The International Federation for Medical and Biological Engineering, IFMBE, is a federation of national and transnational organizations representing internationally the interests of medical and biological engineering and sciences. The IFMBE is a non-profit organization fostering the creation, dissemination and application of medical and biological engineering knowledge and the management of technology for improved health and quality of life. Its activities include participation in the formulation of public policy and the dissemination of information through publications and forums. Within the field of medical, clinical, and biological engineering, IFMBE's aims are to encourage research and the application of knowledge, and to disseminate information and promote collaboration. The objectives of the IFMBE are scientific, technological, literary, and educational.

The IFMBE is a WHO accredited NGO covering the full range of biomedical and clinical engineering, healthcare, healthcare technology and management. It is representing through its 58 member societies some 120.000 professionals involved in the various issues of improved health and health care delivery.

About IFMBE

The International Federation for Medical and Biological Engineering (IFMBE) was established in 1959 to provide medical and biological engineering with a vehicle for international collaboration in research and practice of the profession. The Federation has a long history of encouraging and promoting international cooperation and collaboration in the use of science and engineering for improving health and quality of life.

The IFMBE is an organization with membership of national and transnational societies and an International Academy. At present there are 52 national members and 5 transnational members representing a total membership in excess of 120 000 worldwide. An observer category is provided to groups or organizations considering formal affiliation. Personal membership is possible for individuals living in countries without a member society The International Academy includes individuals who have been recognized by the IFMBE for their outstanding contributions to biomedical engineering.

Objectives

The objectives of the International Federation for Medical and Biological Engineering are scientific, technological, literary, and educational. Within the field of medical, clinical and biological engineering it's aims are to encourage research and the application of knowledge, and to disseminate information and promote collaboration.

In pursuit of these aims the Federation engages in the following activities: sponsorship of national and international meetings, publication of official journals, cooperation with other societies and organizations, appointment of commissions on special problems, awarding of prizes and distinctions, establishment of professional standards and ethics within the field, as well as other activities which in the opinion of the General Assembly or the Administrative Council would further the cause of medical, clinical or biological engineering. It promotes the formation of regional, national, international or specialized societies, groups or boards, the coordination of bibliographic or informational services and the improvement of standards in terminology, equipment, methods and safety practices, and the delivery of health care.

The Federation works to promote improved communication and understanding in the world community of engineering, medicine and biology.

Activities

Publications of IFMBE include: the journal *Medical and Biological Engineering and Computing*, the electronic magazine *IFMBE News*, and the Book Series on Biomedical Engineering. In cooperation with its international and regional conferences, IFMBE also publishes the IFMBE Proceedings Series. All publications of the IFMBE are published by Springer Verlag. The Federation has two divisions: Clinical Engineering and Health Care Technology Assessment.

Every three years the IFMBE holds a World Congress on Medical Physics and Biomedical Engineering, organized in cooperation with the IOMP and the IUPESM. In addition, annual, milestone and regional conferences are organized in different regions of the world, such as Asia Pacific, Europe, the Nordic-Baltic and Mediterranean regions, Africa and Latin America.

The administrative council of the IFMBE meets once a year and is the steering body for the IFMBE: The council is subject to the rulings of the General Assembly, which meets every three years.

Information on the activities of the IFMBE can be found on the web site at: http://www.ifmbe.org.

Foreword

On behalf of the organizing committee of the 13th International Conference on Biomedical Engineering, I extend our warmest welcome to you. This series of conference began in 1983 and is jointly organized by the YLL School of Medicine and Faculty of Engineering of the National University of Singapore and the Biomedical Engineering Society (Singapore).

First of all, I want to thank Mr Lim Chuan Poh, Chairman A*STAR who kindly agreed to be our Guest of Honour to give the Opening Address amidst his busy schedule. I am delighted to report that the 13th ICBME has more than 600 participants from 40 countries. We have received very high quality papers and inevitably we had to turndown some papers. We have invited very prominent speakers and each one is an authority in their field of expertise. I am grateful to each one of them for setting aside their valuable time to participate in this conference.

For the first time, the Biomedical Engineering Society (USA) will be sponsoring two symposia, ie "Drug Delivery Systems" and "Systems Biology and Computational Bioengineering". I am thankful to Prof Tom Skalak for his leadership in this initiative. I would also like to acknowledge the contribution of Prof Takami Yamaguchi for organizing the NUS-Tohoku's Global COE workshop within this conference. Thanks also to Prof Fritz Bodem for organizing the symposium, "Space Flight Bioengineering". This year's conference proceedings will be published by Springer as an IFMBE Proceedings Series.

Finally, the success of this conference lies not only in the quality of papers presented but also to a large extent upon the dedicated team efforts of the many volunteers, in particular members of the Organizing Committee and International Advisory Committee. Their dedicated contribution, diligence and encouragement have been exemplary. I would also like to thank the staff at Integrated Meetings Specialist, who have given their best to ensure the smooth running of the conference. Last but not least, I would like to acknowledge with sincere thanks to our sponsors, supporters and exhibitors.

To all our delegates, I hope the 13th ICBME 2008 will be memorable not only from the scientific perspective but in the joy of meeting old friends and making new ones. Do take time to experience Singapore, especially during this year-end festivity.

Best wishes

Prof James Goh

History of ICBME

In 1983, a number of academics from the Faculty of Medicine and Faculty of Engineering at the National University of Singapore (NUS) organized a Symposium on Biomedical Engineering (chaired by N Krishnamurthy). It was held on NUS Kent Ridge Campus. The scientific meeting attracted great interest from members of both faculties. It also facilitated cross faculty research collaboration. The 2nd Symposium (chaired by J Goh) was held in 1985 at the Sepoy Lines Campus of the Faculty of Medicine with the aim to strengthen collaboration between the two faculties. The keynote speaker was Dr GK Rose, Oswestry, UK. In 1986, the 3rd Symposium (chaired by K Bose & N Krishnamurthy) was organized to promote the theme of "Biomedical Engineering: An Interdisciplinary Approach", it attracted regional participation. The keynote speaker was Prof JP Paul, Strathclyde, UK. It was highly successful and as such motivated the creation of the International Conference on Biomedical Engineering (ICBME). In order to maintain historical continuity, the ICBME series began in 1987 with the 4th ICBME. From 1997 onwards, the ICBME series was jointly organized by Faculty of Engineering & YLL School of Medicine, NUS and the Biomedical Engineering Society (Singapore). The following table shows the growth of the ICBME series over the years:

	Year	Chairs & Co-Chairs	Invited Speakers	Oral Papers	Poster Papers	Total
4th ICBME	1987	AC Liew, K Bose	8	29	10	47
5th ICBME	1988	K Bose, K Ong	7	67	18	92
6th ICBME	1990	YT Chew, K Bose	10	132	34	176
7th ICBME	1992	K Bose, YT Chew	19	140	37	196
8th ICBME	1994	YT Chew, K Bose	25	137	20	182
9th ICBME	1997	K Bose, YT Chew	39	178	23	240
10th ICBME	2000	SH Teoh, EH Lee	34	208	60	302
11th ICBME	2002	J Goh, SL Toh	44	261	150	455
12th ICBME	2005	SL Toh, J Goh	23	370	123	516
13th ICBME	2008	J Goh, SL Toh	36	340	299	675

Estimating Mechanical Properties of Skin using a Structurally-Based Model
J. W. Y. Jor, M. P. Nash, R. M. F. Nielsen, P. J. Hunter
University of Auckland, New Zealand

The Motility of Normal and Cancer Cells in Response to the Combined Influence of Substrate Rigidity and Anisotropic Nanostructure
T. Tzvetkova-Chevolleau, A. Stephanou, D. Fuard, J. Ohayon, P. Schiavone, P. Tracqui
Centre National de la Recherche Scientifique, France

Accurate Estimation of In Vivo Knee Kinematics from Skin Marker Coordinates with the Global Optimization Method
T.-W Lu, T.-Y. Tsai
National Taiwan University, Taiwan

A Brain-oriented Compartmental Model of Glucose-Insulin-Glucagon Regulatory System
G.-H. Lu, H. Kimura
Institute of Physical and Chemical Research, Nagoya, Japan

Mechanical Loading Response of Human Trabecular Bone Cores
M. Kratz, P. Hans, J. David
Universitat Marburg, Germany

Content

Track 1:
Bioinformatics; Biomedical Imaging; Biomedical instrumentation; Biosignal Processing; Digital Medicine; Neural Systems Engineering

Electroencephalograph Signal Analysis During Ujjayi pranayama 1
Prof. S.T. Patil and Dr. D.S. Bormane

A Study of Stochastic Resonance as a Mathematical Model of Electrogastrography during Sitting Position 5
Y. Matsuura, H. Takada and K. Yokoyama

Possibility of MEG as an Early Diagnosis Tool for Alzheimer's Disease: A Study of Event Related Field in Missing Stimulus Paradigm 9
N. Hatsusaka, M. Higuchi and H. Kado

New Architecture For NN Based Image Compression For Optimized Power, Area And Speed 13
K. Venkata ramanaiah, Cyril Prasanna raj and Dr. K. Lal kishore

A Statistical Model to Estimate Flow Mediated Dilation Using Recorded Finger Photoplethysmogram 18
R. Jaafar, E. Zahedi, M.A. Mohd Ali

Automatic Extraction of Blood Vessels, Bifurcations and End Points in the Retinal Vascular Tree 22
Edoardo Ardizzone, Roberto Pirrone, Orazio Gambino and Francesco Scaturro

Recent Developments in Optimizing Optical Tools for Air Bubble Detection in Medical Devices Used in Fluid Transport 27
S. Ravichandran, R. Shanthini, R.R. Nur Naadhirah, W. Yikai, J. Deviga, M. Prema and L. Clinton

General Purpose Adaptive Biosignal Acquisition System Combining FPGA and FPAA 31
Pedro Antonio Mou, Chang Hao Chen, Sio Hang Pun, Peng Un Mak and Mang I. Vai

Segmentation of Brain MRI and Comparison Using Different Approaches of 2D Seed Growing 35
K.J. Shanthi, M. Sasi Kumar and C. Kesavdas

SQUID Biomagnetometer Systems for Non-invasive Investigation of Spinal Cord Dysfunction 39
Y. Adachi, J. Kawai, M. Miyamoto, G. Uehara, S. Kawabata, M. Tomori, S. Ishii and T. Sato

Human Cardio-Respiro Abnormality Alert System using RFID and GPS - (H-CRAAS) 43
Ahamed Mohideen, Balanagarajan

Automatic Sleep Stage Determination by Conditional Probability: Optimized Expert Knowledge-based Multi-Valued Decision Making 47
Bei Wang, Takenao Sugi, Fusae Kawana, Xingyu Wang and Masatoshi Nakamuara

A Study on the Relation between Stability of EEG and Respiration 51
Young-Sear Kim, Se-Kee Kil, Heung-Ho Choi, Young-Bae Park, Tai-Sung Hur, Hong-Ki Min

The Feature-Based Microscopic Image Segmentation for Thyroid Tissue 55
Y.T. Chen, M.W. Lee, C.J. Hou, S.J. Chen, Y.C. Tsai and T.H. Hsu

Heart Disease Classification Using Discrete Wavelet Transform Coefficients of Isolated Beats 60
G.M. Patil, Dr. K. Subba Rao, K. Satyanarayana

Non-invasive Techniques for Assessing the Endothelial Dysfunction: Ultrasound Versus Photoplethysmography 65
M. Zaheditochai, R. Jaafar, E. Zahedi

High Performance EEG Analysis for Brain Interface **69**
Dr. D.S. Bormane, Prof. S.T. Patil, Dr. D.T. Ingole, Dr. Alka Mahajan

Denoising of Transient Visual Evoked Potential using Wavelets **73**
R. Sivakumar

A Systematic Approach to Understanding Bacterial Responses to Oxygen Using Taverna and Webservices **77**
S. Maleki-Dizaji, M. Rolfe, P. Fisher, M. Holcombe

Permeability of an In Vitro Model of Blood Brain Barrier (BBB) **81**
Rashid Amin, Temiz A. Artmann, Gerhard Artmann, Philip Lazarovici, Peter I. Lelkes

Decision Making Algorithm through LVQ Neural Network for ECG Arrhythmias **85**
Ms. T. Padma, Dr. Madhavi Latha, Mr. K. Jayakumar

A Low-Noise CMOS Receiver Frontend for NMR-based Surgical Guidance **89**
J. Anders, S. Reymond, G. Boero and K. Scheffler

Automated Fluorescence as a System to Assist the Diagnosis of Retinal Blood Vessel Leakage **94**
Vanya Vabrina Valindria, Tati L.R. Mengko, Iwan Sovani

A New Method of Extraction of FECG from Abdominal Signal **98**
D.V. Prasad, R. Swarnalatha

Analysis of EGG Signals for Digestive System Disorders Using Neural Networks **101**
G. Gopu, Dr. R. Neelaveni and Dr. K. Porkumaran

A Reliable Measurement to Assess Atherosclerosis of Differential Arterial Systems **105**
Hsien-Tsai Wu, Cyuan-Cin Liu, Po-Chun Hsu, Huo-Ying Chang and An-Bang Liu

An Automated Segmentation Algorithm for Medical Images **109**
C.S. Leo, C.C. Tchoyoson Lim, V. Suneetha

Quantitative Assessment of Movement Disorders in Clinical Practice **112**
Á. Jobbágy, I. Valálik

Design and Intra-operative Studies of an Economic Versatile Portable Biopotential Recorder **116**
V. Sajith, A. Sukeshkumar, Keshav Mohan

Comparison of Various Imaging Modes for Photoacoustic Tomography **121**
Chi Zhang and Yuanyuan Wang

Ultrasonographic Segmentation of Cervical Lymph Nodes Based on Graph Cut with Elliptical Shape Prior **125**
J.H. Zhang, Y.Y. Wang and C. Zhang

Computerized Assessment of Excessive Femoral and Tibial Torsional Deformation by 3D Anatomical Landmarks Referencing **129**
K. Subburaj, B. Ravi and M.G. Agarwal

Modeling the Microstructure of Neonatal EEG Sleep Stages by Temporal Profiles **133**
V. Krajča, S. Petránek, J. Mohylová, K. Paul, V. Gerlaand L. Lhotská

Optimization and Characterization of Sodium MRI Using 8-channel ^{23}Na and 2-channel ^{1}H RX/TX Coil **138**
J.R. James, C. Lin, H. Stark, B.M. Dale, N. Bansal

Non-invasive Controlled Radiofrequency Hyperthermia Using an MR Scanner and a Paramagnetic Thulium Complex **142**
J.R. James, V.C. Soon, S.M. Topper, Y. Gao, N. Bansal

Automatic Processing of EEG-EOG-EMG Artifacts in Sleep Stage Classification **146**
S. Devuyst, T. Dutoit, T. Ravet, P. Stenuit, M. Kerkhofs, E. Stanus

Medical Image Registration Using Mutual Information Similarity Measure **151**
Mohamed E. Khalifa, Haitham M. Elmessiry, Khaled M. ElBahnasy, Hassan M.M. Ramadan

A Feasibility Study of Commercially Available Audio Transducers in ABR Studies **156**
A. De Silva, M. Schier

Simultaneous Measurement of PPG and Functional MRI **161**
S.C. Chung, M.H. Choi, S.J. Lee, J.H. Jun, G.M. Eom, B. Lee and G.R. Tack

A Study on the Cerebral Lateralization Index using Intensity of BOLD Signal of functional Magnetic Resonance Imaging **165**
M.H. Choi, S.J. Lee, G.R. Tack, G.M. Eom, J.H. Jun, B. Lee and S.C. Chung

A Comparison of Two Synchronization Measures for Neural Data **169**
H. Perko, M. Hartmann and T. Kluge

Protein Classification Using Decision Trees With Bottom-up Classification Approach **174**
Bojan Pepik, Slobodan Kalajdziski, Danco Davcev, Member IEEE

Extracting Speech Signals using Independent Component Analysis **179**
Charles T.M. Choi and Yi-Hsuan Lee

Age-Related Changes in Specific Harmonic Indices of Pressure Pulse Waveform **183**
Sheng-Hung Wang, Tse-Lin Hsu, Ming-Yie Jan, Yuh-Ying Lin Wang and Wei-Kung Wang

Processing of NMR Slices for Preparation of Multi-dimensional Model **186**
J. Mikulka, E. Gescheidtova and K. Bartusek

Application of Advanced Methods of NMR Image Segmentation for Monitoring the Development of Growing Cultures **190**
J. Mikulka, E. Gescheidtova and K. Bartusek

High-accuracy Myocardial Detection by Combining Level Set Method and 3D NURBS Approximation **194**
T. Fukami, H. Sato, J. Wu, Thet-Thet-Lwin, T. Yuasa, H. Hontani, T. Takeda and T. Akatsuka

Design of a Wireless Intraocular Pressure Monitoring System for a Glaucoma Drainage Implant **198**
T. Kakaday, M. Plunkett, S. McInnes, J.S. Jimmy Li, N.H. Voelcker and J.E. Craig

Integrating FCM and Level Sets for Liver Tumor Segmentation **202**
Bing Nan Li, Chee Kong Chui, S.H. Ong and Stephen Chang

A Research-Centric Server for Medical Image Processing, Statistical Analysis and Modeling **206**
Kuang Boon Beh, Bing Nan Li, J. Zhang, C.H. Yan, S. Chang, R.Q. Yu, S.H. Ong, Chee Kong Chui

An Intelligent Implantable Wireless Shunting System for Hydrocephalus Patients **210**
A. Alkharabsheh, L. Momani, N. Al-Zu'bi and W. Al-Nuaimy

Intelligent Diagnosis of Liver Diseases from Ultrasonic Liver Images: Neural Network Approach **215**
P.T. Karule, S.V. Dudul

A Developed Zeeman Model for HRV Signal Generation in Different Stages of Sleep **219**
Saeedeh Lotfi Mohammad Abad, Nader Jafarnia Dabanloo, Seyed Behnamedin Jameie, Khosro Sadeghniiat.

Two wavelengths Hematocrit Monitoring by Light Transmittance Method **223**
Phimon Phonphruksa and Supan Tungjitkusolmun

Rhythm of the Electromyogram of External Urethral Sphincter during Micturition in Rats **227**
Yen-Ching Chang

Higher Order Spectra based Support Vector Machine for Arrhythmia Classification **231**
K.C. Chua, V. Chandran, U.R. Acharya and C.M. Lim

Transcutaneous Energy Transfer System for Powering Implantable Biomedical Devices **235**
T. Dissanayake, D. Budgett, A.P. Hu, S. Malpas and L. Bennet

A Complexity Measure Based on Modified Zero-Crossing Rate Function for Biomedical Signal Processing **240**
M. Phothisonothai and M. Nakagawa

The Automatic Sleep Stage Diagnosis Method by using SOM **245**
Takamasa Shimada, Kazuhiro Tamura, Tadanori Fukami, Yoichi Saito

A Development of the EEG Telemetry System under Exercising **249**
Noriyuki Dobashi, Kazushige Magatani

Evaluation of Photic Stimulus Response Based on Comparison with the Normal Database in EEG Routine Examination **253**
T. Fukami, F. Ishikawa, T. Shimada, B. Ishikawa and Y. Saito

A Speech Processor for Cochlear Implant using a Simple Dual Path Nonlinear Model of Basilar Membrane **257**
K.H. Kim, S.J. Choi, J.H. Kim

Mechanical and Biological Characterization of Pressureless Sintered Hydroxapatite-Polyetheretherketone Biocomposite **261**
Chang Hengky, Bastari Kelsen, Saraswati, Philip Cheang

Computerized Cephalometric Line Tracing Technique on X-ray Images **265**
C. Sinthanayothin

Brain Activation in Response to Disgustful Face Images with Different Backgrounds **270**
Takamasa Shimada, Hideto Ono, Tadanori Fukami, Yoichi Saito

Automatic Segmentation of Blood Vessels in Colour Retinal Images using Spatial Gabor Filter and Multiscale Analysis **274**
P.C. Siddalingaswamy, K. Gopalakrishna Prabhu

Automated Detection of Optic Disc and Exudates in Retinal Images **277**
P.C. Siddalingaswamy, K. Gopalakrishna Prabhu

Qualitative Studies on the Development of Ultraviolet Sterilization System for Biological Applications **280**
Then Tze Kang, S. Ravichandran, Siti Faradina Bte Isa, Nina Karmiza Bte Kamarozaman, Senthil Kumar

From e-health to Personalised Medicine **284**
N. Pangher

Quantitative Biological Models as Dynamic, User-Generated Online Content **287**
J.R. Lawson, C.M. Lloyd, T. Yu and P.F. Nielsen

Development of Soft Tissue Stiffness Measuring Device for Minimally Invasive Surgery by using Sensing Cum Actuating Method **291**
M.-S. Ju, H.-M. Vong, C.-C.K. Lin and S.-F. Ling

A Novel Method to Describe and Share Complex Mathematical Models of Cellular Physiology **296**
D.P. Nickerson and M.L. Buist

New Paradigm in Journal Reference Management **299**
Casey K. Chan, Yean C. Lee and Victor Lin

Incremental Learning Method for Biological Signal Identification **302**
Tadahiro Oyama, Stephen Karungaru, Satoru Tsuge, Yasue Mitsukura and Minoru Fukumi

Metal Artifact Removal on Dental CT Scanned Images by Using Multi-Layer Entropic Thresholding and Label Filtering Techniques for 3-D Visualization of CT Images **306**
K. Koonsanit, T. Chanwimaluang, D. Gansawat, S. Sotthivirat, W. Narkbuakaew, W. Areeprayolkij, P. Yampri and W. Sinthupinyo

A Vocoder for a Novel Cochlear Implant Stimulating Strategy Based on Virtual Channel Technology 310
Charles T.M. Choi, C.H. Hsu, W.Y. Tsai and Yi Hsuan Lee

Towards a 3D Real Time Renal Calculi Tracking for Extracorporeal Shock Wave Lithotripsy 314
I. Manousakas, J.J. Li

A Novel Multivariate Analysis Method for Bio-Signal Processing 318
H.H. Lin, S.H. Change, Y.J. Chiou, J.H. Lin, T.C. Hsiao

Multi-Wavelength Diffuse Reflectance Plots for Mapping Various Chromophores in Human Skin for Non-Invasive Diagnosis 323
Shanthi Prince and S. Malarvizhi

Diagnosis of Diabetic Retinopathy through Slit Lamp Images 327
J. David, A. Sukesh Kumar and V.V. Vineeth

Tracing of Central Serous Retinopathy from Retinal Fundus Images 331
J. David, A. Sukesh Kumar and V. Viji

A Confidence Measure for Real-time Eye Movement Detection in Video-oculography 335
S.M.H. Jansen, H. Kingma and R.L.M. Peeters

Development of Active Guide-wire for Cardiac Catheterization by Using Ionic Polymer-Metal Composites 340
B.K. Fang, M.S. Ju and C.C.K. Lin

Design and Development of an Interactive Proteomic Website 344
K. Xin Hui, C. Zheng Wei, Sze Siu Kwan and R. Raja

A New Interaction Modality for the Visualization of 3D Models of Human Organ 348
L.T. De Paolis, M. Pulimeno and G. Aloisio

Performance Analysis of Support Vector Machine (SVM) for Optimization of Fuzzy Based Epilepsy Risk Level Classifications from EEG Signal Parameters 351
R. Harikumar, A. Keerthi Vasan, M. Logesh Kumar

A Feasibility Study for the Cancer Therapy Using Cold Plasma 355
D. Kim, B. Gweon, D.B. Kim, W. Choe and J.H. Shin

Equation Chapter 1 Section 1Space State Approach to Study the Effect of Sodium over Cytosolic Calcium Profile 358
Shivendra Tewari and K.R. Pardasani

Preliminary Study of Mapping Brain ATP and Brain pH Using Multivoxel ^{31}P MR Spectroscopy 362
Ren-Hua Wu, Wei-Wen Liu, Yao-Wen Chen, Hui Wang, Zhi-Wei Shen, Karel terBrugge, David J. Mikulis

Brain-Computer Interfaces for Virtual Environment Control 366
G. Edlinger, G. Krausz, C. Groenegress, C. Holzner, C. Guger, M. Slater

FPGA Implementation of Fuzzy (PD&PID) Controller for Insulin Pumps in Diabetes 370
V.K. Sudhaman, R. HariKumar

Position Reconstruction of Awake Rodents by Evaluating Neural Spike Information from Place Cells in the Hippocampus 374
G. Edlinger, G. Krausz, S. Schaffelhofer, C. Guger, J. Brotons-Mas, M. Sanchez-Vives

Heart Rate Variability Response to Stressful Event in Healthy Subjects 378
Chih-Yuan Chuang, Wei-Ru Han and Shuenn-Tsong Young

Automatic Quantitative Analysis of Myocardial Perfusion MRI 381
C. Li and Y. Sun

Visualization of Articular Cartilage Using Magnetic Resonance Imaging Data 386
C.L. Poh and K. Sheah

A Chaotic Detection Method for Steady-State Visual Evoked Potentials **390**
X.Q. Li and Z.D. Deng

Speckle Reduction of Echocardiograms via Wavelet Shrinkage of Ultrasonic RF Signals **395**
K. Nakayama, W. Ohyama, T. Wakabayashi, F. Kimura, S. Tsuruoka and K. Sekioka

Advanced Pre-Surgery Planning by Animated Biomodels in Virtual Reality **399**
T. Mallepree, D. Bergers

Computerized Handwriting Analysis in Children with/without Motor Incoordination **402**
S.H. Chang and N.Y. Yu

The Development of Computer-assisted Assessment in Chinese Handwriting Performance **406**
N.Y. Yu and S.H. Chang

Novel Tools for Quantification of Brain Responses to Music Stimuli **411**
O. Sourina, V.V. Kulish and A. Sourin

An Autocorrection Algorithm for Detection of Misaligned Fingerprints **415**
Sai Krishna Alahari, Abhiram Pothuganti, Eshwar Chandra Vidya Sagar, Venkata Ravi kumar Garnepudi and Ram Prakash Mahidhara

A Low Power Wireless Downlink Transceiver for Implantable Glucose Sensing Biosystems **418**
D.W.Y. Chung, A.C.B. Albason, A.S.L. Lou and A.A.S. Hu

Advances in Automatic Sleep Analysis **422**
B. Ahmed and R. Tafreshi

Early Cancer Diagnosis by Image Processing Sensors Measuring the Conductive or Radiative Heat **427**
G. Gavriloaia, A.M. Ghemigian and A.E. Hurduc

Analysis of Saccadic Eye Movements of Epileptic Patients using Indigenously Designed and Developed Saccadic Diagnostic System **431**
M. Vidapanakanti, Dr. S. Kakarla, S. Katukojwalaand Dr. M.U.R. Naidu

System Design of Ultrasonic Image-guided Focused Ultrasound for Blood Brain Barrier disruption **435**
W.C. Huang, X.Y. Wu, H.L. Liu

A Precise Deconvolution Procedure for Deriving a Fluorescence Decay Waveform of a Biomedical Sample **439**
H. Shibata, M. Ohyanagi and T. Iwata

Laser Speckle Contrast Analysis Using Adaptive Window **444**
H.-Y. Jin, N.V. Thakor, H.-C. Shin

Neural Decoding of Single and Multi-finger Movements Based on ML **448**
H.-C. Shin, M. Schieber and N. Thakor

Maximum Likelihood Method for Finger Motion Recognition from sEMG Signals **452**
Kyoung-Jin Yu, Kab-Mun Cha and Hyun-Chool Shin

Cardiorespiratory Coordination in Rats is Influenced by Autonomic Blockade **456**
M.M. Kabir, M.I. Beig, E. Nalivaiko, D. Abbott and M. Baumert

Influence of White Matter Anisotropy on the Effects of Transcranial Direct Current Stimulation: A Finite Element Study **460**
W.H. Lee, H.S. Seo, S.H. Kim, M.H. Cho, S.Y. Lee and T.-S. Kim

Real-time Detection of Nimodipine Effect on Ischemia Model **465**
G.J. Lee, S.K. Choi, Y.H. Eo, J.E. Lim, J.H. Park, J.H. Han, B.S. Oh and H.K. Park

Windowed Nonlinear Energy Operator-based First-arrival Pulse Detection for Ultrasound Transmission Computed Tomography **468**
S.H. Kim, C.H. Kim, E. Savastyuk, T. Kochiev, H.-S. Kim and T.-S. Kim

Digital Dental Model Analysis **472**
Wisarut Bholsithi, Chanjira Sinthanayothin

Cervical Cell Classification using Fourier Transform **476**
Thanatip Chankong, Nipon Theera-Umpon, Sansanee Auephanwiriyakul

An Oscillometry-Based Approach for Measuring Blood Flow of Brachial Arteries **481**
S.-H. Liu, J.-J. Wang and K.-S. Huang

Fuzzy C-Means Clustering for Myocardial Ischemia Identification with Pulse Waveform Analysis **485**
Shing-Hong Liu, Kang-Ming Chang and Chu-Chang Tyan

Study of the Effect of Short-Time Cold Stress on Heart Rate Variability **490**
J.-J. Wang and C.-C. Chen

A Reflection-Type Pulse Oximeter Using Four Wavelengths Equipped with a Gain-Enhanced Gated-Avalanche-Photodiode **493**
T. Miyata, T. Iwata and T. Araki

Estimation of Central Aortic Blood Pressure using a Noninvasive Automatic Blood Pressure Monitor **497**
Yuan-Ta Shih, Yi-Jung Sun, Chen-Huan Chen, Hao-min Cheng and Hu Wei-Chih

Design of a PDA-based Asthma Peak Flow Monitor System **501**
C.-M. Wu and C.-W. Su

Development of the Tongue Diagnosis System by Using Surface Coating Mirror **505**
Y.J. Jeon, K.H. Kim, H.H. Ryu, J. Lee, S.W. Lee and J.Y. Kim

Design a Moving Artifacts Detection System for a Radial Pulse Wave Analyzer **508**
J. Lee, Y.J. Woo, Y.J. Jeon, Y.J. Lee and J.Y. Kim

A Real-time Interactive Editor for 3D Image Registration **511**
T. McPhail and J. Warren

A Novel Headset with a Transmissive PPG Sensor for Heart Rate Measurement **519**
Kunsoo Shin, Younho Kim, Sanggon Bae, Kunkook Park, Sookwan Kim

Improvement on Signal Strength Detection of Radio Imaging Method for Biomedical Application **523**
I. Hieda and K.C. Nam

Feature Extraction Methods for Tongue Diagnostic System **527**
K.H. Kim, J.-H. Do, Y.J. Jeon, J.-Y. Kim

Mechanical-Scanned Low-Frequency (28-kHz) Ultrasound to Induce localized Blood-Brain Barrier Disruption **532**
C.Y. Ting, C.H. Pan and H.L. Liu

Feasibility Study of Using Ultrasound Stimulation to Enhancing Blood-Brain Barrier Disruption in a Brain Tumor Model **536**
C.H. Pan, C.Y. Ting, C.Y. Huang, P.Y. Chen, K.C. Wei, and H.L. Liu

On Calculating the Time-Varying Elastance Curve of a Radial Artery Using a Miniature Vibration Method **540**
S. Chang, J.-J. Wang, H.-M. Su, C.-P. Liu

A Wide Current Range Readout Circuit with Potentiostat for Amperometric Chemical Sensors **543**
W.Y. Chung, S.C. Cheng, C.C. Chuang, F.R.G. Cruz

Multiple Low-Pressure Sonications to Improve Safety of Focused-Ultrasound Induced Blood-Brain Barrier Disruption: In a 1.5-MHz Transducer Setup **547**
P.H. Hsu, J.J. Wang, K.J. Lin, J.C. Chen and H.L. Liu

Phase Synchronization Index of Vestibular System Activity in Schizophrenia **551**
S. Haghgooie, B.J. Lithgow, C. Gurvich, and J. Kulkarni

Constrained Spatiotemporal ICA and Its Application for fMRI Data Analysis **555**
Tahir Rasheed, Young-Koo Lee, and Tae-Seong Kim

ARGALI : An Automatic Cup-to-Disc Ratio Measurement System for Glaucoma Analysis Using Level-set Image Processing **559**
J. Liu, D.W.K. Wong, J.H. Lim, H. Li, N.M. Tan, Z. Zhang, T.Y. Wong, R. Lavanya

Validation of an In Vivo Model for Monitoring Trabecular Bone Quality Changes Using Micro CT, Archimedes-based Volume Fraction Measurement and Serial Milling **563**
B.H. Kam, M.J. Voor, S. Yang, R. Burden, Jr. and S. Waddell

A Force Sensor System for Evaluation of Behavioural Recovery after Spinal Cord Injury in Rats **566**
Y.C. Wei, M.W. Chang, S.Y. Hou, M.S. Young

Flow Imaging and Validation of MR Fluid Motion Tracking **569**
K.K.L. Wong, R.M. Kelso, S.G. Worthley, P. Sanders, J. Mazumdar and D. Abbott

High Frequency Electromagnetic Thermotherapy for Cancer Treatment **574**
Sheng-Chieh Huang, Chih-Hao Huang, Xi-Zhang Lin, Gwo-Bin Lee

Real-Time Electrocardiogram Waveform Classification Using Self-Organization Neural Network **578**
C.C. Chiu, C.L. Hsu, B.Y. Liau and C.Y. Lan

The Design of Oximeter in Sleep Monitoring **582**
C.H. Lu, J.H. Lin, S.T. Tang, Z.X. You and C.C. Tai

Integration of Image Processing from the Insight Toolkit (ITK) and the Visualization Toolkit (VTK) in Java Language for Medical Imaging Applications **586**
D. Gansawat, W. Jirattiticharoen, S. Sotthivirat, K. Koonsanit, W. Narkbuakaew, P. Yampri and W. Sinthupinyo

ECG Feature Extraction by Multi Resolution Wavelet Analysis based Selective Coefficient Method **590**
Saurabh Pal and Madhuchhanda Mitra

Microarray Image Denoising using Spatial Filtering and Wavelet Transformation **594**
A. Mastrogianni, E. Dermatas and A. Bezerianos

Investigation of a Classification about Time Series Signal Using SOM **598**
Y. Nitta, M. Akutagawa, T. Emoto, T. Okahisa, H. Miyamoto, Y. Ohnishi, M. Nishimura, S. Nakane, R. Kaji, Y. Kinouchi

PCG Spectral Pattern Classification: Approach to Cardiac Energy Signature Identification **602**
Abbas K. Abbas, Rasha Bassam

Characteristic of AEP and SEP for Localization of Evoked Potential by Recalling **606**
K. Mukai, Y. Kaji, F. Shichijou, M. Akutagawa, Y. Kinouchi and H. Nagashino

Automatic Detection of Left and Right Eye in Retinal Fundus Images **610**
N.M. Tan, J. Liu, D.W.K. Wong, J.H. Lim, H. Li, S.B. Patil, W. Yu, T.Y. Wong

Visualizing Occlusal Contact Points Using Laser Surface Dental Scans **615**
L.T. Hiew, S.H. Ong and K.W.C. Foong

Modeling Deep Brain Stimulation **619**
Charles T.M. Choi and Yen-Ting Lee

Implementation of Trajectory Analysis System for Metabolic Syndrome Detection **622**
Hsien-Tsai Wu, Di-Song Yzng, Huo-Ying Chang, An-Bang Liu, Hui-Ming Chung, Ming-Chien Liu and Lee-Kang Wong

Diagnosis of Hearing Disorders and Screening using Artificial Neural Networks based on Distortion Product Otoacoustic Emissions **626**
V.P. Jyothiraj and A. Sukesh Kumar

Detection of Significant Biclusters in Gene Expression Data using Reactive Greedy Randomized Adaptive Search Algorithm 631
Smitha Dharan and Achuthsankar S. Nair

Development of Noninvasive Thrombus Detection System with Near-Infrared Laser and Photomultiplier for Artificial Hearts 635
S. Tsujimura, H. Koguchi, T. Yamane, T. Tsutsui and Y. Sankai

Using Saliency Features for Graphcut Segmentation of Perfusion Kidney Images 639
Dwarikanath Mahapatra and Ying Sun

Low Power Electrocardiogram QRS Detection in Real-Time 643
E. Zoghlami Ayari, R. Tielert and N. Wehn

Analytical Decision Making from Clinical Data- Diagnosis and Classification of Epilepsy Risk Levels from EEG Signals-A Case Study 647
V.K. Sudhaman, Dr. (Mrs.) R. Sukanesh, R. HariKumar

Magnetic field transducers based on the phase characteristics of GMI sensors and aimed at biomedical applications 652
E. Costa Silva, L.A.P. Gusmão, C.R. Hall Barbosa, E. Costa Monteiro

Effects of Task Difficulty and Training of Visuospatial Working Memory Task on Brain Activity 657
Takayasu Ando, Keiko Momose, Keita Tanaka, Keiichi Saito

Retrieval of MR Kidney Images by Incorporating Shape Information in Histogram of Low Level Features 661
D. Mahapatra, S. Roy and Y. Sun

Performance Comparison of Bone Segmentation on Dental CT Images 665
P. Yampri, S. Sotthivirat, D. Gansawat, K. Koonsanit, W. Narkbuakaew, W. Areeprayolkij, W. Sinthupinyo

Multi Scale Assessment of Bone Architecture and Quality from CT Images 669
T. Kalpalatha Reddy, Dr. N. Kumaravel

An Evolutionary Heuristic Approach for Functional Modules Identification from Composite Biological Data 673
I.A. Maraziotis, A. Dragomir and A. Bezerianos

An Empirical Approach for Objective Pain Measurement using Dermal and Cardiac Parameters 678
Shankar K., Dr. Subbiah Bharathi V., Jackson Daniel

A Diagnosis Support System for Finger Tapping Movements Using Magnetic Sensors and Probabilistic Neural Networks 682
K. Shima, T. Tsuji, A. Kandori, M. Yokoe and S. Sakoda

Increasing User Functionality of an Auditory P3 Brain-Computer Interface for Functional Electrical Stimulation Application 687
A.S.J Bentley, C.M. Andrew and L.R. John

An Electroencephalogram Signal based Triggering Circuit for controlling Hand Grasp in Neuroprosthetics 691
G. Karthikeyan, Debdoot Sheet and M. Manjunatha

A Novel Channel Selection Method Based on Partial KL Information Measure for EMG-based Motion Classification 694
T. Shibanoki, K. Shima, T. Tsuji, A. Otsuka and T. Chin

A Mobile Phone for People Suffering From The Locked In Syndrome 699
D. Thiagarajan, Anupama.V. Iyengar

Generating Different Views of Clinical Guidelines Using Ontology Based Semantic Annotation 701
Rajendra Singh Sisodia, Puranjoy Bhattacharya and V. Pallavi

A High-Voltage Discharging System for Extracorporeal Shock-Wave Therapy **706**
I. Manousakas, S.M. Liang, L.R. Wan

Development of the Robot Arm Control System Using Forearm SEMG **710**
Yusuke Wakita, Noboru Takizawa, Kentaro Nagataand Kazushige Magatani

Tissue Classification from Brain Perfusion MR Images Using Expectation-Maximization Algorithm Initialized by Hierarchical Clustering on Whitened Data **714**
Y.T. Wu, Y.C. Chou, C.F. Lu, S.R. Huang and W.Y. Guo

Enhancement of Signal-to-noise Ratio of Peroneal Nerve Somatosensory Evoked Potential Using Independent Component Analysis and Time-Frequency Template **718**
C.I. Hung, Y.R. Yang, R.Y. Wang, W.L. Chou, J.C. Hsieh and Y.T. Wu

Multi-tissue Classification of Diffusion-Weighted Brain Images in Multiple System Atrophy Using Expectation Maximization Algorithm Initialized by Hierarchical Clustering **722**
C.F. Lu, P.S. Wang, B.W. Soong, Y.C. Chou, H.C. Li, Y.T. Wu

Small-world Network for Investigating Functional Connectivity in Bipolar Disorder: A Functional Magnetic Images (fMRI) Study **726**
S. Teng, P.S. Wang, Y.L. Liao, T.-C. Yeh, T.-P. Su, J.C. Hsieh, Y.T. Wu

Fractal Dimension Analysis for Quantifying Brain Atrophy of Multiple System Atrophy of the Cerebellar Type (MSA-C) **730**
Z.Y. Wang, B.W. Soong, P.S. Wang, C.W. Jao, K.K. Shyu, Y.T. Wu

A Novel Method in Detecting CCA Lumen Diameter and IMT in Dynamic B-mode Sonography **734**
D.C. Cheng, Q. Pu, A. Schmidt-Trucksaess, C.H. Liu

Acoustic Imaging of Heart Using Microphone Arrays **738**
H. Kajbaf and H. Ghassemian

Statistical Variations of Ultrasound Backscattering From the Blood under Steady Flow **742**
Chih-Chung Huang, Yi-Hsun Lin, and Shyh-Hau Wang

Employing Microbubbles and High-Frequency Time-Resolved Scanning Acoustic Microscopy for Molecular Imaging **746**
P. Anastasiadis, A.L. Klibanov, C. Layman, W. Bost, P.V. Zinin, R.M. Lemor and J.S. Allen

Application of Fluorescently Labeled Lectins for the Visualization of Biofilms of Pseudomonas Aeruginosa by High-Frequency Time-Resolved Scanning Acoustic Microscopy **750**
P. Anastasiadis, K. Mojica, C. Layman, M.L. Matter, J. Henneman, C. Barnes and J.S. Allen

A Comparative Study for Disease Identification from Heart Auscultation using FFT, Cepstrum and DCT Correlation Coefficients **754**
Swanirbhar Majumder, Saurabh Pal and Pranab Kishore Dutta

Multi Resolution Analysis of Pediatric ECG Signal **758**
Srinivas Kachibhotla, Shamla Mathur

3D CT Craniometric Study of Thai Skulls Revelance to Sex Determination Using ogistic Regression Analysis **761**
S. Rooppakhun, S. Piyasin and K. Sitthiseripratip

Analysis of Quantified Indices of EMG for Evaluation of Parkinson's Disease **765**
B. Sepehri, A. Esteki, G.A. Shahidi and M. Moinodin

A Test for the Assessment of Reaction Time for Narcotic Rehabilitation Patients **769**
S.G. Patil, T.J. Gale and C.R. Clive

Track 2:
Biosensors, Biochips & BioMEMs; Nanobiotechnology

Microdevice for Trapping Circulating Tumor Cells for Cancer Diagnostics **774**
S.J. Tan, L. Yobas, G.Y.H Lee, C.N. Ong and C.T. Lim

In-situ Optical Oxygen Sensing for Bio-artificial Liver Bioreactors **778**
V. Nock, R.J. Blaikie and T. David

Quantitative and Indirect Qualitative Analysis Approach for Nanodiamond Using SEM Images and Raman Response **782**
Niranjana S., B.S. Satyanarayana, U.C. Niranjan and Shounak De

Non-invasive Acquisition of Blood Pulse Using Magnetic Disturbance Technique **786**
Chee Teck Phua, Gaëlle Lissorgues, Bruno Mercier

Microfabrication of high-density microelectrode arrays for in vitro applications **790**
Lionel Rousseau, Gaëlle Lissorgues, Fabrice Verjus, Blaise Yvert

A MEMS-based Impedance Pump Based on a Magnetic Diaphragm **794**
C.Y. Lee, Z.H. Chen, C.Y. Wen, L.M. Fu, H.T. Chang, R.H. Ma

Sample Concentration and Auto-location With Radiate Microstructure Chip for Peptide Analysis by MALDI-MS **799**
Shun-Yuan Chen, Chih-Sheng Yu, Jun-Sheng Wang, Chih-Cheng Huang, Yi-Chiuen Hu

The Synthesis of Iron Oxide Nanoparticles via Seed-Mediated Process and its Cytotoxicity Studies **802**
J.-H. Huang, H.J. Parab, R.S. Liu, T.-C. Lai, M. Hsiao, C.H. Chen, D.-P. Tsai and Y.-K. Hwu

Characterization of Functional Nanomaterials in Cosmetics and its Cytotoxic Effects **806**
J.-H. Huang, H.J. Parab, R.S. Liu, T.-C. Lai, M. Hsiao, C.H. Chen and Y.K. Hwu

Design and Analysis of MEMS based Cantilever Sensor for the Detection of Cardiac Markers in Acute Myocardial Infarction **810**
Sree Vidhya& Lazar Mathew

Integrating Micro Array Probes with Amplifier on Flexible Substrate **813**
J.M. Lin, P.W.Lin and L.C. Pan

Investigating Combinatorial Drug Effects on Adhesion and Suspension Cell Types Using a Microfluidic-Based Sensor System **817**
S. Arora, C.S. Lim, M. Kakran, J.Y.A. Foo, M.K. Sakharkar, P. Dixit, and J. Miao

Organic Phase Coating of Polymers onto Agarose Microcapsules for Encapsulation of Biomolecules with High Efficiency **821**
J. Bai, W.C. Mak, X.Y. Chang and D. Trau

LED Based Sensor System for Non-Invasive Measurement of the Hemoglobin Concentration in Human Blood **825**
U. Timm, E. Lewis, D. McGrath, J. Kraitl and H. Ewald

Amperometric Hydrogen Peroxide Sensors with Multivalent Metal Oxide-Modified Electrodes for Biomedical Analysis **829**
Tesfaye Waryo, Petr Kotzian, Sabina Begić, Petra Bradizlova, Negussie Beyene, Priscilla Baker, Boitumelo Kgarebe, Emir Turkušić, Emmanuel Iwuoha, Karel Vytřas and Kurt Kalcher

Patch-Clamping in Droplet Arrays: Single Cell Positioning via Dielectrophoresis **834**
J. Reboud, M.Q. Luong, C. Rosales and L. Yobas

Label-free Detection of Proteins with Surface-functionalized Silicon Nanowires **838**
R.E. Chee, J.H. Chua, A. Agarwal, S.M. Wong, G.J. Zhang

Bead-based DNA Microarray Fabricated on Porous Polymer Films **842**
J.T. Cheng, J. Li, N.G. Chen, P. Gopalakrishnakone and Y. Zhang

Monolithic CMOS Current-Mode Instrumentation Amplifiers for ECG Signals **846**
S.P. Almazan, L.I. Alunan, F.R. Gomez, J.M. Jarillas, M.T. Gusad and M. Rosales

Cells Separation by Traveling Wave Dielectrophoretic Microfluidic Devices **851**
T. Maturos, K. Jaruwongrangsee, A. Sappat, T. Lomas, A. Wisitsora-at, P. Wanichapichart and A. Tuantranont

A Novel pH Sensor Based on the Swelling of A Hydrogel Membrane **855**
K.F. Chou, Y.C. Lin, H.Y. Chen, S.Y. Huang and Z.Y. Lin

Simulation and Experimental Study of Electrowetting on Dielectric (EWOD) Device for a Droplet Based Polymerase Chain Reaction System **859**
K. Ugsornrat, T. Maturus, A. Jomphoak, T. Pogfai, N.V. Afzulpurkar, A. Wisitsoraat, A. Tuantranont

A Label-Free Impedimetric Immunosensor Based On Humidity Sensing Properties of Barium Strontium Titanate **863**
M. Rasouli, O.K. Tan, L.L. Sun, B.W. Mao and L.H. Gan

Physical Way to Enhance the Quantum Yield and Analyze the Photostability of Fluorescent Gold Clusters **867**
D.F. Juan, C.A.J. Lin, T.Y. Yang, C.J. Ke, S.T. Lin, J.Y. Chen and W.H. Chang

Biocompatibility Study of Gold Nanoparticles to Human Cells **870**
J.H. Fan, W.I. Hung, W.T. Li, J.M. Yeh

Gold Nanorods Modified with Chitosan As Photothermal Agents **874**
Chia-Wei Chang, Chung-Hao Wang and Ching-An Peng

QDs Capped with Enterovirus As Imaging Probes for Drug Screening **878**
Chung-Hao Wang, Ching-An Peng

Elucidation of Driving Force of Neutrophile in Liquid by Cytokine Concentration Gradient **882**
M. Tamagawa and K. Matsumura

Development of a Biochip Using Antibody-covered Gold Nano-particles to Detect Antibiotics Resistance of Specific Bacteria **884**
Jung-Tang Huang, Meng-Ting Chang, Guo-Chen Wang, Hua-Wei Yu and Jeen Lin

Photothermal Ablation of Stem-Cell Like Glioblastoma Using Carbon Nanotubes Functionalized with Anti-CD133 ..... **888**
Chung-Hao Wang, Yao-Jhang Huang and Ching-An Peng

A Design of Smart Dust to Study the Hippocampus **892**
Anupama V. Iyengar, D. Thiagarajan

Determination of Affinity Constant from Microfluidic Binding Assay **894**
D. Tan, P. Roy

Nucleic Acid Sample Preparation from Dengue Virus Using a Chip-Based RNA Extractor in a Self-Contained Microsystem **898**
L. Zhang, Siti R.M. Rafei, L. Xie, Michelle B.-R. Chew, C.S. Premchandra, H.M. Ji, Y. Chen, L. Yobas, R. Rajoo, K.L. Ong, Rosemary Tan, Kelly S.H. Lau, Vincent T.K. Chow, C.K. Heng and K.-H. Teo

In-Vitro Transportation of Drug Molecule by Actin Myosin Motor System **902**
Harsimran Kaur, Suresh Kumar, Inderpreet Kaur, Kashmir Singh and Lalit M. Bharadwaj

Track 3:
Clinical Engineering; Telemedicine & Healthcare; Computer-Assisted Surgery; Medical Robotics; Rehabilitation Engineering & Assistive Technology

Tumour Knee Replacement Planning in a 3D Graphics System **906**
K. Subburaj, B. Ravi and M.G. Agarwal

Color Medical Image Vector Quantization Coding Using K-Means: Retinal Image **911**
Agung W. Setiawan, Andriyan B. Suksmono and Tati R. Mengko

Development of the ECG Detector by Easy Contact for Helping Efficient Rescue Operation **915**
Takahiro Asaoka and Kazushige Magatani

A Navigation System for the Visually Impaired Using Colored Guide Line and RFID Tags **919**
Tatsuya Seto, Yuriko Shiidu, Kenji Yanashima and Kazushige Magatani

A Development of the Equipment Control System Using SEMG **923**
Noboru Takizawa, Yusuke Wakita, Kentaro Nagata, Kazushige Magatani

The Analysis of a Simultaneous Measured Forearm's EMG and f-MRI **927**
Tsubasa Sasaki, Kentaro Nagata, Masato Maeno and Kazushige Magatani

Development of A Device to Detect SPO_2 which is Installed on a Rescue Robot **931**
Yoshiaki Kanaeda, Takahiro Asaoka and Kazushige Magatani

A Estimation Method for Muscular Strength During Recognition of Hand Motion **935**
Takemi Nakano, Kentaro Nagata, Masahumi Yamada and Kazusige Magatani

The Navigation System for the Visually Impaired Using GPS **938**
Tomoyuki Kanno, Kenji Yanashima and Kazushige Magatani

Investigation of Similarities among Human Joints through the Coding System of Human Joint Properties—Part 1 ..... **942**
S.C. Chen, S.T. Hsu, C.L. Liu and C.H. Yu

Investigation of Similarities among Human Joints through the Coding System of Human Joint Properties—Part 2 ..... **946**
S.C. Chen, S.T. Hsu, C.L. Liu and C.H. Yu

Circadian Rhythm Monitoring in HomeCare Systems **950**
M. Cerny, M. Penhaker

Effects of Muscle Vibration on Independent Finger Movements **954**
B.-S. Yang and S.-J. Chen

Modelling Orthodontal Braces for Non-invasive Delivery of Anaesthetics in Dentistry **957**
S. Ravichandran

Assessment of the Peripheral Performance and Cortical Effects of SHADE, an Active Device Promoting Ankle Dorsiflexion **961**
S. Pittaccio, S. Viscuso, F. Tecchio, F. Zappasodi, M. Rossini, L. Magoni, S. Pirovano, S. Besseghini and F. Molteni

A Behavior Mining Method by Visual Features and Activity Sequences in Institution-based Care **966**
J.H. Huang, C.C. Hsia and C.C. Chuang

Chronic Disease Recurrence Prediction Model for Diabetes Mellitus Patients' Long-Term Caring **970**
Chia-Ming Tung, Yu-Hsien Chiu, Chi-Chun Shia

The Study of Correlation between Foot-pressure Distribution and Scoliosis **974**
J.H. Park, S.C. Noh, H.S. Jang, W.J. Yu, M.K. Park and H.H. Choi

Sensitivity Analysis in Sensor HomeCare Implementation **979**
M. Penhaker, R. Bridzik, V. Novak, M. Cerny, M. Rosulek

Fall Detection Unit for Elderly **984**
Arun Kumar, Fazlur Rahman, Tracey Lee

Reduction of Body Sway Can Be Evaluated By Sparse Density during Exposure to Movies on Liquid Crystal Displays **987**
H. Takada, K. Fujikake, M. Omori, S. Hasegawa, T. Watanabe and M. Miyao

Effects of Phototherapy to Shangyingxiang Xue on Patients with Allergic Rhinitis **992**
K.-H. Hu, D.-N. Yan, W.-T. Li

The Study of Neural Correlates on Body Ownership Modulated By the Sense of Agency Using Virtual Reality **996**
W.H. Lee, J.H. Ku, H.R. Lee, K.W. Han, J.S. Park, J.J. Kim, I.Y. Kim and S.I. Kim

Diagnosis and Management of Diabetes Mellitus through a Knowledge-Based System **1000**
Morium Akter, Mohammad Shorif Uddin and Aminul Haque

Modeling and Mechanical Design of a MRI-Guided Robot for Neurosurgery **1004**
Z.D. Hong, C. Yun and L. Zhao

The Study for Multiple Security Mechanism in Healthcare Information System for Elders **1009**
C.Y. Huang and J.L. Su

Individual Movement Trajectories in Smart Homes **1014**
M. Chan, S. Bonhomme, D. Estève, E. Campo

MR Image Reconstruction for Positioning Verification with a Virtual Simulation System for Radiation Therapy **1019**
C.F. Jiang, C.H. Huang, T.S. Su

Experimental setup of hemilarynx model for microlaryngeal surgery applications **1024**
J.Q. Choo, D.P.C. Lau, C.K. Chui, T. Yang, S.H. Teoh

Virtual Total Knee Replacement System Based on VTK **1028**
Hui Ding, Tianzhu Liang, Guangzhi Wang, Wenbo Liu

Motor Learning of Normal Subjects Exercised with a Shoulder-Elbow Rehabilitation Robot **1032**
H.H. Lin, M.S. Ju, C.C.K. Lin, Y.N. Sun and S.M. Chen

Using Virtual Markers to Explore Kinematics of Articular Bearing Surfaces of Knee Joints **1037**
Guangzhi Wang, Zhonglin Zhu, Hui Ding, Xiao Dang, Jing Tang and Yixin Zhou

Simultaneous Recording of Physiological Parameters in Video-EEG Laboratory in Clinical and Research Settings **1042**
R. Bridzik, V. Novák, M. Penhaker

Preliminary Modeling for Intra-Body Communication **1044**
Y.M. Gao, S.H. Pun, P.U. Mak, M. Du and M.I. Vai

Application of the Home Telecare System in the Treatment of Diabetic Foot Syndrome **1049**
P. Ladyzynski, J.M. Wojcicki, P. Foltynski, G. Rosinski, J. Krzymien, B. Mrozikiewicz-Rakowska, K. Migalska-Musial and W. Karnafel

In-vitro Evaluation Method to Measure the Radial Force of Various Stents **1053**
Y. Okamoto, T. Tanaka, H. Kobashi, K. Iwasaki, M. Umezu

Motivating Children with Attention Deficiency Disorder Using Certain Behavior Modification Strategies **1057**
Huang Qunfang Jacklyn, S. Ravichandran

Development of a Walking Robot for Testing Ankle Foot Orthosis- Robot Validation Test **1061**
H.J. Lai, C.H. Yu, W.C. Chen, T.W. Chang, K.J. Lin, C.K. Cheng

Regeneration of Speech in Voice-Loss Patients **1065**
H.R. Sharifzadeh, I.V. McLoughlin and F. Ahmadi

Human Gait Analysis using Wearable Sensors of Acceleration and Angular Velocity **1069**
R. Takeda, S. Tadano, M. Todoh and S. Yoshinari

Deformable Model for Serial Ultrasound Images Segmentation: Application to Computer Assisted Hip Athroplasty **1073**
A. Alfiansyah, K.H. Ng and R. Lamsudin

Bone Segmentation Based On Local Structure Descriptor Driven Active Contour **1077**
A. Alfiansyah, K.H. Ng and R. Lamsudin

An Acoustically-Analytic Approach to Behavioral Patterns for Monitoring Living Activities **1082**
Kuang-Che Liu, Gwo-Lang Yan, Yu-Hsien Chiu, Ming-Shih Tsai, Kao-Chi Chung

Implementation of Smart Medical Home Gateway System for Chronic Patients **1086**
Chun Yu, Jhih-Jyun Yang, Tzu-Chien Hsiao, Pei-Ling Liu, Kai-Ping Yao, Chii-Wann Lin

A Comparative Study of Fuzzy PID Control Algorithm for Position Control Performance Enhancement in a Real-time OS Based Laparoscopic Surgery Robot **1090**
S.J. Song, J.W. Park, J.W. Shin, D.H. Lee, J. Choi and K. Sun

Investigation of the Effect of Acoustic Pressure and Sonication Duration on Focused-Ultrasound Induced Blood-Brain Barrier Disruption **1094**
P.C. Chu, M.C. Hsiao, Y.H. Yang, J.C. Chen, H.L. Liu

Design and Implementation of Web-Based Healthcare Management System for Home Healthcare **1098**
S. Tsujimura, N. Shiraishi, A. Saito, H. Koba, S. Oshima, T. Sato, F. Ichihashi and Y. Sankai

Quantitative Assessment of Left Ventricular Myocardial Motion Using Shape–Constraint Elastic Link Model **1102**
Y. Maeda, W. Ohyama, H. Kawanaka, S. Tsuruoka, T. Shinogi, T. Wakabayashi and K. Sekioka

Assessment of Foot Drop Surgery in Leprosy Subjects Using Frequency Domain Analysis of Foot Pressure Distribution Images **1107**
Bhavesh Parmar

The Development of New Function for ICU/CCU Remote Patient Monitoring System Using a 3G Mobile Phone and Evaluations of the System **1112**
Akinobu Kumabe, Pu Zhang, Yuichi Kogure, Masatake Akutagawa, Yohsuke Kinouchi, Qinyu Zhang

Development of Heart Rate Monitoring for Mobile Telemedicine using Smartphone **1116**
Hun Shim, Jung Hoon Lee, Sung Oh Hwang, Hyung Ro Yoon, Young Ro Yoon

Cognitive Effect of Music for Joggers Using EEG **1120**
J. Srinivasan, K.M. Ashwin Kumar and V. Balasubramanian

System for Conformity Assessment of Electrocardiographs **1124**
M.C. Silva, L.A.P. Gusmão, C.R. Hall Barbosa and E. Costa Monteiro

The Development and Strength Reinforcement of Rapid Prototyping Prosthetic Socket Coated with a Resin Layer for Transtibial Amputee **1128**
C.T. Lu, L.H. Hsu, G.F. Huang, C.W. Lai, H.K. Peng, T.Y. Hong

A New Phototherapy Apparatus Designed for the Curing of Neonatal Jaundice **1132**
C.B. Tzeng, T.S. Wey, M.S. Young

Study to Promote the Treatment Efficiency for Neonatal Jaundice by Simulation **1136**
Alberto E. Chaves Barrantes, C.B. Tzeng and T.S. Wey

Low Back Pain Evaluation for Cyclist using sEMG: A Comparative Study between Bicyclist and Aerobic Cyclist **1140**
J. Srinivasan and V. Balasubramanian

3D Surface Modeling and Clipping of Large Volumetric Data Using Visualization Toolkit Library **1144**
W. Narkbuakaew, S. Sotthivirat, D. Gansawat, P. Yampri, K. Koonsanit, W. Areeprayolkij and W. Sinthupinyo

The Effects of Passive Warm-Up With Ultrasound in Exercise Performance and Muscle Damage **1149**
Fu-Shiu Hsieh, Yi-Pin Wang, T.-W. Lu, Ai-Ting Wang, Chien-Che Huang, Cheng-Che Hsieh

Capacitive Interfaces for Navigation of Electric Powered Wheelchairs **1153**
K. Kaneswaran and K. Arshak

Health Care and Medical Implanted Communications Service **1158**
K. Yekeh Yazdandoost and R. Kohno

MultiAgent System for a Medical Application over Web Technology: A Working Experience **1162**
A. Aguilera, E. Herrera and A. Subero

Collaborative Radiological Diagnosis over the Internet **1166**
A. Aguilera, M. Barmaksoz, M. Ordoñez and A. Subero

HandFlex **1171**
J. Selva Raj, Cyntalia Cipto, Ng Qian Ya, Leow Shi Jie, Isaac Lim Zi Ping and Muhamad Ryan b Mohamad Zah

Treatment Response Monitoring and Prognosis Establishment through an Intelligent Information System **1175**
C. Plaisanu, C. Stefan

A Surgical Training Simulator for Quantitative Assessment of the Anastomotic Technique of Coronary Artery Bypass Grafting **1179**
Y. Park, M. Shinke, N. Kanemitsu, T. Yagi, T. Azuma, Y. Shiraishi, R. Kormos and M. Umezu

Development of Evaluation Test Method for the Possibility of Central Venous Catheter Perforation Caused by the Insertion Angle of a Guidewire and a Dilator **1183**
M. Uematsu, M. Arita, K. Iwasaki, T. Tanaka, T. Ohta, M. Umezu and T. Tsuchiya

The Assessment Of Severely Disabled People To Verify Their Competence To Drive A Motor Vehicle With Evidence Based Protocols **1187**
Peter J. Roake

Track 4:
Artificial Organs; Biomaterials; Controlled Drug Delivery; Tissue Engineering & Regenerative Medicine

Viscoelastic Properties of Elastomers for Small Joint Replacements **1191**
A. Mahomed, D.W.L. Hukins, S.N. Kukureka and D.E.T. Shepherd

Synergic Combination of Collagen Matrix with Knitted Silk Scaffold Regenerated Ligament with More Native Microstructure in Rabbit Model **1195**
Xiao Chen, Zi Yin, Yi-Ying Qi, Lin-Lin Wang, Hong-Wei Ouyang

Preparation, Bioactivity and Antibacterial Effect of Bioactive Glass/Chitosan Biocomposites **1199**
Hanan H. Beherei, Khaled R. Mohamed, Amr I. Mahmoud

Biocompatibility of Metal Sintered Materials in Dependence on Multi-Material Graded Structure **1204**
M. Lodererova, J. Rybnicek, J. Steidl, J. Richter, K. Boivie, R. Karlsen, O. Åsebø

PHBV Microspheres as Tissue Engineering Scaffold for Neurons **1208**
W.H. Chen, B.L. Tang and Y.W. Tong

Fabrication of Three-Dimensional Tissues with Perfused Microchannels **1213**
Katsuhisa Sakaguchi, Tatsuya Shimizu, Kiyotaka Iwasaki, Masayuki Yamato, Mitsuo Umezu, Teruo Okano

The Effects of Pulse Inductively Coupled Plasma on the Properties of Gelatin **1217**
I. Prasertsung, S. Kanokpanont, R. Mongkolnavin and S. Damrongsakkul

Dosimetry of ^{32}P Radiocolloid for Radiotherapy of Brain Cyst **1220**
M. Sadeghi, E. Karimi

Overcoming Multidrug Resistance of Breast Cancer Cells by the Micellar Drug Carriers of mPEG-PCL-graft-cellulose **1224**
Yung-Tsung Chen, Chao-Hsuan Chen, Ming-Fa Hsieh, Ann Shireen Chan, Ian Liau, Wan-Yu Tai

Individual 3D Replacements of Skeletal Defects **1228**
R. Jirman, Z. Horak, J. Mazanek and J. Reznicek

Brain Gate as an Assistive and Solution Providing Technology for Disabled People **1232**
Prof. Shailaja Arjun Patil

Compressive Fatigue and Thermal Compressive Fatigue of Hybrid Resin Base Dental Composites **1236**
M. Javaheri, S.M. Seifi, J. Aghazadeh Mohandesi, F. Shafie

Development of Amphotericin B Loaded PLGA Nanoparticles for Effective Treatment of Visceral Leishmaniasis **1241**
M. Nahar, D. Mishra, V. Dubey, N.K. Jain

Swelling, Dissolution and Disintegration of HPMC in Aqueous Media **1244**
S.C. Joshi and B. Chen

A Comparative Study of Articular Chondrocytes Metabolism on a Biodegradable Polyesterurethane Scaffold and Alginate in Different Oxygen Tension and pH **1248**
S. Karbasi

Effect of Cryopreservation on the Biomechanical Properties of the Intervertebral Discs **1252**
S.K.L. Lam, S.C.W. Chan, V.Y.L. Leung, W.W. Lu, K.M.C. Cheung and K.D.K. Luk

A Serum Free Medium that Conserves The Chondrogenic Phenotype of In Vitro Expanded Chondrocytes **1255**
Saey Tuan Barnabas Ho, Zheng Yang, Hoi Po James Hui, Kah Weng Steve Oh, Boon Hwa Andre Choo and Eng Hin Lee

High Aspect Ratio Fatty Acid Functionalized Strontium Hydroxyapatite Nanorod and PMMA Bone Cement Filler **1258**
W.M. Lam, C.T. Wong, T. Wang, Z.Y. Li, H.B. Pan, W.K. Chan, C. Yang, K.D.K. Luk, M.K. Fong, W.W. Lu

The HIV Dynamics is a Single Input System **1263**
M.J. Mhawej, C.H. Moog and F. Biafore

Evaluation of Collagen-hydroxyapatite Scaffold for Bone Tissue Engineering **1267**
Sangeeta Dey, S. Pal

Effect of Sintering Temperature on Mechanical Properties and Microstructure of Sheep-bone Derived Hydroxyapatite (SHA) **1271**
U. Karacayli, O. Gunduz, S. Salman, L.S. Ozyegin, S. Agathopoulos, and F.N. Oktar

Flow Induced Turbulent Stress Accumulation in Differently Designed Contemporary Bi-leaflet Mitral valves: Dynamic PIV Study **1275**
T. Akutsu, and X.D. Cao

A Biofunctional Fibrous Scaffold for the Encapsulation of Human Mesenchymal Stem Cells and its Effects on Stem Cell Differentiation **1279**
S.Z. Yow, C.H. Quek, E.K.F. Yim, K.W. Leong, C.T. Lim

Potential And Properties Of Plant Proteins For Tissue Engineering Applications 1282
Narendra Reddy and Yiqi Yang

Comparison the Effects of BMP-4 and BMP-7 on Articular Cartilage Repair with Bone Marrow Mesenchymal Stem Cells 1285
Yang Zi Jiang, Yi Ying Qi, Xiao Hui Zou, Lin-Lin Wang, Hong-Wei Ouyang

Local Delivery of Autologous Platelet in Collagen Matrix Synergistically Stimulated In-situ Articular Cartilage Repair..... 1289
Yi Ying Qi, Hong Xin Cai, Xiao Chen, Lin Lin Wang,Yang Zi Jiang, Nguyen Thi Minh Hieu, Hong Wei Ouyang

Bioactive Coating on Newly Developed Composite Hip Prosthesis..... 1293
S. Bag & S. Pal

Development and Validation of a Reverse Phase Liquid Chromatographic Method for Quantitative Estimation of Telmisartan in Human Plasma..... 1297
V. Kabra, V. Agrahari, P. Trivedi

Response of Bone Marrow-derived Stem Cells (MSCs) on Gelatin/Chitosan and Gelatin/Chitooligosaccharide films..... 1301
J. Ratanavaraporn, S. Kanokpanont, Y. Tabata and S. Damrongsakkul

Manufacturing Porous BCP Body by Negative Polymer Replica as a Bone Tissue Engineering Scaffold..... 1305
R. Tolouei, A. Behnamghader, S.K. Sadrnezhaad, M. Daliri

Synthesis and Characterizations of Hydroxyapatite-Poly(ether ether ketone) Nanocomposite: Acellular Simulated Body Fluid Conditioned Study 1309
Sumit Pramanik and Kamal K. Kar

Microspheres of Poly (lactide-co-glycolide acid) (PLGA) for Agaricus Bisporus Lectin Drug Delivery..... 1313
Shuang Zhao, Hexiang Wang, Yen Wah Tong

Hard Tissue Formation by Bone Marrow Stem Cells in Sponge Scaffold with Dextran Coating..... 1316
M. Yoshikawa, Y. Shimomura, N. Tsuji, H. Hayashi, H. Ohgushi

Inactivation of Problematic Micro-organisms in Collagen Based Media by Pulsed Electric Field Treatment (PEF)..... 1320
S. Griffiths, S.J. MacGregor, J.G. Anderson, M. Maclean, J.D.S. Gaylor and M.H. Grant

Development, Optimization and Characterization of Nanoparticle Drug Delivery System of Cisplatin..... 1325
V. Agrahari, V. Kabra, P. Trivedi

Physics underling Topobiology: Space-time Structure underlying the Morphogenetic Process 1329
K. Naitoh

The Properties of Hexagonal ZnO Sensing Thin Film Grown by DC Sputtering on (100) Silicon Substrate..... 1333
Chih Chin Yang, Hung Yu Yang, Je Wei Lee and Shu Wei Chang

Multi-objective Optimization of Cancer Immuno-Chemotherapy..... 1337
K. Lakshmi Kiran, D. Jayachandran and S. Lakshminarayanan

Dip Coating Assisted Polylactic Acid Deposition on Steel Surface: Film Thickness Affected by Drag Force and Gravity..... 1341
P.L. Lin, T.L. Su, H.W. Fang, J.S. Chang, W.C. Chang

Some Properties of a Polymeric Surfactant Derived from Alginate 1344
R. Kukhetpitakwong, C. Hahnvajanawong, D. Preechagoon and W. Khunkitti

Nano-Patterned Poly-ε-caprolactone with Controlled Release of Retinoic Acid and Nerve Growth Factor for Neuronal Regeneration 1348
K.K. Teo, Evelyn K.F. Yim

Exposure of 3T3 mouse Fibroblasts and Collagen to High Intensity Blue Light **1352**
S. Smith, M. Maclean, S.J. MacGregor, J.G. Anderson and M.H. Grant

Preparation of sericin film with different polymers **1356**
Kamol Maikrang, M. Sc., Pornanong Aramwit, Pharm.D., Ph.D.

