Abstract — **It is proposed that osteocytes embedded in mineralized bone matrix play a role in mechanosensory system during bone remodeling for mechanical adaptation. Various experimental and computer simulation approaches have revealed that the osteocytes sense the mechanical stimulus such as deformation/force and microdamages in bone matrix generated by mechanical loading, and also still have continued discussion. In this study, for interest to morphological character of osteocytes, we investigated site-dependence of mechanosensitivity in the osteocytes through observation of calcium response to applied local deformation. We developed a quantitative method using a microneedle and microparticles to apply local deformation to an isolated chick osteocyte, and analyzed intracellular calcium dynamics to the applied deformation. As the results, the applied local deformation induced calcium response at the vicinity of the stimulated point and caused its diffusive wave propagation to whole intracellular region in a single osteocyte. Furthermore, the large deformation was necessary at the cell body to induce calcium response, while a relatively small deformation was sufficient at the cell process, suggesting that the mechanosensitivity at the cell process was higher than that at the cell body. These results suggest that the cell shape with processes contributes to the mechanism of cellular response to mechanical stimulus in osteocytes, and that the site-dependent mechanosensitivity depends on cell shape in a single osteocyte.**

Keywords — **Osteocytes, Cell Biomechanics, Mechanical stimulus, Calcium signaling response**

I. Introduction

Osteocytes embedded in mineralized bone matrix have been proposed to have functions as a mechanosensor. In bone matrix, osteocytes construct intercellular networks with surrounding osteocytes as well as with osteoblasts on the bone surface. In this network, the osteocytes sense the deformation/damage, which is generated by mechanical loading to trabecular bone, and transmit to other bone cells via intercellular network in the bone matrix, through which coordinate the adaptive remodeling response [1, 2]. Although the character of the mechanical stimulus that acts on the osteocytes as a result of bone loading is still unknown, several potential stimuli affecting osteocyte function are proposed by recent studies. [3-8]. For example, interstitial fluid flow [3, 6] and bone matrix deformation [7, 8] are well proposed as hypothesized mechanical forces for the activation of osteocytes in the bone matrix, which have been continued discussion from each other's positions.

When osteoblasts differentiate into the osteocytes, they change their morphology to a stellate form with many slender processes, which is sustained even *in vitro* culture environment. This characteristic cell shape may bring about difference in mechanosensitivity between cell body and cell processes. The view of site-dependence may also provide information to insight the mechanosensing mechanism of osteocyte in bone matrix.

In this study, we investigated site-dependent response to mechanical stimulus in isolated osteocytes *in vitro*. Local mechanical stimulus was applied to a single osteocyte using a glass microneedle targeting a microparticle adhered to the cell membrane, and cellular response induced by application of a local deformation was observed with the technique of calcium imaging. To evaluate amplitude of stimulus to generate transient, we developed quantitative method to apply local deformation to the osteocytes, and analyzed the intracellular dynamics to the applied deformation.

II. Materials and methods

A. Isolation of osteocytes

Osteocytes were isolated from 13-day-old embryonic chicken calvariae with modification of the method as described in Kamioka et al. [9]. Isolated cells were plated on ϕ = 35 mm glass-bottom dishes at a density of 7.5×10^3-2.0×10^4 cell/dish and were incubated for 15-18 h in α-MEM that contained antibiotic and 2% fetal bovine serum (FBS) at 37°C. The culture dishes were coated with poly-D-lysine and fibronectin in advance.

www.springerlink.com

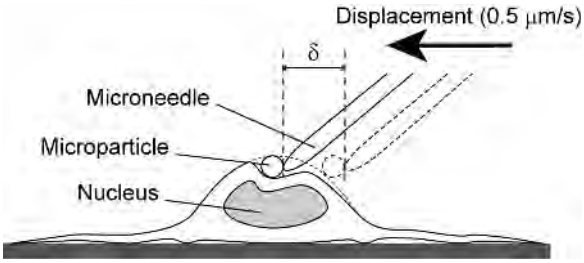

Fig. 1 Application of mechanical stimulus to an osteocyte

B. Applying localized deformation

A local mechanical stimulus was applied to single osteocyte using a glass microneedle via polystyrene microparticles (ϕ = 1.0 μm) attached on the cell membrane, as illustrated in Fig. 1. Microparticles were coated with monoclonal antibody (MAb) OB7.3, which is specific to chicken transmembrane protein Phex [10], to identify osteocytes and improve adhesion properties to osteocyte cell membrane. To confirm microparticle coating with OB7.3 and adhesion of the coated microparticles to the osteocytes, we observed the microparticles with immunofluorescence imaging and field emission scanning electron microscopy in advance. To quantitatively apply the mechanical stimulus, microneedle was moved horizontally at a constant velocity controlled (v = 0.5 μm/s). Using phase contrast microscopy, position and displacement of the microparticles were traced. Then, a series of images was obtained at 0.25 s intervals, and detection of the initial movement of the targeted microparticle was defined as t = 0 s for the measurement of cell deformation. The displacement of the microneedle δ (μm), which corresponds to the microparticle displacement after t = 0 s, was defined as the measure of the mechanical stimulus to the osteocytes. Thus, when calcium response to the mechanical stimulus was observed, the time t was recorded and converted into the microneedle displacement δ, that corresponds to the microparticle displacement.

C. Calcium imaging

The concentration of intracellular calcium ion, $[Ca^{2+}]_i$, was evaluated by ratiometric method. Using two fluorescent indicators with different fluorescent characteristics, by which the ratio of the detected fluorescent intensity was evaluated. Calcium indicators, 6 μM fluo-4 AM and 8 μM Fura Red AM were loaded into the cells. After incubation, the cells were rinsed with Dulbecco's Phosphate Buffer Saline (DPBS), and the medium was replaced by CO_2 independent medium for pH stabilization.

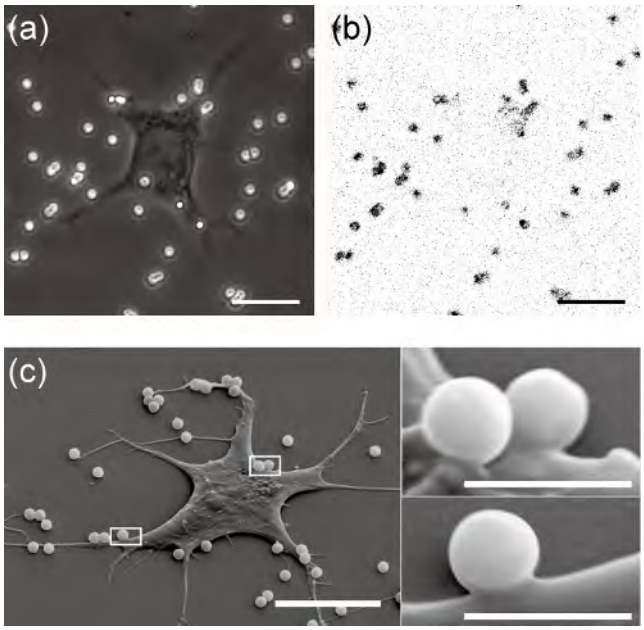

Fig. 2 Microparticles attached on the cell membrane for application of mechanical stimulus. (a) and (b): Surface treatment of microparticles with OB7.3. (a): Transmitted image. Bar = 10 μm (b): Fluorescent image of microparticles labeled by indirect immunofluorescence. Bar = 10 μm (c): FE-SEM images of an osteocyte with microparticles. Right images are both magnified view of images of two regions in left image. Bar = 10 μm (left) and 2 μm (both right)

The calcium response to the applied local deformation was observed using a confocal laser-scanning microscope (LSM510, Carl Zeiss). Image processing and analysis were performed using Image-Pro Plus 4.51 software (MediaCybernetics).

III. Results

The OB7.3-coated microparticles were utilized as a marker of osteocytes as well as a mediator of applied mechanical stimulus to the cell using a microneedle. Microparticles dispersed to culture dish were found to adhere stably to the cell membrane even after washing. Fluorescent immunolabeling confirmed that all observed microparticles in phase contrast image (Fig. 2(a)) were coated by OB7.3 (Fig. 2(b)). Scanning electron microscopic images showed the attachment site of the microparticles to the osteocytes (Fig. 2(c)). The OB7.3-coated microparticles were observed in both cell body and processes and stably attached to cell membrane as shown in magnified images.

The application of mechanical stimulus via microparticle displacement induced calcium transient at the site of defor-

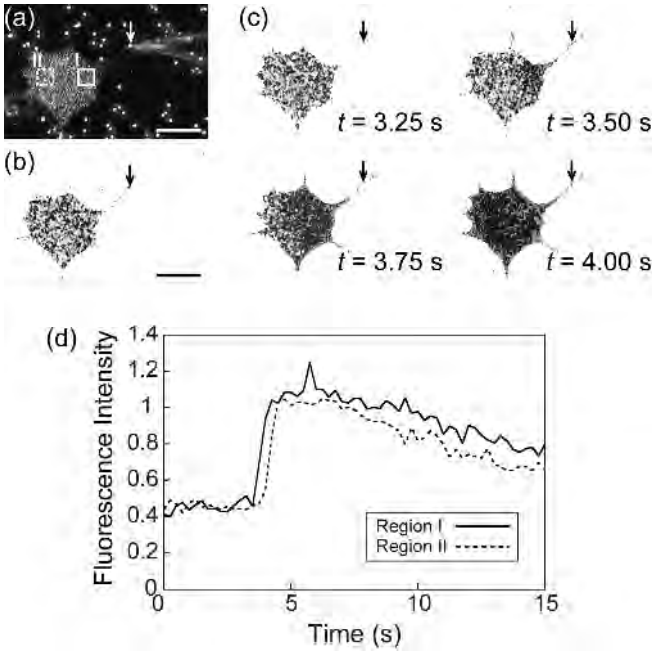

Fig. 3 Calcium response induced by application of local mechanical stimulus. (a): Superimposed image of transmitted and fluorescent image. Bar = 10 μm (b): Fluorescent ratio image at t = 0 s (displaced by pseudo- color). Bar = 10 μm (c): Time-lapse images from t = 3.25-4.00 s. (d): Time course of change in fluorescent ratio of two fluorescent indicators (fluo-4/Fura Red), measured in the regions I and II displayed in (a)

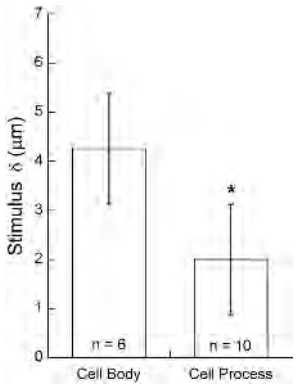

Fig. 5 Stimulus that induces calcium response (*p < 0.05)

mation (Fig. 3). A microparticle targeted for deformation is shown in a superimposed image of the transmitted and fluorescent images (Fig. 3(a), white arrow). Pseudo-colored ratio images are shown at the initiation of application for local deformation (t = 0 s, Fig. 3(b)) and time course at t = 3.25-4.00 s (Fig. 3(c)). When the targeted microparticle adhered on the osteocyte was displaced by the microneedle (black arrow in Fig. 3(b) and 3(c)), a calcium transient was observed in the region adjacent to the microparticle. In addition, the calcium response was propagated to the whole cell body and other cell processes. The intracellular calcium concentration profile examined from two different square regions, I (solid line) and II (dashed line) in Fig. 3(a), was displayed in time course (Fig 3(d)). The calcium transients were seen at 0.25 s interval between the two regions, distant 10μm each other.

Figure 4 shows the percentage of cells responding to applied local deformation. Cells were divided into two groups by the targeted position of the applied stimulus; the cell body and cell process, and the percentage of cells responding to stimulus in each position was determined. The percentage of cells responding to applied stimulus was higher in the cell process (40.0%) than in the cell body (8.5%).

The measure of mechanical stimulus to generate a calcium transient in response to the local deformation of the cell body and the cell process is delineated as displacement of the microparticle δ, and is shown in Fig. 5. The required amplitude of mechanical stimulus to cause calcium transient was different in the cell body and cell process. Displacements for calcium transient were 4.3 ± 0.8 μm and 2.0 μm ± 0.5 μm, respectively.

IV. Discussion

It is believed that location and structural characteristics of osteocyte network in bone matrix have a key role in mechanosensory system for bone mechanical adaptation. Osteocytes in bone matrix are located in cavities called lacuna with their processes elongated into canaliculi. Therefore, the cell process and the cell body of the osteocyte are thought to exist in different mechanical microenvironments. It has been demonstrated by Anderson et al. [7] that interstitial fluid flow due to mechanical loading generates high

shear stress on the cell processes in canaliculi through fluid flow analysis using computer simulation. Moreover, Nicolella et al. [8] observed localized high tissue strain in the perilacunar region under physiological strain levels in bone tissue. These studies indicate that osteocytes in bone matrix may be exposed to site specific mechanical stimuli, and the stimuli are dependent on each specific mechanical microenvironment. However, site-specific mechanical responses in the osteocyte itself, in sites such as the cell process and cell body have not been examined. In this study, therefore, by observing cellular response in the cell process and the cell body under same mechanical environment using isolated cells, we aimed to investigate the difference between cell body and cell process on mechanosensitivity, by which we could expect to understand the meaning of the stellate morphology of osteocytes.

In this study, to apply quantitative local mechanical stimulus to a single primary osteocyte, we developed an experimental system using a microneedle and antibody coated microparticles. This method allowed us to apply localized deformation as well as to identify the osteocytic phenotype in primary culture. Antibody coated microparticle binding is observed as tight in scanning electron microscopy, and is indeed strong to be useful for panning method of osteocyte isolation [11]. Therefore, this method enables us to quantify the local deformation by measuring the magnitude of displacement of the microparticle.

In this experiment, a localized deformation was applied via OB7.3 coated microparticles attached on the osteocyte membrane as a mechanical stimulus to the internal osteocytes. Adhesive structures that transmit the microparticle displacement to the internal force in this *in vitro* study correspond to the adhesive structures *in vivo* to the extracellular matrix. Indeed, it was reported that the osteocytes attach to the bone matrix in canaliculi mediated by tethering elements [12]. In addition, Kamioka et al. [5] and Vatsa et al. [13] had reported that the focal adhesions are distributed at proximal base of the cell process and the cell body of osteocytes in bone matrix, and these focal attachments may induce mechanosensation through perturbation by the deformation of bone matrix and/or the dragged force by fluid flow [14].

It has been suggested that the focal adhesions have an important role in the mechanosensing mechanism and that the cytoskeletal actin filaments binding to extracellular matrix through focal adhesions transmit and focus the forces to the mechanosensitivity (MS) channels on the cell membrane [15]. This finding is based on the visualization of Ca^{2+} influx across individual MS channels close to the focal adhesions as a result of direct mechanical stimulation via actin stress fibers. If the osteocytes in bone matrix achieve their mechanotransduction with activation of the MS channels, the adhesive structures could attribute to transmit the mechanical stimulus.

The previous study reported that there are differences in the actin cytoskeleton between cell processes and the cell body, and showed that osteocyte processes are rich in actin filaments whereas the cell body is not [16]. Other recent study also showed that the elastic modulus of the osteocyte process is higher than that of the cell body [17]. These unique internal structures and the site-dependence of the elastic modulus could modulate the sensitivity to direct deformation. In this study, we observed higher sensitivity to the mechanical stimulus in the cell processes than the cell body. This difference in sensitivity might be due to the different localization of actin filament with high density in cell process and low in cell body. In addition to the stiffness, the distance between stimulated and fixed points could attribute to the difference in mechanosensitivity. That is, the lower stiffness without sufficient internal structure, that is necessary for the force transmission to the focal adhesion at the basal membrane, results in lower sensitivity to the mechanical stimulus.

V. Conclusion

In this study, we observed site-specific response to mechanical stimulus in primary cultured osteocytes. To investigate the cell response to the mechanical stimulus, we developed a quantitative method to apply local deformation to an osteocyte, and analyzed intracellular calcium dynamics to the applied deformation. As the result, we found the higher mechanosensitivity in the cell process. It suggests that cell processes of osteocytes may function as a sensitive part to direct deformation.

Abstract — **The paper is focused on the description of the development of single-purpose devices for determining mechanical properties of the segments of human body. The research were focused on the development and design of a device for establishing the abrasion wear of the THR of the hip joint, and for testing spinal segments. On the basis of the gained knowledge, the attention has also been focused on the development and design of a multi-purpose experimental biomechanical device. Its basic idea was derived from Stewart platform, for the modification of which an animation 3D model was developed.**

Keywords — **Biomechanics, Parallel mechanism, Testing, Steward platform.**

I. Introduction

The basic characteristic of the clinical practice's present biomechanical problems is their complexity which requires mutual mixture of computational and experimental modelling.

Whereas in the computational part, in most cases, commercial software can be used with success, the experimental part requires at least the development, design and manufacturing of fixators and, frequently, of the whole experimental device, including the control system on which specific demands are often put.

At the Institute of Solid Mechanics, Mechatronics and Biomechanics in Brno, we have been dealing with biomechanical problems for more than fifteen years. The attention has mostly been focused on problems of clinical practice. At the present time, we co-operate with several Brno hospitals (St.Anna Teaching Hospital, Traumatic Hospital, Paediatric Hospital, Teaching Hospital in Brno-Bohunice), with some Prague hospitals and with some medical centers in other towns of the Czech Republic. Beside health service facilities, we co-operate also with manufactures of medical and health service devices. Though the development of biomechanics has been made possible primarily due to the development of computer technology and numerical methods related with the solution of tasks of the mechanics of continuum, experimental modelling cannot be said to have lost its significance. It's also to be pointed out that one of the basic characteristics, which distinguish computational modelling from a variety of other computations, is its relation to experiment.

The biomechanical problems that are being solved by experimental modelling at the Institute of Solid Mechanics, Mechatronics and Biomechanics, may be divided into the following groups:

- Determination of mechanical behaviour of biomechanical systems containing implants and fixators,
- Determination of mechanical properties of biologic materials, materials used in clinical practice for implants, and of auxiliary fixation materials.

II. Current state

In the following are briefly described experimental devices designed and made for solving the above mentioned problems, in particular the devices for examining spinal segments and abrasion wear of polyethylene cup of hip joint total endoprostheses.

A. Experimental device for examining the spinal elements

We got engaged in the problems of spinal biomechanics on the initiative of the Head of the Traumatological Clinic of the Brno Traumatological Hospital, Professor Peter Wendsche. We focus mainly on determining various fixators' mechanical interaction with biologic tissues.

In concrete terms, in the first case the matter was the comparison of uni- and bi-cortical fixators of the H-plate type. With view to the geometrical, material and loading complexity of the problem to be solved, and to the time available, only experimental modelling with a limited loading spectrum could be used. Only a comparative tear-out test could be made. This limitation motivated us to equip the testing machine ZWICK Z 020-TND with a torsion head and to design and construct a self contained testing machine enabling to carry out both torsion and bend tests. The above device was designed, without previous experience, by a working team including also workers of mechatronics, who designed the controls of the loading

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2005–2008, 2009
www.springerlink.com

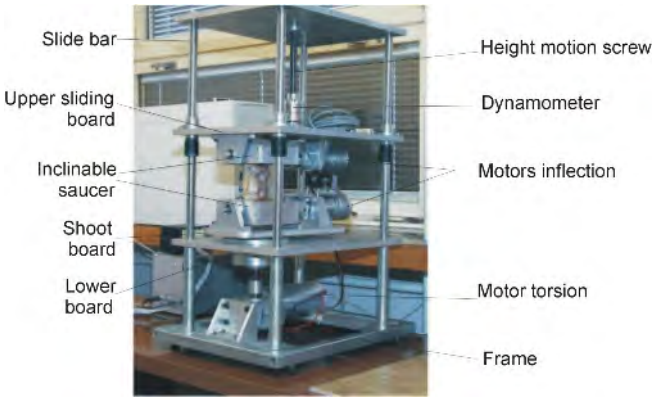

Fig. 1: Device for testing spinal elements

machine. The basic elements and a brief description of this device are shown in Fig. 1.

B. Control unit of experimental device for spine element testing

Test device is equipped with three DC drives with permanent magnets. In particular there are two drives 28DT2R, made by Portescap, and one drive M80x80/I, made by KAG. Each drive is equipped with three-channel optical IRC sensor E9-0100-2.5-1, made by Portescap.

For the test purposes the control using measuring cards CM-2251 by Acquitek was selected. The card has PCI interface, signal processor and memory enabling the control in real time. The card is equipped with 32 analog inputs, 32 digital I/O and 2 analog outputs with maximum sampling frequency of 1MHz. Drives connection to measuring card was realized through power circuit TLE6209R made by Infineon through VHDCI port.

Graphical programming environment NI Labview 7.1 was used for control algorithm development. To meet the on-line control and data processing demands the program uses digital buffers of CM-2251 card using application interface given by the producer. The way the API functions are used is obvious from part of the program shown in Fig. 2. This program performs initialization and initial settings of the card.

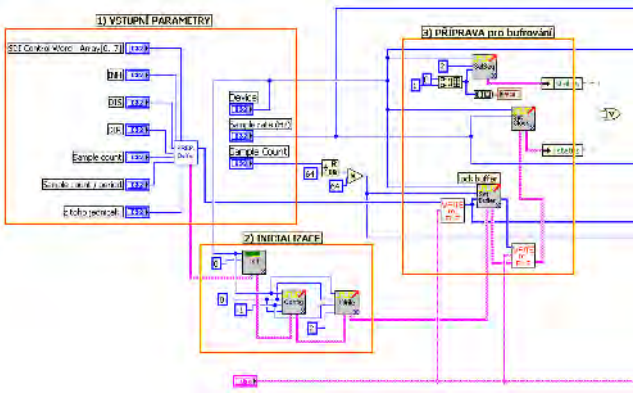

Fig.2: Initialization of control card in NI Labview

C. Experimental device for testing abrasion wear of polyethylene cup of the hip joint total endoprosthesis

The experience in designing a device for testing spinal elements, and the problems to be solved by computational modelling, that are connected with the geometric tolerance between the head and the polyethylene cup, led us to the idea of designing our own device for testing the abrasion wear of the polyethylene socket. This idea has been supported by both the co-operating medical specialists and the manufacturers, since in the past two decades the abrasion wear of polyethylene has been one of the most discussed problems of the durability of hip joint total endoprosthesis. Though the use of high-molecular polyethylene (UHMWPE) has considerably reduced the occurrence of aseptic necrosis, the abrasion wear of the individual components significantly affects their durability. The design of the device was carefully considered and several variants were considered (see Fig. 3 and 4). Required was the highest possible variability enabling not only to make standard tests, but also tests based on computational solution or, possibly, verifying this solution. With view to the device's variability, the variant shown in Fig. 3 was selected for realization.

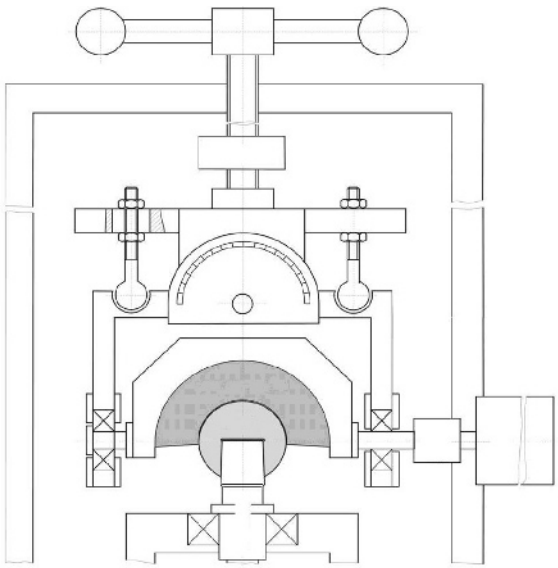

Fig. 3: Device for testing abrasion wear

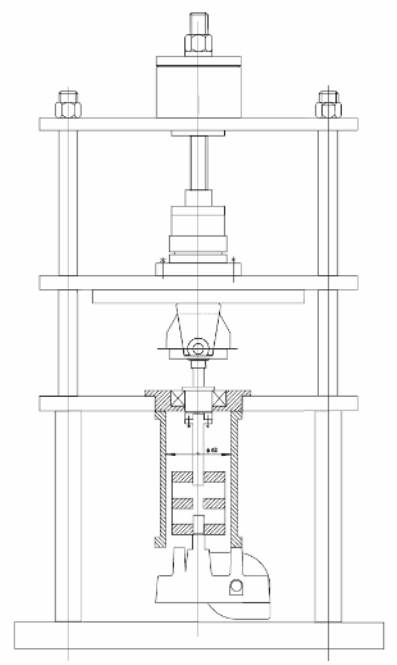

Fig. 4: Realized variant of the device for measuring abrasion wear

Concurrently with the realized variant, a variant with inclined axis of the stem's cone of the total endoprosthesis has been designed, which better captures the load in the applied total endoprosthesis. Schematic sketches do not contain the fixture used for tests made in physiological solution; this will be added in the final phase.

D. Summary of the present state

With view to the remodelling of control algorithms in existing devices and to the limited possibilities of the existing equipment which consists of a universal testing machine ZWICK Z 020-TND, we confine ourselves to making tests in which we can make use of the possibilities and capacity of the universal testing machine. In concrete terms, e.g. tear-out tests, torsion tests in combination with tension or compression. The above limitation, the growing interest and the demands put by clinical practice on biomechanical experiments, which exceed the possibilities of standard testing machines, make us modify the existing devices so as to remove their existing drawbacks.

By analyzing the biomechanical problems, the following requirements have been defined which derive from the need for experimental modelling of movements and loads occurring in biologic environment. These requirements will be taken into account in the modification of the already designed testing devices.

- By analysis of the force load in the hip joint and in the spinal segments, approximate conformity of the load forces was established, whose value is about 2000N.
- The range of possible movements was increased to cover all six degrees of freedom.
- The device must be able to load up the test specimen with the assigned load force and to carry out any loading cycle. The specific features thus defined can be taken into account in case that the merits of the mechanism of parallel kinematics will be made use of in the design.

III. Parallel kinematics mechanism design

A. The design of a geometric model

The demands put on this device derive from the need for experimental modelling of arbitrary movement and load. Its use is very universal in both biomechanics of the backbone and biomechanics of the joints. The device's geometry is motivated by the tests we intend to make on the spinal elements, for which it is suitable to conceive the device as two toroidal plates – interconnected by active elements - into which spinal segments will be fixed.

The concept of parallel kinematics, which is called Stewart platform corresponds to the device of such design. In case that the lower plate is firmly connected with the base, the upper plate is able to move with six degrees of freedom. At the present time, the Stewart platform is widely used and its popularity is due mainly to its following facts, in comparison with serial mechanisms:

- higher stiffness
- better dynamic properties of the mechanism
- higher accuracy of the mechanism
- precise and easy positioning
- wide range of movements

These possibilities can be advantageous in manufacturing experimental devices for solving various biomechanical problems. In particular terms, devices have been designed for testing spinal samples (Fig. 6) and abrasion wear of polyethylene acetabula (Fig. 7). Since unit-built architecture can be used, whole spinal segments can be tested, which is very favourable in case of fixed vertebral bodies, since changes of mechanical properties take place also in the surrounding spinal elements. The assembly scheme is shown in Fig. 8.

The parametric geometric model was designed using the CAD INVENTOR system.

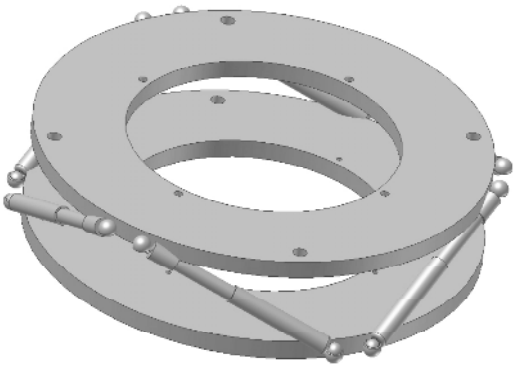

Fig. 5: Scheme of device for testing

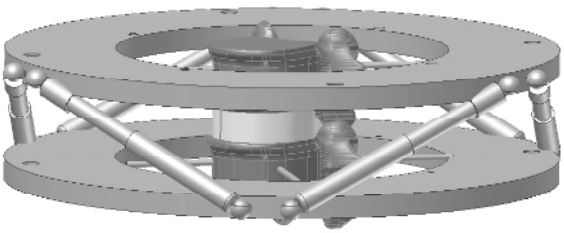

Fig. 6: Scheme of device for testing spinal elements

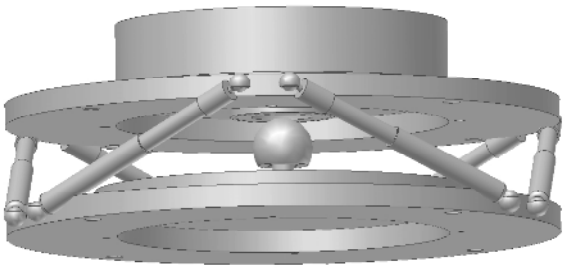

Fig. 7: Scheme of device for testing polyethylene socket

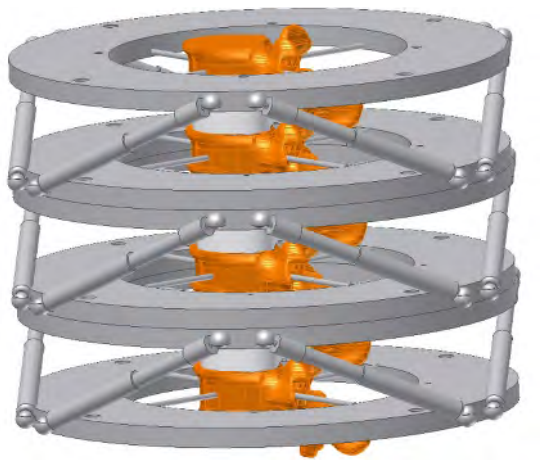

Fig. 8: Scheme of device for testing spinal segments

A device of similar concept could be used for solving problems such as e.g. correction of the scoliotic curve of vertebral column in various cases of scoliosis. The demands put on this device would be substantially more extensive. One of the important problems that need to be solved is that of the active elements.

IV. Conclusions

With regard to the development of testing devices for biomechanical systems, the further progress is aimed to the following objectives:

The primary objective is to complete two testing devices (for testing spinal fixators and abrasion wear). The mechanical part has been completed; the control subsystem is being completed. These works should culminate in the first trimester. Both devices will then be put into operation and the corresponding experiments, supported by computational modelling, will be started.

As regards devices based on Stewart platform, we will proceed as follows: On the basis of calculated kinematic and dynamic values, actuators and sensors will be designed. Then the structural design will be specified with view to the selected actuators and sensors. The device thus designed will then be manufactured.

Stability of Treadmill Walking Related with the Movement of Center of Mass

S.H. Kim[1], J.H. Park[2], K. Son[2]

[1] Graduate School of Mechanical Design Engineering, Pusan National University, Busan, Korea
[2] School of Mechanical Engineering, Pusan National University, Busan, Korea

Abstract — **The human gait is highly coordinative as to achieve combined movements of extremity joints at a desired speed. The purpose of study is to relate the variability of hip joint motion with the movement of the center of mass (COM) of the whole body in the treadmill walking. Each walking speed was converted to Froude number for normalizing different subject statures. Flexion-extension angles of the hip and the anterioposterior movement of COM were calculated. The correlation was relatively low (R^2=0.113) between the movement of COM and the normalized walking speed. These results revealed that the movement of COM must be considered as one of important parameters for the analysis of walking stability on the treadmill**

Keywords — **Center of Mass, Walking Stability, Treadmill Walking.**

I. Introduction

Walking periodicity is more regular on a treadmill than on the ground since the treadmill provides a relatively uniform walking speed. However, frequent fallings on the treadmill occur due to loss of control of the neuromusculoskeletal system. People fail to adapt themselves in the treadmill walking because of the limited space of the treadmill walking even at their preferred speeds. Thus, treadmill walking is differ from overground walking [1].

As walking stability is considered, the center of mass (COM) is an essential parameter because the balance of the body is achieved by controlling of COM. The hip joint is also directly related with walking stability in that it plays an important role to support and move the whole body during normal walking. Therefore, the movement of COM and variability of the hip joint could explain the information on the stability of walking. In this study, temporal change of COM and the hip joint angle were regarded as two major parameters.

The purpose of study is to prove the variability of hip joint motion with the movement of the COM of the whole body in the treadmill walking. The hypothesis was that the COM moves in the anterioposterior direction when one cannot maintain a uniform walking speed: The larger movement of COM results from the larger angular variability of the hip joint.

II. Methods

A. Experiment

Fifteen young healthy subjects (13 males and 2 females: 24.9±4.2 years, 175.6±6.4 cm, 70.5±12.1 kg, 1.0±0.1 m/s) with no history of joint diseases were volunteered for gait analysis [2]. Joint movements of each subject were recorded for 60 seconds on a treadmill (KEYTEC® AC9, Taiwan) using a three-dimensional motion capture system with eight video cameras (DCR-VX2100, Sony, Japan). The spatial displacement error of the motion capture system was less than 2 mm. Prior to the measurement of joint motions, all subjects were given enough time to perform walking exercise on the treadmill with the same walking pattern as they have in daily life. Thirty two reflective markers were attached on the selected bony landmarks of the subjects to calculate the flexion-extension angles of the upper and the lower extremities. All the attachment tasks were performed by one investigator to minimize the possible positioning error (Fig. 1).

Fig. 1 Hemispherical reflective markers attached on body landmarks

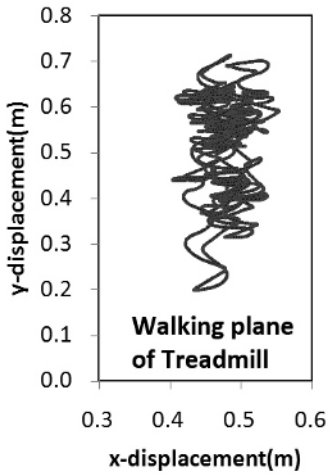
B. Data processing and analysis

Motion data were collected at 60 frames per second and then analyzed through KWON3D motion analysis software (Visol Corp., Korea) [3]. The primary markers (attached markers) and the secondary markers (virtual markers) were used to define the flexion-extension angles of the hip. For example, the knee joint center, where one of the secondary

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2009–2011, 2009
www.springerlink.com

markers was assumed to locate, could be determined by averaging the coordinates of two primary markers attached on the lateral and medial epicondyles. The center of the hip was calculated by adopting the method of Tylkowski and Andriacchi [3] from the left, the right, the middle ASIS (anterior superior iliac spine) and extra greater trochanter markers. The flexion-extension angle was calculated from the inner product of the two vectors representing the longitudinal axes of the adjacent body segments at that joint. Each walking speed was converted to Froude number (FN), V^2/gl (V: speed, g: gravitational acceleration, l: length from the ground to the greater trochanter), as a dimensionless speed for normalizing different lengths of the lower legs.

The coordinates of COM were calculated by Kwon3D software and the anteroposterior movement of COM (MCM) was obtained by the summation of all y-directional trajectory projected to the walking plane (Fig. 2). In order to evaluate variability of the hip joint, temporal and spatial parameters were introduced. Standard deviation for the peak-to-peak intervals (VPI) of flexion-extension angles during the gait was a temporal parameter and angular standard deviation (VAD) was a spatial parameter. When subjects walked on the treadmill, they were assumed to maintain their walking stability by these two parameters.



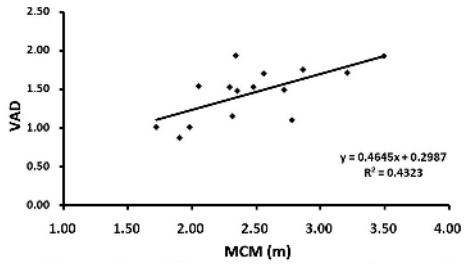


Fig. 2 Projected trajectories of COM on the treadmill for one minute

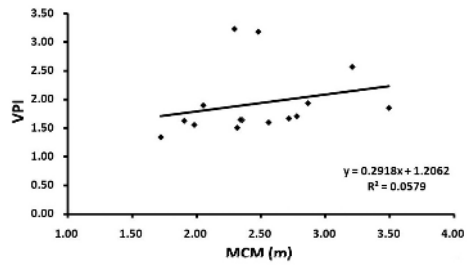
III. Result



Experimental data were obtained from the gait on the treadmill as listed in Table 1. After obtained the data, a paired t-test was performed to test statistical significance between MCM and VAD by using SPSS. And correlation coefficient was calculated by using the least square method on Microsoft Excel. The result showed that the hypothesis

STD	0.48	0.03	0.58	0.34

(a) MCM vs. VAD

(b) MCM vs. VPI

(c) MCM vs. FN

Fig. 3 Correlation results among the parameters

was verified by a finding that the linear correlation coefficient, R^2, was 0.432 ($p<0.05$) between MCM and VAD (Fig. 3a). The correlation was very low ($R^2=0.057$) between MCM and VPI (Fig. 3b). It means that spatial variable (VAD) contributes to compensate for the loss of COM more than temporal variable (VPI) in such uniform speed environment as on the treadmill. Hausdorff et al. [4] reported that stride-to-stride variability can predict falls for the elderly population. This fact was well known or inferred easily. As revealed in our result, MCM cause to increase stride variability during the gait. The correlation coefficient between MCM and FN was also low ($R^2=0.113$) (Fig. 3c). Regarding to this result, FN is not likely to relate with MCM at a comfortable walking speed.

IV. Conclusion

An elementary parameter, COM, was mainly investigated to test its importance in a treadmill walking situation. Although the treadmill provides a relatively uniform walking speed, people often lose control ability due to neuromusculoskeletal system errors. From the results obtained in this study, the changes of COM on the treadmill reveal this physical phenomenon in the statistical sense. For this reason, MCM must be considered as an important parameter for the analysis of walking stability, especially on the treadmill.

Stress Analyses of the Hip Joint Endoprosthesis Ceramic Head with Different Shapes of the Cone Opening

V. Fuis[1] and J. Varga[2]

[1] Centre of Mechatronics – Institute of Thermomechanics Academy of Sciences of the Czech Republic and Institute of Solid Mechanics, Mechatronics and Biomechanics, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic
[2] Institute of Solid Mechanics, Mechatronics and Biomechanics, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic

Abstract — **During the analysis of the fracture surfaces of the destructed hip joint endoprosthesis ceramics heads it was detected that the shape (size and the position) of the cone end in the bottom of the cone opening were very different.**

The paper presents the influence of five typical shapes of the cone end on the stress in the ceramic head. The computational modelling is realized for two outer diameters of the ceramic head – 28 mm and 32 mm and three depths of it's cone. The system FEM – ANSYS was used for computational modelling of the stress and deformation of analyzed system (testing stem and ceramic head). Loading of the analyzed system is according to norm ISO 7206-5. There are assumed shape deviations of the cone surfaces – interaction of the ovality and different degree of taper of the stem and the head cone.

Keywords — **Hip joint endoprosthesis, ceramics head, shape deviations, cone opening.**

I. Introduction

The destructions of the ceramic head of the total hip joint endoprosthesis were realized three years ago Fig. 1. The aim of this destruction was founding the material parameters of the bio-ceramic material based on the Weibull weakest link theory.

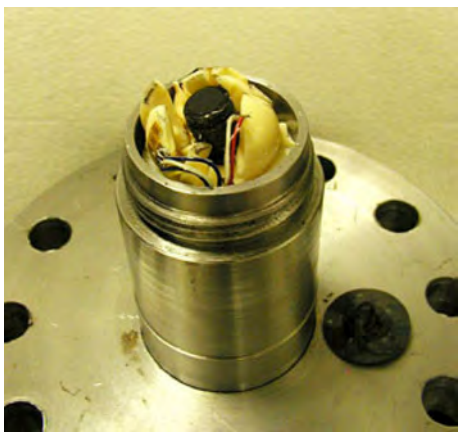

Fig. 1 Destructed hip joint ceramic head

For carrying out the destruction of a set of ceramic heads a special testing jig has been made in which the heads are subjected to compressive load that acts only on the surface of the head's opening. In the course of the test, circumferential strains are measured on the head's external surface by two gauges. The compression load acting on the head was developed by the testing device ZWICK Z 020-TND (Fig. 2) whose head loaded the jig's piston which, in turn, acted on rubber NBR 90 inside the jig, which, subsequently, acted on the ceramic head.

The analysis of the fracture of the destructed heads have found the fact that the shape of the region of the bottom end

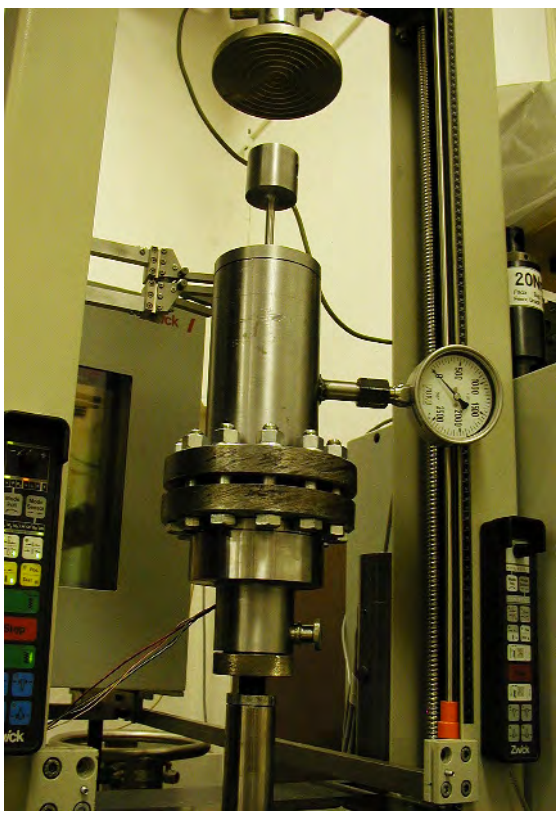

Fig. 2 Testing jig used to the heads destruction

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2012–2015, 2009
www.springerlink.com

of the head's cone (shape transition from the cone to the bottom of the cone opening – Fig. 3) was very different for each destructed head. In addition this region did not correspond to the technical drawing of the factory where the heads were made. This shape transition is a stress raiser (notch) and the ceramic material is brittle material. The brittle material is very sensitive to the tensile stress so the computational modelling of the stress in the head with the mentioned notchs will be presented in this contribution. The FEM system ANSYS was used for computational modelling.

II. Computational Modelling

A. Input parameters

Ideally, the problem of stress calculation would be solved for the physiological conditions in the human body. However, the level of our knowledge and our technical possibilities do not allow it. Therefore the problem is being solved in accordance with norm ISO 7206-5 [1] under force conditions that are different from the physiological ones. The structure modelled according to ISO 7206-5, is shown in Fig. 3. The ceramic head is pressed onto the testing stem cone by the force F which acts on the interface.

There are analysed two variants with different value of the outer head diameter - 32 mm and 28 mm. The depth of the head opening is made with three values – small, medium and large – all these variants were assumed. Finally, five typical shape transitions variants were chosen from the analysis of the destructed heads. These variants are shown in Fig. 4.

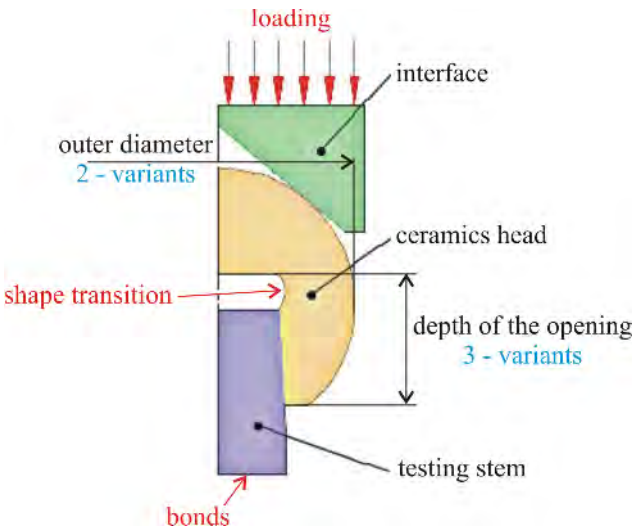

Fig. 3 Modelled system according ISO 7206-5

Fig. 4 Modelled variants of the shape transition

The last group of the geometric input parameters consists of the shape deviations of the contact cone areas of the stem and the head. There are assumed the interaction of the dif-

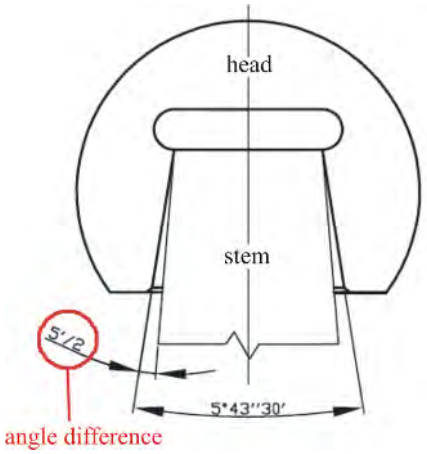

Fig. 5 Shape deviation of the cone areas – different vertex angle

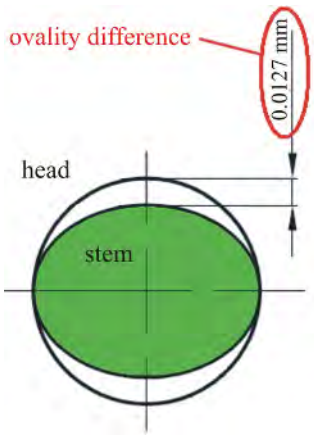

Fig. 6 Shape deviation of the cone areas – ovality of the stem area

ferent vertex angle of the head and the stem cone (the head vertex angle is greater that the stem angle - modelled difference is 2.5' – Fig. 5) and ovality of the stem cone area – modelled deviation is 12.7 μm – Fig. 6.

The steel testing stem and Al_2O_3 head are assumed to be elastic, with the following material parameters (Young's modulus E and Poisson's ratio μ) for the stem: E_s = 210 GPa, μ_s = 0.3; and for the head: E_h = 390 GPa, μ_h = 0.23. The contact between the head and the stem is modelled by the elastic Coulomb friction with f = 0.01.

B. Results of the computational modelling

The most important stress in the head is the maximal tensile stress due to the danger of the brittle limit state of the head. Therefore the first principal stress in the head will be analysed and compared with all assumed geometrical variants. The influence of the shape of the notch (VAR. 1 – VAR. 5) on the tensile stress is shown in Fig. 7 – system without the shape deviations (ideal cone), head outer diameter is 32 mm and the depth of the opening is 23 mm. The highest tensile stress is found at VAR. 1, VAR. 2 and VAR. 3. These variants have the small contact area (see Fig. 4) and therefore the contact pressure and tensile stress are increased [2].

The influence of the head outer diameter and the depth of the opening is shown in Figs. 8 and 9. These figures show the maximum tensile stress in the head without the shape deviations.

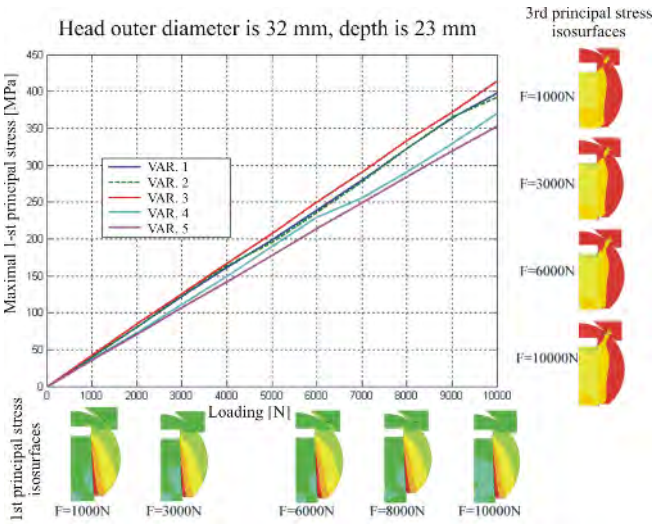

Fig. 7 Maximal tensile stress in the head without shape deviations

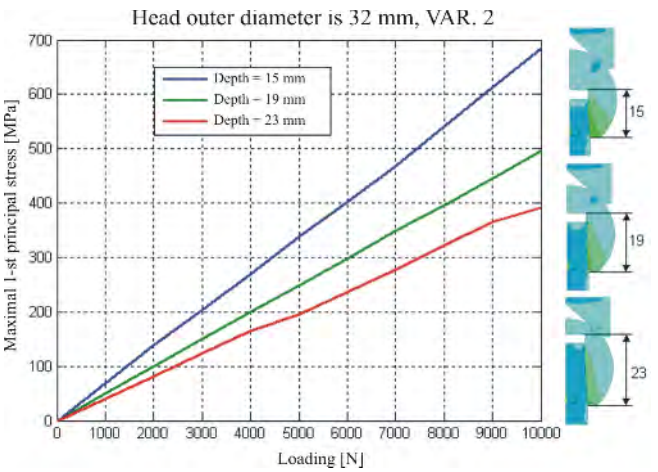

Fig. 8 Maximal tensile stress in the head without shape deviations, head outer diameter is 32 mm, depth is different

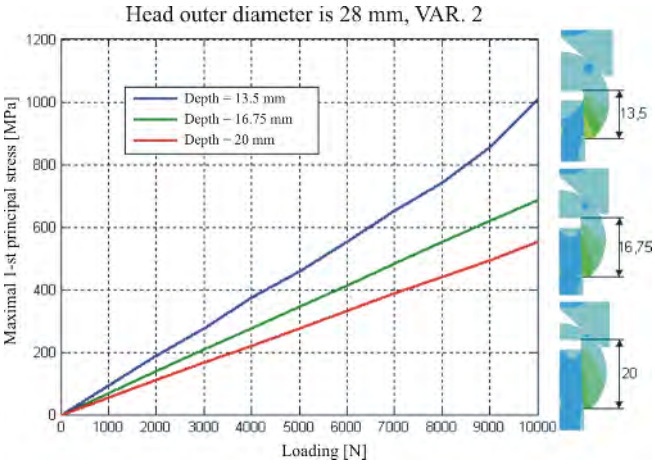

Fig. 9 Maximal tensile stress in the head without shape deviations, head outer diameter is 28 mm, depth is different

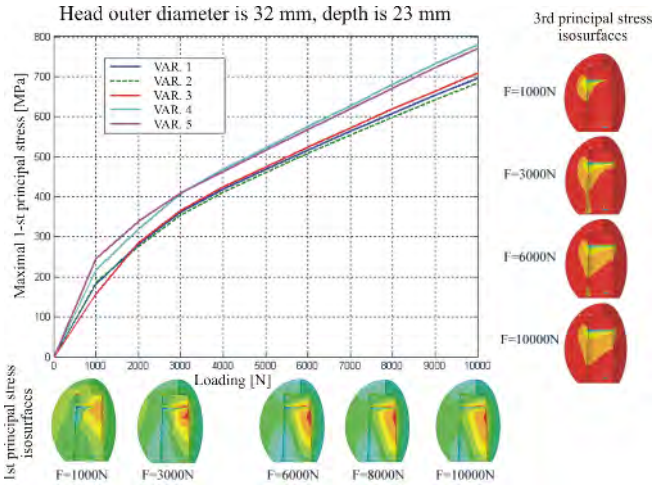

Fig. 10 Maximal tensile stress in the head with shape deviations

Heads with the diameter 32 mm have smaller value of the extreme tensile stress due to the higher circumferential stiffness (more material) than head with diameter 28 mm. In addition the increasing of the depth of the opening caused the decreasing the extreme tensile stresses in the head due to the higher contact area of the cone.

The last two figures (Figs. 10 and 11) show the influence of the interaction of the shape contact cone deviations (Fig. 5 and Fig. 6). Assumed shape deviations significantly increase the extreme tensile stress in the head (about 75 %) and the stress curves are not linear for small loading (from 0 to 4 kN). In this region the contact area is small and the contact pressure is high. The gradual deformation of the contact area (elimination of the shape deviation by the system deformation – increasing the contact area) causes the

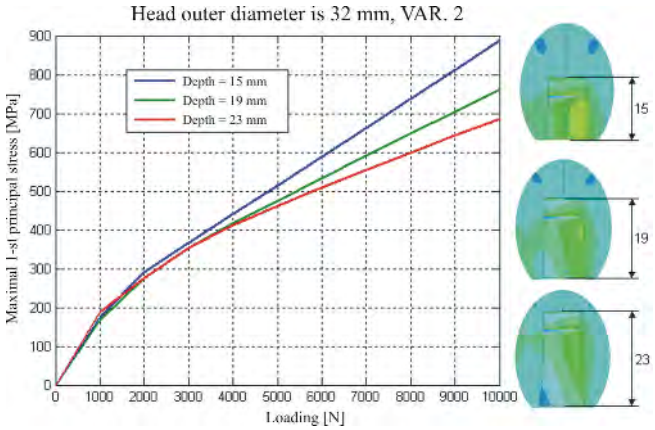

Fig. 11 Maximal tensile stress in the head with shape deviations, head outer diameter is 32 mm, depth is different

transition to the almost linear influence between the stress and the loading in Figs. 10 and 11.

III. Conclusions

The shape deviation of the contact cone areas, the shape of the transition in the head bottom opening, the outer head diameter and the depth of the opening influence the value of the tensile stress in the head. All mentioned geometric parameters are necessary taken in the computational modelling of the stress and the reliability of the head.

Abstract — **Lumbar lordosis is defined as the anterior convexity of the lumbar spine in the sagittal plane. Its degree is variable between individuals, affected many other factors. Clinical methods to define lumbar lordosis are Cobb's angle measurement and the angle between extension line of boundary of the first and fifth vertebral body. In this study, the lordotic angle calculated by reflective markers when the three dimensional motion capture system was used compared to the angle calculated from fluoroscopy. The coordinates of vertebral body center from fluoroscopic images were digitized. The vertebral body center coordinates from fluoroscopic image and the coordinates from markers were used to calculate lumbar lordotic angle with three different method - ratio method, three point method and curve-fit method. The lordotic angles from fluoroscopic image(θ_f) were larger than the angles from markers(θ_m) in all three methods. The ratio method using fluoroscopic image and the curve-fit method using markers showed the largest coefficient of variance(θ_f - θ_m)and the coefficient of variances in all three methods using fluoroscopic image were smaller than using markers. However, the analysis according to Bland-Altiman plot showed a good agreement between both methods(fluoroscopy and marker).**

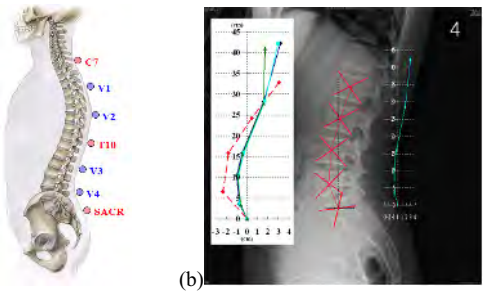
I. Introduction

Lumbar lordosis is defined as the anterior convexity of the lumbar spine in the sagittal plane[1]. Its degree is variable between individuals, affected many other factors.

The fifth lumbar vertebra (L5) is wedge-shaped, the anterior aspect of the vertebral body being approximately 3 mm thicker than the posterior aspect[2]. The vertebrae above L5 are less wedge-shaped, but due to the shape of L5 and the first sacral(Sl) vertebrae, each vertebra above this level lies slightly posterior to the vertebra above it. The intervertebral discs in the lumbar area are also wedge-shaped, especially between L4 and L5, and between L5 and Sl, the intervertebral disc at the L5-Sl interspace being 6-7 mm thicker anteriorly than posteriorly[3]. These factors all contribute to producing the normal lumbar lordosis.

Various methods for measuring the lumbar lordosis have been used in an attempt to quantify the curve. Goniometry, radiography, skin markers over the spinous processes, and use of flexible rulers have all been used [3-7]. Clinical methods to define lumbar lordosis are Cobb's angle measurement and the angle between extension line of boundary of the first and fifth vertebral body. In this study, the lordotic angle calculated by reflective markers when the three dimensional motion capture system was used compared to the angle calculated from fluoroscopy.



II. Methods

A. Subjects

Thirteen healthy males volunteered for this study(age: 23.5±0.76year, body weight: 66.5±6.37kg, height: 172.1±6.03). Each subject was taken pictures of x-ray with quiet standing position, and they were also taken three dimensional motion captures with the same position. For the motion capture, the seven reflective markers(T10~SACR) were mounted on the back. Fig. 2(a).

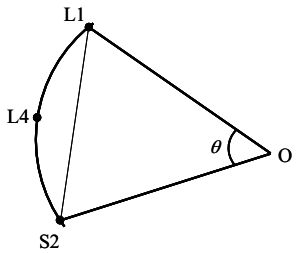
$$curve\ depth = \overline{L4O}$$

$$curve\ length = \overline{S1L2}$$



$$Ratio(\%) = \frac{curve\ depth}{curve\ length} \times 100$$

(a) Ratio method

$$\theta = \pi - a\cos\left(\frac{\overline{L2L4}^2 + \overline{L4S1}^2 + \overline{S1L2}^2}{2 \cdot \overline{L2L4} \cdot \overline{L4S1}}\right)$$

(b) Three point method

$$\theta = a\cos\left(\frac{\overline{OL1}^2 + \overline{OS2}^2 - \overline{L1S2}^2}{2 \cdot \overline{OL1} \cdot \overline{OS2}}\right)$$

(c) Curve fitting method

Fig. 3 Three methods to calculate the lumbar lordosis

B. Lumbar lordosis calculation methods

The data from two different measurements were used for calculation of the lumbar lordosis curvatures. The lumbar lordosis calculation was performed using the three different methods. They were (1) ratio method, (2) three point method, (3) curve fitting method[Fig 3. (a)~(c)].

C. Experiments

The three dimensional motion analysis system(VICON612, UK) and x-ray device E7252X(Toshiba, Japan) were used in this study. The subjects were required to stand quietly and comfortably in radiation room and motion laboratory. x-ray images were digitized to calculate the coordinates.

D. Analysis of data

The coordinates from digitized x-ray images and reflective markers were used for calculation of lumbar lordosis and curvatures.

III. Results

Table. 1 shows the angles and coefficient of variations of lumbar lordosis from x-ray image and markers with three methods. The bland-altman plotted by using these data(Fig. 1). The lordotic angles from fluoroscopic image(θ_f) were larger than the angles from markers(θ_m) in all three methods. The ratio method using fluoroscopic image and the curve-fit method using markers showed the largest coefficient of variance(θ_f-θ_m) and the coefficient of variances in all three methods using fluoroscopic image were smaller than using markers. However, the analysis according to Bland-Altiman plot(Fig. 4) showed a good agreement between both methods(fluoroscopy and marker).

Table 1 Mean, standard deviation (S.D.) and coefficient of variation (C.V.) of lumbar lordosis in a single standing subject, measured by the three methods

		Fluoroscopy(θ_f)			Marker(θ_m)		
Method	Unit	Mean	S.D.	C.V.(%)	Mean	S.D.	C.V.(%)
Ratio	%	12.22	1.72	14.10	5.75	1.47	25.51
Three point	Degree	27.45	3.71	13.52	14.43	3.63	25.17
Curve fit	Degree	54.91	7.42	13.52	28.48	7.79	27.35

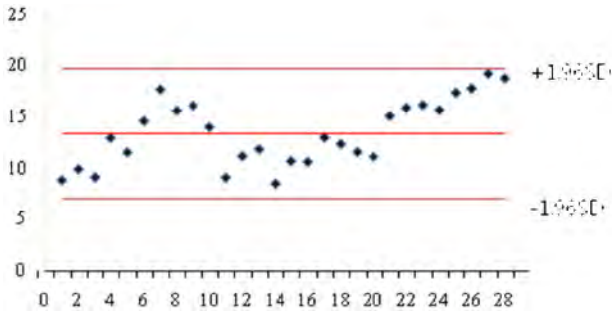


Fig. 4 Bland-Altman plot

IV. Discussions

In this study, in order to know whether the lumbar lordotic curves calculated by three dimensional motion capture system were reliable or not, these lumbar lordotic angles were compared with the angles calculated by using the x-ray images. According to the bland-altman results, motion capture method was reliable. However, the critical limitations of this study were that the x-ray device and motion capture device were not synchronized. And the lumbar curves in different trunk angles might be analyzed with the same methods but only standing position was considered in this study. The number of data from x-ray and markers were not matched. Intraclass correlation of the lordotic angles from the digitized x-ray images should be calculated.

Patient-Specific Simulation of the Proximal Femur's Mechanical Response Validated by Experimental Observations

Zohar Yosibash and Nir Trabelsi

Dept. of Mechanical Engineering, Ben-Gurion University of the Negev, Beer-Sheva, 84105, Israel

Abstract — **The use of subject-specific FE models in clinical practice requires a high level of automation, validation and accurate evaluation of analysis prediction capabilities. This study presents a novel high-order finite element method (p-FE) for generating FE models based on CT data. The geometry is represented by smooth surfaces accurately and an internal smooth surface is used to separate the cortical and trabecular regions upon which a p-FE auto-mesh is constructed within each region (cortical or trabecular). QCT Hounsfield Unit (HU) values are recalculated using a moving average method regardless of the FE mesh and isotropic inhomogeneous linear material properties are assigned to the FE models by a spatial function computed from the QCT data. Anisotropic material properties are also considered in the FE model and their influence on the mechanical response is examined. To validate the FE results we performed QCT scans on three fresh frozen proximal femurs (30 years old male, 20 and 54 years old female) followed by mechanical in-vitro experiments at different inclination angles, measuring head deflection and strains at several points with a total of 77 experimental values recorded. The FE results, strains and displacements were compared to the in-vitro experiments. The linear regression of the experiment results compared to the FE predictions demonstrates the high accuracy and reliability of our methods (slope of 0.955 and R^2=0.957). These results are significantly better than any previous published results known to the authors.**

Keywords — **Proximal femur, p-FEM, Computed tomography (CT), Bone biomechanics.**

I. Introduction

Accurate methods for predicting and monitoring in-vivo bone strength are of major importance in clinical applications. Subject-specific finite element modeling is becoming a commonly used tool for the numerical analysis of the biomechanical response of human bones. The use of subject-specific FE models in clinical practice requires a high level of automation and an accurate evaluation of the numerical errors and analysis prediction capabilities. Geometry and material parameters are two key components when addressing subject specific FE models of bones and both can be estimated from QCT data. The modeling method applies extensive processing of the CT data to extract the required information. Because CT based simulation method is to be used in vivo, the surrounding of the bone while the CT is preformed may influence the model generation and its influence on the results must be carefully examined. Keyak & Falkinstein [1] examined whether FE models generated from CT scans in situ and in vitro yield comparable predictions of proximal femoral fracture load. Their conclusion demonstrate that using CT scan data obtained in situ instead of in vitro to generate FE models can lead to substantially different predicted fracture loads and must be considered when developing subject-specific FE models based on CT scans. The influence of material assignment strategy on the finite element models was investigated in [2, 3, 4, 5]. Different methods for assigning material properties to FE models may produce various distributions of material properties. In most of the previous FE studies conventional h-version FE methods (h-FEMs) were applied [6, 7], inhomogeneous distribution of material properties was attained by assigning constant distinct values to distinct elements, thus the material properties became mesh dependent [4]. In the presented study (details given in [8, 9, 10]) a p-version FE (p-FE) method is suggested. Accurate surface representation of the bone is achieved by a 3-D smoothing algorithm. Isotropic inhomogeneous material model was adopted for which the Young modulus is represented by a smooth functions, independent of the mesh, and different $E(\rho)$ relations are assigned for the cortical and trabecular regions. Transversely isotropic material properties were also considered in the FE model in the shaft region and their influence was investigated. The presented method resulted in an excellent correlation (for both displacements and strains) for the p-FE results and in-vitro experimental observations. This study demonstrates that reliable and validated high-order patient-specific FE simulations of human femurs based on QCT data are achievable for clinical computer aided decision making.

II. Materials and methods

A. In vitro experiment

Three fresh frozen femurs (donors are 30 years old male, 20 and 54 years old female) were used in our study. In-vitro experiments on the fresh-frozen proximal femur were performed to assess the validity of FE simulations. All bones

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2019–2022, 2009
www.springerlink.com

were deep-frozen shortly after harvesting and checked to be free of skeletal diseases. After defrosting, soft tissue was removed and the bone was degreased with ethanol. The proximal femur was cut and fixed into a cylindrical sleeve by six bolts and a PMMA substrate, and strain gauges (SGs) were bonded on its surface. Thereafter QCT scans were performed on a Phillips Brilliance 16 CT. During the CT scan calibration phantoms were placed close to the bone, used thereafter to estimate the inhomogeneous mineral density in the bone. Mechanical experiments started following the QCT scans. The experimental system detailed in [8, 9] includes a mounting jig, loading and measurement equipment and data acquisition equipment. The bone was loaded by a load controlled machine (Instron5500R). Two linear variable differential transformer (LVDT) measured the femur head vertical and horizontal displacements and were positioned on stand arms with their core placed on femur's head – see e.g. Fig. 1.

Several uni-axial strain-gauges (SGs) with 1.6mm active length and 350Ω resistance were installed on the surface of the proximal femur at the inferior and superior parts of the femur neck and on the medial and lateral femur shaft. SGs, load-cell and the LVDT outputs were recorded and processed after the experiments completion. The experiments simulate a simple stance position configuration in which the femur is loaded through its head while the femur is inclined at four different inclinations angles (0,7,15,20 degrees) as shown in Fig 1. Following the in-vitro experiments a p-FE model was generated based on QCT scans and simulations performed to mimic the experiments, after which the FE results were compared to the experimental observations for validation purposes

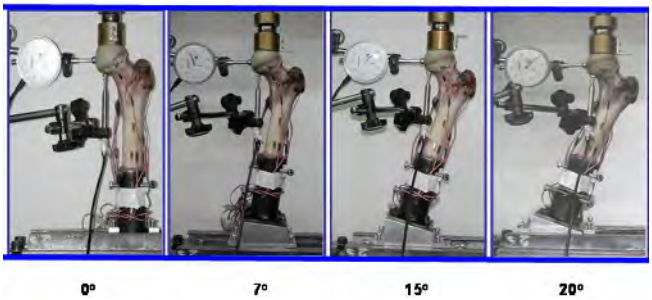

Fig. 1 Experiments on the fresh-frozen bone (#3) at different inclination angles.

B. p-FE models of the proximal femur

The geometry generation, the FE mesh and the evaluation of the material properties methods are detailed in **[9]** and will be only shortly described herein. Femur's geometry was extracted from QCT slices and divided into cortical and trabecular regions. Exterior, interface and interior boundaries were traced at each slice and x-y arrays were generated, each representing different boundaries of a given slice. A smoothing algorithm was applied on these arrays that generate smooth closed splines used for the solid body generation. The solid body was meshed by an auto-mesher with tetrahedral elements using a high order FE commercial code. The surfaces of the bone are accurately represented in the FE model by using the blending mapping method. The schematic flowchart that describes the FE generation from CT scans is provided in Fig. 2.

QCT Hounsfield Unit (HU) values were recalculated using a moving average method regardless of the FE mesh and isotropic inhomogeneous linear material representation was assigned to the FE models by a spatial function generated from the QCT data. Calibration phantoms were used for the bone equivalent mineral density (EQM) calculation.

$$\rho_{EQM} = 0.682 \cdot HU - 5.5 \ [g/cm^3]_{\text{Bone\#2}} \quad (1)$$

$$\rho_{Ash} = 1.22 \cdot \rho_{EQM} + 0.0523 \ [g/cm^3] \quad (2)$$

$$\rho_{Ash} = \sum_{k=0}^{p_k} Z^k \left(\sum_{i,j=0}^{p_i,p_j} a_{ijk} \cdot r^i \cdot \sin(j \cdot \theta) + \sum_{i,j=0}^{p_i,p_j} a_{ijk} \cdot r^i \cdot \cos(j \cdot \theta) \right) \quad (3)$$

Young's modulus was evaluated by Keyak & Falkinstein relations [1]:

$$E_{Cort} = 10200 \cdot \rho_{Ash}^{2.01} \ [MPa] \quad (4)$$

$$E_{Trab} = 5307 \cdot \rho_{Ash} + 469 \ [MPa] \quad (5)$$

Anisotropic material properties were also considered in the FE model their influence was investigated and will be

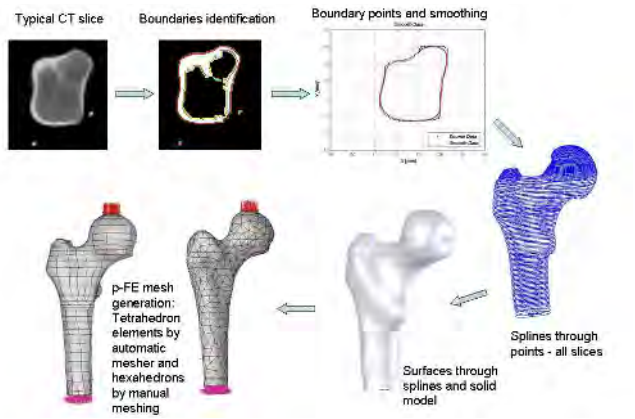

Fig. 2 The flowchart for generating the p-FE model.

reported. The FE boundary conditions describe the experiments as follows: distal face was fully constrained and 1000*N* load was applied on the head planar face in the proper direction (four different inclinations angles).

III. Results

To verify the accuracy of ours CT-based FE model, a comparison between the experimental observations (strains and displacements) and the FE results was conducted. Different models were generated based on the CT data, each having a different planar trimmed surface according to the tilt angle represented in the experiment. All FE models were generated by the same methods (details in [9, 10]). Three fresh frozen bones with a total of 77 experimental values recorded (61 strains and 16 displacements) were used for this verification process. In all FE models isotropic inhomogeneous linear material representation was assigned. Both constant Poisson ratio = 0.3, and inhomogeneous Poisson ratio were considered and the E(HU) relation by Keyak & Falkeinstein [1] were assigned. A 1000N load was applied as traction over the entire planar face in the proper direction. Zero displacements were enforced in the distal face. All models show good convergence in the energy norm, displacement and strain results when p=4 or higher is used. The SGs and LVDTs locations were marked on the each model (for example Fig. 3 present the point of interest in bone #2), and averaged strains and displacements over the finite element's face were extracted from FE results.

FE strains and displacements were compared to these measured in the experiment, at various locations of the femur and for all loading conditions. The results indicate that in most of the measuring points, the predicted strains and displacements correlate very well with the experimental observations. A linear regression of the experiment result vs. the FE prediction, for both displacement and strain, is presented in Fig. 4. The linear regression represents a general assessment of the analysis quality.

The slope of the regression line is 0.957 (very close to one), and the linear regression coefficient R^2 = 0.955 (the intercept in percentage is close to zero).

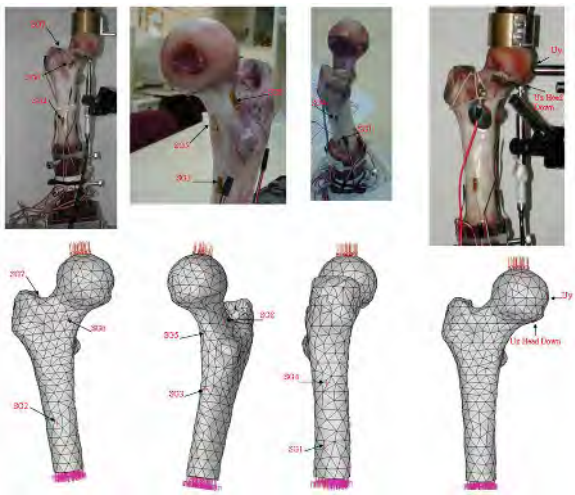

Fig. 3 Locations at which displacements and strains were measured in bone #2.

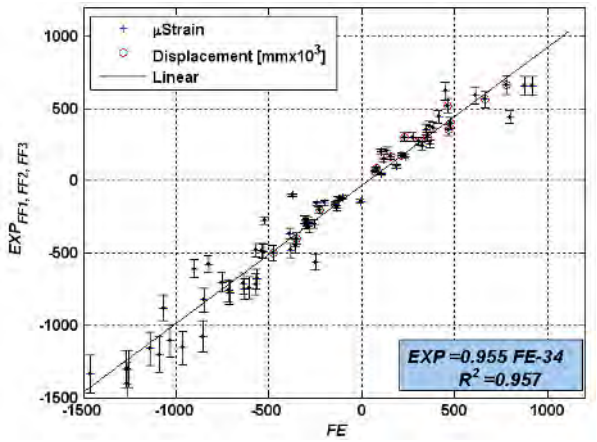

Fig. 4 Linear regression: experimental observation (fresh frozen 1+2+3) vs. FE predictions.

IV. Conclusions

This study was preformed to validate new a method of generating reliable FE models of the proximal femur using subject specific QCT data. The method is based on an accurate surface representation of the bone and the distinction between cortical and trabecular regions, together with a systematic process to evaluate bone material properties. The inhomogeneous Young modulus was represented by continuous spatial functions applied to the FE model. The validation process was conducted using experimental result from three fresh frozen human femurs by comparing displacements and strains to the values extracted from the FE results. The FE results correlate very well with the experimental observation (same range of accuracy for each bone). The excellent agreement between the analyses and experiments are to the best of the authors' knowledge more accurate than other investigations reported in the literature. Limitations of the present work are: (a) method validation has been validated on three normal femurs in vitro. (b) The effect of using CT scan data obtained in situ and in vivo still needs to be examined. (c) FE model did not take into ac-

count the known local anisotropic behavior of all bone tissue.

This study exemplifies that the presented method is in an advanced stage to be used in clinical computer aided decision making, and is being extended in several directions: (a) Implementing an inhomogeneous anisotropic material model in the FE analyses which may better represent cases of torsion and complex loading on the bone, (b) Simulating and optimizing patient-specific "total hip replacement" surgery by FE simulation of the best possible prosthesis in case of neck fractures.

Acknowledgment

The authors acknowledge the help of Prof. Charles Milgrom from the Hadassah Hospital, Jerusalem, for providing the bones, and Dr. Arie Bussiba for his help in performing the experiments.

Design of Prosthetic Skins with Humanlike Softness

J.J. Cabibihan

The Social Robotics Laboratory (Interactive and Digital Media Institute) and
the Department of Electrical & Computer Engineering, National University of Singapore

Abstract — **Prosthetic hands and arms that have realistic appearance and can be controlled by the user's thoughts are emerging. As these technologies mature, it is likely that there will be an increased interest in endowing these with skins having humanlike softness in order to address the psychosocial issues coupled with prosthesis usage in social interactions. The objective of the project described in this paper is to find an optimal design of a prosthetic hand's skin that would be comparable to the softness of the human hand. The project aims to develop simulation and experimental methodologies for selecting skin materials, designing their internal geometries and comparing their behavior to the biomechanical skin behavior of the human hand for activities concerning social touch (e.g. handshakes, high fives, caress, etc.). In particular, this paper is focused on modifying the internal geometry of an artificial fingertip and evaluate whether significant changes in the skin compliance can be achieved. Simulation results show that modifying the internal geometry of the synthetic skin structure can lead to an increase in skin compliance.**

Keywords — **Prosthesis, Artificial Skins, Rehabilitation Robotics, Finite Element Analysis, Social Robotics.**

I. Introduction

Any loss or absence of limbs severs the dignity of man. In addition to the functional requirements, the psychosocial dimension of prosthetic devices must also be addressed. In a social context, the concealment of prosthesis usage could be made possible with prosthetics that have humanlike appearance, function and feel.

Significant progress has been made in realistic looking artificial hands. Current prosthetic hands have achieved very humanlike appearances. In fact, they can now be constructed to match the exact skin tone of the user while the sculptors can artistically create detailed skin surface with fingerprints, hairs and pores (e.g. Livingskin, www.livingskin.com). In a study among upper limb amputees in Singapore, for example, it was concluded that aesthetic prostheses are crucial for patients to cope with the traumatic experience [1].

In terms of functionality, the past five years have brought about many breakthroughs in the development of intelligent prosthetic hands (e.g. CyberHand Project, www.cyberhand.org; Neurobotics, www.neurobotics.org; DARPA's Revolutionizing Prosthesis Project, www.arpa.mil/dso/thrusts/bio/restbio_tech/revprost/index.htm). One of the crucial scientific issues that the researchers addressed was to increase the basic knowledge of neural regeneration and sensory-motor control of the human hand to enable the prosthesis to be felt by the patient and to be controlled in a very natural way. As of 2007, prosthetic arms and grippers can already be controlled by the user's thoughts (e.g. The World's First Bionic Man, www.ric.org/bionic/).

Why should a prosthetic skin be designed to feel like the real human skin? The main purpose of prosthetic devices is to let the user pass unnoticed. Prosthetic hands are expected to be touched by other people and concealing it would be difficult given the choices of materials currently used (For a comparison between the compliance, conformance and hysteresis of synthetic and human fingertips, the interested reader is referred to Ref. [2]). In addition to selecting the appropriate soft synthetic materials, the proper design tradeoffs have to made in order to maintain the wear resistance of the current stiff prosthetic skins but develop an approach in which humanlike softness could also be achieved.

The objective of the project described in this paper is to find an optimal design of a prosthetic hand's skin that would be comparable to the softness of the human hand. Softness has been defined as the perceptual correlate of compliance, which is the amount of deformation caused by an applied force [3]. The present project aims to develop simulation and experimental methodologies for selecting materials and designing their internal geometries in order to achieve similar compliance measures with the skin of the human hand. In particular, this paper is focused on modifying the internal geometry of an artificial fingertip and evaluate whether significant changes in the skin compliance can be achieved. The results are then compared to the skin compliance of the human fingertip. The simulation methodology and the preliminary results are described in the following sections.

II. Methods

A. Materials and Constitutive Equations

Synthetic skins for prosthetic and robotic hands are typically constructed with silicone and polyurethane materials.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2023–2026, 2009
www.springerlink.com

Samples of these two types of materials have been characterized and have been reported elsewhere [2, 4-6]. The silicone sample has a Shore A durometer value of 11 while the polyurethane has a value of 45 (i.e. a lower value indicates a low resistance to an indenter – a softer material). The validation experiments consisting of indentation and imaging tests demonstrated that the visco-hyperelastic constitutive equations were satisfactory for describing the behaviour of the silicone and polyurethane samples.

B. Finite Element Modeling

Fig. 1 shows the two geometries that were modeled using the commercial finite element analysis software Abaqus™ /Standard 6.7-1 (Simulia, Providence, RI). The simulations were run at the Supercomputing and Visualisation Unit of the Computer Centre, National University of Singapore. Both geometries have a 0.8 mm upper layer and 6.2 mm inner layer as measured from the base to the upper surface. Fig. 1a has a solid internal structure while Fig. 1b has a 0.75 mm space with a span of 5 mm, located 1 mm below the skin surface. The eight-node plain strain biquadratic elements were used to model the fingertip. A thickness of 10 mm (dimension towards the page) is set. This is approximately the dimension when a flat surface is in normal contact with the fingertip. The base of the finger geometry was constrained in all degrees of freedom. The materials, and in essence, the behavior of each layer, can be easily modified in the software by changing the material coefficients as obtained in the characterization experiments.

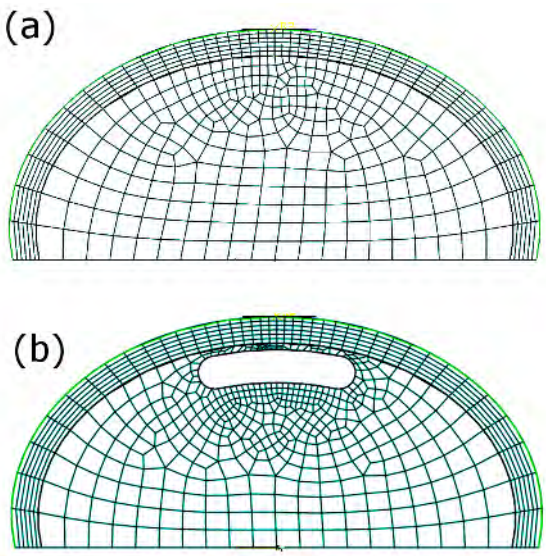

Fig. 1 The geometries of the finite element models Fig. 1a has a solid internal structure. Fig. 1b has a space below the skin surface

C. Measurement of Skin Compliance

The literatures are lacking with a complete data set of the skin compliance of the whole human hand. So far, the published data have been concentrated on the fingertip [3, 7-9]. The full compliance topography of the skin in the human hand will be most useful for comparing synthetic materials aimed at achieving humanlike artificial skins. For this project, the development of a tactile stimulator that will map the compliance of the human hand is underway. In the meantime, this paper will make use of the published fingertip skin compliance data as reported in Ref. [3] for comparing the compliance results of the synthetic fingertip. In their experiments, a flat-end probe was applied to the human fingertip at a constant velocity of 0.5 mm/s until a force of 1.25 N was reached. The same loading conditions were used for the simulations in the present paper.

III. Results

Fig. 2 shows the displacement contour plots from the simulations on the prosthetic fingertip models. The rows are arranged according to the materials used. The left column has a solid internal geometry while the right column has a modified internal geometry.

For a 1 N plate indentation, Fig. 3 shows that a homogeneous internal composition of synthetic materials resulted to an indentation displacement of 0.15 mm for polyurethane and 0.30 mm for silicone. These results are consistent with the validation experiments of quasi-static indentation loading for these materials as reported in [2, 6]. Simulations on the 0.8 mm external layer of the stiff polyurethane over the softer silicone material resulted in an indentation of 0.29 mm or difference of 3.5% from a homogenous layer of silicone.

With the introduction of a 0.75 mm opening with a 5 mm arc length, the compliance of the silicone material increased to 0.67 mm or about 125% from the structure with a solid internal geometry. For polyurethane, the indentation displacement jumped to 0.48 mm or nearly 220% improvement in skin compliance. The combination of a stiff outer layer of polyurethane and a softer inner layer of silicone produced an increase of nearly 120%. Considering that there is only a 5% difference from silicone-only model, which is the most compliant configuration in these simulations, it would be worthwhile to explore combinations with stiff outer layers for wear and tear purposes and soft inner layer for skin compliance in future studies.

Fig. 4 compares the previous results with the skin compliance of the human fingertip, as reported in Ref. [3].

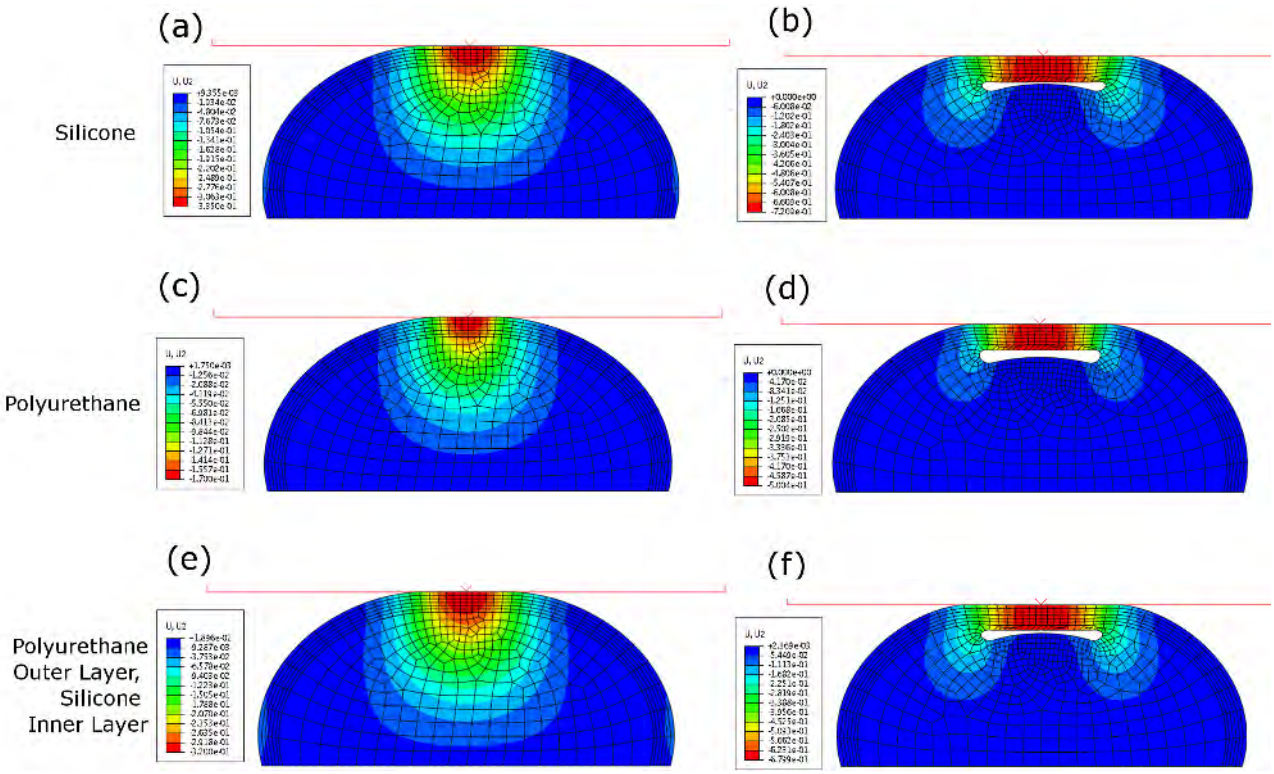

Fig. 2 The displacement contour plots of the prosthetic fingertips when indented with a force of 1 N

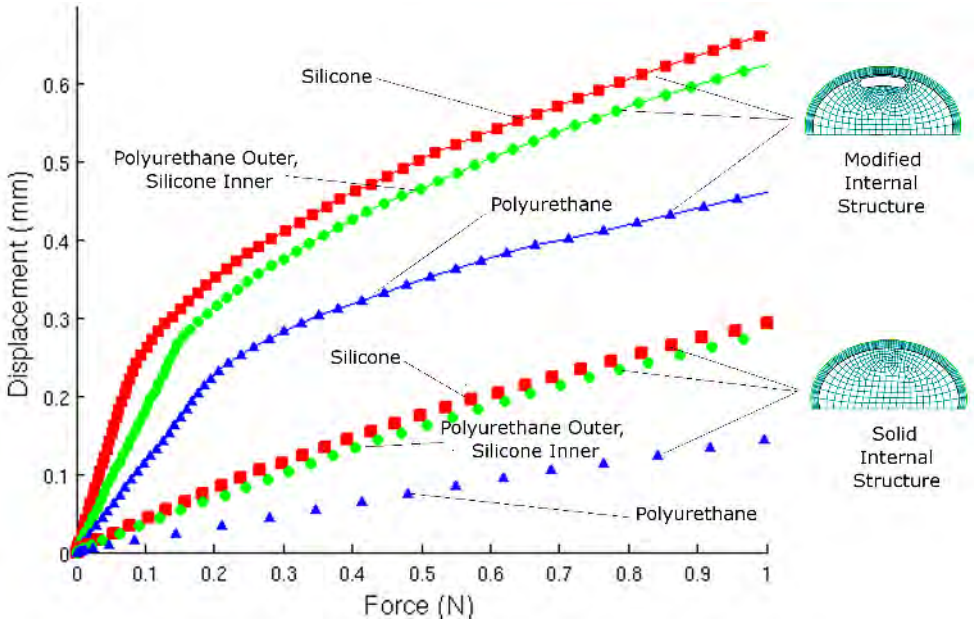

Fig. 3 Simulation results of the skin compliance of synthetic fingertip models of silicone, polyurethane and the combination of both materials. The three lower curves show the results when the geometry has homogeneous internal structure while the three upper curves are from the model with a space in the internal geometry

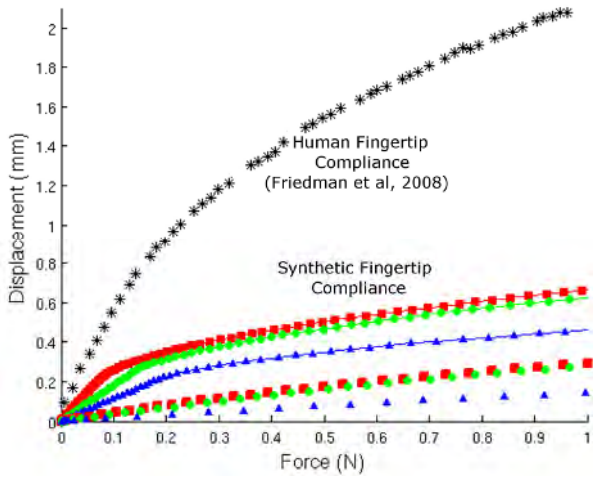

Fig. 4 Comparisons on skin compliance of human and synthetic fingertips

The simulations show that at 1 N loading, the human fingertip can easily reach an indentation displacement of 2 mm. It would take another 200% increase in the compliance of synthetic materials for this to be achieved. Furthermore, this comparison also implies that homogenous layers of silicone or polyurethane (i.e. the bottom curves) with durometer values of 11 and above would be far from the skin compliance of the human fingertip. In a social interaction scenario, such will be easily felt by another person and the prosthesis user may not be able to conceal the usage of the prosthetic device.

IV. Conclusions

In anticipation of the incoming generation of intelligent prosthetic hands and arms, it is conceivable that the next technological step is to make the crude physical features of these devices look and feel more humanlike in order to address safety and social acceptance issues.

This paper presented preliminary results from prosthetic fingertip skin models with simulations consisting of varying the material composition of the fingertips and changing the internal structure. From these, the following conclusions can be made. First, the simulation results showed the possibility of increasing skin compliance by modifying the internal geometry of the prosthetic fingertip structure. This gives an indication that for future work, selecting materials that are softer as compared to the silicone and polyurethane and developing an optimal design of the prosthetic skin's internal structure may enable us to achieve a more compliant prosthetic skin design. Second, by knowing the compliance behavior of the prosthetic skins before physically constructing them, it is possible to try different internal and external layers that could satisfy other requirements for wear and tear, maintenance and others. It is important to note that tactile sensors may be embedded later on and the skin's mechanical behaviour (e.g. compliance and hysteresis) will have to be considered in the context of the response of the embedded tactile sensors. Lastly, the simulation approach using validated finite element models proves to be a useful tool for the ongoing work to optimize the design of prosthetic skins for humanlike softness.

Effect of Data Selection on the Loss of Balance in the Seated Position

K.H. Kim[1], K. Son[1], J.H. Park[1]

[1] School of Mechanical Engineering, Pusan National University, Busan, Korea

Abstract — **A fast and accurate detection of the loss of balance (LOB) can reduce the elderly fall that is one of the most dangerous injuries. Real-time detection of body reactions against a fall will be used to improve the performance of devices for the elderly. The loss of balance is detected by control error anomaly (CEA) that is an unusually large value of the system control error.**

Three men took part in the experiment. Each volunteer was seated on a four-legged chair and he balanced the chair over its rear legs by his foot as long as possible. This system had single input and single output. The input was the foot's ground reaction force and the output was the angular acceleration of the chair. An internal model of balancing task was built of a linear equation of regression from the relationship between input and output. The output of the internal model was assumed as a control signal of the angular acceleration from the central nervous system.

Data selection depends on the size of the foot reaction force data, S1, which were used to construct the internal model and the threshold, S2, which were used to detect the LOB. The size of the force data changed from 0.2 to 3 sec and also the threshold size changed from 0.02 to 0.2 sec. Therefore in the case of detecting the loss of balance under 3-sigma method, the detecting performance was improved in lager S1 and smaller S2.

Keywords — **Balance, Control, Internal Model, Regression, Threshold**

I. Introduction

Elderly falls are one of the most dangerous accidents and normally occur with a fracture of hip bone. More than 35% of elders aged over sixty have experienced fall on the average[1]. Most falls happen unintentionally and these are attributable to a 'loss of balance'.

People knows intuitively what a loss of balance means but it is difficult to understand how to detect the loss of balance and what process works in the central nervous system (CNS). Ahmed et al. proposed 'a loss of balance is required for the CNS to trigger a compensatory response and prevent the ensuing fall'[2,3]. A loss of balance usually results from positioning the center of mass (COM) outside the base of support in static or quasistatic movements. Pai et al. suggested that a dynamic loss of balance occurs when the velocity and position of the COM crossed over fixed upper or lower limit[4]. In the detection of a loss of balance, humans tried to regain the balance with a rapid adjustment of body configuration, such as a compensatory step, and this behavior was the only evidence that was observable externally. Several researches have used this externally visible evidence in order to explain when the compensatory step was needed for various perturbations[5,6].

In this study the failure-detection algorithm that was proposed by Ahmed et al. was used so as to detect the loss of balance[2]. The postural control model of the CNS has an input signal, a controller, a plant, a feedback of output signal, and system variables[7,8]. We monitored the error signal between the output of the plant and the result of the forward internal model which was created using input signal, and found out the loss of balance by detecting a CEA.

Ahmed et al. pursued a number of comparisons between the algorithm success rate and the size difference of input data which were used to construct both the forward internal model in the fixed sampling size of input data. But the proposed forward internal model was a linear regression function which was calculated by a least squares method. Its parameters were different according to the size and this changed parameters directly affected the error signal which was used in the algorithm. Therefore it is necessary to find out the effect of data size on the result of detecting the loss of balance.

II. Materials and Method

To verify the relationship between the data size and the detecting result, we made this test model simple. A volunteer was seated and balanced the chair over its rear legs by his foot as long as possible. This system had one input and one output. The former was the foot's ground reaction force and the latter was the angular acceleration of the chair (Fig 1). An internal model of balancing task was built of a linear equation of regression from the relationship between input and output[2].

The output of the internal model, $\hat{y}(t)$, was assumed to be a control signal of the angular acceleration from the central nervous system. The control error, $e(t)$, was defined as the difference of the angular acceleration between obtained by sensory and expected by the internal model. If the error crossed over the threshold which was set at three standard deviations (3σ), it was regarded as the CEA.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2027–2029, 2009
www.springerlink.com

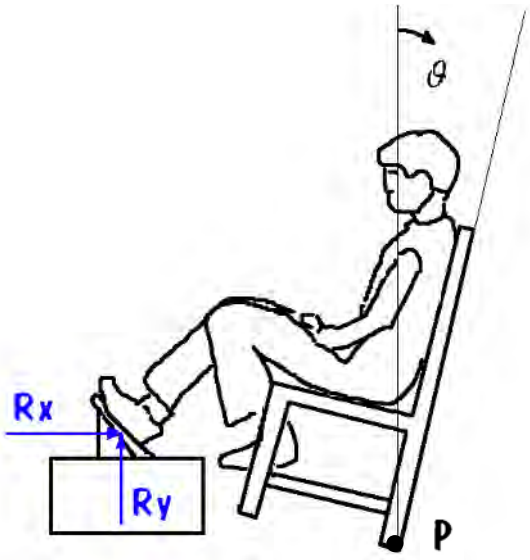

Fig. 1 Schematic of balancing test

$$e(t) = y(t) - \hat{y}(t) \quad (1)$$

$$\hat{y}(t) = a_0 + a_1 u(t) \quad (2)$$

where $y(t)$ is the plant output signal which represents the actual output, the angular acceleration of the chair. And $u(t)$ is the input signal, the torque at the point P, which was obtained by the foot ground reaction force.

Three healthy, young adult volunteers were tested more than 10 times per a person. Four legged chair was used to obtain angular acceleration, the plant output signal, and the input signal was the foot GRF obtained by a force plate(Kistler 9285). Subjects were not allowed to have any motion except a leg which was used to push the force plate. The angular accelerations of the chair and the foot ground reaction forces were measured at 540 Hz. These data were filtered with a fourth-order, low-pass Butterworth filter (Matlab®) and a cutoff frequency of 3 Hz.

The size of input data for creating the forward internal model, S1, was varied from 0.2 to 3 sec and the threshold size, S2, from 0.02 to 0.2 sec with the time interval of 0.2 sec and 0.02 sec, respectively. Figure 2 shows the input data, torque at the point P. Figures 3 and 4 show the angular accelerations of both the plant result and the predicted result by the internal model and the error signal between the plant result and the predicted result, respectively.

We compared the reaction time between the results obtained in this study and the fixed size that S1=2 sec and S2=0.1 sec. Figure 5 shows the reaction time with different sizes of data selection. The lower size of S2 had the faster

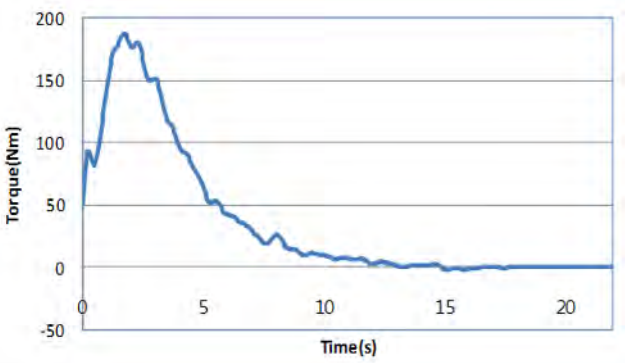

Fig. 2 Torque at the point P exerted by foot

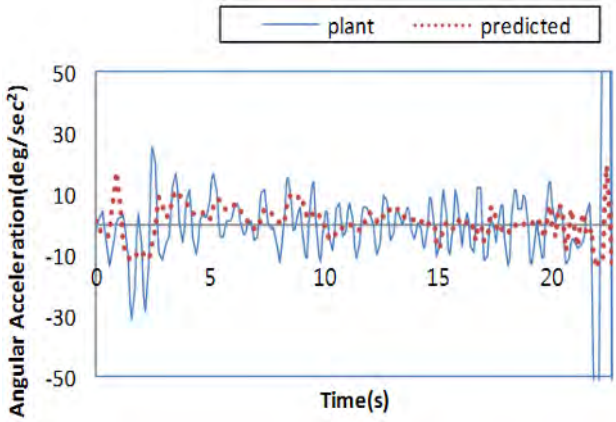

Fig. 3 Angular accelerations of the plant output and the predicted output by the forward internal model

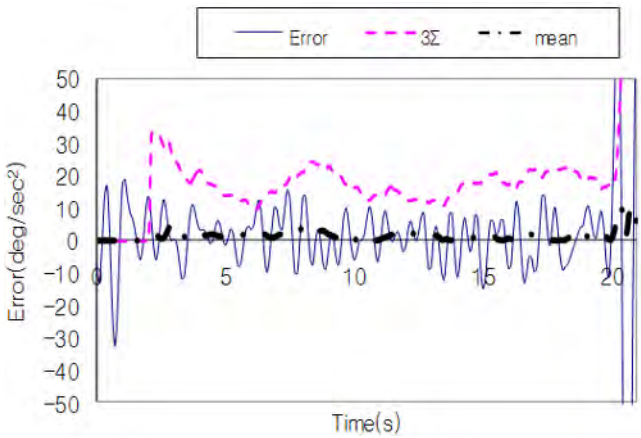

Fig. 4 Error signal between the plant output and the predicted output

detecting time than the fixed size. When S2 was under 0.1 s, most reaction times were faster than the fixed size except the case of S1=1.2 sec. If the threshold size, S2, was constant, the reaction time was faster in larger S1.

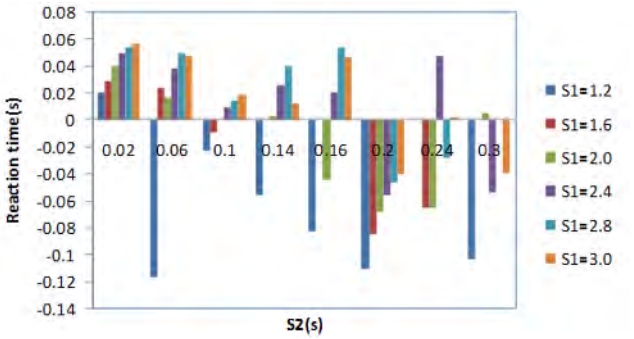

Fig. 5 Comparison between the reaction time and the size of both input data for creating the forward internal model, S1, and threshold size, S2

The size of S1 means the amount of input data used at creating the internal model. This result revealed that more input data improved the ratio of detecting the loss of balance. But the internal model with too large S1 was not physical because the internal model was built in a linear regression function. The cases with the size of S1 over 2.4 sec were satisfied to detect quickly the loss of balance with the size of S2 under 0.16 sec. When the data size was 2.8 sec and the thresh-old size was 0.02 sec, the detection time of the LOB was the smallest.

III. Conclusions

Data selection depends on the size of the force data which were used to construct the internal model and the threshold which were used to detect the LOB. The size of the force data changed from 0.2 to 3 sec and also the threshold size changed from 0.02 to 0.2 sec. Therefore in the case of detecting the loss of balance under 3-sigma method, the detecting performance was improved in lager S1 and smaller S2.

The Effect of Elastic Moduli of Restorative Materials on the Stress of Non-Carious Cervical Lesion

W. Kwon[1], K.H. Kim[1], K. Son[1] and J.K. Park[2]

[1] School of Mechanical Engineering, Pusan National University, Busan, Korea
[2] Department of Conservative Dentistry, Pusan National University, Busan, Korea

Abstract — **Various dental materials have their particular properties with different restorative effects. This study investigates the influence of elastic moduli of the restorative materials on the stress of non-carious cervical lesion. A three-dimensional finite element model was constructed based on the scanned data of an extracted maxillary second premolar. Such five different restorative materials as TF (Tetric Flow), GIC (Glass Ionomer Cement), Z100, amalgam and gold alloy were analyzed to restore the cervical lesion. A load of 150 N was applied on the cusp of buccal and the corresponding stresses calculated in three regions: occlusal, apex and cervical of each restoration model. In the occlusal and cervical regions, as the stiffness of restorative material increased so did the level of stress in the descending order of gold alloy, amalgam, Z100, GIC and TF. In the apex region, however, the order of stress magnitude was reversed. TF of the lowest stiffness yielded the most effective restoration in terms of the reduction of stress in the lesion part while Z100 of a similar elastic modulus to the dentin was the best at the apex.**

I. Introduction

In clinical dentistry, the loss of hard dental tissue is occasionally observed in the cervical region of a tooth. Erosion, abrasion and abfraction are the most common contributors to non-carious cervical lesions (NCCLs)[1]. Occlucal loadings, which concentrate stress on the cervical area of a tooth, have been considered to cause hard tissue loss at the cement-enamel junction (CEJ). This is referred to as abfraction[2] in order to distinguish it from lesions caused by erosion and abrasion.

The origination of this defect is assumed due to the mechanism for cervical tooth loss that links with occlusal loading. For reduction of stress concentration and prevention of the growth of lesion, dentists choose the restorative operation. Though this operation is carried out, the effect varies depending on restorative materials and does not last permanently. The purpose of this study was to investigate the effect of elastic moduli of restoration using a three dimensional finite element analysis.

II. Materials and method

A. Structure of tooth and lesion

The tooth consists of various materials according to its components. There is a cavity so called the pulp which contains vessel and nerves in the middle of the tooth. The dentin, which occupies most of the tooth, builds the whole root and some of crown. The crown is located in the upper of the dentin and coated with the enamel, which is the hardest tissue of the tooth. The root of tooth is fixed on the mandible or maxilla by the periodontal ligament (PDL) which is a type of membrane.

An NCCL occurs in the CEJ where the cement and the dentin meet in the cervical of tooth. An absolutely larger percentage of NCCL is found in the buccal side than in the lingual side. Once a lesion takes place, it grows gradually along the CEJ. The NCCL has to be treated by a restorative operation in order to prevent its growth.

B. Construction of tooth model

A three-dimensional finite element model of the tooth was constructed by several steps of image processing. Firstly, using a micro CT machine (Micro-CT, Skyscan, Belgium), 357 pictures of horizontal sectional configuration were acquired from an extracted maxillary second premolar whose length was 20 mm. Secondly, geometrical data of the outer and inner shapes of tooth components, which included the enamel, the dentin and the pulp, were drawn out through the binary image operation. These configuration data were also treated for the modification of reducing unnecessary nodes. After each modification of CT images, the volume of tooth was rendered through stacking them. Then, free curved surfaces of each tooth component were set up from their contour nodes using a commercial program Rhino 3D (Robert McNeel & Assoc., Seattle, WA, USA). The scheme of constructing process from image operating to finite element modeling is shown in Fig. 1.

A commercial finite element preprocessing program Hypermesh (Altair Engineering Inc., Troy, MI, USA) was used to make a three-dimensional finite element model from the acquired geometric configuration data. The type of lesion

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2030–2033, 2009
www.springerlink.com

was chosen as notch shape. The depth of abfraction was set as 2 mm and a separate treatment was postulated as single restoration with one material. The size of element was different for each component: The lesion and its surrounding had the smallest size (0.05 mm) to investigate the distribution of stress precisely. Other parts, such as the PDL, the pulp and the rest of dentin and enamel had a medium size (0.3 mm). The alveolar bone was created using different element sizes. Elements of the inner surface, which contacts the PDL, were designed with a medium size (0.3 mm); those of the outer surface with a larger size (0.67~1.76 mm) to reduce the number of elements. Figure 2 shows the components of a complete finite element tooth model. Table 1 lists properties of the dental and restorative materials used in this study.[3, 4]

The finite element model was subject to the same constraint as a real tooth. The tooth analyzed was the maxillary second premolar, which located between the first premolar and the first molar, and fixed on the maxillary bone. Hence, the lateral faces of alveolar, which contacted the adjacent tooth, were constrained in y direction. The bottom surface of alveolar was constrained in all directions. A large deviation of load (31 - 453 N) can be yielded by masticatory movement. In this study, a force of 150 N oriented at 45° from the horizontal was assumed to apply on the upper third of buccal and lingual slopes as in Fig. 3.[3]

C. Validation and criterion

The finite element model had to be validated before its use in the analysis. For this purpose, six different models of the lesion part were constructed with various element sizes (0.05, 0.1, 0.15, 0.2, 0.25 and 0.3 mm) and they were subject to the same loading.[5] Then, the comparison of calculated stresses at the apex showed that the stresses of 0.1, 0.15 and 0.2 mm models had relative errors of 0.05, 0.03 and 0.41% to that of the finest model. This result showed the convergence of stress to the exact value with the reduction of element size. For better computational results, the smallest size (0.05 mm) was selected in this study.

In order to estimate the effectiveness of restoration, a criterion was established. The failure of restoration occurs along the boundary of tooth tissue and restorative material due to high stress generated. For longer restoration, stress along the lesion boundary must be lowered. Hence, an objective function was defined as to minimize von Mises stress on lesion where stress concentration is noticeable.[5]

$$\min \{\Sigma S_1 + \Sigma S_2\} \quad (1)$$

ΣS_1 = tensile stress

ΣS_2 = compressive stress

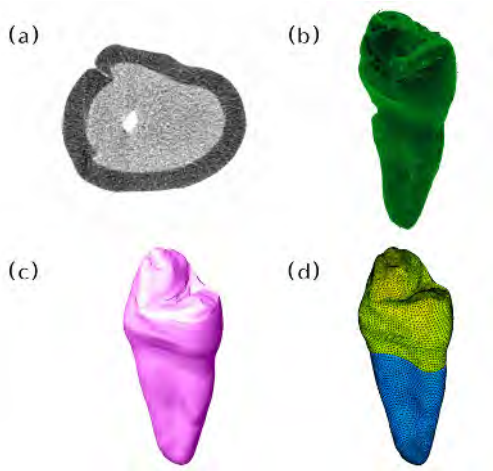

Fig. 1 Procedure reconstructing tooth model: (a) CT image of the second premolar, (b) Reconstructed 3D data using 3D Doctor, (c) Reconstructed 2D surface data using from Rhino 3D, and (d) 3D model of tooth created using Hypermesh

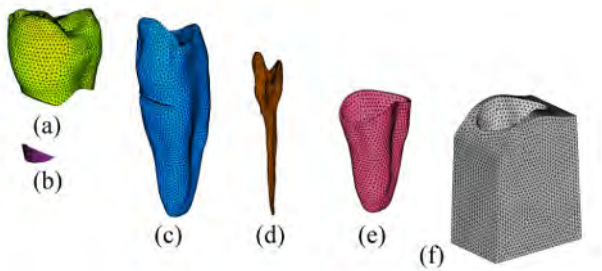

Fig. 2 A finite element tooth model consists of (a) Enamel, (b) Restoration, (c) Dentin, (d) Pulp, (e) PDL, and (f) Bone

Table 1 Mechanical elastic properties of the materials [3, 4]

Materials	Elastic modulus (MPa)	Poisson ratio
Enamel	69,000	0.3
Dentin	16,700	0.3
PDL	12	0.45
Bone	14,700	0.3
Tetric Flow	5,300	0.28
GIC	10,800	0.3
Z100	15,200	0.28
Amalgam	50,000	0.24
Gold Alloy	89,500	0.33

Maximum tensile and compressive strengths of tooth material vary in different literatures. Table 2 lists the range of maximum tensile strengths of the enamel and the dentin.[6] The upper and lower limits of the listed stress were used to compare the restorative effects of materials on the stress along the node lines. When the stress value was over the upper limit, the case was defined as critical; when between the two limits, defined as semi-critical.

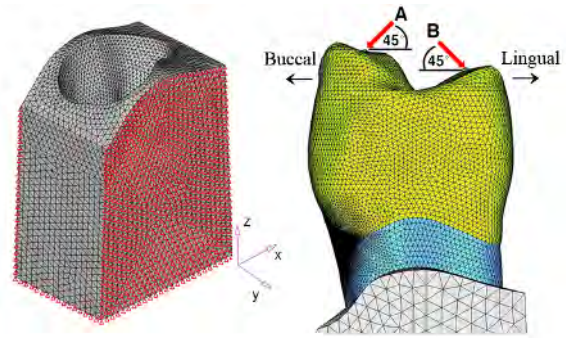

Fig. 3 Scheme of loading condition

Tensile strength of enamel	10 – 24
Tensile strength of dentin	32 – 103

Table 3 Summation of stresses in three regions of five models

Restorative material	Region	Objective function (GPa)		
		S_1	S_2	Sum
Tetric Flow	Occlusal	1.556	2.568	4.124
	Apex	2.109	3.289	5.398
	Cervical	1.897	2.712	4.609
	Sub total			14.131
GIC	Occlusal	2.008	3.342	5.350
	Apex	1.399	2.086	3.485
	Cervical	2.402	4.029	6.431
	Sub total			15.266
Z100	Occlusal	2.073	3.316	5.389
	Apex	1.254	1.885	3.016
	Cervical	3.384	4.793	8.177
	Sub total			16.582
Amalgam	Occlusal	2.491	4.103	6.594
	Apex	1.273	1.762	3.158
	Cervical	6.333	9.127	15.460
	Sub total			25.212
Gold Alloy	Occlusal	3.109	4.996	8.105
	Apex	1.638	2.168	3.806
	Cervical	7.828	11.385	19.213
	Sub total			31.124

As shown in Fig. 3, a compressive stress was generated at lesion and its surroundings when the tooth was under load A; a tensile stress under load B.

III. Results

The stress distributions of lesion surroundings were compared in order to investigate the effect of material stiffness on the restoration. Three regions were chosen and stress values at the nodes in the regions were calculated.[5] The three regions included the occlusal line, i.e., the upper boundary between enamel-dentin and restoration, the apex line, i.e., the vertex of the restoration, and the cervical line, i.e., the lower boundary between dentin and restoration. The summation of stresses along each line is listed in Table 3. The comparison of three lines of five models is listed in Table 4, based on the numbers of critical and semi-critical cases.

A. Comparison in occlusal region

TF of the lowest stiffness was subject to the lowest stress, while the stresses on the other materials became higher as their stiffness increased. The summation of von Mises stress of TF was 4.124 GPa. Those of GIC and Z100 were almost same and they were 5.350 and 5.389 GPa, respectively. Amalgam and gold alloy sustained relatively high stresses, 6.594 and 8.105 GPa, respectively.

In terms of the critical stress, TF was selected as the best since it had 3 critical and 74 semi-critical nodes out of a total of 171 nodes along the occlusal line. GIC had 4 critical and 98 semi-critical nodes and Z100 had 4 critical and 100 semi-critical nodes. Amalgam had 17 critical and 113 semi-critical nodes. On the other hand, gold alloy had the largest number of critical nodes, 37, and the other nodes along the line belonged to the semi-critical cases.

B. Comparison in apex region

Along the apex line, Z100 which has the most similar stiffness to the dentin resulted in the lowest stress level. The summation of von Mises stress of Z100 was 3.106 GPa. Those of TF and GIC were higher than that of Z100 reaching up to 5.398 and 3.485 GPa, respectively. Amalgam and gold alloy yielded 3.158 and 3.806 GPa, respectively. In terms of the critical stress, there was neither critical nor semi-critical node along the apex lines of Z100, amalgam and gold alloy. However, both TF and GIC had 2 semi-critical cases.

C. Comparison in cervical region

The stress along the cervical line became larger as the stiffness of restorative material increased as in Table 3. The restoration using TF was the best yielding a stress summation of 4.609 GPa and it was also good in terms of the critical stress TF and GIC had only 2 semi-critical nodes out of 171 nodes along the cervical line. Z100 yielded 8.177 GPa, however, it had no critical and semi-critical cases. Amalgam and gold alloy resulted in such extremely high stresses as 15.460 and 19.213 GPa, respectively. Their results were also inferior in the number of semi-critical nodes as in Table 4.

Table 4 Number of critical nodes in five models

Restorative material	Region	Critical nodes	Semi-critical nodes
Tetric Flow	Occlusal	3	70
	Apex	0	2
	Cervical	0	2
GIC	Occlusal	4	98
	Apex	0	1
	Cervical	0	2
Z100	Occlusal	4	100
	Apex	0	0
	Cervical	0	0
Amalgam	Occlusal	17	113
	Apex	0	0
	Cervical	0	110
Gold Alloy	Occlusal	37	171
	Apex	0	0
	Cervical	0	137

IV. Conclusions

A three dimensional finite element tooth model was constructed in order to investigate the restorative effects of five different materials. The materials of lower stiffness than the dentin, TF and GIC, resulted in low stress in both occlusal and cervical regions. In the apex region, however, harder materials like Z100, amalgam and gold alloy yielded lower stress level than TF and GIC, and these three materials left neither critical nor semi-critical nodes. Especially Z100 having the most similar stiffness to the dentin resulted in the lowest stress, 3.016 GPa among the five materials.

A single restoration using TF was found to be the best in the overall stress level, but it was not the best in every region. Though Z100 did not reduce the stress level as TF did, it was superior to TF in the apex region where most failure of restoration occurs. Therefore, a multi-layer restoration, which uses Z100 for the inner part and TF for the outer part, is likely to reduce more stress than the single restoration with TF.

Effect of Heat Denaturation of Collagen Matrix on Bone Strength

M. Todoh[1], S. Tadano[1] and Y. Imari[1]

[1] Division of Human Mechanical Systems and Design, Graduate School of Engineering, Hokkaido University, Sapporo, Japan

Abstract — **Bone is often regarded as a composite material consisting of hydroxyapatite (HAp-like) mineral particles, organic matrix (mostly Type I collagen) in microscopic scale. The mechanical properties of bone at macroscopic scale depend on the structural organization and properties of constituents in the microscopic scale. It has been considered that bone density is a predictor of its strength from a macroscopic perspective, but denaturation of the organic matrix would also lead to a significant loss of bone strength. In this study, heat-treated bone was examined as a collagen denatured model, and then four-point bending tests and impact tests were conducted to assess the role of the collagen matrix for mechanical properties of bone.**

Cortical bone specimens were obtained from the mid-diaphyses of bovine femurs and heat treated in an oven for 2 hours at 100, 150, 180 and 200°C, respectively. The specimens were stored in saline until the experiments. The elastic modulus and bending strength caused by collagen denaturation were measured by four-point bending tests using a mechanical testing machine. The tests were performed up to fracture at a deflection rate of 0.5 mm/min, with an inner and outer span of 10 and 24 mm respectively. Toughness was evaluated by measuring fracture energy of the specimens using a self-made impact tester.

As the results of four-point tests, the specimens heated at over 150°C failed with a low strain in the elastic region, suggesting a brittle fracture behavior. The elastic modulus of bone was slightly reduced with the heating temperature, whereas the bending strength significantly decreased, especially at 150°C. The results of the impact fracture test shows heat-induced collagen denaturation has great influence on the toughness of bone. These results suggest that not only denatured collagenmolecules but also collagen cross-links play an important role on the mechanical properties of bone.

