibrium function. We assume that the high density of observed COP decreases during exposure to stereoscopic images [14]. Sparse density (SPD) would be a useful index in stabilometry to measure VIMS (Appendix). In this study, we show that reduction of body sway can be evaluated by the SPD during exposure to 2D/3D movies on a Liquid Crystal Display (LCD).

II. Materials and method

Ten healthy subjects (23.6 ± 2.2 year) voluntarily participated in the study. All of them were Japanese and lived in Nagoya and its surroundings. The subjects gave their informed consent prior to participation. The following were the exclusion criteria for subjects: subjects working the night shift, subjects with dependence on alcohol, subjects who consumed alcohol and caffeine-containing beverages after waking up and less than two hours after meals, and subjects who may have had any otorhinolaryngologic or neurological disease in the past (except for conductive hearing impairment, which is commonly found in the elderly). In addition, the subjects must not have been using any prescribed drugs.

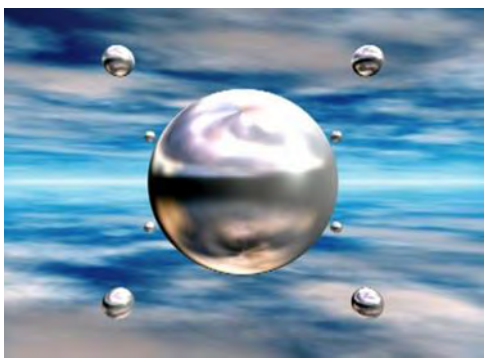

Fig. 1. A scene in the movie.

Fig. 2. The setup of the experiment

We ensured that the body sway was not affected by environmental conditions. Using an air conditioner, we adjusted the temperature to 25 °C in the exercise room, which was kept dark. All subjects were tested from 10 am to 5 pm in the room, which was located in Nagoya University. The subjects were positioned facing an LCD monitor (S1911-SABK, NANAO Co., Ltd.) on which three kinds of images were presented in no particular order: (a) a visual target (circle) whose diameter was 3 cm; (b) a 2-D movie that shows a sphere approaching and going away from subjects irregularly (Fig. 1); and (c) a 3-D movie that shows the same sphere motion as in (b). The distance between the wall and the subjects was 57 cm (Fig. 2).

A. Stabilometry

The subjects stood without moving on the detection stand of a stabilometer (G5500, Anima Co., Ltd.) in the Romberg posture with their feet together for 1 min before the sway was recorded. Each sway of the COP was then recorded with a sampling frequency of 20 Hz during exposure to one of the images. The subjects viewed a movie (image) on the LCD from beginning to end. SSQ was employed before and after this stabilometry.

B. Calculation procedure

We calculated several indices that are commonly used in the clinical field [23] for stabilograms, such as "area of sway," "total locus length," and "total locus length per unit area." In addition, new quantification indices that were termed "SPD" and "total locus length of chain" [24] were also estimated (Appendix).

III. Results and Disscussion

Typical stabilograms are shown in Fig. 3. In these figures, the vertical axis shows the anterior and posterior movements of the COP, and the horizontal axis shows the right and left movements of the COP. The amplitudes of the sway that were observed during exposure to movies (Figs. 3b and 3c) tended to be larger than those of the control sway (Fig. 3a). Although a high density of COP was observed in the stabilograms (Fig 3a and 3b), the density decreased in stabilograms during exposure to stereoscopic movies (Fig. 3c).