Fabrication and Bio-active Evolution of Mesoporous SiO_2-CaO-P_2O_5 Sol-gel Glasses **1359**
L.C. Chiu, P.S. Lu, I.L. Chang, L.F. Huang, C.J. Shih

The Influences of the Heat-Treated Temperature on Mesoporous Bioactive Gel Glasses Scaffold in the CaO - SiO_2 - P_2O_5 System **1362**
P.S. Lu, L.C. Chiou, I.L. Chang, C.J. Shih, L.F. Huang

Influence of Surfactant Concentration on Mesoporous Bioactive Glass Scaffolds with Superior in Vitro Bone-Forming Bioactivities **1366**
L.F. Huang, P.S. Lu, L.C. Chiou, I.L. Chang, C.J. Shih

Human Embryonic Stem Cell-derived Mesenchymal Stem Cells and BMP7 Promote Cartilage Repair **1369**
Lin Lin Wang, Yi Ying Qi, Yang Zi Jiang, Xiao Chen, Xing Hui Song, Xiao Hui Zou, Hong Wei Ouyang

Novel Composite Membrane Guides Cortical Bone Regeneration **1373**
You Zhi Cai, Yi Ying Qi, Hong Xin Cai, Xiao Hui Zou, Lin Lin Wang, Hong Wei Ouyang

Morphology and In Vitro Biocompatibility of Hydroxyapatite-Conjugated Gelatin/Thai Silk Fibroin Scaffolds **1377**
S. Tritanipakul, S. Kanokpanont, D.L. Kaplan and S. Damrongsakkul

Development of a Silk-Chitosan Blend Scaffold for Bone Tissue Engineering **1381**
K.S. Ng, X.R. Wong, J.C.H. Goh and S.L. Toh

Effects Of Plasma Treatment On Wounds **1385**
R.S. Tipa, E. Stoffels

Effects of the Electrical Field on the 3T3 Cells **1389**
E. Stoffels, R.S. Tipa, J.W. Bree

^{99m}Tc(I)-tricarbonyl Labeled Histidine-tagged Annexin V for Apoptosis Imaging **1393**
Y.L. Chen, C.C. Wu, Y.C. Lin, Y.H. Pan, T.W. Lee and J.M. Lo

Cell Orientation Affects Human Tendon Stem Cells Differentiation **1397**
Zi Yin, T.M. Hieu Nguyen, Xiao Chen, Hong-Wei Ouyang

Synthesis and Characterization of TiO_2+HA Coatings on Ti-6Al-4V Substrates by Nd-YAG Laser Cladding **1401**
C.S. Chien, C.L. Chiao, T.F. Hong, T.J. Han, T.Y. Kuo

Computational Fluid Dynamics Investigation of the Effect of the Fluid-Induced Shear Stress on Hepatocyte Sandwich Perfusion Culture **1405**
H.L. Leo, L. Xia, S.S. Ng, H.J. Poh, S.F. Zhang, T.M. Cheng, G.F. Xiao, X.Y. Tuo, H. Yu

Preliminary Study on Interactive Control for the Artificial Myocardium by Shape Memory Alloy Fibre **1409**
R. Sakata, Y. Shiraishi, Y. Sato, Y. Saijo, T. Yambe, Y. Luo, D. Jung, A. Baba, M. Yoshizawa, A. Tanaka, T.K. Sugai, F. Sato, M. Umezu, S. Nitta, T. Fujimoto, D. Homma

Synthesis, Surface Characterization and In Vitro Blood Compatibility Studies of the Self-assembled Monolayers (SAMs) Containing Lipid-like Phosphorylethanolamine Terminal Group **1413**
Y.T. Sun, C.Y. Yu and J.C. Lin

Surface Characterization and In-vitro Blood Compatibility Study of the Mixed Self-assembled Monolayers **1418**
C.H. Shen and J.C. Lin

Microscale Visualization of Erythrocyte Deformation by Colliding with a Rigid Surface Using a High-Speed Impinging Jet **1422**
S. Wakasa, T. Yagi, Y. Akimoto, N. Tokunaga, K. Iwasaki and M. Umezu

Development of an Implantable Observation System for Angiogenesis 1426
Y. Inoue, H. Nakagawa, I Saito, T. Isoyama, H. Miura, A. Kouno, T. Ono, S.S. Yamaguchi, W. Shi, A. Kishi, K. Imachi and Y. Abe

New challenge for studying flow-induced blood damage: macroscale modeling and microscale verification..... 1430
T. Yagi, S. Wakasa, N. Tokunaga, Y. Akimoto, T. Akutsu, K. Iwasaki, M. Umezu

Pollen Shape Particles for Pulmonary Drug Delivery: In Vitro Study of Flow and Deposition Properties 1434
Meer Saiful Hassan and Raymond Lau

Effect of Tephrosia Purpurea Pers on Gentamicin Model of Acute Renal Failure 1438
Avijeet Jain, A.K. Singhai

Successful Reproduction of In-Vivo Fracture of an Endovascular Stent in Superficial Femoral Artery Utilizing a Novel Multi-loading Durability Test System 1443
K. Iwasaki, S. Tsubouchi, Y. Hama, M. Umezu

Star-Shaped Porphyrin-polylactide Formed Nanoparticles for Chemo-Photodynamic Dual Therapies 1447
P.S. Lai

Enhanced Cytotoxicity of Doxorubicin by Micellar Photosensitizer-mediated Photochemical Internalization in Drug-resistant MCF-7 Cells 1451
C.Y. Hsu, P.S. Lai, C.L. Pai, M.J. Shieh, N. Nishiyama and K. Kataoka

Amino Acid Coupled Liposomes for the Effective Management of Parkinsonism 1455
P. Khare and S.K. Jain

Corrosion Resistance of Electrolytic Nano-Scale ZrO_2 Film on NiTi Orthodontic Wires in Artificial Saliva 1459
C.C. Chang and S.K. Yen

Stability of Polymeric Hollow Fibers Used in Hemodialysis 1462
M.E. Aksoy, M. Usta and A.H. Ucisik

Estimation of Blood Glucose Level by Sixth order Polynomial 1466
S. Shanthi, Dr. D. Kumar

Dirty Surface – Cleaner Cells? Some Observations with a Bio-Assembled Extracellular Matrix 1469
F.C. Loe, Y. Peng, A. Blocki, A. Thomson, R.R. Lareu, M. Raghunath

Quantitative Immunocytochemistry (QICC)-Based Approach for Antifibrotic Drug Testing in vitro 1473
Wang Zhibo, Tan Khim Nyang and Raghunath Michael

Fusion Performance of a Bioresorbable Cage Used In Porcine Model of Anterior Lumbar Interbody Fusion 1476
A.S. Abbah, C.X.F. Lam, K. Yang, J.C.H. Goh, D.W. Hutmacher, H.K. Wong

Composite PLDLLA/TCP Scaffolds for Bone Engineering: Mechanical and In Vitro Evaluations..... 1480
C.X.F. Lam, R. Olkowski, W. Swieszkowski, K.C. Tan, I. Gibson, D.W. Hutmacher

Effects of Biaxial Mechanical Strain on Esophageal Smooth Muscle Cells..... 1484
W.F. Ong, A.C. Ritchie and K.S. Chian

Characterization of Electrospun Substrates for Ligament Regeneration using Bone Marrow Stromal Cells..... 1488
T.K.H. Teh, J.C.H. Goh, S.L. Toh

Cytotoxicity and Cell Adhesion of PLLA/keratin Composite Fibrous Membranes 1492
Lin Li, Yi Li, Jiashen Li, Arthur F.T. Mak, Frank Ko and Ling Qin

Tissue Transglutaminase as a Biological Tissue Glue 1496
P.P. Panengad, D.I. Zeugolis and M. Raghunath

The Scar-in-a-Jar: Studying Antifibrotic Lead Compounds from the Epigenetic to the Extracellular Level in One Well..... 1499
Z.C.C. Chen, Y. Peng and M. Raghunath

Engineering and Optimization of Peptide-targeted Nanoparticles for DNA and RNA Delivery to Cancer Cells 1503
Ming Wang, Fumitaka Takeshita, Takahiro Ochiya, Andrew D. Miller and Maya Thanou

BMSC Sheets for Ligament Tissue Engineering 1508
E.Y.S. See, S.L. Toh and J.C.H. Goh

In Vivo Study of ACL Regeneration Using Silk Scaffolds In a Pig Model 1512
Haifeng Liu, Hongbin Fan, Siew Lok Toh, James C.H. Goh

Establishing a Coculture System for Ligament-Bone Interface Tissue Engineering 1515
P.F. He, S. Sahoo, J.C. Goh, S.L. Toh

Effect of Atherosclerotic Plaque on Drug Delivery from Drug-eluting Stent 1519
J. Ferdous and C.K. Chong

Perfusion Bioreactors Improve Oxygen Transport and Cell Distribution in Esophageal Smooth Muscle Construct 1523
W.Y. Chan and C.K. Chong

Track 5:
Biomechanics; Cardiovascular Bioengineering; Cellular & Molecular Engineering; Cell & Molecular Mechanics; Computational Bioengineering; Orthopaedics, Prosthetics & Orthotics; Physiological System Modeling

Determination of Material Properties of Cellular Structures Using Time Series of Microscopic Images and Numerical Model of Cell Mechanics 1527
E. Gladilin, M. Schulz, C. Kappel and R. Eils

Analysis of a Biological Reaction of Circulatory System during the Cold Pressure Test – Consideration Based on One-Dimensional Numerical Simulation – 1531
T. Kitawaki, H. Oka, S. Kusachi and R. Himeno

Identification of the Changes in Extent of Loading the TM Joint on the Other Side Owing to the Implantation of Total Joint Replacement 1535
Z. Horak, T. Bouda, R. Jirman, J. Mazanek and J. Reznicek

Effects of Stent Design Parameters on the Aortic Endothelium 1539
Gideon Praveen Kumar & Lazar Mathew

Multi-Physical Simulation of Left-ventricular Blood Flow Based On Patient-specific MRI Data 1542
S.B.S. Krittian, S. Höttges, T. Schenkel and H. Oertel

Spinal Fusion Cage Design 1546
F. Jabbary Aslani, D.W.L. Hukins and D.E.T. Shepherd

Comparison of Micron and Nano Particle Deposition Patterns in a Realistic Human Nasal Cavity 1550
K. Inthavong, S.M. Wang, J. Wen, J.Y. Tu, C.L. Xue

Comparative Study of the Effects of Acute Asthma in Relation to a Recovered Airway Tree on Airflow Patterns 1555
K. Inthavong, Y. Ye, S. Ding, J.Y. Tu

Computational Analysis of Stress Concentration and Wear for Tibial Insert of PS Type Knee Prosthesis under Deep Flexion Motion 1559
M. Todo, Y. Takahashi and R. Nagamine

Push-Pull Effect Simulation by the LBNP Device 1564
J. Hanousek, P. Dosel, J. Petricek and L. Cettl

An Investigation on the Effect of Low Intensity Pulsed Ultrasound on Mechanical Properties of Rabbit Perforated Tibia Bone **1569**
B. Yasrebi and S. Khorramymehr

Influence of Cyclic Change of Distal Resistance on Flow and Deformation in Arterial Stenosis Model **1572**
J. Jie, S. Kobayashi, H. Morikawa, D. Tang, D.N. Ku

Kinematics analysis of a 3-DOF micromanipulator for Micro-Nano Surgery **1576**
Fatemeh Mohandesi, M.H. Korayem

Stress and Reliability Analyses of the Hip Joint Endoprosthesis Ceramic Head with Macro and Micro Shape Deviations **1580**
V. Fuis, P. Janicek and L. Houfek

Pseudoelastic alloy devices for spastic elbow relaxation **1584**
S. Viscuso, S. Pittaccio, M. Caimmi, G. Gasperini, S. Pirovano, S. Besseghini and F. Molteni

Musculoskeletal Analysis of Spine with Kyphosis Due to Compression Fracture of an Osteoporotic Vertebra **1588**
J. Sakamoto, Y. Nakada, H. Murakami, N. Kawahara, J. Oda, K. Tomita and H. Higaki

The Biomechanical Analysis of the Coil Stent and Mesh Stent Expansion in the Angioplasty **1592**
S.I. Chen, C.H. Tsai, J.S. Liu, H.C. Kan, C.M. Yao, L.C. Lee, R.J. Shih, C.Y. Shen1

Effect of Airway Opening Pressure Distribution on Gas Exchange in Inflating Lung **1595**
T.K. Roy, MD PhD

Artificial High – Flexion Knee Customized for Eastern Lifestyle **1597**
S. Sivarasu and L. Mathew

Biomedical Engineering Analysis of the Rupture Risk of Cerebral Aneurysms: Flow Comparison of Three Small Pre-ruptured Versus Six Large Unruptured Cases **1600**
A. Kamoda, T. Yagi, A. Sato, Y. Qian, K. Iwasaki, M. Umezu, T. Akutsu, H. Takao, Y. Murayama

Metrology Applications in Body-Segment Coordinate Systems **1604**
G.A. Turley and M.A. Williams

Finite Element Modeling Of Uncemented Implants: Challenges in the Representation of the Press-fit Condition **1608**
S.E. Clift

Effect of Prosthesis Stiffness and Implant Length on the Stress State in Mandibular Bone with Dental Implants **1611**
M. Todo, K. Irie, Y. Matsushita and K. Koyano

Rheumatoid Arthritis T-lymphocytes "Immature" Phenotype and Attempt of its Correction in Co-culture with Human Thymic Epithelial Cells **1615**
M.V. Goloviznin, N.S. Lakhonina, N.I. Sharova, V.T. Timofeev, R.I. Stryuk, Yu.R. Buldakova

Axial and Angled Pullout Strength of Bone Screws in Normal and Osteoporotic Bone Material **1619**
P.S.D. Patel, D.E.T. Shepherd and D.W.L. Hukins

Experimental Characterization of Pressure Wave Generation and Propagation in Biological Tissues **1623**
M. Benoit, J.H. Giovanola, K. Agbeviade and M. Donnet

Finite Element Analysis into the Foot – Footwear Interaction Using EVA Footwear Foams **1627**
Mohammad Reza Shariatmadari

Age Effects On The Tensile And Stress Relaxation Properties Of Mouse Tail Tendons **1631**
Jolene Liu, Siaw Meng Chou, Kheng Lim Goh

Do trabeculae of femoral head represent a structural optimum? **1636**
H.A. Kim, G.J. Howard, J.L. Cunningham

Gender and Arthroplasty Type Affect Prevalence of Moderate-Severe Pain Post Total Hip Arthroplasty..... 1640
J.A. Singh, S.E. Gabriel and D. Lewallen

Quantification of Polymer Depletion Induced Red Blood Cell Adhesion to Artificial Surfaces..... 1644
Z.W. Zhang and B. Neu

An Investigation on the Effect of Low Intensity Pulsed Ultrasound on Mechanical Properties of Rabbit Perforated Tibia Bone..... 1648
B. Yasrebi and S. Khorramymehr

Integrative Model of Physiological Functions and Its Application to Systems Medicine in Intensive Care Unit 1651
Lu Gaohua and Hidenori Kimura

A Brain-oriented Compartmental Model of Glucose-Insulin-Glucagon Regulatory System 1655
Lu Gaohua and Hidenori Kimura

Linkage of Diisopropylfluorophosphate Exposure and Effects in Rats Using a Physiologically Based Pharmacokinetic and Pharmacodynamic Model..... 1659
K.Y. Seng, S. Teo, K. Chen and K.C. Tan

Blood Flow Rate Measurement Using Intravascular Heat-Exchange Catheter..... 1663
Seng Sing Tan and Chin Tiong Ng

Mechanical and Electromyographic Response to Stimulated Contractions in Paralyzed Tibialis Anterior Post Fatiguing Stimulations 1667
N.Y. Yu and S.H. Chang

Modelling The Transport Of Momentum And Oxygen In An Aerial-Disk Driven Bioreactor Used For Animal Tissue Or Cell Culture..... 1672
K.Y.S. Liow, G.A. Thouas, B.T. Tan, M.C. Thompson and K. Hourigan

Investigation of Hemodynamic Changes in Abdominal Aortic Aneurysms Treated with Fenestrated Endovascular Grafts..... 1676
Zhonghua Sun, Thanapong Chaichana, Yvonne B. Allen, Manas Sangworasil, Supan Tungjitkusolmun, David E. Hartley and Michael M.D. Lawrence-Brown

Bone Morphogenetic Protein-2 and Hyaluronic Acid on Hydroxyapatite-coated Porous Titanium to Repair the Defect of Rabbit's Distal Femu 1680
P. Lei, M. Zhao, L.F. Hui, W.M. Xi

Landing Impact Loads Predispose Osteocartilage To Degeneration 1684
C.H. Yeow, S.T. Lau, Peter V.S. Lee, James C.H. Goh

Drug Addiction as a Non-monotonic Process: a Multiscale Computational Model..... 1688
Y.Z. Levy, D. Levy, J.S. Meyer and H.T. Siegelmann

Adroit Limbs..... 1692
Pradeep Manohar and S. Keerthi Vasan

A Mathematical Model to Study the Regulation of Active Stress Production in GI Smooth Muscle..... 1696
Viveka Gajendiran and Martin L. Buist

Design of Customized Full Contact Shoulder Prosthesis using CT-data & FEA..... 1700
D. Sengupta, U.B. Ghosh and S. Pal

An Interface System to Aid the Design of Rapid Prototyping Prosthetic Socket Coated with a Resin Layer for Transtibial Amputee..... 1704
C.W. Lai, L.H. Hsu, G.F. Huang and S.H. Liu

Correlation of Electrical Impedance with Mechanical Properties in Models of Tissue Mimicking Phantoms..... 1708
Kamalanand Krishnamurthy, B.T.N. Sridhar, P.M. Rajeshwari and Ramakrishnan Swaminathan

Biomechanical Analysis of Influence of Spinal Fixation on Intervertebral Joint Force by Using Musculoskeletal Model **1712**
H. Fukui, J. Sakamoto, H. Murakami, N. Kawahara, J. Oda, K. Tomita and H. Higaki

Preventing Anterior Cruciate Ligament Failure During Impact Compression by Restraining Anterior Tibial Translation or Axial Tibial Rotation **1716**
C.H. Yeow, R.S. Khan, Peter V.S. Lee, James C.H. Goh

The Analysis and Measurement of Interface Pressures between Stump and Rapid Prototyping Prosthetic Socket Coated With a Resin Layer for Transtibial Amputee **1720**
H.K. Peng, L.H. Hsu, G.F. Huang and D.Y. Hong

Analysis of Influence Location of Intervertebral Implant on the Lower Cervical Spine Loading and Stability **1724**
L. Jirkova, Z. Horak

Computational Fluid Analysis of Blood Flow Characteristics in Abdominal Aortic Aneurysms Treated with Suprarenal Endovascular Grafts **1728**
Zhonghua Sun, Thanapong Chaichana, Manas Sangworasil and Supan Tungjitkusolmun

Measuring the 3D-Position of Cementless Hip Implants using Pre- and Postoperative CT Images **1733**
G. Yamako, T. Hiura, K. Nakata, G. Omori, Y. Dohmae, M. Oda, T. Hara

Simulation of Tissue-Engineering Cell Cultures Using a Hybrid Model Combining a Differential Nutrient Equation and Cellular Automata **1737**
Tze-Hung Lin and C.A. Chung

Upconversion Nanoparticles for Imaging Cells **1741**
N. Sounderya, Y. Zhang

Simulation of Cell Growth and Diffusion in Tissue Engineering Scaffolds **1745**
Szu-Ying Ho, Ming-Han Yu and C.A. Chung

Simulation of the Haptotactic Effect on Chondrocytes in the Boyden Chamber Assay **1749**
Chih-Yuan Chen and C.A. Chung

Analyzing the Sub-indices of Hysteresis Loops of Torque-Displacement in PD's **1753**
B. Sepehri, A. Esteki and M. Moinodin

Relative Roles of Cortical and Trabecular Thinning in Reducing Osteoporotic Vertebral Body Stiffness: A Modeling Study **1757**
K. McDonald, P. Little, M. Pearcy, C. Adam

Musculo-tendon Parameters Estimation by Ultrasonography for Modeling of Human Motor System **1761**
L. Lan, L.H. Jin, K.Y. Zhu and C.Y. Wen

Mechanical Vibration Applied in the Absence of Weight Bearing Suggest Improved Fragile Bone **1766**
J. Matsuda, K. Kurata, T. Hara, H. Higaki

A Biomechanical Investigation of Anterior Vertebral Stapling **1769**
M.P. Shillington, C.J. Adam, R.D. Labrom and G.N. Askin

Measurement of Cell Detaching force on Substrates with Different Rigidity by Atomic Force Microscopy **1773**
D.K. Chang, Y.W. Chiou, M.J. Tang and M.L. Yeh

Estimation of Body Segment Parameters Using Dual Energy Absorptiometry and 3-D Exterior Geometry **1777**
M.K. Lee, M. Koh, A.C. Fang, S.N. Le and G. Balasekaran

A New Intraoperative Measurement System for Rotational Motion Properties of the Spine **1781**
K. Kitahara, K. Oribe, K. Hasegawa, T. Hara

Binding of Atherosclerotic Plaque Targeting Nanoparticles to the Activated Endothelial Cells under Static and Flow Condition **1785**
K. Rhee, K.S. Park and G. Khang

Computational Modeling of the Micropipette Aspiration of Malaria Infected Erythrocytes **1788**
G.Y. Jiao, K.S.W. Tan, C.H. Sow, Ming Dao, Subra Suresh, C.T. Lim

Examination of the Microrheology of Intervertebral Disc by Nanoindentation **1792**
J. Lukes, T. Mares, J. Nemecek and S. Otahal

Effects of Floor Material Change on Gait Stability **1797**
B.-S. Yang and H.-Y. Hu

Onto-biology: Inevitability of Five Bases and Twenty Amino-acids **1801**
K. Naitoh

An Improved Methodology for Measuring Facet Contact Forces in the Lumbar Spine **1805**
A.K. Ramruttun, H.K. Wong, J.C.H. Goh, J.N. Ruiz

Multi-scale Models of Gastrointestinal Electrophysiology **1809**
M.L. Buist, A. Corrias and Y.C. Poh

Postural Sway of the Elderly Males and Females during Quiet Standing and Squat-and-Stand Movement **1814**
Gwnagmoon Eom, Jiwon Kim, Byungkyu Park, Jeonghwa Hong, Soonchul Chung, Bongsoo Lee, Gyerae Tack, Yohan Kim

Investigation of Plantar Barefoot Pressure and Soft-tissue Internal Stress: A Three-Dimensional Finite Element Analysis **1817**
Wen-Ming Chen, Peter Vee-Sin Lee, Sung-Jae Lee and Taeyong Lee

The Influence of Load Placement on Postural Sway Parameters **1821**
D. Rugelj and F. Sevšek

Shape Analysis of Postural Sway Area **1825**
F. Sevšek

Concurrent Simulation of Morphogenetic Movements in Drosophila Embryo **1829**
R. Allena, A.-S. Mouronval, E. Farge and D. Aubry

Application of Atomic Force Microscopy to Investigate Axonal Growth of PC-12 Neuron-like Cells **1833**
M.-S. Ju, H.-M. Lan, C.-C.K. Lin

Effect of Irregularities of Graft Inner Wall at the Anastomosis of a Coronary Artery Bypass Graft **1838**
F. Kabinejadian, L.P. Chua, D.N. Ghista and Y.S. Tan

Mechanical Aspects in the Cells Detachment **1842**
M. Buonsanti, M. Cacciola, G. Megali, F.C. Morabito, D. Pellicanò, A. Pontari and M. Versaci

Time Series Prediction of Gene Expression in the SOS DNA Repair Network of Escherichia coli Bacterium Using Neuro-Fuzzy Networks **1846**
R. Manshaei, P. Sobhe Bidari, J. Alirezaie, M.A. Malboobi

Predictability of Blood Glucose in Surgical ICU Patients in Singapore **1850**
V. Lakshmi, P. Loganathan, G.P. Rangaiah, F.G. Chen and S. Lakshminarayanan

Method of Numerical Analysis of Similarity and Differences of Face Shape of Twins **1854**
M. Rychlik, W. Stankiewicz and M. Morzynski

Birds' Flap Frequency Measure Based on Automatic Detection and Tracking in Captured Videos **1858**
Xiao-yan Zhang, Xiao-juan Wu, Xin Zhou, Xiao-gang Wang, Yuan-yuan Zhang

Effects of Upper-Limb Posture on Endpoint Stiffness during Force Targeting Tasks **1862**
Pei-Rong Wang, Ju-Ying Chang and Kao-Chi Chung

Complex Anatomies in Medical Rapid Prototyping **1866**
T. Mallepree, D. Bergers

Early Changes Induced by Low Intensity Ultrasound in Human Hepatocarcinoma Cells **1870**
Y. Feng, M.X. Wan

Visual and Force Feedback-enabled Docking for Rational Drug Design **1874**
O. Sourina, J. Torres and J. Wang

A Coupled Soft Tissue Continuum-Transient Blood flow Model to Investigate the Circulation in Deep Veins of the Calf under Compression **1878**
K. Mithraratne, T. Lavrijsen and P.J. Hunter

Finite Element Analysis of Articular Cartilage Model Considering the Configuration and Biphasic Property of the Tissue **1883**
N. Hosoda, N. Sakai, Y. Sawae and T. Murakami

Principal Component Analysis of Lifting Kinematics and Kinetics in Pregnant Subjects **1888**
T.C. Nguyen, K.J. Reynolds

Evaluation of Anterior Tibial Translation and Muscle Activity during "Front Bridge" Quadriceps Muscle Exercise **1892**
M. Sato, S. Inoue, M. Koyanagi, M. Yoshida, N. Nakae, T. Sakai, K. Hidaka and K. Nakata

Coupled Autoregulation Models **1896**
T. David, S. Alzaidi, R. Chatelin and H. Farr

Measurement of Changes in Mechanical and Viscoelastic Properties of Cancer-induced Rat Tibia by using Nanoindentation **1900**
K.P. Wong, Y.J. Kim and T. Lee

Surface Conduction Analysis of EMG Signal from Forearm Muscles **1904**
Y. Nakajima, S. Yoshinari and S. Tadano

A Distributed Revision Control System for Collaborative Development of Quantitative Biological Models **1908**
T. Yu, J.R. Lawson and R.D. Britten

Symmetrical Leg Behavior during Stair Descent in Able-bodied Subjects **1912**
H. Hobara, Y. Kobayashi, K. Naito and K. Nakazawa

Variable Interaction Structure Based Machine Learning Technique for Cancer Tumor Classification **1915**
Melissa A. Setiawan, Rao Raghuraj and S. Lakshminarayanan

Assessing the Susceptibility to Local Buckling at the Femoral Neck Cortex to Age-Related Bone Loss **1918**
He Xi, B.W. Schafer, W.P. Segars, F. Eckstein, V. Kuhn, T.J. Beck, T. Lee

Revealing Spleen Ad4BP/SF1 Knockout Mouse by BAC-Ad4BP-tTAZ Transgene **1920**
Fatchiyah, M. Zubair, K.I. Morohashi

The impact of enzymatic treatments on red blood cell adhesion to the endothelium in plasma like suspensions **1924**
Y. Yang, L.T. Heng and B. Neu

Comparison of Motion Analysis and Energy Expenditures between Treadmill and Overground Walking **1928**
R.H. Sohn, S.H. Hwang, Y.H. Kim

Simultaneous Strain Measurements of Rotator Cuff Tendons at Varying Arm Positions and The Effect of Supraspinatus Tear: A Cadaveric Study **1931**

Electroencephalograph Signal Analysis During Ujjayi pranayama

Prof. S.T. Patil[1] and Dr. D.S. Bormane[2]

[1]Computer Dept. B.V.U. College of Engineering, Pune, India. Stpatil77@gmail.com
[2]Principal, Rajarshi Shahu Engineering college, Pune, India. bdattatraya@yahoo.com

Abstract — **Ujjai pranayama is one part of the Pranayama, as traditionally conceived, involves much more than merely breathing for relaxation. Ujjai pranayama is a term with a wide range of meanings. "The regulation of the incoming and outgoing flow of breath with retention.". Ujjai pranayama also denotes cosmic power. Because of this connection between breath and consciousness. Pranayama has devised ujjai pranayama to stabilize energy and consciousness.**

A wavelet transformation is applied to electroencephalograph (EEG) records from persons under ujjai pranayama. Correlation dimension, largest lyapunov exponent, approximate entropy and coherence values are analyzed. This model & software is used to keep track on the improvement of the persons mind, aging, balance, flexibility, personnel values, mental values, social values, love, sex, knowledge, weight reduction and body fitness.

Keywords — **Ujjai pranayama, approximate entropy, EEG, coherence, largest lyapunov exponent, correlation dimension, wavelets.**

I. Introduction

A. Ujjai pranayama

The word ujjai pranayama means stretch, extension, expansion, length, breadth, regulation, prolongation, restraint and control to create energy, when the self-energizing force embraces the body, fast inhalation and fast exhalation, followed by inhaling through right nostril and performing kumbhaka with bandhas and exhaling through left nostril. Patanjali has said that one develops concentration and clarity of thought by practicing ujjai pranayama. It helps in increasing the mental and physical powers of endurance. It is the path to deeper relaxation and meditation and is a scientific method of controlling breath. It provides complete relaxation to the nervous system. It provides relief from pain caused by the compression of nerve ending. It helps in increasing oxygen supply to the brain which in turn helps controlling the mind.

B. Electroencephalography

The brain generates rhythmical potentials, which originate in the individual neurons of the brain. Electroencephalograph (EEG) is a representation of the electrical activity of the brain.

Numerous attempts have been made to define a reliable spike detection mechanism. However, all of them have faced the lack of a specific characterization of the events to detect. One of the best known descriptions for an interictal "spike" is offered by Chatrian et al. [1]: " transient, clearly distinguished from background activity, with pointed peak at conventional paper speeds and a duration from 20 to 70 msec". This description, however, is not specific enough to be implemented into a detection algorithm that will isolate the spikes from all the other normal or artifactual components of an EEG record. Some approaches have concentrated in measuring the "sharpness" of the EEG signal, which can be expected to soar in the "pointy peak" of a spike. Walter [2] attempted the detection of spikes through analog computation of the second time derivative (sharpness) of the EEG signals. Smith [3] attempted a similar form of detection on the digitized EEG signal. His method, however required a minimum duration of the sharp transient to qualify it as a spike. Although these methods involve the duration of the transient in a secondary way, they fundamentally consider "sharpness" as a point property, dependent only on the very immediate context of the time of analysis. More recently, an approach has been proposed in which the temporal sharpness is measured in different "spans of observation", involving different amounts of temporal context. True spikes will have significant sharpness at all of these different "spans". The promise shown by that approach has encouraged us to use a wavelet transformation to evaluate the sharpness of EEG signals at different levels of temporal resolution.

C. Data Collection

Medic-aid systems, Chandigarh (India), machine was used to aquire 32-channel eeg signal with the international 10-20 electrode coupling. The sampling frequency of the device is 256 Hz with 12-bit resolution and stored on hard disc. 32 channel EEG data was recorded simultaneously for both referential and bipolar montages. Recordings are made before, meanwhile and after the person is doing ujjai pranayama, and also we have kept track on recording the EEG data after one, two and three months of the same

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 1–4, 2009
www.springerlink.com

persons doing ujjai pranayama. Such 10 persons data is collected for analysis.

II. Parameters

The present work pertains to the analysis of the EEG signal using various characteristic measures like Correlation Dimension(CD), Largest Lyapunov Exponent(LLE), Hurst exponent(HE) & Approximate Entropy(AE).

A. Correlation Dimension

The dimension of a graph can give much more information about the nature of the signal

Grassberger & Procaccia Algorithm is used

$$C(r) = \frac{2}{N(N-1)}) \sum_{i=1+w}^{N} \theta(r - / x_i - x_j /)$$

N-no. of data points θ -Heaviside function
r- radial distance w-Tac x j step away from x i

B. Approximate Enropy

amount of disorder in the system. Amount of information stored in a more general probability distribution. Steyn-Ross algorithm is used

$$AE(m,r,l) = \frac{1}{L-m} \sum_{i=1}^{L-m} Log^{m+1} C_i(r) - \frac{1}{L-(m+1)} Log^{m} C_i(r)$$

Where m= Pattern Length = 2
r = noise threshold = 15%
L= Time interval between two datasets.
Ci (r) = correlation integral

C. Largest Lyapunov Exponent

It is rate at which the trajectories of a signal separate one from other.

Wolf algorithm is used to calculate Largest Lyapunov Exponent

$$\delta Z(t) = e\lambda t / \delta z_0 /$$

δz0=Initial seperation
λ= λ1, λ2, λ3,…….. λn Phase spaces

D. Hurst Exponent

Evaluates presence or absence of long range dependence and it degree. Hurst algorithm is used

$$H = Log(\frac{R}{S}) / LogT$$

R/S - Rescaled Range,
T- Duration of sample of data

III. Results

Artifactual currents may cause linear drift to occur at some electrodes. To detect such drifts, we designed a function that fits the data to a straight line and marks the trial for rejection if the slope exceeds a given threshold. The slope is expressed in microvolt over the whole epoch (50, for instance, would correspond to an epoch in which the straight-line fit value might be 0 μv at the beginning of the trial and 50 μ v at the end). The minimal fit between the EEG data and a line of minimal slope is determined using a standard R-square measure.

We usually apply the measures described above to the activations of the independent components of the data. As independent components tend to concentrate artifacts, we have found that bad epochs can be more easily detected using independent component activities. The functions described above work exactly the same when applied to data components as when they are applied to the raw channel data.

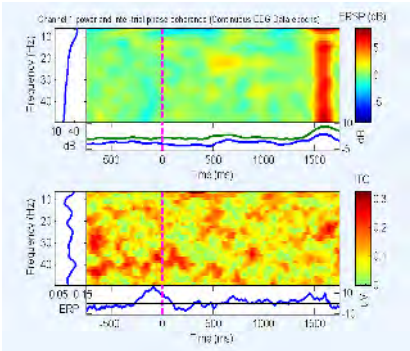

Fig.1: time frequency components

It is more interesting to look at time-frequency decompositions of component activations than of separate channel activities, since independent components may directly index the activity of one brain EEG source, whereas channel activities sum potentials volume-conducted from different parts of the brain. to visualize only frequencies up

to 30 Hz. decompositions using FFTs allow computation of lower frequencies than wavelets, since they compute as low as one cycle per window, whereas the wavelet method uses a fixed number of cycles (default 3) for each frequency.

The following time window appears IN Fig.1. The ITC image (lower panel) shows strong synchronization between the component activity and stimulus appearance, first near 15 Hz then near 4 Hz. The ERSP image (upper panel) shows that the 15-Hz phase-locking is followed by a 15-Hz power increase, and that the 4-Hz phase-locking event is accompanied by, but outlasts, a 4-Hz power increase.

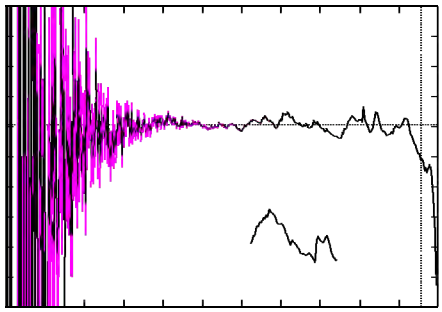

Fig.2: correlation dimension

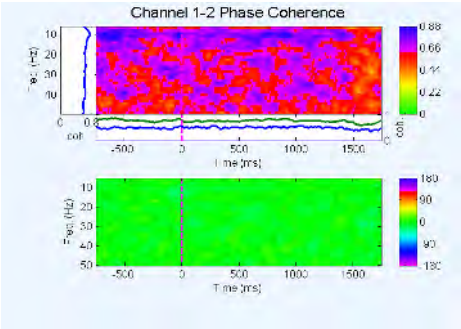

Fig.3: cross-coherence

To determine the degree of synchronization between the activations of two components, we may plot their event-related cross-coherence as shown in fig.3. (a concept first demonstrated for EEG analysis by Rappelsberger). Even though independent components are (maximally) independent over the whole time range of the training data, they may become transiently (partially) synchronized in specific frequency bands. In the cross window below, the two components become synchronized (top panel) around 11.5Hz (click on the image to zoom in). The upper panel shows the coherence magnitude (between 0 and 1, 1 representing two perfectly synchronized signals). The lower panel indicates the phase difference between the two signals at time/frequency points where cross-coherence magnitude (in the top panel) is significant. In this example, the two components are synchronized with a phase offset of about -120 degrees (this phase difference can also be plotted as latency delay in ms, using the minimum-phase assumption.

Channel statistics may help determine whether to remove a channel or not. To compute and plot one channel statistical characteristics.

Some estimated variables of the statistics are printed as text in the lower panel to facilitate graphical analysis and interpretation. These variables are the signal mean, standard deviation, skewness, and kurtosis (technically called the 4 first cumulants of the distribution) as well as the median. The last text output displays the Kolmogorov-Smirnov test result (estimating whether the data distribution is Gaussian or not) at a significance level of p=0.05.

The upper right panel shows the empirical quantile-quantile plot (QQ-plot). Plotted are the quantiles of the data versus the quantiles of a Standard Normal (i.e., Gaussian) distribution. The QQ-plot visually helps to determine whether the data sample is drawn from a Normal distribution. If the data samples do come from a Normal distribution (same shape), even if the distribution is shifted and re-scaled from the standard normal distribution (different location and scale parameters), the plot is linear.

IV. Conclusion

From this model & software we conclude that,

- The EEG signal after ujjai pranayama becomes less complex.
- Corretion dimension, Largest lyapunov exponent, Approximate entropy & Hurst exponent decreases.
- Less parallel functional activity of the brain
- predictability of the EEG signal increases.

V. Discussion

During the ujjai pranayama Meditation technique individuals often report the subjective experience of Transcendental Consciousness or pure consciousness, the state of least excitation of consciousness. This study found that many experiences of pure consciousness were associated with periods of natural respiratory suspension, and that during these respiratory suspension periods individuals displayed higher mean EEG coherence over all frequencies and brain areas, in contrast to control periods where subjects voluntarily held their breath. Results are 98 % true when discussed with doctors.

BIOGRAPHIES

Prof. S.T. Patil- Completed B.E. Electronics from Marathwada University, Aurangabad in 1988. M.Tech. Computer from Vishveshwaraya Technological University, Belgum in July 2003. Persuing Ph.D. Computer from Bharati Vidyapeeth Deemed University, Pune. Having 19 years of experience in teaching as a lecturer, Training & Placement Officer, Head of the department & Assistant Professor. Presently working as an Assistant Professor in computer engineering & Information Technology department in Bharati Vidyapeeth Deemed University, College of Engineering, Pune (India). Presented 14 papers in national & international conferences.

Dr. D.S. Bormane- Completed B.E. Electronics from Marathwada University, Aurangabad in 1987. M.E. Electronics from Shivaji University, Kolhapur. Ph.D. computer from Ramanand Tirth University, Nanded. Having 20 years of experience in teaching as a Lecturer, Assistant Professor, Professor, and Head Of Department. Currently working as a Principal in Rajrshi Shahu College of Engineering, Pune (India). Published 24 papers at national & international conferences and journals.

Abstract — **Electrogastrography (EGG) is an abdominal surface measurement of the electrical activity of the stomach. It is very important clinically to record and analyze multichannel EGGs, which provide more information on the propagation and co-ordination of gastric contractions. This study measured the gastrointestinal motility with an aim to obtain a mathematical model of EGG and to speculate factors to describe the diseases resulting from constipation and erosive gastritis. The waveform of the electric potential in the Cajal cells is similar to the graphs of numerical solutions to the van der Pol equation. Hence, we added the van der Pol equation to a periodic function and random white noises, which represented the intestinal motility and other biosignals, respectively. We rewrote the stochastic differential equations (SDEs) into difference equa-tions, and the numerical solutions to the SDEs were obtained by the Runge–Kutta–Gill formula as the numerical calculus, where we set the time step and initial values to be 0.05 and (0, 0.5), respectively. Pseudorandom numbers were substituted in the white noise terms. In this study, the pseudorandom num-bers were generated by the Mersenne Twister method. These numerical calculations were divided into 12000 time steps. The numerical solutions and EGG were extracted after every 20 steps. The EGG and numerical solutions were compared and evaluated by the Lyapunov exponent and translation error. The EGG was well described by the stochastic resonance in the SDEs.**

Keywords — **Electrogastrography (EGG), numerical analysis, Stochastic Resonance**

I. Introduction

It is known that attractors can be reconstructed by dynamical equation systems (DESs) such as the Duffing equation, Henon map, and Lorenz differential equation. It is very interesting to note that the structure of an attractor is also derived from time series data in a phase space.

The DESs were obtained as mathematical models that regenerated time series data. Anomalous signals are introduced by nonstationary processes, for instance, the degeneration of singular points in the potential function involved in the DESs; their degree of freedom increases or stochastic factors are added to them. The visible determinism in the latter case would be different from that in the case where random variables do not exist.

It is well known that the empirical threshold translation error of 0.5 is used to classify mathematical models as being either deterministic or stochastic generators [1]; however, the estimated translation error is generally not the same as that in the case of smaller signal-to-noise (S/N) ratios. Takada (2008) [2] quoted an example of analyzing numerical solutions to the nonlinear stochastic differential equations (SDEs):

$$\dot{x} = y - agradf\ (x) + \mu w_1(t)\,, \tag{1.1}$$

$$\dot{y} = -x + \mu w_2(t)\ , \tag{1.2}$$

$$s.t.\quad f(x) = \frac{1}{12}x^4 - \frac{b}{2}x^2 \tag{2}$$

where $w_1(t)$ and $w_2(t)$ were independent white noise terms $(\mu = 0,1,\cdots,20)$. By enhancing μ in eq.(1), we can obtain numerical solutions for smaller S/N ratios.

Percutaneous electrogastrography (EGG) is a simple method to examine gastrointestinal activity without constraint. EGG is a term generally applied to the measurement of human gastric electrical activity. In 1921, Walter C. Alvarez reported performing EGG for the first time in humans [3]. In EGG, the electrical activity of the stomach is recorded by placing the electrodes on the surface of the abdominal wall [4]. In the stomach, a pacemaker on the side of the greater curvature generates electrical activity at a rate of 3 cycles per minute (3 cpm); the electrical signal is then transferred to the pyloric side [5]–[7]. Previously, it was difficult to measure this electrical activity because the EGG signal was composed of low-frequency components and high-frequency noise caused by the electrical activity of the diaphragm and heart. However, the accuracy of EGG measurements has improved recently, and gastroenteric motility can be evaluated by spectrum analysis of the EGG signals [8]–[9].

Many previous studies on EGG have been reported, and most of these studies pertain to the clinical setting [10], e.g.,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 5–8, 2009
www.springerlink.com

evaluation of the effects of hormones and drugs on EGG and the relationship between EGG and kinesia. EGG has been used to study the effects of warm compresses (for the improvement of constipation) on gastrointestinal activity [11], the usefulness of warm compresses in the epigastric region for the improvement of constipation [12], and characterization of intestinal activity in patients with chronic constipation[13].

Gastric electrical potential is generated by interstitial cells of Cajal (ICCs) [14]. ICCs are pacemaker cells that spontaneously depolarize and repolarize at a rate of 3 cpm. They demonstrate low-amplitude, rhythmic, and circular contractions only if the electrical potential is over a threshold.

Human gastric pacemaker potential migrates around the stomach very quickly and moves distally through the antrum in approximately 20 seconds, resulting in the normal gastric electrical frequency of 3 cpm. This moving electrical wavefront is recorded in EGG, in which the gastric myoelectrical activity is recorded using electrodes placed on the surface of the epigastrium. However, electrogastrogram also contains other biological signals, for instance, electrical activity of the heart, intestinal movements, and myenteric potential oscillations in general.

In the present study, the gastrointestinal motility was measured with an aim to obtain a mathematical model of EGG and to speculate factors to describe the diseases resulting from constipation and erosive gastritis.

II. Methods

A. Mathematical Model and the Numerical Simulations

As a mathematical model of the EGG during sitting position, we propose the following SDEs in which the periodic function is added to Eq.(1.1).

$$\dot{x} = y - \lambda\, gradf\,(x) + s(t) + \mu w_1(t) \tag{3.1}$$

$$\dot{y} = -x + \mu w_2(t) \tag{3.2}$$

The function $s(t)$ and the white noise $w_i(t)$ represent intestinal movements and other biosignals, for instance, myenteric potential oscillations that are weak and random, respectively $(i = 1,2)$.

In most cases, there is an optimum for noise amplitude, which has motivated the name stochastic resonance (SR) for this rather counterintuitive phenomenon. In other words, the SR occurs when the S/N ratio (SNR) of a nonlinear system is maximized for a moderate value of noise intensity [15]. In this study, we numerically solve eq.(3) and verify the SR in the SDEs . We also investigate the effect of the SR and evaluate the SDEs as a mathematical model of the EGG.

B. Physiological Procedure

The subjects were 14 healthy people (7 M & 7 F) aged 21–25 years. Sufficient explanation of the experiment was provided to all subjects, and a written consent was obtained from them.

EGGs were obtained for 30 min in the sitting position at 1 kHz by using an A/D converter (AD16-16U (PCI) EH; CONTEC, Japan). EGGs were amplified using a bioamplifier (MT11; NEC Medical, Japan) and recorded using a tape recorder (PC216Ax; Sony Precision Technology, Japan).

To remove the noise from the time series of EGG data obtained at 1 kHz, resampling was performed at 0.5 Hz. For analysis, we then obtained a resampled time series as follows;

$$x_i = \frac{1}{2000}\sum_{j=0}^{1999} y(2000\,i + j) \quad (i = 0,1, \cdots ,1799)$$

In this experiment, 9 disposable electrodes (Blue Sensor; Medicotest Co. Ltd., Ølstykke, Denmark) were affixed on ch1–ch8 and e, as shown in Fig. 1. The electrode affixed on e was a reference electrode. Prior to the application of electrodes, the skin resistance was sufficiently reduced using SkinPure (Nihon Kohden Inc., Tokyo, Japan). Several methods have been proposed for analyzing the EGG data. The EGG data obtained at ch5, which is the position closest to the pacemaker of gastrointestinal motility, were analyzed in this study.

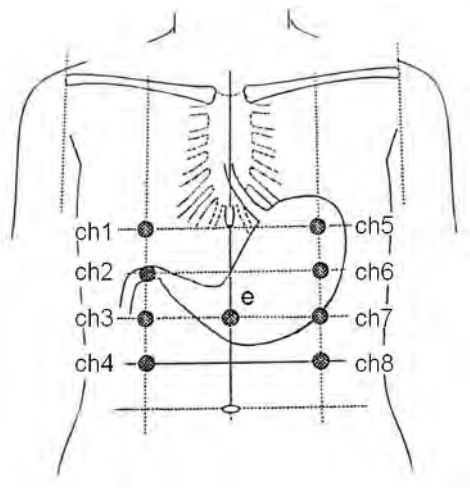

Fig. 1 Positions of electrode

C. Calculation Procedure

1. We rewrote eq.(3) as difference equations and obtained numerical solutions to them by the Runge–Kutta–Gill formula as the numerical calculus; the initial values were (0, 0.5). Pseudorandom numbers were substituted for . The pseudorandom numbers used here were generated using the Mersenne Twister [16]. These numerical calculations were performed in N = 12000 time steps. The unit of the time step is 0.05.
2. Values in the numerical solutions were recorded every 40 time step, which is related to a signal sampling rate of 0.5 Hz.
3. The autocorrelation function was calculated for each component of the numerical solution.

III. Results and Discussion

In the 12000 time steps, there was no exception wherein the numerical solutions did not diverge. For $\mu = 0,1,\cdots,20$, the value of τ derived from the first component of the numerical solution was not different from that derived from the second component.

With regard to eq.(3), the SR occurred under the condition of an appropriate coefficient μ. Some biosystems are based on the nonlinear phenomenon of SR, in which the detection of small afferent signals can be enhanced by the addition of an appropriate amount of noise [15]. Furthermore, this mechanism would facilitate behavioral, perceptive, and autonomic responses in animals and humans, for instance, information transfer in crayfish mechanoreceptors [17], tactile sensation in rats [18], availability of electrosensory information for prey capture [19], human hearing [20], vibrotactile sensitivity in the elderly[21], and spatial vision of amblyopes [22]. Here, we examined whether the SR generated by eq.(3) can describe the EGG time series (Fig.4).

A cross-correlation coefficient $\hat{\rho}_{zs}$ between observed signal $x(t)$ and the periodic function $s(t)$ was calculated as a substitute for the SNR in previous studies in which the occurrence of the SR was investigated. Fig. 2 shows $\hat{\rho}_{xs}$ between the numerical solutions and the periodic function in eq.(3.1). The cross-correlation coefficient was maximized for a moderate value of noise intensity $\mu = 12$ (Fig. 2). Thus, the SR could be generated by eq.(3) with $\mu = 12$, which is regarded as a mathematical model of the EGG in this study. We then compared this numerical solution with the EGG data (Fig. 3). Temporal variations in the numerical solutions were similar to those in the EGG data (Fig.4).

Numerical solutions involved in the SR highly correlated with the periodic function $s(t)$, which represented intestinal movements (6 cpm). Gastric electrical activity in a healthy person might synchronize with the intestinal one.

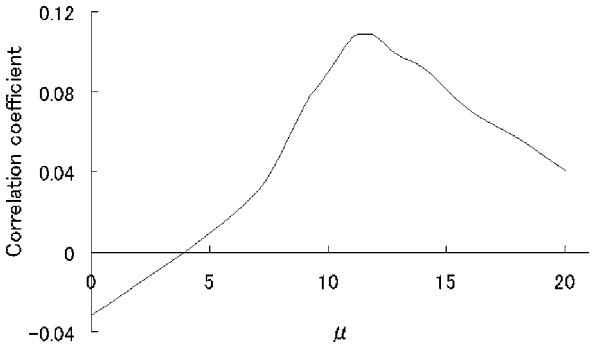

Fig. 2 The autocorrelation function for each component of the numerical solution

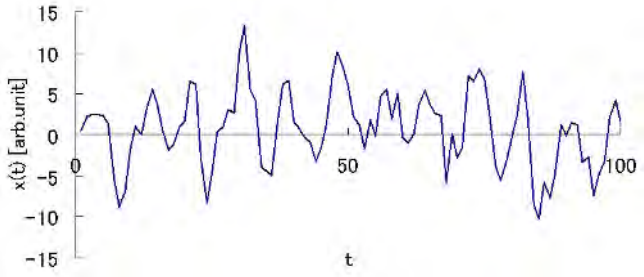

Fig. 3 An example of numerical solutions. $(\mu = 12)$

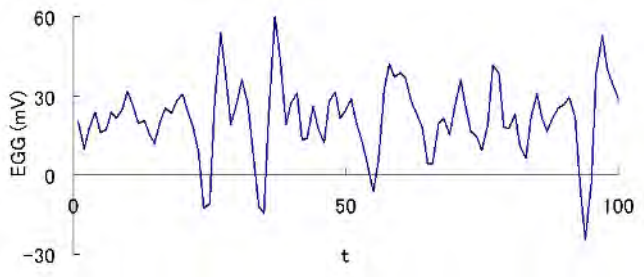

Fig. 4 A typical EGG time series. (Sampling frequency is 0.5 Hz.)

In the next step, we would quantitatively evaluate the affinity by using translation errors [23] and Lyapunov exponents [24]-[26] in embedding space. Translation error (E_{trans}) measures the smoothness of flow in an attractor, which is assumed to generate the time-series data. In general, the threshold of the translation error for classifying the time-series data as deterministic or stochastic is 0.5, which

is half of the translation error resulting from a random walk. The chaos processes are sensitively dependent on initial conditions and can be quantified using the Lyapunov exponent [26]. If the Lyapunov exponent has a positive value, the dynamics are regarded as a chaos process.

Possibility of MEG as an Early Diagnosis Tool for Alzheimer's Disease: A Study of Event Related Field in Missing Stimulus Paradigm

N. Hatsusaka, M. Higuchi and H. Kado

Applied Electronics Laboratory, Kanazawa Institute of Technology, Kanazawa, Japan

Abstract — **We are investigating a diagnosis to find Alzheimer's disease (AD), which is a kind of dementia and one of the most prominent neurodegenerative disorders, using a magnetoencephalography (MEG). MEG is one of non-invasive technique to investigate the brain function by using an array of superconducting quantum interference device (SQUID) sensors arranged around the head. In this study, we observed the event-related field in 'missing stimulus' paradigm. The subjects were presented short beep tones with a certain interval. Some tones were omitted randomly from the sequence and this omission was called 'tone-omitted event'. We focused on the specific magnetic field component induced by the tone-omitted event. 32 patients with early AD and 32 age-matched controls were examined by 160-ch whole-head MEG system. The MEG signals related to the tone-omitted events were collected from each subject. The amplitude of the averaged waveform in the AD group was significantly smaller than that in the control group. This result suggests that MEG is useful for AD diagnosis.**

Keywords — **MEG, Alzheimer's disease, auditory stimulus, Event Related Field, missing stimulus paradigm**

I. Introduction

Magnetoencephalography (MEG) is one of the non-invasive methods to investigate the neural activity in the brain, based on biomagnetism measurement. MEG can detect magnetic field generated by electronic neural activity of the brain. The neural activity is inducing by post synaptic activity in the cortex. The intensity of the magnetic field elicited from the brain is several femto or pico tesla. Such small magnetic field can be detected only by superconducting quantum interference device (SQUID) sensors. A recent whole-head MEG system is equipped with a head-shaped array of more than one hundred SQUID sensors.

There are several brain imaging techniques to measure the brain function other than MEG system. Positron emission topography (PET) and single-photon emission computed tomography (SPECT) observe the brain function by using radioactive isotope doped in the subject's body. Functional MRI observes the brain function using a strong magnetic field. These systems measure the chemical changes by metabolic activity of nerves. MEG and electroencephalography (EEG) can directly observe the neural electronic activity. The EEG has the lower spatial resolution than the MEG because the electric potential distribution on the scalp is influenced by the difference of the conductivity among the tissues, such as skull and scalp etc. On the other hand, the magnetic field distribution is not distorted because the permeability of the body tissues is constant and is the almost same as the space permeability. MEG has higher temporal and/or higher spatial resolution than other techniques.

Alzheimer's disease (AD) is one of the most severe neurodegenerative disorders. AD diagnosis is mostly based on clinical features, and difficult to find this disease in early stages. MEG is expected to be an early diagnosis tool for cerebrodegenerative disorder. We are developing diagnostic protocols to find out the early stage of AD using MEG system.

II. Missing stimulus paradigm

Intensity of MEG signals responding to single stimulus is usually too small and submerged in noise. Therefore, the stimulus is repeatedly given to the subject and every MEG signal evoked by the stimulus is averaged to improve the signal to noise (S/N) ratio. For example, in the case of typical auditory evoked magnetic field measurement a tone must be repeated more than one hundred times. It takes several minutes to acquire the signals with the good S/N ratio.

It is often difficult for AD patients to control their concentration of attention to the stimulus during the MEG measurement. The missing stimulus paradigm is a kind of passive attention tasks, in which subjects don't need to pay attention to stimuli. The subjects were presented short beep tones with a certain interval. Some tones were omitted randomly from the sequence and omissions were called 'tone-omitted event'. In EEG study with the missing tone stimulus paradigm, it was reported that the specific response with about 200 ms in latency, called N200, was evoked by the tone-omitted event [1][2]. The N200 response is one of the event-related potential (ERP). It is considered as the components related to the stimulus discrimination and is used in cognitive function [3]. The missing tone stimulus paradigm is expected to be useful for diagnosis of the dementia because the subject has only to receive the tone sequence with the omission passively.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 9–12, 2009
www.springerlink.com

In this study, we measured event related magnetic field (ERF) which is the magnetic counterpart of ERP in the missing tone stimulus paradigm. AD patients and age-matched controls (NC) were examined. We compare the results of both group and discuss the possibility of MEG as an early diagnosis tool.

III. Materials and Methods

A. MEG measurement

MEG measurement was performed in a magnetically shielded room using a 160-ch whole-head type MEG system developed at Kanazawa Institute of Technology shown in Figure 1. The MEG signals were processed by an on-line band pass filter of 0.1-200 Hz and digitally sampled at 1000 Hz. Subjects lay down on a bed and closed their eyes during the measurement. Auditory stimuli were delivered to the left ear of the subjects through an air tube.

B. Subjects

32 patients with early AD [mean age, 70.8±9.2(SD); 19 male, 13 female] and 32 NC subjects [mean age, 71.4± 4.7(SD); 13 male, 19 female] participated in this study. AD patients were recruited and were ascertained clinical diagnosis of AD by the neurologists at Kanazawa University Hospital. Demographic clinical and neuropsychological data on subjects are shown in Table I. All subjects were checked by Mini Mental State Examination (MMSE). In addition, AD subjects were examined by Clinical Dementia Rating (CDR) scale.

C. Stimulus

We presented a sequence of 1000 Hz short beep tones (50 ms width, 80 dB) at fixed temporal intervals (800 ms inter-stimulus-interval). Some tones were omitted randomly with a probability of 15 % from the sequence. Time sequence of missing stimulus paradigm and MEG recording are illustrated in fig.2. One stimulus sequence was 3 minutes-long and about 30 stimuli were omitted. The stimulus sequence is repeated twice. We didn't tell to the subjects that there would be the omit events in the stimulus sequence. The subjects were told not to mentally count the number of the tones.

The MEG data for 2000 ms around the tone-omitted event were extracted. Each extracted data from a subject was averaged to improve the S/N ratio.

Table 1 Demographic clinical and neuropsychological data of AD and NC

Group	AD group mean±S.D.(range)	NC group mean±S.D.(range)
Number of subjects	32	32
Age	70.8±9.2 (54-86)	71.4±4.7 (64-83)
Sex (males/females)	19/13	13/19

Fig. 1 160-channel whole-head MEG system.

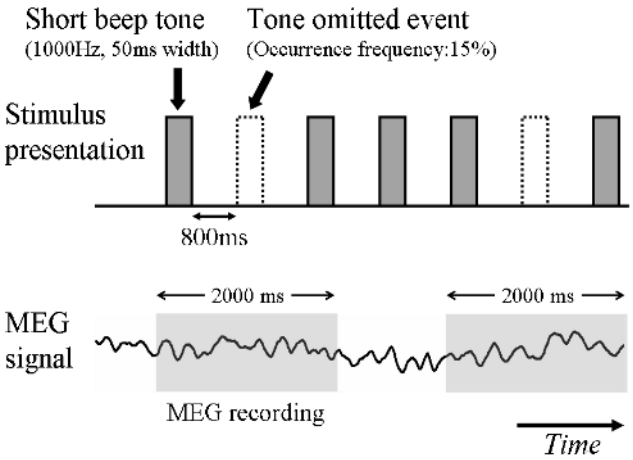

Fig. 2 Time sequence of the missing stimulus paradigm and MEG signal.

IV. Results

After the MEG measurement, we investigated whether the subjects noticed the omission of the some tones in the stimulus sequence. As a result, it was found that 15 NC subjects noticed the omitted events. 17 NC subjects and all AD patients did not notice the omission. We analyzed only

the right hemisphere which is dominant hemisphere to left ear stimulation.

Fig.3(a) shows an example of the averaged MEG signals including the most prominent response from a NC subject. There are three obvious peaks, A, B, and C, in the averaged MEG signal. The peak A and C correspond the typical auditory response to tone stimuli called N100m. The isofield contour map corresponding to the peak A is shown in Fig.3(b). The magnetic field pattern at the peak A was observed over the superior temporal area and its source was estimated at primary auditory cortex. The peak B was found at about 200 ms after the omitted event. This is considered as the magnetic counter part of the N200 response to the tone omitted event. In this paper, we call it N200m response. The isofield contour map corresponding to the N200m response is shown in Fig.3(c). The magnetic field pattern of the N200m response was similar to that of the N100m response. The source location of the N200m response was also close to that of the N100m response.

We estimated group mean waveforms of the averaged MEG signals separately between AD group and NC group as shown in Fig.4. The N200m response and N100m response were prominently observed in the NC group. On the other hand, the N200m response was not clear in the AD group. The amplitude of the signals corresponding to N200m response in the AD group was significantly smaller than that in the NC group ($p < 0.02$, paired t-test).

We separated the NC subjects into two groups. One is the group of the subjects who noticed the tone omission (omission-conscious group). The subjects in the other group didn't notice the omission (omission-unconscious group). We estimated group mean waveforms around the N200m response for the AD group, the NC omission-conscious group, and the NC omission-unconscious group separately as shown in Fig.5. We didn't obtain significant difference of the amplitude of the N200m response peak between the omission-unconscious group and omission-conscious group by paired t-test. This means the N200m response is found from the NC subject independently of consciousness of the tone omission.

On the other hand, all AD patients didn't notice the tone omission. The amplitude of the MEG signal corresponding to the N200m response from the AD group was significantly smaller than that from the NC omission-unconscious group ($p < 0.05$, paired t-test).

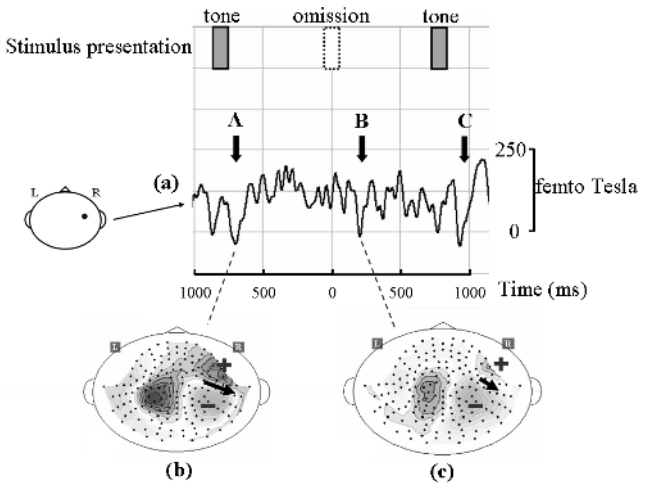

Fig. 3 The averaged MEG signals including the most prominent response from a NC subject.

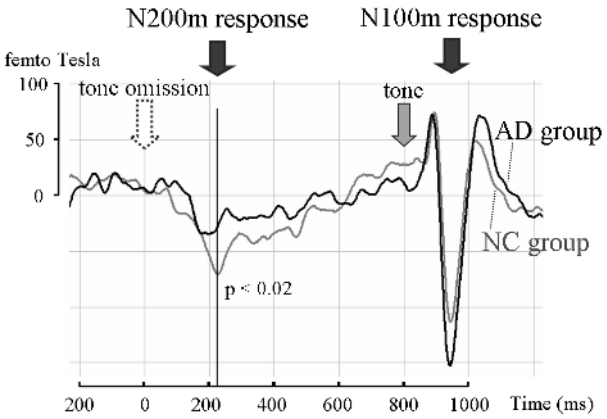

Fig. 4 The group mean waveforms of AD group and NC group.

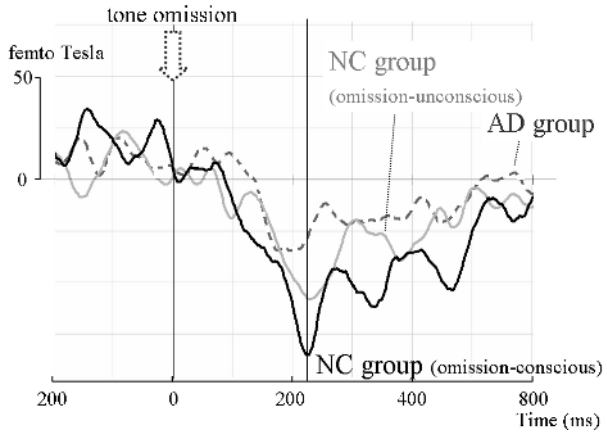

Fig. 5 The group mean waveforms of NC omission-conscious / unconscious group and AD group.