Keywords — **Biomechanics, Bone, Collagen matrix, Stiffness, Fracture energy**

I. Introduction

Bone has a hierarchical structure at different structural levels and is often regarded as a composite material consisting of hydroxyapatite (HAp-like) mineral particles, organic matrix (mostly Type I collagen) and water phases in microscopic scale. The mechanical properties of bone at macroscopic scale depend on the structural organization and properties of constituents in the microscopic scale [1-3]. Considerable attempts have been made to investigate the effect of the microscopic constituent on the mechanical properties of bone. It is the interaction between the mineral and organic material that determines the mechanical properties. The effect of mineral content on the stiffness, strength or viscoelasticity of bone has been widely investigated [4-7]. However, the mechanical role of organic phase in bone has been little known. According to the composite theory, the stiff mineral controls the stiffness and strength of bone, whereas the collagen matrix controls the toughness and viscoelasticity of bone. The bone density is considered as a predictor of its strength from perspective, but the denaturation of collagen matrix would also lead to a significant loss of bone strength.

The current study examined the effect of collagen denaturation to the mechanical properties of bovine cortical bone by heat treatment. Specimens were heat-treated in an oven at 100 to 200°C for 2 hours. The elastic modulus and bending strength caused by collagen denaturation were measured by four-point bending tests using a universal testing machine. The toughness was evaluated by measuring fracture energy of the bone specimens using a pendulum-typed impact tester.

II. Materials and Methods

A. Collagen denaturation

Cortical bone specimens with average sizes of 30.0×4.0×1.5 mm for four-point bending tests and 30.0×3.0×3.0 mm for impact tests were harvested from the mid-diaphyses of bovine femur with longer side edge aligned along the femoral axis. Rough cuts were done by using hand-saw and fine cuts by using low-speed diamond saw (SBT650, South Bay Technology, Inc. USA).

The specimens were heat-treated in an oven (AVO-250, AS ONE Corp., Japan) at 100, 150, 180 and 200°C for 2 hours. This temperature range was selected for this study because the collagen network in bone denatures at certain specific temperatures: 60°C for the non-calcified collagen and 150°C for the calcified collagen [8]. Based on the results of previous studies using X-ray diffraction and scanning electron microscopy techniques, at such low temperatures no significant changes in the crystal structure and morphological characteristics of the mineral phase would be expected [9].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2034–2037, 2009
www.springerlink.com

Until the mechanical experiments, the specimens were preserved in a saline solution.

B. Mechanical tests

Four-point bending tests, with an inner and outer span of 10 and 24 mm, were performed using universal testing machine (Model4411, Instron Corp., USA) to evaluate the elastic modulus M [Pa] and bending strength σ_b [Pa] of cortical specimens with different heating temperature by the following equations, respectively.

$$E = Fa^2(3l+2a)/t^3bv \quad (1)$$

$$\sigma_b = 3Fl/2t^2b \quad (2)$$

where F [N] is the applied load measured by load cell (maximum load 5 kN), a [m] is the inner span, l [m] is the outer span, b [m] is the width of specimen, t [m] is the thickness of specimen and v [m] is the deflection.

All the bending tests for heat-treated samples were carried out at constant deflection rate of 0.5 mm/min at room temperature. Elastic modulus was calculated as the slope, measured with a least-squares linear regression in the linear region of the load vs. deflection curve.

Impact tests were performed using pendulum-typed impact tester (self-made; pendulum mass = 750 g; arm length = 210 mm; initial mass height = 75 mm) (Fig. 1) to evaluate the fracture energy of cortical specimens with different heating temperature.

Fracture energy W [J] was defined as the following equation.

$$W = Mgl(\cos\theta_2-\cos\theta_1)-L \quad (3)$$

where M [kg] is mass of pendulum arm, g [m/s^2] is gravitational acceleration, l [m] is pendulum arm's length, θ_1 [rad] is initial angle of pedulum arm, θ_2 [rad] is pendulum arm angle after bone fracture and L [J] is the energy loss of pendulum tester.

All experiments for heat-treated samples were carried out at room temperature.

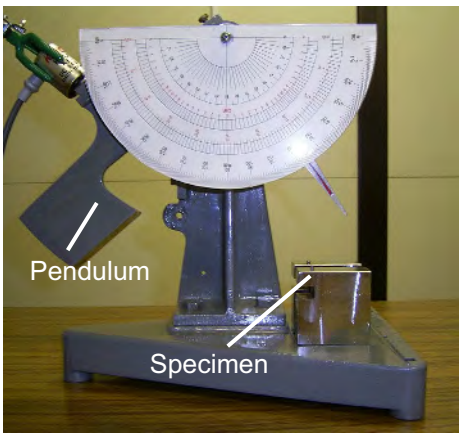

Fig. 1 Pendulum-typed impact tester for measuring fracture energy of heat denaturated cortical bone

C. Measurement of denatured collagen

To quantify the effect of heat denaturation, the denatured collagen in cortical bone specimens were measured by using α-chymotripsin selective digestion technique. Specimens were demineralized by immersing in 10% disodium EDTA (ethylene diamine tetraacetic acid) solutions (4°C, pH=7.4) for 7 days. Each specimen after demineralization was weighed by using an electronic balance (GF-200, A&D Corp. Ltd., Japan) after drying in vacuum oven (AVO-250, AS ONE Corp., Japan) at room temperature (25°C) for 3 hours. After demineralization, specimens were immersed in α-chymotripsin solution (1.0 mg/ml) at 37°C by using a heating bath (B-490, Buchi Labortechnik AG, Switzerland) for 24 hours, and then weighed again.

Percentage denatured collagen DC [%] was defined as following equation.

$$DC = (W-W_d)/W \quad (4)$$

where W [kg] and W_d [kg] are weight before and after immersing in α-chymotripsin solution.

D. XRD Analysis

The crystallinity of mineral phase in each specimen was evaluated by X-ray diffraction technique. The samples were scanned with Zr filtered Mo-Kα X-ray radiation (RINT2000, Rigaku Co., Japan) at 40 kV and 40 mA, at 0.3 deg/min, over a 2θ range of 10°-30°.

III. Results

Figure 2 shows the changes in cortical bone specimens by heat denaturation. Increasing the heating temperature, the surface of specimen gradually turned brown. This phenomenon was occurred by forming the nonenzymatic cross-link in collagen, so-called Maillard reaction. Some studies indicated that there is an age-related increase in nonenzymatic cross-links in collagen [10].

The typical bending load vs. deflection curves for denatured specimens at different temperature are shown in Fig. 3. The ultimate deflection of denatured specimens over 150°C is significantly small compared to the others.

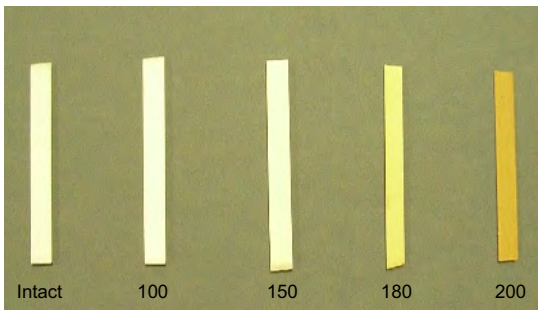

Fig. 2 Changes in cortical bone specimens by heat denaturation of collagen

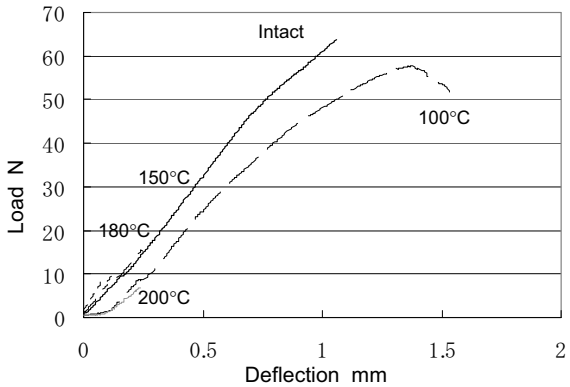

Fig. 3 Load vs. deflection curve by four-point bending test

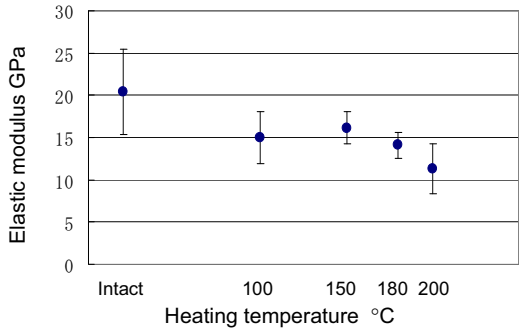

Fig. 4 Elastic modulus vs. heating temperature

The elastic modulus (obtained from the linear region of Fig. 3) and tensile strength (obtained from the maximum stress) vary with the increase of heating temperature as shown in Fig. 4 and Fig. 5, respectively. The elastic modulus of intact specimen is 20 GPa, whereas that of denaturated specimen (200°C) is less, equal to 12 GPa. The tensile strength of intact tissue is 178 MPa and that of denaturated tissue is 38 MPa.

The fracture energy varies with increase of heating temperature as shown in Fig. 6. The fracture energy of intact specimen is 12.8 J and that of denatured specimen is 4.5 J.

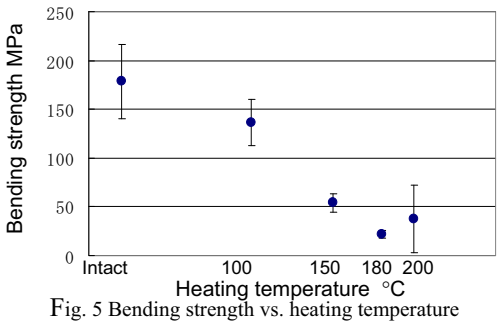

Fig. 5 Bending strength vs. heating temperature

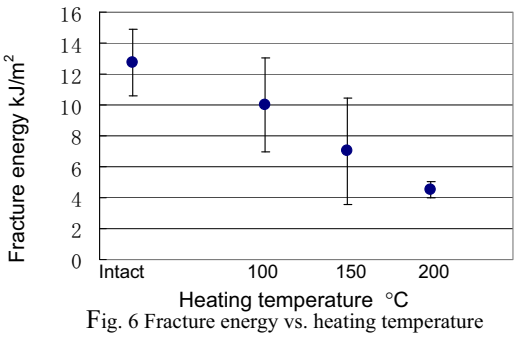

Fig. 6 Fracture energy vs. heating temperature

IV. Discussion

Figure 7 shows the X-ray diffraction profiles from denatured specimens at different heating temperature. From the results, at this temperature range (<200°C) no significant changes in the crystal structure was confirmed. Thus, the heat treatment could exclusively induce collagen denaturation without damaging the mineral phase.

As the results of the mechanical tests, the fracture toughness of cortical bone specimen significantly decreased as the temperature increased. Previous studies suggested that the fracture toughness decrease could be due to a decreased ability of the organics to sustain stress that arises from a weakening of the bonding between collagen fibrils at higher temperatures [11].

The relationship between the weight loss by α-chymotrypsin selective digestion and the heating temperature is shown in Fig. 8. The increase of weight loss as increased temperature indicates that the amount of denatured collagen increase as temperature. However, this amount was maximal in heating at 150°C. On the contrary, the weight loss by selective digestion decreased over 150°C. This indicates that both of the increase of denatured collagen and the increase of cross-links in collagen by a Maillard reaction. Therefore, these results suggest that not only denatured collagen molecules but also collagen cross-links play an important role on the mechanical properties of bone.

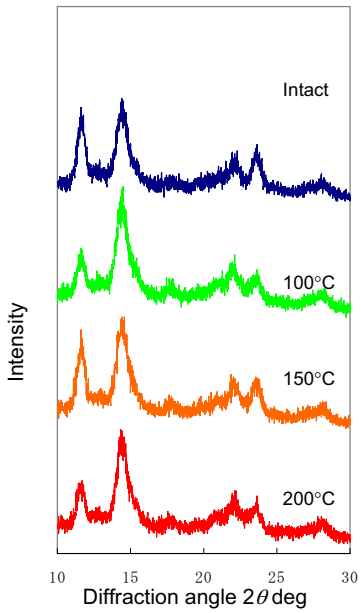

Fig. 7 X-ray diffraction pattern from denatured specimens at different temperature

V. Conclusions

This study examined the effect of collagen denaturation to the mechanical properties of bovine cortical bone by heat treatment. The collagen phase was denatured by heat treatment. The elastic modulus, bending strength and fracture energy were measured by the mechanical tests. The results of this study indicate that the heat-induced collagen denaturation has much influence on the mechanical properties of bone.

Non-linear Image-Based Regression of Body Segment Parameters

S.N. Le[1], M.K. Lee[2,3] and A.C. Fang[1]

[1] Department of Computer Science, National University of Singapore, Singapore
[2] School of Sports, Health and Leisure, Republic Polytechnic, Singapore
[3] Physical Education and Sports Science, National Institute of Education, Nanyang Technological University, Singapore

Abstract — **Biomechanical analysis of human movement often requires accurate estimation of body segment parameters (BSP). These values are segmental inertial properties, including mass, center of mass and moments of inertia. They can be measured directly on living subjects using techniques such as Magnetic Resonance Imaging (MRI), Computed Tomography (CT) and gamma-mass scanning. Despite their accuracy, these methods involve high radiation and require expensive scanners that are not always readily available to biomechanics researchers. Another popular way to estimate BSP is by studying regression equations on experimental data, commonly from cadaveric studies. These approaches, however, have been criticized for the limited cadaveric data.**

We propose a novel in vivo regression method for computing BSP using non-linear image-based techniques. Our method was first facilitated with X-ray images of sample subjects acquired from Dual-energy X-ray Absorptiometry (DXA), where the radiation dose is approximately 1/10th that of a standard chest X-ray. A feature-based image transformation was then applied to predict a mass distribution image for the new subject, while he was not required to undergo DXA scanning. The subject's BSP values were subsequently computed using the mass distribution obtained from the predicted image. Cross-validation of moments of inertia among population samples shows that our method has mean percentage errors of 7.5% for limbs and 7.1% for head and torso, while the corresponding errors are 9.3% and 15% in cadaver-based non-linear regression method. It suggests that our image-based regression approach is promising for estimating BSP on living subjects. It is not limited by ranges of cadaveric data or differences between living and dead tissues.

Keywords — **Body Segment Parameters, Dual-energy X-ray Absorptiometry, Image Warping, Regression Method.**

I. Introduction

Body segment parameters (BSP) are the inertial properties of each segment of the anthropometric model, which consist of mass, center of mass and moments of inertia. The accuracy of BSP estimation has a significant influence on mechanical quantities computations, including calculating the kinetics of motion using inverse or forward dynamics [6, 18], gait analysis [16], and determining the sensitivity of joint resultants [1].

Where in vivo methods are unavailable, one popular way to estimate BSP is by constructing statistical models from cadaveric data [4]. [2] and [19] developed regression equations using non-uniform spatial scaling of segmental mass. In other studies, moments of inertia were estimated from segmental measurements [10] or body mass and standing height of the subject [5]. Although cadaver-based methods provide a convenient means to predict BSP, they have been criticized for limited number of samples and variety of sample population. Due to obvious difficulties in acquiring comprehensive cadaveric data, researchers have turned to in vivo methods.

Three-dimensional (3-D) in vivo imaging techniques, such as MRI [14], CT [11, 15] and gamma-mass scanning [20], have been used for determining accurate 3-D BSP. However, they have been criticized for the high level of radiation involved, cost of the scans and limited availability of expensive scanners.

In recent years, two-dimensional (2-D) in vivo imaging techniques using Dual-energy X-ray Absorptiometry (DXA) has been found to be useful for obtaining accurate 2-D BSP [7]. Despite their 2-D nature, the results hold promise as, compared to 3-D imaging, DXA scanning is less expensive while delivering a much lower dose of radiation.

We propose a new approach for estimating a subject's BSP using a feature-based image warping technique facilitated by a set of sample DXA images. Our method predicts a mass distribution image that is statistically representative of the subject by computing a non-linear image transformation based on feature correspondences. To provide the features required in the transformation, each DXA image was annotated with external anthropometric and body segmentation information. Subsequently, BSP values were obtained directly from the predicted mass image. The novelty of our approach is that mass distributions are represented and processed in their raw image form. This is in contrast with previous approaches where regression models are formulated by associating aggregated quantities, such as moments of inertia with external anthropometric. We retain the details in spatial variations of mass, which would have been lost in the aggregated quantities.

In section II, we present our method of estimating BSP from DXA images using non-linear image-based tech-

niques. Section III compares the errors between our computed BSP and that from cadaver-based non-linear regression equations [15]. Section IV presents further discussions and conclusions.

II. Materials and method

A. Dual-energy X-ray Absorptiometry

DXA machine (QDR-1000/W, Hologic Inc., Bedford, MA, USA) uses two X-ray beams of alternating intensities to measure areal body density (gcm^{-2}) and body composition. The scanning process is done with the help of Hologic QDR Software. The high-energy beam passes through all matter in its path and is attenuated depending on the amount of mass present, which can be illustrated by plotting the attenuations along each scanline of the scanned image. Attenuation values are recorded in rectangular cells of 1.303cm x 0.618cm or 150 x 106 pixels per whole body, resulting in a scan area of 195.5cm x 65.5cm. Higher attenuation indicates higher mass in each cell (Fig. 1).

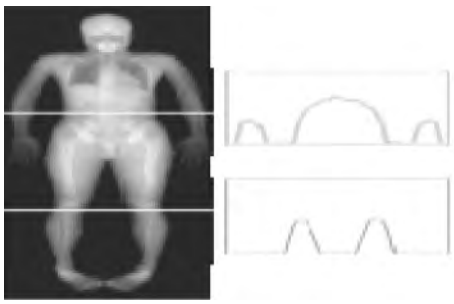

Figure 1: Whole body DXA scan of an adult male subject. Two scanlines crossing belly and knees show attenuation values changing according to the mass present. The raw attenuation image has a resolution of 150 x 106.

B. Mass distribution image from DXA

Prior to building mass distribution image, we increased the resolution of DXA attenuation image by applying a bicubic spline interpolation [17]. The process is necessary for an accurate BSP computation. We applied two cubic spline interpolations, one along horizontal direction and one along vertical direction to increase each dimension by 3 times and 5 times respectively. The added pixels' attenuations were interpolated from original pixels' values. The resulting image has a dimension of 750 x 318, or 0.2606cm x 0.2059cm per pixel.

Each pixel represents the attenuations of the high-energy beam linearly attenuated by the amount of mass present along the beam [7]. The relationship between attenuation and mass can be represented as follows:

$$m(x) = \sigma(a(x)) = m_1 a(x) + m_0 \quad (1)$$

where $m(x)$ and $a(x)$ are the mass (g) and attenuation values respectively at pixel position $x \in R^2$.

We obtained m_1 and m_0 by scanning reams of consumer-grade photocopier paper arranged in five stacks of increasing height (Fig. 2, Left). The projected region of each stack was determined using a flood-fill algorithm [9] initiated by a mouse click at the approximate center of each region. The mass of each stack was then measured with a weighing scale of precision level up to 0.001kg.

The per-pixel projected mass was calculated by taking the mass of each stack divided by the number of pixels in corresponding region. Similarly, the average per-pixel attenuation in each region was calculated by dividing the sum of the attenuation values by the number of corresponding pixels. In addition, we averaged the background attenuation, which has zero mass, to obtain a total of six mass-versus-attenuation calibration points. The calibration line was used to compute the parameters for Eq. 1.

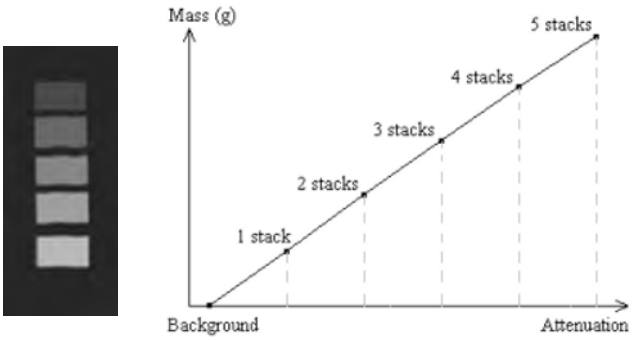

Figure 2: Phantom setup for calibrating the relationship between mass and attenuation. (Left) Scanned image of five stacks of photocopy paper with increasing mass. (Right) Attenuation-to-mass calibration line, which goes through background point and five points representing five stacks.

C. BSP computation using mass distribution image

Whole body image is segmented into 14 parts (Fig. 3). The segmenting lines between limbs cross the bones at joints. We computed BSP for each segment using mass per pixel values obtained directly from mass distribution image.

Mass of each segment k, M_k, was computed by taking the sum of masses at all pixels belonging to that segment:

$$M_k = \sum_{x \in k} m(x) \quad (2)$$

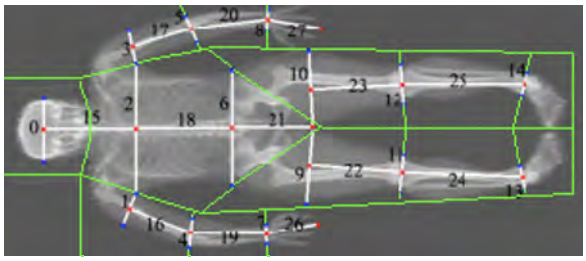

Figure 3: Body composition image produced by Hologic QDR Software together with our defined body segmentation and feature lines. Green lines segment the whole body into 14 parts. White lines are the features required for predicting a new mass image. Mediolateral lines are numbered from 0 to 14, while longitudinal lines are numbered from 15 to 27.

where the attenuation-to-mass conversion (Eq. 1) was used to evaluate each pixel's mass.

Center of mass of segment k, c_k, is computed as follows:

$$c_k = \frac{1}{M_k}\sum_{x\in k} m(x)x \tag{3}$$

Moments of inertia of segment k about the front-to-back axis passing through c_k is calculated as follows:

$$I_k = \sum_{x\in k} m(x)\,|\,x - c_k\,|^2 \tag{4}$$

D. Mass distribution image prediction

Mass distribution image of the new subject is predicted by warping the image of another subject based on the differences between two subjects' features (Fig. 4). The technique is called feature-based image warping [3], where source image is transformed into destination image so that features in source image become corresponding features in destination image.

We used 28 features for the warping of mass image (Fig. 3). The 15 mediolateral lines determine segmental width. The 13 longitudinal lines connect the midpoints of mediolateral lines and indicate segmental length.

For each mass image prediction, we built a pair of feature lines, one for source image and one for predicted image. Source features were built directly from body composition image and its segmentation (Fig. 3), while destination features were predicted from source features and the relationships between external measurements of source and destination subjects, such as segmental length and girth. It can be done with common assumptions that the cross-sectional area of each body segment was elliptical [12] and the ratio between segmental width and thickness is almost constant

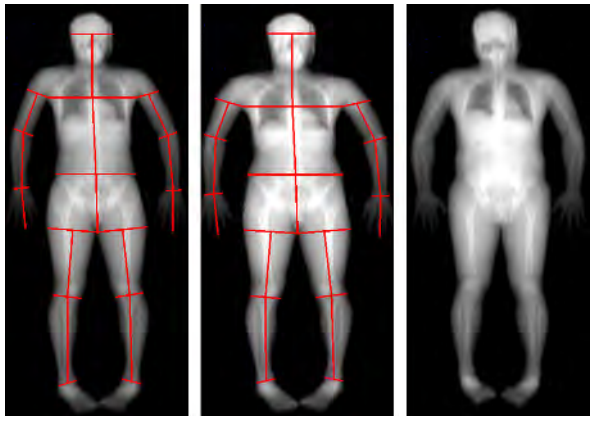

Figure 4: (Left) Mass image and features of a chosen source subject. (Middle) Predicted mass image with new features built from source features and relationships between two subjects' measurements. (Right) New subject's actual mass image.

for each segment [19]. Hence, the ratio between segmental widths of source and predicted images is almost identical to the ratio between measured segmental girths of source and destination subjects. After mediolateral features were determined, longitudinal features for predicted image were created by connecting the midpoints of mediolateral lines.

In order to obtain a good approximation to destination subject's actual mass distribution, it is important to choose a source subject that resembles destination body type closely. Root-mean-square difference between features length in source and destination subjects was minimized to give a good match in front view. Since mass image does not store depth information, we also compared total body mass divided by sum of squares of features length to avoid significant difference in body thickness of source and destination subjects. The predicted mass image is subsequently normalized so that predicted whole body mass is equal to the actual mass.

III. Results

We built a set of mass distribution images from 18 adult male participants with age from 18 to 52, height from 170cm to 182cm and weight from 53kg to 76kg. Feature lines and body segmentation were defined for each image, together with external body measurements and mass.

To evaluate the errors of our method, we estimated BSP for each subject using image-based regression and examined them with values computed directly from DXA, which has been found to be an accurate criterion for 2-D BSP information [7]. The errors were then compared with that in non-linear cadaver-based regression method [19] (Table 1).

Table 1: Percentage errors for the moments of inertia computed by cadaver-based regression approach [19] and by our image-based regression method.

	Cadaver-based Regression (%)	Image-based Regression (%)
Head	15	6.9
Torso	15	7.3
Mean	15	7.1
Upper Arm	10	8.1
Lower Arm	11	6.6
Hand	15	9.5
Upper Leg	8	6.2
Lower Leg	5	6.1
Foot	7	8.8
Mean	9.3	7.5

In image-based method, the mean errors are 7.5% for limbs and 7.1% for head and torso, while the corresponding errors are 9.3% and 15% in cadaver-based method. The differences are significant, especially for head and torso, which contain a large fraction of body mass.

IV. Conclusions

In this paper, we propose a non-linear image-based regression approach for estimating accurate BSP. Our approach works for all ranges of body types and dimensions since it is not based on cadaveric data. It does not require as many body measurements as in traditional regression methods, and involves much lower radiation level and cost compared to other imaging techniques. Moreover, the accuracy of our method can be easily improved by building a larger database of source images, which is feasible since the subjects are living humans.

One limitation of our approach is the lack of features for small areas such as shoulders and feet, which may lead to errors in those regions. Our approach is currently two-dimensional, due to the lack of depth information in DXA image. It can be extended to three-dimensional by incorporating modeling techniques. An extension to DXA for 3-D reconstruction has also been recently studied [13].

Abstract — **This paper proposes a marker-less motion measurement and analysis system for quantitative evaluation of movements of infants. In this system, movements of infants are measured using a single video camera, and then changes of body position and motion in infants are calculated from binarized images, which are extracted using background subtraction or inter-frame difference. Furthermore, eight indices are derived for quantitative evaluation of movements of infants, such as body activity level and amount of body motion. Base on these data, doctors can therefore get an intuitive understanding of the movements of infants without long-period observation. This is considered helpful for supporting diagnosis and detecting of infants' disability or function diseases in the early stages. In this paper, the evaluation indices and features of movement between 14 full-term infants (FTIs) and 11 low-birthweight infants (LBWIs) are compared using the prototype developed. The experimental results show that, with some LBWIs, the upper body moves more than the lower body compared with FTIs, demonstrating that the proposed system can quantitatively evaluate the difference between the movements of FTIs and LBWIs.**

I. Introduction

Early detection of neuromotor disorders and prediction of later movement problems in infants is of paramount importance to improve and mitigate the severity of such conditions. Techniques for detection of infant neuromotor disorders based on infant movements have been widely adapted and discussed in clinical environments [1][2]. However, objective and quantitative evaluation of infant movements is difficult even for highly trained doctors. Techniques that enable simple screening test and quantitative evaluation of the movements of newborn babies would therefore be useful in the early detection of infant neuromotor disorders, and would also reduce the burden on doctors.

Recently, quantitative evaluation methods for the movement of newborns have been developed using three-dimensional movement analyses [3][4]. These previous studies suggest the possibility of distinguishing between full-term and pre-term infants [4]. However, these camera systems are concerned with the burden on newborn babies, since a large number of markers are necessary to measure the movements. Furthermore, it might be difficult to measure the movements for screening in general clinical environments, because such systems are expensive and time-consuming. To overcome these problems, it is preferable to develop a method that can measure and evaluate movements quantitatively, without using markers.

This paper proposes a system to measure and quantitatively evaluate infant movements. In this system, feature quantities related to body movements of infants are extracted from video images recorded by a single video camera without using markers. The body movements are then evaluated using eight indices (such as body activity, amount of body motion and symmetry of limb movements), computed from the feature quantities. Display of the evaluation results and feature quantities enables users to easily understand the changes in an infant's condition.

II. System for measurement and analysis system

The structure of the proposed system is shown in Fig. 1. The details of each process are explained in the following subsections.

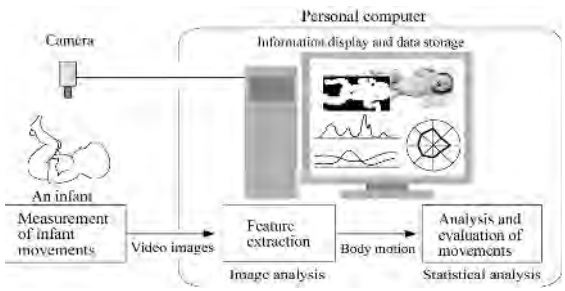

Fig. 1 Concept of the proposed motion measurement and analysis system for the infants

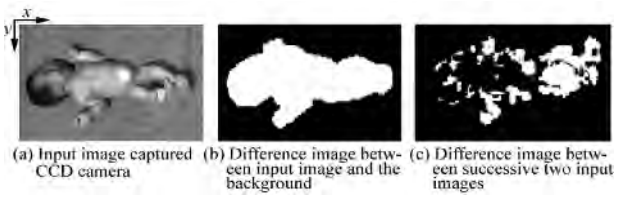

Fig. 2 Binary images obtained from input images

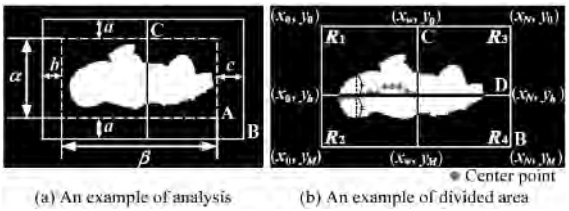

Fig. 3 Initialization of motion analysis image

A. Measurement of infant movements

A camera is used to measure the movements of an infant in an incubator. The video images were stored on a computer database using a video image grabber board (sampling frequency: f_S [Hz]).

B. Feature extraction

Examples of video images and binary images for extraction of the movement features are shown in Fig. 2. In this paper, brightness components are extracted from video images, and are then binarized using background subtraction (to create a *body position distribution image*) with a threshold T (the pixel values of the area are set as 1 (white), and those of the background area are set as 0 (black); see Fig. 2(b)). In addition, a binary image representing the infant's movement area (called as a *movement distribution image*) is extracted using inter-frame difference (the pixel values of the movement areas become 1; see Fig. 2(c)).

Here, in order to improve the computational efficiency, the region-of-interest (ROI) area related to infant's body movement is extracted for analysis. First, a rectangle around the white pixels of the body position distribution image integrated for a number of consecutive seconds is defined as area A ($\alpha \times \beta$ [pixels]) (see Fig. 3(a)). Then, margins (a, b, and c) are set on the four sides of area A, respectively, and the extended area is defined as B (see Fig. 3(b)). The origin point (x_0, y_0) of area B is top-left. Suppose the number of pixels on the x- and y-axes are N and M, the numbers of pixels on the x- and y-coordinates of the image are set as x_n (n = 1, 2, …, N) and y_m (m = 1, 2, … , M), respectively.

By setting baselines in the area B, it can be divided into four areas, one represents each of the infant's limbs. First, area A is divided at the ratio of d to (1-d) based on the ratio of upper to lower body, and the row $x = x_w$ is then defined as baseline C. Further, the area of the upper body ($x_0 < x_n < x_w$, $y_0 < y_m < y_M$), which is extracted from area A by baseline C, is divided into the left and right sides of the body, and that line is then defined as baseline D. In this paper, for the decision of baseline D, the middle points of the longest row of white pixels are calculated in each row of the y-axis. The line of the x-axial $y = y_h$ ($0 < h < M$) included in the large numbers of the middle points is decided as baseline D. Here, the areas corresponding to each region divided using baselines C and D are defined as R_k (k = 1, 2, …, 9), where R_1 to R_4 represent the area of the infant's left shoulder, right shoulder, left leg and right leg, respectively. In addition, R_5 is the area of the upper body, R_6 is the lower body, R_7 signifies the left side of the body, R_8 describes the right side of the body, and R_9 is the entire body.

As the feature quantities of infant movements in each area R_k (k = 1, 2, …, 9), the *change of position* ${}^{(k)}W_l$ and *motion* ${}^{(k)}O_l$ with respect to time are defined as follows:

$$ {}^{(k)}W_l = \sum_{n=0}^{N-1}\sum_{m=0}^{M-1} {}^{(k)}g_l(x_n, y_m) \tag{1} $$

$$ {}^{(k)}O_l = \sum_{n=0}^{N-1}\sum_{m=0}^{M-1} {}^{(k)}g_l'(x_n, y_m) \tag{2} $$

$$ {}^{(k)}g_l'(x_n, y_m) = \left| {}^{(k)}g_l(x_n, y_m) - {}^{(k)}g_{l-1}(x_n, y_m) \right| \tag{3} $$

Here, ${}^{(k)}g_l(x_n,y_m)$ is the value of each pixel in the body position distribution image in area R_k (${}^{(k)}g_l(x_n,y_m) = 1$ represented by the white pixels, and ${}^{(k)}g_l(x_n,y_m) = 0$ by the black pixels; ${}^{(k)}g_0(x_n,y_m) = {}^{(k)}g_1(x_n,y_m)$), l (l = 1, 2, …, L) is the frame number, and L describes the total number of frames in the video image.

C. Analysis and evaluation of movements

In the analysis and evaluation stage, quantitative evaluation indices are calculated based on medical knowledge [5] from the feature quantities of body movements. In this paper, the computational and standardization methods of eight indices to enable comparison of the differences in movements are described as follows.

(1) Body activity and amount of body motion

Body activity and amount of body motion referred as the rate of activity time and the amount of motion within the measurement time are calculated from the change in motion ${}^{(k)}O_l$. First, the threshold ${}^{(k)}M_{th}$ defined by Eq. 4 is used to judge whether movement has occurred in the infant.

$$ {}^{(k)}M_{th} = r\,{}^{(k)}W_l \quad (0 < r < 1) \tag{4} $$

Points at which the change in motion ${}^{(k)}O_l$ increases to threshold ${}^{(k)}M_{th}$ are defined as the infant's activity time, and body activity ${}^{(k)}ACT$ is then calculated from the ratio of activity time to all measurement time as follows:

$$ {}^{(k)}ACT = \frac{1}{L}\sum_{l=1}^{L} {}^{(k)}A_l \times 100 \tag{5} $$

$$ {}^{(k)}A_l = \begin{cases} 1 & ({}^{(k)}O_l \geqq {}^{(k)}M_{th}) \\ 0 & ({}^{(k)}O_l < {}^{(k)}M_{th}) \end{cases} \tag{6} $$

Next, the amount of body motion ${}^{(k)}MOV$ during the movement per unit time is calculated using Eqs. 7 and 8.

$$ {}^{(k)}MOV = \frac{1}{L}\sum_{l=1}^{L} \frac{{}^{(k)}M_l}{{}^{(k)}S} \tag{7} $$

$$ {}^{(k)}M_l = \begin{cases} O_l & ({}^{(k)}O_l \geqq {}^{(k)}M_{th}) \\ 0 & ({}^{(k)}O_l < {}^{(k)}M_{th}) \end{cases} \tag{8} $$

Here, ${}^{(k)}S$ is the number of pixels in each area.

(2) Displacement and fluctuations in COG

Center of gravity (COG) displacement of body position and fluctuations in COG *x*- and *y*-axially are extracted from the change of position ${}^{(k)}W_l$ and the body position distribution image. From this image, the coordinates of COG ($G_{x,l}$, $G_{y,l}$) are calculated by Eqs. 9 and 10.

$$ G_{x,l} = \frac{1}{{}^{(k)}W_l}\sum_{n=0}^{N-1}\sum_{m=0}^{M-1} x_n \, {}^{(9)}g_l(x_n, y_m) \tag{9} $$

$$ G_{y,l} = \frac{1}{{}^{(k)}W_l}\sum_{n=0}^{N-1}\sum_{m=0}^{M-1} y_n \, {}^{(9)}g_l(x_n, y_m) \tag{10} $$

Displacement in the COG D_m is defined as follows:

$$ D_m = \frac{1}{L}\sum_{n=0}^{N-1}\left(\frac{\sqrt{D_{x,l}^2 + D_{y,l}^2}}{{}^{(k)}W_l} \right) \tag{11} $$

where $D_{x,l} = G_{x,l} - G_{x,l-1}$, $D_{y,l} = G_{y,l} - G_{y,l-1}$, $G_{x,0} = G_{x,1}$, $G_{y,0} = G_{y,0}$. In addition, fluctuations in COG *x* and *y* signify the center frequencies of the power spectrum density calculated using the fast Fourier transform (FFT) from the *x*- and *y*-coordinates of the COG.

(3) Symmetry of movement, ratio of amount of body motion and ratio of body activity

Symmetry of movement describes the correlation between each area divided in the images calculated using the standardized cross-correlation function from the change in motion ${}^{(k)}O_l$ smoothed through a second-order Butterworth low-pass filter (cutoff frequency: f_p [Hz]). In addition, the ratios of amount of body motion and of body activity are defined as the ratio between feature quantities of each area.

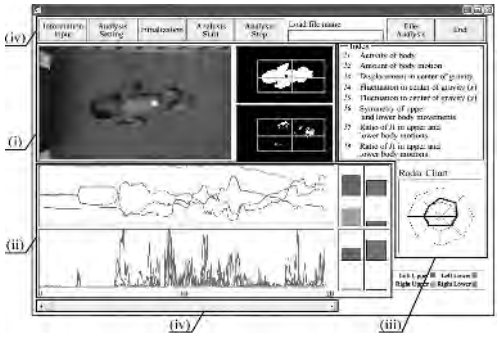

Fig. 4 An example of the operation scene of the prototype system

(4) Standardization of indices

The calculated evaluation indices for the infant are normalized to enable comparison of the differences in movement. In this paper, the standard normally distributed variables I_j are converted to the mean and standard deviations of the measurement data for full-term infants using Eq. 12.

$$ I_j = (z_j - \mu_j)/\sigma_j \tag{12} $$

Here, *j* corresponds to the index number, z_j is the computed value in each index, and μ and σ describe the average and standard deviation of each index in the full-term infant group, respectively. In the proposed method, I_1 represents the activity of the entire body ${}^{(9)}ACT$, I_2, I_3, …, I_8 signify the amount of entire body motion ${}^{(9)}MOV$, the entire displacement in COG D_m, and fluctuations in COG *x*- and *y*-axially, the symmetry of movement, the ratio of body mot-ion activity ${}^{(5)}ACT$ / ${}^{(6)}ACT$, and the ratio of amount of body motion ${}^{(5)}MOV$ / ${}^{(6)}MOV$, respectively.

D. Graphical output

The measured infant movements, the feature quantities, and the indices are provided to doctors on a display. A screenshot of interface of the proposed system is shown in Fig. 4. During operation, the monitor displays the following information: (i) a video image of the infant recorded using a camera, and the extracted binary images (distribution of body position and movement); (ii) feature quantities of position and movement calculated from the distribution of body position and movement; (iii) indices and radar charts computed from the feature quantities of position and movement; (iv) operation buttons and a scrollbar to allow video playback for a specific period, and changes in the scale of the waveform. The doctor can visually check infant's movements by playing the section of video corresponding to the time when abnormality appears in the feature quantities or radar chart.

III. Experiments

Method: Subjects consisted of 14 full-term infants (FTIs) (A-N) and 11 low-birthweight infants (LBWIs) (2,500 [g] or less) (O-Y). The 10 FTIs (A-J) were measured for 5 minutes, and the other infants were tested for about 50 minutes. In addition, the evaluation indices were extracted for 5-minute intervals, and the mean value and standard deviation for all measurement times were then calculated. The calculated indices were standardized on the basis of the values obtained from the 14 FTIs. The parameters of the experiments were f_S=30 [Hz], f_p=5 [Hz], d=0.55, r=0.01 and T=15 or T=45. The window length of FFT was 128 sets of sampled data, and the number of overlapping was 127; the corresponding values for the standardized cross-correlation function were 300 and 299, respectively.

Results: Radar chart representation of results of the indices is shown in Fig. 5 (a) and (b), which illustrate the indices of FTIs and LBWIs, respectively. Each axis shows the standard deviation of the 14 FTIs (A-N), the solid lines describe the average number of FTIs, and the dotted lines show the minus triple, triple and sextuplicate of the standard deviation in Fig. 5. Further, the heavy line shows the average value, and the shaded area indicates the standard deviation in each index. As an example of the feature quantities

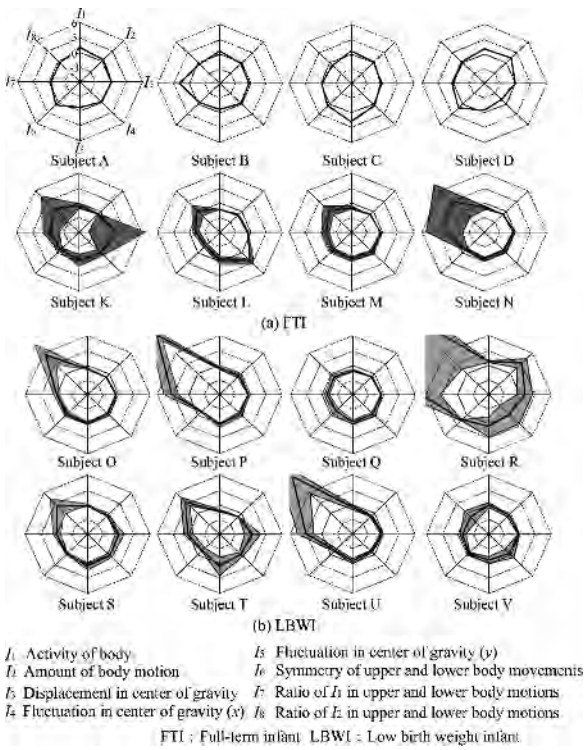

Fig. 5 Evaluation indices in each FTI and LBWI

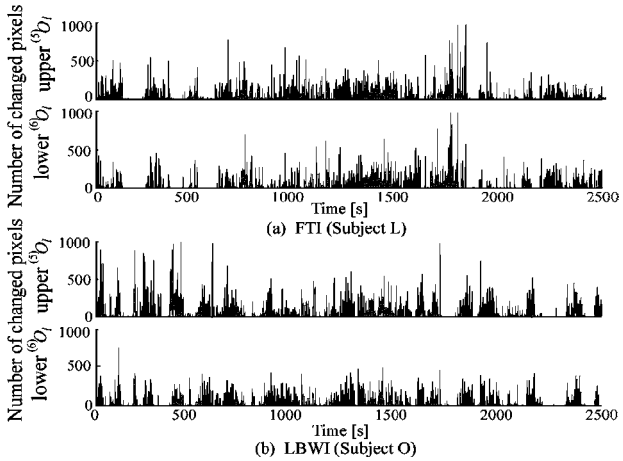

Fig. 6 The change of the FTI Subject L and LBWI Subject O

used for index computation, the change in motion of the upper and lower body of an FTI and a LBWI are shown in Fig. 6. The horizontal axis represents time, and the vertical axis describes the change in motion $^{(k)}O_l$.

IV. Discussion

The evaluation experiments demonstrated that all indices were close to the average value for all FTIs, except subjects K and N, but the indices are of large variation with most LBWIs (especially subjects O, P, R, T and U). Since the values of index I_8 for these subjects were large, it is thought that the lower body movements were small compared with movement of the upper body. Further, from the example of the movements of subject O (Fig. 10), it can be observed that those of the upper body were larger than those of the lower body. These results lead us to the conclusion that the extracted evaluation indices were able to reflect the movements of infants.

On the other hand, it is observed that some LBWIs have the same tendency as the mean values of the FTIs (subjects Q, S, and V). These results mean that the LBWIs do not have diseases despite their low birthweight and high risk of impaired motility function. Further, although subjects K and N were FTIs, their evaluation index variance was large, suggesting that their movements might be near those of LBWIs because their birthweights were comparatively low (subjects K and N were 2,738 [g] and 2,562 [g], respectively). Since the number of experimental subjects was small and the measurement time was short, it is necessary to investigate and make improvements for accurate evaluation.

V. Conclusion

This paper proposes a quantitative system to measure and evaluate infant movements. The system calculates eight evaluation indices from feature quantities of motion extracted from binarized images of infants without markers using a single video camera. This enables doctors to understand changes in an infant's movement condition, as video images, feature quantities and evaluation indices can be monitored on a real-time basis. In future research, we plan to increase the number of infants and measurement time, and investigate the relationships between motility function and abnormal movements in disabled and high-risk infants.

Cardiorespiratory Response Model for Pain and Stress Detection during Endoscopic Sinus Surgery under Local Anesthesia

K. Sakai and T. Matsui

[1] Digital Human Research Center, National Institute of Advanced Industrial Science and Technology (AIST)

Abstract — **The effect of surgical procedure on breathing movement and the effect of characteristics of breathing movement on changes in heart rate and blood pressure during actual endoscopic nasal surgery were analyzed using analysis of variance and Bayesian network modeling. As the result, the probabilistic causal relationship between respiratory irregularities, increasing blood pressure and patients' complaint of pain was found. This result is expected to be used as patient pain and stress detection method without discomfort during actual surgery under local anesthesia.**

Keywords — **Patient response model, Pain, Stress, Endoscopic sinus surgery, Bayesian network**

I. Introduction

During surgery conducted under local anesthesia, the patient is overtly conscious of pressure, vibration and sound from the surgical procedure. These stressful feelings change the hemodynamics, resulting in an elevation of blood pressure [1, 2]. Moreover, the pain, which is not completely blocked by anesthesia, causes interruption of the surgery. Therefore to understand causal influences among surgical procedures and patients' responses is important for surgical education, and its computational model can apply to pain and stress detection.

In the experimental physiological field, the presence of pain and stress is assessed using autonomic indices such as mental sweating, hart rate and blood pressure. In the actual surgery, the existence of pain and stress is generally estimated by the blood pressure changes [3], but it is quite difficult to measure patient's beat-to-beat blood pressure without discomfort, and autonomic indices can be change not only by the effect of autonomic activity but also the effect of body movement and/or breathing activity.

With this in view, the purpose of this study is to investigate whether the respiratory response could be efficient indices for detecting patient's pain and stress. During surgery, with an increase in surgical pressure, shapes such as "pause phases" were observed on the respiratory waveform. On feeling pain, patients seem to breathe unsteadily. These characteristic breathing patterns seem to indicate the perception of surgical pressures and are likely to be efficient indices for determining blood pressure fluctuations resulting from the patient's stress.

Based on these suppositions, in this study, we defined twelve respiratory indices indicating breathing depth, breath holding and irregularities in breathing to investigate the influence of characteristics on respiratory waveform on changes in heart rate and blood pressure and also assess the effect of surgical stimulus such as pressing, tearing mucosa and breaking bony wall on the patient's responses.

II. Endoscopic sinus surgery

The subjects were patients who had sinusitis and underwent endoscopic sinus surgery using local anesthesia. Sinusitis is a result of the retention of mucus in the paranasal sinuses. This occurs as a result of the route, which reaches the paranasal sinuses from the nasal cavity, being blocked by polypus and/or inborn structural errors of the bone wall. The aim of the surgery is, therefore, to remove the polypus and bone walls and make clearer routes.

III. Method

A. Subjects

Patients in this study were five Japanese adults who provided written informed consent for observation and measurement of their physiological parameters during a surgical procedure and publication of this data.

B. Measurement

All measurements were taken during actual surgery.

Respiratory waveform was monitored using a Piezo respiratory belt transducer (AD Instruments) at abdominal circumference. Heart rate (HR) and continuous systolic blood pressure (BP) were measured using a BP-608EV Patient Monitor (Colin Medical Technology). At the same time, an endoscopic view of surgery and the scene in the operating room were recorded using video cameras. Complaints of pain, vibration or pressure were also recorded.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2048–2051, 2009
www.springerlink.com

Table 1 Surgical procedures and types

Surgical Procedure	Type	n
Insert tool only	Insert only	69
Insert anesthetic pack Pull mucosa/bony wall Press mucosa/bony wall Break mucosa/bony wall	Touch	240
Area movement (forward)	AM>	13
Tear mucosa Squeeze tool into narrow area Thrust tool into mucosa/bony wall	Press Hard	53
Pull mucosa/bony wall with vibration	Pull Hard	24
Break bony wall with vibration	Break Hard	31
Move tool at high speed	Tool vibration	29
Area movement (backward) Stop tool movement Short period for tool change	Pause	28
Pain complaint	Pain	26

C. Segmentation of Surgical Scene

The surgery can complete in around two hours. The surgery has two sections, the operation and the rest section, and repeating the two of them carries the surgery forward. In the rest section, the patient does nothing but waits until the local anesthesia takes effect. On the other hand, in the operation section, the surgeon works on the patient.

In this study, using the recorded endoscopic view and footage of the operating room, each operation sequence was segmented into nine types of section by changes in the procedures of the surgeon (Tab. 1).

D. Indices

The recorded waveform was divided into three phases: "inspiration"; "expiration"; and "pause" [4]. In this study, the start and end point of the "pause" phase were called "PS" and "PE", respectively, and the end point of the "inspiration" phase was the "Peak" point. In addition, the sequence of "Peak" points and the sequence of "PS" and "PE" points were called "Peak Line" and "Bottom Line", respectively.

In this study, three types of characteristic shape on respiratory waveform were focused, (a) "Breath depth change", (b) "Panting" and (c) "Breath holding" (Fig. 1). To evaluate these characteristics, the following nine indices were employed.

To evaluate trends in "Breath depth changes", the following four indices were calculated:

- Changes in Peak points (*vPeak*) and Bottom points (*dBottom*): the amounts of changes from start-level (i.e., first sample in the period) were calculated.
- Mean Respiratory Waveform Amplitude (*mAmp*) and its differences between one section and the previous section (*dmAmp*): *mAmp* index was the mean amplitude of the respiratory waveform in one segmented section.

"Panting" was evaluated as respiratory irregularity, and was then assessed using the following two indices:

- Peak Line Variability (*vPeak*), Bottom Line Variability (*vBottom*) and the mean of these indices (*vPB*): Standard deviation of changes in the height of points on "Peak Line" and "Bottom Line" in each segmented section.

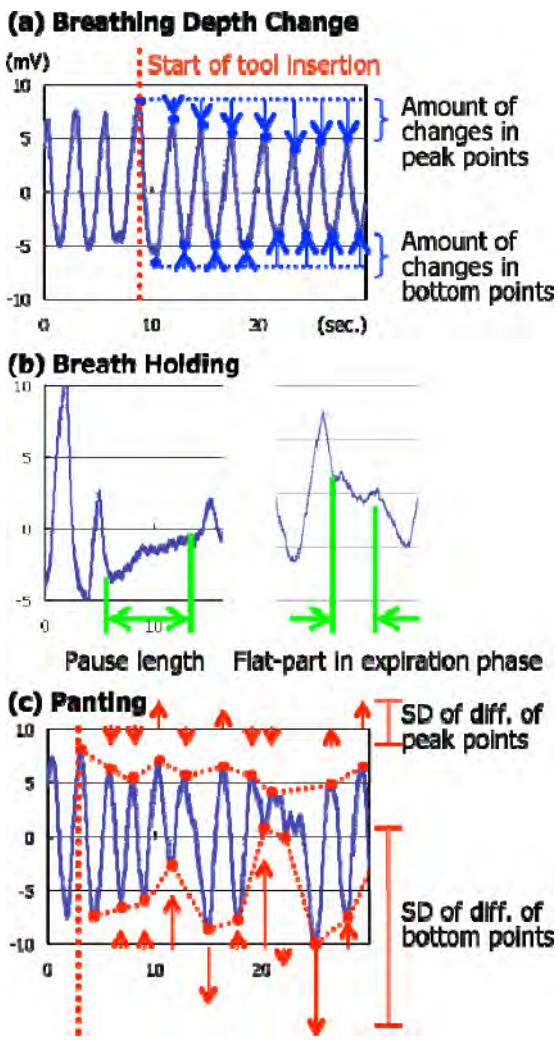

Fig. 1 Characteristics on respiratory waveform

In addition, the following index were employed for assessing "Breath holding" behavior resulting from tense situations:

- Mean Pause Length (*mPause*) and its differences between one section and the previous section (*dmPause*): *mPause* index was the average length of Pause phases included in one segmented period.

To evaluate trends in HR and BP changes in each segmented period, the amount of changes from start-level were calculated and called *dHR* and *dBP*, respectively.

E. Analysis and Modeling

In this paper, we focused on an effect of characteristics of breathing movement on changes in heart rate and blood pressure and the effect of type of surgical procedure on breathing movement.

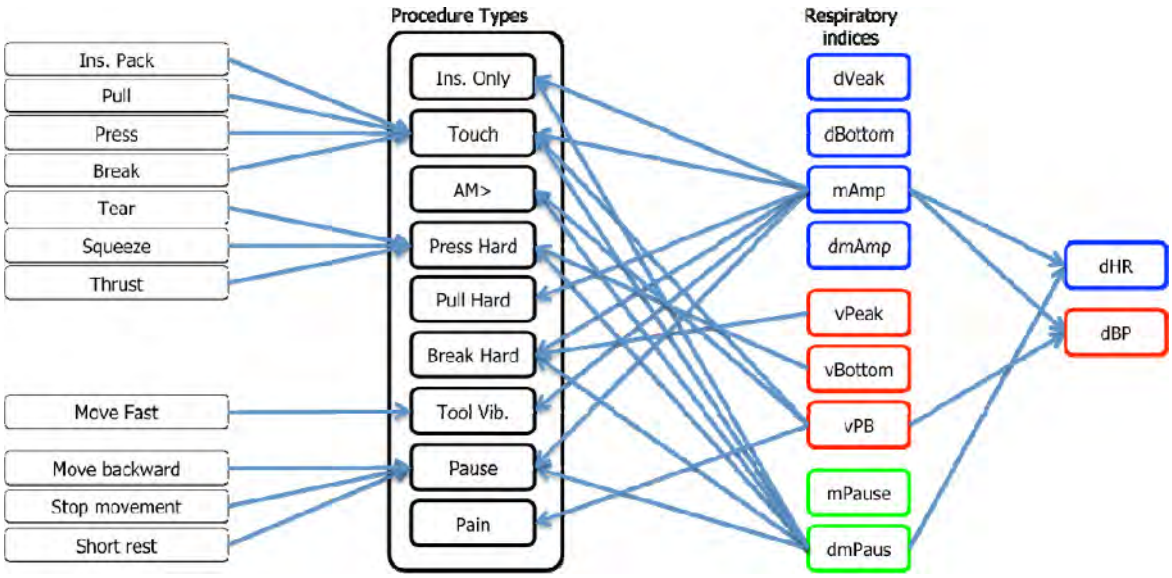
First, the probabilistic causal relationship model between characteristics on respiratory waveform and changes in HR and BP were assessed using Bayesian network model construction method. In this step, all possible tree structures with child node *dBP* and parent node(s) as indices of characteristics on respiratory waveform were created. The score of Akaike's information criterion (AIC) was then calculated for each tree. Finally, the one tree structure with the lowest score was selected as the most likely tree structure for the observed data. Additionally, the quantitative effects of selected parent nodes for each *dHR* and *dBP* were analyzed using analysis of variance (ANOVA). In all tests, a level of significance of 0.05 was accepted as significant. Significant effects were further analyzed using Scheffe or Games-Howell multiple comparisons. In this analysis, all indices of each patient were normalized and discretized into two (small or large) or four (+2: large increase, +1: small increase, -1: small decrease, -2: large decrease) states depending on their percentile rank within the distribution.

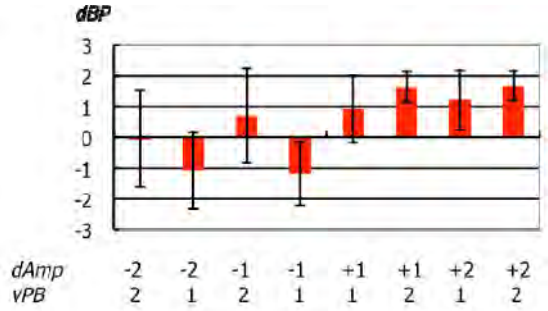
Next, the effect of surgical procedure on indices of characteristics of respiratory waveform was evaluated by constructing Bayesian network model.

IV. Result and Discussion

According to the result of model construction, the *mAmp* and *dmPause* nodes were selected as the parent nodes for *dHR*. On the other hand, the *mAmp* and vPB nodes were selected for *dBP* (Fig. 2 right side). The quantitative effect of these parent indices on *dHR* and *dBP* were calculated (Fig. 3).

Fig. 3 (a) shows the effect of *dAmp* and *vPB* on the changes in blood pressure. Basically the change in blood pressure seems to be influenced by *mAmp* movement. The *vPB* (2) indicates an excessive rise and/or drop in peak and bottom height by patient's panting. Patient's panting behavior seems to be caused by an excessive straining resulting from surgical pressure, and likely to be cause of an increasing blood pressure. On the other hand, the *dAmp* movement seems to strongly influence the change in heart rate (Fig. 3 (a)).





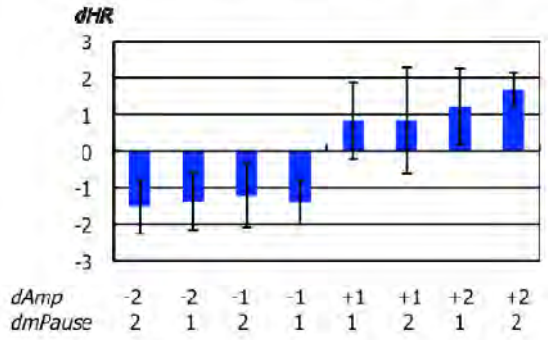


Fig. 2 Characteristics on respiratory waveform

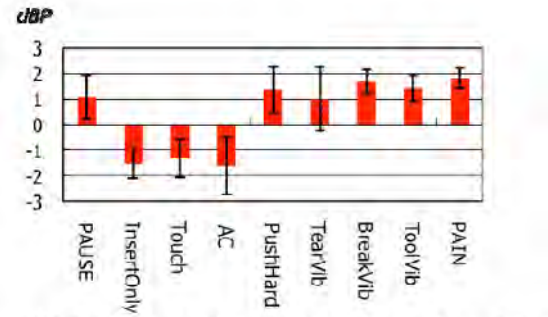
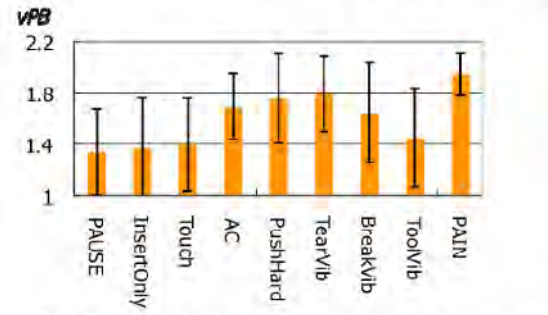


(a) Plot of *dBP* value between pairs of *dAmp* and *vPB*



(b) Plot of *dHR* value between pairs of *dAmp* and *dmPause*

Fig. 3 Effects of selected respiratory indices on changes in *dHR* and *dBP*

(a) Plot of *dBP* value between types of surgical procedure

(b) Plot of *vPB* value between types of surgical procedure

Fig. 4 Effects of surgical procedure on changes in *dBP* and *vPB*

Next, the probabilistic relation between types of surgical procedure and physiological indices were evaluated. The result showed in left side of Fig. 2. The resultant model indicates that most procedures were influenced by *mAmp*, *vPB* and *dmPause* indices. In particular, the *vPB* index showed equally high value as the *dBP* in "PAIN" section (Fig. 4). In "PushHard" and "TearVib." sections, the *vPB* also showed high value. We consider the possibility that the patient feel pain but does not complain, that is a hidden pain, in the section.

V. Conclusions

The effect of surgical procedure on breathing movement and the effect of characteristics of breathing movement on changes in heart rate and blood pressure during actual endoscopic nasal surgery were analyzed using analysis of variance and Bayesian network modeling.

As the result, indices representing the characteristic shapes on the respiratory waveform showed the ability to predict direction of changes in blood pressure, and the probabilistic causal relationship between respiratory irregularities, increasing blood pressure and patients' complaint of pain was found. This result is expected to be used as patient pain and stress detection method without discomfort during actual surgery under local anesthesia.

A Study on Correlation between BMI and Oriental Medical Pulse Diagnosis Using Ultrasonic Wave

Y.J. Lee, J. Lee, H.J. Lee, J.Y. Kim

Korea Institute of Oriental Medicine/Dept. of medical research, South Korea

Abstract — **Pulse diagnosis refers to the process of diagnosing a patient by feeling an artery on the wrist based on the shape that the pulse takes while the hold-down pressure increase. Currently, the hucklebone artery on the wrist is usually felt, and the pulse is taken on Chon, Gwan and Cheok using three fingers. This study is to examine the structural difference in the location of pulse diagnosis by measuring and analyzing blood diameter, blood depth, and blood flow velocity of the location of pulse diagnosis by using ultrasonic wave (VOLUSION730 PRO, GE Medical, U.S.A).This study also attempted to grasp whether the characteristics of blood vessels differ depending on Body Mass Index (BMI) and analyzed their correlation with Oriental medical pulse diagnosis. The male subjects without cardiovascular diseases were divided into the normal BMI group, the underweight group, the overweight group and 10 people of each group were measured. Blood depth, blood diameter and blood flow velocity at the location of pulse diagnosis (Chon, Gwan, Cheok) of the wrists of left and right hands were measured and the pulse wave was measured by using pulse diagnosis instrument (3-D Mac, DaeyoMedi, Korea).The results of this study showed that the characteristics of blood vessels differ depending on the degree of obesity, and the characteristics of floating pulse and sinking pulse of Oriental medical pulses were related to the degree of obesity. This shows that the characteristics of the blood vessels of subjects and BMI information are the major indicators for diagnosis and are the matters that must always be considered when developing the algorism of pulse diagnosis.**

Keywords — **Pulse diagnosis, Oriental Medicine, Ultrasound wave, Radial artery**

I. Introduction

The significance of the Pulse Diagnosis is to analyze the health condition of the human body, to analyze the various pulses ranging from the normal-pulse of healthy people to the abnormal-pulse of the patients, and to investigate the source and characteristics of the disease. And it is helpful in prognosis of the disease[1]. Pulse diagnosis is a method of identifying the conditions of a disease by feeling the pulse of the radial artery on the wrist of the patient with the oriental medial doctor's fingers[2]. The risen part around the radial styloid process on the wrist is called a Gogol, the position where the pulses are measured from the styloid process is called 'Gwan', and the positions next to Gwan that the doctors can feel the pulses with the middle finger and the third finger are called 'Chon' and 'Cheok' respectively[3]. Since Chon, Gwan, and Cheok are located around the styloid process, there is a big variation in the blood flow velocity because of the geometric characteristics of the vessel as shown in the figure 1. It was observed that the blood flow velocity at the Chon position was rapidly reduced compared to the velocity at the Gwan and Cheok positions[3]. That is, the oriental medical doctors feel the variation of the blood flow velocity when they do the pulse diagnosis at Chon, Gwan, and Cheok positions, and that becomes an index to be used for diagnostics.

This paper analyzed the dependency of the characteristics of vessel at the pulse measurement positions to the characteristics of the body type of the normal people. If the characteristics of the vessel change depending on the body mass index (BMI) then the diagnosis method should be adjusted according to BMI. The subjects were divided into three groups comprising Normal, Underweight, and Overweight. And vessel diameter, vessel depth, and blood flow velocity were measured at the pulse diagnosis measurement position with ultrasonic wave and the characteristics were analyzed. And also pulse waveforms were measured to determine whether the characteristics of the pulse change depending on the body type.

II. Method

A. Subjects

Thirty male subjects of ages in 20s (age of 24.07±2.01) who don't have cardiovascular diseases and who don't take relevant medication were taken to the experiment. Three groups of subjects were recruited, underweight(below 20kg/m^2) group of 10 people, normal weight(below 20~25kg/m^2) of 10 people, and overweight(below 25~30kg/m^2) group of 10 people. Subjects were asked to stop smoking and drinking alcohol from one day before the test, they took the rest for 30 minutes before the test, and ultrasonic wave and pulse wave were measured in a sitting posture.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2052–2055, 2009
www.springerlink.com

B. Experiment method

Ultrasonic wave and pulse wave were measured at the pulse diagnosis positions (Chon, Gwan, and Cheok) on the arteries of the left and right wrist as shown in the figure 1. In order to measure the accurate pulse diagnosis positions, Chon, Gwan, and Cheok positions were marked on the wrist at the positions taken from the pulse diagnosis of oriental medical doctors and both ultrasonic and pulse wave were measured at those positions. The ultrasonic wave was measured with thin wires wrapped at the marked measurement positions so that the measurement positions could be identified in the ultrasonic image. Vessel depth, vessel diameter, and blood flow velocity were measured, and the average values taken from the three repeated measurements on each item were analyzed. Pulse waves were measured with the pulse diagnosis machine and the coefficient of floating and sinking pulse which is a parameter in diagnosing floating pulse and sinking pulse was calculated.

C. Measurement of Ultrasonic Wave and Pulse Wave

Vessel depth, vessel diameter, and average blood flow velocity were measured with the ultrasonic wave equipment for medical purpose (Volusion 730 PRO, GE Medical, USA), and 12L probe was used. Incident angle of the color Doppler mode ultrasonic wave was 20°, and the angle for the blood flow velocity measurement was 60°. Electrolyte low gel pad (Parker Laboratorics Inc., USA) was used for more stable measurement. Pulse diagnosis machine(3-D Mac, Daeyo Medi, Korea) was used to measure the pulse waves, and the pulse wave were measured at the location of Chon, Gwan, and Cheok of the left and right wrist.

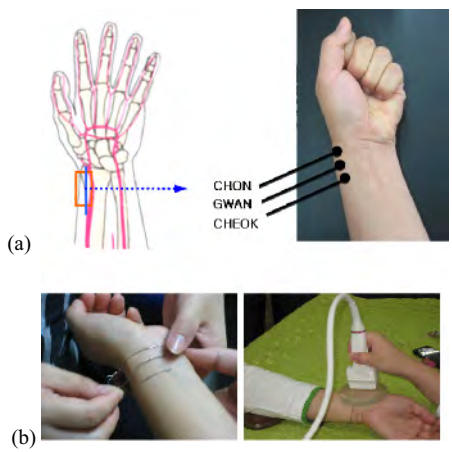

Fig. 1 (a) Pulse measuring positions (Chon, Gwan, and Cheok) and non-pulse measuring positions (P1, P2, and P3) on the radial artery (b) Measurement positions marking method and actual measurement picture.

D. coefficient of floating and sinking pulse

When diagnosing pulse in Oriental medicine, OMD feels change of pressure in blood vessel applying pressure at the pulse position by his finger. According to his pressing and the change of pulse pressure in blood vessel, OMD diagnoses 'floating and sinking pulse'. When contact pressure is small, if maximum pressure is felt, we define this by 'floating pulse'. And when contact pressure is big, if maximum pressure is felt, we define this by 'sinking pulse'. By using the PH-curve that is measured by this pulse analyzer, we can arrange this Oriental medical concept as below figure 2.

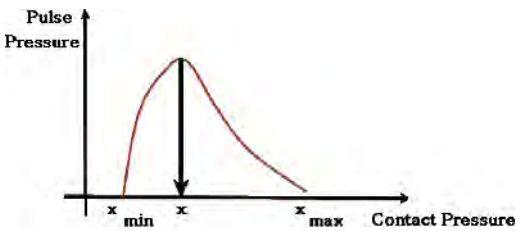

Fig. 2 Coefficient of floating and sinking pulse.

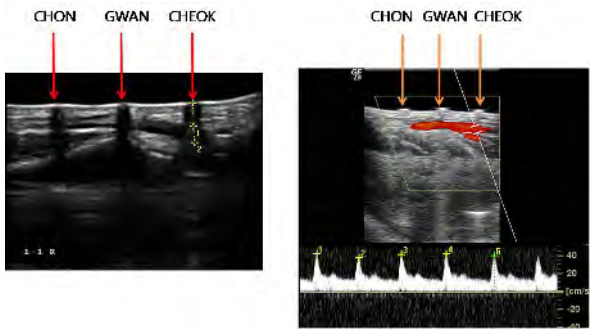
$$\text{coefficient of floating and sinking} = \frac{10\times(X - x_{\min})}{(x_{\max} - x_{\min})} \quad (1)$$

III. Result

A. Measurement result



Vessel depth, vessel diameter, and blood flow velocity were measured at the Chon, Gwan and Cheok positions using the ultrasonic wave for 30 subjects as shown in the figure 3. And also the pulse waves were measured by using the pulse diagnosis machine and the coefficients of floating and sinking pulse were calculated by the equation (1). The results are summarized into the table 1 below. The analysis result of the correlation between the test results and BMI groups (under-weight, normal, and over-weight) are also shown in the table 1 below. To determine the correlation between all variables non-parametric method of Spearman's ranking correlation was used. Statistical significance of all data was 0.05.

The results of the correlation analysis revealed that the vessel depth showed a strong correlation to BMI, but the vessel diameter and blood flow velocity showed a relatively lower correlation to BMI. This means that the vessel diameter is not dependent on the fatness of subjects but the vessel depth which represents the depth of the vessel from the skin varies. And also the correlation between the coefficient of

Table 1 The measurement results at Chon, Gwan, and Cheok position, and correlation analysis results

	Left Chon	Left Gwan	Left Cheok	Right Chon	Right Gwan	Right Cheok

BMI and Vessel Depth **	0.541(0.046)	0.630(0.016)	0.316(0.019)	0.589(0.027)	0.829(0.00)	0.771(0.001)
BMI and Vessel Diameter **	0.244(0.40)	0.594(0.025)	0.534(0.049)	0.106(0.719)	0.434(0.121)	0.385(0.174)
BMI and Average Blood Flow Velocity **	0.319(0.267)	0.068(0.817)	-0.059(0.84)	0.332(0.246)	0.134(0.648)	-0.011(0.97)
BMI and Coefficient of floating and sinking pulse **	0.842(0.00)	0.356(0.211)	0.227(0.434)	0.682(0.007)	0.666(0.009)	-0.138(0.63)

floating and sinking pulse and BMI was relatively high from the analysis. The strong correlation between the coefficient of floating and sinking pulse which quantifies the pulse feeling position depending on the applied pressure to the radial artery and BMI suggests that the body type is a very important factor in diagnosing the floating pulse and sinking pulse. In addition, there were three measurement positions where the correlation between the coefficient of floating and sinking pulse and vessel depth higher was not very high but higher than 0.5, which suggested that the coefficient of floating and sinking pulse is deeply affected by the vessel depth as well as BMI.

(a) (b)

Fig. 3 Measurement result of (a) vessel depth and vessel diameter B-mode and (b) blood flow velocity color Doppler mode at Chon, Gwan, and Check positions.

IV. Conclusion

Pulse diagnosis is a foundation of diagnosis in Oriental Medicine. But the pulse is a phenomenon by many different factors including the characteristics of the vessel and pulsation of heart, and many factors need to be considered in developing pulse diagnosis machines.

Pulses are measured at the positions called Chon, Gwan, and Cheok on the radial artery. The measurement positions of Chon, Gwan, and Cheok have dynamic blood flow characteristics where the blood vessel is risen by radial styloid process which is called Gogol[4]. And also the radial artery at the measurement positions is located average 2.7 mm below the skin which is very close to the skin. Experiments were done in this paper to determine effects of the characteristics of the vessel and BMI of human body among the various factors.

The experiment results showed that the vessel at left and right Gwan raised by the styloid process was located at the nearest position to the skin and Chon was located at the deepest position. An also the same characteristics of the rapid reduction of blood flow velocity at the left and right Chon as the existing research[3] were observed. The analysis of the vessel for each separate BMI group showed that the vessel depth had a strong correlation to BMI. The distance between the skin to the vessel was measured longer for the higher BMI, and this means that the basic factors of diagnosing floating pulse and sinking pulse are affected by BMI. The floating and sinking pulse[5, 6] which are defined as the level of the finger pressing and the pressure in the vessel that is felt can be defined as the coefficient of floating and sinking pulse, and the coefficient of floating and sinking pulse was also shown to be correlated to BMI.

In result, Chon Gwan, and Cheok measurement positions are located very close to the radial artery, but it was revealed that the characteristics at each position were different and also affected by BMI. It was also shown that BMI affected the diagnosis of floating and sinking pulse. Therefore we have learned that the design of diagnosis algorithm based on BMI of the testee is absolutely necessary and the standard for the measurement method that depends on the characteristics of the vessel of testee need to be developed.

Abstract — **Subjects with Diabetes Mellitus (DM) are the major parts in transtibial amputees. The purpose of this study is to investigate the difference on the material properties of soft tissues and biomechanical performance between the DM and non-DM subjects. There are two volunteers with transtibial amputation involved in this study. One is suffered from DM, the other is not. This study were executed within two major phased. Firstly, the stiffness of soft tissue at five regions of stump was received from the self-made force-displacement instrument. Then, the finite element models of the two subjects were established to simulate the biomechanics of transtibial prosthesis. From the results, the stiffness of non-DM subject is averagely 1.6 times higher than the DM subject. In the finite element analysis, the DM subject were presented the higher magnitudes at the maximum sliding distance, the interface stresses, Von Mises stress and Von Mises strain. It means the soft tissue of DM subjects with lower stiffness had higher chance to be broken. When manufacturing the prosthesis for DM subjects, the prosthesists should notice this invisible problem..**

Keywords — **Diabetes Mellitus, transtibial amputees, elastic modulus, finite element analysis**

I. Introduction

Amputated patients need prostheses to achieve the independent of functional activity [1]. There were many reasons to cause amputations, and diabetes mellitus (DM) was the most one. Amputations with DM were more difficult to manufacture fitness prostheses because DM would cause the changes of local sensation and material properties of soft tissue [2]. The purpose of this study was to investigate influence of DM on material properties of soft tissues and biomechanical performance.

II. Materials and methods

There are two volunteers with transtibial amputation involved in this study. One is suffered from DM, the other is not. The detail information of subjects was listed in Table 1. This study were executed within two major phased. Firstly, the stiffness of soft tissue at five regions of stump was received from the self-made force-displacement instrument. Then, the finite element models of the two subjects were established to simulate the biomechanics of transtibial prosthesis.

A. Measuring the stiffness of soft tissue

A self-developed handheld indentor device, which included a digital meter to provide the deformation of the soft tissue and a load cell to detect the applied loading, was used to measure the pain information. During the test, the examiner maintains the indentor perpendicular to the test region and applies the load as slow as possible on the subject (1mm/sec roughly). In total, five regions (patella tendon, medial condyle, fibular head, popliteal fossa and stump end) were tested for five successful measurements. The recorded force-displacement curve during test for each region was transferred to Young's Modulus with the following equation:

$E = P(1-v^2) / 2awk$

P: indention force
v: Poisson's ratio
w: indentation depth
a: radius of the indentor
h: thickness of the test tissue
k: a geometry and material-dependent factor (v,a/h)

B. Establishing the finite element (FE) Mesh Models

All subjects have been informed and agreed for suffering the computer tomography (CT) scan. 3 mm interval transverse CT images were taken with the subjects lying at supine position.

From each image, the contours of different materials i.e., bone, soft tissue and the soft liner, could be segmented by an image processing system. Forty points, evenly spaced, were selected on each material boundary. Linking these 40 points with spline-curve, the section areas of each material were generated and piled up to build the volume models. These volume models were then meshed with brick ele-

www.springerlink.com

ments (8 node hexahedral elements). The surface-to-surface contact elements were employed at the stump-socket interface. This type of contact element has better performance than the traditional point-to-point contact pairs in simulating sliding behavior within the stump-socket interface. The ANSYS 10.0 FE software (ANSYS Inc., Canonsburg, PA, USA) was utilized for all analyses.

To simulate the loading phase of single standing, four spread nodes of the top layer of bone were assigned the same magnitude of downward displacement to minimize the moment and rotation of stump. The displacement was kept downward until the reaction force reached to one body weight. The boundary conditions were assigned at the out layer of liner to simulate nearly no deformation appeared at the hard socket.

Bone, soft tissue and liner were assigned as the major materials in the FE models. The elastic modulus of bone and liner were assigned as 15500 and 0.8 MPa. The elastic modulus of the soft tissue was assigned in regions separately based on the stiffness of soft tissue measured from indentor tests. The other elastic modulus of stump and liners were obtained from the literature [3,4]. The Poisson ratios of bone, soft tissue and liner were assigned to be 0.3, 0.45 and 0.49 respectively, also from the literatures [3,4].

III. Results

A. Stiffness and Young's modulus of soft tissue

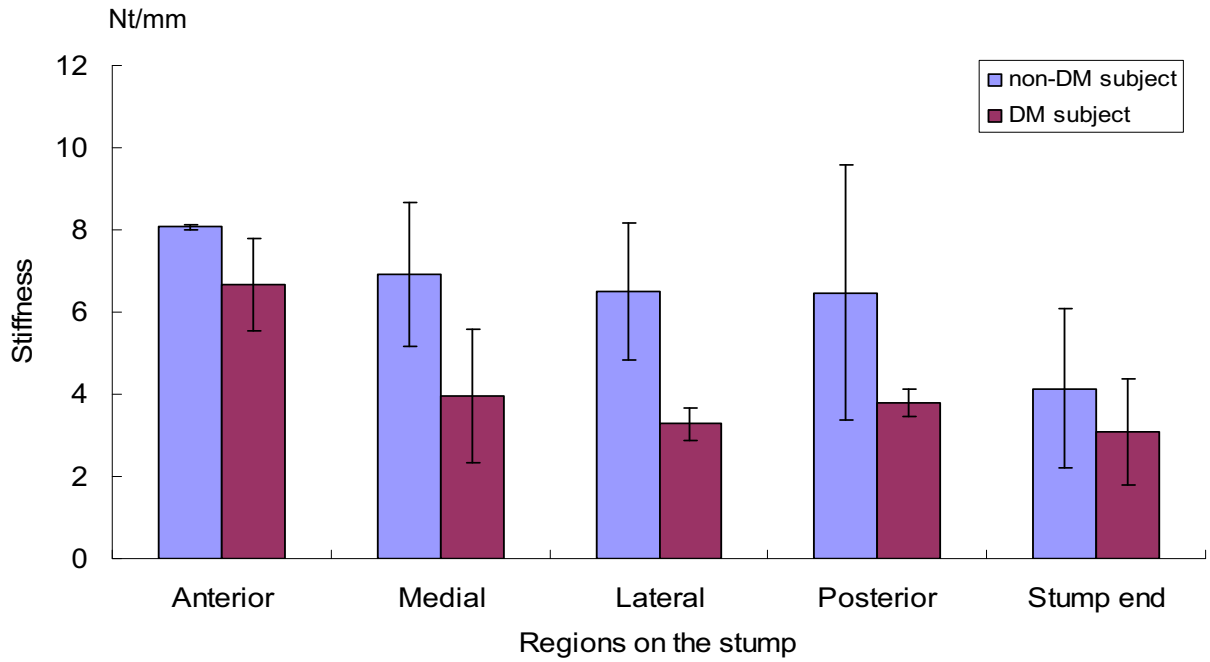
There are some differences between the DM subject and non-DM subject in stiffness of soft tissue especially at medial, lateral and posterior regions showing in Fig. 1. Averagely, the stiffness of non-DM subject is 1.6 times higher than the DM subject. Table 2 illustrated the Young's modulus of the subjects at all five regions. The highest value (0.57~0.72 MPa) of Young's modulus was at anterior (patellar tendon) region, and on the other hand, the lowest value (0.28~0.37 MPa) of Young's modulus was at stump end region.

Table 1 Detail information of subjects

	Amputated side	Sex	Years	Body weight (kgw)	Reasons of suffered amputation
Non-DM subject	Left	Male	33	56	Trauma
DM subject	Left	Female	71	53	Diabetes

Table 2 Values of four indexes from the simulation results of two subjects

	Slide distance (mm)	Von Mises		Interface stresses(KPa)	
		Stress	strain	Pressure	Shear stress
Non-DM subject	0.809	0.203	0.118	54	11
DM subject	1.229	0.259	0.078	106	21



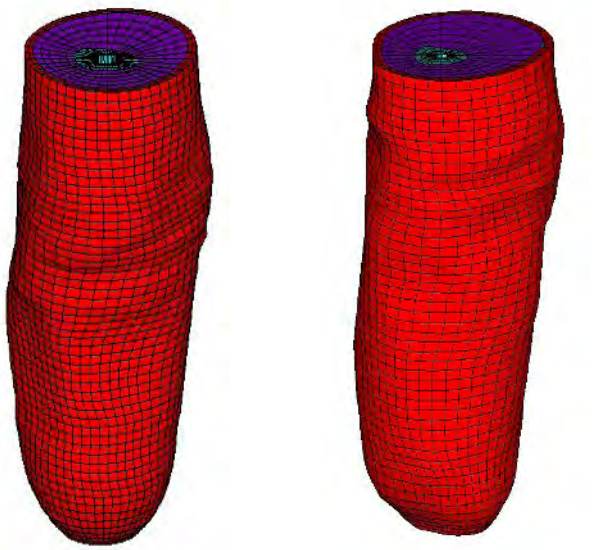


Fig. 1 stiffness at the regions on the stumps of two subjects

B. *Simulation results from finite element (FE) model*

The geometry of the models was showed in Fig. 2. The difference of geometry between the subjects was easily noticed. Three indexes, sliding distance, Von Mises stress and strain and interface stress from finite element analysis were used to describe the biomechanical performance. As shown in Table 3, the DM subject was presented the higher magnitudes than non-DM subject at all indexes except the Von Mises strain.

(b) DM subject

IV. Discussion and conclusions

From the results, we knew the DM subject had a softer soft tissue and higher values of biomechanical indexes. All these reasons indicated that DM subject had higher chance to break tissue. But the results were also influenced by the characteristics of subjects, like body weight, geometry and material properties of stump. In order to eliminate these influences, we simulated the other two situations. First, the material properties of soft tissue from non-DM subject were decreased to 0.6 times as patient suffered DM and second, the material properties of soft tissue from DM subject were increased to 1.6 times as patient recovered to normal. The results were illustrated as table 3. As the elastic modulus of soft tissue decreased, all values of the indexes were increased in two FE models. The higher values of indexes meant that soft tissue might be hurt when wearing the transtibial prosthesis. When manufacturing the prosthesis for DM subjects, the prosthesists should notice this invisible problem.

In the conclusions, the differences of the material properties of soft tissues and biomechanical performance between the DM and non-DM subjects were discussed in this study. The stiffness of soft tissue of non-DM subject is averagely 1.6 times higher than the DM subject and the DM subject was presented the higher magnitudes at the indexes of maximum sliding distance, the interface stresses, Von Mises stress and Von Mises strain. The results might provide a reason to explain the difficulties to manufacture a fitness prosthesis to DM subjects.

Abstract — **Endothelial dysfunction is an initial step of atherosclerosis and is associated with cardiovascular diseases. Measurement of flow-mediated vasodilation in the brachial artery using ultrasound is noninvasive and an accurate indicator of nitric oxide production. However, ultrasound based measurement sometimes depends on the observer's skill. The purpose of this study was to evaluate response in reactive hyperemia employing viscoelastic indices, including stiffness and viscosity measured by strain-gauge plethysmography (SPG) in beat-to-beat. We measured viscoelastic parameters and pulse wave velocity (PWV) in 4 young (23±1 years) and 3 elderly (55±4 years) subjects. Our results showed that there were significant differences in viscosity after cuff deflation (0 to 100 sec) between the young and the elderly ($p<0.001$). However, there was no significant difference in PWV after cuff deflation between the young and the elderly ($P=0.11$). These findings suggest that the proposed viscoelastic indices represent the changes of arterial mechanical properties, which might be derived from flow-mediated vasodilation.**

Keywords — **atherosclerosis, reactive hyperemia, strain-gauge plethysmography, viscoelastic indices, PWV.**

I. Introduction

Cardiovascular and cerebral vascular diseases are the major cause of mortality in Japan. These conditions are strongly associated with atherosclerosis [1]. Previous studies have evaluated arteriosclerosis using arterial elastic properties such as pulse wave velocity (PWV) [2], arterial elasticity [3] and arterial compliance [4]. However, arterial elasticity is useful for the quantification of arterial sclerosis rather than of atherosclerosis.

Endothelial dysfunction is thought to be an important factor in the development of atherosclerosis [5], [6]. It is well known that endothelium function plays a role in releasing nitric oxide to regulate the relaxation of smooth muscle cells within the vascular wall. The function can be evaluated from endothelial-mediated dilatory response, and two methods that evaluate this response are known. One involves measuring forearm blood flow after the administration of an NO agonist and antagonist [7]. These vasoactive substances must be administered via a catheter inserted into the brachial artery, and the method may become invasive and includes potential risk and discomfort. The other method involves a reactive hyperemia test that evaluates flow-mediated dilation promoted by increasing blood flow created by cuff inflation to suprasystolic pressure. This method is widely used because it is noninvasive and allows repeated measurement [8], [9]. However, its drawbacks include the high cost of ultrasound devices and the fact that measurement depends on the observer's skill.

To address the problem, Baldassarre *et al*. assessed endothelial function during reactive hyperemia using strain-gauge plethysmography [10]. This study takes into account only the compliance component between the strain-gauge plethysmogram (representing the strain) and blood pressure (representing the stress). However, it is important for precise estimation of mechanical dynamics to consider the viscous component as well as the compliance component.

We therefore propose a new method to evaluate response in reactive hyperemia using viscoelastic indices measured by strain-gauge plethysmography. In this paper, the proposed indices are measured during a reactive hyperemia experiment, and we assess whether response in reactive hyperemia differs between the young and the elderly subjects.

II. Arterial wall impedance model

Fig. 1 illustrates the proposed impedance model of the arterial wall. This model represents only the characteristics of the wall in an arbitrary radius direction. The impedance characteristic can be described using the stress $F(t)$ and the displacement $r(t)$ of the arterial wall as follows [11]:

$$dF(t) = B\dot{r}(t) + K(r(t) - r_e) \tag{1}$$

where B and K are the coefficients of viscosity and the elastic modulus respectively, $\dot{r}(t)$ is the first derivative of strain in the arterial wall, and r_e is the equilibrium point of the arte-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2059–2063, 2009
www.springerlink.com

rial wall without internal pressure. Here, the dynamic characteristic on the basis of t_0 is described as follows:

$$dF(t) = B\dot{dr}(t) + Kdr(t) \tag{2}$$

where $dF(t) = F(t) - F(t_0)$ and $dr(t) = r(t) - r(t_0)$. To estimate the impedance parameters given in (2), it is necessary to measure $F(t)$ and $r(t)$. The stress exerted on the arterial wall is equal to the arterial pressure. This stress can be given as follows:

$$F(t) = k_f P_b(t) \tag{3}$$

where $P_b(t)$ is the arterial pressure, and k_f is the constant.

On the other hand, the strain of the blood vessel in the radius direction is recorded using strain-gauge plethysmography, which can measure changes in limb volume. The vascular volume change measured by the strain-gauge plethysmogram is represented as follows [12]:

$$r(t) = k_l P_l(t) \tag{4}$$

where $P_l(t)$ is the strain-gauge plethysmogram and k_l is the constant.

The stress exerted on the arterial wall $F(t)$ is expressed by the arterial pressure $P_b(t)$ given by equation (3). And the displacement of the arterial wall $r(t)$ is represented by the strain-gauge plethysmogram $P_l(t)$ in (4). The arterial wall impedance parameters can be estimated by using the least square method from the measured $P_b(t)$ and $P_l(t)$. the vascular dynamic characteristics can be derived as follows:

$$dP_b(t) = \tilde{B}\, d\dot{P}_l(t) + \tilde{K}\, dP_l(t) \tag{5}$$

where the parameters, stiffness $\tilde{K}$ and viscosity $\tilde{B}$ correspond to the viscoelastic properties of the arterial wall in the measured part.

III. Reactive hyperemia experiments

In order to investigate the validity of the proposed method, we conducted reactive hyperemia experiments. Endothelial dysfunction is a major risk factor for atherosclerosis, and endothelial function in aging tends to be impaired [13]. We therefore attempted to assess the difference in response during reactive hyperemia between the young and the elderly, and Fig. 2 illustrates the experimental setup. A blood pressure cuff was placed around the upper right arm, and inflated to 50 mmHg above systolic pressure by a rapid cuff inflator (E20, DE Hokanson). The strain-gauge connec- ted to a plethysmograph (EC6, DE Hokanson) was placed around the right forearm, and continuous blood pressure was measured from the left arm using a biological information monitor (BP-608, Omron Healthcare). The forearm was then elevated 10 cm above the heart level as necessary to facilitate venous drainage, and electrocardiogram (*ECG*) was measured to recognize the cardiac cycle. All signals were stored on a personal computer after AD transformation with a sampling time of 10 ms. In total, 4 young (22-24 years) and 3 elderly (50-59 years) healthy subjects were recruited. The measurements, which were repeated three times, were performed in a resting state and in an ischemic state by inflation of the brachial cuff and after cuff deflation, each for five minutes. All subjects rested for at least 10 minutes prior to the measurement. After reactive hyperemia measurement, PWV was assessed with an automatic pulse wave analysis device (BP-203 RPEII, Colin Co). The measured values of each subject were taken as the average of the three reactive hyperemia trials.

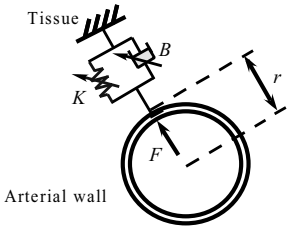

Fig. 1 Arterial impedance model

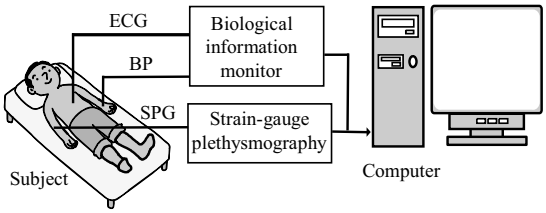

Fig. 2 Experimental setup for measurement

IV. Experimental results

In the experiment, *ECG*, P_b and strain-gauge plethysmogram signals were measured. Since factors such as motion of the patient's hand may affect the measured signals, digital filters were used to regulate the frequency characteristics of the signals. The electrocardiogram was filtered out through a second-order infinite impulse response (IIR) band-pass filter (5-40 Hz), the blood pressure was filtered through a second-order IIR band-pass filter (0.5-8 Hz), and the strain-gauge plethysmogram was filtered through a second-order IIR band-pass filter (0.5-8 Hz).

Fig. 3 shows an example of the experimental results for Subject A, plotting the arterial pressure P_b, the amplitude of

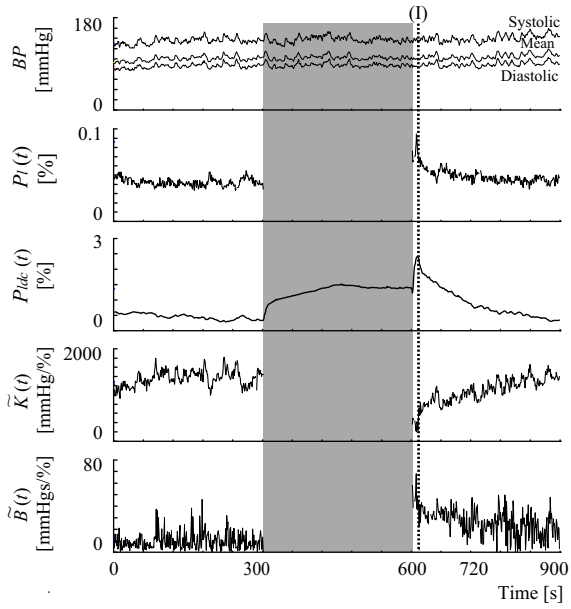

Fig. 3 An example of results in reactive hyperemia

strain-gauge plethysmogram P_{lac}, the direct component of strain-gauge plethysmogram P_{ldc}, stiffness $\widetilde{K}$ and viscosity $\widetilde{B}$ in order from the top. The shaded areas correspond to the ischemic period. The results show no remarkable change in the blood pressure, but both the amplitude and the direct component of strain-gauge plethysmogram (P_{lac}, P_{ldc}), increased relative to resting values 10-15 s after cuff deflation ((I) in Fig. 3) and gradually returned to the resting value. On the other hand, $\widetilde{K}$ decreased to the minimum relative to the resting value 10-15 s after cuff deflation ((I) in Fig. 3) and gradually returned to the resting value. $\widetilde{B}$ increased to the peak relative to the resting value about 5 s after cuff deflation ((I) in Fig. 3) and gradually returned to the resting value.

Fig. 4 and Fig. 5 shows the results for the 4 young and 3 elderly with figures (a) and (b) representing the time course of $\widetilde{K}$ and $\widetilde{B}$ respectively. Each time-course curve is the mean value for the three trials of each subject. In the graph, the baseline is the average of the resting values (0-300 s), and each value after cuff deflation (600-900 s) is the average during 5 s. The results show that each $\widetilde{K}$ reached the minimum about 10 s after cuff deflation ((I) in Fig. 4(a) and Fig. 5(a)) and then returned to the baseline. Each $\widetilde{B}$ reached the maximum about 5 s after cuff deflation ((II) in Fig. 4(b) and Fig. 5(b)) and then returned to the baseline. This change was consistent for all subjects.

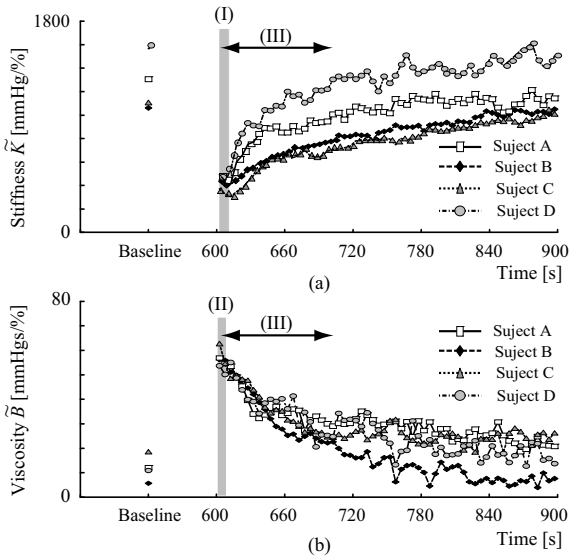

Fig. 4 Time courses of (a) Stiffness and (b) Viscosity in young

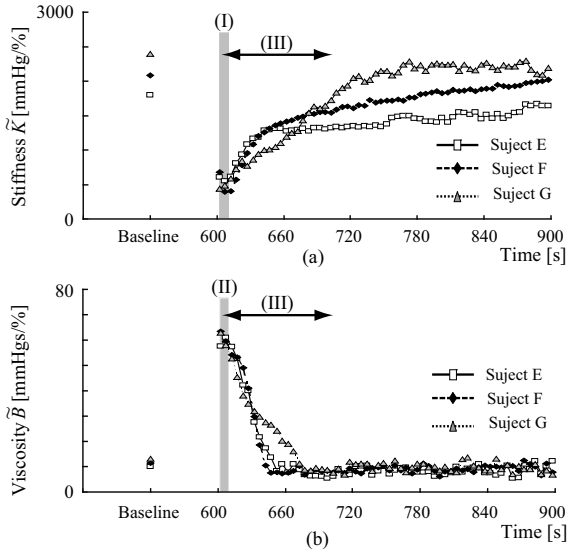

Fig. 5 Time courses of (a) Stiffness and (b) Viscosity in elderly

From the Fig. 4(a) and Fig. 5(a)), $\widetilde{K}$ shows similar changes between the young and the elderly. By contrast, $\widetilde{B}$ shows greater values for young than for elderly after cuff deflation 600 to 700 s area ((III) in Fig. 4(b) and Fig. 5(b)). Therefore, in order to investigate the difference between the young and the elderly were compared with two paired t-tests, and the values $\widetilde{B}$ for young were significantly higher than for elderly from 600 to 700 s ($P< 0.001$).

Table 1 Differences between young and elderly subjects

	Young (Mean ± SD)	Elderly (Mean ± SD)	P *
Age [years]	23 ± 1	55 ± 4	0.001
Area of normalized $\widetilde{K}$	195 ± 25	268 ± 53	0.058
Area of normalized $\widetilde{B}$	64.1 ± 4.5	37.7 ± 3.6	0.001
PWV [cm/s]	1112 ± 112	1607 ± 499	0.11

* Significance level for two-tailed paired *t*-test of young and elderly

V. Discussion

The results of Figs. 5 and 6 confirm a consistent change with all subjects. They also show that, before returning to the baseline, $\widetilde{K}$ reached the minimum 10 s after cuff deflation, $\widetilde{B}$ reached the maximum 5 s after cuff deflation. In conventional studies, the changes during reactive hyperemia are increased blood flow (10 s after cuff deflation) and flow-mediated dilation (about 50 s after cuff deflation) [9]. Here, the period with the maximum change in the proposed method ((I) and (II) in Figs. 5 and 6) corresponds to the period with the maximum increased blood flow reported in previous studies. Moreover, the proposed method measures the characteristics of vessels presented in the forearm.

The comparison using the two-tailed paired t-test between the young and the elderly of the viscoelastic indices and PWV are shown in Table 1. The difference between the young and the elderly for the time course after cuff deflation, the areas of $\widetilde{K}_{rate}$ and $\widetilde{B}_{rate}$ are defined by calculating their integrals between 600 and 700 s. The results show a significant difference ($P < 0.001$) in viscosity. For this reason, the proposed viscoelastic indices represent the modification of arterial mechanical properties derived from flow-mediated dilation, and the strain-gauge plethysmogram represents the increase of the forearm circumference derived from flow-mediated dilation. On the other hand, PWV showed no significant difference ($P = 0.11$).

From these results, viscosity and the strain-gauge plethysmogram show a significant difference between the young and the elderly. It is thought that the changes in these proposed indices after cuff deflation represent the flow-mediated dilation response because previous studies [13] showed that flow-mediated dilation was significantly impaired in the group of the elderly as a whole compared with the young. It was therefore confirmed that the proposed method has the potential to evaluate endothelial function.

VI. Conclusions

In this study, we proposed the new method to evaluate response in reactive hyperemia using viscoelastic indices measured by strain-gauge plethysmography, and then conducted reactive hyperemia experiments to investigate the validity of the proposed method. The results show that, before returning to resting values, $\widetilde{K}$ reached the minimum 10 s after cuff deflation, $\widetilde{B}$ reached the maximum 5 s after cuff deflation with the consistent tendency through all subjects. Additionally, we attempt to assess the difference in response during reactive hyperemia between the young and the elderly, and confirmed the significant difference with time courses of proposed stiffness $\widetilde{K}$ and viscosity $\widetilde{B}$. Our proposed technique is definitely less expensive both from hardware and manpower points of view.

Future research will be directed to assess the additional availability of the proposed method to evaluate the endothelium function by the comparison with an ultrasonic method and the measurement with subjects of various ages. Furthermore, measurement setup will be improved for the robust and comfortable measurement of reactive hyperemia using the strain-gauge plethysmography.

Abstract — **Purpose: The purposes of this study were to analyze the technique movement as grand battement derrie in Chinese dance, to examine the tiny change in muscles during this skill, and to know what factor dominate this technique. Methods: Twenty-two female university in dance department students volunteered to participate in this study. Strength of bilateral paraspinatus muscles and gluteus muscles were calculated using load-cells, flexibility of trunk and hip were evaluated by goniometers, and the fine changes of muscular activity were measured by electromyography. All subjects performed eight times of grand battement in Chinese dance and scored by professional dancer to define the esthetics score of this technique. Results: The dominant side exhibited shorter reaction time than non-dominant side in paraspinatus muscles and gluteus muscles, high level group showed longer muscular activity and shorter resting time than lower level group, which were observed by electromyography. Higher level group were significant greater and better than lower level group in gluteus muscular strength and hip flexibility, but not in trunk. There was significant positive correlation between muscular strength of gluteus and score of technique, but not in trunk. There was significant positive correlation between hip flexibility and esthetics score of technique, yet not in trunk. Conclusion: There are faster reaction times in dominate side to provide the stability before motion occurred. The gluteus muscles and hip flexibilities are the key factor for the performance in grand battement derrie in Chinese dance.**

I. Introduction

Every dancing posture is results that the human joint moves continuously in the dance movement, though activity degree of every joint of human body must be limited, has suitable progressive potentiality via training. [1]After softness degree which studies the Chinese dance dancer behaves, propose the temperature of volume of muscles and the soft tissue, nervous and surrounding environment around tension of joint capsule and ligament intensity, joint around the difference, joint of the skeleton structure, will influence the scope of activities of joint. Need at not kicking appropriate to extend and make by strength fast shank and waist muscle a lot of scholar together after being think to after above play, one burst of big ligaments of the hip joint and Y intestines can't be done up excessively tightly hard in the course, otherwise the scope of activities will be limited, supporting the knee of leg at the time of in addition the activity needs to stretch in order to increase whole movement stability, can't rock at will. Move the leg while moving, the shank, shoulder and arm all can't be excessively stiff, need appropriate to relax shank, shoulder with arm prevent from loose shoulder alike to produce, truck cooperate extending together with the pelvis upwards also at the same time, make the back straight and upright and reduce the load of lumbar vertebrae, can increase the lumbar vertebrae and scope of activities of pelvis, can also prevent the waist injury from producing [3. 4. 7. 8. 9. 10]

Move science at present and medical science clinical to use skin electric picture make detail muscle mobilize way measure in a large amount. Movement science can analyze slighter muscule activity way through the electric picture of skin; Medical science clinical to use skin electric picture measure, reply and is good for patient's muscle telecom phenomenon in a large amount too. Dance some foreign scholar more less, make in-depth analysis to small-scale movement and single position only in the field, for example: Whether Grand plie, Demi plie, or the foot dance injures [5. 6]. So guide the motive of the persons who break out, kick in the activity way with slight muscle of movements after analyzing the Chinese dance through the electric picture of skin, understand the organization of human body and muscle operation method, improve skill movements, and prevent or reduce the production of the dance injury.

Because the dance injures the importance trained to the professional skill of dance with muscle ability, this research passes (Electromyography; EMG) , muscular strength and whether degree,etc. analyze, in order to understand Chinese kick movement level behave group behind the dance, habitually practise, examine to habitually practise side muscular strength react time difference, person who decay, muscle shrink array and have skin telecom complex reaction time. Cooperate with instruments such as Load-cell and

V. Propose

Result of research this, offer dancer, dance teaching person and research and propose following suggestion to dance movement future separately: First, to dancer and dance teaching person, propose dancer can by with hip joint skin group for key muscle muscular strength and soft degrees of training of group of main fact, the movements of kicking after in order to improve China's dance movement behave; Must moreover substantiate the physiology and dissect and gain knowledge, could be with the correct dance movement of guidance of the efficiency and security, improve the learner's skill and avoid the production of the dance injury. Second, to the research of dance technology in the future, because the Taiwan dance is studied in the majoritily with the artistic quality of humanity more at present, it is less likely to further investigate by scientific method of the movement. Through sport science further investigates, not only may expand the visual field of dance, can further quantize the skill movements of the dance by scientific process, digitisation method, entrust to the new life that the dance movement analyses scientifically.

Abstract — **Introduction The most common symptoms after ankle sprains were chronic ankle instability, proprioception defect and probable neuromuscular adaptation. The purpose of this study was to identify the normal landing pattern using detailed biomechanical analysis including analysis of the kinematics and ground reaction force, and to compare the landing pattern in the subjects with recurrent ankle sprain and normal subjects. METHODS Ten male adults were recruited in this study (5 subjects with recurrent lateral ankle sprains group, 5 subjects with normal control group). All subjects would be asked to perform maximal standing jumps and drop landing from 3 platforms with different heights (0.37 m, 0.67 m, & 0.97 m, respectively). Those movements were collected by VICON 512 (Oxford Metrics, UK) motion analysis system and the kinematics was analyzed using self making software with MATLAB. The ground reaction force of both lower limbs was recorded by two AMTI force platforms, and the kinetic data were calculated with inverse dynamics. RESULTS In the different landing height, the main differences of kinematics were the maximum flexion angles of hip and knee joints in normal landing patterns and the flexion angles increased with the landing height, as well as the flexion of pelvis, hip abduction, and knee external rotation in the subjects with recurrent ankle sprains. When compare those two groups, the landing pattern in the subjects with recurrent ankle sprain was significant smaller than normal subjects in knee flexion (65.71°±6.43° vs. 70.19°±13.76°) and hip flexion (34.15°±5.42° vs. 42.54°±10.07°). The time to maximum angles in ankle dorsiflexion and foot pronation were also quite different between these two groups. The maximum vertical ground reaction force in sprain group was significant smaller than normal group. CONCLUSION In this study, we have revealed the adaptation of performing drop landing in the individuals with recurrent ankle sprains. It could be considered as a recommendation of the rehabilitation..**

Keywords — **Motion Analysis, Recurrent Lateral Ankle Sprain, Landing Pattern**

I. Introduction

Forty-seven percent of ankle sprains occurred in the ankle that had been previously sprained. The most common symptoms after ankle sprains were chronic ankle instability, proprioception defect and probable neuromuscular adaptation [1-3]. Moreover, Ekstrand and Gillquist suggested that there was 47% of ankle sprains occur in the ankle that had been previously sprained [4]. It meant that around half of ankle sprain subjects would have great potential to be the candidates with recurrent and chronic ankle sprains. Furthermore, studies have shown that between 20-50% of ankle sprain suffers result in residual ankle symptoms [2]. The most reported residual ankle symptoms were chronic ankle instability, proprioception defect and probable neuromuscular adaptation [5]. The biomechanics of landings has been investigated but limited in two-dimensional analysis in the past literature [6-11]. And no study investigate the differences of landing pattern between normal and recurrent ankle sprain subjects. Therefore, it is reasonable to presume that there must be some factors that cause the ankle more susceptible to subsequently sprain, or chronic ankle instability.

There are two theories for recurrent ankle sprains. The first one is the 'mechanical instability' theory, which suggests that the instability is caused by damage to the integrity of supporting ligaments. The second is the 'functional instability' theory, which reveals that the instability is due to damage to the nerves in the ankle area that would normally feedback information to the brain about the position of the ankle, interacting with balance mechanism. If the latter explanation were true, ankle sprain would be expected to affect the balance strategy. Since the most common injury mechanism in recurrent ankle sprain was landing on irregular surface. To understand the response to this kind of impact activity, this study would investigate biomechanical changes in subjects with recurrent ankle sprain and compare with healthy subjects.

Therefore, the first aim of this study was to identify the normal landing pattern using detailed biomechanical analysis including analysis of the kinematics and ground reaction force. The second aim of the study is to investigate the landing pattern in the subjects with recurrent ankle sprain and compare this landing pattern with that in normal subjects.

II. Method

Five male adults with recurrent lateral ankle sprains were recruited in this study, and five healthy male adults who were free from any injury of lower extremity were enrolled

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2068–2071, 2009
www.springerlink.com

as control group. Recurrent lateral ankle sprain is defined as that the subject has more than two sprain episodes with the same ankle in the past three months or had been definitely diagnosed by a doctor. However, during the testing session, there should be no acute symptoms such as edema and resting pain that would influence the activities.

The reflective markers would be placed on several bony landmarks as the figure shown below, to define segments of lower extremity, which includes the landmarks on pelvis, left anterior superior iliac spine (LASI), left posterior superior iliac spine (LPSI), right anterior superior iliac spine (RASI), right posterior superior iliac spine (RPSI), thigh include great trochanter (GTRO), medial and lateral part on thigh (THI), left femoral epicondyle (LFC), right femoral epicondyle (MFC), shank contain tibial tuberosity (TT), head of the fibula (HF), lateral malleolus (LMA), medial malleolus (MMA), hindfoot include posterior base of calcaneus (HEE), navicular tuberosity (FOO), 5th metatarsal base (TOE), forefoot contain navicular tuberosity (FOO), 5th metatarsal base (TOE), dorsal aspects of 1st, & 5th metatarsal heads (D1T & D5T) and toe contain nail of big toe (BTO) , dorsal aspects of 1st, & 5th metatarsal heads (D1T & D5T). In addition, the segment definition in trunk includes jugular notch of sternum (STRN), the spinous process of C7 (CER7), left acromion head (LSHO), right acromion head (RSHO) .

The subjects would be asked to perform level walking initially to warm-up and then maximal vertical jumps and drop landings from platforms with four selected heights (0.37 m, 0.57 m, 0.77m, & 0.97 m, respectively). [Fig.1], [Fig.2]. Subjects would repeat at least 3 times for each condition. The kinematic data would be collected at 120 Hz

Fig.1 A subject was performing: (a) static alibration (b) level walking (c,d) maximal standing jump

Fig.2 Four platforms with different heights: (a) 0.37m (b) 0.57m (c) 0.77m (d) 0.97m

with the VICON 512 (Oxford Metrics, UK) motion analysis system with BodyBuilder® to establish the segmental coordination systems. With dual AMTI force platform system could simultaneously record the ground reaction force of both limb at sampling rate of 600 Hz, kinetic data calculate with inverse dynamics.

The *landing phase* defined as starting at the first contact with force plate and end at the maximum knee flexion angle to investigate the response to this impact activity. The *kinematic variables* including maximum joint angle and time to maximum angle were analyzed and compared between groups. *Vertical ground reaction force* was normalized with subject's body weight, and the maximum value was calculated and compared between groups and heights. All the variables were analyzed using 2-way ANOVA with independent variables of groups and heights. Significant level was set at 0.05.

III. Result

Landing phase duration was increased with the platform height increased in both groups, and was shorter in subjects with recurrent ankle sprain [Fig.3].

When drop landing from platforms with different height, the main differences of kinematics were the maximum flexion angles of hip and knee joints in normal landing patterns and the flexion angles increased with the height. When drop landing from platforms with different height, the main differences were the maximum flexion angles of hip and knee joints, as well as the flexion of pelvis, hip abduction, and knee external rotation in the subjects with recurrent ankle sprains. When compare those two groups, the landing pattern in the subjects with recurrent ankle sprain was signifi-

cant smaller than normal subjects in knee flexion (65.71° ± 6.43° vs. 70.19° ± 13.76°) and hip flexion (34.15° ± 5.42° vs. 42.54° ± 10.07°). [Fig.4].

The time to maximum angles in ankle dorsiflexion and foot pronation were also quite different between these two groups. The maximum vertical ground reaction force in sprain group was significant smaller than normal group. [Fig.5].

The maximum vertical ground reaction force on each limb was compared between groups and platform heights. Significant difference was found between groups, and the value was smaller in normal subjects [Table 1].

* p value < 0.04

IV. Discussion

Landing phase duration was increased with the platform height increased in both groups. It indicated that more time was required to response to a larger impact, and to decelerate a bigger contact downward velocity, in order to regain

the balance from this impact activity. And the landing phase was shorter in subjects with recurrent ankle sprain, means that they reach their maximum knee flexion angle earlier. This could result from the instability or sensory impair of ankle joint, and subjects with ankle sprain had to count on the shock absorption ability of knee joint earlier to stop the downward tendency. The control mechanism and chronic adaptation of recurrent ankle sprain subjects could be another possible reasons. This shorter landing phase, which could result in bigger impact and poorer shock absorption, is the reason why causing ankle joint more prone to injury. Or the injury experiences cause the individual to chronic adapts his landing pattern. In this preliminary study, we cannot define the cause-effect relationship between them.

The maximum vertical ground reaction force (GRF) on each limb was compared between groups and platform heights, and the mean value was smaller in normal group [Table 1]. It implied there were less impulses in normal subjects.

The comparison of the GRF patterns between groups, we noticed that the vertical components of ground reaction force (vGRF) had an interesting trend in normal group, especially landing from a higher platform, which demonstrated that they reached a peak vGRF and decrease quickly then kept in a plateau, value of a hundred percent of their body weight, when knee flexion angle reach its maximum value vGRF decrease gradually to their balanced weight. However, sprain group demonstrated different pattern, that vGRF reached its peak value then gradually decreased to the balance weight earlier, without the buffering period before maximum knee flexion. According to the Newton's law, a constant force causes a constant acceleration if the mass of the object keeps unchanged. Considering the plateau demonstrated in normal subjects before reaching maximum knee flexion, they tried to keep a constant deceleration of center of mass (COM) to counteract to the downward acceleration caused by the gravitation. It could be a protection mechanism providing a buffering effect to prevent our musculoskeletal system keeps bearing a changing acceleration (jerk).

V. Conclusion

The preliminary results including kinematics and ground reaction force could have a glimpse of the general normal landing pattern. The landing pattern in the subjects with recurrent ankle sprain had showed significant difference compared with normal subjects with our detail biomechanical analysis. In this study, we have revealed the adaptation of performing drop landing in the individuals with recurrent ankle sprains. It could be considered as a recommendation of the rehabilitation guide.

There are still lots of issues related to this topic, such as landing on a tilting surface, muscle activation sequence, role of vision, and anticipatory postural adjustment during landing. All the issue are interesting and worthy to investigate in the further study.

The Influence of Low Level Near-infrared Irradiation on Rat Bone Marrow Mesenchymal Stem Cells

T.-Y. Hsu[1], W.-T. Li[1,2,*]

[1] Department of Biomedical Engineering, Chung-Yuan Christian University, Chung-Li, Taiwan
[2] Research and Development Center for Biomedical Microdevice Technologies, Chung-Yuan Christian University, Chung-Li, Taiwan

Abstract — **Low-level light irradiation (LLLI) has been known to lead to cell proliferation, increase of ATP synthesis, change in mitochondrial membrane potential and the induction of the synthesis of cell cycle regulatory proteins. The purpose of the study was to find the influence of near-infrared (850 nm) light emitting diodes (LEDs) irradiation on mesenchymal stem cells (MSCs) derived from rat bone marrow. Maximal increase in MSCs proliferation was observed with multiple dose of LLLI at 10 mW/cm^2 and 4 J/cm^2. No apparent variation in temperature (26.1 to 26.3 ^{o}C) during irradiation was found, which suggested photochemical effect could be the key factor for biomodulation. The parameters were used in the subsequent research. The number of CFU-F increased slightly ($p<0.05$) when rat MSCs were illuminated at 10 mW/cm^2 and 4 J/cm^2. No apparent increase in lactate dehydrogenase release indicated that membrane integrity remained intact after LLLI. Reactive oxygen species production decreased indicated LLLI might have anti-oxidative effect. Intracellular level of ATP increased 1.53 fold after LLLI. Both alkaline phosphatase activity and osteocalcin secretion increased in osteogenic MSCs treated with multiple dose of LLLI. However, triacylglyceride accumulation in adipogenic cells decreased after LLLI. In conclusion, multiple dose of LLLI at 850 nm not only enhances proliferation but also modulates differentiation of MSCs.**

Keywords — **low level light irradiation, mesenchymal stem cell, near-infrared, light emitting diode.**

I. Introduction

Mesenchymal stem cells (MSCs) contribute to the regeneration of mesenchymal tissues and are essential in providing support for the growth and differentiation of hematopoietic stem cells within the bone marrow microenvironment. MSCs are able to differentiate into cell types such as osteocytes, adipocytes, chondrocytes, myocytes, cardiomyocytes, endothelial cells, neurons and hepatocytes *in vitro* [1]. Their easy isolation, expansion, and low immunogeneity make them ideal for stem cell therapies. Approaches such as genetic immortalization, formulation of growth media, use of various bioreactors, have been used to maintain MSCs' life span and expand sufficient cells for clinical treatment.