A theory has been proposed to obtain SDEs as a mathematical model of the body sway on the basis of the stabilogram. According to Eq. (1), there were several minimal

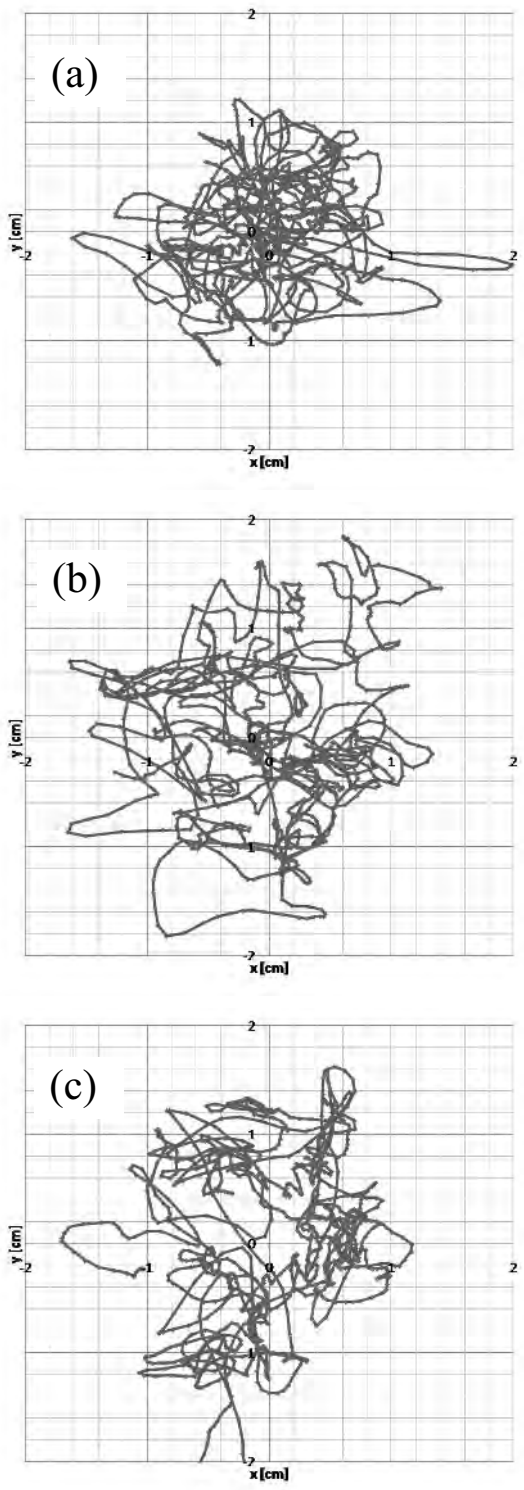

Fig. 3. Typical stabilograms observed when subjects viewed (a) a static circle, (b) the 2-D movie, and (c) the stereoscopic movie.

points of the temporally averaged potential function involved in the SDEs (Fig. 3). The movies, especially stereoscopic images, decrease the gradient of the potential function. 2-D images should reduce the body sway because there is no disagreement between vergence and visual accommodation. The reduction can be evaluated by the SPD during exposure to the movies on the LCD. We have succeeded in estimating the decrease in the gradient of the potential function by using the SPD in accordance with a one-way analysis of variance.

APPENDIX

Here, we describe the new quantification indices, or 'SPD' and 'total locus length of chain' [25].

A. Sparse density (SPD)

SPD was defined by a scaling average of the ratio $G_j(1)/G_j(k)$, where $G_j(k)$ is the number of divisions having more than k measured points; a stabilogram was divided into quadrates whose latus was j times longer than the resolution. If the centre of gravity is stationary, the SPD value becomes 1. If there are variations in the stabilograms, the SPD value becomes greater than 1. In this manner, SPD depends on the characteristics of the stabilogram and the motion process of the COP.

B. Chain

The force acting on the centre of gravity of the body was defined in terms of the difference in the displacement vectors. In particular, we focussed on singular points at which statistically large forces were exerted. On the basis of these forces, chains were eliminated from the stabilogram in the form of a consecutive time series42. If the times measured at these points were in the temporal vi-cinity, these points were connected by segments (sequences). Figures formed by these sequences were called 'chains' because of the shape of the connections. The figures of sequences of points at which large forces were exerted show that the chain had a cusp pattern.

ACKNOWLEDGMENT

Movies shown to subjects in this study were produced Olympus visual communications Co. Ltd.