V. Discussion

We could detect the N200m response evoked by the tone omitted event in the NC group. This response was observed

regardless of consciousness of the stimulus in the NC group. However, it was not found in the AD group. This indicates that the absence of the N200m response to the tone omission would be an index of the early stage of AD.

There is a well-known event related potential called mismatch negativity (MMN) in EEG study. It is related to the 'deviant' in the stimulus sequence and is detected even if subjects didn't pay attention to the stimuli. To obtain auditory MMN, a passive oddball paradigm should be applied. In this paradigm, some tones in a stimulus sequence replaced to deviant tones with a certain probability. The subject is given the stimulus sequence with an instruction to ignore the tones. The specific negative component at about 200 ms only after the deviant stimulus is found. This component is called MMN.

The magnetic counterpart of auditory MMN is also detected using MEG with the passive oddball paradigm. It is called mismatch field or MMNm. Pekkonen et al. reported that the auditory MMNm would also be an index of the early stage of AD using the passive oddball paradigm. It is also useful examination for AD patients because the concentration of the attention to the stimulus during the MEG measurement is not necessary as well as the missing stimulus paradigm.

The response to the deviant tone in the passive oddball paradigm is mixture of the N100m response to the tone itself and the MMNm component. Therefore, the extra treatment is always necessary to extract the MMNm component from the obtained MEG response. The MMNm is usually extracted by the subtraction of the MEG response to the standard stimulus from that to the deviant.

In contrast to the MMNm test, the N200m response to the missing tone can be obtained without such an extraction process because the N100m response is not included in the response to the missing tone event.

We compared only amplitude of ERFs between AD subjects and NC subjects in this study. However, the amplitude of MEG signals is affected by the head size and relative position between the head and the sensor array. We are considering two parameters, the ratio between the N200m response and the N100m response and the correlation between magnetic field patterns. To use these parameters, the variable magnetic intensity among the subjects is normalized.

VI. Conclusion

We evaluated the specific MEG component in the missing stimulus paradigm. We could find the significant difference of the amplitude the MEG signals related to the omitted event between AD patients and NC subjects. The method using MEG proposed in this paper can be easily applied to any human subjects. It indicated that the absence of the response to the omitted tone event would be a good index for diagnosis of the early stage of AD.

Abstract — **The aim of this paper is to investigate new neural network algorithms, architectures and models which are inspired by the image processing capability of the visual system in the human brain, and subsequently to apply these models to medical imaging(MI) applications. Realizing the neural network architecture on FPGA that supports parallelism and reconfigurability. A sincere attempt is taken up to implement the complex and massive parallel architecture on FPGA optimising speed, area, and power with out compromising on image quality and SNR that is a very important criteria for medical image compression. Multi layered neural network (NN) architecture is proposed for compression of high-resolution image, the architecture is implemented on FPGA as it supports reconfigurability. The architecture considered has N-M-N (64-4-64) multi-layered NN structure, which achieves compression ratio of (CR) 93.75. Compression ratio is reconfigurable with change in M. The architecture is generalized and can achieve compression ratios from 2 to 99, which is reconfigurable. Performance of any neural network architecture for compression depends on training; this architecture considers general back propagation training. The training is performed offline, with known set of image samples consisting most of the properties of any standard image. The Mean Square Error (MSE) computed during every iteration of training is scaled and fed back into the network to update the weight matrix at specific points, this reduces the training time. As the weight matrix occupies more space for storage, the redundancies in the weight matrix are exploited and a storage space is created with minimum memory requirement on FPGA. Compression ratios obtained demonstrate performance superiority of the network as compared with JPEG compression standard. Inserting noise on the compressed sets of data, tests the network performance. The hardware complexity, area requirement, speed is compared and discussed; there is a saving of 22% of space on FPGA, with 40% increase in speed, and reducing the power by 12%. The major advantage of this architecture is its reconfigurability on the architecture size that achieves different compression ratios.**

Keywords — **FPGA, Neural Networks, ANN, Matlab, VHDL, Canonic Signed Digit (CSD), Multipliers.**

I. Introduction

"A picture is worth a thousand words." This axiom expresses the essential difference between our ability to perceive linguistic information and visual information. Image that conveys more information than any other data requires huge storage unit and bandwidth for transmission. There is lot of challenges to realize image compression on either hardware or software. Whenever there are challenges there are opportunities.

Recently, there has been an increased interest in the investigation of parallel information processing systems [1]. These so called "artificial neural networks," or simply "neural networks" are networks of simple computational units operating in a parallel and highly interconnected fashion. A neural network can be defined as a "massively parallel distributed processor that has a natural propensity for storing experiential knowledge and making it available for use" [1].

Neural network based image compression techniques mainly involves selection of the network, selection of suitable training technique, selection of suitable training samples, training of the network and calculation of weights, freezing the weight matrix with bias and using the trained network for compression and decompression. In this work the NN architecture with N-M-N (64-4-64) is selected, which can achieve compression ratios from 2 to 99, back-propagation technique algorithm is used for accurate training but this consumes time, appropriate data sets have been selected for accurate computation of weight matrix that can compress any image having the common features.

Section II discusses the back-propagation technique for training the neural network for image compression. Section III discusses the design and Section IV discusses the results and V conclusion.

II. Neural network training

The neural network architecture selected in this work comprises of 64 input forming the input layer which is fed to the hidden layer of size 4x1, the outputs of the output layer is further fed to the output layer of size 64 to get back the original matrix. Back-propagation is one of the neural network training which are directly applied to image compression coding [2,3,4]. The neural network structure

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 13–17, 2009
www.springerlink.com

can be illustrated as in Figure.1. The input layer and output layer are fully connected to the hidden layer. Compression is achieved by designing the value of *K*, the number of neurons at the hidden layer, less than that of neurons at both input and the output layers. The input image is split up into blocks or vectors of 8 X 8, 4 X 4 or 16 X 16 pixels. In accordance with the neural network structure shown in Fig.1, the operation of a linear network can be described as follows:

$$h_j = \sum_{i=1}^{N} w_{ji} X_i, 1 \le j \le K \qquad (2.1)$$

For encoding and

$$\overline{X_i} = \sum_{j=1}^{K} w'_{ij} h_j, 1 \le i \le N \qquad (2.2)$$

For decoding where $xi \in [0, 1]$ denotes the normalized pixel values for grey scale images with grey levels [0, 255] [2,5,6].

In this work the image samples have been appropriately selected to achieve accuracy in the image compression and decompression. The image data sets should consist some of the properties like edges, diagonals, curves, random variations and discontinuities. Figures,3,4, and 5 shows the kind of image samples selected for training the network.

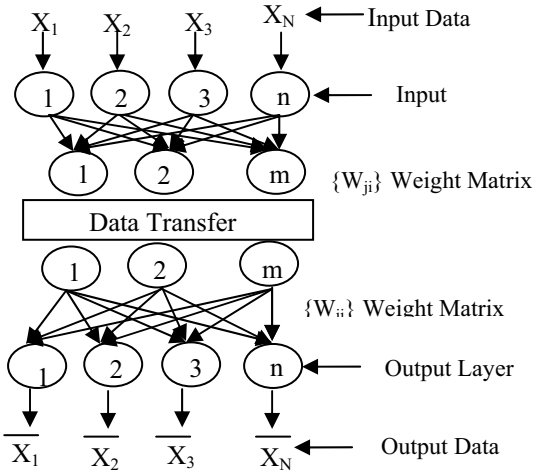

Fig.1 Simple Compression Model

III. Design

Table 1 shows the compression ratios with the network sizes. The training is accomplished on the network with maximum nets. This helps in varying the dimension, which can be reconfigured as per the requirements. Cottrell et al [6] has used a two layered neural network model with neurons in the second layer (output layer) more than the neurons in the first layer as shown in figure 1.

The input image of size N×N is regrouped in to smaller blocks of 4×4. Each 4×4 block is further converted to 16×1 linear matrix, and rearranged in to a linear set of 16×M matrix. The input matrix of size 16×1 is transformed to 4×1 by the first layer. The 4×1 matrix is further decompressed to 16×1 by the output layer bellow equation explains the process of compression.

Table 1. Network Size and Compression Ratios

Network size	Size of hidden layer	Compression ratio
64-64-64	64	0%
64-32-64	32	50%
64-16-64	16	75%
64-08-64	08	87.5%
64-04-64	04	93.75%
64-01-64	01	98.5%

[4×16] [16×1] = [4×1]
[W_f] [I] = [C]

W_f is the weight matrix on the input, I is the input matrix, C is the compressed output of the first layer. C matrix is fed to output layer to get back the original matrix.

$$[16\times4]\,[4\times1] = [16\times1]$$

$$[Ws]\,[C] = [D]$$

For the input to be equal to the target i.e. I=D, the weight matrix W_f and Ws is to be identified, which is achieved by the setting W_f and W_s to initial values and updating the values of W_f and W_s based on error between D and the actual target [T=I]. This processing of updating the weights to get minimum error in the output is training. The following are the complexities in training and hardware implementation:

1) To update the entire 128 weight matrix requires more time the updation time increases with increase in number of iterations.
2) Most of the weights are found to be redundant; even then they are stored separately in a memory.
3) The weights are in the range of ± 1.2, hence there is a need for accurate binary representation.
4) Compression depends upon number of neurons considered in the first layer.
5) There is a need for generalization of the network so that it can compress and decompress any set of image data.

The proposed work addresses these issues. The architecture is realized on FPGA. The results obtained are compared with the architecture reported in the literature.

Proposed Work

The Neural Network architecture of size 64-4-64 a two-layered network is considered. The input weight matrix which is of size [4×64] and output weight matrix of size [64×4] is initialized to an arbitrary value. To generalize the network for compression and decompression of any image, 20 sets of image samples are considered having all the properties of an image such as vertical lines, horizontal lines, diagonals, curves, edges, plain surfaces and sharp edges. The network is trained using these data sets, so that the weight matrix obtained can work with any unknown image having the basic qualities of the image. Keeping track of the way in which the weight matrix is being updated the algorithm developed for training is modified so that the weight gets updated only at required positions, which reduces the total time required for training. As the training is done offline using MATLAB simulator, the total time in training with the proposed work is compared in table 2. The time is reduced as the weights are not updated at every node, but is updated only at specific points based on the previous history of the network. This is shown in figure2.

Table2. Column3 depicts the total CPU time taken for training based on modified algorithm. Column 4 in table2 depicts the difference between the actual weights and the weights calculated using the proposed method.

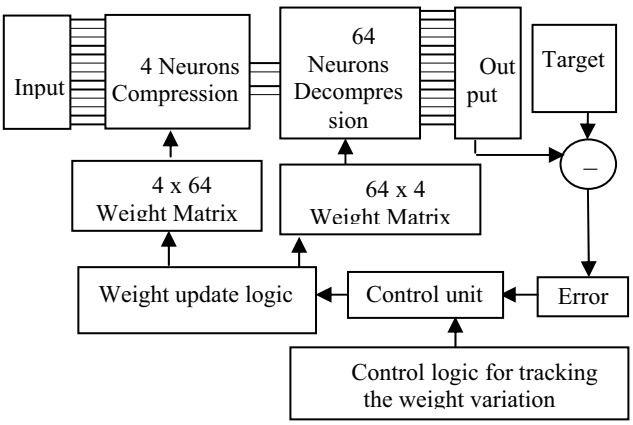

Fig. 2 Proposed model for updating the weights at specific location

Fig. 3 Medical Image (MRI Scan)

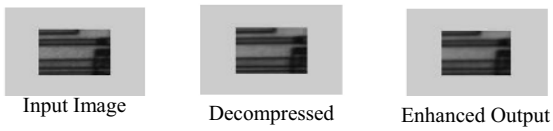

Fig. 4 Real World Pictures (Gunshot)

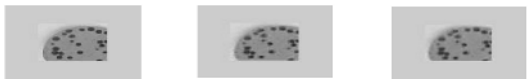

Fig. 5 Electronic Image (Circuit)

The MATLAB results after training and simulation it was found that even in the presence of noise the output layer was able to generate the original data. This is one of the major advantages of using NN techniques for compression. Enhancing further the decompressed data can eliminate the noise obtained at the receiver.

The accuracy of the receiver in reproducing the original image increases with increase in training sets and number of iteration. In this work the training is carried out until the error is reduced to 0.001. The weights calculated in the proposed method have the valves ranging from ±1.2. In order to represent the weight using binary number system, canonic signed digit number system is used which can represent the numbers ranging from ± 4/3. The advantage of this number system is such that it reduces the number of operations required in implementing the product of two matrices.

Table 2 CPU time for weight calculations/training

Images	Normal CPU time	Proposed CPU time	Error in weight matrix between general-proposed architecture
Test1	346 units	186 units	± 0.02
Test2	524 units	254 units	± 0.18
Test3	686 units	320 units	± 0.01
Test4	496 units	210 units	± 0.11
Test5	128 units	90 units	± 0.06

Simulation Results

Simulation waveforms obtained from for the CSD Multiplier done using Xilinx ISE and ModelSim, it is shown in figure 6 for 40 x 0.6.

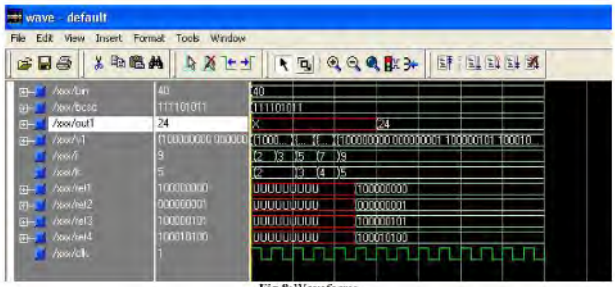

Fig. 6 CSD multiplier waveforms using ModelSim

Storage space requirement

The weight matrix on the input side consists of 4×64 and the output side consists of 64×4, there are totally 128 weight elements. Each weight is represented using 10-bit BCSD number system; this consumes a space of 1280bits. The weight matrix observed which is shown table4, explains the redundancy in the weights. It also demonstrates the range of the weight matrix, hence very much suitable for CSD representation.

Table 3. Weight Matrix 4x16 – only few columns are shown
net_s.IW (1,1) ans =

Columns 1 through 4

0.0023	0.0105	0.0342	0.0546

The results obtained have been compared with its MATLAB counterpart. It is found that both the results almost match. This RTL code is synthesized using Xilinx ISE targeting Spartan III 400K gate device.

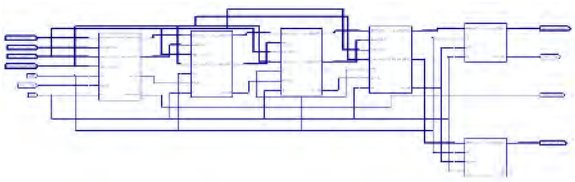

Fig. 7 Synthesized RTL using Xilinx ISE on Spartan III 400K gate device

IV. Hardware analysis and results

After the implementation of the above said CSD multiplier based NN architecture for image compression with modified weight storage matrix on FPGA we obtain the following results. Time taken, power consumed and hardware utilization by one multiplier to produce output is 13ns, 25mW, and 20%.

Table 4. Summary of the hardware implementation results

Gate count		Power	Max Frequency
Modified	General		
80K out of 400K (20% of the entire gate count available)	102K out of 400K gates (26% of the entire gate count available)	25mW (Leakage and switching power) reduced by 12% as when compared to the general architecture	13ns (76 MHz) increased by 40% as when compared to the general architecture

The number of I/O cells including the input, compressed data, output and control pins is reduced to 78; this can be reduced further if we increase the compression ratio. Figure 8 show the comparison of the area, timing and power report for different network size taken in table 1. The timing, area and power get optimized with higher compression ratio, however affecting the quality of the image.

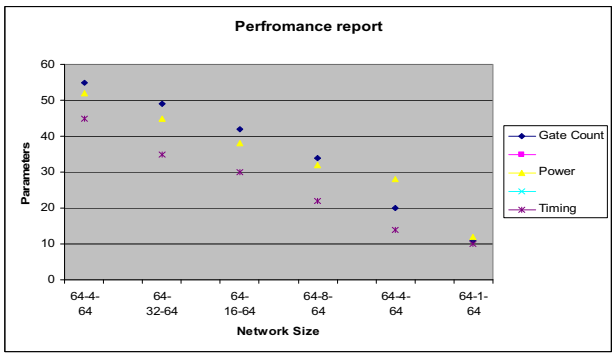

Fig. 8 Comparison of area, time and power.

V. Conclusion

The results obtained and discussed in this work clearly demonstrates the superiority of NN based techniques for medical image compression. With NN techniques being adopted SNR is within the expected limits and is better than classical techniques. SNR is remaining constant with increases in compression ratio. This demonstrates the effectiveness of NN based techniques proposed in this paper

for medical image compression. Different compression ratios can be achieved by only changing the hidden layer size. This is achieved by selecting the appropriate weights required at the input layer and out put layer. FPGA implementation of the proposed work optimizing speed, area, and power is discussed. This can be further optimized when implemented on ASIC, which looses the property of reconfigurability. Proper selection of training data sets with number of training iterations introduces redundancy in the weight matrix which can be exploited to reduce the storage space and hence optimized area. Selection of image sets for training imposes a limitation on the performance; different medical images have multiple properties that cannot be captured with unique weight matrix. This networks performance is found efficient for only a set class of medical images.

[3] Department of Electrical, Electronic & Systems Engineering, Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia

Abstract — **Noninvasive measurement of brachial artery (BA) flow mediated dilation (FMD), commonly measured by high resolution ultrasonography, has provided a non-invasive means for the evaluation of endothelial function. Recently, another technique based on finger photopletysmogram (PPG) analysis has been proposed by the authors. In this paper, simultaneous measurement of BA FMD and PPG signals data from 86 human subjects (43 healthy and 43 risk) is analyzed and a statistical model is proposed to estimate the BA FMD based on PPG signals, the BA diameter at baseline as well as other demographics factors such as age and gender. Linear regression by multivariate analysis was conducted to obtain the variables that were significantly related to BA FMD. The mean of absolute error for the model was 0.16 ± 0.12 and the estimated data (via PPG) is correlated to the measured one (via ultrasound) with a correlation factor R = 0.725. As a confirmation, it was found that the estimated FMD for the risk group (22.3 ± 3.4 %) was significantly lower than that of the healthy group (25.9 ± 3.5 %), $p < 0.01$, whereas a similar trend was observed from the measured data: risk group (22.3 ± 5.2 %) versus healthy group (26.1 ± 7.8 %), $p < 0.001$. The model can estimate peak BA (ultrasound) FMD from the information of the baseline BA diameter and peak PPG AC, allowing for an alternative means of evaluating the endothelial function.**

Keywords — **Endothelial function, flow mediated dilation, photoplethysmography**

I. Introduction

Endothelial function (EF) – a phenomenon known as the ability of the vascular endothelium to vasodilate [1] in response to physiologic and pharmacologic vasodilators [2], is commonly measured non-invasively through high resolution ultrasound measurement of the brachial artery (BA) before and after flow mediated dilation (FMD) stimulation by temporary cuff occlusion at the BA. Due to the main drawbacks of the technique which include the requirement of skilled operators to handle the ultrasound system and measure in real-time the BA diameter, and extended cuff occlusion time (up to 5 minutes) to stimulate for FMD response, we have proposed the evaluation of EF by analysis of the finger photoplethysmogram (PPG).

Parallel data acquisition of peak BA FMD and peak PPG pulse amplitude (AC) responses were conducted to validate the efficacy of the newly proposed method. We have demonstrated that the analysis of pulse amplitude changes of the finger PPG induced by BA FMD is capable of detecting the FMD response in the peripheral circulation in a similar manner to the conducting artery [3]. In this paper, using the available data of BA FMD and PPG AC gathered from the previous study, we examined a statistical modeling using linear multiple regression.

Data of 43 healthy subjects (free from any cardiovascular disease (CVD) risk factor) and 43 risk subjects (possessing at least one CVD risk factor) were included in the analysis of the statistical model. The healthy and risk groups comprised of males and females subjects of age matched. The main objective of the statistical modeling is to predict the individual subject's BA FMD response by using the subject's clinical parameters and the recorded PPG AC data.

II. Methods

A. Fundamentals of linear multiple regression

In a linear bivariate system, when two variables are correlated, then knowing one variable will allow one to predict the other variable by prediction through the linear regression equation. The stronger the correlation, the closer the variable will fall to the regression line and therefore the more accurate the prediction. Linear multiple regression is simply the extension of the linear bivariate principle, where one can predict a variable on the basis of several other variables. Having more than one independent variables is more rational and useful when predicting biological process as it is more likely to be influenced by some combination of several factors. Using the multiple linear regression one can test theories (or models) precisely which set of independent variables is influencing the dependent variable of the investigated system. The linear multiple regression can be represented as the following relationship:

$$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \ldots + \beta_k X_{ki} + \varepsilon_i \quad (1)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 18–21, 2009
www.springerlink.com

where Y_i is the dependent variable
$X_{1,2,...ki}$ are the independent variables
β_0 is the y-intercept
$\beta_{1,2,...k}$ are the slopes between $X_{1,2,...ki}$ and Y_i
ε_i is random error

Modeling by linear regression requires one to make a few assumptions regarding the predicted (dependent) variables and the model errors. The predicted variable is assumed to be linearly distributed and can be tested using the Kolmogorov Smirnov (K-S) test for normality. The errors for the model are assumed to be independent and the probability distribution of the error is normal with constant variance and zero mean.

In order to achieve the main objectives to predict the BA FMD response by the use of recorded peak PPG AC data, the following processes have been involved throughout the course of statistical modeling:

- study the associations between outcomes and predictors
- investigate the behaviour of model residues and multicolinearity of the predictors
- obtain a mathematical equations that represent the linear model
- predict cases using the regression model
- evaluate model performance

B. Statistical modeling using SPSS

In SPSS, the independent variables are identified as the predictor variables while the dependent variable is identified as the criterion variable. Multiple regression requires a large number of observations. The number of cases (participants) must substantially exceed the number of predictor variables used in the regression. The absolute minimum is five times as many participants as predictor variables [4]. A more acceptable ratio is 10:1, but some people argue that this should be as high as 40:1 for some statistical selection methods [4].

In the statistical methods, the order in which the predictor variables are entered into (or taken out of) the model is determined according to the strength of their correlation with the criterion variable. Several versions of statistical methods include Enter, Forward, Backward and Stepwise selection [4]. The Enter method is the direct method where variables entered are evaluated in the model. In Forward selection, SPSS enters the variables into the model one at a time in an order determined by the strength of their correlation with the criterion variable. The effect of adding each is assessed as it is entered, and variables that do not significantly add to the success of the model are excluded. In Backward selection, SPSS enters all the predictor variables into the model. The weakest predictor variable is then removed and the regression re-calculated. If this significantly weakens the model then the predictor variable is re-entered - otherwise it is deleted. This procedure is then repeated until only useful predictor variables remain in the model. The Stepwise method is the most sophisticated of these statistical methods where each variable is entered in sequence and its value assessed. If adding the variable contributes to the model then it is retained, but all other variables in the model are then re-tested to see if they are still contributing to the success of the model. If they no longer contribute significantly they are removed. Figure 1 shows the snapshot of SPSS screen window for linear regression analysis.

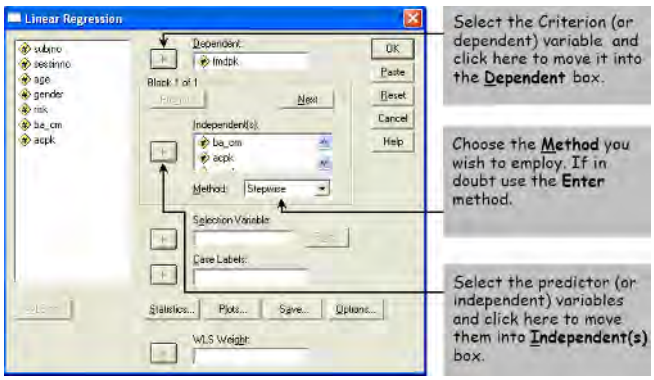

Fig. 1 Linear regression using SPSS

C. Model parameters

Beta (β): The β value is a measure of how strongly each predictor variable influences the criterion variable. It is also a measure of the correlation between the observed value and the predicted value of the criterion variable.

R Square (R^2): It is the square of the measure of correlation that indicates the proportion of the variance in the criterion variable which is accounted for by the model.

Adjusted R Square: It is the value calculated which takes into account the number of variables in the model and the number of observations (participants) the model is based on.

Multicolinearity: It is the correlations between pairs of variables which represent the measure of combined effects.

D. Model validation

Evaluation of the linear multiple regression model can be done by variation measure, residual analysis, parameter significance and test for multicollinearity. The indication of multicollinearity is correlations of pairs of X variables are more than correlations with Y variable. The remedy to this

problem is eliminating one correlated X variable from the model [5].

III. Results and discussion

Eighty six subjects (43 healthy and 43 risk) were included in the statistical model. The selected healthy and risk subjects have similar group mean age (42.7 ± 8.9 versus 46.5 ± 10.7, p = 0.077). All test variables (age, BA diameter, peak FMD and peak PPG AC) for the sample population were normally distributed. The first step to linear regression analysis was to obtain the information regarding the correlation between two variables. This was done by tabulating the Pearson correlation coefficients of pairs of variables. The variables that are significantly correlated will be entered into an initial model.

Since each of the variables included in the correlation test is correlated to some extent to another variable, the age, gender, risk, BA diameter, and peak PPG AC have been entered as the independent variables that were expected to influence the dependent variable of peak FMD. Results of the initial model coefficients computed using the enter method in SPSS were found non-significant ($p > 0.05$ in all situations) for age, gender and risk for CVD. However, the coefficients for BA diameter and peak PPG AC were significant coefficients ($p < 0.05$). Therefore, the age, gender and risk for CVD were removed from the model and the coefficients of the new model are shown in Table 1. In this model, only baseline BA diameter and peak PPG AC are the independent predictors for estimating the peak FMD.

All coefficients remain significant after the removal of the three variables in the initial model. Model residues (Table 2), which are the differences between observed value and the predicted value, for the new model have no outliers (minimum and maximum > ± 3), are independent (Durbin-Watson estimate ranges between 0 and 4.0 in Table 3) and are normally distributed [5]. There was no multicollinearity between BA diameter and peak PPG AC that is indicated by high tolerance, which gives the strength of the linear relationship among the independent variables [5]. Therefore, this model can be accepted and considered as the final model. The coefficients (B) from the final model coefficients represent the values of β_0, β_1 and β_2 of the generalized linear multiple regression as represented by equation 1. The final model can be represented as:

$$\text{peak FMD} = 35.72 - 4.71 \times \text{BA diameter} + 0.03 \times \text{peak PPG AC} \quad (2)$$

The adjusted R square (Table 3) indicates that 44.4 % of the BA diameter and peak PPG AC data are taken together to influence the dependent peak FMD data in the model. The estimated model output were then computed and compared to the measured data. The correlation between model output (estimated using equation 2) and measured data as well as the mean of the absolute error, which is the absolute difference between measured and estimated data, were evaluated to provide information regarding the model performance and the group statistics (Table 4).

Table 1 Model[a] coefficients

	Unstd. Coeff.		Std. Coeff.

Table 4 Group statistics for the final model

	Healthy group			Risk group			*t*-test
	N	Mean	SD	N	Mean	SD	p value
Measured peak FMD	43	26.4	7.67	43	22.3	5.19	0.005
Estimated peak FMD	43	26.6	4.29	43	22.4	4.21	< 0.001
Model error	43	0.16	0.115	43	0.17	0.120	0.728*

* Not significant

The estimated FMD for the healthy group (26.4 ± 7.67 %) was significantly higher than that of the risk group (22.3 ± 5.19 %), p = 0.005; similar trend as observed from the measured data, risk group (22.4 ± 4.21 %) versus healthy group (26.1 ± 7.8 %), $p < 0.001$. There was no difference between the two groups in terms of the absolute model error (0.16 ± 0.115 versus 0.17 ± 0.120), p = 0.768. Thus, the model absolute error can be represented as the total mean

error of 0.16 ± 0.117. The model output (estimated peak FMD) is correlated with the measured peak FMD for the sample population (R = 0.725) (Fig. 2). The receiver operating characteristics (ROC) for the estimated model output and measured data is shown in Fig. 3. Obviously, the model has better performance as the total area under the ROC for the model is larger than that of the measured data.

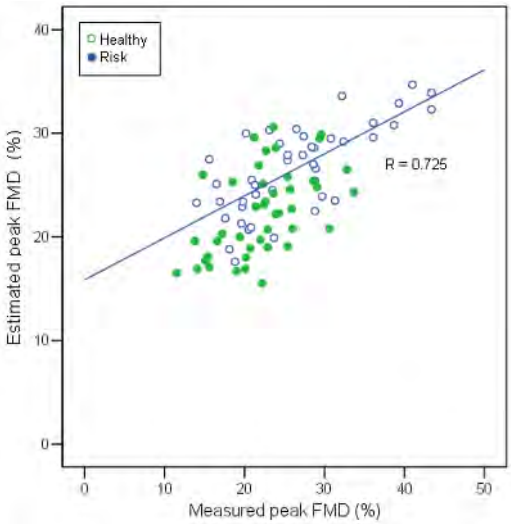

Fig. 2 Regression of the estimated and measured data

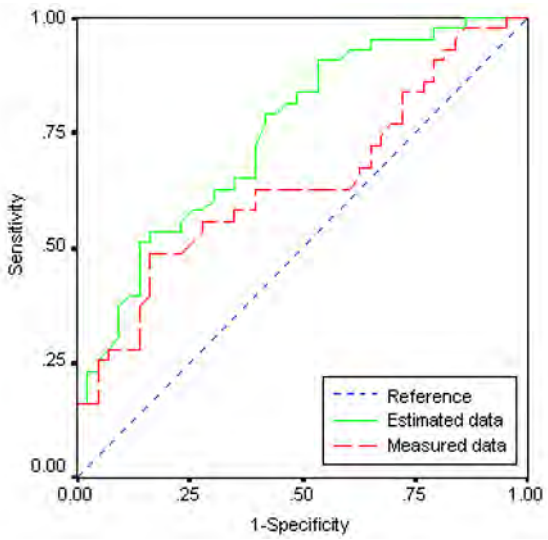

Fig. 3 ROC curve for the model (estimated) output and measured data

IV. Conclusions

In this paper, we demonstrated an exercise of statistical modeling. The results show that a statistical model by linear multiple regression can predict (by calculation) the peak BA FMD. The model uses the information of baseline BA diameter and peak PPG AC for a person to calculate for an estimated peak FMD for the person. The model provides means of estimating the peak BA FMD allowing for an alternative technique of evaluating the endothelial function.

Automatic Extraction of Blood Vessels, Bifurcations and End Points in the Retinal Vascular Tree

Edoardo Ardizzone, Roberto Pirrone, Orazio Gambino and Francesco Scaturro

Università degli Studi di Palermo
Dipartimento di Ingegneria Informatica
Building 6-3rd floor – 90128 Palermo (Italy)

Abstract — **In this paper we present an effective algorithm for automated extraction of the vascular tree in retinal images, including bifurcations, crossovers and end-points detection. Correct identification of these features in the ocular fundus helps the diagnosis of important systematic diseases, such as diabetes and hypertension. The pre-processing consists in artefacts removal based on anisotropic diffusion filter. Then a matched filter is applied to enhance blood vessels. The filter uses a full adaptive kernel because each vessel has a proper orientation and thickness. The kernel of the filter needs to be rotated for all possible directions. As a consequence, a suitable kernel has been designed to match this requirement. The maximum filter response is retained for each pixel and the contrast is increased again to make easier the next step. A threshold operator is applied to obtain a binary image of the vascular tree. Finally, a length filter produces a clean and complete vascular tree structure by removing isolated pixels, using the concept of connected pixels labelling. Once the binary image of vascular tree is obtained, we detect vascular bifurcations, crossovers and end points using a cross correlation based method. We measured the algorithm performance evaluating the area under the ROC curve computed comparing the number of blood vessels recognized using our approach with those labelled manually in the dataset provided by the Drive database. This curve is used also for threshold tuning.**

Keywords — **Anisotropic Diffusion, Matched Filter, Retinal Vessels, ROC curve.**

I. Introduction

The retinal image is easily acquirable with a medical device called fundus camera, consisting in a powerful digital camera with a dedicated optics [1].

The two main anatomical structures of the retinal image involved in the diagnostic process are the blood vessels and the optic disc. In particular, the vascular tree is a very important structure because the analysis of the vascular intersections allows discovering lesions of the retina and performing clinical studies [2]. We propose a vessel extraction method that has been tested on the fundus images provided by the DRIVE database [6][4]. It contains 20 test images where three observers performed manual extraction of the retinal vessels along with the corresponding ROIs to distinguish the foreground from the background. In [10] the vessel extraction is performed using an adaptive threshold followed by a multi-scale analytical scheme based on Gabor filters and scale multiplication. The method described in [11] makes use of a tracking technique and a classification phase based on fuzzy c-mean for vessel cross-section identification. Moreover, a greedy algorithm is used to delete false vessels. A final step is devoted to detect bifurcations and crossing points. In [12] the optic nerve and the macula are detected using images acquired with digital red-free fundus photography. After the vascular tree extraction, spatial features like average thickness, and average orientation of the vessels are measured. Our method starts removing artefacts using the anisotropic diffusion filter. Then a suitable matched filter kernel has been developed that is used with a contrast stretching operator to put in evidence the vessels with respect to the background. A threshold is used to obtain a binary image of the vasculature. The threshold has been experimentally tuned using the ROC curve, which describes the efficiency of the vessels classification with respect to the reference one provided by the Drive dataset. The last step is the use of a length filter to erase little and isolated. End-, bifurcation-, and crossover- points are detected like in [8]. In the rest of the paper the processing steps are detailed and the performance evaluation set-up is described. Finally some conclusions are drawn.

II. Blood vessels extraction

A. Artifacts removal

The retinal image is corrupted by strong intensity variations. A circle-shaped luminance peak can be seen in the region of the optical nerve, the fovea region exhibits intensity attenuation, because it is a depression on the retinal surface, and a diffuse shading artifact afflicts all the eye fundus. Before applying any segmentation task, an intensity compensation phase must be performed. Being the retinal image a RGB one, we consider the G channel of the RGB triad as the intensity image component (see fig.1-a). The most common way to suppress intensity variations consists in the application of the homomorphic filter, but it generates a halo artifact on the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 22–26, 2009
www.springerlink.com

boundary between the retina and the background (see fig.1-b). The filter must take into account a suitable Region Of Interest (ROI) to select the retina, thus avoiding this undesirable phenomenon. The G channel image is filtered using an anisotropic diffusion filter [13] and it is tuned in correspondence of the region selected by the ROI. The ROI is created as a binary image where the region surrounded by the boundary of the retina is filled with 1s (see fig.1-c). The boundary is extracted using a Canny edge detector. The resulting image (see fig. 1-d) is obtained using the following formula:

$$R(i,j) = \frac{G(i,j)}{G_f(i,j)}$$

Where $G_f(i,j)$ is the filtered versions of the original image $G(i,j)$. We wanted low-pass behavior for the anisotropic diffusion filter D, so adopted the Gaussian-like diffusion function instead of the Lorentzian-like one:

$$D(\nabla G) = e^{\frac{|\nabla G|^2}{k^2}}$$

Being an edge-preserving filter aimed to noise removal, the value of the parameter k must be enough high to warrant the low-pass behavior and it has to be selected as a function of the retinal intensity gradient ∇G in correspondence of the ROI. The parameter k is chosen as follows:

$$k = \alpha \cdot std(\nabla G)$$

α =5 and 50 iterations have been used for all the dataset. The intensities of the resulting image $R(i,j)$ have been normalized to the interval [0,1] to be independent by the input dynamics. A side effect of the adopted filtering is a contrast decreasing, so a contrast stretching is performed, as shown in fig.1-e. The target dynamics to be obtained by the stretching operator has been selected as follows:

$$[\mu - \beta \cdot \sigma, \mu + \sigma]$$

where μ and σ are the mean and the standard deviation, respectively. To avoid residual halo phenomenon, the output dynamics has been limited to 60% of the available one, and the input interval is unbalanced by the β coefficient, as it can be seen above. The value of β has been set to 1.5 for all the dataset. A final noise removal step based on anisotropic filter is performed, obtaining the image in fig.1-f. We determined experimentally the parameters for this task: k=0.3 and 3 iterations.

B. Matched Filter

The matched filter is a spatial filter whose kernel is the template of the vessel cross section. The kernel can be rotated so that it imitates the vessel displacement; it is convolved with the image to enhance the blood vessels. A suitable definition of the kernel is fundamental to obtain good performance. We used a kernel defined as follows:

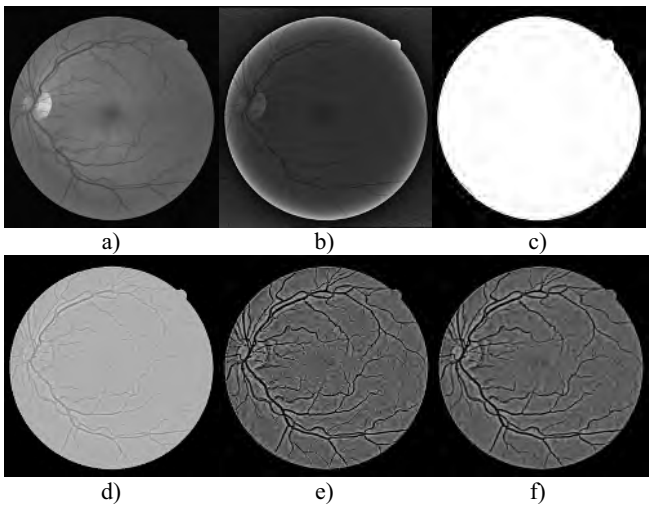

Fig. 1 a) Green channel of the RGB original image; b) the image in a) filtered with a standard homomorphic filter; c) the ROI; d) filtered image $R(i,j)$ using anisotropic diffusion; e) applying contrast stretching to the image in d); f) noise removal.

$$x_\theta = x\cos(\theta) + y\sin(\theta)$$

$$y_\theta = -x\sin(\theta) + y\cos(\theta)$$

$$f_1(x_\theta, y_\theta) = 0.5 - \frac{1}{1 + \left(\sqrt{\left(\frac{x_\theta}{\sigma_x}\right)^2 + \left(\frac{y_\theta}{\sigma_y}\right)^2}\right)^{esp}}$$

$$f_2(x_\theta, y_\theta) = -0.5 \cdot \frac{1}{1 + \left(\sqrt{\left(\frac{x_\theta}{k_1 \cdot \sigma_x}\right)^2 + \left(\frac{y_\theta}{k_2 \cdot \sigma_y}\right)^2}\right)^{esp}}$$

$$f(x_\theta, y_\theta) = f_1(x_\theta, y_\theta) \cdot f_2(x_\theta, y_\theta)$$

Here θ is the rotation angle, σ_x and σ_y control the length along the main directions, *esp* determines the roundness of the inverted Gaussian, k_1 and k_2 control lateral elongation along both x and y, and we subtract the mean value of f to keep them positive. We obtain 12 kernels varying θ [2]. The best results have been obtained using a 15x15 pixels wide kernel and the following parameters: σ_x = 100, σ_y = 0.18, *esp* = 2, $k_1 = k_2 = 3$ (see fig.2). Like in [8], a contrast stretching is performed on the Matched Filter Response (MFR) in the range $[\bar{x} - \sigma,\ \bar{x} + 2\sigma]$ where $\bar{x}$ is the mean value of the dynamics, and σ is the standard deviation.

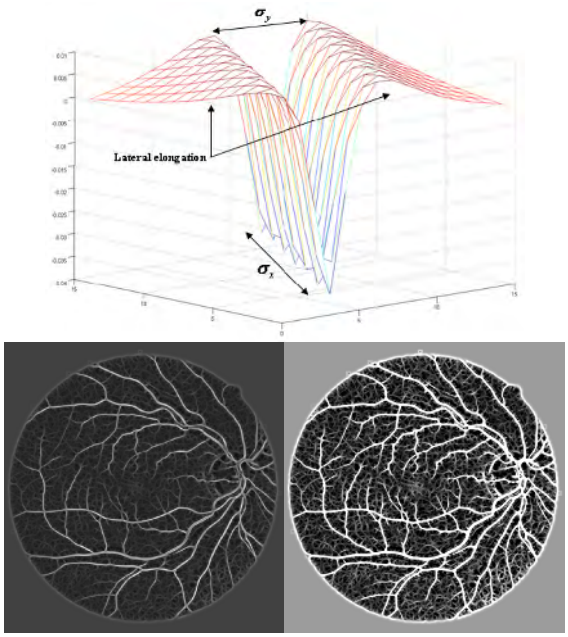

Fig. 2 UP: The kernel used for the Matching filter; DOWN: The Matched filter result (left) and contrast stretching application (right).

C. Threshold operator

A sliding threshold operator has been applied to the MFR image to obtain a binary image, which allows detecting blood vessels as connected components. The threshold value has been tuned comparing our result with the corresponding segmented image in the dataset. A ROC curve (Receiver Operating Characteristic) [7] has been drawn that is a Sensitivity vs. (1-Specificity) diagram while moving the threshold. These quantities are defined as follows:

$$Sens = \frac{TP}{TP + FN} \; ; \; Spec = \frac{TN}{FP + TN}$$

True positives (TP) are the recognized vessels, true negatives (TN) are non-vessel objects, and false positives (FP) are binary objects considered erroneously as vessels. Finally, we considered the background component in both images as the false negative (FN). The threshold value is selected in correspondence of the closest point to the unitary value of sensitivity and (1-specificity) (see fig. 4).

D. Small objects removal

The length filter cleans the image obtained applying the threshold operator by deleting little and isolated objects. Each object is labeled using the 8-connected component criterion and its area is measured. The object whose area is less than a threshold is cancelled. We fixed this value to 150 pixels.

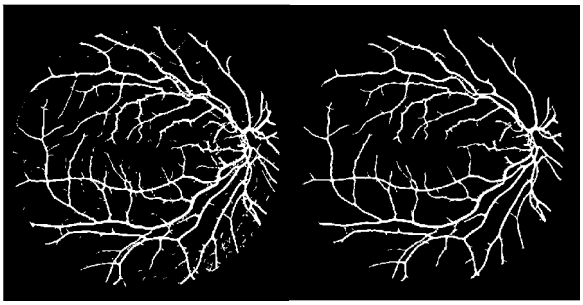

Fig. 3 Binary image obtained using the threshold (left), and small object removal (right).

III. Performance Evaluation

The efficiency analysis can be performed measuring the ROC curve area [7]. A ROC curve has been obtained for each test image in Drive database increasing the threshold values of the threshold. The mean sensitivity-specificity values have been used to draw the ROC curve in fig.4. The area under the ROC curve with our method is 0.953. Table 1 shows a comparison among different methods in literature (see [9] for a review) and our approach.

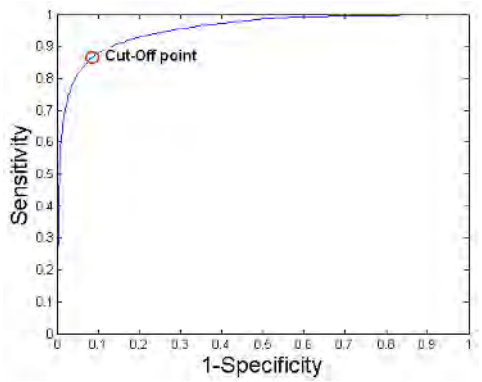

Fig. 4 ROC curve mean(sensitivity) vs. 1-mean(specificity) computed on the test images of DRIVE. The red circle indicates the best Cut-Off point used to select the threshold value.

IV. Feature points detection

End-points, bifurcations, and crossover points are detected like in [8]. Briefly, the morphological skeleton filter is applied on the binary image of the vascular tree and dedicated kernels are convolved with the resulting image to detect the feature points (see fig. 5 and fig. 6).

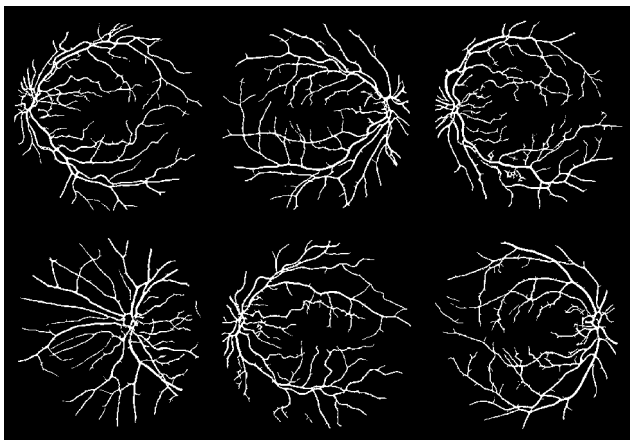

Fig. 5 Some examples of vascular trees extracted by the algorithm.

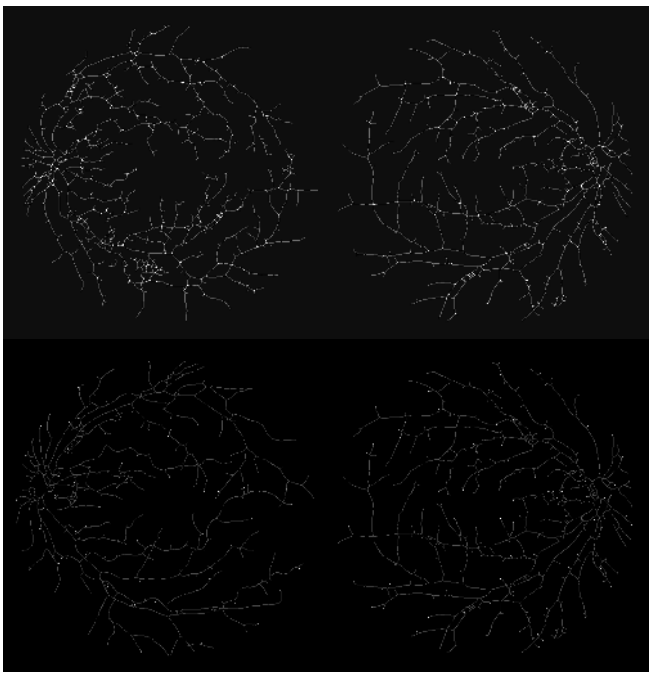

Fig. 6 Feature points detected on the trees depicted in fig. 5.

V. Conclusions and future work

A method for vessels extraction on retinal images has been presented. The performance is comparable with the most recent methods presented in literature, as shown in tab.1. The pre-processing plays a fundamental role so that better artifacts removal techniques and local filters must be developed to increase the contrast between vessels and background. In this way the Matched filter will be able to enhance the vessels in a better way.

Abstract — **Modelling techniques for optimizing bubble detection tools in the infrared band used in conjunction with a drug transport mechanism for the transport of intravenous fluids in clinical practice have been evaluated qualitatively using simulation techniques. Sensors which are used in signal processing often have limitation when they are made to work in noisy environment. Noise in the working environment can be from various sources such as from power line, high frequency RF fields and background luminance. In case of certain optical sensors, coupling schemes and the interference from devices which are in close proximity to the sensors can also contribute to significant noise. Qualitative studies on the effect of background luminance noise have provided a good understanding on the degree of susceptibility of the optoelectronic receiver for various luminance noises resulting in interferences in the output of a tool developed for the detection of air bubbles in fluid pathways called the "Optical Bubble Detection Tool". Experience gained from the earlier studies has provided the required knowledge for developing a design which is less susceptible to external disturbances. The dynamic excitation method for the "Optical Bubble Detection Tool" was introduced by modifying the electronic interface of the earlier "Optical Bubble Detection Tool". This was easily achieved by understanding the requirements of the pulsed current for energizing the transmitter of the "Optical Bubble Detection Tool". As the frequency of excitation and the intensity of the emitted infrared are factors which decide the resolution and sensitivity of the "Optical Bubble Detection Tool", it was optimized for several operating environments which are under the influence of other external radiations in the visible range and non-visible range.**

Keywords — **Bubble detection tool, Background luminance noise, Optical sensors**

I. Introduction

The rate of infusion in intravenous fluid delivery depends on the selected drug, dosage and the pathological condition of the subject receiving infusion. It is important that any drug transported into the body through the venous circulation should be free from air bubbles as accidental induction of air bubble in the vascular system can cause serious complications and is sometimes fatal [1].

Air bubble detection in a drug transport system is an important safety parameter and there are a few ways of detecting air bubble in the tubing of the drug transport system. Our studies were focused on two popular tools namely the "Ultrasound Bubble Detection Tool" and the "Optical Bubble Detection Tool". As the coupling factor between transducer and the tubing are very critical in the "Ultrasound Bubble Detection Tool", it demands specific tubing and interfaces for reliable detection. This problem related to coupling factor is however not a serious issue with the "Optical Bubble Detection Tool" designed for detecting air bubble in the drug transport system.

Studies on the development of the "Optical Bubble Detection Tool" were conducted with matched emitters and receivers working in the infrared band and we optimized the receiver and the transmitter based on the optical band suitable for intravenous drug delivery applications [1].

Sensors used in signal processing often have limitations when they are made to work in noisy environment. Noise in the working environment can be from various sources such as from power line, high frequency RF fields, background luminance in case of certain optical sensors, coupling schemes and the interference from electro mechanical devices which are in close proximity to the sensors. Noise components associated with the electronic detector circuit and system electronics have been discussed in detail by several authors [2, 3] and these are mostly Johnson noise, Flicker noise and Short noise. Most of the problems related to electrical noise and RF interference can be overcome by using suitable signal conditioners and the proper shielding techniques. However, noise problems associated with the optical devices due to background luminance and other optical interference cannot be easily handled by simple electronic signal conditioning tools and thus necessitates alternative techniques to overcome the limitations [1]. Based on our experimental study, we have modeled the "Optical Bubble Detection Tool" to improve its performance in real time applications. We have carefully analyzed the factors which are critical in operating the "Optical Bubble Detection Tool" in a given Infra Red (IR) band based on a simulation study and have also assessed the performance of the tool under various conditions [4].

www.springerlink.com

II. Materials and methods

Before evaluating the modeling techniques for this system, it is important to have some idea on the system architecture and the various modules it contains for meeting the requirements of the system as a whole.

The system architecture contains modules such as the optoelectronic module, microcontroller module, and the electromechanical module and these modules are all integrated in such a way that it is possible for the user to configure a model specific application protocol in drug delivery. Each module is further discussed in detail in this paper.

III. Modeling protocols

The conventional excitation mode, incorporating static excitation, is the most common mode of excitation seen in the earlier systems. A steady source of light in the infrared or near infrared range is generated with the help of constant current source generated from the common power supply. The steady beam of light after passing through the fluid transport tubing is translated as voltage variations reflecting the optical density of the medium transported. The advantages of the conventional excitation mode are that it is easy to tune the system for the required range of excitation for capturing the signals corresponding to a specific optical density and it is quite convenient to optimize the wavelength for a given optical pathway for the detection of the air bubble in the fluid transport tubing [5].

Though this excitation mode can easily be configured for the detection of the air bubble, it has many disadvantages in real time applications. The disadvantage of this excitation mode is that this mode is usually more susceptible to the ambient noise signal present around the source and the receiver. Thus, this system necessitates a very reliable optical shielding around the optical pathway to prevent interference from external luminance, which is present in any clinical setup. Qualitative studies on the effect of background luminance noise have provided a good understanding on the degree of susceptibility of the optoelectronic receiver for various luminance noises resulting in interferences in the output of the "Optical Bubble Detection Tool". The performance of the "Optical Bubble Detection Tool" for various operating conditions related to the external environment and the flow pattern has shown that there is no major deviation in the linearity of the system related to flow in the static excitation mode. However, in this mode, the "Optical Bubble Detection Tool" was found to be highly susceptible to the ambient noise created by the surrounding background luminance. A simplified scheme of the system is as shown in Fig. 1.

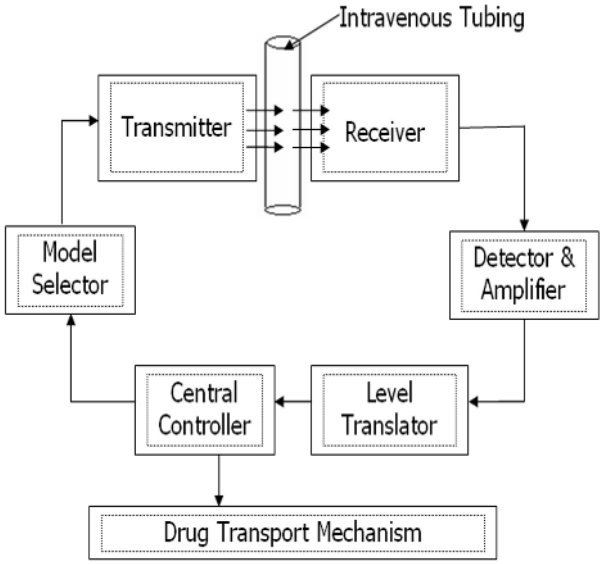

Fig. 1 Scheme for modelling "Optical Bubble Detection Tool" designed for Drug Transport System.

Studies conducted on the performance of the optoelectronic interface under various conditions have provided valuable data related to static excitation techniques.

Table 1 Result for Static Excitation Mode

Test Condition	Output in the Presence of Ambient Noise	
Air bubble present	Heavily Shielded Sensor	Unshielded Sensor
	Logic 1 (2.7V).	Logic 1 (2.7V).
Air bubble absent	Logic 0 (>0.6V).	Logic 1 (2.7V).

The limitations of the "static excitation" method have provided the basis for implementing "dynamic excitation" methods for using the "Optical Bubble Detection Tool". This has been further improved by the modeling techniques investigated during the development of the "Optical Bubble Detection Tool" in the drug transport system.

A. Dynamic Excitation Mode

In general, parameters such as optical wavelength, modulation frequency and receivers' capture threshold are critical in deciding the overall efficiency of the bubble detection system.

The dynamic excitation mode can be achieved in several ways and the most efficient way is to customize the parameters for a specific task related to the detection of bubble in the presence of common external interference in the given clinical setup. The dynamic excitation method for the "Op-

tical Bubble Detection Tool" was first introduced by modifying the electronic interface of the existing "Optical Bubble Detection Tool". This was easily achieved by providing pulsed current for energizing the transmitter of the "Optical Bubble Detection Tool". As the frequency of excitation and the intensity of the emitted infrared are factors which decide the resolution and sensitivity of the "Optical Bubble Detection Tool", it is to be optimized for an operating environment which is under the influence of other external radiations in the visible range and non-visible range. The microcontroller module, which is the heart of the central controller, is fully supported by essential interfaces such as system console and LCD display for setting the rate of infusion of the intravenous fluid and also for selecting an appropriate model for "Optical Bubble Detection Tool" [5].

Table 2 Results for Dynamic Excitation Mode

Test Condition	Output in the Presence of Ambient Noise	
Air bubble present	Heavily Shielded Sensor	Unshielded Sensor
	Logic 1 (2.7V).	Logic 1 (2.7V).
Air bubble absent	Logic 0 (>0.6V).	Logic 0 (>0.6V).

It can be seen that the results obtained using the dynamic excitation mode are more promising in the absence of air bubble, especially in situations where the output is to be realized in the presence of ambient noise with not fully shielded optical sensors.

IV. Operating principles

Flow of fluids in the drug transport mechanisms for therapeutic applications is assisted by the electromechanical module. The electromechanical module provides controlled peristalsis of the intravenous fluid through the transport tubing in a pre-programmed fashion and this is made possible by using the system console. The system console is user friendly and helps the user to set the parameters for treatment.

The "Optical Bubble Detection Tool" interfacing the central controller is at the entry point of the fluid transport mechanism and monitors for any air bubbles in the contents transported in the tubing.

A. Microcontroller Module

The basic program flow chart of the microcontroller architecture is shown in Fig. 2.

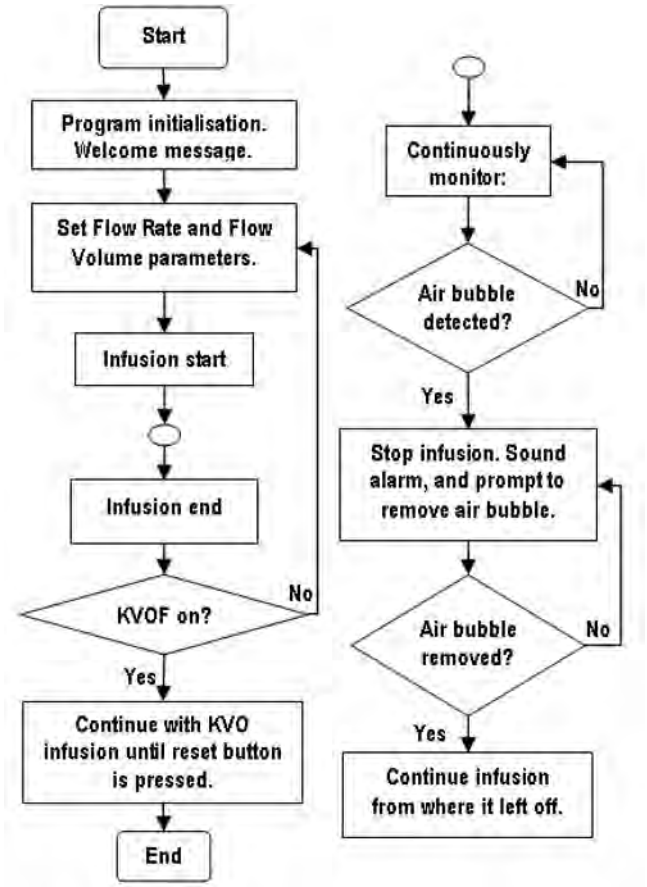

Fig. 2 Flowchart of the microcontroller module.

Intravenous fluid delivery mechanism is precisely controlled with the help of a microcontroller which has interfaces such as those linked to optical bubble detection system, system console for setting parameters, LCD display for displaying parameters and electromechanical module consisting of the linear peristalsis mechanism for regulating the fluid flow rate.

The ports of the microcontroller interfacing the system console allows the user to enter data related to flow volume and flow rate, and also to activate the "keep vein open function (KVOF)" if required.

B. System operations

After running the initialization routine, the microcontroller displays a welcome message on the LCD display of the system and prompts the user to set in parameters related to Flow Rate and Flow Volume. These parameters are entered using the system console.

Once the infusion process is activated, the process goes on and will end once the set amount of fluid is delivered at the pre-programmed rate. At the end of the fluid delivery it is possible to activate another function called the KVOF, which will ensure that the fluid pathway inside the intravenous needle will not get occluded due to the presence of venous blood flow.

If by accident, an air bubble should be present in the intravenous fluid infused, the "Optical Bubble Detection System" will detect the bubble and would activate an alarm for the user to remove the bubble before it could be infused into the venous system.

V. Preliminary studies

A. Reliability studies of flow rate and volume

The Linear Peristalsis Driver has been tested in real-time. We have tested the reliability of the device after setting a given Flow Rate and Flow Volume by running the system with the standard infusion package consisting of the infusion bag and intravenous tubing containing the drip chamber. By validating the settings for repeated trials for various settings, of flow rates and flow volumes, the reliability of the system was established under conditions existing in clinical setup.

B. Reliability studies on bubble detection

The sensitivity of the "Optical Bubble Detection Tool" was also checked under various conditions to record the immunity offered by the bubble detection circuitry in the presence of several luminance backgrounds. The luminance backgrounds were simulated to record the output of the "Optical Bubble Detection Tool" based on qualitative assessment.

VI. Results

In our studies we have modeled the "Optical Bubble Detection Tool" with the help of the central controller for dynamic excitation mode and we have found pulsed frequencies from 2 kHz to 10 kHz suitable in designing an application specific model for a given working environment. It was also possible to optimize the intensity of excitation based on the selected model working under a given situation.

VII. Conclusion

Studies carried out with the "Optical Bubble Detection Tool" in clinical practice has clearly indicated that the dynamic excitation mode modeled with the help of the central controller is more promising in providing reliable data in a noisy clinical environment. The electromechanical module of the system was found reliable in providing linear peristalsis of fluid over a long duration during preliminary studies.

General Purpose Adaptive Biosignal Acquisition System Combining FPGA and FPAA

Pedro Antonio Mou, Chang Hao Chen, Sio Hang Pun, Peng Un Mak and Mang I. Vai

Department of Electrical and Electronics Engineering, Faculty of Science and Technology, University of Macau, Macau SAR, China

Abstract — **This paper introduces a general purpose intelligent adaptive biosignal acquisition system both using Field Programmable Gate Array (FPGA) and Field Programmable Analog Array (FPAA). The design system inherits the powerful properties from the above devices to provide a stable and adaptive platform for processing various biosignals like ECG, EMG and EEG, etc. This system implementation solves the complexity in biosignal samples acquisition in home healthcare and stability in long term monitoring. It can be dynamically reconfigured and adapt to acquire different biosignals without changing any hardware. This system provides a simplified testing platform allowing different algorithms for processing real time biosignals embedded into it. In additions, the RS232 serial data port (or USB) can implement a connection with personal computer to ease and speed up the acquiring of biosignal samples or test results for further analysis. Alternatively, the system is also designed for outputting acquired and/or processed biosignals to PDA/PC at real time for visual inspection of results.**

Keywords — **adaptive, biosignal, acquisition, FPAA, FPGA**

I. Introduction

According to the World Health Organization (WHO), the percentage of death and disability caused by chronic diseases (including cardiovascular diseases) will soar from 43% in 2002 to 76% in 2020 [1]. WHO and governments in the world foresee this great demand for medical services and recognize the importance to reduce the rapidly growing pressure on limited medical resources. In addition, the growing concerns of people on self healthiness also speed up the pressure on medical resources and demand for home healthcare system.

Home healthcare system and telemedicine is one of the effective methods to assist in reducing the pressure on public medical resources by distributing health-caring and monitoring to patients' home or other remote locations. The cost in money and time can be controlled at a lower level (which could be very high in rural areas or developing countries) while providing more conveniences to patients in reading self-healthiness, and moreover, feasible to have functions for long term health status logging which is very rare but useful in today's medical system for treatment and prevention of diseases (including chronic diseases).

The emergence and rapid development of home healthcare system makes affordable and portable home healthcare devices available to patients. But on the other hand, these existing or proposed systems are usually signals dependant (for example, ECG only) like [2], [3]. One important reason or the difficulty for these systems to extend the usage to a wider range of biosignals is the fundamental differences between various common biosignals. Different biosignals require frontends with different characteristics (amplification, bandwidth, etc) for acquisition, and of which is an essential procedure before any processing or analysis. This difference restricted the possibility of having a single general purpose system which is efficient and capable of acquiring different biosignals at the same time with higher flexibility, lower cost and smaller in size for non-clinical medical usage.

In this paper, a novel concept is proposed to build a general purpose adaptive biosignal acquisition system combining Field Programmable Gate Array (FPGA) and Field Programmable Analogue Array (FPAA) to act as an intelligent and re-configurable general frontend for various biosignals including electrocardiogram (ECG), electromyography (EMG), electroencephalography (EEG), etc. This adaptive frontend can provide a simplified platform for integrating different algorithms for processing different biosignals at real time in home healthcare.

II. System architecture

In designing the acquisition system, characteristics and inherent properties of several hardware are studied and analyzed. To support a re-configurable environment and opportunity for converting to SOC in future, FPGA is chosen to be responsible for the digital part and FPAA for the analog part, with an ADC between them.

A. Field Programmable Gate Array (FPGA)

Field Programmable Gate Array, or FPGA, is a kind of semiconductor device with programmable and re-configurable logic blocks and interconnects which can build up digital components like basic logic gates (AND, OR, etc), make up more complex functions such as decoders or other mathematical functions. Because of this freely re-configura-

The work presented in this paper is supported by The Science and Technology Development Fund of Macau under grant 014/2007/A1 and by the Research Committee of the University of Macau under Grants RG051/05-06S/VMI/FST, RG061/06-07S/VMI/FST, and RG075/07-08S/VMI/FST.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 31–34, 2009
www.springerlink.com

ble characteristic, it can be programmed to process different functions in parallel and independently, using different sections in one FPGA. For example, the control of biosignal acquisitions can work independently with an ECG QRS detection algorithm and sending acquired data to a host computer without affecting each other. In our system, FPGA acts as the main controller to manage different components and I/Os between them.

B. Field Programmable Analogue Array (FPAA)

Field Programmable Analogue Array, or FPAA, is an analog counterpart device to FPGA but it contains configurable analog blocks instead of logic blocks which can be programmed and used to implement analog signal processing functions like amplifications, differentiation, integration, subtraction, addition, multiplication, log, exponential and configured to build up operational amplifiers and filters. The feasibility and performance in processing biosignals using FPAA is studied and tested in [34] with acceptable results. In the proposed system, FPAA acts as a general frontend to be dynamically programmed by the FPGA.

C. Biosignals Acquisition

The characteristics between different bioelectric signals vary a lot [5]. As illustrated in Fig. 1, the frequency range for electrocardiogram (ECG) is between 0.05-100Hz with a dynamic range of 1-10mV. For surface electromyography (surface EMG), the frequency range becomes 2-500Hz with a 50μV-5mV dynamic range. While for electroencephalogram (EEG), the dynamic range becomes 2μV -0.1mV although the frequency range is 0.5-100Hz which is similar to other signals. Comparing only these three commonly discussed biosignals, the great variance in the dynamic range among different biosignals induced the design challenge of a general frontend for multiple biosignals acquisition.

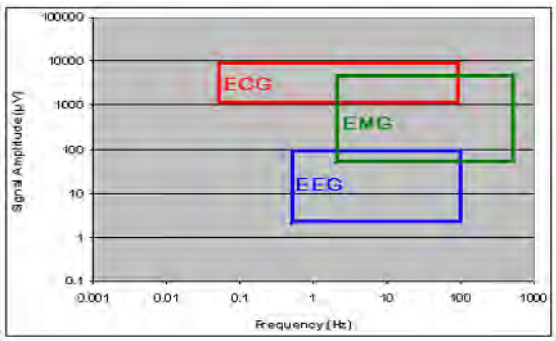

Fig. 1 – Signal Amplitude (μV) against Frequency (Hz) of different biosignals ECG, EMG and EEG

D. General Purpose Adaptive Biosignal Acquisition System

In order to achieve and build a general frontend for the acquisition of multiple biosignals, FPGA and FPAA are combined to be used in the proposed system.