Low level light irradiation (LLLI) has been shown to enhance proliferation and cytokine secretion of a number of cells, which may be an alternative for MSCs expansion. The primary defining factor for LLLI is power with a range of 10^{-3} to 10^{-1} W, which results in imperceptible temperature elevations (0.5~0.75^{o}C) [2]. Coherent and non-coherent light with the same wavelength, intensity, and irradiation time provide the similar photobiological effect [2]. The mechanism by which low intensity lasers induce biomodulation of cell activity has been well described by Karu [3]. LLLI seems to act mainly in cells with committed functions. Several questions remain open on the intracellular responses of stem cells to LLLI. Abramovitch-Gottlib *et al.* used a combination of low level laser irradiation and coralline matrix to enhance the osteogenic phenotypes of mesenchymal stem cells [4]. Our previous study has shown that LLLI of 630 nm light emitting diodes (LEDs) could enhance replicative and colony formation potentials of MSCs derived from human bone marrow [5]. Tuby *et al.* demonstrated that LLLI of 804 nm diode laser (50 mW/cm^2, 1 or 3 J/cm^2) promoted proliferation of cultured mesenchymal and cardiac stem cells from rats [6]. Kim et al. found that 647-nm light emitting diodes (LEDs) irradiation enhances osteogenic differentiation in mouse MSCs [7]. Eduardo *et al.* reported laser phototherapy (660 nm) on human dental pulp stem cells improved the cell growth when cultured under nutritional deficit conditions [8]. To date, LLLI using 850-nm LEDs has not been applied as an approach to promote proliferation or differentiation of isolated MSCs. The purpose of the present research was to study the effects on the proliferation and differentiation potential of rat MSCs by near-infrared LLLI.

II. Materials and methods

A. Cells and cell culture

Female Wistar rats (150-250 g, Laboratory Animal Center, National Taiwan University Hospital, Taipei, Taiwan) were sacrificed by anesthesia under the guidelines approved by the Institutional Animal Care and Utilization Committee. Bone marrow were collected from the femurs and tibias by flushing it with serum-free complete medium [Alpha minimum essential medium (α-MEM) containing 2 mM L-glutamine, 100 U/ml antibiotic- antimycotic and 0.1 mM

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2072–2075, 2009
www.springerlink.com

non-essential amino acids; Gibco/BRL, Invitrogen, CA, USA]. Cells were filtered through a 100-μm nylon mesh (BD Falcon, CA, USA) and subjected to 40% percoll (Sigma, MO, USA) density gradient centrifugation. Mononuclear cells were collected from the interface and suspended in complete medium supplemented with 10% fetal bovine serum (FBS, lot selected from Hyclone, UT, USA). After 24 h incubation at 37°C and 5% CO_2, nonadherent cells were discarded and the adherent cells were grown to 90% confluence in complete medium containing 10% FBS. MSCs (passage 0) were detached by trypsinization and harvested by centrifugation at 500 x g for 10 min. The cells were grown in a 10-cm culture dish with fresh medium replaced every 3 to 4 days. All cells used for the experiments were the third passage.

B. Light irradiation

A home-made infrared LEDs array composed of 23 x 30 LED (GaAIAs) lamps (LUIR034, emission wavelength: 850 ± 21 nm, Lenoo Electronics Co., Hsinchu, Taiwan) was used. The irradiance of a LED array was adjusted by direct current from a standard power supply. The irradiance at the surface of the cell monolayer was measured by a power meter (Orion, Ophir Optronics Ltd., UT, USA) and the parameters used were 10 and 15 mW/cm^2. The radiant exposure of 2 and 4 J/cm^2 were used, which was regulated by the time period of illumination. A culture plate was supported on a clear polycarbonate platform and irradiated from below. The distance from the LED array to the surface of cell monolayer was 0.7 cm. The temperature of the medium fell between 26.1 to 26.3°C during the course of illumination (15 mW/cm^2 and 4 J/cm^2). All culture plates were maintained under semi-dark at room temperature (RT) and atmosphere for the length of the irradiation. Rat MSCs without LED exposure placed under the same condition were used as control. All experiments were performed in triplicate and three sets of separate experiments were conducted

C. Cell proliferation

Rat MSCs (100 cells/well) were plated on a 96-well microplate in the complete medium supplemented with 10% FBS. Cells were irradiated every other day and their proliferation was measured by direct cell counting after Liu's staining (Tonyar Biotech. Inc., Taiwan). To determine whether near infrared LLLI caused any damage to rat MSCs, cells (10^4 cells/well) were allowed to adhere on a 96-well microplate for 24 h. Membrane integrity was assessed by the release of lactate dehydrogenase (LDH) from cells using CytoTox 96® Non-radioactive Cytotoxicity Assay (Promega, WI, USA) at various time points after LLLI.

Here, colony-forming unit-fibroblast (CFU-F) assay is a functional method to quantify stromal progenitors. One hundred rat MSCs were seeded on a 10-cm dish in the complete medium supplemented with 10% FBS. The cells were subjected to LLLI at 10 mW/cm^2 and 4 J/cm^2 every other day. After 21 days, the colonies (≥ 50 cells) were stained with 3% crystal violet and counted.

D. Reactive oxygen species analysis

Reactive oxygen species (ROS) formation was detected using 2',7'-dichlorofluorescin diacetate (DCFDA, Sigma, MO, USA). Rat MSCs ($2x10^5$ cells/well) were plated on a 6-well plate and incubated with DCFDA (20 μM) for 1 h before LLLI. Cells were washed twice with Dulbecco's phosphate buffered saline (PBS, Sigma, MO, USA) after LLLI, and lysed by sonication. DCF (2',7'-dichlorofluorescein) fluorescence in cell lysate was analyzed by an ELISA reader (Fluoroskan Ascent FL, Thermo Fisher Scientific, Inc., MA, USA) (ext: 488 nm). The protein amount in each sample was determined by bicinchoninic acid protein assay (Sigma, MO, USA).

E. ATP analysis

Rat MSCs (10^4 cells/well) were seeded on a 96-well microplate and illuminated at 24 h. Intracellular ATP level was measured after LLLI using CellTiter-Glo® Luminescent Cell Viability Assay (Promega, WI, USA).

F. MSCs differentiation

To observe the effect of LLLI on osteogenic differentiation of rat MSCs, cells ($2.5x10^3$ cells/well) were grown in the complete medium on a 96-well microplate for 6 days. Then, cells were incubated in the osteogenic medium (complete medium containing 2% FBS, 10 μM β-glycerophosphate, 10^{-7} M dexamethasone and 50 μM ascorbic acid 2-phosphate) for 28 days while cells were subjected to LLLI every other day. Alkaline phosphatase (ALP) activity and osteocalcin secretion of MSCs were assessed every week. ALP activity was assayed based on the conversion of *p*-nitrophenyl phosphate (*p*-NPP) into *p*-nitrophenol (*p*-NP) in the presence of ALP. Cell lysate (10 μl) was mixed with 100 μl of 6.7 mM *p*-NPP (Sigma, MO, USA), followed by incubation at 37°C for 30 min. After stopping the reaction with 50 μl of 3 N NaOH, the absorbance at 405 nm of *p*-NP was measured with an ELISA reader (Multiskan Spectrum, Thermo Fisher Scientific, Inc., MA, USA). The expression of osteocalcin was analyzed by ELISA. Culture supernatant

(80 μl) was added into each well of a 96-well ELISA plate (NUNC, Thermo Fisher Scientific, Denmark) and incubated at 4°C overnight. Rabbit anti-rat antibodies against osteocalcin (Santa Cruz Biotechnology Inc., CA, USA) were added to the wells at 1:250 and incubated at 4°C overnight. After washing with PBS, 30 μl of alkaline phosphatase-conjugated goat anti-rabbit secondary antibody (Santa Cruz Biotechnology Inc., CA, USA) (1:250) was added and incubated at RT for 2 h. After washing with PBS, 100 μl of ALP substrate (Promega, WI, USA) was added and the absorbance at 620 nm was read after 2 h incubation at RT.

To observe the effect of LLLI on adipogenic differentiation, rat MSCs ($2.5x10^3$ cells/well) were grown in the complete medium on a 96-well microplate for 6 days. Then, the medium was changed into adipogenic medium (complete medium containing 2% FBS, 0.5 mM 3-isobutyl-1-methylxanthine, 10^{-6} M dexamethasone, 60 μM indomethacin and 5 μg/ml insulin) and the medium was replaced every 3 to 4 days. Adipogenesis was assessed by Oil Red-O stain. To quantify the amount of triacylglyceride, 50 μl of isopropanol was added into each well to dissolve Oil Red-O at RT for 10 min. The absorbance at 510 nm was read by an ELISA reader.

G. Statistical analysis

The result was expressed as the mean ± standard deviation. A two-tailed Student's *t* test was used for comparing the results between the irradiated and non-exposed groups. A *P* value of <0.05 was considered to be statistically significant.

III. Results and Discussion

A. Effect of near infrared LLLI on MSCs proliferation

Rat MSCs received multiple dose of 850-nm LLLI at 10 mW/cm^2 showed significant increase in cell growth (Fig. 1). The proliferation of cells increased 1.25 and 1.17 fold of the control under the irradiation of 4 and 2 J/cm^2, respectively. However, MSCs proliferation was inhibited by multiple exposures of 15 mW/cm^2 light. The parameters of 10 mW/cm^2 and 4 J/cm^2 were used for the following experiments. The number of CFU-F is used as an *in vitro* correlate for proliferative potential of MSCs. As shown in Table 1, CFU-F number increased slightly after received multiple dose of LLLI at 10 mW/cm^2 and 4 J/cm^2. No apparent increase in LDH release was found indicated that membrane integrity remained intact after LLLI (data not shown). The results concluded that multiple dose of LLLI at 850 nm enhanced the proliferative potential of MSCs.

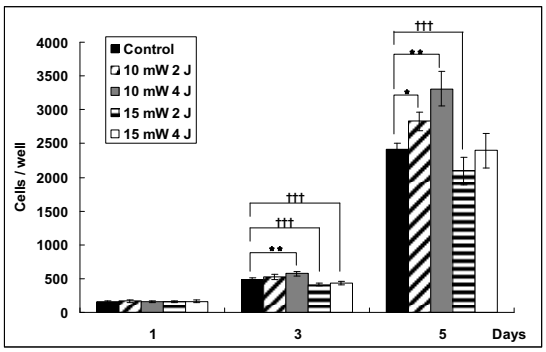

Fig. 1 The effect of near infrared LLLI on cell number

Table 1 Effect of 850 nm LLLI on CFU-F number of rat MSCs

	Number of CFU-F (≥ 50 cells)	Size of CFU-F	
		2~5 mm	5~8 mm
Control	36.6 ± 5.22	33.2 ± 4.38	3.4 ± 1.14
Irradiation	39.4 ± 4.16	36.6 ± 3.91	2.8 ± 0.48

B. Effect of near infrared LLLI on ROS production

Two morphologically distinct cell types, wide spindle-shaped and thin spindle-shaped cells, were found in the culture of rat MSCs. Wide spindle-shaped cells lost proliferative ability rapidly. ROS production from two cell types was observed after 10 mW/cm2 and 4 J/cm2 LLLI (Fig. 2). The level of ROS decreased 0.49 and 0.85 fold of the non-exposed control in wide spindle-shaped and thin spindle-shaped cells, respectively. The result suggests near infrared LLLI has anti-oxidative effect on rat MSCs.

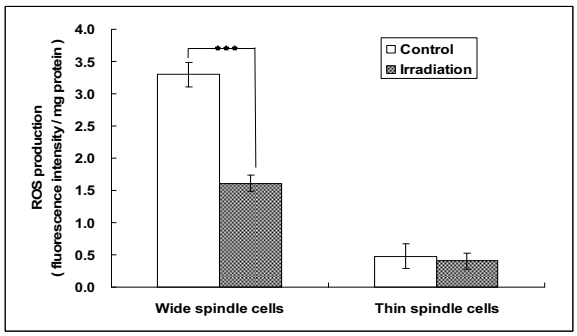

Fig. 2 The effect of 850-nm LLLI on ROS production

C. Effect of near infrared LLLI on intracellular ATP level

Intracellular ATP level of rat MSCs was measured after 10 mW/cm^2 and 4 J/cm^2 LLLI (Fig. 3). ATP level increased 1.53 fold of the non-exposed control. The result suggests 850-nm LLLI enhances mitochondrial activity of rat MSCs.

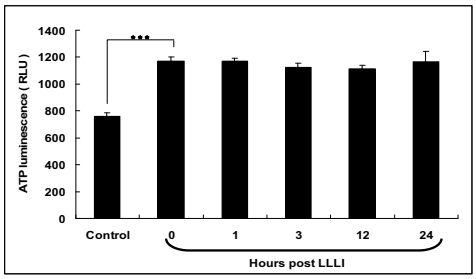

Fig. 3 The effect of 850-nm LLLI on intracellular ATP level

D. Effect of near infrared LLLI on rat MSCs differentiation

Rat MSCs were subjected to osteogenic induction while received LLLI at 10 mW/cm^2 and 4 J/cm^2 every other day. ALP activity and osteocalcin secretion of MSCs were assessed every week (Fig. 4). It was observed that both ALP activity and osteocalcin secretion were significantly stimulated by LLLI compared with control at day 14 and 21. ALP activity decreased as the increase of osteocalcin which is an indicator of mineralization during osteogenesis.

Rat MSCs were subjected to adipogenic induction while received multiple dose of light irradiation at 10 mW/cm^2 and 4 J/cm^2. It was observed that the level of triacylglyceride accumulation was significantly inhibited by LLLI compared with control during the 14-day period of adipogenesis (Fig. 5).

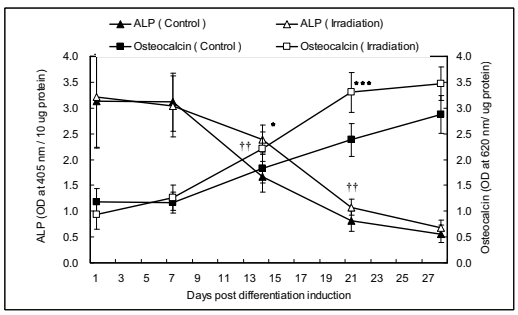

Fig. 4 The effect of 850-nm LLLI on osteogenic differentiation

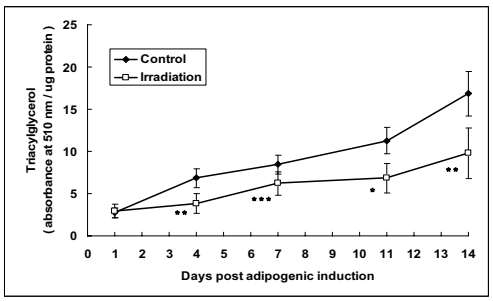

Fig. 5 The effect of 850-nm LLLI on adipogenic differentiation

IV. Conclusions

The study demonstrates that the abilities of multiple dose of LLLI at 850 nm to enhance proliferation and osteogenic differentiation of rat MSCs. Adipogenesis of rat MSCs were inhibited by near infrared LLLI. Our findings open the possibility of modulating stem cell differentiation by LLLI.

Abstract — **The aim of this contribution is to demonstrate the possibility of performing macrometric and micrometric protein patterns in order to study focal adhesions of human cells on different materials. A laser is used to produce a pattern of extracellular matrix protein (e. g. fibronectin) as in photolithographic techniques. Maskless lithography is performed, using a common instruments such as Raman spectroscopy microprobe. This technique can be applied to all surface curvatures, different geometries and a wide range of materials. We demonstrated the resistance of fibronectin to the lithographic process. There are evidences of the functionality of fibronectin with adhesion of human HUVEC cells.**

Keywords — **Focal adhesions, proteins patterning, laser writer, Raman lithography.**

I. Introduction

Focal adhesions (FAs) are the connection between cells and extracellular matrix (ECM). They act as a mechanosensor for forces and transmit signals from the ECM to the cell. FAs influence motility, proliferation and survival of the cell [1,2].

Focal adhesions are characterized by proteins couples, membrane protein and ECM protein.

Regulating and controlling movements of cells is the key issue for understanding cytokinesis [3] and the proliferation of tumors. Recent studies indicate that modifying cell-ECM adhesion structures can inhibit metastasis during the carcinogenesis [4].

FAs are involved not only in tumoral diseases, but they are also the target of Helicobacter pylori, that produces a disruption of the gastric epithelium in vivo (gastric ulcer) [5].

By an engineering point of view, focal adhesions are directly involved in biomaterials, that interact with biological systems. These materials can be the external environment for cells. Controlling biological adhesion is a very important parameters for this materials class [6,7].

In this contribution we report the possibility of performing macrometric and micrometric pattern of ECM proteins, in particular of fibronectin.

Previous works [8,9] indicated the possibility of performing traditional lithography for protein pattern (photolitography, microcontact printing, laminar flow or stencil patterning). All this techniques require a mask, that is relatively expensive and requires a flat surface.

In a previous work [10], maskless lithography was described. This method is easily applied to protein patterning on surface, with no restriction on geometries of the pattern and the surface and for a wide range of materials. Another advantage is the higher resolution achievable than the mask based lithography: holes of 1 μm diameter can be obtained very reproducibly.

A double fluorescent antibodies complex is used to point out fibronectin patterning. This method is very accurate and demonstrate that the protein is not denaturated. Structural integrity of fibronectin is the necessary condition for having an antibodies complex.

Finally macrometric and micrometric patterning are compared and cell adhesion tested.

II. Experimental section

A. Chemicals and Materials

Positive Shipley Microposit S1813 photoresist and Microposit MF CD 26 developer were acquired from Rohm and Haas (Germany). Standard glass slides for optical microscopy (25 x 75 mm) were obtained from Menzel-Glaser (Germany).

Fibronectin (human plasma) was obtained form BD Biosciences (U.S.A.), rabbit anti-fibronectin IgG antibody was acquired from Sigma Aldrich (U.S.A.) and Alexa Fluor 488 goat anti-rabbit IgG from Invitrogen (U.S.A.).

B. Substrates preparation for lithography

As described in a previous work [10], glass slides were cleaned in pirana solution. The photoresist was spin coated and then backed (soft baking) in oven.

C. Standard lithography (macrometric structures)

The traditional photolithographic techniques involve a photomask. The mask was lightened with UV light (Hitachi

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2076–2078, 2009
www.springerlink.com

F8T5 8W) for 20 s and the pattern on the mask was transferred to the photoresist.

The exposed photoresist was removed by immersion in the developer for 60 s. Structures of 500 μm or more were produced.

After the development, the samples was dried and then lightened with UV light for 15 s with no mask.

D. Maskless lithography (micrometric structures)

The glass slides covered with photoresist were exposed to a laser at 514.5 nm (green light), through a Raman Microprobe (Renishaw Invia, Wotton under Edge, UK) in the backscattered configuration equipped with an optical microscope (Leica DM/LM). The process is described in [10].

Holes of 1 μm were obtained, as reported in Fig. 1. After the development, the samples was illuminated with UV light for 15 s with no mask.

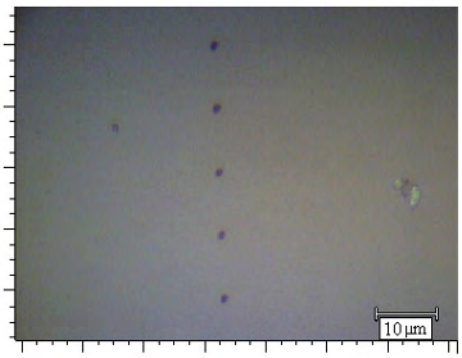

Fig. 1: Optical micrographs of holes of 1 μm in positive photoresist produced with the Raman microprobe. The picture was acquired with Laica DM/LM microscope with the objective 50x Leica N Plan.

E. Fibronectin deposition

Fibronectin (concentration of 1 mg/ml) was then deposited on the substrates and dried for 15 minutes in a laminar flow hood.

The samples were washed in the developer for 10 s in order to remove the remaining, exposed photoresist. After this step, the sample was ready for the test with the double antibodies complex or for the cell adhesion.

F. Fluorescent marker and micrograph

Anti-fibronectin antibody (1:100 diluted in PBS) was deposited for 30 minutes and then the substrate was rinsed in PBS.

The same process was performed for the second antibody, fluorescent antibody Alexa Fluor 488 anti-rabbit (1:100 diluted in PBS).

After this final steps the pattern was ready for the examination with a fluorescent microscope Nikon Eclipse E800 with 20x and 40x Nikon Plan objectives.

III. Results and Discussion

The result of the fibronectin pattern is reported in Fig.2 for the macrometric scale and in Fig. 3 for the micrometric scale.

Fig. 2 shows fluorescent micrograph of a macrometric fibronectin pattern on a glass slide with the double antibodies complex. The resolution of the lithography is good, although the distribution of the fibronectin is not constant on all the exposed surface.

Better results are obtained with a lower concentration of fibronectin (20 μg/ml), but only for cell deposition. In this case, the fibronectin density is more constant, but not enough for obtaining good signals from the fluorescent excitation of the antibody's fluorophores.

Fig. 3 shows a micrometric protein pattern. As in the case of the traditional lithography (macrometric structures), the distribution of the fibronectin is not constant all along the spots. Some filaments are present, but a line of protein spot is clearly visible.

Fluorescent spot of 3 μm are showed; the holes in the photoresist were 2 μm.

Fig. 3 is only an example of the possible micrometric geometries, that can be produces with maskless lithography. Arrays of protein spots are also obtained.

A test of the quality of the processed fibronectin is showed in Fig. 4. HUVEC cells are deposited on the patterned glass substrates and stained with Fast DiI (Invitrogen, U.S.A.).

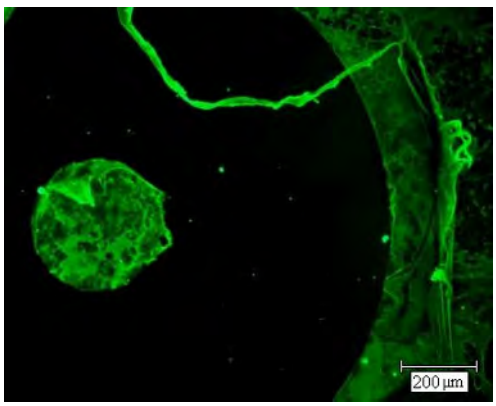

Fig. 2: Fluorescent micrographs of macrometric (0.5 mm) pattern of fibronectin on glass slides. The picture is realized with a double fluorescent antibodies complex with Nikon Eclipse E800 microscope with 20x Nikon Plan objective.

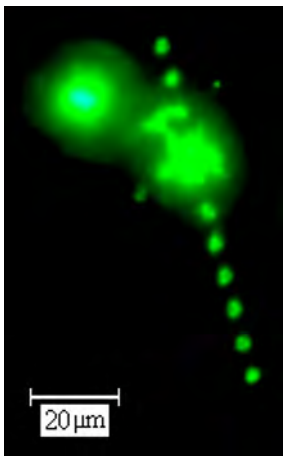

Fig. 3: Spots of 3 µm of fibronectin on glass slides.
The picture is realized with a double fluorescent antibodies complex.

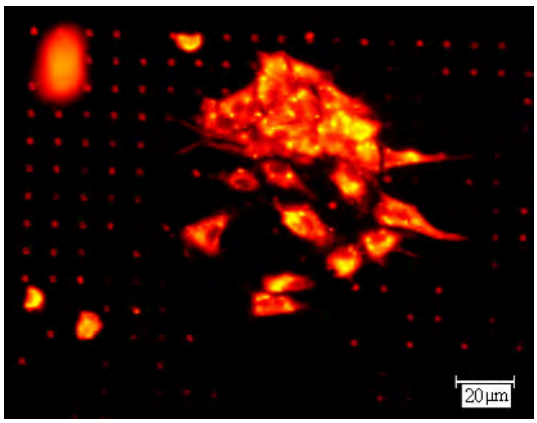

Fig. 4: Fluorescent micrographs of fibronectin pattern with HUVEC cells.
They anchor preferably on the proteins spots and assume
a geometric shape due to the array lattice constant.

Fibronectin is autofluorescent. This characteristic can be very useful for optical characterisation. In Fig. 4 proteins are not stained. In the pictures is evident how cells anchor preferably on the proteins spots and assume a geometric shape due to the array lattice constant.

The results here presented are performed on glass slides. Preliminary studies indicate that the same process can be applied to different materials, such us silicon, gold and silicon nitride, although, during preliminary tests, the last one gave the worst results.

IV. Conclusions

The resistance of fibronectin to the photolithographic process is demonstrated.

The lithographic development step is most critical step of the process. The protein is washed with a solution with high pH. Fluorescent micrographs and cells adhesion demonstrate that fibronectin is still functional. This aspect open a wide range of application for this technology.

Future developments involve non-flat surface, for example on micro electro-mechanical system (MEMS).

Preliminary studies demonstrate that fibronectin can be the right extracellular matrix protein to be pattern MEMS materials. This kind of devices presents the right dimensions for studying mechanical properties of cell, but it is very difficult to control the localization of the adhesions points. Patterning protein on selected areas can increase the performance and the accuracy of these devices.

Parametric Model of Human Cerebral Aneurysms

Hasballah Zakaria[1] and Tati L.R. Mengko[1]

[1] School of Electrical Engineering and Informatics, Bandung Institute of Technology, Indonesia

Abstract — **The goal of this work was to create a more realistic idealized model of human cerebral aneurysms that captures all features common to arterial bifurcations and can accurately reproduce patient specific geometries. This idealized model can then be used both for parametric studies in representative cerebral aneurysm as well as for computationally efficient studies of cerebral aneurysm in specific patients.**

The model was extended from our previous work on parametric model of arterial bifurcations by adding the aneurysm geometry to the apex of bifurcation where it is most likely to occur. The true 'reference' geometry was reconstructed from CT medical images of two patients that had been diagnosed with cerebral aneurysm. The idealized model can be viewed as of the joining of two daughter vessels and a shape of an aneurysm at its apex point. The idealized model was generated via Solidworks (SolidWorks Co.).

The ability of the idealized model to 'accurately' reproduce the geometry of a real human cerebral aneurysm was evaluated using a point wise geometric error, defined as the distance between the true and idealized model divided by the parent diameter. The maximum geometric error was less than 17.5% while the average geometric error was less than 5.8%. The distribution of WSS, wall pressure and the flow structures was qualitatively similar.

Keywords — **Parametric Model, Cerebral Aneurysm, CFD.**

I. Introduction

It is well established that the maintenance and health of the arterial wall is strongly affected by hemodynamics, and hence by the geometry of the surrounding vasculature [1, 2, 3]. 3D reconstructions of arterial segments are valuable for studies of vascular disease due to their intrinsic relevance. However, it is not possible to use them to systematically vary geometric features for parametric studies [4]. In addition, fundamental geometric features such as bifurcation angle and non-planarity are difficult to define in these reconstructions. Idealized vascular models are inherently suited for parametric studies, but they are limited by their tendency to oversimplify the geometry of real vessels. In this work, this limitation of idealized models is addressed through a new parametric arterial model.

In previous work, a hierarchy of three parametric bifurcation models was introduced [5]. The models are relatively simple, yet capture all geometric features identified as common to cerebral bifurcations in the complex transition from parent to daughter branches. In this work we extended the bifurcation model to include aneurysm shape at the apex of the bifurcation where it is more likely to occur.

II. Materials and methods

A. Parametric Models

Parametric models can be view as bifurcation model explained in detail in our previous work [5] and additional aneurysm shape at the apex of the bifurcation. To model the aneurysm shape two cross sections were extracted from the real model: neck cross section and mid cross section. The neck cross section was extracted from the base of the aneurysm where it joined with the bifurcation arteries while the mid cross section represented the largest longitudinal cross section of the aneurysm shape.

Seven Cross Sections Parametric Model

The seven cross sections parametric model included five cross sections from the bifurcation model as defined in our previous work and additional two cross sections, the neck cross section and the mid cross section, extracted from aneurysm shape. In addition to these seven cross sections the height of the aneurysm defined as the distance from the base to the top dome of the aneurysm was also needed. The two intermediate cross section was not clearly defined since these cross section affected by the aneurysm shape. To resolve this problem we use approximation to the cross section base on parent and two daughter branches cross section as follows:

$$D_3 = \sqrt{2}D_0D_1 \Big/ \left(\sqrt{D_1^2+D_2^2}\right) \; ; \; D_4 = \sqrt{2}D_0D_2 \Big/ \left(\sqrt{D_1^2+D_2^2}\right) \quad (1)$$

Twelve Parameters Parametric Model

The twelve parameters parametric model included seven parameters from the bifurcation model as defined in our previous work and additional five parameters that defined the aneurysm shape. The seven parameters for the bifurcation model were diameter of parent cross section D_0, diameter of two daughter branches D_1 and D_2, bifurcation angles

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2079–2082, 2009
www.springerlink.com

α_1 and α_2, non planar angle β and the round radius of curvature R. Additional five parameters for the aneurysm shape were the neck diameter N, the aneurysm diameter D_5, the height of the aneurysm H, aneurysm angle α_3 and non planar angle of the aneurysm β_1. The angle α_3 and β_1 follow the definition of α, β for the bifurcation arteries.

B. Creation of Reference Geometric Model

Two reference models of human saccular cerebral bifurcations were reconstructed from CT serial images of the two patients that had been detected with aneurysms. The two reference models included one ACom aneurysm and one basilar aneurysm (see Fig. 1).

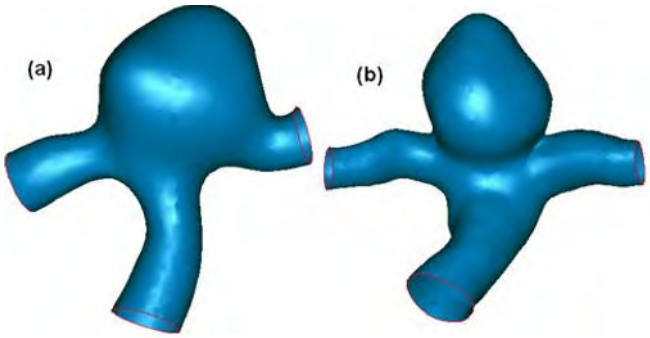

Fig. 1 Reference Geometric Model.
(a) ACom aneurysm. (b) Basilar aneurysm.

C. Development of Parametric Model

The idealized model was generated via Solidworks (SolidWorks Co.). Three protrusion objects were used to model the left, the right and half of the aneurysm sections using the centerline curve as the trajectory and the cross sections. An ellipsoid shape was used to model the dome of the aneurysm. A round was then applied at the sharp joint of the bifurcation and the aneurysm.

Seven Cross Sections Parametric Model

Cross sectional data was extracted from the reference model, five from bifurcation geometry and two from the aneurysm geometry. The cross section data was then replaced by centroid, normal, and equivalent diameter where $D_{eq} = \sqrt{4A/\pi}$ except for the intermediate cross sections. The intermediate cross section diameters were approximated using equation (1). The bifurcation geometry reconstructed using the five cross sections data then the aneurysm shape was added to this bifurcation geometry.

Twelve Parameters Parametric Model

The diameters of cross sections were approximated by their equivalent. All angles were measured from the normals of the cross section relative to the direction of parent artery. The angle definitions defined in our previous work [5]. The bifurcation geometry was developed using seven parameters using the method described in our previous work then the aneurysm shape was added to this bifurcation geometry.

D. Hemodynamic Modeling

Flow simulations in both the parametric and reference geometries were based on the numerical approximation of the 3D Navier–Stokes equations. A flow-condition based-interpolation (FCBI) finite element procedure was used [8]. The finite element method was implemented using ADINA software (ADINA Inc.). The blood viscosity and density were specified as μ = 0.0035 Pa s and ρ = 1050 kg/m^3, respectively. The blood was modeled as incompressible and Newtonian.

At the rigid vessel wall, the velocity was prescribed to be zero. To diminish entrance and exit effects, a cylindrical section of length three times the parent or daughter branches diameter was attached to the inlet and outlets of each bifurcation. At the extended inlet, a parabolic velocity profile was specified with average velocity V chosen to attain a Reynolds number, (Re = $\rho V D/\mu$), of 400, a value characteristic of flow in cerebral vessels. Zero traction boundary condition was used on the outlets.

Mesh density studies supported a finite element mesh of approximately 35,000 hybrid elements each aneurysm models to give enough accuracy for this study.

III. Results

A. Development of Parametric Models

The geometric parameters for each of the two models were extracted from the arterial surface of the two reference geometries and used to generate the models using the methodology outlined in previous section.

B. Comparison of Geometric Features

The ability of the parametric model to reproduce the geometry of a real cerebral bifurcation was quantified using a point wise geometric error function, defined as the shortest distance between the reference and parametric model, normalized by the parent diameter. Fig. 2 showed the contour of geometric error.

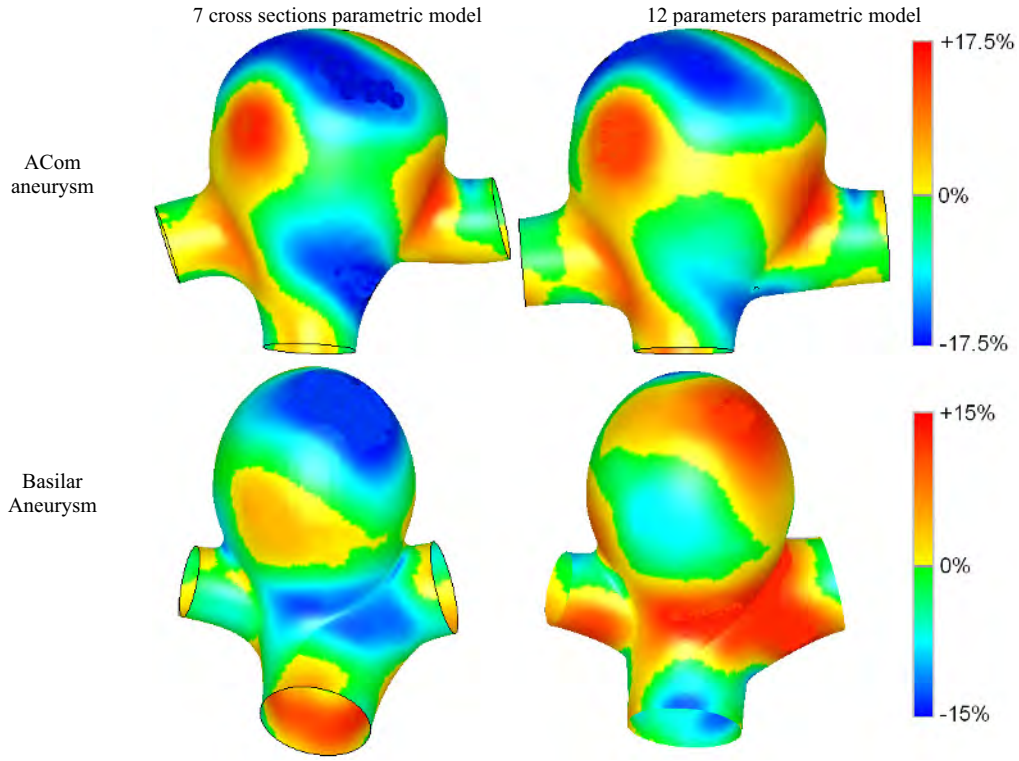

Fig. 2 Nondimensional geometric error for the parametric models, defined as the distance between the parametric and reference bifurcations, divided by the diameter of the parent branch.

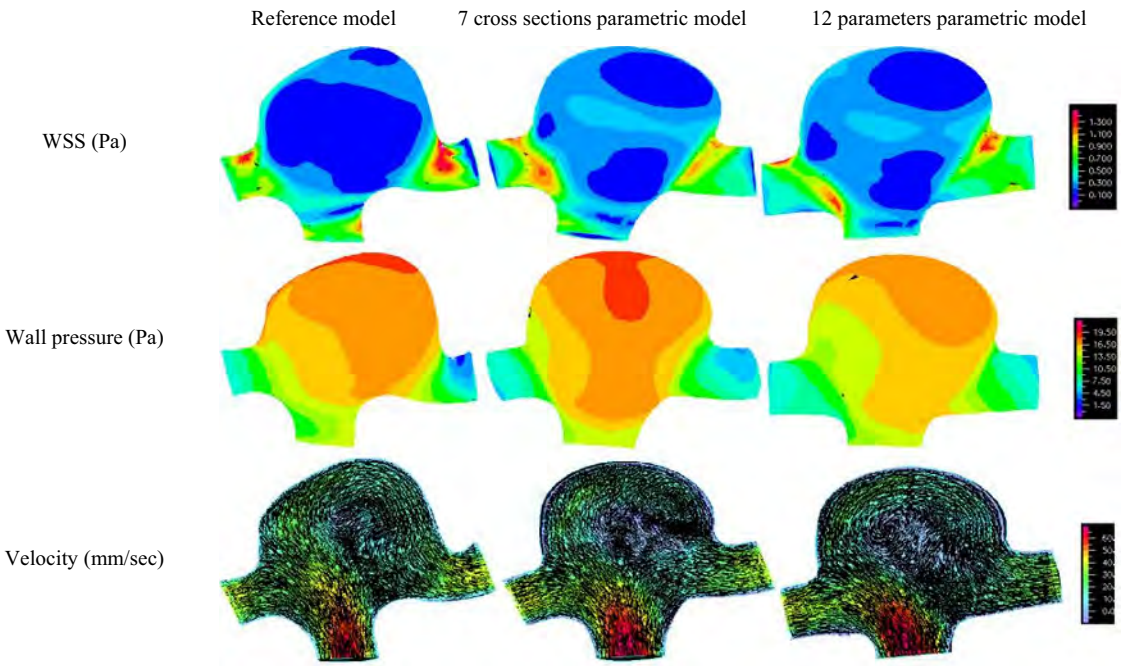

Fig. 3 Contours of wall shear stress (WSS), wall pressure and the flow structures (velocity vectors) for the reference and each of the corresponding parametric ACom aneurysm models.

The geometric error of the parametric models was relatively low. The average of the point wise geometric error for ACom and Basilar aneurysms was less then 5.8% and 4.2%, respectively, for all models. The maximum point wise geometric error for ACom and Basilar aneurysms was less than 17.5% and 15%, respectively, for all models.

C. Comparison of Hemodynamics

Figures 3 showed contour plots of the wall shear stress, wall pressure and flow structures (velocity vectors) for ACom aneurysm for flow at a Reynolds number of 400.

The distribution of WSS and wall pressure as well as the flow structures were qualitatively similar for two parametric models and the reference geometry.

Table 1 showed the quantitative comparison of WSS and wall pressure. The maximum WSS and wall pressure difference was 31.2% and 18.3%, respectively.

Table 1 Quantitave differences of hemodynamics features

Aneurysm	Model	WSS (Pa)		Wall pressure (Pa)	
		Mag	% diff	Mag	% diff
Acom aneurysm	Reference	2.109		19.830	
	7 cross section	1.451	-31.2%	19.900	0.4%
	12 paramaters	1.715	-18.7%	19.200	-3.2%
Basilar aneurysm	Reference	3.061		22.790	
	7 cross section	2.411	-21.2%	26.390	15.8%
	12 paramaters	2.188	-28.5%	26.970	18.3%

IV. Discussions

Methodology to develop parametric model has been introduced. We proposed two methods, seven cross sections and twelve parameters parametric model. Using parametric model we can vary the parameters to get different aneurysm geometry. These different models then can be analyzed to get the most critical model prone to rupture.

To reduce the parameter, the cross section approximated by circular shape. This circular shape can be changed to other shape, i.e. ellipse, to improve its accuracy to mimic the original cross section.

In general, the common WSS characteristic were maximum near the neck, very low inside the dome and normal in the artery. Wall pressure elevated inside the dome and at the impact zone but this elevated pressure was quite small compare to the transmural pressure [3, 7, 8, 9]. These features also showed in this study (Fig. 3). All parametric models also showed similar WSS and wall pressure distribution although the magnitude differences were high.

The flow structures inside the aneurysm generally consist of one circulation for model with low aspect ratio (H/N < 1.6) and possible secondary circulation for model with high aspect ratio [7, 10]. Two aneurysm models in our study both have low aspect ratio (0.71 and 0.92). We also observed one circulation in all models of our study.

Computational Simulation of Three-dimensional Tumor Geometry during Radiotherapy

S. Takao[1], S. Tadano[1], H. Taguchi[2] and H. Shirato[2]

[1] Division of Human Mechanical Systems and Design, Graduate School of Engineering, Hokkaido University, Sapporo, Japan
[2] Department of Radiology, Graduate School of Medicine, Hokkaido University, Sapporo, Japan

Abstract — **In Radiotherapy, shapes of tumors are important information to determine irradiation area and energy. In this study a simulation method is proposed to calculate changes of tumor geometry during radiotherapy. Relationships between tumor geometry and the amount of radiation energy were estimated from fundamental equations in solid mechanics as a mechanical analogy. Parameters between the radiotherapeutic effect and the geometric factor were defined as reduction resistance and reduction ratio. The values of these parameters were initially determined based on a widely-used radiobiological model (Linear-Quadratic model) and then revised by comparing with the change of actual tumor shape. To simulate uneven tumor shrinkage, the values of reduction resistance were varied depending on the tumor heterogeneity. Finite element models of tumors were constructed from CT images taken before the start of radiotherapy. For precise assessment of therapeutic effect, it would be useful to examine tumor morphological features. Three-dimensional (3D) tumor shape was represented in two-dimensional (2D) map like a global map. Distances from origin (center of gravity of the tumor) to surface were visually indicated by colors in this map. Tumor volumes were indicated by sizes of the maps. Tumors in head and neck were analyzed in this study. Simulation results of tumor geometries were compared with actual tumor geometries and found to have similar tendencies. The 2D color maps enabled to evaluate the 3D morphological features of the tumors. Therefore this study provides the methodology to evaluate changes of 3D tumor geometry during radiotherapy.**

Keywords — **Radiotherapy, Tumor geometry, Mechanical analogy, Finite element analysis**

I. Introduction

Radiotherapy is a common treatment for cancer patients along with surgical treatment and chemotherapy. In radiotherapy, ionizing radiation such as X-rays or electron beams damages DNA in cancer cells and kills the cells. However, as surrounding normal cells also contain DNA, excessive irradiation to normal tissue may cause radiation injury as a side effect. Therefore it is important to concentrate radiation energy (dose) on tumor region. Recent advances in high-precision radiotherapy enable to focus a higher dose to the tumor region while minimizing unwanted radiation exposure to normal tissue. Intensity-Modulated Radiation Therapy (IMRT) varies intensities and profiles of beams from various directions to fit the tumor size and shape. However, as the tumor moves or shrinks during radiotherapy, the surrounding normal tissue may become included in the high-dose region [1]. Therefore, if we can predict three-dimensional (3D) tumor geometry during radiotherapy, this information would be useful for determining the optimal radiation field and dose in IMRT.

Prediction of tumor growth and shrinkage has long been an important subject for radiation biologists. Recently, tumor growth and response to radiotherapy have become subjects for computer scientists to translate the cell biology into human tumors [2, 3]. These models based on cell biology are attractive in nature but seem difficult to calculate tumor geometry and apply in 3D treatment planning.

In the present study, we proposed a novel simulation method to calculate changes of tumor geometries during radiotherapy. This method considered the tumor a solid body. The relationships between radiation dose and geometric change of the tumor were estimated from fundamental equations in solid mechanics using mechanical analogy. Computer simulation to calculate the therapeutic response was carried out using finite element analysis (FEA) software.

II. Simulation Method

A. Fundamental relationships in radiotherapy

Cancer cells are killed and removed by radiation exposure during radiotherapy. It causes not just volumetric but geometric changes in tumor (Fig. 1). In this method, the change of tumor geometry is related to a deformation of a solid body using mechanical analogy [4]. The amount of exposure dose X can be related to the magnitude of a surface force T, the amount of absorbed dose D to the magnitude of the stress σ, the cell mortality fraction M to the strain ε, and tumor displacement R to the displacement u. With these correspondences, the change of tumor geometry can be described by following equations by analogy with fundamental equations in solid mechanics.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2083–2087, 2009
www.springerlink.com

The relationship between D and M is expressed in tensor notation as

$$dM_{ij} = C_{ijkl} dD_{kl} \tag{1}$$

where C_{ijkl} is a parameter which determines radiosensitivity. Components of C_{ijkl} are represented by two parameters; reduction resistance E and reduction ratio v. The parameter E prescribes tumor radiosensitivity and are determined based on a radiobiological model (Linear-Quadratic model; LQ model). According to the LQ model, a cell mortality fraction M after exposure to an absorbed dose D is given by,

$$M = 1 - \exp(-\alpha D - \beta D^2) \tag{2}$$

where α and β are parameters of radiosensitivity [5]. The parameter v represents interpatient variation of radiosensitivity.
D must satisfy the following equation

$$\frac{\partial(D_{ij})}{\partial x_j} = 0 \tag{3}$$

The relationship between M and R is defined as follows

$$dM_{ij} = \frac{1}{2}\left[\frac{\partial(dR_i)}{\partial x_j} + \frac{\partial(dR_j)}{\partial x_i}\right] \tag{4}$$

The boundary condition which prescribes the amount of radiation dose transmitted through the tumor surface is given by

$$d\overline{X}_i = dD_{ij} n_j \tag{5}$$

The geometric boundary condition is given by

$$d\overline{R}_i = dR_i \tag{6}$$

From these equations, the change of tumor geometry can be calculated numerically using such as finite element method.

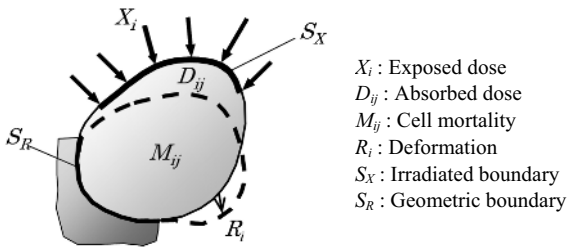

Fig. 1 Change of tumor geometry in radiotherapy

B. Tumor heterogeneity

Tumor shows internal heterogeneity of radiosensitivity, and it may result in uneven tumor shrinkage, i.e. change of tumor geometry. However, it is difficult to measure the distribution of tumor radiosensitivity. In this study, intratumoral distribution of radiosensitivity is estimated from the degree of tumor shrinkage in the early stage of treatment. The site where tumor radius decreases greatly is considered to be more radiosensitive, and the site where tumor radius does not decrease significantly is more radioresistant. As radiosensitivity is represented by parameter E in this model, heterogeneity of radiosensitivity can be expressed by the distribution of the values of E.

C. Evaluation of tumor geometry

To describe 3D tumor geometry quantitatively, spherical coordinate system O-$R\theta\varphi$ whose origin is at the center of gravity of the tumor is introduced. θ represents azimuthal angle ($-180° \le \theta \le 180°$) and $\theta = 0°$ is anterior direction. Positive rotation angle is counterclockwise around the origin. φ represents polar angle ($-90° \le \varphi \le 90°$) and $\varphi = 0°$ is horizontal plane. Distance from the origin to tumor surface at (θ,φ) is expressed by $R(\theta,\varphi)$. Three-dimensional tumor geometry can be evaluated with the values of $R(\theta,\varphi)$. It also enables to compare calculated and actual tumor geometries. Moreover, for visual understanding of 3D geometry, two-dimensional (2D) color map like a global map is introduced (Fig. 2). In this map, values of tumor radius $R(\theta,\varphi)$ are represented by color and plotted on θ-φ plane. For example, red indicates that the radius is large and blue is small. Sizes of each map represent their projected volumes.

III. Simulation of Head and Neck Cancer

A. Clinical cases

This simulation method was applied to two cases of head and neck tumor (tumor A and B) treated in Hokkaido university hospital. Initial volumes of each tumor were 3.5 and 55.1 cm^3, respectively. Both patients were treated with IMRT and administered 2.0 Gy per fraction to a total dose of 66 Gy (tumor A) or 70 Gy (tumor B). Overall treatment time was about seven weeks. The patients were treated with radiotherapy only, i.e., with neither chemotherapy nor surgery.

B. Finite element modeling of tumor

Finite element models of tumors were constructed based on the tumor contours defined by a radiation oncologist on CT images. A group of sequential cross-section contours was loaded into biomedical imaging software (Analyze PC 7.0, Mayo Foundation, Rochester, MN) and interpolated to 1 mm intervals. From these images, 3D surface models of the tumors were constructed and saved in DXF format. The DXF files are converted into IGES files with the help of the 3D CAD software (Mechanical Desktop 4, Autodesk, San Rafael, CA). Finally, the IGES files were imported into the FEA software (ANSYS 11.0, ANSYS, Canonsburg, PA), and then the 3D FE models of the tumors were constructed. The element was a 10-node tetrahedral type.

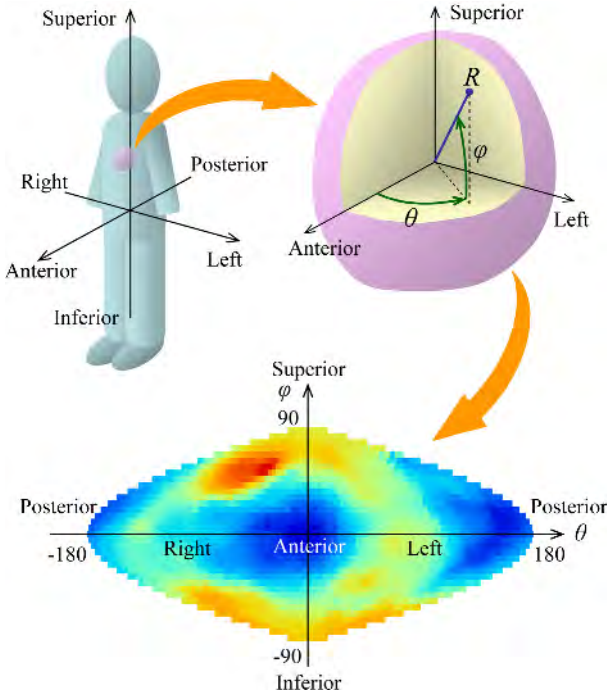

Fig. 2 Representation of tumor geometry in 2D color map

C. Simulation procedure

The method requires to determine values of four parameters; α, β E, and v. The parameters α and β in the LQ model describe radiosensitivity, and were all set as $\alpha = 0.1$ and $\beta = 0.01$ ($\alpha/\beta = 10$) for tumors as early-responding tissue [6]. The value of parameter v was adjusted for each case so that discrepancies between calculated and actual tumor volume were minimized. If the calculated volume was less than the actual tumor volume, the value of v was incremented and then the tumor volume was recalculated. This iterative calculation process was continued till the difference between the calculated and actual tumor volumes reached a minimum. After that, distribution of parameter E was determined through an iteration process in order to minimize discrepancies between calculated and actual tumor geometries. The value of parameter E of the element at (θ,φ) was determined as follows;

$$E(\theta_i,\phi_j)^{n+1} = \frac{R(\theta,\phi)_T}{R(\theta,\phi)_S^n} E(\theta,\phi)^n \tag{7}$$

where superscript indicates the number of iterations, subscript S and T for simulation and actual tumor, respectively. These calculations were performed using finite element analysis software.

IV. Results and Discussion

This study aimed to establish a computational simulation method to express changes of tumor geometry during radiotherapy. Simulation parameters were determined based on the changes of tumor geometry in the early stage of the treatment. Using these parameters, tumor geometries in the latter half of the treatment period were calculated sequentially. Figure 3 shows 3D exterior view of tumor A at the end of the treatment. Figure 4 indicates comparisons of tumor geometries calculated using our method with actual tumor geometries. Two-dimensional color map provides visual understandings of 3D tumor geometry. Simulation could represent tendencies of tumor geometrical changes in the first 18 days. Calculation to predict tumor geometries in the rest of the treatment was performed subsequently. The

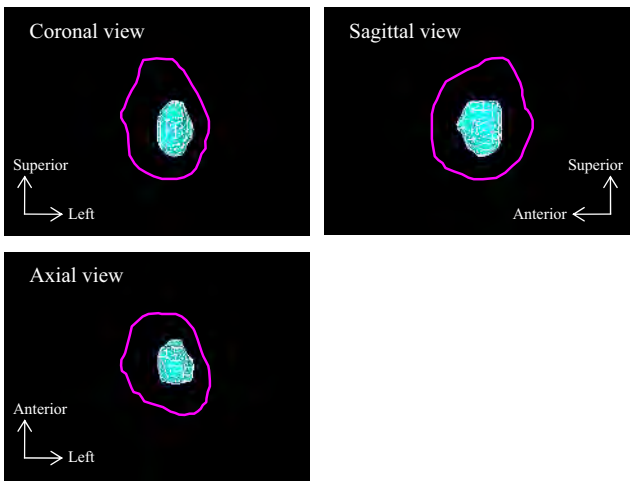

Fig. 3 Exterior view of a tumor at the end of treatment. Line profile indicates tumor geometry before start of treatment

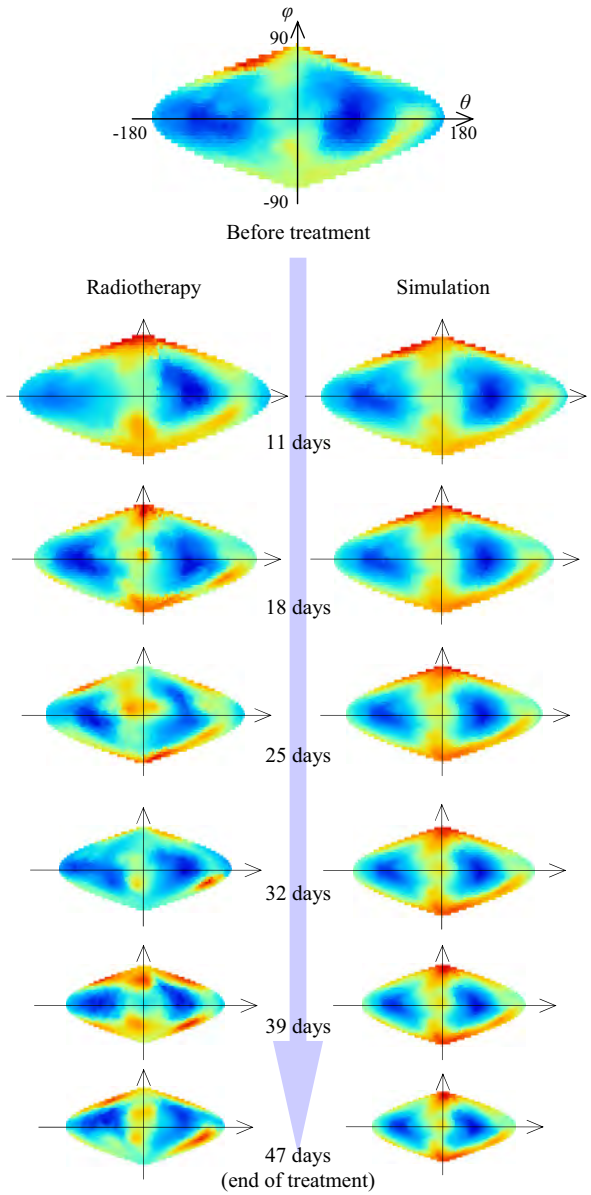

Fig. 4 Comparison of tumor geometries calculated in this method with actual tumor geometries using 2D color map

calculated tumor geometry at the end of the treatment was found to conform to actual tumor geometry. The discrepancy between calculated and actual tumor geometry could be quantitatively evaluated by tumor radius $R(\theta,\varphi)$. The discrepancies between calculated and actual tumor radius (calculated tumor radius - actual tumor radius) at the end of the treatment were 0.61 mm (maximum), -1.53 mm (minimum), and 0.58 mm (average absolute value) for tumor A, 3.08 mm (maximum), -6.23 mm (minimum), and 2.24 mm (average absolute value) for tumor B, respectively, while average of actual tumor radius was 5.31 mm for tumor A, and 13.2 mm for tumor B, respectively.

These calculations were performed on the assumption that tumors were irradiated evenly. Although dose distribution in IMRT is considered to be uniform to a certain extent, actual dose distribution should be taken into consideration for more precise calculation.

Calculated tumor geometries in the latter half of the treatment strongly depended on tumor geometries in the early stage of the treatment, because values of parameter E were determined only from early tumor geometries. Our present method can not handle the cases that tumor geometry changes drastically during treatment. We should investigate factors affecting tumor radiosensitivity e.g. angiogenesis, hypoxia, or cell cycle, and appropriately determine the values of parameter E considering these factors.

V. Conclusion

This study proposed a novel simulation method to calculate changes of tumor geometries during radiotherapy. Although some difficulties still remain to be solved, tumor geometries could be calculated using our approach.

Finite Element Modeling of Thoracolumnar Spine for Investigation of TB in Spine

D. Davidson Jebaseelan[1], C. Jebaraj[2], S. Rajasekaran[3]

[1] Research Scholar, AU-FRG ICC, Anna University, Chennai, India
[2] Professor and Chairman, Faculty of Mechanical Engg, Anna University, Chennai, India
[3] Director and Head, Department of Orthopaedics and Spine Surgery, Ganga Hospitals Pvt. Ltd. Coimbatore, India

Abstract — **The current study develops a finite element model of a thoracolumnar-spine for numerical investigation of spine degraded by spinal tuberculosis. With computational capability to be used in a optimal manner, a simplified model with vertebral bodies, intervertebral-disc, ligament and musculature structures are developed. The geometry of the spinal units were extracted from CT-Scan data using existing image processing codes from T1toS1, a total of 17 levels. The polylines generated is imported as IGES to CAD-software Ideas11NXseries. 3D points were generated on the polylines in the locations of vertebral bodies, intervertebral-disc, posterior segments, and facet joints with their appropriate orientation and were connected using spline curves. Appropriate section for the various segments is built from the polylines and assigned to vertebral bodies, intervertebral-disc, and posterior processes that were then modeled with beam elements. The seven major ligaments of spine were modeled using link elements with appropriate crossectional area and non linear properties. The MMRotatores muscle that runs along transverse processes is modeled using link element with appropriate material and geometry data. The necessary boundary conditions were assigned solved using Ansys 10. The validation of the model is done using experimental results available in the literature. The Spine TB is characterized by destruction of spinal-bodies depending on the progress and its stage. The disruption finite element model illustrates the snaping of the vertebral column phenomena observed clinically**

Keywords — **Finte element method, spine mechanics, tuberculosis, spine collapse.**

I. Introduction

Finite element modeling of spine along with all components are increasingly being used to understand its behaviour in intact condition, deformity due to spine diseases, subsequent surgical interventions and the following prostheses development[5].

There has been lot of finite element studies on numerically analyzing the behaviour of spine when its affected by spinal diseases leading to deformities. Patients with rheumatoid atlantoaxial dislocation often have latent buckling because of misalignment of the cervical spine, and biomechanically unstable [4].

Spondylolysis increases disc stresses at the area it is affected as well as cranial adjacent level, and leading to increase in stresses and angular displacement at the affected caudal level, when compared to the cranial level.[6]

Osteoporosis, one of the frequent disorders of the vertebra. Studies by Annie Polikiet [1] by degrading the material property to five models. The authors suggest that an increasing degree of anisotropy might be representative of a progressing osteoporosis as shown by the increase in principal strain in the various models.

Studies done on transcortical tumors[3], by modeling tumor volumes as isotropic hyperelastic with Mooney-Rivlin strain energy and permeability showed decreased load induced canal narrowing.

Progressive deformity manifests as an increase either in angular kyphosis or by a buckling collapse[8]. Mechanical instability results in deformation of the vertebral bodies and ribs. The eventual magnitude of an idiopathic scoliotic curve is seen to vary and is unpredictable and there has been many studies to investigate the reasons for the progression of this scoliotic deformity.

Buckling behaviour is caused due to the instability caused due to progressive disruptive lesions in the posterior part of the spine[2][8], thus when the posterior wall of an vertebra is destroyed there is potential for retropulsion of bone into the spinal canal [3].

A review of buckling issues found that using simplied FE modeling by beam and link elements, with the former being used to represent the vertebral body, disc and posterior components and the latter for ligaments and muscles shows good results[9].

The review of literature found that spine collapse due to spinal tuberculosis has shown that clinal perspective of the disease has been done extensively. But apart from S.Rajasekaran[8] and hand full of researches the biomechanical reasons behind the collapse still needs to be explored. And to study the mechanism of collapse finite element modeling could be a good tool for studying the spine behaviour due to spinal tuberculosis which has not been attempted to the knowledge of the authors. Vertebral tuberculosis is the most common form of skeletal tuberculosis, constituting about 50% of all cases of skeletal tuberculosis The disease progresses until there is gross destruction of the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2088–2091, 2009
www.springerlink.com

bones and joints with deformity, subluxation, contractures, and abscess formation. The spine with tuberculosis is also unstable when facets and posterior complex are destroyed along with vertebral bodies[8]. However, the pattern of collapse of the spine leading to severe deformities and the factors influencing the collapse were not analyzed[8].

The objective of the current work is to develop the methodology for a validated simplified non linear finite element model of spine from S1 to T12 a total of 17 levels and makes an effort to model one case of disruption due to spine tuberculosis. The preliminary results of this efforts are discussed in this article.

II. Methodology

The line geometry was generated from a serial CT-scan data of 1mm thick of S1-T1, 17 levels in all from a middle aged male. The CT data had an existing curvature deformity in the lumbar. As the current work is essentially to develop the methodology to develop a non linear simplified numerical model, the deformity was accepted and was taken into account during the validation process as well.

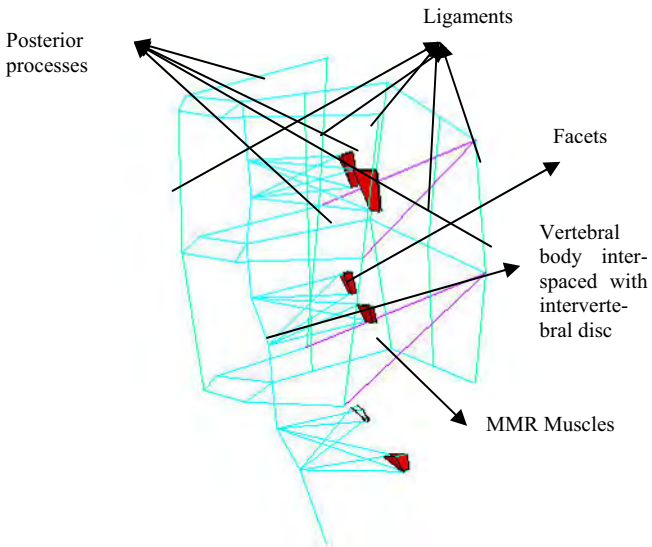

Fig. 1 CAD model of a spine FSU depicting the spine com ponents used in the model

The polylines output from the image modeler, was imported as IGES to the CAD-software Ideas11NXseries. The serial polylines of the vertebral bodies were smoothened and appropriate surfaces where created. 3D points are generated on the polylines and the surfaces in the locations of vertebral bodies, intervertebral-disc, posterior segments, and facet joints along with their appropriate orientation as per the literature. The 3D points were connnected using spline curves from S1 to T17 connecting the vertebral bodies interspaced by in the intervertebral disc. The posterior components including the transverse processes, articulating processes, laminae are connected from appropriate points using splines (Fig 1).

Appropriate sections for the various segments in the vertebral body is built from the polylines and assigned to vertebral bodies, intervertebral-disc, and posterior processes. The initial line mesh along with their sectional properties is carried out using Ideas 11. The elements and nodes thus generated was was solved using Ansys 10.0 Finite element software along with appropriate element, property assignment and the post processing using the same Finite element code

A. Finite element Model

The work of Van der Plaats et al [9]was taken as base for the current work of developing the simplified model. As mentioned by them the following components of the motion segment was considered: Vertebral body, the intervertebral disc, facet joints, the seven spinal ligaments, MM Rotatores spinal musculature and the posterior structures including the transverse processes, articulating processes and laminae. Beam elements along with the sectional properties were assigned to the vertebral bodies, intervertebral disc, and the posterior structures. The facet joints were modeled using Shell and contact joints. The vertebral body and posterior components were assigned a modulus of 12100 N/mm^2[1] and the disc with 7 N/mm^2[9]. The cancellous bone and different intervertebral components nuclues pulposus, fibres and annulus fibrosis are not accounted for in this model.

The seven spine ligaments were modeled as tension only link elements. The pre-strained conditions and cross section of the ligaments and muscles were adopted from Van der Plaats et al.,[9] was used in this current work(Table1). The MM Rotatores spine muscle was modeled as link elements and the insertion points as per the literature,the transverse processes of the lower vertebra were connected to the spinous process of the upper vertebra The model (Fig 2) was planned to study the disruptions caused by the lesions of spinal tuberculosis. As predominantly buckling behaviour was to be studied the work of *Lucas and Bresler*[7] was used to validate the current work. The first condition considered for validating, the spine was situated in a vertical position with the sacrum fixed and a lateral load of 30 N was applied to the base point of Tl. The frontal plane rotations obtained by the model are compared to the experimental results of Lucas and Bresler[7]. In the second condition the stability of the column was examined by incrementally

applying compressive loads until the onset of significant lateral deflections.

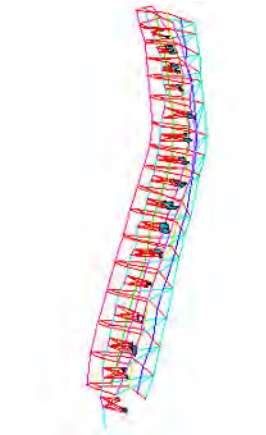

Fig. 2 The simplified Finite element model from S1 to T1

To prevent buckling in the sagittal plane antero posterior bending was restrained at the midthoracic and midlumbar levels by preventing motion in the horizontal direction and the horizontal translation and axial rotation constrained of the coordinates of T 1 which corresponds to the experimental set-up of Lucas and Bresler[7]. The buckling load is to be compared with the experimental results.

Table 1 Material Properties and Cross section of the the ligaments and Muscles[9]

Ligament/muscle	Youngs modulus (N/mm2)	Cross-sectional area(mm2)
ALL	8	50
PLL	8	25
CL	8	20
TL	5	10
LF	24	30
ISL	5	26
SSL	5	26
MMR	25	10

III. Results and Discussion

The model validation carried out as done by Lucas and Bresler[7], the first researchers to determine experimentally the buckling loads of the ligamentous thoracolumbar spine for the first condition with a lateral load of 30N and under complete restriction at the S1 level showed that the frontal rotations at each levels were in agreement in certain levels and had variation in other levels. The basic difference between the experimental work of Lucas and Bresler to the current work is the inclusion of the initial strain of the ligaments and muscles. Also the MM Rotatores muscle has been included for the current analysis. Moreover as mentioned previously the initial deformity in the CT data in the lumbar did prominently be seen from the displacement in the graph shown in Fig 3. But the trend shown by the experimental work can be seen here.

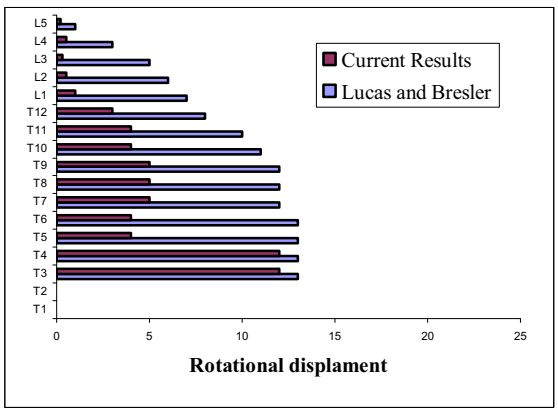

Fig. 3 Rotational Displacent from S1 to T1 levels

In the second validation of carrying out buckling analysis under the conditions explained below the buckling load was found to be 140N against the experimental value of 170N of Lucas and Bresler[7]. Inspite of the buckling loads being comparable, the variation can be attributed to the material properties of the ligaments used initial strain rather than non linear stress strain plot that could have prominently shown the hardening capability.

A. Behaviour of thorcolumnar spine with spine tuberculosis

An initial study was undertaken to observe the normal behaviour of spine under the boundary conditions of S1 completely constrained and allowing only axial movement at the T1 level depicting the musculature action (Fig 4a).The buckling analysis of this model was carried out using the sub-domain solution procedure with the appropriate strum sequence check. The first mode shape is shown in Fig 4a and it is found that this behaviour is largely comparable to the work of Van der Plaats et al.[9]

As observed in the introduction that most of the TB lesions affect the thorocolumnar, lumbar junction- the articular processes, the facets and the vertebral body was disrupted at this junction. This condition was modeled using the birth and death of element formulation technique wherein the elements in the above components was, de

selected. To achieve the "element death" effect, the ANSYS program does not actually remove "killed" elements. Instead activates them by multiplying their stiffness by a severe reduction factor .

The first mode shape showed an increase in the kyphosis angle but subsequently there was more lateral movement Fig 4b.

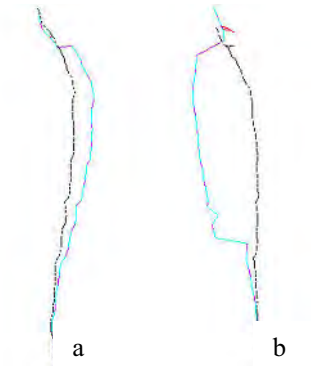

Fig. 4 a Mode shape of in the intact condition
b: Mode shape in the disrupted model

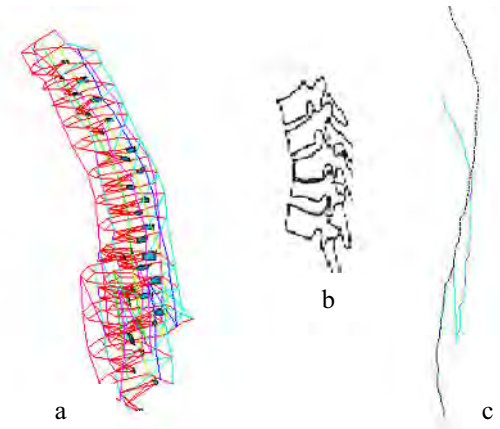

Fig. 5 aThe spine Collape due the disruption b: clinically observed collapse[8] c: snapping phenomena shown using the vertebral bodies

In this condition when 400N is applied the normal physiological load in standing posture, the spine collapse was seen as shown by S.Rajasekaran et.al[8]. The subluxation and the restabilization of the spine can be seen as shown in fig 5a,b. The ligament and musculature structure where as well disrupted in the adjacent levels that could further lead to neurological deficiet. The axial stress and displacement at the killed junction shown found to be nil and accordingly the snapping behaviour at that level could be explained(Fig5c). Further work needs to be done to study the mechanism of this collapse and the components that predominantly plays a role in this collapse has be studied

IV. Conclusion

The current work could successfully develop a simplified model to study the spine collapse due to spine tuberculosis using Beam and link elements. The results and the trend are comparable to the experimental results of the lucas and-Bresler[7]. The simulation of the disruption has been studied using buckling and element death concept and the spine collapse is seen to have similarity to that observed by clinical observations. Further studies are on to quantify the displacements and also to study the reasons for the collapse and the biomechanical etiology of the progression of the deformity due to spinal tuberculosis.

Contact Characteristics during Different High Flexion Activities of the Knee

Jing-Sheng Li, Kun-Jhih Lin, Wen-Chuan Chen, Hung-Wen Wei, Cheng-Kung Cheng

Institute of Biomedical Engineering, National Yang Ming University, Taipei, Taiwan

Abstract — **Squatting, kneeling and sitting cross-legged activities require a very high range of motion of the knee joint. Many studies have focused on the kinematics of these activities using motion capture systems or fluoroscopy images with reconstructed computer models. These methods do not report the contact characteristics in high flexion activities. Although magnetic resonance images could easy to calculate the contact area, the magnetic resonance scan requires many times and is not suitable for functional activity. The purpose of this study was to build a procedure to investigate the contact characteristics for different high flexion activities based on bi-plane orthogonal X-ray images with computational models reconstructed by computer tomographic and magnetic resonance images. Computational bone models, including the femur, tibia, fibula and patella, were reconstructed by computer tomographic images. Computational cartilage models, including femur, tibia and patella, were reconstructed by magnetic resonance images. We used the sensitivity test to test the mapping accuracy and the error value is less than 5% so that the mapping is reasonable. There is no contact in standing in patellofemoral joint. The contact location in patella is moving upward from the distal patella with knee flexion. When squatting, the contact location separates to two parts. The contact in kneeling and sitting cross-legged also presents the same result. The contact area in patellofemoral joint is increasing with flexion, but decreasing to 849.94mm^2 in squatting. The contact area in kneeling and sitting cross-legged is 388.63mm^2 and 815.16 mm^2, respectively.**

Keywords — **high flexion activities, contact**

I. Introduction

In our daily living, squatting, kneeling and sitting cross-legged activities that require a very high range of motion of the knee joint are usually seen in Asia. Although some studies have focused on the kinematics in these such high flexion activities using motion capture systems, the major limitation is skin shifting during exercise [1-2]. The limitation may make influence on the true bony motion and increase the errors of measurement. Other studies catch the motion using fluoroscopy images and have constructed computer models to investigate the kinematics of knee joint, even investigate the articular contact points [3-5]. In addition, the contact area is usually calculated using magnetic resonance images, and the magnetic resonance scan requires many times so that magnetic resonance scan is not suitable for functional activity [6-7]. The purpose of this study was to build a procedure to investigate the contact characteristics for different high flexion activities based on bi-plane X-ray images with computer model reconstructed from magnetic resonance images.

II. Materials and Methods

One young subject (24 y/o, 184cm, 80kg) without any knee pathology and history was included in this study. Computational bone models, including the femur, tibia, fibula and patella, were reconstructed by computer tomographic images (transverse plane, 2mm thickness, resolution: 512x512 pixels). Computational cartilage models, including the femur, tibia and patella, were reconstructed by magnetic resonance images (sagittal plane, 2.2mm thickness, resolution: 256x512 pixels). Bi-plane orthogonal X-ray images were taken from standing to squatting, kneeling and sitting cross-legged activities. In addition, all images were taken in Department of Radiology, Taipei city hospital. Afterward, we built an orthogonal flame and put two orthogonal X-ray images on (Figure 1). After fitting with a series of bi-plane X-ray images successfully, we calculated the contact area using the interferential part.

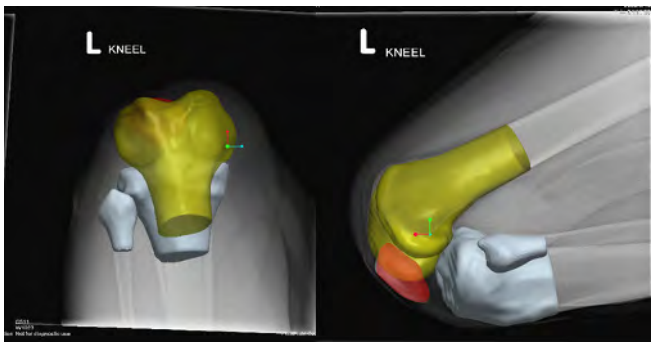

Fig. 1 Computational bone models fit with bi-plane orthogonal X-ray images.

III. Results

There is no contact in standing in patellofemoral joint. The contact location in patella is moving upward from the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2092–2094, 2009
www.springerlink.com

distal patella with knee flexion. When squatting, the contact location separates to two parts. The contact in kneeling and sitting cross-legged also presents the same result. Patellofemoral contact in femur was shown in Figure 2. Tibiofemoral contact in femur was shown in Figure 3. The contact area in patellofemoral joint is increasing with flexion, but decreasing to 849.94mm^2 in squatting. The contact area in kneeling and sitting cross-legged is 388.63mm^2 and 815.16 mm^2, respectively (Figure 4).

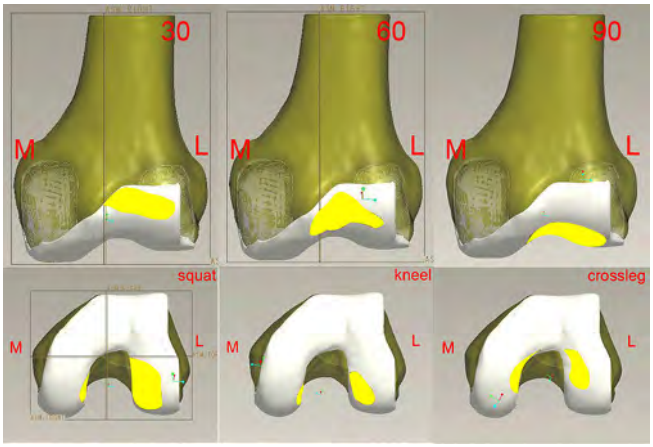

Fig. 2 Patellofemoral joint contact locations were shown in zone yellow. Patella glided from anterior and upper end of femoral cartilage to trochlear groove.

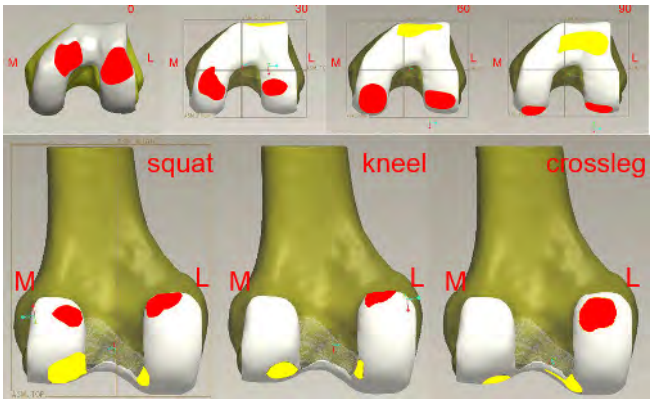

Fig. 3 Tibiofemoral joint contact locations were shown in zone red.

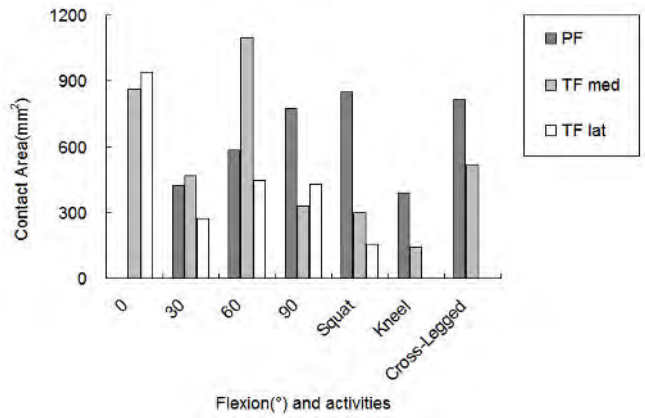

Fig. 4 Contact area in patellofemoral and tibiofemoral joints.

IV. Discussion

Using computer model fitting with bi-plane X-ray could help to explain the contact characteristics in functional activities. We also used the sensitivity test to test the mapping accuracy and the error value is less than 5% so that the mapping is reasonable. In contact location, patella glided from anterior and upper end of femoral cartilage to trochlear groove, and femur contacted tibia from distal part to posterior part of femoral cartilage. In contact area, similar trend was found in contact area between flexion 0° and 60° compare with those using open magnetic resonance scan to measure the contact area [7]. Besides, there was no contact in kneeling and sitting cross-legged in tibiofemoral joint, this result may attribute to more adduction in these activities. Decreasing tibiofemoral contact area in these three high flexion activities may relate to joint degeneration. The limitation of this study is the less subject number.

V. Conclusion

To sum up, this study can provide the contact characteristics of knee joint in high flexion activities; furthermore, we can use the computational model rather than static magnetic resonance scan to measure the contact area in more functional condition.

Thumb Motion and Typing Forces during Text Messaging on a Mobile Phone

F.R. Ong[1]

[1] School of Mechanical and Manufacturing Engineering, Singapore Polytechnic, Singapore

Abstract — **The objective of the study was to determine the thumb motion and typing forces when text messaging on a mobile phone. Thumb motion was captured using a 6-camera reflective marker based motion capture system. Typing forces were measured using four load cells in a force plate arrangement fitted into the phone. Thumb flexion-extension occurred mainly in the IP and MCP joints. The maximum flexion for IP joint was 20.2º at key '*' and was 18.3º at key '#' for MCP joint. Abduction-adduction of MCP and CMC joints were smaller than flexion-extension and thumb opposition. The maximum abduction for MCP and CMC joints were 7.2º and 8.7º respectively at key '*'. The maximum thumb opposition for MCP and CMC joints were 17.0º at key '4' and 13.5º at key '9' respectively. The incidence of peak force was shown to link to high flexion angle of the IP joint and in thumb opposition of the MCP joint. No incidence of peak forces was found in the right column of the keypad.**

Keywords — **Thumb, text messaging, repetitive strain injury.**

I. Introduction

The popularity of text messaging or SMS on mobile phones has given rise to a new injury called Text Messaging Injury (TMI) [1, 2]. TMI is a form of Repetitive Strain Injury (RSI), which is described by pain associated with loss of function in a limb resulting from repetitive movement or sustained static loading. TMI is normally caused by overuse of the thumb during text messaging on a mobile phone. Besides TMI, there are other terms, such as Blackberry Thumb and Gamers Thumb, to describe RSI related to wireless handheld and video games devices.

The research into the effects of text messaging on the thumb and related fingers has been limited. Most RSI research concentrated on computers since keyboard users or office workers have been identified to have high levels of job discomfort. It has been found that upper extremity musculoskeletal disorders, such as carpal tunnel syndrome (CTS), are associated with computer keyboard usage [3]. Factors contributing to CTS and job discomfort were found to be related to speed and force of keyboard operation.

Text messaging usually involves the use of the thumb of one hand to type on the phone keypad. The movement of the thumb covers motions in the planes of flexion-extension, abduction-adduction and opposition. These motions occur simultaneously in three dimensions and as a result, it is difficult to determine the kinematics of the thumb. Measurements of thumb motion have been made using marker based optical motion capture system, goniometry and fluoroscopy [4-7].

TMI is affecting more and more children and young adults due to excessive text messaging. The objective of the study was to determine the thumb motion and typing forces on the keypad of a mobile phone during text messaging.

II. Methods

Twenty male volunteers between the ages of 20 to 22 years participated in this study. These subjects have no history of RSI or any musculoskeletal disorder.

Thumb motion was captured using a 6-camera reflective marker based motion capture (MOCAP) system (Vicon MX13) at a frame rate of 120Hz. Thirteen 5mm hemispherical retro-reflective markers were attached on the thumb and index finger of the subjects, as shown in figure 1. The interphalangeal (IP), metacarpophalangeal (MCP) and carpometacarpal (CMC) joints had a pair of reflective markers each to define the approximate joint axis.

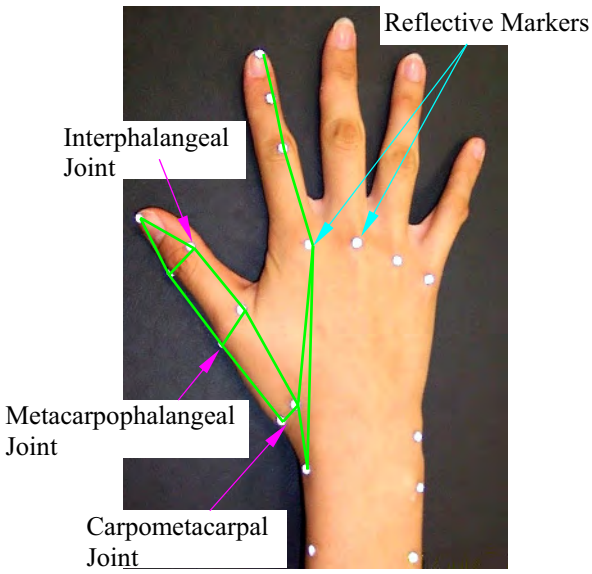

Fig. 1 The marker set-up of the hand

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2095–2098, 2009
www.springerlink.com

Text messaging forces were measured using four load cells in a force plate arrangement, which fit into the mobile phone casing. Figure 2 shows the set-up of the phone with load cells. The cover is placed on top of the load cell housing for keystroke contact. Another five markers were attached on the mobile phone. The force measurements were synchronised to the MOCAP via the Vicon MX Control.

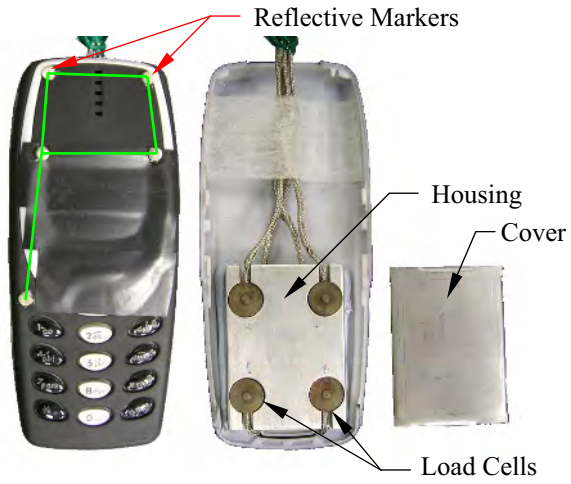

Fig. 2 The set-up of the mobile phone

The subjects were seated in front of a table with the mobile phone. Before the start of data acquisition, the subjects were asked to practice on a message that reads: "13#*_We_Will_Win_Gold_Medal._Please_Support_Us._13*#". The starting position of the thumb and finger was not defined as the subjects started in their natural position. This message contains 52 key strokes and figure 3 shows the number of key hits per key in relation to the typed message. Upon completion, the markers on the hand were labelled and linked according to figure 4. The typing forces were the sum of forces measured by the four load cells.

1 4 hits	**2** 2 hits	**3** 8 hits
4 3 hits	**5** 5 hits	**6** 4 hits
7 7 hits	**8** 3 hits	**9** 3 hits

Fig. 3 Number of key hits per key on the keypad

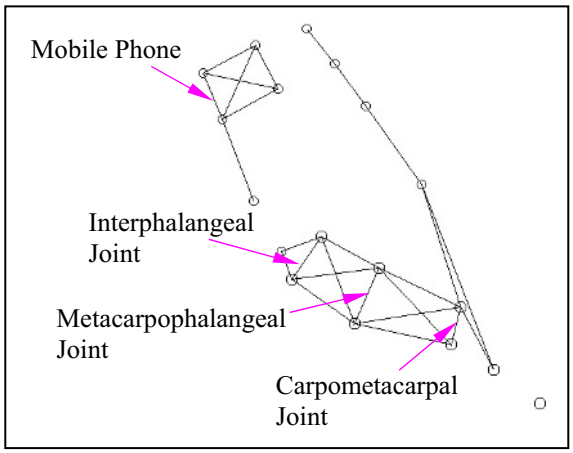

Fig. 4 Labelling and linking of markers

III. Results and Discussion

From the twenty subjects, results were obtained only from ten subjects due to excessive marker occlusion and inconsistent marker placement especially on the MCP and CMC joints. A couple of left handed subjects were also excluded. The IP joint was assumed as a hinge joint, while the MCP and CMC joints were assumed as universal joints. During data recording, it was noticed that the subjects made compensatory movement to reposition the phone in order to reach keys at extreme locations (top left or bottom right). This compensatory movement was not considered in the determination of thumb motion.

The interphalangeal (IP) and metacarpophalangeal (MCP) joints were found to be mainly responsible for flexion-extension movements of the thumb. The average maximum relative angular displacements for IP, MCP and CMC joints were 24.1º, 18.7º and 8.8º respectively, as shown in Table 1. Abduction-adduction movements of the thumb were executed mainly by the CMC joint. The average maximum displacement angle was 10.0º and 8.2º for CMC and MCP joints respectively. Both MCP and CMC joints were found to experience more opposition movement (18.2º and 14.9º respectively) than abduction-adduction motion.

Table 1 Average maximum relative angular displacement

Thumb Motion	Flex/Ext		Abd/Add		Opposition	
	Average	S.D.	Average	S.D.	Average	S.D.
IP	24.1	6.2	-	-	-	-
MCP	18.7	4.6	8.2	2.6	18.2	5.4
CMC	8.8	4.3	10.0	4.7	14.9	7.2

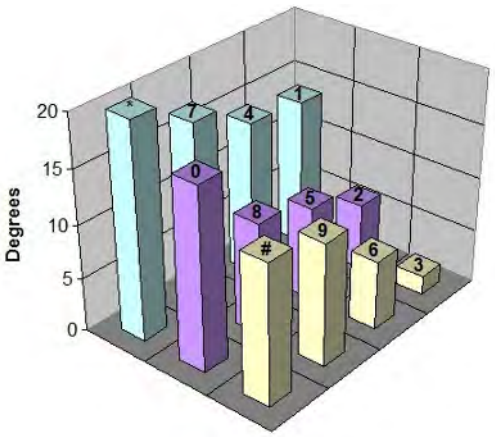

Fig. 5 Flexion-Extension of IP joint

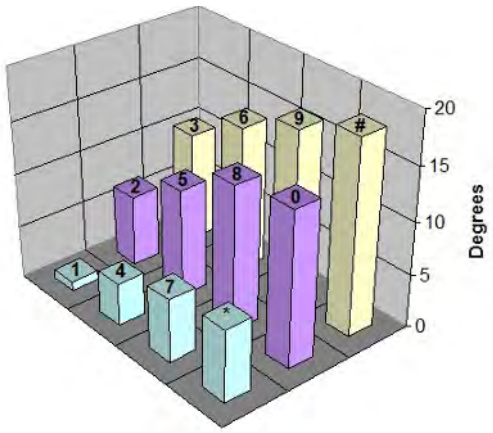

Fig. 6 Flexion-Extension of MCP joint

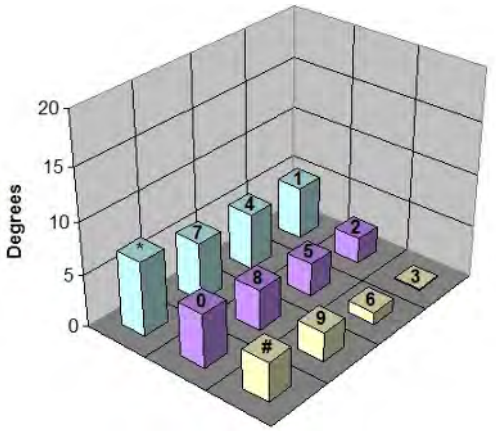

Fig. 7 Abduction-adduction of MCP joint

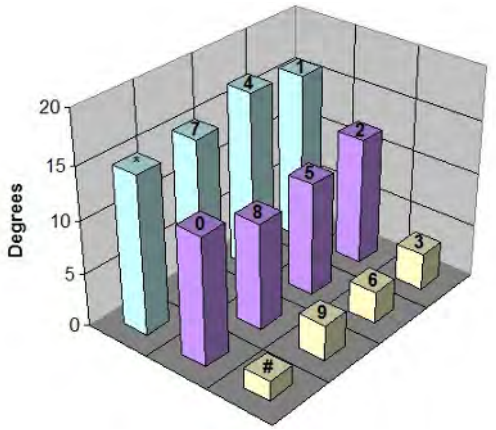

Fig. 8 Thumb opposition of MCP joint

Figure 5 show the average angular displacement for IP joint in flexion-extension. The maximum flexion was 20.2º (S.D. 9.5º) at key '*' and maximum extension was 1.8º (S.D. 2.7º) at key '3'. A pattern of diagonal reduction of flexion from key '*' to key '3' was found at IP joint. Most of the maximum IP flexion occurred at keys '*' and '0'.

A pattern mirroring IP flexion-extension was also found on the flexion-extension of MCP joint, as shown in figure 6. Maximum average flexion was 18.3º at keys '#' (S.D. 5.0º) and maximum extension was 0.9º at keys '1' (S.D. 1.7º). Most of the maximum MCP flexion occurred at key '#'.

Figure 7 shows the abduction-adduction of MCP joint. The maximum abduction was 7.2º (S.D. 3.4º) at key '*' and the maximum adduction was 0.1º (S.D. 0.4º) at key '3'. Thumb opposition at MCP joint was more than abduction-adduction and it increased consistently from the right column to the left column of the keypad, as shown in figure 8. The maximum thumb opposition was 17.0º (S.D. 5.7º) at key '4' and the maximum adduction was 1.8º (S.D. 1.9º) at key '#'. Most of the maximum MCP thumb opposition occurred at keys '1' and '4'.

Figure 9 shows the flexion-extension of CMC joint. Flexion was found to increase from the left column to the right column of the keypad. Figure 10 shows abduction-adduction of the CMC joint, which is similar to MCP abduction-adduction. The maximum abduction was 8.7º (S.D. 5.3º) at key '*' and the maximum adduction was 0.8º (S.D. 1.7º) at key '3'. The dominant movement at CMC joint was the thumb opposition, as shown in figure 11 and it mirrored MCP thumb opposition (Fig. 8). The maximum thumb opposition was 13.5º (S.D. 7.7º) at key '9' and the maximum adduction was 2.0º (S.D. 3.8º) at key '1'.

Maximum typing forces occurred mostly on extreme keys, in particular key '1'. There was no incidence of maximum typing forces on the right column keys of the phone. The maximum forces ranged from 3.8N to 15.7N and the average maximum force was 8.5N (S.D. 4.0N). Subjects that had low IP flexion at keys '#' and '9' were

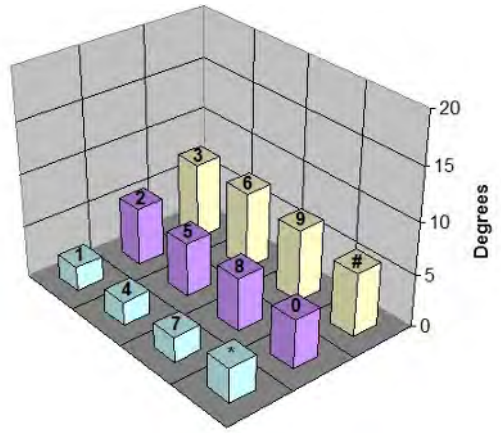

Fig. 9 Flexion-extension of CMC joint

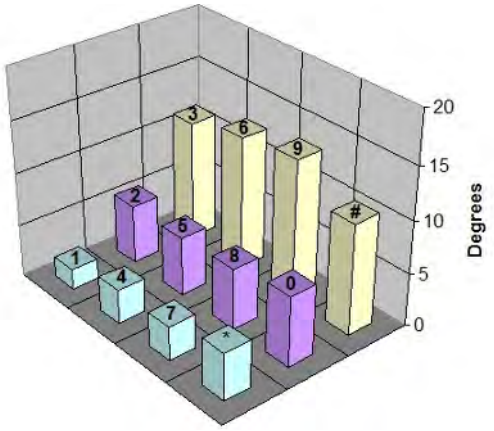

Fig. 11 Thumb opposition of CMC joint

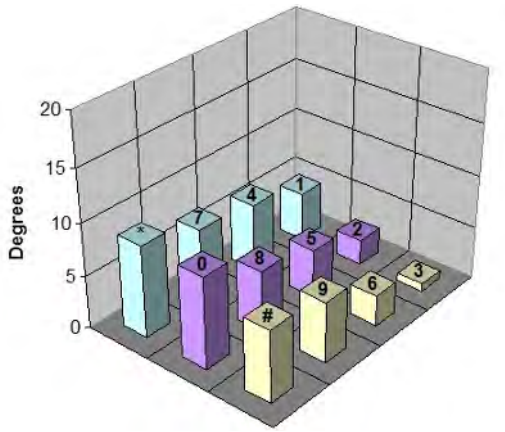

Fig. 10 Abduction-adduction of CMC joint

compensated by high MCP flexion. Subjects also showed reduced thumb opposition and repositioned the phone when reaching those keys.

IV. CONCLUSIONS

Flexion-extension of the thumb occurred mainly in the IP and MCP joints. The maximum flexion for IP joint was 20.2º at key '*' and were 18.3º at key '#' for MCP joint. Angular displacements in abduction-adduction of MCP and CMC were smaller in comparison to flexion-extension. The maximum abduction for MCP and CMC joints were 7.2º and 8.7º respectively at key '*'. Thumb opposition of the MCP and CMC joints were more significant than their abduction-adduction. The maximum angular displacements for thumb opposition were 17.0º at key '4' and 13.5º at key '9' respectively. No incidence of peak forces was found in the right column of the keypad. The results indicated that the incidence of peak force was linked to high angular displacement in flexion of the IP joint and in thumb opposition of the MCP joint.

ACKNOWLEDGMENT

This study was supported in part by a grant from Singapore Totalisator Board. The author acknowledged the Final Year Project Students from the School of Mechanical and Manufacturing Engineering of Singapore Polytechnic for their assistance in data collection and analyses, and Mr Tham Kwok Liang for co-supervising the project.

Oxygen Transport Analysis in Cortical Bone Trough Microstructural Porous Canal Network

T. Komeda[1], T. Matsumoto[1], H. Naito[1] and M. Tanaka[1,2]

[1] Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka, Japan
[2] Center for Advanced Medical Engineering and Informatics, Osaka University, Osaka, Japan

Abstract — **Oxygen supply is one of primal concerns in bone modeling and remodeling. In the cortical bone, oxygen is transported through the vascular system in the Haversian and Volkman's canals and through the periosteocytic space of canaliculi mainly. In this study, the oxygen transport by convection and diffusion was modeled for both of the vascular channel network and the bone canaliculi network. The oxygen distribution and its nonuniformity were examined for the cortical shaft of rat tibia using the constructed model with CT-imaged bone structure.**

Keywords — **Biomechanics, Cortical Bone, Microstructure, Canal Network, Oxgen Transport.**

I. Introduction

Cortical bone is of compact hard tissue macroscopically, but has porous canal network consisting of Haversian and Volkman's canals microscopically. The modeling and remodeling of cortical bone structure is deeply depending on the mechanical environment, and they are supported by the sufficient supply of physiological substances permitting the activities of bone cells. The oxygen is a primal substance supplied by the vascular system in the canal network. However, the oxygen transport in the cortical bone is not well understood yet. In this study, the oxygen transport in the cortical bone was modeled by considering the transport in the blood flow in vascular system in the canal network and in the bone matrix including lacunae-canaliculi network. Using the proposed transport model, the distribution of oxygen concentration was analyzed with CT-imaged bone microstructure of Haversian/Vilkman's canals, and demonstrated was the non-uniformity of oxygen supply in cortical bone.

II. Oxygen transport model

A. Haversian and Volkman's canal networks

Haversian and Volkman's canals consist a canal network system in cortical bone and it works as the vascular channel network. This network structure is considered as a collection of one-dimensional tube representing individual canal segment. Each segment is assumed to be a straight tube connecting the branching or joining nodes of the network, and one vessel tube is considered for each canal segment. Let consider a vessel tube *ij* in the canal connecting a node *i* and its adjacent node *j*, and define a line coordinate *s* along the tube *ij*. As a one-dimensional convection-diffusion problem in a straight tube, the governing equation of oxygen concentration C^p_{ij} at position *s* and time *t* is written as

$$\frac{\partial C^p_{ij}(s,t)}{\partial t} = -\bar{u}_{ij}\frac{\partial C^p_{ij}(s,t)}{\partial s} + D^p\frac{\partial^2 C^p_{ij}(s,t)}{\partial s^2} - \frac{2}{r_{ij}}D^{pt}S_{rate}\frac{C^p_{ij}(s,t)-C^t(\mathbf{x},t)}{h} \quad (1)$$

where u_{ij} is the average flow velocity assuming Hagen-Poiseuille law, D^t and D^{pt} are the diffusion coefficients in plasma and vascular wall, r_{ij} is the vessel radius, S_{rate} denote the area ratio of canaliculi cross section and canal wall, and *h* is the vascular wall thickness. The last term of the right hand side is for the interaction with the canaliculi network, where the position *s* in the vessel coordinate corresponds to the position $\boldsymbol{x}$ in the bone matrix in three dimension. It is noted here, the volume or diameter of the vessel is neglected in the interaction between the vessel and matrix.

B. Bone lacunae-canaliculi network

Oxygen transport in the bone matrix is mainly conducted through lacunae-canaliculi network. Bone canaliculi connecting lacunae are distributed densely in the matrix in comparison with Haversian/Volkman's canals in cortical bone. A homogenized model is, thus, employed for the modeling of oxygen transport in bone matrix with lacunae-canaliculi network [1]. For the unit cell of bone matrix including lacunae and canaliculi, a cuboidal periodic unit cell is recruited. The apparent diffusion coefficient D^t in the bone matrix continuum is then derived based on this unit cell model as follows.

The osteosyte cytoplasmic processes occupy tiny canals of canaliculi but do not fill entirely. The remaining periosteocytic space, pericellular annular space between the canalicular wall and the osteocyte process membrane, is

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2099–2101, 2009
www.springerlink.com

filled with fiber matrix and periosteocytic fluid providing the transport pathway of nutrients and waste. The diffusion coefficient D_{fiber} in a canaliculus is then derived based on the fiber matrix theory [2]. By using this diffusion coefficient, the apparent diffusion coefficient is described as

$$D^t = \frac{A_{fc} N_c D_{fiber}}{L_c^2} \tag{2}$$

for a cuboidal unit cell which each surface is characterized with N_c canaliculi coming from the bone lacuna in it. Here, A_{fc} and L_c are the cross-sectional area of transport pathway in a canaliculus and the size of unit cell.

As the result, oxygen concentration $C^t(\boldsymbol{x},t)$ in the bone matrix as a homogenized continuum is described by three-dimensional diffusion equation as

$$\frac{\partial C^t(\mathbf{x},t)}{\partial t} = \frac{1}{V_p}\left\{ D^t \frac{\partial^2 C^t(\mathbf{x},t)}{\partial \mathbf{x}^2} + 2\pi r_{ij} L(\mathbf{x}) D^{pt} S_{rate} \frac{C_{ij}^p(s,t) - C^t(\mathbf{x},t)}{l} - Q \right\} \tag{3}$$

where V_p is the volume fraction of lacunae-canaliculi, $L(x)$ is the direction cosine of vessel tube, and Q denotes the oxygen consumption per unit bone volume. The second term of the right hand side is for the oxygen exchange with the vessel ij, and vanishes when no vessel passes the position $\boldsymbol{x}$.

III. Toransoport analysis

A. Analysis object and conditions

Canal network structure: As an analysis object, the tibial cortical bone of Wistar rat of 5 weeks old is used, and the cortical bone microstructure is obtained by SPring-8 synchrotron radiation CT [3] as shown in Fig.1. The spatial distribution of canal network is not uniform as seen in Fig. 2 illustrating the endosteal surface and the radial section at different regions indicated in Fig. 1.

Blood flow condition: In the juvenile cortical bone, blood flow occurs mainly from endosteal side to periosteal side. Referring to this feature, the blood pressure P was assumed to be proportional to the distances from periosteum and the distal end surface:

$$P = \frac{p_r}{d_{er} - d_{ir}}\left(d_{er} - 2r\right) + p_z z$$

where p_r = 1.28mmHg and p_z = 0.1 p_r. The viscosity of 4.17×10-3Pa·s is assumed for blood flow in vascular vessels.

Oxygen transport condition: At the entrance of individual vascular channel, the oxygen concentration was set to be constant of 0.21mg/ml. No oxygen transportation was assumed through proximal and distal end surfaces, periosteum and endosteum in this analysis. The parameters related to oxygen transport were summarized in Table 1.

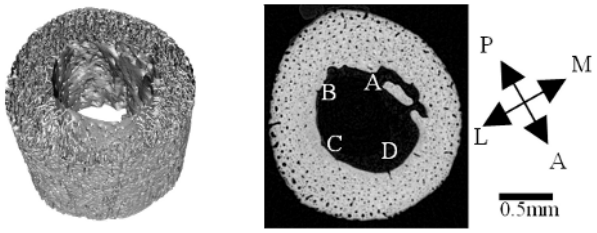

Fig. 1 Microstructure of cortical shaft of rat tibia (Left: Volume rendered image. pixel size is 3.1μm. Right: Transverse section)

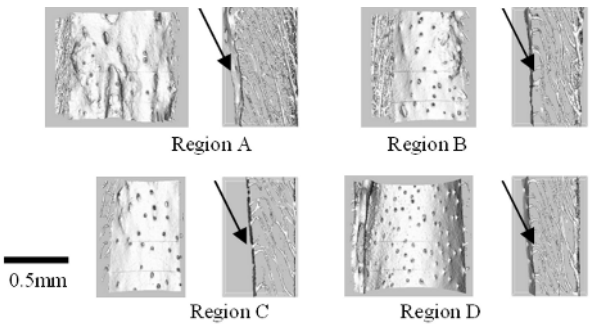

Fig. 2 Canal distribution on different region of endosteum (Indicated by allow in radial sections)

Table 1 Parameters for analysis

Diffusion coefficient in blood	D^p (m^2/s)	2.1×10^{-9}
Diffusion coefficient in bone matrix	D^t (m^2/s)	2.25×10^{-12}
Diffusion coefficient at vessel wall	D^{pt} (m^2/s)	2.1×10^{-9}
Oxygen concentration at entrance	C_{in} (mg/ml)	0.21
Consumption rate at basal metabolism [4]	Q (mg/ml/s)	5.0×10^{-7}

Numerical procedure: The set of transport equations were solved by the finite difference method, with the uniform orthogonal grid of interval of 49.6mm corresponding to 16 pixel interval in CT image representing bone matrix and the one-dimensional grids of interval 20mm~30mm representing vascular channel network. For the space, used were the fourth-order scheme, the central difference for the diffusion and the upwind difference for the convection, and were the second-order scheme, the upwind difference for the time.

B. Distribution of oxygen concentration in cortical bone

The spatial distribution of oxygen concentration in cortical bone was obtained at the steady state. Due to the influence of the boundary condition at the proximal and distal end surfaces at z=0mm and 2.48mm, the attention was focused on the mid shaft region between z=0.99 and 19.8mm. The distributions of oxygen concentration at axial cross-section at different axial heights were shown in Fig. 3 demonstrating the influence of non-uniform distribution of canals in axial cross-section. In the region A, the oxygen concentration was remarkably lower than those in other regions. It is moderate in the region C. By referring to the deficiency in blood flow through vascular channel network, some relations might be suggested between the spatial distribution of oxygen concentration and the vascular channel distribution in the cortical bone.

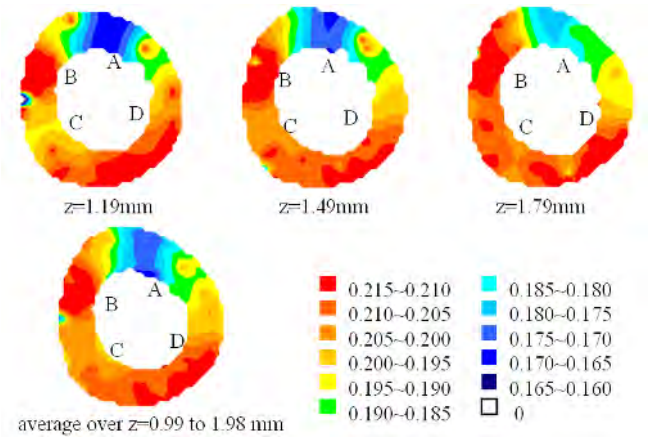

Fig. 3 Distribution of oxygen concentration at different transverse sections

IV. Concluding Remarks

Oxygen transport phenomena in the cortical bone were modeled considering both the vascular channel network and the lacunae-canaliculi network, and formulated a set of oxygen transport equations. Oxygen transport analysis based on the proposed model with real microstructure of rat tibia suggested that the oxygen transport in cortical bone largely depends on local flows, and flows are under the great influence of vascular channel distribution, a major microstructure of cortical bone.

Abstract — **Articular cartilage has the depth-dependent laminar structure, and the mechanical behavior of articular cartilage is strongly dependent of its microstructure characterized by three-dimensional, depth-dependent anisotropic arrangement of collagen fibre, chondrocyte and so on. In this study, a method identifying the mechanical properties of cartilage is described by using a viscoelastic model of cartilage considering its anisotropic and inhomogeneous microstructure and the time history of reaction force observed in the indentation test. The method is examined with bovine femoral cartilage at the medial and lateral regions.**

Keywords — **Articular cartilage, Microstructure model, Mechanical property, Degeneration, Indentation test.**

I. Introduction

Articular cartilage is a soft tissue covering the articular surface of diarthrodial joints, and considered as biphasic (solid and fluid) material. The solid phase shows laminar structure varied along cartilage depth, and generally divides into three layers: surface, middle, and deep layers. The depth-dependent structure is deeply involved in mechanical behavior and property, which is a major determinant of cartilage function of shock absorbing or load bearing [1].

In this study, the transversely isotropic and transversely homogeneous microstructural model [2] considering its anisotropy and inhomogeneity was extended to take the viscoelasticity of solid phase into account. Then, the model was used to identify the mechanical properties of cartilage under the different load supporting conditions based on the indentation test. The mechanical parameters determined were validated through component analysis by Fourier transformed infrared microscopic spectroscopy (FT-IR).

II. Materials and methods

A. Micro-structural model

As the mechanical model of cartilage, the biphasic model consisting of solid phase and fluid phase [3] has been a standard one where the solid phase is assumed to be isotropic body conventionally. Recently, Federico and coworkers[2] have proposed the transversely isotropic and transversely homogeneous (TITH) model in order to take the depth-dependent microstrucral characteristics in the solid phase, where the effect of chondrocyte and collagen fibre is incorporated by means of Eshelby theory, assuming the linear elasticity for all of proteoglycan-matrix, cells and collagen fibre. This is the elastic TITH model. In the present study, this model is extended to take the viscoelasticity of collagen fibres in to account. That is, the solid phase consists of isotropic proteoglycan-matrix, ellipsoidal inclusion of chondrocytes and collagen fibres. The orientation of collagen fibre, volume fractions of collagen fibre and the chondrocyte and shape of chondrocyte are determined stochastically in a depth-dependent manner based on the anatomical data [4][5][6]. A Kelvin viscoelastic body is assumed for the collagen fibre, while the proteoglycan-matrix and cells were assumed to be linear elastic bodies as is in the original model. The stress of the solid phase $\boldsymbol{\sigma}(\xi)$ was composed of the non-fibre matrix $\boldsymbol{\sigma}_M(\xi)$ and the fibre $\boldsymbol{\sigma}_F(\xi)$ as follows:

$$\begin{aligned}\boldsymbol{\sigma}(\xi) &= \left[d_o(\xi)\boldsymbol{\sigma}_o + d_c(\xi)\boldsymbol{\sigma}_c(\xi)\right] + d_f\boldsymbol{\sigma}_f(\xi) \\ &= \boldsymbol{\sigma}_M(\xi) + \boldsymbol{\sigma}_F(\xi),\end{aligned} \tag{1}$$

where ξ denotes the normalized cartilage depth, d_r is the volumetric content of each component r (r=0:PG-matrix, r=c:chondrocyte, f:collagen fibre). The stress of non-fibre matrix depends mainly on elasticity tensor $\mathbf{C}_o$ and $\mathbf{C}_c$, strain-concentration tensor $\mathbf{A}_c$. The stress of fibre depends on elasticity tensor $\mathbf{C}_f$, strain-concentration tensor $\mathbf{A}_f$,. the distribution density $\varphi(\xi: \theta)$ and relaxation function $G(t)$ of collagen fibre.

B. Indentation test and parameter identification

Fresh normal bovine femoral heads were used as specimens. Cartilage at the medial and the lateral regions on a femur head underwent indentation test. Medial region is a load-supporting region, whereas lateral region is non load-supporting region. The indentation test was carried out with the indenter of 1 mm in diameter, indentation displacement of 0.1 mm, indentation speed of 0.2 mm/s, and relaxation time of 180 seconds. Thicknesses of cartilage at the indentation points were measured from X-ray transmission imaging. Three-dimensional simulation of the indentation test was performed using the present viscoelastic TITH model with assuming the same condition in experiment. The

www.springerlink.com

volumetric content of collagen fibre, elastic modulus of collagen fibre, permeability and other model parameters were identified by comparing the experimental and calculated response of reaction force. The collagen content was evaluated with the integrated area of wave range of infrared light absorbed by Amide I [5] observed by FT-IR measurement.

III. Results and discussion

Fig. 1 shows reaction force responses in time by the experiment and by calculation using model-fitted parameters. The reaction force was lager at the lateral region than that at the medial region, and the instantaneous and relaxed elastic moduli were higher at the lateral region than those at the medial region (Table 1). The identified axial and transverse elastic moduli in lateral region were higher than those in medial region. The axial elastic modulus was lower than the transverse elastic modulus, in the surface layer. In deep layer, on the other hand, the axial elastic modulus was higher than the transverse elastic modulus (Table 2). The identified elastic modulus of collagen fibre was higher at the lateral than at the medial region. The collagen content was estimated rich at the lateral region in comparison with that at the medial region. According to the previous studies [7], the thickness of cartilage at the load support (medial) region is thicker than that at non-load support (lateral) region, and the elastic modulus of thick cartilage is lower than that of thin cartilage [8]. The present model gave higher collagen contents at the lateral region, where collagen modulus was also high (Table 2). FT-IR analysis also showed rich collagen content with the lager area of Amide I at the lateral region (Table 1). In conclusion, these results suggests that viscoelastic TITH model considering collagen fibre and chondrocyte inclusions is an effective tool to describe the mechanical properties with reflecting material composite characteristics in cartilage appropriately.

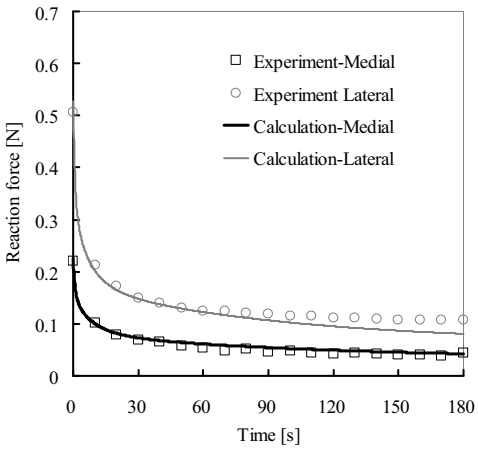

Fig. 1 Reaction force in indentation test.

Table 1 Characteristics measured.

	Medial		Lateral
Thickness [mm]	1.416	>	0.898
Instantaneous elastic modulus [MPa]	1.039	<	1.813
Relaxed elastic modulus [MPa]	0.251	<	0.492
Area of Amide I	40.83	<	50.24

Table 2 Parameters identified at medial and lateral region

Elastic modulus [MPa]	Medial		Lateral
ζ=0.8 (surface layer)			
Axial	0.536	<	0.797
Transverse	0.770	<	1.329
ζ=0.2 (deep layer)			
Axial	0.853	<	1.579
Transverse	0.744	<	1.190
Collagen content [%]	34.649	<	48.411
Collagen elastic modulus [MPa]	1.758	<	4.011

Abstract — **Bone structure is deeply related to its mechanical function, and is maintained adaptation by remodeling. Among many investigations concerning the mathematical modeling of bone remodeling, the physiological range of mechanical stimuli has been studied mainly. In this study, mathematical models of surface remodeling in disuse and overuse windows are formulated by paying attention to the osteocyte apoptosis and targeted remodeling, and are unified with that in the physiological window. The fundamental characteristics of the unified model are examined through numerical cases.**

Keywords — **Biomechanics, Bone Remodeling, Remodeling Simulation, Osteocyte apoptosis, Targeted remodeling**

I. Introduction

Mechanical loading is a crucial factor in maintaining the bone structure at the normal healthy state, and bone architecture is adapted to the external loading conditions. Mechanostat theory/hypothesis by Frost [1] gives us a basic framework to grasp the mechanical adaptation by remodeling of bone in accordance with the mechanical usage. Several windows of mechanical usage are distinguished by referring to the strain magnitude in this context. Concerning the mathematical modeling and computer simulation of bone remodeling and adaptation, much attention has been focused on the physiological window (PW) for normally adapted healthy condition. Bone formation and resorption in two different windows adjacent to the PW are considered in this study. One is the disuse window (DW) of smaller strain magnitude, where the osteocyte apoptosis becomes dominant, and the other is the overuse window (OW) of larger strain magnitude, where the targeted remodeling becomes dominant.