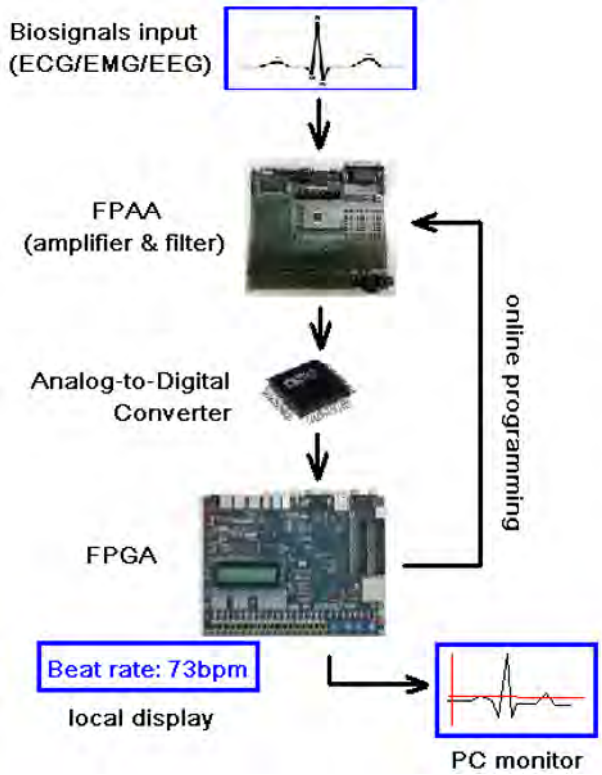

Fig. 2 – Architecture overview of acquisition system

In this adaptive acquisition system as illustrated in Fig. 2, biosignals input is amplified and filtered by the FPAA, digitized through the Analog-to-Digital Converter (ADC) and fed into the FPGA. FPAA is under the control of FPGA and the inherent re-configurable property of FPAA allows its amplification and filter to be dynamically re-configured through a serial interface. Appropriately selected parameters for the amplifiers and filters are programmed into the FPAA in order to retrieve a less tainted biosignal from the noisy human-body. This allows the acquisition frontend to adapt different biosignals to a common and an acceptable input range of the ADC before they can be processed in digital within the FPGA. In this way, signals will always be within the operating input range of the ADC.

Acquired samples of signal can be transferred to the PDA/PC for post-processing and displaying in real-time, and on the other hand, the FPGA provides a platform for embedding different signal processing algorithms to manipulate the

acquired data. It allows a single or multiple algorithms to be embedded for processing biosignals in parallel and independently. Local display is used as an indicator for verification of the results of the processed biosignals.

III. Implementation

In building the adaptive acquisition system, we used a DE2 FPGA evaluation board from Altera, an AN231 FPAA board from Anadigm and a 24-bit ADC AD7764 from Analog Device. Standard VHDL is also chosen as the programming language to implement the initial framework of the whole system because it leaves the opportunity for migrating the whole system to a System-On-Chip (SOC) in the future. The 24-bit ADC employed in this system is mainly for improving the dynamic range of the system to cope with any unexpected input. It also has an adjustable sampling rate for controlling power consumption (slower is lower). As this system mainly targets at non-clinical medical device for home healthcare or portable device, a low cost FPGA and FPAA with VHDL combination was chosen. This combination can provide the system with numerous advantages including but not limited to higher flexibility, lower power consumption, smaller in size.

In implementing the re-configurable frontend, configuration data of the FPAA for acquiring different biosignals are stored inside the FPGA non-volatile memory preventing data lost when power lost. Configuration code is loaded into the FPAA according to the input biosignals. The system allows user to easily switch the frontend between an ECG, an EMG or even an EEG configuration in real-time. Once the FPAA is configured correctly, the FPGA can start acquiring the signal samples through the ADC.

Through this dynamic programmable frontend and the freely programmable property of FPGA, the area inside FPGA is able to be designed into two separate sections. The first part is for configuring FPAA and acquiring samples from ADC, while the other part is reserved for embedding different signal processing algorithms and acting as the backend system for analyzing real-time data, which can miniaturize the system.

Transmission of acquired samples to personal computers (PC) using RS232 (or USB in the future) is considered in the design for extended usage which requires higher computational power for complicated algorithms that does not migrate-able to FPGA.

IV. Results

A general purpose adaptive biosignals acquisition system has been built for evaluation in this paper. For each biosignal (ECG, EMG, EEG), a separate configuration is designed to be programmed into the adaptive FPAA frontend which is stored inside the FPGA. The 24-bit ADC is configured to work at a sampling rate around 507Hz which is limited by the combination of DE2 onboard 27MHz clock generator and the decimation rate of AD7764. Although this is not a preferred sampling rate, this is enough for our experiment on verifying the system functionality.

In the experiment, an ECG patient simulator PS-420 from Metron is used instead of a human subject to provide raw ECG signal. An EEG simulator EEGSIM from Glass Technologies has also be used to acquire raw EEG signal, while the EMG signal is acquired from a human subject. A simple PC program is written to receive and display the acquired samples from FPGA through RS232 in real-time as shown in Fig. 3 for visual inspection. A simple algorithm [6] is also tuned and migrated into the FPGA with Standard VHDL for verification of the real-time signal processing capability with embedded algorithms. This algorithm can perform QRS detection and calculate the beat rate of the ECG signal. The local display on the FPGA evaluation board is used as an output displaying the beat rate in beat per minute (BPM). Algorithms for processing EMG and EEG are not implemented and the acquiring of these signals is only verified by real-time output of acquired data.

From Fig. 3, an ECG signal can be acquired using the system with clear characteristics and the embedded algorithms can successfully retrieve the heart beat rate. Comparing acquired EEG signal between Fig. 4 and Fig. 5, the EEG signal, which is acquired using our acquisition system, shown in Fig. 5 is similar to the signal from the EEG simulator captured using ADI PowerLab shown in Fig. 4.

After evaluative testing of the system, it is possible to achieve an adaptive frontend with acceptable performance using existing devices. The acquired samples of signal are similar to the input signal with amplification which is possible for post-processing, even for the microvolt-level signals. The combination of FPGA and FPAA is also proved to be able to cooperate with embedded algorithms to retrieve useful information from the input biosignals, for example, showing the correct beat rate of the input ECG.

The final resources usage of the FPGA is around 10% of "Logic Elements" for the system without counting the embedded algorithms in the post-processing part. The addition of a simple QRS detection algorithm (migrated to FPGA using standard VHDL) consumed a total of over 50% of "Logic Elements". This is considered as a weakness or disadvantage because this means that signal processing algorithms need effort to be tuned and optimized when migrating to work in FPGA using standard VHDL.

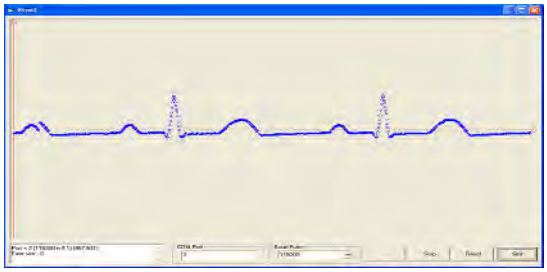

Fig. 3 – Simple program to receive and display the acquired samples in real-time for quick visual inspection (ECG)

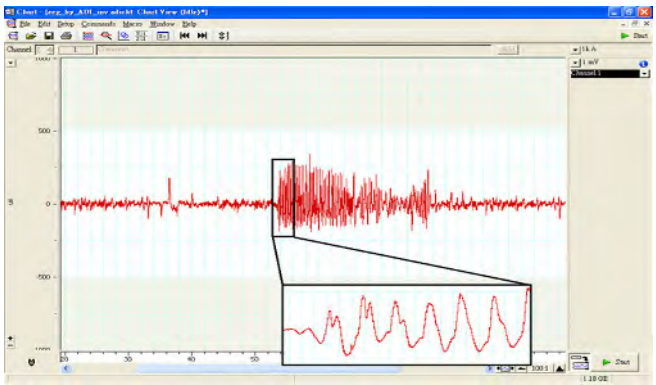

Fig. 4 –EEG signal from EEGSIMcaptured using ADI PowerLab

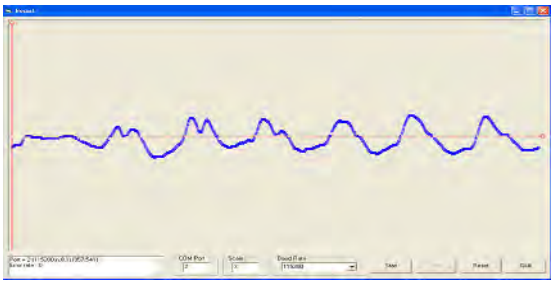

Fig. 5 – Simple program to receive and display the acquired samples in real-time for quick visual inspection (EEG)

V. Conclusions

A general purpose adaptive biosignals acquisition system is proposed and built for evaluation. The results from the evaluative testing are presented as a proof of concept in combining existing devices like FPGA and FPAA to form a simple and single platform at low cost for evaluating biosignal processing algorithms embedded into FPGA using multiple real-time biosignals. On the other hand, this can also be used as the essential part in building non-clinical medical devices for home healthcare or portable device with its inherent characteristics of low power and small in size, like a long term ECG monitoring device.

In designing the system, transformation of system from existing hardware to SOC is also considered, and therefore, standard VHDL language is chosen to provide maximum flexibility in the future. On the other hand, the difficulties and effort in migrating algorithms into the system for post-processing still needs to be analyzed and "automatic FPAA configurations selection" is considered as one of the useful feature in the current status.

Acknowledgment

I would here like to express my gratitude to all those who gave me the possibility to complete this paper. I want to specially thank you my supervisors, the department of Electrical and Electronics Engineering of the University of Macau and The Science and Technology Development Fund of Macau.

Abstract — **Automatic segmentation of human brain from MRI scan slices without human intervention is the objective of this paper. The DICOM images are used for segmentation. The Segmentation is the process of extraction of the White matter (WM), Gray matter (GM) and Cerebrospinal Fluid (CSF) from the MRI pictures. Volumetric calculations are carried out on the segmented cortical tissues. The accuracy in determining the volume depends on the correctness of the segmentation algorithm. Two different methods of seed growing are proposed in this paper.**

Keywords — **kull Stripping, Segmentation, Seed growing, White matter, Gray matter.**

I. Introduction

Segmentation in image processing has wide range of applications. Segmentation in medical imaging in general has wide applications. The imaging modalities such as CT and MRI along with image processing has revolutionized the diagnosis and treatment scenario. In brain MRI, segmentation is helpful in determining the volume of different brain tissues such as White Matter(WM), Gray Matter(GM) and Cerebrospinal Fluid(CSF). The volumetric changes in these brain tissues help in the study of neural disorders like Multiple Sclerosis, Alzheimer's disease, epilepsy etc. Brain MRI segmentation also helps in detection of tumours [4]. Many research papers are published in this area. Automatic segmentation also helps in guiding neurosurgery.

We have presented two different methods for segmentation based on region growing and presented a comparison of these two methods in this paper.

We have organized the remainder of this paper into the following sections. 2. Segmentation and the relative work in the area. 3. Overview 4. Method 1 Region growing based on seed value and connectivity. 5. Method 2. Region growing based only on seed value 6. Experimental Results 7. Comparison and conclusion

II. Segmentation

Segmentation or classification of data is defined as extracting homogeneous data from a wider set of data. Pixels with similar intensity or texture belong to the same group. Classification is based on looking for such similar properties in an image. There are numerous segmentation techniques available which are applied to medical imaging. Region growing is an important technique used for segmentation. One of the first region growing technique is the seed growing. Seed growing is done by choosing some pixels as seed points. The input seed points can be chosen based on a particular threshold value. Spatial information could also be specified along with the threshold gray value for choosing the seed pixel. Region of interest (ROI) can be grown from the seed and extracted. The result of segmentation depends on the correctness of the seed values chosen. Segmentation techniques based on seed growing can be fully automatic or semi automatic needing intervention. In some cases only the result need to be confirmed through the operator. Computer vision helps in saving much of the time. Manual segmentation will need hours together for segmenting a single image.

A lot of work has been done in the area of MR images segmentation. [2] uses edge based techniques combined with spatial intensity. Many image models are used for classifying such as Hidden markov model which uses random field model [5]. Many works are published using classification algorithms based on Fuzzy classification methods such as Fuzzy K means and FCM algorithms [7,8,9,10]. Fuzziness in classification helps to classify data better compared to hard clustering. Neural network and neuro fuzzy algorithms are also applied [11]. [3] uses the geometric snake model to extract the boundary and combines that along with the fuzzy clustering. The latest development in MR image segmentation [13] which uses propagation of charge fluid model through the contours of the imaging data. This method requires no prior knowledge of the anatomic structure for the segmentation.

III. Overview

Fig.1. Shows the different stages which gives the overview of the system developed in both the methods.

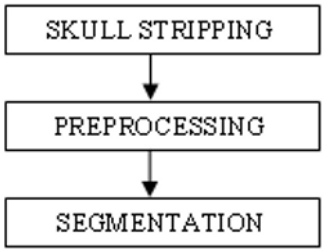

Fig. 1 System Overview

A. Skull Stripping

Volumetric analysis of brain requires segmenting the cortical tissues from the non cortical tissues. Removing these non cortical tissues is termed as skull stripping.

Surrounding extra cortical tissues such as fat, skin, eye ball are removed and separated from the brain tissues. Skull stripping classifies the image into two classes, brain and non brain tissues. Skull stripping forms the first processing step in the segmentation of brain tissues. The skull removed MRI pictures are used for further classification of the brain tissues into White matter, Gray matter and Cerebrospinal fluid.

The T1 weighted axial MR images has a distinct dark ring surrounding the brain tissues. We have exploited this spatial property and performed skull stripping.

Result of skull stripping is shown in Fig.2. Fig 2(a) is the original MR image and Fig 2(b) shows the skull stripped image.

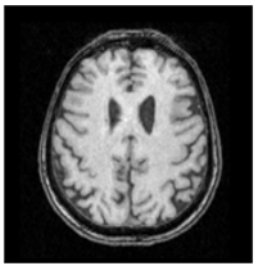

Fig. 2(a) Original image

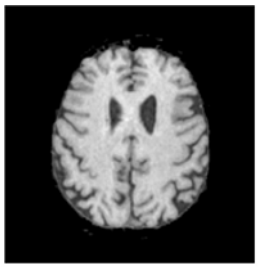

Fig. 2(b) Skull Stripped

B. Preprocessing

The MR images show variations and noise due to the inhomogeneity of the RF coils. Various filter transformations developed to enhance the MR brain images so far are discussed in [1]. We have used a median filter of mask size 3 X 3 which retains the information of the edges and at the same time avoids blurring.

C. Segmentation of Brain Tissues

After skull stripping and filtering the next step is to segment the brain into its constituent tissues such as White Matter (WM), Gray Matter(GM) and Cerebro Spinal fluid(CSF). We have developed two different methods based on the two dimensional seed growing. Both the methods proposed here are fully automatic.

IV. Method 1 based on seed value and connectivity

We have used the a priori information from the DICOM images regarding the intensity values of the different tissues represented in the DICOM images. The maximum intensity in the image correspond to the pixels representing WM in the skull stripped image. GM pixels are represented by intensity values lesser than WM. CSF pixels are represented by the lowest intensity values. These values from the histogram decide the threshold values in selecting the seed values. These ideas remained the same in both the methods developed.

A. Algorithm for Segmenting White Matter

- The algorithm begins by choosing the pixels automatically rather than manually.
- We computed the regional maxima from the histogram of the skull stripped image to get the seed value of the WM.
- The pixels within a range of small deviation to this seed value were grown through consecutive iterations.
- The number of iterations depend on the size of the image. The iterations have to be exhaustive such that all the pixels were checked.
- To make the algorithm more stable we checked along with the seed value the connectivity. The four neighbourhood connectivity ensures that the region is well connected. The connectivity test can be extended to eight point connectivity.
- An image corresponding to the mask of the WM was grown through iterations satisfying both the input criterion of seed value with a minimum deviation and four connectivity.
- The white matter was extracted from the skull stripped image using the WM mask and image arithmetic.

B. Segmenting gray matter

Study of the DICOM images show that the pixel values with a smaller offset to the white matter represents the gray matter. The algorithm for segmenting the gray matte is the same as in the previous step but for the seed point pixel value. Following the same procedure we segment the gray matter.

C. Segmenting Cerebrospinal fluid

After removing the white matter and the gray matter from the skull stripped image we are left with third constituent of the cortical tissue the cerebrospinal fluid. This is extracted using simple image arithmetic from the skull stripped image after removing WM and GM.

The segmented tissues using this method are shown in Fig. 3 (a) to 3(c).

V. Method 2 based on seed value

The second method we have developed is based only on the intensity value. It checks the pixels only for the intensity and neighbourhood connectivity is not a criterion for seed growing.

- The algorithm begins from the maximum intensity value. This is taken as the seed point for the white matter region. All the pixels with this value are added to grow the white matter region.
- In the next iteration the intensity value is decremented by one and the new pixels are added to the white matter region.
- Simultaneously the gray matter region is grown starting from the lower intensity and incrementing the intensity by one.
- This process is continued through the iterations.
- After every iteration an index is measured, we called it as the segmentation index.
- Segmentation index = (Total count till last iteration-Count in the present iteration) / Total count
- As the region grows the index value changes.
- With decrease in the index values, we test for common pixels between the two regions.
- The iterations are terminated if common pixels are found.

VI. Experimental results

We used the T1 weighted axial view MR brain images. The algorithm was implemented using MATLAB. The template image used was one the mid slices of the MRI slice no.44.

Results using Method 1. Fig. 3(a) Segmented White matter, Fig. 3(b) Segmented Gray matter

Fig. 3(c) Segmented CSF of MRI slice No.44

Results using Method 2. Fig. 4(a) White matter, Fig. 4(b) Gray matter

VII. Comparison and conclusion

Segmentation using both the methods yield the same result. The first method as it considers the neighbourhood connectivity takes excessively larger computation time for one single slice. The connectivity can also be tested across the 3 D images. The second method is faster as it picks all similar pixels simultaneously. The number of iterations change from one image to another. This method also ensures that all the pixels are properly classified and every pixel belong to one and only one class. In both the methods we have taken the seed values from the histogram and they

are totally automatic. For region growing we have allowed offsets in the seed values , this will take into account the variations of the intensity value within the same class due to the inhomogeneity of the RF coils of the MRI scanner. Table 1 shows the comparison of the iterations for an image of size 512*512.

Table 1. Comparison of Methods

Method	Method 1	Method 2
No. of iterations	512*512	Maximum 20 -25
Common count	180 (Slice. No.44)	Zero

Abstract — **We are investigating an application of the biomagnetic measurement to non-invasive diagnosis of spinal cord function. Two multichannel superconducting quantum interference device (SQUID) biomagnetometer systems for the measurement of the evoked magnetic field from spinal cords were developed as hospital-use apparatuses. One is optimized for sitting subjects. Another is for supine subjects. Both systems are equipped with an array of vector SQUID gradiometers. The conduction velocity, which is one of the significant information for the functional diagnosis of the spinal cord, was non-invasively estimated by the magnetic measurement.**

Keywords — **Biomagnetism, SQUID, biomagnetometer, medical device, non-invasive diagnosis, spinal cord.**

I. Introduction

Biomagnetic measurement is a method to investigate the behavior of nerve system, muscles, or other live organs by observation of magnetic field generated by their activity. The intensity of the magnetic field elicited from the body is quite small, which is several femto or pico tesla. Only SQUID (superconducting quantum interference device) based magnetometers can detect such weak magnetic field. One of the large applications of SQUID biomagnetic measurement is MEG (magnetoencephalography)[1,2]. The MEG is an apparatus to detect the magnetic field from the brain nerve activity by a sensor array with more than one hundred SQUID sensors arranged around the head. It can non-invasively provide the information of brain nerve activity at high temporal and spatial resolution, and is already used in many hospitals and brain research institutes.

In the field of the orthopaedic surgery and neurology, there is a strong demand for the non-invasive diagnosis of the spinal cord dysfunction. The conventional lesion localization of the spinal cord disease relies on image findings from MRIs or X-ray CTs in addition to clinical symptoms, physical findings and neurological findings. However, the doctors were often dissatisfied with false-positive findings because the abnormal findings on the image are not always symptom-related. Therefore, evaluation of spinal cord function based on electrophysiological examination is also necessary for the accurate diagnosis of spinal cord disease.

We are investigating the SQUID biomagnetic measurement systems as a non-invasive functional diagnosis tool for spinal cord[3–5]. In this paper, the multichannel SQUID measurement systems recently developed for the application in hospitals and preliminary examination with the systems are described.

II. Instrumentation

A. System Configuration

We focused on the cervical spinal cord evoked magnetic field (SCEF) measurement because spinal cord disease mainly occurs at the cervix. Two cervical SCEF measurement systems were developed. One was optimized for sitting subjects. The other was for supine subjects. The system for sitting subjects needs comparatively small footprint. Space-saving is a large advantage upon installation of the system to common hospitals. On the other hand, the supine mode system can be applied to patients, even if they have severe spinal cord disease, and provide larger observation area than the sitting mode system.

Fig. 1 shows the configuration of the system for supine subjects. Basically, both systems have the same configuration. An X-ray imaging apparatus was integrated to the

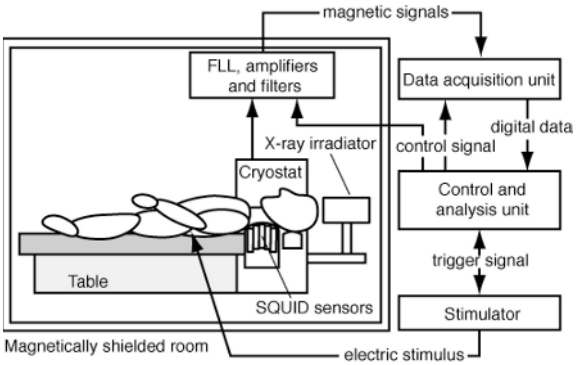

Fig. 1 Configuration of the supine mode system.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 39–42, 2009
www.springerlink.com

SQUID system to acquire anatomical structure images at the cervix. The two most distinctive components of the systems are the sensor arrays of vector SQUID gradiometers and the uniquely shaped cryostats, which are described in detail in this section.

B. Sensor array

The sensor arrays were composed of vector SQUID gradiometers[6] shown in Fig. 2(a). The vector SQUID gradiometer detects three orthogonal components of the magnetic field at one time thanks to the combination of three gradiometric pickup coils as shown in Fig. 2(b). Fig. 2(c) shows the sensor array of the sitting mode system. It has 5 × 5 matrix-like arrangement for the observation area of 80 mm × 90 mm. The sensor array arrangement and the observation area of the supine mode system are 8 × 5 and 140 mm × 90 mm, respectively. The sensors are positioned along the cylindrical surface to fit to the posterior of the cervix. All SQUID sensors are driven by flux locked loop (FLL) circuits for the linearization of the output and the improvement of dynamic range[7]. The resulting sensitivity and typical noise level in the white noise region are about 1–1.5 nT/V and 2.3 fT/Hz$^{1/2}$, respectively.

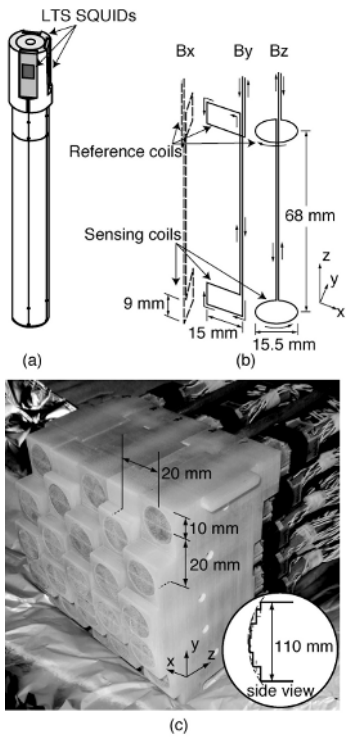

Fig. 2 Vector SQUID sensor array. (a) Conceptual drawing of a vector SQUID gradiometer. (b) Structure of pickup coils (c) Appearance of the sensor array of the sitting mode system.

C. Cryostat

The cryostat is a double-layered vessel with a vacuum thermal insulating layer to hold the SQUID sensors in liquid helium and to keep them in a superconducting state. The cryostats and their inner parts are made of glass fiber reinforced plastic to avoid interference from magnetic materials.

Fig. 3 shows the inner structure and the appearance of the cryostats. The cryostats of both sitting mode and supine mode have the same uniquely designed structure. They have a cylindrical main body to reserve liquid helium and a protrusion from its side surface. The sensor array of the sitting mode system is installed in the protrusion oriented in the horizontal direction. The sensor array of the supine mode system is also installed in the protrusion but is oriented in the vertically upward direction. In both systems, the surface that is in contact with the subject's cervix has a cylindrical curve, as does the front of the sensor array. The cool-to-warm separation of this surface is less than 7 mm. The cryostats are supported by the non-magnetic gantries and made tiltable so that the relative position between the sensor array and the cervix would readily be adjusted. The capacity of cryostats of

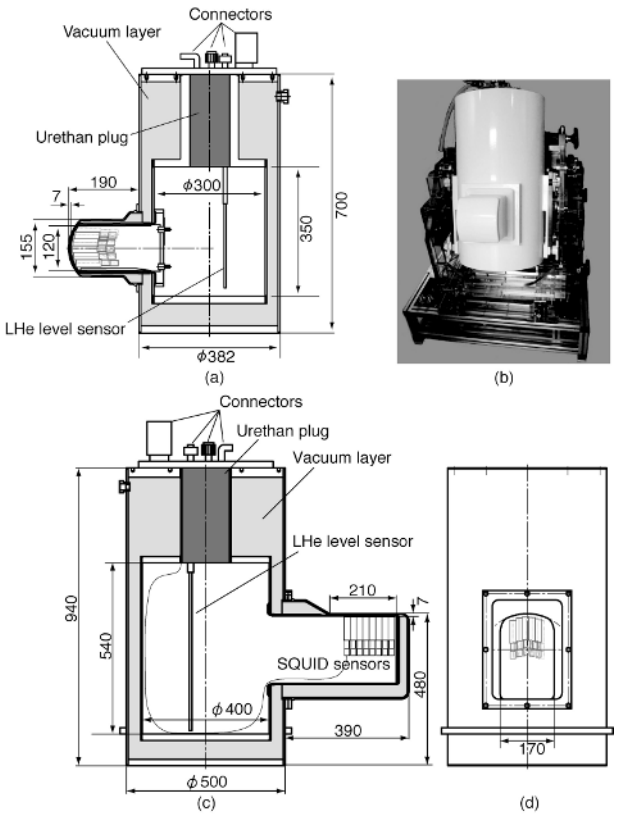

Fig. 3 (a) Inner structure and (b) appearance of the cryostat of the sitting mode system. (c) Inner structure and (d) front view of the cryostat of the supine mode system.

the sitting and the supine mode systems are about 25 liters and 70 liters, respectively. The intervals of the liquid helium refill are 84 hours and 120 hours, respectively.

III. SCEF MEASUREMENT

A. Material and method

For performance verification of the systems, preliminary cervical SCEF measurement of normal subjects was executed in a magnetically shielded room. Three volunteer male subjects, TS, MT, and KK at the ages of 23–30 were examined with the sitting mode system. The subject TS was also examined in the supine mode. All subjects didn't have dysfunction at the cervix.

In the sitting mode measurement, the subjects sat on a chair in the reclining position with the posterior of the cervix tightly fitted to the protrusion of the cryostat as shown in Fig. 4(a). In the supine mode measurement, the subject lay on a bed in the supine position with the cervix and the head running off the edge of the bed. The cervix was in close contact with the upper surface of the protrusion of the cryostat as shown in Fig. 1 and Fig. 4(b).

Fig. 4(c) and (d) are lateral X-ray images showing the relative positions between the cervical spine and the sensor array and the orientation of the coordinate system. The median line of the subject's body was roughly positioned at the center of the observation area in each measurement.

Fig. 4 SCEF measurement (a) in the sitting mode and (b) in the supine mode. Lateral X-ray image (c) in the sitting mode and (d) in the supine mode.

Electric stimulation was given to the median nerve at the left wrist with skin surface electrodes. The stimuli were repetitive square pulse current whose intensity and duration were 6–8 mA and 0.3 ms, respectively. The repetition rate was 17 Hz or 8 Hz.

Signals from all SQUID sensors were filtered with band pass filters of 100–5000 Hz before digital data acquisition. The sampling rate of the data acquisition was 40 kHz. The stimulus was repeated 4000 times and all responses were averaged for the improvement of the S/N ratio. After the data acquisition, a digital low pass filter of 1290 Hz was applied to the averaged data.

B. Result and discussion

The SCEF signals were successfully detected from every subject and the pattern transition of the SCEF distribution over the cervix was clearly observed about 10 ms after the stimulation. The SCEF pattern transition of every subject had the same tendency. Fig. 5(a) and (b) show the transition of the SCEF distribution from the subject TS acquired by the sitting mode system and the supine mode system, respectively. The maps represent views from the posterior of the subject. Upper and lower sides correspond to the cranial and caudal directions, respectively. The arrow maps show the orientation and intensity of the SCEF components tangential to the body surface. The contour maps represent the distribution of the radial component.

In both Fig. 5(a) and (b), a large outward component was found in the left side of the observation area in the early stage of the SCEF transition. After that, the zero field line of the radial component took on the anti-clockwise rotation. The tangential component was also turning as well as the radial component. This rotation was in good agreement with a result of a preceding study[8]. In the right side of the observation area, the progression of an inward component along the *y*-axis from the lower side to the upper side, which was parallel to the spinal cord, was clearly found. The inward component was followed by an outward component. This was interpreted that a quadrupole distribution, which is the specific magnetic distribution pattern corresponding to the axonal action potential[9], was partially observed. The whole of the behavior of the inward and outward extrema was observed in Fig. 5(b) while some part of the extrema was missing in Fig. 5(a). Thus, the wide observation area of the supine mode system is effective to survey the complicated pattern transition of cervical SCEF induced by the brachial nerve stimulation.

The conduction velocity, which is significant to functional diagnosis of the spinal cord, was estimated from the movement of the extrema to be about 60–90 m/s. This value was within the normal physiological range.

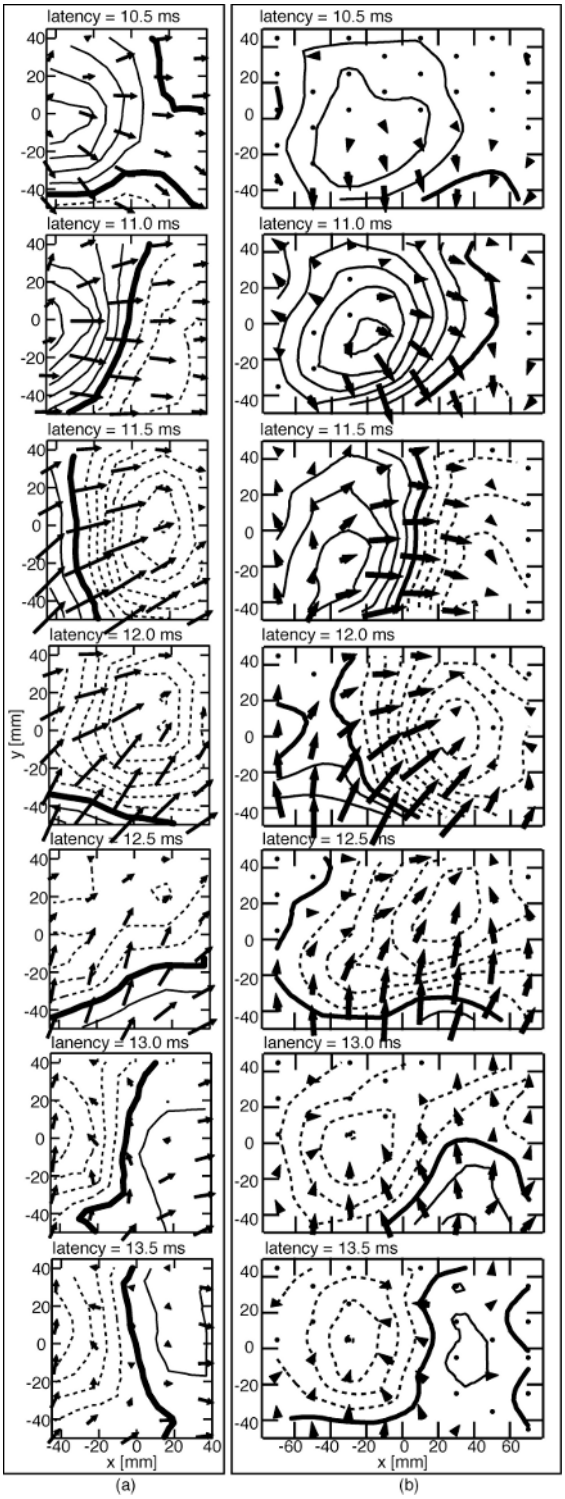

Fig. 5 Transition of the SCEF distribution between 10 ms and 13.5 ms in latency (a) in the sitting mode and (b) in the supine mode. Plain, dotted, and bold lines in the contour maps represent outward, inward, and zero magnetic fields, respectively. The interval between contour lines is 5 fT.

IV. Conclusion

Two SQUID spinal cord evoked field measurement systems, sitting mode and supine mode, were developed in the scope of the application at hospitals. The systems are equipped with an array of vector SQUID gradiometers and a uniquely shaped cryostat optimized for sitting or supine subjects. Using the developed systems, the SCEF signals were successfully detected and their specific pattern transitions were observed. The supine mode system had a wider observation area and was more suitable for the acquisition of the complicated SCEF distribution that induced especially by the brachial peripheral nerve stimulation.

The signal propagation along the spinal cord was found and its velocity was non-invasively estimated. This indicates that the SCEF measurement will be a powerful tool for the non-invasive diagnosis of the spinal cord dysfunction.

Human Cardio-Respiro Abnormality Alert System using RFID and GPS - (H-CRAAS)

Ahamed Mohideen, Balanagarajan

Syed Ammal Engineering College, Anna University, Ramanathapuram, India

Abstract — **The most crucial minute in a human's life is the minute in which he oscillates between life and death. These deaths caused due to the failure of heart and respiratory mechanisms because of lack of medical assistance in time are increasing. This paper tries to give an insight of a technology about a whole new wireless and RFID (Radio Frequency Identification) enabled frontier in which victim's actual location is integral for providing a valuable medical service.**

This paper will be demonstrating for the first time ever the usage of wireless telecommunications systems and miniature sensor devices like RFID passive tags, which are smaller than a grain of rice and equipped with a tiny antenna which will capture and wirelessly transmit a person's vital body-function data, such as pulse/respiration rate or body temperature, to an integrated ground station. In addition, the antenna in the ground station will also receive information regarding the location of the individual from the GPS (Global Positioning satellite) System. Both sets of data of medical information and location will then be wirelessly transmitted to the ground station and made available to save lives by remotely monitoring the medical conditions of at-risk patients and providing emergency rescue units with the person's exact location.

It gives a predicted general model for Heart and respiration abnormality alert system. It discusses in detail the various stages involved in tracking the exact location of the Victim using this technology.

Keywords — **RFID tags, RFID reader, GPS, H-CRAAS.**

I. Introduction

InformID is an out of sight, out of mind medical technology that can save lives. This device consists of two parts. The first is a small tag shown in Fig-1 that is easily concealed on an individual and carries crucial medical information. The second is a reading device that, in the case of an emergency, a paramedic or doctor could use in a hands free way to access this important information. This protected medical information would then allow doctors and paramedics to quickly and easily diagnose and identify medical conditions and emergencies on a patient to patient basis. InformID is a truly unique medical system because it is powerless and wire free!

I.A. Overview: Medical applications for RFID are quickly becoming accepted as a safe and effective means in which to track patients in hospitals and to easily keep track of pets and children. Once this technology gains mass appeal, what other potential venues are available for using such a cheap, simple and effective identification technology.

Such technology has yet to be used effectively as preventative measures for medical complications of an average live at home individual. Many devices have come and gone that claim to help or aid the elderly in medical situations, but are deplorable in concept and highly ineffective at both preventing and solving medical crisis's in a time effective manner.

To better understand the intention of this project and the underlying problem, below is a sample scenario that I feel is worth potentially solving with the current state of RFID technology.

"An individual at their personal residence needs medical assistance and dials 9-1-1 but does not remain conscious for long. As paramedics arrive on scene, they are faced with many questions. Who is the individual in need of assistance and what is the nature of their problem? Does the medical emergency require medical assistance elsewhere or immediate resuscitation on the scene? What are the victim's vital signs? Is there an important medicinal history that could be vital to solving the medical problem?"

The above situation is quite often the brunt of any paramedics work during an average day. The time taken to answer those questions can ultimately determine the victims' chances of survival. It is my goal to aid a paramedic's deci-

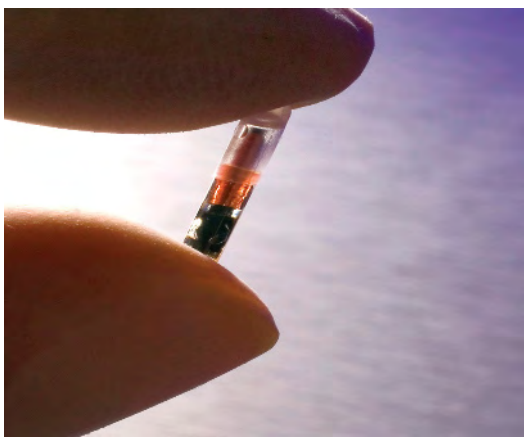

Fig 1- Grain sized RFID tag

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 43–46, 2009
www.springerlink.com

sion-making process by potentially answering some of these questions using RFID technology. The key to potentially uncovering a viable solution to the problem lies mainly with the transparency of the technology involved, and a system that is totally passive that can be referenced only if the paramedic has the time or needs the information

Table 1 Different class of RFID

RFID tag class	Definition	Programming
Class0	Read only passive tags	Programmed by the manufacturer
Class1	"Write-once, Read-many" passive tags	Programmed by the customer cannot be reprogrammed
Class2	Rewritable passive tags	Reprogrammable
Class3	Semi passive tags	Reprogrammable
Class4	Active tags	Reprogrammable
Class5	Readers	Reprogrammable

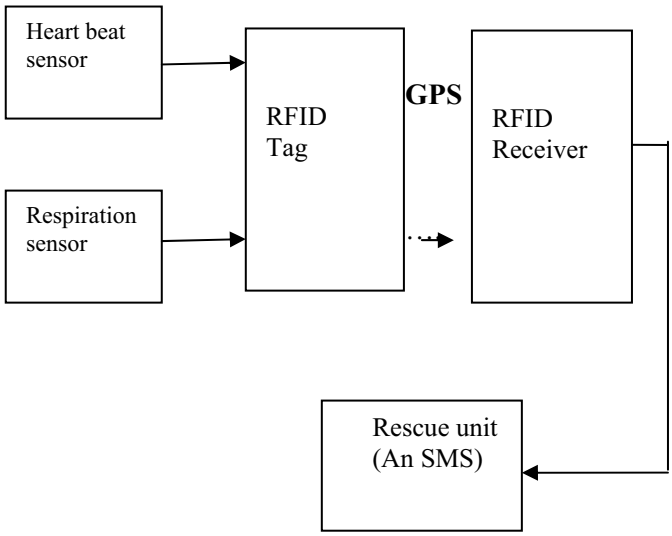

Fig 2- Block description of H-CRAAS

Radio Frequency Identification (RFID) is a system of transmitting a unique encrypted number wirelessly between a tag and a transponder (reader). The number is 96 bits long and has enough unique combinations to potentially label every atom in the universe. RFID is both interesting and unique for a variety of reasons. The system of reading embedded tags does not need line of site transmission like a barcode reader. Instead, multiple tags may be read simultaneously just by being within a few feet of them. RFID tags are unique in that they come in two flavors, passive and active. A battery of some sort, allowing the tag to be read at long ranges, usually powers active tags. A passive tag, much like the one used in my proposed system, does not require a power source at all! Instead, the range in which the tag can be read is very limited (sometimes less than six inches). RFID is safe and effective for maintaining privacy. Each tag is encrypted to allow a specific reader or set of readers to access their information

II. Methodology

II.A. Sensors: By Using separate sensors the heartbeat and respiration rate is monitored continuously. The outputs of the sensors are then given to the separate port in the RFID tag in the digitized form.

II.B. RFID tag: The RFID tag is working with the principle of Code Division Multiple Access (CDMA). Since RFID is a multiport tag, the two-sensor output is given separately. The RFID tag then analyzes the 8-bit digital inputs. If any one of the codes exceeds the predefined value then the corresponding code is encoded as a 4-bit code and it is transmitted to the RFID receiver. Passive e RFID systems that we used typically couple the transmitter to the receiver depending on whether the tags are operating in the near or far field of the reader, respectively.

II.C. Global positioning system (GPS): This technology is mainly used to collect the details of the victim's exact area of location, so that it is easy for the rescue unit to reach the victim with required medical assistance.

II.D. RFID receiver: With the information of the location of the victim under crucial condition the reader make an alert to the rescue unit. So that it is possible for them to reach the victim soon.

II. E. Rescue unit: Soon after the alert from the reader near by the rescue unit should reach the location as soon as possible.

III. Experimental results

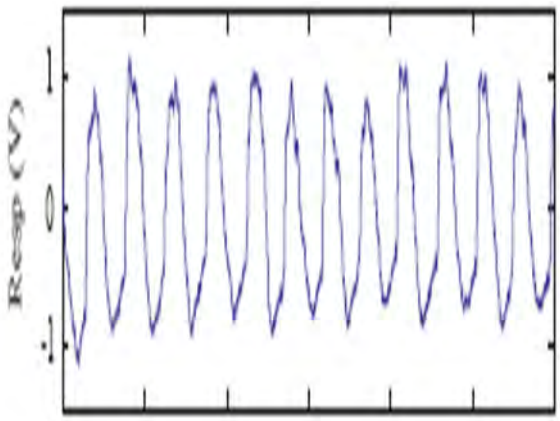

Fig 3- Output of normal respiration rate

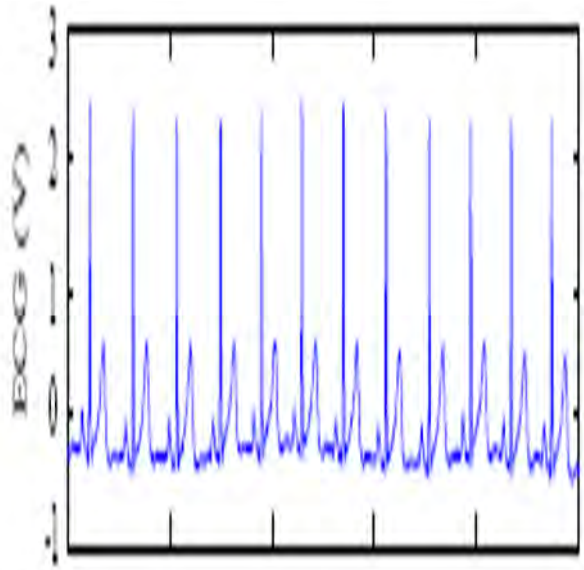

Fig 4- Output of normal heart beat rate

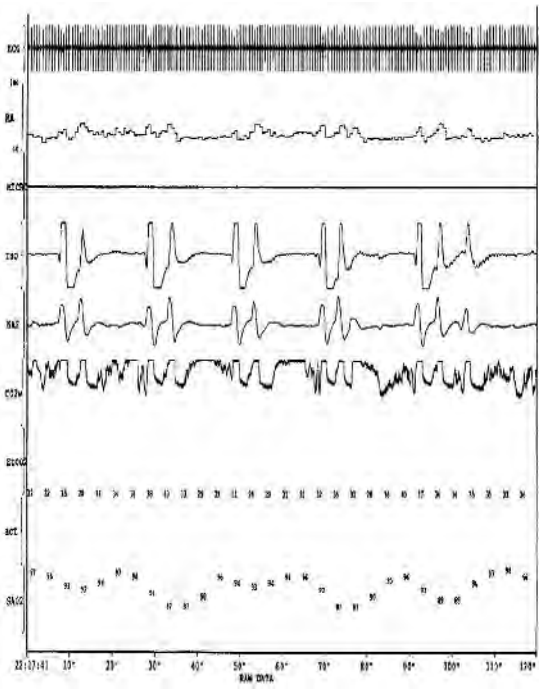

Fig 5- Output of abnormal heartbeat and respiration rate

IV. Conclusion

This new technology will open up a new era in the field of Biomedical Engineering. This paper aimed to provide an alert and there by providing required medical assistance to the victim. We have achieved this through the technology RFID and GPS. This technology would probably become cheaper in the future. In the near future we hope this new technology would probably reduce the deaths due to heart and respiratory abnormalities.

V. Acknowledgement

First of all our sincere gratitude goes to Almighty, because “without him we are nothing”, next our unfined thanks goes to our lovable parents because they are the backbone of all our endeavours. And our heartfelt thanks goes to our Correspondent, Principal, Vice Principal, HOD, and all other staff members who supported us in all possible ways to complete our paper. Finally we would like to thank our friends for their thankless encouragement and dedicated support.

Abstract — **The aim of this study is to develop a knowledge-based automatic sleep stage determination system which can be optimized for different cases of sleep data at hospitals. The main methodology of multi-valued decision making includes two modules. One is a learning process of expert knowledge database construction. Visual inspection by a qualified clinician is utilized to obtain the probability density functions of parameters for sleep stages. Parameter selection is introduced to find out optimal parameters for variable sleep data. Another is automatic sleep stage determination process. The decision making of sleep stage is made based on conditional probability. The result showed close agreement comparing with the visual inspection. The developed system is flexible to learn from any clinician. It can meet the customized requirements in hospitals and institutions.**

Keywords — **Automatic sleep stage determination, Expert knowledge database, Multi-valued decision making, Parameter selection, Conditional probability.**

I. Introduction

There are two sleep states: rapid eye movement (REM) sleep and non rapid eye movement (NREM) sleep. The NREM sleep consists of stage 1 (S1), stage 2 (S2), stage 3 (S3) and stage 4 (S4). Another stage of awake is often included, during which a person falls asleep. The most well-known criteria for sleep stage scoring were published by Rechtschaffen and Kales (R&K criteria) in 1968 [1]. Currently, sleep stage scoring has been widely used for evaluating the condition of sleep and diagnosing the sleep related disorders in hospitals and institutions.

Automatic sleep stage determination can free the clinicians from the heavy task of visual inspection on sleep stages. The rule-based waveform detection methods, according to R&K criteria, can be found in many studies. The waveform detection method was firstly applied by Smith et al. [2], [3]. Waveform and phasic event detection of rule-based and case-based hybrid reasoning method was proposed in [4]. An expert system based on characteristic waveforms and background EEG activity by using a decision tree was described in [5]. The limitations of R&K criteria have been noticed [6]. The insufficiency is that it only provides typical characteristic waveforms of healthy and normal persons for staging.

Although various methodologies have been developed, effective technique is still needed for clinical application. Sleep data is inevitably being affected by various artifacts [7]. Individual differences are also commonly existed even under the same recording condition. For the patients with sleep-related disorders, their sleep data has particular characteristics. The recorded sleep data containing complex and stochastic factors will increase the difficulties for the computerized sleep stage determination techniques to be applied for clinical practice.

In this study, sleep stage determination is considered as a multi-valued decision making problem in the field of clinics. The main methodology, proposed in our previous study, has been proved to be successful for sleep stage determination [8], [9]. The aim of this study is to develop a flexible technique adapting to different cases of sleep data, which can meet the customized requirements in hospitals and institutions. Visual inspection by a qualified clinician is utilized to obtain the probability density function of parameters during the learning process of expert knowledge database construction. A process of parameter selection is introduced in order to make our algorithm flexible. Automatic sleep stage determination is manipulated based on conditional probability.

II. Methods

A. Data acquisition

The sleep data investigated in this study was recorded in the Department of Clinical Physiology, Toranomon Hospital, at Tokyo, Japan. Four subjects, aged 49-61 years old, were participated. These patients had breathing disorder during sleep (Sleep Apnea Syndrome). Their overnight sleeping data were recorded after the treatment of Continuous Positive Airway Pressure (CPAP) based on the polysomnographic (PSG) measurement. The PSG measurement used in Toranomon Hospital included four EEG (electroencephalogram) recordings, two EOG recordings and one

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 47–50, 2009
www.springerlink.com

EMG (electromyogram) recording. EEGs were recorded on central lobes and occipital lobes with reference to opposite earlobe electrode (C3/A2, C4/A1, O1/A2 and O2/A1) according to the International 10-20 System [10]. EOGs were derived on Left Outer Canthus and Right Outer Canthus with reference to earlobe electrode A1 (LOC/A1 and ROC/A1). EMG was obtained from muscle areas on and beneath chin and termed as chin-EMG. Initially, EEGs and EOGs were recorded under a sampling rate of 100 Hz, with a high frequency cutoff of 35 Hz and a time constant of 0.3s. Chin-EMG was recorded under a sampling rate of 200 Hz, with a high frequency cutoff of 70 Hz and a low frequency cutoff of 10 Hz.

B. Visual inspection

A qualified clinician F.K. in Toranomon hospital scored sleep stages on the overnight sleep recording of subjects. In total, seven types of stages were inspected. In the stage of the awake, predominant rhythmic alpha activity (8-13 Hz) can be observed in EEGs (O1/A2, O2/A1) when the subject is relaxed with the eyes closed. This rhythmic EEG pattern significantly attenuates with attention level, as well as when the eyes are open. The awaking EOG consists of rapid eye movements and eye blinks when the eyes are open, while few or no eye movements when the eyes closed. The clinician determined the awake with eyes open (O(W)) or awake with eyes closed (C(W)) according to the alpha activity (8-13 Hz) in O1/A2 and O2/A1 channels as well as the existence of eye movements in EOG channels. The REM sleep was scored by the episodic REMs and low voltage EMG. The NREM sleep was categorized into S1, S2, S3 and S4 stages. S1 was scored with low voltage slow wave activity of 2-7 Hz. S2 was scored by the existence of sleep spindle or K-complex. Usually, S3 is defined when 20% to 50% of slow wave activity (0.5-2 Hz) presented in an epoch, whereas more than 50% for S4 according to R&K criteria. For elder persons, S3 and S4 of deep sleep may not be obviously determined. The clinician inspected S3 and S4 based on a relatively different presence of slow wave activity (0.5-2 Hz) within an epoch.

C. Multi-valued decision making

1) Expert knowledge database construction

The overnight sleep recording from subjects were divided into consecutive 30s epochs for training purpose. Each epoch was subdivided into 5s segments. A set of characteristic parameters, extracted from the periodogram of EEGs, EOGs and EMG, were calculated for each segment. There are three types of parameters: ratio, amplitude and amount. Totally, 20 parameters were calculated. The parameters of consisting segments were taken average to derive the parameter value of one epoch.

The epochs were classified into sleep stage groups according to the visual inspection by clinician. The histogram for each parametric variable was created for each sleep stage. The probability density function (*pdf*) was approximately evaluated using histogram with Cauchy distribution. The *pdf* of parameter y in stage ζ is mathematically expressed by

$$f(y \mid \zeta) = \frac{b}{\pi((y-a)^2 + b^2)}, \tag{1}$$

where a is the location and b is the scale of Cauchy distribution. a is determined by media and b is determined by quartile [11].

The distance of the *pdfs* between stage i and stage j was calculated by

$$d(i, j) = \left| a_i - a_j \right|. \tag{2}$$

The larger distance indicates smaller overlap between the *pdfs*. It is measured by

$$d(i, j) > \max\{3b_i, 3b_j\}. \tag{3}$$

When the distance is larger than three times of the deviations of the probability density functions of both stages, the parameter is selected.

2) Automatic sleep stage determination

The overnight sleep recordings of subjects were divided into the same length of epochs and segments as the training data. The values of selected parameters were calculated for each segment.

Initially, predicted probability of first segment $P_{1|0}$ for various sleep stages shared the probability equally with a value of $1/n$. n is the number of the types of sleep stages.

The joint probability of the parameters for current segment k was calculated by

$$f(y_k \mid \zeta^i) = \prod_{l=1}^{m} f(y_k^l \mid \zeta^i), \tag{4}$$

where $y_k = \{y_k^1, y_k^2, \cdots, y_k^m\}$ is a parameter vector, and ζ^i denotes the sleep stage. In Eq.4, parameters in y_k were assumed to be independent with each other.

Conditional probability of segment k was calculated based on the Bayesian rule,

$$P_{k|k}(\zeta^i) = \frac{f(y_k \mid \zeta^i) P_{k|k-1}(\zeta^i)}{\sum_{j=1}^{n} f(y_k \mid \zeta^j) P_{k|k-1}(\zeta^j)}, \tag{5}$$

where $P_{k|k-1}(\zeta^i)$ is the predicted probability of current segment.

The sleep stage ζ^* was determined by choosing the maximum value among the conditional probabilities corresponding to various sleep stages as

$$\zeta^* : \max(P_{k|k}(\zeta^i)) \cdot \tag{6}$$

The predicted probability $P_{k+1|k}(\zeta^i)$ of next segment *k+1* was given by

$$P_{k+1|k}(\zeta^i) = \sum_{j=1}^{n} t_{ij} P_{k|k}(\zeta^j), \tag{7}$$

where t_{ij} denotes the probability of transition from stage *i* to stage *j*.

III. Result

A. Probability density function

The overnight sleep recordings of two subjects were utilized as the training data for expert knowledge database construction. The *pdfs* of the selected parameters are illustrated in Fig. 1. In the ratio of *ω1* (0.5-2 Hz) in EEGs, S3 and S4 of deep sleep had lager location values separated from other stages. S3 and S4 were slightly separated from each other among the training subjects of elder persons. The amplitude of *ω2* (2-7 Hz) in EEGs, REM and light sleep (S1, S2) showed relatively large location values comparing with others. The ratio of *ω3* (8-13 Hz) in EEGs can be the evidence for C(W). The amplitude of *ω4* (25-35 Hz) in EEGs indicated that stage awake of O(W) and C(W) were separated from other stages. The amount of *ω5* (2-10 Hz) in EOGs, S2 showed larger location value comparing with other stages. In the amount of *ω6* (25-100 Hz) in EMG, REM had the smaller location value comparing with other sleep stages. The combination of those selected parameters was utilized for manipulating the automatic sleep stage determination.

B. Sleep stage determination

The overnight sleep recordings of another two subjects were analyzed, which were different from the training data. The result of automatic sleep stage determination was evaluated comparing with the visual inspection. The recognition of sleep stage was appreciably satisfied. The average accuracy of two test subjects showed that stage awake was 85.8%, stage REM was 76.2%, light sleep (S1 and S2) was 80.6% and deep sleep (S3 and S4) was 95.7%.

IV. Discussion

A. Expert knowledge database

Rule-based method, which had been designed based on R&K criteria, can be found in many studies of computerized sleep stage scoring. The R&K criteria provide rules for sleep stage scoring with typical and normal waveforms of healthy persons. Additionally the conventional rule-based

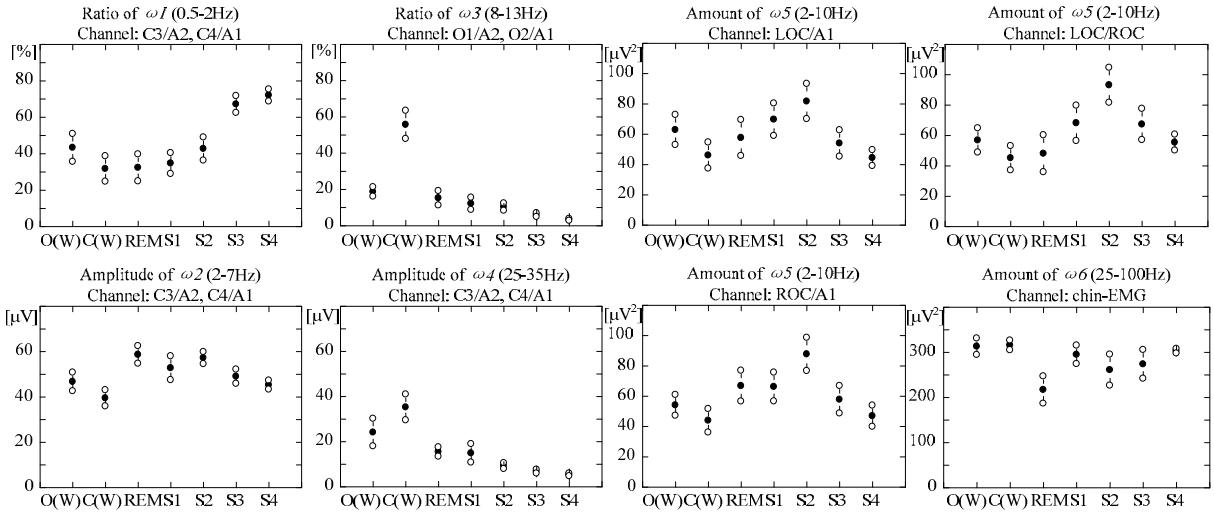

Fig. 1 Probability density functions of Cauchy distribution for the selected parameters corresponding to each sleep stage. The horizontal axis indicates the types of stages. The vertical axis is the value of parameters. "●" denotes the location of Cauchy distribution. "○" denotes the scale of Cauchy distribution.

methods did not consider the artifacts and surrounding circumstance in clinical practice. However, sleep data is inevitably affected by internal and external influences. The influences are complex and variable. Using R&K criteria only, those rule-based methods may be successful for the sleep data under ideal recording condition of healthy persons, but not for the sleep data under usual recording condition of patients at hospitals.

Unlike the rule-based method, our method is expert knowledge-based. The visual inspection by a qualified clinician takes an important role during the learning process of expert knowledge database construction. The clinician made visual inspection not only referring to R&K criteria, but also considering the artifacts and surrounding circumstance in the hospital. The visual inspection by a qualified clinician, thus, can be reliable to construct the knowledge database of probability density functions of parameters and manipulate the automatic sleep stage determination.

B. Parameter selection

Parameter selection was one component included in our learning process of expert knowledge database construction. The principle of parameter selection is to decrease the positive error and negative error of sleep stage determination. In our study, one parameter is not expected to distinguish all the sleep stages from each other. The *pdfs* of some stages may be overlapped. If the *pdf* of the stage is separated from others, this parameter can be selected. The next parameter would be selected if it can distinguish the stages in the overlapped part of previous parameters. A distance of three times of the deviation, which covers 99% of the *pdf*, is adopted for measurement. The combination of the selected parameters is optimized for manipulating the automatic sleep stage determination algorithm.

C. Clinical significance

In this study, the patients were from Toranomon hospital. Toranomon hospital is named for the diagnosing and treatment of Sleep Apnea Syndrome. A qualified clinician F.K. from Toranomon hospital made visual inspection on sleep stages. According to the visual inspection, expert knowledge database was constructed. The result of automatic sleep stage determination showed close agreement comparing with the visual inspection. Our system can satisfy the sleep stage scoring requirement in Toranomon hospital. In addition, our method is flexible to learn from any clinicians. Accordingly, the developed automatic sleep stage determination system can be optimized to meet the requirements in different hospitals and institutions.

V. Conclusion

An expert knowledge-based method for sleep stage determination was presented. The process of parameter selection enhanced the flexibility of the algorithm. The developed automatic sleep stage determination system can be optimized for clinical practice.

Abstract — **In this paper, we analyzed the relation between Respiration and EEG. For this, we acquired the EEG signal, ECG signal and respiration signal synchronously with keep time. And we defined SSR and Macrate which represent beat rate of heart per single unit of respiration and relational ratio of alpha wave and beta wave in EEG respectively. The reason why we defined SSR and Macrate is to compare and analyze two signals quantitatively. From the examination result about 10 reagents, we verified our proposal.**

Keywords — **EEG, SSR, MACRATE, RESPIRATION**

I. Introduction

Traditionally, it is said that alpha wave is strongly appeared when the person is in stable state [1]. And in oriental medicine, it is said that long-length respiration is close to more stable state than short-length respiration [2].

Then in this paper, we tried to analyze the relationship between EEG and respiration from the viewpoint of stable state. But in that case, there is no outstanding method to compare the degree of stability between EEG and respiration quantitatively.

Because of this, we defined SSR and Macrate which mean respectively relational ratio of stable state in EEG and relational heartbeat count per one period of respiration. To find out SSR and Macrate from the biomedical signals, it is essential to extract alpha and beta wave of EEG and feature points of ECG and respiration signal.

Wavelet transform is widely used in the field of signal processing, compression and decompression, neural network and etc. Comparing with Fourier transform, it has strong advantage that don't lose information of time location when the data transformation from spatial domain to frequency domain [3]. It could be significant thing to notice the occurring points of particular event during the processing data in frequency domain. Then wavelet transform could be proper method in case of this paper which aims at pursuit of variation of EEG spectrum with flow of time.

Using wavelet transform, in this paper, we decomposed the EEG signal to various signals which has different frequency bandwidth such as alpha wave and beta wave. And we estimated the power spectrum of EEG, alpha wave and beta wave to calculate the SSR.

In case of Macrate, respiration count and heartbeat count from ECG are essential for calculation. We used zero-crossing method to extract respiration count per minute and used wavelet based algorithm [4] to extract heartbeat count per minute.

II. Definition of Macrate and SSR

We defined SSR(Stable State Ratio) as following equation (1). Alpha wave is said that it is strongly extracted when the state is stable and beta wave is strong when the state is active. But everybody has his own amount of alpha wave then it cannot explain accurate degree of stable state of EEG. And then we used relative ratio of stable state and active state of EEG.

$$SSR = \frac{power\ spectrum\ of\ alpha\ wave}{power\ spectrum\ of\ beta\ wave} \quad (1)$$

We assumed the most stable state period as the period which one unit length of respiration is most long in the whole data of 20 minute respiration data. The Macrate is defined as following equation 2.

$$Macrate = \frac{beat\ count\ \ per\ \ minute}{respiration\ count\ \ per\ \ minute} \quad (2)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 51–54, 2009
www.springerlink.com

III. Feature Point Extraction and Relational Analysis

To compute SSR, extraction of alpha wave and beta wave from EEG and estimation of power spectrum are necessary. EEG data used in this paper is the data from the frontal lobe (the sixth channel) among the data of eight channel EEG data. And its sampling frequency is 256 Hz. Then the valid range of frequency are 0 ~ 128Hz according to the Nyquist sampling principle. Following table 1 shows the seven level decomposition results of EEG data using wavelet transform

Table 1: Frequency band of EEG signal according to the decomposition level.

Level	A	Frequency	D	Frequency
1	cA_1	0 Hz ~ 64 Hz	cD_1	64 Hz ~ 128 Hz
2	cA_2	0 Hz ~ 32 Hz	cD_2	32 Hz ~ 64 Hz
3	cA_3	0 Hz ~ 16 Hz	cD_3	16 Hz ~ 32 Hz
4	cA_4	0 Hz ~ 8 Hz	cD_4	8 Hz ~ 16 Hz
5	cA_5	0 Hz ~ 4 Hz	cD_5	4 Hz ~ 8 Hz
6	cA_6	0 Hz ~ 2 Hz	cD_6	2 Hz ~ 4 Hz
7	cA_7	0 Hz ~ 1 Hz	cD_7	1 Hz ~ 2 Hz

Generally, according to frequency, brain wave pattern is classified to alpha wave correspond to 8~12Hz, beta wave correspond to 13~35Hz , theta wave correspond to 4~7 Hz, delta wave correspond to 0.3~3.5 Hz and etc. Alpha wave is the signal which is outstanding pattern among the various brain wave patterns and it is generally appeared when the eyes is closed, the stable state mentally and silence circumstances from the frontal lobe or occipital region of head [1].

As shown in the above table 1, the frequency band of alpha wave is belonged in the component cD_4. To decompose that component again using wavelet, cD_4A_1(8 ~ 12 Hz) and cD_4D_1(12 ~ 16 Hz) is appeared. Because frequency band of alpha wave is about 8 ~ 12Hz, we choose the cD_4A_1 component as alpha wave and cD_3 component as beta wave.

With extracted alpha and beta wave, we estimated the power spectrum of wave to find out SSR which represents the degree of stability quantitatively. There are generally three kinds of method in power spectral analyzing method such as correlation function method (Blackman-Tukey), FFT method and linear prediction model method. Among these, B-T method and FFT method are generally used and linear prediction model is used when the data length of acquisition is very short relatively [5]. So we used FFT method in this paper, it is because the length of EEG signal was sufficiently long as its length was 20 minutes.

Next, to get the Macrate, extraction of heartbeat from ECG and respiration count per minute is necessary. At first, to recognize QRS complex of ECG and to achieve heartbeat count per minute, we used wavelet method [6]. At second, to recognize period of respiration, we used zero crossing method

Relational analysis is the method which is used to find out the linear relationship between two different variables. And generally relational coefficient as seen as following equation (3) is used.

$$r = \frac{S_{XY}}{\sqrt{S_{XX}}\sqrt{S_{YY}}}, \qquad -1 \le r \le 1 \tag{3}$$

In this paper, we aimed to find out the quantitative relation between EEG and respiration at the viewpoint of stable state. Then, with accomplished SSR and Macrate, we did relational analysis.

IV. Results

The data used in this paper was EEG signal, ECG signal and respiration signal which were synchronized with time accurately from 10 persons for 20 minutes respectively. The following figure 1 shows acquired EEG signal and extracted alpha & beta signal by wavelet method. And the following figure 2 shows moving spectral result of alpha wave spectrum over EEG signal spectrum, beta wave spectrum over EEG signal spectrum and alpha wave spectrum over beta wave spectrum for 20 minutes. In the figure 3, horizontal axis means time and vertical axis rate of each spectrum.

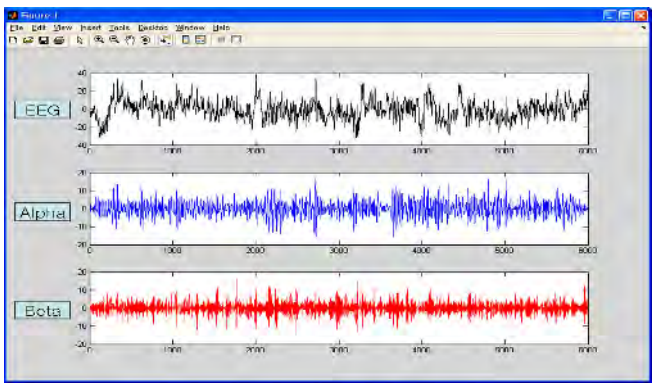

Figure 1: Extraction of alpha wave and beta wave.

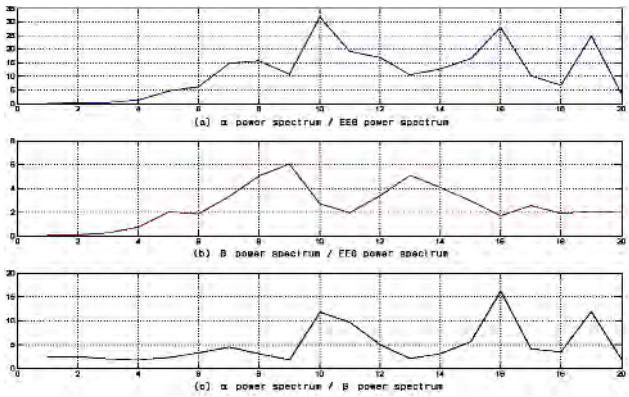

Figure 2: The result of power spectrum of EEG.

The following figure 3 shows SSR in most high Macrate in the whole respiration signal. In the figure 3, upside figure is SSR and downside figure is Macrate. And these two signals are synchronized with accurate time.

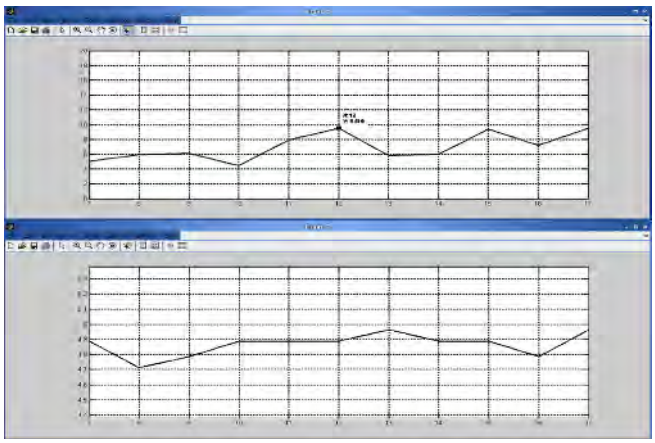

Figure 3: The SSR and Macrate.

The following table 2 is result of relational analysis about SSR and Macrate about a reagent. And figure 4 is the scatter plot of table 2. Relational analysis in this paper was performed by SPSS software version 12K.

Table 2: The result of relational analysis between SSR and Macrate

		SSR	Macrate
SSR	r	1	.431
	P-value		.000
	N	114	114
Macrate	r	.431	1
	P-value	.000	
	N	114	114

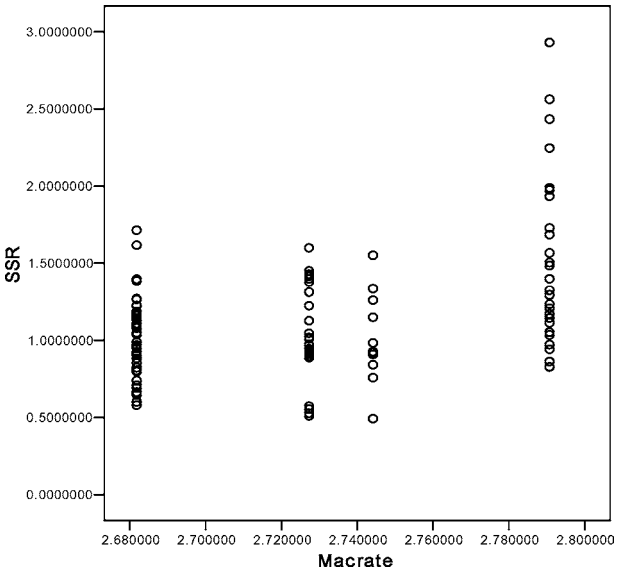

Figure 4: Scatter plot of result which is shown in table 2.
It can see that SSR is more growing in high Macrate.

The following table 3 is the result of all 20 reagents. As shown in table, SSR and Macrate have relation from 20.5% to 43.1%

Table 3: The result of relational analysis about 10 reagents

Reagent	Result	Reagent	Result
1	0.247	6	0.268
2	0.239	7	0.380
3	0.220	8	0.431
4	0.356	9	0.292
5	0.205	10	0.237
Average		0.290	

V. Conclusion

In this paper, we analyze the relationship between SSR and Macrate in order to find out quantitative relation between EEG and respiration at the viewpoint of stable state. To accomplish this aim, we extracted the feature points of bio-signals such as EEG, ECG and respiration signal from 10 reagents. And we defined and calculate the SSR and Macrate as a quantitative index of stable state. And last, from the relational analysis, we could come to conclusion that EEG and respiration have relation each other. Future work contains more plenty of experiment and etc.

Abstract — **Thyroid diseases are prevalent among endocrine diseases. The microscopic image of thyroid tissue is the necessary and important material for investigating thyroid functional mechanism and diseases. A computerized system has been developed in this study to characterize the textured image features of the microscopic image in typical thyroid tissues, and then the compositions in the heterogeneous thyroid tissue image were classified and quantified. Seven image features were implemented to characterize the histological structure representation for tissue types including blood cells, colloid, fibrosis tissue, follicular cell. The statistical discriminant analysis was implemented for classification to determine which features discriminate between two or more occurring classes (types of tissues). The microscopic image was divided to be contiguous grid images. The image features of each grid image were evaluated. Multiple discriminant analysis was used to classify each grid image into the appropriated tissue type and Markov random fields were then employed to modify the results. 100 random selected clinical image samples were employed in the training and testing procedures for the evaluation of system performance. The results show that accuracy of the system is about 96%.**

I. Introduction

Thyroid diseases including nodules, goiters, adenomas, even carcinomas, and other related diseases are prevalent among endocrine diseases [1,2]. A thyroid nodule is the common initial manifestation of most thyroid tumors. There are many methods in clinical examination for thyroid diseases. Observation and examination of histological tissue images can help in understanding the cause and pathogenesis of the thyroid diseases. The benignancy or malignancy of thyroid nodules and tumors can be discriminated by microscopic observation on image features of tissue.

From the viewpoint of morphological architectures in histopathology, many specific image features are important indexes and references for thyroid diseases [3]. The functional unit of the main endocrine system in the thyroid is the follicle, a closed spheroid structure lined by a single layer of epithelial cells. It is filled with colloid. With the onset of nodular goiter, the number of follicles is increased and the epithelial cells are enlarged and columnar. The follicle is a colloid-rich area. Epithelial cells lining the follicles are flat and most of the follicles are distended with colloid. Fig. 1 (a) shows the typical image of nodular goiter. Fig.1 (b) shows the architectural characteristics of papillae in papillary carcinoma. The cells are arranged around well-developed papillae. The stroma is represented by loose connective tissue. Fig. 1(c) shows the microscopic image of follicular adenoma. These types of tumors exhibit morphological evidence of follicular cell differentiation. A detail of the adenoma depicted in Fig.1(c) shows a regular microfollicular and solid architectural pattern with little cytological atypia. Medullary carcinoma usually has clear microscopic evidence of infiltration into the surrounding thyroid parenchyma. Blood vessel invasion is common, and involvement of lymph vessels and regional lymph nodes are also frequently found.

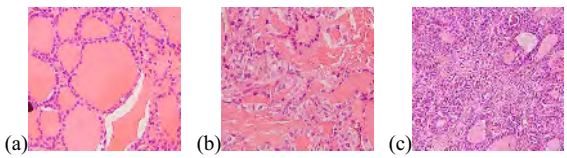

Fig. 1 Typical tissue microscope image of thyroid disease (H&E staining, 200X) (a) Thyroid nodular goiter (b) Papillary carcinoma (c) Follicular adenoma

Because of the histological complexity and diversity, the image examination and related clinical practices are redundant and time-consuming. Furthermore, the quality of clinical reading heavily depends on the experiences of clinical practicer. Therefore, a computerized system has been developed in this study to characterize the textured image features of the microscopic image in typical thyroid tissues, and then the compositions in the heterogeneous thyroid tissue image are classified and quantified. The image features and morphological differentiation of follicles within the thyroid are the determined characteristics for various diseases. With advancements of methodologies in digital image processing, digital images can assist in deducing meaningful revelations from implicit details. Armed with the image characteristics of thyroid tissue, the theorems and technologies of digital image processing and

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 55–59, 2009
www.springerlink.com

feature classification can be implemented for thyroid tissue microscopic image feature characterizing and quantifying.

In this paper, methodologies using image and texture analysis techniques regarding characterizations and quantifications of typical microscopic images of follicles, colloid, blood cells, stroma are proposed. The results of identical tissue segmentation from heterogeneous images by implementing the statistics-based image segmentation with MRF modification technique are presented as well.

II. Materials and Methods

A. Image Acquisition

Slices of histopathological thyroid tissue were made through routine paraffin embedding and hematoxylin-eosin (H&E) staining. The digitized tissue images were obtained from microscope (Nikon 80i) at magnification of 100x using a DSLR camera (Nikon D80). The image resolution was set as 3872×2592 pixels and 24 bits per pixel. The aperture and shutter of camera was kept consistent between samples.

B. Statistical image Features analysis and tissue characterization

Seven image features including pixel-level features and high-order texture features were used in the study to evaluate the image characteristics of five typical histological thyroid tissues. The statistical pixel-level features include *mean of Brightness*, *Standard Deviation of Brightness*(SDB), *mean of Hue*, *Entropy*, and *Energy* of the selected image areas. These features provide quantitative information about the pixels within a segmented region [4]. *Hurst* value derived from fractal analysis reveals the roughness of the selected image areas. The high-order texture features are *Regularity* of *statistical feature matrix*(SFM). The statistical stepwise selection was implemented to exclude insignificant features. Then multiple discriminant analysis was used for the classification of features. Our previous study for tissue classification with these image and texture features has been proposed in [5].

C. Markov Random Fields

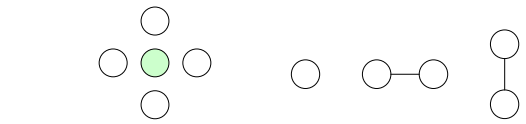
Markov random fields (MRF) theory is a stochastic model-based approach for texture analysis. The image and texture features are considered in the random status. For every latticed image, with the neighborhood system and the property of joint condition probability density, the texture data can be fitted with defined stochastic models and the one which gives the best approximation to the data can be determined. The approach are widely used for image recovery and denoising.[6-9]

Based on the concept of MRF, the states of the sites in the system have to be limited. After evaluating the conditional probabilities between neighber sites, the probabilities would be applied to determine the state of the site. With finite states space, the transition probability distribution can be represented by a matrix, called the transition probability matrix(TPM). The TPM with sites in n states takes the following basic form

$$P = \lfloor p_{ij} \rfloor \quad 0 \le i, j \le n \text{ , and} \tag{1}$$

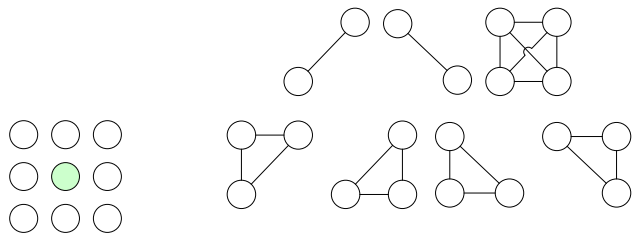
$$p_{ij} \ge 0, \quad \sum_{j=0}^{\infty} p_{ij} = 1 \quad \text{for any } i \text{ .} \tag{2}$$

- Neighborhood System and Clique



Let $S = \{s_{11}, s_{12}, ..., s_{ij}, ..., s_{nn}\}$ be a set of sites (grid images in this study). A set $NSS \equiv \{NSS_{s_{ij}}\}_{s_{ij} \in S}$ is called a neighborhood site set on the set of sites S if

$$s_{ij} \notin NSS_{s_{ij}} \tag{3}$$



and

$$s_{ij} \in NSS_{s_{ml}} \Leftrightarrow s_{ml} \in NSS_{s_{ij}} \text{ .} \tag{4}$$

The size of *NSS* is determined by the geometrical configuration. A subset $c \subseteq S$ is a clique if every pair of distant sites in c is neighbors. C denotes the set of c. Fig. 1 shows two kinds of neighborhood system in different order with cliques.

(a) First order

(b) Second order

Fig. 1 neighborhood system and cliques

- Gibbs Distributions

Let $\Lambda = \{1,2,3,...,L-1\}$ denote the common state space, where L is the number of the state. In this study, Λ labels the classified type of tissue. Therefore, all of the sites in the MRF must belong to Λ.

Let $\Omega = \{\omega = (\omega_{s_1},...,\omega_{s_N}) : \omega_{s_i} \in \Lambda, 1 \le i \le N\}$ be the set o all possible configurations. X is an MRF with respect to *NSS* if

$$P(X = \omega) > 0 \quad \text{for all } \omega \in \Omega ; \tag{6}$$

$$\begin{aligned} &P(X_s = x_s \mid X_r = x_r, r \neq s) \\ &= P(X_s = x_s \mid X_r = x_r, r \in NSS) \end{aligned} \tag{7}$$

The probability distribution $P(X = \omega)$ in Eq(6) is uniquely determined by these conditional probabilities. Gibbs distribution and Hammersley-Clifford theorem were proposed to characterize the probability distribution [8]. The Gibbs distribution has a probability measure π on Ω with the following equation:

$$p(X = \omega) = \frac{1}{Z} e^{-U(\omega)}, \tag{8}$$

where Z is the normalizing constant represented by:

$$Z = \sum_{\omega \in \Omega} e^{-U(\omega)}, \tag{9}$$

and

$$U(\omega) = \sum_{c \in C} V_c(\omega). \tag{10}$$

The function $U(\cdot)$ is called the energy function, and $V_c(\cdot)$ is called a potential function determined from the relational entries of TPM depending on the values ω_s of ω for which $s \in C$.

D. System Operation

The aforementioned theories were implemented in this system to train the ability for recognition and improve the performance of the system for the tissue classification in heterogeneous tissue microscopic image. Fig. 2 shows the schematic flowchart of the proposed system. The image samples were divided to be contiguous grid images. Two phases, the training phase and recognition phase, were then established in the procedures and they are described in the following paragraphs.

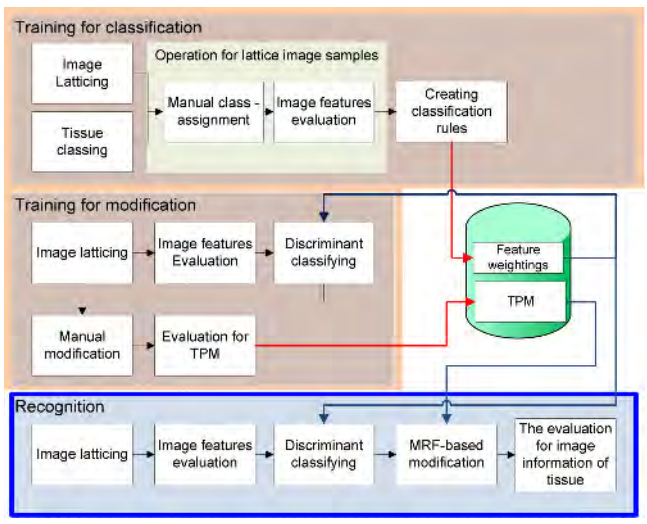
- Training phase

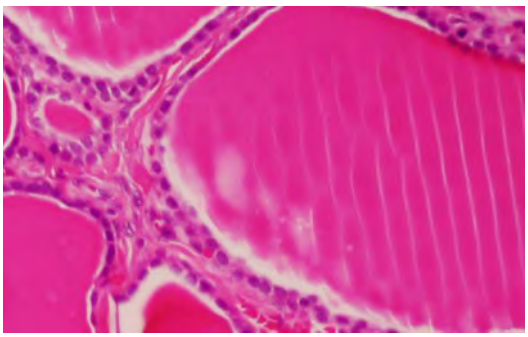
Two steps were included in this phase. One step was performed to evaluate the feature weightings for applying the discriminant classification rules. The tissue type of every grid image was manually assigned. These aforementioned statistical texture features were then calculated. Finally, discriminant analysis was implemented to evaluate the feature weightings of discriminant classification rules for types of tissue including blood cells, colloid, fibrosis tissue, and follicular cell.

The following training step is performed to estimate the transition probability matrix for MRF-based class modification. The images in the database for training were extracted and latticed. All of the grid image were roughly classified by applying the discriminant analysis. The misclassified grid images were manually corrected. Finally, the MRF algorithm was implemented to the grid images to establish the TPM.

- Recognition phase

For every grid image of latticed microscopic image, the aforementioned image and texture features were implemented to characterize the histological structure representation for tissue types. These image and texture feature were implemented to evaluate the characteristics of textures. Using the feature weightings, the statistical discriminant analysis was implemented for classification to determine tissue type of grid image. MRF using established TPM were then employed to modify the results of the misclassified grid images.





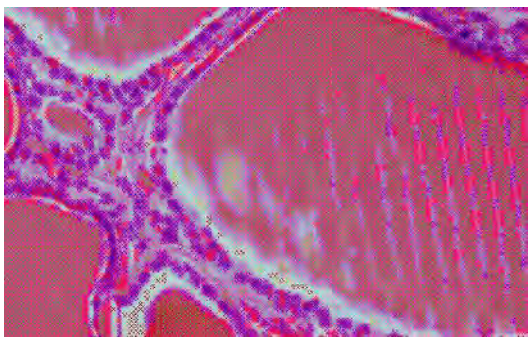


Fig. 2 Schematic flowchart of this proposed system

III. Results and discussion

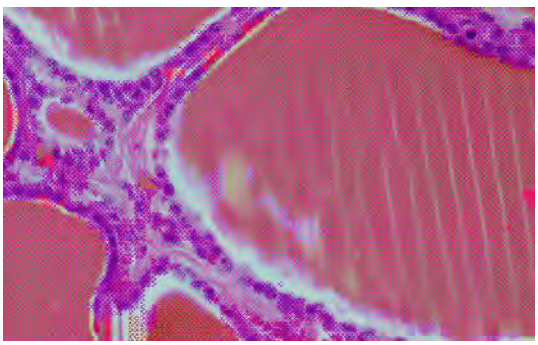

Fig. 3 shows an example of image segmentation by using this proposed system. This image in (a) mainly contains two types of tissue: follicular cells and colloid blocks. Because of the problem of tissue samples making and preserving, some empty areas and fissures appear between normal tissues. Fig. 3(b) shows the result of image classification applying discriminant analysis. Some grid images were misclassified as blood cells (red blocks). As shown in (c), after the process of MRF-based modifications, most of the misclassified grids were corrected.

(a) Original image with follicular cells and colloid

(b) The results of classification after discriminant analysis

(c)The results of modification after using MRF

Fig. 3 The examples for microscopic image segmentation with heterogeneous tissues

Sensitivity, specificity, and accuracy of four approaches with different combinatorial methods were evaluated. These methods used in this four approaches were: 1) the discriminant analysis (DA), 2) the discriminant analysis with empirical rules (DA+ER), 3) discriminant analysis with empirical rules and MRF-based modification (DA+ER+MRF), and 4) discriminant analysis and MRF-based modification (DA+MRF). The empirical rules were determined from the statistical distribution of the image features of tissue classes. The images of every kind of tissue were selected by our clinical fellow.

100 random selected clinical image samples were employed in the training and testing procedures for the evaluation of system performance. 50 images are used for training and the others are used for testing. The performance evaluations of the proposed methodologies are listed in Table 1. The results show the two approaches using MRF have higher sensitivity and specificity. The approach of DA+MRF has the highest performance with accuracy about 96%.

Table 1 Performance Measure of the proposed methods

	DA	DA+ER	DA+ER +MRF	DA+MRF
Sensitivity	0.576	0.561	0.655	0.793
Specificity	0.919	0.917	0.951	0.977
Accuracy	0.897	0.896	0.936	0.966

IV. Conclusions

In this paper, the microscopic images of thyroid heterogeneous tissues were characterized and classified by combinatorial approaches applying image features classification, statistical discriminant analysis and MRF based class modification. The results show the algorithm has good performance and high capability for classification of pathological tissues of thyroid nodule. We hope that the information provided from these succeeding studies will have a reliable means for the related clinical analysis of thyroid diseases.

Abstract — **In this work the authors have developed and evaluated a new approach for the feature analysis of normal and abnormal beats of electrocardiogram (ECG) based on the discrete-wavelet-transform (DWT) coefficients using Daubechies wavelets. In the first step the real ECG signals were collected from the normal and abnormal subjects. DWT coefficients of each data window were calculated in the Matlab 7.4.0 environment using Daubechies wavelets of order 5 to a scale level of 11. The detail information of levels 1 and 2 was discarded, as the frequencies covered by these levels were higher than frequency content of the ECG. Thus for a scale level 11 decomposition, coefficients associated with approximation level 11 and details level 3 to 11 were retained for further processing. The recorded ECG was classified in to normal sinus rhythm (NSR) and three different disease conditions, namely: atrial fibrillation (AF), acute myocardial infarction (AMI) and myocardial ischaemia based on the discrete wavelet transform coefficients of isolated beats from the multi-beat ECG information.**

Keywords — **ECG, Discrete-wavelet-transform (DWT), atrial fibrillation (AF), acute myocardial infarction (AMI), myocardial ischaemia.**

I. Background

Cardiac arrhythmias can be catastrophic and life threatening. Special kind of arrhythmia: atrial fibrillation (AF) has its special pattern on the shape of ECG; it perturbs the electrocardiogram and in the same time complicates automatic detection of other kinds of arrhythmia [1]. The problem has been described as a challenge by both Computers in Cardiology and PhysioNet. Permanent and paroxysmal AF is a risk factor for the occurrence and the recurrence of stroke, which can occur as its first manifestation. However, its automatic identification is still unsatisfactory [2]. Atrial fibrillation (AF) is an arrhythmia associated with the asynchronous contraction of the atrial muscle fibres. It is the most prevalent cardiac arrhythmia in the western world, and is associated with significant morbidity. Heart diseases, in particular acute myocardial infarction (AMI), are the primary arrhythmic events in the majority of patients who present with sudden cardiac death [3]. Myocardial ischaemia is yet another cardiac disorder which needs urgent medical attention. The single most common cause of death in Western culture is ischaemic heart disease, which results from insufficient coronary blood supply [4]. Approximately 35 percent of all human beings who suffer from cardiac disorders in the United Sates die of congestive heart failure, the most common cause of which is progressive coronary ischaemia [5].

II. Introduction

Cardiac arrhythmias detection is important because they determine the emergency conditions (risk of life). Heart abnormalities are not identifiable in the electrocardiogram (ECG) recorded from the surface of the chest at the very early stage. They become visible in the ECG after the disease is in place. If certain heart diseases are not diagnosed, evaluated and treated at the early stage, such a condition may lead to the risk of sudden cardiac death. Since heart diseases can be treated, early recognition is important.

In particular, AF beat, AMI and myocardial ischaemia indicate susceptibility to life-threatening conditions. Moreover, the probability of recovery is often greatest with proper treatment during the first hour of a cardiac disturbance [6]. Measurements of the width or duration of waves in the ECG widely used to define abnormal functioning of the heart [7], to detect myocardial damage and to stratify patients at risk of cardiac arrhythmias is not only time consuming and slow but also inadequate. We therefore need a faster and accurate method of cardiac analysis using wavelet coefficients. In this study, a new wavelet-based technique has been proposed for the identification, classification and analysis of arrhythmic ECG signals.

In the recent times the wavelet transform has emerged as a powerful time–frequency signal analysis tool widely used for the interrogation of nonstationary signals. Its application to biomedical signal processing has been at the forefront of these developments where it has been found particularly useful in the study of these, often problematic, signals: none

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 60–64, 2009
www.springerlink.com

more so than the ECG. The method is particularly useful for the analysis of transients, aperiodicity and other non-stationary signal features where, through the interrogation of the transform coefficients, subtle changes in signal morphology may be highlighted over the scales of interest. The method proposed by the authors makes use of the isolated beats from real ECG records by importing the ECG data files into Matlab 7.4.0 environment.

III. Methods

The authors collected the ECG records from 233 subjects and examined with the help of an expert cardiologist and are used throughout this study. The control data of 120 records comprising 80 normals (NOR) and 40 abnormals (ABN) with arrhythmias were sorted and analyzed using Daubechies wavelet transform. Then a validation group of 70 subjects' ECG records known as the *test data* were studied using these criteria. Out of the 70 records 40 taken from normal persons and 30 with pathological heart beats were analyzed which allowed the authors to establish the specific cardiac cycle characteristics to differentiate the healthy sinus rhythm from the abnormal cardiac functioning using wavelet analysis.

The ECG data files are converted to text (.txt) files and later to Mat (.mat) files. The Mat files were imported in to Matlab workspace and with the help of the code written in Matlab version 7.4.0 the decomposition of coefficients were computed.

This method decomposes the ECG originally into 5 transformed signals at 11 different scales and makes use of scales 3 to 11 of the wavelet transform. In this method only scales 3 to 11 are used to characterize the ECG signal as these prove to give optimum results. A derived criterion is applied on a combination of such scales to determine the abnormal cardiac waves, in addition to the specific level of coefficients as discussed hereafter.

For this study, the Daubechies wavelet family was retained that represented the most commonly used family of orthogonal wavelets for detecting ECG events. The member of the corresponding family, DB5, to use was then picked out: on the one hand by relying on a thorough investigation of related literature. And on the other, by analyzing the results of the applications. The complete separation of relevant waves from the ECG signals prior to interpretation is still an open problem because of the noisy nature of the input data.

A. Experimental setup and data acquisition

The battery operated, portable and cost effective ECG acquisition system has been designed and developed as a separate part of this project [8]. The module, developed and implemented is used for ECG recording. The ECG is amplified, filtered (0.5 -120 Hz) and converted into digital form before being processed. The signal is sampled at 2 kHz. A digital signal processing system, PC with Matlab 7.4.0 was placed for data acquisition, processing and storage. The 30 seconds of signals comprising 36 cycles for a normal heart rate of 72 beats per minute were recorded and stored for analysis.

Authors have used discrete wavelet transform (DWT) for data processing to extract classifier features' decomposition coefficients allowing authors to differentiate the heart diseases from the sinus rhythm (SR).

B. Selection of the wavelet functions

There is no absolute rule to determine the most adequate analyzing wavelets; the choice must always be specific to the application as well as to the analysis requirements. The efficiency in extracting a given signal based on wavelet decomposition depends greatly on the choice of the wavelet function and on the number of decomposition scales [9]. In this study, a straightforward approach for wavelet selection was based on: 1) Literature where wavelets have already been used for ECG processing. 2) Suitability of a particular member of the family of wavelets for the analysis of specific cardiac abnormality signals. The Daubechies wavelets DB5 have shown to be very adequate for the present analysis, based on the similarity between ECG samples and the selected member of the considered family. These two approaches resulted in an optimal group of results. Table 1 shows the ECG waves, their morphology and the suggested diseases.

Table 1 ECG waves, morphology and the suggested diseases

Wave	Morphology	Disease
P wave	Absent	Atrial fibrillation
S-T segment	Eleveted	Acute myocardial infarction
S-T segment	Depressed	Myocardial ischaemia
T wave	Too tall	Acute myocardial infarction
T wave	Inverted	Myocardial ischaemia

IV. Results and validation

The authors used their own ECG database to carry out tests on the method used, which is aimed at helping doctors analyze patient records. Finally real ECG records were used to determine the DWT coefficients. The method proposed by the authors makes use of the isolated beats from real ECG records. The sample numbers of onset of P wave and

offset of T wave were provided in the Matlab code for single cycle extraction and each ECG cycle both normal and abnormal was viewed before the corresponding mat file being used for computation of DWT coefficients. The DWT coefficient values corresponding to P and T waves and S-T segment appearing with certain morphologies are analyzed and classified. The efficiency of algorithm performance of the presented method was tested on the *control data* group and over the validation database namely *test data* group. Wavelet decomposition coefficients computed for *quite representative signals* were classified and tabulated for analysis. Real ECG signals recorded on healthy and pathological persons provided a very interesting aspect for the heart beats evaluation, given that the total ECG vector was viewed in the Matlab 7.4.0 environment and the positions of the arrhythmias in the signal were known *a priori* and hence could be isolated and compared to the result of the normal cycle extraction. The decomposition coefficients cd3 to cd11 of a normal sinus beat; the intervals and amplitudes defined by its features being within the normal limits are tabulated for the analysis.

Single cycles of normal cardiac cycles are shown in figures 1 and 2. The corresponding decomposition coefficients cd3 to cd11 are shown in table 2 for subject 1 and cycle 1.

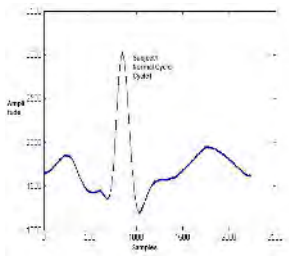

Figure 1 Normal cardiac cycle

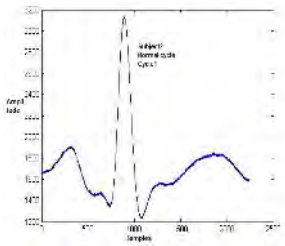

Figure 2 Normal cardiac cycle

Table 2 Detail coefficients cd3-cd11

Sub No	Cd11	Cd10	Cd9	Cd8
Sub1c1	-30.5687	-5.2672	-1.085	-0.7601
Cd7	Cd6	Cd5	Cd4	Cd3
-0.4279	-0.1813	-0.0518	-0.5416	-0.0335

All the coefficients cd3 to cd11 are found to be negative for the normal cardiac cycle.

The single cardiac cycles with P wave absent indicating atrial fibrillation are shown in figures 3 and 4.

The corresponding detail coefficients cd8 to cd11 pertaining to the low frequencies of P wave for cycles one each of subjects 1 and 2 are shown in table 3. The positive value of cd11 indicates the abnormal (P wave absent)

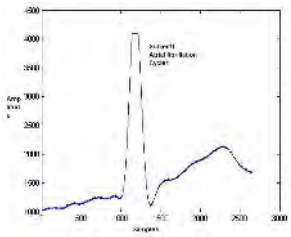

Figure 3 Atrial fibrillation

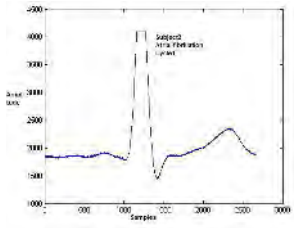

Figure 4 Atrial fibrillation

Table 3 Detail coefficients cd8-cd11

Sub No	Cd11	Cd10	Cd9	Cd8
Sub1c1	10.120	-12.948	-1.2119	-0.6643
Sub2c1	12.938	-6.9889	-0.0571	-0.0877

condition. The negative values of cd8 to cd10 and cd10 being the most significant one as examined by the authors represent presence of normal T wave.

S-T segment elevation merges with upstroke of the T wave and makes it too tall both being suggestive of acute myocardial infarction as shown in figures 5 and 6. The corresponding detail coefficients cd8 to cd11 are shown in table 4. In this particular abnormality it is again seen that the coefficients cd8 to cd11 are negative indicating the presence of normal P wave and too tall T wave. The authors used a derived criterion of combination of scales' coefficients is applied and determined that cd10 (11) is positive viz. 1353.417, 1404.941 for subjects 1 and 2 respectively.

Also S-T segment depression overlaps with the upward deflection of the T wave tending it to be inverted, which suggests myocardial ischaemia are shown in figures 7 and 8.

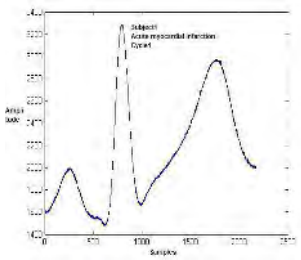

Figure 5 Acute myo cardial infarction

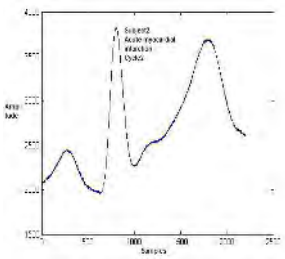

Figure 6 Acute myo cardial infarction

Table 4 Detail coefficients cd8-cd11

Sub No	Cd11	Cd10	Cd9	Cd8
Sub1c1	-50.254	-10.701	-1.5729	-1.4563
Sub2c1	-54.196	-14.072	-2.4537	-1.5028

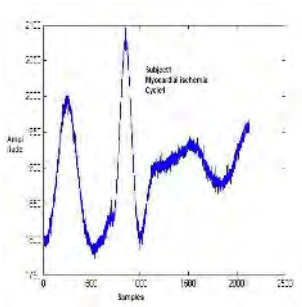

Figure 7 Myocardial ischaemia

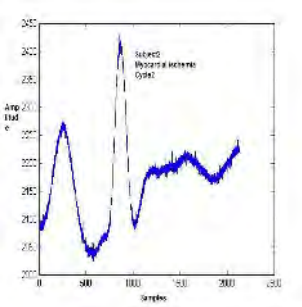

Figure 8 Myocardial ischaemia

The corresponding detail coefficients cd8 to cd11 pertaining to the low frequencies of T wave for cycles one each of subjects 1 and 2 are shown in the table 5. The negative value of cd11 indicates the presence of normal P wave. The coefficients cd8 to cd10 being positive represent the abnormal (inverted) T wave. Scales 8, 9 and 10 were found to characterize the ECG signals well enough for the detection T wave whereas scale 11 was used for the detection of the P wave.

Table 5 Detail coefficients cd8-cd11

Sub No	Cd11	Cd10	Cd9	Cd8
Sub1c1	-14.392	1.0497	0.0689	0.0742
Sub2c1	-12.257	1.6625	0.1379	0.1069

The classification of recorded ECG into normal cycles and diseases such as atrial fibrillation, acute myocardial infarction and myocardial ischaemia based on DWT coefficients is summarized in table 6.

Table 6 Classification of NSR and cardiac diseases based on DWT coefficients

	Cd8-Cd10	Cd11	Cd10 (11)
Normal *	Negative	Negative	Negative
AF	Negative	Positive	--------
AMI	Negative	Negative	Positive
Myocardial Ischemia	Positive	Negative	--------

* For normal ECG cycles all DWT coefficients including cd3-cd7 (table 2) are found to be negative.

V. Discussion and Concluding Remarks

The wavelet transform has emerged over recent years as a key time–frequency analysis and coding tool for the ECG. The wavelet transform allows a powerful analysis of non-stationary signals, making it ideally suited for the high-resolution interrogation of the ECG over a wide range of applications. It provides the basis of powerful methodologies for partitioning pertinent signal components, which serve as a basis for potent diagnostic strategies.

Much work has been conducted over recent years into AF, AMI and myocardial ischaemia centered on attempts to understand the pathophysiological processes occurring in sudden cardiac death, predicting the efficacy of therapy, and guiding the use of alternative or adjunct therapies to improve resuscitation outcomes. The authors have achieved 99.1% sensitivity for discriminating, AF episodes, AMI and myocardial ischaemia beats. The final structure for the proposed Matlab code is short and computationally very efficient and easily lends itself to real-time implementation. In conclusion, it has been shown that the wavelet transform is a flexible time–frequency decomposition tool that can form the basis of useful signal analysis and coding strategies. It is envisaged that the future will see further application of the wavelet transform to the ECG as the emerging technologies based on them are honed for practical purpose.

Detecting and separating P wave, T waves and S-T segment can be a difficult task. This technique provided a basis for distinguishing healthy patients from those presenting with atrial fibrillation, acute myocardial infarction and myocardial ischaemia. The study of the changes in DWT coefficients on a beat-by-beat basis provided important information about the state of heart mechanisms in both physiological and pathological conditions. The authors found that wavelet analysis was superior to time domain analysis for identifying patients at increased risk of clinical deterioration. The approaches shown here have proved to yield results of comparative significance with other current methods and will continue to be improved.

Abstract — **Endothelial dysfunction, which can be non-invasively assessed by flow mediated vasodilation (FMD), predicts an increased rate of adverse cardiovascular events. The endothelial dysfunction is considered as a leading cause of development and progression of the atherosclerotic process. The main aim of this study is to review different non-invasive methods to assess the endothelial dysfunction and to propose enhancements to a new method based on photoplethysmography (PPG). First, non-invasive techniques developed for the evaluation of peripheral endothelial function (including the Doppler ultrasound (US)) will be reviewed. Although non-invasive, US -based techniques present a few disadvantages. To remedy to the above disadvantages, another technique based on pulse wave analysis is introduced. Although amplitude-based features from the photoplethysmogram has produced encouraging results, there are cases where the complete equivalence with US-FMD based on ultrasound measurement cannot be established. Therefore more elaborated features combined with data processing techniques are proposed which seem promising enough for the PPG-based technique to be used as a replacement method for US-FMD measurement. The ultimate aim is to assess the endothelial function and the presence of significant atherosclerotic events leading to peripheral vascular disease using a practical, simple, low-cost, non-operator dependent and alternative non-invasive technique in a clinical setting.**

Keywords — **Endothelial function, Flow mediated vasodilation, Photoplethysmography.**

I. Introduction

Endothelial cells play a critical role to control the vascular function. They are multifunctional cells which regulate vascular tone, smooth muscle cell growth, passage of molecules across their cell membranes, immune response, platelet activity and fibrinolytic system [1,2]. They are located in vascular wall which is consisted of 3 layers; intima that is the closest to the blood lumen, media is in the middle and adventitia which is the exterior ones. The endothelium is a thin layer of cells which are placed in the interior surface of intima. The strategic location of the endothelium allows it to sense changes in hemodynamic forces by membrane receptor mechanisms and respond to physical and chemical stimulus which provokes the endothelium to release nitric oxide (NO) with subsequent vasodilation [1,2,3].

Endothelial dysfunction (ED) is implicated in the pathogenesis and clinical course of the majority of cardiovascular diseases. It is thought to be an important factor in the development of atherosclerosis, hypertension, and heart failure and is strongly correlated with all the major risk factors for cardiovascular disease (CVD). ED by definition is any kind of alteration in the physiology of the endothelium which produces a decompensation (failure of compensation in cardiac) in its regulatory functions which represents a systemic disorder that affects the vasculature [4].

Many blood vessels respond to an increase in flow, or more precisely shear stress, by dilating. This phenomenon is designated as flow mediated vasodilation (FMD) where vascular dilation occurs in response to agents which stimulate the secretion of nitric oxide. FMD appears to be mediated primarily by the action of endothelium derived nitric oxide (NO) on vascular smooth muscle. Generation of NO is dependent on the activation of the enzyme endothelial Nitric Oxide Synthase (eNOS). Inhibition of this enzyme abolishes FMD in arteries. In recent years, various non-invasive techniques have been developed for the evaluation of coronary and peripheral endothelial function. Doppler ultrasonography is one of the non-invasive techniques which is based on detecting alterations in arterial vasoreactivity under different physiological and pharmacological stimuli [4].

II. Non-invasive techniques

A. FMD Ultrasound

Flow-mediated vasodilation is an endothelium-dependent process that reflects the relaxation of the artery when it is faced with increased flow following shear stress which is raised during post-occlusive reactive hyperemia.

In this technique the ultrasound system (US) must be equipped with two-dimensional (2D) imaging, color and spectral Doppler, an internal electrocardiogram (ECG) monitor and a high-frequency vascular linear array transducer with a minimum frequency of 7 MHz. Timing of each

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 65–68, 2009
www.springerlink.com

image frame with respect to the cardiac cycle is via simultaneous ECG recording on the US video monitor. Flow stimulus in the brachial artery (BA) is produced by a blood pressure (BP) cuff which is placed above the antecubital fossa. The arterial 5-min occlusion is created by cuff inflation to suprasystolic pressure (typically 50 mmHg above the systolic pressure). Both BA diameter and ECG should be measured simultaneous during image acquisition to define when the artery is the largest. Based on the cardiac cycle, the diameter of the BA should be measured in the beginning of the R-wave which identifies the start of the systole. In this phase vessel expands to accommodate the increase in pressure and volume generated by left ventricular contraction.

Although this technique is non-invasive, it has some disadvantages. Firstly, this technique is subject to variations due to the subjectivity of the operator performing the experiment and requires a skilled operator. Secondly, accurate analysis of BA reactivity is highly dependent on the quality of US images and it is sensitive to the US probe location. Thirdly it is to say that arteries smaller than 2.5 mm in diameter are difficult to measure and vasodilation is generally less difficult to perceive in vessels larger than 5.0 mm in diameter. Blockage of blood supply to the BA for a relatively long period of time (up to 5 minutes) is another issue. The blockage duration has to last enough to ensure that the dilation reaches few millimeters for the imaging system to be able to detect it; otherwise image artifacts will prevent the investigation from having a clear view of the amount of dilation. This is why the main focus of this study is introducing the next method which is considered in previous research and promotes it to get the comparable results [5]. Another limitation of US-FMD is that due to the size of the equipment, the patient needs to be physically transferred to the laboratory where the test could be performed.

B. FMD Photoplethysmography

Photoplethysmography (PPG) is a non-invasive technique that measures relative blood volume changes through optical method. By this it is possible to measure the pulsation of the blood. During systole that the artery's diameter increases, the amount of transmitted light drops due to hemoglobin absorption and it goes into reverse during diastole. So there is a pulsatile signal which varies in time with the heart beat that is including both low (DC) and high frequency (AC) component. This means that the pulsatile signal is superimposed on a DC level which is related to respiration, sympathetic nervous system activity and thermoregulation. Whereas, the high frequency component is due to cardiac synchronous changes with each heart beat in skin micro-vascular blood volume [9]. As plethysmographic signal carries very rich information about cardiovascular regulation, it seems to be justified the use of advanced signal analysis techniques for the study of plethysmographic signals.

There are several studies based on pulse wave analysis to consider the properties of arteries as well as studying large-artery damage which is the common cause of mortality and in industrialized countries. They showed significant correlations between PWV (Pulse Wave Velocity) and cardiovascular risk factors, such as hypertension, high cholesterol level, diabetes and smoking [6]. Pulse wave analysis is a well recognized way to evaluate aortic stiffness and, consequently, could be useful to evaluate the vascular effects of aging, hypertension, and atherosclerosis [7,8]. Moreover, the multi-site PPG concept has considerable clinical potential. Some of these studies are based on disease diagnostic in the lower limbs by investigating the clinical value of objective PPG pulse measurements collected simultaneously from the right and left great toes [9]. The previous study [5] which would be improved here was conducted to investigate if there is any relationship between US measurement and finger PPG pulse amplitude (AC) change in response to FMD of the corresponding BA.

C. Simultaneous exams of PPG and Ultrasound

The ultrasound data were gathered by the help of a high resolution ultrasound system (US) with a 7.5 MHz linear array transducer. The subjects were asked to abstain from food, alcohol and caffeine for at least 8 hours prior to the experiment. The US images were captured while subjects were in supine position at rest and the transducer was placed at few centimeters above the elbow on the right arm. The arterial occlusion was created by cuff inflation 50 mmHg above systolic BP for 4 minutes. The baseline diameter was obtained from the average of 3 measurements before introduction of blockage. Shear stress that caused endothelium-dependent dilation would be made by releasing the cuff suddenly. BA diameter was measured from the longitudinal image of the artery using wall tracking technique, manually at intervals of approximately 30 seconds for approximately 5 minutes following the release of blood flow blockage. Beside US equipment, two PPG systems consisting of the sensors, software and hardware were used to record PPG signals from the right and left index fingers respectively.

By comprising diameter changes in two methods of PPG and US, we can see that AC of the PPG signal is similar to the US-FMD. However, this similarity is not observed for all subjects, probably for the following reasons:

1- The US-FMD dilation is not properly measured. It should be emphasized that the artery is being imaged with a high-resolution scanner but the viewing angle and position of the imaging probe held by the operator play an important role in correct evaluation of the dilation.

2- Currently, the measurement is done manually whereas images taken during the US-FMD experiment are examined one by one and the diameter is measured by positioning the cursor at chosen landmarks. It has been widely reported in the literature that this might be one of the main sources for errors.
3- The AC of the PPG is not sufficient to explain the FMD response alone. This is why we propose to complement this value by other demographic parameters.

In this study both ultrasound FMD and PPG FMD techniques were analyzed simultaneously. Furthermore, we focus on the role of clinical risk factors for cardiovascular diseases (CVD) in PPG FMD responses.

III. Results of PPG and Ultrasound Cross Study

Eighty one subjects aged 21 to 76 years were included in this study. The subjects were divided into three groups: Group 1 comprises healthy individuals (25 subjects), Group 2 comprises individuals having any one risk factor (31 subjects) and Group 3 comprises individuals having more than one risk factor (25 subjects).

Healthy subjects are free from any major CVD risk factors. The risk factors include obesity which is assessed by BMI (Body Mass Index), diabetes which is assessed by HbA1c and glucose level, hypertension which is assessed by systolic blood pressure and diastolic blood pressure and hypercholesterolemia which is assessed by LDL (low-density lipoprotein cholesterol) and total cholesterol in this study. To have a clear comparison graph of all risk factors, they were normalized in each group between 0 and 1. By this it means that for each risk factor the minimum value refers to 0 and maximum value refers to 1. The border line of each risk factor is identified in Table 1.

In signal processing, the amplitude of the PPG signal (AC value) was extracted from the left and right index fingers, before blockage (Figure 1) and after release (Figure 2).

Table 1 Risk factors

Risk factors	Border line	Normalized value	Min value	Max value
Systolic BP	>140 mmHg	0.57	100mmHg	170 mmHg
Diastolic BP	>90 mmHg	0.63	51 mmHg	112 mmHg
Glucose level	>6 mmol/L	0.17	4.1 mmol/L	15.2 mmol/L
HbA1c	>6.5 %	0.25	4.5 %	12.5 %
Total Cholesterol	>5.2 mmol/L	0.57	2 mmol/L	7.59 mmol/L
LDL	>3 mmol/L	0.42	1.2 mmol/L	5.47 mmol/L
BMI	>30	0.49>30	18.98	0.73 41.15

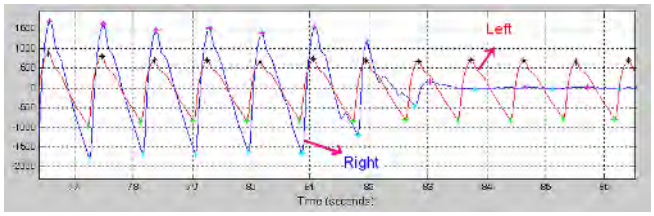

Fig. 1 PPG signals of the left and right arm before blockage

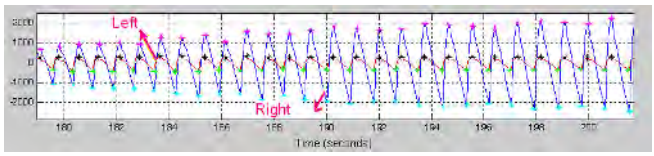

Fig. 2 PPG signals of the left and right arm after release blockage

The PPG signal of the left arm remains the same before blockage and after release and can be used as the baseline values. On the other hand, the amplitude of PPG signal of right arm decreases to zero during occlusion and increases after release.

Both PPG and ultrasound signals are normalized in amplitude between 0 and 1 and are shown along with the clinical data. In both PPG and ultrasound exam, all subjects show reactions to BA occlusion. Examples of the responses from each group are shown in Figure 3, 4 and 5, respectively. The dotted line shows the ultrasound response and the continuous line shows the PPG response. The clinical data refers to BMI, systolic BP, diastolic BP, heart rate, glucose level, HbA1c, total cholesterol, HDL, LDL, triglyceride, age and gender (female = 1, male = 0) from left to right. The risk is shown by the marker on top of identified risk factor. In 70 % of subjects who are in the first group (healthy) and second group (having only one risk factor),

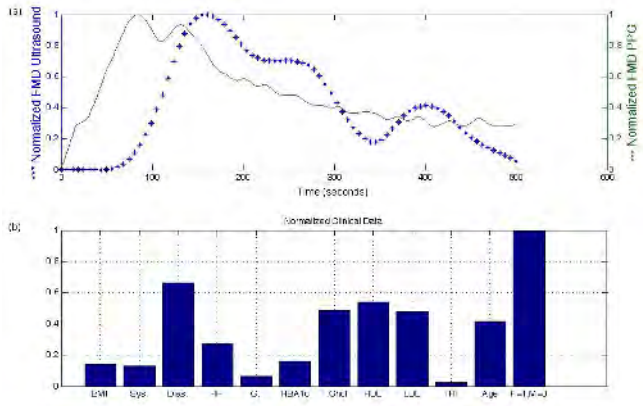

Fig. 3 Normalized (a) PPG and ultrasound responses and (b) clinical data (healthy subject)

both responses follow each other (Figure 3 and 4). In Figure 4 the risk factor refers to hypercholesterolemia (high in total cholesterol and LDL). In the third group which included subjects having more than one risk factor, PPG and ultrasound responses follow each other only in 50 % of the subjects (Figure 5). In this group the risk factors refer to hypercholesterolemia and diabetes.

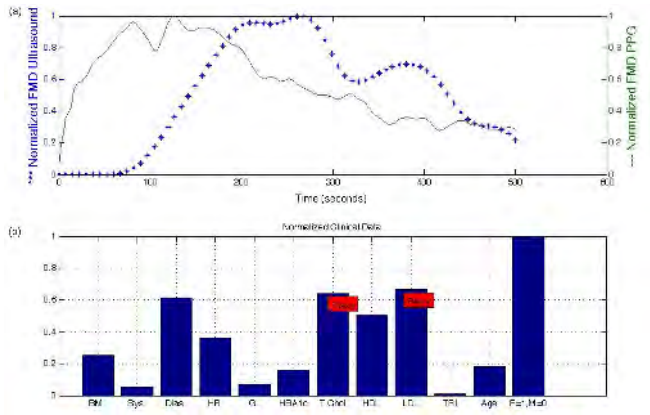

Fig. 4 Normalized (a) PPG and ultrasound responses and (b) clinical data (subject with only one risk factor)

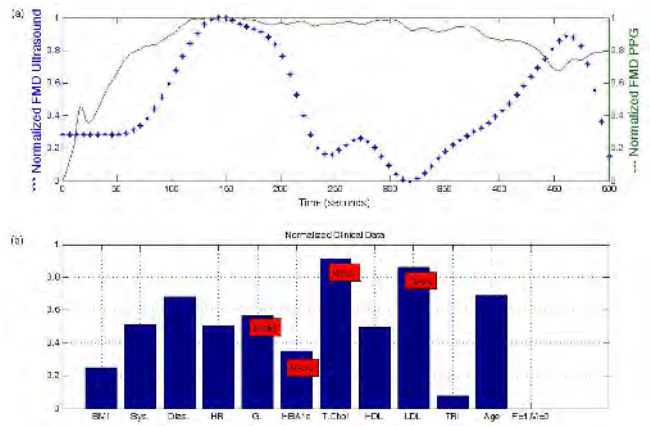

Fig. 5 Normalized (a) PPG and ultrasound responses and (b) clinical data (subject with more than one risk factor)

IV. Conclusions

In summary the results of this study show that PPG FMD and ultrasound FMD responses are similar in most of the healthy subjects as well as among those having just one risk factor. However, it is hard to say that with the increase in number of risk factors, the PPG and ultrasound responses can follow each other. This finding could explain the reason for non-similarity observed in some of the subjects in the earlier study.

Abstract — **A successful brain interface (BI) system enables individuals with severe motor disabilities to control objects in their environment (such as a light switch, neural prosthesis or computer) by using only their brain signals. Such a system measures specific features of a person's brain signal that relate to his or her intent to affect control, then translates them into control signals that are used to control a device. Recently, successful applications of the discrete wavelet transform have been reported in brain interface (BI) systems with one or two EEG channels. For a multi-channel BI system, however, the high dimensionality of the generated wavelet features space poses a challenging problem. In this paper, a feature selection method that effectively reduces the dimensionality of the feature space of a multi-channel, self-paced BI system is proposed. The proposed method uses a two-stage feature selection scheme to select the most suitable movement-related potential features from the feature space. The first stage employs mutual information to filter out the least discriminant features, resulting in a reduced feature space. Then a genetic algorithm is applied to the reduced feature space to further reduce its dimensionality and select the best set of features. An offline analysis of the EEG signals (18 bipolar EEG channels) of four able-bodied subjects showed that the proposed method acquires low false positive rates at a reasonably high true positive rate. The results also show that features selected from different channels varied considerably from one subject to another. The proposed hybrid method effectively reduces the high dimensionality of the feature space. The variability in features among subjects indicates that a user-customized BI system needs to be developed for individual users.**

Keywords — **EEG, Multiresolution Wavelet, Fuzzy C-means, Brain, BCI, Ensemble classifier**

I. Introduction

The brain generates rhythmical potentials, which originate in the individual neurons of the brain. Electroencephalograph (EEG) is a representation of the electrical activity of the brain. Numerous attempts have been made to define a reliable spike detection mechanism. However, all of them have faced the lack of a specific characterization of the events to detect. One of the best known descriptions for an interictal "spike" is offered by Chatrian et al. [1]: " transient, clearly distinguished from background activity, with pointed peak at conventional paper speeds and a duration from 20 to 70 msec". This description, however, is not specific enough to be implemented into a detection algorithm that will isolate the spikes from all the other normal or artifactual components of an EEG record. Some approaches have concentrated in measuring the "sharpness" of the EEG signal, which can be expected to soar in the "pointy peak" of a spike. Walter [2] attempted the detection of spikes through analog computation of the second time derivative (sharpness) of the EEG signals. Smith [3] attempted a similar form of detection on the digitized EEG signal. His method, however required a minimum duration of the sharp transient to qualify it as a spike. Although these methods involve the duration of the transient in a secondary way, they fundamentally consider "sharpness" as a point property, dependent only on the very immediate context of the time of analysis. More recently, an approach has been proposed in which the temporal sharpness is measured in different "spans of observation", involving different amounts of temporal context. True spikes will have significant sharpness at all of these different "spans". The promise shown by that approach has encouraged us to use a wavelet transformation to evaluate the sharpness of EEG signals at different levels of temporal resolution.

Bio kit datascope machine is used to aquire 32-channel eeg signal with the international 10-20 electrode coupling. The sampling frequency of the device is 256 Hz with 12-bit resolution and stored on hard disc. 32 channel EEG data was recorded simultaneously for both referential and bipolar montages. Recordings are made before, meanwhile and after the person is doing anulom vilom, and also we have kept track on recording the EEG data after one, two and three months of the same persons doing anulom vilom. Such 10 persons data is collected for analysis.

II. Problem formulation

Visual analysis and diagnosis of EEG signal using time domain analysis is very time consuming & tedious task it may vary from person to person. Frequency domain analysis also have limitations like more samples to be analyzed for

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 69–72, 2009
www.springerlink.com

getting accurate results, More memory space required for storage of data, More processing time, More filter length, Non-linear phase, Lack of artifact removal, baseline rejection, lack of data epochs rejection, visualization of Data info, event fields and event values. In Greedy method decomposition problems. In Orthogonal matching complex computations.

EEG has several limitations, most important is its poor spatial resolution. EEG is most sensitive to a particular set of post-synaptic potentials: those which are generated in superficial layers of the cortex, on the crests of gyri directly abutting the skull and radial to the skull. Dendrites which are deeper in the cortex, inside sulci, are in midline or deep structures or produce currents which are tangential to the skull have far less contribution to the EEG signal. The meninges, cerebrospinal fluid and skull "smear" the EEG signal, obscuring its intracranial source. It is mathematically impossible to reconstruct a unique intercranial current source for a given EEG signal. This is referred to as the inverse problem.

III. Problem Solution

Bio-kit data acquisition system, Mumbai (India), is used to acquire 32-channel EEG signal with the international 10-20 electrode coupling. The sampling frequency of the device is 256 Hz with 12-bit resolution and stored on hard disc of a computer. To study the effect of a long term (six months or greater) practice of different techniques of ujyai, resting state and before examination on

the EEG signals of young to middle aged Males and Females. 32-channel EEG data was recorded simultaneously for both referential and bipolar montages. The Electrical waveforms were obtained for all the subjects under different groups mentioned above.The research work in this thesis proposes analysis of four different types of wavelets, including the Daubechies wavelets with 4 (Db4) and 8 (Db8) vanishing moments, symlets with 5 vanishing moments (Sym5), and the quadratic B-spline wavelets (Qbs). The quadratic B-spline wavelet was chosen due to its reported suitability in analyzing ERP data in several studies. Db4 and Db8 were chosen for their simplicity and general purpose applicability in a variety of time-frequency representation, whereas Sym5 was chosen due to its similarity to Daubechies wavelets with additional near symmetry property. Different mother wavelets have been employed in analysis of the signals; performances of six frequency bands (0–1Hz, 1–2 Hz, 2–4Hz, 4–8 Hz, 8–16 Hz and 0–4 Hz) have been individually analyzed, The proposed pearl ensemble based decision is designed, implemented and compared to a multilayer perceptron and AdaBoost classifier based decision; and most importantly, the earliest possible diagnosis of the alzeimer's disease is targeted. Some expected, and some interesting outcomes were observed, with respect to each parameter analyzed. To exploit the information on the time frequency structure using different Wavelet transforms like Daubechies (Db4 and Db8), sym5 and the quadratic B-spline wavelets (Qbs). along with The proposed pearl ensemble based decision is designed, implemented and compared to a multilayer perceptron and AdaBoost classifier based decision during meditation. To estimate deterministic chaos like correlation dimension, largest lyapunov exponent, approximate entropy and hurst exponent of 207 persons (subjects) before attending written examination state, normal resting state and during meditation state.

Figure: 1. shows the result of the classification of one experimental subject. Here the optimal number of clusters is 3. I have normalized every feature vector into 0 to 1.

From the figure above we could obtain that alpha increased in the middle interval and decreased in the late interval of ujyai. After ujyai, the appearance of cluster #3 (centered on Cz) increased.

As EEG is normally characterized by its frequency, the EEG patterns are conveniently classified into four frequency ranges: the delta (0-4Hz), theta (4-8 Hz), alpha (8-13 Hz), and beta (13-25 Hz). The meditationEEGsignals, although composed of these standard rhythmic patterns, are found to orchestrate

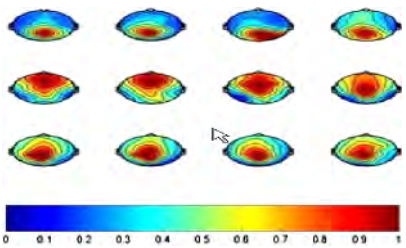

Fig:1. Three clusters

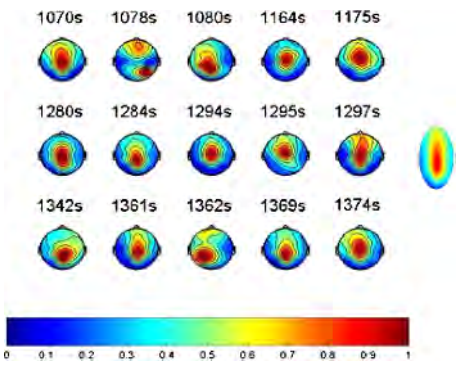

Fig:2. Selected samples and the centre of cluster # 1.

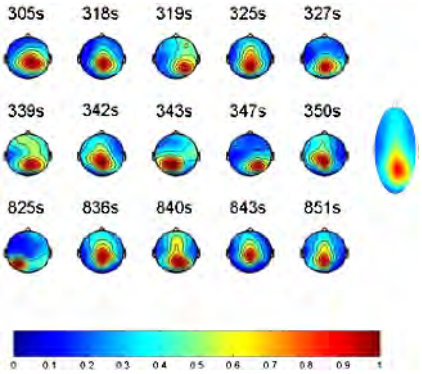

Fig:5. Selected samples and the centre of cluster #2.

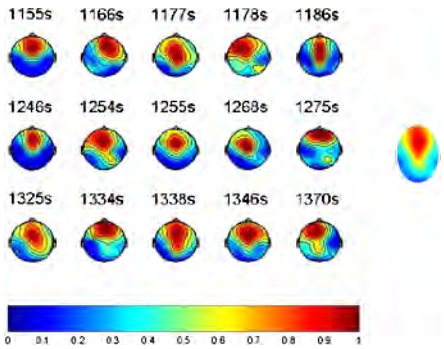

Fig:6. Selected samples and the centre of cluster #3.

symphonies of certain tempos. After systematic study by applying the FCM-merging strategies to a number of meditation EEG data sets, results of clustering indicate that rhythmic patterns reflecting various meditationstates normally involve five patterns:

IV. Conclusion

During the Meditationtechnique individuals often report the subjective experience of Transcendental Consciousness or pure consciousness, the state of least excitation of consciousness. This study found that many experiences of pure consciousness were associated with periods of natural respiratory suspension, and that during these respiratory suspension periods individuals displayed higher mean EEG coherence over all frequencies and brain areas, in contrast to control periods where subjects voluntarily held their breath. Results are 98 % true when discussed with experts and doctors.

In this study we developed a scheme to investigate the spatial distribution of alpha power, and we adopted this procedure to analysis this characteristics of meditators and normal subjects. The results show that alpha waves in the central and frontal regions appear more frequently in the experimental group.From the previous study, the enhancement of frontal alpha during meditationmay be related to the activation of the Anterior Cingulate Cortex (ACC) and medial Prefrontal Cortex (mPFC). The ACC has outflow to the autonomic, viscermotor and endocrine systems. Previous findings suggested that during meditation some changes of autonomic patterns and hormone are related to the ACC. Furthermore, the ACC and mPFC are considered to modulate internal emotional responses by controlling the neural activities of limbic system, that is, they may function via diffusing alpha waves. Besides, the trends of non-alpha are different in two groups. In control group the alpha wave was getting less during relaxation, and in the post-session it returned to the level which is the same in the pre-session. The reason of this trend may be drowsiness. Multiresolution M-Band wavelet (proposed) is most effective for EEG analysis in terms of high degree of accuracy with low computational load. This thesis reports a novel idea of understanding various meditationscenarios via EEG interpretation. Experimental subjects narration further corroborates, from the macroscopic viewpoint, the results of EEG interpretation obtained by the FCM-merging strategies. The FCM clustering method automatically identifies the significant features to be used as the meditationEEG interpreting protocol. The results show that the state of mind of a human body becomes more stable with ujyai, whereas the tense conditions affect inversely causing disturbance in the mind.

Denoising of Transient Visual Evoked Potential using Wavelets

R. Sivakumar

ECE Department, RMK Engineering College, Kavaraipettai, Tamilnadu, India

Abstract — **Transient Visual Evoked Potential (TVEP) is an important diagnostic test for specific ophthalmological and neurological disorders. The clinical use of VEP is based on the amplitudes and the latencies of the N75, P100, and N145 peaks. The amplitude and latencies of these peaks are measured directly from the signal. Quantification of these latency changes can contribute to the detection of possible abnormalities. We have applied the wavelet denoising method to 100 numbers of pre-recorded signals using all the available wavelets in MATLAB signal processing toolbox. From the results it is clear that the positive peak is clearer in the denoised version of the signal using the wavelets Sym5 and Bior3.5. As opposed to the previous studies however our study clearly shows that the output using the former wavelet effectively brings out the P100 when compared to the latter. The first negative peak N75 is clear in the denoised version of the signal using the wavelets Bior5.5 Bior6.8 and coif4. The second negative peak N145 is clear using all the above wavelets. All the three peaks are fairly clear in the denoised output using the wavelet sym7.**

Keywords — **Transient Visual Evoked Potential, Latency, denoising, wavelets, MATLAB.**

I. Introduction

Evoked Potentials (EPs) are the alterations of the ongoing EEG due to stimulation. They are time locked to the stimulus and they have a characteristic pattern of response that is more or less reproducible under similar experimental conditions. In order to study the response of the brain to different tasks, sequence of stimuli can be arranged according to well defined paradigms. This allows the study of different sensitive functions, states etc., thus making the EPs an invaluable tool in neurophysiology. Transient Visual Evoked Potential (TVEP) is an import diagnostic test for specific ophthalmologic and neurological disorders. The clinical use of VEP is based on the amplitudes and the latencies of the N75, P100, and N145 peaks. Quantification of these latency changes can contribute to the detection of possible abnormalities [1-3].

Due to the low amplitudes of EPs in comparison with the ongoing EEG, they are hardly seen in the original EEG signal and therefore several trials are averaged in order to enhance the evoked responses. Since EPs are timed licked to the stimulus their contribution will add and while ongoing EEG will cancel. However, when averaging information related with variations between the single trials is lost. This information could be relevant in order to study behavioral and functional processes. Moreover, in many cases a compromise must be made when deciding on the number of trials in an experiment. If we take a large number of trials we optimize the EP/EEG ratio but if the number of trial is too large, then we could deal with effects such as tiredness, which eventually corrupts the average results. This problem can be partially solved by taking sub-ensemble averages. However, in many cases the success of such procedure is limited, especially when not many trials can be obtained or when characteristics of the EPs change from trial to trial.

Several methods have been proposed in order to filter averaged EPs. The successes of such methods world imply the need of less number of trials and would eventually allow the extraction of single trial EPs from the background EEG. Although averaging has been used since the middle of 1950's, up to now none of these attempts has been successful in obtaining single trial EPs, at least in a level that they could be applied to different types of EPs and that they could be implemented in clinical settings.

Most of these approaches involves Wiener filtering (or a minimum mean square error filter based on auto-and cross-correlations) and have the common drawback of considering the signal as a stationary process. Since EPs are transient responses related with specific time and frequency locations, such time-invariant approaches are not likely to give optimal results. Using the wavelet formalism can solve these limitations, as well as the ones related with time-invariant methods [4-6].

The wavelet transform is a time-frequency representation proposed first in, that has an optimal resolution both in the time and frequency domains and has been successfully applied to the study of EEG-EP signals. The objective of the present study is to follow an idea originally proposed and to present a very straight forward method based on the wavelet transform to obtain the evoked responses at the single trial level. The key point in the denoising of Eps is how to select in the wavelet domain the activity representing the signal (the EPs) and then eliminate the one related with noise (the background EEG [7-10].

In fact, the main difference between our implementation and previous related approaches is in the way that the wavelet coefficients are selected. Briefly, such choice should consider latency variations between the single trial responses and it should not introduce spurious effects in the time range where the EPs are expected to occur. In this

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 73–76, 2009
www.springerlink.com

respect, the denoising implementation we propose will allow the study of variability between single trials, information that could have high physiological relevance.

II. Material and methods

Experiments were carried with subjects in the Neurology Department of the leading Medical Institute. TVEP was performed in a specially equipped electro diagnostic procedure room (darkened, sound attenuated room). Initially, the patient was made to sit comfortably approximately 1m away from the pattern-shift screen. Subjects were placed in front of a black and white checkerboard pattern displayed on a video monitor. The checks alternate black/white at a rate of approximately twice per sound. Every time the pattern alternates, the patient's visual system generates on electrical response that was detected and was recorded by surface electrodes, which were placed on the scalp overlaying the occipital and parietal regions with reference electrodes in the ear. The patient was asked to focus his gaze onto the center of the screen. Each eye was tested separately (monocular testing). Scalp recordings were obtained from the left occipital (O1) electrode (near to the location of the visual primary sensory area) with linked earlobes reference. Sampling rate was 250 Hz and after band pass filtering in the range 0.1-70 Hz, 2 s of data (256 data pre-and post-stimulations) were saved on a hard disk (Figure 1).

The average TVEP is decomposed by using the wavelet multi resolution decomposition. The wavelet coefficients are not correlated with the average VEP are identified and set to zero. The inverses transform is applied to recover the denoised signal. The same procedure is extended to all single trials. The denoising method was applied to a number of pre-recorded signals using all the available wavelets to analyze the peaks (N75, P100 and N145).

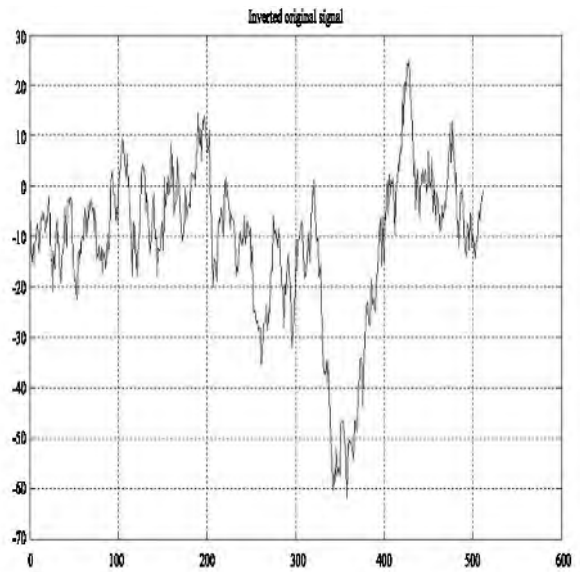

Figure 1 Single Trial TVEP

III. Results and discussion

The results show that the positive peak P100 is clearer in the denoised version of the signal using the wavelets Sym5 and Bior3.5 (Figure 2). The first negative peak N75 is clearer in the denoised version of the signal using the wavelets Bior5.5, Bior6.8 and coif4. The second negative peak N145 is clear in all the wavelets. All the peaks were clear in the denoised output using the wavelet sym7. This would greatly help the medical practitioners.