II. Simulation model

A. Mathematical model of remodeling

Surface remodeling by referring to the mechanical stimuli was used for the mathematical model of bone remodeling in this study. For the PW, the nonuniformity of the stress/strain distribution was picked up as the mechanical stimuli [2][3]. For the material point x_c of on bone surface, driving force for remodeling was evaluated by

$$\Gamma_c = \ln\left(\sigma_c \sum_i^N \omega(l_i^c) \Big/ \sum_i^N \omega(l_i^c)\sigma_i \right) \tag{1}$$

where σ_c denotes the stress at $\boldsymbol{x}_c$ and σ_i denotes the representative stress at $\boldsymbol{x}_i$ with distance l_i from $\boldsymbol{x}_c$. The value Γ_c represents the magnitude of local stress non-uniformity around the surface point $\boldsymbol{x}_c$. The probability $f(\Gamma_c)$ of bone gain/loss at $\boldsymbol{x}_c$ is described by referring to this value: no bone gain/loss for $\Gamma_c = 0$, bone gain for $\Gamma_c > 0$, and bone loss for $\Gamma_c < 0$. In this window, the activation frequency AF_f or AF_r for the bone gain or loss governed by the probability $f(\Gamma_c)$ is referred to as the unit, i.e. $AF_f = AF_r = 1$.

In the DW for the strain smaller than the threshold ε_{du}, only considered is the resorption caused by the osteosyte apoptosis [4]. The increase of activation frequency of resorption by the decrease of the strain [5] was expressed as

$$AF_r(\bar{\varepsilon}) = \begin{cases} AF_{r\max} & (0 \le \bar{\varepsilon} < \varepsilon_{\min}) \\ \left(\dfrac{\varepsilon_{du}}{\bar{\varepsilon}} \right)^a, \quad a = \dfrac{\ln AF_{r\max}}{\ln(\varepsilon_{du}/\varepsilon_{\min})} & (\varepsilon_{\min} \le \bar{\varepsilon} < \varepsilon_{du}) \end{cases} \tag{2}$$

where $\bar{\varepsilon}$ stands for equivalent strain, $AF_{r\max}$ is the maximum of $AF_r(\bar{\varepsilon})$, and ε_{min} is the threshold strain for hyperresorption (Fig.1).

In the OW for the strain larger than the threshold ε_{ol}, only considered is the formation caused by the targeted remodeling [6]. Its activation frequency is also elevated by the increase of strain stimuli and is expressed as

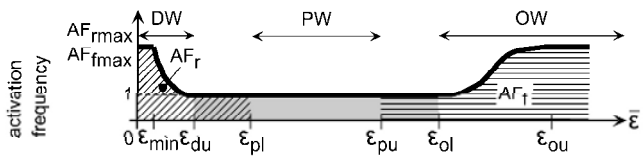

Fig. 1 Activation frequency over DW, PW and OW.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2104–2105, 2009
www.springerlink.com

$$AF_f(\bar{\varepsilon}) = \begin{cases} \dfrac{AF_{f\max}}{2}\left\{\sin\pi\left(\dfrac{\bar{\varepsilon}-\varepsilon_{ol}}{\varepsilon_{ou}-\varepsilon_{ol}}-\dfrac{1}{2}\right)+1\right\}+1 & (\varepsilon_{ol} \le \bar{\varepsilon} < \varepsilon_{ou}) \\ AF_{f\max} & (\bar{\varepsilon} \ge \varepsilon_{ou}) \end{cases} \quad (3)$$

where $AF_{f\max}$ is the maximum of $AF_f(\bar{\varepsilon})$. It is noted that the pathological overuse is not considered and the upper limit ε_{ou} is enforced for the OW (Fig.1).

B. Femur model for simulation

The profile human proximal femur and its initial random trabecular structure are represented using boxel finite elements as is shown in Fig.2 (A). The fixed boundary conditions are imposed on the distal end, and the daily loading conditions were assumed for the remodeling simulation. The representative daily loading case of one-legged stance and extreme ranges of motion of abduction and adduction, illustrated in Fig.2 (B), (C) and (D), are enforced with the proportion of 3:1:1. The remodeling at the internal surface is simulated and the profile of outer cortical shell is remained as is. The isotropic elastic body of Young`s modulus 20.0 GPa and Poisson`s ratio 0.3 is assumed for the bone material.

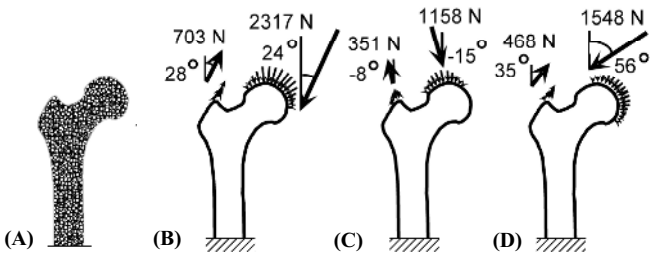

Fig. 2 (A) Initial structure of human proximal femur ,(B) one-legged stance, (C) abduction, and (D) adduction.

III. Results and Discussions

The trabecular structures simulated by the integrated model considered in the above and by the PW model only are shown in Fig.3. The gray scale indicates the equilibrant strain at each element. The initial random pattern of trabecular structure changed its alignment to line up with directions of principal stress in the metaphysis region and the thickness of cortical bone in the diaphysis increased under daily loading condition. In addition, indices of trabecular structure in femoral head and intertrochanteric region (#2) were approximately consistent with clinical observation [7]. Moreover, bone volume in Ward's triangle region (#3) decreased significantly under disuse condition while bone volume and cortical bone thickness (#1) increased under overloaded condition. These characteristics have been found in clinical observations. In comparison with the PW only model, the present results were more realistic demonstrating the importance of osteocyte apoptosis and targeted remodeling in the simulation model for remodeling analysis.

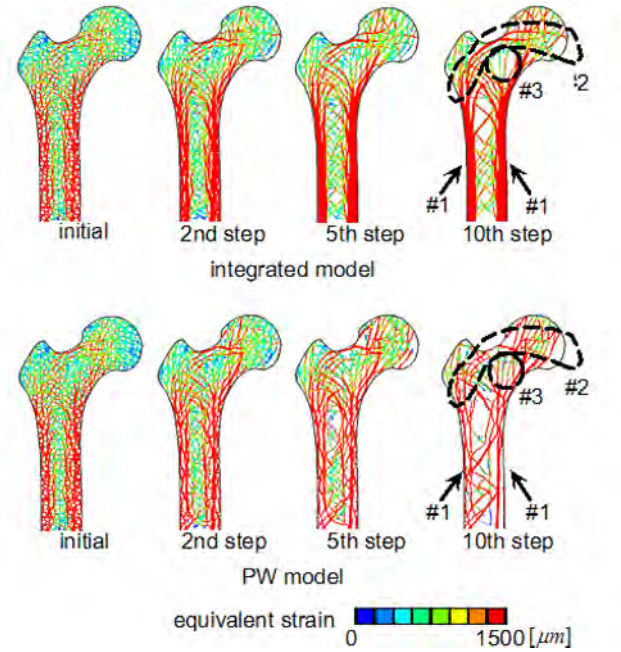

Fig. 3 Morphological change of trabecular structure in proximal femur simulated by integrated model and PW model.

Abstract — **Previous studies have demonstrated that low intensity pulsed ultrasound (LIPUS) may accelerate wound healing and activate the proliferation of skin cells. Those studies however did not thoroughly explore the bioeffect with respect to ultrasonic frequency of insonations. Hence, experiments were arranged and carried out to extensively investigate the proliferation of human foreskin fibroblasts (HFFs) insonated for 3 minutes daily with various 20% pulsed ultrasounds of 1 kHz repletion frequency, fixed 200 mW/cm2 (SATA), and frequencies of 0.5, 1, and 3 MHz, within a period of 3 days. The viability of insonified HFFs was sampled and evaluated for every 12 hours by trypan blue staining and optical microscopy. Results showed that the rates of HFFs proliferation associated with insonations by both 1 and 3 MHz are larger than those of control groups. However, those of HFFs insonated with a 0.5 MHz ultrasound tend to be smaller than that of control groups. The timing corresponding to the largest rate of HFFs proliferation was found to vary with the frequency of insonation, in which it corresponds to 36 h and 24 h associated with insonations of 1 and 3 MHz ultrasound, respectively. Specifically, the insonations of HFFs with 1 and 3 MHz tend to activate the largest proliferation rates to be 1.5 and 1.3 fold, respectively, larger than that of the control group. The temperature in the culture plate was measured before and after ultrasonic insonation and that varied only within 1 oC implying that the activation of HFFs proliferation is associated with the non-thermal effect of ultrasonic stimulation.**

Keywords — **Human foreskin fibroblasts, Cell proliferation, low intensity pulsed ultrasound.**

I. Introduction

The migration and formation of fibroblasts in an injury tissue is a crucial procedure for wound healing process. The fibroblasts may activate the synthesis of collagen and finally repair the damage tissues with the formation of scar tissues. In addition to its important role in wound healing process, fibroblasts almost may attribute to any rapid production of connective tissue matrix, such as the development of embryo and tissue culture [1]. Therefore, it is interesting and important to investigate effects that could be beneficial to growth of fibroblasts for further applications in tissue engineering.

Ultrasound is a means of mechanical wave propagation. As ultrasound waves are insonified into a biological tissue, a certain energy of the acoustic waves may disturb particles or molecules in the path of wave propagation, that leads them to deviate from their original positions. Depending on the intensity, the insonified ultrasound could generate thermal and/or non-thermal effects onto tissues [2]. These effects could be further applied to stimulate the wound tissue or cultured cells [3].

Dyson et al. [4] applied a 3.55 MHz ultrasound of different intensities ranged from 0.25 to 8 W/cm^2, 20% duty cycle, the pulse repetition period of 10 ms, to stimulate the wounded ear of mature rabbits for 5 min per day. They found that the regeneration performance in the wounded tissues seemed to be better in accordance with those received stimulations from low intensity ultrasounds. The improvement of tissue regeneration was assumed due to non-thermal effect by low intensity ultrasounds. However, as the intensity of the applied ultrasound increases to be higher than a few W/cm^2, the cultured cells tended to be damage or hemolysis associated with effects of the ultrasonic cavitation or others [5].

Although several previous studies have demonstrated the capabilities of low intensity ultrasounds could enhance either protein or collagen synthesis in human fibroblasts [6], there is no unified ultrasonic exposure including intensity, frequency, and pulse repetition period (PRP), implemented to stimulate cells. Yet, our previous study did validate that the fibroblast proliferation is effectively enhanced as the cells were exposed to 20% duty cycle and 200 mW/cm^2 of ultrasound for 3 minutes per day. This study is to further investigate the effect of various frequencies of the same low intensity ultrasound on the proliferation of fibroblasts.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2106–2109, 2009
www.springerlink.com

II. Materials and methods

The human foreskin fibroblast, cell line of HS68 obtained from Bioresearch Collection and Research Center at Food Industry Research and Development Institute, Hsin-chu, Taiwan, was used in this study. The cells were cultured in the DMEM (Gibco, BRL) medium supplemented with a 4 mM L-glutamine adjusted to contain a 1.5 g/L sodium bicarbonate (Gibco, BRL), 4.5 g/L glucose, and 10% fetal bovine serum (Biological Industries) at 37 ^{o}C in a 5% CO_2 humidified incubator.

The ultrasonic stimulation system was developed to insonate cells, which is primarily comprised of a ultrasonic tune burst generator able to generate three frequencies including 0.5, 1 and 3MHz. Specifically, tone burst signals were generated by multiplying sinusoidal waves of different frequencies with a train of square waves in which its width and period was fixed to be 1 ms. The arrangement of ultrasonic system for stimulating cultured cells is shown in Figure 1, in which ultrasound emitted by a transducer is directly coupled by the distilled water in the water bath into the bottom of a 24 well culture plate. The low intensity ultrasounds of a fixed 20% duty cycle of different frequencies were adjusted to be fixed to a 200 mW/cm^2 (I_{SATA}) calibrated by measurements using an ultrasound power meter (UPM DT-1, Ohmic instruments). Ultrasounds of the same intensity at different frequencies of 0.5, 1 and 3MHz were then applied to stimulate fibroblasts in the culture plate.

Initially, a number of 20000 cells were seeded into one of the well in the culture plate. Subsequently, the insonated cells respectively received corresponding frequencies of ultrasound exposures each for 3 minutes per day. The fibroblasts of the control group were also brought onto the culture plate holder at the same time as that of the experimental group to assure nearly equivalent factors condition may be applied for each experiment. The temperature in the culture plates was also monitored and maintained at 37^{o}C throughout the entire insonation process with a temperature controller. The fibroblasts were then quantified by counting the suspended cells, obtained from trypsinizing a monolayer of the fibroblasts in three wells of the culture plate, using trypan blue dye through a hemocytometer.

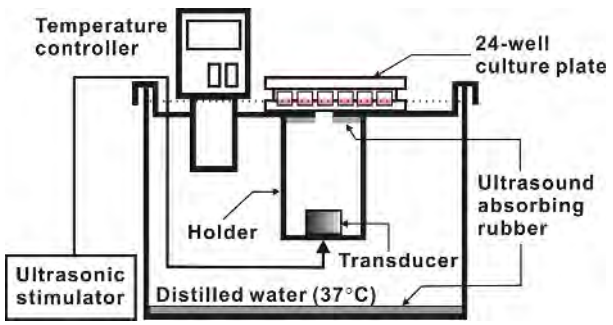

Figure 1 The arrangement for the stimulation of fibroblasts by ultrasound.

III. Results

After fibroblasts were subcultured from the cell line in a 24-well culture plate, it typically takes 3 days of doubling time before they are confluent. To better daily monitor the changes of cell numbers, the growth ratio of cell proliferation, calculated by normalizing the cell number of control or insonated groups sampled at a certain day, indicated as X* and X_c in the Y-axis of Figure 2, by those of at first day of subculture groups, indicated as X^*_0 and X_{c0}, were calculated. According to results in Figure 2, the average ratios of fibroblast proliferation display different feature corresponding to different frequencies of ultrasound been applied. With tone bursts of a 20% duty cycle and a fixed 200 mW/cm^2 intensity ultrasound insonified into the cell culture plate, those cells stimulated by 1 and 3 MHz tend to response better cell proliferation in terms of growth ratio than those insonified by a 0.5MHz ultrasounds. Especially, the growth ratio of cell proliferation approached to 1.5 and 1.3 fold than that of the control group with respect to insonation by 1 and 3MHz ultrasound, respectively, after that fibroblasts were exposed to ultrasound for 36 and 24 hours.

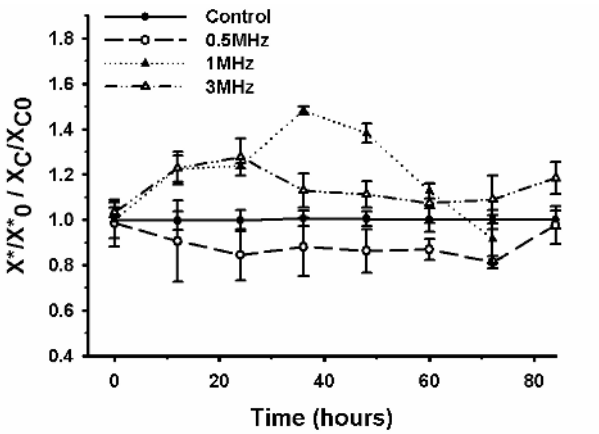

Figure 2 Normalized growth ratio of cell proliferation associated with different frequency ultrasounds as a function of time.

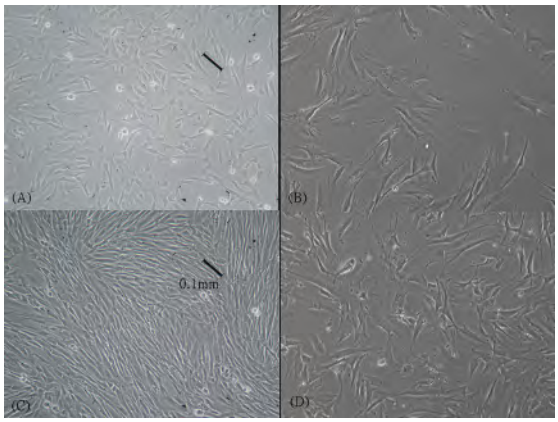

Figure 3 Morphology (100X) of investigated fibroblasts taken from a light microscope at 36 hours, (A) control group; (B) insonated by 0.5MHz; (C) insonated by 1MHz; (D) insonated by 3MHz ultrasound.

The effect of ultrasound stimulation on fibroblasts may be readily discerned with the morphology of cells from the control and experimental groups after ultrasound shown in Figure 3. The enhancement of cell proliferation with respect to ultrasound insonation may be directly compared by the morphology of fibroblasts of the control group and that of stimulated with a 1MHz ultrasound. In comparison with Figures 3(A) and (C), it may be readily seen that cell proliferation is activated for those under 1 MHz ultrasound insonation.

IV. Discussion

A previous research applied different acoustic powers for 10 minutes to insonify the osteoblasts has found that there could be a threshold of ultrasonic power able to detach the monolayer cells and leading to the deformation of cell morphology [7]. Results of another previous study from the same group also postulated that these results could be due to the exerted mechanical stress that improves the permeability of cell membrane to allow more supply of appropriate ions into the cells [8]. Current results suggest that the enhancement of fibroblast proliferation associated with ultrasonic insonification is a balance interaction between exposure time and the instantaneous ultrasonic frequency. The fibroblast proliferation is maximally activated corresponding to cells insonated by a 1MHz of a fixed 200 mW/cm^2 ultrasound at 20% duty cycle after exposure for 36 hours. The effect of cell proliferation stimulated by a higher frequency ultrasound, 3MHz, also tended to be capable of increasing the fibroblast proliferation, but that the effect is not as profound as those insonation with in 1MHz ultrasound. It is suggested that the number of times of vibration to stimulate cells with a higher frequency ultrasound, 3MHz, is much larger than that of lower frequency, 1MHz, to result in the appearance of the peak of cell proliferation beforehand. On the other hand, there is no significant difference between the response of cells stimulated by 0.5 MHz ultrasound and that of control group. The temperature difference in the culture plate was within 1^{o}C before and after ultrasound insonation also indicating that the non-thermal effect of ultrasound could be the primary factor contributing to the proliferation of cells.

V. Conclusion

In this study, the ultrasonic insonation system was developed and was applied to explore effect of ultrasound frequencies on the fibroblast proliferation. Different frequency ultrasounds were employed to insonate cultured fibroblasts. Results showed that the exposure of 1 and 3 MHz ultrasounds may activate the cell proliferation, and the effect of 0.5 MHz insonation however is not significant. Specifically, the insonation with a 1 MHz ultrasound of a 200 mW/cm^2 intensity of 20% duty cycle performs better enhancement of cell proliferation than those of by other frequencies of ultrasound.

Acromio-humeral Interval during Elevation when Supraspinatus is Deficient

Dr. B.P. Pereira[1], Dr. B.S. Rajaratnam[2], M.G. Cheok[2], H.J.A. Kua[2], Md. D. Nur Amalina[2], H.X.S. Liew[2], S.W. Goh[2]

[2]Nanyang Polytechnic, School of Health Sciences. Singapore.

Abstract — **Background & AIM: A narrowed acromio-humeral interval (AHI) during the first 30º of shoulder abduction usually indicates a tear to the supraspinatus muscle. Most investigations studied narrowing of the AHI in a static 0º abduction position. The purpose of this exploratory study was to quantify changes in the AHI during the first 30º of abduction when the supraspinatus was torn for future design of orthopaedic prosthesis and improvements to rehabilitation protocols.**

Method: A cadaveric shoulder was exposed and studied in detail. Next, a biomechanical model was constructed based on known physiological cross sectional area (PCSA) of the rotator cuff and deltoid muscles. Manual traction was applied to the model during abduction and changes in AHI record on video for analysis. Then, the model excluded the action of the supraspinatus and the change in AHI re-evaluated.

Results: The AHI measured at rest was 7.86mm (range= 7-14). When the supraspinatus was intact, at 30º of abduction the average AHI was 5mm (range= 0.428-0.571). However, when supraspinatus was absent, the crest of the greater tuberosity impacted the acromion at about the range of 9-12º of abduction.

Conclusion: This biomechanical evaluation of the shoulder indicated that the supraspinatus besides being an important dynamic stabilizer of the glenohumeral joint maintain a sufficient interval between the acromium and the humeral head for unobstructed arm elevation. When supraspinatus is absent, shoulder impingement also occurs below 30º of abduction.

Keywords — **shoulder; glenohumeral joint; supraspinatus tear; acromiohumeral interval; impingement**

I. Introduction

An intact rotator cuff actively stabilize the shoulder joint by three main mechanisms; 1. compresses the humeral head into the glenoid fossa, 2. raises joint contact pressure, 3. centers the humeral head in the glenoid fossa. To prevent complete superior translation of the humerus, the rotator cuff must compress the humeral head against the glenoid force. In the absence of a properly functioning rotator cuff, the unopposed action of the deltoid muscles impinges the humeral head superiorly against the corocoacromial arch, hence full abduction is prevented.

The supraspinatus must generate a force 20 times greater than the weight of the load for shoulder abduction. The muscle has the highest incidence of tear (37%) among the rotator cuff muscles and commonly occurs in the sport-active and elderly populations. The amount of humeral translation is greatest during the first 30 degrees of abduction[1].

Terrier[1] study was done using a 2-D finite element model (computational model) data derived from several authors. It also did not include a realistic analysis of any cadaveric model. An[2] reported that depression of the humeral head was most effectively achieved by the latissimus dorsi (5.6 +/- 2.2 mm) and the teres major (5.1 +/- 2.0 mm). The infraspinatus (4.6 +/- 2.0 mm) and subscapularis (4.7 +/- 1.9 mm) showed similar effects while the supraspinatus (2.0 +/- 1.4 mm) was least effective in depression. Thomson[3] found that no significant alterations in humeral translation occurred with a simulated supraspinatus paralysis, nor with 1-, 3-, and 5-cm rotator cuff tears, provided the infraspinatus tendon was functional.

Cotton & Rideout[4] defined the AHI as the smallest distance between the thin line of dense cortical bone marking the inferior aspect of acromion and the articular cortex of the humeral head. Golding[5] reported that the range of the AHI was 7-13 mm in normal subjects. While Weiner & Macnab[14] reported the range betwneen 7 to 14 mm. Those with stage II impingement and rotator cuff tears demonstrated a significant rise in the head of the humeral during the first 40 degrees of abduction[6-7]. However, examination were conducted in the static resting position.

This study aims to use a biomechanical model of the shoulder to examine the changes in the AHI during the first 30 degrees of abduction when the supraspinatus is deficient. The results from this study would help better understand the biomechanics of the shoulder when the supraspinatus is absent. The study hypothesize that without the supraspinatus, the AHI will be decreased to an abnormal range during shoulder abduction to 30 degrees.

II. METHOD

A. Cadaveric study

We performed a cadaveric dissection to obtain coordinate data on muscle coordinates as well as physiological cross-sectional area (PCSA) values of the muscles included in our model. PCSA is directly proportional to muscle force and may be used to predict the maximal muscle forces[8], calculated based on the following equation [9-10].

$$\text{PCSA } (\text{cm}^2) = \frac{\text{Muscle mass (g) } \cos(\theta)}{\rho\ (\text{g/cm}^3)\ \text{fiber length (cm)}},$$

whereby muscle density (ρ) is 1.0597 g/cm^3 and θ is fibre pennation angle[11].

A shoulder was harvested from a fresh adult cadaver, the age unknown. The scapulothoracic and sternoclavicular joints were disarticulated. No defects were noted on macroscopic examination. The skin and subcutaneous tissues were removed. Next, the superficial layer of muscles were removed, leaving the anterior, middle and posterior deltoids as well as the rotator cuff muscles. Each muscle was identified, and pins were inserted into the sites of attachment to record their position. Measurements of muscle lengths and pennation angle of muscle fibres were made based on photographs taken. The sites of attachments were digitized using MicroScribe-3DL. Bony landmarks on the scapula and humerus were also digitized so that bone length measurements can be calculated. Our original intention was to normalize the points of muscular origins and insertion so that the data can be applied onto our biomechanical model. However, during the dissection, it was discovered that the cadaveric specimen had Grade III tear of the supraspinatus. Apart from that, we also intended to derive our own PCSA values from the cadaveric specimen. However, as the cadaver was atrophied, it would underestimate the muscle mass resulting in an inaccurate PCSA value. Hence, we used PCSA values based on a previous study[12] – Table 1.

Table 1: Physiological cross-sectional area (PCSA) of muscles (Oizumi et al. [12])

Muscle	PCSA (cm2)
Anterior deltoid	4.5
Middle deltoid	13.5
Posterior deltoid	3.9
Supraspinatus	4.5
Infraspinatus	5.8
Subscapularis	9.7
Teres minor	2.6

B. Biomechanical shoulder model

Bone models of scapula and humerus were mounted onto a retort stand. A metal piece was used to represent the clavicle. The scapula was oriented at 30º of protraction and 20º of anterior tilt. The humerus was aligned to the medial border of scapula, defined as 0º of glenohumeral (GH) abduction. Screws were inserted into attachment sites of supraspinatus, infraspinatus, subscapularis, teres minor, and anterior, middle and posterior deltoid tendons on the scapula and humerus. Wires were fastened to tendon insertion screws and attached to the pulley system, representing the line of action of the muscles. Weights were added to represent ratios of the muscle forces based on the PCSA values. Weights were attached to the distal humerus to simulate weight of normal arm. An electronic goniometer was placed along the proximal shaft of the humerus to record the abduction range occurring at the GH joint (Figure 1).

Figure 1 – The biomechanical model. P = pulley system, W_{ms} = weights representing muscle forces, W_{arm} = weight of arm, RS = retort stand, GS = goniometer sensor, GR = goniometer reader.

C. Testing protocol

A manual force was applied to move the humerus through a range of 90˚ of abduction in the coronal plane. This was first done with the supraspinatus intact, simulating a normal shoulder. A total of 6 trails were performed. Next, the weights representing the supraspinatus muscle force were removed, simulating a shoulder with a torn supraspinatus. Again, a manual force was applied to abduct the humerus through the greatest possible range with a total of 6 trails being done. The movement was monitored using video recording. Calculations of changes in the acromiohumeral interval (AHI) between 0 to 30˚ of GH abduction were made as the greatest amount of superior humeral translation occurred in the first 30º when

supraspinatus is deficient[1]. This was done using photographic analysis

III. Results

The biomechanical shoulder model found that when supraspinatus was left intact in the shoulder model and its humerus elevated at 0 degree, the AHI was measured an average of 0.786cm. At 30 degrees of elevation, the crest of the greater tuberosity passes below the acromion at its closest proximity (average, 0.500cm). The results have been tabulated in Table 2.

Table 2: Measurements of Acromiohumeral interval (AHI) when Supraspinatus is intact.

	AHI
At 0 degree	0.786 (SD value)
At 30 degrees	0.500 (SD value)

When supraspinatus was removed from the model, we observed that it was unable to reach 30 degrees. The humerus internally rotated more than that when supraspinatus was intact. This also led to early impingement occurring at 9-12 degrees of humerus elevation.

IV. Discussion

The glenohumeral joint under normal circumstances, maintains a balance between its high degree of mobility and its lack of intrinsic stability. From our biomechanical model of the shoulder, this research seeks to examine what happens when there is a full supraspinatus tear using the acromiohumeral interval as a measurement. We obtained results for the AHI of normal shoulder at 0º and 30 º and that with a simulated full-supraspinatus tear. The AHI was found to be 7.86mm for a normal shoulder. This was within the range of 7-13mm as reported by Golding[5], 6 to 14mm as reported by Cotton & Rideout[4], and 7 to 14mm as reported by Weiner & Macnab [13]. It was stated patients with rotator cuff tears tend to have an AHI of less than 5 mm[13]. This radiological study of the acromio-humeral interval in 60 normal shoulders and 59 shoulders with known tears of rotator cuff concluded that a narrowing of this interval is a frequent concomitant of a tear of the rotator cuff. In 44% (26 out of 59) of the cases, the acromio-humeral intervals were measured to be of 5.00mm or less. It is not known if the study used shoulders with complete or incomplete lesions. No statistical analysis was conducted as well.

Narrowing of the acromio-humeral interval has been defined one of the 5 key radiological diagnosis of rotator cuff tears as proposed by Cotton & Rideout[4]. The other key aspects are as follows: cystic appearances in the bone of the upper two-thirds of the anatomical neck of the humers[5]; recession, cortical irregularity, sclerosis or trabecular atrophy of the greater tuberosity of the humerus[4]; a distinct notch or gap between the articular surface of the head of the humerus and the greater tuberosity[4]; irregular new bone formation on the lateral margin of the acromion. It seems likely that all these changes are explicable on a basis of previous trauma. However, whether this results from a solitary severe incident or many minor episodes is a matter of conjuncture.

One of the observations of our study was that, in the absence of supraspinatus, impingement occurs at 9 to 12 degrees when the shoulder was abducted. This was not found in present literature. We suggest that this novel result could be explained by the loss of synergistic relationship between the middle deltoid and the supraspinatus. The unopposed action of the middle deltoid during the initiation of abduction led to an increased superior humeral translation. From the study we also observe the humerus to be more internally rotated as it moved. This could be a secondary contributing factor to explain the occurrence of early impingement. An imbalanced force couple between the internal and external rotators would lead to an excessive internal rotation of the arm, even in the initial phase of abduction. Langenderfer et al[14] examined muscle-tendon parameters and predicted moment generating capacity for rotator cuff muscles including supraspinatus, teres major and infraspinatus muscles. Supraspinatus was found to have the greatest moment capacity at 10 degrees of arm abduction. Hence, in the present of a supraspinatus tear which was simulated in our study, the humeral head was found to be increasingly internally rotated during arm abduction. This could lead to increase incidence of early impingement occurring at the acromion.

V. Clinical implication and limitations

The results of this study suggest that strengthen the other humeral depressors such as the teres major, latissimus dorsi and long head of biceps can reduce narrowing of the AHI after a supraspinatus tear. Depression of the humeral head was most effectively achieved by the latissimus dorsi and the teres major[15]. After a supraspinatus tear, the upwards pull of the middle deltoid is relatively unopposed and may leads to superior displacement of the humeral head during arm elevation or abduction. Thus, it is proposed that proper strengthening exercises that adopt dynamic theory of muscle synergy will create compressive forces on the glenoid

face that prevent superior displacement of the humeral head. We found the shoulder to be impinged at 9-12 degrees. Thus, there is a need to re-establish a dynamic relationship between the shoulder muscles in the early ranges of gleno-humeral abduction and this study support Haahr et al[16] recommendations for successful rehabilitation of patients with stage II impingement syndrome.

The current exploratory study evaluated the relationship between the glenoid fossa and the humeral head. Other joints involved during shoulder abduction such as the scapulo-thoracic or acromio-clavicular joint were not taken into consideration. In the present study, the scapula was chosen to be fixed in our biomechanical model and passive restraints were not analysed. We also recommend that a pneumatic hydraulic system be used to provide a constant force to the humerus shaft.

VI. Conclusion

Biomechanical evaluation of our research indicates that the supraspinatus is an important dynamic stabilizer of the glenohumeral joint and for maintaining of a normal AHI. When supraspinatus is absent, the performance of abduction will result in early impingement below 30º of abduction.

Can Stretching Exercises Reduce Your Risks of Experiencing Low Back Pain?

Dr. B.S. Rajaratnam[1], C.M. Lam[2], H.H.S. Seah[1], W.S. Chee[1], Y.S.E. Leung[1], Y.J.L. Ong[1], Y.Y. Kok[2]

[1]Nanyang Polytechnic, School of Health Sciences. Singapore. [2] Nanyang Polytechnic, School of Engineering, Singapore.

Abstract — **Background and Aim: Stretching exercises are recommended for treat and prevention of symptoms of low back pain. Its effectiveness to improve postural alignment that contributes to low back pain has not been evaluated during prolonged sitting. The aim of this biomechanical study was to evaluate if performing stretching exercises during prolong sitting improved postural alignment.**

Method: 14 healthy subjects were randomly assigned to a control (C) and experimental (E) groups. Subjects in the (C) sat continuously for 2 hours to watch a movie while subjects in (E) were instructed to perform stretching exercises during the sitting period. Kinematic of changes in spinal posture throughout the sitting period was identified by retro-reflective markers placed on the trunk and pelvis. Subjects also expressed their Body Perceived Discomfort (BPD) they experience at the end of the prolonged sitting period.

Results: Trunk inclination (t=-0.737, P=0.489), thoracic kyphosis (t= 1.685, P =0.143) and lumbar lordosis (t=-0.236, P =0.821) did not change significantly between the first hour and second hours of sitting within (C). There was also no significant differences in kinematics of the various spinal measures among (E) which performed stretching exercises during the prolonged sitting period (trunk inclination: t=-1.560, P=0.170, thoracic kyphosis: t=-0.907, P=0.399 & lumbar lordosis: t=-0.015, P =0.988). However, BPD scores between groups at the neck (P=0.005), upper back (P=0.003), mid and low back (P=0.005) and buttocks (P=0.016) were significantly lower among (E) compared to (C).

Conclusion: This novel biomechanical study recommends the performance of stretching exercises to reduce the discomforts along the spine during periods of prolong sitting. The reduction of discomfort was not due to change in spinal alignment. Hence, ergonomic chairs that maintain static proper alignment are not effective as a treatment or prevention of low back pain.

Keywords — **Back pain, Exercise, Prolong Sitting, Kinematic analysis**

I. Introduction

Low back pain (LBP) is a common cause of discomfort in modern society. 80% of the population will suffer low back pain (LBP) at least once in their lifetime [1-2]. In sedentary workers and students, it has been found that prolonged sitting constitutes a potential risk factor for the development of LBP [3]. It has been found that the two major occupational risk factors of LBP are static muscle load, and flexed curvature of the lumbar spine; both involved in seated work tasks. Compared to standing or lying supine, sitting could cause the pelvis to rotate posteriorly, resulting in decreased sacral inclination and lumbar lordosis, and increased forces at the discs. In addition, there is an interaction between LBP and biomechanical changes such as decreased lumbar lordosis, malalignment of lumbar curvature, and narrowing of disc space [4], which might all occur in sitting. Thus, it is reasoned that maintaining spine postures near neutral alignment, avoiding excessive spine flexion, and minimizing joint loading by adopting an upright posture are important factors in maintaining back health and preventing LBP [5].

In addition, the European legislation's ergonomics guidelines, states that "Under the intended conditions of use, the discomfort, fatigue, and psychological stress faced by a worker must be reduced to the minimum possible." Subjective level of discomfort an important evaluation criterion for static postures and proposed, that an individual's subjective level of discomfort can be used as a predictor for the risks of LBP [6].

The effectiveness of interventions for treating back pain has been extensively studied. In one systematic review, exercise therapy was found to be slightly more effective than no treatment and other conservative treatments in reducing pain and improving function in patients with chronic LBP [7]. Steven et al [8] also noted that exercises are the most effective preventive intervention in the management of recurrent LBP as compared to back classes and lumbar supports.

Most of the previous known researches have been focused on the effects of exercises on managing acute or chronic LBP. Some have further explored the effects of such exercises on prevention of recurrent LBP. However the effectiveness of exercises on prevention of LBP in subjects with no history of LBP is unknown.

The Health Promotion Board (HPB) of Singapore [9] has designed a set of stretching exercises for individuals who are involved in prolonged sitting at work or in school. It is proposed that if these exercises are perform during a prolonged sitting interval, they might help individuals maintain a neutral spine posture and decrease static muscle load, thus reducing the risks of experiencing LBP. Thus, the aim of this study is to find out if performing stretching exercises in between prolong sitting improve spine postural alignment and reduce the subjective level of discomfort of the back.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2114–2117, 2009
www.springerlink.com

The null hypothesis is stretching exercises performed in between prolong sitting has no effect on spine postural alignment and subjective level of discomfort of the back.

II. Method

A. Protocol

Subjects sat for 2 hours continuously to watch a movie. 1 minute of kinematic data were collected at the end of every 5 minutes interval. Subjects fill up a body perceived discomfort (BPD) scale at the end of the protocol.

The subjects in the experimental group had a 10 minute stretching exercise interval by following 6 exercises recommended by HPB between the 55^{th}-65^{th} minute. Reach radius was limited within a 25cm radius boundary, and subjects kept their feet flat on the ground (Figure 1).

Fig. 1. Subject seated, with feet kept firmly on the ground and upper limbs kept within a boundary marked out on the table.

B. Instrumentation

i. Equipment

A motion analyser **(**Qualysis system) collected three dimensional coordinates of retro-reflective markers. 3 cameras quipped with infrared light emitting diodes captured retro-reflective markers placed on subjects. Subjects sat on a wooden stool with a desk in front of them.

ii. Marker location

The spinal model was similar to Frigo et al. [18] and Pauline W. et al. [19] studies. The landmarks were the seventh spinous vertebral process (M1), the apex of kyphosis (M3), the apex of lordosis (M6), lower edge of the sacrum (M8), middle between M1 and M3 (M2); markers M4 and M5 were equally spaced in between M3 and M6, mid position of the two posterior superior iliac spines (M7). (Fig. 2).

The shoulder girdle was identified by putting markers on the left and right acromions (Al and Ar).

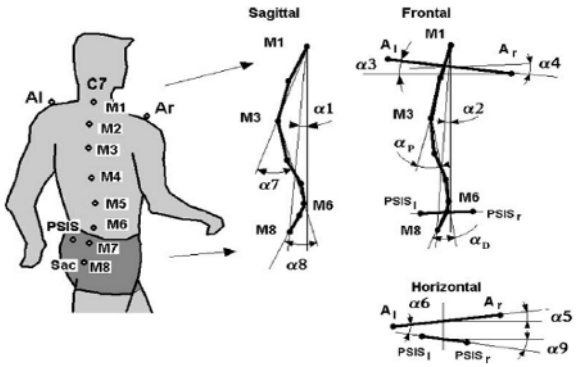

Fig. 2. Model of markers location and definition of meaningful segmental angles: α2- frontal trunk inclination; α7- angle of kyphosis; α8- angle of lordosis. from Frigo C. et al. (2003).

iii. Modeling and data processing

The absolute planes of motion were defined with reference to the laboratory axes: frontal plane- perpendicular to the line of progression (x-axis); horizontal plane (y-axis); sagittal plane- perpendicular to the intersect of the frontal and horizontal planes (z-axis). The following were considered to be of relevance for our study:

- Sagittal and frontal trunk inclination (α1 and α2 in Fig. 2). Angles between the M1-M8 line and the vertical line in the sagittal and frontal plane projections;
- Angle of kyphosis. Two spine segments were defined by markers M1-M3 and M3-M6 and were projected on the local sagittal plane the angle between them (α7) was computed and depicted in Fig. 2.
- Angle of lordosis. This was defined as the angle between the two spine segments M3-M6 and M6-M8 projected on the local sagittal plane (α8 in Fig. 2)

iv. Subjective level of discomfort

The Body Perceived Discomfort (BPD) scale (0-10) determined subjects' level of discomfort after the 2 hour of prolonged sitting. 0 being no discomfort and 10 being extreme discomfort) discomfort.

C. Subjects

14 subjects (7 males, 7 females) with the following characteristics (mean, range): age 20.6 years (18-24); weight 55kg

(42-64); height 1.66m (1.59-1.80) with no previous past medical history of low back pain were recruited. Informed consent was obtained from all subjects. The protocol was approval by Nanyang Polytechnic, School of Health Sciences Projects Committee.

D. Statistics

Statistical Package for the Social Sciences (SPSS) for Windows (version 14.0) was used to study the effects of a 10 minute exercise intervention during a 2 hour prolong sitting period on postural alignment (i.e., lumbar lordosis, thoracic kyphosis and trunk inclination) and the exercises on a person's subjective feeling of discomfort. The Independent-Samples T-test determined if the changes in postural alignment prior to the exercise intervention (0-55th minute) between both groups were significant. Paired-Samples T-test compared the amount of changes in postural alignment, prior to (0-55th minute) and after (65-120th minute) the intervention, within each group (i.e., control and experimental). The level of statistical significance was set at 5% throughout the experiment.

III. Results

A. Kinematic Analysis

The initial (before the intervention; 0-55th min) average change in range of motion for trunk inclination, angle of kyphosis and angle of lordosis, between the control and experimental groups, were compared using the Independent-Samples T Test. Levene's test for equality of variances for all 3 angles were significant (P>0.05) and thus equal variances were not assumed. The results showed no significant differences between the two groups in terms of trunk inclination (P=0.408), kyphosis (P=0.276) and lordosis (P=0.254) prior to the intervention.

The Paired-Samples T Test found that within the control group, there were no significant changes in the average change of trunk inclination (P=0.489), kyphosis (P=0.143) and lordosis (P=0.821) angles throughout the entire 2-hour prolong sitting period. Within the experimental group, there were also no significant changes in the average change of trunk inclination (P=0.170), kyphosis (P=0.399) and lordosis (P=0.988) angles before and after the intervention; throughout the entire 2-hour prolong sitting period.

B. BPD

Average ratings of BPD scores of the neck, upper back, mid and low back, and the buttocks found that subjects in the intervention group reported significantly less neck (P=0.005), upper back (P=0.003), mid and low back (P=0.005) and buttocks (P=0.016) discomfort compared to subjects in the control group.

IV. Discussion

Helander & Quance [10] studied the effects of a rest interval during prolong sitting, and found that 2, 20-minutes rest interval during a 4 hour prolong sitting period was the most effective in maintaining proper spine alignment. Stretching could provide rest and relief for the passive and active structures of the low back [5,11]. This is the first study that evaluated the effects of stretching exercises on spine postural alignment during prolonged sitting.

The experimental group had significantly lower BPD scale scores of the neck, upper back, mid and low back and buttocks, compared to the control group at the end of the 2 hour prolong sitting period. Operators exhibited increased body discomfort after prolong sitting session without movement or stretches [12] and an increase risk of injury [13]. This study found that stretching exercises performed between prolong sitting reduced discomfort, and possibly decreased the risk of injury.

However, the kinematic analysis results showed that stretching exercise during the 2 hour prolong sitting period resulted in no significant differences in spinal posture. May be 2 hours of prolong sitting period was not affect postural alignment as other studies defined prolong sitting as periods of 3-4 hours [11,14-16]. Another confounding factor of the present study was different in postural alignment of men and women. Female participants sat with more anterior rotation of the pelvis, less lumbar flexion and very little trunk flexion when compared to the males [5].

The present study results show that the average change of spinal postural alignment for the subjects in the experimental group displayed a greater spread of results compared to the subjects in the control group. Some may have improved postural alignment after stretching, while others did not. Many factors may be relevant for the occurrence of LBP [17] and stretching exercises might be very important for an individual who has a given risk factor such as decreased spine flexibility, but not so for another individual with decreased strength or poor posture.

The limitations of our study include 1) the possible influence of environmental and psychosocial factors (e.g. being in a new environment, the temperature of the room, their present stress level) on the subjects' BPD scale scores, 2) the inability to allow our subjects' to lean against a back rest, like how they might do in school or work, 3) the inability to control every single movement of the subjects (e.g.

coughing, sneezing, scratching), and lastly 4) experimenters' biasness. Every effort, however, was made to limit the errors that might have arisen from the above circumstances.

V. Conclusion

Stretching exercise performed in between prolong sitting period did not seem to have an effect on one's postural alignment. However, stretches were effective in reducing one's subjective level of discomfort and thus can be recommended during prolonged sitting. Based on the great variability of responses from the subjects in the experimental group to the stretching exercises, a multidimensional approach may be more effective in reducing the risk of LBP. Further research is recommended to better understand the effects of rehabilitation intervention to minimize the risk of LBP.

Streaming Potential of Bovine Spinal Cord under Visco-elastic Deformation

K. Fujisaki, S. Tadano, M. Todoh, M. Katoh, R. Satoh

Division of Human Mechanical Systems and Design, Graduate School of Engineering, Hokkaido University, Japan

Abstract — **Spinal cord is mainly composed of white matter and gray matter. These tissues have solid phase and liquid phase. When they deform, liquid phase in the tissue flows out through between solid phases. The interaction and frictional resistance between two phases perform the macroscopic visco-elastic behavior. In addition, solid phase in soft tissue contains a lot of negatively-charged proteoglycan. This electro chemical behavior affects visco-elastic properties of the tissue. Triphasic theory was proposed to describe the mechanical properties of the tissue of arthrodial cartilages considering with solid, liquid phase and negative ion phase. In this study, the electro-kinetic behavior of white matter and gray matter were investigated under several compressive loading. Column-shaped specimens in diameter of 5mm and height of 5mm were made from both matters in a bovine cervical spinal code. Each specimen was set in physiological saline. The streaming potential was measured under compression loading, stress relaxation and cyclic loading. As a result, the streaming potentials showed linear relation to tissue stress in compression and relaxation progress. Although the streaming potential changed according to applied stress in cyclic loading, the potential amplitude was gradually decreased with increasing of the loading cycles.**

Keywords — **Biomechanics, Spinal cord, Streaming potential, Uniaxial loading.**

I. Introduction

Spinal cord is a part of central nerves constructed from numerous cells, nerve fibers and biological films. An important physiological function of the spinal cord is signal transductions of organic activities. This tissue is protected by bone structures; vertebral bodies, vertebral discs and vertebral canals including posterior structures of column, to perform the function properly. Spine injury is occurred caused by vertebral bone fracture or bruising damage in the case of accidents on the road or at sports. The spinal cord has high fault incidence to applying loads. Thus understanding of applied stress in various situations is important to prevent the injury. Although many kinds of stress/strain analyses were conducted for spine structure, mechanical properties of spinal cord were not really investigated. To explain the mechanical properties of biological soft tissue, some physics models have been proposed in analytical studies, the properties are described by approximately elasticity, visco-elasticity [1, 2] and biphasic model considering the interaction of solid and liquid phases [3-5]. When they deform, liquid phase in the tissue flows out through between solid phases. The interaction and frictional resistance between two phases perform the macroscopic visco-elastic behavior. In addition, solid phase in soft tissue contains a lot of negatively-charged proteoglycan. Strain of the tissue changes charge density on the proteoglycan and disrupts the balance of electrochemical equilibrium. This electric charge affects visco-elastic deformation of the tissue. Triphasic theory was proposed to describe the mechanical properties of arthrodial cartilages [6-10] considering with solid, liquid phase and negative ion phase. When the electric potential is detected in deformed tissue, its value changes concerned with the liquid flow. This relatively electric potential change is called streaming potential. The streaming potential has been measured in arthrodial cartilages [11-14] and interspinal disc [15]. The interaction containing the negative ion, according to the triphasic theory should be used in analysis for mechanical characteristics of spinal cord. In this study, the electro-kinetic behavior of white matter and gray matter were investigated under several compressive loading.

II. Streaming potential detecting system

Since the diffusion resistance of liquid phase in spinal cord affects deformation of the tissue, mechanical properties of the tissue are nonlinearly changed by applying force. The uni-axial loading tests of spinal cord were conducted with uni-axial inner liquid flow condition. Figure 1 shows the measurement system constructed in a commercially material testing machine (Instron 4411, Instron Co., with 50N load cell) setup for using mainly compressive test with an indenter. A specimen is placed in an acrylic ring. The ring is put on a porous plastic plate. The ring restrains circumference of the specimen from deforming. The porous filter prevents to flow out of the solid phase and does not obstruct to flow in or out of the liquid phase. These structures are set at inside a clear acrylic bath filled with physiological saline. An electrode of Ag/AgCl is bonded at the tip of the indenter via an insulating part. This type of electrode is useful for testing in physiological condition because this material is not melted in solution containing chlorine ions, thus the biological specimen does not give damages during measurements. Another electrode is located

www.springerlink.com

in the bath kept away from the specimen as a reference electrode. The electric potential detected by electrodes is through an amplifying device (CDV-700A, Kowa electric instruments), and recorded in PC by using a sensor interface (PCD-300A, Kowa electric instruments) concurrently with applying load.

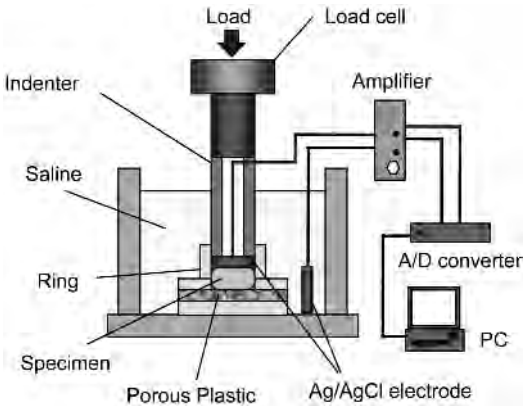

Fig. 1 A model of electric potential measurement system

III. Experimental procedure

A. Specimen

Inner structure of spinal cord can be identified by observation of cross sectional surfaces as two phases classified into gray matter; with H-shaped locating near the center of the section, and white matter; surrounding for the gray matter, and spinal meninges encircling these matters. A part of spine including spinal cord was cut out from a Holstein cow, female, 24 month old, which is recently death. The spinal cord was extracted from the spine before freezing. Column-shaped specimens in diameter of 5mm and height of 5mm are made from the area in gray matter and white matter, respectively, in the spinal code under refrigerated state. Compressive direction of each specimen was aligned with spinal axis. These specimens were cryogenically-preserved in freezer of -35 ˚C until just before experiments.

B. Preparation for experiment

A frozen specimen was thawed at the setting position in the testing device dropped in physiological saline at a condition of room temperature of 22 ˚C. Height of the specimen changes drastically by selling phenomena. To prevent the resistance force occurring caused by swelling in loading tests, the specimen was given satisfied time for 30 min before beginning the tests. Since the swelled volume varies from one specimen to another, an initial position to start loading cannot be provided constant. The initial condition about height of the specimen was determined as a specific position with resistant force to be 0.05 N; measured by load cell, in a situation of compression force applied through the indenter.

C. Experimental condition

Three kinds of investigations; compression with compression rate of 5, 10, 20, 30, 60 %/min, cyclic loading of 0.1, 0.05, 0.01 Hz in compression side, and stress relaxation, were conducted under wet condition of physiological saline at the room temperature of 22 ± 1˚C. The electric potential between the electrodes amplified 1000-fold was detected by sensor interface with the sampling frequency of 10 Hz, and recorded them together with applying load obtained from the load cell attached at the indenter.

IV. Result

A. Compression test

Electric potential was measured to be negatively charge according to increasing the value of applied compressive strain. Figure 2 shows a relationship between electric potential and compressive stress obtained at a white matter specimen. This electric potential change was less than 0.1 mV measured under compression condition of the maximum strain of tissue up to 30 %. The relationship between electric potential and stress was almost linear with high correlation coefficient (R^2 = 0.9911). Proportionality constant (electrokinetics factor: *ke*) was measured on each specimen of gray matter and white matter under different compression rate, as shown in Fig. 3. Although these values

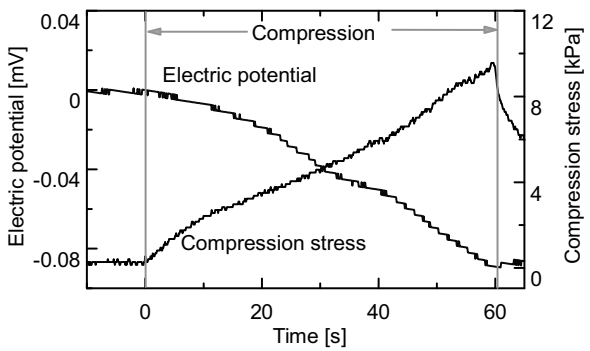

Fig. 2 Compressive stress and electric potential measured under compression process

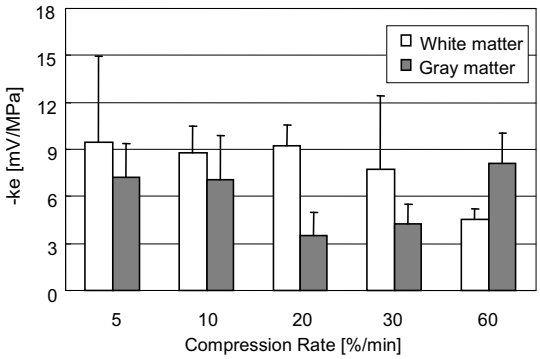

Fig. 3 Relationship between electrokinetic coefficient *ke* (mean ± S.D. (n=4)) and compression rate

were obtained as scattering results even in same type of specimen, the difference of each matter was clearly shown in the results. The *ke* was higher value on white matter than on gray matter except the result measured at 60 %/min straining. The minimum value on gray matter was obtained at 20 %/min, the value on white matter began to decrease in higher compression rate more than 30 %/min.

B. Cyclic loading test

Figure 4 shows a short part of a time chart in a cyclic loading test of a white matter with ±5 % strain. The electric potential changed according to the loading. The response of electric charge showed almost no time delay and measured pattern had negatively peaks at maximum compressive position in the loading. However the electric potential had instability change in periods for the indenter moving from compressive positions to unloading initial positions. Figure 5 shows the amplitude change of a white matter under each condition. The amplitude was slightly decreasing with cyclic number increasing.

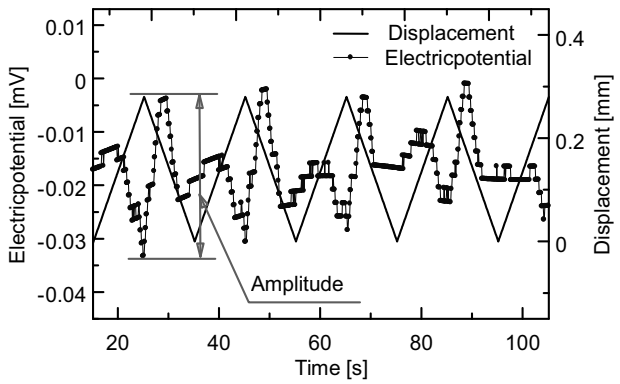

Fig. 4 Electric potential change during cyclic loading at white matter with ±5 % strain

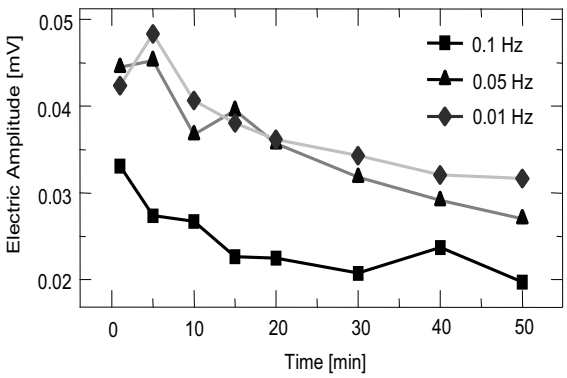

Fig. 5 Changes of electric potential amplitude of white matter under cyclic loading

C. Stress relaxation

A result of electric potential change measured in relaxation period was shown in Fig. 6. Precondition was 30 % straining with compression rate of 30 %/min on a white matter. The electrokinetics factor *ke* was obtained from linear relationship of the electric potential and stress measured in the relaxation for each specimen of gray matter and white matter. The mean value of *ke* on each specimen was 16.0 [mV/MPa] for white matter and 12.4 [mV/MPa] for gray matter. These values were higher than the values obtained under compression process.

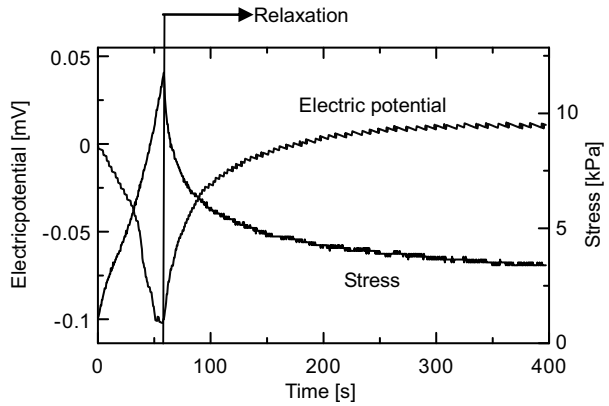

Fig. 6 Compressive stress and electric potential measured under elaxation process

V. Discussion

In this experiment, streaming potential could be detected as electric charge on a specimen under compressive loading in physiological saline. The streaming potential changes on two kinds of specimens made from gray matter or white

matter were measured with different values depending on compressive speed (Fig. 3). The values of the electric potential were less than 0.1 mV. These values were seemed like lower than the streaming potential measured at other tissue; reported in arthrodial cartilage [15]. This result might be provided by difference of volume fraction of proteoglycan in the spinal code.

Reduction of amplitude of electric charge occurred in cyclic loading. The result indicated that the solid structure containing proteoglycan destructed by cyclic loading because the reduction depended on number of cycles. The nerve fibers existing in white matter includes a lot of myelin which acts insulating material in signal transfer in nerves. The myelin attached on the indenter might disturb detection of the electric potential in white matter. On the other hand, the white matter has temperature-dependent properties. It might be affected by heat generation in friction of inner liquid flowing under cyclic loading. In this study, thermal condition was not controlled and the value was same as room temperature.

The linear relationship between the stress and electric potential generating there was obtained not only compression processes but also stress relaxation processes. The applied stress was to be almost free after about 200 s passed from a compressed state. This phenomenon was same tendency as shown in an analytical study of stress relaxation under compression of arthrodial cartilage based on tripahic theory [8]. The streaming potential should be considered connecting to visco-elastic properties. And both gray matter and white matter should be considered in triphasic study as same as arthrodial cartilages.

VI. Conclusion

Streaming potential measurements were conducted under uni-axial loading conditions. The streaming potential was measured under compression loading, stress relaxation and cyclic loading. As a result, these values showed linear relation to tissue stress in compression and relaxation process. Although the streaming potential changed according to applied stress in cyclic loading, the potential amplitude was gradually decreased with increasing of the loading cycles.

Abstract — **Malignant transformation is correlated with changes in cellular and nuclear structures and mechanical property of cancer cells. Here, atomic force microscopy (AFM) indentation using a spherical probe was carried out to characterize the elasticity of benign and cancerous human breast epithelial cells at both room temperature and physiological temperature. Our results show that malignant (MCF-7) breast cells have an apparent elastic modulus half of their non-malignant (MCF-10A) counterparts at ambient temperature. Also as temperature increases from 24 ºC to 37 ºC, apparent elastic modulus of both benign and cancerous cells decreases, especially for MCF-10A. Our study demonstrates that as a result of the malignant transformation, the breast cancer cells become softer. This change may aid in facilitating easy migration and invasion during metastasis. Also, temperature, which may cause the change in cytoskeletal dynamics and structural remodeling, affects cell elasticity and must be taken into account when probing the mechanical property of cells.**

Keywords — **AFM, breast cancer, cell mechanics, indentation, temperature effect.**

I. Introduction

Cancer has long been one of the leading causes of death in the world and is presently responsible for about 25% of all deaths [1]. In particular, breast cancer is the most common form of cancer afflicting females, as one in very eight woman develops breast cancer at some stage of their lives, and it causes about 15% of cancer deaths in women [1].

Mechanical properties of individual living cells are closely related to the health and function of the human body. Any deviations in the mechanical properties of living cells may affect their physiological functions and consequently give rise to diseases state [2,3]. It is known that some diseases, like cancer, can induce mechanical property changes in living cells, and the mechanical property may potentially serve as a useful biomarker in the early detection of cancer [2]. Moreover, investigating the mechanical property of cancer cells may help to better understand the physical mechanisms responsible for cancer metastasis and predict the potency of cancer metastasis. This can potentially lead to the development of novel strategies for cancer prevention and diagnosis.

With the recent advances in biomechanics and nanotechnology, it has now become possible to probe mechanical influences acting on biological structures not only as small as cells but also biomolecules. For example, biophysical tools and techniques such as atomic force microscopy [4,5], micropipette aspiration [6,7], and the optical stretcher [8,9] have been used to probe the mechanical property of different types of cells (see [2,3,10] for reviews). Also, mechanical models have been developed to study the mechanical properties of these cells [11]. *In vitro* study by different techniques showed that some cancerous cells are softer than their normal counterparts [4,8,9,12,13] (see [13] for reviews). In addition, AFM has been applied to investigate the mechanical properties of *ex vivo* cancer cells obtained from patients [14]. Lincoln *et al*. were the first to investigate the deformability of non-malignant and malignant human breast epithelial cells using the optical stretcher and they found that malignant cells can stretch five times more than their non-malignant counterparts [8,9]. In another study, Lekka *et al*. used the atomic force microscope (AFM) to study the elasticity of normal human bladder epithelial cells (Hu609 and HCV29) and cancerous ones (Hu456, T24 and BC3726) by AFM indention of these cells [4]. They found that normal cells are an order of magnitude stiffer than normal cells, which was attributed to the reorganization of the cytoskeleton. However, it is worth noting that their experiments were carried out at room temperature and they did not consider the effects of using different loading rates during indentation.

The objective of this study is to characterize the elasticity of non-malignant (MCF-10A) and malignant (MCF-7) human breast epithelial cells using AFM indentation with a spherical probe at different temperature. We will quantify and compare the apparent elastic modulus of these two cell lines. In addition, the effects of temperature and using different loading rates during indentation will be discussed.

II. Materials and Methods

Benign human breast epithelial cells (MCF-10A) and malignant human breast epithelial cells (MCF-7) were used in this study. For the purpose of routine culture, MCF-7 and MCF-10A cells were maintained at 37 °C in a 5% CO_2 incubator (Sanyo, Japan). MCF-7 was cultured in Dulbecco/Vogt modified Eagle's minimal essential medium (Sigma-Aldrich, USA), which was supplemented with 10% fetal bovine serum (HyClone, USA) and 1% penicillin (Gibco, USA), while MCF-10A was cultured in mammalian epithelium basal medium (Cambrex, USA). Cells grown to 80% confluence and up to 20 passages were subcultured using 1×trypsin (Invitrogen, Canada).

For the indentation studies, cells harvested from the subculture were seeded on sterilized 12 mm coverslips (Heinz glass, Germany) and kept in a 6 well microplate (IWAKI, Japan) which would stay in the incubator for 2–3 days prior to indentation. The medium was changed one day after seeding to clear any dead cells on the coverslip.

A Nanoscope IV multimode AFM with a picoforce scanner (Digital Instruments Inc., USA) was used to carry out the experiments. A modified silicon nitride AFM cantilever (NovaScan, USA) having a spring constant of 0.01 N/m with a 4.5 μm diameter polystyrene bead tip was used to indent the cells. During the experiment, the glass coverslip grown with cells was mounted on the AFM stage and the cells were kept in their culture medium using a standard fluid cell (Digital Instruments Inc., USA). In order to study temperature effects, a heater (Digital Instruments Inc., USA) was used to control the temperature of the sample during indentation.

Indentation was carried out at the cell centre using different loading rates from 0.03 to 1 Hz. The ramp size used in this study was 3 μm [15] and an indentation force of 0.2 nN was applied for the tests in order to minimize any substrate contributions and to exert a small deformation on the cell. The apparent elastic modulus was subsequently determined using the Hertz model, since this model is able to account for the geometry of the spherical probe used in this present study and it has been used extensively in other AFM studies to evaluate the apparent elastic modulus of cells [16]. Here, the Hertz model is used to study the small deformation behavior of a cell being indented by a hard axisymmetric indenter [17].

Fig.1 depicts schematically the indentation carried out on the centre of a cell using a 4.5 μm diameter bead attached to an AFM cantilever. The relationship between the indentation depth and the deflection of the cantilever is also illustrated. Once the contact point (refer to [18] for details on determination of contact point) has been identified, the deflection–z position curve (see Fig. 2) is converted to a plot of cantilever deflection against indentation depth (Fig. 3), which can then be used to derive the apparent elastic modulus using the Hertz's model. In this model, the apparent elastic modulus, E, can be obtained using the following formula [15]:

$$H \cdot k = \frac{4}{3}\frac{E}{1-\nu^2}\sqrt{RD^3} \quad (1)$$

where E is the apparent elastic modulus to be determined, ν is the Poisson's ratio, R is the radius of the spherical bead, D is the indentation depth (see Fig. 1), H is the cantilever deflection and k is the spring constant of the cantilever. The cell was assumed incompressible and a Poisson's ratio of 0.5 was used [15].

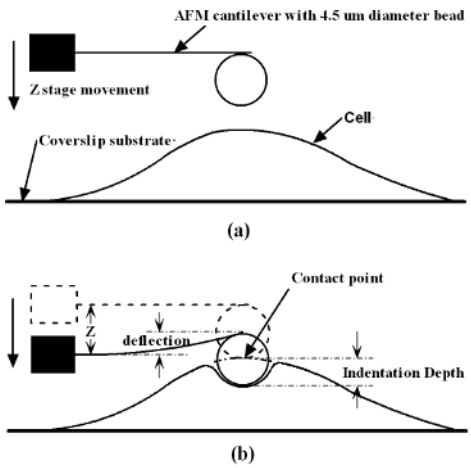

Fig. 1: (a) Schematic of the experimental setup for the indentation of a cell using a 4.5 μm diameter spherical probe. (b) An illustration of the relationship between the indentation depth, z-stage movement and the vertical deflection of the cantilever. The indentation depth is given by the difference between the movement of the z-stage and the vertical deflection of the cantilever. The deflected cantilever is drawn as a solid line while the undeflected cantilever is drawn dashed.

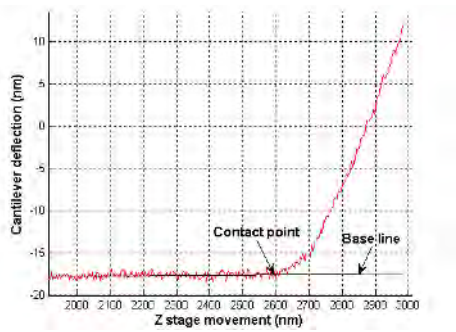

Fig. 2: A typical deflection–z position curve obtained from an AFM indention on a MCF-7 cell.

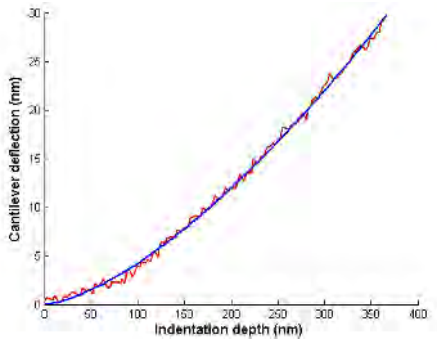

Fig. 3: A typical cantilever deflection–indentation depth curve obtained from the above indentation curve (Fig. 2) fitted by the Hertz's contact model.

III. Results and Discussion

This section presents the results obtained from the indentation tests carried out on two human breast cell lines MCF-10A and MCF-7, using different loading rates and temperature. The effects of temperature and different loading rates on the characterization of elasticity of these cells were subsequently discussed.

A. Effects of loading rates

The dependence between the apparent elastic modulus and the loading rates used in this present study for both MCF-10A and MCF-7 at the physiological temperature of 37 ºC are shown in Fig. 4. It is evident that higher values of the apparent elastic modulus are associated with increased loading rate. The cell is stiffer when probed using a higher loading rate due to their viscoelastic behaviour [19,20]. There is an increase in the apparent elastic modulus with a corresponding increase in the loading rate for both MCF-7 and MCF-10A. Previous indentation works (see [4,5,21]) carried out on other types of cancerous cells and fibroblasts did not take into account this dependence of the apparent elastic modulus on the loading rate. Our study shows that loading rate needs to be considered when performing mechanical test using AFM. At the physiological temperature of 37 ºC, the apparent elastic modulus of MCF-10A is about 1.5 times higher than that of MCF-7 at the same value of the loading rate.

Since the measured apparent elastic modulus varies according to the loading rate, the loading rate was fixed at 0.1 Hz for the subsequent study to evaluate the effect of temperature on the elastic modulus of MCF-10A and MCF-7. A loading rate of 0.1 Hz was chosen as the deflection–position curves obtained at this value of the loading rate exhibits characteristics associated with typical deflection–position curves obtained during the indentation process. Moreover, the contact point on the deflection–position curve was found to be extremely well-defined with a loading rate of 0.1 Hz. In addition, using a low loading rate, such as 0.1 Hz to study the apparent elasticity of cells is able to account for the static deformation behavior, which is biologically significant as cancer cells migrate through surrounding tissue matrix or get plugged in a capillary during metastasis [22].

B. Effects of temperature

Fig. 5 shows the stiffness of cells, determined using indentation, at both room temperature and 37°C. It can be observed that the apparent elastic modulus is smaller at a higher temperature. For MCF-10A at 37 ºC, the apparent elastic modulus is about 1.6 times smaller than the corresponding value at ambient temperature. In addition, we can also observe that MCF-7 is softer than MCF-10A at both 24 ºC and 37 ºC. Thus it is evident that temperature does have

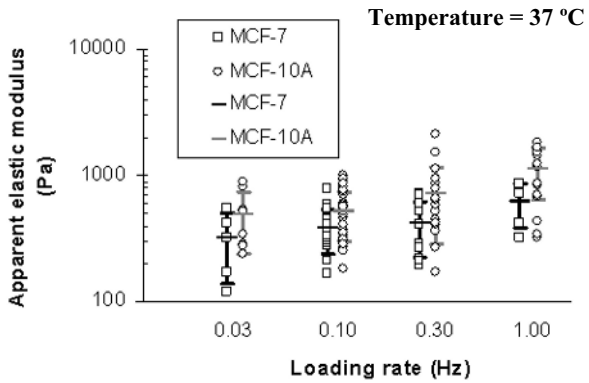

Fig. 4: Plot of the apparent elastic modulus against loading rate for MCF-10A and MCF-7 at 37 ºC. Error bars indicate standard deviations. Within an error bar, the centre line drawn indicate mean value.

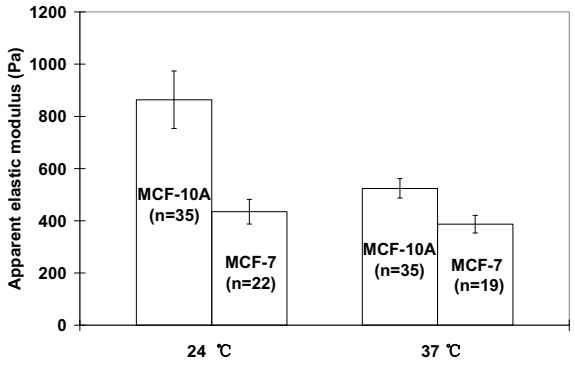

Fig. 5: Apparent elastic modulus of MCF-10A and MCF-7 cells tested at different temperatures and at a loading rate of 0.1 Hz. Error bars indicate standard error and n denotes the number of samples tested.

an effect on the mechanical properties of cells and it needs to be taken into account during probing cell elasticity.

Actin is a major component of the cellular cytoskeleton system (actin filament, intermediate filament, microtubule) and contributes significantly to the mechanical properties of the cell. In addition, actin structure is a highly dynamic structure and is strongly correlated with dynamic events such as migration and proliferation [23]. The reduced stiffness of both benign and cancerous cells as temperature increases may be attributed to the remodeling of the actin structure and a change occurring in its dynamic state due to the temperature change.

IV. Conclusions

The apparent elastic modulus of MCF-10A and MCF-7 were determined by means of AFM indentation using a spherical probe. Our results show that apparent cell elasticity increase with loading rate and decrease as temperature increase from 24 ºC to 37 ºC. Temperature has a more significant effect on the mechanical properties of MCF-10A. As mentioned earlier, actin remodels very quickly and is correlated with dynamic behavior of the cells. It is therefore not a static but a dynamic structure, and so the mechanical property measured is possibly a reflection of the dynamic state of the cell. Our indentation results, which were obtained using different loading rates, showed that cancerous MCF-7 is softer than benign MCF-10A at both room and physiological temperatures. This implies that malignant cells are more deformable and may aid in the metastasis of these cells.

Correlation between Balance Ability and Linear Motion Perception

Y. Yi[1] and S. Park[1]

[1] Department of Mechanical Engineering, KAIST, Daejeon, Republic of Korea

Abstract — **In this study, we investigated the correlation between balancing ability and motion perception. To provide the condition that declined balance ability, subjects were restrained their sole sensation. The balance ability was evaluated by measuring the center of pressure (COP) during quiet standing. Body kinematics was also monitored by using the motion capture system. We quantified the motion perception by measuring the threshold of perceived direction of linear motion. This result suggests that the COP represents the balance ability for quiet standing. However COP is insufficient for representing the balance ability during body movement. To describe the stability during motion, motion perception might compensate the COP.**

Keywords — **Motion perception, Center of pressure, Balance, Posture, Somatosensation**

I. Introduction

For the perception of motion, human use several sensory information such as vision, vestibular cues and somatosensation. This sense is induced by muscle spindle and Golgi tendon organ in muscles. These organs respond to change of muscle length or muscle tension. In upright stance, cutaneous cues provoked by pressure from soles are also used to perceive the movement of body. Like these sensory cues are processed in the central nervous system. Then, the resultant of processed information is used to perceive body motion or maintain the postural balance.

There are many studies that examine the characteristic of each sensation for motion perception. It is considered that these works are essential fundament to clarify the process of perceiving the motion. Many researchers have studied the threshold of sensory organs. Above all, vestibular organ, well known system in charge of the motion perception, has been extensively investigated. In contrast with the vestibular system, the influence of somatosensation on the motion perception has limitedly been studied. There are several studies that partially or peripherally deal with the somatosensation. Recently, several studies showed that additional cutaneous stimulus to soles enhanced the postural balance [1]. These results suggest that cutaneous information of sole and proprioception of leg, that is, lower limb somatosensation are strongly correlated with the balance ability in standing posture. Moreover, we previously showed that the cutaneous sense of soles played important role to the motion perception [2].

The balance ability was evaluated by observing the change of the posture sway. Usually, less posture sway was regarded as better balance ability. It remains unclear, however, whether the reduced postural sway directly demonstrates the improved subjective motion perception. In this study, we investigated the correlation between balancing ability and motion perception.

II. Methods

A. Subjects

Eight healthy male volunteers, who reported no history of balance disorders, aged between 20 and 27 years, were participated. All subjects read and signed KAIST IRB approved consent form. They were fully informed of potential risks such as falling, but not informed about the purpose of the experiment.

B. Stimuli

33 sets of a single sinusoidal acceleration at 0.25Hz with peak amplitude ranged 0~8mG were applied. Stimulus frequency was chosen as 0.25Hz to have reliable vestibular acceleration signals, which previously reported to be nearly unity gain at the stimulus above about 0.1Hz [3]. The pilot study for estimating the range of the threshold showed the range of threshold is about 2mG. Therefore the range of peak acceleration magnitude was determined from 0 to 8mG. To measure the detection threshold with high resolution, the peak acceleration magnitudes were designed to have small increased size for the smaller magnitude ranged from 0 to 2mG. For the fast process, the increment size is increased for the magnitude greater than 2mG. One trial set consisted of randomly ordered 33 velocity trajectories: 16 peak acceleration magnitudes of both directions and one standstill (0mG) stimulus.

C. Conditions

Subject participated in two conditions of 12 trial set which consists of 33 randomly ordered side-to-side support translation. In control condition (CC), subjects were tested without any restraint as shown in Fig 1. While in restrained plantar sensation condition (RC), subject stood on a cush-

www.springerlink.com

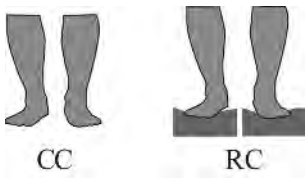

Fig. 1 Experimental conditions

ioned support surface to restrict cutaneous cues from soles. In each trial, platform was translated to either subject's left or right according to the velocity profile.

D. Procedure

Body kinematics was measured using motion capture system (Hawk; Motion Analysis Inc., Santa Rosa, CA). Subject attached reflective markers at head, neck, hip, and a support (Fig. 2A). The center of pressure (COP) was measured for a quiet standing by using a forceplate (AccuGait; AMTI, Watertown, MA), sampled at 100Hz.

Prior to experiment, subjects rehearsed a few practice trials to make familiar with the procedure of the test. During each session, subjects closed their eyes and lights over the platform were turned off and curtains surrounding the platform were drawn to prevent the room light from streaming. During the experiment, subjects stood on the platform with barefoot, loosened up their arms, and held report buttons at hand (Fig. 2B). Foot position was specified for consistency across the experiment. Subjects were provided white noise via the headphone to block auditory cues from motor operation noise. Before the onset of stimulus, subjects heard double beeps that indicate the platform movement. After side to side support translation, a single beep signaled subjects to report their perceived direction of motion by pressing one of hand held buttons. The experiment was designed according to a two-alternative-forced-choice (2AFC) psychophysical procedure. Therefore subjects were forced to make a choice of one of the two alternatives such as left or right, even when they weren't sure about the direction of motion. To minimize fatigue, subjects had 5 minutes break between each set.

E. Data analysis

Reported perceived direction of motion was analyzed using the cumulated standard distribution for psychometric function to obtain perception threshold. We defined the probability of motion detection as the percentage of correct report of 'right side' movement. Hence, 100% meant that the subject always report right side movement while 0% indicated that the subject never reported right side movement. The plotted probability of motion detections was fitted using psychometric function. We then defined the detection threshold of the translational motion as the difference between stimuli at the performance level of 50% and 75 % (Fig 3).

COP data for the quiet stance trials were band-pass filtered with cutoff frequency of 0.5 and 3.5 Hz. The initial 20 seconds of the data were discarded to eliminate the transient effect. Root mean square (RMS) of the COP in medial-lateral direction was calculated for a measure of postural sway. Body kinematics data were examined using covariance analysis [4]. While COP variance only shows the postural sway, covariance analysis provides correlation between body joints. Covariance of hip angle (θ_{hip}) and ankle angle (θ_{ankle}) was used to estimate the joint kinematics and postural sway.

Statistical analyses were used to test the significance of the effect of the designed conditions to the motion perception, COP variance and posture coordinate variance using paired t-test, and to the correlation between balance ability and motion perception using correlation analysis.

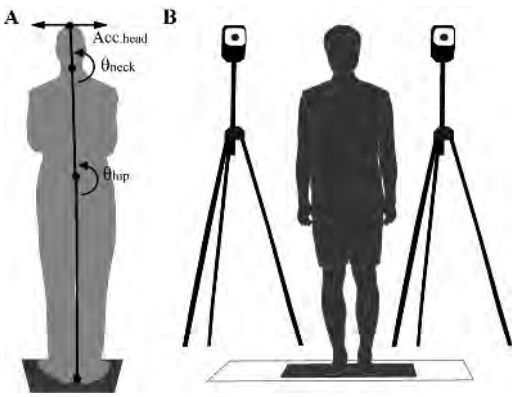

Fig. 2 Experimental setup

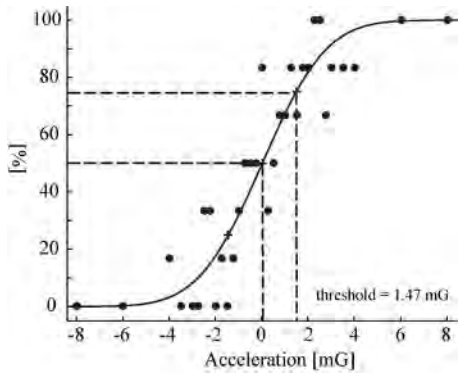

Fig. 3 Probability of motion detections and psychometric function

III. Results

A. Changes of threshold

When plantar somatosensory cues were restrained, significantly increased detection thresholds were observed (Fig. 4). As opposed to CC, detection probability for the RC gradually changed as a function of stimulus magnitude. This change made that the psychometric function was flattened, and indicated the increase in the threshold. Paired t-tests showed that the difference was significant ($p < 0.1$). While the average threshold of CC was 1.37 ± 0.41mG, the average threshold was 1.56 ± 0.39mG when the plantar cutaneous sensation was constrained.

In our previous research, we tested not only the cutaneous sensation but also ankle proprioception with the ankle brace. The results of former study showed the more step rise in the change of the thresholds ($p < 0.01$). The difference between the studies was only ankle restraint. Therefore we figured out that the difference of the result caused by the ankle proprioception. However there was no significant difference, when we performed the pilot study with only restraint ankle condition. With these matters, we concluded that if ankle proprioception and sole cutaneous sensation work together, it exerted a more influence than sum of them. The results were consistent with the previous study that interaction of several constraints to sensory organs exerted a more powerful influence than sum of effect of each constraint [5].

Our experiments showed that change of the joint angles of neck and hip was negligible. If there existed changes of body kinematics between two conditions, then body kinematics would affect the result. And the motion of head provoked additional influences of vestibular organ. We analyzed motion capture data by comparing the changes of peak angles and peak accelerations. The result of statistical difference presented in Table.1 indicated that a body kinematics and vestibular cue were not significantly changed between treatments. Therefore we thought that the change of the detection threshold was caused by designed conditions.

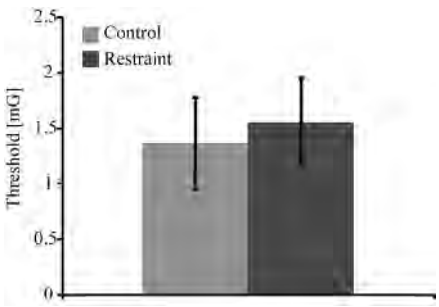

Fig. 4 Threshold of linear motion perception

Table 1 Statistical result of body kinematics

		p-value Control vs. Restraint	
		Standstill	Perturbation
Acceleration	Head	0.749	0.862
Joint angle	Neck	0.814	0.755
	Hip	0.725	0.906

B. Balance ability and motion perception

Our experiments showed that change of the COP was negligible. We calculated the COP in medial-lateral direction because experiments were performed along the medial-lateral direction. RMS of COP was 0.0008 ± 0.0004 in CC and 0.0008 ± 0.0003 in RC. This result showed that there was no significant difference between two conditions (Fig. 5). It meant that the designed condition did not influence to postural sway. That suggested that human did not have trouble to maintain the balance in medial-lateral direction even if the plantar cutaneous sensation was reduced.

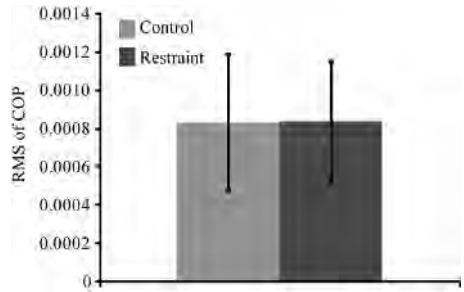

Fig. 5 RMS of the COP in medial-lateral direction

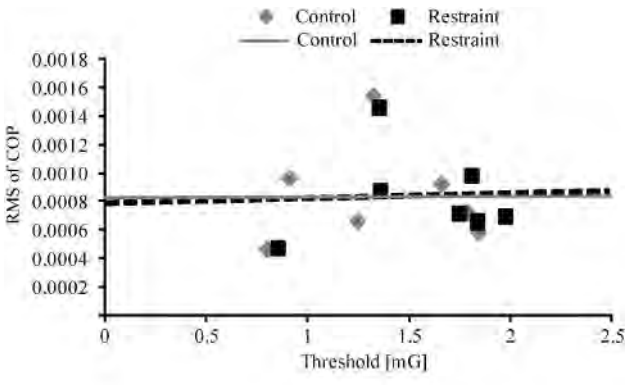

Fig. 6 Correlation between COP and threshold

Balance ability did not directly demonstrate motion perception. To examine the correlation between balance ability and motion perception, we compared RMS of COP with motion perception threshold. Linear regression line was presented at Fig. 6. Spearman correlation coefficient was 0.056 in control condition and 0.012 in restraint condition indicating that there was no correlation both of two conditions. This result suggests that the COP represents the balance ability for quiet standing. However COP is insufficient for representing the balance ability during body movement. To describe the stability during motion, motion perception might compensate the COP.

C. Postural coordinate

Hip strategy indicated significant difference between CC and RC. Covariance matrix (Q) of θ_{hip} and θ_{ankle} consisted of variance of ankle motion (Q11), variance of hip motion (Q22) and covariance of ankle-hip motion (Q12). In case of Q11, the results were 0.0012 ± 0.0005 in CC and 0.0012 ± 0.0007 in RC, there was no difference between two conditions (Fig. 7). Q22, on the other hand, indicated significant difference with 0.0033 ± 0.0022 in CC and 0.0040 ± 0.0028 in RC. Paired t-tests indicated significant ($p < 0.03$) increase in Q22. This result implied that human body used more hip strategy to maintain a balance when the plantar sensation was restrained. Moreover, body kinematics data revealed that there was no significant change of hip angle between CC and RC. It means more the hip use than the ankle use for balancing, not a significant change between the conditions.

RMS of COP was also showed that there was no significant change between two conditions. Nonetheless, Q22 was significantly increased. It meant that the Q22 might be able to be used as the index for the balance ability. COP could not sufficiently work. For example, COP could not figure out the Parkinson patients' balancing instability. In this case, covariance analysis might be useful to evaluate the balance ability.

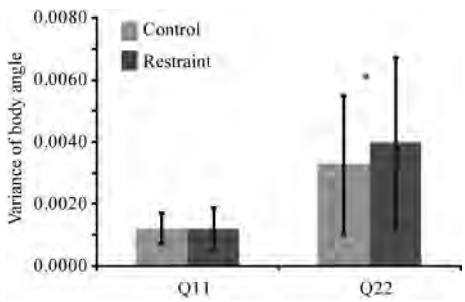

Fig. 7 Covariance matrix in medial-lateral direction

IV. Conclusions

Perception threshold of linear motion was increased when plantar cutaneous cues were reduced which implies that the plantar somatosensation influences the motion perception of the linear acceleration in absence of visual information. Balance ability, however, did not directly demonstrate motion perception. There was no correlation between COP and motion perception threshold. This result suggests that the COP represents the balance ability for quiet standing, although COP is insufficient for representing the balance ability during body movement. To describe the stability during motion, motion perception might compensate the COP. Moreover, we showed the potentiality that covariance can be used as the index for the balance ability.

Heart Rate Variability in Intrauterine Growth Retarded Infants and Normal Infants with Smoking and Non-smoking Parents, Using Time and Frequency Domain Methods

V.A. Cripps[1], T. Biala[1], F.S. Schlindwein[1] and M. Wailoo[2]

[2] University of Leicester/Department of Health Science, Leicester, UK

Abstract — **Intrauterine growth retardation (IUGR) and low birth weight have been linked with an increased risk of cardiovascular disease, hypertension and stroke in later life. Studies have shown cardiovascular mortality is associated with altered autonomic nervous system activity, which can be assessed using measurements of how the heart rate is changing over time, known as heart rate variability (HRV). A reduced HRV indicates a reduction in the autonomic activity. Heart rate data of 24 children, at age 9-10 years, was analysed, to investigate the HRV of IUGR and normal birth weight children in relation to their parents' smoking habits. In the time domain Poincaré plots were produced, and in the frequency domain periodograms created using the FFT and the Lomb method. The Lomb method can cope with non-uniformly sampled data series without the need for interpolation and re-sampling. Measurements of the low to high frequency ratios showed no difference between the groups of children in the study, however measurements of the energy of peaks in the high frequency region due to respiratory sinus arrhythmia showed a reduction in high frequency strength for IUGR children with smoking parents, when compared to IUGR children with non-smoking parents.**

Keywords — **Heart rate variability, intrauterine growth retardation, Lomb periodogram, Poincaré plots.**

I. Introduction

The heart rate can be measured by examining the electrical activity of the heart muscle using an electrocardiogram (ECG). The ECG recording of two heart beats is shown in Figure 1. The RR interval is defined as the difference in time between two consecutive R peaks (i.e. the time interval between two heart beats). Analysis of how the RR interval changes over time is known as HRV. The greater variation in the length of the RR interval the greater the HRV. The heart rate is controlled by several mechanisms: humoral, chemical, direct (such as the Frank-Starling mechanism) and, particularly, neurological, via the nervous system [1]. Specifically, the heart rate is controlled by the autonomic nervous system, the part of the nervous system responsible for the body's 'control system'. The autonomic nervous system is split into two divisions; sympathetic and parasympathetic (also known as vagal). The two branches work concomitantly; an increased heart rate is produced by an increase in the sympathetic and a decrease in the parasympathetic activity.

Studies have shown that there is a significant relationship between the autonomic nervous system and cardiovascular mortality, with lethal arrhythmias linked to either increased sympathetic or decreased parasympathetic activity, as well as a higher risk of post-infarction mortality with reduced heart rate variability [2]. Analysis of heart rate variability can be undertaken in both the time and the frequency domain.

In the time domain, statistical methods are used to find the standard deviation of the RR intervals, the SDNN, which estimates overall HRV. Graphical methods, such as Poincaré plots, are also used and are discussed. Analysis in the frequency domain is used to find the power of components within different spectral bands. Studies have shown that a low birth weight increases the risk of coronary heart disease, stroke, hypertension and non insulin-depended diabetes [3]. A study in Helsinki has also suggested than being IUGR may pose a risk of depression in young adult men [4]. Barker [3] suggests that during intrauterine development the organs and body systems are 'plastic', that is they are able to adapt and respond to be best suited to their environment and proposes a controversial hypothesis of fetal origin to adult heart disease.

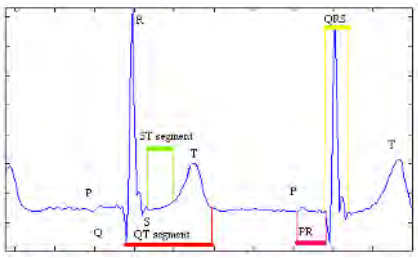

Figure (1) ECG recording of two heart beats

www.springerlink.com

II. Methods

In this study, two cohorts of children were used; those of normal birth weight and those who were intrauterine growth retarded (IUGR). IUGR was defined as 'any baby with a foetal abdominal girth two or more standard deviations below the mean or who by birth weight was below the second centile at term' [5]. Data from 73 children, 33 of normal birth weight and 40 IUGR, were collected at the Leicester Royal Infirmary. The ECG was recorded over a 24 hr period when the children were at 10 years old, as well as data on parental smoking during pregnancy and during the last 10 years. From the children in the larger study, a sub-set of 24 were selected within the four groups shown in Table 1.

Table 1: Groupings employed to select the 24 children used in this study.

Birth weight of child	Smoking status of parents
IUGR	smokers
IUGR	non-smokers
normal	smokers
normal	non-smokers

In this paper the following methods were used to analyse the data:-

A. Time domain analysis- Poincaré plots

One geometrical method with which to analyse normal RR intervals in the time domain is the use of a Poincaré plot, where the current RR interval is plotted against the previous. The resulting 'clouds' can then be enclosed by an ellipse and measured, giving an indication of the HRV. SD1, the width of the cloud or the standard deviation around the identity axis x1, is a measure of the short-term HRV - more precisely the measure of variability over a single heart beat. SD2, the length of the cloud along the line of identity or the standard deviation around axis x2, is a measure of long term HRV [6].

B. Frequency domain-Fourier transform

The discrete Fourier transform (DFT) is used to transform a discrete signal from the time domain into the frequency domain. It can be efficiently computed using a 'Fast Fourier Transform' (FFT) algorithm. The power in the signal is found by squaring the absolute value of the returned FFT result and can be plotted against frequency to produce a periodogram. The FFT requires a uniformly sampled signal, which is not the case in RR data, so the RR data needs to be interpolated and resampled at at least twice the maximum frequency of interest in the original signal to avoid aliasing. The resampling process alters the frequency content of even a noise-free time series by non-linear low-pass filtering [7], i.e. high frequencies are attenuated.

C. Frequency domain - Lomb periodogram

The Lomb method, developed by Lomb and later elaborated on by Scargle, is a technique designed to calculate the power in a signal with unevenly spaced data points and involves least squares fitting the time domain data points to a sine or cosine series. 'It weights the data on a 'per point' basis, instead of a 'per time interval' basis, when uneven sampling can render the latter seriously in error' [8]. No interpolation of the data series is required. The Lomb normalised periodogram, $P_N(\omega)$, is defined by the following equations as given in [8]:

$$P_N(\omega) = \frac{1}{2\sigma^2}\left\{\frac{[\sum_j (h_j-\bar{h})\cos\omega(t_j-\tau)]^2}{\sum_j \cos^2\omega(tj-\tau)} + \frac{[\sum_j (h_j-\bar{h})\sin\omega(t_j-\tau)]^2}{\sum_j \sin^2\omega(t_j-\tau)}\right\} \quad (1)$$

Where is defined by the relation

$$\tan(2\omega\tau) = \frac{\sum_j \sin 2\omega t_j}{\sum_j \cos 2\omega t_j} \quad (2)$$

$$\bar{h} = \frac{1}{N}\sum_1^N h_i \quad (3)$$

$$\sigma^2 = \frac{1}{N-1}\sum_1^N (h_i-\bar{h})^2 \quad (4)$$

where N is the number of data points, are the data points measured at time , ω = 2π f is the angular frequency and τ is an offset constant that makes (ω) independent of shifting all the 's by any constant.

D. Respiratory sinus arrhythmia

In healthy individuals the heart rate varies at the frequency of ventilation, known as respiratory sinus arrhythmia (RSA). During inspiration, the chest expands causing the intrathoracic pressure to decrease. This increases the blood return from the body to the right side of the heart and, via the Bainbridge reflex, causes the heart rate to accelerate. Conversely, during expiration the heart rate decelerates via the baroreceptor reflex [9]. Recordings of the autonomic nerves show that sympathetic nerves are activated during inspiration and

parasympathetic ones during expiration. RSA is most pronounced when we are sleeping and can be seen as an increase in activity around 0.3Hz, in the HF region. The greater the heart rate variability in an individual, the more pronounced the peak associated with RSA.

III. Results

A. Poincaré plots

Four Poincaré plots were produced, as seen in Figure 2. Measurements of the eight clouds were taken and are given in Table 2.

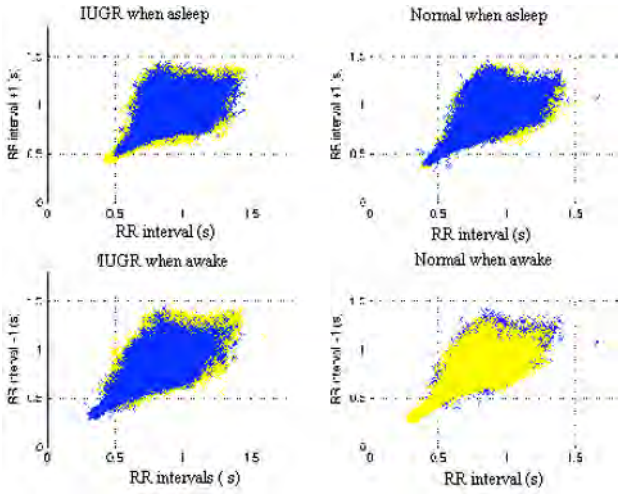

Figure (2) - Poincaré plots for the IUGR and Normal Children, when awake and asleep. 12 children are plotted on each sub-plot, 6 with smoking parents, in blue, and 6 with non-smoking parents, in yellow.

Table 2: SD1 and SD2 measurements of clouds in the Poincaré plots of figure 2.

Birth weight	Parents, smoking status	Awake or asleep	SD1(arbitrary units)	SD1(arbitrary units)
IUGR	smokers	awake	0.247	0.505
IUGR	smokers	asleep	0.263	0.453
Normal	smokers	awake	0.224	0.529
Normal	smokers	asleep	0.242	0.495
IUGR	non-smokers	awake	0.259	0.518
IUGR	non-smokers	asleep	0.277	0.505
Normal	non-smokers	awake	0.221	0.484
Normal	non-smokers	asleep	0.271	0.482

B. FFT

Periodograms for the 24 children were produced using the FFT, to allow comparison with the periodograms produced using the Lomb method. The FFT periodogram for NB (A female child) is shown in Figure 3. A strong series of peaks centred around 0.25Hz can clearly be seen, corresponding to activity associated with RSA during sleep, between the hours of 5 and 17 (recording started around 4 PM).

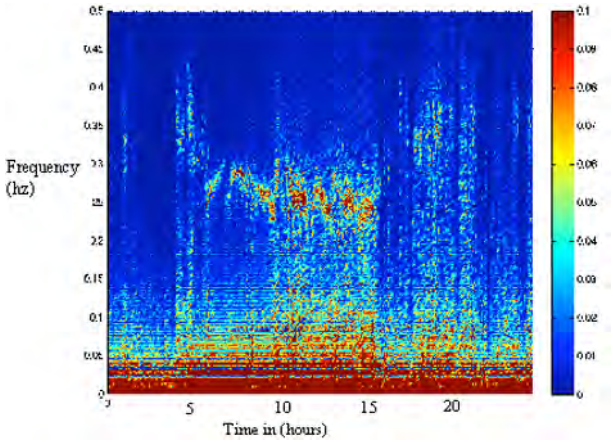

Figure (3): FFT periodogram for child NB, a female child, IUGR at birth whose parents smoked 30 cigarettes a day in total.

C. Lomb periodogram and strength of RSA peaks.

Lomb periodograms were also produced for the same children, four of which are included in this report – one from each of the groups under investigation. Figure 4 shows the Lomb method periodogram for child NB.

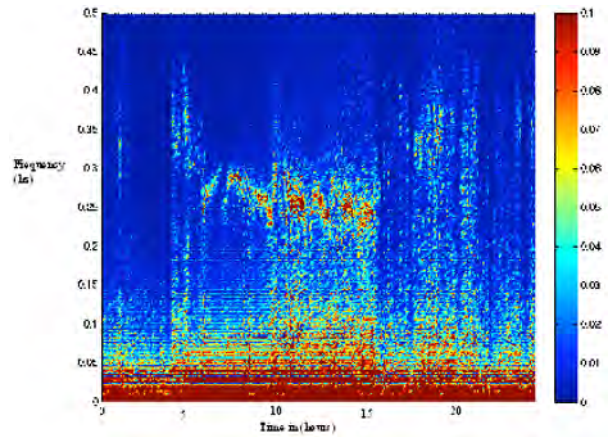

Figure (4): Lomb periodogram for child NB, a female child, IUGR at birth, whose parents smoked 30 cigarettes a day in total.

Strong activity corresponding to RSA can be seen in both diagrams in the region of 2 – 3 Hz, during the hours when the child was asleep. The normalised energy of the periodograms, for frequencies in the HF range 0.15 - 0.40Hz over the 'sleep' hours, was measured and the

average normalised energy for each group of six children is also shown. The four averages were compared using the Student's t-Test, at the 5% significance level, as shown in Table 3.

The LF/HF ratio for each child was also calculated, along with the mean ratio and the standard deviation of the group. Student's -t-test was then performed on the pairings, as seen in Table 4.

Table 3: Student's t-test comparison of HF energy of the groups, tested at 5% significance level.

Group 1	Group 2	t-test Probability	Null hypothesis
IUGR smokers	IUGR non-smokers	0.0378	Yes
Normal smokers	Normal non smokers	0.0925	No
IUGR smokers	Normal smokers	0.3795	No
IUGR non-smokers	Normal non-smokers	0.2367	No

Table 4: Student' t-test comparisons of the LF/HF asleep and awake ratios of the groups, tested at the 5% significance level.

Group 1	Group 2	t–test Prob-asleep	Reject Null Hypothesis	t-test Prob-awake	Reject null hypothesis
IUGR smokers	IUGR non smokers	0.4174	No	0.1058	No
Normal smokers	Normal non-smokers	0.1107	No	0.2765	No
IUGR smokers	Normal smokers	0.0585	No	0.1771	No
IUGR non smokers	Normal non-smokers	0.1135	No	0.784	No

IV. Conclusions

In the time domain, Poincaré plots were produced for the 24 children used in this study. The comparison between the four groups has shown no significant difference during asleep and awake hours.

In the frequency domain, periodograms were produced using the FFT and Lomb methods. Comparisons of the spectra produced using the two techniques showed spectral leakage and high frequency attenuation on the FFT periodograms. Therefore, although the Lomb method used in this instance took longer to execute, Lomb periodograms were used for further investigation in the frequency domain.

Analysis of the LF/HF ratios during sleep and awake hours has shown no significant difference between IUGR and normal birth weight children, regardless of their parents smoking status. This study has also looked at the energy associated with the activity around 0.3Hz due to RSA. One potentially very interesting finding has emerged from this analysis, as a significant decrease in the energy of the RSA peaks for IUGR children with smoking parents, when compared to IUGR children with non-smoking parents, was noticed.

The IUGR children in this study who had smoking parents showed reduced strength RSA peaks in the HF region and, by extrapolation, a reduced strength LF region (with a LF/HF ratio that was not significantly different to the other groups). The effects of nicotine and other chemicals, through passive exposure to tobacco smoke, may result in a reduction of the action of autonomic nervous system in these individuals, suggesting IUGR children are more at risk from living in smoking households than normal birth weight children.

Biomechanics of a Suspension of Micro-Organisms

Takuji Ishikawa

Department of Bioengineering and Robotics, Tohoku University, Sendai, Japan

Abstract — **Micro-organisms play a vital role in many biological and medical phenomena, such as bioreactors for medicine or food, and human digestion assisted by enterobacteria. Many researchers have tried to predict behavior of micro-organisms, and proposed macroscopic population models. However, it is worth asking how these models are constructed from individual behavior of micro-organisms. In this article, I will outline briefly some of the fluid mechanics aspects of individual and collective behavior of micro-organisms as well as the suspension properties, which will be useful for constructing a better continuum model for a suspension of micro-organisms.**

Keywords — **Micro-organisms, Bacteria, Suspension, Locomotion, Coherent structures**

I. Introduction

Micro-organisms play a vital role in many biological and medical phenomena. In the human body alone the number of micro-organisms is approximately 10^{14} about twice the number of the body's cells. In the intestines of an adult male, for instance, approximately 1.5 kg of enterobacteria form a unique ecosystem called the bacterial flora. The flora plays an important role in the digestion and absorption of food, and in protecting against infections. Another example is the infection of the stomach by the *Helicobacter pylori* bacteria, which are responsible for serious stomach diseases. Not only bacteria, but also some human cells may behave like independent micro-organisms due to their locomotion. Sperm, for instance, can swim about 10-20 body lengths per second, and its motility is essential in reproduction. The rolling motion of a leukocyte on endothelium cells of an arterial vessel is also a crucial phenomenon in terms of cellular immunology.

Moreover, micro-organisms are used in biotechnology for medicine and food; they form plankton blooms in the oceans that affect the oceanic ecosystem; they sometimes cause harmful red tides in coastal regions of the ocean that have serious repercussions on fish farms; and they absorb CO_2, which affects the global climate. Because of the considerable influence that micro-organisms have on human life, the study of their behavior is an important area of scientific research.

Many researchers have tried to predict behavior of micro-organisms, and proposed mathematical models. There are some standard models, called food web models [1]. However, most of the former macroscopic and population models were empirically derived, and used many *ad hoc* functions and constants. It is worth asking how the macroscopic population level models are constructed from individual behavior of micro-organisms. In this article, I will outline briefly some of the fluid mechanics aspects of micro-organisms' individual and collective behavior. Firstly, some of our recent researches on hydrodynamic interaction between a pair of micro-organisms will be introduced. Secondly, the collective motions of micro-organisms and suspension properties, such as rheological and diffusion properties, will be discussed. I hope that the readers take this study as an interesting example of research, rather than a complete definition of the field.

II. Pairwise interactions of micro-organisms

To model the motion of a real micro-organism mathematically is a massive undertaking. Micro-organisms alter their behavior depending on many parameters relating to their environment. The variety of shapes both inter- and intra-species is also vast. Any model capable of being analysed mathematically will therefore require considerable simplifications. Even with the simplified models, however, some fundamental biomechanics in micro-organisms' behavior can be analyzed correctly. In the following sections, I will introduce three example of pairwise interaction of micro-organisms, which can be successfully analyzed by using computational biomechanics.

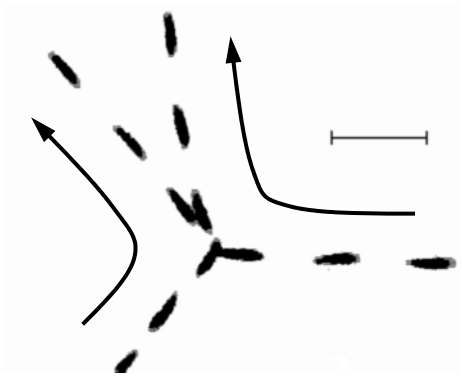
A. Interactions of swimming Paramecia

In a suspension of micro-organisms, the cells tend to change their swimming directions not only by the hydrodynamic interactions but also by the biological interactions. Thus, at first, whether the interaction of swimming micro-organisms can be described by fluid mechanics or not was investigated, using a unicellular freshwater ciliate *Paramecium caudatum*. Biological reactions of a solitary *Paramecium* cell to mechanical stimulations were investigated experimentally by Naitoh and Sugino [2]. Avoiding reactions occur when a cell bumps against a solid object with its anterior end. The cell swims backward first, then gyrates about its posterior end, and finally resumes normal forward

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2134–2138, 2009
www.springerlink.com

locomotion. Escape reactions occur when the cell's posterior end is mechanically agitated. The cell increases its forward swimming velocity for a moment, and resumes normal forward locomotion.

Interactions between two *Paramecia* were investigated experimentally by Ishikawa and Hota [3]. A typical hydrodynamic interaction, restricted in a 2D plane, observed in the study is shown in figure 1. When one cell collides with the anterior end of the other cell, the two cells tend to swim side by side at first, and then move away from each other at an acute angle. All the cells interactions were classified as hydrodynamic interactions, avoiding reactions or escape reactions. The total number of interacting cells recorded in the study was 602 (the total number of cases was 301). It was found that about 85% of cells interact hydrodynamically. We could conclude that the cell-cell interaction was mainly hydrodynamic and that the biological reaction accounted for a minority of events.



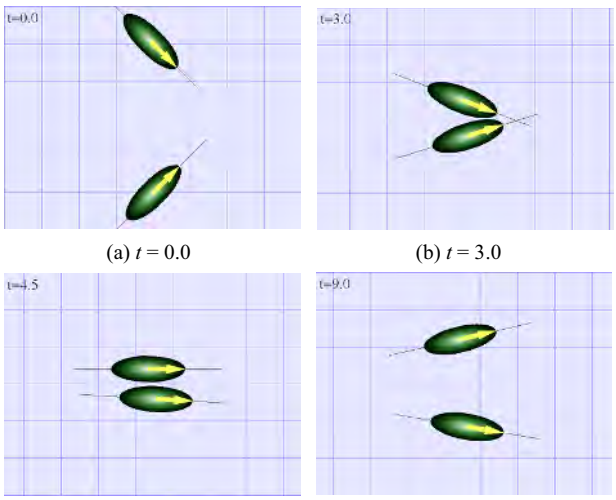


Fig. 1 Sample sequences showing the interaction of two *P. caudatum*. The time interval between each sequence is 1/3 sec. Long arrows are added to schematically show cell motion. Scale bars, 500 μm [3]

Next, we tried to computationally analyze the interaction between two *Paramecia*. We modeled the *Paramecium* as a squirmer [4], which can propel itself by generating tangential velocities on its surface. In fact, it is a reasonable model to describe the locomotion of ciliates, which propel themselves by beating arrays of short hairs (cilia) on their surface in a synchronised way. In particular, the so-called symplectic metachronal wave, in which the cilia tips remain close together at all times, employed for example by *Opalina*, can be modeled simply as the stretching and displacement of the surface formed by the envelope of these tips.

The sedimentation velocity of *P. caudatum* is much less than its swimming speed, therefore it is reasonable to assume the squirmer as neutrally buoyant. Swimming speeds of the *P. caudatum* is about several hundred μm/s. However, the Reynolds number based on the swimming speed and the radius of individuals is usually less than 10^{-2}, so the flow field around the cells can be assumed to be Stokesian with negligible inertia compared to viscous effects. Brownian motion can be neglected because the *P. caudatum* is too large for Brownian effects to be important. The governing equations for the flow field and the squirmer motion can be solved accurately by a boundary element method [4].

Figure 2 shows the numerical results of the interactions between two squirmers in which the squirmers collide with their anterior ends. The two cells tend to swim side by side at first, and then move away from each other at an acute angle. This tendency is similar to the experimental results shown in figure 1. We also performed simulations with various initial conditions, and found that the hydrodynamic interaction data in the experiments agreed well with the numerical results [3].

(a) $t = 0.0$ (b) $t = 3.0$

(c) $t = 4.5$ (d) $t = 9.0$

Fig. 2 Sequences (a) to (d) show the numerical results of the interactions between two squirmers against the dimensionless time t. The orientation vectors of the squirmers are shown as large arrows on the ellipsoids [3].

B. Waltzing motion of Volvox

Recently, R. E. Goldstein's group at Cambridge University found an interesting interaction between two multicellular freshwater ciliates, *Volvox*. When they placed suspensions of *Volvox* in glass-topped chambers, they observed the frequent formation of stable bound state of two colonies orbiting each other, referred to as a *waltzing motion*. Since Goldstein's group and myself were interested in whether the waltzing motion appeared due to the biological interaction or the hydrodynamic interaction between *Volvox*, we performed numerical simulations to clarify the mechanism of such motion [5].

In modeling a *Volvox* computationally, we assumed that a *Volvox* was a rigid sphere generating a force distribution slightly above the surface. The flow field around a *Volvox* was assumed to be Stokesian, and sedimentation and bottom-heaviness were taken into account. Equations for the flow field and the force distribution were solved by a boundary element method by coupling with the force-torque conditions of the cell bodies.

If we initially place two *Volvox* below the wall, they first swim towards the wall and show steady hovering motion adjacent to the wall. Then, they tend to attract each other gradually until they come in close contact. Finally, they show stable waltzing motion with steady rotational velocities (see figure 3), in a similar manner to the experimental observations. We also performed trial simulations without the wall boundary, without the bottom-heaviness, without the swirl velocity (no tilt angle), or without the sedimentation (body force), and concluded that the wall boundary, the bottom-heaviness and the swirl velocity are necessary in reproducing the waltzing motion.

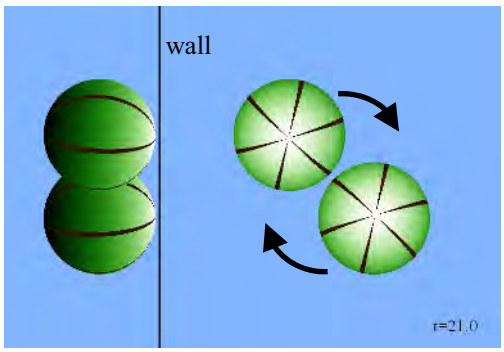

Fig. 3 Schematics of the interactions between two *Volvox* models. The wall is indicated as a solid line, and the left side of it is the side view, whereas the right of it is the top view.

C. Interactions of swimming bacteria

Recently, there has been increasing interest in the collective dynamics of swimming bacteria, because some species of bacteria show spatiotemporally coherent structures [6]. Since the mechanism of the coherent structure is still unclear, we investigated the stability of pairwise swimming motion of bacteria [7].

In investigating the hydrodynamic interactions between two swimming bacteria, we assumed that each bacterium was force-free and torque-free, with a Stokes flow field around it. The geometry of each bacterium was modeled as a spherical or spheroidal body with a single helical flagellum. The movements of two interacting bacteria in an infinite fluid otherwise at rest are computed using a boundary element method. The results show that as the two bacteria approach each other, they change their orientations considerably in the near field. The bacteria always avoided each other, and no stable pairwise swimming motion was observed in this study.

III. Suspensions of Model Micro-Organisms

A. Rheological and diffusion properties

The size of individual micro-organisms is often much smaller than that of the flow field of interest. In such cases, the suspension of micro-organisms can be modeled as a continuum in which the variables are volume-averaged quantities. However, the continuum models proposed so far are restricted to dilute suspensions. If one wishes to analyse larger cell concentrations, for example a suspension of enterobacteria, it will be necessary to consider the interactions between micro-organisms. Then the particle stress tensor, as well as the velocities of the micro-organisms and the diffusion tensor, in the continuum model will need to be replaced by improved expressions.

In discussing suspension properties, we employed a spherical squirmer model for simplicity. By performing Stokesian dynamics simulations [8], as shown in figure 4, we could calculate hydrodynamic interactions in an infinite suspension accurately from lubrication flows to far-field many body interactions.

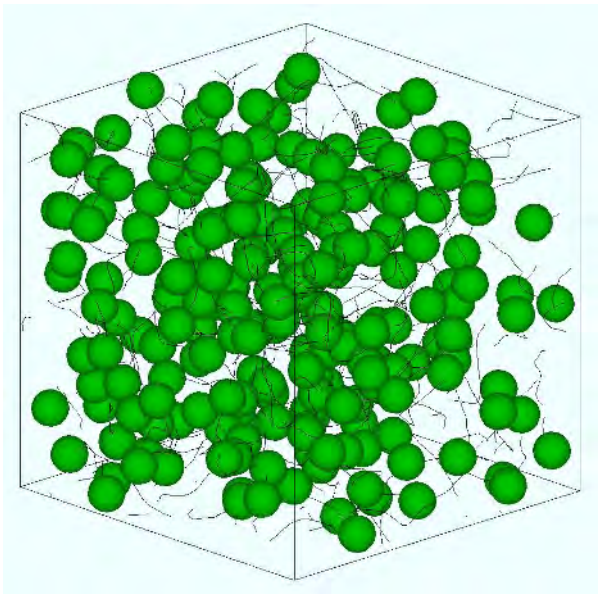

Fig. 4 Instantaneous position of 216 identical squirmers in a fluid otherwise at rest. Solid lines are trajectories of the squirmers during five time interval.

The rheological properties of a cell suspension relate the stress field and the velocity field in the suspension. In the case of bottom-heavy squirmers, the stresslet generated by the squirming motion directly contributed to the bulk stress at order of c, where c is the volume fraction of cells, and the suspension showed strong non-Newtonian properties [9]. When the background simple shear flow was directed vertically, the apparent viscosity of the suspension of bottom-heavy squirmers became smaller than that of inert spheres. On the other hand, when the shear flow was horizontal and varied with the vertical coordinate, the apparent viscosity became larger than that of inert spheres. The rheology of a suspension of micro-organisms is different from that of passive particles.

Understanding the diffusive behavior of swimming micro-organisms is also important in order to obtain a better continuum model for a cell suspension. The diffusive property in a suspension of squirmers was discussed in Ishikawa and Pedley [10]. The results showed that the spreading of squirmers was correctly described as a diffusive process over a sufficiently long time scale, even though all the movements of the squirmers were deterministically calculated.

B. Coherent structures in a suspension

Systems of swimming micro-organisms exhibit an interesting variety of collective behavior such as clustering and migration; examples include coherent structures of swimming bacteria [6]. It is important to discuss whether the collective motions are biologically and evolutionarily favourable or not in various conditions.

In order to improve our understanding of the experimental observations, we investigated various types of coherent structures in suspensions of squirmers by performing Stokesian dynamics simulations [11]. A sample result of the band formation in a mono-layer suspension is shown in figure 5. The numerical results interestingly illustrate that various coherent structures, such as aggregation, meso-scale spatio-temporal motion and band formation, can be generated by purely hydrodynamic interactions between micro-organisms.

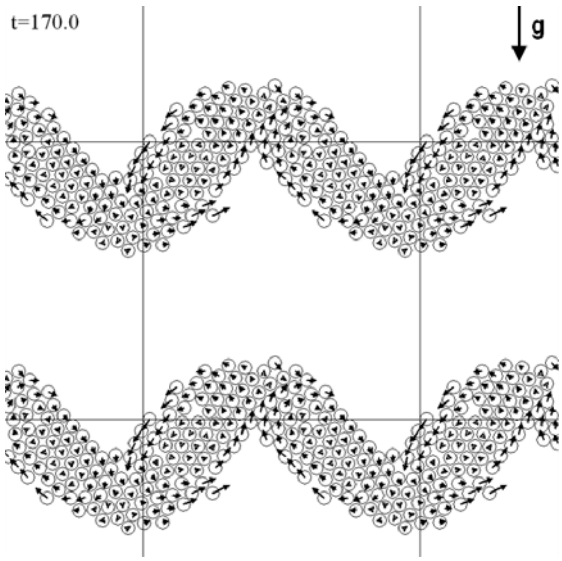

Fig. 5 Velocity vectors of bottom-heavy squirmers in a mono-layer suspension, relative to the average squirmer velocity [11].

IV. Conclusions

In this study, the locomotion, the collective motions and the suspension properties of micro-organisms have been clarified. Obtained fundamental knowledge will be useful for constructing a better continuum population model for a suspension of micro-organisms. Though biomechanics have been successful in describing some of micro-organisms' behaviors, including the present study based of fluid mechanics, there are still plenty of unsolved phenomena. I expect that many researchers will be interested in this research field and will clarify the natural beauty exhibited by micro-organisms in the near future.