In fact, there are many different functions suitable as wavelets, each one having different characteristics that are more or less appropriate depending on the application. Irrespective of the mathematical properties of the wavelet of choose, a basic requirement is that it looks similar the patterns we want to localize in the signal. This allows a good localization of the structures of interest in the wavelet domain and moreover, it minimizes spurious effects in the reconstruction of the signal via the inverse wavelet transform. For this, the previous analysis have been done by choosing quadratic bioorthogonal B-splines as mother functions doe to their similarity with the evoked response [7-9]. B-splines are piecewise polynomials that form a base in L2. Bur our analysis shows that the there is more wavelets that can be used which similar to TVEPs.

We presented a method for extracting TVEPs from the background EEG. It is not limited to the study of TVEP/EEG and similar implementation can be used for recognizing transients even in signal with low signal to noise ratio. The denoising of EPs allowed the study of the variability between the single responses, information that could have a high physiological relevance in the study of different brain functions, states etc., It could be used to eliminate artifacts that do not appear in the same time frequency ranges of the relevant evoked responses. Our results proved that the method proposed in this paper gives better averaged EPs due to the high time-frequency resolution of the wavelet transform, this being hard to achieve with conventional Fourier filters. Moreover, since trials with good evoked responses can be easily identified, These advantages could significantly reduce the minimum number of trials necessary in a recording session, something of high importance for avoiding behavioral changes during the recording (e.g., effects of tiredness) of even more interesting, for obtaining EPs under strongly varying conditions, as with children, or patients with attention problems.

A Systematic Approach to Understanding Bacterial Responses to Oxygen Using Taverna and Webservices

S. Maleki-Dizaji[1], M. Rolfe[3], P. Fisher[2], M. Holcombe[1]

[1] The University of Sheffield, Computer Science, Sheffield, United Kingdom
[2] The University of Manchester, Computer Science, Manchester, United Kingdom
[3] The University of Sheffield, Department of Molecular Biology and Biotechnology, Sheffield, United Kingdom

Abstract — ***Escherichia coli* is a versatile organism that can grow at a wide range of oxygen levels; although heavily studied, no comprehensive knowledge of physiological changes at different oxygen levels is known. Transcriptomic studies have previously examined gene regulation in *E. coli* grown at different oxygen levels, and during transitions such as from an anaerobic to aerobic environment, but have tended to analyse data in a user intensive manner to identify regulons, pathways and relevant literature. This study looks at gene regulation during an aerobic to anaerobic transition, which has not previously been investigated. We propose a data-driven methodology that identifies the known pathways and regulons present in a set of differentially expressed genes from a transcriptomic study; these pathways are subsequently used to obtain a corpus of published abstracts (from the PubMed database) relating to each biological pathway**

Keywords — ***E. coli*, Microarray, Taverna, Workflows, Web Services**

I. Introduction

Escherichia coli has been a model system for understanding metabolic and bio-energetic principles for over 80 years and has generated numerous paradigms in molecular biology, biochemistry and physiology [1]. *E. coli* is also widely used for industrial production of proteins and speciality chemicals of therapeutic and commercial interest. A deeper understanding of oxygen metabolism could improve industrial high cell-density fermentations and process scale-up. Knowledge of oxygen-regulation of gene expression is important in other bacteria during pathogenesis where oxygen acts an important signal during infection [2] and thus this project may underpin better antimicrobial strategies and the search for new therapeutics. However, current approaches have generally been increasingly reductionist, not holistic. Too little is known of how molecular modules are organised in time and space, and how control of respiratory metabolism is achieved in the face of changing environmental pressures. Therefore, a new systems-level approach is needed, which integrates data from all spatial and temporal domains. Many transcriptomic studies using microarrays have analysed data in a user-intensive manner to identify regulons, pathways and relevant literature. Here, a two-colour cDNA microarray dataset comprising a time-course experiment of *Escherichia coli* cells during an aerobic to anaerobic environment is used to demonstrate a data-driven methodology that identifies known pathways from a set of differentially expressed genes. These pathways are subsequently used to obtain a corpus of published abstracts (from the PubMed database) relating to each biological pathway identified. In this research Taverna and Web Services were used to achieve the goal.

II. Taverna and web services

Web services provide programmatic access to data resources in a language-independent manner. This means that they can be successfully connected into data analysis pipelines or workflows (Figure 1). These workflows enable us to process a far greater volume of information in a systematic manner. Unlike that of the manual analysis, which is severely limited by human resources, we are only limited by the processing speed, storage space, and memory of the computer executing these workflows. Still the major problems with current bioinformatics investigations remain; which are the lack of recording experimental methods, including software applications used, the parameters used, and the use of hyperlinks in web pages. The use of workflows limits issues surrounding the manual analysis of data, i.e. the bias introduced by researchers when conducting manual analyses of microarray data. Processing data through workflows also increases the productivity of the researchers involved in the investigations, allowing for more time to be spent on investigating the true nature of the detailed information returned from the workflows. For the purpose of implementing this systematic pathway-driven approach, we have chosen to use the Taverna workbench[3,4]. The Taverna Workbench allows bioinformaticians to construct complex data analysis pipelines from components (or web services) located on both remote and local machines. These pipelines, or workflows, are then able to be executed over a set of unique data values, producing results which can be visualised within the Taverna workbench itself. Advantages of the Taverna workflow work-

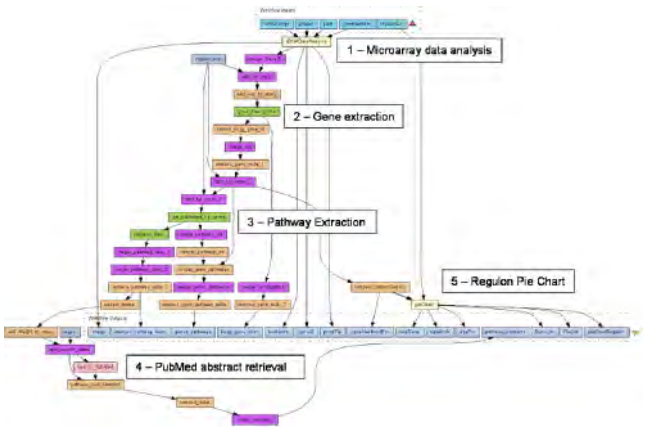

Figure 1 – Workflow Diagram

bench include, repeatable, re-useable the and limiting user bias by removing intermediate manual data analysis. Greater volume of data can be processed in a reduced time period We propose a data-driven methodology that identifies the known pathways from a set of differentially expressed genes from a microarray study (Figure 1). This workflow consists of three parts: microarray data analysis; pathways extraction; and PubMed abstract retrieval. This methodology is implemented systematically through the use of web services and workflows.

A. Microarray Data Analysis

Despite advances in microarray technology that have led to increased reproducibility and substantial reductions in cost, the successful application of this technology is still elusive for many laboratories. The analysis of transcriptome data in particular presents a challenging bottleneck for many biomedical researchers. These researchers may not possess the necessary computational or statistical knowledge to address all aspects of a typical analysis methodology; indeed, this is something which can be time consuming and expensive, even for experienced service providers with many users. Currently available transcriptome analysis tools include both commercial software (GeneSpring [5], ArrayAssist [6]) and non-commercial software (Bioconductor [7]).

The open source Bioconductor package [7] is one of the most widely used suites of tools used by biostatisticians and bioinformaticians in transcriptomics studies. Although both highly powerful and flexible, users of Bioconductor face a steep learning curve, which requires users to learn the *R* statistical scripting language as well as the details of the Bioconductor libraries.

The high overheads in using these tools provide a number of disadvantages for the less experienced user such as, requirement for expensive bioinformatics support, considerable effort in training, less than efficient utilisation of data, difficulty in maintaining consistent standards methodologies, even within the same facility, Difficult integration of additional analysis software and resources and limited reusability of methods and analysis frameworks.

The aim of this work was to limit these issues. Users will, therefore, be able to focus on advanced data analysis and interpretational tasks, rather than common repetitive tasks. We have observed that there is a core of microarray analysis tasks common to many microarray projects. Additionally, we have identified a need for microarray analysis software to support these tasks that has minimal training costs for inexperienced users, and can increase the efficiency of experienced users.

Microarray Data Analysis part provides support to construct a full data analysis workflow, including loading, normalisation, T-test and filtering of microarray data. In addition to returning normalised data, it produces a range of diagnostic plots of array data, including histograms, box plots and principal components analysis plots using R and Bioconductor.

B. Pathway extraction

This part of the workflow searches for genes found to be differentially expressed in the microarray data, selected based on a given p-value from the Microarray Data Analysis part. Gene identifiers from this part were subsequently cross-referenced with KEGG gene identifiers, which allowed KEGG gene descriptions and KEGG pathway descriptions to be returned from the KEGG database.

C. PubMed abstract retrieval

In this part, the workflow takes in a list of KEGG pathway descriptions. The workflow then extracts the biological pathway process from the KEGG formatted pathway descriptions output. A search is then conducted over the PubMed database (using the eFetch web service) to identify up to 500 abstracts related to the chosen biological pathway. At this stage, a MeSH tag is assigned to the search term, in order to reduce the number of false positive results returned from this initial search. All identified PubMed identifiers (PMID) are then passed to the eSearch function and searched for in PubMed. Those abstracts found are then returned to the user along with the initial query string – in this case, the pathway [3].

D. Pie chart

At present, results from transcriptional profiling experiments (lists of significantly regulated genes) have largely been interpreted manually, or using gene analysis software

(i.e. GeneSpring, GenoWiz) that can provide links to databases that define pathways, functional categories and gene ontologies. Many databases, such as EcoCyc [8] and RegulonDB [9], contain information on transcriptional regulators and regulons (genes known to be regulated by a particular transcription factor), and automatic interpretation of a transcriptional profiling dataset using these databases is still in its infancy. When applied to the results of a transcriptional profiling experiment, this may confirm the importance of a regulator that is already known, or suggest a role for a previously unknown regulator, which may be investigated further. The pie chart shown indicates the number of genes in a dataset that are regulated by a known transcriptional regulator, or by combination of regulators, and can suggest previously unknown regulatory interactions. The information for each regulon comes from files that are created manually from the EcoCyc database.

III. Case study: escherichia coli

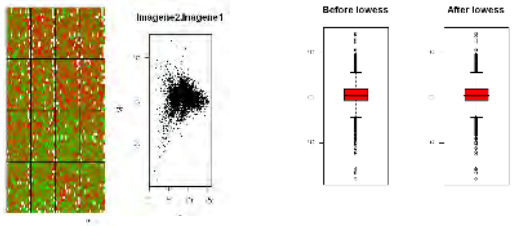
Escherichia coli is a model laboratory organism that has been investigated for many years due to its rapid growth rate, simple growth requirements, tractable genetics and metabolic potential [10]. Many aspects of *E. coli* are well characterised, particularly with regards to the most familiar strain K-12, with a sequenced genome[11], widespread knowledge of gene regulation (Regulon DB; [9] and well documented metabolic pathways (EcoCyc; [8]). Indeed, it has been said that more is known about *E. coli* than about any other organism [1] and for these reasons *E. coli* stands out as a desirable organism on which to work (Mori, 2004).

A. Growth conditions

Escherichia coli K-12 strain MG1655 was grown to a steady-state in a Labfors-3 Bioreactor; Infors HT; Bottmingen, Switzerland) under the following conditions (vessel volume 2 L; culture volume 1 L; Evans medium pH 6.9 [12]; stirring 400 rpm; dilution rate 0.2 h^{-1}). To create an aerobic culture 1 L min^{-1} air was sparged through the chemostat, whilst for anaerobic conditions 1 L min^{-1} 5 % CO_2 95 % N_2 ($^{v}/_{v}$) was passed through the chemostat. For steady-state to be reached, continuous flow was allowed for at least 5 vessel volumes (25 hours) before cultures were used. Gas transitions were carried out on steady-state cultures by switching gas supply as required.

B. Isolation of RNA

A steady-state chemostat culture was prepared and samples were removed from the chemostat for RNA extraction just prior to the gas transition and 2, 5, 10, 15 and 20 minutes after the transition. Samples were taken by direct elution of 2 ml culture into 4 ml RNAprotect (Qiagen; Crawley, UK) and using RNeasy RNA extraction kit (Qiagen Crawley, UK) following the manufacturers instructions. RNA was quantified spectrophotometrically at 260 nm.



C. Transcriptional Profiling

16 µg RNA for each time point was labelled with Cyanine3-dCTP (Perkin-Elmer; Waltham, USA) using Superscript III reverse transcriptase (Invitrogen; Paisley, UK). Manufacturers instructions were followed for a 30 µl reaction volume, using 5 µg random hexamers (Invitrogen; Paisley, UK) with the exception that 3 nmoles Cyanine3-dCTP and 6 nmoles of unlabelled dCTP was used. Each Cyanine3-labelled cDNA sample was hybridised against 2 µg of Cyanine5-labelled K-12 genomic DNA produced as described by Eriksson[13]. Hybridisation took place to Ocimum OciChip K-12 V2 microarrays (Ocimum; Hyderabad, India) at 42 °C overnight and washed according to the manufacturers instructions. Slides were scanned on an Affymetrix 428 microarray scanner at the highest PMT voltage possible that didn't give excessive saturation of microarray spots. For each time point, two biological replicates and two technical replicates were carried out.

IV. Results

To analyze the transcriptional dataset, the proposed workflow was applied; this workflow can accept raw transcriptional data files and ultimately generates outputs of differentially regulated genes, relevant metabolic pathways and transcriptional regulators, and even potentially relevant published material. This has many advantages compared to standard transcript profiling analyses. From a user aspect, it will be quicker than the time-consuming analysis that currently occurs, and ensures that the same stringency and statistical methods are used in all analyses, and hence should make analyses more user-independent. It can also remove any possibility that users can subconsciously 'manipulate' the data. In order to run the work flow following parameters have been set: NormalizationMethod = rma, Statistical testMethod = limma, p-value = 0.05, foldChange = 1, geneNumber = 100.

The workflow results directly progress from a microarray file to outputs in the form of plots or text files in the case published abstracts from the PubMed database (Figure 2). Tables displaying the processed data can also be visualised From the outputs, the relevance of the transcriptional regulators FNR, ArcA, PdhR were immediately noticeable.

V. Discussion

This workflow has successfully been used to interrogate a transcriptomic dataset and identify regulators and pathways of relevance. This has been demonstrated using experimental conditions in which the major regulators are known; however, the study of less characterised experiments the resulting outputs may have exciting and unanticipated results. From a knowledge point-of-view, an investigators experience is usually over a limited research theme; hence only regulators and pathways already well known to a researcher tend to be examined in detail. This workflow allows easy interrogation of a dataset to identify the role of potentially every known *E. coli* transcriptional regulator or metabolic pathway. This can suggest relevant transcriptional networks and unexpected aspects of physiology that would otherwise have been missed by conventional analysis methods.

Abstract — **The blood brain barrier (BBB) is an anatomical structure composed of endothelial cells, basement membrane and glia; preventing drugs and chemicals from entering the brain. Our aim is to engineer an *in vitro* BBB model in order to facilitate neurological drug development that will ultimately benefit patients. Tissue engineering approaches are useful for the generation of an *in vitro* BBB model. Our experimental approach is to mimic the anatomical structure of the BBB on polyester terphthalate (PET) cell culture inserts. Endothelial cells derived from brain capillaries, different peripheral blood vessels and epithelial cells (MDCK) were cultured on the apical side of the filter. Different concentrations of thrombin were applied on compact monolayer of MDCK. Physiological functions of this BBB model was evaluated by measuring the transendothelial resistance (TEER) using an EndOhm™ electrode. The epithelial cytoskeletal organization was observed by staining with BBZ-phalloidin. Epithelial monolayer formation and later distortion by thrombin was confirmed by fluorescence microscopy. Measurements of the TEER generated values up to 2020 ohm/cm^2. A dose response of thrombin was observed, showing the permeability changes in the epithelial cells (MDCK). A relationship between permeability values TEER and cytoskeletal organization was observed.**

I. Introduction

The presence of a barrier separating blood from brain and vice versa was described for the first time more than 100 years ago by Paul Ehrlich (1885) and confirmed later by Edwin Goldman (1909). Both researches showed that trypan-blue, an albumin-binding dye, following intravenous injection dispersed in whole body except the brain. On the other hand, direct subarachnoidal injection selectively stained only the brain. Neurological disorders include a large variety of brain diseases which may be treated with drugs. Unfortunately, the many drugs do not cross the Blood Brain Barrier (BBB). To evaluate pharmacokinetic properties of neurological drugs mainly animal studies are performed, which render the development of drugs a long high cost process. Therefore, there is a need to develop an *in vitro* BBB model to measure permeability of novel drugs which are under research and development. The aim of our research was to develop and characterize a new in vitro model involving endothelial and epithelial cells (MDCK). A novel approach was adopted to study the effects of thrombin on the permeability of a monolayer on transwel cell culture insert. Later, the results obtained from TEER measurements and changes in cytoskeleton were observed.

II. Materials and Methods

used to culture MDCK cells, 80,000 cells/cm^2 on transwell cell culture inserts. Ready to use phosphate buffered saline (PBS) and sterile 0.25% trypsin solution with 1:2000 ethylene-diamino-tetra-acetate (EDTA) was used to detach the cells from the surface of the flask., Transepithelial transport [6] was measured by Transepithelial Electrical Resistance, TEER [1] to calculate any increase or decrease in permeability of our model. MDCK cells need minimum ingredients to produce a high) TEER.

B. Phalloidin & BBZ Staining

Phalloidin / BBZ Stains were used to Stain Actin Filaments and Nuclei of cells. A cocktail of the stain was made by mixing 0.1 % triton –x in PBS, 2.5 µg /ml BBZ (2.5 µl from stock) and 1 µg/ml Phalloidin (1 µl/ml from stock). The samples were fixed with 10% formalin at RT for 30 minutes and then were washed for 2 – 3 minutes with PBS. Phalloidin/BBZ cocktail was applied for 20 minutes at room temperature and again the samples were washed 3*3 minutes with PBS and the images were observed under fluorescence Microscope.

C. Statistical Analysis

Statistical analysis were chosen as non parametric tests because the group size was n=9. Kruskal-Wallis- Test and Mann-Whitney-U tests were applied. The difference between the groups was accepted as significant when $p<0.05$.

D. TEER for different cell lines

Different endothelial cells and epithelial cell (MDCK) was seeded on the inserts and TEER was measured at different time intervals. TEER value in plotted against time.

In above experiment it was seen that the MDCK cells are able to produce a higher TEER value as compare to other cells. The epithelial cells producing tight junction proteins were purified to get cells producing tight junction proteins, thus producing a higher TEER value.

Again in the series of getting a high value of TEER; experiments were performed and we were able to get a higher value of TEER with MDCK cells. The Cells need minimum essential medium and it was observed that cell do not like frequent changes of medium.

E. Thrombin Concentrations

Thrombin is known to have receptors for epithelial cells [5]. It has cellular effects by Protease Activating Receptors (PARS) [2, 3]. We used thrombin to increase the paracellular permeability. The higher concentrations of thrombin used were 5 U/ml, 3 U/ml and 1 U/ml and the lower doses

were 0.01 u/ml, 0.001 u/ml, 0.0001 u/ml, 0.03 u/ml, 0.003 u/ml, 0.0003 u/ml.

III. Results

A. Thrombin dose Response on MDCK monolayer

The cells were treated with thrombin and then the culture medium was replaced with normal MEM media (serum added) and recovery of the cells was observed after four hours of serum MEM media addition. MDCK cell monolayer was stained with BBZ & Phalloidin staining technique and microscopic images were taken

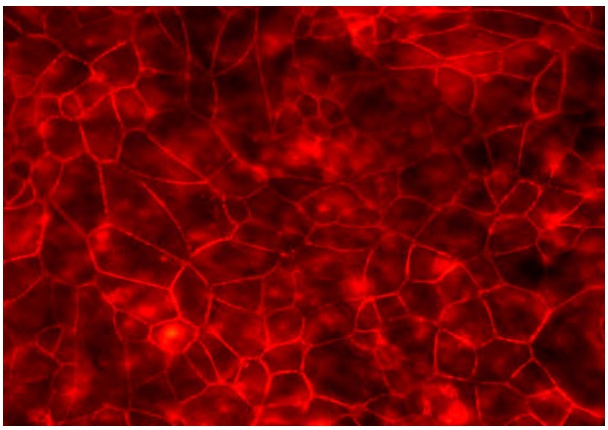

Fig. 3 MDCK Monolayer

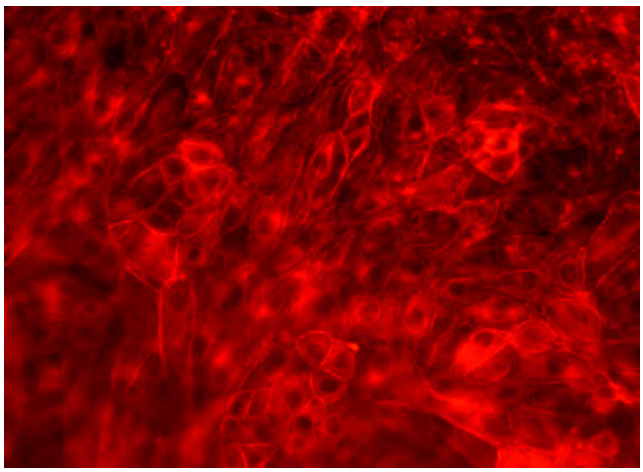

Fig. 4 MDCK Monolayer after thrombin treatment

The Serumless MEM medium was replaced with normal MEM medium and the MDCK cells showed a remarkable recovery towards their normal cytoskeleton structure

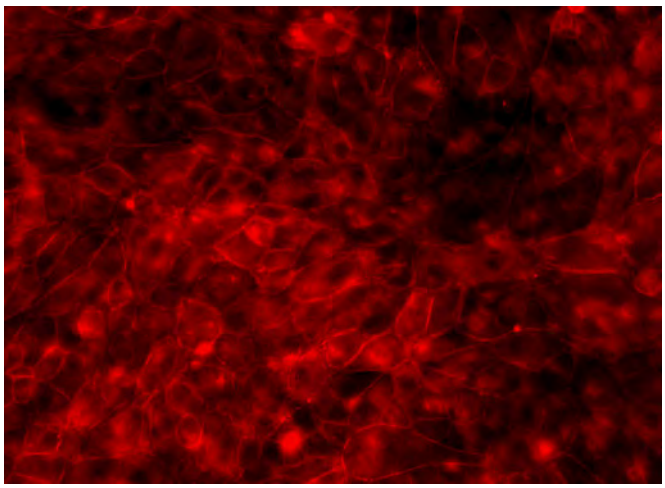

Fig. 5 MDCK Cells showing Recovery

MDCK Cells exposed to different thrombin concentrations and TEER was plotted against different thrombin concentrations. It was observed that we were able to get maximum increase in permeability at a lower concentration of thrombin i.e. 0.003 U/ml.

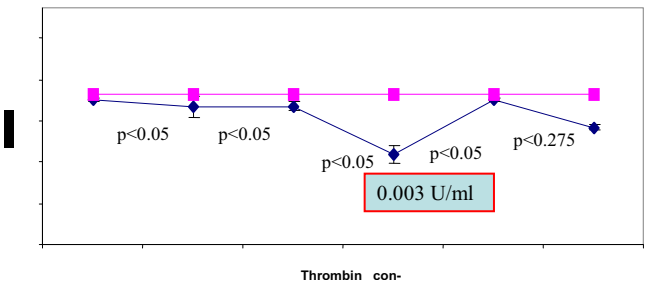

Fig. 6 n=9: Data as given average

All the thrombin groups were significantly different compared to control (p<0,05)

IV. Discussion

In vitro Blood Brain Model was made using different endothelial cells. And it was tried to obtain TEER of physiological level. But endothelial cells were not able to produce a high TEER value.

Efforts were made to increase the TEER of endothelial cells by using different growth factors (vNGF, mNGF, forskolin). Although we found some positive effects of vNGF but we were not able to increase TEER considerably. But with MDCK we obtained a good value of TEER. Because

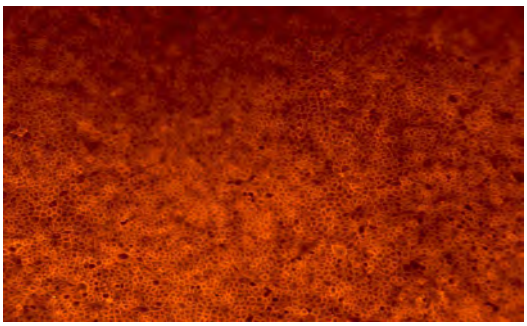

Fig. 7 MDCK compact monolayer

MDCK cells produce tight junction proteins and making a very nice and compact monolayer.

Epithelial cells are also used for i*n vitro* BBB modeling [4] because of their ability to produce a very tight monolayer by making tight junctions With MDCK cellular model a good TEER value of 2020 ohm/cm^2 was obtained. Studies have shown that endothelial cells and epithelial cells have receptors for thrombin [8]. The novel approach for thrombin effects on the permeability of epithelial cells (MDCK) was adopted and the effects of different concentrations of thrombin were seen. Thrombin concentrations from 5 U/ml, 3 U/ml and 1 U/ml were tried but we were not able to obtain good results. But it was observed that at lower concentrations the effect of thrombin is more as compare to higher concentration. Later very low concentrations of thrombin were used and dose response of thrombin was observed.

Six different concentrations of thrombin (0.01 u/ml, 0.001 u/ml, 0.0001 u/ml, 0.03 u/ml, 0.003 u/ml, 0.0003 u/ml) were used. It was observed that 0.003 u/ml showed maximum decrease in TEER or increase in permeability. From images we observed contraction of actin filaments and disruption of cytoskeleton caused a rapid decrease in TEER. Figure 3 & 7 show us a normal compact MDCK monolayer. In figure 4 we can see a very clear contraction and disorder of actin filaments; giving space ions to cross and causing a decrease in TEER. In figure 5 cells moving towards recovery can be seen after adding serum and inactivating thrombin (four hours). That shows us that thrombin is causing contraction in actin filaments, causing immediate decrease in TEER; showing increase in the permeability.

V. Conclusions

Endothelial cells were not able to make tight junctions and producing a high TEER value and thus were not used for our *in vitro* BBB cell culture model and permeability measurement. Epithelial cells (MDCK) were able to produce a higher TEER value because of tight junctions. Epithelial cells (MDCK) have thrombin receptors and thrombin can cause a rapid increase in the permeability.

Decision Making Algorithm through LVQ Neural Network for ECG Arrhythmias

Ms. T. Padma[1], Dr. Madhavi Latha[2], Mr. K. Jayakumar[1]

[1]GRIET/BME, JNTU, Hyderabad, India
[2]JNTUCE/ECE, JNTU, Hyderabad, India

Abstract — **In this paper, learning vector quantization artificial neural network method was used for designing decision support system for Electrocardiogram (ECG) analysis. Four types of ECG patterns were chosen from the data obtained from ECG simulator device to be recognized, including Bradycardia, tachycardia, monomorphic preventricular contraction, myocardial infraction R-R interval, QRS complex duration, ST-segment slope change features were performed as the characteristic representation of the original ECG signals to be fed into the neural network models. LVQ network was trained and tested for ECG pattern recognition and the experimental results, performance graphs are plotted for varying number of samples. The LVQ network exhibited the best performance and reached an overall accuracy of 95.5% when. trained with 200 samples with learning rate at 0.9.**

Keywords — **ECG, Arrhythmia, LVQ Neural Network, Euclidean distance, Supervised learning.**

I. Introduction

Artificial neural networks can classify the data based on the features extracted from the biomedical signals. In this paper an attempt is made to design a decision support system for ECG analysis using Learning Vector Quantization (LVQ) neural network [4]. Five important features are extracted from the ECG [5] signal and are fed to the LVQ algorithm, which is implemented in MATLAB software [1].

II. Motivation

A typical ECG [9] waveform contains P wave, QRS complex and T wave in each heart beat Fig. 1 recognizing an ECG [6] pattern is essentially the process of extracting and classifying ECG feature parameters, which may be obtained either from the time domain or transform domain. The features being frequently used for ECG analysis in time domain include the wave shape, amplitude, duration, areas, and R-R intervals.

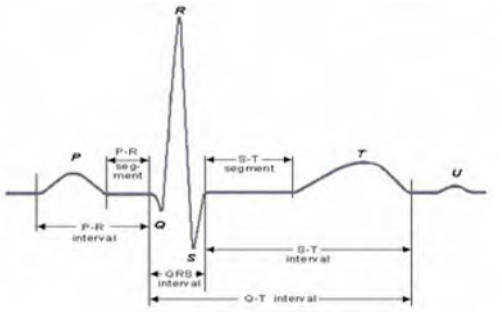

Fig. 1 Typical ECG waveform

The basic problem of automatic ECG analysis occurs from the non-linearity in ECG signals and the large variation in ECG morphologies [10], [11] of different patients. And in most cases, ECG signals are contaminated by background noises, such as electrode motion artifact and electromyogram - induced noise, which also add to the difficulty of automatic ECG pattern recognition.

III. Implementation

Various methods for pattern recognition, artificial neural network models have been successfully applied to the problem of ECG [8] classification. Artificial neural network is characterized by its nonlinearity and robustness, which confirms its efficiency on dealing with non-linear problems and good tolerance in the presence of noise and disturbance.

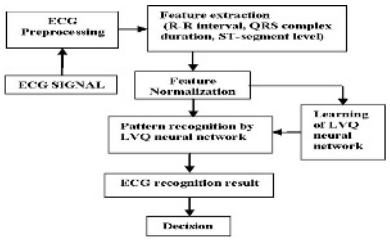

Fig. 2 Block diagram for Decision support system

Compared with the traditional clustering methods, the artificial neural network models have good adaptive ability to environmental changes and new patterns, and the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 85–88, 2009
www.springerlink.com

recognition speed of neural network is fast, owing to its parallel processing capability. The objective of our work is to design a decision supporting system for ECG analysis using Learning vector quantization neural network.

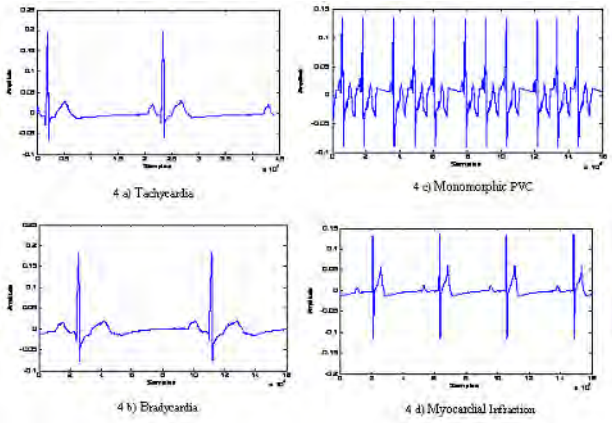

Fig. 3 different types of ECG Arrhythmias

IV. ECG Acquisition

Data acquisition is the sampling of real world to generate data that can be manipulated by a computer. Data acquisition typically involves acquisition of signals and processing the signals to obtain the desired information. The components of data acquisition system include appropriate sensors that convert any measured parameter to an electrical signal, which is acquired by data acquisition hardware. The signals like ECG, EMG EEG etc. are the analog signals, which are subjected to digitize before sending them to a computer. Analog to digital conversion of the data can be done using a data acquisition card or a sound card, where they have inbuilt A/D converters.

The vital parameter ECG is generated using a 12 lead ECG simulator [7]. The analog output from the simulator is sent to sound card extension slot of the computer through a wire. A/D converter present in the sound card converts it into digital signal which is read by the system bus as shown in fig.3. The obtained digital data is used for further analysis and classification.

V. Feature extraction

The task envisaged for signal processing is mainly the estimation of clinically important features from the ECG constituents, which, in turn will enable ECG waveform interpretation. The patterns that must be recognized in the ECG waveform like complexes, Inter wave segments Cardiac intervals,

In most cases of pattern recognition, feature extraction is needed to generate an adequately accurate representation of the original signals with lower dimension, which turns to form the input vector space. The ECG patterns to be recognized exhibit dissimilarity both in heartbeat timing and ECG morphology, so the following features were chosen like QRS complex duration, R-R interval, R-wave amplitude, ST segment slope change

VI. Learning vector quantization

Kohenen network has shown that it is possible to fine tune the class boundaries of a self organizing mapping (SOM) in a "supervised" way and has developed several methods for doing this. They are all variations of learning vector quantization. Vector quantization is a standard statistical clustering technique, which seeks to divide the input space into areas that are assigned as "code book" vectors. In LVQ network, target values are available for the input training pattern and the learning is supervised. In training process, the output units are positioned to approximate the decision surfaces. After training, an LVQ [2] net classifies an input vector by assigning it to the same class as the output unit that has its weight vector (reference or codebook vector) closest to the input vector.

In order to understand the LVQ techniques it should be borne in mind that the closest weight vector W_i to a pattern x may be associated with a node j that has the wrong class label for x. This follows because the initial node labels are based only on their most frequent class use and are therefore not always reliable. The procedure for updating W_j is given by,

$$\Delta W_j = \alpha(x - W_j) \quad \text{:if X is classified correctly}$$
$$= \alpha(x - W_{j)} \quad \text{:if X is classified incorrectly.}$$

The negative sign in the misclassification makes the weight vector move away from the cluster containing x, which on average, tends to make weights vectors move away from class boundaries.

A. ARCHITECTURE

The architecture is similar to the architecture of a Kohenen self organizing neural out without a topological structure assumed for the output units. In LVQ net, each

output unit has a known class, since it uses supervised learning, thus differing from Kohenen's SOM, which uses unsupervised learning. This is a competitive net where the output is known; hence it is a supervised learning network.

Take first 'm' training vectors and use them as weight vectors, the remaining vectors are used for training.

1. Initialize the reference vectors randomly and assign the initial weights and class randomly.
2. K-means clustering method can be adapted.

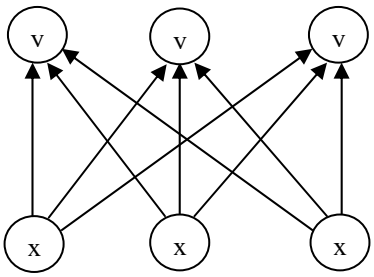

Fig. 4 Learning vector quantization neural net.

B. TRAINING DATA SET

The ECG data used to perform pattern recognition were taken from the ECG simulator database, which contains 200 recordings of two channel ambulatory ECG signals. Each record was annotated by cardiologists and the annotations were provided along with the ECG data. In this study, only one channel of ECG signals derived from modified-lead II was used. We chose four types of ECG patterns from the database, which are respectively annotated as the Premature Ventricular Contraction (PVC), Tachycardia, Bradycardia and Myocardial Infarction.

C. TRAINING ALGORITHM

The algorithm for the LVQ net is to find the output unit that has a matching pattern with the input vector. At the end of the process, if x and w belong to the same class, weights are moved toward the new input vector and if they belong to a different class, the weights are moved away from the input vector. In this case also similar to Kohenen self organizing feature map, the winner unit is identified. The winner unit index is compared with the target, and based upon its comparison result; the weight updating is performed as shown in the given algorithm [12] below. The iterations are further continued by reducing the learning rate.

The algorithm is as follows:

Step1: Initialize weight (reference) vectors.
Initialize learning rate.
Step2: While stopping is false, do step 3-7.
Step3: For each training input vector x, do steps 4-5.
Step4: Compute J using squared Euclidean distance.

$$D(j) = \sum (W_{ij} - x_i)^2$$

Find *j* when *D (j)* is minimum.

Step5: Update W_j as follows:

If $t = c_j$ then

$$W_{j(new)} = W_{j(old)} + \alpha[x - W_{j(old)}]$$

If $t \neq c_j$ then

$$W_{j(new)} = W_{j(old)} - \alpha[x - W_{j(old()}]$$

Step6: Reduce the learning rate.
Step7: Test for the stopping condition.

The condition may be fixed number of iterations or the learning rate reaching a sufficiently small value.

D. EXPERIMENTATION

An ECG signal with abnormal high heart rate is generated using a simulator, which signal is preprocessed and five features like R-R interval, QRS duration, Heart rate, ST slope change, R-amplitude are extracted from it. These features are fed to a Learning vector quantization neural network algorithm as shown above. Here the weight vectors are initialized as

Initial weight matrix

0.5100	1.2400	0.8100	0.8100
80.0000	80.0000	100.0000	76.0000
120.0000	48.0000	68.0000	68.0000
-0.0000	-0.0000	-0.0000	-0.0000

The stopping condition given here is the number of epochs equals to 100. After 100 epochs the weight updating process stops and the resultant model is used for further classification

Weights after 100 epochs

0.5362	1.6310	0.8169	0.8352
83.6009	84.8964	106.483	82.8675
118.641	36.9193	68.7839	67.7639
-0.0000	-0.0000	-0.0000	-0.0000

The neural network model thus developed is trained with 200 ECG signals to increase the efficiency of the network.

Then it is fed with the new ECG signal features, from the simulator, to classify into different classes. In our case four classes are considered like Tachycardia, Bradycardia, pre mature ventricular contraction and myocardial infarction. Any new signal fed to this model gets classified into one of these classes.

VII. Results

The result of the given signal is shown in a prompt dialog box which is created as a part of the program. This dialog box gives us the all values of the signal along with the distance calculated and prediction obtained. Next two figures shown are the results obtained for the sample signal taken.

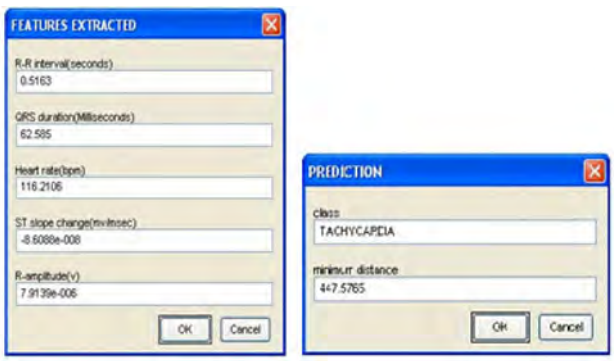

Fig. 5 dialogue box for feature extraction and prediction

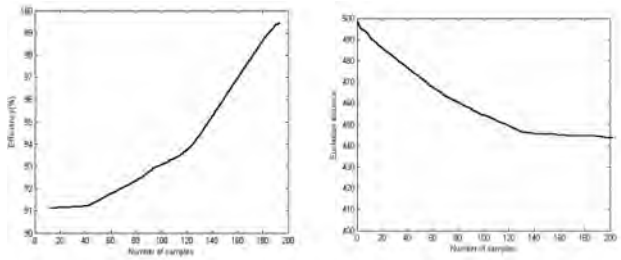

Fig. 6 trained data for Euclidean distance and efficiency

VIII. Conclusion

The decision support system is designed and that decides the subject based on only one parameter, ECG. The number of classes into which the signal is classified is constrained to four. It was observed that the efficiency of LVQ neural network for classifying the given input ECG signal increases as the number training samples increases and the Euclidean distance from class centre decreases. The changes in learning rate effects the classification efficiency. The classification efficiency increases as the learning rate is increased (from 0.1 to 0.9). As an extension to this work other biomedical signals like Respiratory signal, lab reports, Spo2 etc can also be used for the classification. The number of classes can also be extended.

A Low-Noise CMOS Receiver Frontend for NMR-based Surgical Guidance

J. Anders[1], S. Reymond[1], G. Boero[1] and K. Scheffler[2]

[1] Ecole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland
[2] University of Basel, University Hospital, Basel, Switzerland

Abstract — **In this paper a novel architecture for an integrated NMR receiver front-end for surgical guidance applications is described. While the chip consumes only 9 mA supply current from a 3.3 V power supply it has a measured input referred noise density of 0.7 nV/√Hz. The receiver consists of the reception coil, an on-chip tuning capacitor an LNA and a 50 Ω output buffer. The system is designedfor operation in a B_0-field of 1.5 T corresponding to a frequency of 63MHz. It is implemented in a 0.35 µm CMOS high voltage process and occupies a chip area of 500 µm × 760 µm.**

Keywords — **CMOS, NMR, MRI, Surgical Guidance**

I. Introduction

Interventional radiology (IR) is used to perform minimally invasive procedures using image guidance. These procedures can be either for diagnostic purpose (e.g. angiogram) or for treatment purpose (e.g. angioplasty). IR is usually performed by inserting small needles or catheters into the human body and guiding their way using radiological methods such as X-ray, computed tomography, ultrasound or magnetic resonance imaging (MRI) to provide roadmaps for the Interventional Radiologist. In this paper, a chip is presented that will facilitate the monitoring of surgical equipment such as scalpels, scissors or tweezers using MRI-based tracking.

The paper is organized as follows. In section II.A a brief review of the physics behind nuclear magnetic resonance (NMR) – the phenomenon underlying MRI – will be given: section II.B explains how NMR can be used for surgical guidance. Having presented the necessary application background, section III will then introduce the circuit details of the receiver along with the simulated results: section IV presents the measured performance of the receiver, and section V presents our concluding remarks.

II. Working principle

A. Nuclear Magnetic Resonance

The physical mechanism underlying MRI is nuclear magnetic resonance (NMR). NMR exploits the fact that nuclei possessing an odd number of protons or neutrons have an intrinsic magnetic moment. In an external static magnetic field (B_0-field), the spins precess at the Larmor-frequency, ν_0, given by

$$\nu_0 = \frac{\gamma B_0}{2\pi}, \tag{1}$$

where γ is the gyromagnetic ratio of the nucleus, around this field. The net magnetization however is aligned with the B_0-field. If one now applies an RF-magnetic field (B_1-field) with a frequency close to ν_0 (resonance condition) and linearly polarized in a direction perpendicular to the B_0-field for a time τ, the net magnetization will be rotated around the axis of the B_1-field by a certain angle θ according to

$$\theta = \gamma B_1 \tau_1 \tag{2}$$

The NMR receiver then detects the component of the net magnetization in the plane perpendicular to the B_0-field as an induced voltage in the reception coil.

B. Surgical Guidance

The chip can be attached to any surgical instrument that would not interfere with the MRI image. By monitoring the frequency of the induced voltage in the reception coil and knowing the gradients in the static B_0-field during the image sequences, one can easily calculate back the position of the chip and thereby the position of the instrument to which it is attached to visualize it on the MRI image.

III. Circuit description

A. Coil Optimization

Given a reasonable size for an implantable device (here we fix the outer coil diameter to be 500 µm) the procedure below allows us to determine the coil that gives the best signal to noise ratio (SNR) at the LNA output. If we choose a particular metal layer and fix the spacing between two adjacent windings (here 3 µm) by the minimum design rule, the only two free parameters are the number of turns, N, and the inner radius, r_{in}. The SNR to optimize is considered at the output of the equivalent resonant circuit shown in Fig.(1):

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 89–93, 2009
www.springerlink.com

$$\sqrt{SNR} = \frac{V_{ind}\left(Q + R_v / \left(R + 2R_v\right)\right)}{\sqrt{4kT\left(\left(R + 2R_v\right)\left(1 + Q^2\right) + R_{in}\right)}} \quad (3)$$

where V_{ind} is the NMR voltage induced across the coil, R is the coil resistance, $Q = \left(\omega L\right)/\left(R + 2R_v\right)$ is the circuit quality factor, L is the coil self inductance [2], R_v is the metal leads and vias resistance and R_{in} is the LNA input referred noise resistance obtained from Spectre simulations. This expression is valid when C is tuned so that the coil circuit is resonant.

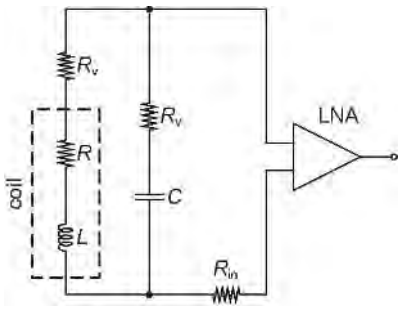

Fig. 1 Equivalent circuit for coil optimization

To calculate the induced voltage, we use the reciprocity principle [4]:

$$V_{ind} = \omega M \int B_{z,u} dv, \quad (4)$$

where M is the sample magnetization, which is assumed to be homogeneous over the sample volume V and $B_{z,u}$ is the perpendicular magnetic field produced by a unitary current circulating in the coil. The integration is performed over a volume that we model as a cylinder. Fig.(2) shows the SNR levels as a function of the two free parameters for the situation corresponding to the fixed parameters shown in Tab.1.

Table 1 Coil optimization parameters

Parameter	Value
Optimization Frequency	63 MHz
R_{in}	16 Ω
R_v	1Ω
Sample material	H_2O
Sample size	250 µm (diameter) × 250 µm
Coil-sample distance	10

The SNR maximum occurs at 16 turns and r_{in} = 75 µm, but if we impose an additional constraint, namely that the self resonating frequency remains well above the excitation frequency (here we chose f_{self} larger than 1 GHz), then too large winding numbers are prohibited. The chosen tradeoff coil is represented by the red dot in Fig.(2), it corresponds to N = 13 and r_{in} = 70 µm. Note that for very low N, the LNA produces the majority of the noise, resulting in poor SNR. At larger N, both the induced voltage and the coil resistance scale with N, which produces the relatively weak N dependence of the SNR. The upper right corner of Fig.(2) corresponds to narrow highly resistive coils.

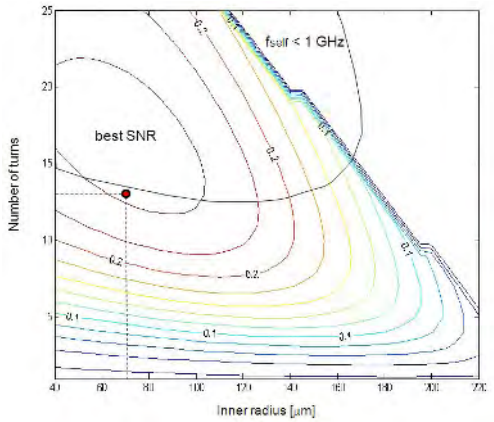

Fig. 2 Contour plot of coil optimization

B. LNA Design

The core of the LNA is a differential voltage amplifier consisting of input pairs M_{n1}-M_{n2} and M_{p1}-M_{p2} in parallel, cascoding devices Mn3-M_{n4} and load devices M_{p3} and M_{p4}. The parallel combination of the NMOS and the PMOS input pair effectively increases the transconductance for a given bias current and thus minimizes the input referred noise and maximizes the voltage gain [1], [2]. The differential topology is beneficial for on-chip signal processing. Unfortunately, conventional MRI receivers do not support differential signaling. Therefore, to be compatible with these systems, a differential-to-single-ended conversion had to be performed on chip. The most natural way to perform this conversion is a current-mirror load as it can be found in many Op-Amp circuits. However, in contrast to the Op-Amp case, where the external feedback defines the output DC voltage, in the design at hand this simple solution is not applicable for the following reason: no shunt-peaking can be applied because the tight area requirements prohibit the use of an additional inductor which would anyway have a very poor quality factor at the operating frequency of 63 MHz. Therefore, the amplifier has to provide the desired gain over the full bandwidth from DC up to the operating frequency. Because such a large bandwidth is hardly achievable in a 0.35 µm CMOS process, an open-loop archi-

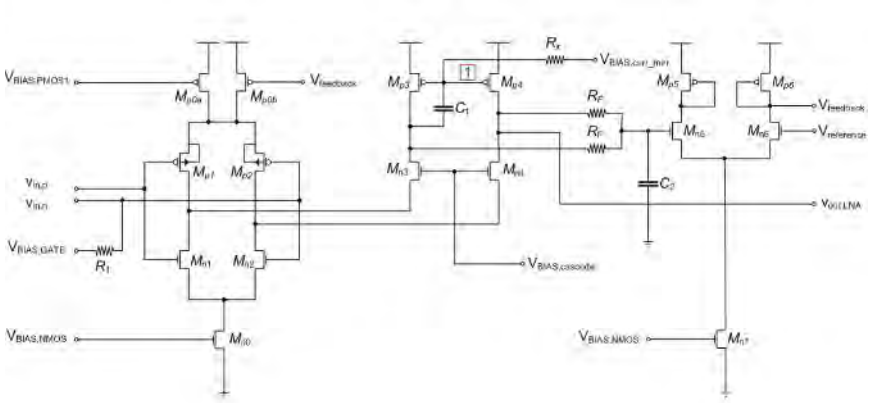

Fig. 3 LNA schematic

tecture had to be used. To still be able to set the DC output voltage of the current mirror in a way that is robust against process variations and mismatch in the input pairs, the AC behavior of the load has been separated from its DC performance in the following fashion. For DC signals, the capacitor C_1 can be viewed as an open-circuit and the voltage at the gates of transistors M_{p3} and M_{p4} is set by the biasing voltage $V_{bias,curr_mirr}$; that is M_{p3} and M_{p4} effectively present a current source load. To set the DC voltages at their drains, a common-mode-feedback (CMFB) network consisting of sensing resistors R_2 and R_3, differential pair M_{n5}-M_{n6} and diode connected loads M_{p5}-M_{p6} has been added. The CMFB is closed through transistor M_{p0b}. By means of this feedback, the output common mode voltage is compared to the reference voltage, $V_{reference}$, and adjusted appropriately. Of course, the CMFB has to be disabled for signals around the operation frequency of 63 MHz where the current mirror operation is needed to perform the differential-to-single-ended conversion. To achieve this, the values of capacitors C_1 and C_2 had to be carefully chosen. Capacitor C_2 defines the bandwidth of the CMFB and should be as large as possible because it should only set the DC operation point of the load and not affect the circuit's AC behavior. Thus, it will be treated as a short circuit in the following AC analysis. Capacitor C_1 on the other hand must perform the current mirroring at the operation frequency and thus C_1, and R_X, should be large enough to place the corresponding zero at a sufficiently low frequency. For a quantitative analysis we will now take a closer look at the transfer function $A_{diff}(s)$ from the input, $v_{in,p}$-$v_{in,n}$, to the output $v_{out,LNA}$. Neglecting the output load capacitance, the transfer function can be approximated by

$$A_{diff}(s) = g_{m,in}R_F \frac{\left(1+\frac{s}{s_{z1}}\right)\left(1+\frac{s}{s_{z2}}\right)}{\left(1+\frac{s}{s_{p1}}\right)\left(1+\frac{s}{s_{p2}}\right)}, \tag{5}$$

where

$$s_{z1} = -\frac{1}{2C_1 g_{m,p3} R_F R_X},\ s_{z2} = -\frac{2g_{m,p3}}{C_X},$$
$$s_{p1} = -\frac{1}{C_1 g_{m,p3} R_F R_X} = 2s_{z1},\ s_{p2} = -\frac{g_{m,p3}}{C_X} = \frac{1}{2}s_{z2}, \tag{6}$$

where $g_{m,in}$ is the total differential input capacitance, i.e. $g_{m,in}=g_{m,n1}+g_{m,p1}$, and C_x is the total capacitance from node 1 to ground. In the design at hand, R_x and C_1 were chosen to place the first zero, s_{z1}, around 10 MHz, which does not degrade the AC performance, i.e. the gain in the frequency region of interest is given by $2g_{m,in}R_F$, and still leads to reasonable device sizes for R_x and C_1.

The total input referred noise is dominated by the input differential pairs and it suffices to model the noise as an input referred voltage source because induced gate noise can be neglected for the given values of coil resistance [8], rendering the input transistor's drain noise the main overall noise contributor. With these assumptions, the total input referred voltage noise density can be expressed as

$$V_{noise}(f) = \sqrt{2\frac{4kT\left(\gamma_n g_{m,n} + \gamma_p g_{m,p}\right)}{\left(g_{m,n}+g_{m,p}\right)^2} + 4kTR_{G,tot}} \tag{7}$$

where γ_n and γ_p are booth equal to 2/3 for transistors in saturation and strong inversion, $g_{m,n}$ and $g_{m,p}$ are the differential transconductance of the NMOS and PMOS differential pair and $R_{G,tot}$ is the total gate resistance of the input transistors. Clearly, to avoid a degradation of the noise performance by the gate resistance it has to be a lot smaller than the coil resistance amplified by the coils Q-factor. This was achieved by careful layout of the input differential pairs. These were laid out as common centroids were each half transistor was first divided in six diffusion areas and then fingered.

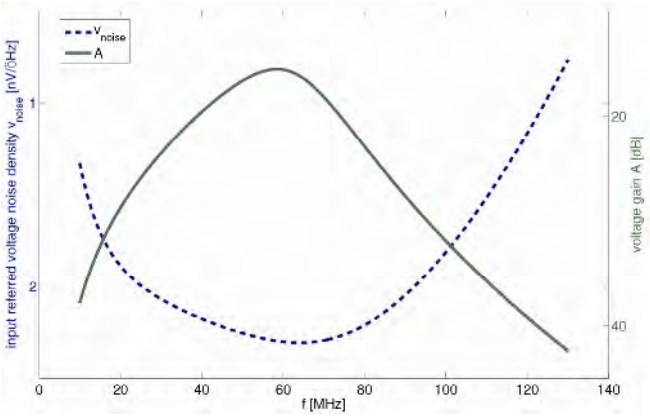

Fig. 4 Simulated LNA input noise and gain (extracted view)

The simulated (extracted view) LNA noise and gain performance are shown in Fig.(4).

IV. Measurement Results

The LNA performance has been verified using an NMR experiment with cis-PolyIsoprene as a sample. The corresponding free induction decay (FID) and spectrum are shown in Fig.(6) and Fig.(7). Knowing the sample dimensions and the reception coil properties it is possible to calculate the induced voltage in the coil with the aid of Eq.(4). Then, knowing the amplification of the rest of the receiver chain, one can deduce the LNA gain with an uncertainty of less than 2 dB. Once the gain has been calculated, the input referred noise was calculated from the measured output referred noise density and the gain value. The obtained values are listed in Tab. 2 together with the corresponding values from extracted view simulations. One clearly sees the good agreement between measurement and simulation.

Table 2 Performance Summary

	Measured	Extracted Sim
Voltage gain [dB]	43±1	44
Input referred noise [nV/√Hz]	0.7	0.7

V. Conclusion

A receiver front-end for NMR-based surgical guidance in 0.35 µm CMOS has been designed. The performance was evaluated using real NMR experiments and it proves to be at least an order of magnitude better in terms of sensitivity than the state of the art [9]. In the future, the receiver will be extended by co-integrating the mixer, as well as the local oscillator and a low-frequency gain stage chip on chip.

Automated Fluorescence as a System to Assist the Diagnosis of Retinal Blood Vessel Leakage

Vanya Vabrina Valindria[1], Tati L.R. Mengko[1], Iwan Sovani[2]

[1] Institut Teknologi Bandung(ITB), Imaging and Image Processing Group (I2PRG), Bandung, Indonesia
[2] Cicendo Eye Hospital, Bandung, Indonesia

Abstract — **Leakage in retinal blood vessel may cause retinal edema which is a sign of diabetic retinopathy. Diabetic retinopathy is a severe and widely spread eye disease which can be regarded as manifestation of diabetes on the retina. So far the most effective diagnosis for this eye disease is early detection through FFA (Fluorescence Fundus Angiography) regular screening that can lead to successful laser treatments in preventing visual loss. FFA is a fundus photography technique which captures the flow/circulation of contrast agent (fluorescence) in retinal blood vessel. The problem arises since the fluorescence is a costly contrast agent and has some side effects to the patients. Some patients felt nauseous and lose their consciousness when the substance was injected to their body. To lower the risks of such screening, the Automated Fluorescence (AF) system is developed to detect the presence of leakage in retinal images obtained from fundus camera, without contrast agent injection (non-invasive).**

An alternative method for automated detection of the vasculature in retinal images is introduced, which includes Gabor wavelet 2-D, scale addition, and Butterworth high-pass filtering. The experimental results demonstrate the accuracy of the algorithms in detecting both large and small vessels and the efficiency in reducing noise. Method for detection of retinal leakage consists of ANN (Artificial Neural Network), CLAHE (Contrast-Limited Adaptive Histogram Equalization), and morphological operation. The leakage feature in Gabor wavelet image is recognized by the trained ANN system, and this image is combined with CLAHE image in order to give a better detection result. Output images that have been tested by ophthalmologists, give 92% satisfaction in blood vessel detection and 75% correspondence with reference images in leakage detection.

Keywords — **leakage, retina, diabetic retinopathy, Gabor, Artificial Neural Network.**

I. Introduction

Image processing holds an important aspect in medical field, especially in assisting diagnosis. Diagnosis is one of the medical procedures to recognize the pathology of the patient. Fundus image shows the map of the retina, such as optic disk, macula area, fovea, and blood vessels. In several cases, the information of retinal vasculature and leakage area are needed to be enhanced. The FFA(*Fundus Fluorescence Angiography*) technique can give a detail information about circulation in the retina. Contrast agent (fluorescence) is injected to vena and it will flow to the blood vessels inside the patient body. This contrast agent makes the obtained images appear more detail and can be used for diagnosis. But, the problem arises since the fluorescence has some side effects to patients. Some patients feel nauseous and lose their consciousness when the subtance is injected to their body. Moreover, fluorescence is a costly contrast agent.

The solution to solve those problems is to develop an image processing technique which can give an image with leakage area similiar to the FFA image, without contrast agent injection to the patient. Without image processing, the information needed for diagnosis cannot be appeared clearly in fundus image.

In previous work [13], blood vessels and leakage area in retina images were enhanced by *matched filter* and ANN. This system failed to detect small blood vessels, presented noise on the retinal image background, and showed only 50% correspondence with reference images in leakage detection.

In this paper, the AF system is proposed to diagnose blood vessels leakage in diabetic retinopathy patients. The purposes of this paper are to find the appropriate methods to give an image with clear leakage area and to improve the previous system. With this AF system, doctors can approximate the location of blood vessels leakage in retinal image to do the LASER therapy and patients will feel more comfortable with the diagnosis.

II. Materials and Methods

A. Pre-processing of blood vessel detection

Input image from fundus camera – shown in Fig.1 is processed in pre-processing 1. In order to obtain the blood vessel information, three channels (RGB) of the images need to be extracted. The green channel was selected since it is more contrast in blood vessels than in the other channels. An obstacle for identification of retinal blood vessels is the wide variability in the colour of fundus from different

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 94–97, 2009
www.springerlink.com

patients. We apply a colour normalization method to make the images invariant with respect to the background pigmentation variation between individuals. The colour normalization was performed using histogram specification [18]. Then, we invert the normalized green channel of the image, so that the vessels appear brighter than the background (see Fig.1).

B. Pre-processing of leakage detection

1. Pre-processing of ANN process

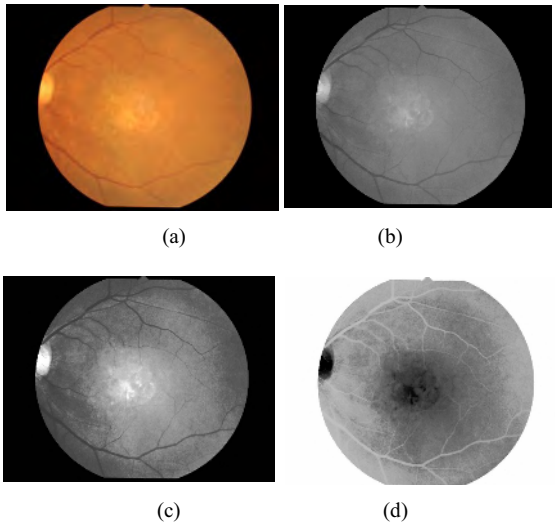
Input images for ANN training are green channel extracted image and its Gabor wavelet image. These images have the feature information needed for blood vessel leakage detection

2. Pre-processing of optic disk detection

Based on our observation, the optic disk is brighter and easier to be segmented in blue channel image. After extracting the blue channel from the input image, we normalize it with the reference image used in the previous step.

C. Main processing of blood vessel detection

One of the retinopathy diabetic symptoms is neovascularization – which can be recognized by abnormal vasculature structure of small blood vessels. It is much more difficult to detect small blood vessels due to their low contrast and tortuos patterns in the images.



1. Blood vessel detection using Gabor wavelet 2-D

Gabor function here serves as the basis function (mother wavelet) in wavelet transform. The mother wavelet and its Fourier transform are well localized in time and frequency domain. This condition implied that the wavelet transformation is effective for singularity detection, such as blood vessels. The continous Gabor wavelet transform is defined as :

$$T(s,\tau_x,\tau_y) = \iint f(x,y)\psi^*_{s,\tau_x,\tau_y}(x,y)dxdy \qquad (1)$$

where *f(x,y)* is the input image, τ_x and τ_y are the translation parameters, *s* denotes the scaling parameter and ψ^* denotes the complex conjugate of ψ. Another benefit of Gabor filter is the availability of phase or orientation angle at each pixel, that may provides the largest magnitude response [16]. Then, the Gabor wavelet transform is computed for orientation θ, from 0 up to 170 degrees at step 10 degrees.

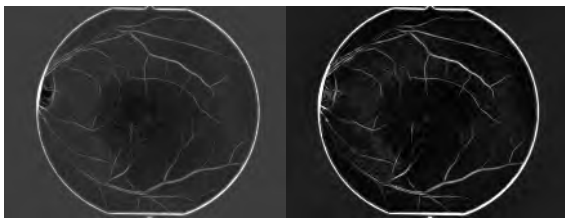
To meet the criterion for wavelet basis function, Gabor function must be arisen by translation and scaling. The centre coordinates of a pattern in multi-resolution analysis should contain *s*.

(a) (b) (c) (d)

Fig.1 Images in pre-processing 1. (a) Color input image. (b) Green channel image. (c) Normalization. (d) Inverted normalized image

Ignoring translation to multi-resolution analysis; we modified the equation to:

$$x' = \frac{x\cos\theta + y\sin\theta}{s}, y' = \frac{-x\sin\theta + y\cos\theta}{s} \qquad (2)$$



Gabor function consists of two parts, the complex exponential function and the Gaussian function. Therefore, the Gabor wavelet function in this paper is defined as:

$$\psi_G(x,y) = \frac{1}{2\pi s\sigma_x\sigma_y}\exp\left[-\frac{1}{2}\left(\frac{x^2}{\sigma_x^2}+\frac{y^2}{\sigma_y^2}\right)\right]\exp(jf_0y) \qquad (3)$$

In [14], frequency $f_o = 3$ is chosen for y-axis and $f_o = 0$ for x – axis. We set the σ_y parameter to 1, making the pattern characteristic to be strongly detected. In order to to make a sharper detection, [16] the value of σ_x should be adapted to the scale, with respect to the thickness of the detected blood vessels. The Gaussian amplitude is one half of its maximum at $x = s/2$ and $y = 0$. Thus, the parameter σ_x can be set as $s/2\sqrt{(2 \ln 2)}$.

We apply the Fourier transform to the conjugated basis function ψ_G^*. Then, 2-D Gabor wavelet transform is implemented as the inner product of an image and ψ_G^* in frequency domain:

$$T(s) = f(\omega_1,\omega_2).\psi^*_{G_s}(\omega_1,\omega_2) \qquad (4)$$

(a) (b)

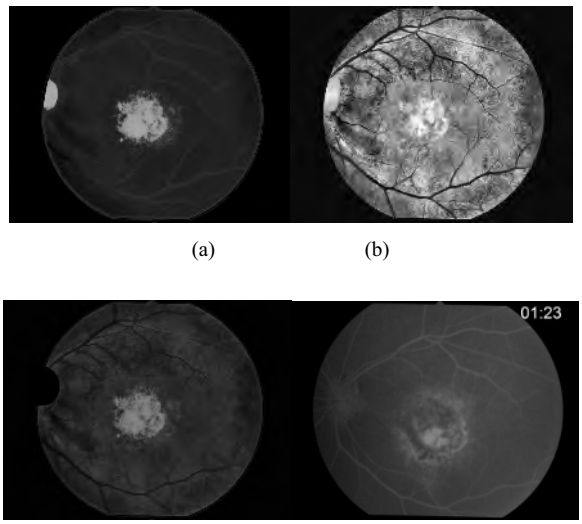
Fig.2 Images in main processing of blood vessels detection. (a) Gabor wavelet 2-D image. (b) Enhancement result

For each scale, we compute the maximum response of its transform result. Some advantages of multi-resolution analysis are noise reduction and line filter response enhancement. In line detection, the parameter *s* must be carefully selected to capture the information of lines with different widths. After multi-resolution filtering using Gabor, we do the scale addition between the filter responses at two adjacent scales [17].

2. Enhancement

To produce a sharper detection in both large and small blood vessels; a high-pass filtering is applied to the image, as shown in Fig.2 (b). We use second order Butterworth high-pass filter with cut-off frequency 1, 8.

D. Main processing of leakage detection



Generally, the retinal blood vessel leakage in fundus image is characterized by smoother texture and brighter intensity than the background. In a non-diffuse leakage, both the leakage source and edema area can be detected. On the other hand, in diffuse leakage, only edema area which can be detected due to many leakage sources in the blood vessels.

1. Artificial Neural Network (ANN)

In ANN training stage, we use backpropagation algorithm to train the ANN. To compose the feature vectors, two input images used in this stage consist of Gabor wavelet image and normalized green channel of fundus image. Meanwhile, the target image used here is FFA image.

By implementing the designed ANN to this system, we can obtain an output image with the detected retinal leakage area. In ANN main processing stage, we use feed-forward algorithm. Input images in this process are Gabor wavelet image and normalized green channel of fundus image. Applying those images to ANN system, it results in an output image with strong leakage area detection, as shown in Fig.3 (a).

The design of network in training and main processing consists of three layers; one input layer, one hidden layer and one output layer. Input layer has two input nodes, hidden layer has three nodes and output layer has one node.

(a) (b)

(c) (d)

Fig.3 Images in main processing of leakage detection. (a) ANN image. (b) CLAHE image. (c) Segmented optic disk. (d) Output image. (e) FFA image as a reference image

2. Contrast enhancement using CLAHE

CLAHE image gives a more detail blood vessels structure and accurate leakage area. Next, the CLAHE image is combined with the image obtained from ANN process. Using this combination, over-exposure in optic disk area can be reduced and leakage area in those two images is strengthened. To minimize wrong leakage detection, blood vessel appears darker than the leakage area (see Fig.3 (b)).

3. Optic disk detection

We use morphological operation to detect the optic disk in retina image. After we threshold the image to get the raw segmentation of optic disk area, the label is dilated and segmented. For each segmented area, we compute its circularity.

Then, we subtract the combined CLAHE and ANN image with the segmented optic disk. The aim of this subtraction is to discard the bright area in retina image except the leakage or edema, so that wrong detection can be minimized. Output image of this system in Fig.3(c) gives a high correspondence of leakage area with the reference image (FFA) in Fig.3(d).