Acknowledgment

Part of the work presented in this paper was performed in collaboration with Prof. T. J. Pedley and Prof. R. E. Goldstein, University of Cambridge. I am also grateful for helpful discussions with Prof. T. Yamaguchi and Dr. D. Giacche, Tohoku University.

Abstract — **The authors have been developing a surgical navigation system for the graft replacement of thoracoabdominal aortic aneurysm and applied clinically 30 times since July 2006. This system supports surgeons to figure out the patient's intercostal level before thoracotomy.**

However, in the current navigation system, there is a problem that patient's postures are different between preoperative CT scanned data and intraoperative real data. In this paper, it is aimed to improve current navigation system to follow global deformation arising from difference of patient's postures. And the mathematical method is discussed that matches image space with real space globally by correcting the image.

It is assumed that the deformation of thoracic cage is affected by the weight of trunk, and that of lumbar is affected by the torsion. To match both spaces, the algorithm that makes image slanted at the thoracic region and rotated at the lumbar region was developed. The angle of inclination for slanting and that of torsion for rotating were calculated from body weight, width of costale and elastic coefficient of bone.

This algorithm was evaluated by using MRI images of two volunteers those were scanned in dorsal position and right decubitus position. As a result, fitting between image space and real space decreased by 20% by operating this algorithm. It was concluded that this algorithm is effective to match both spaces. Foreseeable future, this algorithm will use in navigation used in clinical.

Keywords — **Surgical Navigation, Aortic Surgery, Postural Deformity, Image Correction**

I. Introduction

Surgical navigation system assists surgeons by representing patient's images and therapeutic position of therapeutic target with an optical positioning measurement device during surgery. For example, it has been used for brain surgery to detect the invisible tumor by visualizing the affected area with MR images. It is reported that surgeons could reduce the insufficient procedures and improve the operative performance [1].

Recently, the authors have developed the surgical navigation system for aortic vascular surgery that supports surgeons to figure out the intercostal level of the target artery during surgery. Especially, the system helps surgeons to confirm the appropriate trajectory due to grasp the anatomical relationships before opening patient's chest [2].

However, in the current navigation system for aortic surgery, the matching error between the virtual image space and real surgery space is observed that is caused of the difference of patient's posture. To reduce the matching error, the authors developed the algorithm that follows global deformation arising from difference of patient's postures.

This paper presents a new method for the navigation system for aortic vascular surgery to compensate the deformation by applying the algorithm of the image-correction.

II. Method

A. Algorithm

In the current navigation system for thoracoabdominal aortic surgery, the patient's postures are different between preoperative CT scanned data and intraoperative real data. Although the CT images are acquired with the supine position, the surgery is performed with the right lateral decubitus position to keep the surgical field sufficiently (Fig.1). According to the rotation of the body trunk, the bone structures are shaped. Besides, internal parts of the body are deformed under the influence of the gravity. These changes lead to the mismatching between the patient's image and the real body.

The following algorithm modifies the patient's image to fit the real body. In order to deform volumetric image and match both spaces, each axial image slices are slanted by the inclination angle θ that is determined the attribution of thoracic cage at the chest region. And those are rotated at

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2139–2142, 2009
www.springerlink.com

the angle of 4.7 degree that is resulted from preliminary experiment at the lumber region[3].

The angle of inclination θ is determined as follows.

$$\theta = \tan^{-1}\frac{(\pi-2)Fr}{4\sqrt{2}EA\kappa} \quad (1)$$

A :cross section of the costale
E :elastic constant of the bone
F :gravitation force of organ in the chest
r :radius of body trunk
κ :section modulus of curved beam

B. Experiment

To investigate the validity of above algorithm for regisitration, the feature of body structure of healthy volunteers was scanned by MRI (PHILIPS Intera 1.5Master). In this measurement, Body postures for scanning were supine position and lateral position, and the chest area from the first thoracic vertebrae to the 2nd lumbar vertebra was scanned at each postures. The subject of scanning was healthy male who was 180cm tall and weights 70kg.

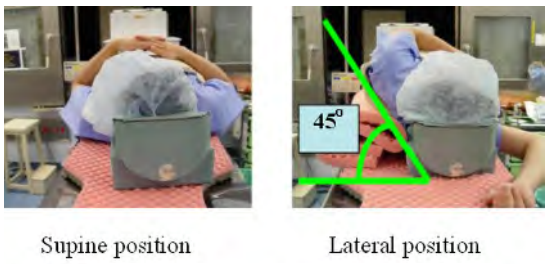

Fig.1 The position of patient

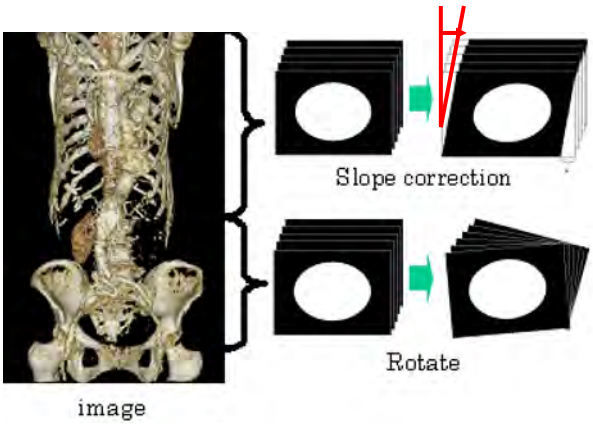

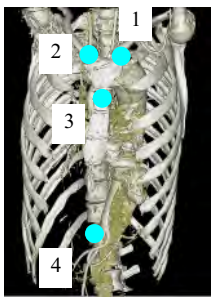

Fig.2 Correction of slice image

These scanned images were saved as DICOM and these images at supine position were corrected by using numerical analysis software MATLAB. Then images were fitted to compare how the corrected images are fitted to those at lateral position. To fit images, several anatomical specific points of the first lumbar vertebra were chosen as a basing points of fitting, because displacement of lumbar vertebra arising from the difference of body position was small. And, before and after corrected images of supine position were fitted into image of right lateral position and calculate the misalignment errors of two images on the sternum (left and right clavicular head, manubriosternal joint and xiphoid process) those are shown in Fig.

III. Result and Discussion

The scanned images are shown in fig.4(a) and (b). The anatomical specific points of these images are circled by green line.To fit the image of supine position to that of right lateral position for this time, image of supine position was slanted for θ = 0.1 rad that was calculated form (1). In this case, elastic constant of the bone E in (1) is 17.0[GPa].The corrected image of fig.4(a) is shown in fig.4(c). The misalignment errors at each positions on the strenum were shown in Table.1.

As shown in Table.1, comparing after corrected image with before corrected image, the misalignment errors reduced by 19.8% an average of anatomical specific points at the sternum. Notice that, the misalignment errors reduced by 26.2% at the manubriosternal joint. This results show that this algorithm tends to be effective for the center of chest that deforms dynamically.

1. left clavicular head
2. right clavicular head
3. manubriosternal joint
4. xiphoid process

Fig.3 Anatomical specific points on the strenum

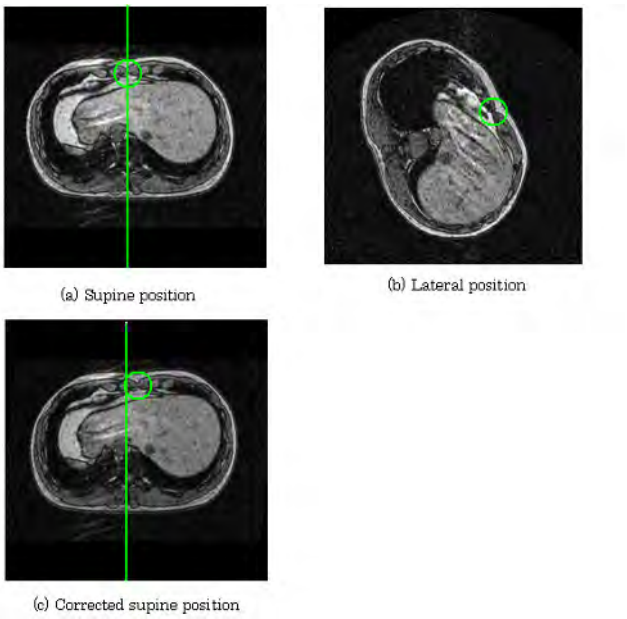

Fig.4 Images scanned by MRI

Table.1 Misalignment of both images at each anatomical specific points

	Before correction[mm]	After correction[mm]	Reduction rate[%]
1	41.1	34.2	16.8
2	34.9	27.1	22.2
3	32.9	24.3	26.2
4	31.3	26.9	13.8
Average	35.0	28.1	19.8

IV. Conclusion

To correct the difference of patient's posture in the aortic surgery, the authors projected the algorithm that deform the image in accordance with real space. This algorithm was examined by comparing the images those were scanned by MRI. As a result, the misalignment errors reduced by 20% an average of anatomical specific points at the sternum, and it was concluded that this algorithm is effective for matching both images.

Foreseeable future, the image corrected by this alorithm will be mounted to navigation system for aortic surgery and used in clinical.

VI. Apprendix

The following is the deriveration of (1).

We assumed that the body trunk at the chest area could be modeled as fig.4 that was flamed by the thoracic cage. In this model, the radius of the trunk is defined as r, the length of rib section is defined as a, and the angle of the body around the body axis is 45 degree. The gravity of trunk is equally dispersed to posterior and right. In this case, only the rightward force is considered because rightward displacement should be calcurated.

In fig.4, S_0S_2 is defined as the centerline of the costale, S is defined as the arbitrary point on the S_0S_2, and Φ is defined as the angle beween the line perpendicular to S_0S_2 and y axis. The location of S_0 is static because S_0 is rested on the bed. The location of S is affected by the weight of internal organ and flexure of the costal. If the location of S shifts ωdφ rotationally, the displacement at S_2 can show the superposition of two displacements those are $SS_2\omega d\varphi$ perpendicular to SS_2 and εds for tangential displacement at S, where ω is the rate of change of φ, and ε is flexure of S_0S_2. Therefore the displacements of X and Y axial components at S is given as follows.

$$\cdot d\Delta(x_2 - x_0) = -y\omega d\phi + \varepsilon dx \qquad \cdots (2)$$

$$\cdot d\Delta(y_2 - y_0) = (x - r)\omega d\phi + \varepsilon dy$$

Δ is calculated by integrating (2) from S_0 to S_2.

$$\cdot\Delta(x_2 - x_0) = -\int_0^{\frac{\pi}{2}} y\omega d\phi + \int_0^{r}\varepsilon dx$$
$$\cdot\Delta(y_2 - y_0) = \int_0^{\frac{\pi}{2}} (r - x)\omega d\phi + \int_{-r}^{0}\varepsilon dy \quad \cdots (3)$$

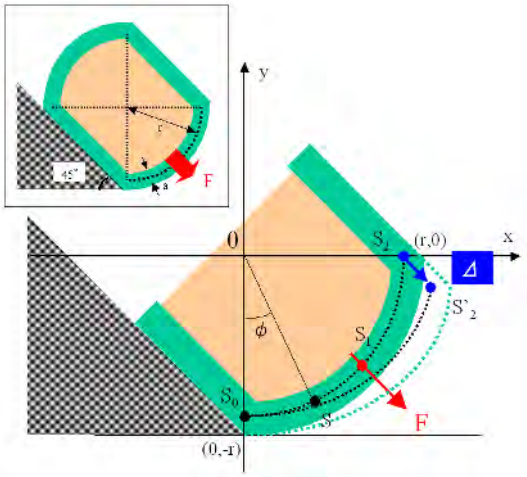

Fig.5 Displacement of thoracic cage

In this case, ε and ω is represented as follows.

$$\begin{cases} \varepsilon = \dfrac{1}{EA}\left(N + \dfrac{M}{r}\right) \\ \omega = \dfrac{1}{EA}\left(N + \dfrac{M}{r} + \dfrac{M}{r\kappa}\right) \end{cases} \qquad \begin{cases} M = Fr\sin\left(\dfrac{\pi}{4} - \phi\right) \\ N = -F\sin\left(\dfrac{\pi}{4} - \phi\right) \end{cases}$$

Therefore the (3) is represented as follows.

$$\cdot\ \Delta x = \frac{Fr}{EA\kappa}\int_0^{\frac{\pi}{2}} \sin\left(\frac{\pi}{4} - \phi\right)\cos\phi d\phi = \frac{Fr}{4EA\kappa}\left(\frac{\pi}{\sqrt{2}} - \sqrt{2}\right) \quad \cdots (4)$$

$$\cdot\ \Delta y = \frac{-Fr}{EA\kappa}\int_0^{\frac{\pi}{2}} \sin\left(\frac{\pi}{4} - \phi\right)\sin\phi d\phi = \frac{-Fr}{4EA\kappa}\left(\frac{\pi}{\sqrt{2}} - \sqrt{2}\right)$$

By combining Δx and Δy, Δ is considered as follows.

$$\Delta = \frac{Fr(\pi - 2)}{4EA\kappa} \quad (5)$$

A :cross section of the costale
E :elastic constant of the bone
F :gravitation force of organ in the chest
r :radius of body trunk

And κ is the section modulus of curved beam and defined as follows in this case.[4]

$$\kappa = \frac{r}{A}\int_A \frac{dA}{r + \eta} - 1 = \frac{2r}{\pi a^2}\int_{-a}^{a} \frac{\sqrt{a^2 - \eta^2}}{r + \eta} d\eta - 1 = \frac{2r^2}{a^2}\left\{1 - \sqrt{1 - \left(\frac{a}{r}\right)^2}\right\} - 1$$

θ (the angle to slant) can be elicitated as follows.

$$\theta = \tan^{-1}\frac{\Delta}{\sqrt{2}r} = \tan^{-1}\frac{(\pi - 2)Fr}{4\sqrt{2}EA\kappa}$$

Bioengineering Advances and Cutting-edge Technology

M. Umezu

Center for Advanced Biomedical Sciences, TWIns, Waseda University, Tokyo, Japan

Abstract — **There is a forty-year history of research collaboration by doctors at Tokyo Women's Medical University and engineers at Waseda University. The synergism culminated in 2008 with the establishment of the Center for Advanced Biomedical Sciences within the framework of the Tokyo Women's Medical University-Waseda University Joint Institution for Advanced Biomedical Sciences (TWIns). The center provides a singular environment for consolidating research in life science, bioengineering, and medicine. At first our new conceptual laboratories, called "DRY Lab" is introduced. There are three laboratories: Surgical Training Lab, GLP-compliant Lab and Medical Visualization Lab. These laboratories have a complement function of an animal (WET) laboratory. Secondly, an implantable centrifugal blood pump called EVAHEART as an exemplary product of this collaboration is introduced. Cardiac surgeon Kenji Yamazaki of Tokyo Women's Medical University, Sun Medical Technology Research Corporation, Waseda University, and the University of Pittsburgh originated the EVAHEART project in 1991. More than fifty companies contributed technologies that improved performance of the device. Teamwork between groups with divergent thinking and expertise led to optimized designs of components such as the impeller, shaft/seal mechanism, and blood-compatible materials. In clinical trials, fourteen of eighteen patients treated with EVAHEART had favorable postoperative outcomes. In the first case, the pump sustained the patient for more than three and one-half years. Among the four patients who died, none had a cause of death related to the device itself. Consequently, it is confirmed that this synergistic environment will help us create new scenarios and trials which are unconstrained by conventional knowledge.**

Keywords — **Biomedical engineering, Consolidating research, DRY Lab, EVAHEART, Implantable blood pump.**

I. Introduction

The Tokyo Women's Medical University-Waseda University Joint Institution for Advanced Biomedical Sciences, TWIns, opened in March of 2008 after a forty-year history of research collaboration on projects related to artificial organs, biological measurement and biomaterials. The institution, which is located next to the Tokyo Women's Medical University Hospital in Shinjuku, Tokyo, is a new center for the advancement of biomedical research based on a synergy of medicine, science, and engineering [1].

For Waseda University, there are two major objectives for the formation of the new center. The first objective is to consolidate into one place the research for life science and biology which had been broadly dispersed in different campuses. The second objective is to develop new fields through synergetic partnerships in medicine, science, and engineering, and to provide a singular environment for that development. In this environment where the fields of medicine, science, and engineering mix in a variety of different approaches, unconstrained research topics can be achieved. A vision has been created for the new center to act as a base for the dispersion of new scenarios that shatter previous conventions.

In this paper, one of our new conceptual laboratories for a training program for medical personnel called "DRY-Lab" is introduced. Moreover, Japanese-made implantable blood Pump (EVAHEART) is also introduced as an examplary product of this collaboration.

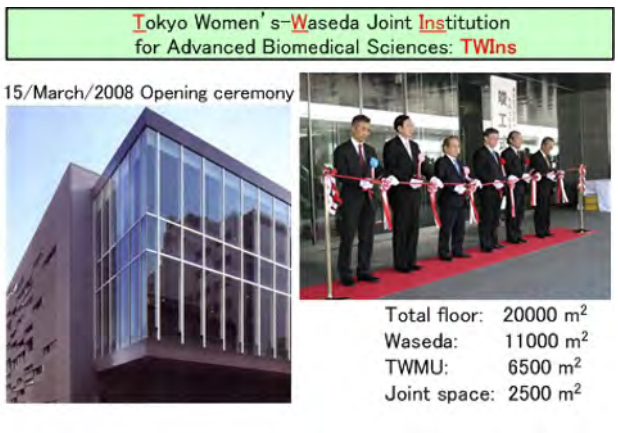

Fig.1 Overview of TWIns

II. Establishment of DRY Lab Training Center / Promotion of Engineering Based Medicine (EBM)

A. Concept of DRY Lab

Animal and cadaver WET Lab is a common opportunity of surgical training, particularly in the United States. The advantage of WET lab is hands-on training in clinically-familiar environments. However, opportunities of animal

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2143–2146, 2009
www.springerlink.com

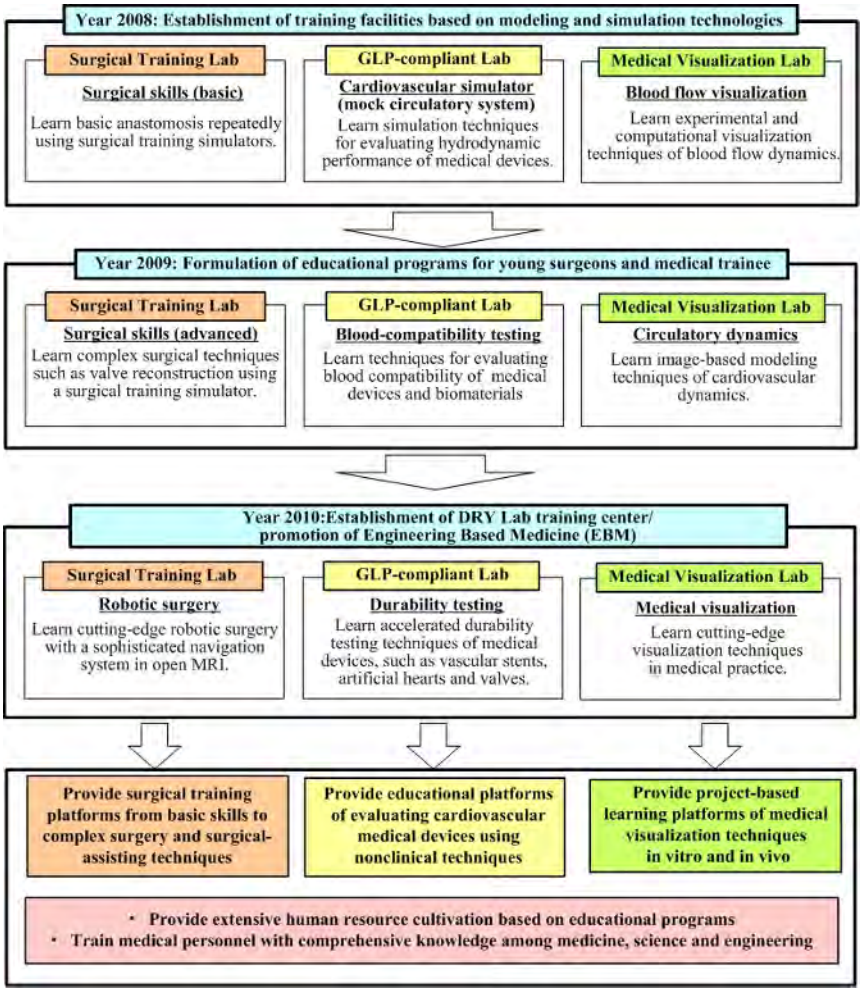

Fig.2 Overview of DRY Lab and yearly schedule for the next three years

experiments have become increasingly limited including the use of biological tissues. Therefore, a self-training system prior to WET Lab would be an effective procedure. Herein, we propose such educational environments for training medical personnel, and this new concept is termed DRY Lab in contrast to WET Lab [2].

B. Overview of DRY Lab

DRY Lab features nonclinical hands-on training based on modeling and simulation technologies using consolidated functions among medicine, science and engineering at TWIns. More specifically, DRL Lab consisted of three major laboratories: 1) Surgical Training Lab, 2) GLP-compliant Lab, and 3) Medical Visualization Lab. An underlying technical platform among these laboratories stems from artificial organ developments and evaluation techniques, particularly hemodynamics, blood compatibility and durability. All these technologies are sophisticated for educational purpose.

Fig.2 shows an overall figure of DRY Lab for the next three years. Surgical Training Lab is to educate from repeated training of basic anastomosis to advanced surgeries, such as valve reconstruction and robotic surgeries, using original surgical simulators. In contrast, GLP-compliant Lab provides development and evaluation techniques of cardiovascular medical devices and biomaterials. Medical Visualization Lab is to educate modeling and simulation techniques in conjunction with clinical medicine, including blood flow analysis, circulatory dynamics and cutting-edge medical visualization techniques.

In year 2010, we would start a DRY Lab training center with established educational programs. Extensive human resource cultivation would be achieved for training clini-

cians, bioengineers, and bioscientists with comprehensive knowledge among medicine, science and engineering. This training center would promote another EBM in contrast to Evidenced Based Medicine, namely "Engineering Based Medicine".

III. Development of EVAHEART and Clinical Trials

A. Brief Introduction of EVAHEART

The first clinical trial of a Japanese implantable centrifugal type ventricular assist device, EVAHEART (Fig.3) [3-4], was done in 2005 at Tokyo Women's Medical University. Since then, a total number of implantation reached 18 cases. During this long-term support, there is no major device failure and related death. And the longest period has reached more than three and half years. To achieve this success, bioengineers have established a methodology of various types of *in vitro* tests to minimize risk factors, such as hydrodynamic performance tests, fatigue tests, and biocompatibility tests, which are briefly introduced in this chapter.

Fig.3 EVAHEART system (clinical model)

B. Biocompatibility test for inner coating of the blood pump

Biocompatibility is one of the most important factors to realize a safe and reliable long-term use of a blood pump. A test protocol using our original circuit [5] is as follows:

1. Heparinized fresh porcine blood harvested from the same animal circulate in the circuit comparative study.
2. Therefore, the same amount of identical blood is injected into two circuits for comparison.
3. Pulsatile circulation to simulate hemodynamic pressure / flow condition is preferable to obtain practical data.

Fig. 4 is one of the results after one hour circulation of fresh bovine blood. Anticoagurant agent (heparin) was used to maintain the ACT of around 300sec. The same amount of blood was divided into two identical circuits. As can be

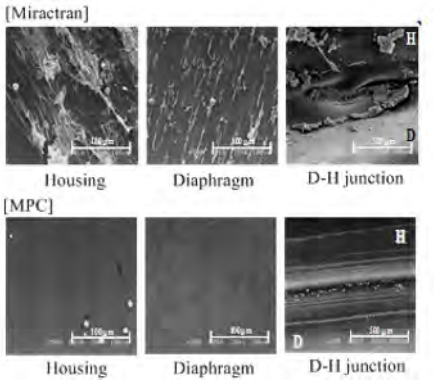

Fig.4 Example of biocompatibility results from our in vitro blood circuit (comparison between Miractran and MPC)

Fig.5 EVAHEART from a patient undergoing heart transplantation (POD: 1165 days). There is no thrombus observed.

seen, fibrin network was observed and some blood cells were captured on the Miractran surface of the left ventricular pump. On the contrary, MPC surface was clean [6]. Although both coating materials are polyurethane, biocompatibility was clearly differentiated. This excellent biocompatibility of MPC has been clinically proved. Fig. 5 shows an example of a pump photograph from a patient undergoing heart transplantation. No thrombus was observed after a pumping duration of 1165 days.

C. Quality Improvement of Life with EVAHEART

Table 1 is a patient summary of EVAHEART for pilot study. The first three patients suffered from DCM (Dilated Cardio-Myopathy), but after implantation, all patients discharged and high quality of life with EVAHEART can be maintained for over 1000 days. In the first case, the patient always lay on bed before implantation, and could not move due to a severe heart failure. However, he started to walk in the hospital only a few days after the implantation of EVAHEART. During support, he never felt an existence of EVAHEART with a weight of 420g [7]. He spent ten months for rehabilitation training, and he was discharged

Table 1 Clinical outcome of the first three patients with EVAHEART

No.	Age/sex	Diag.	Institute	POD (2008.10.31)
1	46 y M	DCM	TWMU	1274 (ongoing)
2	29 y M	DCM	TWMU	1165 (transplanted)
3	40 y F	DCM	NCVC	1147 (transplanted)

Table 2 Categorized clinical outcome with EVAHEART

Outcome	No. of cases	Pumping duration
Alive, ongoing	12	250 ~ 1274
Transplanted	2	1147, 1165
Died	4	61～407

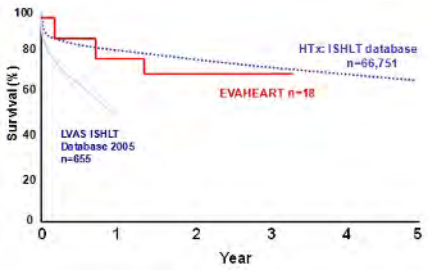

Fig.6 Survival rate of patients with EVAHEART

from the hospital. Then, his medical cost became only 1/100 as compared with that in the hospital. Moreover, he found a full-time job after 18 months later.

As the pumping duration for the first three patients exceeds 1100 days without any major problems, survival rate with EVAHEART is much better than that with other devices. For example, survival rate with US pulsatile implantable devices exhibited only 30 % after 18 months pumping. [8]. Table 2 summaries the current status of EVAHEART. The survival rate have been comparable to heart transplantation as shown in Fig.6.

IV. Conclusion

The authors have been establishing a methodology to eliminate considerable risk factors through a development of practical *in vitro* test circuits at DRY Lab in TWIns. It was confirmed that all *in vitro* tests were effective to ensure safety toward clinical applications. Therefore, clinical trials can be performed without any major problems. According to the comment by the first patient with EVAHEART, he does not wish to receive donor heart; he is satisfied with his present quality of life. Throughout the development and clinical trials of EVAHEART, the authors believe that the role of TWIns will generate much more new trials for advanced biomedical engineering.

Abstract — **Potential application of the PLGA nano-fiber/film composite for vascular tissue regeneration was examined. The composite was prepared by solvent-casting and electro-spinning method. The PLGA nano-fiber was coated on the surface of the prepared PLGA film. The surface of the composite film was characterized by contact angle measurement and scanning electron microscope (SEM). The film made by only nano-fiber showed more hydrophobic than control (PLGA film made by solvent-casting); however, optimal amount of nano fibers coating could assist cell adhesion and spreading on the film. For human umbilical vein endothelial cells (HUVECs) proliferation on 6-day culture, the NF-30 (30min. nano-fiber spread specimen) composite was 1.5 times more cells proliferated than that of the NFO-1h (nano-fiber only specimen). The SEM images showed that the HUVECs on the NF-30 specimen spread widely than the other groups. The result indicates that the nano-fibers on films have an effect on cell adhesion and spreading because the adequate amount of nano-fibers on the surface of the films provide similar structure to natural ECM morphology. Conclusively, nano-fiber/film composite provided an adequate environment for cell proliferation and showed the potential application for vascular tissue regeneration.**

Keywords — **HUVECs, PLGA, electro-spinning, nano-fiber, ECM**

I. Introduction

Atherosclerotic vascular disease is one of the largest causes of mortality in western society [1]. This problem is widely happened in coronary artery and peripheral vascular system [2]. One of the commonest treatment methods is coronary artery bypass graft surgery. The procedure involves bypassing occluded arteries with either autologous veins or arteries. However, this method typically confronts limitation of autologous grafts. Up to 30% of patients do not have sufficient autologous bypass veins due to prior stripping, disease or discordant size [3]. Accordingly, there have been efforts and various attempts for development of small diameter (< 6mm) vessel substitutes. Biodegradable polymer, poly D, L-lactic-co-glycolic acid (PLGA) can be used for scaffolds of vascular grafts and tissue engineering due to its biocompatibility and biodegradability as well as capable of tissue regeneration ability [4-6].

Electro-spinning technique has recently issued a great deal of attention for biomedical applications, specially, vascular tissue engineering [7-9]. The advantage of an ultra fine, continuous nano-fiber is high porosity, variable pore-size distribution, high surface-to-volume ratio, and most importantly, morphological similarity to natural extracellular matrix (ECM) [4].

There have been many approaches to vascular graft research by nano-fiber composites [5, 9, 10]. In this study, for the adequate environment for HUVECs attachment and proliferation, the PLGA nano-fiber/film composite was fabricated by electro-spinning and solvent-casting methods. The nano-fiber layered on the surface of PLGA film, which has similar structures to ECM, could improve cell attachment and proliferation for vascular HUVECs. The quantity of nano-fiber on the surface of the films was controlled by electro-spinning time. The PLGA solution was ejected form syringe by 10min, 30min, 1h and 2h on the surface of the films. The structure and cytocompatibility of the prepared specimens were investigated.

II. Matreials and methods

A. Electrospinning apparatus

The electro-spinning apparatus consisted of a High-voltage-power supply (40k, Tek Kam Measurement, Korea), spray nozzle, and collector. A stainless still needle of syringe was used as the spray nozzle (+) and a copper plate was used as the collector (-).

B. Preparation of the PLGA nano-fiber/film composite

The PLGA 7525 film was prepared by solvent-casting method. 2g of PLGA 75:25(M_w = 111kD, Brookwood Pharmaceuticals, Inc.) was dissolved in 12ml of chloroform. (DUKSAN PURE chemical Ltd., Korea) The solution was stirred at room temperature for 24h and cast into a mold.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2147–2150, 2009
www.springerlink.com

The solvent was allowed to evaporate for 3 days at ambient conditions, and vacuum freeze-dried for 2days. Then, polymer solution was prepared by dissolving PLGA 7525 in 1:1 mixture of *N,N*-dimethlformamide and tetrahydrofuran (Junsei chemical Co., Ltd., Japan), mixing it well by overtaxing the mixture [4]. The PLGA nano-fiber was produced by electro-spinning process on the prepared PLGA films. The PLGA solution (30 wt%) was placed in a 20ml syringe with an 18-G needle. It was ejected 10min, 30min, 1h and 2h on the surface of the films with driving voltage 18kV and air gap 20cm.(NFC series) For nano-fiber-only film (NFO-1h), the polymer solution was ejected for 1 hour on the metal plate.

C. Characterization of the PLGA nano-fiber/film composite

The morphology of the PLGA nano-fiber/film composite was observed by the field emission scanning electron microscope (FE-SEM) (HITACHI S-4300DSE., Japan) at 3 kV. Static contact angle measurement of the specimens conducted and characterized by contact angle analyzer (Phoenix 150).

D. Cell culture & proliferation

Human umbilical vein endothelial cells (HUVEC) were cultured in Medium200 with Low-serum Growth supplement and antibiotic (Gentamicin/Amphotericin solution). Cells and reagents were purchased from Cascade Biologics (Portland, OR). The HUVEC were cultured at culture flasks in a humidified incubator at 37 °C and 5% CO_2 atmosphere. The medium was replaced every 2 days.

The PLGA nano-fiber/film composite specimens (10×10 mm^2), were sterilized with 70% ethanol and subsequent air-drying, were placed in the bottom of a 24-well culture plate. The specimens were performed pre-wetting in the media for 24h.

The HUVECs (1.2×10^6 cells/film) were seeded on the specimens and cultured in a humidified incubator containing 5% CO_2 at 37 °C. Cell viability and proliferation were determined at 1st, 3rd and 6th day by MTT assay. (Rocke Diagnostics Corporation) The absorbance was measured by multi micro plate reader (synergy HT, BIO-TEK®) at 570nm. The specimens of 9th day harvest were fixed by addition 1 ml of 3.0 % formaldehyde solution for cell morphology analysis by SEM.

E. Statistical analysis

All the quantitative values were expressed as mean ± standard deviation (S.D.) for all comparisons. The one-way ANOVA test by SPSS for window (SPSS INC., version 12) was used for significance of difference among the specimens. The difference of value was considered to be statistically significant at $p<0.05$.

III. Results and discussion

A. Characterization of the PLGA nano-fiber/film composite

The SEM images were investigated the surface morphology of the PLGA nano-fiber/film composite and control PLGA films. (Fig. 1) The electro-spun fibers deposited as a non-woven, linear and bead-free form on the PLGA films. Total amount of electro-spun nano-fiber on surface of the films was varied with time-dependent values. The NFC-10 and NFC-30 composites showed that the nano fibers were deposited partially on the film surface, less dense compared with NFC-1 and NFC-2 composites. (Fig. 1 (a), (b)) The NFC-1 and NFC-2 composites have not revealed the bottom of the films, an increase in density of nano-fibers deposited on the films. (Fig. 1 (d), (e))

The mean fiber diameter at the surface of composite was obtained from the SEM images.

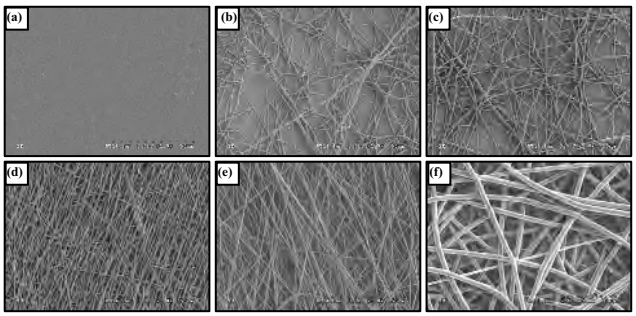

Fig. 1 SEM observation of the PLGA nano-fiber composite and control PLGA films (a) PLGA film (b) NFC-10 (c) NFC-30 (d) NFC-1 (e) NFC-2 (f) NFO-1

Table 1 Diameter of PLGA nano-fiber/film composite

Specimens	Diameter ($x10^{-6}$ m)
PLGA film	-
NFC-10	1.00±0.30
NFC-30	0.96±0.34
NFC-1	1.36±0.53
NFC-2	1.30±0.46
NFO-1	0.98±0.17

The contact angles of the PLGA nano-fiber/film composites were increased from 55° up to 115°, as expressed in Fig. 2. The NFC-30 specimen (Fig. 2 (b)) was similar to control

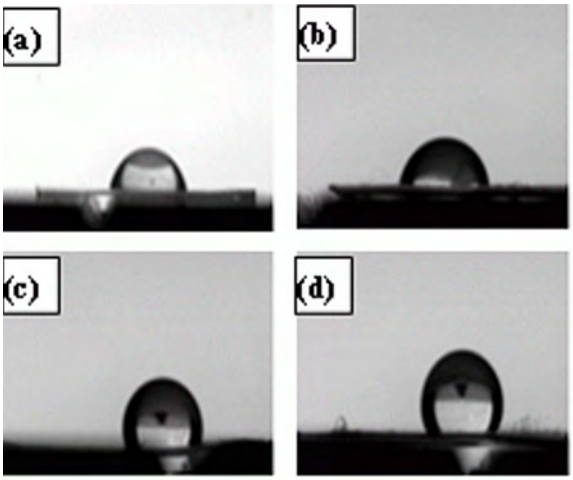

Fig. 2 Contact angle image the PLGA nano-fiber/film composite (a) PLGA film (b) NF-30 (C) NF-1 (d) NF-2

film (Fig. 2 (a)) to 55°. The NFC-1 and NFC-2 specimens were showed 110° and 115°, respectively. (Fig. 2 (c) and (d)) Denser the nano-fiber, the surface was more hydrophobic due to the increment of surface tension.

B. Cellular proliferation and morphology

The proliferation of HUVECs at 1, 3, and 6-day culture on the prepared specimens is shown in Fig. 3. The HUVECs proliferation assaying at 6th-day, there were no significant differences between the average value of control film and NFC-10 & NFC-30 specimens. However, nano-fiber treated group showed very narrow range of standard deviation for cell proliferation compared to control group. Despite contact angle increment, cell proliferation and adhesion was no significant distinction between the NFC-30 and the NFC-1. It means that a little higher contact angle is not affected to the HUVECs' adhesion and proliferation.

The NFC-30 showed about 1.5 times higher than only NFO-1 mesh specimen at 6th-day. ($p<0.05$) This might be caused by shrinkage-deformation of nano fibers of the NFO-1 mesh specimen [11, 12]. Fig. 4 (f) showed deformed pores by shrinkage of NFO-1 specimen. This deformation interfered with cell viability as well as proliferation on the NFO-1 mesh specimen.

Fig. 4 provides visual comparisons of cell adhesion and spreading for nano-fiber composite and control PLGA films for 9-day culture. It shows that the HUVECs on the NFC-30 specimen spread widely than the NF-10 (Figure 4. (b) and (c)). This result indicates that the nano-fibers on films have an effect on adhesion and spreading of cells which anchored by nano fibers at the surface. Because the nano-fibers of the surface of the films provide structure similar to natural ECM. The NFC-1 and NFC-2 (Fig. 4 (d) and (e)) specimens showed less deformed than NFO-1 (Figure 4. (f)). It appeared that the PLGA film prevented the nano-fiber from deformation.

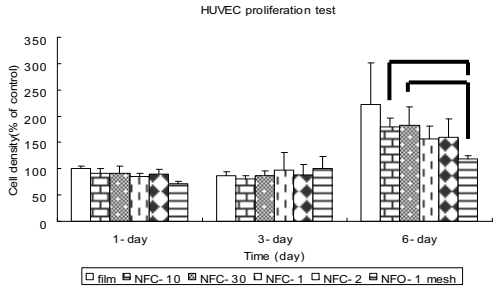

Fig. 3 Proliferation of HUVECs on the PLGA nano-fiber/film composite. (n=6) (*$p<0.05$)

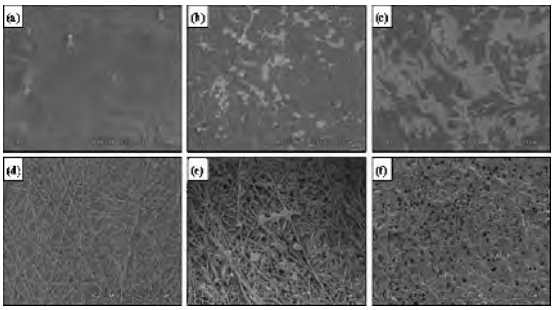

Fig. 4 SEM image: In vitro HUVECs adhesion and proliferation on the PLGA nano-fiber composite after 9th days. (a) PLGA film, (b) NF-10, (c) NF-30, (d) NF-1, (e) NF-2, (f) NFO-1 mesh

IV. Conclusions

In the present study, the HUVECs were cultivated from the adequate amount of nano fiber coating on surface of film/scaffold. The nano fibers on the surface of the films were more hydrophobic than control film; however, optimal amount of nano fibers could assist cell adhesion and spreading. The result showed not effective on cell proliferation for nano-fiber coated film; however, it showed narrower standard deviation for cellular proliferation. Presumably and conclusively, nano-fibrous structure could have an effect for cell proliferation as well as adhesion as if it treated with optimized amount and structure. In future, we try to find the optimized amount and nano-scaled structure for improving cellular adhesion and proliferation.

Muscle and Joint Biomechanics in the Osteoarthritic Knee

W. Herzog

The University of Calgary, Faculties of Kinesiology, Engineering and Medicine, Calgary, Canada

Abstract — **Osteoarthritis (OA) is a debilitating disease associated with joint pain, swelling, stiffness and characterized by loss of articular cartilage from the joint surfaces. The causes for osteoarthritis onset and progression remain largely unknown, but abnormal mechanical loading of joints has been implicated as a primary mechanism for OA. Since most of the loading of joints comes from muscular contraction, the role of muscles in controlling joint actions and producing loads has been of major interest in osteoarthritis research.**

A general goal of our studies has been to elucidate the role of muscles in a variety of animal and human models of OA. Muscle function was measured using a variety of approaches including direct muscle force measurements in live animal models of OA in conjunction with electromyography, 3-dimensional kinematics and kinetics. We found that OA causes selective muscle inhibition, that muscle control is lost to a large degree in animal models of OA, that muscles atrophy following OA onset, and that muscle weakness might be an independent risk factor for osteoarthritis. Furthermore, muscular training in animal models of osteoarthritis has been successful at restoring strength, but, depending on the detailed loading conditions, has also led to increased rates of OA progression as quantified using histological assessment and Mankin scoring.

Taken together, we conclude that an understanding of muscle function is essential for the prevention and treatment of osteoarthritis, and conservative treatment modalities involving muscle control and strength might play key roles in OA prevention and delay.

Keywords — **osteoarthritis, muscles, joints, biomechanics, animal models**

I. Methods

Force measurements in animal models of osteoarthritis are performed using buckle type tendon force transducers [1] and muscle coordination patterns are quantified using *electromyographical (EMG) recordings* of selected muscles [2]. *Pressure patterns* in the intact knee are measured using low and medium grade Fuji pressure sensor film [3, 4, 5]. *Osteoarthritis onset and progression* are quantified via gross morphology, histological assessment (Mankin scoring; [6], and biochemical or molecular biology approaches [7, 8].

For our research on animal models of muscle weakness, we used botulinum toxin type-A (Botox) injections into the target muscles at a dosage of 3.0-3.5 units per kg mass of the animals [9, 10].

II. Selected results

Our early work on osteoarthritis was focused on the cat anterior cruciate ligament transected (ACLT) knee, which we showed to be a bona fide model of osteoarthritis. Following ACL transection, the medial aspect of the joint capsule, including the medial collateral ligament, becomes thickened (Figure 1), osteophytes form at the joint margins, and the articular cartilage initially increases in thickness, becomes softer and joint contact areas increase while peak pressures decrease (Figure 2). Immediately following ACL transection, the vertical ground reaction forces decrease (Figure 3), and so do the muscular forces in the experimental compared to the contralateral hind limb (Figure 4). EMG signals in the knee extensors become intermittent, rather than the normal continuous firing patterns (Figure 4) and knee flexor muscles show additional bursts at the precise moment of first ground contact, presumably to prevent anterior tibial translation relative to the femur when the ACL is missing (Figure 4). Anterior-posterior stiffness of the knee (evaluated with an anterior drawer test) is dramatically decreased following ACL transection in the cat, but recovers to normal values within 4 months of intervention (Figure 5).

Following Botox injection into the rabbit knee extensor musculature, the size of the muscles (Figure 6), muscle mass (Figure 7) and strength (Figure 8) were decreased significantly. Similarly, the vertical push-off forces during hopping were also reduced in the experimental compared to the contralateral (non-injected) hind limbs (Figure 9).

Fig. 1: Intact (left) and ACL-transected cat knee (right) at 12 weeks following intervention. Note the thickening of the medial joint capsule (curved arrow), and the osteophyte formation at the edges of the joint (straight arrows) in the experimental ACL-transected knee.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2151–2154, 2009
www.springerlink.com

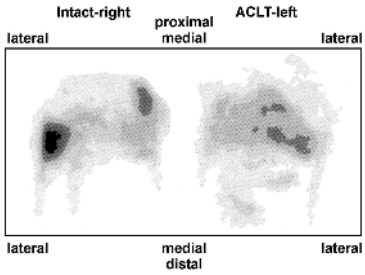

Fig. 2: Patellofemoral contact pressures measured with Fuji Presensor film in an intact knee and the contralateral anterior cruciate ligament transected knee at 16 weeks post-intervention. Increased pressures are represented by darker staining. Note the greater peak pressures in the intact joint and the greater contact area in the anterior cruciate ligament-transected joint (*ACLT*), as predicted theoretically. This result was consistent for five independent observations and for the whole range of loading conditions (not shown).

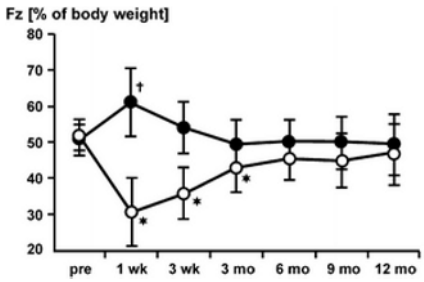

Fig. 3: Vertical ground reaction forces as a percentage of body weight for the transected (*open circles*) and contralateral (*closed circles*) hind limbs before anterior cruciate ligament transection (ACLT) and at different time points post-ACLT. *Asterisks* and *dagger* indicate significant differences from pre-transection values of the corresponding leg. The values are means (± SD) for seven cats, with multiple steps for each cat.

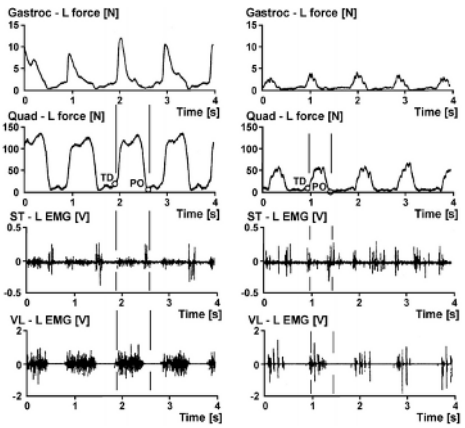

Fig. 4: Gastrocnemius (*gastroc*) and quadriceps (*Quad*) forces and semitendinosus (*ST*) and VL EMGs from a representative cat before (*left*) and 7 days after (*right*) anterior cruciate ligament transection (ACLT). Results are shown for four full step cycles of slow walking. TD and PO are indicated in both panels for one step cycle and they contain the stance phase of the target hind limb. Note the decrease in force from before to after ACLT and the obvious changes in the EMG patterns.

Botox-induced muscle weakness caused visible changes to the articulating surfaces of the knee (Figure 10) and histological analysis revealed increased progression of osteoarthritis in the experimental hind limbs (Figure 11). Histological sections of the muscles following 6 months of Botox treatment revealed that muscles had lost contractile material that was replaced by fat (Figure 12).

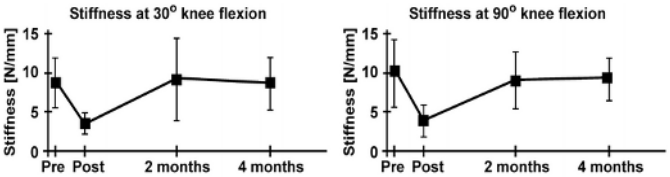

Fig. 5: Anterior–posterior stiffness of cat tibial displacement relative to the femur, before (*pre*), immediately after (*post*) and at 2 and 4 months after anterior cruciate ligament transection (n=4) for knee flexion at angles of 30° and 90°. Note that the anterior stiffness of the cat knee decreases dramatically after anterior cruciate ligament transection, but that this stiffness is back to normal at 4 months post-intervention. Similar results were observed for internal rotation stiffness of the cat tibia relative to the femur (not shown).

Fig. 6: Example of muscle mass loss following BTX-A injection. Top row: rabbit quadriceps muscles from control (contralateral) leg; bottom row: the corresponding quadriceps muscles from the experimental hind limb one month following injection of 3.5 units/kg BTX-A, as described in the methods section.

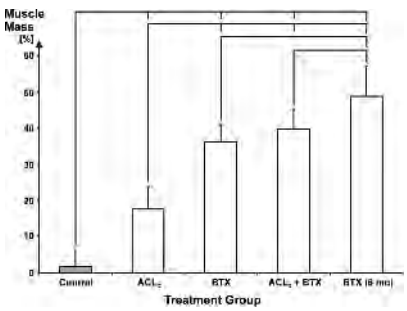

Fig. 7: Percent loss of muscle mass in control, ACL-transected (ACL_x), Botox injected after 1 month (BTX), ACL_x and BTX combined, and repeat Botox injections for 6 months (BTX, 6 months). Percent loss of muscle mass was determined relative to the contralateral control leg.

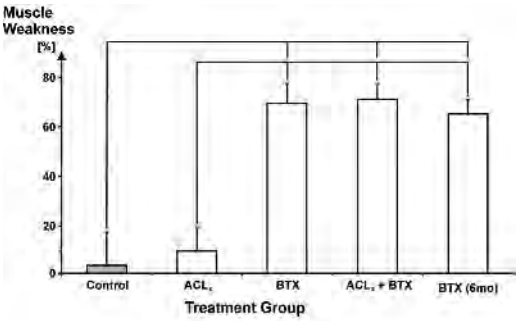

Fig. 8: Percent muscle weakness in control, ACL-transected (ACL_x), Botox injected after 1 month (BTX), ACL_x and BTX combined, and repeat Botox injections for 6 months (BTX, 6 months). Percent loss of strength was determined relative to the contralateral control leg.

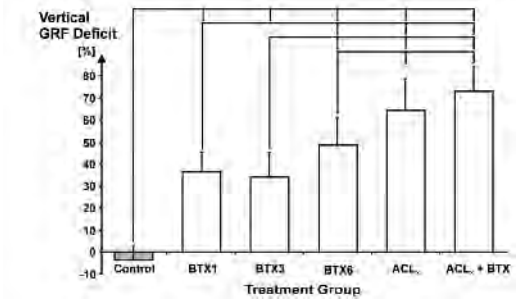

Fig. 9: Decrease in the vertical push off force during hopping for control, ACL-transected (ACL_x), Botox injected after 1 month (BTX1), 3 months (BTX3), 6 months (BTX6), ACL-transected (ACL_x), and ACL_x and BTX combined. Push off forces were significantly ($p < 0.05$) smaller in all experimental groups compared to control, were smaller following 6 months of repeat BTX-A injections (BTX6) than either following 1 or 3 months (BTX1, BTX3, respectively), and were smaller yet for the two ACL transection groups (ACL_x and ACL_x + BTX) than any other experimental group.

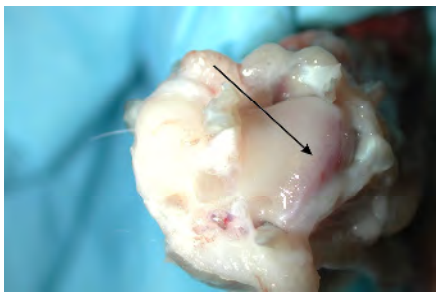

Fig. 10: Example of reddening on the margins of the tibial plateau (arrow) in a knee 1 month following a single Botox injection into the knee extensor musculature.

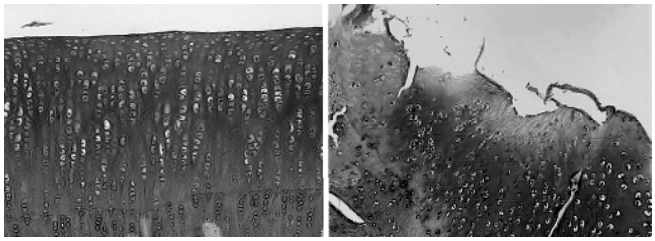

Fig. 11: Example of histological slides from a control (left) and an experimental (BTX-A injection, one month) knee articular cartilage. The control animal shows normal cartilage structure, while the experimental cartilage shows surface disruption and loss of structural integrity.

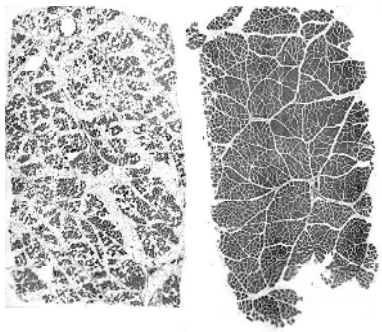

Fig. 12: Example of a cross-sectional histological slide of quadriceps musculature from a control animal (right) and an experimental animal following six months of repeat Botox injections. Note the structural integrity and dense contractile material (dark areas) in the control animal, and the loss of structure and invasion of fat (light areas) in the experimental muscle.

III. Conclcusion

From the results of our studies conducted over the past decade, we conclude that muscle loading and coordination is altered following interventions to joints that cause degeneration leading to osteoarthritis. Specifically, ACL transection in animal models causes an initial decrease in knee extensor forces, and additional bursts of activation in knee flexors, presumably to offset the mechanical function of the lost ACL. In contrast to common believe, articular cartilage thickness increases initially in many models of early OA, causing joint surfaces to be softer. This results in load transmission across the joint over increased contact areas and reduces peak pressures for given loading conditions.

Muscle weakness is an associate of joint degeneration and OA, but it has never been clear if weakness might also be a risk factor for joint degeneration and OA. Prospective studies in human cohorts suggest that indeed, elderly with knee extensor weakness are more likely to develop signs of OA than those with normal knee extensor strength [11, 12]. The series of studies with Botox-induced rabbit knee extensor weakness performed here suggest that muscle weakness

is an independent risk factor for OA, and that proper strength training might prevent OA onset and progression. However, recent results from our group in ACL deficient rabbits suggest that training offsets the ACLT induced knee extensor atrophies, but if not performed properly, might simultaneously accelerate the rate of knee osteoarthritis progression.

Multidisciplinary Education of Biomedical Engineers

M. Penhaker[1], R. Bridzik[2], V. Novak[2], M. Cerny[1] and J. Cernohorsky [1]

[1]VSB - Technical University of Ostrava/Department of Measuring and Control, Ostrava, Czech Republic
[2] Video-EEG/Sleep laboratory, Clinic of Child Neurology, University Hospital Ostrava, Czech Republic

Abstract — **Biomedical engineering, clinical engineering and medical informatics represent interdisciplinary branches which are very progressive and acknowledged and which intervene into many spheres. The mentioned branches apply various technical principles and skills in biology and medicine: from proposals, construction and implementation, to the servicing of medical technology. These inspired to change the structure of curricula of the study branch and also the conception of some classes to better cover the legislative needs. Nowadays the study field biomedical engineering is educated as study fild in bachelor and master study at VŠB – Technical university of Ostrava, Faculty of electrical engineering and computer science with cooperation of Medico–Social faculty of the University of Ostrava and University Hospital Ostrava teaching medico - social courses. The courses are mainly provided in special laboratories which combines multi-technical proposition to solve during education in teams.**

Keywords — **biomedical engineering, study, education process**

I. Introduction

Biomedical engineering, clinical engineering and medical informatics represent interdisciplinary branches which are very progressive and acknowledged and which intervene into many spheres. The mentioned branches apply various technical principles and skills in biology and medicine: from proposals, construction and implementation, to the servicing of medical technology. Up until now, biomedical engineering has been taught at the Department of Measurement and Control within the master program as one of its majors called, "Measurement and Control in Biomedicine". Changes both concerning the overall higher education system in Czech Republic and resulting from the entry of Czech Republic into the EU influenced the formation of a new type of biomedical study field.

The new bachelor study branch "Biomedical technologies" has been proposed and accredited at the Faculty of Electrical Engineering and Computer Science. From a technical point of view, the branch is very close to the field of "Measurement and Control" and that is why the department of measurement and control guarantee this study branch. The previous experience gained by the training of the mentioned master program made a very good groundwork for administration of the bachelor program. However, the cooperation of lecturers from other faculty departments, which are specialists in particular topics is expected and required.

II. Conception of study

The bachelor program "Biomedical technologies" combines both technical courses and socio-health and medical courses Fig.1 . The classes are taught at the Faculty of Electrical Engineering and Computer Science and at the Medico–Social Faculty of the University of Ostrava respectively and also at University Hospital Ostrava. Thus, the branch has an inter-disciplinary character and qualified teachers from both universities have become involved in its realization.

The graduates will be specialists in installing, operating, monitoring and innovating medical technique and advancements in medical institutions and may work in a direct contact with patients. They will be sufficiently educated in anatomy, physiology, pathology and other health and social disciplines. However, they must not work as a nurse. They also will be able to assist in selected areas of medical research and to use related information technology to this purpose.

III. Conception of interdisciplinary study

The preparation of the bachelor interdisciplinary program Biomedical Technologies (BMT) began already in year 2002 along with the transformational and developmental project of the Ministry of Education for youth and physical education of the Czech Rep (CZ). Groundwork for accreditation was prepared for this project and in year 2003 this branch was accredited by an accreditation committee of the Ministry of Education CZ as another study branch of the educational program Electrical Engineering, Telecommunications and Computers. At that time a law had not yet been passed that had to do with the existence and influence of non-medical staff in the public health work force because the government was waiting for further changes in legislation resulting from the Czech Republic's entrance into the EU. This law was therefore passed a year later as number 96/2004 of the Statute Book on non-medical staff in healthcare.

This law defines, for the first time, the term lifelong learning in healthcare and exchanged activities, which are perceived as lifelong education. This law also modified the process of obtaining certification to work without a supervisor, which until then supervision was a requirement for this field of work. Detailed conditions are specified in the edict 423,424/2004 of the Statue-Book under the government number of 463/2004 of the Statue-Book, which applies to the sector of specialized education and selected employees with specialized professions. These edicts are part of the administered law regulation, which defines an altogether new standing of technical staff in the healthcare system. It has been shown that because of an increasing amount of sophisticated health diagnostic, laboratory and therapeutic machines, there is an increasing need for qualified technical staff without skilled supervision. These edicts have a strong impact on branches such as Biomedical Technologies and Biomedical Engineering, which are explicitly discussed and cited in relation with standard professions like "Biomedical Technician" or "Biomedical Engineer" in which the graduates will find employment.

Another edict, number 39/2005 of the Statue-Book, follows and extends the edict in accordance with EU edicts and makes minimal alterations to both theoretical and practical classes which gives the program professional qualification with which to operate and create non-medical healthcare professionals.

The edicts require the following criteria in order to acquire qualifications as a Biomedical Technician:

- The obtainment of the Biomedical Technician title is possible after studying in the accredited (by Ministry of Healthcare!) bachelor program in the standard time of a minimum of three years.
- From this, practical classes must make up at least 600 semester hours in the case that they are taken as part of daily study program as opposed to long distance studies.
- The program must provide knowledge and skills according to the edict number 424/2004 of the Statue-Book that gives the requirements for healthcare workers and other specialized workers.

The program must include basic general theoretical and practical classes:

a) The theoretical education must provide the following knowledge:

- Basic knowledge in anatomy, physiology and pathology for programs that supply basic services for the performance of technical health care.
- In technical programs; knowledge in signal and image processing (introduction to the theory of signal processing, analysis and interpretation of biosignals and biomedical sensors), in equipment health care instruments (knowledge in basic electrical circuits, diagnostic, therapeutic, laboratory and complex healthcare equipment and visual systems in clinics), in informatics and cybernetics (basic knowledge in statistics, support of computer diagnostics, telemedicine, information systems in health care, introduction to the theory of simulation and modelling), in electro technical subjects (knowledge in math, physics, theoretical electrotechnics, electronics, electrical measurements and programming).

Technical law and norms that apply to healthcare, in management of health care technology and the basics of scientific methodology in scientific research.

b) The practical classes must provide the following skills and knowledge:

- In classes that take place in school laboratories and in healthcare centres.
- A minimum of 50 hours of practical classes must take place in healthcare workplaces that use diagnostic healthcare equipment.
- A minimum of 30 hours of practical classes must take place in healthcare workplaces that use therapeutic healthcare equipment.
- A minimum of 20 hours of practical classes must take place in healthcare workplaces that use laboratory healthcare equipment.

To show how in year 2003 accreditation for the BMT program corresponds with the required edict number 39/2005 of the Statue-Book, we will show some statistic information from this program.

IV. Statistical data about BMT

Classes, both theoretical and practical, are taught by two universities and University Hospital Ostrava; by the Faculty of Electrical Engineering and Computer Science at VŠB-TU Ostrava and by the Medico-Socio Faculty at the University of Ostrava. The faculty of Electrical Engineering and Computer Science, makes up 54,3% of total hours and provides technical and language classes with the exception of Latin. Among the required classes are Math I and II, Physics, Optical Electronics, Biophysics, Electrical Circuits, Signal Analysis, Basic Computer Skills, Measurement and Processing of Data, Information Systems in Healthcare, Sensors in Biomedicine, Electronic Instruments technique, Electronic Instruments Measurement and Monitoring and Control Systems. Another class that is required that belongs to two semester practical classes is the Healthcare Electronic Equipment class that consists of basic and specialized healthcare technique, including its clinical application according to individual medical fields. The Electrical Engineering and Computer Science department offers optional courses in Biocybernetics and Biotelemetry.

The Medico-Socio faculty and physician from University hospital Ostrava provides required classes in healthcare such as First Aid, Basics of Anatomy, Physiology, Pathology, Psychology, Chemistry and Biology, Work Hygiene and Epidemiology, Microbiology and Immunology. Also included in the required courses are Ethics in Healthcare, Management and Operations in Healthcare, Healthcare Law, Marketing in Healthcare, Public Healthcare, Security, and Latin and Specialized Terminology. Other required classes are courses focused on practical therapeutic and diagnostic technique. In this area are included classes such as Clinical Propedeutics, Technique in Diagnostic Sickness in Internal and Surgery Sectors, Healing Technique in Radiotherapy and Nuclear Medicine in Healthcare Equipment. Furthermore, the Medico-Socio faculty offers optional courses such as Audiometry, Rehabilitation Methods and Technique, Equipment Technique and Compensation Aids for the Handicapped, Examining Methods and Equipment Technique in Optometry, Civilization Diseases and Physical Body Workload Risks.

A very important part of the program is the related specialized workplace classes taken place at healthcare clinics that make up 120 hours, which over qualifies the norms according to the edict number 39/2005 of the Statue-Book. In their first year, students complete 14 daily practical classes in the area of Technique in Diagnostics of Disease and in the second year, they complete similar practical courses in Technique in Therapy of Disease. Thus the Socio-Medico department classes of the University of Ostrava make up 45,7% of the total program.

Statistics that are more detailed (number of credits and hours taught) in relation to the healthcare and technical courses of the BMT program are shown in the following table, Table 1.

Table 1: Table of skills in subject representation according year, Hours also in percent

	Electrical (Technical)		Health (Humanity)		Others specialized subjects	
Yr.	Hrs.	Lect./ exerc.	Hrs.	Lect./ exerc.	Hrs.	Lect./ exerc.
1	476	252/224	294	168/126	70	42/28
2	448	252/196	196	140/56	56	42/14
3	209	77/132	242	110/132	44	44/0
∑	1133	581/552	732	418/314	170	128/42
%	48,8	24/23,8	31,5	18/13,5	7,2	5,4/1,8

Here are 22 (35,5%) electro-technical classes and 26 (42%) healthcare classes, language classes are 3 (5%) and the rest of the classes from both departments are 11 (17,5%). From the semester hour point of view, technical classes make up 1133 hours (48,8%) and healthcare classes make up 732 hours (31,5%). Language classes make up 126 hours (5,5%) and other classes make up 170 hours (7,2%). The remaining classes, professional practice at the clinical workplace, make up 120 hours (7%). This statistic is calculated from all the classes offered, in practice the overall number of credits is smaller because students choose a limited number of optional credits so that they will complete the requirement of 180 optional credits during the program.

V. Profile and enforce of graduate

The graduates will be specialists in installing, operating, monitoring and innovating medical technique and advancements in medical institutions and may work with in direct contact with patients. They will be sufficiently educated in anatomy, physiology, pathology and other health and social disciplines. However, they must not work as a nurse. They also will be able to assist in selected areas of medical research and to use related information technology to this purpose.

Currently, graduates can find employment most often as assistances in clinical healthcare, in equipment security and in operating healthcare equipment. In order to obtain a certificate to practice in the profession without skilled supervision, the Ministry of Health needs to accredit the program. The structure and contents of the new bachelor study field Biomedical Technologies conforms to legislative requirements and all graduates of these biomedical professions are ready to practice in the profession in accordance with newly accepted legislative requirements. accepted legislative requirements.

VI. Support of eueopean social fund project

The legislative changes inspired the needs to change the structure of curricula of the study branch and also the conception of some classes to better cover the legislative needs.

The faculty applied for support to cover expenses combined with such reconstruction the grant agency of The Ministry of Education Youth and Sports for the European Social Fund (ESF) helps people improve their skills and, consequently, their job prospects. The ESF is the EU's main source of financial support for efforts to develop employability and human resources. It helps Member States combat unemployment, prevent people from dropping out of the labor market, and promote training to make Europe's workforce and companies better equipped to face new, global challenges

In Czech Republic one branch of ESF is focused on the following important activities

- Training in the fields of research, science and technology
- Development and improvement of training, education and skills acquisition, including the training of teachers
- Development of systems for anticipating changes in employment and in qualification needs
- Advancement of the study branch Biomedical technique and of employability of its graduates on the employment market in reference to law number 96/2004 of statute-book

From general point of view the global goal of the project is the advancement of study field Biomedical Technology with long-term perspective of better employability of its student on both on the Czech end EU labor market. The specific measures are realized within three key activities :

The change of the structure and contents of particular classes with emphasis on practical part of the subjects

The realization of the new mood of guidance of practical training in hospital by mentors

The production of good-class set of study materials to cover both technical end medical part of the study program.

VII. Conclusions summary and perspective

This new bachelor branch was successfully accredited in year 2003. The education in this branch started in the winter semester of the academic year 2004/2005. In the year 2004 the Czech Republic passed a law, number 96/2004 of the Statute Book, about non-medical sanitary professions. Detailed conditions and requirements for obtaining the certificate for practice of profession without skilled supervision was subsequently modified in the regulation number 423/2004 and 39/2005 of the Statute Book and in the decree number 463/2004 of the Statute Book. These legislative changes have a strong impact on branches like biomedical technology, respectively, biomedical engineering.

Although the instruction of this interdisciplinary program is new and there do not exist curriculum's and past experiences with graduates in such a branch, the cooperation between universities is very close and all evaluations, both from the students and from the teachers of the first year will lead to changes and alterations in the curriculum so that the quality of the branch will continue to grow.

After the completion of the bachelor program, the graduates have an opportunity to continue their studies in the master program that is taught at VSB -Technical University of Ostrava at the Faculty of Electrical Engineering and Computer Science in the area of "Measurement and Control of Technology in Biomedicine". After the completion of the master program, a doctoral program is offered in Technical Cybernetics.

Now when the new study concept five years last, we can estimate level of three institutions in education process cooperation with the great impact on student knowledge and abilities for his profession.

Acknowledgment

This work was partially supported by the faculty internal project "Biomedical engineering systems" and by the project of the European Social Fund (ESF) CZ.04.1.03/-3.2.15.1/0020 which is co-financed by the European Union and by the state budget of the Czech Republic.

Abstract — **In the 12-lead electrocardiograph currently being used general medical practice, electrodes are positioned at 6 locations in the chest region and the cardiac potential is measured. This research increases the number of electrode to 124 at evenly-spaced intervals over the body surface of the chest, side and back. The commonly used band elimination filter is not used as a countermeasure for exclusion of the noise from such electrodes, and a body surface electrocardiograph has been developed that makes it possible to perform high-speed sampling of the cardiac potential at 80-100 times the conventional rate. From the sampling data obtained with high spatial resolution, maps and animations of the body surface potential distribution are created and displayed from the 1D waveform as well as from the 2D/3D waveforms.**

Keywords — **Body surface electrocardiography, Body surface potential map, Body surface potential animation, high spatial resolution, Band eliminate filter**

I. Introduction

Most conventional body-surface electrocardiograms are obtained by standard 12-lead electrocardiography, in which cardiac potentials are detected in the thoracic region using unipolar lead, and changes in cardiac potentials in various regions are the clinically examined. Data obtained by conventional electrocardiography are typically analyzed using one-dimensional wave patterns. For example, whether QRS intervals are constant, the duration of QRS intervals, whether the intervals between the PQ intervals are constant, heart rate, the presence or absence of P waves, and the presence or absence of an atrioventricular block can be diagnosed from the one-dimensional wave patterns. To eliminate the effects of noise, of which inductive noise at the power supply frequency (hum) is the most important, band-eliminating filters are used [1-4]. However, since these frequencies (0.05-100 Hz) are required for the accurate measurement of cardiac potentials, the application of a band-eliminating filter alters the electrical properties of the detected cardiac potentials, resulting in an inaccurate measurement [5].

To perform a more detailed analysis of electrocardiographic wave patterns by that involve small changes, the observation of changes in cardiac potentials at a larger number of sites without applying such filters and three-dimensional expression are necessary. In the present study, we experimentally produced a body-surface electrocardiograph without filter measuring potentials at 124 sites on the body surface, from in thoracic to the back regions, and examined its resolution in two- and three-dimensional body-surface potential mapping and its accuracy in the detection of cardiac potentials.

II. Materials and Methods

A. Improvement of the shielding effect

In our system, to eliminate inductive noise without a band-eliminating filter, the shielding effect was increased by placing the device in a metal box, to minimize the effects of inductive noise. In this system, 124 electrode sites were used, consisting of 64 in the thoracic region, 48 on the back, and 12 on the left body side, and the entire region around the heart was sufficiently covered with these electrodes. The distance between the electrodes and the amplifier was about 10 cm, which is shorter than that in conventional electrocardiographs. The amplifier was encased in a metal box, and the metal box covered the entire region around the heart thus minimizing the effects of inductive noise. To further increase the shielding effect, the distance between the body surface and metal box was shortened during the measurement by stroking the electrode (Fig. 1-1). In addition, the heart was positioned in the region close to the center of several electrode boxes to increase the shielding effect (Fig. 1-2).

www.springerlink.com

B. Electrodes with skin contact resistance at a constant level

In this system, to maintain the contact resistance of electrodes at a constant level, they were moved with the up-and-down movement of the skin caused by respiration and cardiac pulsation. To decrease changes in contact resistance, the electrodes were made so as to correspond to individual body shapes, and the body surface was pressed at a constant level during the stroking of the electrode rod to which a spring was fixed. To maintain constant contact conditions, it was necessary to move the electrodes with the body movement, and a decreased friction resistance of the electrode rod and its guide was required. This was achieved by stabilizing the contact condition by moving the electrode with the body movement using a guide comprised of a fluorine resin (PTFE) with very good folding properties, the static friction resistance (0.02 N) of which is lower than the dynamic friction resistance (0.05 N). PTFE, which has the highest electric property among solid insulating materials, is stable over wide frequency and temperature ranges.

C. Configuration of the system

In this system, the number of channels was 124, the maximal input voltage ±5 mV/±10 mV, the resolution 10 bit, and the sampling interval 0.1 ms.

A spring was fixed to each electrode rod so that it was stroked when placed on the body surface, and each electrode was pressed at a constant level. The distances between the body surface or electrode and the metal box were decreased by stroking the electrode rod, thus increasing the shielding effect. Since the friction resistance of the electrode rod guide made of PTFE was low, it followed body movements caused by respiration and cardiac pulsation (Figs. 2and3). Cardiac potentials induced on the body surface were transmitted to an amplifier via the electrode, electrode rod, and spring. The electrical potential determined by adding the values for the bilateral hands and the left foot were used as the standard (0 V), and the voltage for each electrode was detected (Fig. 4). Cardiac potentials induced on the body surface were amplified 1,000- or 2,000-fold using a buffer, a preamplifier, and an amplifier, converted into digital signals using an AD converter, and transmitted to a personal computer. Data input into the personal computer were expressed both two- and three- dimensionally.

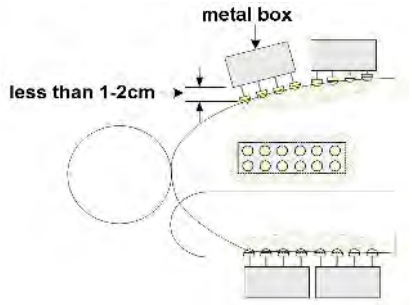

Fig. 1-1 Figure of measurement from a right side surface.

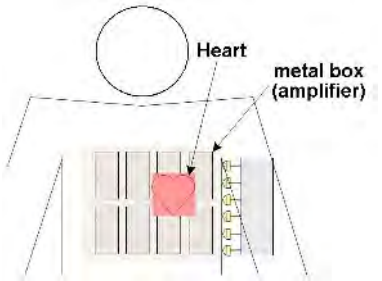

Fig. 1-2 Figure of measurement from the front.

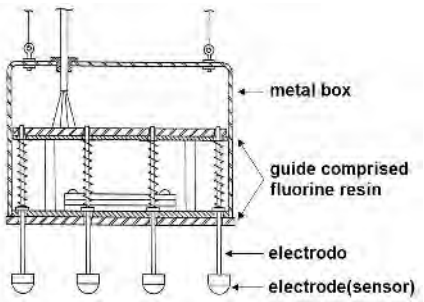

Fig. 2 Structure in an electrode case.

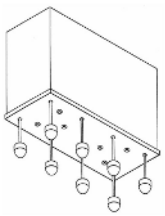

Fig. 3 External representation of an electrode case.

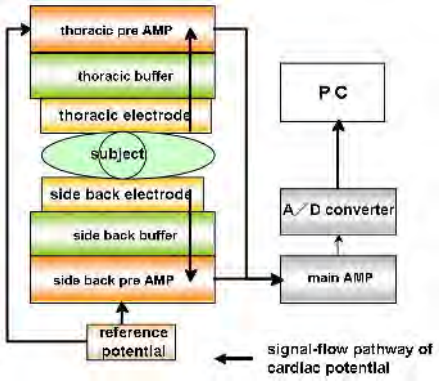

Fig. 4 A general view of the system.

III. Results

Figs. 5-1 and 5-2 show the conventional one-dimensional expression of voltage on the ordinate and time on the abscissa. The dark lines show data obtained with, and the light lines show those without a band-eliminating filter. A band-eliminating filter of 50/60 Hz was used. In Fig. 5-1, the peak attenuation ratio for R and T waves were quite differently, i.e., large in the former and almost no changes in the latter. As shown in Fig. 5-2, the phase of the QRS waves was not constant.

Fig. 6 show the electrocardiogrphic wave forms for 124 recording points. All electrocardiogrphic waves were detected clearly without noise. Figs. 7-1 and 7-2 show three-dimensional graphs of differences in voltage between the sensors at the same time. Fig. 7-2 shows data obtained with a band-eliminating filter, and Fig. 7-1 shows those without a band-eliminating filter. The size of the spike was smaller in the former than in the latter.

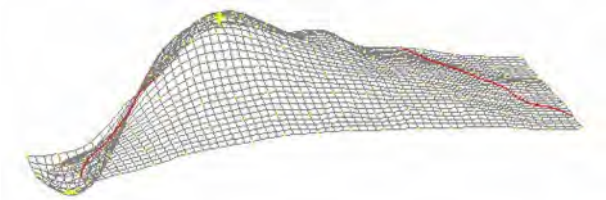

Fig. 7-2 Three-dimensional graphs without a band-eliminating filter.

IV. Discussion

A. Inductive noise affecting eletrocardiograms and filtering

Noise caused by applying electrocardiographs interferes with the accurate detection of cardiac potentials. The major noise is inductive noise (hum) caused by the frequency of the power supply, and there is generally 50/60 Hz of noise unless the measurement is performed in a completely shielded room. This noise is induced by the electrodes, and is picked up by the amplifier along with cardiac potentials. Since the frequency required for electrocardiography is 0.05-100 Hz, the frequency of inductive noise overlaps with this frequency range. Therefore, cardiac potentials cannot be detected by simply eliminating noise with a filter, and it is not possible to differentiate between cardiac potentials and noise in the measurement. The high input impedance of the preamplifier required for the amplification of very low cardiac potentials further increases the effects of inductive

noise [6]. Filtering eliminates inductive noise at 50/60 Hz, which is included in the frequency range of the cardiac electric waves, and also changes specific frequency components of cardiac electric wave patterns. However, a frequency analysis of cardiac electric wave patterns per heartbeat demonstrates that most of the energy consists of frequency components lower than the frequency of the power supply, and the amount of energy with components of the frequency of the power supply is very low. Therefore, even though inductive noise can be eliminated using a filter, changes in cardiac electric wave patterns caused by filtering may be small. However, when rapid changes in cardiac electric wave patterns occur during a very short period, e.g., around the QRS peak, the effects of high frequency components are large, and the peak amplitude is rapidly attenuated by filtering. In other words, the entire cardiac electric waves are not attenuated, but partial amplitudes, corresponding to high frequency components, are attenuated. The attenuation of amplitudes varies with the rate of change of cardiac electric wave patterns. This rate of change fluctuates within 1 heartbeat, and varies with the electrodes. Therefore, marked attenuation partially occurs as the result of eliminating inductive noise from cardiac electric wave patterns by filtering, and the rate of change varies with the electrodes, because cardiac electric wave patterns that are induced by the electrodes differ. Since filtering changes not only amplitudes but the phases as well, depending on the frequency components, eliminating noise caused by the power supply from cardiac electric wave patterns can alter the amplitudes and phases depending on the time and the electrode.

In this system, the peak attenuation ratio of R and T waves differed substantially, i.e., large in the former and almost no changes in the latter, as shown in Fig. 6. Furthermore, the phase of the QRS waves was not constant. A possible cause of these properties was that the voltage attenuation and phases were not constant because the frequency components of the cardiac electric waves differ between the channels, even though the attenuation rate of the filter is constant at each frequency. If the rate of change was not constant, the two- and three-dimensional expression of differences in the voltage between one electrode and the next was considered to be inaccurate.

B. Contact resistance of electrodes and local batteries

The contact resistance between the electrode and skin is several hundred Ω to several hundred MΩ depending on the contact conditions and the region [7]. To prevent the attenuation of cardiac potentials caused by contact resistance, the input impedance of the preamplifier must be high, and cardiac potentials are readily affected by inductive noise.

In addition to contact resistance, local batteries of several hundred mV are generated between the electrodes and the skin [8]. These voltages (several hundred mV) are higher than the cardiac voltage, of which the peak is several mV. With changes in contact resistance by up-and-down movement caused by respiration and cardiac pulsation, the voltages of the local batteries change. The movement of the body surface during the measurement is irregular, and changes in the voltages of the local batteries are also irregular, causing frequency properties in the local batteries. Since these frequency properties overlap with the frequency range of the cardiac voltage, changes in local batteries are measured as the cardiac voltage, resulting in an inaccurate measurement.

If the sensors cannot follow body movements, the contact conditions are changed. Therefore, to produce a highly accurate body-surface electrocardiograph, it becomes very important to eliminate the noise caused by the power supply without a filter and make the voltages of the local batteries constant by achieving constant contact resistance between electrodes and the skin.

V. CONCLUSIONS

To more accurately detect cardiac potentials, inductive noise was suppressed without the use of a filter, and changes in the electrical properties of cardiac potentials (changes in the amplitude and phase of cardiac electric wave patterns) were prevented. Furthermore, the electrodes were made, so as to follow the up-and-down movement of the body surface caused by respiration and cardiac pulsation, during which local batteries generated on the electrodes and the body surface could be maintained at a constant level, and cardiac potentials alone could be detected. The number of electrodes for the detection of cardiac potentials was 124 in the thoracic to back regions, thus permitting more information to be obtained.

These findings suggest that the accurate measurement of cardiac potentials and body-surface potential mapping with a high resolution is possible using this system. The findings also suggest that the detection of certain cardiac electric phenomena, currently considered to be impossible by conventional electrocardiographs, is feasible. Clinical studies will be pursued using this system.

Biomedical Engineering Education Prospects in India

Kanika Singh

Indira Gandhi National Open University, New Delhi, India
Pusan National University, Busan, South Korea

Abstract — **The importance of education lies in its scope which should be well-matching with the growing technology. The paper here discusses about the Biomedical Engineering Education. The interface between electrical engineering and the life sciences has grown enormously. The biomedical engineering program has become a globally expanding discipline with time. The BME education in India needs proper planning and designing. In this paper, we discuss the scenario of BME in India and give suggestion for a successful future.**

Keywords — **Biomedical Engineering Education, India, Prospects**

I. Introduction

Biomedical Engineering has the concept of interdisciplinary engineering which portrays the modern engineering concept. The engineering has been widely accepted in the world and hence may be considered to a globally acceptable discipline. The BME has a strong multidisciplinary integration which involves the electrical, chemical, mechanical, computer and civil engineering. According to NIH, Bioengineering integrates physical, chemical, mathematical, and computational sciences and engineering principles to study biology, medicine, behavior, and health. It advances fundamental concepts; creates knowledge from the molecular to the organ systems levels; and develops innovative biologics, materials, processes, implants, devices, and informatics approaches for the prevention, diagnosis, and treatment of disease, for patient rehabilitation, and for improving health (NIH definition). BME is a constantly changing field.

Hence such a discipline requires careful planning when designing BME educational programs which may produce successful professionals.

These professionals often work in tandem with other life scientists, chemists, and medical

scientists to aid the cause of preventive and curative medicine. Whereas biomedical engineers develop devices, systems and procedures to aid medical research or help solve heath and medical problems. The sudden spurt in radical research concepts that have lent a whole new direction to treatment modalities is essentially due to developments in this field.

In this paper, scenarios of Indian university have been given. The objective of this paper is to briefly present the India scenario of BME education, the challenges it faces and the future steps towards the appropriate education of BM engineers for the region.

Biomedical engineering has immense scope for path breaking research.

II. Scenario of Indian Universities with BME Education

A. Scenario

Previous days, the graduation in a related subject such as electrical, chemical or mechanical engineering and then team this up with a specialization in biomedical engineering.

Generally, biomedical engineers may seem like an elite class of practitioners, the ever-increasing Biomedical engineers who are considered to be the specialists or experts have all had humble beginnings, which can be traced back to an ordinary engineering degree.

However, recently there have been several Bachelor courses in Biomedical Engineering but are less popular as compared to the main stream engineering. In order to specialize in this field most Indian students opt for masters programs. There is also a provision of pursuing master in Biomedical Engineering after completion of their medical degree. But the Ph.D programs in India are very few in number.

Some of the renowned institutes providing BME at the masters and doctoral levels at IIT Mumbai. Banaras Hindu University, Varanasi 221005 (UP) and Birla Institute of Technology and Science, Vidya Vihar, Pilani 333031 (Rajasthan) offer an M.Tech in biomedical engineering.

The chief specialties in this field include bioinstrumentation, biomaterials, biomechanics, cellular, tissue and genetic engineering; clinical engineering; rehabilitation engineering; orthopedic surgery; medical imaging; and systems physiology.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2164–2166, 2009

B. Challenges for BME in India

Engineering education in India faces some classic and some new challenges. Most of these challenges are common to all engineering disciplines, including biomedical. In the era of the Internet and telecommunications changes, as Gupta et al. [3] point out, the major challenges of engineering education are: a) the need for formalized lifelong learning; b) the need to broaden "engineering fundamentals" beyond mathematics and physics; c) inadequacy of the first professional degree for engineering careers; d) need for engineering practice.

The Biomedical Engineering education in India is generally a part of an interdisciplinary field. Some courses have been adapted from Biosciences, Biotechnology, Electrical engineering, Computer Engineering, Mechanical Engineering etc. The programs run in different institutes have no standardized syllabus. At times, it does not meet the requirements for the jobs because of the lack of latest knowledge.

C. Suggestion and Improvements of BME in India

Presently, the BME in India needs a lot of improvement in order to compete globally.

Bioengineering education presents special interdisciplinary programmes. The most important is to educate students in basic knowledge and improve their skills needed. The context of Bioengineering in India is not meeting the demands of the companies and is still underdevelopment.

There is a need to increase the knowledge by improving the learning technologies.

This is a significant pedagogical challenge. Hence some suggestions are quoted in the text:

i) Using several internet tools

The use of web-based tools is of prime-importance. The web, information media or using CDROMs, DVDs, etc. Online free library access with Medical journal accessibilities in the university.

ii) Increase the number of Undergraduate programs and students

There is a need for introducing new technologies in the curriculum with increase in undergraduate programs. The curriculum must involve the theoretical and practical learning [5].

The need for biomedical engineering education should be emphasized at this level to increase the number of Biomedical Engineers.

iii) Specialized graduate programs should introduced

The students should be taught advanced courses. They can be several company scholarship programs for having several track program which may be more skill oriented. Graduate studies should be complimentary to undergraduate and must have in-depth knowledge.

iv) Continuing Education

This is most important to have a continuous study by updating the knowledge time to time. Especially the practicing engineers must be stay in touch with the latest developments.

v) Recruitment possibilities for Biomedical Engineers

Generally in India the job prospects of Biomedical Engineers are not up-to the mark. The students have several problems attaining the job. Most importantly for the Engineering institutes have very little collaboration with medical hospitals and health companies. Hence the university or the institutes must strengthen relationships with health care networks.

vi) Internship programs/ Joint Ph.D programs

There is a need for having several internship programs in order to have a better practical knowledge of the subject. The joint Ph.D programs can bring a difference in research and high-class Ph.D. Hence such internship programs and Joint Ph.D programs must be encouraged.

vii) Government funding opportunities

There is a need for increase in government funding opportunities in biomedical Education in India. The increase in funding in biomedical R&D field may help in better health care educations.

III. Conclusions and Future Perspective

The Biomedical engineers must recognize the place of work after their graduation. There is a possibility of working in a variety of settings, from hospitals, research institutes and facilities, educational institutes, and pharmaceutical companies to government establishments, and regulatory agencies. The Biomedical Engineers can also work as counselors in medical firms or consultants. The scope for further progress therefore seems infinite.

Abstract — **A body surface electrocardiograph employs 124 spot electrodes positioned wider area around human hart to detect heart potential generated by the hart beat in sync, collect and configure plural position potential signals to make up body surface electrocardiography showing human heart condition dynamically and graphically.**

This electrocardiography displays not only conventional one-dimensional time variation at a very limited position obtained with 12 leading electrodes electrocardiograph or Holter electrocardiograph showing, but also three dimensional and motion images of body surface electrocardiography by examining wider area at faster sampling rate with higher resolution.

We expect such electrocardiography could possibly show additional or new information which is not obtained by conventional one-dimension electrocardiograph.

We study a utility of the body surface electrocardiograph, i.e., what can be seen by the body surface electrocardiography, examining many body surface potential distribution of variety of examinees obtained by the electrocardiograph.

This paper reports significant difference between a regular person and person with higher cardiopulmonary, and aging variation.

Keywords — **Body surface electrocardiograph, ECG, body surface potential distribution, electrocardiogram.**

I. Introduction

A body surface electrocardiograph employs 124 spot electrodes positioned wider area around human hart to detect heart potential generated by the hart beat in sync, in particular, the 124 spot electrodes consist of 8 row x 8 column as chest electrodes, 6 x 2 as body side electrodes, and 8 x 6 as back electrodes. See Fig. 1. Each electrode detects heart potential individually, and the body surface electrocardiograph collects and configures these position potential signals to make up body surface electro-cardiography showing human heart condition dynamically and graphically. See Figs. 2 and 3.

This special electrocardiography displays not only conventional one-dimensional time variation at a very limited position obtained with conventional 12 leading electrodes electrocardiograph or Holter electrocardiograph showing, but also three dimensional and motion images of body surface electrocardiography by examining wider area at faster sampling rate with higher resolution.

We expect such electrocardiography could possibly show additional or new useful information which is not obtained or hard to obtain with a conventional one-dimension electrocardiograph.[1-8]

We have been continuing study a utility of the body surface electrocardiograph, i.e., what can be seen and detected by the surface potential distribution, examining many body surface potential distribution of variety of examinees obtained by the body surface electrocardiograph.

This paper reports significant difference between a regular person and person with higher cardiopulmonary, and aging variation.

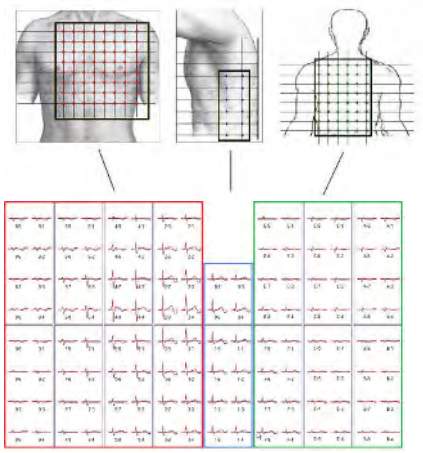

Fig. 1. A collection of individual electrocardiogram detected by each electrode positioned at chest, side and back of the body.

www.springerlink.com

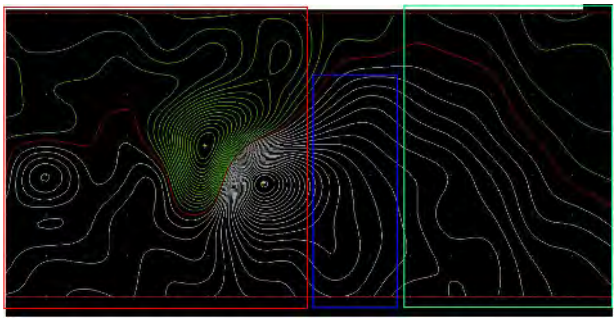

Fig. 2. A two-dimensional surface potential distribution configured and integrated by each electrocardiogram shown in Fig. 1.

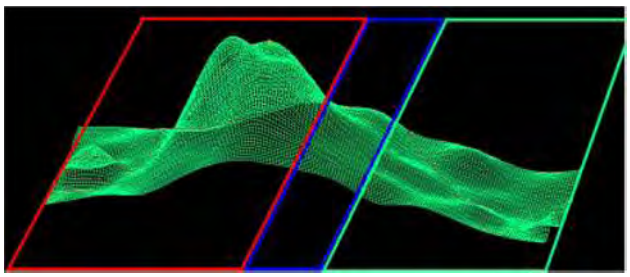

Fig. 3. A three-dimensional surface potential distribution of Fig. 2.

II. Materials and Methods

We developed a prototype of the body surface electrocardiograph measuring instrument as shown in Fig. 4. This measuring instrument has 124 electrodes, some of which are suspended by an arm from the examinee, some protrude from the side of the examinee, and the rest protrude from the backside of the examinee.

The detected signals are buffered, A/D converted, and input into a controller to draw a body surface electrocardiograph. We prepared PC installed with a special program to draw such body surface potential distribution, thus the body surface electro-cardiograph is monitored on the PC display.

Specifically, the measurement instrument we employed is that the number of channels was 124, the maximal input voltage ±5 mV/±10 mV, the resolution 10 bit, and the sampling interval 0.1 ms.

A spring was fixed to each electrode rod so that it was stroked when placed on the body surface, and each electrode was pressed at a constant level. The distances between the body surface or electrode and the metal box were decreased by stroking the electrode rod, thus increasing the shielding effect. Cardiac potentials induced on the body surface were transmitted to an amplifier via the electrode, electrode rod, and spring. The electrical potential determined by adding the values for the bilateral hands and the left foot were used as the standard (0 V), and the voltage for each electrode was detected. Cardiac potentials induced on the body surface were amplified 1,000- or 2,000-fold using a buffer, a preamplifier, and an amplifier, converted into digital signals using an A/D converter, and transmitted to a personal computer. Data input into the personal computer were expressed both two- and three- dimensionally.

We examined body surface electrocardiogram of various examinees, having different age, motility, heart disease, using the above measuring instrument. In particular, we compared the body surface potential distributions of a regular person and person with higher cardiopulmonary, i.e., an athlete. In addition, we studied the aging variation.

Fig. 4. An overview of the prototype of the body surface electrocardiograph measurement instrument.

III. Results and Discussion

Though there were variations among individuals and ages, we generally found that some transition pattern of normal healthy person, which shows firstly excitation of right ventricle, then excitation of left ventricle.

A. Cardiopulmonary

More specifically, the right ventricle excitation shows a peak of the positive potential at first, then the peak gradually decreases and finally reaches negative peak. By contrast, the left ventricle excitation generates potentials after the right ventricle excitation. Particularly, after the positive peak of the right ventricle excitation, the negative peak of the left ventricle excitation begins gradually at a bit late timing, and followed by the negative peak of the right ventricle excitation. See Fig. 6.

On the other hand, regarding the body surface potential distribution obtained from a person with higher cardiopul-

monary, it shows different tendency. Particularly, compared with the above normal person, the body surface potential distribution shows a timing of maximum positive peak of the left ventricle excitation, at the same time, maximum negative peak of the right ventricle excitation occurs. See Figs. 7. It shows symmetric wave pattern of positive and negative peak. Such same time excitation might help higher cardiopulmonary, leading stronger cardiodynamics.

Fig. 6. A three-dimensional body surface potential distribution of normal person.

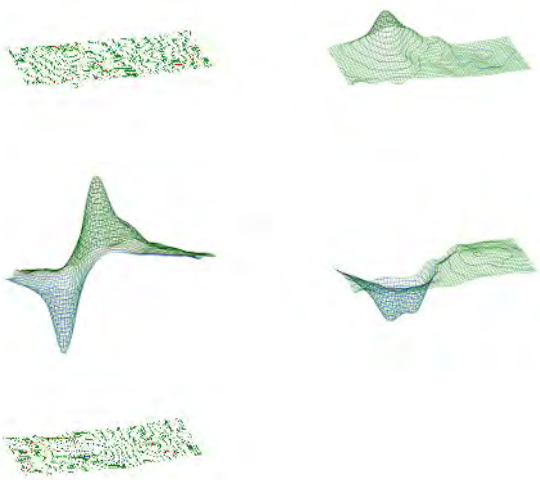

Fig. 7. A three-dimensional body surface potential distribution of person having higher cardiopulmonary.

B. Aging of wave pattern

Next, we have examined any change caused by aging. In this example, we compared wave pattern of three Japanese men who are 55, 60 and 65 years old, which are shown in Figs. 8-10.

In view of these Figs., comparing with the positive maximum peaks of the left ventricle excitation, and the negative maximum peak of the right ventricle excitation, respectively, we found that the maximum peaks decrease gradually with aging.

Also, shape of wave pattern deformed gradually from shaper peak pattern to get duller and broader with wider tail. This tendency presumes degeneration of positive electromotive force might occur with aging.

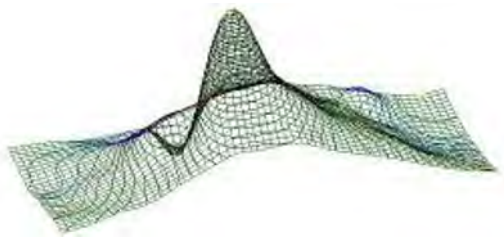

Fig. 8. A three-dimensional body surface potential distribution of 55 years old man.

Fig. 9. A three-dimensional body surface potential distribution of 60 years old man.

Fig. 10. A three-dimensional body surface potential distribution of 65 years old man.

IV. Conclusiotn

We have measured and examined many examinees' three-dimensional body surface potential distributions, and found some tendency of cardiopulmonary and dependency of age.

As for normal healthy person, transition pattern shows firstly excitation of right ventricle, then excitation of left ventricle.

In contrast, regarding a person with higher cardiopulmonary, it shows a timing of maximum positive peak of the left ventricle excitation and maximum negative peak of the right ventricle excitation occurs at the same time.

Also, aging would influence the peak intensity of wave pattern.

Although it has been more than dozens years past since the body surface electrocardiograph was reported for the first time, its measuring method and instrument are not yet commonly utilized or become widespread. One of the reasons of such unpopularity is that the utility is still unknown. We keep exploring the underlying utility of such, and hope it would be more common in future, helpful to early detection of cardiopathy, resulting in contribution to society.

Harnessing Web 2.0 for Collaborative Learning

Casey K. Chan[1,2], Yean C. Lee[3] and Victor Lin[4]

[1] Division of Bioengineering, National University of Singapore, Singapore
[2] Department of Orthopaedic Surgery, National University of Singapore, Singapore
[3] Department of Biological Sciences, National University of Singapore, Singapore
[4] WizPatent Pte Ltd, Singapore

Abstract — **The web has shifted from viewing pages of information to on-the-fly user-generated content. As promising as it might be in collaborative learning, Web 2.0 has yet to deliver expected results. This "read-write" capability of Web 2.0 should in theory enhances interactions between users on the web. This article attempts to decrypt the problem and propose that the limited usage of the web in collaborative learning is due to the lack of efficient information management in particular an easy-to-use sharing scheme.**

Keywords — **reference, management, sharing, collaboration, learning**

I. Introduction

Recent years marked a major shift in the way internet is utilized. The web had shifted from the page metaphor to user generated content, much of which is microcontent. The information flow on the web is no longer one way from authors to readers, it's now easier for user to respond

The shift began when personal homepages changed to personal blogs. Blogs not only enable ease-of-publishing; it also allows comments, thus facilitating interactions between users. The web changed from pages of information to user generated microcontent. Information is grabbed from one page to another, firstly via links, later using bookmarklets. Bookmarklets are javascript bookmarks which allow users to grab information from one website to a web service where users can share the grabbed information and links.

Presumably, this shift to Web 2.0 is deemed to change the way teaching and learning is conducted. Despite the promises of Web 2.0, results have not yet been delivered as expected. Full scale collaborative learning did not happen; the more prominent usage is still limited to information mining, distribution of lecture notes and discussion forums.

We content that the slow adoption of Web 2.0 in teaching and learning is due to inefficiency of the information sharing systems in web applications.

II. Operating system in the web

Operating system is the software component of a computer system which acts as a host for applications to run on the system. Because operating systems control distribution of hardware resources between applications, they arbitrate how applications will run in a computer.

A similar parallel can be seen in web browsers. Traditionally, web browsers are used only to view web pages. As web content becomes richer and more interactive, the functionalities built into web browsers increased. Web browsers have developed to a stage where no Netscape developer in 1994 could anticipate: they now possess huge computing capability, enabling many processes to run in the browsers on the client machine without burdening the servers. Web browsers have evolved to be platforms for applications to run in.

Postback refers the event when a web page is sent to server and after some processing, the server sends the web page back to the client. Asynchronous Javascript and XML (AJAX) is a collection of web application techniques that allows retrieval of information from server in the background without affecting the whole interface of web applications; information retrieval and web page refresh happen separately and thus asynchronous. By using AJAX and minimizing postback, the responsiveness of web applications can be increased significantly.

III. Teaching and learning in the web

Teaching and learning are all about exchanging of information. When there's an outflow of information from one person to another, the person is teaching and the opposite is true for learning. Traditionally in lower education level, information flows unidirectional from teachers to students. As they progress to higher levels, students are expected to contribute to their juniors at lower educational level. However, in the current world where information is readily available on the web, this practice becomes increasingly obsolete.

A majority of studies indicate that collaborative learning is more effective than unidirectional learning [2]. As students take their own initiative to gain information from peer discussions, they would need tools to share information. For example, references, links, journal articles and other learning materials would need to be shared with other users.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2171–2172, 2009
www.springerlink.com

Without the web, sharing of information and files is a difficult process. Even now with the widespread internet adoption, sharing of information and files between users is still cumbersome requiring multiple clicks and advanced settings.

Many of the information sharing web applications like Refworks, Digg, and Delicious stick to old technologies where high degree of postback is needed to refresh information. Responsiveness of learning applications is important as numerous researches have shown that the train of thought would be broken as interruption time increases [3]. It is especially important in blackboard applications where classroom environment is replicated on the web.

Furthermore, many of these web applications allow users to share links and references but not files. Admittedly, links and references sharing are important for web based learning as they point students to sources of information. However, without file sharing features, management of files becomes inefficient. As shown by Howison and Goodrum, managing bibliographic data separately from PDF is not as productive as managing them together like in mp3 files [4]. A successful implementation of a collaborative learning environment will hence require highly responsive web applications which allow easy management as well as sharing of both links and files.

An example of optimal implementation of learning application is WizFolio [5]. WizFolio allows users to grab information and references from any webpages and store the information on the web. More importantly, files can be attached to these indexes and users can share the information they have collected with other users.

IV. Conclusions

Web 2.0 undoubtedly has increased interactions between web users. The shift from static pages to user-generated content indicates that a shift of learning strategies is required. Collaborative learning, the learning process resulted from self-initiated information gathering and peer discussion, requires efficient information management web applications. These web applications have to be highly responsive and provide solutions to efficient sharing of files as well as references and links.

Electrochemical In-Situ Micropatterning of Cells and Polymers

M. Nishizawa, H. Kaji, S. Sekine

Tohoku University/Department of Bioengineering and Robotics, Sendai, Japan

Abstract — **We report two novel techniques "Electrochemical Bio-Lithography" that enables in-situ cellular micropatterning, and "Ultra Anisotropic Electrodeposition" for making micropatterns of conducting polymers. The former technique for cellular micropatterning was combined with dielectrophoresis (DEP) and AFM, and we have realized the in-situ spatiotemporal cellular micropatterning in various environments. On the other hand, we have found the micropatterned hydrophobic area around electrode serves as a template for in-situ circuit formation with conducting polymers. Importantly, since the electropolymerization can be conducted without significant damage to the existing cell cultures, these two techniques can be combined to form hybrid micropatterns of cells and conducting polymers.**

Keywords — **Cell Culture, Conducting Polymer, Bioassay**

I. Introduction

Recent technical progress in cell culturing has made bioassays possible using cellular networks combined with electrode arrays, in which smart bio-interfacing between microelectrodes and biological cells is of central importance.

The principle of our original "Electrochemical Bio-Lithography" technique is based on our finding that a heparin-coated surface, initially anti-biofouling, rapidly becomes cell-adhesive upon exposure to dilute hypobromous acid that can be locally generated by electrochemical means. Since this lithography can be conducted even during cultivation, we have succeeded to spatiotemporally induce the cell adhesion, growth and migration, and realized the in-situ cellular micropatterning [1-4].

Conducting polymers such as polypyrrole (PPy) and poly(3,4-ethylenedioxythiophene) (PEDOT) are excellent candidates for bioelectrode materials owing to their inherent electrical conductivity, controllability of surface biochemical properties, and biocompatibility. In particular, the large surface area due to a fibrous structure increases the interfacial electrical capacity, ensuring noninvasive electrical stimulation of biological cells. And "Ultra Anisotropic Electrodeposition" technique is based on our finding that that electrodeposited film of conducting polymer grows along a self-assembled monolayer (SAM) of alkylsilane or heparin coated substrate at more than 10 times faster rate [5-6].

The present works are the combination and integration of these techniques with dielectrophoresis (DEP) [7-8], silicone elastic tubing [9], or atomic force microscopy (AFM) [10] for high throughput bioassay chip, blood vessel disease model, in-situ analysis of single cell migration, and fully organic cell stimulation system.

II. Micropatterning of Cells

A. Combination with dielectrophoresis in microchannel

Fig. 1a shows the basic strategy for patterning cells within a microchannel. We prepared a microfluidic device with a Pt microelectrode array, which are 20 μm in width and are separated by 50 μm, at the upper wall of the channel. After a 0.1 M phosphate buffer saline (PBS) containing 25 mM KBr (pH 7.4) was introduced into the heparin-coated channel, a potential pulse of 1.7 V vs. Ag/AgCl was applied to one of the electrodes for 0.5 sec to generate hypobromous acid (HBrO) that quickly removes the antibiofouling heparin, exposing protein-adhesive surface. Subsequently, a solution of 30 μg mL^{-1} fibronectin, cell-adhesive protein, was introduced into the channel and incubated for 20 min, followed by a wash with PBS. After the channel was filled with a medium (13 mS cm^{-1}) containing HeLa cells (4 x 10^6

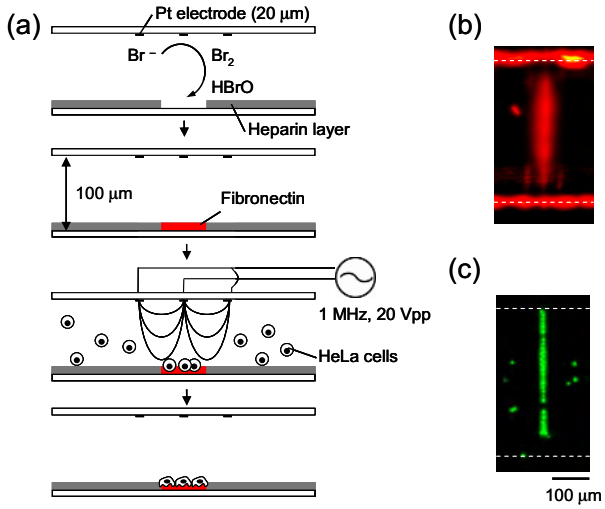

Fig. 1 (a) Schematic representation of the cellular patterning within the microchannel (side view). (b, c) A fluorescent micrographs (top views) of (b) Cy3-labeled fibronectin and (c) HeLa cells (stained with CellTracker Green) concentrated by negative DEP.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2173–2176, 2009
www.springerlink.com

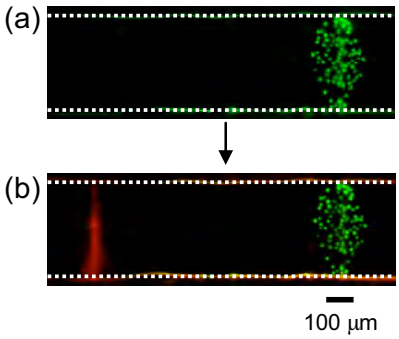

Fig. 2 Patterning of two types of HeLa cells within a single microchannel. After the first cell type (stained with Cell-Tracker Green) was immobilized (a), another cell-adhesive region was created and the second cell type (stained with CellTracker Orange) was captured by applying the DEP force at a flow rate of 0.1 μL min^{-1} (b). The dotted lines in the images denote the position of the side wall of the channel.

cells mL^{-1}), negative DEP (1 MHz, 20 Vpp) was used to concentrate cells on the pre-patterned cell adhesive region. Fig. 1b shows a fluorescence micrograph of Cy3-labeled fibronectin that was locally immobilized on the bottom wall of the channel, corresponding to the position of the electrode. After the channel was filled with a suspension of HeLa cells and negative DEP was carried out, HeLa cells quickly moved in the direction of weak electric fields to form a line pattern on the bottom wall within 15 sec, as shown in Fig. 1c. Even after DEP operation for another 15 min, no damage was observed for the adhered cells, as judged by a live/dead staining test.

Fig. 2 shows an array of two types of HeLa cells patterned in the microchannel by repeating a set of the electrochemical lithographic treatment and the cell manipulation by the negative DEP. After the first cell type (stained with CellTracker Green) was immobilized at the right side of the channel (Fig. 2a), the second cell type (stained with CellTracker Orange) was trapped in the fibronectin-immobilized region (left side of the channel) at a fluid flow rate of 0.1 μL min^{-1} by using another set of the microelectrodes array. Since most of the cells flowing from the upstream (left side of the channel) can be captured on the fibronectin region and, even if some cells happen to flow to the downstream, the cells hardly attach on the prepatterned region of the first cell type in the presence of the fluid flow, the two types of cells could be localized in the single channel without cross contamination of these cell types (Fig. 2b).

B. Patterned co-cultures in elastic tubing

A Pt needle microelectrode is used to locally generate the oxidant and form a cell-adhesive region on the inner surface of tubing precoated with heparin (Fig. 3a). Since the needle electrode can be inserted into the tubing through its wall, it is unnecessary to install the electrode within the tubing beforehand. After the first cell type is attached on the electrochemically treated region (Fig. 3b), the remaining heparin-coated region is complexed with poly-L-lysine (PLL) [11] to switch the heparin surface from cell-repellent to cell-adhesive thereby facilitating adhesion of a second cell type (Fig. 3c).

An example of the patterned co-cultures that can be achieved within the tubing structure using a combination of the microelectrode technique and electrostatic deposition is shown in Fig. 4. The heparin-coated silicone tubing was processed to make the first cellular pattern on the inner wall using a needle electrode in the same manner as described in Fig. 3. A fluorescence micrograph of NIH-3T3 fibroblasts (stained with CellTracker Green) with adhesion around the electrode insertion site is shown in Fig. 4a. At this stage of the process, the inner surface of the tubing outwith the cell adhesion region is covered with heparin. To alter the anti-biofouling property of the heparin surface to allow adhesion of the second cell type, PLL and fibronectin were in turn added to the tubing. To avoid any cytotoxic effect of PLL on the pre-patterned cells, the PLL treatment was carried out at a low concentration (40 μg mL^{-1}) and for a short exposure time (20 min). Subsequently, a suspension of HepG2 hepatocyte cells was incubated for 30 min in the tubing, followed by a wash with fresh medium to remove non-adherent cells. To visualize the co-cultures, HepG2 cells were fluorescently labeled with CellTracker Orange before

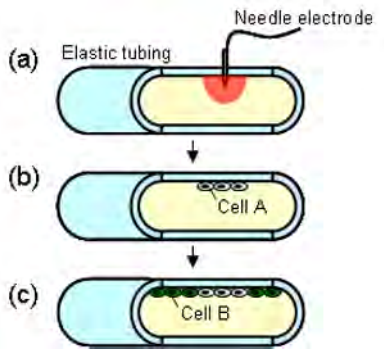

Fig. 3 Strategy for patterning cells inside elastic tubing structure. (a) A needle electrode is inserted through the tubing wall. The electrode electrochemically generates an oxidizing agent that locally detaches the anti-biofouling heparin layer on the inner wall. The removal of the heparin permits localized cell attachment. (b) The first cell type is then seeded and allowed to adhere to the treated region. (c) Poly-L-lysine is electrostatically deposited onto the region retaining heparin in order to switch the surface property to allow cell adhesion. A second cell type can then be seeded, resulting in the formation of patterned co-cultures within the tubing.

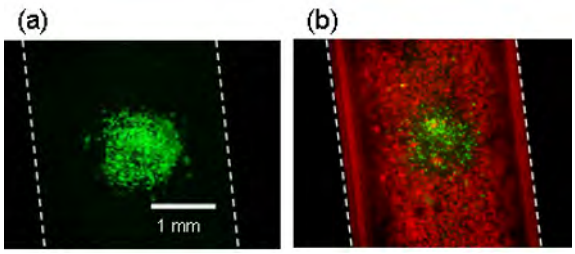

Fig. 4 Patterned co-cultures of NIH-3T3 fibroblasts (green) and HepG2 hepatocytes (red) inside the tubing structure. (a) NIH-3T3 cells were initially seeded on the cell adhesion region generated by the needle electrode. (b) After the surrounding region was switched from cell-repellent to cell-adhesive by PLL and fibronectin deposition, HepG2 cells were seeded.

seeding. Fluorescence micrograph of the stained co-cultures validates the formation of patterns inside the tubing (Fig. 4b). The post-seeded HepG2 cells (Fig. 4b, red cells) attached to the region surrounding the pre-patterned NIH-3T3 cells (Fig. 4b, green cells). Although some HepG2 cells attached within the location of the NIH-3T3 cells, this could be effectively eliminated by allowing the first cell type a longer initial culture period to enable its population to increase in density and spread. It should be noted that the perfusion system for long-term cell culture was not used here because the focus of the study was on the surface treatment of the tubing.

C. Miniaturization of patterns using AFM

An oxygen plasma treated quartz glass substrate was immersed in polyethyleneimine (PEI) and heparin (hep) solution in turn in order to assemble an electrostatic bilayer of PEI/hep. The electrochemical AFM probe having an electrode (ca. 500 nm in diameter) at the tip was positioned close to a PEI/hep-coated antibiofouling substrate and used to locally generate hypobromous acid from a dilute Br^- solution to render the substrate surface protein-adhesive (Fig. 5). The treated substrate was immersed in fibronectin solution, followed by seeding HeLa cells on the substrate.

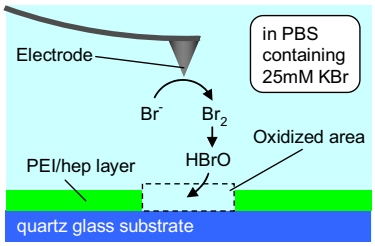

Fig. 5 Schematic illustration of the AFM configuration integrated with the electrochemical bio-lithography technique. The electrode at the apex of the AFM probe is positioned above the PEI/hep-coated substrate surface. To pattern the substrate surface, a reactive oxidant, HBrO, is electrochemically generated at the probe tip electrode by applying a voltage pulse of 1.5 V (supplied by an AA-size battery) between the probe electrode and the counter electrode.

The reaction in which the electrogenerated oxidant changed the substrate surface properties was sufficiently rapid to be diffusion controlled. The size of FN pattern could be controlled 2-15 μm in diameter by the electrolysis period. Also the scanning probe enabled us to make arbitrarily shaped patterns. These subcellular scale adhesive patterns (Fig. 6a) allowed the adhesion of single cells (Fig. 6b). Each cell on the small circular patterns was not able to spread. On the other hand, the cell on the 20 μm square frame pattern spread and became square-like.

Fig. 7 shows an array of two types of proteins prepared by stepwise patterning. After the first protein (FN-Cy2, green) was patterned, the electrochemical treatment was conducted, followed by the immobilization of the second protein (FN-Cy3, red).

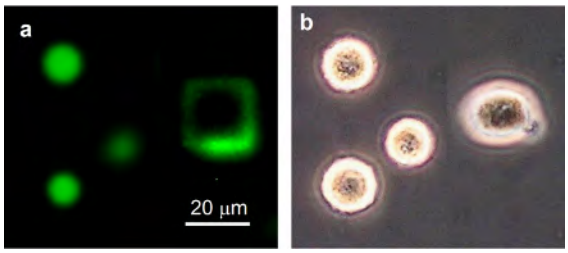

Fig. 6 (a) Fluorescent micrograph of Cy2-labeled FN and (b) phase-contrast micrograph of HeLa cells.

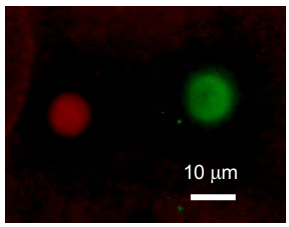

Fig. 7 Patterning of multiple types of proteins using stepwise electrochemical treatment. After the first protein FN-Cy2 (green) was patterned, the electrochemical treatment was conducted, followed by the immobilization of the second protein FN-Cy3 (red).

III. Micropatterning of Conducting Polymers

A. In situ micropatterning of conducting polymer

The micropatterns with SAM of alkylsilane or heparin lead to a micropatterns of PPy upon the polymerization (Fig. 8). Importantly, the electropolymerization of PPy can be conducted even during cell cultivation without significant damage to the existing cells.

Fig. 9 demonstrates the in-situ electrical wiring to cultured cells. A hydrophobic pattern was previously formed around electrode, HeLa cell was put on the pattern, and then polypyrrole was synthesized. We preliminarily studied the toxicity of the pyrrole monomer by culturing HeLa cells in a culture media containing 0.1 M pyrrole. Even after 1 day of cultivation, more than 80 % of HeLa cells were alive and still proliferated, suggesting a comparatively brief exposure to pyrrole solution during polymerization (typically for a few min) would not significantly affect the cellular viability.

Fig. 8 Photographs of the PPy micropattern growing from a twin microband (20μm width) electrodes. The pretreatment with SAM of Octadecylsilane was conducted as to give a checked pattern.

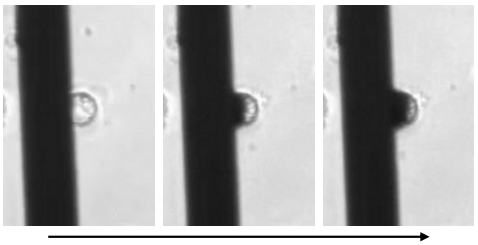

Fig. 9 Photographs of the PPy micropattern which is growing with wrapping a HeLa cell

B. Electrochemical biolithography

The surface modification with heparin can be easily detached by a non-invasive electrochemical biolithography [1], and thus we can draw micropatterns of PPy by using a needle-type microelectrode as a "pen" (Fig. 10). Since this lithography can be applied even during cell cultivation, we can expect the formation of hybrid micropatterns of conducting polymer and living cells.

IV. Conclusions

We have described methods for electrochemical in-situ micropatterning of proteins, cells and conducting polymers. Since the present electrochemical technique can be conducted under typical physiological conditions, we could make patterns sequentially such as co-cultures. And these smart bio-interfacing with micropatterned conducting polymers will contribute to the realization of these next-generation bioassay chips.

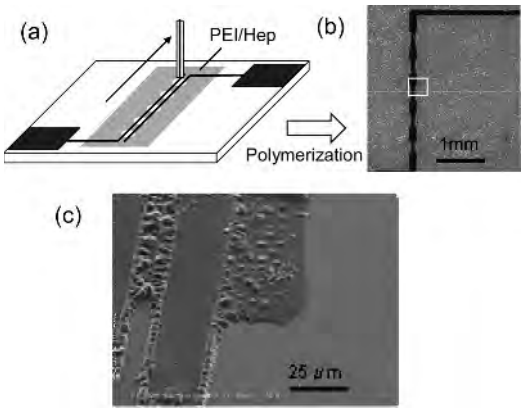

Fig. 10 (a) Schematic drawing of the micropatterning of PEI/Hep by electrochemical biolithography. A Pt microelectrode was approached to ca. 50 μm above the substrate surface, and scanned with 0.5 mm steps along the twin-microband electrode, waiting for 10 sec at each step with application of 1.7 V vs. Ag/AgCl in 25 mM KBr buffered solution. Abstract — **In many countries, cardiovascular diseases are the main cause of death. Since the whole blood circulation depends on the heart, it cannot rest in order to recover as most of other muscles can. In some patients with not so severe damages in the myocardium, a rotary blood pump (RBP) may temporarily unload the native heart and can permit the recovery of the cardiac function. Since both implantation and withdrawal of the RBP are invasive procedures, the recovery should be detected with accuracy before weaning of the RBP. Therefore, the objective of this study is to estimate the cardiac function of assisted hearts using the maximum ventricular elastance E_{max} which is a cardiac function index representing the left ventricle contractility. Conventionally, the index E_{max} has been estimated using left ventricle pressure (*LVP*) and volume (*LVV*) during multiple cardiac cycles and under different loads. The two main problems of this method are that a precise measurement of *LVV* is invasive, and that induced changes in load should be avoided in cardiac patients. The single beat methods have the advantage that can be used with no changes on left ventricle load. In particular, the parameter optimization method (POM) permits E_{max} also to be calculated also using flow instead of volume in the case of non-assisted hearts. The conventional estimation of E_{max} and also the estimation using the POM with *LVP* and *LVV* had already been validated under the assistance of the RBP. This study shows that, in particular in cases with non-opening of the aortic valve, E_{max} can also be estimated by the POM using pump flow instead of *LVV*.**

Keywords — **Ventricular Assist Device, Ventricular Elastance, Cardiac Function, Bridge-to-Recovery.**

I. Introduction

Although heart transplantation is the best treatment for serious cardiac diseases and one of the most common organ transplantations performed worldwide, the shortage in donors limits the treatment's applicability. In order to diminish the donor shortage problem, rotary blood pumps (RBPs) have been used as an alternative treatment either as bridge to transplant, destination therapy or, more recently, as bridge to recovery. The so-called bridge to recovery refers to a treatment that combines the RBP, which unloads the ventricles, with pharmacological treatments or even with regeneration therapy permitting the myocardial recovery.

In such treatment, after the recovery of the cardiac function is detected, the RBP can be weaned and the patient can have a regular life again. Due to the invasiveness and the risk of the pump removal and in particular of its reimplantation, the recovery must be precisely detected before the pump weaning. The conventional methods for assessment of the cardiac function are based on the behavior of unassisted hearts; therefore it is important to re-evaluate those methods considering the hemodynamic changes that the assistance of the RBP brings to the circulatory system.

Thus, in this paper we present an evaluation of the parameter optimization method (POM) for the estimation of the maximum elastance (E_{max}) comparing the estimation using the left ventricular volume (*LVV*) to the estimation using the pump flow (*LPF*). The E_{max} has already been validated as a cardiac function index during assistance of RBPs [1]. However, clinical limitations of the conventional estimation method motivated the choice of the POM that is a single beat estimation method that permits the estimation of the E_{max} using the flow instead of the left ventricular volume (*LVV*), therefore, being less invasive than the multiple beats method.

II. Materials and Methods

A. Parameters Optimization Method

The left ventricular elastance ($E(t)$) is defined as the ratio between the left ventricular pressure (*LVP*) and (*LVV*) corrected by a dead volume (V_0), as shown in the equation below.

$$E(t) = \frac{LVP(t)}{LVV(t) - V_0} \tag{1}$$

The elastance reaches its maximum at a point near the end of the systolic period, being this value of maximum elastance independent of the ventricular load and sensible to changes in the ventricular contractility.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2177–2180, 2009
www.springerlink.com

The POM is a single-beat estimation method, *i.e.* a method for estimating E_{max} using the *LVV* and *LVP* of a single cardiac cycle, that is based on two important assumptions about the cardiac cycle: (*i*) V_0 should be constant and (*ii*) the elastance is approximately linear during the ejection period.

From (1) V_0 can be calculated as

$$V_0 = LVV(t) - \frac{LVP(t)}{E(t)} \tag{2}$$

The equation error (3) is defined considering that V_0 should be constant and that the $E(t)$ can be approximated to a linear function. Using (3), the POM consists on finding the linear approximation for the elastance that leads to the smaller fluctuation on V_0 calculated at two instants t_0 and t_k during the ejection period by minimizing the root mean square of the error ε_k.

$$\varepsilon_k = LVV(t_k) - \frac{LVP(t_k)}{at_k + b} - LVV(t_0) + \frac{LVP(t_0)}{at_0 + b} \tag{3}$$

Once the linear approximation of the $E(t)$ is found, it is possible to calculate V_0 as in (4).

$$V_0 = \frac{1}{n-i+1}\sum_{k=i}^{n} LVV(t_k) - \frac{LVP(t_k)}{E(t_k)} \tag{4}$$

Finally, the instantaneous elastance $E(t)$ is obtained from (1) substituting the calculated V_0, and then from the maximum of $E(t)$, E_{max} is also attained.

The POM permits, alternatively, the E_{max} to be estimated by substituting the *LVV* by the integration of the total flow, which is a less invasive measurement, as in (5).

$$LVV(t_k) = LVV_{ED} - \int_{t=t_{ED}}^{t_k} TF(t)dt \tag{5}$$

where LVV_{ED} is the *LVV* at the instant t_{ED} corresponding to the end of the diastolic period.

Since LVV_{ED} is the same reference for all points in the cardiac cycle, (3) can be rewritten as: [2]

$$\varepsilon_k = \int_{t=t_{ED}}^{t_k} TF(t)dt - \frac{LVP(t_k)}{at_k + b} - \int_{t=t_{ED}}^{t_0} TF(t)dt + \frac{LVP(t_0)}{at_0 + b} \tag{6}$$

In the case of the assisted heart the total flow (*TF*) pumped from the heart during the systole is composed by the sum of the aortic flow (*AoF*) and the pump flow (*LPF*).

Moreover, in the particular case of the full bypass, there is no flow through the aortic valve and the *TF* is composed only by *LPF* which can be easily measured at the pump cannula or even estimated from the pump operation state, using the rotational speed and the motor electric current, for example.

B. Experiment Protocol

For the comparison of the chosen methods were used animal experiment data measured in three adult goats (female, 52-58kg) with the left ventricle assisted by the centrifugal pump NEDO PI-710 gyro pump (Baylor College of Medicine, Houston, US) in experiments #1 and #2, and by the centrifugal pump EvaHeart LVAS (Sun Medical Tec.Res.Co., Japan) in experiment #3. The RBP had the outflow cannula connected to the descending aorta and the inflow cannula inserted into the left ventricular apex, as represented in Fig.1.

All measurements were recorded under open-chest condition. Data were recorded during 60s with a constant mean rotational speed, for each data set, the mean rotational speed (N_L) was changed in order to evaluate the sensitivity of the estimation to changes in the assistance level. *LVP* and *LVV* were measured by a conductance catheter (Leycom, Netherlands) inserted inside the left ventricle through the ascending aorta. After the experiment, *LVP* was pre-processed with a zero-phase low pass filter (cutoff frequency f_0=10Hz), and *LVV* with a de-noising symlet wavelet (sym8).

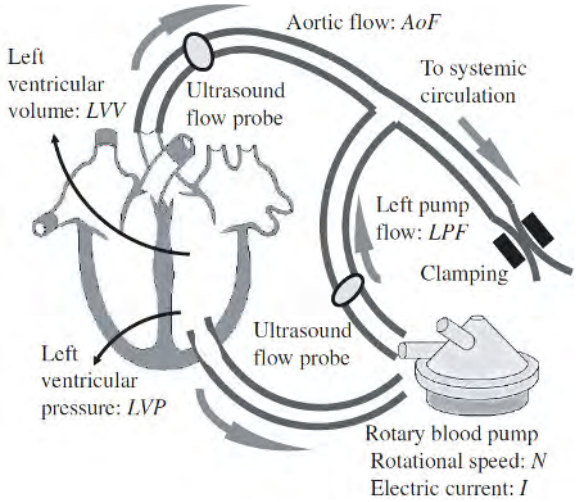

Fig. 1 Animal Experiment Setting

Additionally, *LPF* and *AoF* were measured with ultrasound flow probes (Transonic Inc., US) as reference for the pump control.

The measurements were performed after the Propranolol administration in order to induce the full bypass. In experiment #3, in particular, one measurement was performed before the Propranolol injection with the full bypass induced by the increase of the pump rotational speed in order to evaluate the sensibility of the estimation to changes in the ventricular contractility.

III. Results

Figs. 2-4 show the estimated values of E_{max}, represented by their mean and their standard deviation, comparing the estimated values using *LVV* against the estimated values using *LPF* for different assistant levels. In the experiment #3, one of the measurements was performed before the Propranolol injection (control data).

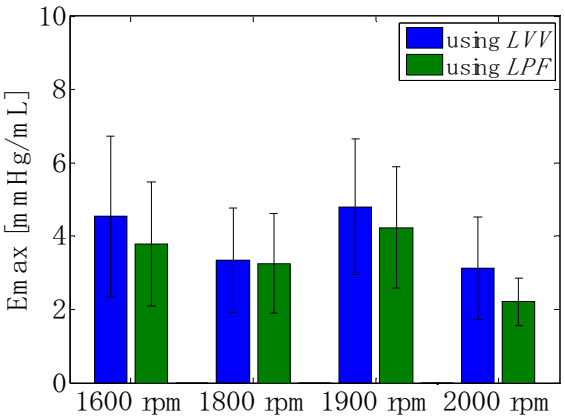

Fig. 2 Values of E_{max} (mean and standard deviation) estimated using the POM – Experiment #1

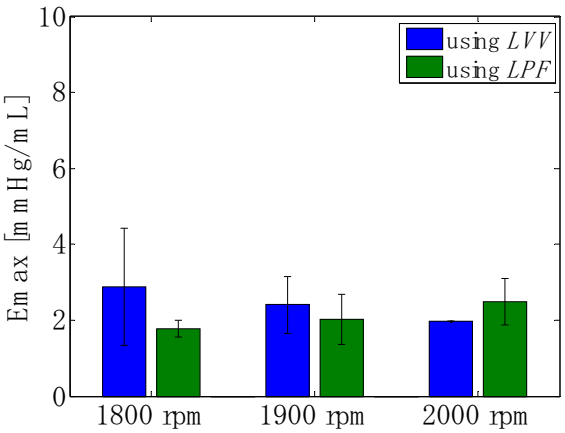

Fig. 3 Values of E_{max} (mean and standard deviation) estimated using the POM - Experiment #2

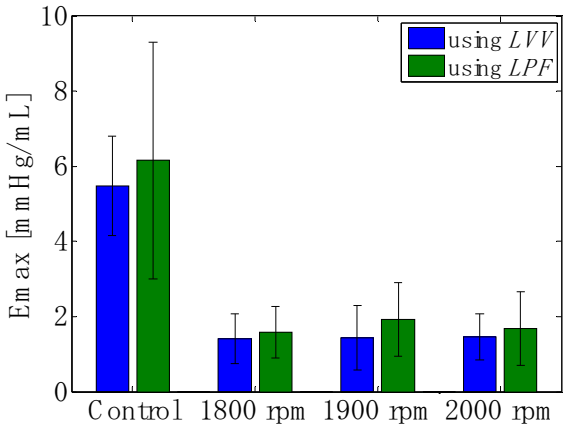

Fig. 4 Values of E_{max} (mean and standard deviation) estimated using the POM - Experiment #3

IV. Discussion

Due to the hemodynamic changes that the assistance with RBPs brings to the circulatory system, it is important to revalidate the cardiac function indices before using them to detect the recovery of the assisted heart.

The E_{max} was chosen in this study because it had already been validated during assistance; however, a less invasive estimation method was still necessary. The POM is a single beat estimation method that permits the estimation of the E_{max} using flow instead of the *LVV*, which is desirable for a clinical application due to the considerably less invasiveness. Moreover, in the particular case of full bypass, the only invasive measurement is the *LVP*, which could be eventually substituted by the pressure in the pump inlet.

The results show that there was no significant difference between the E_{max} estimated using *LVV* and using *LPF*. Besides, the estimated values were independent of the pump rotational speed, which is fundamental for the application of a cardiac function index during assistance with RBPs.

Finally, in the experiment #3, it was possible to compare data corresponding to different cardiac functions: before and after the Propranolol injection. The results show that the estimation of E_{max} using the POM could detect changes in the contractility.

The high standard deviation in some cases was also observed in the estimation of E_{max} when there was partial bypass and is believed to be due to the generality of the hypothesis of the method. Other single-beat methods with more specific hypothesis showed better accuracy however

were valid for a more limit range of conditions, besides not permitting the substitution of the *LVV* by *LPF.* [3]

Before achieving any definitive conclusions about the detection of the cardiac function during assistance with RBP using the POM, it is important to evaluate this method in a wider data set considering also a richer variety of cardiac functions in order to evaluate the sensitivity to changes in the contractility.

The main limitation that was found in this study was that the full bypass condition might be risky when the cardiac function is not impaired. In this study, in experiment #3 it was obtained by increasing the rotational speed however this might be a risky procedure depending on the patient's condition. It is necessary to study a better approach to induce the full bypass.

Moreover, small differences were expected in the estimation using *LPF* caused by noise in the flow which would be amplified by its integration during the ejection period. Errors could also be caused by difference in the calibration of the *LVV* and the *LPF.* In order to minimize such errors, the *LPF* was employed in the calibration of the *LVV* after the experiment.

V. Conclusion

Although the assistance with RBPs changes considerably the hemodynamics of the left ventricle, the E_{max} estimated with POM reflected the changes in the cardiac function in the data set evaluated independently of the level of pump assistance.

The results indicate that it is possible to assess the cardiac function without the invasive measurement of the *LVV*, and also indicate that if the full bypass can be performed by the RBP even during short periods, then only the *LVP* and the *LPF* are required for the estimation of E_{max}.

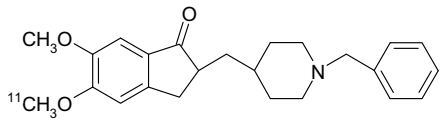
Molecular PET Imaging of Acetylcholine Esterase, Histamine H1 Receptor and Amyloid Deposits in Alzheimer Disease

N. Okamura, K. Yanai

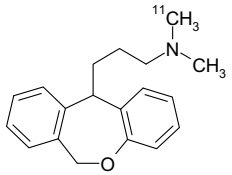
Department of Pharmacology, Tohoku University School of Medicine, Sendai, Japan

Abstract — **Depositions of amyloid plaques, neurofibrillary tangles and subsequent neurotransmitter deficits are neuropathological characteristics of Alzheimer's disease. Non-invasive monitoring of these changes in the brain is potentially useful for early diagnosis of Alzheimer's disease. Here we introduce the method for measuring the density of amyloid plaques and neurotransmitters using ^{11}C-labeled donepezil, doxepin and BF-227. Positron emission tomography (PET) imaging by [^{11}C]donepezil visualized the distribution of acetylcholine esterase in the brain. PET study using [^{11}C]doxepin also demonstrated the distribution of histamine H1 receptor in the brain. Density of acetylcholine esterase and H1 receptor was prominently reduced in the patients with Alzheimer's disease. [^{11}C]BF-227 PET successfully visualized neocortical depositions of amyloid plaques in the brain and clearly differentiated the patients with Alzheimer's disease from healthy individuals. These tracers would be useful for early and accurate diagnosis of dementia and monitoring anti-dementia therapy.**



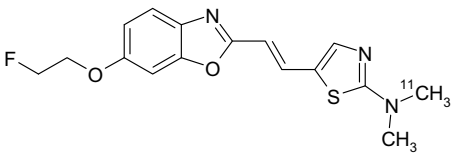
Keywords — **Alzheimer's disease, positron emission tomography (PET), acetylcholine, histamine, amyloid**

I. Introduction



Alzheimer's disease (AD) is a common neurodegenerative disorder in the elderly. Substantial neuropathological evidences suggest that progressive deposition of amyloid deposits, such as amyloid plaques and neurofibrillary tangles, is the characteristic neuropathological change in AD. Amyloid plaques are composed of amyloid β protein (Aβ), which is generated by proteolytic reaction of β and γ-secletase from amyloid precursor protein. Excessive Aβ generation causes the Aβ aggregation and the formation of amyloid plaques, followed by the formation of neurofibrillary tangles, neuron death and neurotransmitter deficit.

Noninvasive detection of amyloid plaques in the brain is a useful strategy for early diagnosis of AD. Measuring neurotransmitter function is also helpful for determination of treatment protocol of dementia. Molecular imaging techniques using positron emission tomography (PET) and single photon emission computed tomography (SPECT) have been developing for noninvasive detection of these intracranial changes. PET is more practical than SPECT because of the advantages in sensitivity, quantitativity and spatial resolution.



We have successfully visualized acetylcholinesterase (AChE) density using [^{11}C]donepezil and histamine H1 receptor (H1R) density using [^{11}C]doxepin (Fig. 1) [1-3]. We have developed original imaging agent BF-145, BF-168 and BF-227 (Fig. 1) for in vivo detection of amyloid plaques in AD [4-6]. Here we demonstrate clinical PET study using these tracers in AD patients.

[^{11}C]donepezil

[^{11}C]doxepin

[^{11}C]BF-227

Fig. 1 Chemical structures of [^{11}C]donepezil, [^{11}C]doxepin and [^{11}C]BF-227

II. Functional Neuroimaging in Alzheimer's Disease

A. Imaging acetylcholinesterase using [^{11}C]donepezil

Donepezil hydrochloride is most widely used drug for the treatment of cognitive dysfunction in AD patients. It selectively binds to and inhibits AChE. Radiolabeled donepezil can thus be used as a tracer to measure the density of AChE. To visualize AChE in the brain, [^{11}C]Donepezil was used as

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2181–2183, 2009
www.springerlink.com

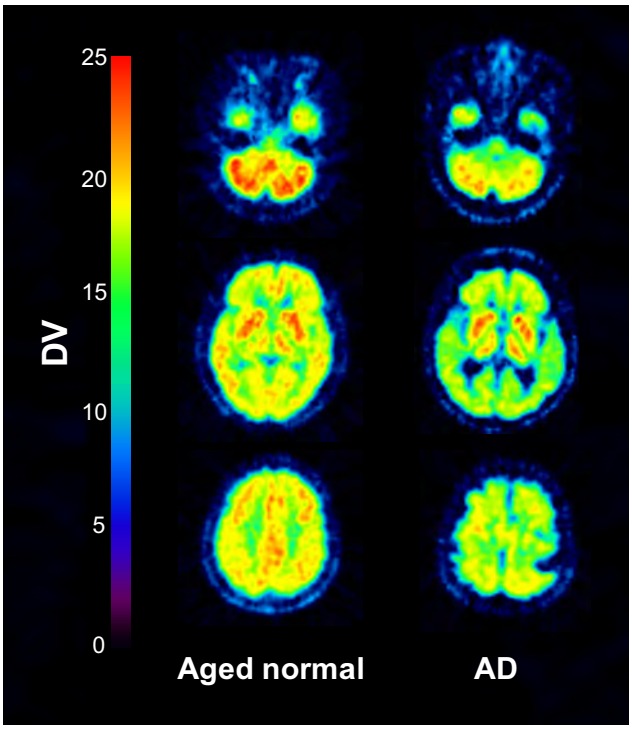


Fig. 2 Distribution volume (DV) images of [^{11}C]donepezil in the brain of aged normal (left) and AD patient (right)

a tracer for PET imaging. Tissue time activity curves of [^{11}C]donepezil indicated initial rapid brain uptake followed by gradual clearance from the brain. High concentrations of radioactivity of [^{11}C]donepezil were observed in AChE-rich brain regions such as the striatum, thalamus, and cerebellum, whereas radioactivity uptake in the neocortex including frontal, temporal, and parietal cortices was moderate. Distribution volume (DV) images of [^{11}C]donepezil clearly revealed higher concentrations of tracer distribution in the striatum and cerebellum than in neocortex (Fig. 2). Patients with AD exhibited reduction of DV in the hippocampus and neocortex, compared with aged normal subjects. Orally administered donepezil induced substantial reduction of DV in all regions of brain examined. The amount of binding of orally administered donepezil to AChE is considered a key factor determining therapeutic response of this drug. In vivo evaluation of AChE occupancy using [^{11}C]donepezil PET could thus be a powerful strategy for determining the optimal dose of donepezil in AD therapy [1].

B. Imaging histamine H1 receptor using [^{11}C]doxepin

We previously established the method for measuring histamine H1 receptor density in the brain using [^{11}C]doxepin. To confirm whether central histaminergic neuron is injured in AD brain or not, we applied this tracer to the patients with AD. The parametric images of binding potential were generated by Logan graphical analysis as described previously. The binding potential of H1 receptors showed a significant decrease particularly in the frontal and temporal areas of AD brain compared to aged normal subjects (Fig. 3). In addition, the receptor binding correlated closely to the severity of AD. The difference in the binding potential between AD patients and aged normal subjects was greater than that in the cerebral blood flow, and the rate of decrease in the binding potential with the progression of AD was greater than the rate of decrease in the cerebral blood flow. These results indicate the prominent disruption of the histaminergic neuron in the neurodegenerative processes of AD [7].

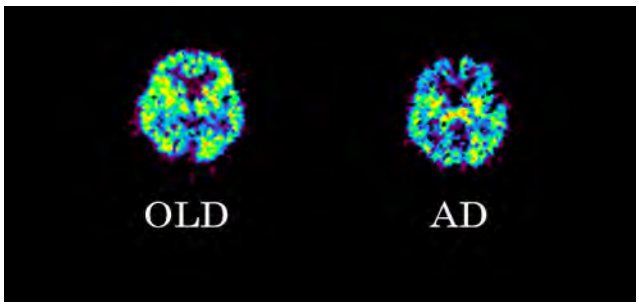

Fig. 3 Binding potential images of [^{11}C]doxepin in the brain of aged normal subject (OLD) and AD patient

C. Imaging amyloid deposits using [^{11}C]BF-227

Non-invasive detection of amyloid plaques is potentially useful for presymptomatic diagnosis of AD. Therefore, we have explored amyloid-binding agents and developed 6-(2-fluoroethoxy)-2-[2-(4-methylaminophenyl)ethenyl] benzoxazole (BF-168), [2-(4-methylaminophenyl)ethenyl]-5-fluorobenzoxazole (BF-145) and 2-[2-(2-dimethylaminothiazol-5-yl)ethenyl]-6-[2-(fluoro)ethoxy] benzoxazole (BF-227) as promising candidates for PET amyloid imaging probe [4-6, 8, 9]. These benzoxazole derivatives have high binding affinity for Aβ aggregates in vitro and high BBB permeability.

Clinical PET study using [^{11}C]BF-227 demonstrated neocortical retention of this tracer in AD patient (Fig. 4). About 60% of subjects with mild cognitive impairment (MCI), a group of individuals at a high risk of developing dementia, also showed abnormal retention of BF-227. Especially, MCI subjects who progressed to AD during follow-up showed prominent retention of BF-227 in the neocortex. These findings suggest that neocortical retention of BF-227 means high risk of conversion to AD. Voxel-by-voxel analysis of BF-227 PET images demonstrated higher retention of BF-227 in the temporo-parietal region in AD patients (Fig. 5).

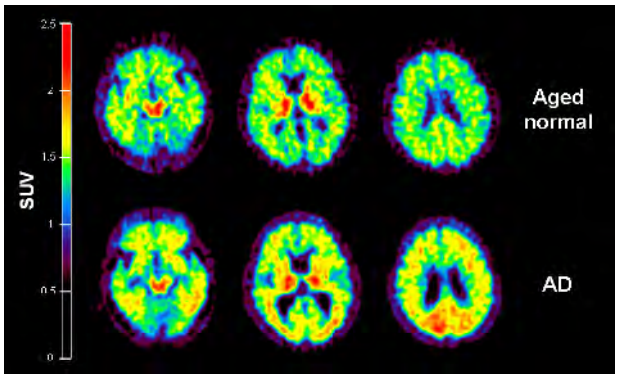

Fig. 4 Biodistribution of [^{11}C]BF-227 in the brain of aged normal control and AD patient

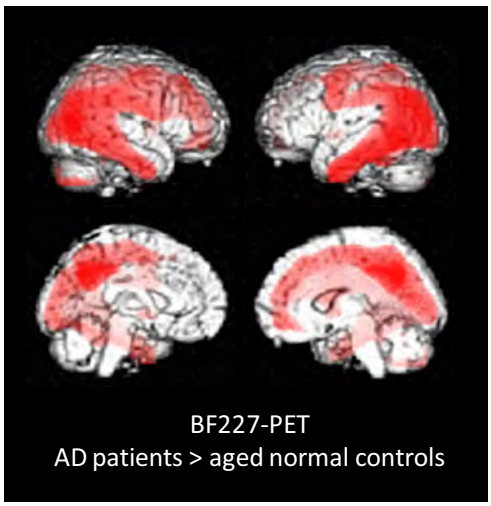

Fig. 5 Voxel-by-voxel analysis of [^{11}C]BF-227 PET images in the comparison between aged normal controls and AD patients (SPM2 analysis, $p<0.001$, uncorrected)

Pattern of this distribution resembles the distribution of neuritic plaques in postmortem AD brains. Microscopic observation also indicates preferential binding of BF-227 to neuritic plaques in AD brain section. These results suggest that neocortical retention of BF-227 reflects the level of neuritic plaques in the brain [10].

III. Conclusions

Molecular imaging technique is a powerful tool for understanding the pathophysiology of neuropsychiatric disease. The distributions of AChE, histamine H1 receptor and amyloid plaques in human brain were successfully visualized using PET. These imaging technologies would be useful for early and accurate diagnosis of AD and monitoring anti-dementia therapy. These technologies and forthcoming anti-dementia therapy will cooperatively contribute to the prevention of dementia.

Shear-Stress-Mediated Endothelial Signaling and Vascular Homeostasis

Joji Ando and Kimiko Yamamoto

Laboratory of System Physiology, Department of Biomedical Engineering,
Graduate School of Medicine, University of Tokyo, Japan

Abstract — **Endothelial cells (ECs) change their morphology, cell function, and gene expression in response to shear stress, the frictional force exerted by flowing blood. This suggests that ECs recognize shear stress and transmit signals to the interior of the cell. The molecular mechanisms of shear-stress mechanotransduction, however, are not completely understood. Our previous studies demonstrated that Ca^{2+} plays an important role in shear-stress-mediated endothelial signaling. When cultured human pulmonary artery ECs (HPAECs) were exposed to flow, the intracellular Ca^{2+} concentration increased in a shear-stress-dependent manner. The flow-induced Ca^{2+} response occurred in the form of an influx of extracellular Ca^{2+} via an ATP-operated cation channel, P2X4. We recently found that shear-stress-induced activation of P2X4 requires ATP, which is supplied in the form of endogenous ATP released by HPAECs. HPAECs released ATP in response to shear stress, and the ATP release was mediated by cell-surface ATP synthase located in caveolae/lipid rafts. At present, however, it remains unclear how shear stress activates cell-surface ATP synthase. To gain insight into the physiological role of this P2X4-meidated shear-stress mechanotransduction in vivo, we generated *P2X4*-deficient mice. *P2X4*-deficient mice do not exhibit normal EC responses to shear stress, such as Ca^{2+} influx and subsequent production of nitric oxide, a potent vasodilator. The vasodilation induced by acute increases in blood flow in situ is markedly suppressed in *P2X4*-deficient mice. *P2X4*-deficient mice have higher blood pressure values and excrete smaller amounts of NO products in their urine than wild-type mice. No adaptive vascular remodeling, i.e., decrease in vessel size in response to a chronic decrease in blood flow, is observed in the *P2X4*-deficient mice. Thus, P2X4-mediated shear-stress mechanotransduction plays an important role in the vascular homeostasis, including in the control of blood pressure and vascular remodeling.**

Keywords — **Endothelial cell, purinoceptor, ATP, ATP synthase, Ca^{2+}**

I. Introduction

Endothelial cells (ECs) are in direct contact with blood flow and exposed to shear stress, the frictional force exerted by flowing blood. A number of recent studies have revealed that ECs recognize changes in shear stress and transmit signals to the interior of the cell, which leads to cell responses that involve changes in cell morphology, cell function, and gene expression. These EC responses to shear stress are thought to play important roles in blood-flow-dependent phenomena, such as vascular tone control, angiogenesis, vascular remodeling, and atherogenesis. The precise mechanisms of shear-stress mechanotransduction, however, are not completely understood.

II. Ca^{2+}-mediated shear-stress mechanotransduction

Our previous studies demonstrated that Ca^{2+} signaling plays an important role in shear-stress mechanotransduction [1-2]. Human pulmonary artery ECs (HPAECs) that had been labeled with a fluorescent Ca^{2+} indicator, Indo-1, were exposed to controlled levels of shear stress in a parallel-type flow chamber, and changes in the intracellular Ca^{2+} concentration were monitored. The intracellular Ca^{2+} concentration increased in a shear-stress-dependent manner. There is a good correlation between shear stress and Ca^{2+} concentration. This means that ECs can accurately convert information regarding shear stress intensity into changes in Ca^{2+} concentration. When extracellular Ca^{2+} was removed with EGTA, the shear-induced Ca^{2+} response completely disappeared, indicating that the response was due to an influx of extracellular Ca^{2+} across the cell membrane.

III. P2X4 purinoceptor as a mechanotransducer

We found that P2X4, the subtype of ATP-operated cation channels known as P2X purinoceptors, play a crucial role in the shear-stress-dependent Ca^{2+} influx [3-4]. HPAECs were treated with antisense oligonucleotides (AS-oligos) targeted to the P2X4 receptor or control scramble-oligos (S-oligos), and their Ca^{2+} responses were determined. A shear-stress-dependent Ca^{2+} response was seen in the cells treated with control S-oligos, but not in those treated with

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2184–2187, 2009
www.springerlink.com

AS-oligos (Fig. 1). To further examine the role of P2X4 in flow-related Ca^{2+} signaling, we transfected P2X4 cDNA into human embryonic kidney (HEK) cells, which are basically insensitive to flow, and established cell lines that stably express P2X4 receptors. The control HEK cells did not show any significant increase in Ca^{2+} concentration when exposed to flow, whereas the HEK cells that stably expressed P2X4 exhibited a stepwise increase in Ca^{2+} concentrations in response to graded increments in shear stress. These findings suggest that P2X4 receptors have a 'shear-transducer' property through which shear stress signals are transmitted into the cell interior via the Ca^{2+} influx.

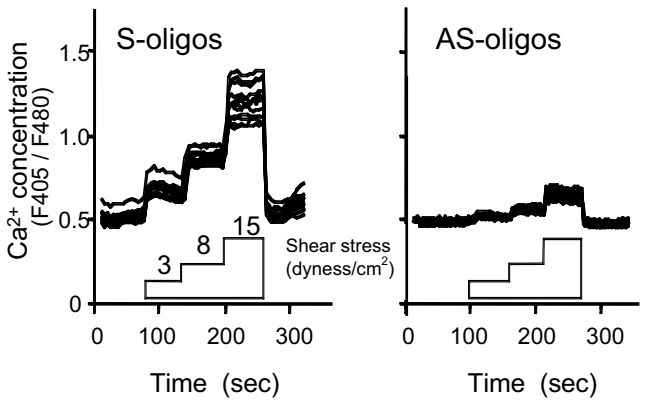

Fig.1. Effects of AS-oligos to P2X4 on shear-induced Ca^{2+} responses in HPAECs.

IV. Shear-induced ATP release via cell surface ATP synthase

Our recent study revealed that shear-stress-induced activation of P2X4 requires ATP, which is supplied in the form of endogenous ATP released by ECs [5]. We determined the amount of ATP released into the perfusate using a sensitive luciferase luminometric assay. HPAECs released ATP in response to shear stress, and the ATP release increased as the intensity of shear stress increased. ATP synthase inhibitors, such as angiostatin and an antibody against ATP synthase, markedly suppressed the shear-stress-dependent ATP release, which resulted in significant inhibition of the shear-stress-dependent Ca^{2+} response (Fig. 2). This means that endogenously released ATP plays an important role in the shear-stress-induced activation of P2X4 receptors. These findings also indicated that ATP synthase is involved in the shear-stress-induced ATP release.

We found that HPAECs express ATP synthase on the cell surface [6]. The cell-surface ATP synthase is distributed in lipid rafts and co-localized with caveolin-1, a marker protein of caveolae.

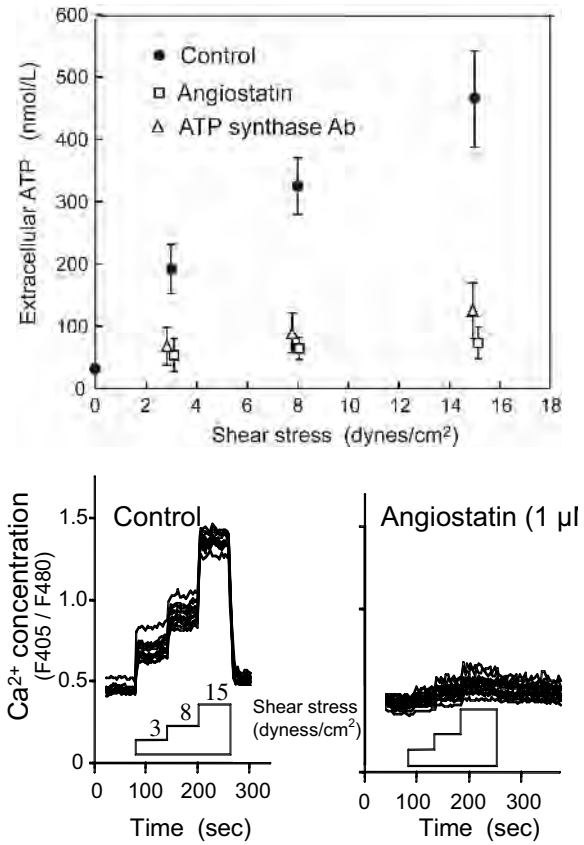

Fig.2. Effects of ATP synthase inhibitors on shear-induced ATP release and Ca^{2+} response by HPAECs.

Depletion of plasma membrane cholesterol with methyl-β cyclodextrin disrupted the lipid rafts and abolished the co-localization of ATP synthase with caveolin-1, which resulted in a marked reduction in shear-stress-induced ATP release. To further examine the role of caveolin-1 in the flow-induced ATP release, we used siRNA to specifically knock down expression of caveolin-1. Transfection of ECs with caveolin-1 siRNA resulted in a significant reduction in caveolin-1 protein expression and markedly inhibited the flow-induced ATP release. These results suggest that the localization and targeting of ATP synthase to caveolae/lipid rafts is critical for shear stress-induced ATP release. However, it remains unknown how shear stress activates cell-surface ATP synthase.

V. Shear Sensing and Its Roles in Vascular Homeostasis

A. Ca^{2+} responses and NO production

To gain insight into the roles of this shear-sensing mechanism via P2X4 in vascular homeostasis, we generated a *P2X4*-deficient (-/-) mouse [7]. The absence of P2X4 receptors impaired the EC response to flow stimulation. When the pulmonary vascular ECs of wild type (+/+) mice were exposed to flow, intracellular Ca^{2+} concentration increased stepwise in tandem with the increases in shear stress, whereas no flow-induced Ca^{2+} responses occurred in the ECs of -/- mice. Since increases in intracellular Ca^{2+} concentrations directly lead to the production of a potent vasodilator, nitric oxide (NO), the ECs were examined for changes in NO production with a fluorescence indicator, diaminofluorescein (DAF-2). NO production by the ECs of +/+ mice increased in response to flow, and the response was shear-stress-dependent (Fig.3). The ECs of -/- mice, however, did not show flow-induced NO production, indicating that P2X4 channels are involved in endothelial NO production.

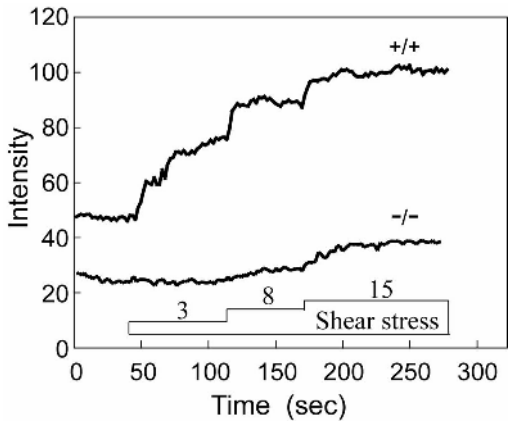

Fig. 3. Impaired production of NO in response to shear stress

B. Vasodilatory responses

We examined the effects of *P2X4* deficiency on the endothelium-dependent vasodilator response in the murine cremaster muscle. When acetylcholine (ACh) or ATP was administered through a jugular vein, the arterioles that had been pre-constricted with phenylephrine dilated dose-dependently in the +/+ mice. In the -/- mice, however, the ATP-induced vasodilation was markedly suppressed, but the ACh-induced vasodilation was not suppressed at all. Occlusion of one of the branches of an arteriole with a glass micropipette increases blood flow through the other branch, and the increase in blood flow caused marked vasodilation in the +/+ mice, but much less prominent vasodilation in the -/- mice (Fig.4). Blockade of NO synthesis by N^G-nitro-L-arginine methyl ester (L-NAME) markedly reduced the flow-induced dilation in both types of mice. These findings suggest that the flow-sensitive vasomotor mechanisms that regulate vascular tone are impaired in *P2X4*-deficient mice.

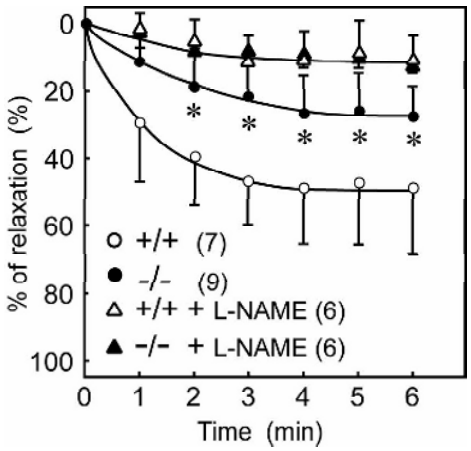

Fig. 4. Impaired vasodilatory responses in *P2X4* deficient mice Changes in vessel diameter are expressed as percentages: 0% represents the diameter of the vessel constricted with phenylephrine, and 100% represents the diameter of the vessel dilated with papaverine. Sample numbers are indicated in parentheses. *P<0.01

C. Blood pressure

A marked difference was observed in mean blood pressure determined by an intra-arterial catheter measurements, with significantly higher values recorded in the -/- mice than in the +/+ mice (125 ± 8 vs 104 ± 10 mmHg). There was no difference in their pulse rate (661 ± 74 bpm in +/+ mice vs. 668 ± 69 bpm in -/- mice). A difference was also observed in the general production of NO. The daily amount of nitrite and nitrate (NOx) excreted in the urine was significantly smaller in the -/- mice than in the +/+ mice. The decrease in NO production may be partly responsible for the increase in blood pressure in the -/- mice.

D. Vascular remodeling

Chronic changes in blood flow through large arteries induce structural remodeling of the vascular wall. Increases

in blood flow cause enlargement of vessel diameter, while decreases in blood flow have the opposite effect. To examine the role of the P2X4 receptor in flow-dependent vascular remodeling, the left external carotid artery of mice was ligated for 2 weeks. The ligation reduced flow in the left common carotid artery (LC), and we compared the diameter of the LC and the right common carotid artery (RC) histologically at the end of the 2-week period. Ligation of the left external carotid artery resulted in a significant reduction in lumen diameter in the LC in the +/+ mice, but not in the -/- mice (Fig.5). The absence of the flow-induced change in diameter in the *P2X4*-deficient mice resembled the structural changes that occur in eNOS-deficient mice [8], suggesting that *P2X4* plays a critical role through endothelial NO production in controlling vascular structural adaptation to chronic changes in blood flow.

These results indicate that endothelial P2X4 channels are critical to the flow-sensitive mechanisms that regulate vascular tone and vascular remodeling.

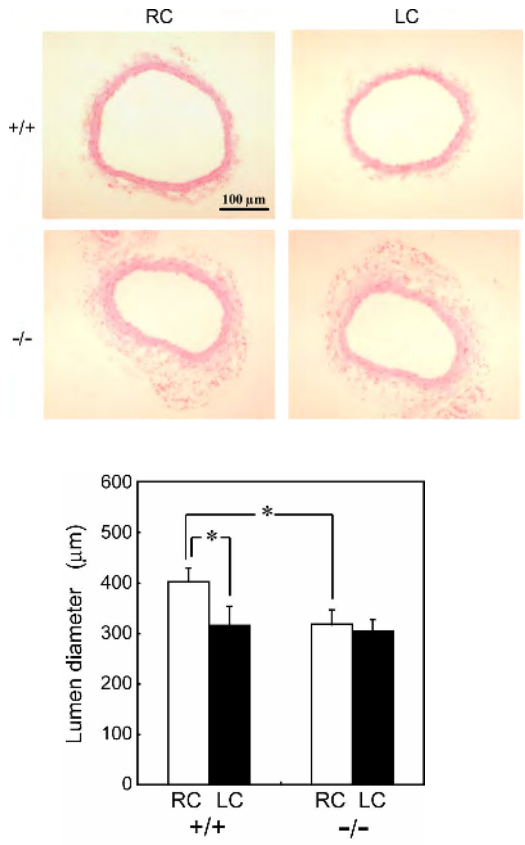

Fig. 5. Impaired blood flow-induced vascular remodeling. Upper: Hematoxylin-eosin-stained corss sections of the right common carotid artery (RC) and left common carotid artery (LC). Lower: Quantitative nalysis of changes in lumen diameter. *P<0.01. n=10 and 12 mice for $P2X4^{+/+}$ and $P2X4^{-/-}$ mice, respectively.

Abstract — **Detailed and accurate information of hemodynamics is essential for clarification and advanced diagnosis of circulatory diseases. In order to reproduce complicated real flow field, the concept of flow observer, which integrates measurement and computation by feedback process, have been proposed. By applying the method to the MR (Magnetic Resonance) measurement, we propose MR-measurement-integrated (MR-MI) simulation: the difference between the Phase-contrast MRI (PC MRI) data and the computational result of three-dimensional velocity vector field is fed back to the numerical simulation. The objective in this study is to evaluate the MR-MI simulation by numerical experiment dealing with an unsteady blood flow in a cerebral aneurysm. In the numerical experiment, we first defined a standard solution with velocity profiles obtained by PC MRI measurement at boundaries as a model of real blood flow. Then, MR-MI simulation was carried out by assuming a uniform velocity profile at the upstream boundary and pressure zero and free flow conditions at the downstream boundaries. During the computation, a feedback signal being proportional to the difference between the standard solution and the computational result was applied at each grid point in the aneurysm. As the result, the MR-MI simulation reproduced the standard solution in the aneurysm owing to the feedback process. The error derived from the inaccurate boundary conditions decreased to 22% in one cardiac cycle, comparing to the ordinary simulation. Consequently, the MR-MI simulation accurately provided the wall shear stress distribution on the cerebral aneurysm as hemodynamic information.**

Keywords — **Bio-fluid mechanics, Hemodynamics, Measurement-integrated simulation, Phase-contrast MRI, Cerebral aneurysm**

I. Introduction

Wall shear stress (WSS) and pressure have been indicated as hemodynamic factors for the development, progress and rupture of aneurysms [1,2]. Therefore, information on blood flow field in blood vessels is essential to elucidate the pathological mechanism of cerebral aneurysms and to establish the advanced diagnosis.

In order to reproduce complicated real flow field, the concept of flow observer, which integrates measurement and computation by feedback process, have been proposed [3]. We have developed the ultrasonic-measurement-integrated (UMI) simulation by integrating ultrasonic Doppler measurement and numerical simulation of blood flow, and revealed the efficiency of the method [4]. However, for blood flow in a brain, the UMI simulation is hardly feasible because the ultrasound is reflected by the cranial bone.

Hence, in this paper, we propose MR-measurement-integrated (MR-MI) simulation by integrating the MR measurement, which enables us to measure the blood flow in a brain, and the numerical simulation. Figure 1 shows the schematic diagram of MR-MI simulation system of blood flow. In the MR-MI simulation, artificial body forces, which are generated by comparing three-dimensional velocity vectors obtained by PC MRI measurement and the corresponding computational results, are added to the numerical simulation. This feedback process is expected to act to reproduce the real blood flow field computationally, by making the computational result converge to that. With this methodology, it is prospective that the numerical solution whose resolution is better than the MR measurement is acquired and the effect of errors included in measurement is eliminated.

This study investigates the computational accuracy of blood flow field and hemodynamic information in the MR-MI simulation with the simplified boundary conditions by numerical experiments dealing with the reproduction of

www.springerlink.com

unsteady blood flow field in an aneurysm which developed at a bifurcation of a cerebral artery.

II. Method

Governing equations of MR-MI simulation of blood flow are the Navier-Stokes equations and the pressure equation for incompressible and viscous fluid flow,

$$\rho\left(\frac{\partial \mathbf{u}}{\partial t}+(\mathbf{u}\cdot\nabla)\mathbf{u}\right)=\mu\Delta\mathbf{u}-\nabla p+\mathbf{f} \tag{1}$$

$$\Delta p=-\nabla\cdot\rho(\mathbf{u}\cdot\nabla)\mathbf{u}+\nabla\cdot\mathbf{f} \tag{2}$$

where $\mathbf{u}$ is the velocity vector, p is the pressure, ρ is the density, and μ is the viscosity. $\mathbf{f}$ denotes the feedback signal, and it is described by the following equation by comparing three-dimensional velocities obtained by PC MRI measurement and numerical simulation respectively at feedback points defined in a domain where measurement data is obtained.

$$\mathbf{f}=-K_{\mathrm{v}}^{*}\frac{\mathbf{u}_{\mathrm{c}}-\mathbf{u}_{\mathrm{s}}}{U}\left(\frac{\rho U^{2}}{L}\right) \tag{3}$$

where K_{v}^{*} is the feedback gain (nondimensional). It is noted that the special case with $K_{\mathrm{v}}^{*}=0$ means the ordinary numerical simulation without feedback. U is the characteristic velocity, L is the characteristic length. The subscripts c and s represent a computational result and real flow (or the standard solution), respectively. In the computation, all parameters were nondimensionalized with the characteristic values. After that, the above governing equations were discretized by means of the finite volume method and were solved with an original program based on an algorithm similar to the SIMPLER method.

In a numerical experiment in this study, we first obtained a standard solution as a model of real blood flow with velocity vectors obtained by the PC MRI measurement at boundaries. Then, MR-MI simulation was performed using the data of the standard solution, and examined how well it can reproduce the standard solution.

The objective was the blood flow in a cerebral aneurysm at the bifurcation between basilar and superior cerebellar arteries. A 70-year-old female patient participated in this study, and the PC MRI data was obtained after the approval by the institutional review board of Hamamatsu University School of Medicine and the informed consent. The PC MRI data, which holds information on blood vessel configuration and the velocity vector of blood flow, were obtained at 20 phases in one cardiac cycle with the sampling time of $\Delta t = 0.046$ s. The configuration including the cerebral aneurysm and the parent artery was reconstructed by means of the image data processing software, Flova (Renaissance of Technology Corp., Hamamatsu, Japan), from the PC MRI data. We assumed that the blood vessel was rigid because the deformation was subtle, and generated several computational grid systems with different resolutions. Compromising between the reproducibility of blood vessel shape and the computational load, a staggered equidistant grid system with $N_x \times N_y \times N_z = 30 \times 27 \times 26$ ($\Delta x = \Delta y = \Delta z = 0.5\times10^{-3}$ m) shown in Fig. 2 was chosen. With the same software, one inlet, A, and two outlets, B and C, were determined (see Fig. 2), and the velocity information on the boundaries were exported by the linear interpolation. The variation of flow rate at the inlet A is shown in Fig. 3.

A periodic solution obtained with the three-dimensional velocity vectors obtained by PC MRI measurement at boundaries with time increment of $\Delta t = 0.046$ s was defined as the standard solution. The reference velocity and the reference length for nondimensionalization of parameters

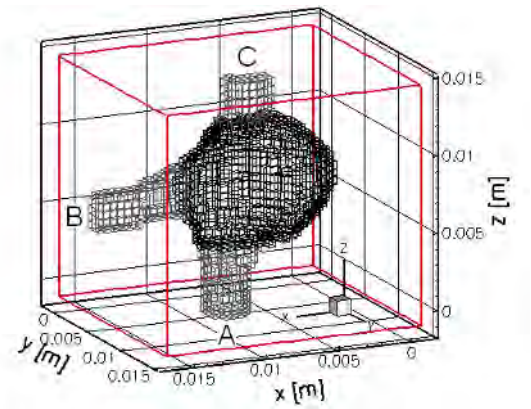

Fig. 2 Computational grid (30×27×26) with the feedback domain (black grid lines).

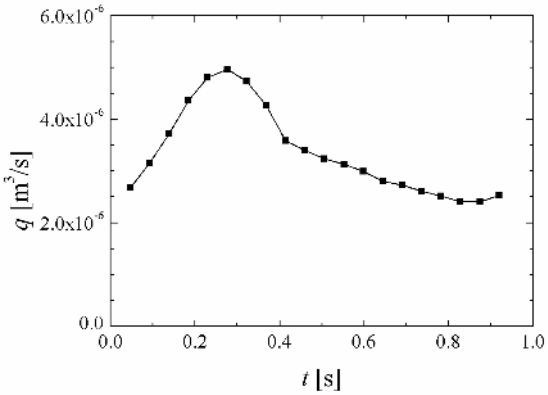

Fig. 3 Time-variation of flow rate at the inlet A obtained by PC MRI measurement.

Table 1 Computational conditions.

Entrance flow	2.68×10^{-6} m^3/s
Maximum mean velocity u'_{max} (U)	0.42 m/s
Entrance diameter D (L)	4.0×10^{-3} m
Density ρ	1.0×10^{3} kg/m^3
Viscosity μ	4.0×10^{-3} Pa·s
Maximum Reynolds number Re_{max}	423
Womersley number α	5.2

were the maximum mean velocity u'_{max} at peak flow and the diameter D at the upstream boundary, respectively. Variables used in this study are summarized in Table 1.

In MR-MI simulation, we applied a uniform velocity profile at the upstream boundary, and free flow as well as pressure zero conditions at the two downstream boundaries, assuming the complicated velocity vectors at boundaries were unknown. Note that the variation of flow rate was assumed to be known. The computational time increment was set at Δt = 0.046 s, which corresponded to the time resolution of the MR measurement. Velocity field was initialized at zero in each simulation.

The feedback points were arranged at all grid points in the feedback domain M (2.0×10^{-3} m $\le x \le 10.5\times10^{-3}$ m, 2.0×10^{-3} m $\le y \le 11.5\times10^{-3}$ m, 3.0×10^{-3} m $\le z \le 11.5\times10^{-3}$ m, see black grid lines in Fig. 2), which covered the whole cerebral aneurysm and the adjacent parent artery with the assumption that PC MRI measurement was to be done in this domain.

The computational accuracy of the MR-MI simulation was evaluated by comparing with that of the ordinary simulation without feedback. For the evaluation of each simulation, the space-averaged error norm of velocity vector in a monitoring domain Ω was defined as follows:

$$\bar{e}_{\Omega}(\mathbf{u}_1, \mathbf{u}_2, t) = \left[\frac{1}{3N} \sum_{\mathbf{x}_n \in \Omega} \left\{ (u_1 - u_2)^2 + (v_1 - v_2)^2 + (w_1 - w_2)^2 \right\} \right]^{\frac{1}{2}} \quad (4)$$

where $\mathbf{u}_1 = (u_1, v_1, w_1)$ and $\mathbf{u}_2 = (u_2, v_2, w_2)$ mean two velocity vectors to be compared, and N is the total number of the monitoring points in the domain Ω. In addition, space-time-averaged error norm $\bar{e}_{\Omega T}(\mathbf{u}_1, \mathbf{u}_2)$ of velocity vector was defined by averaging the $\bar{e}_{\Omega}(\mathbf{u}_1, \mathbf{u}_2, t)$ in one cardiac cycle T.

III. Results and Discussion

For the investigation, the numerical solution in the 5th cycle, in which the standard solution became periodic, was used as the solution in each simulation. Note that MR-MI simulation already provided the periodic solution in the 3rd cycle, and the acceleration of the convergence was confirmed. MR-MI simulation was carried out with increasing the feedback gain in increments of 0.5. As the result, computation diverged at the $K_v^* \ge 2.5$.

Periodic variation of space-averaged error norm of velocity vector in the aneurysm (or in the feedback domain M) with respect to the standard solution, $\bar{e}_M(\mathbf{u}_c, \mathbf{u}_s, t)$, in the ordinary simulation ($K_v^* = 0$) and in MR-MI simulations with $K_v^* = 1, 2$ are shown in Fig. 4. Because the inaccurate boundary condition was applied, the ordinary simulation contains error in the blood flow field in the cerebral aneurysm. The phase of the variation of the space-averaged error norm in Fig. 4 corresponds to that of the variation of blood flow rate in Fig. 3; the magnitude of $\bar{e}_M(\mathbf{u}_c, \mathbf{u}_s, t)$ becomes the largest at the peak flow. On the other hand, the MR-MI simulation can suppress the error norm at each moment, implying the improvement of the computational accuracy. In this study, the error norm was the smallest at the maximum feedback gain, $K_v^* = 2$, and decreased to 22% of that in the ordinary simulation in one cardiac cycle.

Since the relationships of hemodynamic factors to cerebral aneurysms are discussed in many studies, it is important how accurately the MR-MI simulation can provide hemodynamic information. Wall shear stress (WSS) was calculated by first-order numerical differentiation of the velocity vectors at every time instant in each simulation. The distributions of magnitudes of WSS on the cerebral aneurysm at peak flow are compared in Fig. 5(a). In addition, the differences of the magnitude of the WSS from the standard solution in the ordinary simulation and the MR-MI simulation with $K_v^* = 2$ are shown in Fig. 5(b). All simulations show similar WSS distributions in Fig. 5(a). However, detailed observation reveals the locally large difference against the standard solution exists in the ordinary simulation, as indicated with arrows in Fig. 5(b). The incorrect hemodynamic information may lead to a wrong diagnosis. In contrast, the

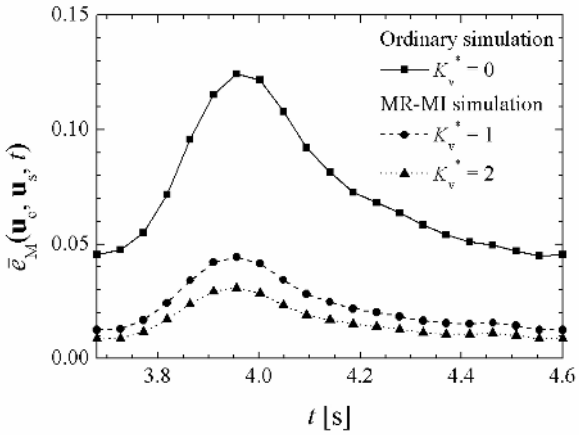

Fig. 4 Variation of the space-averaged error norm of the velocity vector in the cerebral aneurysm.

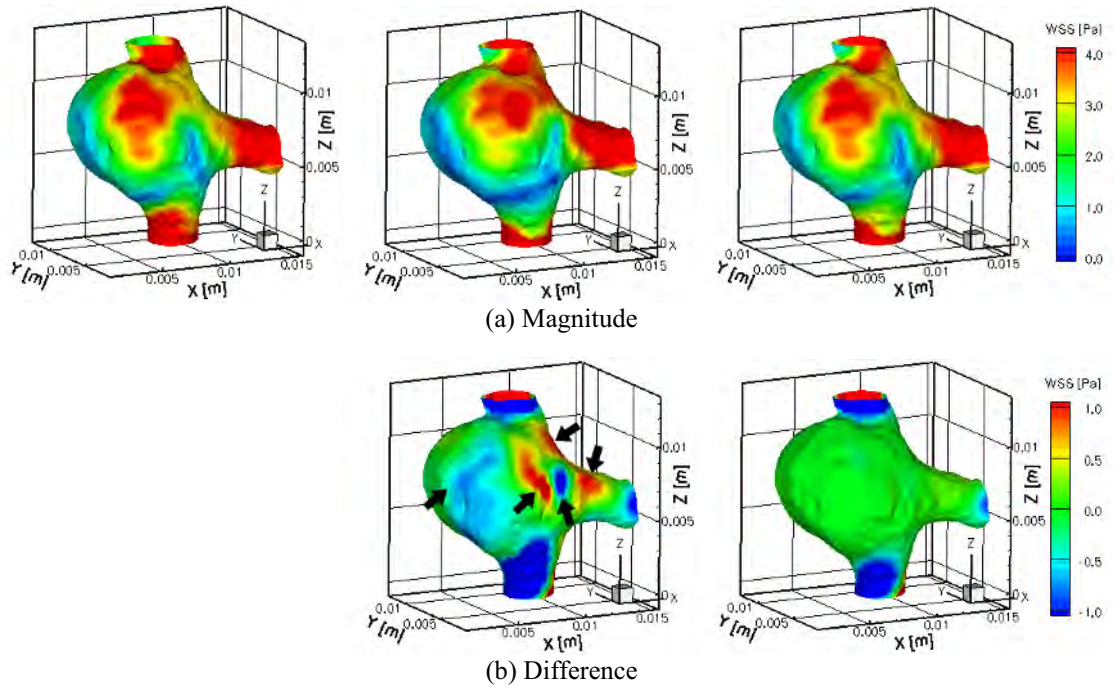

Fig. 5 (a) Wall shear stress distribution on the cerebral aneurysm at the peak flow of the standard solution (left), ordinary simulation ($K_v^* = 0$) (middle) and MR-MI simulation with $K_v^* = 2$ (upper right), and (b) the difference with respect to the standard solution.

difference of the magnitude of WSS is almost zero in the whole aneurysmal domain in MR-MI simulation (see Fig. 5(b)), accurately reproducing the WSS distribution on the cerebral aneurysm of the standard solution. Therefore, the MR-MI simulation can provide reliable information on WSS distribution which is an important hemodynamic factor for the diagnosis of cerebral aneurysms.

IV. Conclusions

The computational accuracy of MR-measurement-integrated (MR-MI) simulation was investigated by numerical experiment dealing with reproduction of three-dimensional unsteady blood flow field in a cerebral aneurysm. The MR-MI simulation substantially improved the computational accuracy by reducing the error in the cerebral aneurysm derived form the inaccurate boundary conditions for the sake of the feedback based on the errors in velocity vectors with respect to the standard solution. For the reproduction of the standard solution, the error decreased to 22% in one cardiac cycle, comparing to the ordinary simulation. Consequently, the MR-MI simulation accurately provided the wall shear stress distribution on the cerebral aneurysm as hemodynamic information.

Acknowledgment

The authors would like to express their thanks to Mr. Yasuhide Ohkura for his cooperation with Flova, and to the support of Tohoku University Global COE Program “Global Nano-Biomedical Engineering Education and Research Network Centre”. Specificity of Traction Forces to Extracellular Matrix in Smooth Muscle Cells

T. Ohashi[1], H. Ichihara[1], N. Sakamoto[1] and M. Sato[1,2]

[1] Graduate School of Engineering, Tohoku University, Sendai, Japan

Abstract — **Adherent cells are known to exert traction forces to adhere to their extracellular matrix at focal adhesions, where integrins interact with the extracellular matrix and mediate various cellular signals. Therefore, it is hypothesized that extracellular matrix-mediated integrin expression may modulate cellular traction forces, resulted in alterations in cell physiology. In this study, to test the hypothesis, traction force measurements are performed on bovine thoracic smooth muscle cells using a polydimethylsiloxane-based micropillar substrate coated with different types of extracellular matrix. The top of the micropillars was selectively coated with fibronectin (FN), vitronectin (VN), and type I collagen (COL I) at 30 and 50 μg/ml and cells were plated on the extracellular matrix-coated micropillars. For FN and VN, the cells have several spikes at the cell periphery, whereas, for COL I, the cell expresses relatively oval shape. At 30 μg/ml, traction forces were 5.5 ± 0.6, 5.8 ± 1.3 and 8.5 ± 2.2 nN for FN, VN, COL I, respectively. At 50 μg/ml, traction forces significantly increased compared to 30 μg/ml and were 12.4 ± 6.8, 13.5 ± 4.0 and 18.1± 4.7 nN for FN, VN, COL I, respectively. These results indicate that extracellular matrix may specifically modulate integrin expression followed by development of actin stress fibers, possibly leading to changes in traction forces.**

Keywords — **Smooth muscle cells, Traction forces, Extracellular matrix, Integrin expression**

I. Introduction

Adherent cells are known to exert traction forces to adhere to their extracellular matrix at focal adhesions, where integrins interact with the extracellular matrix and mediate various cellular signals, possibly leading to modulations of a variety of physiological functions in cell proliferation, migration, etc. Integrins are obligate heterodimers containing two distinct chains, called the α and β subunits, very specific to the types of extracellular matrix such as fibronectin, vitronectin, collagen, etc. It is also known that change in cellular traction forces may modulate cell physiological functions. Therefore, it is speculated that extracellular matrix-mediated integrin expression may modulate cellular traction forces, resulted in alterations in cell physiology.

So far, a lot of efforts have been made to estimate cellular traction forces using micropillar substrates [1]. In this study, we performed traction force measurements using a micropillar substrate coated with different types of extracellular matrix including fibronectin (FN), vitronectin (VN), and type 1 collagen (COL1). Fluorescence observations of actin filament structures were also performed to study their relevance to magnitude and directions of traction forces.

II. Methods

A. Cell culture

Smooth muscle cells were obtained from bovine thoracic aortas. Cells were seeded in tissue culture flasks with DMEM + 10% FBS. Cell populations from the 4th to 9th generation were studied.

B. Fabrication of substrate with micropillar array and coating of extracellular matrix

A mould of silicon substrates with arrays of micropillars (3 μm in diameter, 10 μm in height, and 8 μm spacing) was fabricated using micromachining techniques, and polydimethylsiloxane was poured into the mould to produce a substrate membrane with micropillars. The top of the micropillars was selectively coated with FN, VN, and COL1 at 30 and 50 μg/ml and cells were plated on the substrates.

C. Traction force measurements and fluorescence staining

Cell spreading produces deflection of micropillars, which was measured from brightfield images to determine traction forces. After traction force measurements, cells were fixed with 10% formaldehyde, permeabilized with 0.1% Triton X-100, and then labbeled with Alexa Fluor594 and Alexa Fluor488 to visualize actin filaments and vinculin, respectively.

III. Results

Figure 1 typically shows actin filament networks, vinculin, and traction forces in smooth muscle cells cultured on FN, VN, and COL1 at 30 μg/ml. Cells cultured on FN and VN developed multiple protrution, while this protrution was not observed in cells cultured on COL1. Focal adhesion protein vinculin clearly expressed as a horseshoe-shaped

www.springerlink.com

structure at both ends of actin fibers, where cells exerted traction forces. In Fig. 2, traction forces were 5.5 ± 0.6, 5.8 ± 1.3 and 8.5 ± 2.2 nN for FN, VN and COL1, respectively, at 30 μg/ml. Traction forces for COL1 were significantly higher than those for FN and VN. As the concentration increased from 30 μg/ml to 50 μg/ml traction forces significantly increased, resulting in 12.4 ± 6.8, 13.5 ± 4.0 and 18.1± 4.7 nN for FN, VN and COL1, respectively.

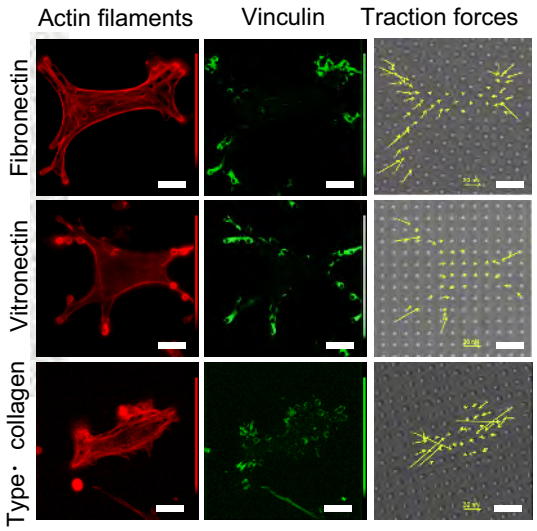

Fig. 1 Actin filaments, vinculin, and traction forces of cells cultured on FN, VN, and COL1 at 30 μg/ml. Bars = 20 μm.

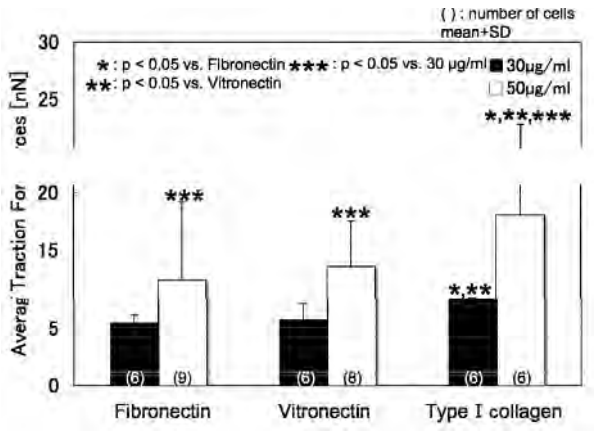

Fig. 2 Traction forces of cells cultured on FN, VN, and COL1 at 30 and 50 μg/ml.

IV. Discussion

Cells attached to and spread on the substrates. The micropillars showing large deformation were found to connect to thick actin filaments, suggesting that actin filaments can be a major component contributing to generation of traction forces. Under all the three conditions, traction forces were obviously exerted towards the center of the cell, particularly showing higher forces at the cell periphery than at the center of the cells.

For FN and VN, cells have several spikes at the cell periphery, probably indicating the stage of cell migration. By contrast, for COL1, cells express relatively oval shape. Traction forces for COL1 were significantly higher than those for FN and VN. This can be explained by the fact that well-organized actin filament networks were observed in cells cultured on COL1-coated micropillars. This result thus indicates that extracellular matrix specifically modulate integrin expression followed by activation of integrin-mediated signalling pathways, possibly leading to development of actin stress fibers via Rho activation in response to different types of extracellular matrix [2].

Another finding in this study is that cells can exert traction forces in an extracellular matrix concentration-dependent manner. This suggests that cells could form focal adhesion complexes including more integrins at higher concentrations of extracellular matrix.

V. Conclusion

The effects of different types of extracellular matrix on smooth muscle cell traction forces were studied using micropillar array coated with fibronectin, vitronectin, and type 1 collagen. The results indicate that extracellular matrix-mediated integrin expression may modulate traction forces via formation of stress fibers. It is also indicated that cells can exert traction forces in an extracellular matrix concentration-dependent manner.

Cochlear Nucleus Stimulation by Means of the Multi-channel Surface Microelectrodes

Kiyoshi Oda[1, 2], Tetsuaki Kawase[1,3], Daisuke Yamauchi[1], Hiroshi Hidaka[1] and Toshimitsu Kobayashi[1]

[3] Department of Rehabilitative Auditory Science Graduate School of Biomedical Engineering , Sendai, Japan

Abstract — **The electrically evoked brainstem potential was measured in guinea pigs with 260-channel surface microelectrode implanted on the cochlear nucleus. Even when surface bipolar stimulations with 200μm separation of two electrodes are employed, the unequivocal waves of electrically evoked auditory brainstem responses (EABRs), which increased in amplitude with increasing stimulation current, were constantly derived. Electrophysiological mapping using the 260-channel surface microelectrode indicated that more precise electrophysiological mapping may be possible based on the EABR-positive boundary.**

The multi-channel surface microelectrode was expected to be usefully applied to the probe to determine the optimal location for the positioning of the ABI and stimulating electrode in ABI in clinical use.

Keywords — **surface bipolar stimulations. electrically evoked auditory brainstem responses (EABRs).**

I. Introduction

Auditory brainstem implants (ABI) are an artificial organ technology in which electrodes are implanted in the brainstem in order to restore the hearing of patients who have lost their hearing as a result of auditory nerve dysfunction [1]. ABI have reached the clinical trial stage in Europe and the United States and satisfactory outcomes have been demonstrated in successful cases, bringing great hope to these patients. However, the success rate has been less than satisfactory [2,3].

The overall performance of ABI has not been as good as cochlear implant that stimulates spinal ganglion cells yet [4]. One hypothesis (the selectivity hypothesis) is that the ABI does not make selective contact with the tonotopic dimension of the cochlear nucleus, limiting the number of independent channels of spectral information. If each electrode activates a broad area of neurons, and adjacent electrodes activate largely overlapping populations, this overlap will have the effect of smearing the representation of spectral place [4]. In order to stimulate fewer populations in cochlear nucleus and locate cochlear nucleus surface precisely intraoperatively, the bipolar stimulation with very short separation and many stimulating points is ideal in theory.

In the present study, the 260-channel surface microelectrode was employed to measure electrical evoked auditory responses, and these responses were utilized to map the cochlear nucleus in an animal model.

II. Method

The use and care of animals reported in this study was approved by Tohoku University's Animal Care and Use Committee. Male albino guinea pigs weighing 400-700g with normal Preyer's reflexes were used in this experiment. The animals were free of both illness and middle ear infections at the time of study. Before the surgery, general anesthesia was set up by intramuscular injection of mixture of xylazine (10mg/kg) and ketamine (40mg/kg). 1% xylocaine was also used as local anesthesia. All recordings were made in a sound-attenuated, electrically shielded room. A click stimulus was used to measure the auditory evoked brainstem response (AABR) (Neuropack μ, Nihon Kohden) in order to confirm normal auditory function.

The animals were then placed in a supine position, and an incision was made in the skin behind the ear to expose and remove the skull to allow cerebellar retraction and sub-

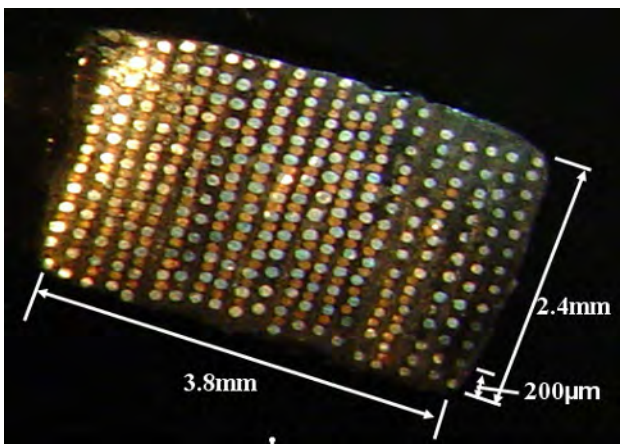

Fig. 1. 260-channel microelectrode Diameter of each electrode is 100μm. Electrode is made of platinum.

www.springerlink.com

sequent visualization of the cochlear nucleus. The 260-channel microelectrode shown in Fig. 1 was placed on the surface of the cochlear nucleus. This specialized device has 260 electrodes in an area of only 3.8mm x 2.4 mm, with the inter-electrode distance set at only 200 μm.

Of the 260-channel electrode channels on this microelectrode, two points were stimulated arbitrarily and the electrical evoked brainstem responses (EABR) were recorded. In order to record the EABR, the active electrodes were placed on the surface of the auditory region, and the reference electrodes, consisting of stainless steel needles, were placed behind the ear. EABR were recorded using the same type of system as for AABR (Neuropack μ, Nihon-Kohden) under the following measurement conditions: number of average, 500 times; low cut filter, 200 Hz; high cut filter, 3000 Hz. As regards the electrical stimuli, a SEN-3041 pulse generator (Nihon Kohden) and SS-203J Isolator were used to generate bipolar pulses of 80 μsec in duration.

III. Result

Using the 260-channel systems, we succeeded in recording reproducible EABR when the cochlear nucleus was stimulated electrically. Mapping is considered to be most effective when the stimulation used is capable of recording reproducible waveforms with high sensitivity and an excellent S/N. Therefore, after taking into consideration the I/O characteristics of the EABR, electrical stimulation from the dynamic portion of the signal (600 μA -1000 μA) was, for the most experiments, used to carry out the mapping. Figure 2 shows the results of mapping of the cochlear nucleus using representative EABR. In this case, the 260-channel microelectrode was placed on the dorsal portion of the cochlear nucleus. We could distinguish positive EABRs indicated by blue arrows from undetectable EABRs indicated by red arrows in 3.8 by 2.4 mm area.

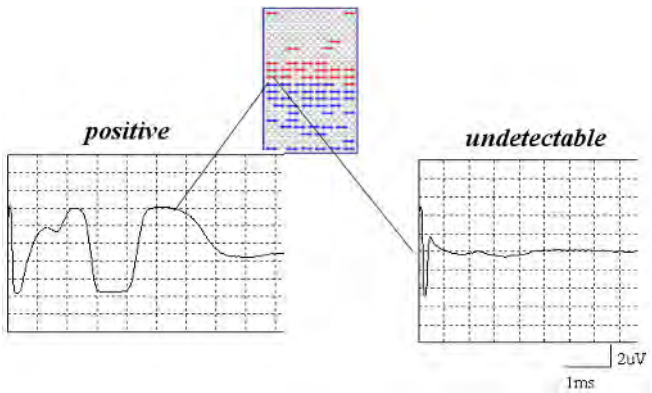

Fig. 2. Mapping by 260-channel microelectrode

IV. Discussion

There are two possible electrode configurations – penetrating and surface ones. Xuguang Liu et al. tested electrical stimulation of the cochlear nucleus with both types of arrays on guinea pigs and cats. In guinea pigs, the penetrating electrodes had advantages over surface arrays in the sense of lower thresholds and wider dynamic ranges. But, histologically the presence of VCN oedema could be inferred from the decreased neuron densities and increased mean soma areas in guinea pigs implanted with penetrating electrodes. On the contrary, there is no apparent pathological changes on the surface or within the implanted cochlear nuclei in guinea pigs implanted with surface electrode [5].

There are two manners of stimulation – bipolar and monopolar. Russell L. Snyder et al. evaluated the spread of activity evoked by cochlear implant by monitoring activity at the guinea pig inferior colliculus. Monopolar stimulation are less selective than bipolar. Contacts with less separation between electrodes evoke more selective excitation but with higher thresholds than contacts with greater separation [6].

The reason we choose bipolar surface electrodes is emphasis on safety and selectivity as described above and clinical application as a placing electrode in the future.

In Figure 2., following very slight shifts in the stimulation region, the EABR suddenly disappeared or the shape of the waveforms changed, indicating that the microelectrode used was capable of applying relatively localized electrical stimulation. The EABR-positive boundary could be distinguished by means of electrophysiological mapping. However, the relation between this boundary and the actual anatomical boundary remains unclear.

We are succeeded in measuring EABR by the 260-channel bipolar surface microelectrode with an inter-electrode distance of 200 μm.

In the present study, bipolar stimulation with an inter-electrode distance of 200 μm was capable of adequately recording EABR. Furthermore, following very slight shifts in the stimulation region, the EABR suddenly disappeared or the shape of the waveforms changed, indicating that the microelectrode used was capable of applying relatively localized electrical stimulation. These results indicate that the use of a microelectrode as the stimulating electrode in ABI may make it possible to achieve a more precise discrimination of pitch

V. Conclusions

In the present study, EABR were recorded using a surface microelectrode with an inter-electrode distance of only 200 μm, which are less than one fifth the electrode separation of the electrode devices presently in clinical use. These same

microelectrodes were used to conduct mapping of the cochlear nucleus and found that the electrophysiological boundaries could be identified quite clearly with this method.

Effects of Mechanical Stimulation on the Mechanical Properties and Calcification Process of Immature Chick Bone Tissue in Culture

T. Matsumoto, K. Ichikawa, M. Nakagaki and K. Nagayama

Biomechanics Laboratory, Nagoya Institute of Technology, Nagoya, Japan

Abstract — **In order to study the adaptation mechanism of bone tissues, we cultured immature bone slices obtained from chick tibia under mechanical stimulation. We first cultured 2 to 3-mm-thick slices for 3 days while giving them cyclic compression up to 0.3N at the rate of 3-4 cycle/min. Both the stiffness and the calcified area of the bone tissues increased significantly under cyclic compression. Such increases did not occur in their static control, nor specimens deactivated with liquid nitrogen. We then cultured 0.2mm-thick slices for 24 hours while being stretched by 10%. Calcified area was significantly larger in stretched specimens than in the non-stretched control. Traveling direction of the calcification was roughly equal to the stretch direction. Collagen fibers showed alignment in the stretch direction over 5% of stretch. These results indicate that dynamic and quasi-static stretch stimulate calcification especially in the direction of stretch, and the calcification may occur preferentially along the direction of collagen fibers. The alignment of collagen fibers in the stretch direction and facilitated calcification along collagen fibers may have something to do with the alignment of trabecular bone in the direction of principal stress.**

Keywords — **Mechanical adaptation, Biomechanics**

I. Introduction

It is well known that the bones change their shape and internal structures adaptively in response to the mechanical environment to which they are exposed [1]. The mechanisms of these responses are, however, not well known.

In order to study the mechanism of adaptation of bone tissues, an approach to culture bone tissues under a controlled mechanical environment to observe their mechanical and histological changes during culture would be useful. For this purpose, we have developed an apparatus in which bone slices can be cultured under cyclic compression to find that the mechanical stimulation for 3 days increased stiffness of immature bone slices obtained from chick tibia by stimulating tissue calcification [2]. To know the details of histological changes during culture, we have developed another apparatus in which bone slices can be stretched and cultured under a microscope. We found that static stretch also stimulated tissue calcification especially in the direction of collagen fiber alignment [3]. In this paper, we introduce our apparatuses and results obtained in these studies.

II. Changes in the Mechanical Properties of Bone Specimen During Cyclic Complession Culture

A. Materials and methods

Specimens: We used immature bone tissues obtained from the tibias of 0-day-old chicks. A bone slice with a thickness of 2-3 mm was obtained in a plane perpendicular to the tibial axis at the position 2-3 mm from the proximal end of each tibia. The slices were then cultured in a cyclic compression apparatus for 3 days in an osteogenic medium, *i.e.*, BGJb (Gibco, USA) supplemented with 10% fetal calf serum (ICN, USA), 75μg/ml ascorbic acid (Wako, Japan), 5mM β-glycerol phosphate (Wako), and 10^{-7}M dexamethasone (Wako). To confirm that the changes observed in cyclic compression culture was active response of bone tissues, we also used slices that had been frozen with liquid nitrogen and thawed to deactivate cells in the tissues.

Cyclic Compression Culture: The apparatus we used for the cyclic compression culture is shown in Fig. 1 Three slices obtained from the right tibias was cultured simultaneously under cyclic compression along with their contralateral static controls under a standard culture condition (37°C, 100% humidity, 5%CO_2 and 95% air) in an acrylic box. Each of the specimens in a 35-mm culture dish was com-

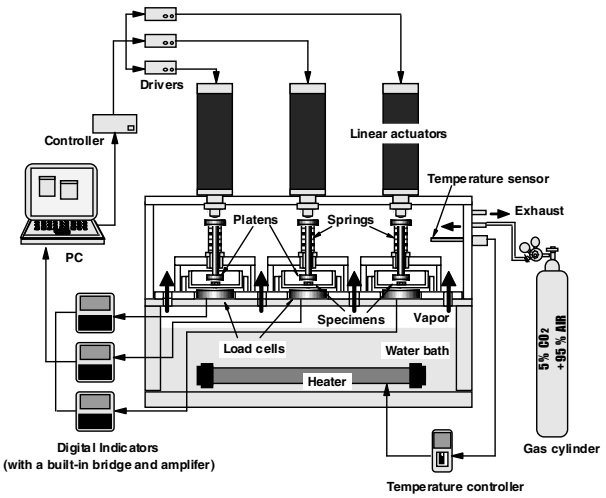

Fig.1 Real time monitoring system for the mechanical properties of bone tissue in cyclic compression culture.

www.springerlink.com

pressed cyclically in the direction of tibial axis for 3 days with a linear actuator (MAS-23, Chiba Precision, Japan) via a platen. Load applied the specimen was measured with a load cell (TC-USR-23, TEAC, Japan). The slices were loaded at the rate of 50 μm/s until the load became 0.3 N and held for 5 s then unloaded at the same rate. This makes overall loading rate 3-4 cycle/min depending on the stiffness of the slice.

Compression Test: Mechanical properties of the slices were determined with a compression test before and after culture. Slices were compressed at the rate of 0.5μm/s up to 0.5N to obtain nominal stress-strain curves. Nominal stress σ and strain ε was calculated as $\sigma = F/A_0$ and $\varepsilon = x/t$ where F and x are the load and displacement, respectively, applied to the slice, and A_0 and t the cross sectional area and the thickness, respectively, of the slice after culture. To reduce ambiguity of the origin of the curve, zero stress was taken as σ = 0.003 N.

Fresh and deactivated specimens cultured under cyclic compression were denoted as CCC and dCCC, respectively. Similarly, specimens cultured under static culture were denoted as SC and dSC. We also measured stiffness of specimens freshly obtained from the tibias of 0 and 3-day-old chicks, and denoted them as CON0 and CON3, respectively.

Specimen Viability Check: After the culture, some of the specimens were sliced in the direction parallel to the tibial axis with a microslicer (DTK-1000, Dosaka-EM, Japan) to obtain a 200-μm-thick slice at the center of the specimen. The slices were then stained with Viability/Cytotoxicity Assay Kit for Animal Live & Dead Cells (Biotium, USA) in which calcein AM stains live cells green while EthD-III stains dead cells red to assess cell viability in the tissue.

Measurement of Calcification: Some of the specimens were sliced to 200 μm in thickness in the direction perpendicular to the tibial axis with the microslicer. The slices were stained with 1% Alizarin Red S (Wako) to identify calcified area.

B. Results and discussion

Specimen Viability: Fig. 2 summarizes the cell viabilities at edge and central sections in each group. Due to the specimen preparation process, the cell viability was 50-60% even in the control (CON). The viability was significantly lower in the cultured groups (SC and CCC) with significant difference between them. The viability was higher in the central section in CON and SC, while it was higher in the edge section in CCC. This may indicate necrosis of cells in the central section due to increase in oxygen demand caused by the mechanical stimulation. However, almost 50% of cells were viable in CCC compared to control. In contrast, no cells were alive in deactivated groups (dCCC and dSC).

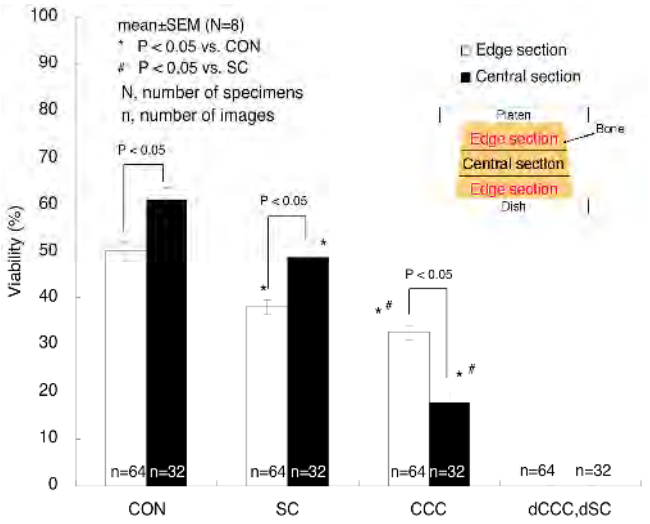

Fig.2 Cell viability in bone specimens. Cell viability was defined as relative number of living cells to whole cells.

Effects of Cyclic Compression Culture on Specimen Stiffness: Nominal stress-strain curve became steepened after cyclic compression culture (CCC) while the curve did not change in deactivated group (dCCC) (Fig. 3). Apparent elastic moduli of the bone tissues were calculated in the four stress ranges (Fig. 4). The moduli increased significantly under cyclic compression (Fig. 5). Such increases did not occur in their static control and specimens deactivated with liquid nitrogen. With regard to calcification, calcified area was 21.7±0.9% (mean±SEM, n=4) before culture (CON0) and did not change significantly after static culture (SC, 24.2±0.9%), while it increased significantly after cyclic compression culture (CCC, 31.4±1.8%) and was almost comparable to CON3 (33.6±1.2%). Furthermore, there was a significant correlation between apparent elastic moduli and area fraction of calcified area (Fig. 6). These results indicate that cyclic compression stimulates calcification and thus tissue hardening.

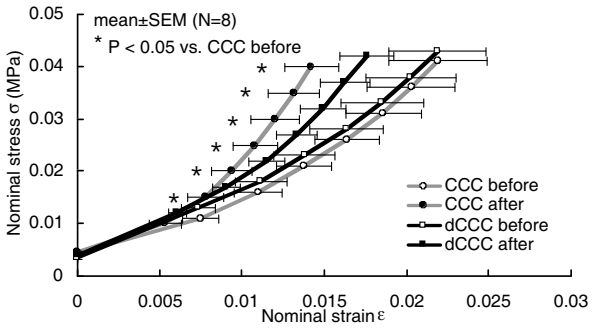

Fig.3 Mean stress-strain cure of group CCC and dCCC.

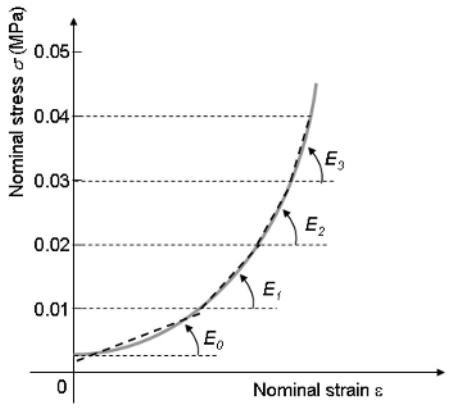

Fig.4 Apparent elastic moduli calculated from stress-strain curves.

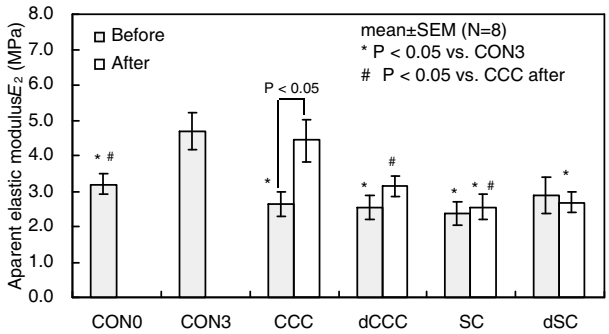

Fig.5 Apparent elastic modulus E_2 in six groups

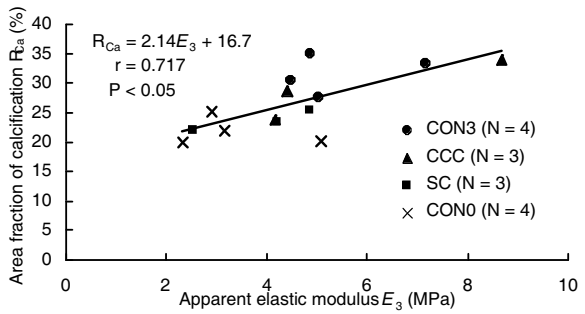

Fig.6 Correlation between calcification and mechanical properties.

III. In situ observation of bone slices during static stretch culture

A. Materials and methods

Specimens: Tibias taken from 2- to 4-day-old chicks were used. Bone slices with a thickness of 200 μm were prepared similarly to the slices used for quantification of the calcification in Chapter II. The slices were then cultured in a stretch apparatus for 24 h in the osteogenic medium used in the cyclic compression culture.

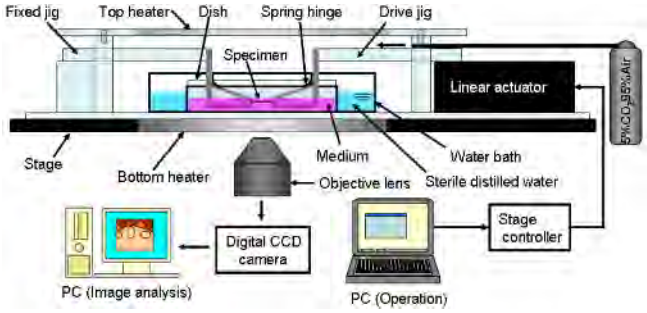

Fig.7 In-situ observation system for bone calcification in culture under stretch stimulation.

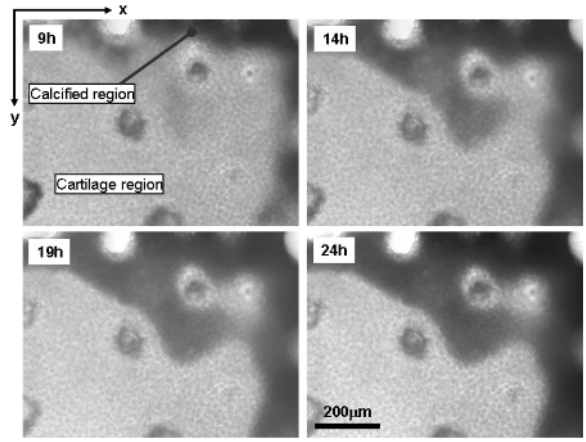
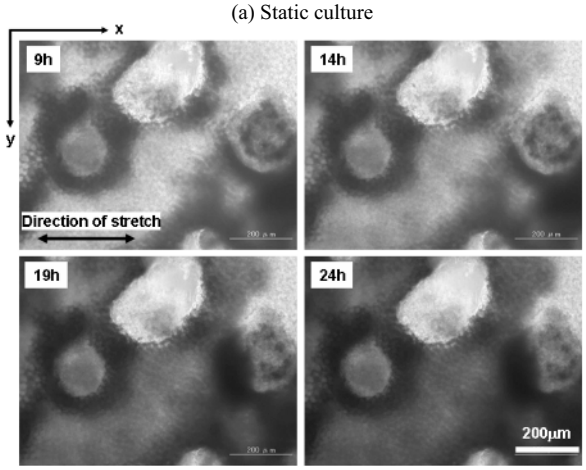
Static Stretch Culture: The apparatus we used for the static stretch culture is shown in Fig. 7. A specimen was held horizontally with two arms via spring hinges under the standard culture condition in a specimen chamber. The specimen can be stretched in a desired pattern by moving a linear actuator (TSDM60-20X, Sigma Koki, Japan) connected to the drive jig that stretches specimen. In this study, the slice was cultured for 24 hours while being stretched statically by 10%.

In Situ Observation of Calcification: Check: Calcified area was identified as a dark region in bright field images. In a preliminary study, we found that calcification did not occur in the first 9 h in culture. The culture chamber was first stored in an incubator for 9 h from the beginning of the culture and then set on the stage of an inverted microscope (IX71, Olympus, Japan) equipped with a digital CCD camera (DP70, Olympus). Bright field images were taken every 10 min from 9 to 24 h in culture. The recorded images were then binarized by an image processing software (ImageJ 1.37, NIH, USA) to obtain calcified area $A_{Ca}(t)$ at time t (h). A calcification ratio $R_{Ca(Carti)}$ was calculated as:



$$R_{Ca(Carti)} = \frac{A_{Ca}(t) - A_{Ca}(9)}{A_{Carti}(9)} \quad (1)$$

where $A_{Carti}(9)$ indicates non-calcified (cartilage) area at 9 h.

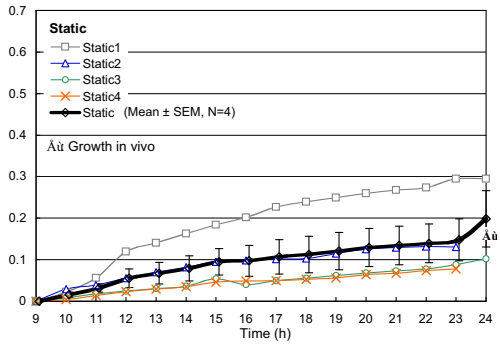


Observation of Collagen Fiber Alignment: Alignment of collagen fibers was visualized with a polarized light microscope (BX51N-33P-O, Olympus). Bone slices were set on the microscope stage under crossed polarized illumination. Polarized images were taken by the digital CCD camera (DP70) while polarizer and analyzer were rotated every 10° from 0 to 90°. All of the images were then superposed to obtain a collagen fiber image in all directions.

B. Results and discussion

The area of calcification was significantly larger in stretched specimens than in the non-stretched control (Figs.8 and 9). Traveling direction of the calcification was roughly equal to the stretch direction (data not shown). Change in the align-

(a) Static culture



(b) Stretch culture

ment of collagen fibers of the sliced specimens in response to stretch was observed with polarized light microscopy in fresh slices while they were stretched gradually. Collagen fibers showed coherent alignment in the stretch direction over 5% of stretch. These results indicate that quasi-static stretch also stimulates calcification especially in the direction of stretch, and the calcification may occur preferentially along the direction of collagen fibers. The alignment of collagen fibers in the stretch direction and facilitated calcification along collagen fibers may have something to do with the alignment of trabecular bone in the direction of principal stress.

IV. Concluding Remarks

We have shown the possibility of inducing mechanical adaptation response in bone tissues cultured under a controlled mechanical environment. *In situ* observation of bone

Abstract — **Sedative side effects of antihistamines have been recognized to be potentially dangerous in car driving, but the mechanism underlying these effects has not yet been elucidated. The aim of the present study is to examine regional cerebral blood flow (rCBF) responses during a simulated car-driving task following oral administration of d-chlorpheniramine using positron emission tomography (PET) and [^{15}O]H_2O. Healthy volunteers drove a car in a simulated environment following oral administration of a sedative antihistamine, d-chlorpheniramine, or placebo. Their rCBF was measured in the conditions of resting, active driving, and passive driving. Performance evaluation revealed that the number of lane deviations significantly increased in the d-chlorpheniramine condition ($p<0.01$). Subjective sleepiness was not significantly different between the two drug conditions. The regions of diminished brain responses were detected following d-chlorpheniramine treatment in the parietal, temporal and visual cortices and in the cerebellum. These results suggest that d-chlorpheniramine tends to suppress visuo-spatial cognition and visuo-motor coordination even when the subjects do not recognize subjective feeling of sedation.**

Keywords — **Positron emission tomography (PET), regional cerebral blood flow (rCBF), sedative antihistamine, driving performance**

I. Introduction

Car driving is one of our everyday tasks and is also a series of complex perceptual and psychomotor tasks that require the integration of various basic neural functions such as attention, visuo-spatial cognition, motor programming and control, and visuo-motor coordination [1, 2]. Cognitive and psychomotor impairments following the administration of sedating drugs can lead to impairment of driving performance, and increase a driver's risk of injury. So far, a number of studies have been conducted to determine the effects on driving behavior following oral administration of psychoactive drugs such as sedative antihistamines [3, 4]. Sedative antihistamines such as diphenhydramine and d-chlorpheniramine can cross the blood-brain barrier and block histamine H_1 receptors (H_1Rs) in the histaminergic neuronal system of the brain, resulting in sleepiness, drowsiness, fatigue and psychomotor disturbances that might result in car injury [1, 2, 5]. A simulated car-driving study by Weiler and colleagues demonstrated that sedative antihistamines had a greater impact on driving performance than alcohol [3]. To elucidate the neural correlates of car-driving, recent neuroimaging studies have employed a simulated driving task using functional magnetic resonance imaging (fMRI)[6-8] and PET [9]. However, no study has revealed the neural mechanism of impaired driving performances due to antihistamines. The main purpose of the present study was, using PET with [^{15}O]H_2O, to examine regional cerebral blood flow (rCBF) responses during car driving following oral administration of d-chlorpheniramine.

II. Study design

A. Subjects And Method

Fourteen healthy Japanese male volunteers ranging from 20 to 25 years old were recruited to the present study. The present protocol was approved by the Ethics Committee of Tohoku University Graduate School of Medicine. Each subject was given d-chlorpheniramine repetab (6 mg) or a placebo (a lactobacteria tablet) in each study. The same subjects were studied for each drug after a wash-out period of at least 6 days. PET scan was started approximately 2 hours following the drug administration. The subjects were requested to drive a car, wearing a head-mounted display (HMD: Glasstron PLM-A35, SONY, Tokyo, Japan) to enable them to watch the projected "in-car" views of the outer world (Figure 1). The intravenous infusion line for [^{15}O]H_2O injection was inserted into a subject's right antecubital vein. For a simulated driving task, a commercial

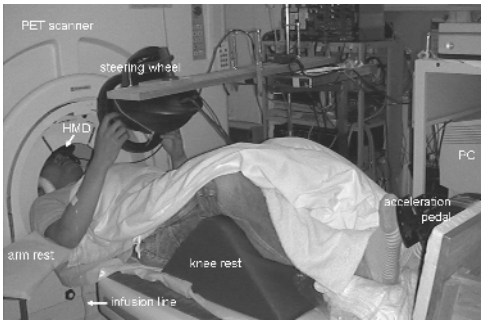

Figure 1. Setting of PET experiment on simulated car-driving (reproduced from the ref. [5] by the courtesy of John Wiley & Sons, Ltd.)

computer software (Gekisoh99, Twilight Express Co., Ltd., Tokyo, Japan) was used. The subjects were requested to drive smoothly as in normal car driving, but also as fast as possible from the start to the goal point, avoiding collision and deadlocks.

The rCBF images were obtained at the whole brain level using a PET scanner (SET 2400W, Shimadzu Co., Ltd., Japan). PET rCBF images were compared under the following 3 conditions: 1) "resting", 2) "active driving" where the subjects drove, and 3) "passive driving" conditions where the subjects watched the changing in-car view that had been videotaped previously, respectively. Performance of the subjects was evaluated in terms of the following 4 criteria: (a) total duration (sec) of driving from the start to the goal point, (b) number of collisions, (c) number of lane deviations, and (d) number of deadlocks. Additionally, subjective sleepiness was also evaluated using the Stanford Sleepiness Scale (SSS)(Figure 2).

The rCBF images were processed and analyzed using a Statistical Parametric Mapping (SPM) software package (SPM99)[10]. The resulting set of voxel values for each contrast constitutes a statistical parametric map of the t-statistics. We compared rCBF changes during active driving compared to the resting between the d-chlorpheniramine and placebo conditions. We determined the localization of the peak activation related to the active driving condition as compared with the resting and passive driving conditions.

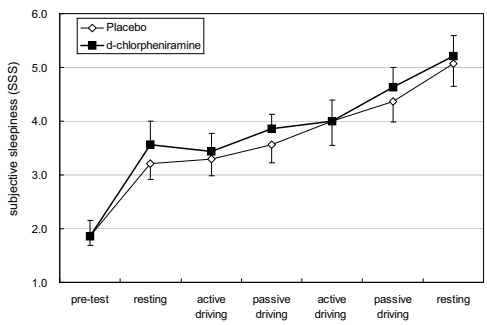

Figure 2. Subjective sleepiness measured using SSS. (reproduced from the ref. [5] by the courtesy of John Wiley & Sons, Ltd.)

III. Results

In all 14 subjects, performance evaluation revealed that the number of lane deviations significantly increased in the d-chlorpheniramine condition compared with the placebo condition (mean ± S.E.M.: 2.57 ± 0.60 vs. 6.36 ± 1.80, respectively: $p < 0.01$) though all other performances measures demonstrated no significant differences. Subjective sleepiness was not significantly different between the two drug conditions (Figure 2). Each performance score and the sleepiness scores did not correlate significantly.

Regions with increased rCBF during the active driving condition compared to the resting and the passive driving conditions were detected in the primary sensorimotor, premotor, cingulate, posterior parietal, temporal, and occipital cortices and in the cerebellar hemisphere, etc. (Figure 3). Lower rCBF following d-chlorpheniramine treatment was observed in the bilateral frontal, right parietal, bilateral temporal and bilateral insular cortices.

Finally, the intensity of rCBF alteration [active driving] – [resting]) were compared between the d-chlorpheniramine and placebo conditions. The regions with decreased rCBF following d-chlorpheniramine treatment were detected in the bilateral parietal, temporal, and occipital cortices (Figure 3).

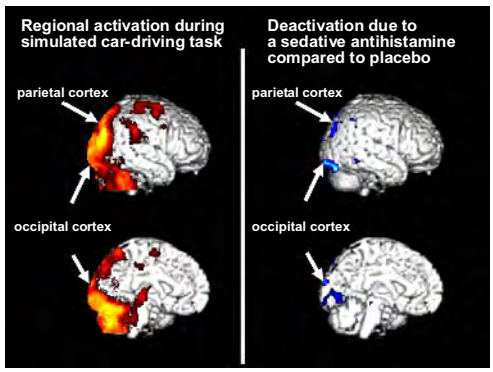

Figure 3. Results of PET analysis demonstrating regional activation during active driving compared to the resting (yellow & red), and regions with diminished activation under the influence of sedative antihistamine (blue).(reproduced from the ref. [5] by the courtesy of John Wiley & Sons, Ltd.)

IV. Discussions & Conclusion

Antihistamines are potentially dangerous agents to drivers, and a large number of studies have demonstrated their

effects on driving behaviors [1, 3, 4]. Their main therapeutic target in various allergic disorders is H1Rs in the peripheral blood; however, sedative antihistamines can easily cross the BBB and block the H1Rs of neurons in the brain, resulting in sedation characterized by sleepiness, drowsiness, fatigue and psychomotor disturbances [5]. Ironically, sedative antihistamines are more easily available over the counter than newer less-sedating antihistamines [3]. So far, neural correlates of car driving have been demonstrated using fMRI and PET and the reproducibility of the findings was demonstrated in the present study as well by comparing with the results of other studies. [6-9].

For the evaluation of impaired driving performance due to sedative antihistamines, Weiler and colleagues demonstrated that a steering stability was impaired by both alcohol and diphenhydramine, whereas coherence ability was impaired following only the administration of diphenhydramine [3]. In the present study, impaired performance (increased lane deviations) was demonstrated following d-chlorpheniramine treatment. In addition, this result suggests that subjective sleepiness is not always a reliable measure of sedation and that driving performance can be impaired among drivers even when they themselves do not recognize sedation. The present study demonstrated the presence of regions with significantly "diminished" rCBF responses following d-chlorpheniramine treatment in the posterior parietal, temporal, occipital regions as well as in the cerebellum. Thus, the present results suggest that d-chlorpheniramine suppresses neural activities associated with visuo-spatial cognition and visuo-motor coordination. In general, visual information projected onto the occipital cortex is transferred to the posterior part of the parietal cortex via the dorsal pathway for higher visual processing of motion and visuo-spatial information.

Abstract — **Our purpose was to evaluate exercise-induced organ glucose metabolism using ^{18}F-2-fluoro-2-deoxyglucose ([^{18}F]FDG and three-dimensional positron emission tomography technique (3D-PET), comparing two analytical procedures. Eleven healthy male subjects were studied as controls (n=6) and exercise group (n=5). Exercise group subjects performed ergometer bicycle exercise for 40 minutes at 40% and 70% $\dot{V}O_{2max}$. [^{18}F]FDG (39.2 ± 2.6 MBq) was injected 10 min after exercise. A whole body 3D-PET scan was performed immediately after exercise using PET scanner (SET-2400W, Shimadzu Co. Kyoto, Japan). PET image data was reconstructed by filtered 3D back projection algorithm with supercomputer (SX-4/128H4, Synergy Center, Tohoku Univ). Controls were studied using identical study criteria with exercise group. Two analytical procedures, semiquantitative (standardized uptake value; SUV) and quantitative (regional metabolic rate of glucose; rMRGlc) [Autoradiographic method (Phelps et al.)] were applied to assess organ glucose metabolism. ROIs (regions of interest) were drawn on lower limb muscles (e.g., thigh and lumbar/gluteal muscles) and viscera (e.g., liver, heart and brain). To compare analytical procedures, correlation coefficient analysis was done between SUV and rMRGlc data of lower limb muscles, brain and heart. Quantitative analysis revealed that rMRGlc was increased ($p<0.05$) in skeletal muscles of thigh and lumbar/gluteal region, and decreased in brain ($p<0.05$) at mild or moderate exercise loads. Semiquantitative analysis revealed the identical results except in lumbar/gluteal muscles. It was found a correlation between SUV and rMRGlc at thigh, brain and heart, however; correlation was not suggestive at lumbar/gluteal muscles. We validated the semiquantitative procedure (SUV) taking absolute quantification method of glucose metabolic rate as a standard. It was observed, the rMRGlc was increased in thigh muscles and decreased in brain at mild or moderate workloads. However, discrepancies between SUV and rMRGlc in one organ demonstrate, semiquantitative approach needs a great care when metabolic rate of glucose utilization changes at whole-body level.**

Keywords — **[18F]FDG-3DPET, Exercise, Glucose-Metabolism, Semiquantification, Autoradiography.**

I. Introduction

Previous reports [1, 2] employed semiquantification method (standardized uptake values: SUV) to reveal organ glucose metabolic changes after exercise task, using ^{18}F-2-fluoro-2-deoxyglucose and three-dimensional positron emission tomography technique ([^{18}F]FDG and 3DPET). Recently, Kemppainen J. and co-workers assessed the glucose metabolism of lower limb skeletal muscle and myocardium using absolute quantification method (rMRGlc) [3]. However, no reports have evaluated whole-body glucose metabolic changes after exercise using 3D-PET technique, comparing semiquantitative and quantitative analytical methods.

Our purpose was to evaluate workloads-induced whole-body organ glucose metabolism using two analytical methods (semiquantitative and quantitative), as to establish a relationship between two PET quantification procedures.

II. Study design

A. Subjects

Eleven healthy male volunteers collaborated with this investigation. All subjects abstained from eating and drinking for at least 5 hours before the experiment. They were asked not to perform any kind of physical exercise from one day before investigation. 5 subjects served as exercise group whose ages ranged from 21 to 23 y (21.80 ± 0.84 y; mean ±S.D.). Another 6 subjects, aged mean 24 ± 5.34 y (range; 19 ~ 33 y) were studied as resting control maintaining the same study protocol without exercise. [^{18}F]FDG dose for control was in average 42.48 ± 6.63 MBq (mean ± S.D.). A written fully informed consent was obtained from each subject before the study. This study protocol was approved by the Clinical Committee for Radioisotope Studies of Tohoku University.

B. Study Protocol

Ergometer bicycle exercise was arranged at 40% and 70% $\dot{V}O_{2max}$ workloads. $\dot{V}O_{2max}$ was measured by intermit-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2204–2206, 2009
www.springerlink.com

tent exercise on an ergometer bicycle (Monark 818E, Sweden), and oxyzen consumption rate was determined by an automated metabolic unit machine (AE280-S, Minato Co. Ltd. Osaka, Japan). Before the experiment, subjects rested for 20 minutes in a dim lit quiet room. One teflon catheter was inserted to their antecubital veins of the left hand for blood sampling to measure plasma glucose, lactate and insulin. Another teflon catheter was inserted to opposite antecubital veins for [^{18}F]FDG administration. Then, they started ergometer bicycle riding at the speed of 60 revolution/min (Monark 818E, Sweden) at both workloads (40% and 70% $\dot{V}O_{2max}$). [^{18}F]FDG was injected through a catheter at 10 min later following exercise task. The radioactivity dose for the exercise group was 38.37 ± 2.15 MBq (mean ± S.D.). After injection, subjects continued to pedal the bicycle for another 30 min, completing a total of 40 min task. Immediately after intravenous administration of [^{18}F]FDG, heated arterialized venous blood was sampled from cubital vein opposite to the injection site. Plasma [^{18}F]FDG concentrations were measured both during exercise and PET scan for 24 times. Plasma metabolite concentrations (i.e., Glucose, lactate and insulin) were measured at two points such as pre and post exercise states.

Subjects lay down in supine position on PET table with eyes open following exercise task. The PET room was kept dimmed and quiet. The scan protocol was as follows: a 3 dimensional (3D) whole-body emission scan (3 min × 9F) was performed from knee to the vertex followed by transmission scan (3 min × 9F) using a PET apparatus (SET2400W, Shimadzu, Kyoto, Japan). The transmission scan (post-injection mode) was performed with a ^{68}Ge/^{68}Ga external rotating line source (370 MBq at purchase).

C. Quantitative Methods

Regions of interest (ROIs) were set on the skeletal muscles of thigh, lumbar/gluteal regions, and visceral organs such as liver, heart and brain etc. (Figure 1). To evaluate the rate of glucose utilization, an autoradiographic method [4] was applied using the following equation:

$$rMRGlc = \frac{Cp}{LC}\left[\frac{K^*_1 k^*_3}{k^*_2 + k^*_3}\right]\left[\frac{C^*i(T) - C^*e(T)}{C^*m(T)}\right]$$

In another, semiquantitative analysis (Standard uptake value; SUV) was done by using the following equation:

$$\frac{Mean\ ROIcts\ (cps/pxls) \times Body\ weight(g)}{Injected\ dose\ (\mu Ci) \times Calibration\ factor\ (cps/\mu Ci)}$$

D. Statistical Analysis

Group comparisons were done by using one-way analysis of variance (ANOVA) and Tukey's test (post-hoc) analysis. The significant differences were set at $p<0.05$. Correlation was calculated using Pearson's correlation coefficient analysis.

III. Results

[^{18}F]FDG uptake was only remarkable in the brain, heart and urinary bladder in the resting subject, while high uptake was visualized in skeletal muscles at exercise state (Figure 1). Glucose metabolism (SUV and rMRGlc) was increased in the skeletal muscles of thigh and lumbar/gluteal regions ($p<0.05$), and was decreased in the brain ($p<0.05$) after exercise task (40% and 70% $\dot{V}O_{2max}$ workloads). A correlation between SUV and rMRGlc was found among organs (i.e., Thigh, liver, heart and brain), except in the lumbar/gluteal muscles. Figure 2 clearly depicted a good correlation between SUV and rMRGlc in the brain; however, a non-suggestive correlation was found in the lumbar/gluteal skeletal muscle. The changes in plasma metabolites were as follows: stable plasma glucose concentrations, an increase ($p<0.05$) plasma lactate concentration at post-exercise condition of 70% $\dot{V}O_{2max}$ (5.3 ± 2.4 mmol/liter) to compare with pre-exercise condition (0.9 ± 0.2 mmol/liter). The plasma insulin concentration was decreased ($p<0.05$) only at post-exercise workload of 70% $\dot{V}O_{2max}$ (2.0±0.7 μU/mol) than pre-exercise condition (4.6±1.5 μU/mol).

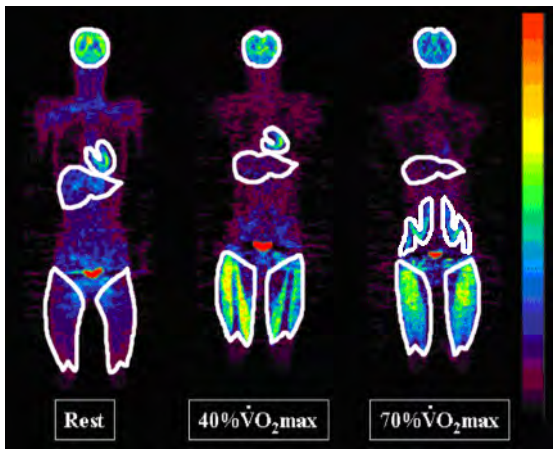

Figure 1. ROIs procedure and [^{18}F]FDG uptake of individual organs at rest (left) and exercise loads ; 40% and 70% $\dot{V}O_{2max}$ (right).

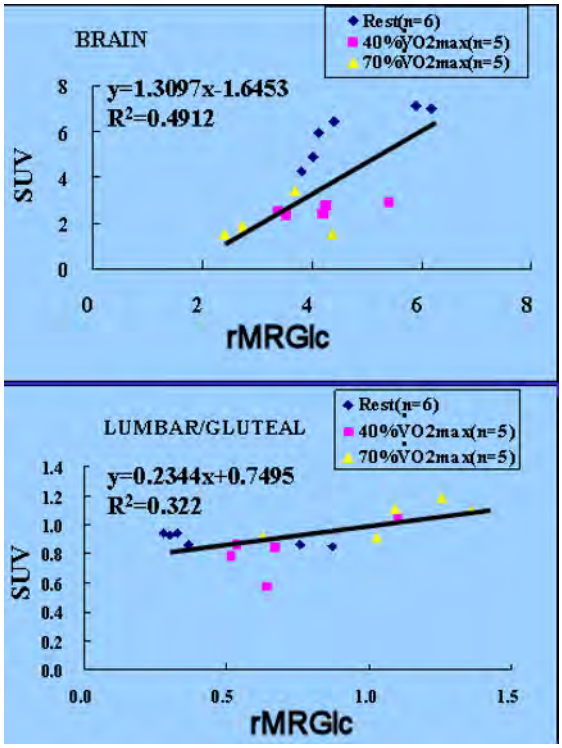

Figure 2. Correlation between SUV and rMRGlc in the brain and lumbar/gluteal muscles, showing good correlation in the brain and non-suggestive correlation in the lumbar/gluteal skeletal muscles.

IV. Discussions & Conclusion

Organ glucose uptake either increased or decreased almost linearly with exercise loads up to moderate workload (70% $\dot{V}O_{2max}$). In spite of complexity of energy metabolic controls such as glucose-fatty acid metabolic interaction, aerobic-anaerobic interaction, and involvement of glycogenolysis [5], exercise-induced organ glucose metabolism were successfully assessed with [^{18}F]FDG-3DPET technique and two analytical approaches. Organ glucose uptake either increased or decreased almost linearly with exercise loads up to moderate workload (70% $\dot{V}O_{2max}$), suggesting of homeostatic metabolic control. Semiquantitative method without blood samplings was found useful to estimate a rough trend of glucose consumptions. However, one organ failed to have good correlations between SUV and rMRGlc, the lumbar and gluteal muscles for example, which demonstrates that semiquantitative approach needs a great care when metabolic rate of glucose utilization changes at whole-body level.

Strain Imaging of Arterial Wall with Reduction of Effects of Variation in Center Frequency of Ultrasonic RF Echo

Hideyuki Hasegawa[1,2] and Hiroshi Kanai[2,1]

[1] Graduate School of Biomedical Engineering, Tohoku University, Sendai, Japan
[2] Graduate School of Engineering, Tohoku University, Sendai, Japan

Abstract — **Atherosclerotic change of the arterial wall leads to a significant change in its elasticity. For assessment of elasticity, measurement of arterial wall deformation is required. For motion estimation, correlation techniques are widely used, and we developed a phase-sensitive correlation method, namely, the *phased-tracking method*, to measure the regional strain of the arterial wall due to the heartbeat. Although phase-sensitive methods using demodulated complex signals require less computation in comparison with methods using the correlation between RF signals or iterative methods, the displacement estimated by such phase-sensitive methods are biased when the center frequency of the RF echo apparently varies. One of the reasons for the apparent change in the center frequency would be the interference of echoes from scatterers within the wall. In the present study, a method was introduced to reduce the influence of variation in the center frequencies of RF echoes on the estimation of the artery-wall strain when using the phase-sensitive correlation technique. The improvement in the strain estimation by the proposed method was validated using a phantom. The error from the theoretical strain profile and the standard deviation in strain estimated by the proposed method were 12.0% and 14.1%, respectively, significantly smaller than those (23.7% and 46.2%) obtained by the conventional phase-sensitive correlation method. Furthermore, in the preliminary *in vitro* experimental results, the strain distribution of the arterial wall well corresponded with pathology, i.e., the region with calcified tissue showed very small strain, and the region almost homogeneously composed of smooth muscle and collagen showed relatively larger strain and clear strain decay with respect to the radial distance from the lumen.**

Keywords — **ultrasound, center frequency, phase shift, radial strain of arterial wall, elasticity**

I. Introduction

We have developed a phase-sensitive correlation method, namely, *phased-tracking method*, for estimating the displacement distribution in the arterial wall for strain imaging [1]. In such methods, ultrasonic pulses with finite frequency bandwidths are used. Therefore, the apparent change in center frequency occurs due to the interference of echoes from scatterers in the wall. Under such a condition, the displacement estimates are biased because it is obtained using the phase changes and center frequencies of received RF echoes. An autocorrelation-based method was proposed to compensate for this apparent change in center frequency [2,3]. In this method, center frequency distributions in two frames must be assumed to be the same. However, they become different when the scatterer distribution is changed by the artery-wall deformation.