III. Results

Experiments have been carried out on 64 images from our database. The database consists of two different sizes of images: 42 images of 1600x1216 pixels size and 22 images of 2588x1958 pixels size. Those images were sorted by

ophthalmologists to represent various conditions in retinal leakage. The performances are evaluated by four ophthalmologists from Cicendo Eye Hospital.

1. Blood vessel detection

Based on the ophthalmologists' visual observations, the detection of blood vessels gives a subjective satisfaction of 92%. Thus, the detection provides an optimal result in both sizes of images which can be used for diagnosis.

False detection occurs in some images for pathologies, such as exudates or abnormal retinal layer. The previous work [13] shows some difficulties in small blood vessel detection and noise reduction. Our approach separates the images of leakage area detection and blood vessel detection, ignoring any pathology in blood vessel detection.

2. Leakage detection

Output images and FFA reference images are labeled with five-part circle mark on the macula area. Both images are compared to see their correspondence of retinal leakage area. The results indicate that our approach is able to achieve 75% accuracy in retinal leakage detection.

However, the limitation of this detection is that it cannot distinguish leakage source from macula edema. Using Gabor wavelet in this AF system, leakage can be detected with stronger boundary and brighther area. This result shows that texture is an important feature in leakage detection.

IV. Conclusions

The results obtained indicate that AF system could assist in the detection and diagnosis of retinal blood vessel leakage in retinopathy diabetic without injecting the contrast agent to patients. Moreover, methods as above could give more accurate boundary in leakage area detection and better results in detecting both small and large vessels.

AF system gives a detail and accurate blood vessel detection in pathological retina images. This paper demonstrates the advantages of Gabor 2-D wavelet in detecting the thin blood vessels and capturing the texture information of leakage in images of retina.

Although strong boundary of leakage in macula area is presented, visual observation shows some difficulties of the method that must be solved by future work. Future work aims at analyzing the edema area accurately and classifying the edema from leakage source.

A New Method of Extraction of FECG from Abdominal Signal

D.V. Prasad[1], R. Swarnalatha[2]

[1]Department of Electronics & Instrumentation Engineering, BITS, PILANI, Dubai
[2]Department of Electronics & Instrumentation Engineering, BITS, PILANI, Dubai

Abstract — **This paper presents a method for extracting fetal ECG (FECG) from composite abdominal signal Adaptive filtering techniques along with denoising techniques were used to extract fECG. The results were validated using real signals. The signals are recorded at the thoracic and abdominal areas of the mother. The thoracic signal is purely that of mother (mECG) while the abdominal signal contains both mothers and fetus ECG signals (mECG + fECG). The results clearly show the effectiveness of the method in extracting fECG from very low maternal to fetal signal noise ratio.**

Keywords — **fECG, mECG, TECG**

I. Introduction

The fetal electrocardiogram (FECG) is the electrical activity of the fetal heart. It contains information on the health status of the fetus and therefore, an early diagnosis of any cardiac defects before delivery [1]. Non invasive techniques of fetal monitoring are Doppler ultrasound, fetal electrocardiography and fetal magneto cardiography. Among these methods the most commonly used is Doppler ultrasound because it is simple to use and cheap. However this method produces an averaged heart rate and therefore cannot give beat to beat variability. Fetal electrocardiogram offers the advantage of monitoring beat to beat variability. The disadvantage of fetal electrocardiogram is its reliability [2]. There are many technical problems with non invasive extraction of fECG. The fECG signal is corrupted by different sources of interferences such as maternal EMG, 50 Hz power line interference and base line wander. The low amplitude of the signals, the different types of noise and overlapping frequencies of mother and fetal ECG make the extraction of fECG a difficult task [3].

The fetal heart rate variations during pregnancy and labour have been used as an indirect indicator of fetal distress. Observation over longer periods may yield more information about the status of the fetus. The detection of fetal QRS complex on surface records is very difficult task which is mainly due to overlapping of mothers ECG. The mECG and fECG are partly uncorrelated. Also the mECG signal is very much stronger than the fECG signal embedded in it.

The noise in which fECG is embedded is also stronger depending on the gestation age. In this paper an improved method of extracting the P QRS T waves of the fetal ECG from composite abdominal signal is proposed. The proposed method uses cancellation of mothers ECG and denoising methods to improve the extracted signal quality. Real abdominal signals were used to test the algorithm.

II. Method

The block diagram of the proposed algorithm is shown in Fig 1.

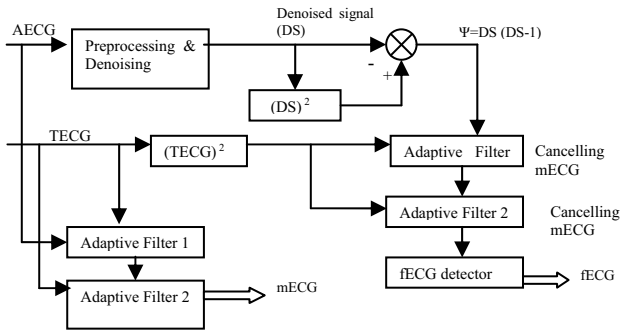

Fig 1 Block Diagram of the proposed algorithm

The proposed method detects fetal QRS wave from the preprocessing of abdominal ECG (AECG) and subsequent cancellation of maternal ECG in the abdominal ECG. The thoracic signal (TECG) which is mECG is used to cancel mECG and the fetal ECG detector extracts the fECG.

Preprocessing

The preprocessing consists of the following steps [4].(a) Read the abdominal ECG (b) Separate the high resolution components and low resolution components (c) Compensate for the phase (d) Derive the noise component (e) Separate the noise from the original signal (f) Reconstruct the signal back (g) Repeat the construction process iteratively.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 98–100, 2009
www.springerlink.com

Fetal QRS Detection

Fetal ECG detection was done by improving SNR of fetal QRS complex to the other components of the signal using a nonlinear operator. This reduces the maternal P and T waves. The operator is defined as follows.

$$\Psi = DS\ (DS\text{-}1)$$

where DS is the preprocessed and denoised signal obtained from the original abdominal ECG. Fig 2 (a) shows the abdominal signal to be analyzed and the maternal ECG recorded from thoracic region is shown in Fig 3(a). Fetal ECG can be extracted by direct application of BSS [5]. However such methods fail to give precise extraction. In order to reduce the mothers ECG effects on extraction, mECG was eliminated by using two stage adaptive filtering. The reference signal taken is shown in Fig 3(b) which is the squared signal of the thoracic signal corresponding to mECG Fig 3(a).The advantage of this method is that the reference signal need not closely mimic the signal to be cancelled. If such a reference signal could be generated, than this method can be applied where only the mothers ECG is available. The adaptive filter adopted behaves as an exponential averager, storing in the coefficients of the filter an averaged alias of the signal [6]. The output of the adaptive filter 1 is again adaptive filtered with $(TECG)^2$ to obtain the signal shown in Fig 3(d). The resultant signal depends on the value for the constant of adaptation. The output 3(d) is applied to fECG detector and extracted fECG and mECG are shown in Fig 4(b) and 4(c).

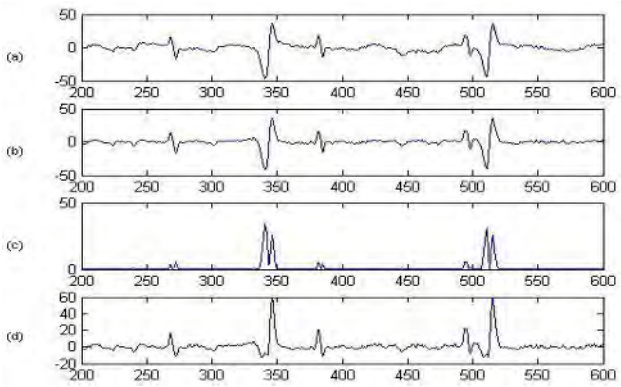

Fig 2. (a)Original abdominal ECG (b) Preprocessed signal (c) Square of preprocessed signal (d) Signal after adding b and c

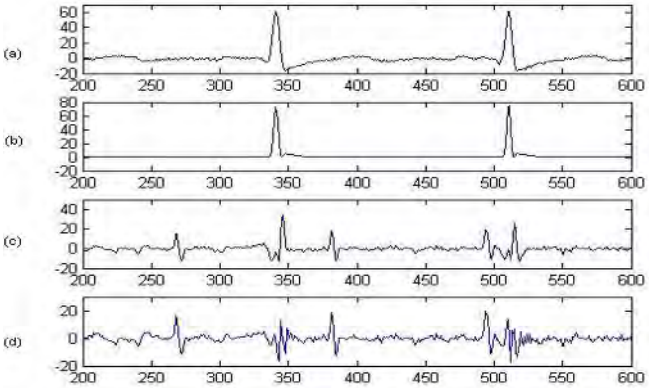

Fig 3. (a) Thoracic ECG (b) square of Thoracic ECG (c) Output of Adaptive filter 1 (d) Output of Adaptive filter 2

III. Results

The proposed algorithm was assessed by using real composite signal comprising of mECG and fECG. The noise is to due to mother's electromyogram activity. The performance of the method is seen from the extracted waveforms centering on R wave peak. The P and T waves can also be seen. Fig 4 gives the extracted fECG and mECG. Fig 5 shows the power spectrum of the original signal and the extracted fECG and mECG. The results show that the P, R and T waves are clearly visible in the extracted signals.

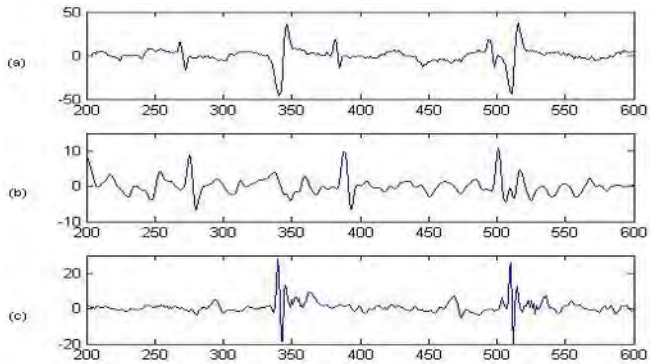

Fig 4. (a) Original abdominal ECG (b) Extracted fECG (c) Extracted mECG

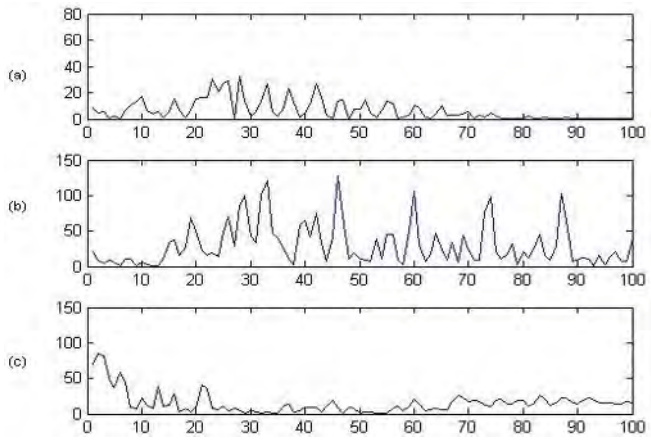

Fig 5. Power spectrum of (a) Original Abdominal ECG
(b) Extracted fECG (c) Extracted mECG

IV. Conclusions

The limitations of conventional methods led to the design of this extraction system which uses conventional system to improve the estimate the fetal ECG and maternal ECG. A two stage adaptive filter system is shown to retrieve fetal ECG from actual patients maternal ECG. It is not easy to see how well the fECG extraction is achieved by looking at a large number of samples. Thus a frame of 400 samples is taken to illustrate the effectiveness of the algorithm. In this frame there are both overlapping and non overlapping between maternal and the fetal components in the abdominal signal. This is a significant challenge to the extraction algorithm. The results show that the algorithm was able to successfully extract the fECG signal. It can be noted the visual quality of the extracted fECG is comparable to other methods. The advantage of this method is that the reference signal need not closely mimic the signal to be cancelled.

Analysis of EGG Signals for Digestive System Disorders Using Neural Networks

G. Gopu[1], Dr. R. Neelaveni[2] and Dr. K. Porkumaran[3]

[1] Research Scholar, Dept. of EEE. PSG College of Technology, Coimbatore- 04, India
[2] Assistant Professor, Dept. of EEE. PSG College of Technology, Coimbatore- 04, India
[3] Professor & Head, Dept. of BME, Sri Ramakrishna Engineering College, Coimbatore-22,India

Abstract — **A novel approach is proposed to analyze the digestive system disorders using the developed Electrogastrogram [EGG] setup. Current days the role of Endoscopy is more for the investigation of digestive system disorders, which is very tedious, expensive and invasive. EGG is a non-invasive, cheap and painless study. EGG is considered as a preliminary investigation before the Endoscopy procedure. Based on the finding from the EGG, if it is uncomplicated Gastric diseases, Benign (non cancer) we can start the treatment solely on EGG report alone. Only in case of suspected Malignancy (cancer) and complicated benign disorders we can go for Endoscopy procedure. The biosignal are recorded from the patients and normal individual cutaneously from the stomach includes the various stages such as amplification, filtering, pulse width modulation and demodulation. The EGG data are acquired using DSO or Data scope software and the same is analyzed using Matlab's neural network toolbox. The Adaptive Resonance Theory (ART1) and Learning vector Quantization (LVQ) networks are used as a Neural Network classifiers to classify the digestive system disorders. The proposed method is used to investigate the digestive system disorders such us ulcer, dyspepsia, etc.The investigation is carried out with 180 human being includes inpatient, outpatient of gastroenterology department and normal individual and normal individual. As a result of this investigation the EGG values for ulcer patient is between 4-4.5 cpm (cycle per minute), dyspepsia patient is between 1-2.5 cpm and for normal individual is between 3-3.5 cpm.The proposed new method results in greater accuracy comparable with other conventional methods to provide fair amount of accuracy.**

Keywords — **Electrogastrogram, Adaptive Resonance Theory, Learning vector Quantization, ulcer, dyspepsia.**

I. Introduction

A non-invasive, painless study is used to measure the gastric electrical activity of a stomach [1, 2] cutaneously is called Electrogastrogram [EGG]. EGG includes two components such as spikes and slow waves in the gastric myoelectrical activity of the stomach. The contraction of a stomach muscle produces a spike, where as slow wave activity controls the propagation and maximum frequency of the gastric electrical activity. In human 3 cycles per minute (cpm) is a normal frequency of the gastric slow wave.

The abnormality in the gastric slow wave frequency is known as gastric dysrhythmia which includes bradygastria (the frequency of the slow wave less than 2 cpm), tachygastria (the frequency of the slow wave greater than 4 cpm) and arrhythmia (no specific cyclic rhythm). Gastric dysrhythmia observed with the patients having gastric motility disorders and gastrointestinal symptoms namely nausea, dyspepsia, vomiting, abdominal pain, stomach ulcer, etc,[9].

EGG recorded in the patient with two conditions namely preprandial conditions (before food) and postprandial condition (after food) [13, 14]. The abnormality is found from the no raise in power and change in the frequency of the EGG signal obtained from the postprandial condition.

This paper deals with the classification of the EGG signals of the patients with the normal individual using the neural approach with a ART1 and LVQ networks. The EGG can be considered as an experimental procedure since its exact role in the diagnosis of digestive disorders of the stomach has not been defined yet.

II. Electrogastrogram

An EGG is similar to an electrocardiogram of the heart. It is a recording of the electrical signals that travel through the muscles of the stomach and control the muscle's contraction. EGG used when there is a suspicion that the muscles of the stomach or the nerves controlling the muscles are not working normally.

EGG done by placing the electrode cutaneously over the stomach and the electrical signals coming from the stomach's muscles are sensed by the electrode and recorded on a computer for analysis by lying patient quietly.

In normal individuals the EGG is a regular electrical rhythm generated by the muscles of the stomach and the power (voltage) of the electrical current increases after the meal. In patients with abnormalities of the muscles or nerves of the stomach, the rhythm often is irregular or there is no post-meal increase in electric power. EGG will not have any side effects and it is painless study.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 101–104, 2009
www.springerlink.com

III. EGG RECORDING SETUP

The Ag/Agcl electrodes are used as a sensor for recording EGG [4, 3, 5]. The electrodes are used to tap the electrical signals directly surface of the stomach. The electrical signals generated are usually of very low amplitude ranging from 0.01 to 0.5 mV.This is given as an input to an instrumentation amplifier which has a variable gain of 1000 to 10,000. The amplified signals under goes filtering section which includes high pass filter, low pass filter and notch filter to obtain the frequency response from 0.015 Hz to 0.5 Hz for Lower Cutoff frequency and 0.1 Hz to 2 Hz for upper cutoff frequency. The Mode Switch is used for selecting a calibration Mode and EGG measuring Mode. If the calibration mode is selected the clock pulse generated from square wave oscillator is obtained to confirm that the setup is in good condition for recording EGG. Now EGG Mode is selected for recording with in the frequency response range from 0.5 Hz to 0.1 Hz. The required amplified EGG signal is viewed via Digital Storage Oscilloscope or data scope for analysis purposes as shown in Figure 1 below.

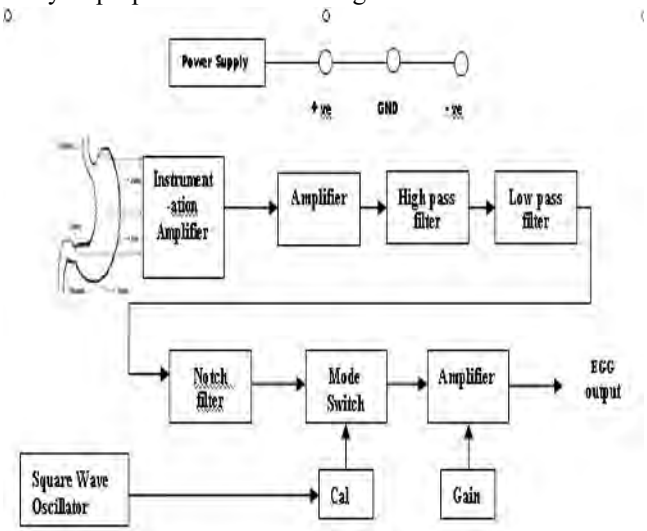

Fig. 1 General block diagram for recording EGG

IV. EGG ELECTRODES POSITIONING

The electrical signals are generally produced in the mid-corpus of the stomach where the electrical activity takes place. The positioning of the Ag/ Agcl electrodes for tapping of these signals is as shown Figure 2. Two electrodes A and B are placed in the fundus and the mid corpus of the stomach. The third electrode C is placed as ground at the end of the stomach region for patient safety [4].

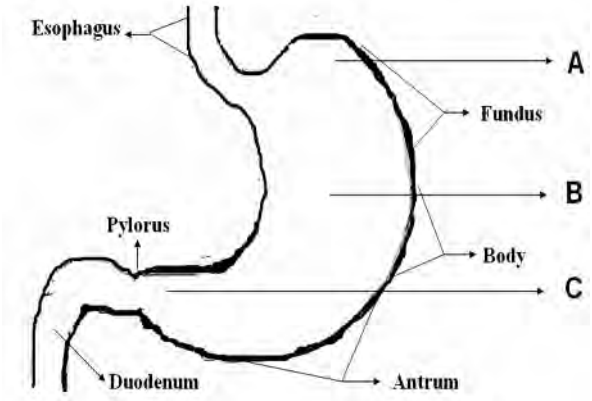

Fig. 2 Electrode Positioning for Recording EGG

V. MATERIALS AND METHODS

The patients who are consecutively attending a hospital outpatient's gastroenterology clinic for digestive system disorder were studied. The patients included 80 with Dyspepsia, 45 with Nausea, and 55 with Stomach ulcer. A gastrointestinal symptom profile was recorded on all patients immediately before the EGG [10, 12]. This profile detailed the presence or absence of the following dyspeptic symptoms in their previous history: Dyspepsia, Stomach ulcer, Nausea, vomiting and abdominal pain. The EGG was performed on the patient both preprandial condition and postprandial condition. All medication with the potential affect to gastric function was discontinued for more than 48 hours before the recording. Patients were studied in a semi recline position and requested to avoid any major movements. The skin was lightly abraded with gauze before placement of adhesive gel EGG electrodes. Two bipolar skin electrodes were placed on the abdomen, one on the fundus and the other on the mid-corpus. A reference electrode was placed on the right side of the abdomen. Visual inspection of the waveform detected any obvious major movement artifacts. These were defined as abnormally large positive or negative peaks in the tracing and were detected from the analysis. The EGG data was observed by the DSO or the Data Scope set up running on a personal computer. The EGG frequency, amplitude are recorded and its respective values are stored for further analysis of the same to investigate the digestive system disorders as shown in Figure 3

The EGG analysis is based on the frequency and amplitude of the signals. For the periods before and after the test meal, the frequency and amplitude values are observed. Normal electrical activity was defined as a frequency between 2-4 cycles per minute [6, 7]. Activity of 0-2 cycles per minute was termed bradygastria, and 4-9 cycles per minute as tachygastria. The percentage of normal electrical

activity, bradygastria, and tachygastria were calculated both before and after the test meal. The amplitude of the dominant frequency was measured both before and after the test meal. The electrical frequency is stable and does not change significantly after a standard test meal.

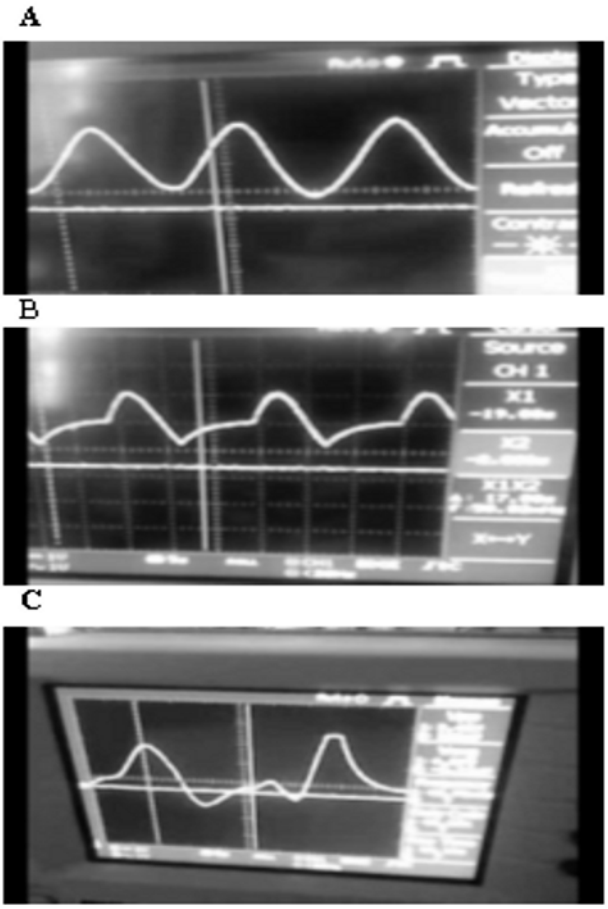

Fig. 3 EGG Signals recorded with DSO: A- for Normal Individuals, B-for Dyspepsia Patient and C- for Ulcer patient

VI. Algorithm

1. Lightly abrade the skin with abrasive pads, and put a spot of gel on the electrode contact area.
2. Two electrodes are placed on the Fundus and the mid-corpus and a reference electrode is placed on the right side of the abdomen.
3. The output of the electrodes is given to the Instrumentation amplifier.
4. The amplified output signal is filtered using high pass filter, low pass filter and notch filter.
5. The setup is calibrated with a clock pulse from square wave generator then it is changed to EGG measuring mode.
6. The EGG signal is obtained for a minute from DSO and its corresponding data are stored for analysis by neural network tool.
7. This data is displayed on the DSO or PC using data scope software and the data's are recorded for preprandial and postprandial conditions.
8. The recorded data are classified with two types Neural Network classifiers namely ART1 and LVQ Neural Network Classifiers.
9. As a result of classification the LVQ Classification rate is more than the ART1
10. The threshold for Classification of various disorders was fixed based on the observations and in consultation with the physician and the same was trained with Neural Networks tools.

VII. Neural networks classifier

The recognizer recognizes only whether the signal is known or unknown i.e., whether it is already in database or not. The purpose of using classifiers [11] is to find the actual identity of the digestive system disorders such us dyspepsia and ulcer. In this paper, Adaptive Resonance Theory (ART1) Network and Learning Vector Quantization (LVQ) Network are used as classifiers.

ART1 is designed for clustering binary vectors using unsupervised learning. This network is designed to control the degree of similarity of patterns placed on the same cluster. The network produces the clusters by itself if such clusters are identified in the input data, and stores the clustering information about patterns or features without prior information about the possible number and type of clusters.

LVQ is defined for adaptive pattern classification. The class information is used to fine-tune the code vector so as to improve the quality of the classifier decision regions. It is assumed that a set of training pattern with known classifications is provided along with an initial distribution of reference vectors. Learning vector Quantization (LVQ) [8] is a method for training competitive layers in a supervised manner. A competitive layer automatically learns to classify input vectors. If two input vectors are very similar, the competitive layer probably will put them in the same class. There is no mechanism in a strictly competitive layer design to say whether or not any two input vectors are in the same class or different classes.

VIII. Results and discussion

The effectiveness of the proposed methodology is illustrated in the Table. 1. From the table the classification rate of digestive system disorders with LVQ Neural Network classifier is more precise than ART1 Neural Networks Classifier. This result is obtained with 180 human beings data.

Digestive System Disorder's EGG with its frequency	Neural Network Classifier				Classification Rate in %	
	ART1(Adaptive Resonance Theory)		LVQ (Learning Vector Quantization)		ART1	LVQ
	Total Samples	Correctly Classified	Total Samples	Correctly Classified		
Normal Individual (3-3.5) cpm	30	25	30	29	83.33	96.66
Dyspepsia (1-2.5) cpm	70	60	70	69	85.71	98.57
Ulcer (4-4.5) cpm	80	67	80	78	83.75	97.50

Table 1 Comparison of LVQ and ART1 Classification

IX. Conclusions

In this paper a simplified novel approach is proposed for the recording of gastro electrical activity of the stomach. The EGG setup is used to record the activity of patients suffering from digestive disorders like Dyspepsia, Stomach ulcer , Nausea and Cyclic vomiting syndrome. About more than 180 patients were tested using this setup and the results are classified with Neural Network classifier namely ART1 and LVQ. The classification rate is found to be high in LVQ when compare to ART1 for the disorders Dyspepsia and ulcer. In future, the data can be analyzed with wavelet tool to perform further analysis which may improve the accuracy of diagnosis and also increase the scope.

Abstract — **There are several assessments used to measure pulse wave velocity. We have ever designed an instrument to measure brachial-femoral pulse wave velocity by photoplethysmograpy with infrared sensors. This method is reliable and correlate with another instrument recorded with tonometry. Our method demonstrates the difference of velocity between brachial and femoral arteries. On some occasions, the measurement gets a false-negative result when the examinee has similar atherosclerotic changes of both brachial and femoral arteries. Therefore, we design a measurement to assess pulse wave velocities by the time difference between R wave of ECG and initiation point of the pulse wave. The infra-red sensors can be placed on the eardrops, fingertips or toes then measure pulse wave velocities in different arterial systems including carotid artery, brachial artery and femoral artery directly. These measurements also reflect atherosclerotic changes of aortic arch and descending aorta respectively. Although atherosclerosis is a systemic disorder, patients sometimes get various involvements in different regions of the arterial tree. In this study, 33 healthy adults (25 males and 8 females) are enrolled. They received measurement of pulse wave velocity by our new method and brachial-femoral pulse wave velocity. There is the statistically significant correlation between this new method and brachial-femoral pulse wave velocity ($r=0.453$, $p<0.01$). In the mean time, the new assessment shows the pulse wave velocities are different in carotid, brachial and femoral arterial system. The ratio of the speeds is 1:2:3, which relates to diameters of these vessels inversely. This finding is fit the continuity equation, Q=AV, in hydraulics.**

Herein, we demonstrate a new method, which can be used to measure pulse wave velocity in different arterial systems. This method is reliable and reproducible. In addition to be applied in assessment of aortic stiffness, it can also be used to evaluate atherosclerosis of different arterial systems.

Keywords — **PWV, ECG, cardiovascular diseases**

I. Introduction

Myocardial infarction, stroke, hypertension, etc. are common modern diseases that are related to arterial stiffness, and there is no apparent symptom in the early stage of formation of arterial stiffness. Therefore, to develop a proper and validate method for assessing the stiffness of arteries can reduce prevent further damage to personal heath or eventually lead to cardiovascular diseases [1].

There are two categories for assessing arterial stiffness: invasive [2] and non-invasive [1][3]. Invasive method has the advantage of directly observe or contact with the blood vessels which brings high accuracy of evaluating the health of arteries, but this is also its weakness since it needs to inject medicine into the blood vessels or even operation needed, which may cause unknown risks to the testing subjects, and these inconveniences make invasive technique not suitable for daily homecare environment. Hospitals are now leant toward non-invasive method of arterial stiffness assessment, and one of most commonly used instrument is Pulse Wave Velocity by Applanation Tonometry (PWV-AT) [1]. PWV-AT utilizes pressure sensor to extract the pulse waveforms from carotid and femoral arteries, it combines electrocardiogram (ECG) for reference point, the time difference among the reference point, femoral and carotid arteries is used for calculating pulse wave velocity (PWV) [4]-[6]. PWV is considered to be the golden standard for evaluating the stiffness of arteries, but using PWV-AT is very time consuming (more than 1 hrs) and specially trained operators are needed for the assessment.

To make non-invasive arterial stiffness assessment more suitable and convenience for homecare, a hand-foot PWV instrument (PWV-DVP) [3]was introduced in previous study, and its correlation with traditional PWV-AT is high ($r=0.678$) [3]. However, in hand-foot PWV system testing subject still needs to be in supine position and take off his or her shoes off, we had modified out instrument further to bring greater ease for user, the hand-ear PWV instrument (PWV-DVPE) [7] was developed, it gathers pulse waveforms from hand and ear in sitting position and it is accurate as former systems ($r=0.702$) [7].

Although both PWV-DVP and PWV-DVPE were proven to have the capability to assess the stiffness of arteries, as PWV-AT, both utilize two pulse waveforms from two different sites of body for PWV calculation, this may cause difficulty to differentiate which site is stiff, and some stud-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 105–108, 2009
www.springerlink.com

ies [8] had indicated that if both sites are affected by arterial stiffness then the PWV value measured would be close to healthy blood vessel's PWV value. This study proposes a new method which utilizes ECG combined with hand, foot and ear pulse waveforms (ECG_H-PWV, ECG_F-PWV and ECG_E-PWV). Again, to be more suitable for homecare, we use Lead-II ECG to make it more convenient for users, make them easier to monitor their personal health. 33 health subjects were tested in this study, they had received tests of 3 different pulse waveforms combined with ECG and were able to show statistical significance and responded well to risk factor- age.

II. PWV-DVP & PWV-DVPE

Previously, PWV-DVP [3] places the sensor on the subject's finger and toe for measuring, therefore the subject needs to take off the socks and rests in supine position; PWV-DVPE [7] showed that it can improve the disadvantage of PWV-DVP which requires taking off socks and resting in supine position by measuring subject's pulse waveforms of ear and finger with sitting position. Before measuring with PWV-DVP and PWV-DVPE, measuring tape is used to measure the subject's length, which are the distance from the sternal notch to the left index finger (l_1), the distance from the sternal notch to the left second toe (l_2) and the distance from the sternal notch to the left ear lobe (l_3) (Fig. 1), then calculate $\Delta l_1=l_2-l_1$, $\Delta l_2=l_1-l_3$ and use following PWV formula:

$$PWV = \Delta l_i / \Delta t_i \ , i = 1,2 \qquad (1)$$

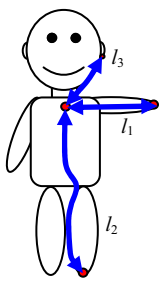

Fig. 1 Measured Distance

In PWV-DVP and PWV-DVPE calculation, the Δl_i is the difference of the distance among the measuring places, it may cause a problem where the error of the measurement occurs. For example, PWV-DVP requires to measure difference of the distance of the sternal notch to the finger and the toe before measuring hand-foot PWV. If both subject's vessel of the hand and foot become stiff, then difference of the transmitting time of the two pulse waves is Δt, and PWV-DVP=$\Delta l_1/\Delta t$. If only subject's vessel of the hand had become stiff, then the pulse wave velocity of the finger become fast, but if the vessel of the foot didn't become stiff, then the pulse wave velocity of the toe would not be fast, so it makes the difference of the transmitting time of two pulse wave (Δt') becomes bigger, shown in the Fig. 2. Because Δt' >Δt, PWV-DVP' is smaller than PWV-DVP, this would lead the subject to misunderstand this PWV value is an indication of healthy arteries. In similar, if the subject's vessels of the hand and foot both become stiff, then the pulse waves of the finger and toe become fast, and the difference of the transmitting time of two pulse waves does not become smaller, it may also cause the PWV-DVP value to be normal and the subject dose not assess the level of arterial stiffness accurately.

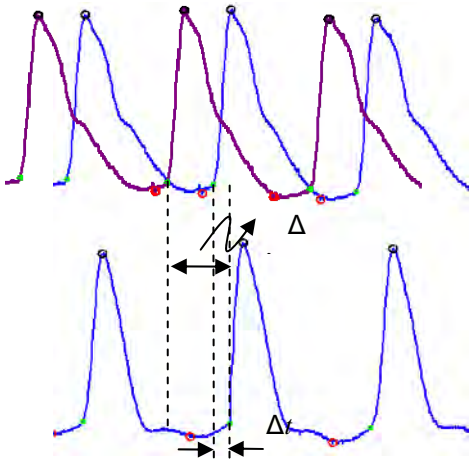

Fig. 2 The part vessel of the hand become stiffness, the difference of the transmitting time increase result from the pulse wave of inside vessel become fast (Δt'>Δt)

III. METHOD

In this experiment, we did not eliminate any subject. The study group comprised 33 healthy subjects (25 male/ 8 female), the mean age of these subjects was 25 (aged 19 to 47), none of the subjects had any cardiovascular diseases history. Table 1 described the characteristics of the study population.

Blood pressure was measured with the subjects in sitting position after 5 minutes, in a quiet, temperature-controlled environment set at 24°C. Then we measure subject's distance from the sternal notch to the left index finger (l_1), left second toe (l_2), and left ear lobe (l_3); moreover, we placed the ECG (Lead-II) sensors on the subject's right wrist (negative), left ankle (positive), and right ankle (ground). Before

Table 1 The characteristics of the study population

	Male (n=25)	Female (n=8)
Age, yr	26.2±5.8	22.1±2.2
Body Height, cm	171.8±4.6	158.1±6
Body Weight, kg	68.16±10.8	52±10.8
Body Mass Index (BMI), kg/m^2	23.1±3.5	20.7±3.5
Heart Rate, bpm	79.4±11.7	92.2±12.3
Systolic Blood Pressure (SBP), mmHg	115±11	115.9±15.5
Diastolic Blood Pressure (DBP), mmHg	69.9±7.9	72.9±9

measuring PWV, let the subject rest in the supine position (4 min), then obtained and stored the ECG-Finger pulse wave, ECG-Toe pulse wave, and ECG-Ear pulse wave at the same time. Afterward system could automatically calculate ECG_H-PWV, ECG_F-PWV, and ECG_E-PWV. Overall we recorded 20 times data and average as one time result. The ECG_H-PWV, ECG_F-PWV, and ECG_E-PWV formulas are as following:

$$ECG_H-PWV = l_1 / \Delta t_3 \quad (2)$$

$$ECG_F-PWV = l_2 / \Delta t_4 \quad (3)$$

$$ECG_E-PWV = l_3 / \Delta t_5 \quad (4)$$

In the formulas, Δt_3, Δt_4, and Δt_5 are the R wave of ECG to pacemaker of the finger, the toe, and the ear pulse wave, respectively. Fig. 3 shown the difference time of the R wave of ECG to the finger's pacemaker, Δt_4 and Δt_5 are similar.

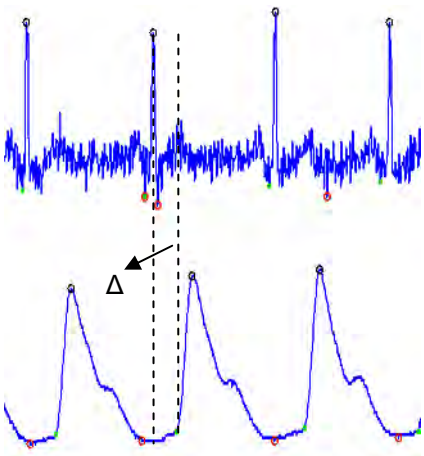

Fig. 3 The difference time of ECG R wave to finger's pacemaker

IV. Results

As Table 2 shown, this study measured five types of PWV for 33 healthy subjects, and ECG matched the value which the finger, the toe and the ear pulse wave could observe the minimum value that happened to ECG_E-PWV and could not over 2 m/s, and the maximum value was ECG_F-PWV. As Table 3 shown, these three methods were relative to each other in statistical significance. As Fig. 4 shown, ECG_F-PWV and PWV-DVP had statistical significance, but PWV-DVP and PWV-DVPE did not (r=-0.41, p=0.819)

Table 2 The characteristics of the study population

	Male	Female	All Subjects
ECG_H-PWV, m/s	4.6±0.5	4.3±0.4	4.5±0.5
ECG_F-PWV, m/s	6.1±0.5	5.5±0.6	6±0.6
ECG_E-PWV, m/s	1.4±0.1	1.3±0.1	1.4±0.1

ECG_E-PWV	r=0.470, p<0.01	r=0.443, p<0.01	

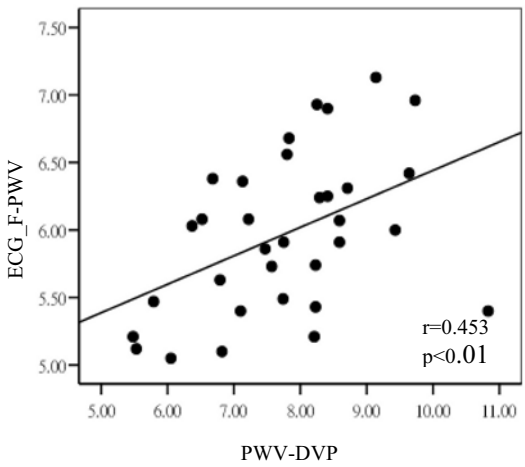

Fig. 4 The linear regression analysis of ECG_F-PWV and PWV-DVP

As Table 4 shown, age was risk factor of cardiovascular diseases for ECG_H-PWV, ECG_F-PWV and ECG_E-PWV(r=0.386, p<0.05, r=0.362, p<0.05 and r=0.457, p<0.01), and SBP only had statistical significance with

ECG_E-PWV(r=0.467, p<0.01), but height and weight had statistical significance with ECG_F-PWV(r=0.491, p<0.01, r=0.429, p<0.05).

Table 4 Relations of ECG_H-PWV, ECG_F-PWV and ECG_E-PWV with risk factor

	ECG_H-PWV	ECG_F-PWV	ECG_E-PWV
Age	r=0.386(p<0.05)	r=0.362(p<0.05)	r=0.457(p<0.01)
Height	r=0.217(p=0.225)	r=0.491(p<0.01)	r=0.307(p=0.083)
Weight	r=0.118(p=0.514)	r=0.429(p<0.05)	r=0.290(p=0.102)
SBP	r=0.236(p=0.186)	r=0.305(p=0.084)	r=0.467(p<0.01)

V. Discussion

This study mainly goal is to measure PWV by Lead-II ECG to collocate each part pulse wave, to decrease the error caused by difference of the distance of varied sites in previously measured PWV-DVP and PWV-DVPE. The proposed system can assess the level of the arterial stiffness accurately.

In this experiment, 33 subjects are measured ECG_ H-PWV, ECG_F-PWV, and ECG_E-PWV, all the ECG_F-PWV value have the highest PWV and the ECG_E-PWV value are the lowest. Because the blood circulation system is a closed system, the blood flow volume in each minute is constant; therefore, the blood flow velocity is related to vessel cross-sectional area. The blood flow velocity is inversely proportional with vessel cross-sectional area. Therefore if the blood vessel cross-sectional area is smaller, the blood flow velocity becomes faster. Because the aorta cross-sectional area is bigger than arteriole, and the ECG_F-PWV value is the highest and the ECG_E-PWV value is the lower. Therefore the experimental result conforms to the blood hydromechanics principle.

The measurement of pulse wave velocity has been proven to be a reliable and noninvasive method to evaluate the progression of atherosclerosis. We design a novel multichannel instrument to measure pulse wave velocities in different arterial systems. The method can measure pulse wave velocity directly by using time difference between R wave of ECG and initiation point of pulse wave recorded in eardrops, fingertips and toes. The first one assesses atherosclerotic changes in ascending aorta, common carotid and external carotid artery. The second one evaluates stiffness in the aortic arch and brachial artery. The last one represents atherosclerotic changes in the aortic arch, descending aorta, femoral and tibial arteries. The instrument with easy performance can be applied in patients with atherosclerosis involving different arterial systems.

An Automated Segmentation Algorithm for Medical Images

C.S. Leo[1], C.C. Tchoyoson Lim[2], V. Suneetha[1]

[1] School of Engineering, Nanyang Polytechnic, Singapore
[2] Department of Neuro-radiology, National Neuroscience Institute, Singapore

Abstract — **The goal of image segmentation is to identify and differentiate one object or region from another. The problems associated with image segmentation or groupings have always been a challenge to the image processing community especially in the case of medical imaging where segmentation can play a key role to 3D model re-construction for medical diagnosis and planning. Though it can be said that there is no 'one-size-fits-all' algorithm available and that manual segmentation remains the best available technique, current on-going works have focused on hastening the computational intensive process and to achieve a high level of accuracy with as little human intervention as possible. This is especially true when fast segmentation is required for tomography images such as MRI or CT images.**

In this paper, we present an automated segmentation algorithm that utilizes an integrated hybrid method based on intensity, region growing and edge related techniques. The algorithm checks for connectivity and continuity to ensure that the segmented region is of one enclosed entity. Results have shown the algorithm to be fairly accurate and it is able to detect irregular shapes. The algorithm is also implementable on a Single Instruction Multiple Data (SIMD) or on multiple SIMD cards. The automated hybrid segmentation method can be robust, fairly accurate and simple to implement.

Keywords — **Segmentation, Intensity, Pixels, Image-Processing, MRI**

I. Introduction

Segmentation has always remained as an important and challenging part of image processing as wide-ranging practical medical applications can often be derived from it. Some of these applications can range from simple analysis as in the case of anatomical structure, size measurement to a more sophisticated task such as Computer-aided surgery and tissue engineering applications. In many of these cases, accuracy and speed is of paramount importance. It is therefore not surprising that many researchers have attempted to research and develop new and creative methods to segment regions [1]; the most difficult task being the segmenting of soft tissue as in the case of brain tumor or liver tissues. In MRI, bone structures are always easy to detect as they appear as the brightest region in an image. However, this is not necessary so for soft tissues.

In this paper, we will present an automated segmentation algorithm that utilizes an integrated hybrid of techniques that is based on intensity, region growing and edge-based. The algorithm checks for connectivity and continuity to ensure that the segmented region is of one enclosed entity.

II. Current segmentation methods

Many current segmentation techniques use the gray scale histogram such as thresh-holding; spatial and intensity technique (e.g. Region Growing) or others using fuzzy set theoretic approaches. Active contours or 'snakes'' can be used to segment objects automatically. In this method, the basic idea is to shape and reshape a curve, or curves subject given the constraints from the input data. The curve would eventually evolve until its boundary segments the object of interest. This framework has been used successfully by Kass et al. [2] to extract boundaries and edges. However, one problem with this approach is that the topology of the region to be segmented must be known in advance. During evolution, curves may change connectivity and split.

Noise has also been a source of concern in segmentation. As some techniques may not be very effective for noisy images, works have been done using the Markov Random Field model [3] which is robust to noise, but is computationally intensive. To speed-up in the computational performance, parallelizing the processes were used. Neural network architectures can help to get the output in real time because of their parallel processing ability, have also been used for segmentation [4] and they work fine even when the noise level is very high.

III. Integrated hybrid method

Our integrated hybrid method is a series of 3-stage processing integrated together to achieve the goal of segmentation. The 3 stages include Region-Growing, Flood-and-Fill followed by Edge Detection algorithm in that order.

As in the case of traditional region growing algorithm, the process begins with the selection of a seed pixel. The pixel selected must be a point within the region to be

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 109–111, 2009
www.springerlink.com

segmented as its position shall be used as the starting point; and its intensity as the initial input for computing the reference value, μ. The computation of the reference value is the mean of the surrounding 3x3 pixels intensity values. Convoluting in a clockwise manner, the algorithm proceeds to check adjacent pixels surrounding the starting point. A pixel is considered accepted as part of the region only if it is within the threshold limit, β, from the reference value. (A good estimate of the threshold limit is about 15 percent of the reference value). Also, at least one of the adjacent pixels must have been identified as part of the region. The adjacent pixels can be the pixel beneath or the left adjacent pixel. The purpose of checking adjoining pixels is to ensure that there is continuity. In this way, there will not be any stand-alone pixels present.

$$|f(x_n,y_n) - \mu| \leq \beta \qquad (1)$$

where: β : Threshold value.

For each new layer, a new reference value has to be computed. This subsequent reference value will be the average of all the accepted pixel intensities of the previous layer. The process repeats layer after layer until it encompasses the whole region. For each pixel that has its intensity falls within the selected range, a flag or marker is used to keep track. This marker acts as an indicator to highlight that it is part of the accepted region and will be used in the next stage of the algorithm.

In image processing, noise has always been a source of concern as it can increase complexity and affects the segmentation computation. After the first stage (region growing) where noise can be an issue, the subsequent 2 stages computation is independent of any noise. Using an outer boundary that enclosed the region entirely, we work towards the previously segmented region by using the 'flood and fill' concept The idea is to draw a boundary stretching beyond the intended region and then 'flood and fill' the region outside. It is done by using each pixel along the boundary to check for pixels in respective north, south, east and west directions until it touches the first marked pixel along the row or column (See Figure 1).

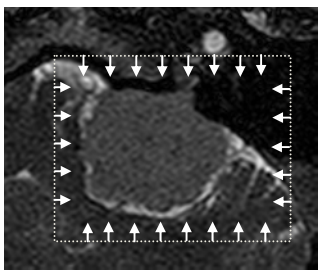

Fig 1: Filling of region starting from boundary

As the 'flood and fill' computation does not require any pixel intensity comparison, any noise within the region does not complicate the processing. The task is to create a mask (i.e. another set of array) of the entire region by setting it to either 255 (white) or 0 (black). The default is white unless the filling process overrides it to black (See Figure 2).

0	0	255	0	0
0	0	255	0	0
0	255	255	255	255
0	255	255	255	255
255	255	255	0	0
0	255	255	255	0
0	0	255	255	0
0	255	255	255	0

Fig 2: Filling of mask with zeros

In the final step of the method, edge detection is used to obtain the outline of the bounded region. With the mask obtained previously, image gradient can then be easily computed. The computation of the image gradient computation, G(x,y), is as follows:

$$G(x,y) = \sqrt{\left(\frac{\partial(f(x,y))}{\partial x}\right)^2 + \left(\frac{\partial(f(x,y))}{\partial y}\right)^2} \qquad (2)$$

Effectively what this mean is that for every pixel in the mask, subtract the right adjacent pixel value with the left adjacent pixel and squared it. This computation is repeated vertically with pixels above and beneath it. Gradient is obtained by taking only the positive root of the square root of the sum of these two values. The result will be an outline surrounding the segmented region.

IV. Results

The result has so far been encouraging and the algorithm has been tested extensively and found to be feasible. The advantage of this algorithm is that in all cases, a continuous outline of the segmented region with no broken lines is always obtained (See Figure 3a and 3b). This is because, the outline is computed using gradient of only a black and white mask. Noise within the segment region is eliminated as the 'flood and fill' stage fills the region from an enclosed boundary outside the segmented region towards the

segmented region and hence noise within the region does not constitute a hindrance to the computation. The result of the segmentation shows that it is able to enclose very irregular shapes as the topology of the region is not an important factor. Also, throughout the process, the algorithm works mainly on pixel intensity, hence coding can be simple and does not require sophisticated formulas. It is also foreseeable that parallel processing especially using the Single Instruction Multiple Data (SIMD) or Hybrid System [5] is also possible in this case.

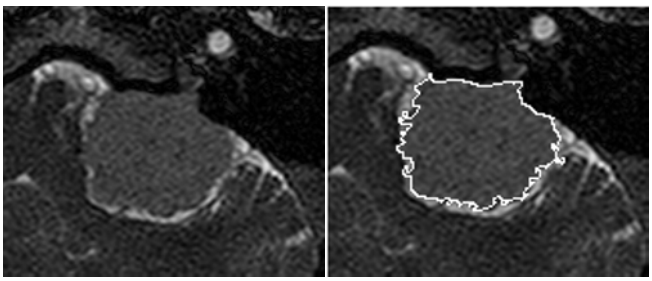

Fig 3a: Original MRI image showing the tumor

Fig 3b: Segmented tumor region

V. Conclusion

In this paper, we have presented an automated segmentation algorithm that utilizes an integrated hybrid method. It is a series of 3-stage processing combined together to achieve the goal of segmentation.. The algorithm checks for connectivity and continuity to ensure that the segmented region is of one enclosed entity. Results have shown the algorithm to be fairly accurate and it is able to detect irregular shapes**.** The method can be robust, simple to implement and also possible to be implemented using parallel processing.

Quantitative Assessment of Movement Disorders in Clinical Practice

Á. Jobbágy[1], I. Valálik[2]

[1] Budapest University of Technology and Economics/Dept. Measurement and Information Systems, Budapest, Hungary
[2] St. John's Hospital/Dept. Neurosurgery, Budapest, Hungary

Abstract — **Assessment of tremor and dystonia is crucial to characterize their patients' clinical state. Three different devices have been used: (1) PAM, a passive marker based motion analyzer, (2) a digitizing tablet with spiral drawing test, and (3) a 3D accelerometer. PAM fits excellently to testing different kinds of human movements by detecting the displacement. Even the involuntary movements of different regions on the face can be quantitatively assessed. Seventeen disk shaped adhesive markers were attached to the face of two patients with Meige syndrome, presenting blepharospasm and oromandibular dystonia. 20-s recordings were taken with PAM, an inexpensive and clinically easily applicable motion analyzer. The evaluation of the recordings before, and after surgery showed significant reduction of the intensity and rate of uncontrolled movements while the difference between the movement of the left and right cheeks diminished substantially. The paper gives the marker pattern used as well as the evaluation method. Tracking a spiral with a pen on a digitizing tablet is challenging for patients with movement disorders affecting their upper limbs. 68 patients with neural diseases were tested, altogether 544 recordings were made and evaluated. Typical trajectories are shown together with the evaluation. Tremor is present even in healthy subjects. A 3D accelerometer based, clinically applicable tool has been developed. 60-s recordings were taken from ten healthy subjects. Persons held the device in their hand while their wrist was supported. The time-frequency diagrams of the recordings show patient specific characteristics. Based on recordings taken at rest the actual stress level can be estimated. Though not measured generally, this is an important parameter during many clinical tests, especially during blood pressure measurement.**

Keywords — **movement disorders, quantitative assessment, tremor, dystonia.**

I. Introduction

There are a lot of difficulties in quantifying human movement disorders like tremor and dystonia. We have been searching for simple, clinically applicable and highly informative methods for assessment. Three devices have been used. PAM, a passive marker based motion analyzer [1], a digitizing tablet and a 3D accelerometer.

There are no widely used standard tests with a big enough measurement data set. The tests we suggest need to be completed by a great number of patients as well as age-matched control subjects. The measured data are expected to provide the necessary feedback to specify a clinically applicable test procedure.

II. Passive marker based motion analyzer

Passive marker based motion analysis fits well to testing human movements. The markers are lightweight, and they can easily be attached to any anatomical landmark point of the body surface.

General purpose motion analyzers [2] are not optimal for routine clinical assessment of movement disorders. These devices are expensive and require technically skilled operators. If the distance between the marker trajectories and the camera lens is fixed, a two dimensional view is enough to assess the movement. Such an analyzer has been developed at Budapest University of Technology and Economics. The analyzer, PAM (see Figure 1.), is inexpensive, its operator interface is simple. PAM is especially suitable for testing the finger-tapping movement [3].

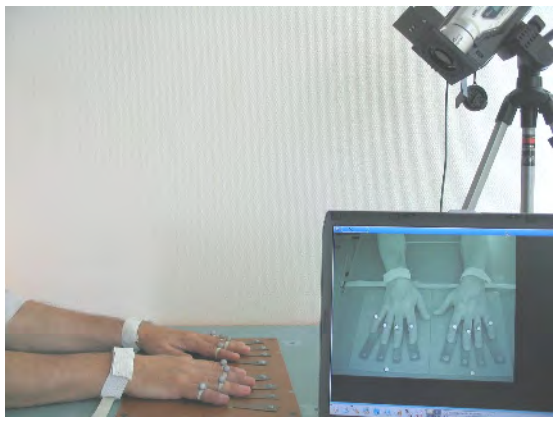

Fig. 1. PAM used for testing the finger-tapping movement.

A challenging task is to measure the actual state of patients with the Meige syndrome [4]. It is difficult to quantify the muscle contractions on the face where the application of electromyography (EMG) is not well tolerated by patients and the number of electrodes is limited. During PAM recording of blepharospasm and oromandibular dystonia seventeen 5-mm diameter markers were attached to the face of

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 112–115, 2009
www.springerlink.com

the patients, see Figure 2. The subjects were asked to sit still for 20 s. Based on the trajectories, the total displacement was determined for each anatomical landmark point where markers were attached to.

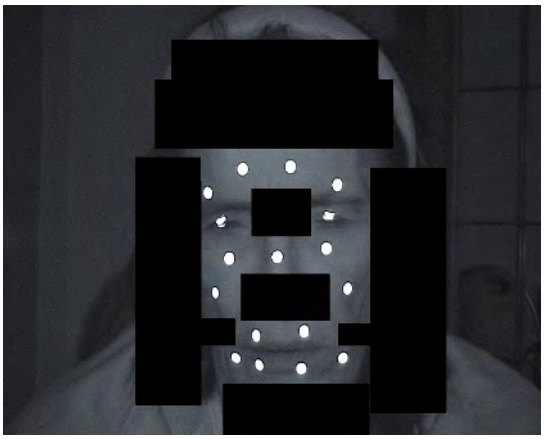

Fig. 2. Marker pattern used in testing patients with Meige syndrome.

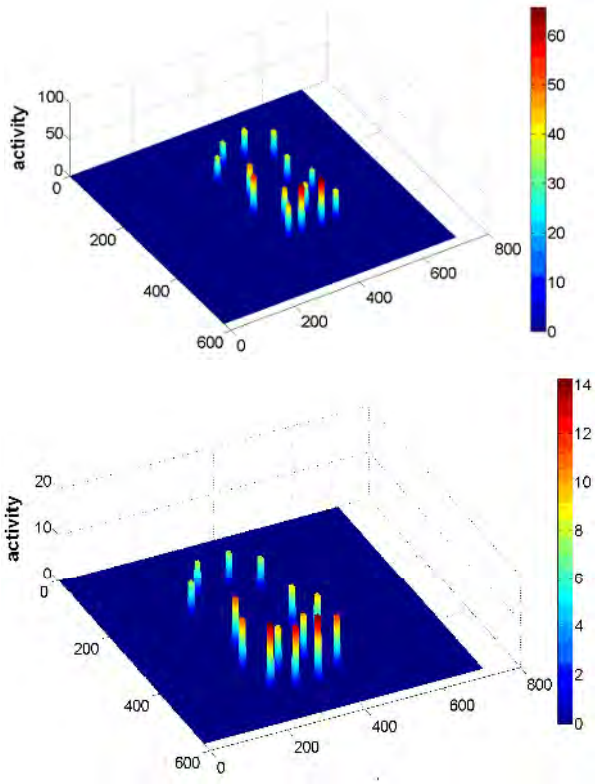

Fig. 3. Activity of marked points on the face, before (top) and after (bottom) operation for patient M1. Notice the different scaling.

Figure 3. and 4. show the results of a patient before (top) and after (bottom) surgical procedure, namely ventro-posteo-lateral pallidotomy on the left side of the brain. The change in the activity of marked points (Figure 3.) and in the relative activity of four sections of the face (Figure 4.) show impressive improvement after surgery. The activity dropped to approximately one fourth, and the two cheeks' behavior became rather symmetrical.

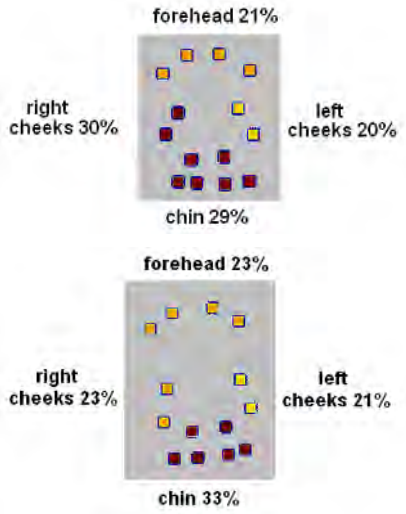

Fig. 4. Activity of four sections of the face before (top) and after (bottom) operation for patient M1.

Blepharospasm and oromandibular dystonia is well characterized by the displacement vector set of all markers at a given moment, see Figure 5.

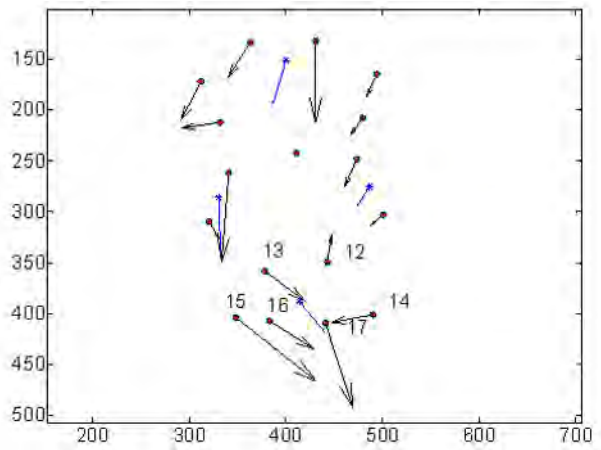

Fig. 5. Displacement vectors of markers on a frame.

This made possible the filtering out of head movement which was further aided by a marker attached to the bridge of the nose. Figure 5. reflects movement of sections of the face on a still image. While the head moves downwards and to the right, some markers move from right to left and marker 12 on the chin moves upwards. The resulting vectors of the markers on every section of the face are also shown. The directions of the resulting vectors are different.

Passive marker based motion analysis can give an objective measure of the blepharospasm and oromandibular dystonia that is hardly possible based on human observation. ***The result of the measurement facilitates the decision whether or not neurosurgical operation is needed.*** The procedure is also appropriate for grading the efficacy of both drug therapy and surgical intervention.

III. Digitizing tablet

A spiral is drawn on the tablet that has to be followed by the patient using the related pen. The reference spiral and the trajectory drawn by a Parkinsonian patient are shown in Figure 6. The trajectory was analyzed using software developed in MATLAB. High-pass filtering makes possible the analysis of kinetic hand tremor.

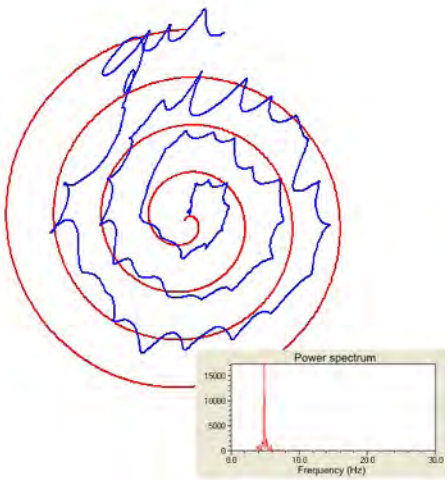

Fig. 6. Reference spiral, trajectory of tracking and the power spectrum of a Parkinsonian subject

On the other hand different movement disorders, like dystonia (see Figure 7.), myoclonus or bradykinesia can be recognized and analyzed during different treatment algorithms. Based on initial displacement dataset, along with both time and frequency domain analysis a quantitative mistracking assessment scoring can be developed for clinical use.

Up to now the spiral test was performed in the St. John's Hospital by 68 patients. Altogether 544 recordings were made and evaluated. The results help the neurologist in differential diagnosis of different tremor types and in deciding on the proper treatment. In case of insufficient drug effect the method has been used by neurosurgeon to make proper indication for surgery in order to control the tremor and to select the targeted brain area for intervention.

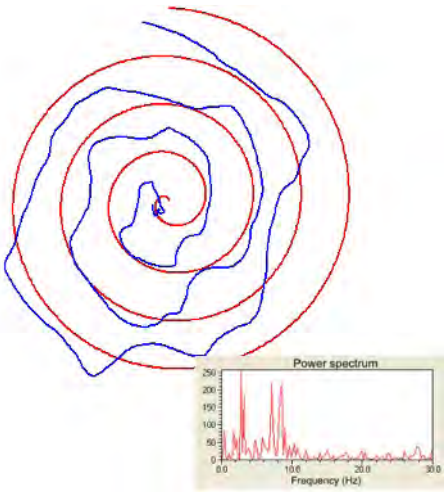

Fig. 7. Reference spiral, trajectory of tracking, and the power spectrum of a patient with left hand dystonia

IV. Three dimensional accelerometer

A battery operated, wireless 3D accelerometer was developed at Budapest University of Technology and Economics. The size of the device is 61 x 30 x 15 mm. The

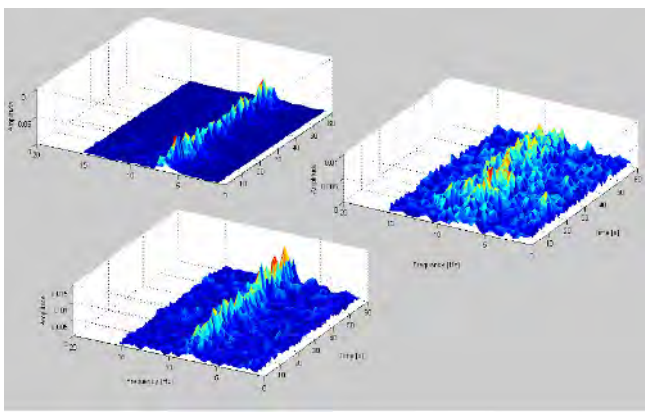

Fig. 8. Hand tremor of three subjects without known neural disease.

actual position of the device – and thus the hand that holds it – cannot be determined, tremor assessment is based on the acceleration data set. The main advantage of this method is that the recording can be done in different conditions, even out of laboratory. Figure 8. shows the result of three subjects without known neural disease. The frequency spectra over time are rather different for the three subjects. The spectra – and their later changes – give valuable information about possible tremor foci.

V. Conclusions

Many diseases influence the movement coordination of patients. Objective assessment of movement disorders greatly helps neurologists and neurosurgeons to make differential diagnosis as well as track the progress of the disease or beneficial effect after surgery. Preferred devices are easy in handling and suitable for clinical application after short training of the operator.

Abstract — **An economic, versatile, compact and portable biopotential amplifier [Electroneurograph] has been designed and implemented intra operatively. The most significant features of the instrument are variable cutoff for the low pass filter, variable gain, attenuation and optical isolation for the output. A fourth order low pass filter with bessel characteristic was designed using active filters. An attenuator is provided in between the gain stage and optical isolator such that the signals during supramaximal stimulations are attenuated. In this versatile bio-potential recorder, one of the outputs of the amplifier is isolated optically using IC MOC 3020 such that patient safely is ensured. The output portion of the instrumentation amplifier which is named head stage is designed separately and the inputs from the electrodes are given to the head stage by means of shielded coaxial cable. Also the whole bio-potential amplifier is properly shielded and grounded to minimize the noise effect. Offset control is provided for base line shift. The stimulating and recording electrodes were placed in appropriate positions and evoked responses were recorded. Conduction velocity was calculated by measuring the latency of waveform by stimulating at two different points along the nerve. Nerve conduction studies have been undertaken on leprosy patients who had undergone median and ulnar nerve corrective surgery and the result presented.**

Keywords — **Electroneurograph, Biopotential amplifier, Conduction velocity, Nerve action potential, Supramaximal stimulation.**

I. Introduction

Neurological examination of peripheral nerve function refers to nerve conduction study which is based on evoked potentials. Evoked potentials are obtained when electric pulses are passed through excitable tissues like nerves and muscles. With this method it is easy to conduct study of neurological examinations like conduction velocity measurements and location of nerve lesion. The present paper deals with conduction velocity measurements in patients suffering from leprosy using a stimulator and a bio-potential recorder to find the most proximal site of conduction failure which helps the surgeon to perform the corrective surgery [1]. Leprosy is not known to present without neural involvement. The most commonly affected nerves are those of the extremities, in particular the ulnar, the median, lateral popliteal, posterior tibial nerves and their branches. Leprosy invariably results in enlargement of peripheral nerves. Due to the thickening of the multi layered perineurium, its normal properties like semi permeability and elasticity are adversely affected which in turn would block the transmission of impulses.

Leprosy is characterized by involvement of the cutaneous sensory nerves and superficial nerve trunks. The phrenic nerve which is a deeply situated motor nerve is accessible for electro diagnostic studies. The nerve conduction time (NCT), amplitude and duration of compound muscle action potential (CMAP) were recorded. For comparison with peripheral nerves, the motor and sensory conduction of the median nerve was studied [2]. Selected leprosy patients were studied for sensory nerve action potential (SNAP) and motor nerve action potential (MNAP). 55 peripheral nerves were involved in the patients. Ulnar nerve was the commonest by median and posterior tibial nerves. Motor conduction and sensory conduction studies have demonstrated that marked slowing of conduction may occur in affected nerves and changes in latency and amplitude were observed [3][4]. Supramaximal stimuli were used for most of the recordings. Here studies have been done on both clinically affected and clinically unaffected nerves of patients with Leprosy.The forgoing observation promted our team to focus attention in the design and implementation of a low cost, portable, versatile biopotential recorder.

II. Methodology

In order to study the function of neurons it is necessary to stimulate the nerve and study the action potentials generated by it, which can be accomplished by electrical stimulation which is easily controllable. It can be either constant voltage or constant current. It actually involves passing an appropriate electric current through a region of tissue and there by causing the neurons in the area to be depolarized. The nerve stimulation techniques are performed with a variable stimulus generator. The stimulus frequency, stimulus intensity and stimulus duration must be known, adjustable and have an ON / OFF control. In Leprosy patients, for recording the mixed motor and sensory nerve action potential, the stimu-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 116–120, 2009
www.springerlink.com

lus given was a rectangular pulse of 50 μ S or 100 μ S duration or a capacitive discharge waveform of the same duration. The standard stimulus is a rectangular wave pulse of current passing between the cathode and the anode. The cathode is always placed closer to the recording electrodes than the anode, because the cathode activates by depolarizing and the anode may block conduction in some axons by hyperpolarization. Standard nerve conduction studies use a supramaximal stimulus, selected to be one third greater than that required to obtain a response of maximal amplitude. A stimulus of 25 mA, 100 V and 0.1 m S duration is usually adequate. However, for abnormal nerves, the stimulus may need to be as high as 75 mA, 300 V and 0.5 m S in duration [5].The electrode positions for the recordings and responses of the ulnar nerve and median nerve are shown in fig.3 and fig. 4 respectively.