In this study, a new method using the phase-sensitive correlation technique, which does not require the assumption that center frequency distributions in two different frames are the same, was examined for reducing the influence of center frequency variation on the estimation of artery-wall strain. The improvement of accuracy by the proposed method was validated using a cylindrical phantom. Furthermore, preliminary *in vitro* experimental results were obtained and are herein presented [4].

II. Methods

A. Displacement estimation using conventional autocorrelation methods

The phases of echoes from a moving target, which is located at depth d in the initial frame, are different in two consecutive n-th and (n+1)-th frames. This phase shift, $\Delta\theta_d(n)$, depends on the displacement of the target between these two frames. Therefore, the instantaneous displacement $\Delta x_d(n)$ between these two consecutive frames is estimated as follows:

$$\Delta x_d(n) = \frac{c_0 \Delta\theta_d(n)}{4\pi f_{0e}}, \tag{1}$$

where c_0 and f_{0e} are the speed of sound and the frequency used for displacement estimation, respectively. Phase shift $\Delta\theta_d(n)$ is estimated by the complex cross-correlation function $\gamma_{d,n}$ using the complex quadrature demodulated signals $z(d; n)$ of received RF echo as follows:

$$\Delta\theta_d(n) = \angle\gamma_{d,n} = \sum_{d\in R} z^*(d + x_d(n); n) \cdot z(d + x_d(n); n+1), \tag{2}$$

where * shows the complex conjugate. The accumulated displacement $x_d(n)$ is obtained by accumulating the instantaneous displacement with respect to time.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2207–2210, 2009
www.springerlink.com

B. Translational motion compensation

The translational motion of the wall is compensated by tracking the echo from the luminal interface using the conventional method described in Sec. II-A because the echo from the luminal interface is dominant and is less influenced by the interference from other echoes from scatterers in the wall. In this study, *key frames* are defined as the frames at which the estimated displacement of the luminal interface $\Delta x_{d=l}(n)$ reaches the integral multiple of the spacing of the sampled points ΔX. Figures 1(a) and 1(b) shows the RF echoes from the cylindrical phantom used in this study in two successive *key frames*. The region of interest (ROI) is manually assigned in the initial frame and, then, its position at each time is automatically determined by estimating the displacement of the luminal interface (the nearest edge of the ROI). The displacement of the luminal interface between two successive *key frames* is almost a spacing of sampled points, and the translational motion can be compensated by shifting the ROI by one point as shown in Figs. 1(c) and 1(d). After translational motion compensation, the phase shift $\Delta\theta_d(n)$, which is caused by the displacement contributing to strain, of echoes between these two *key frames* is estimated at each depth d along the arterial radial direction, and the displacement distribution $\{x_d(n)\}$ is obtained from $\Delta\theta_d(n)$ using eq. (1). Finally, strain distribution is obtained by the spatial differentiation of displacements $\{x_d(n)\}$ in the arterial radial direction.

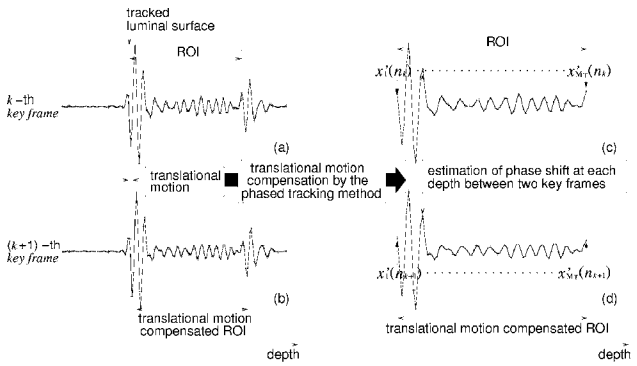

Fig. 1 Displacement estimation with translational motion compensation. Original RF signals in two consecutive (a) k-th and (b) (k+1)-th key frames. Translational motion compensated RF signals in (c) k-th and (d) (k+1)-th frames.

C. Error correcting function

After compensation of translational motion, the displacement contributing to strain is estimated using the phase shift of RF echoes. In such a situation, a large error resulting from the translational motion is removed, but error due to the mismatch between the frequency used for displacement estimation and the actual center frequency still remains in the estimation of the displacement contributing to strain even after the compensation of translational motion. In the present study, an error correcting function is introduced to further reduce this error. The error correcting function $\beta_{d,k}$ in k-th *key frame* (n_k-th frame) is defined as follows:

$$\beta_{d,k} = \frac{\dfrac{c_0}{4\pi f_{0e}}\left|\angle\left(\gamma'_{d,k}\cdot\gamma^*_{d,k}\right)\right|}{\Delta X}, \tag{3}$$

$$\gamma'_{d,k} = \sum_{d\in R} z^*(d + x_l(n_k); n_k)\cdot z(d + x_l(n_k); n_{k+1}), \tag{4}$$

$$\gamma_{d,k} = \sum_{d\in R} z^*(d + x_l(n_k); n_k)\cdot z(d + x_l(n_{k+1}); n_{k+1}), \tag{5}$$

where ΔX is the spacing of sampled points. *Key frames* are assigned so as to be $|x_l(n_{k+1})-x_l(n_k)|=\Delta X$, and the signal $z(d+x_l(n_k);\ n_{k+1})$ in $\gamma_{d,k}$ is artificially displaced by a spacing of sampled points in comparison with $z(d+x_l(n_{k+1});\ n_{k+1})$ in $\gamma'_{d,k}$. Based on eq. (1), this artificial displacement can be expressed as $c_0|\angle(\gamma'_{d,k}\cdot\gamma^*_{d,k})|/4\pi f_0$ by the difference between angles $\angle\gamma'_{d,k}$ and $\angle\gamma_{d,k}$ of $\gamma'_{d,k}$ and $\gamma_{d,k}$, and it should be ΔX. Equation (3) shows the ratio of the artificial displacement estimated by the phase shift $c_0|\angle(\gamma'_{d,k}\cdot\gamma^*_{d,k})|/4\pi f_0$ to actual one ΔX. The error-corrected displacement $\Delta x_{c,d}(n_k)$ between n_k-th and n_{k+1}-th key frames contributing to strain can be obtained as follows:

$$\Delta x_{c,d}(n_k) = \frac{1}{\beta_{d,k}}\frac{c_0}{4\pi f_{0e}}\angle\gamma_{d,k}. \tag{6}$$

The displacement distribution is obtained by estimating the displacement $x_{c,d}(n)$ at each depth d which corresponds to the arterial radial direction. Finally, strain distribution is obtained by estimating the regional slope of the displacement distribution using the least-squares method [4].

D. Experimental setup

In this study, a cylindrical phantom and excised artery were measured by ultrasound. The outer and inner diameters of the phantom, made of silicone rubber (elastic modulus E: 749 kPa), are 10 and 8 mm, respectively. The phantom contains 5% carbon powder (by weight) to obtain sufficient scattering from the inside of the wall.

Figure 2 shows a schematic diagram of the measurement system. A change in pressure inside the phantom or artery was induced by circulating a fluid using a flow pump. The change in internal pressure was measured by a pressure sensor (NEC, Tokyo, 9E02-P16).

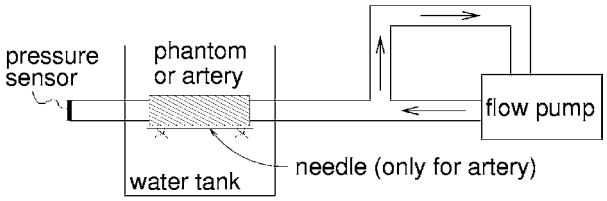

Fig. 2 Experimental system.

Pressure-diameter testing was applied to the phantom to obtain the elastic modulus of silicone rubber. In the pressure-diameter testing, the change in external diameter of the phantom was measured with a laser line gauge (VG-035, KEYENCE, Osaka, Japan).

In ultrasonic measurement, the phantom and artery were measured with a linear-type ultrasonic probe (Aloka, Tokyo, SSD-6500). The nominal center frequency was 10 MHz. RF echoes were acquired at 40 MHz at a frame rate of 286 Hz.

In the *in vitro* experiment, a femoral artery excised from a patient with arteriosclerosis obliterans was measured. The artery was placed in a water tank filled with 0.9% saline solution at room temperature. A needle was attached to the external surface of the posterior wall using strings to identify the section to be imaged during the ultrasonic measurement. After the ultrasonic measurement, the pathological image of the measured section was obtained by referring to the needle.

III. Basic Experimental Results

Figure 3(a) shows the strain distribution along the ultrasonic beam (the radial direction of the phantom) estimated by the conventional autocorrelation method [1]. Plots and vertical bars show means and standard deviations of 46 individual ultrasonic beams. The dashed line shows the theoretical strain profile, which is obtained by the measured internal pressure and elastic modulus (E =749 kPa) of the wall measured by the pressure-diameter testing, given by [5]

$$\varepsilon_r = -\frac{3}{2}\frac{r_i^2 r_o^2}{\left(r_o^2 - r_i^2\right)r}\frac{p}{E}, \tag{8}$$

where r_i and r_o are the original inner and outer radii, respectively.

Although mean values follow the theoretical strain profile, the standard deviations of strains estimated by the conventional method [1] are large. In Fig. 3(b), the center frequency estimation proposed in [2] was used together with the conventional method [1]. However, the strain estimates are not improved so much. Figure 3(c) shows the strain distribution obtained by the proposed method. Strain estimates were improved significantly by translational motion compensation and error correction.

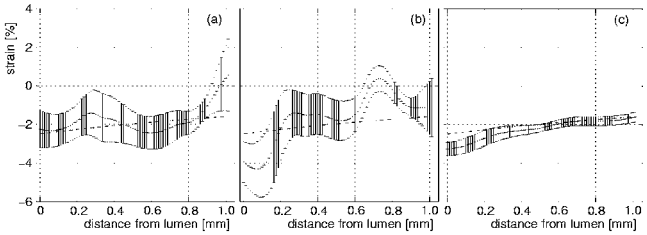

Fig. 3 Estimated strain distribution. (a) Conventional method [1]. (b) Conventional method with center frequency estimation [2]. (c) Proposed method with translational motion compensation and error correction.

IV. In Vitro Experimental Results

Figure 4(a-1) and 4(b-1) show the B-mode images of two different regions in the excised femoral artery. The region shown in Fig. 4(a-2) shows very low strain. On the other hand, the region shown in Fig. 4(b-2) shows relatively larger strain, and there is a clear strain decay with respect to the distance from the lumen [5]. Figures 4(a-3) and 4(b-3) show the elasticity images obtained by eq. (8) using the measured internal pressure and estimated strain distributions. By comparing the elasticity images and pathological images of the corresponding sections shown in Figs. 4(a-4), 4(b-4), 4(a-5), and 4(b-5), the very hard region surrounded by the green line in Fig. 4(a-3) corresponds to calcified tissue. On the other hand, the region composed of smooth muscle and collagen shows a relatively homogeneous and lower elastic modulus distribution. These results show that the proposed method successfully reveals the difference in the deformation properties resulting from different tissue compositions.

V. Discussion

The estimation of stress distribution in the arterial wall is one of the most difficult problems. In our study [6], the stress distribution in the arterial wall was assumed to be constant. Even in the case of a homogeneous cylindrical shell, the stress (strain) distribution is dependent on the distance from luminal surface. When an artery is a homogeneous cylindrical shell, the stress (strain) distribution can be theoretically derived based on eq. (8). However, it is difficult to estimate the stress (strain) distribution when an artery is inhomogeneous in the wall thickness and elastic properties. Therefore, in our study, the average stress was used to normalize the measured strain.

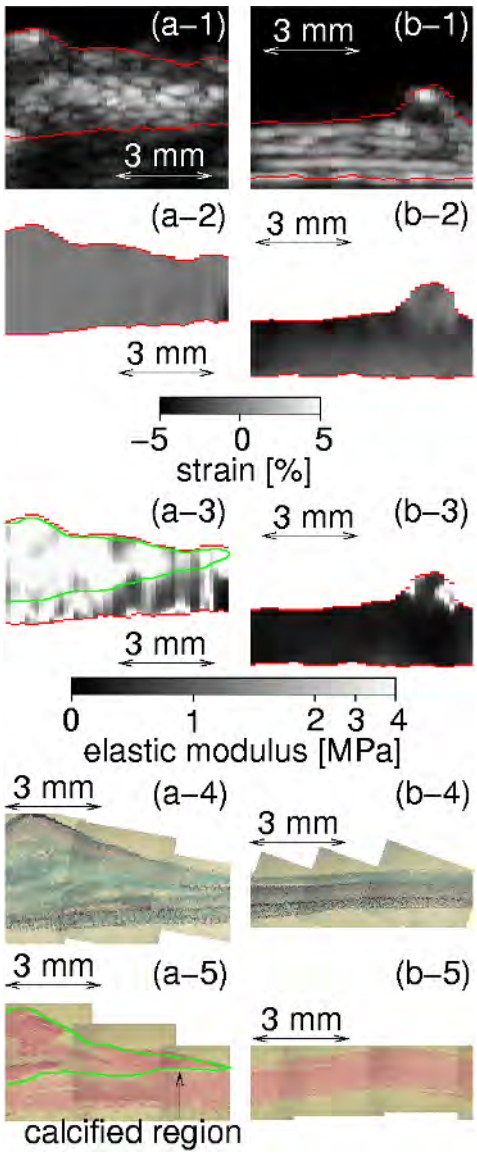

Fig. 4 *In vitro* experimental results for two regions in an excised femoral artery: (a) region with calcified tissue and (b) that without calcified tissue and composed of smooth muscle and collagen; (1) B-mode images, (2) strain images, (3) elasticity images, and (4) and (5) pathological images with elastica-Masson and hematoxilin-eosin staining, respectively.

This strategy is effective to compensate for the dependence of strain on the pulse pressure. When only the strain itself is considered to evaluate the elasticity, the strain is dependent on the pulse pressure which does not relate to the elasticity. As described in this paper, use of the stress distribution of a cylindrical shell given by eq. (8) is another solution to compensate for the pulse pressure variation.

VI. Conclusions

In the displacement estimation based on the phase changes of echoes, the displacement estimates are biased when the center frequency of the RF echo changes. Such an apparent change in the center frequency could be caused by the interference of echoes from scatterers. To reduce the influence of the center frequency variation on the estimation of artery-wall strain, in this study, an error correcting function, which does not require the assumption that the center frequency distributions in two different frames are the same, was introduced. As a result, the proposed method provides better strain estimates in comparison with conventional phase-sensitive correlation methods.

In Situ Analysis of DNA Repair Processes of Tumor Suppressor BRCA1

Leizhen Wei and Natsuko Chiba

Department of molecular immunology, Institute of Development, Aging and Cancer (IDAC), Tohoku University, Japan

Abstract — **Germline mutations in the breast cancer susceptibility gene BRCA1 predispose women to breast and ovarian cancer. BRCA1 is involved in many cellular processes, DNA repair, transcription, cell cycle, chromatin remodeling, and apoptosis. Although the tumor suppressor activity of BRCA1 seems to be attributed to its involvement in DNA repair system, its mechanism is still unclear. We have established a laser light micro-irradiation system to create various types of DNA damage in living cells including DNA double-strand breaks (DSBs), single-strand breaks (SSBs), and base damage, which has enabled us to detect BRCA1 accumulation at the site of DNA damage in a real-time course. Furthermore, we generated local UV irradiation in cell nuclei by an isopore membrane filter and analyzed the BRCA1 response to UV irradiation by immunocytochemistry. We found that the N and the C-terminus of BRCA1 independently accumulated at DSBs with distinct kinetics. N-terminal BRCA1 accumulated immediately after laser-irradiation at DSBs and dissociated rapidly. In contrast, the C-terminus of BRCA1 accumulated more slowly at DSBs, but remained at the sites. Interestingly, the N and the C-terminus of BRCA1 accumulate at the site of DSBs, dependent on distinct repair factors. Furthermore, we found that BRCA1 accumulates at SSBs via its C-terminus. These demonstrate that different BRCA1 interactions with repair factors influence its multifunction in DNA repair. Furthermore, BRCA1 immediately accumulated at the locally UV-irradiated sites. The accumulation was abrogated by treatment with transcription inhibitors. BRCA1 accumulates to the UV irradiated sites via its N and C-terminus. The BRCA1 accumulation was dependent on the presence of another DNA repair protein, which is involved in transcription coupled repair. These finding suggest that BRCA1 is involved in transcription coupled repair pathway. These precise analyses of BRCA1 DNA repair function will contribute to the development of molecular diagnosis and molecular targeting therapies for personalized medicine.**

Keywords — **BRCA1, DNA damage.**

I. Introduction

Breast-cancer susceptibility gene 1 (*BRCA1*) was identified in 1994 by positional cloning [1]. *BRCA1* encodes 1863 amino acids (a.a.), and more than 200 different *BRCA1* germ-line mutations associated with cancer susceptibility have been identified. Carriers of *BRCA1* mutations also have increased susceptibility to ovarian cancers; the risk of breast cancer development is about 50-80%, and that of ovarian cancer development is 12-60%, in *BRCA1* mutation carriers. *BRCA1*-related breast cancers are characterized by an early onset, a high frequency of bilateral involvement, and a poor prognosis.

Somatic *BRCA1* mutations are rarely observed in sporadic breast cancers. However, *BRCA1* mRNA and protein expressions are downregulated in about 30% of sporadic breast cancers and 70% of ovarian cancers. Therefore, the reduced expression or function of *BRCA1* is thought to be an important contributing factor in sporadic cancers.

BRCA1 contains a RING domain in its amino (N)-terminus and two tandem BRCT domains in its carboxy (C)-terminus. The BRCT domain is frequently found in DNA repair proteins, and functions as a binding module for phospho-serine peptides. BRCA1 has also a nuclear export signal (NES), a nuclear localization signal (NLS), and a DNA-binding region. After DNA damage, BRCA1 is phosphorylated by Chk2 or ATM (Fig. 1). The N-terminal region of BRCA1 directly interacts with BARD1, thereby enhancing the ubiquitin polymerase activity of BRCA1 [2,3].

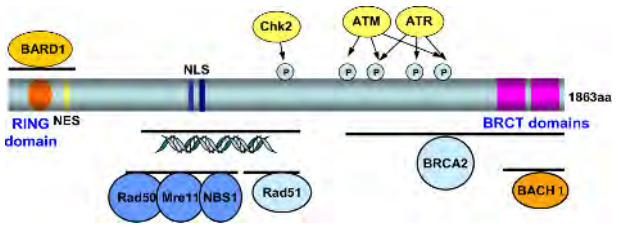

Fig. 1 Structure of the BRCA1 protein. BRCA1 contains an N-terminal RING domain, a nuclear export signal (NES), a nuclear localization signal (NLS), a DNA binding region, and two C-terminal BRCT domains. BRCA1 is associated with a number of proteins, as indicated. Sites phosphorylated by Chk2 or ATM are indicated by arrows.

BRCA1 has been implicated in a number of cellular processes, including the regulation of DNA damage repair, transcription, cell cycle, chromatin remodeling, and apoptosis. Among various function of BRCA1, the tumor suppressor activity of BRCA1 is to be primarily attributed to its involvement in DNA repair. However, the precise mechanism of what role BRCA1 plays in DNA repair pathway is not fully understood. So, we are collaborating with Dr. Akira Yasui, Department of Molecular Genetics, Institute of

Development, Aging and cancer, Tohoku University, and are analyzing the cellular response of BRCA1 to various DNA damage using molecular imaging technique.

II. Results

1 BRCA1 response to various DNA damage induced by laser micro-irradiation

1.1 Laser micro-irradiation system

To elucidate the molecular mechanisms of DNA repair processes for various DNA damage of BRCA1, we are analyzing the BRCA1 accumulation at the DNA damaged site induced by laser micro-irradiation in living cells.

Our experimental system is a laser micro-irradiation apparatus combined with a confocal microscopy. We use a 365nm pulse laser system for the irradiation of cells in the epi-fluorescence path of the microscope system. A lower dose or higher dose of irradiation was obtained by passing lasers through distinct filters in front of the lens. A 405nm pulse laser system is also used. The power of laser scan can be controlled by the number of scan (Fig. 2). By using these system, various types of DNA damage, such as single-strand breaks (SSBs), double-strand breaks (DSBs) and oxidative base damage, were produced at restricted nuclear regions of cells [4, 5].

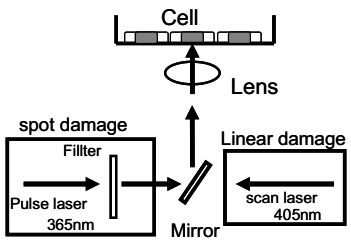

Fig. 2 Laser micro-irradiation systems. The left column shows the 365 nm pulse laser irradiation system, producing the lower dose and the higher dose irradiation, which are regulated by the filter in front of the mirror. The right column shows the 405 nm laser system. Fluorescent images were obtained and processed using an FV-500 confocal scanning laser microscopy system. A 405 nm scan laser system for irradiation of cells in the epifluorescence path of the microscope system was used. One scan of the laser light at full power delivers approximately 1600 nW. To primarily induce DSBs, we scanned cells 500 times using the 405 nm laser at full power, which has been shown The 405 nm laser light was focused through a 40× objective lens.

We found that BRCA1 accumulates at various DNA damage sites induced by laser-irradiation using this system.

1.2 BRCA1 localizes at DSBs via its N- and C-terminal regions

We next examined the real time localization of GFP-tagged BRCA1 in living cells after laser-irradiation. GFP-BRCA1 was transfected into Saos-2 cells and the cells were then laser-irradiated. As shown in Figure 3, GFP-BRCA1 clearly accumulated at the irradiated sites.

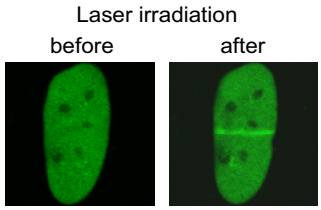

Fig. 3 GFP-tagged BRCA1 accumulates at DSB sites in Saos-2 cells.

We identified the regions in BRCA1 that mediate this accumulation. Several GFP-tagged deletion mutants of BRCA1 were constructed and transfected into Saos-2 cells. We identified that either the N- or C-terminal region alone is sufficient for BRCA1 accumulation at DSBs.

The mean intensity of GFP-BRCA1 at the accumulation site was quantified and the kinetics of accumulation of full-length and a.a.1-304 and a.a.1527-1863 fragments were examined for 600 seconds after irradiation. Interestingly, the N-terminal (a.a.1-304) fragment rapidly and maximally accumulated at the DSBs within 20 seconds, whereas the C-terminal (a.a.1527-1863) fragment slowly and gradually accumulated, reaching a plateau at 360 seconds. Full-length BRCA1 exhibited a pattern of accumulation that reflected the combination of N- and C-terminal fragment patterns. Taken together, the above kinetic analyses suggest that the N- and C-terminal regions of BRCA1 may accumulate at DSBs through different mechanisms.

Then, we compared the clearance kinetics of the N- and C-terminal fragments of BRCA1 from DSBs. The accumulation of the N-terminal fragment along the line of irradiation was detected 10 min after laser-irradiation, but was almost completely lost by two hours after irradiation. In contrast, the fluorescence of the C-terminal fragment at DSBs was present at two hours after irradiation. These results indicate that the C-terminal region is unique in its ability to remain at the DSBs and that BRCA1 displays domain-specific kinetics in terms of its initial accumulation and subsequent retention at the damaged sites.

1.3 Accumulation of BRCA1 at DSBs requires the other DNA repair factor

Next, we examined whether BRCA1 accumulation at DSBs is dependent on specific DNA repair factors, using factor-deficient cells. The N- and C-terminal fragments accumulated at laser-induced DSBs in ATM-deficient AT1KY/T-n cells, H2AX-/- MEF cells, CHO-derived CHO9, and XR-C1 (DNA-PKcs -/-) cells. However, in XRV15B (Ku80 -/-) cells, the N-terminal fragment of BRCA1 failed to accumulate at DSB sites, whereas the C-terminal fragment did accumulate. Therefore, accumulation of the N-terminal fragment, but not the C-terminal fragment, of BRCA1 at DSBs is Ku80 dependent.

1.4 BRCA1 localizes at SSBs via its C-terminal regions

Next, we examined the real-time accumulation at SSBs of GFP-tagged BRCA1 in living cells after laser-irradiation. GFP-BRCA1 was transfected into Saos-2 cells, the cells were laser-irradiated, and the mean intensities of GFP-BRCA1 were quantified. GFP-BRCA1 clearly accumulated at the irradiated sites (Fig. 4). This accumulation was slow and gradual. The kinetics of BRCA1 accumulation at SSBs was different from that at DSBs sites.

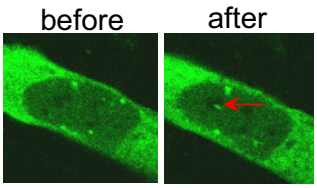

Fig. 4 GFP-tagged BRCA1 accumulates at the SSB sites induced by laser-irradiation in Saos-2 cells. Arrow indicates the laser-irradiated sites.

We next identified the BRCA1 regions that mediate BRCA1 accumulation at sites of irradiation. The full-length BRCA1, as well as the deletion mutants Δ305-770, Δ775-1292, Δ1-302, and Δ1527-1863, were transfected into Saos-2 cells. All of the BRCA1 deletion mutants except Δ1527-1863 accumulated at SSBs. The C-terminal a.a.1527-1863 fragment accumulated at the laser-irradiated sites. These results suggest that the BRCA1 C-terminus is important and sufficient for BRCA1 accumulation at SSBs.

2 BRCA1 response to local UV irradiation

In the field of DNA repair, BRCA1 is engaged in DNA DSB repair pathways, homologous recombination (HR), and non-homologous end-joining (NHEJ). BRCA1 is also involved in TCR processes [6], and BRCA1-deficient cells are defective in a process in which oxidative base damages are removed preferentially from the transcribed DNA strand [7]. After UV irradiation, BRCA1 localizes to nuclear foci and is phosphorylated at Ser1423 and Ser1524 by ATR. Previously, we and other groups reported that BRCA1 ubiquitinates RNAPII after UV irradiation [8, 9, 10]. The predominant DNA damages produced by UV irradiation are cyclobutane pyrimidine dimmers (CPD) and 6-4 photoproduct adducts. These lesions are removed by nucleotide excision repair (NER), which eliminates a wide variety of bulky helix–distorting DNA lesions. NER operates via two pathways, global genome repair (GGR) and TCR. GGR can repair DNA lesions at any location in the whole genome, while TCR selectively removes DNA lesions on the transcribed strands of expressed genes.

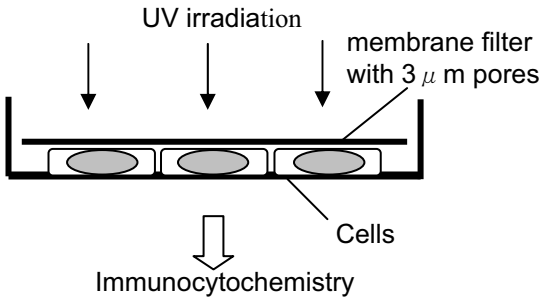

Fig. 5 Schematic of cellular exposure to local UV irradiation using a membrane filter.

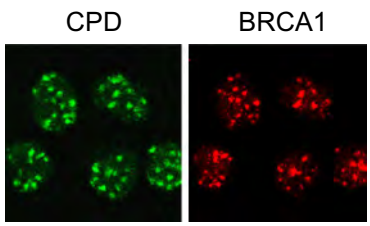

Fig. 6 BRCA1 accumulation at sites of local UV irradiation. Saos-2 cells were fixed after UV irradiation through membrane filters, and were stained with antibodies against CPD and BRCA1.

To gain further insights into BRCA1 regulation of the TCR pathway, we induced UV damage in small restricted areas of cell nuclei by using an isopore membrane filter. Cells monolayered in 35-mm glass-bottom dishes were covered with a polycarbonate isopore membrane filter (3-μm diameter pores), and were UV-irradiated (254-nm) with a dose of 60 J/m^2 (Fig. 5). The polycarbonate blocked the 254-nm UV light, and cells were exposed only though the filter pores. Immunostaining with an antibody against BRCA1 revealed that BRCA1 immediately accumulated at

the site of local UV irradiation and colocalized with CPD (Fig. 6). This accumulation was abolished by a transcriptional inhibitor, and was dependent on the presence of a protein that is involved in the NER pathway. Furthermore, BRCA1 was associated with this repair factor. Our data reveal the mechanism of BRCA1 involvement in the TCR pathway at lesions induced by UV irradiation.

III. Discussion

It was recently reported that the inhibition of poly (ADP-ribose) polymerase 1 (PARP1), a critical enzyme in the SSB repair pathway, leads to a severe, highly-selective toxicity in *BRCA1*-deficient cells [11]. This seems to be because PARP inhibition results in unrepaired SSBs, giving rise to DSBs. These provide new concepts for the development of potential cancer treatments. The reduced expression or function of BRCA1 is observed in sporadic cancers, suggesting that the precise analysis of BRCA1-related proteins will contribute to the discovery of novel molecular targets for cancer chemotherapy.

In cancer treatment, it is important to select a treatment method and predict its effectiveness in individual cancer patients. Molecular targeting therapies are focus of investigation with a view to developing novel approaches to cancer control. New biomarkers are similarly essential for improved cancer diagnostics. Our research has focused on the identification and functional analysis of critical proteins mediating carcinogenesis and on the development of diagnostic biomarkers and molecular targets for therapies for personalized medicine. Molecular imaging techniques will be useful tools for these aims.

Evaluating Spinal Vessels and the Artery of Adamkiewicz Using 3-Dimensional Imaging

Kei Takase, Sayaka Yoshida and Shoki Takahashi

Department of Radiology, Tohoku University, School of Medicine, Sendai, Japan

Abstract — **Accurate localization of the artery of Adamkiewicz (AKA) is important in planning treatment of patients with thoracoabdominal aortic disease. We assessed the usefulness of three-dimensional imaging devices such as multidetector-row helical** computed tomography (MDCT) **and 3 Tesla (T) MRI in the preoperative evaluation of the artery of Adamkiewicz (AKA) and its parent artery. Patients with thoracoabdominal vascular diseases underwent MDCT of the entire aorta and iliac arteries. Sub-millimeter collimation was used with the rapid injection of concentrated contrast material. The AKA and intercostal/lumbar arteries from which it originated were examined using multiplanar and curved planar reconstruction images and cine-mode display. The visualization of the AKA, as well as its branching level and site of origin, and the continuity of the intercostal/lumbar arteries with the AKA were investigated. 3T-MRA was also performed in patients whose AKA was difficult to visualize because of artifact from bony structures.**

In 90% of the patients the AKA was clearly visualized. The entire length from the trunk of the intercostal/lumbar arteries to the AKA, and finally to the anterior spinal artery could be traced using cine-mode display or on curved planar reconstruction images in 80%. These patients were treated by open surgical treatment based on a consideration of the vascular supply to the AKA or treated by stentgraft insertion. No postoperative ischemic spinal complications occurred in these patients except two. 3T-MRA increases success rate of visualizing AKA when used with MDCT. MDCT with Sub-millimeter collimation and a rapid injection protocol permits the evaluation of the AKA for its entire length and provides information on the intercostal and lumbar arteries and entire aorta. 3T-MRA has complementally role with MDCT.

Keywords — **Artery of Adamkiewicz, MDCT, Aortic dissection, Aortic aneurysm**

I. Introduction

Accurate localization of the artery of Adamkiewicz (AKA) is important in planning the surgical or interventional radiological treatment of patients with thoracoabdominal aortic disease. Preoperative information on the localization of this artery may reduce the risk of postoperative ischemic spinal complications (1–7). Although conventional angiography is reported to be useful (3–6), various complications of spinal angiography have been described (3,5). Noninvasive detection of the AKA using magnetic resonance imaging (MRI) and its usefulness for surgery has also been reported with a detectability of 69 to 84% (7,8,9). Due to the limited scanning field of view, however, MRI cannot demonstrate the entire aorta and intercostal and lumber arteries simultaneously with information on the AKA. Multidetector-row helical CT (MDCT) with a four-slice detector and 2-mm collimation has recently been reported to be effective in demonstrating the AKA (10), although that study did not focus on patients requiring an aortic vascular graft or stentgraft in the T8–T12 region, where the AKA likely originates and postoperative ischemic spinal complications are likely to occur. Moreover, no previous studies have included a radiological evaluation of the patency of the parent intercostal or lumbar arteries branches of the AKA, or the intercostal/lumbar arteries adjacent to the parent artery, which can provide collaterals to the AKA when needed.

Recently, MDCT with 8, 16, 32, or 64 detector rows has become available, permitting imaging of the entire aorta and iliac arteries with less than 1-mm collimation. This study evaluated the capacity of 16-slice MDCT with 0.5-mm collimation and a rapid injection protocol to evaluate the continuity of the AKA and its parent artery and to visualize the intercostals and lumbar arteries adjacent to the parent artery for preoperative evaluation of patients with thoracoabdominal aortic disease.

II. Materials and method

A. Patients

We performed a retrospective analysis of CT images from 36 consecutive patients (32 men, 4 women; mean age, 56.1 years; range, 34-77 years) with diagnosis of thoracic aortic aneurysm (14 patients) or aortic dissection (22 patients) including thoracoabdominal aorta, who underwent aortic replacement surgery (25 patients) or stentgraft insertion (11 patients). Informed consent for contrast-enhanced CT had been obtained from all patients before the examinations.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2215–2218, 2009
www.springerlink.com

B. Radiological Imaging

The CT scanner was an Aquilion 16-detector row helical CT scanner (Toshiba, Tokyo, Japan). Scans were obtained with the following parameters: 0.5 second per rotation, 0.5 mm collimation. Patients were requested to hold their breath for approximately 20 seconds during the scanning followed by shallow breathing.

Before scanning was started, 130-150 ml of contrast material (Iopamiron, Schering, Berlin, Germany; 370 mgI/ml) was injected via an antecubital vein at a rate of 4.0-4.5 ml/s. If a suitable antecubital vein could not be found, the right external jugular vein was used for contrast injection. The scan delay was set using an automatic triggering system (SureStart, Toshiba Medical Systems). Continuous low-dose CT fluoroscopy (120 kV, 50 mA) at the level of the ascending aorta was initiated 10 s after the start of contrast injection. The CT value in a circular region of interest placed in the ascending aorta was measured 3 times per second, and when the CT value reached the threshold (absolute CT value of 85 Hounsfield Units) at 3 consecutive sampling points, helical scanning was started automatically.

Axial slices were reconstructed with a 0.5-mm slice thickness at 0.3-mm intervals. For the evaluation of the artery of Adamkiewicz, the reconstruction field of view was set to the area around the aorta and spine.

Images were processed using a stand-alone workstation (Zio M900 Quadra, Amin, Tokyo, Japan). Volume-rendering images of the entire aorta were routinely generated. Curved planar reconstruction (CPR) images were generated so that the anterior spinal artery, the artery of Adamkiewicz, and its parent artery could be traced over as long a distance as possible. 3T-MRA was also performed in patients whose AKA was difficult to visualize because of artifact from bony structures.

The following points were evaluated: 1. the side and level of the artery of Adamkiewicz; 2. the continuity of the artery of Adamkiewicz with the anterior spinal artery, the intercostal/lumbar arteries, and their posterior branches; 3. the patency of the intercostal/lumbar arteries branching from the artery of Adamkiewicz.

III. Results

In 33 of the 36 patients (91.7%), the artery of Adamkiewicz within the bony spinal canal was clearly delineated, permitting both the level of origin and the side of the artery to be identified (Figure 1). In 3 patients with a thoracic aortic aneurysm, the artery of Adamkiewicz was not visualized and enhancement of the anterior spinal artery was poor. The continuity over the entire length from the stem of the intercostal/lumbar arteries and their posterior branches, to the artery of Adamkiewicz, and finally to the anterior spinal artery could be traced in 29 of the 36 (80.1%) patients (Figure 1). In two of the remaining 7 patients, the continuity was visualized by MRI (Figure 2). In the remaining patient, continuity between the posterior branch of the intercostal / lumbar artery and the artery of Adamkiewicz could not be clearly visualized. In 13 patients the parent artery of AKA was occluded (Figure 3).

Figure 1. Three dimensional reconstruction of the artery of Adamkiewicz visualized by MDCT image. Curved planar image along the intercostal artery through anterior spinal artery clearly demonstrates the origin and anatomy of the artery of Adamkiewicz.

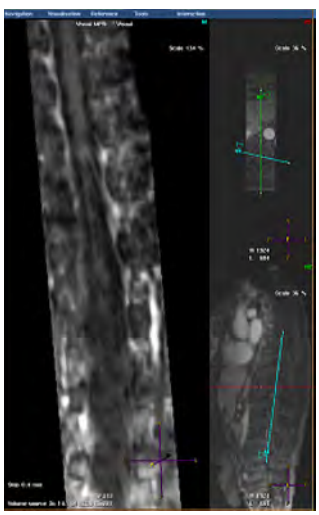

Figure 2. MRI image using Keyhole technique demonstrates the artery of Adamkiewicz and the anterior spinal artery. Because of the high temporal resolution, the artery of Adamkiewicz can be distinguished from the radiculomedullary vein.

Figure 3. Curved planar image along the intercostal artery through anterior spinal artery shows the intercostal artery, its posterior branch, the artery of Adamkiewicz and the anterior spinal artery. The origin of the intercostal artery is occluded due to thick mural thrombus of thoracoabdominal aortic aneurysm.

(a) (b)

Figure 4. MDCT after stentgraft insertion to thoracic aorta. (a): Stent graft can be seen from the aortic arch through the thoracoabdominal aorta by volume rendering image. (b): Curved planar reformation image shows the intercostal artery, its posterior branch, the artery of Adamkiewicz, and the anterior spinal artery. Although the origin of the intercostal artery is covered with the stentgraft, the blood flow to the spine is maintained by collateral circulation to these arteries.

In 25 patients who underwent aortic replacement surgery, intercostal arteries were reconstructed based on the information of CT localization of the artery of Adamkiewicz. Two patients with aortic dissection showed incomplete spinal complication.

Although the origin of AKA was completely coverd by stentgraft in 8 of the the 11 patients who underwent stentgraft insertion, no spinal complication was dedtected in the stent group. In these 8 patients, AKA was visualized by follow up CT after stentgraft insertion.(Figure 4)

The patency of the artery of Adamkiewicz from its origin through the anterior spinal artery can be diagnosed.

IV. Discussion

Sixteen-slice MD-CT with 0.5-mm collimation and a rapid injection protocol permitted the artery of Adamkiewicz to be visualized and also provided information concerning the adjacent intercostal/lumbar arteries. The continuity from the intercostal/lumbar arteries through the artery of Adamkiewicz could be traced in high percentage of the patients. Patients with aortic diseases involving the thoracoabdominal region typically present with stenosis or occlusion of the intercostal/lumbar arteries, and the parent arteries of the artery of Adamkiewicz (i.e., the intercostal/lumbar arteries) must therefore also be evaluated. Some patients were found to have occlusion of the intercostal/lumbar arteries at multiple levels in the region superior or inferior to the origin of the artery of Adamkiewicz. In the patients in the present study, the vascular supply to the artery of Adamkiewicz was thought to be highly dependent on collaterals. Concerning the patients who underwent stentgraft insertion, no patients had spinal complication after the procedure. Vascular supply to the spinal cord in these patients were thought to be maintained by collateral circulation.

Although MDCT permits visualization of AKA, continuity from the stem of the intercostal/lumbar arteries and their posterior branches, to the artery of AKA is sometimes difficult because of close approximation of the artery and the spine. In such cases, MRI plays an complementary role of MDCT.

Recently developed 3T-MRI will enable visualization of AKA with high temporal resolution permitting distinction between AKA and radiculomedullary vein. (Figure 2) In conclusion, MDCT with Sub-millimeter collimation and a rapid injection protocol permits the evaluation of the AKA for its entire length and provides information on the intercostal and lumbar arteries and entire aorta, which provides useful information for treatment of thoracoabdominal aortic diseases.

Development of a Haptic Sensor System for Monitoring Human Skin Conditions

D. Tsuchimi, T. Okuyama and M. Tanaka

Department of Biomedical Engineering, Tohoku University, Sendai, Japan

Abstract — **Human skin, which mainly consists of epidermis, dermis and hypodermis, is the largest organ of a human body. It has a lot of roles, for example, protection function, moisture maintenance function and sensory function. Moreover, it becomes a parameter for estimation of the health condition and beauty, because the skin is the outermost layer of a human body. At present, ocular inspection and palpation are generally used for detection of human skin condition such as surface appearance, and extensibility. Ocular inspection and palpation are important diagnosis procedures to examine patient's skin condition quickly. However, it is difficult to quantify an evaluation by these diagnosis procedures, because it is very subjective. A development of handy method in order to evaluate the skin condition objectively is craved to dermatologists, and cosmetic industries. So far, various methods of evaluating skin condition objectively have been developed. However, these methods are substitutions of ocular inspection, or only measure some specific physical parameters of skin such as elasticity.**

In this paper, the sensor that can measure various parts of human body in various conditions is developed. The polyvinylidene fluoride (PVDF) film, that is a kind of piezoelectric materials, is used as the sensory receptor in the sensor system. The functionality and signal processing of the sensor system are investigated by measurement of 15 kinds of artificial skin models, which are made of silicone rubber with different elasticity and roughness. Finally, the clinical test for human skin is conducted using the sensor system. Skin of medial forearm and base of thumb of 6 subjects are measured by the sensor. The obtained results show that two parameters calculated from the sensor output correspond to the subjective evaluations of extensibility and smoothness of the skin.

Keywords — **Haptic sensor, skin conditions, extensibility, smoothness, PVDF, signal processing.**

I. Introduction

Palpation is important for a clinician to diagnose a patient. A clinician assesses smoothness, softness, extensibility by palpation. But, this type of clinical assessment is very subjective; therefore, it is irreproducible from one clinician to another or even from time to time for the same clinician. Development of noninvasive technology in dermatology and cosmetology has advanced considerably for the past dozen years or so [1]. Concerning skin surface properties, some attempts were made by measuring skin friction coefficients [2, 3], image analysis [4] and fringe projection [5]. All these methods are useful to evaluate the skin surface properties, but their results cannot be compared with sensory evaluation by clinician.

Recently, Tanaka [6] and Tanaka et al. [7, 8] developed a haptic sensor for monitoring skin condition by using PVDF film as a sensory receptor. The sensor [7] is moved by hand over a skin with constant speed and force. But, an output of the sensor is greatly affected by a fluctuation of the scanning speed of the hand. In order to clear up this defect, a stepping motor is introduced to drive the sensor [8]. However, in return for stability of scanning speed, wide space to fix the sensor on the skin is needed. With this situation in mind, the authors have been developed a hand-manipulated haptic sensor system for monitoring skin conditions [9]. As a preliminary experiment, influence of scan speed on evaluating roughness of an object was investigated using the developed sensor system, and a fluctuation of the scan speed was compensated by signal processing.

In this paper, measurements of extensibility and smoothness of the object, which made of silicone rubber, was carried out using the hand-manipulated sensor system. Finally, extensibility and smoothness of the human skin were measured, and the results were compared with their sensory evaluation.

II. Sensor system

Geometry of the haptic sensor is presented on Fig. 1. A base of sensitive part is an acrylic plate. PVDF film and gauze were stacked in sequence. The PVDF film was covered with acetate film which protects the PVDF film against damage and water. The gauze improves sensitivity of the sensor. Guide roller was placed on both sides of the sensitive part to improve manipulation performance, and an encoder was mounted on it to measure sliding speed. Two strain gauges were attached to the chassis to measure forces applied to the sensitive part and guide roller.

In experiment, the sensor was contacted with a measurement object. Then the sensor slid over the surface of the object by hand in order to collect information about its extensibility and smoothness. Piezoelectric output of the PVDF film, output of strain gauges and output of encoder were digitized and stored into a digital oscilloscope. Signal processing for the obtained data was done in a personal computer. The experimental setup and measurement conditions are shown in Fig. 2 and Table 1, respectively.

Measurement term	2(s)
Contact force	0.4(N)
Scanning speed	40(mm/s)

III. Evaluation Experiment

An Evaluation experiment was carried out using skin model made of silicone rubber. And the effectiveness of the sensor system in evaluation of extensibility and smoothness was testified.

Measurement object was shown in Fig. 3. It was made up of two layers. E layer was thin silicone rubber; surface geometry of an abrasive paper was printed on its surface. It prepared 15 types: they were combination of Young's modulus and maximum grain size of printed abrasive paper. H layer was thick and soft silicone rubber. Properties of each layer are shown in Table 2. Additionally, thickness and Young's modulus of each layer referred from epidermis and hypodermis of human skin [10, 11, 12].

The measurement object was fixed on a stage. The sensor was contacted with the E layer of the measurement object, and the sensor slid over the surface of the object by hand. The sensor scanned 5 times per object.

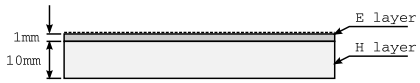

Fig. 3 The measurement object.

Table 2 Properties of measurement object.

Layer	Thickness	Young's modulus	MGS*
E layer	1(mm)	$1.0*10^{-1}$ (MPa)	40(μm)
		$1.0*10^{-1}$ (MPa)	60(μm)
		$2.9*10^{-1}$ (MPa)	70(μm)
			80(μm)
			100(μm)
H layer	10(mm)	$3.7*10^{-2}$ (MPa)	-

*MGS: Maximum grain size of printed abrasive paper.

Extensibility of the object was evaluated using outputs of two strain gauges (G_1 and G_2). The output of G_1 arose from a contact force applied on the sensitive part (F_{sens}), and the output of G_2 arose from a contact force applied on the sensitive part and guide rollers (F_{all}). Moreover, there was 1mm step between the sensitive part and the guide roller as shown in Fig. 1. Therefore the difference between outputs of G_1 and G_2 were influenced by extensibility of the measured object. A relationship of F_{sens} and F_{all} is written as:

$$k = \frac{F_{all} - 2F_{sens}}{d} \tag{1}$$

Here, d is 1mm step between the sensitive part and the guide roller, and k is compound constant of spring of the measured object. Fig. 4 shows the relationship between the k and the Young's modulus of the E layer. The values of the k are found to be proportional to the Young's modulus of the measured object. The outputs of strain gauges when the sensor contacted with the measurement object was used to analysis. Correlation coefficient between the k and the Young's modulus was 0.99.

Smoothness of the object was evaluated using the outputs of the sensor. The outputs attributed to contact between the measured object and the gauze attached on the surface of

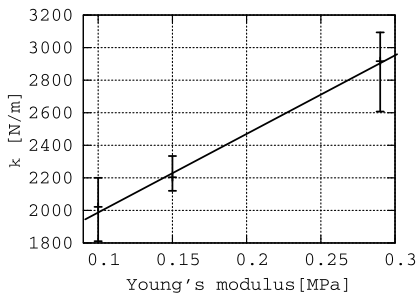

Fig. 4 k vs. Young's modulus of E layer.

the sensor. Therefore, frequency property of the sensor output was affected by the scan speed of the sensor, roughness of the surface of the sensor and the measured object. In addition, it was found that variance of the sensor output is associated with the roughness of measured object [13]. Therefore, the sensor output was divided into 6 parts according to wavelet multiresolution decomposition. Divided frequency ranges of the sensor output are shown in Table 3. Variances of the divided sensor outputs were calculated. As a result, it was found that the variances of level 4 to 6 waves had strong correlation with smoothness of the E layer of the measured objects, and correlation coefficients were 0.86 to 0.92. The variance of the level 6 wave had the strongest correlation especially. Fig. 5 shows a relationship between the variance of level 6 wave and maximum grain size of abrasive paper printed on the E layer. In this figure, gradients of these graphs come under the influence of extensibility of the measured object, but the extensibility can be evaluated by strain gauzes outputs, therefore the smoothness of the measured object can be evaluated except the influence of extensibility.

IV. Clinical Test

The present sensor system and signal processing were applied to a clinical test of human skin. The developed sensor was used to scan skin surfaces of 6 people (young male with healthy skin; their average age is 24). Scan regions were base of thumb and medial side of forearm of a nondominant hand. Results of the sensor output were compared with a result of subjective evaluation. In the subjective evaluation, an evaluator scored both extensibility and smoothness of skins according to five-grade evaluation (−2, −1, 0, 1, 2). Measurement conditions using the sensor system are shown in Table 4. The base of thumb and the medial side of forearm had curved surfaces; therefore, measurement term was shorten to 0.2(s), and sampling frequency was set to 50(kHz) for precision enhancement.

The results of the subjective evaluation and typical output signal from the sensor are presented in Table 5 and Fig. 6, respectively.

About extensibility evaluation, it was found that the results of the subjective evaluation and the strain gauge outputs showed the same tendency, and correlation coefficient between the results of the subjective evaluation and the k was 0.69 at medial side of forearm and 0.76 at base of thumb. Relationships between the results of subjective evaluation and k are shown in Fig. 7.

Next, about smoothness evaluation, because the obtained data contained the sensor output before the sensor sliding,

Table 3 Frequency ranges divided by wavelet multiresolution decomposition.

Decompose Level	1	2	3	4	5	6

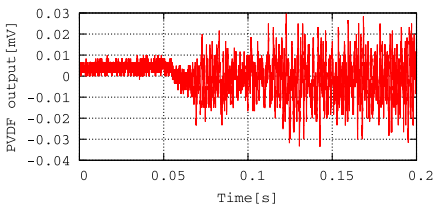
Table 5 Results of subjective evaluation. In this table, value "-2" is smooth/soft, and value "2" is rough/hard.

	Forearm		Base of thumb	
Subject No.	Roughness	Hardness	Roughness	Hardness
1	1	0	1	-1
2	0	0	0	1
3	2	-1	1	-1
4	-1	2	-1	1
5	-1	-1	2	1
6	-2	1	0	0



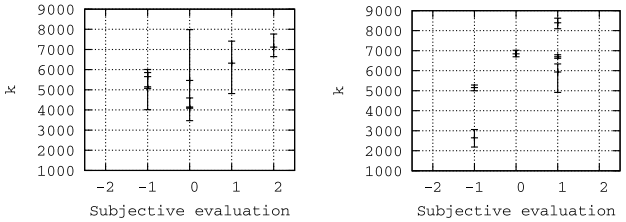


Fig. 6 Typical sensor output (forearm).

(a) Medial side of forearm. . (b) Base of thumb.

Fig. 7 Relationships between the result of the subjective evaluation and *k*. (a) at medial side of forearm, and (b) at base of thumb.

Table 6 Correlation coefficients between the results of subjective evaluation and variances of sensor outputs.

	Decompose level			
	3	4	5	6
Medial side of forearm	0.86	0.74	0.73	0.64
Base of thumb	0.80	0.76	0.78	0.91

second-half of sensor output was used for analysis of smoothness. As a result, the results of the subjective evaluation and variances of sensor outputs showed the same tendency. Correlation coefficients between the results of subjective evaluation and variances of the sensor outputs are shown in Table 6.

In this table, the correlation coefficient of medial side of forearm peaks at level 3, and one of base of thumb peaks at level 6. The variances of the sensor outputs are attributed to roughness of surface of a measured object. A crista cutis in base of thumb is larger than one in medial side of forearm; therefore, the correlation coefficient of medial side of forearm peaks at lower decompose level than one of base of thumb.

V. Conclusions

The haptic sensation system was designed using PVDF film as a sensory receptor. The effectiveness of the sensor system for monitoring skin conditions was investigated. The PVDF output, the contact force and the scan speed were obtained. Measurement of skin model made of silicone rubber was undertaken, and the sensor output was compared with extensibility/smoothness of measured object. Finally, the sensor system was applied to the clinical test of skin conditions. The results can be summarized as follows:

1. In experiment using skin model, extensibility of measured object can be evaluated with outputs of two strain gauges attached to the sensor, and smoothness can also be evaluated with variance of calculated sensor output.
2. In clinical test, the two indexes obtained from the haptic sensor system have good correlation with subjective assessments of the human skin conditions.

Abstract — **We made transparent arteriole membranous models by using grayscale lithography. We employed a sacrificial model made of WAX and PVA mixture as a novel molding material. Our goal is to complement previous surgical simulators for practice and rehearsal of medical treatments. Since block vessel models cannot recreate moderate compliance which is similar to that of the real blood vessel, here we propose fabrication method for transparent arteriole membranous model which has circular cross section smaller than 500 μm in diameter. Fabrication method of the model as well as evaluation result of the molding material is reported.**

Keywords — **photolithography, blood vessel model, surgical simulator**

I. Introduction

In the tissue engineering field, many engineered approaches have been studied, including artificial hearts, artificial joints and synthetic vascular prostheses [1,2]. We have been developing the three-dimensional(3D) elastic membranous blood vessel models in tailor-made by using 3D WAX models [3,4]. We have been developing a surgical simulator by connecting the elastic membranous models (Fig.1.). Surgical simulators are used in practice and rehearsal for catheter treatments and new treatment methods by doctors. Meanwhile, we constructed a pulsatile pump which can reproduce patient-specific pulsative blood streaming obtained by ultrasonic measurement or other modalities, connected it to the aorta model and reproduced human-like pulsatile blood streaming inside the simulator (vascular model can reproduce vascular pulsation with the streaming.).

This surgical simulator's model is bigger than 500 μm in diameter because of brittleness of WAX. Blood vessel models smaller than 500 μm in diameter are needed to simulate more similar vessel environment.

Fig. 1 Surgical simulator for endovascular neurosugery, which allows evaluating stress condition on arterial structure applied with surgical operation and blood streaming, using photoelastic modality.

There are diseases in under Φ500 μm blood vessels, such as arteria basilaris, but previous surgical simulator is not applicable for rehearsal and training of these diseases. Therefore, surgical simulator with Φ10 - 500 μm arteriole and capillary vessel models are needed. We have been designed arteriole and capillary vessel models shown in Fig.2, and fabricated by using photolithography [5-7].

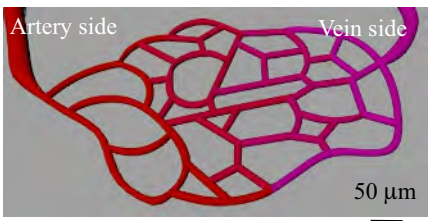

Fig. 2 Designed arteriole and capillary vessel model.

Figure 3 shows multiscale fabrication methods of blood vessel models. We used over exposure method, reflow method, gray-scale lithography, and layer stack molding machine. In these processes, photolithography process such as over exposure method, reflow method, gray-scale lithog-

www.springerlink.com

raphy are used for fine structure. Because of a limit of fabrication accuracy, it is necessary to choose an appropriate method to fabricate a model with aimed diameter. After exposure, fabricated photoresist patterns are transcribed onto poly(dimethylsiloxane) (PDMS). Arteriole and capillary vessel block models with circular cross section are completed by bonding two patterned PDMS substrates using plasma treatment and heating process (Fig.4.).

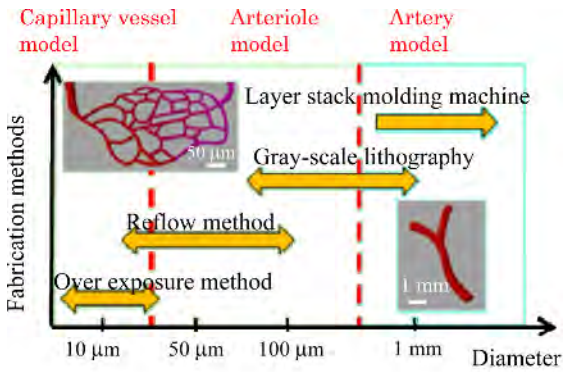

Fig. 3 Fabrication methods for multiscale blood vessel models.

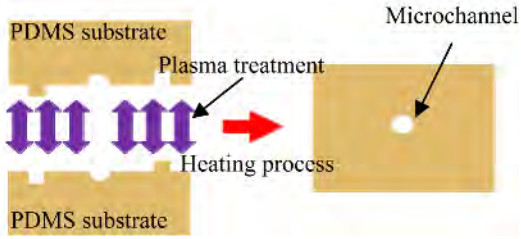

Fig. 4 Concept of making capillary vessel model. After plasma treatment, we align two patterned PDMS substrates and bond by heating to complete blood vessel model.

However, block models cannot recreate moderate compliance which is similar to that of the real blood vessel [8-10]. To solve this problem, we think arteriole and capillary vessel membrane models are needed for surgical simulator. And, sacrificial models are needed to make membrane models. But because of brittleness of WAX, we could not make sacrificial models by using layer stack molding machine as previous fabrication method.

In this paper, we propose a novel fabrication method for transparent arteriole membranous models. We tried to improve the brittleness of WAX by mixing WAX with PVA (polyvinyl alcohol). After making sacrificial models made of mixture material, arteriole membranous models were completed by dip coating. Merits of making membranous models smaller than Φ500 μm for surgical simulator are (1) enabling to target blood vessel diseases on about Φ100 μm blood vessel as arteria basilaris and (2) enabling to make a surgical simulator with high precision. Here, we report fabrication method and results of fabricated arteriole membranous model as well as evaluation of the molding material (WAX and PVA mixture material).

II. Evaluation of WAX + PVA Mixture Material

In this fabrication process, WAX and PVA mixture material is used to build sacrificial models. These models are very useful for fabricating membrane models smaller than 500 μm in diameter. If we used only WAX for making sacrificial models, the temperature is needed to control. And WAX is not suitable to this fabrication process because of WAX's fragility. If we used only PVA for making sacrificial models, PVA model is deformed easily by model's own weight when dip coating, since it has low bend strength. Therefore, we proposed the method of fabricating sacrificial models with WAX and PVA mixture material. We can easily forecast the mixture has the properties of both WAX and PVA. We evaluated the properties of mixture by changing the mix ratio. Evaluated properties are Young's modulus as mechanical property and melting time of mixture material in different liquid (solubility) as chemical property. We evaluated samples made by different mix ratio (mix ratio WAX : PVA = 1:0, 1:4, 2:3, 3:2, 4:1, 0:1).

A. Evaluation of mechanical property (Young's modulus)

Tensile tester is used for evaluation experiments of Young's modulus. Samples made by WAX and PVA mixture material are made 50 mm × 10 mm × 2 mm (long × wide × thick) in size. After finishing this experiment, we plotted the load-displacement curve. We did the tensile experiment for three times for each WAX and PVA mix ratio. Using these curve data, we calculated the Young's modulus. Young's modulus of each mix ratio is calculated by averaging the experimental results. Table 1 shows Young's modulus by each mix ratio. Young's modulus of PVA is 9.57 MPa. On the other hand, Young's modulus of WAX is 20.6 MPa. We observed Young's modulus of mixture material is getting higher by increasing the ratio of WAX. And, Table 2 shows extension. Extension is expression of material's brittleness and ductibility. We observed extension of mixture material is getting higher by increasing the ration of PVA. Therefore, we can control the mechanical property of WAX and PVA mixture material by changing mix ratio.

Table 1 Experimental rigidity

PVA:WAX ratio[%]	Young's modulus [MPa]
1:0	9.57
4:1	9.69
3:2	8.78
2:3	15.7
1:4	22.8
0:1	20.6

Table 2 Experimental extension

PVA:WAX ratio[%]	Extension [%]
1:0	75
4:1	75
3:2	75
2:3	44
1:4	4.0
0:1	6.0

B. Evaluation of chemical property (solubility)

We observed melting time of each different ratio mixture materials in different liquid by checking mass changes. We defined solubility of each mix ratio from experiment. We used ultrasound bath set at 50 temperatures for solubility experiments. We provided DI water, acetone, and DI water + acetone liquid mixture for melting. DI water easily melts PVA. Acetone easily melts WAX. We provided liquid mixture of 1:1 mix ratio, since melting samples was WAX and PVA mixture material. The liquid was used in the melting experiments. Figure 5 shows the experimental results of observing solubility of each sample in DI water and acetone liquid mixture. Because of DI water's feature, mixture material samples were melted easily. In this result, we looked mass changes of the WAX sample. This is caused by heating in the process of ultrasound bath and etching effects. We looked acetone melted few mixture material in this experiment, although acetone can melt WAX easily. It happened since WAX was coated with PVA, and acetone could not reach WAX. On the other hand, we forecasted that mixture material is melted by liquid mixture. We verified it by experiment. Comparing these results, all mixture materials cloud be melted in DI water and acetone liquid mixture, however, solution rate was decreasing. We observed PVA absorbed DI water and increased mass when experiments started. These results suggest DI water and acetone liquid mixture is suitable to melt WAX and PVA mixture material.

III. Fabrication of Arteriole Membrane Models

Since WAX is fragile, we adopted mixture of WAX and PVA as a material of sacrificial model, which has higher rigidity than WAX. In fabrication processes of membrane models, we made model patterns by grayscale lithography and transcribed the resist patterns onto PDMS. We provided and aligned two patterned PDMS substrates filled with WAX and PVA mixture material on patterned side, and dried at room temperature. We completed sacrificial models for making membranous blood vessel model. This sacrificial model was coated with PVA for smoothing the surface and later coated with transparent silicone resin by dip coating for membranous structure. After dip coating, sacrificial model and PVA for smoothing were dissolved by DI water and acetone, and we got transparent arteriole membrane models. Figure 6 shows Φ500 μm arteriole membranous model made by these processes. The fabricated model had circular cross-section.

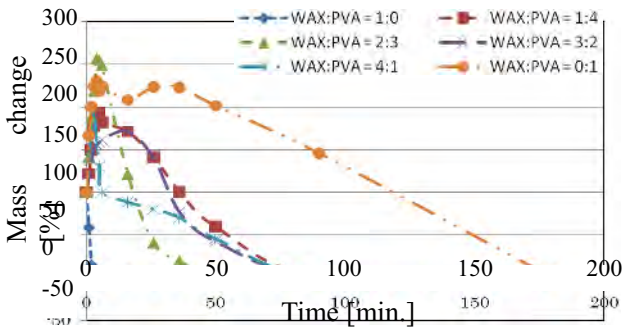

Fig. 5 Evaluation of chemical features in acetone + DI water.

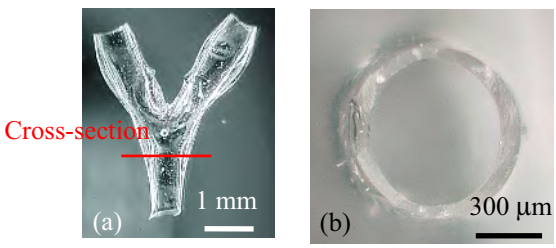

Fig. 6 Φ500 μm arteriole membrane model made by using WAX and PVA mixture material and grayscale lithography. (a)fabricated arteriole membrane model. (b)cross-section of fabricated arteriole membrane model.

A. Fabrication process of sacrificial models

For fabricating arteriole membrane models, sacrificial models as molds for dip coating of PVA and silicone resin are needed. We fabricated sacrificial models with this WAX and PVA mixture. Patterned PDMS substrates were made by grayscale lithography with nega-photoresists and transcribing the resist patterns onto PDMS for molding sacrificial models. Fabrication process flow is following.

(a) Grayscale lithography process.

1. Coating photoresist on glass substrate.
2. Exposure with the best exposure condition.
3. Development with the best time.
4. Transcribing the resist patterns onto PDMS.

(b) Fabrication process of sacrificial models.

1. Coating WAX and PVA mixture material on patterned side of PDMS substrate.
2. Splitting and removing superfluous mixture.
3. Aligning and bonding two patterned PDMS substrates filled with mixture on patterned side.
4. After drying at room temperature, removing the PDMS substrates and completing sacrificial models
5. Removing mixture stacking on the sacrificial models

B. Fabrication process of membrane models

We fabricated arteriole membrane models by using the sacrificial models. This sacrificial model was coated with PVA for smoothing the surface and later coated with transparent silicone resin for membranous structure by dip coating based on previous method. After dip coating, sacrificial model and PVA for smoothing were dissolved by DI water and acetone, and we got transparent arteriole membrane models. Fabrication process flow is following.

1. Dip coating the sacrificial models with 10wt% PVA solution for smoothing the surface.
2. After drying PVA, dip coating the sacrificial models coated with PVA with silicone resin.
3. Dissolving sacrificial models and PVA for smoothing by DI water and acetone liquid mixture.
4. Drying membranous silicone structures and completing blood vessel membrane models.

Figure 6 shows fabricated arteriole membrane model. We observed the membranous and hollow structure. This arteriole membrane model had circular cross-section shown in Fig.6(b). Circularity of inside of the membrane model was calculated by dividing the shortest axis by the longest axis. Using this expression, calculated circularity of this model was 90%.

IV. Conclusion

In this paper, we proposed fabrication method of Φ100 - 500 μm arteriole membrane models for surgical simulator. These blood vessel models are fabricated for connection to the previous surgical simulators. These membrane models will make surgical simulator enable to rehearse and train treatments for diseases at Φ100 - 500 μm blood vessels, and enable to make surgical simulator with high precision. We reported fabrication method of arteriole membranous model as well as evaluation of the molding material (WAX and PVA mixture material). We made arteriole membrane models by using grayscale lithography and WAX and PVA mixture material. It is very important to use WAX and PVA mixture material. We evaluated mechanical and chemical properties of WAX and PVA mixture material. We observed Young's modulus of mixture material is getting higher by increasing the ratio of WAX. In addition, we observed mixture's extension is getting higher by increasing the ratio of PVA in it. We observed DI water and acetone liquid mixture is most effective for melting WAX and PVA mixture material. Based on the proposed approach, we overcame the brittleness of the previous sacrificial model.

Finally, we succeeded in making the membranous and hollow structural arteriole model. This arteriole membrane model had circular cross-section inside the channel, and circularity of this channel was 90%.

In the future, we plan to improve our model by (1) matching moderate compliance which is similar to that of the real blood vessel, (2) making complicated membrane models and (3) checking durability and reliability of these models as a surgical simulator. We also plan to complete arteriole and capillary vessel network models by connecting each element.

Normal Brain Aging and its Risk Factors – Analysis of Brain Magnetic Resonance Image (MRI) Database of Healthy Japanese Subjects

H. Fukuda[1], Y. Taki[1], K. Sato[1], S. Kinomura[1], R. Goteau[1], R. Kawashima[2]

[1]Department of Nuclear Medicine and Radiology, and [2]Department of Neuroimaging,
Institute of Development, Aging and Cancer (IDAC), Tohoku University, Sendai, Japan

Abstract — **We collected brain MRI of 2,000 healthy Japanese subjects and constructed an MRI database together with their characteristics such as age, sex, present and past disease history and cognitive functions. Volumetric analysis of the brain revealed that gray matter volume linearly decreased with time, while white matter volume remained relatively unchanged during aging. We defined a standard brain for each age group and sex, which is a brain having gray matter volume on the regression line for the gray matter loss with age. This is a first objective criterion for standard brain for his/her age. Then, we performed longitudinal study in the same subjects with 8 years interval. The analyses revealed that there are sex difference in speed and pattern of gray matter loss with aging. Gray matter loss with aging was slower in women that that in men.**

Voxel based morphometry (VBM) was performed to investigate correlation between regional gray matter volume and characteristics of the subject, such as cerebro-vascular risk factors, scores of cognitive and memory functions, and mental status. These attributes were used as dependent variables, and regional gray matter volume as an independent variable. The correlation analyses revealed that there were negative correlations between gray matter volume and hypertension, lifetime alcohol intake, obesity.

To clarify clinical significance of ischemic lesion in the white matter on T2-weighted brain MRI, we developed an algorism for automatic detection of the ischemic lesions. Using this system, we made probabilistic map of the lesion for each subject and the probabilistic maps for age of 40^{th}, 50^{th}, $.60^{th}$ and 70^{th}, by simply averaging the data belonging to the age group. The lesion map revealed that ischemic lesion localized mainly around the ventricle and total lesion volume increased with increasing of age.

Keywords — **Brain aging, Magnetic Resonance Image (MRI), database, Volumetry.**

I. Introduction

Recently, the importance of human neuroimaging database was recognized greatly. The most important purpose and needs for database are electronic data sharing in neuroscience community as well as the construction of more sophisticated and complete model of brain structure and function. This model of normal brain structure and function can be used as the references not only for neuroimaging study for humans but also for computer aided automated diagnosis of the brain diseases.

Most remarkable recently developed method for brain image analysis is a voxel based morphometry (VBM). It includes anatomical standardization of the brain to a standard brain, brain tissue classification, and finally voxel based statistical analysis based on general linear model. This technique enables us to extract brain regions which show correlations between tissue volume and variables, such as age, sex and subject's characteristics. We can analyze not only age-related normal changes but also diseased brain, such as dementia. It has been believed that functional imaging precede structural imaging to detect early pathological findings of the diseases. However, recent the high resolution structural imaging and sophisticated analytical technique enable us to detect the brain diseases at very early stage.

We have collected 2,000 brain MRI of healthy Japanese and constructed an MRI database together with their characteristics such as age, sex, blood pressure, present and past disease history and cognitive functions [1] (Fig. 1). This is a largest database in Japan and one of the largest one in the world. Using this MRI database, we measured brain volume of different tissue segment, evaluated age-related volume changes and the correlation between regional brain volume and risk factors for cerebro-vascular atherosclerosis.

II. Materials and Method

A. Subjects

In this study, we analyzed 860 men and 840 women. Their age and characteristics are described in Table 1.

Table 1 Description of the subjects

	Men (n=860)	Women (n=840)
Age	44.5±17.8	47.6±15.1
Body mass index	23.4 ± 3.2	22.4 ± 3.1
Systolic blood pressure (mmHg)	129.5±16.5	125.7±18.2
Diastolic blood pressure (mmHg)	78.6±11.2	75.1 ± 11.9
Smoking habit (%)	62	17.1
Drinking habit (%)	91	65.4
Hypertension (%)	15.4	11.3
Diabetes mellitus (%)	4.3	2.1
Hypercholesterolemia (%)	7.2	12.1
Ischemic heart disease (%)	2.3	1.3

B. Image processing and statistical analysis using VBM

All the brains with different size and shape were transferred into a standard stereo-tactic space (Talairach space) and their size and shape were transformed into a standard template brain using liner and non-linear parameters (anatomical standardization). Next step is brain tissue segmentation. A brain images were segmented into gray matter, white matter, cerebrospinal fluid space (CSF) and outer brain space depending on the differences of signal intensities on T1 weighted MRI of each tissue (Fig. 2). The voxel values of each segmented image consisted f 256 grade signal intensities according to their tissue probability. The volumes of each tissue segment were calculated by summing up the value of all the voxels which belong to each tissue segment.

The standardized and segmented gray matter images were smoothed by convoluting a 12-mm-FWHM isotropic Gaussian kernel. Then, the smoothed gray matter images were statistically analyzed by voxel based morphometry (VBM) technique using SPM2 package (Fig. 2). VBM was performed to investigate correlation between regional gray matter volume and attributes to the subject, such as age, cerebrovascular risk factors, and scores of cognitive functions. This approach is not biased toward any one brain region and permits the identification of unsuspected potential brain structural abnormalities. Simple or multiple regression analysis was performed using SPM2. These attributes were used as dependent variables, and regional gray matter volume as an independent variable. We set the significance level at $P<0.05$ for multiple comparison. The method is a voxel based t-statistics extended to the three dimensional space based on the general linear model. Simple or multiple regression analysis and group comparison using t-test were performed.

C. Volume measurement of ischemic change

White matter hyper-intensities (WMH) on T2 weighted MR images (T2WI) are known as ischemic changes and frequently observed in elderly people. The changes are related not only to age but also to cerebrovascular risk factors, such as hypertension. However, the clinical significance of the changes in the healthy, neurologically non-diseased elderly people has not been clarified yet. Moreover, the WMH on T2WI are usually rated subjectively by radiologists and it is subject depends on the skill and condition of rater. We have developed an algorism for automatic detection and quantification of WHM using artificial neural network which can classify the brain into different tissue compartments [2].

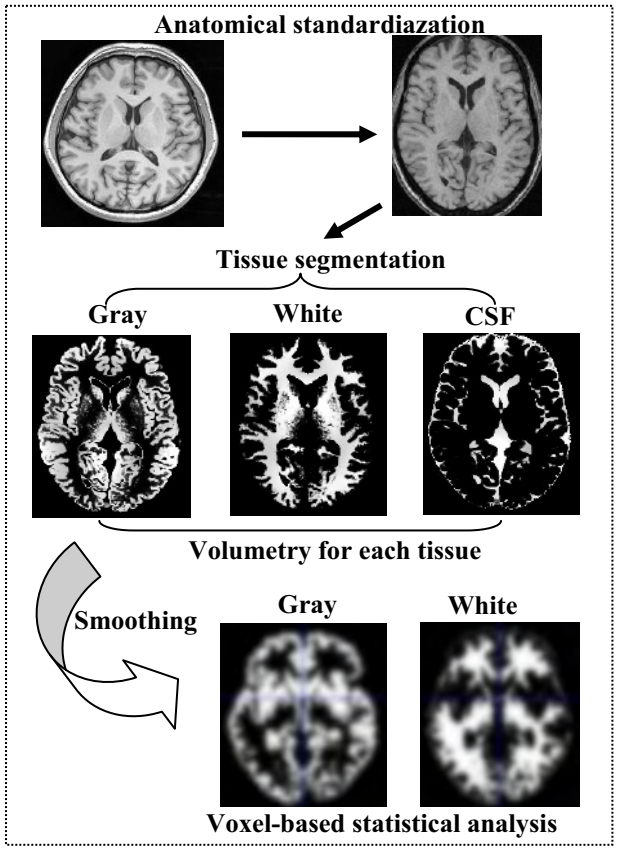

Fig. 2 Anatomical standardization, tissue segmentation of the brain MRI and statistical analyses

III. Results and Discussion

A. Brain volume change during aging

Figure 3 shows brain volume change with age in each tissue segment. Volume of each tissue segment was expressed as the ratio to whole brain volume. Gray matter ratio, which is the gray matter volume divided by whole brain volume, linearly decreased with age. White matter ratio slightly increased in younger age and remained unchanged during aging. However, there was no significant volume change with age. CSF volume ratio increased with age [3] (Fig. 3), in particular later age.

Gray matter ratio decreased linearly with age. Therefore, a brain with mean gray matter ratio can be a representative brain for the age group. We calculated regression line for the gray matter ratio change with age. We defined "a normally aged brain for his/her age", which is a brain with gray matter ratio on the regression line (Fig. 3). This is a first objective criterion for normally aged brain. We determined the normal range of the gray matter ratio as the value within ± 2SD from the mean value on the regression line.

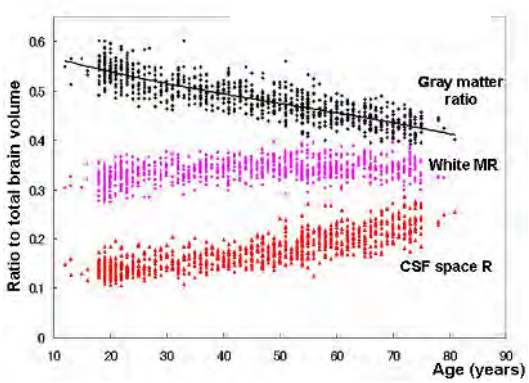

Fig. 3 Age-related volume change of the human brain

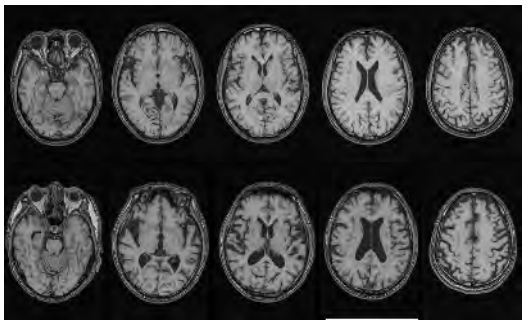

Fig. 4 MRI of normally aged (upper column) and atrophic brain (lower column) with 70-year old.

Upper brain images on Fig. 4 showed a normally aged brain of 70 yrs old man determined by this criteria. The lower images represent atrophic brain for his age (70 years old), of which gray matter ratio exceeded -2SD limits. Enlargement of ventricle and sulci was observed compared to the normally aged brain.

B. Longitudinal analysis of brain volume change during aging

Brain volume change described above are obtained from cross sectional analysis and do not represent age related change in strict sense. We performed a longitudinal study in the same subjects between 8 years interval of MRI study. The results indicated that gray matter ratio for men decreased linearly with age as was in our previous cross sectional analysis. While those for women decreased slowly than that for men until the age of 50 and then went down as the similar slope for men (Fig. 5). White matter volume increased until age of 40 and went down thereafter in either men or women, although variation of the data was large (data are not shown).

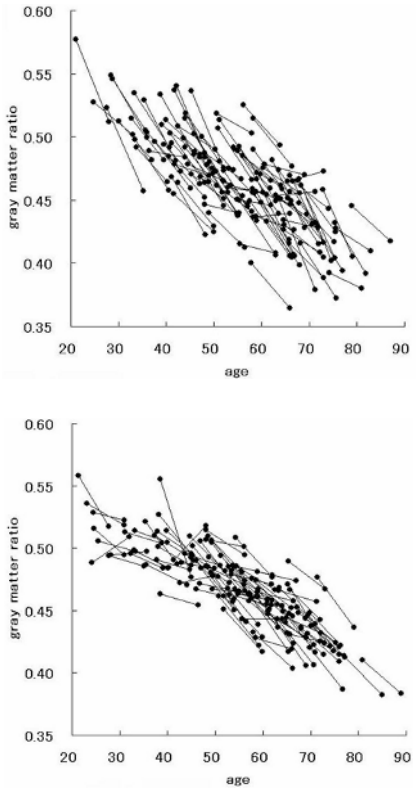

Fig. 5 Longitudinal analysis of brain volume change with aging. Two MRI measurements with 8-year interval Upper: men, lower: Women.

C. Risk factors for brain volume decrease

We analyzed correlation between regional gray matter volume and subject's characteristics using VBM technique. We found that total gray matter volume and regional gray matter volume negatively correlated with systolic blood pressure [3]. Most of the regions mainly distributed in watershed regions between major cerebral arteries, although other region was included.

Figure 6 shows the gray matter regions that had a significant negative correlation between the lifetime alcohol intake and the regional gray matter volume. The gray matter volume of the bilateral middle frontal gyri showed a significant negative correlation with the log transformed lifetime alcohol intake [4].

We tested correlation between gray matter ratio and obesity. As an indicator for obesity, we used body mass index (BMI). Volumetric analysis revealed that there are significant negative correlation between BMI and the gray matter ratio only in men ($p < 0.001$, adjusting for age, systolic blood pressure, and lifetime alcohol intake). On the other hand, we could not find any correlation in women [5].

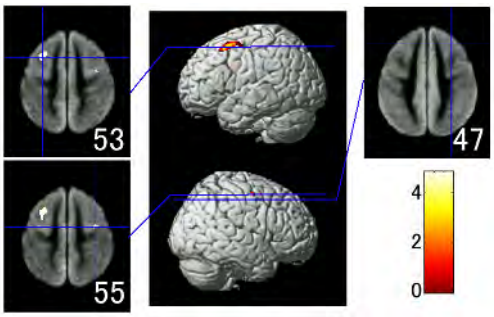

Fig.6 Brain regions that showed negative correction between gray matter volume and life time alcohol intake

D. Ischemic lesion volume

We defined the ischemic lesion by an automated system and made lesion map in each subject. Figure 7 shows probabilistic lesion map for each decade, which was made by summing up lesion map of a subject belonging to the same age group. The lesion distributed along the ventriculi and total lesion volume increased with increasing of age. Correlation analysis revealed that the total lesion volume correlated with the gray matter volume decrease in the frontal part of the brain.

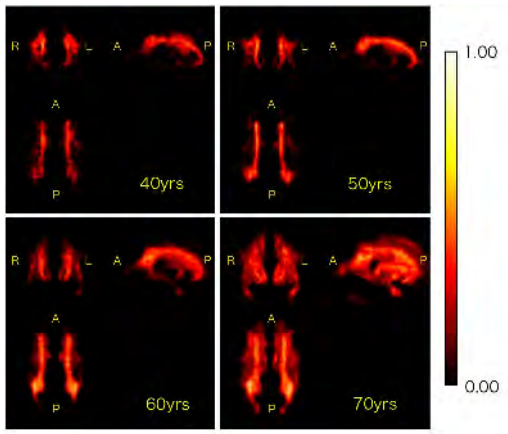

Fig. 7 The probabilistic lesion map for each decade (40th, 50th, 60th and 70th year-old)

IV. Conclusions

We constructed a large scale brain MRI database for healthy Japanese and clarified age-related volume changes of the human brain and their risk factors. This may contribute to the understanding of normal brain aging, as well as age-related brain diseases, such as dementia.

Ackowledgement

Motion Control of Walking Assist Robot System Based on Human Model

Yasuhisa Hirata, Shinji Komatsuda, Takuya Iwano and Kazuhiro Kosuge

Department of Bioengineering and Robotics, Tohoku University, Sendai, Japan

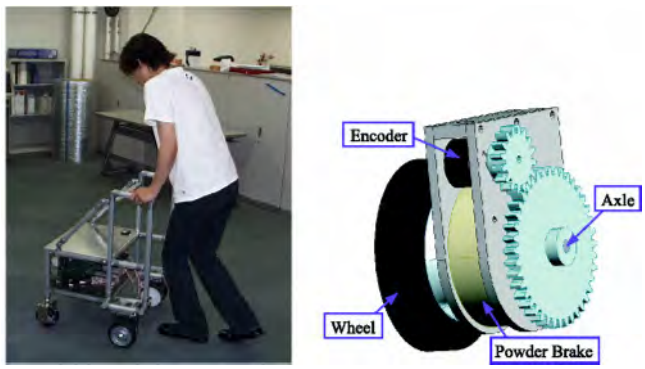
Abstract — **In this paper, we introduce walking assist robot systems for the elderly people to manage the independent living over a long period of time in serious aging society. This research especially focuses on the motion control method of the walking assist robot systems based on the human linkage model calculated in real time. According to the human linkage model, the robot systems could calculate a position of the user's center of gravity and the joint moment applied around the each joint of the user in real time. Based on the information of the user, the robot systems could support the walking appropriately. The motion control algorithms based on the human model are implemented to the walker-type walking assist system and the wearable walking assist system experimentally, and experimental results illustrate the validity of the proposed methods.**

Keywords — **Walking Assist Robot System, Human Model, Estimation of Human States**

I. Introduction

With the coming of aging societies, the population of the elderly people would rapidly increase in many countries. Many elderly people would have some handicaps for locomotion, because of the decline of the physical strength, muscular strength, etc. In the daily life, the ability of walking is one of the most fundamental functions for humans to maintain the high quality of life. For assisting the walking of the human, several intelligent systems using robot technologies have been proposed [1]- [3].

We have also introduced two kinds of walking assist system. First one is the walker-type walking assist system called RT Walker as shown in Fig.1. Walker-type waling assist system could support the weight of the user and keep his/her balance. In addition, RT Walker achieves several functions such as collision avoidance and path following by controlling the brake torques of the rear wheels [4].



Second one is the wearable walking assist system called Wearable Walking Helper as shown in Fig.5, which consists of knee orthosis, prismatic actuator and sensors [5]. The knee joint of the orthosis has one degree of freedom rotating around the center of the knee joint of the user on sagittal plane. The mechanism of the knee joint is a geared dual hinge joint. The prismatic actuator, which is manually back-drivable, consists of DC motor and ball screw. By translating the thrust force generated by the prismatic actuator to the frames of the knee orthosis, the device can generate support moment around the knee joint of the user.

For controlling both walking assist robot systems, we utilize the human linkage model. According to the human linkage model, the robot systems could calculate a position of the user's center of gravity and the joint moment applied around the each joint of the user in real time. Based on the information of the user, the robot systems could support the walking appropriately. In the following parts of this paper, we introduce the human linkage models for controlling the RT Walker and the Wearable Walking Helper, and experimental results with both systems illustrate the validity of them.

II. User Model for Walker-Type Assist System

A. Method for Generating Human Model

In this section, we explain the generation method of the human model that has seven rigid body links in sagittal plane. In this research, we set up two Laser range finders (LRFs) on the walker as shown in Fig.2(a). One of them is attached to the same height with hip joint of the user with standing state and measures the relative distances between the human surface and the walker along the vertical direction. This laser range finder measures the relative distances from −50[*deg*] to 30[*deg*] every 10[*deg*] under the assumption that the height of the hip joint of the user with

www.springerlink.com

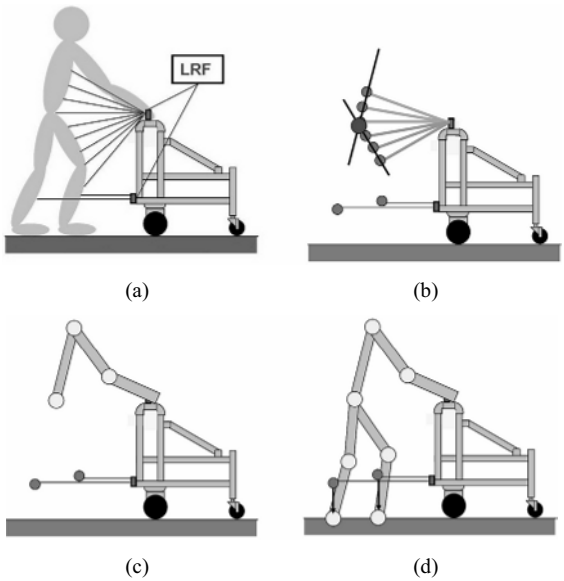

Fig. 2. Generation Method of Human Model Using Laser Range Finders

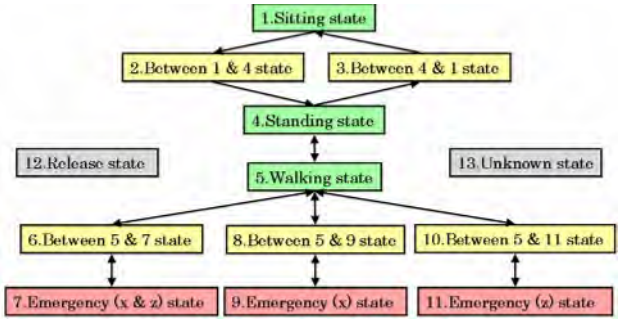
standing state is 0[*deg*]. Another laser range finder is set up at the lower part of the walker, and it measures the distances between each leg and the walker.

For generating the human model, firstly, the data of LRFs are collected. Three points on the surface of the lower body and three points on the surface of the upper body are obtained from the upper part LRF. The equations of the straight lines that show the upper-body and the lower half of the body are derived to detect the position of the human hip joint during the motion of the user using walker. These equations are derived based on the least square method. The intersection of these straight lines is calculated as shown in Fig.2(b), and the intersection point is regarded as the position of the hip joint of the human model.

The position of the shoulder is calculated by using the detected hip joint position, known length of the upper body link and the inclination of the straight line. From the shoulder position and the hand position, the angles of the arm joints are calculated by solving the inverse kinematic equations as shown in Fig.2(c). The angles of the legs joints are obtained by solving the inverse kinematic equations based on the position of the hip joint and the position of the feet obtained by LRF attached to the lower part of the walker as shown Fig.2(d).

B. Experiments for Estimating User States

If we can estimate the user states during the usage of the walker, we can change the function of the walker appropriately based on the user states. In this paper, we consider the estimation method of the user states based on the human model. For the simplicity of the discussion, in this paper, we consider thirteen states of the user during the usage of the walker as shown in Fig.3. Main states of the user during the usage of the walker are Sitting state, Standing state and Walking state.



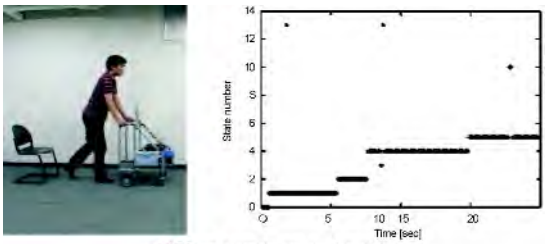


Fig. 3. Transition of Human States

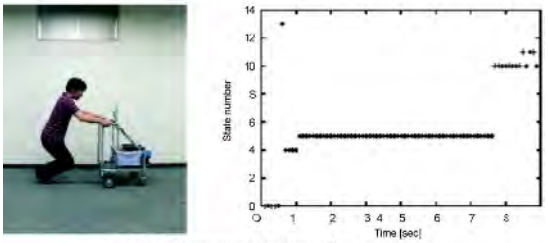
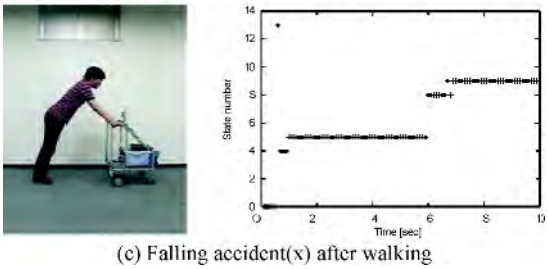


The user sometimes faces the dangerous situations including the falling accident, which are estimated by the system as Emergency states. Emergency states consist of three states. One is the falling accident that the user apart from the walker (Emergency (*x*) state), second one is the falling along the vertical direction (Emergency (*z*) state), and third one is the falling along *x* and *z* directions (Emergency (*x* & *z*) state). In Release state, the user releases his/her hand from the grip of the walker, and Between states are the intermediate states with respect to the Sitting, Standing, Walking and Emergency states. If the system does not recognize any states of the user, the Unknown state is selected.

For estimating the user states, in this paper, we pay attention to the position of the center of gravity of the user on the sagittal plane which is calculated from the human model explained in the previous section. To illustrate the validity of the estimation method by using the human model, a user behaves three motions experimentally with the walker. One is motion that the user stands up from the chair and then walks as shown in Fig.4(a), second one is the falling accident along the vertical direction after walking as shown in Fig.4(b), and third one is the falling accident along *x* axis after walking as shown in Fig.4(c).



In these experiments, we decided the thresholds of the center of gravity for estimating the user states experimentally. Estimation results are also shown in Fig.4. In the experimental data of Fig.4, the numbers of the vertical axis express the user states as shown in Fig.3. From these results, you can see that the system can recognize the user states successfully. Based on the estimated states of the user, we could design the several functions of the intelligent walkers such as fall-prevention function, variable motion characteristic function, sit-to-stand assist function, and so on.

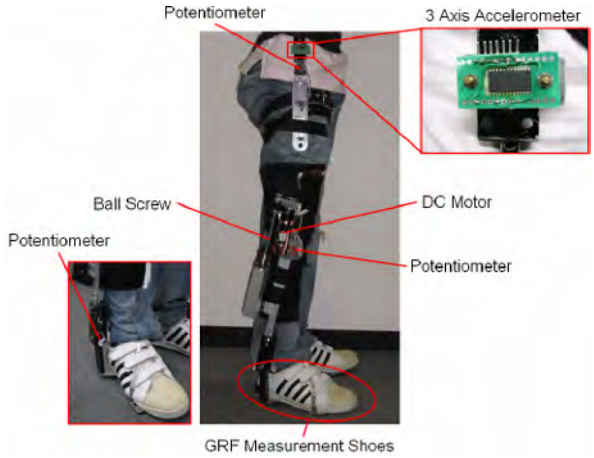
III. User Model for Wearable Assist System

A. Model-Based Control Algorithm

In this section, we introduce a control algorithm of the wearable walking support system as shown in Fig.5 based on the human model. Firstly, we derive the knee joint moment based on an approximated human model, and then the support joint moment, which should be generated by the actuator of the support device, is calculated.

To control Wearable Walking Helper, we use an approximated human model as shown in Fig.6. Under the assumption that the human gait is approximated by the motion on the sagittal plane, we consider only Z - X plane. The human model consists of four links, that is, Foot Link, Shank Link, Thigh Link and Upper Body Link and these links compose a four-link open chain mechanism.

To derive joint moments, we first set up Newton-Euler equations of each link. At the link *i,* Newton-Euler equations are derived as follows:



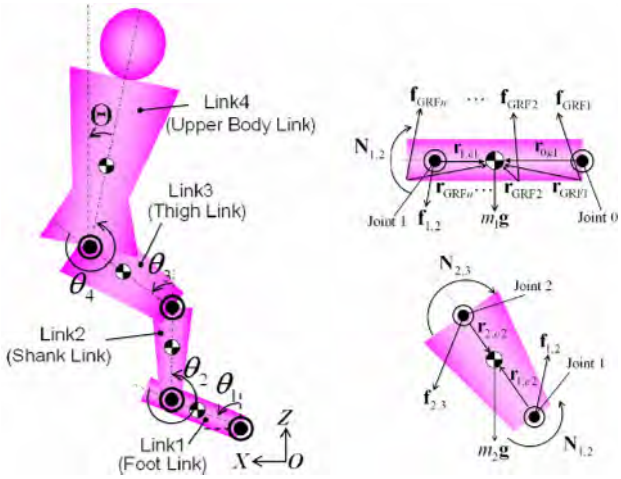


Fig. 5. Wearable Walking Helper

(a) Coordinate Systems (b) Foot and Shank Links

Fig. 6. Human Model

$$\mathbf{f}_{i-1,i} - \mathbf{f}_{i,i+1} - m_i\mathbf{g} = m_i\dot{\mathbf{v}}_{c_i} \quad (1)$$

$$N_{i-1,i} - N_{i,i+1} + \mathbf{r}_{i,c_i} \times \mathbf{f}_{i,i+1} - \mathbf{r}_{i-1,c_i} \times \mathbf{f}_{i-1,i} = I_i\frac{d\dot{\theta}_i}{dt} \quad (2)$$

where, $\mathbf{f}_{i-1,i}$, and $\mathbf{f}_{i,i+1}$ are reaction forces applying to the joint i and i + 1, respectively. m_i is the mass of the link i, $\mathbf{g}$ is the vector of gravity acceleration and $\dot{v}_{ci}$ is the translational acceleration of the gravity center of the link i. $N_{i-1,i}$ and $N_{i,i+1}$ are the joint moments applying to the joint i and i + 1, respectively. $r_{i,ci}$ is the position vector from the joint i to the gravity center of the link i and r_i - 1,c_i is the position vector from the joint i - 1 to the gravity center of the link i. I is the inertia of the link i and θ_i is the rotation angle of the joint i.

The knee joint moment $N_{2,3}$ can be derived by using the equations of foot link and shank link as follows:

$$\begin{aligned}\tau_k = N_{2,3} = &- I_1\frac{d\dot{\theta}_1}{dt} - I_2\frac{d\dot{\theta}_2}{dt} \\ &- m_1(\mathbf{r}_{1,c_1} - \mathbf{r}_{1,c_2} + \mathbf{r}_{2,c_2}) \times (\dot{\mathbf{v}}_{c_1} - \mathbf{g}) \\ &- m_2\mathbf{r}_{2,c_2} \times (\dot{\mathbf{v}}_{c_2} - \mathbf{g}) \\ &+ (\mathbf{r}_{1,c_1} - \mathbf{r}_{1,c_2} + \mathbf{r}_{2,c_2}) \times \sum \mathbf{f}_{GRF} \\ &- \sum(\mathbf{r}_{GRF} \times \mathbf{f}_{GRF})\end{aligned} \quad (3)$$

where $\mathbf{f}_{GRF}$ is Ground Reaction Force exerted on the foot link.

To prevent the decrease in the remaining physical ability of the elderly, the support joint moment τ_{sk} is calculated as a part of the derived joint moment τ_k. The Support joint moment is designed based on the gravity term τ_{gra} and the GRF term τ_{GRF} from equation (3) as follows:

$$\tau_{sk} = \alpha_{gra}\tau_{gra} + \alpha_{GRF}\tau_{GRF} + \tau_g \quad (4)$$

where α_{gra} and α_{GRF} are support ratios of the gravity and GRF terms, respectively. By adjusting these ratios in the range of $0 \le \alpha < 1$, support joint moment τ_{sk} can be determined. The gravity term τ_{gra} and the GRF term τ_{GRF} can be expressed as following equations.

$$\begin{aligned}\tau_{gra} = &m_1(\mathbf{r}_{1,c_1} - \mathbf{r}_{1,c_2} + \mathbf{r}_{2,c_2}) \times \mathbf{g} \\ &+ m_2\mathbf{r}_{2,c_2} \times \mathbf{g}\end{aligned} \quad (5)$$

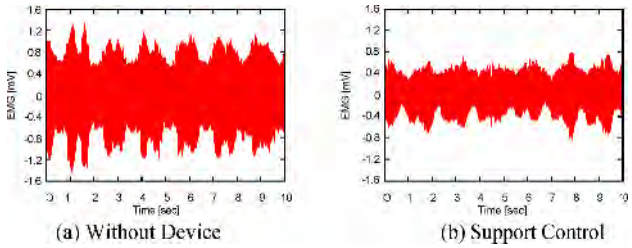
$$\begin{aligned}\tau_{GRF} = &(\mathbf{r}_{1,c_1} - \mathbf{r}_{1,c_2} + \mathbf{r}_{2,c_2}) \times \sum \mathbf{f}_{GRF} \\ &- \sum(\mathbf{r}_{GRF} \times \mathbf{f}_{GRF})\end{aligned} \quad (6)$$

τ_g is also expresses the term of the weight of the device derived by the device model with closedloop mechanism [6].

B. Walking Experiments

In this section, we conducted experiments to support a user during gait by applying the proposed method to Wearable Walking Helper. To show the proposed method is effective for the reduction of burden on the knee joint, we conducted the experiments in two conditions: the subject walked without support device and the subject walked with support device implementing the proposed control method. During the experiments, we measured EMG signals of muscles conductive to the movement of the knee joint.

In the gait cycle, the Vastus Lateralis Muscle is active in most of the stance phase and the Rectus Femoris Muscle is active in last half of the stance phase and most of the swing phase. Therefore, during the experiments, we measure EMG signals of the Vastus Lateralis Muscle and the Rectus Femoris Muscle. The experiments were performed by the university student who is 23-years-old man. Support ratios α in the equation (4) are set to 0.6. Note that, for reducing the impact forces applied to the force sensors attached on the shoes during the gait, we utilized a low pass filter whose parameters were determined experimentally.



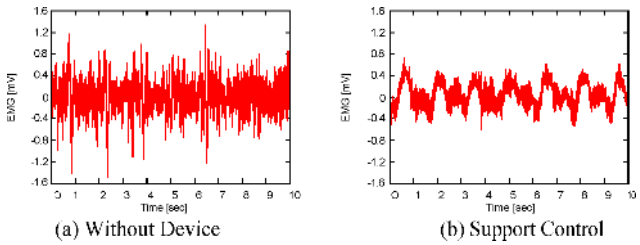


Fig. 7. EMG Signals of Vastus Lateralis Muscle

(a) Without Device (b) Support Control

Fig. 8. EMG Signals of Rectus Femoris Muscle

Fig.7 and Fig.8 show EMG signals of the Vastus Lateralis Muscle and the Rectus Femoris Muscle during the experiments in two conditions explained above. From these results, EMG signals of both the Vastus Lateralis Muscle and the Rectus Femoris Muscle became small in the experiment with support device implementing the proposed control method compared to the experiment without support device. These experimental results show that it is possible to support the walking by using the proposed method.

IV. Conclusions

This paper especially focused on the motion control of the walking assist robot systems based on the human model calculated in real time. According to the human linkage model, the robot systems could calculate a position of the user's center of gravity and the joint moment applied around the each joint of the user in real time. Based on the information of the user, the robot systems could support the walking appropriately. The motion control algorithms based on the human model were implemented to the walker-type walking assist system called RT Walker and the wearable walking assist system called Wearable Walking Helper experimentally, and experimental results illustrated the validity of the proposed methods based on the human model.

Abstract — **Prestin is believed to be the motor protein expressed in the plasma membrane of outer hair cells (OHCs). In this study, characterization of prestin was carried out by site-directed mutagenesis focusing on the unique amino acids in prestin. Five prestin mutants, namely, M122I, C192A, M225Q, C415A and T428L, were engineered to be separately expressed in HEK293 cells. The characteristics of those mutants were then investigated. As a result, it was found that the charge density of M225Q, which reflects the charge transfer of prestin in the plasma membrane, was 1.7 times larger than that of wild-type prestin (WT), although the charge density of the other mutants were similar to that of WT. On the other hand, the amount of M225Q molecules in the plasma membrane was 1.2 times greater than that of WT molecules. The increase in the amount of prestin molecules due to the mutation of M225 probably indicates that prestin became more stable, but such increase does not correspond to the increase of the charge density. Hence, the mutation of M225 was considered to increase the stability of prestin, leading to an increase in the ratio of active prestin molecules to the total amount of prestin molecules in the plasma membrane.**

Keywords — **Inner ear, Motor protein, Prestin, Mutation.**

I. Introduction

The motor protein prestin, one of members of the SLC26 family, in the plasma membrane of OHCs in the inner ear is thought to change its conformation in response to modifications in the membrane potential, resulting in motility of OHCs [1, 2]. This motility enhances the sensitivity and frequency selectivity of mammalian hearing. Based on previous studies, several characteristics of prestin including its secondary structure has been investigated (Fig. 1(A)) [3-5]. However, the mechanism of the conformational change of prestin has not yet been clarified, thus necessitating elucidation of the amino acids of prestin involved in its conformational change. Alignment analysis of amino acid sequences of the SLC26 family showed that M122, C192, M225, C415 and T428 were only present in prestin in that family (Fig. 1 (B)). The predicted positions of these amino acids are shown in Fig. 1(A). As the conformational change of prestin involved in the motility of the OHCs is a unique function in the SLC26 proteins, prestin-specific amino acids may realize such function. In this study, to clarify the roles of those amino acids in prestin, the effects of mutations in those amino acids on characteristics of prestin were investigated. Five prestin mutants, namely, M122I, M225Q, C192A, C415A and T428L, were engineered to be expressed in HEK293 cells. Their characteristics were then examined by the whole-cell patch-clamp method and Western blotting.

II. Materials and Methods

A. Generation of prestin mutant genes and transfection

Point mutations were introduced into M122, C192, M225, C415 and T428. Each codon encoding those amino acids

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2237–2240, 2009
www.springerlink.com

was replaced by glutamine, alanine, isoleucine, alanine and leucine, respectively, resulting in five genes of prestin mutants, namely, genes of M122I, M225Q, C192A, C415A and T428L. Additionally, to detect prestin by antibodies, genes of FLAG-tagged prestin mutants were also created. Those genes were transfected into HEK293 cells.

B. Measurement of nonlinear capacitance

WT prestin-expressing cells exhibit bell-shaped NLC in response to the change of membrane potential [6]. As NLC is associated with a voltage-dependent charge transfer of prestin, NLC is accepted as a signature of the activity of prestin. The activity of prestin was therefore evaluated with NLC measured by the whole-cell patch-clamp technique. NLC is well fitted to the derivative of a Boltzman function [7],

$$C_{\mathrm{m}}(V) = C_{\mathrm{lin}} + C_{\mathrm{nonlin}} = C_{\mathrm{lin}} + \frac{Q_{\max}}{\alpha \mathrm{e}^{\frac{v-v_{1/2}}{\alpha}}\left(1+\mathrm{e}^{-\frac{v-v_{1/2}}{\alpha}}\right)^2} \quad (1)$$

where C_{lin} is linear capacitance which is proportional to the surface area of the plasma membrane, $Q_{\max}$ is maximum charge transfer of prestin in whole plasma membrane, V is membrane potential, $V_{1/2}$ is the voltage at which the maximum charge is equally distributed across the membrane and α is the slope factor of voltage dependence of charge transfer. When membrane potential was changed from –140 mV to 70 mV, membrane capacitance was recorded. To estimate the NLC of the unit cell surface, the normalized NLC $C_{\mathrm{nonlin/lin}}$ was defined as

$$C_{\mathrm{nonlin/lin}}(V) = \frac{C_{\mathrm{nonlin}}}{C_{\mathrm{lin}}} = \frac{\left(C_{\mathrm{m}}(V) - C_{\mathrm{lin}}\right)}{C_{\mathrm{lin}}} \quad (2)$$

where C_{nonlin} is the nonlinear component of the measured membrane capacitance. Furthermore, to compare the normalized data of the prestin mutants with that of WT prestin, $C_{\mathrm{nonlin/lin}}(V)$ was divided by the maximum $C_{\mathrm{nonlin/lin}}(V)$ of WT and termed relative $C_{\mathrm{nonlin/lin}}(V)$. In addition, to evaluate the maximum charge transfer of prestin in the unit plasma membrane, $Q_{\max}$ was divided by C_{lin} and designated as charge density. The unit of charge density is fC/pF.

C. Western blotting

Mutations in membrane proteins often cause their misfolding and transport-defect to the cell membrane. Hence, the amount of the prestin mutants in the cell membrane were compared with that of WT prestin by Western blotting. Plasma membrane fractions of transfected cells were extracted using a Plasma Membrane Protein Extraction Kit (MBL, Nagoya, Japan) according to the manufacturer's instructions. Plasma membrane fractions obtained from 2.5×10^5 cells were dissolved in 5 µl SDS sample buffer. After boiling for 5 min at 100ºC, 5 µl of the sample were subjected to Western blotting.

III. Results

Figure 2 shows representative data of relative $C_{\mathrm{nonline/lin}}$. Fitting parameters, namely, α and $V_{1/2}$, as well as the charge density were shown in Table 1. M122I, C192A, C415A and T428L showed NLC and the maximums of their NLC curves were similar to that of WT. In addition, the $V_{1/2}$ of those mutants and α of T428L were statistically different from those of WT. On the other hand, interestingly, the maximum of the NLC curve of M225Q was significantly larger than that of WT. The charge density of M225Q is 1.7 times larger than that of WT. The charge density reflects the amount of active prestin molecules in the plasma membrane. Thus, the increase in the charge density may indicate an increase of such amount. Although α was unchanged, the $V_{1/2}$ of M225Q was statistically shifted in the hyperpolarization direction

Result of Western blotting using plasma membrane fraction was shown in Fig. 3(A). In both WT and M225Q, only the 100 kDa band was observed. To compare the amount of M225Q molecules in the plasma membrane with that of WT molecules, the intensity of the 100 kDa band in M225Q was divided by that in WT and termed relative intensity as shown in Fig. 3(B). The intensity of the 100 kDa band in M225Q was 1.2 times greater than that in WT on an average, indicating that the amount of M225Q molecules is slightly higher than that of WT molecules.

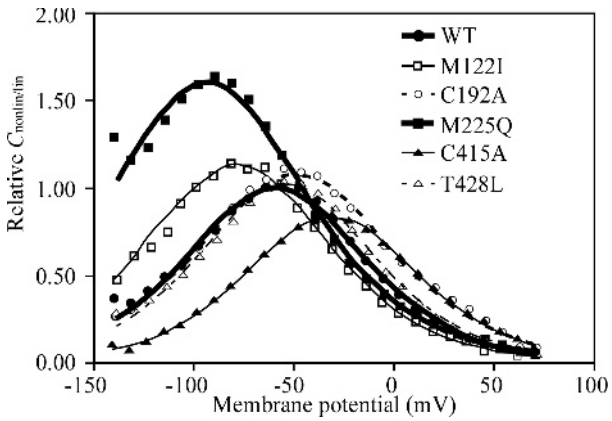

Fig. 2. Representative data of relative $C_{\mathrm{nonlin/lin}}$. M122I, C192A, C415A and T428L showed NLC similar to that of WT. On the other hand, NLC of M225Q was significantly larger than that of WT.

Table 1 Fitting parameters and charge density. Asterisks indicate statistical significance of the difference in any parameters between WT and its mutants.

Gene	α (mV)	$V_{1/2}$ (mV)	Charge density (fC/pF)
WT (n = 11)	32.0 ± 3.8	-61.2 ± 4.2	14.4 ± 7.1
M122I (n = 26)	30.3 ± 2.7	-70.8 ± 6.6*	18.9 ± 7.1
C192A (n = 16)	30.4 ± 3.2	-55.0 ± 6.6*	18.4 ± 6.6
M225Q (n = 12)	31.9 ± 2.8	-94.1 ± 5.0*	25.4 ± 5.5*
C415A (n = 13)	37.4 ± 6.4	-37.4 ± 6.4*	13.3 ± 4.3
T428L (n = 13)	28.5 ± 2.5*	-50.0 ± 5.7*	14.5 ± 5.9

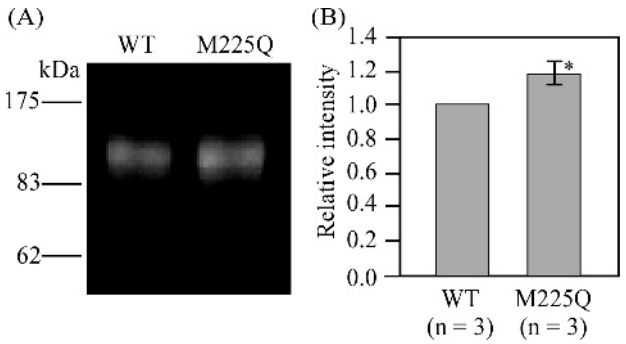

Fig. 3. Results of Western blotting using plasma membrane fraction of transfected cells. (A) Representative image of Western blotting. Only the 100 kDa bands were detected in WT and M225Q. (B) Relative intensity. The intensity of M225Q is statistically larger than that of WT ($P < 0.05$).

IV. Discussion

This study was focused on M122, C192, M225, C415 and T428, which were considered to be unique amino acids of prestin when the amino acid sequence of prestin was compared with those of the other SLC26 proteins. To clarify the roles of those amino acids in prestin, M122I, M225Q, C192A, C415A and T428L were engineered to be expressed in HEK293 cells and then the characteristics of these mutants were investigated by the whole-cell patch-clamp and Western blotting. As shown in Fig. 2 and Table 1, the charge density of M122I, C192A, C415A and T428L was similar to that of WT, but their $V_{1/2}$ and α were significantly different from those of WT prestin. Meanwhile, M225Q exhibited a 1.7 times larger charge density than that of WT. The $V_{1/2}$ of M225Q was statistically shifted in the hyperpolarization direction. The α and $V_{1/2}$ represent voltage reactivity of prestin. Hence, our results imply that all amino acids focused on in this study are related to the voltage reactivity of prestin. As the charge density reflects the amount of active prestin in the plasma membrane, the result of the patch-clamp recording for M225Q indicates that M225 is involved in such amount.

To compare the amount of M225Q in the plasma membrane with that of WT, Western blotting using the plasma membrane fraction of WT-expressing cells and M225Q-expressing cells was performed. As shown in Fig. 3(B), the intensity of the 100 kDa band in M225Q was 1.2 times greater than that in WT on the average. The intensity of that band reflects the amount of prestin molecules in the plasma membrane, namely, the sum of the amount of active prestin molecules and that of inactive prestin molecules. Thus, the 1.2-times increase in the intensity of the 100 kDa band indicates an increase of 1.2 times in the total amount of prestin molecules in the plasma membrane. The increase of prestin molecules in the plasma membrane may possibly result from the stabilization of prestin by the mutation. As described above, the charge density increased 1.7 fold by the mutation. Hence, the increase of the charge density cannot be explained by the increase of the total amount of prestin in the plasma membrane. One possible explanation for the increase of the charge density may be that the mutation in M225 made prestin stable, leading to an increase in the ratio of active prestin molecules to the total amount of prestin molecules in the plasma membrane.

V. Conclusions

Our findings indicate that the mutation in M225 may make prestin more stable, resulting in an increase in the ratio of active prestin molecules to the total amount of prestin molecules in the plasma membrane, which leads to the increase of the charge density.

Abstract — **Recent anticancer drugs are made to be larger to selectively pass the tumor vessel and to stay in the interstitium. Understanding of the drug movement in a single molecule is indispensable to optimize drug delivery. Here we report the tracking of single nano-particles with different sizes in tumor xenografts *in vivo*. The motions of the nano-crystals were clearly observed and random with one-way movement. The analysis of the trajectory shows that contribution of diffusion and interstitial fluid current to the delivery processes. The diffusion coefficient was inversely related to the size and position and velocity was related to the position of the particles. Our data are basic and important for understanding pharmacokinetics and convenient finding for constructing novel drug delivery system.**

Keywords — **Nanomedicine, Drug Delivery System**

I. Introduction

Numerous drugs have been developed to maximize drug effects to the targeted tumor by controlling their diameter to the appropriate size in order to selectively pass the tumor vasculate utilizing the characteristics of a cancer vasculate having larger pore than a normal vasculate. The large hole selectively passed large nanoparticle experimentally. The size dependency of the drug delivery in a tumor interstitium was estimated quantitatively from observing the averaged dispersion of the larger drugs *in vivo*. On the other hand, Single particle tracking is a powerful method to understand unprecedented reductive information of individual drug molecules such as antibody delivery process.

Single particle tracking *in vivo* enabled us the tracking of the tumor cell metastasis and delivery process of the antibody, but there is no quantitative analysis *in vivo*. In this study, we focused on the quantification of the influence of molecular size by homogenously fluorescence nanoparticles in the tumor xenografts based on the single particle tracking. We used real-time single particle tracking using confocal scanning unit. Quantitative information such as position was obtained. Velocity, diffusion coefficient are calculated using time-resolved trajectories of the single particles by analyzing the data.

As a result, we successfully identified the processes of delivery and quantitatively analyzed them to understand the rate limiting constraints on single nano-particle delivery in interstitial space *in vivo*.

Understanding of the vascular pore size effect and interstitial pathway to the cancer cells quantative analysis in a single molecule and a particle level is necessary to optimize the drug delivery.

II. Material and methods

1.1. Nanocrystals

We used 'Fluospheres' manufactured from high-quality, ultraclean polystyrene microspheres by Invitrogen, Molecular Probe (Oregon, USA) and Quantum dot 705 ITK kit (Quantum Dot Corp., Hayward, CA). We selected sizes of 20, 40, 100nm.

1.2. Cell lines

The human breast cancer cell line KPL-4[1] was kindly provided by Dr. J. Kurebayashi (Kawasaki Medical School, Kurashiki, Japan). KPL-4 cells were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 5% fetal bovine serum.

1.3. Experimental Animals

A suspension of KPL-4 (1.0×10^7 cells / 100 µl DMEM) tumor cell was transplanted subcutaneously into the dorsal skin of female Balb/c nu/nu mice at 5 - 7 weeks of age (Charles River Japan, Yokohama, Japan). Several weeks after tumor inoculation, mice with a tumor volume of 100 - 200 mm^3 were selected.

The mice were placed under anesthesia by the intraperitoneal injection of a ketamine and xylazine mixture at a dosage of 95 mg / kg and 5 mg / kg, respectively.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2241–2243, 2009
www.springerlink.com

1.4. Imaging systems

The optic system consisted of an epi-fluorescent microscope, Nipkow lens type confocal unit and an electron multiplier type CCD camera (Fig.1). This system can captures images of single nanoparticles at a video rate of 33 ms/frame. The xy-position of the fluorescent spot was calculated by fitting to a 2D-Gaussian curve. The single molecule could be identified by the fluorescence intensity. And quantitative and qualitative information such as velocity, directionality and transport mode was obtained using time-resolved trajectories of particles.

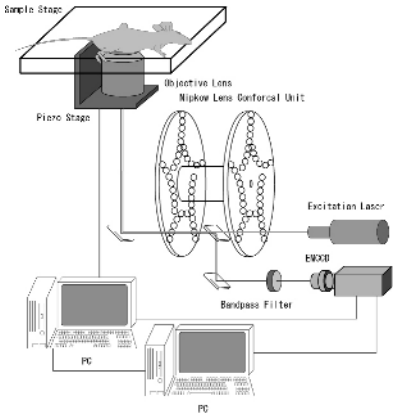

Fig.1. Imaging system

1.5. Analysis

Mean square displacement (MSD) values of individual nano-crystals are defined by the following equation:

$$\mathrm{MSD}(n\Delta t) = \frac{1}{N-n}\sum_{i=1}^{N-n}\left[\left(x_{i+n}-x_i\right)^2+\left(y_{i+n}-y_i\right)^2\right]$$

$$\mathrm{MSD}(\Delta t) = 4\mathrm{D}\Delta t + v^2(\Delta t)^2$$

$$\lim_{t\to 0}\mathrm{MSD}(\Delta t) = 4\mathrm{D}\Delta t$$

III. Results

After the injection, many particles had extravasated and moved into the perivascular area close to the tumor vessels (Fig. 2). Particle diffuses within a highly restricted area and then moves suddenly to the next point. We acquired trajectories of the three sizes of particles in the three parts of the tumor (perivascular, interstitial and intercellular).

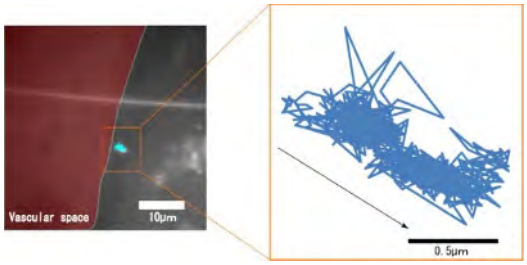

Fig.2. Trajectory of the single nano-particle

The MSD plots of the particles in the perivascular area (Fig.3). The plots are in parabolic shape, indicating that the movements are consisted of convection with superimposed random diffusion.

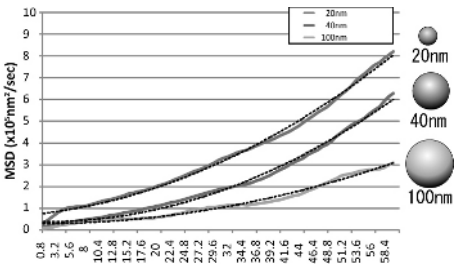

Fig.3. The MSD plots in the perivascular area

Velocity depends on the position (Fig.4) of the particle size. Velocity was weakly dependent on the size but dependent on the position from perivascular region.

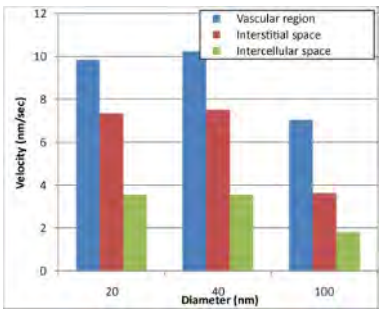

Fig.4. The relationships of diameter and velocity

IV. Conclusion

Our data of velocity is consistent with previous experimental results that it was weakly dependent on the size[2] but dependent on the decreasing interstitial flow from perivascular region[3]. We assume that our data means that the reason of the convectional movement not having been

interrupted by the size but by the position was that the 3D-structure of extracellular matrix was not so tight to restrict the current of the different sizes of the particles but confine diffusion.

Abstract — **We propose a numerical method for simulating three-dimensional hemodynamics arising from malaria-infection. Malaria-infected red blood cells (IRBCs) become stiffer and develop the property of cytoadherent and resetting. To clarify the mechanism of microvascular obstruction in malaria, we need to understand the changes of hemodynamics, involving interaction between IRBC, healthy RBCs, and endothelial cells. In the proposed model, all the components of blood are represented by a finite number of particles. The membrane of RBCs is expressed by two-dimensional network. Malaria parasites inside the RBC are represented by solid objects. The motion of each particle is described by the conservation laws of mass and momentum for incompressible fluid. We examine several numerical tests, involving the stretching of IRBCs, and flow in narrow channels, to validate our model. The obtained results agree well with the experimental results. Our method would be helpful for further understandings of pathology of malaria-infection.**

Keywords — **Infected red blood cell, hemodynamics, numerical modeling, computational fluid dynamics.**

I. Introduction

Malaria is one of the most serious infectious diseases on earth. There are several hundred million patients with several million deaths arising from malaria infection. When a parasite invades and matures inside a red blood cell (RBC), the infected RBC (IRBC) becomes stiffer and cytoadherent and these two outcomes can lead to microvascular blockage [1]. Experimental techniques for cell mechanics have been advanced and applied to study the mechanical property of IRBCs. Methods to quantify the stiffness of the IRBCs include the micropipette aspiration [2-4] and the optical tweezers [5]. Suresh et al. [5] used the optical tweezers to investigate the change of mechanical response of IRBCs at different development stages. They clarified that the shear modules can increase by ten-fold in the final schizont stage. The recent reviews are found in [6-8].

Microvascular blockage may be resulted from the hemodynamics, involving the interactions between IRBCs, healthy RBCs and endothelial cells. Recently, microfluidics has been used to investigate the effect of IRBCs on the capillary obstruction. Shelby et al. [9] demonstrated that IRBCs in the late stages of the infection cannot pass through micro channels that have diameters smaller than those of the IRBCs. However, this experiment is still limited to the effect of the single infected cell. The hemodynamics arising from malaria infection has not been studied well. This is due to the limitation of the current experimental techniques. First, it is still difficult to observe the RBC behavior interacting with many other cells even with the recent confocal microscope. Second, the three-dimensional information on flow field is hardly obtained. Third, capillaries in human body are circular channels with complex geometry, but such complex channels cannot be created in micro scale. Instead, numerical modeling can be a strong tool for further understanding the pathology of malaria. Finite element modeling was performed for the stretching of an IRBC by optical tweezers [5]. Dupin et al. [10] also modeled the stretching of the IRBC using lattice Boltzmann method. We have also developed a hemodynamic model involving adhesive interactions [11]. In this paper, we present our methodology and preliminary numerical results.

II. Method

A. Particle method

Blood is a suspension of RBCs, white blood cells, and platelets in plasma. An RBC consists of cytoplasm enclosed by a thin membrane. Assuming that plasma and cytoplasm are incompressible and Newtonian fluid, the governing equations are described as

$$\frac{D\rho}{Dt} = 0\,, \tag{1}$$

$$\frac{D\mathbf{u}}{Dt} = -\frac{1}{\rho}\nabla p + \nu\nabla^2\mathbf{u} + \mathbf{f}\,, \tag{2}$$

where the notation t refers to the time, ρ is the density, $\mathbf{u}$ is the velocity vector, p is the pressure, ν is the dynamic viscosity, $\mathbf{f}$ is the external force per unit mass, and D/Dt is the Lagrangian derivative.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2244–2247, 2009
www.springerlink.com

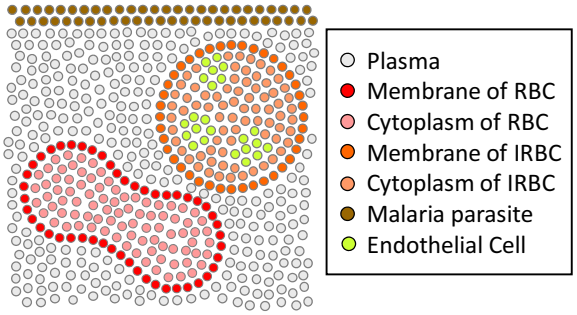

Fig. 1 Free mesh modeling of blood

Our model is based on a particle method. All the components of blood are represented by of particles (Fig. 1). Note that each particle is not a real fluid particles but a discrete point for computation. Fluid variables are calculated at the computational point and it is moved by the calculated advection velocity every time step. In conventional mesh methods, each computational point requires the connection to neighboring points for the discretization of Eqs. (1) and (2) and thus the computational meshes are generated. When a red blood cell approaches to other cell, however, the computational meshes can be distorted and destroyed easily. In contrast to mesh methods, the particle method does not require such computational meshes and the computation is stable even when many cells interacting with each other. Another advantage of the particle method is the coupling with the front-tracking. The particle method tracks the front of membrane using the membrane particles and the no-slip condition on the membrane is directly imposed to Eq. (2) by using the position and velocity of membrane particles. We use moving particle semi-implicit (MPS) method [12] for solving Eqs. (1) and (2). In the MPS method, differential operators in the governing equations are approximated using the weight function, for example,

$$\nabla\phi_i = \frac{d}{n^0}\sum_{j\neq i}\frac{\phi_j-\phi_i}{\left|\mathbf{r}_{ij}\right|^2}\mathbf{r}_{ij}w\left(\left|\mathbf{r}_{ij}\right|\right), \tag{3}$$

$$\nabla^2\phi_i = \frac{2d}{\lambda n^0}\sum_{j\neq i}\left(\phi_j-\phi_i\right)w\left(\left|\mathbf{r}_{ij}\right|\right), \tag{4}$$

where ϕ is a fluid variable, d is the space dimension number, n^0 is the reference particle number density, λ is the constant, $\mathbf{r}$ is the position of particle, $\mathbf{r}_{ij} = \mathbf{r}_j - \mathbf{r}_i$, and w is the weight function.

B. Modeling of IRBCs

The membrane of IRBCs is represented by the two-dimensional network consisting of the finite number of particles (Fig. 2). Particle j is connected to particle i by linear spring, giving a force,

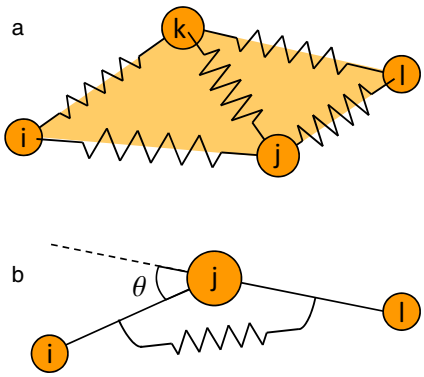

Fig. 2 Spring network model of IRBC membrane: (a) stretching force; (b) bending force.

$$\mathbf{F}_j^s = k_s\left(\left|\mathbf{r}_{ij}\right| - l_0\right)\frac{\mathbf{r}_{ij}}{\left|\mathbf{r}_{ij}\right|}, \tag{5}$$

where k_s is the spring constant and l_0 is the equilibrium distance. A bending force is also considered in our model:

$$\mathbf{F}_j^b = \mathbf{F}_k^b = \frac{\mathbf{F}_i^b + \mathbf{F}_l^b}{2}, \tag{6}$$

$$\mathbf{F}_i^b = k_b\tan\left(\frac{\theta}{2}\right)\mathbf{n}_{ijk}, \tag{7}$$

$$\mathbf{F}_l^b = k_b\tan\left(\frac{\theta}{2}\right)\mathbf{n}_{jkl}, \tag{8}$$

where k_b is the spring constant, θ is the angle between the triangles Δ_{ijk} and Δ_{jkl}, and $\mathbf{n}_{ijk}$ is the normal vector to the triangle Δ_{ijk}. The external force per mass is given as

$$\mathbf{f}_i = \frac{\mathbf{F}_j^s + \mathbf{F}_j^b}{\rho V_0}, \tag{9}$$

where V_0 is the reference volume $V_0 = r_0^3$, r_0 is the averaged particle distance at initial time step. Note that the spring constants k_s and k_b should be model parameters to control the deformation of IRBCs. As described in the next section, we adjust these model parameters through numerical experiments.

A malaria parasite inside IRBCs is modeled by a rigid object constructed by some particles. The treatment of the rigid object in the MPS method was proposed by Koshizuka et al [13].

C. Time integration

The time step size of time integration is limited by several factors. Most famous one in computational fluid dynamics is the Courant number limitation for the time integration of advection term. In the micro circulation, the diffusion number can be the most serious parameter because of small Reynolds number. Also, the behavior of RBC membrane may limit to the time step size. To avoid the use of small time step size, we employ a fractional time step method with sub time steps. The fractional time step method is written by

$$\mathbf{u}^{*} = \mathbf{u}^{n} + \nu\nabla^{2}\mathbf{u}^{n}\Delta t, \tag{10}$$

$$\mathbf{u}^{**} = \mathbf{u}^{*} + \mathbf{f}^{*}\Delta t, \tag{11}$$

$$\mathbf{u}^{n+1} = \mathbf{u}^{**} - \nabla p^{n+1}\Delta t, \tag{12}$$

where the superscripts n is the time step, $\mathbf{u}^{*}$ and $\mathbf{u}^{**}$ are the intermediate velocity. However, the time step size Δt in Eqs. (10) and (11) may be not small enough for the stable computation. Thus we introduce the sub time step, for example,

$$\mathbf{u}^{*} = \mathbf{u}^{n} + \sum_{m=0}^{M-1}\nu\nabla^{2}\mathbf{u}^{n,m}\Delta\tau, \tag{13}$$

$$\mathbf{u}^{n,m+1} = \mathbf{u}^{n,m} + \nu\nabla^{2}\mathbf{u}^{n,m}\Delta\tau, \tag{14}$$

where the superscript m is the sub time step, and $\Delta\tau = \Delta t / M$ is the sub time step size. The sub time step size is determined by the diffusion number limitation.

III. Results

A. Stretching of IRBCs

A well known method to quantify the mechanical response of IRBCs is the stretching by the optical tweezers. Suresh et al. measured the axial and transverse diameters of IRBCs at different development stages with several stretching forces. We examine this stretching test numerically to validate our model. In the three-dimensional computational domain, we put an IRBC at initial time step. Then we stretch the IRBC horizontally with a stretching force as shown in Fig. 3. The time integration is carried out until the axial and transverse diameters are well converged. If the obtained results do not follow the experimental results, the values of model parameters k_s and k_b are changed and the computation is carried out again. Finally we can get the appropriate values of the model parameters. Figure 4 shows the comparison between the numerical results and the experimental results by Suresh et al. [5] for the IRBC in the schizont stage. When we use the appropriate parameters, the numerical results agree well with the experimental results. A small difference can be found in the axial diameter, in particular, for high stretching forces. This may be due to the linear elastic modeling of RBC membrane.

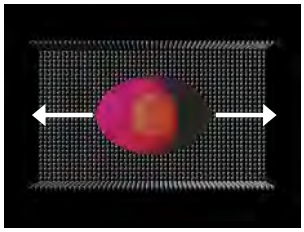

Fig. 3 Numerical test of stretching of the IRBC.

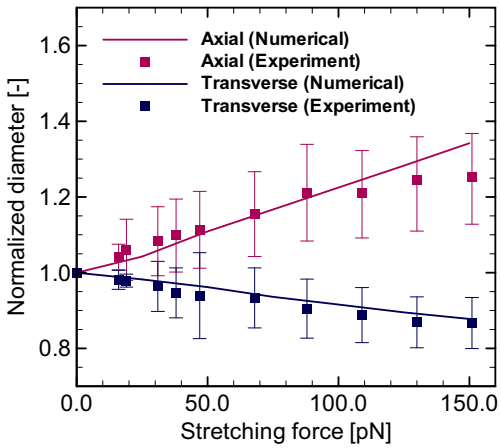

Fig. 4 Comparison between the numerical and experimental results for the stretching of the IRBC in the schizont stage.

B. Flow in narrow channels

We also simulate the flow into narrow channels using our numerical model. Here, we consider the flow of a healthy RBC (HRBC) and a schizont IRBC in a 6-μm-square channel. The flow is driven by the pressure difference between the inlet and outlet. Snapshots of the numerical simulation are presented in Fig. 5. As observed in experimental studies, the HRBC passes through the narrow channel with large deformation. In contrast to the HRBC, the schizont IRBC hardly flows into the narrow channel. These results follow the experimental observation by Shelby et al [9]. They revealed that IRBCs in the late trophozoite and schizont stages occluded flow into the channel with 6μm width. The depth of their channels was fixed to 2μm and thus the effect of such a small depth was not clarified. In contrast to their experiments, our results clearly demonstrate that the IRBCs can occlude the flow even in the 6-μm-square channels.

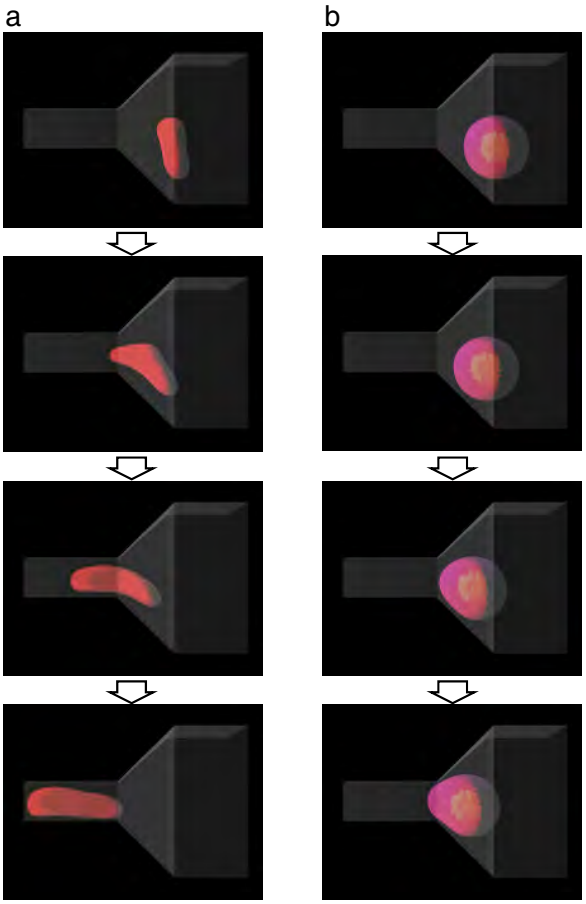

Fig. 5 Snapshots of the behavior of the IRBC in narrow channel: (a) HRBC; (b) IRBC in the schizont stage.

IV. Conclusions

We have developed a numerical model of three-dimensional hemodynamics arising from malaria infection. Particle based spatial discretization and the sub time step time integration can provide us stable computations for the micro scale blood flow involving the interaction with many cells. We performed the stretching of IRBCs and the numerical results agreed well with experimental results. The flow in narrow channels was also examined for the 6-μm-square channel. As reported in experimental studies, the IRBC in the late stage of infection could not pass through the narrow channels. In this paper, we have not considered the adhesion property of IRBCs. We have already developed an adhesion model [11] and this adhesion model can be applied easily to the current hemodynamic model. In the next paper, we will show the effects of the adhesion to micro circulation.

Abstract — **The incidence of breast cancer is in the first place as a cause of death among Japanese women. The breast cancer is a type of cancer which can be cured relatively easily when detected early. However, it is now clear that the detection of breast cancer is difficult without imaging modalities such as X-ray mammography and/or ultrasonic echography. These imaging devices are useful, however, morphological information only are not enough for differentiating cancer from other benign diseases. Positron emission tomography (PET) for whole-body diagnosis can give us functional information regarding the degree of malignancy. But still there remain various problems such as limited spatial resolution and motion artifacts due to respiratory movement, as well as an issue of the high costs. To compensate these weak points, we have started development of the positron emission mammography (PEM) dedicated for the local diagnosis of the breast tissue.**

We had developed a test device, "PEM simulator" last year. And we have developed a prototype PEM scanner. In the present paper, basic features are introduced regarding a gantry, chair, detector unit and measurement system of the PEM scanner, as well as our first results obtained by using this prototype scanner.

Keywords — **positron emission mammography (PEM), positron emission tomography (PET), [^{18}F]fluorodeoxyglucose (FDG), X-ray mammography, breast cancer.**

I. Introduction

The incidence of breast cancer is in the first place as a cause of death among Japanese women. The breast cancer is a type of cancer which can be cured relatively easily if it is detected early enough, because the breast cancer grows surface of the body. The highest incidence of breast cancer is seen among the thirties and forties. The high incidence among these generations would affect our society considerably because the women in these generations are usually serving important roles in their families and working places.

Recently imaging modalities such as X-ray mammography and/or ultrasonic echography are useful for the detection of breast cancer. However, these modalities give us morphological information only. Younger women or women who have no history of breastfeeding are tending to developing of mammary gland. A case of X-ray mammography, the developing of mammary gland makes shadows to mammography images and makes the detection of breast cancer difficult.

Positron emission tomography (PET) for whole-body diagnosis can give us functional information of cancer tissues including the degree of malignancy that can be reflected by the level of accumulation of a tracer, [^{18}F]fluorodeoxyglucose (FDG). But still there remain various problems such as limited spatial resolution and motion artifact due to respiration movement, as well as an issue of the very high costs for installment and maintenance. In measuring events of the coincidences of positrons, larger distance between detectors, as seen with PET scanners, for whole-body imaging makes a limit of spatial resolution.

In order to compensate these weak points, we have started development of a positron emission mammography (PEM) scanner dedicated for the local diagnosis of the breast tissues. The PEM scanner is much smaller than conventional PET. Therefore, the smaller scanner can have an improved spatial resolution and lowered costs.

II. PEM in the world

These days, a number of positron emission tomography for detecting breast cancer was constructed 1-5 . Murthy et al. have combined PEM with X-ray mammography to overlay these images [6]. Lecoqa and Varela have used LYSO as a scintillator and avalanche photo diode as scintillation detector [7]. Raylmana et al. have developed a dedicated system for biopsy of breast cancer 8.

III. Development prototype PEM scanner

A. PEM simulator

We are developing PEM scanner. We will make a prototype PEM scanner for commercial use. This scanner will

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2248–2249, 2009
www.springerlink.com

detect smaller tumor, be cheaper and smaller than conventional PET scanner. We aim less than 1-2 millimeter in spatial resolution. The price will be 20 percents than conventional PET scanner.

We have developed some test devices and the PEM simulator last year. One of them is block detector device. The device is constructed by flat-panel photo multiplier tube (FP-PMT), inorganic scintillator crystals array, aluminum case and signal processing circuit. The FP-PMT is multi anode PMT which has 16x16 anodes and has position sensitivity.

The PEM simulator is a testing and an evaluating system of PEM scanner. The simulator has four block detector devices, high voltage supply units for photo multiplier tubes and signal processing units. The signal processing unit consists of analog amplifier, analog to digital converter, FPGA devices and communication interface for PC.

We used this device for evaluation of a basic property of PEM scanner we are developing. We measured point sources and line sources and took some distribution images of positron sources.

B. Large area PEM detector unit

We have developed a large area PEM detector unit. The size of the detector unit is 156 x 208 mm^2. It consists of three 140.8 x 44 mm^2 inorganic scintillator crystals arrays (Fig. 1) and 3 x 4 FP-PMTs (Fig. 2). These are stored in a aluminum case shielded from lights (Fig. 3). Two PEM detector units are used the prototype PEM scanner and set up parallel. We are measuring some radioactive phantoms with using these detector units.

We are developing control and acquisition software, a gantry and a chair, too. Finally we will assemble the detector unit and these parts and construct the PEM scanner. We will check a safety of the scanner and measure in clinical use.

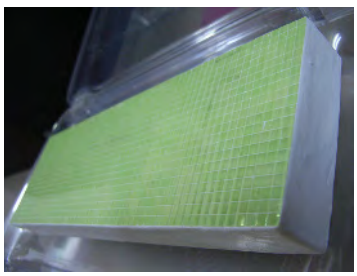

Fig. 1 An inorganic scintillator crystals arrays. The size of the crystal is 2.2 x 2.2 x 15 mm^3 and the size of the arrays is 140.8 x 44 mm^2.

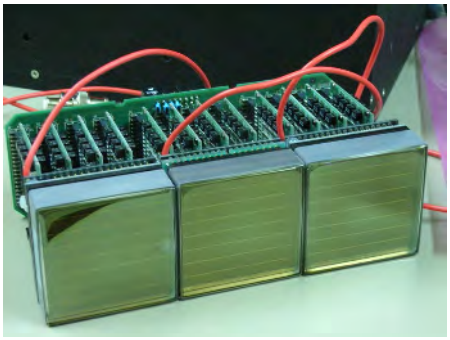

Fig. 2 A part of FP-PMTs of the PEM detector unit.

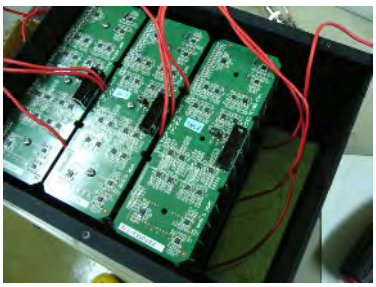

Fig. 3 A cover of the PEM detector unit is opened. We can see an aluminum case, an inorganic scintillator crystals allay and electronic circuits for FP-PMTs.

Radiological Anatomy of the Right Adrenal Vein: Preliminary Experience with Multi-detector Row Computed Tomography

T. Matsuura, K. Takase and S. Takahashi

Dept of Radiology, Tohoku University School of Medicine, Sendai, Japan

Abstract — **OBJECTIVE. The purpose of our study was to determine how frequently the right adrenal vein could be unequivocally identified on MDCT and what spectrum of anatomic variations was seen among the right adrenal vein. MATERIALS AND METHODS. Post-contrast MDCT were obtained using an 8-detector row helical CT scanner in 104 patients with thoracoabdominal vascular disease. Both axial and multiplanar images were reviewed by two radiologists. The following points regarding the right adrenal vein were evaluated: the degree of visualization; the relationship to accessory hepatic or other veins; the anatomy including the location of the orifice in relation to the surrounding structures, direction from the inferior vena cava, and length and diameter. RESULTS. The right adrenal vein was detected in 79 (76%) of 104 patients. The right adrenal vein formed a common trunk with an accessory hepatic vein in 6 (8%) of the 79 patients. The orifice was craniocaudally located between the level of vertebrae T11 and L1. Among the 73 patients, the right adrenal vein joined the inferior vena cava in the right posterior quadrant in 71 (97%) and in the left posterior quadrant in 2 patients (3%). The transverse direction from the inferior vena cava was posterior and rightward in 56 (77%) and posterior and leftward in 17 (23%), and the vertical direction from the inferior vena cava was caudal in 65 (89%) and cranial in 8 patients (11%). The length and diameter averaged 3.8 and 1.7 mm, respectively. CONCLUSION. MDCT enabled the identification of the right adrenal vein and delineation of its anatomy, including the position and relationship to surrounding structures.**

Keywords — **CT, anatomy, right adrenal vein, adrenal venous sampling, aldosteronism**

I. Introduction

Primary aldosteronism is the most common form of secondary hypertension [1, 2]. Unilateral aldosterone-producing adenoma and bilateral idiopathic hyperaldosteronism are the two most common subtypes of primary aldosteronism, and distinguishing between them is critical for treatment planning, because the former is treated with adrenalectomy while the latter is treated medically [3]. CT and MRI are both still unreliable methods for distinguishing the subtypes of primary aldosteronism [4-6], for which adrenal venous sampling is often undertaken [6, 7].

Selective adrenal venous sampling can be difficult to perform because catheterization of the right adrenal vein (RAV) generally remains difficult [6-11]. The difficulty associated with RAV catheterization appears to result from the small size and variable anatomy of the RAV, which is a vein that usually drains directly into the inferior vena cava (IVC) at a variable angle [8, 12].

MDCT could possibly guide adrenal venous sampling if it were capable of delineating the anatomy of the RAV. Although Daunt referred to the feasibility of identifying the RAV with MDCT [12], to our knowledge, a detailed analysis regarding visualizing the anatomy of the RAV with MDCT has never been made. We undertook this study to determine how frequently the RAV could be identified on MDCT and what spectrum of anatomic variations was seen among the RAV.

II. Materials and methods

This study was approved by the hospital institutional review board and is compliant with the Health Insurance Portability and Accountability Act (HIPAA). Informed consent was waived by the hospital institutional review board.

A. Patients

We performed a retrospective analysis of CT images from 104 consecutive patients (69 men, 35 women; mean age, 67 years; range, 26–89 years) with a presumptive diagnosis of thoracoabdominal vascular disease.

B. CT examination

The CT scanner was an 8-detector row helical CT scanner. Before scanning was started, 100 mL of contrast material containing 300 mg of iodine per milliliter was injected at a rate of 3.5 mL/sec. Transverse sections were reconstructed with a 1-mm section thickness. We used a cine-mode display of transverse and multiplanar reformation (MPR) images to evaluate the RAV. Two radiologists analyzed the CT images.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2250–2253, 2009
www.springerlink.com

C. Points of evaluation

We evaluated the following points regarding the RAV: the degree of visualization; whether the common trunk was formed before entering the IVC with accessory hepatic or other veins; the anatomy of the RAV including the location of the orifice, direction, length and diameter of the RAV when it directly joined the IVC. For describing the direction of the RAV, we used a three-dimensional coordinate system and aligned the rectangular coordinate axes with the body axes (i.e., anteroposterior = *x*-axis, transverse = *y*-axis, and vertical = *z*-axis). The positive *x*-, *y*-, and *z*-axes pointed posteriorly, rightward, and caudally, respectively.

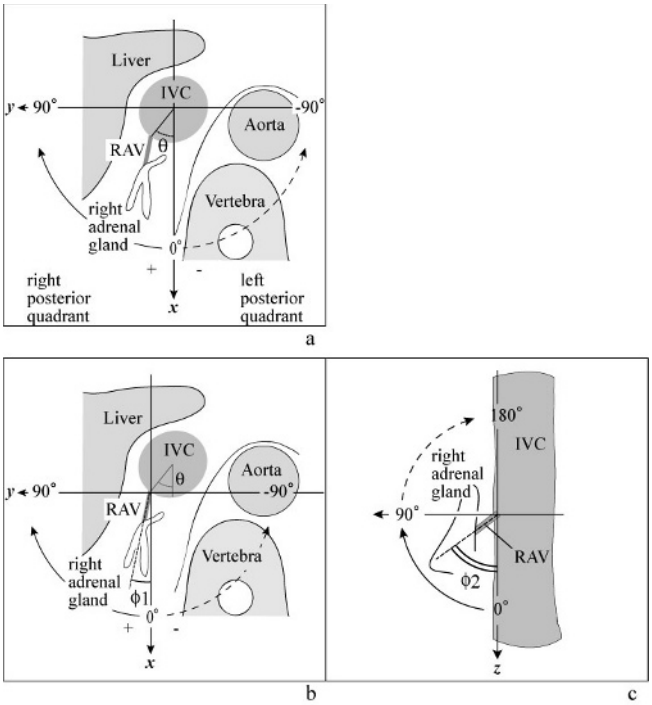

Fig. 1 The position of the right adrenal vein (RAV) orifice and its relationship to the surrounding structures, and the direction of the RAV (a) The transverse plane observed from the inferior shows the position of the RAV orifice, which was estimated along the circumference of the inferior vena cava (IVC) as an angle θ between the radius line through the orifice and the *x*-axis in the *x*-*y* plane. The intersection of the *x*- and *y*-axes is specified as the center of the IVC. The angle θ was measured positively in the clockwise direction from the *x*-axis with a negative angle being in the counterclockwise direction. When θ falls between 0° and 90°, the RAV is described as entering the IVC in the right posterior quadrant; when θ falls between –90° and 0°, it is described as entering in the left posterior quadrant. (b) The transverse plane shows the direction of the RAV from the IVC, which was measured in the *x*-*y* plane as an angle ϕ1 between the projected figure of the RAV and the *x*-axis. The intersection of the *x*- and *y*-axes is specified as the junction between the RAV and IVC. The angle ϕ1 was measured positively in the clockwise direction from the *x*-axis with a negative angle being in the counterclockwise direction. (c) The vertical plane shows the craniocaudal direction of the RAV from the IVC, which was measured as an angle ϕ2 between the RAV and the *z*-axis. The intersection of the *x*-*y* plane and *z*-axes is specified as the junction between the RAV and IVC. The angle ϕ2 was measured from the *z*-axis to the RAV.

Degree of visualization of the RAV: The rate of visualization was checked. The degree of visualization was arbitrarily graded on a 5-point scale as follows: "excellent", "good", "fair", "poor", and "none". We defined the former three categorized groups (excellent, good, and fair) as those with an unequivocally identified RAV, in which the following anatomical analyses were made, and the latter two groups (poor and none) were categorized as those with an unidentified RAV and excluded from the following analyses.

Relationship of the RAV to accessory hepatic or other veins: We examined whether a common trunk for the RAV and accessory hepatic or other veins was formed before entering the IVC. When the RAV directly entered the IVC but almost shared a common orifice with accessory hepatic or other veins, it was also recorded.

Location of the RAV orifice in relation to surrounding structures: The craniocaudal level of the RAV orifice was specified relative to vertebral bodies and discs. Vertebral bodies were divided into three segments: superior, middle, and inferior. The position of the orifice was also evaluated along the circumference of the IVC as an angle θ in the *x*-*y* plane (Figure 1a).

Direction of the RAV from the IVC: To evaluate the direction of the RAV from the IVC, two angles were measured: the first was the angle ϕ1 between the RAV and *x*-axis when the RAV was projected onto the *x*-*y* plane (Figure 1b), while the other was the craniocaudal angle ϕ2 between the RAV and z-axis when the RAV was projected onto the vertical plane that paralleled the RAV (Figure 1c).

Length and diameter of the RAV: We measured the length of the RAV between the exit from the right adrenal gland and entry to the IVC, and the diameter of the RAV at the junction with the IVC.

III. Results

Degree of visualization of the RAV: The degree of visualization was excellent in 36 (35 %; Figure 2a), good in 30 (29%; Figure 2b), fair in 13 (13%), poor in 7 (7%), and none in 18 (17%) of 104 patients. Therefore, the RAV was detected in 79 (76%) of 104 patients according to our identification criteria (excellent to fair), in which the following anatomical analyses were made.

Relationship of the RAV to accessory hepatic or other veins: Among the 79 patients who had an identifiable RAV (excellent to fair), the RAV and accessory hepatic vein formed a common trunk before entering the IVC in 6 (8%; Figure 3), the RAV entered the IVC directly but almost

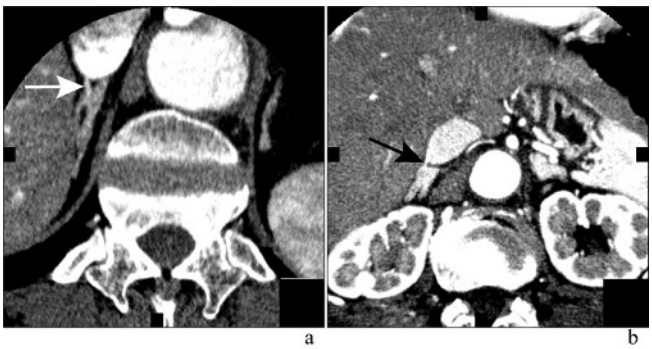

Fig. 2 Examples of the right adrenal vein (RAV) showing variable degree of visualization (a) 54-year-old man. A para-axial multiplanar reformatted image shows excellent visualization of the RAV (arrow) running through the intervening adipose tissue to join the right posterior quadrant of the inferior vena cava (IVC). (b) 87-year-old woman. A para-axial multiplanar reformatted image shows the RAV (arrow) and the right adrenal gland located close to the inferior vena cava (IVC). Although the RAV is a small structure, good visualization of the RAV is attained owing to dense enhancement.

Fig. 3 56-year-old man. A para-axial multiplanar reformatted image shows the right adrenal vein (RAV, arrow) that drains to the accessory hepatic vein (arrowhead) before entering the IVC.

shared a common orifice with an accessory hepatic vein in 7 (9%), and the RAV entered the IVC independently of other vein in the remaining 66 (84%) patients. No case occurred in which the RAV formed a common trunk with veins other than accessory hepatic vein.

Location of the RAV orifice in relation to surrounding structures: The orifice was craniocaudally located between the level of T11 and L1 (Figure 4a). In 50 (69%) of the 73 patients, the RAV joined the IVC at the level ranging from the middle third of T12 to the superior third of L1. Angle θ representing the position of the orifice along the circumference of the IVC is shown in Figure 4b. Angle θ ranged from –7° to 71° (mean, 39°). The RAV joined the IVC in the right posterior quadrant in 71 (97%) of the 73 patients, most frequently in a range of angulation between 20° and 60°. In 2 (3%) of the 73 patients, it occurred in the left posterior quadrant.

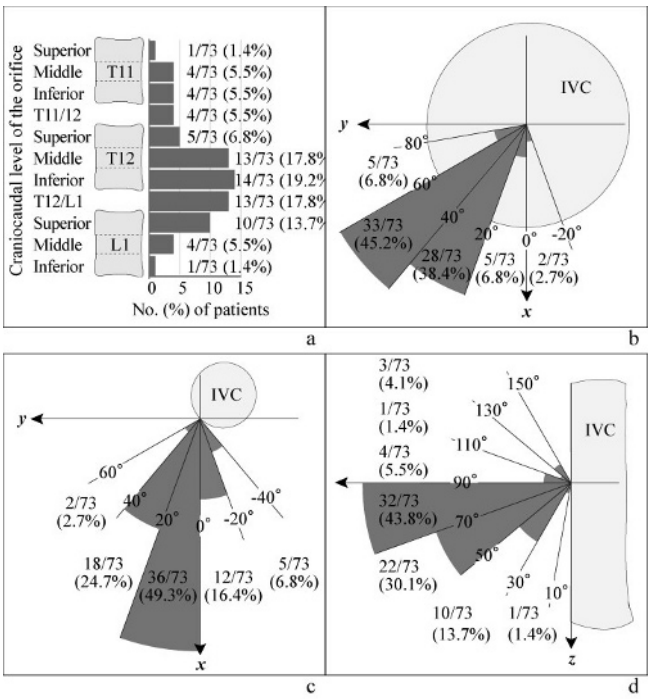

Fig. 4 The location of the right adrenal vein (RAV) orifice, and the direction of the RAV from the inferior vena cava (IVC) (a) The craniocaudal level of the RAV orifice in relation to the vertebral bodies and discs. (b) The position of the RAV orifice along the circumference of the IVC evaluated as angle θ. (c) The direction of the RAV from the IVC in the transverse plane which is represented as the angle with the x-axis (ϕ1). (d) The direction of the RAV from the IVC in the vertical plane which is represented as the craniocaudal angle with z-axis (ϕ2).

Direction of the RAV from the IVC: The angles, ϕ1 in the transverse plane and ϕ2 in the vertical plane, are shown in Figure 4c, d. The angle ϕ1 ranged from –36° to 47° (mean, 8°), ranging between 0° and 20° in almost half of the patients. The direction from the IVC was posterior and rightward in 56 (77%) and posterior and leftward in 17 (23%) of the 73 patients. The angle ϕ2 ranged from 30° to 136° (mean, 73°), and most patients showed a value between 50° and 90°. The direction from the IVC was caudal in 65 (89%) and cranial in 8 (11%) of the 73 patients.

Length and diameter of the RAV: The mean length was 3.8 mm, and the mean diameter at the junction with the IVC was 1.7 mm.

IV. Discussion

MDCT enabled the identification of the RAV in most patients. In the cases in which the RAV was identified, the RAV anatomy including the position in relation to the IVC and surrounding structures was well evaluated. The results

concerning the length, diameter, craniocaudal level of the orifice were all similar to those of the earlier studies using autopsy or venography [8, 13-18].

The position of the orifice along the circumference of the IVC was most commonly located in the right posterior quadrant of the IVC in our study, which accord with those in the literature. However, we also found rare cases whose orifice was located in the left posterior quadrant in 2 (3%) of the 73 patients, which has never been described [8, 18].

A common trunk of the RAV with an accessory hepatic vein was found in 6 (8%) of the 79 patients in our series. In addition, the RAV took a separate course but almost shared a common orifice with an accessory hepatic vein in another 7 (9%) of the 79 patients. In the literature [14-16], a common trunk of the RAV with an accessory hepatic vein has been reported in approximately 10–21%; a common trunk might have included both types of variation, although no detailed distinction between them were provided.

Catheterization of the RAV remains difficult. Its success rate generally remains around 60–70% [6, 8-11]. The difficulty may arise owing to the small size of the RAV, its anatomic variations in the junction with the IVC, and/or confusion with accessory hepatic veins that may form a common stem with the RAV [8, 12].

A reliable way to delineate the RAV anatomy before adrenal venous sampling was not previously available, but our study suggests the potential for MDCT to provide detailed information on the RAV anatomy similar to other small arteries [12]. Such information would be useful in planning adrenal venous sampling. We believe that preoperative recognition of the RAV anatomy would be especially valuable for RAV catheterization and subsequent venous sampling.

V. Conclusions

MDCT enabled the identification of the RAV and delineation of its anatomy, including the position and relationship to the surrounding structures such as the IVC in a high percentage of patients. This preoperative information may be helpful in the catheterization of the RAV for adrenal venous sampling.

Abstract — **The clinical meaning of left atrial vortex has been not fully elucidated. We developed a new left atrial model to simulate intra-atrial flow and a simple method to observe atrial vortex by magnetic resonance imaging (MRI).**

A flow simulation model of the left atrium (LA) was developed based on slices of the LA image acquired by 1.5T MRI scanner system. Images were reconstructed by commercial software and a computational model was created by using tetrahedral mesh. In order to give the model consecutive temporal change, we presumed that deformation of LA is related to mitral valve annular movement. Then we traced its temporal change and approximated. The flow simulation was performed with FLUENT. Pressure boundary conditions were set based on data in a literature.

The results of flow simulation in LA were validated qualitatively by MRI velocity mapping. Left atrial vortex was observed in both simulation and MRI velocity mapping. A representative slice to observe left atrial vortex by MRI was determined with the assistance of the simulation model.

Keywords — **MRI, atrial vortex, simulation model**

I. Introduction

Clinical meaning of left atrial vortex has been not fully elucidated. The left atrium (LA) serves as both a conduit and a reservoir. During diastole, it directs inflow from the pulmonary veins towards the mitral annulus, and during ventricular systole it retains the inflow volume until the mitral valve reopens.

Kilner mentioned that patterns of atrial filling seem to be asymmetric in a manner that allows the momentum of inflowing streams to be redirected towards atrio-ventricular valves [1]. Although flow dynamics of the left ventricle has been investigated by physical, computational modeling and by invasive and non-invasive imaging. But atrial flow has not been investigated intensively. Fyrenius visualized normal left atrial flow using magnetic resonance imaging (MRI) and in all normal subjects vortical flow was observed in the atrium during systole and diastolic diastasis [2].

Much attention has been directed toward the role of stretch and mechanoelectric feedback in the atria. Atrial stretch plays an apparent role in the development of atrial fibrillation in a wide spectrum of clinical conditions [3]. Local flow change may affect on the electrical character of left atrium.

MRI is an excellent tool to evaluate atrial flow. Magnetic resonance velocity mapping is a reliable tool for analysis and visualization of blood flow in vivo. But reconstruction of multi-slice MRI data set is needed to visualize 3D flow and datasets are fragmentary.

A simulation model helps us comprehend atrial flow dynamics and might provide insights the origin of atrial vortex. The purpose of this study was to examine the flow in the left atrium by numerical simulation via modeling from magnetic resonance (MR) images and invent a simple method to evaluate atrial vortex.

II. Methods

A. Building a simulation model

Magnetic resonance images of the LA of a 23-year-old healthy male volunteer were acquired using a 1.5T MRI scanner system (Achieva 1.5T, Philips Electronics, Best, Nederland), SENSE cardiac coil and two-dimensional balanced turbo field echo (TR (repetition time) = 3.3 msec, TE (echo time) = 1.7 msec, FA (flip angle) = 60 °, slice thickness = 5 mm, FOV (field of view) = 400 mm, matrix size = 256×256). This study was approved by the regional ethics committee of Miyagi Cardiovascular and Respiratory Center.

Four chamber T1 weighted images were acquired in twelve slices at 5 mm intervals to create images of the whole LA. 15 seconds is needed to obtain 20 phases of MR images during the R-R interval in one cross section. Then the scan time for obtaining the whole LA was 6 minutes.

Figure 1 shows an acquired MR image with a white ellipse indicating the LA. The pulmonary veins are connected to the right and left sides of the LA, and the mitral valve is located at the bottom.

Images were reconstructed by commercial software Mimics 7.3 (Materialise N.V., Belgium), and a computational model was created by using tetrahedral mesh. In order to give the model consecutive temporal change, we presumed that deformation of LA is related to mitral valve annular movement. Figure 2 shows a scheme of deformation. First, the location of the mitral valve in an XY coordi-

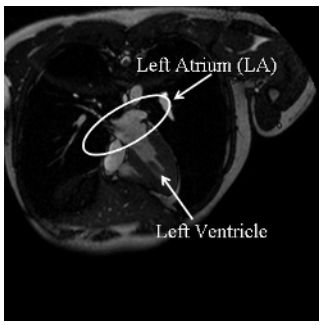

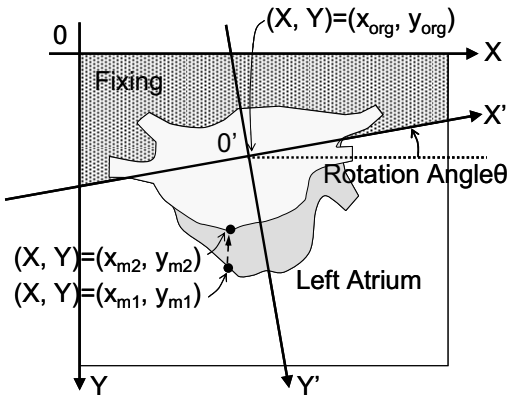

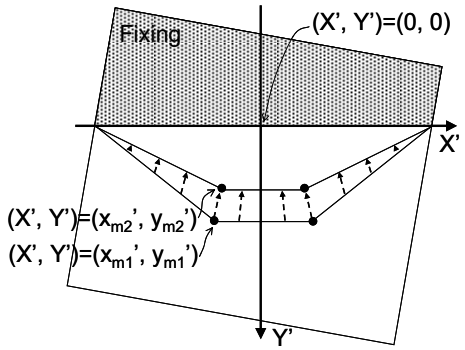

Fig. 1 A slice of Left Atrium MR image

(a) XY coordinate

(b) X'Y' coordinat

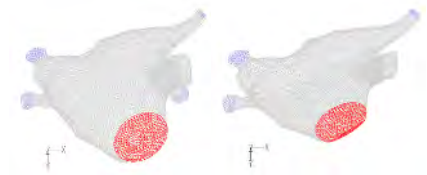

Fig. 2 Movement of mitral valve and deformation of left atrium

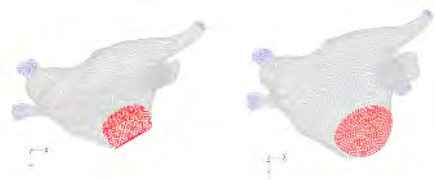
nate system (the upper left point is the origin) was set by (x_{m1}, y_{m1}) in phase 1 and by (x_{m2}, y_{m2}) in phase 2. Next, an X'Y' coordinate system was set with the Y' axis parallel to movement of the mitral valve and the original point located at (x_{org}, y_{org}) in XY coordinate system. The points (x_{m1}, y_{m1}) and (x_{m2}, y_{m2}) in the XY coordinate system were converted into the points (x_{m1}', y_{m1}') and (x_{m2}', y_{m2}') in the X'Y' coordinate system, respectively. For the purposes of simplification, location of the right side of the mitral valve was set with the left side symmetrically against the Y' axis. The point (x_1', y_1') on the wall in the X'Y' coordinate system in phase 1 was moved to point (x_2', y_2') by the following equations when the Y' coordinate was positive



$$x_2' = \left\{ \frac{y_1'}{y_{m1}'} \left(\frac{x_{m2}'}{x_{m1}'} \right) + 1 \right\} x_1' \tag{1}$$

$$y_2' = \frac{y_{m2}'}{y_{m1}'} y_1' \tag{2}$$

Movement in the Y' direction of Eq. (2) is simple compression, but movement in the X' direction of Eq. (1) depends on the Y' coordinate. In the case of a negative Y' coordinate, the location of the point was fixed. This conversion was performed in each slice and linear interpolation was performed between the slices and among the models of 20 phases. Fig. 3 shows the computational models of four phases.

(c) phase10 (end systole) (d) phasse15 (diastole)

Fig. 3 Computational model of each phase

Then we traced its temporal change and approximated. The flow simulation was performed with FLUENT. Pressure boundary conditions were set based on data in a literature [4]. Four inlets were given as 10 mmHg from data regarding pulmonary veins. An outlet was divided into systolic and diastolic phases. In the systolic phase (phase1-10), the pressure was set at 0-10 mmHg based on and in the diastolic phase (phase11-20), the outlet was assumed to be a wall. An initial condition was given as a stationary solution in phase 1. The other conditions are indicated in Table 1.

Table 1 Computational conditions

Parameters	value
Heart rate	91 bpm
Cardiac cycle *T*	659 ms
Time step *dt*	3.295 ms
Density ρ	1050 kg/m^3
Viscosity μ	3.5×10^{-3} Pas

B. Magnetic resonance velocity mapping

A 23-year-old healthy male volunteer with normal transthoracic echocardiographic findings was studied. The same subject was recruited. This study was approved by the regional ethics committee of Miyagi Cardiovascular and Respiratory Center.

Velocity measurements were performed using a 1.5T MRI scanner system (EXCELART 1.5 T, Toshiba Medical Systems,Tokyo,Japan), Torso SPEEDER coil and phase shift magnetic resonance angiography (TR = 24 msec, TE = 10 msec, FA = 20°, slice thickness = 5mm, FOV = 350 mm, matrix size = 256×256, VENC = 1m/sec). All three velocity components were measured in supine position with 50 sec breath holding in a four chamber view. 13 slices were obtained in 100 minutes.

Velocity vector filed was generated by all three velocity components from phase contrast data and projected onto 2D magnitude images. Visualization was created using Tecplot 360 2008 (Tecplot Inc., Bellevue, USA).

III. Results

A. Simulation data

Left atrial vortices were identified during systole and diastole. Figure 4 shows computed streamlines in systole and diastole period of the LA. During systole, the bloodstream in the LA rotated counterclockwise and developed to the vortex and disappeared with the onset of early diastole. During diastole, the bloodstream from the four inlets passing almost uniformly towards the mitral valve, the vortex flow appeared following peak early diastolic inflow and disappeared with the onset of atrial systole. The vortex in systole was more clearly observed than in diastole and its center was located the left side of the center of the LA.

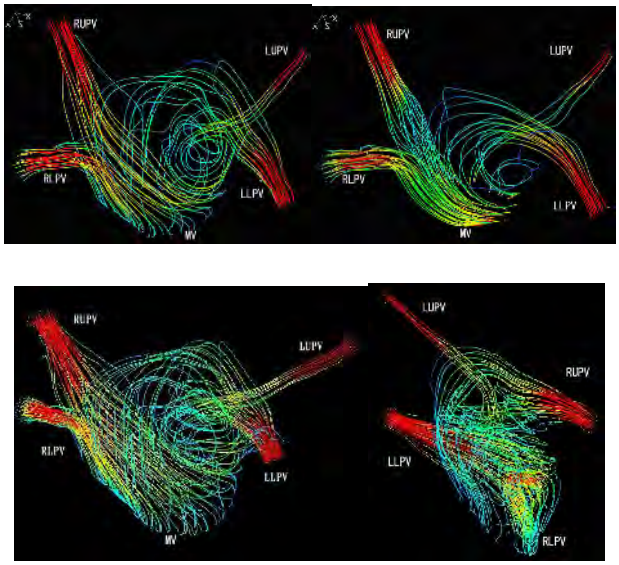

Fig. 4 Computed streamlines of blood flow in LA (upper left; vortex in systole, upper right; vortex in diastole, lower left; cranio-caudal view of systolic vortex, lower right; left lateral view of systolic vortex, RUPV: right upper pulmonary vein, RLPV: right lower pulmonary vein, LUPV: left upper pulmonary vein, LLPV: left lower pulmonary vein, MV: mitral valve)

B. In vivo data

Two discrete left atrial vortices were identified during systole and diastole, rotated counterclockwise. Fig5 shows velocity mapping of blood flow in LA in systole and diastole. The vortex in systole was more clearly observed than in diastole and its center was located around the center of the LA.

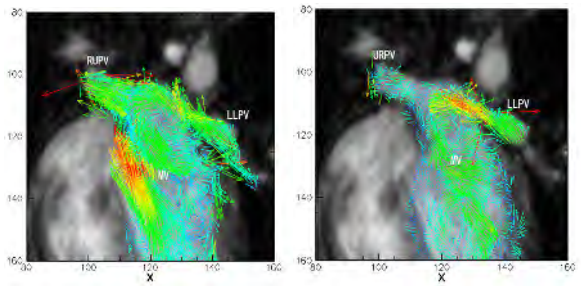

Fig. 5 Velocity mapping of blood flow in LA (left; systole, right: diastole, RUPV: right upper pulmonary vein, LLPV left lower pulmonary vein)

IV. Discussion

A. Model validation

Both simulation and in vivo data showed two discrete left atrial vortices were identified during systole and diastole. These results qualitatively agree with MR velocity mapping of LA by Kilner et al [1]. However, the velocities of flow in the LA were different between the computed value and measured by MRI or ultrasonic echo (data was not shown). This is probably because boundary conditions were different from the actual conditions of the subject. Although the boundary conditions were taken from data in the literature in this study, it would be necessary to set these conditions based on measurement data to obtain a more accurate result. Also, deformation of the LA was represented only by movement of the mitral valve on the left side of the LA in this research, but it is necessary to consider the validity of the model utilized. Especially, movement of the mitral valve of the right side of LA should be independently obtained for more accurate determination of LA deformation.

B. Left atrial vortex evaluation

Left atrial vortex in systole was clear and its center was located around the center of LA in both simulation and in vivo data. We propose that a slice which include around the center of LA, pulmonary veins (at least one vein) and mitral valve would be a representative slice to evaluate the left atrial vortex. Further study is needed to elucidate the meaning of left atrial vortex. MR velocity mapping in LA would be applied not only for healthy subjects but also for pathologic. However, in this study, it took 100 minutes to obtain whole LA flow velocity data, that is not realistic in clinical apply. Longer examination cause discomfort to the patient and increase the chance of artifact. At single slice it takes 3 minutes to obtain 3D velocity profiles, it would be tolerant for pathologic subjects.

V. Conclusions

In this study, numerical simulation of blood flow in the LA modeled from MR images was performed. The deformation of the LA was presumed from the location of the mitral valve. Computed results qualitatively agreed with data in the literature. Quantitative study with examination of boundary conditions and wall motion should be conducted in a future study. And we propose a slice for atrial vortex evaluation which include around the center of LA, pulmonary veins (at least a vein) and mitral valve. MR velocity mapping in LA would be applied for pathologic subject comfortably and accurately to clarify the meaning of left atrial vortex.

Abstract — **We have proposed the intelligent Si neural probe which can realize high density and multifunctional recording of neuronal behaviors. In this device, LSI chips such as amplifiers, A/D converters, and multiplexers are integrated on the Si neural probe. In this paper, we report the development of a novel multichannel Si neural microelectrode with microfluidic channels which is the key part of the intelligent Si neural probe. The microelectrode has microfluidic channels fabricated using a wafer bonding technology to deliver drugs into the brain when neuronal action potentials are recorded. And also, our microelectrode has recording sites on both front- and back-side of Si to realize high density recording. We fabricated the carefully-designed multichannel Si neural microelectrode, and we evaluated characteristics of both recording sites and microfluidic channels. From the liquid ejection test, we confirmed that there was no void at bonding faces. We observed the liner relationship between the flow rate and the pressure drop, and the relationship was identical to that from the calculation, which indicated that the microfluidic channel was successfully formed. Moreover, both front- and back-side recording sites had impedance values of 2.5 MΩ and 2.7 MΩ at 1 kHz, respectively, which indicated that both recording sites had equivalent characteristics. The neuronal action potentials from CA1 area in a hippocampal slice were successfully recorded by using the fabricated microelectrode.**

Keywords — **Si intelligent neural probe, multichannel neural microelectrode, simultaneous multi-site recording**

I. Introduction

With the progressing of ageing society, the number of patient with brain diseases such as paralysis, epilepsy, and Parkinson's disease has been increasing remarkably. However, medical cures for these diseases have not been established yet. For medical care or rehabilitation of brain diseases, not only patients but also their families have been under heavy strain. In order to improve these situations, neurophysiology has attracted much attention all over the world. In neurophysiology, recording of neuronal signals from the brain plays an important role in advanced studies of neuronal circuit dynamics and relationships between actions of the body and activities of the brain. In the past few decades, various types of microelectrodes made of Si have been developed to record neuronal signals from the brain of animals, and lots of useful results were obtained [1-3]. We have proposed an intelligent Si neural probe system, and have been developing key parts of the system [4]. Figure 1 shows the configuration of the intelligent Si neural probe system.

In this system, a large number of recording sites are located on the tips of the intelligent Si neural probe for simultaneous multi-site recording of neuronal action potentials. Since neuronal signals are extremely low, electric circuits such as amplifiers (AMPs), A/D converters (ADCs), and multiplexers (MUXs) are integrated on the Si neural probe directly. Therefore, weak neuronal signals recorded from the brain are amplified with keeping low noise levels.

In the present paper, we propose a novel multichannel Si neural microelectrode with microfluidic channels which is the key part of the intelligent Si neural probe. We fabricated the carefully-designed multichannel Si neural microelectrode, and we evaluated characteristics of both recording sites and microfluidic channels. Subsequently, by using the fabricated microelectrode, we performed *in-vitro* experiments of recording neuronal signals on a CA1 region in a hippocampal slice obtained from the brain of guinea pigs.

II. Multichannel Si Neural Microelectrodes with Microfluidic Channels

A. Proposal of multichannel Si neural microelectrodes with microfluidic channels

Si microelectrodes have been widely used because Si microelectrodes can be fabricated by using advanced CMOS processes which produce several important advantages such as mass production, high repeatability, and high accurate processes, and also Si is highly biocompatible material. However, number of neurons that can be observed by using conventional Si microelectrodes is limited, and only neuronal action potentials can be recorded from neurons. Additionally, considering neuron damages by a Si microelectrode, further improvement of Si microelectrode has been demanded. To solve these problems, we propose a novel multichannel Si neural microelectrode with microfluidic channels which has recording sites on both front- and back-side of Si. By integrating microfluidic channel into the microelectrode, it will be possible to deliver drugs into the neural tissue, and we can understand the drug's effect to neurons. Moreover, by placing recording sites on both sides, high density 3-D recording of neuronal action potentials can be realized.

The overall structure of the multichannel Si neural microelectrode with microfluidic channels is shown in Fig. 2. This microelectrode has 4 recording sites on both front- and back-side for neuronal cell sorting. To analyze a deeper part of the brain such as basal ganglia or apply to large animals like primates, this microelectrode has a length of 40 mm. The width and thickness were 100 μm and 200 μm, respectively. Recording sites are made of Au with circular pattern. Diameter of circular pattern is 12.5 μm and the distance between two patterns is 40 μm in center to center. Wirings are also made of Au and isolated by SiO_2 films. Behind 200 μm from the tip of the microelectrode, the recording site for differential amplification is placed. The microfluidic channel has the length of 40 mm, the width of 50 μm, and the depth of 10 μm. The fluidic outlet at the microelectrode tip has diameter of 10 μm, and the fluidic inlet is 50 × 10 μm^2 large. At the middle of the microelectrode, bonding pads for connecting to external recording apparatus were formed. Back-side pads leaded from back-side recording sites are formed by Si etching and connected to recording apparatus by wire bonding through Si via.

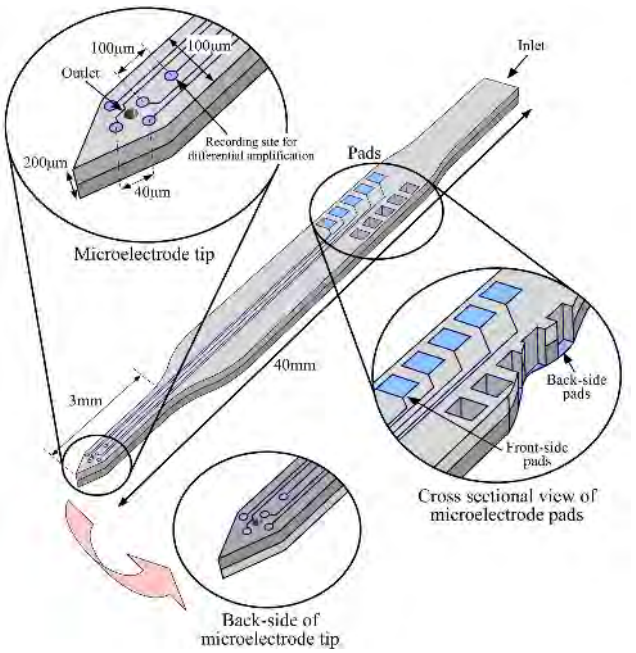

Fig. 2 Structure of the multichannel Si neural microelectrode with microfluidic channels

B. Fabrication of multichannel Si neural microelectrodes with microfluidic channels

Our microelectrode was fabricated by combining standard photolithography with bulk micromachining process. Two 100μm thick Si wafers were used as a substrate of the microelectrode. The fabrication sequence of the microelectrode is illustrated in Fig. 3. First, microfluidic channel with

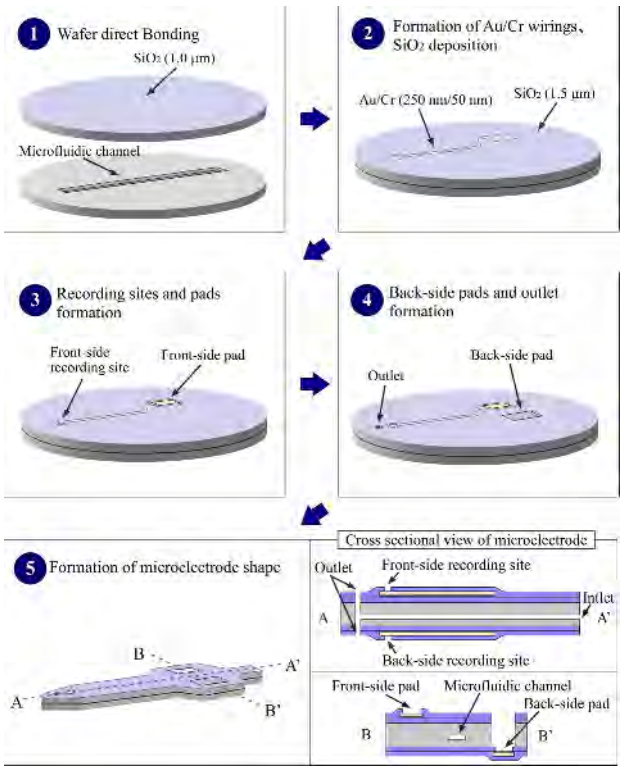

Fig. 3 Fabrication sequence of the multichannel Si neural microelectrode

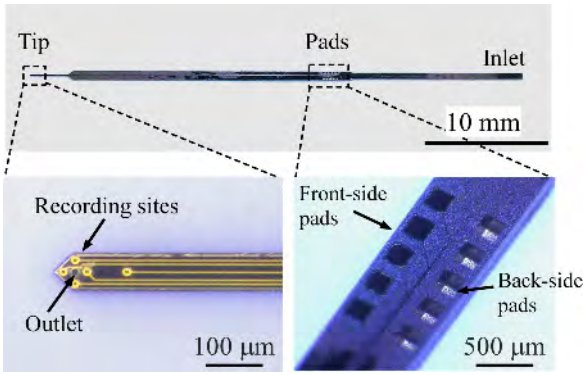

Fig. 4 Fabricated multichannel Si neural microelectrode

the depth of 10 µm was formed on surface of a Si wafer by using deep reactive ion etching (DRIE) with SF_6 and C_4F_8 gases. The etched wafer and unprocessed wafer were rinsed by standard clean 1 (SC-1), and surfaces of the both wafers were covered with thin oxidized layer accordingly. Then, these wafers were stacked and bonded by hydrogen bonds. By annealing these wafers, hydrogen bonds changed to covalent Si-O bonds with the reaction below:

$$SiOH - OH_2 - OH_2 - OHSi \leftrightarrow Si - O - Si + 3H_2O. \quad (1)$$

Next, Au/Cr wirings were formed on the front surface of the wafer by sputtering and wet etching with an iodine etchant and a ceric ammonium nitrate solution. The thickness of Au and Cr were 250 nm and 100 nm, respectively. Then, SiO_2 with a thickness of 1.5 µm was deposited using plasma enhanced chemical vapor deposition (PECVD) for insulation of wirings. Back-side surface of Si wafer was also processed with the same sequence. After that, recording sites and bonding pads were formed by wet etching with buffered HF solution (HF/NH_4F 1/10), followed by formation of the shape of the microelectrode and back-side pads using DRIE. As a result, the multichannel Si neural microelectrode was obtained. As shown in Fig. 4, the multichannel Si neural microelectrode was fabricated successfully.

III. Results and Discussion

A. Evaluation of microfluidic channels of multichannel Si neural microelectrode

At first, we confirmed the strength of the fluidic channel. In the experiment, we injected red ink into the fluidic channel with flow pressure of 1000 mmHg. Fig. 5 shows the ejection of red ink from the fluidic outlet. From this experiment, it was confirmed that the microfluidic channel had enough strength to inject fluidic medicine.

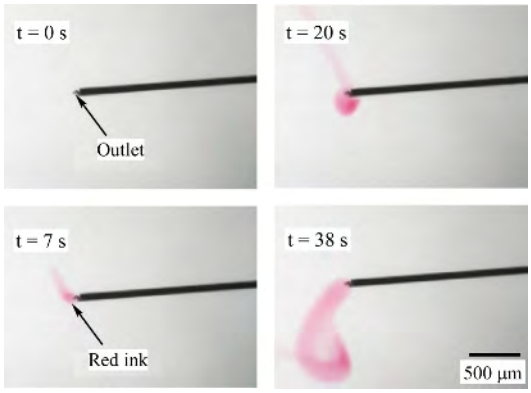

Fig. 5 Photographs of ejected red ink from the fluidic outlet

We also evaluated relationships between the flow rate and the pressure drop through microfluidic channel. We changed a flow rate from 0.1 to 0.4 µl/min with the syringe pump. We measured the pressure drop across the channel with the pressure meter, and we compared measured value with theoretical calculations. The pressure drop (Δp) is defined as:

$$\Delta p = \frac{\mu V (Re \times f) L}{2D^2} \quad (2)$$

where µ is the viscosity of fluid (~8.9×10-4 kg/ms at 25 °C for water), Re × f is the product of the Reynolds number and the Darcy friction factor (~64 in laminar flow), L is the length of the channel (40 mm), and D is the hydraulic diameter of the channel as defined by

$$D = 4 \times (\text{Cross-sectional area / wetted perimeter}). \quad (3)$$

As shown in Fig. 6, the measured values agreed well with the theoretical calculations. From this graph, we confirmed that the micro channel shape was fitted as we designed.

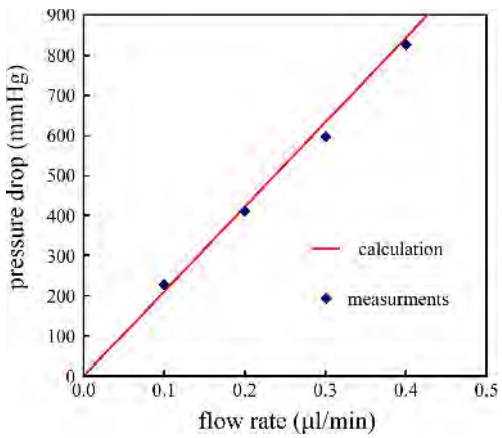

Fig. 6 Relationship between the flow rate and the pressure drop

B. Characterization of recording sites of multichannel Si neural microelectrode

In order to characterize the interface between recording site and electrolyte, we measured electrical impedance of the fabricated multichannel Si neural microelectrode before animal experiments. Measurements were performed with the frequency ranging from 100 Hz to 10 MHz using the 10 mV AC sine signal in 0.9 % saline solution. An Ag/AgCl electrode and a Pt electrode were employed as a reference electrode and counter electrode, respectively. Figure 7 shows the impedance characteristics of the fabricated microelectrode. While front-side recording site had the impedance value of 2.5 MΩ at 1 kHz, back-side recording site had the impedance value of 2.7 MΩ at 1 kHz. It was indicated that both sites had almost the same electric characteristics.

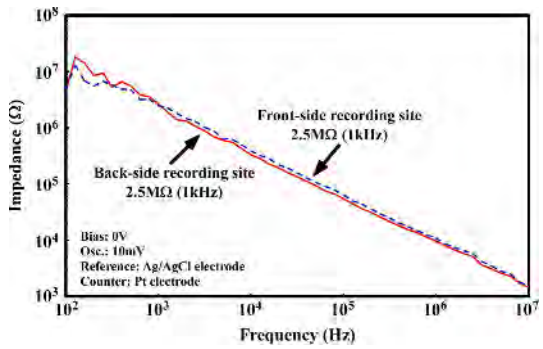

Fig. 7 Impedance spectra of the fabricated multichannel Si neural microelectrode

C. Neuronal action potential recording using multichannel Si neural microelectrode

We performed the *in-vitro* experiment of neuronal action potentials recording using the fabricated multichannel Si neural microelectrode.

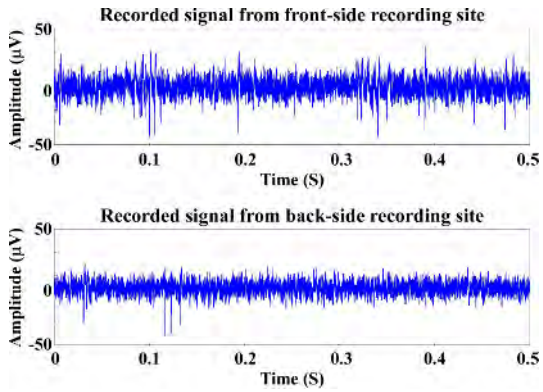

Fig. 8 Recorded neuronal action potentials of hippocampal slice

The experiments were authorized by the committee for experiment on animal of Graduate School of Information Sciences, Tohoku University. Multiple neuronal potentials were recorded from CA1 area of 400-μm-thick hippocampal slice obtained from the brains of guinea pigs (200 - 250 g). As shown in Fig. 8, we successfully recorded neuronal action potentials from both front- and back-site.

IV. Conclusions

We proposed the novel multichannel Si neural microelectrode with microfluidic channels having recording sites on both front- and back-side of Si. The microelectrode was fabricated successfully by using wafer direct bonding techniques. From fluidic experiments, it became clear that there was no void at bonding interfaces, and the bonding strength of the fabricated microelectrode withstood the flow pressure larger than 1000 mmHg. Additionally, we confirmed the measured fluidic characteristics of the microfluidic channel agreed well with the theoretical calculations. Both front- and back-side recording sites of the fabricated microelectrode had impedances of 2.5 MΩ and 2.7 MΩ at 1 kHz, respectively, which indicated both recording sites had equivalent characteristics. Using our microelectrode, we successfully recorded neuronal action potentials of hippocampal slice from recording sites of both sides.

Influence of Fluid Shear Stress on Matrix Metalloproteinase Production in Endothelial Cells

N. Sakamoto[1], T. Ohashi[1] and M. Sato[1,2]

[1] Graduate School of Engineering, Tohoku University, Sendai, Japan
[2] Graduate School of Biomedical Engineering, Tohoku University, Sendai, Japan

Abstract — **Arterial bifurcations are known to be common sites for formation of cerebral aneurysms. It has been reported that shear stress of more than 7 Pa under physiological conditions exerts on near the flow divider of the bifurcations. It is thus speculated that such high shear stress may induce production of matrix metalloproteinases (MMPs) in endothelial cells (ECs), leading to the aneurysm formation. However, the detailed mechanism is still unknown. In this study, we evaluated the effect of magnitude of shear stress on expressions of MMP-2 and -9, known to degrade elastic fibers and associate with the early stage of formation of aneurysms. ECs isolated from human umbilical veins were exposed to shear stress of 2 Pa or 7 Pa for 24 hours using a parallel-plate flow chamber. After flow-exposure experiments, ECs were cultured with serum-free medium for 12 hours. Then, MMP-2 and -9 activities in the conditioned medium was detected by gelatin zymography. While activated MMP-2 expression did not change between 2Pa and 7Pa, pro MMP-2 activity increased with increasing the magnitude of shear stress. The level of pro MMP-9 activity also increased according to the increase in shear stress, and was significantly higher at 7 Pa compared to the static. These results suggest that higher shear stress near the flow divider at bifurcation of cerebral arteries may enhance degradation of elastic fibers in vessel walls, possibly leading to formation of cerebral aneurysms.**

Keywords — **Endothelial cells, High shear stress, Cerebral aneurysm, Matrix metalloproteinases**

I. Introduction

Vascular endothelial cells (ECs) are constantly exposed to fluid shear stress due to blood flow and show functional changes. One of the major functions of ECs includes remodeling of vessel walls, in which ECs secrete matrix metalloproteinases (MMPs) to degrade extracellular matrix (ECM) such as elastin and collagen. Particularly, it has been pointed out that increases in expression of MMP-2 and -9 associate with the early stage of the formation of aneurysms [3]. ECs are also known to stimulate ECM production by smooth muscle cells and pericytes. Therefore, the balance between degradation and production of ECM tightly governs vascular remodeling and is believed to play a central role in pathogenesis of arterial aneurysms [1].

Bifurcations of cerebral arteries are known to be preferred sites of cerebral aneurysms. It is reported that shear stress of more than 7 Pa exerts on near the flow divider of the bifurcations [2]. Hence, it is speculated that such high shear stress occurred around the arterial bifurcation is involved in pathological remodeling, leading to aneurysm formation. However, little is known of how high shear stress contributes to pathologenesis of cerebral aneurysms.

In this study, we apply high shear stress to ECs and evaluate the changes in production of MMP-2 and -9.

II. Methods

A. Cell culture

Human umbilical vein ECs were cultured with Medium 199 (M199) containing 20% heat-inactivated fetal bovine serum, supplemented with 10 ng/ml basic fibroblast growth factor. Cells were used from 4th to 7th generations for experiments.

B. Flow-exposure experiment

After ECs attained confluence, the cells were exposed to shear stress of 2 Pa or 7 Pa for 24 hours using a parallale-plate flow chamber. The flow chamber was incorporated in a flow circuit, and the culture medium in the flow circuit was equilibrated with 5% CO_2 and maintained at 37 °C.

C. Gelatin zymography

After flow-exposure experiment, the ECs were cultured with serum free medium for 12 hours. The medium conditioned for 12 hours was concentrated by ultrafiltration. The sample was then loaded onto a 7.5% SDS-polyacrylamide gel containing 1 mg/ml gelatin. After electrophoresis, the gel was washed with 2.5% Tween 20 and then incubated at 37°C for 20 hours in 50 mmol/L Tris–HCl buffer, containing 1% Tween 20. After staining with Coomassie blue R-250, the gel was dried and then scanned. Gelatinolytic activity was revealed as clear bands against a blue-stained background.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2262–2263, 2009
www.springerlink.com

III. Results

The activities of pro MMP-9, and pro and activated MMP-2 were detected by gelatin zymography in this study (Fig. 1). Levels of MMP-2 and -9 activities were quantified by the relative intensity of bands and expressed as the percentage of the activities of those of static ECs. The level of pro MMP-2 and -9 increased according to the increase in the magnitude of shear stress, and significantly higher at 7 Pa compared to the static (Figs. 2 and 3). The level of activated MMP-2 was higher at 2 Pa than control but there was no significant difference between 2 Pa and 7 Pa.

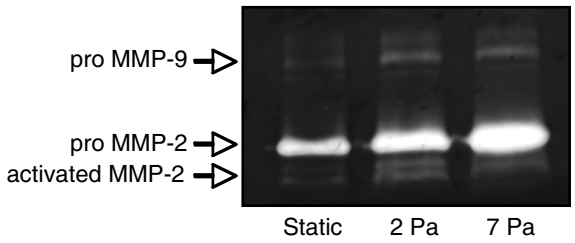

Fig. 1 Typical result of zymography showing proMMP-9, proMMP-2, and activated MMP-2

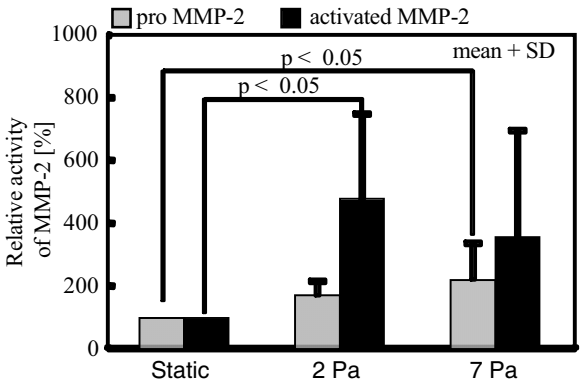

Fig. 2 Relative activity of MMP-2 expressed by endothelial cells

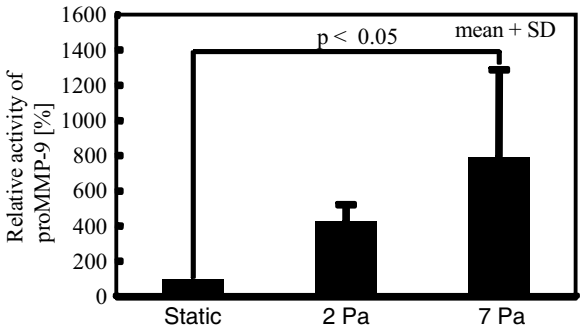

Fig. 3 Relative activity of MMP-9 expressed by endothelial cells

IV. Discussion

It is known that degradation of elastic media is the consistent histophatholocial feature of aneurysmal walls [4]. In this study, the expression of MMP-2 and -9, known to play a central role in degradation of elastin [3], increased according to the increase in the magnitude of shear stress. This result suggests that high shear stress near the bifurcation of cerebral arteries may cause degradation of elastic fibers. However, since proMMPs acquire their full proteolytic activity after activation, it is further required to study expression of activators for MMPs including membrane type-MMP and plasminogen activator. In addition, because the activity of MMPs is regulated by the inhibitors of MMPs, the tissue inhibitor of metalloproteinases (TIMPs), the expression of TIMPs should be also examined towards understanding the role of pro MMPs in the formation of aneurysms.

V. Conclusion

In this study, we applied shear stress of 2 Pa and 7 Pa to ECs and assessed expressions of MMP-2 and -9. Both proMMP-2 and proMMP-9 increased according to the increase in shear stress. These results suggest that higher shear stress enhances degradation of elastic fibers in vessel walls, possibly leading to the formation of cerebral aneurysms.

Development of Brain-Computer Interface (BCI) System for Bridging Brain and Computer

S. Kanoh[1], K. Miyamoto[1] and T. Yoshinobu[1]

[1] Graduate School of Engineering, Tohoku University, Sendai, Japan

Abstract — **A brain-computer interface (BCI) is a non-muscular communication channel which allows physically disabled people to re-establish interaction with their surrounding environment. The aim of this system is to detect user's intentions or thoughts from brain activities which are measured as EEG (electroencephalogram) or other non-invasive recording techniques.**

We have developed the BCI system to detect user's motor imagery from motor-related EEG activities. It was shown that online training with a feedback of EEG band-power on specified frequency range made the accuracy of command detection higher. And we proposed an auditory BCI based on auditory stream segregation, on which users were requested to attend to one of the tone streams and their object of interest was detected from auditory event-related potentials.

In this article, the concept and some of our recent researches on BCI are introduced.

Keywords — **brain-computer interface, EEG, motor imagery, feedback training, auditory stream segregation**

I. Introduction

For the better communication tools for severe paralyzed patients due to stroke, spinal cord injury or motor neuron diseases like ALS (amyotrophic lateral sclerosis), the new human interface system called Brain-Computer Interface (BCI) has attracted interests [1]. The aim of this system is to detect user's intentions or thoughts from brain activities which are measured as EEG (electroencephalogram) or other non-invasive recording techniques. The measured signal is pre-processed and classified to detect the command corresponding to the user's intention.

An EEG-based BCI system using motor imagery has been developed by the authors [2, 3]. The activation elicited by motor imagery of user's limb (e.g. left hand, right hand or feet) is observed as a power increase (ERS: event-related synchronization) or decrease (ERD: event-related desynchronization) of EEG in a specific frequency range. It is known that motor function of every part of the body is represented in the primary motor cortex, and these representations are arranged topologically (somatotopically) on the map ("motor homunculus").

We have also developed an EEG-based BCI system using auditory stimuli [4]. In this system, subjects are requested to pay attention to one kind of specific tone stimulus, and the target (attended) object is detected by pattern classification of measured EEG responses. When subject is presented an oddball sequence, a repetition of frequently presented tones (standard stimuli) with some of which randomly replaced by infrequently presented tones (deviant stimuli), the ERP (event-related potential) components called MMN (mismatch negativity) and P300 are observed in the responses to deviant stimuli at the latency of about 100ms and 300ms, respectively. The magnitude of these ERP components is known to be changed with selective attention to the "target" tones.

II. EEG-based BCI to detect motor imagery: effect of feedback training to improve performance [3]

A. Introduction

One way to realize such a BCI is to detect motor imagery of user's limbs from EEG [5].

The BCI presented in this work is based on the detection of changes in oscillatory EEG components (ERS/ERD) induced by motor imagery [6]. From an engineering point of view, the simplest way to transfer information is to use binary control signals. For the realization of this binary signal, Pfurtscheller et al and the authors have developed the system named "Brain Switch", which detects the presence of a user-specific motor imagery [2, 7]. This system detects the enhancement of EEG activities in a user-specific frequency component (ERS) in a user-specific bipolar EEG channel on a threshold basis. The Brain Switch has already successfully been employed to restore the grasp function of a spinal cord injury patient [7].

However, one crucial issue to gain control of a BCI is the training protocol. It is known that the feedback training, in which information on target brain activation is presented to the subjects during the task, is effective to modulate neuronal activities on motor imagery [7]. Due to the inherent variability and non-stationarity of brain signals, the user has to learn to reliably generate the requested patterns by feedback training. For the best feedback effects, the three above mentioned parameters (frequency range, EEG channel, and object limb for motor imagery) need to be specifically selected for each user.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2264–2267, 2009
www.springerlink.com

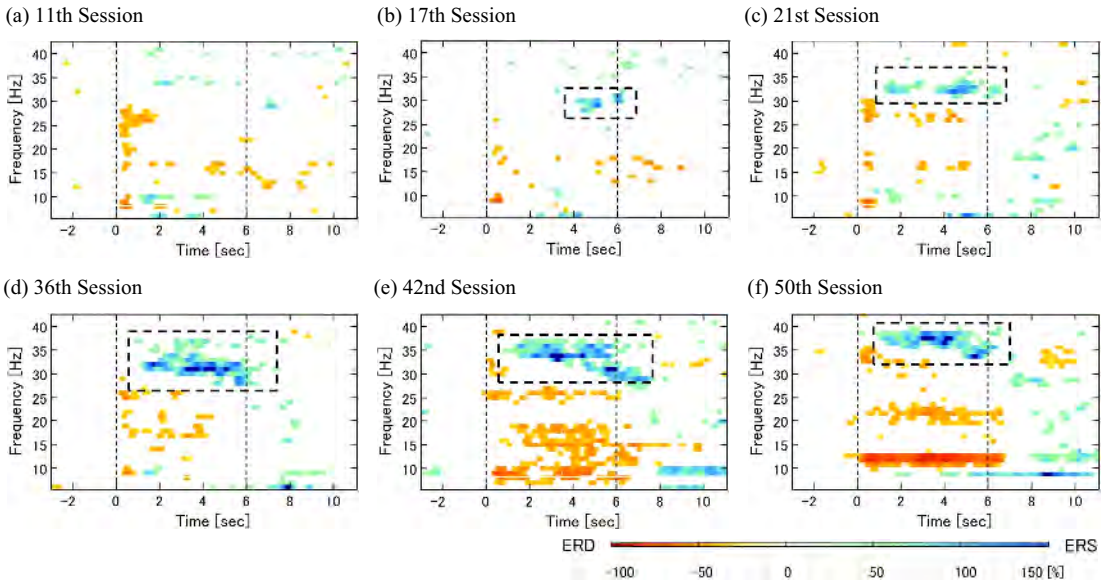

Fig. 1 Result of time-frequency analysis of the data on training sessions on foot motor imagery (Subject 1). Only significant ERS and ERD responses from reference period (-1.5 to -0.5 s) are shown. Source location was CZ–FCZ (bipolar). Open dashed boxes denote ERS activities during foot motor imagery (time 0 to 6 s).

The authors reported the process and effect of long-term on-line feedback training for BCI based on motor imagery [3]. In this section, the changes of EEG band power during online feedback experiments and the results of threshold-based command detection are introduced.

B. Methods

Two able-bodied subjects took part in the experiments, which consisted of screening sessions and BCI feedback training sessions.

Screening sessions were used to collect EEG activity from subjects during cue-guided motor imagery and to set up the parameters for the feedback training. Thirty-two EEG channels were recorded from Ag-AgCl electrodes (reference and ground were left and right earlobe, respectively). Additionally, 3 EOG channels and 4 bipolar EMG channels (left forearm, right forearm, left leg, right leg) were recorded. The measured signals were bandpass-filtered between 0.5 and 100 Hz and sampled at 250 Hz. The subjects were requested to imagine movements of limbs (left hand, right hand or both feet) instructed by LCD display in front of them.

Time-frequency ERS/ERD maps [8] of monopolar recordings and bipolar re-referenced channels (pairs of nearest neighboring electrodes) were computed and visually inspected. The following three conditions were selected for feedback experiments: motor imagery task (left hand, right hand or both feet), single bipolar EEG channel (one pair of electrodes) and frequency band with major ERS activity during motor imagery as a source of feedback information.

Screening sessions were recorded on the first and after every tenth feedback training session. The identified conditions were fixed and the same conditions were used during the following 10 training sessions.

In feedback training sessions, the length of a bar graph, continuously presented on a computer screen, was proportional to the power in the chosen frequency band. The subjects were requested to extend the length of the bar graph by performing the selected motor imagery task. The band power was estimated by bandpass filtering (Butterworth order 5) of the found EEG channel, squaring the samples and averaging over the past 1 s period.

After each session, time-frequency ERS/ERD maps were computed and an off-line Brain Switch simulation was calculated to evaluate the effect of feedback training. A Brain Switch accepts a command each time the power in the predefined band exceeds a threshold for a certain period of time (dwell time [9]). After detection, a refractory period follows for reducing the same command a second time. (See ref. [2] for details.)

These parameters for command detection (threshold, dwell time, and refractory period) were optimized by ROC analysis [9], and the command detection was simulated. If the band power exceeded the threshold in the motor imagery period (time 0 s until 6 s) and it resulted the detection

of the first command in each trial, it was counted as a desired command detection (true positive), otherwise detected command were treated as an unexpected one (false positive). The number of true and false positives (NTP and NFP, respectively) were calculated and evaluated.

C. Results and Discussion

In this paper, results in Subject 1 are shown. The results of time-frequency analysis on training sessions in Subject 1 are shown in Fig. 1. It was observed that the frequency band of such narrow-band ERS during motor imagery increased as training went on. The ERS elicited by motor imagery initially appeared at around 28–30 Hz in about 15th to 17th training session (Fig. 1(b)). The frequency band gradually increased to around 30 Hz and finally went up to about 35 Hz (Fig. 1(f)).

In this subject, NTP increased from the 21st training session, nevertheless the NFP did not change. It was found from interviews after each training session that the subject sometimes had a feeling that he could control the length of the bar graph displayed on a computer screen during experiments. As there were no significant ERS responses for this subject before taking part in this experiment, it was found that this subject gained the ability to generate ERS on motor area voluntarily by motor imagery of feet.

From the result of Subject 1, feedback could enhance the band power in the same frequency band. It was found that subjects where no EEG response related to motor imagery was observed initially could acquire the ability to produce enhancement of EEG band power during motor imagery.

In this study, the conditions for feedback training (especially the target frequency band) were chosen empirically by experimenters by taking the results of previous sessions into account. Moreover, the present training paradigm was rather boring for the subjects. The proposal of efficient training strategies and protocols to boost the effects of feedback training is left for further studies.

III. An auditory BCI system based on stream segregation [4]

A. Introduction

ERP (event-related potential) elicited by sensory stimuli can also be used for realizing EEG-based BCI system. The BCI-based spelling system to choose one of 36 characters by using visual ERP was proposed [10]. In this system, a matrix of 6 by 6 characters was presented and one of each row or column blinked sequentially in random order. Users were requested to focus on one of the characters, and the P300, one of the ERP components, which was elicited by the highlight of focused characters, was analyzed and detected. But in such a system, users are required to watch and focus on the visual display anytime they want to use. Hill et al [11] proposed the ERP-based BCI system in auditory domain. In this system, users were presented two kinds of tone sequences on each ear asynchronously, and they were requested to attend the sequence from one of the ears. In this system, more than thirty electrodes were used to measure ERP to achieve higher accuracy.

The authors proposed an auditory BCI system based on auditory stream segregation to realize a two-alternative choice, and is tested by the experiments with two-channel EEG measurements [4]. In this system, series of short tones with two frequency ranges were presented alternatively to subject's right ear, and subjects were requested to attend one of the “streams” which were perceived to be segregated as higher and lower tone sequences.

B. Auditory Stream Segregation

Auditory illusions or other interesting perceptual phenomena, e.g. figure-ground perception (cocktail-party effect) or perceptual grouping, have been studied in psychophysics to uncover the nature of computational theory of auditory information processing. Such studies, which are known as auditory scene analysis [12], have shown that a lot of interesting phenomena related to Gestalt psychology, and their neuronal correlates have been investigated. (e.g. ref. [13])

When two kinds of tones with different frequencies (A, B) are presented alternatively on time (e.g. ABABAB...) with short inter-stimulus interval, such sequence can be perceived as two segregated tone streams (AAAAA ..., and BBBBB...). Such phenomenon is called as auditory stream segregation, and can be treated as one of the auditory illusions on which similarity on tone frequency overcomes the factor of time continuity.

C. Methods

Schematic diagram of tone sequence presented to subjects in this experiment is shown in Fig. 2. Two kinds of auditory oddball sequences consisted of tone bursts were presented alternatively on each tone. Six subjects were required to pay attention to one of the two streams. The EEG signal was recorded with Ag-AgCl electrodes at two locations (Cz, F3), and referred to right earlobe with a forehead ground.

The responses to deviant stimuli was classified by LDA (linear discriminant analysis) to discriminate whether the subject paid attention to each of the streams by classifying the response to the deviant stimuli embedded to each of the streams. Data was divided to 10 s block and final judgment of detection was executed on each block data on the basis of decision by majority.

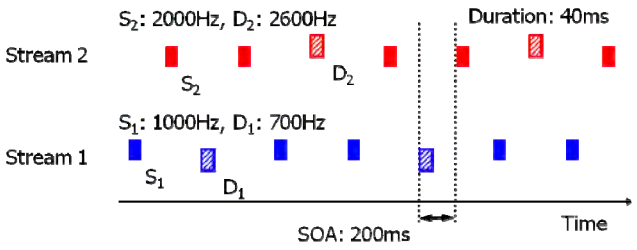

Fig. 2 Presented tone sequences on proposed auditory BCI based on stream segregation

D. Results and Discussion

The result of detection whether the subject attended to stream 1 or 2 was judged by the decision by majority of all the classification results in the time windows of 10 s. More than 95% correct detection rate and bit transfer rate of about 5 bit/min (one judgment in every 10 seconds, maximum 6 bit/min) were achieved. But by using 10-fold cross-validation, correct detection rate was 60~70%. It was shown that the present paradigm could be used for BCI.

In the previous study on auditory BCI, the two independent tone sequences were presented to both ears and discriminated which ear the target (attended) sequences were presented, so only 1 bit (left or right) was obtained by one detection [11]. But on the proposed system, auditory stream segregation of tone sequences presented to one ear was utilized and it can be extended to many-to-one choice BCI by increasing the number of tone streams to be segregated.

The non-stationality on EEG and low S/N ratio of measured EEG data are thought to be the reasons on 10-fold cross-validation shown above. To increase the accuracy, preprocessing methods for artifact reduction and increasing the stability of classification (e.g. down-sampling, filtering) and feature selection/extraction techniques should be improved.

IV. CONCLUSIONS

In this article, two of our recent researches on EEG-based BCI, effect of feedback training for BCI based on motor imagery and a new paradigm of auditory BCI, were shown.

Although previous studies on BCI have been mainly focused on "reading out" of user's intensions or thoughts from the brain signal, to modulate brain's activities in non-invasive way will also be essential for BCI or its application for clinical use. Moreover, the task for controlling BCI system (or for modulating brain activities) should be natural and easy for users.

Efficient methods of online feedback training and further investigation of new tasks for BCI are left for further studies.

Abstract— **Thromboembolic and haemorrhagic complications are the primary causes of mortality and morbidity in patients with artificial hearts, which are known to be induced by the interactions between blood flow and artificial material surfaces. The authors have been developing a new mechanical artificial myocardial assist device by using a sophisticated shape memory alloy fibre in order to achieve the mechanical cardiac support from outside of the heart without a direct blood contacting surface. The original material employed as the actuator of artificial myocardial assist devices was 100um fibred-shaped, which was composed of covalent and metallic bonding structure and designed to generate 4-7 % shortening by Joule heating induced by the electric current input. Prior to the experiment, the myocardial streamlines were investigated by using a MDCT, and the design of artificial myocardial assist devices were refined based on the concept of Torrent-Guasp's myocardial band theory. As the hydrodynamic or hemodynamic examination exhibited the remarkable increase of cardiac systolic work by the assistance of the artificial myocardial contraction in the originally designed mock circulatory system as well as in the acute animal experiments, the chronic animal test has been started in a goat. Total weight of the device including the actuator was around 150g, and the electric power was supplied percutaneously. The device could be successfully installed into thoracic cavity, which was able to be girdling the left ventricle. In the chronic animal trial, the complication in respect to the diastolic dysfunction by the artificial myocardial compression was not observed.**

Keywords— **Artificial myocardium, shape memory alloy fibre, chronic animal experiment, myocardial band, hemodynamics.**

I. Introduction

Chronic heart failure (CHF) is functionally and structurally characterized by pathophysiological remodeling of the ventricle. In general, ventricular assist devices (VADs), such as artificial hearts, are used for the surgical treatment of the patients with the final stage of severe heart failure [1-4]. However, thromboembolic and haemorrhagic complications are still the primary causes of mortality and morbidity in patients with VADs, which are known to be induced by the interactions between blood flow and artificial material surfaces. Several concepts of the mechanical assistance from outside of the ventricle have been presented so far, such as Anstadt's ventricular cup, providing a solution to these problems without direct contacting surfaces against blood [5-12]. And also some new devices, such as Myosprint, demonstrated improvements in eliminating mitral regurgitation in dysfunctional left ventricle as well as in preventing the ventricular enlargement which was to compensate for the reduction in cardiac function [13-14]. Although the passive implantable devices, which are girdling the ventricle from the outside, have been already applied for clinical trials in patients with chronic congestive heart failure for the passive assistance as well as for the prevention of enlargement of the left ventricle to compensate for the reduction in cardiac function, there might be a limitation to passive assistance in the case of sudden changes of cardiac contractile function, such as angina of effort. We have been developing an artificial myocardial assist device by using a covalent type nano-tech shape memory alloy fibre, which is capable of assisting natural cardiac contraction from outside of the ventricular wall as

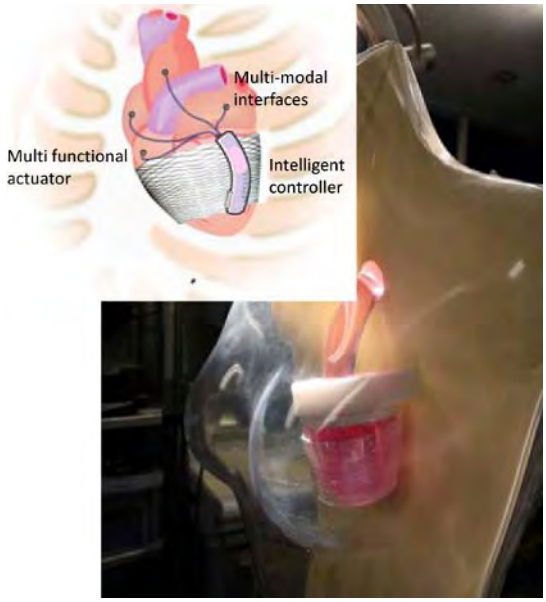

Fig. 1 Schematic illustration and an installation in the mock of an artificial myocardium attached on the ventricular wall; the synchronous contraction can be achieved according to the natural physiological demand.

shown in Figure 1. The purpose of this study was to examine the function of the artificial myocardium, which was designed to assist the heart synchronously with native contraction, and its feasibility in chronic animal experiments.

II. Materials and Methods

A. Myocardial assist device description

The artificial myocardium consists of ten shape memory alloy fibres which were covered by silicone rubber as shown in Figure 2. Special features of the shape memory alloy fibre material (Biometal®) which was to be employed as the actuator of the artificial myocardium were as follows: a) composition of covalent and metallic bonding structure, b) 4-7 % shortening by Joule heating induced by the electric current input, c) linear characteristics of electric resistance against shortening, d) strong maximum contractile force of 10N with 100um-fibre, e) high durability of over one billion cycles, f) contractile frequent response by 1-3 Hz, g) selectable maltensitic temperature by fabrication processing from 45 to 70 Celsius, and h) elective diameter size smaller than 30um [15-17]. The contraction of the device can be controlled by an originally-designed microcomputer system. The device is controlled and performed by electrical signal input, which is supplied percutaneously. Each signal for the contraction is regulated by the controller and synchronized with native electrocardiogram (Figure 3 and 4). Originally-designed ladder-

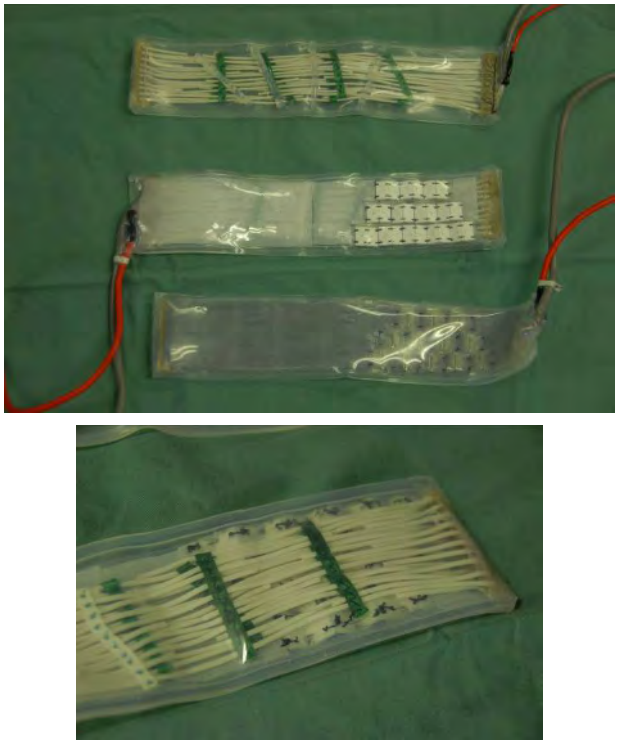

Fig. 2 Several types of myocardial assist device developed for the feasibility study in chronic animal experiments (top), and the details of the connection of shape memory alloy fibres covered with silicone tubing (bottom).

shaped hinges were constructed on the parallelly-linked shape memory alloy fibres belt, specifically on the surface attaching to the left ventricular free wall in order to simulate the wall-thickening effect as well as to promote the mechanical shortening perpendicularly to the left ventricular long axis.

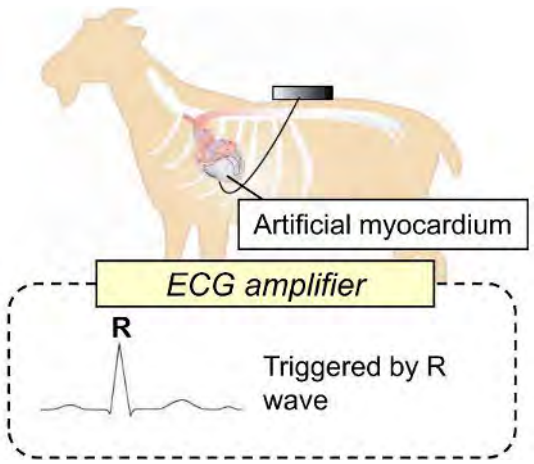

Fig. 3 Schematic illustration of the signal connection for the control of mechanical myocardial contraction in the animal experiments.

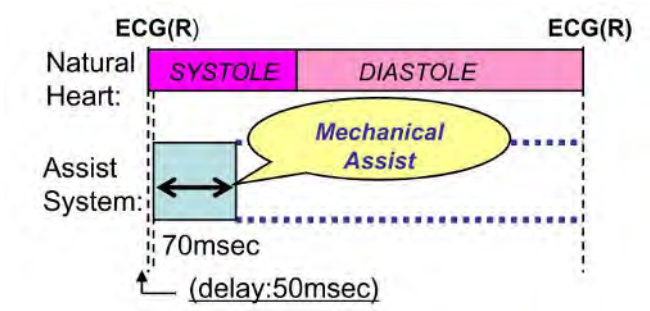

Fig. 4 Schematic drawing of the contraction signal input for the artificial myocardium synchronized with electrocardiogram (ECG-R).

B. Mechanical design of the device based on the anatomical examination of native heart

Myocardial streamline was confirmed by the MDCT investigation in a healthy goat heart which was extracted and unfolded based on the Torrent-Guasp's myocardial band concept as shown in Figure 5 [17]. The orientation of the device contraction might promote native systolic function while avoiding both the external and internal critical structures of the heart. The myocardial streamline was detected from the data with plastic markers plot by MDCT, and the angular configuration to the left ventricular long axis was calculated.

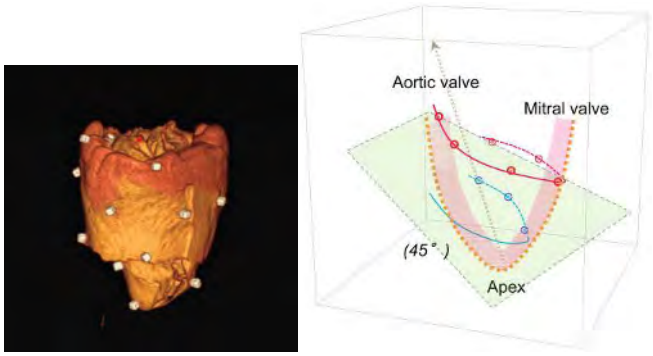

Fig. 5 MDCT examination of the healthy goat heart unfolded by the Torrent-Guasp's concept and reconstructed with plastic markers (left), and the native myocardial streamline orientation calculated from the data as the reference of implantation of the artificial myocardium (right).

C. Experimental procedure

The chronic animal experiments were performed in healthy female adult Japanese Saanen goats (n=2), which weighed 45 kg. Implantation of the device was performed as part of an open-chest cardiac procedure on a beating heart under the normal inhalation and anesthesia followed by endotracheal intubation using 2.5% halothane. The band-shaped myocardial assist device was installed into the thoracic cavity girdling from the apex to the base and one of the ends was parallel to the left ventricular long axis myo cardial streamline on its free wall side. Coronary vasculature was visually identified and avoided on the exterior of the heart during the implantation. There was no direct suture on the tissue or muscles with the device. Prior to the measurement, postoperative care without mechanical assistance was carried out for one week. These animal trials were electively terminated after postoperative one month.

All animals received humane care in accordance with "the Guideline for the Care and Use of Laboratory Animals" published by the National Institute of Health (NIH publication 85-23, revised 1985) as well as with "the Guidelines for Proper Conduct of Animal Experiments" formulated by Science Council of Japan (2006) and the guidelines determined by the Institutional Animal Care and Use Committee of Tohoku University.

III. Results and Discussion

A. Adverse events

There were no serious infections and surgical procedural failures in the implantation of the device from the beginning and throughout the study in all cases (Figure 6). And the unanticipated complication in respect to the device-related diastolic dysfunction by the artificial myocardial compression was not observed. Several mechanical structural device failures could be investigated after the extraction of them.

Fig. 6 Successful implantation of the artificial myocardium without unanticipated complications in relation to infections or surgical procedural failures.

B. Hemodynamic effects

Left ventricular and aortic pressures were obtained and remarkably increased by the mechanical assistance as shown

in Figure 7. Each waveform was calculated as the average of the data in the period of 90sec. 'Control' indicates the waveforms taken without assistance, while 'Assisted' were with mechanical contraction. There were no significant changes in the left ventricular end diastolic pressure, so that it was suggested that there might not be any diastolic dysfunction during the mechanical assistance using the artificial myocardium. As a result, left ventricular systolic pressure was increased from 110 to 118 mmHg (7%), and assisted flow rate was elevated for 70msec, which was equivalent of the mechanical contractile duration, from the data calculated (Figure 7). Consequently, the assistive effect on cardiac output during the assistance was calculated to be 3% higher than the control condition without mechanical contraction.

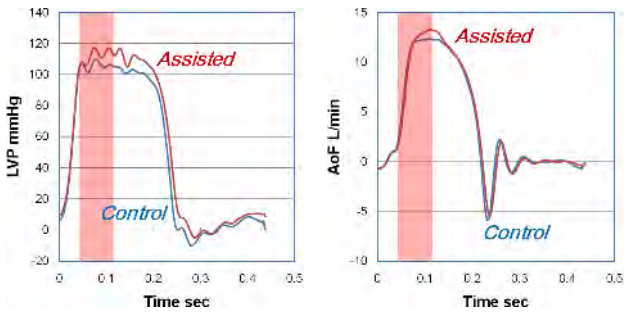

Fig. 7 Changes in hemodynamic waveforms obtained at a goats with the mechanical assistance by using the artificial myocardium. Each waveform was calculated as the average of the data in the period of 90 sec. 'Control' indicates the waveforms taken without assistance, while 'Assisted' were with mechanical contraction. The area colorized shows the duration of signal input for 70msec from 50msec subsequent of electrophysiological cardiac contraction detected by 'ECG-R'.

IV. Conclusions

The first animal trials of the artificial myocardium using shape memory alloy fibre demonstrated both feasibility and efficacy in healthy adult goats. The result indicated the development of the active ventricular assist device was useful because of its ability to consistently reduce or eliminate the complications in relation to thrombosis or hemolysis along with simple mechanism for the effective actuation.

Abstract — **Nano-materials are expected to be used for medical applications such as research on pharmacokinetics and novel therapeutic agents. Their acute toxicity should be examined and systemic distribution of the nano-materials should also be estimated. We established a high resolution in vivo 3D microscopic system for a novel fluorescence imaging method at single molecular level. We measured in vivo movement of CdSe nano-particles (quantum dots (QDs)) conjugated with monoclonal anti-HER2 antibody (Trastuzumab) in tumor vessel to breast cancer cells. The HER2 protein expressed in cancer cells and its in vivo dynamics were visualized by QDs at nano-scale. It suggests future utilization of the system to improve drug delivery system to target the primary and metastatic tumors for made to order treatment. We also describe a novel contrast medium for X-ray and its distribution in organs. Nano-sized silica coated silver iodide beads exhibited contrast enhancementin the tumor for over one hour. Sentinel node navigation is one of the important clinical applications for fluorescence nano-particles and silver iodide beads. Our experimental data of those nano-particles in experimental model have shown the potential of fluorescence and X-ray measurement to be alternatives to existing tracers. Future innovation in cancer imaging by nano-technology and novel measurement technology will provide great improvement, not only in clinical field of prevention, diagnosis and treatment of human disease, but also in basic medical science.**

Keywords — **Single molecular imaging, quantum dots, HER2, nano-technology, silica coated silver iodide beads,**

I. Introduction

Nano-materials are widely applied to medical diagnoses and treatments such as research on pharmacokinetics and novel therapeutic agents in this decade. Functional nano-particles, such as quantum dots, nano-micelle, nano-sized gold particles, silica coated silver iodide beads and dendrimers. They have unique properties and are potentially useful in medicine.

Their acute toxicity should be examined and systemic distribution of the nano-materials should also be estimated. We established a high resolution in vivo 3D microscopic system for a novel fluorescence imaging method at single molecular level. We assessed utility of this system by in vivo measurement of anticancer antibody conjugated quantum dots. Nano-particles with functions can be also used for macro scale measurements.

Recent studies have proved the great influence of particle size in malignancies because the tumor vessels have immature pores and the permeability increases [1]. This phenomenon is called extended permeability and retention (EPR). So the size of nano-particles has an important function to develop anticancer drugs. The size of nano-particles is also important for sentinel node navigation surgery.

Distribution of nano-particles is also an important issue to utilize nano-particles for medicine.

In this study, we aimed to clarify the in vivo movement of nano-particles in interstitium of a tumor, because the size may affect not only accumulation of nano-particles but also movement in interstitium. We establish utility of functional nano-particles along with development of novel optical measurement methods for both nano-scale and macro-scale.

In this study, we measured in vivo movement of various sizes of nano-particles in tumor interstitium. We also performed contrast enhancement of rat and tumor by novel X-ray contrast media of silica coated silver iodide beads.

II. Materials and methods

A. Nano-scale measurement of fluorescent nano-particles

We used 'Fluospheres', manufactured polystyrene microspheres by Invitrogen, Molecular Probe (Oregon, USA) for the size of 40 and 100nm. And we employed Quantum dot 705 ITK kit (Quantum Dot Corp., Hayward CA) for the size of 20nm.

A human breast cancer cell line KPL-4[1] was kindly provided by Dr. J. Kurebayashi (Kawasaki Medical School, Kurashiki, Japan) [2]. KPL-4 was cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 5% fetal bovine serum.

A suspension of KPL-4 (1.0×10^7 cells / 100 μl DMEM) cells was transplanted subcutaneously into the dorsal skin of female Balb/c nu/nu mice at 5 - 7 weeks of age (Charles river laboratories Japan, Yokohama, Japan). Several weeks after tumor inoculation, mice with a tumor volume of 100 - 200 mm^3 were used for the study. The mice were placed under anesthesia by ketamine and xylazine.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 2272–2274, 2009
www.springerlink.com

The optical system consisted of an epi-fluorescent microscope, Nipkow lens type confocal unit and an electron multiplier type CCD camera. This system can capture images of single nano-particles at a rate of 33 ms/frame. The xy-position of the fluorescent spot was calculated by fitting to a 2D-Gaussian curve. The single molecule could be identified by the fluorescence intensity. And quantitative and qualitative information such as velocity, directionality and transport mode was obtained using time-resolved trajectories of nano-particles.

The movement of nano-particles was detected in the tumor after intravenous administration by the optical system.

B. 2.2 Contrast enhancement of a tumor by novel X-ray contrast media

We produced the silica-coated silver iodide beads (AgI beads) in size of 40-80 nm by the Stöber method. Pottasium iodide and $AgClO_4$ was used for the formation of the silver-iodide core. Silica-coating of the fluorescent microspheres was carried out with ammonia-catalyzed reaction of tetraethylorthosilicate (TEOS) in ethanol–water solution. Ethanol solution of TEOS was added to aqueous PVP solution under stirring after addition of the suspension of the fluorescent microspheres. Hydrolysis reaction of TEOS was initiated by addition of the aqueous ammonia solution to form silica shell on the microspheres for 24 h under stirring. Silica coated silver iodide nano-particles have diameter of 40-80 nm [3].

Saline suspension of the silica-coated AgI beads was intravenously administered to rats with xenografts of human breast cancer (KPL-4). The CT images were sequentially acquired at 15, 30 and 60min., after intravenous administration.

These studies were carried out in accordance with the Institutional Animal Use and Care Regulations of Tohoku University, after receiving approval from the Committee on Animal Experiments.

III. Results

A. 3.1 Nano-scale measurement of fluorescent nano-particles in tumor

The movement of single particles was observed in perivascular, interstitial and intracellular regions of tumors. We could successfully detected by our measurement system. The HER2 protein expressed in cancer cells and its dynamics *in vivo* were visualized by QDs and fluorescence polystylene beads at nano-scale.

Fluorescent nano-particles in various sizes are also detected by the optical system. We investigated three kinds of area of perivascular region, interstitium and intercellular region in the interstitium of the tumor.

In the perivascular area, 20 nm particles exhibited almost uni-directed movement by interstitial flow. In contrast, 40 and 100 nm particles showed uni-directed movement with increased random diffusion.

In the tumor interstitial region, the movement of 20 nm consisted of uni-directed movement and random diffusion. And 40 and 100 nm particles showed a movement almost affected by diffusion.

In the intercellular region, a 20 nm particle movement appeared to be much restricted. The movements of 40 and 100 nm particles appeared to represent only diffusion. They were indicating Brownian motion.

B. 3.2 Contrast enhancement of a tumor by novel X-ray contrast media

We could observe enhancement of a tumor after administration of AgI beads. The Hounsfield number of the tumor gradually increased and got the maximum value in 60 min.

IV. Discussion

In the study for single particle fluorescent imaging of cancer, we captured the specific movement of nano-particles in various sizes in live mice after nano-particles had been injected into the tail vein of mice. In the former study, we could observe six stages of drug delivery, 1) vessel circulation, 2) extravasation, 3) movement into the extracellular region, 4) binding to HER2 on the cell membrane, 5) movement from the cell membrane to the perinuclear region after endocytosis and 6) in the perinuclear region [4]. That study suggests that there are many stages to be considered for better drug delivery. The ineterstitium plays a very important role for drug delivery, as it is the scaffold of the tumor cells and the structure of the interstitium defines interface of tumor cells to drugs. The movement of the particles in each process was also found to be ”stop-and-go”, *i.e.*, sometimes the particles stay within a highly restricted area and then move suddenly after release. This indicates that the movement was promoted by a motive power and constrained by both the 3D-structure and protein-protein interactions. The motive power of the movements was produced by the diffusion force driven by thermal energy [2-4], interstitial lymph flow and active transport by motor proteins [5]. The cessation of movement is most likely induced by a structural barricade such as a matrix cage [2-4] and/or specific interaction between proteins, *e.g.*,

an antibody and HER2 [4], motor proteins, and rail filaments such as actin filaments and microtubules [5]. Our study strongly suggests that the size of drug carrier can be an important drug delivery modifier. If we choose the carrier in size of 20nm, it may reach cells soon and immediately diminish. Larger size can stay interstitium longer. Smaller particles can be used for drugs for treatment. To let drugs to access cancer cells. Larger particles can be used for localization of malignant lesion for surgical or radiological treatment.

There have been many different approaches to tumor-targeting "nanocarriers" including anti-cancer drugs, for passive targeting such as Myocet [5], Doxil [6] and for active targeting such as MCC-465 [7], anti-HER2 immunoliposome [8]. There is still very little understanding of the biological behavior of nano-carriers, including such crucial features as their transport in the blood circulation, interstitial behavior, cellular recognition, translocation into the cytoplasm, and final fate in the target cell. These results suggest that the transport of nano-carriers can be quantitatively analyzed in the tumors of living animals by the present method.

There are two forms of transportation mechanism regarding a particle material to lymphatic system. One is physical and active extracellular transportation; a particle passes through lymph capillaries. The other one is intracellular transportation of a particle. Foreign materials shift to the lymph capillaries after phagocytosis of the particle.

Silica coated silver iodide beads had contrast enhancement in xenograft of breast cancer. In our former study, the slow increase in contrast enhancement of liver and spleen would be attributed to sedimentation of silica coated silver iodide beads in the capillary system. Enhancement of the tumor may be attributed to EPR other than the sedimentation of silica coated silver iodide beads in the capillary system.

Nano-materials for medicine would be a great aid to improve the made to order medicine by their highly sensitive and super selective property for diagnoses. Advanced sensing technologies such as single molecular imaging technique are also required to make the best use of the functional nano-materials for achievement of hyper sensitive and super selective imaging. These novel products of advanced nano-technologies may realize revolution of medicine in near future.

ACKNOWLEDGEMENT

This work was supported by Grants-in-aid for Research Projects, Promotion of Advanced Medical Technology (H14-Nano-010 and H18-Nano-001), from the Ministry of Health, Labor and Welfare, Japan and the 21st Century Global Center of Excellence (GCOE) Program "Future Medical Engineering based on Bio-nanotechnology", the Japan Society for the Promotion of Science.