III. Biopotential recorder

There are some recent progress in the development of amplifiers and other signal acquisition and signal conditioning systems for biopotential recording [6]. A typical design of the various stages of a biopotential amplifier is formed by preamplifier or instrumentation amplifier, low pass filter, 50Hz notch filter[7] [8]. The developed biopotential recorder consists of a head stage which is a combination of a two stage instrumentation amplifier and a high pass filter followed by difference amplifier, offset control, low pass filter, gain stage, attenuator and isolator. CMRR should be above 90 dB and the sensitivity should be around 10 μ V. The DC power is given by a rechargeable battery. Protection circuits are also used to protect the head stage from high voltage hazards. The block diagram of the recorder is shown in fig.1

A. Instrumentation Amplifier (Head Stage)

For recording biopotential signals from the body, the first and most crucial stage of the instrument is the instrumentation amplifier which consists of the head stage and difference amplifier. The evoked potentials picked up by Ag/AgCl concave disc electrodes are fed to the stage, designed using quad operational amplifier TL 084. A two stage instrumentation amplifier is designed with a gain of 3000 to get an output voltage of 6V for an input of 2 mV. A capacitor is connected in series with R1 of the instrumentation amplifier which acts as a high pass filter, whose cutoff frequency is fixed at 100 Hz to reduce the 50 Hz mains interference. A cutoff of 100 Hz is selected because the signal of interest for our study lies between 150 Hz to

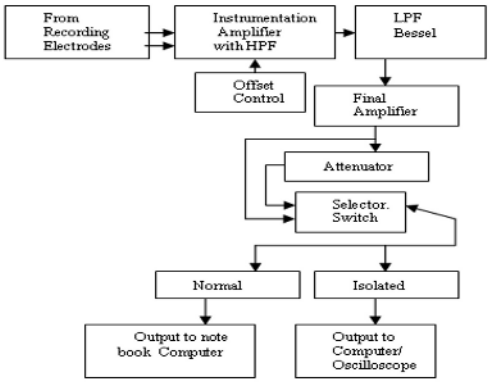

Fig. 1 Block Diagram of Biopotential Recorder

2KHz. Since the circuit provides a CMRR of 97 dB, the recording performance of the amplifier is adequate.

The head stage consisting of two gain stages along with high pass filter is enclosed in a shielded metal cabin and kept close to the recording electrodes to eliminate noise pick up [9]. The transfer characteristics of the instrumentation amplifier along with the high pass filter is

$$Vo/\ Vi = [\ 1+(R_1C + 2\ R_2\ C)s] / (1+ R_1Cs) \qquad (1)$$

Where Vi and Vo are the input and output voltage of the amplifier. R_2 is the feedback resistance and R_1 and C are connected in series between the output of the operational amplifier. The CMMR vs. frequency of the instrumentation amplifier is shown in fig. (2) a.

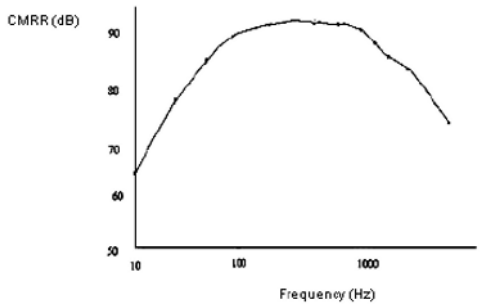

Fig. (2) a CMRR vs. freq. of instrumentation Amplifier

B. Low pass filter

For better cutoff, a fourth order low pass filter with bessel characteristics is designed with variable cutoff at 2 KHz and 3 KHz using active filters. The bessel filter has the most damped characteristics and are used where flat low frequency and good transient responses are needed [10].

In the case of linear response, the out put will simply be a delayed version of the input but in the non linear case the

output will exhibit significant ringing. It turns out that the steeper the cutoff characteristics in the transition band, the higher the amount of ringing [11] . The frequency response of the bessel filter is shown in the fig. 2(b).

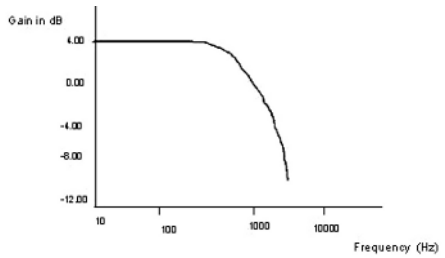

Fig. (2) b. Frequency response of Bessel filter

C. Final Amplifier

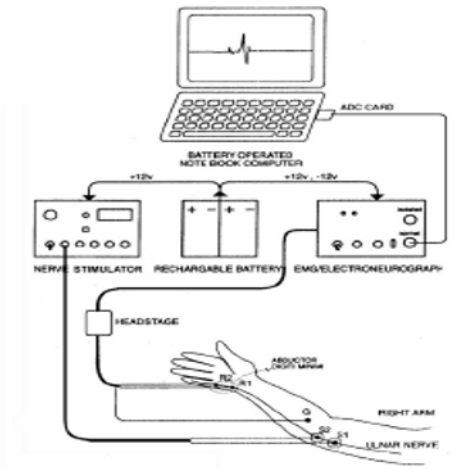
A non inverting amplifier with selective gain of 1, 2, 5 and 10 are provided for final amplification. This is implemented by using low noise quad operational amplifier TL 084. The output of the amplifier is coupled through a 0.1 μ F capacitance to eliminate DC offset in the amplified signal. An offset control is provided for adjusting the DC shift occurring at the output of the amplifier.

D. Attenuator and Isolator

An attenuator is provided in between the gain stage and the optical isolator. This is provided to attenuate the signals during supramaximal stimulation, other wise the signal gets saturated. For connecting the high voltage display devices one of the amplifier outputs is isolated optically using IC MOC 3020.

IV. Recording

Electroneurography is the recording and study of action potential propagation along peripheral nerves. The nerve conduction studies helps to distinguish between axonal degeneration, segmental demyelination and abnormal nerve function. For nerve conduction studies the parameters of the evoked responses required are the amplitude, latency and area of the responses recorded. By using the newly developed electroneurograph, electrophysiological studies have been conducted on leprosy patient. The above studies have been done on mainly the ulnar nerve and median nerve since these nerves are the most accessible ones. The method adopted for the measurement of conduction velocity is by stimulating at two different points along the nerve and measuring the latency for each electrical response recorded from the muscle. For each stimulation the time between the start of the stimulus and the onset of the response is measured which is termed as the 'Latency'. The length of the nerve segment is then obtained by measuring on the surface of the skin the distance between the cathodes when placed for each stimulation. The conduction velocity is obtained by dividing the nerve length between the two stimulation points by difference in Latency which is expressed in meter per second [12]. The recording setup is shown in fig. 3.



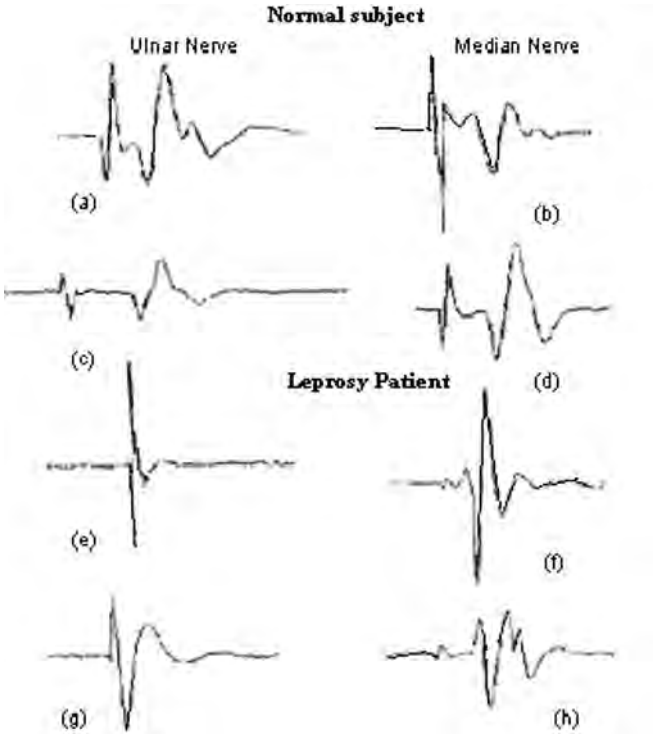


Fig. 3 Recording setup of Nerve action Potential

The conduction velocity of both ulnar and median nerves from elbow to wrist of both arms was calculated. From the recordings it is observed that the ulnar nerve is not functional in both arms where as the median nerve appears to have retained function. The recorded waveform of the ulnar and median nerve of leprosy patient compared with normal patient is shown in fig. 4. The conduction velocity of the median nerve from elbow to wrist was calculated for both arms. In the right median nerve, a conduction velocity of 59.72 m/s and in the left median nerve, a conduction velocity of 57.5 m/s was measured as shown in Table 1. Comparing the conduction velocity of the median nerve from the normal subjects, it was observed that the median nerves of both arms were functioning normally. However, latency at wrist (6.6 ms) was found to be larger than compared with the latency of the normal subjects which was around 3.1 ms.

Some conduction delay is observed between the wrist and thumb indicating nerve compression or nerve damage. A prolonged latency is found in this case which could be due to carpal tunnel syndrome.

(a), (b), (e), (f) – Simulation at wrist
(c), (d), (g), (h) -- Simulation at elbow

Fig (4). The recorded waveform of the ulnar and median nerve of leprosy patient compared with normal subject.

Table 1. Conduction velocity of median nerve

Hand	Nerve	Latency at wrist in sec	Latency at elbow in sec	Difference in latencies (▲L)	Difference in mtrs (▲L)	velocity in m/s
Right	Ulnar	.....	.....	.....	.....	.....
	Median	0.0066	0.0102	0.0036	0.215	59.72
Left	Ulnar	.....	.....	.....	.....	.....
	Median	0.0059	0.0099	0.0040	0.23	57.5

V. Results and conclusion

In the recordings, the 50Hz interference was negligible because of the HPF and the base line was seen to be almost a straight line. As the noise level is less than 5 μ V, the recordings were adequately sensitive [13]. From the recordings of the leprosy patients, the conclusions are,

1. The median nerve appears normal between the elbow and wrist but some conduction delay or blockage between the wrist and abductor pollicis brevis. So the conduction delay could be due to carpal tunnel syndrom. 2. The ulnar nerve is unstimulatable in both arms. 3. The abductor digiti minimi muscle of both arms is not responding to voluntary command.

VI. Conclusion

This method can be used to perform conduction studies on normal volunteers and also subjects with clinical conditions with maximum patient safety. It can also be used in remote areas where there is no electric power. This instrument helps the doctors to locate the exact position of the nerve lesion or nerve damage in the case of peripheral neuropathy and to do corrective surgery. The results of conduction velocity studies from presently available literature are comparable with those of our studies indicates not only the proper functioning of the electroneurograph but also the appropriateness of methodology of our study.

Comparison of Various Imaging Modes for Photoacoustic Tomography

Chi Zhang and Yuanyuan Wang

Department of Electronic Engineering, Fudan University, Shanghai 200433, China

Abstract — **Photoacoustic tomography (PAT) has shown great potential in many medical applications. According to the geometry of electromagnetic irradiation and acoustic signal detection, PAT can be categorized into three imaging modes, the forward mode, the backward mode and the sideward mode. To deeply understand their theorems and suitable applications, simulation studies are carried out to compare the precision and noise robustness of reconstructions of these modes. The absorbed energy density of the irradiated tissue is modeled by the Monte Carlo method. Then generated photoacoustic signals are simulated by the finite-difference time-domain method. Four representative algorithms are employed to reconstruct the image from simulated signals. It is found that in the sideward mode, the reconstructed image around the center of the scanning circle has better precision and stronger robustness to noise compared with the marginal region. In both forward and backward modes, the region relatively close to transducers can be reconstructed more clearly, but is more sensitive to noises. The sideward mode has better precision but slower reconstruction speed compared with forward and backward modes. Moreover, the choice of the time-domain or frequency-domain reconstruction algorithm is shown to have an impact on the noise pattern of the reconstructed image. Therefore, the sideward mode PAT is suitable for the precise imaging of protuberant human tissues, and the optimum imaging region (OIR) is around the center of the scanning circle. The forward/backward mode PAT is suitable for the fast imaging of plane human parts, and the OIR is at an appropriate distance from the scanning line.**

Keywords — **Photoacoustic tomography, imaging mode, comparison.**

I. Introduction

Photoacoustic tomography (PAT), emerging as a new technique of noninvasive medical imaging, combines the optical contrast and ultrasonic resolution, and has demonstrated great potential in many important medical applications including breast tumor detection and brain functional imaging [1-3].

In PAT, a short-pulsed laser or microwave is used to irradiate the biological tissue, which results in generation of acoustic waves due to thermoelastic expansion. The acoustic wave, called photoacoustic wave, is then detected by the ultrasonic transducer and utilized to reconstruct the absorbed energy density of the tissue. According to the geometry of electromagnetic irradiation and photoacoustic signal acquisition, PAT can be categorized into three imaging modes [4], the forward mode [5], the backward mode [6] and the sideward mode [7]. In the forward mode the ultrasonic transducer and radiation source are on opposite sides of the object, while in the backward mode they are on the same side. In the sideward mode, the ultrasonic transducer is perpendicular to the direction of electromagnetic irradiation. These three modes hold different mechanisms, therefore being suitable for different applications.

In this paper, the principles of these three modes are theoretically analyzed. Simulation studies are conducted to corroborate the analysis. The generation and propagation of photoacoustic signal are simulated by the combination of Monte Carlo (MC) model [8-9] and finite-difference time-domain (FDTD) method [10, 4]. The image reconstruction is fulfilled by four representative algorithms [11-14]. It is found that these modes vary in precision and noise sensitivity and have diverse optimum imaging regions (OIR).

II. Methods

A. Three modes

The medical applications of these three modes depend largely on their physical configurations. The backward mode may be the most convenient one to be carried out. Since the irradiation source and ultrasonic transducer are on the same side, these two parts can be integrated into one device, working like the transducer in B-mode ultrasound imaging. So the backward mode can be applied to the detection of most human parts. The forward mode, with the irradiation source and ultrasonic transducer on opposite sides, is not suitable for the imaging of thick tissues. This is because the laser attenuates very quickly in biological tissues. As a result, the detected photoacoustic signal of thick tissue on the opposite side of irradiation source is much weaker than that detected on the same side. In both the backward and forward modes, the ultrasonic transducer array is usually employed for the fast imaging. The sideward mode is the only one in which the transducer can scan around (normally in the circular geometry) biological tissues to acquire photoacoustic signals. In fact, although time consuming, the circular scanning is often used in PAT due to the high imaging resolution. However, limited by its physical configura-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 121–124, 2009
www.springerlink.com

tion, this mode can only be conveniently applied to the imaging of protuberant human parts.

Simulation studies are carried out to compare the precision and noise robustness of reconstructions of these three modes. The simulation is conducted in the 2-D case to reduce the computational complexity, but the conclusion can be easily extended to the 3-D case. The simulation process is described in following sections.

B. Monte Carlo model

In PAT, the biological tissue is first irradiated by a short-pulsed laser. The basic equation of PAT is given by [11]

$$\nabla^2 p(\mathbf{r},t) - \frac{1}{c^2}\frac{\partial^2 p(\mathbf{r},t)}{\partial t^2} = -\frac{\beta}{C_p} A(\mathbf{r}) \cdot \frac{\partial I(t)}{\partial t} \qquad (1)$$

where **r** is the spatial position, t is the time, $I(t)$ is the laser pulse function, $A(\mathbf{r})$ is the absorbed energy density, $p(\mathbf{r}, t)$ is the acoustic pressure, β is the coefficient of volumetric thermal expansion, c is the acoustic speed and C_p is the specific heat. Here the MC model, a gold standard technique in the simulation of biomedical optics, is utilized to simulate the light propagation and $A(\mathbf{r})$.

The MC model treats light as photons and ignores wave features. The light propagation is modeled by photon movements. The step length of the photon movement between sites of the photon-tissue interaction (scattering) is given by probability distributions, and the refraction and reflection occurring at the interface of different mediums are calculated by Snell's law and Fresnel's formulas. By simulating the movements of a large amount of photons, this model can precisely simulate the light propagation and optical absorption in tissues. But at the same time, this statistical model is computationally inefficient.

The MC model used here is similar to that described in [9], which can be referred to by readers for more details.

C. Finite-difference time-domain method

Given that $A(\mathbf{r})$ is calculated by the MC model, the generated photoacoustic signal p, as shown in (1), can be simulated by the FDTD method, which has been widely used in the simulation of acoustic waves and electromagnetic waves. In the FDTD method, parameters in (1) are discretized so that (1) can be expressed as difference equations. Then p can be calculated by the numerical method.

The excitation pulse I is very short, so extremely dense meshes are required in the FDTD method. However, in most practical applications, the used ultrasonic transducer is with the center frequency at the order of MHz. Therefore, there is no need to model frequencies higher than the bandwidth of the detector. Accordingly, a useful improvement is to rewrite (1) as [10]

$$\nabla^2 (p * h) - \frac{1}{c^2}\frac{\partial^2 (p * h)}{\partial t^2} = -\frac{\beta}{C_p} A \cdot \frac{\partial (I * h)}{\partial t} \qquad (2)$$

where h is the impulse response of the ultrasonic transducer and * represents the convolution. Obviously the detected photoacoustic signal is $p * h$ and is generated by the source $I * h$ as shown by (2). Since high frequency components of I are filtered by h, better precision can be achieved even using relatively sparse meshes in the FDTD simulation.

The specific steps of the FDTD method can be found in [15] and will not be introduced here on account of space limitation.

D. Four reconstruction algorithms

Detected by the ultrasonic transducer, the photoacoustic signal can be used to reconstruct the inner image of the tissue. Since the performance of reconstruction algorithm is important to the image quality, here four representative and commonly used algorithms are chosen for the image reconstruction.

The scanning geometries of these three modes play a critical role in the choice of reconstruction algorithms. Therefore, in the sideward mode the spherical time-domain reconstruction (STDR) algorithm [11] and the deconvolution reconstruction (DR) algorithm [12] are chosen; the former is a time-domain method and the latter is a frequency-domain method. In both backward and forward modes, the planar time-domain reconstruction (PTDR) algorithm [13] and the Fourier-based projection (FP) algorithm [14] are applied; the former is a time-domain method and the latter is a frequency-domain method. Algorithms in different domains are used for each mode in order to reduce the effect of algorithm's performance and focus on the characteristic of different modes.

E. Parameters

The optical absorption distribution of the simulated tissue is shown in Fig. 1. The image size is 18 mm×18 mm. It can be seen that nine objects are imbedded in the background of turbid medium.

In the forward mode, the laser source irradiates homogeneously from the left side, and the ultrasonic transducer scans along a line on the right side (6.3 mm from the centre of Fig. 1, 120 positions with the interval of 0.12 mm). In the backward mode, the laser source still irradiates from the left side, and the ultrasonic transducer scans along a line on the left side (6.3 mm from the centre of Fig. 1, 120 positions

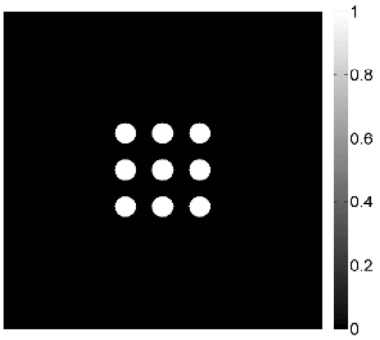

Fig. 1 The optical absorption distribution of the simulated tissue.

with the interval of 0.12 mm). In the sideward mode, the laser source irradiates from the outside perpendicular to the image plane, and the ultrasonic transducer scans along a circle (with the radius of 9 mm, 240 positions).

Parameters of the MC model are set as follows: the index of refraction is 1.33, the scattering coefficient is 15 cm^{-1}, the absorption coefficient of objects is 4 cm^{-1}, the absorption coefficient of the background is 0.05 cm^{-1} and the anisotropy factor is 0.9.

Parameters of the FDTD method are set as follows: the acoustic speed is 1500 m/s, the space interval of the mesh is 0.03 mm and the time interval is 5 ns.

III. Results and discussions

Figure 2 shows the reconstructed images (from noisy signals with the signal-to-noise ratio of 7 dB). The three columns from left to right correspond to the results of forward, backward and sideward modes, respectively. The two rows from top to bottom correspond to the results of time-domain and frequency-domain algorithms, respectively.

In both the forward and backward modes, it can be found that the objects relatively close to the transducer are reconstructed more clearly. This is because the transducer only scans along a line with a finite length, causing the image reconstruction to be a limited-view problem [12, 16]. Since close objects have a larger view than distant ones, they can be reconstructed more clearly. At the same time, the near region is more sensitive to noises when reconstructed using time-domain algorithms, because in the reconstruction the signal, including noise, is divided by the distance. The noise effect is averaged at various distances when using frequency-domain algorithms. Additionally, considering the performance limitation of the transducer's near field region, the OIR of forward/backward mode PAT should be at an appropriate distance from the scanning line.

In the sideward mode the objects are reconstructed with good precision, clearer than those in forward and backward

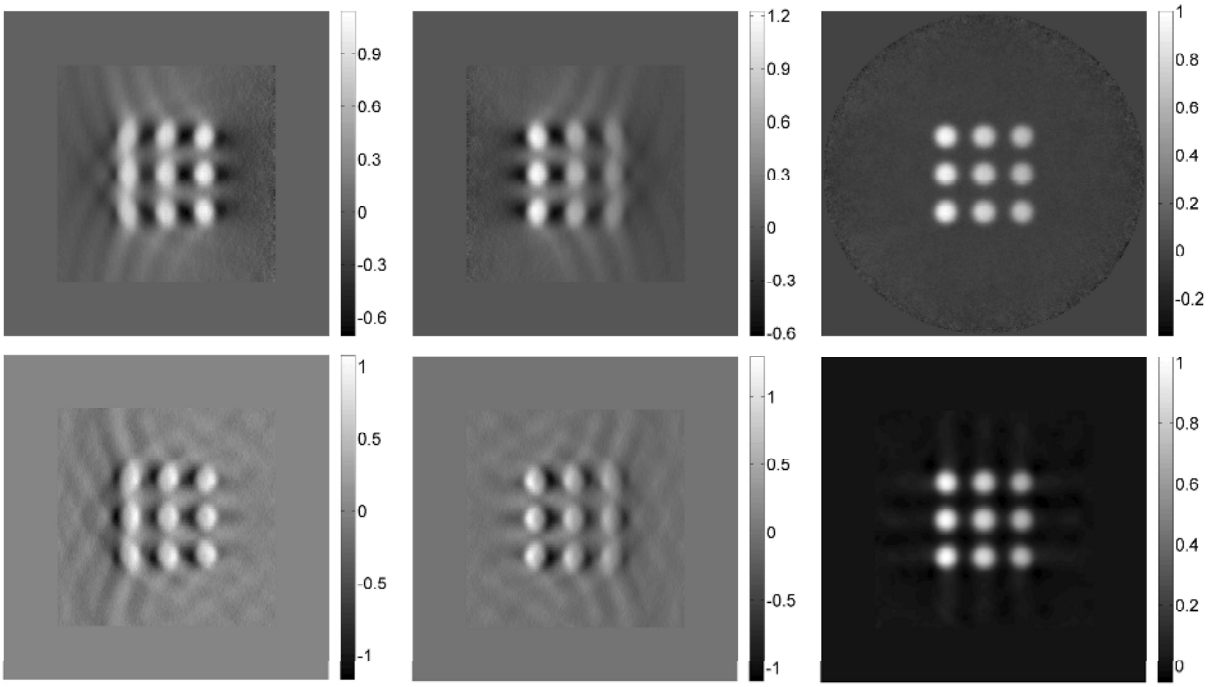

Fig. 2 Reconstructed images of the tissue (as shown in Fig. 1). The three columns from left to right correspond to the results of forward, backward and sideward modes, respectively. The two rows from top to bottom correspond to the results of time-domain and frequency-domain algorithms, respectively.

modes, because here the image reconstruction is a full-view problem. It can be seen that the region relatively close to the scanning circle is more sensitive to noises when reconstructed by the time-domain algorithm. This effect results from the same reason as discussed in forward and backward modes. Also, similar to forward and backward modes, the frequency-domain algorithm could homogenize the noise effect. In short, obviously, the OIR of the sideward mode PAT is around the center of the scanning circle.

IV. Conclusions

Three modes of PAT—forward mode, backward mode and sideward mode—are described and analyzed in this paper. Simulation studies are carried out, in which the light propagation and optical absorption are simulated by the MC model, and the generated photoacoustic signal is simulated by the FDTD method. Four representative algorithms, two time-domain ones and two frequency-domain ones, are utilized for the image reconstruction.

In the forward mode and backward mode PAT, the region relatively close to transducers can be reconstructed more clearly, but is more sensitive to noises. Meanwhile, the fast or even real-time imaging is possible by using the transducer array. So the forward/backward mode is suitable for the fast imaging of plane human parts, and the OIR is at an appropriate distance from the scanning line.

In the sideward mode PAT, the reconstructed image around the center of the scanning circle has good precision and strong robustness to noise, generally better than forward and backward modes. But this mode can only be conveniently applied to the imaging of protuberant tissues, limited by its physical configuration, and is slow due to the circular scanning. Therefore, the sideward mode is suitable for the precise imaging of protuberant human parts, and the OIR is around the center of the scanning circle.

Ultrasonographic Segmentation of Cervical Lymph Nodes Based on Graph Cut with Elliptical Shape Prior

J.H. Zhang[1], Y.Y. Wang[2] and C. Zhang[2]

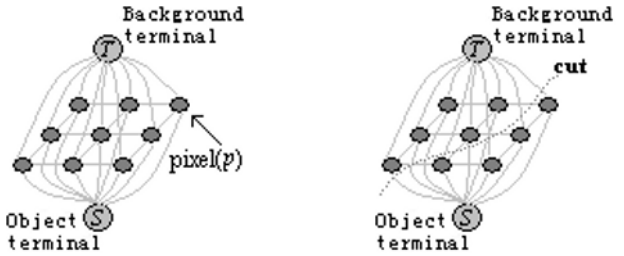
[1] Department of Electronic Engineering, Yunnan University, Kunming, China
[2] Department of Electronic Engineering, Fudan University, Shanghai, China

Abstract — **A modified graph cut algorithm was proposed under the elliptical shape constraint to segment ultrasonograms of cervical lymph nodes. Since cervical lymph nodes were usually oval-shaped, the prior of the elliptical shape information, which was expressed as a distance function, was used to constrain the cut cost of the graph cut algorithm. The initially segmented contour was fitted by an ellipse to get the constraint. Then the segmentation was obtained by minimizing the cut cost function constrained by the elliptical prior. The procedure was iterated until the tolerance of convergence was met. Under the same user inputs, the algorithm successfully segmented nodes on low contrast sonograms whereas the traditional graph cut approach failed. For 30 ultrasonograms, the distance between contours manually delineated by the radiologist and those segmented by the proposed algorithm was far less than the distance resulted from the traditional graph cut algorithm. Both the qualitative and the quantitative evaluation of segmentation results indicate that utilizing the elliptical shape prior can significantly improve the graph cut algorithm for segmenting cervical nodes on sonograms.**

Keywords — **Graph cut, elliptical shape prior, cervical lymph node, ultrasonogram.**

I. Introduction

Lymph node is one of the important organs, acting as the immunologic filter in the body. The abnormity of lymph nodes often denotes pathological changes within their attributive areas. Therefore, the evaluation of lymph nodes is meaningful for the disease diagnosis. Since cervical lymph nodes are prone regions of the lymphadenopathy, they are especially important in the clinical examination. Among all kinds of imaging modalities, the ultrasound is the preferred technique for the evaluation of cervical lymph nodes, due to its good attributes of non-invasion, absence of radiation, real time, low cost, and convenience. However, ultrasonic images often exhibit the poor quality with speckle noises and low contrast, which results in difficulties in image processing procedures, especially in the image segmentation. Most fully automatic segmentation techniques are slow, and cannot satisfy the accuracy requirement for the clinic practice, while interactive segmentation methods have the advantage of the reliability under users' control.



The graph cut developed by Boykov *et al.* [1] is an interactive image segmentation method based on the energy minimization, which finds the globally optimal segmentation under hard constraints from users and soft constraints including both the boundary and region information. However, even with a significant amount of user inputs, the performance of the traditional graph cut approach is not satisfactory to segment cervical lymph nodes on sonograms. Many segmentation methods [2-4] have taken advantage of the shape information to improve the performance. Especially, Freedman *et al*. [3] improved the graph cut method by using the level-set template to add shape constraints. In their method, a particular fixed template should be known and transformed to get the appropriate shape prior. Since cervical lymph nodes are usually oval-shaped, we incorporated the elliptical shape prior, which was adaptively obtained from the initial segmentation, into the graph cut approach to get better segmentation results. It should be noted that Slabaugh *et al.* [4] also proposed to use the elliptical shape prior to improve the graph cut segmentation, where the ellipse constraint was incorporated into the graph cut in a different way from our method. They also obtained improvement for lymph nodes segmentation in MR images that had the higher quality than ultrasonograms.

II. Materials and methods

A. Graph cut

In this section, we review the graph cut algorithm [1] for the interactive segmentation. To segment a given image, an undirected graph $G = <V, E>$ is created. The graph is composed of a set of vertices V and a set of undirected edges E that connect vertices, as shown in Fig.1(a). Vertices include all pixels P in the image and two special terminals (S and T) which respectively correspond to the object (O) and background (B) labels assigned to pixels by a user. Therefore, $V = P \bigcup \{S,T\}$. Each pixel $p \in P$ has two terminal edges connecting it to terminals, S and T, i.e., $\{p, S\}$ and $\{p, T\}$. Each pair of neighboring pixels is connected by the neighborhood edge N. Therefore, $E = N \bigcup \{\{p,S\},\{p,T\}\}$.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 125–128, 2009
www.springerlink.com

(a) (b)

Fig. 1 A graph and its minimum cost cut: (a) a graph for a 3×3 image; (b) minimum cost cut

As illustrated in Fig. 1(b), a cut partitions vertices into two sets separating two terminals. Accordingly, the image is segmented into the object (A_p = 1, A_p, the attribute of the pixel p), and the background (A_p = 0). The cost of the cut is the sum of all costs of edges that are severed by the cut. Typically, the cost of the neighborhood edge is defined by

$$w(p,q)=\exp\left[-\frac{(I_p-I_q)^2}{2\sigma^2}\right]\frac{1}{dist(p,q)} \qquad \{p,q\}\in N, A_p\neq A_q \tag{1}$$

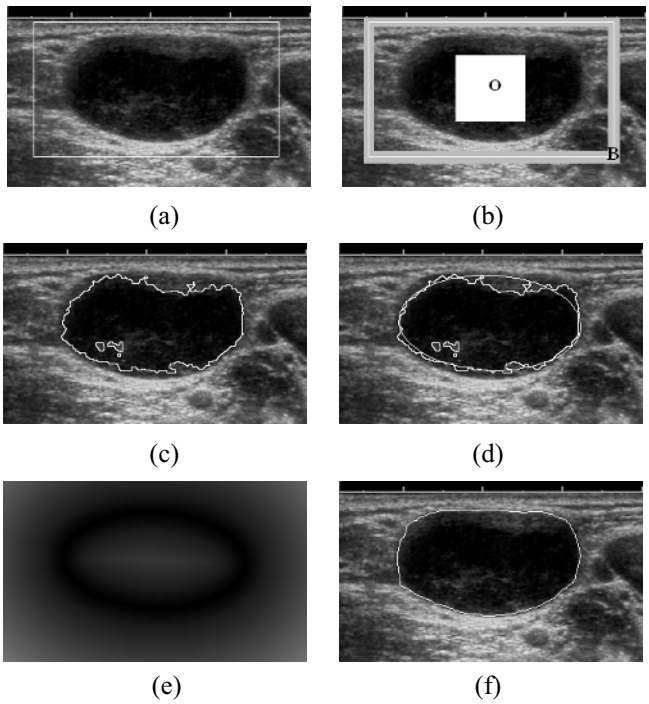
where I_p and I_q are intensities of pixels p and q respectively; dist(p, q) is the Euclidean distance between two pixels; and σ is an empirical value, used as the threshold for the difference between two pixels. It can be seen that if two pixels are significantly different ($|I_p - I_q| > \sigma$), the cost is low. However, this function penalizes those cuts between pixels with similar intensities.

On the other hand, according to labels (O and B) assigned by users, costs for terminal edges are respectively defined as

$$w(p,S)=\begin{cases} K & p\in \mathrm{O} \\ 0 & p\in \mathrm{B} \\ -\ln \Pr(I_p/\mathrm{B}) & \text{else} \end{cases} \tag{2}$$

$$w(p,T)=\begin{cases} 0 & p\in \mathrm{O} \\ K & p\in \mathrm{B} \\ -\ln \Pr(I_p/\mathrm{O}) & \text{else} \end{cases} \tag{3}$$

where $K = 1 + \max_{p\in P} \sum_{q:\{p,q\}\in N} w(p,q)$, and Pr($I_p$/O) and Pr($I_p$/B) are histograms of the object and background intensity distributions, respectively derived from labels. Therefore, user inputs provide hard constraints for the segmentation.



The boundary between the object and the background is obtained by finding the cost cut on the graph G, which minimizes the energy function:

$$E=\lambda\sum_{p\in P}[w(p,S)+w(p,T)]+\sum_{p\in P,\{p,q\}\in N} w(p,q) \tag{4}$$

where the first term is usually called the region term, the second one is the boundary term, and λ is the weight factor between two terms. In such way, the segmentation is performed under hard constraints from users, and soft constraints incorporating both the boundary and region information.

B. Improved graph cut with elliptical shape prior

Even though the graph cut algorithm has many successful applications [1, 5], it shows limitations to segment cervical nodes on ultrasonograms. Due to the poor quality of ultrasonic images with speckle noises and low contrast, a large amount of user inputs are needed to obtain an accurate boundary. Since the shape of the cervical node is usually oval, the elliptical shape constraint is incorporated into the graph cut to reduce the sensitivity to speckle noises and to avoid the leak in weak boundaries. The proposed algorithm is illustrated in Fig. 2.

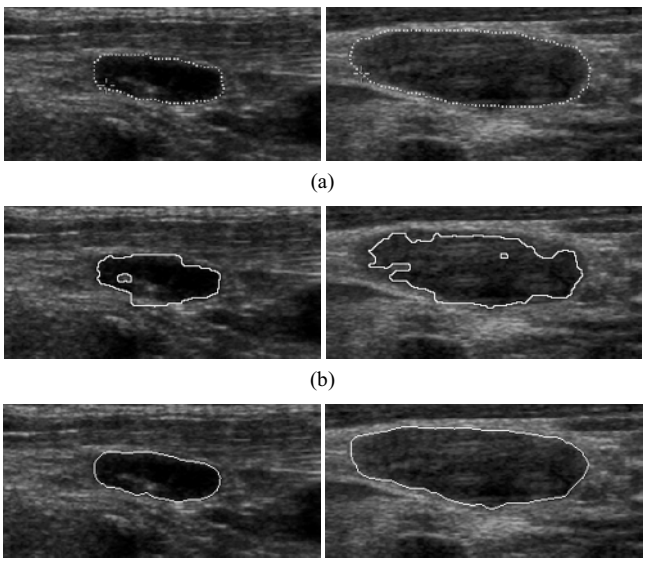
(a) (b) (c) (d) (e) (f)

Fig. 2 Improved graph cut segmentation: (a) ROI selected by a user; (b) "O" and "B" labels created by the computer; (c) initial contour obtained by the traditional graph cut; (d) ellipse fitted to the initial contour; (e) distance function of the ellipse; (f) final segmented contour

In the graph cut method [1], background and object labels should be assigned by a user. To compare the improved graph cut with the traditional one under the same user inputs, the user is required to select the region of interest (ROI) with a rectangle, as shown in Fig. 2(a). In Fig.2(b), pixels in the central square of the ROI are assigned as "object" seeds, where the width of the square is just half of the width of the ROI. Pixels in the surrounding region of the ROI are assigned as "background" seeds of ten pixels wide. Fig. 2(c) shows the boundary obtained by the traditional graph cut. The result is not satisfactory. In the following, the elliptical shape constraint is combined with the graph cut to iteratively improve segmentation results.

Firstly, as shown in Fig. 2(d), we fitted an ellipse to the previously obtained boundary using the algorithm described in [6]. Secondly, we generated a distance function $D(p)$ between the pixel p and the nearest point on the ellipse [7], as illustrated in Fig. 2(e). The zero distance corresponds to points on the ellipse. Thirdly, the energy function was modified by incorporating the distance function to realize the elliptical shape constraint:

$$E = (1-\mu)\left\{\lambda\sum_{p\in P}[w(p,S)+w(p,T)]+\sum_{p\in P,\{p,q\}\in N}w(p,q)\right\} + \mu\sum_{p\in P,\{p,q\}\in N}D\left(\frac{p+q}{2}\right) \quad (5)$$



where $\mu \in [0, 1]$ is a weighting factor. Therefore, under the same region and boundary conditions, the cost of a cut near the ellipse will be smaller than that further from the ellipse. Lastly, the new energy function is minimized to obtain the new segmentation. These steps are iterated until the convergence. The convergence is achieved when either the number of iteration is reached or the difference between the current and previous results is smaller than a preset tolerance. The final segmented contour is shown in Fig. 2(f).

The segmented contour will be more like an ellipse when the value of μ is large. In this study, we took $\mu = 0.5$ for the segmentation of cervical nodes on ultrasonograms. For the segmentation of higher quality images, a smaller value of μ should be taken to reduce elliptical constraints. The value of σ was set as the average of difference values between two neighboring pixels in a given image. As for the parameter λ, it was demonstrated in the traditional graph cut that segmentation leak may take place in weak edges when the region term in Eq. (4) is missing, i.e. $\lambda = 0$. If $\lambda \neq 0$, results are almost the same for a large range of λ (λ = 7-43). Therefore, we assigned $\lambda = 10$ in this study.

III. Experimental results and discussions

A total of 30 sonograms of cervical nodes were used in this study. Images were obtained by a Sequoia 512 ultrasound system with a high-frequency transducer of 8-14MHz in Huashan Hospital of Fudan University, Shanghai, China. Images were segmented by the traditional graph cut approach and the proposed method. As an example, segmentation results of two nodes were presented in Fig. 3. The manual segmentation by a radiologist was presented in Fig. 3(a); the segmentation by the traditional graph cut was shown in Fig. 3(b); and the segmentation by the proposed method was shown in Fig. 3(c). User inputs were the same for two graph cut based methods, i.e., a rectangle selected by a user.

It was shown that the segmentation of the traditional graph cut could not satisfy the accuracy for the subsequent image processing. More labels must be added to improve segmentation results. Under the same user inputs, the proposed algorithm successfully segmented contours of nodes.

(a) (b) (c)

Fig. 3 Segmentation comparison for cervical nodes on sonograms: (a) segmentation by a radiologist; (b) segmentation by the traditional graph cut; (c) segmentation by the proposed algorithm

On the other hand, to quantitatively evaluate these methods, distances between contours manually delineated by the radiologist and those segmented by the computer was calculated. Two distance measures, the average minimum Euclidean distance (AMINDIST) [8] and the Hausdorff distance [9], were considered in this study. For two contours $A = \{a_1,...,a_m\}$ and $B = \{b_1,...,b_n\}$, the $AMINDIST(A,B)$

measures the average distance, while the Hausdorff distance $H(A, B)$ measures the maximum distance between two contours. They are respectively defined as

$$AMINDIST(A,B) = \frac{\sum_{i=1}^{m} MINDIST(a_i, B)}{2m} + \frac{\sum_{j=1}^{n} MINDIST(b_j, A)}{2n} \quad (6)$$

and

$$H(A,B) = \max\{\max_{i\in\{1,\ldots,m\}}\{MINDIST(a_i,B)\}, \max_{j\in\{1,\ldots,n\}}\{MINDIST(b_j,A)\}\} \quad (7)$$

where $MINDIST(x,B)$ is the minimum Euclidean distance between the point x to the contour B, i.e.,

$$MINDIST(x,B) = \min_{i\in\{1,\ldots n\}} \| x - b_i \| \quad (8)$$

For 30 sonograms studied, means of two distances resulted from the traditional graph cut, and the proposed algorithm were listed in Table 1. Results show that under the same user inputs, the proposed method is superior to the traditional graph cut.

Table 1 Comparison of segmentation results for 30 ultrasonograms

	AMINDIST (pixels)	Hausdorff (pixels)
Traditional graph cut	13.9	27.6
Improved graph cut	4.6	10.4

IV. Conclusions

An improved algorithm has been proposed to segment cervical nodes on ultrasonograms. The method takes advantage of the elliptical shape information of cervical nodes to improve the graph cut method. Both the qualitative and the quantitative evaluation of segmentation results indicate that the incorporation of the elliptical shape prior into the graph cut can significantly improve the graph cut segmentation results of cervical nodes on sonograms. The method has a potential to segment other objects with the elliptical shape, such as for the cell or the face detection.

Besides the elliptical shape prior, the investigation of other shape information in the graph cut algorithm for wider applications is one of our future research directions.

Computerized Assessment of Excessive Femoral and Tibial Torsional Deformation by 3D Anatomical Landmarks Referencing

K. Subburaj[1], B. Ravi[1] and M.G. Agarwal[2]

[1] OrthoCAD Network Research Centre, Indian Institute of Technology Bombay, Mumbai, India
[2] Department of Surgical Oncology, Tata Memorial Hospital, Mumbai, India

Abstract — **Bone torsional deformity is excessive anatomical or axial twist of proximal portion with respect to distal. Accurate, simple, and quick measurement of torsional deformities at preoperative stage is clinically important for decision making in prosthesis design and surgery planning. Commonly used 2D methods for assessing excessive torsion use radiographic images or a set of slices of CT/MR images. The slices representing reference axes of distal and proximal portion are superimposed; the angle between the axes provides a measure of torsion. Representing 3D anatomical landmarks and reference axes in a 2D transverse slice or projected radiographic image leads to inaccurate and inconsistent values. Owing to the complex 3D shape of bones (ex. femur and tibia), there is a need for 3D model based assessment methods with little or no human intervention. Excessive torsion in the tibia and femur affects the procedure of total knee replacement. We present an automated methodology for assessing excessive torsional deformation of femur and tibia bone based on 3D anatomical landmarks based referencing. Reconstructed 3D bone model from a set of CT scan images using tissue segmentation and surface fitting is used in this methodology. Anatomical landmarks on femur and tibia bone are automatically identified based their shape and predefined landmarks spatial adjacency matrix. The identified 3D anatomical landmarks and computed functional and reference axes (femur: neck axis, condylar axis, and long axis; tibia: tibial plateau axis, long axis, and malleolus axis) are used for measuring torsional deformation, using 3D shape reasoning algorithms. The methodology has been implemented in a software program and tested on five sets of CT scan images of lower limb. The computerized methodology is found to be fast and efficient, with reproducible results.**

Keywords — **anatomical landmarks, femoral torsion, tibial torsion, torsional deformities, virtual surgery planning**

I. Introduction

Anatomically deformed femur and tibia (secondary to trauma, congenital defects, prior surgery, etc) give significant challenges to orthopaedic surgeons [1]. This also changes the loading pattern [2] owing to the altered functional axes and distorted anatomic landmarks. Bone torsional deformity can be defined as the excessive anatomical or axial twist of proximal portion with respect to distal one. In case of femur (F), it is a projected angle of femur neck axis and femur condylar line on a plane, which is perpendicular to the longitudinal axis of the bone. This is measured as femoral anteversion or retroversion according to nature of the twist. In tibial bone, tibial torsion is measured as twist of the tibial plateau axis with respect to distal tibia malleolus line.

Torsional deformation has been studied, both in vivo and in dry bone, using a variety of techniques by various researchers. This leads to a wide range of reported femoral and tibial torsion values. The most accurate technique of assessment is by measuring the angle formed by the pins inserted in bone to represent the axes required to measure. However, this method cannot be used in vivo. The next best methods are based on diagnostic medical images, which give a good representation of the underlying anatomy [3]. In image based (2D) studies, various sources of images are used such as x-ray [4], ultrasonic [5], CT [6,7,3], and MRI [8]. In 3D studies, Kim et al [7] studied the femoral anteversion on a set of dry bones using CT data. The fundamental axes (neck axis, long axis, and condylar line) are estimated semi-automatically from the extracted edge coordinates. Liu et al [9] used interactively located landmarks on a digitized model for tibial torsion assessment.

In summary, estimating deformities is important in anatomical understanding for performing virtual surgery planning. 2D methods of measuring torsion using images suffer from inherited issues in various stages, such as (i) orientation of patient (ii) inexact abduction, flexion, and rotation of hip while scanning, (iii) selecting reliable 3D anatomical landmarks, and (iv) choosing best slice representing reference axis. It is difficult to estimate and represent complex 3D reference axes in a x-ray image or CT slice. There is a poor consensus concerning the optimal techniques for their clinical assessment [10]. Researchers have used varieties of axes and reference landmarks in measuring torsion with no established standard in defining them. None of the available methods are suitable for automatic assessment of anatomical deformations. Owing to the complex 3D shape of bones, there is a need for a 3D assessment method, which is simple, reliable, robust, and suitable for use in busy clinical environment.

II. Materials and methods

A. Computerized Methodology

Our objective is to accurately measure the torsional deformation of long bones of the lower limb. Each step of the proposed methodology is as follows:

*Algorithm: A*ssessment of torsional deformities
Input: A set of CT scan images of the lower limb
Output: Torsional deformation of the long bones

Procedure:
Step 1: Reconstruct 3D bone models from CT images
Step 2: Identify the required anatomical landmarks
Step 3: Compute medial axis of the long bones
Step 4: Segment the medial axis for computing axes
Step 5: Compute reference axes from the landmarks
Step 6: Measure torsional deformation by reference axes

The reference axes and centers which are needed to assess the torsional deformation are given in table 1.

Table 1 Reference axes

Axis	Terms	Axis	Terms
FNA	Femoral Neck Axis	TML	Tibial Malleolus Line
CL_F	Condylar Line of Femur	CL_T	Condylar Line of Tibia
LA_F	Longitudinal Axis of Femur	LA_F	Longitudinal Axis of Tibia

B. Reference Axes

Anatomical Landmarks: The required anatomical landmarks (Fig. 1) in computing reference axes include, on femur bone: medial and lateral epicondyles (ME and LE), most distal point of each (medial and lateral) condyle (MC and LC), and greater and lesser tronchater (GT and LT); on tibia bone: medial and lateral intercondylar tubercles (spines) (MT and LT), most medial and lateral points of tibial plateau (MP and LP), and medial and lateral malleolus (MM and LM). Anatomical landmarks are localized and identified based on their intrinsic geometric characteristics and spatial-adjacency (Fig. 4). It employs curvature derivatives (curvature gradient, peaks, ridges, pits, and ravines), as well as topology (relative position) of identified landmark regions [12].

Centre of the Femur Head (C_{FH}): The femur head is approximated into sphere from a set of profiles of the cortical bone extracted from CT images. These edge profiles are approximated to circular shape before used as a reference for fitting the sphere. Centre of sphere referred as the centre femur head.

Condylar Lines: Condylar line of the femur (CL_F) is defined as a connecting line between MC and LC landmarks. Condylar line of the tibia (CL_T) is defined as a line connecting MP and LP landmarks on the tibial plateau.

Malleolus Line (TML): A line connecting medial malleoli (MM) on tibia and lateral malleoli (LM) on fibula.

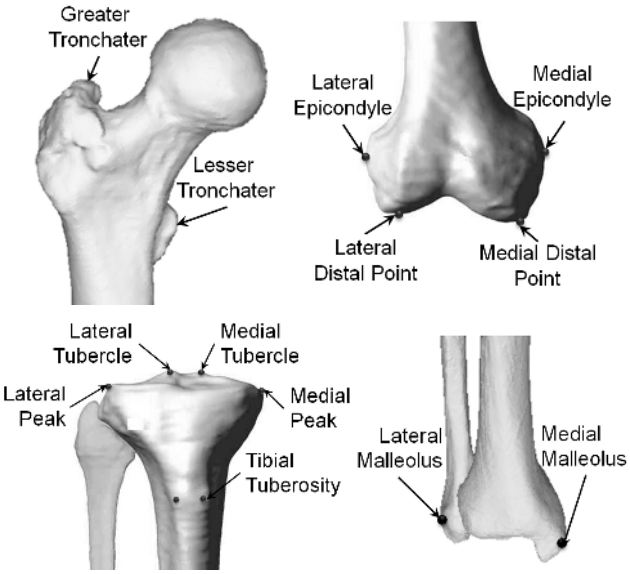

Fig. 1 Required anatomical landmarks on (a) proximal femur, (b) distal femur, (c) proximal tibia, and (d) distal tibia

Longitudinal or Anatomical Axis: This axis passes through the middle of the bone structure rather than connecting only end points. To compute LA_F, we used medial axis [12] of middle long portion (5/8) of the femur. The steps are

Step 1: Orient and divide the femur model into sections
Step 3: Compute medial axis for each section
Step 4: Collect the medial points of the long section
Step 5: Fit a best curve for localizing the axis

The same procedure is applied for computing longitudinal axis of tibia (LA_T) also.

Femoral Neck Axis: Medial axis of the top division (1/4) of the femur is used to establish the femoral neck axis (FNA). This is carried out by identifying a junction in medial axis.

C. Measurement of Torsional Deformation

Femoral Torsion: Three reference axes (FNA, CL_F, and LA_F) are required in computing femoral torsion. Due to the complex orientation, FNA and CL_F are projected on a plane perpendicular to the LA_F. The angle formed between these projected lines measured as femoral torsional angle (Fig. 2).

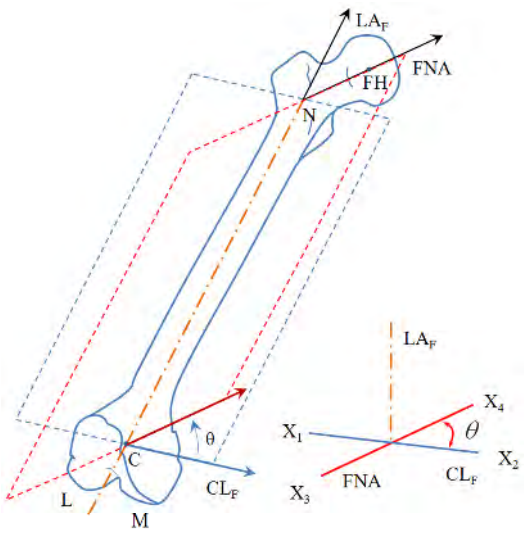

Fig. 2 Method of measuring femoral torsion

Tibial Torsion: Three reference axes (CL_T, TML and LA_T) are required in computing tibial torsion. TML and CL_T are projected on a plane perpendicular to the LA_T. The angle formed between these projected lines is measured as tibial torsional angle (Fig. 3).

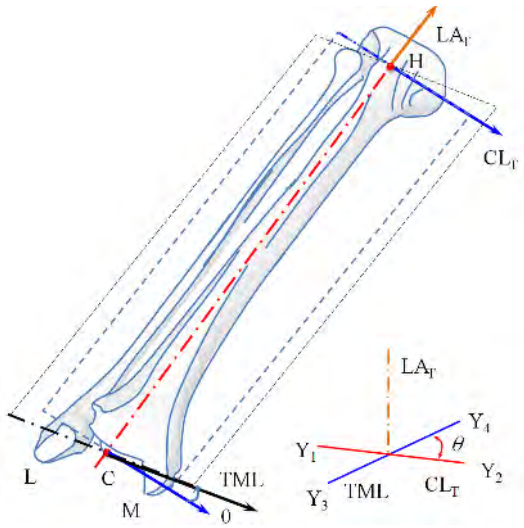

Fig. 3 Method of measuring tibial torsion

III. Implementation and Results

The results are presented here for a knee reconstructed from a set of 496 CT scan image slices (pixel size was 0.782 mm and slice thickness was 2 mm). The CT images were imported in DICOM format, followed by filtering and bony tissue segmentation; the 3D bone surface model is reconstructed in a lab-built 3D reconstruction software program. The reconstructed model's accuracy range with respect to the original model was 0.65 to1.95 mm [11]

Anatomical landmarks are identified on this triangulated surface model before dividing it for medial axis computation. Both landmarks (Fig. 4) and medial axis (Fig. 5) are used in establishing reference axes as explained in section II-B. Since the identified landmarks are on bone rather on body surface, errors caused by skin movement and patient's position during data acquisition are minimized. Each anatomical landmarks is referred in terms of the relative coordinates with respect to the coordinate system established for the corresponding bone. The anatomical landmarks are identified with the accuracy range of 2 to 6 mm [12].

Once the reference axes are established, measurement of torsional deformation is carried out as per the methods de-

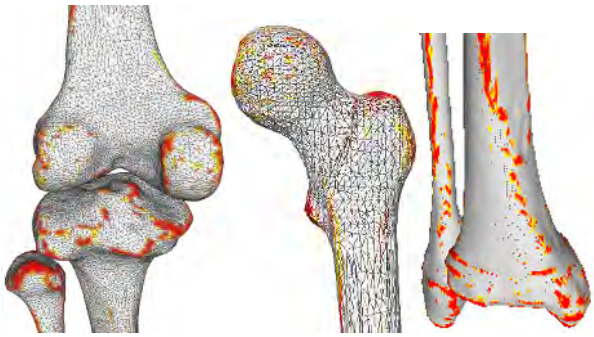

Fig. 4 Identified anatomical landmarks of femur and tibia bone

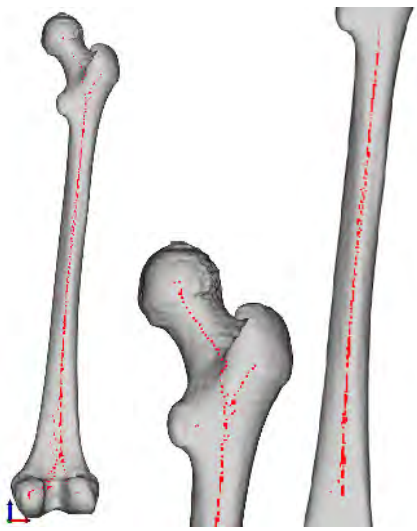

Fig. 5 Medial axis for reference axis (a) complete model, (b) for determining femur neck axis, and (c) for longitudinal axis of the femur

scribed in section II-C. Figure 6a and 6b show the measurement of the femoral and tibial torsion with reference axes and landmarks respectively. The measured femoral torsion was 12.8^0 (anteversion) and tibial torsion was 22.12^0.

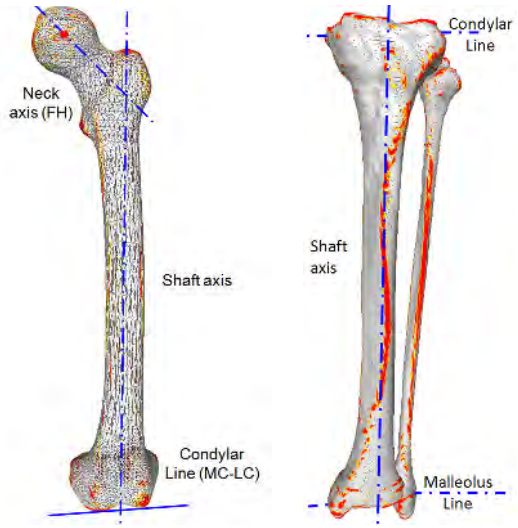

Fig. 6 Measurement of femoral and tibial torsion

Three sets of CT scan images were used in verifying the effectiveness of the proposed methodology. The measured femoral and torsional deformation angle are verified with respect to the angle obtained by manually placed reference axes on the same 3D reconstructed bone models. The deviation observed in femoral torsion was 1.98^0 to 3.13^0 and in tibial torsion was 2.12^0 to 2.89^0. Even though the sample lot is low in numbers to establish the relations, the results and accuracy obtained establish the superiority of the 3D based approach.

IV. Conclusions

This article presents a new methodology for assessing torsional deformities of long bones (femur and tibia) of the lower limb. The method ensures repeatability by the characterized anatomical landmarks (bone) and established reference axes (medial axis and landmarks referencing). The method offers automated, fast, and non-invasive measurement of torsional deformation. It works well where non-imaging methods (laser scanning and palpation) do not work; when anatomical landmarks are on bone rather on body surface. For example on obese patients, the required anatomical landmarks on legs are often not distinguishable from the surrounding subcutaneous fat.

Further work includes verification of reproducibility and accuracy with more data. We plan to use the measured deformation values in virtual surgery planning of total knee replacement and implant fixation analysis.

Abstract — **The electroencephalogram (EEG) and neonatal sleep analysis provide sensitive markers of brain maturation and developmental changes in term and preterm newborns. A new method for automatic sleep stages indication was developed. The procedure is based on processing of time profiles using adaptive segmentation and subsequent classification of extracted signal graphoelements. The time profiles, functions of the class membership in the course of time, reflect the dynamic EEG structure and may be used for indication of changes in the neonatal sleep. The method is able to detect the sleep stage changes even in preterm infants´ EEG.**

Keywords — **EEG, neonates, adaptive segmentation, profiles.**

I. Introduction

One of the most important indicators to study the maturation of the child brain is the electroencephalogram (EEG). Visual analysis of the EEG activity in newborns is a difficult and tedious task; a quantitative method of objective analysis is needed.

The critical evaluation of recent techniques of automated sleep analyses in neonatal neurointensive care units can be found in [1]. One of the first approaches to formalize the visual EEG analysis was a structural analysis of the EEG segments by hierarchical modeling of the EEG [2]. The pioneering work in the field of adaptive segmentation was done by Bodenstein and Praetorius [3]. For the segment boundary detection, the difference measure computed from fixed and moving windows was estimated. This prevents the multichannel adaptive segmentation from working independently in each channel. Barlow [4] was the first who applied the structural time profiles for description of tracé alternant and REM sleep patterns in the neonatal sleep EEG. The profiles were computed from one EEG channel and spectral and statistical parameters were computed from the segments without further analysis of the dynamic structure of the profile.

We have developed a new method for automatic sleep stages detection in neonatal EEG based on time profiles processing and modeling the sleep EEG microstructure using adaptive segmentation and cluster analysis. We have applied it to fullterm neonatal EEG [5], and tested it also on modeling the EEG of preterm infants. It is based on processing and smoothing of the temporal profiles. The purpose of the present study was to show, that the method is sufficiently sensitive to detect the sleep stages both in the EEG of the preterm and fullterm infants. The detection curve specification is based on adaptive segmentation, feature extraction and subsequent classification by cluster analysis. The resulting structural time profiles (temporal profiles) are further processed to reveal the sleep stages in preterm infant EEG. In fullterm EEG, sleep stages are reflected in compressed voltage graphs of the raw EEG, where the increased voltage during quiet sleep (QS) and decreased voltage during active sleep (AS) manifests itself in compressed time scale of 1-2 hours. This signal structure is not apparent in preterm neonates in postconception age (PCA) of 38 weeks and less and in the cases of abnormal recordings. So it is more suitable to use more advanced methods for hidden EEG structure disclosing. The automatic sleep stage detection is very desirable for functional brain maturation study in neonates, where sleep stages are determined by an expert visually. Further on, for objective quantitative analysis of the maturation of the child brain, we need the precise signal statistics [6]. Adaptive segmentation can contribute to this purpose by finding the instants of burst/interburst events and changes of signal stationarity. Both aforementioned tasks can be made by structural analysis of the EEG time profiles. The structural time profiles analysis can provide a unified approach both to the sleep state change detection and feature extraction and signal statistics computing. In some cases the method can reveal the hidden structure of the neonatal sleep EEG, which was not apparent in compressed time scale and therefore was very difficult to detect automatically. The alternative approach using both EEG and polygraphic channels is discussed in [7].

II. Material

Three groups of healthy sleeping newborns of different age (total 40 infants) were recorded in standard conditions

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 133–137, 2009
www.springerlink.com

with reference montage (linked ears) for 90-120 minutes. The postconceptial age (PCA) was 31-40 weeks. An experienced physician evaluated the records. He marked the periods of quiet sleep (QS) and active sleep (AS) by flags during visual inspection of the EEG recordings. The polygraphic channels were not used for the automatic analysis. The antialiasing bandpass filter (0.4 – 50 Hz) was used for signal conditioning. The typical periods of quiet and active sleep were marked by flags. Polygraphic channels were recorded, but not used in the signal analysis. The bipolar montage was used to eliminate the moving artefacts. The sampling frequency was 256 Hz for newer recordings and 128 Hz for the older ones.

III. Methods

The procedure is based on processing of time profiles computed by adaptive segmentation and subsequent feature extraction and classification of signal graphoelements

Adaptive segmentation: The used adaptive segmentation method is based on two connected windows that are sliding along the signal. The change of stationarity is indicated by local maxima of their difference measure (the difference of the mean amplitude and the mean frequency in the window). The threshold limits the small random fluctuations of the measure. This approach makes the multichannel adaptive segmentation working independently and simultaneously in all channels possible [8]. The algorithm divides the EEG signal into piece-wise stationary segments of variable length depending on the change of stationarity of the signal. The feature extraction from such relatively homogeneous epochs is more effective than from the fixed epochs. This holds especially true when analyzing such highly variable pattern as tracé alternant. The example of multichannel adaptive segmentation of the signal recorded during quiet and active sleep is shown in Figure 1.

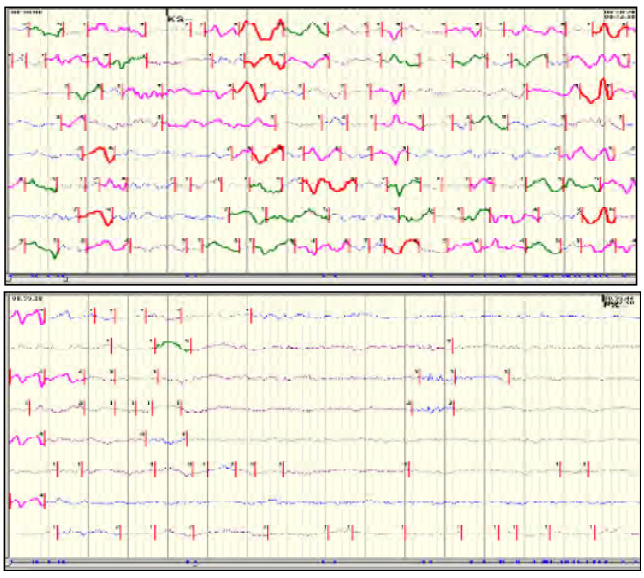

Fig. 1. Multichannel adaptive segmentation and classification. Quiet sleep (above), active sleep (below). Numbers indicate the segment labels - the class's membership. Vertical lines designate the segment boundaries.

Feature extraction: The EEG segments detected by adaptive segmentation were described by ten features: the amplitude variance, power in the frequency bands delta, theta, and alpha, mean frequency, first and second derivative of the signal [8].

Classification: The EEG segments characterized by the above features were classified into several classes by cluster analysis (k-means algorithm [9]). The classes were ordered by increasing value of amplitude. The example of classification of quiet and active sleep segments is shown in Fig. 1. The segments are designated by relevant class number and identified by different color directly in the real EEG recordings.

Multichannel temporal profiles:

The temporal profiles are the functions of the class membership in the course of time in relevant channels. They reflect the dynamic microstructure and the trends in EEG recordings; they represent a compressed schematic plot of the EEG signal (see Fig. 2). If computed from several channel derivations, they reflect also the topography of the EEG, and possible asymmetry [6]. In our case the 8 channel recording was used.

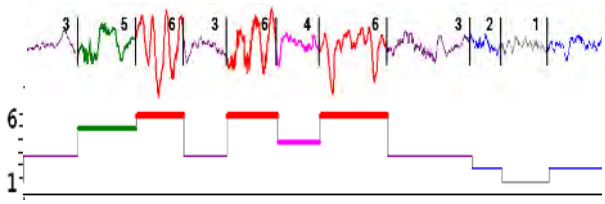

Fig. 2. The temporal profile – the class membership in the course of time (below). The corresponding EEG with segment membership identified by a color is above. The numbers denote the classes, vertical lines are the segment boundaries estimated by adaptive segmentation.

Algorithm: The processing of time profiles consists of the following steps (Fig. 3):

1. Multichannel time profiles were created by adaptive segmentation and cluster analysis.
2. Profiles were divided by vertical raster of the width WL_{Bin}.

3. The class membership was averaged in all channels into one curve. The moving average is computed in the window of length WL_{Mean}.
4. WL_{Mean} is subtracted from the averaged class membership and it is squared (variance of the class membership)
5. The resulting curve is smoothed by another MA (moving average) filter of the length WL_{Smooth}.
6. The sleep stage change is signaled by threshold crossing.

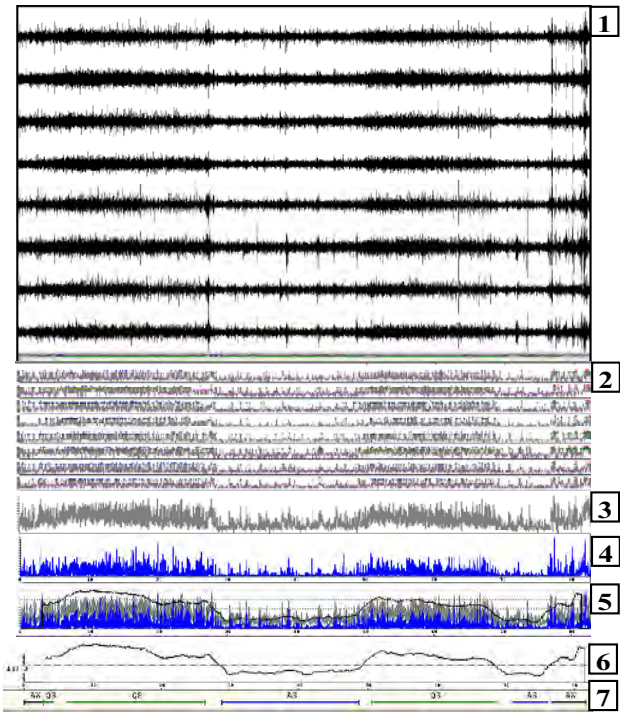

Fig. 3. The temporal profile computing and processing. 1-comprimed original EEG (80 min), 8 channels. 2-temporal profiles. 3-average of 8 profiles. 4-profiles variance (subtraction of the mean and squaring). 5-variance smoothing (solid black line). 6-sleep stages detection by threshold crossing. 7-visual evaluation by a physician (AW-awake, QS-quiet sleep, AS-active sleep). Full term neonate of 40 weeks PCA.

The length of MA filters was found experimentally. They differ for preterm and full term neonates (Tab.1).

Nevertheless, as soon as they were set (one set of values for one group with the same age, the other for the group of a different age), the parameters remain the same for each group (age must be known in advance). Another parameter which contributed to the detection curve smoothing was the width of the raster used for summing and averaging the class membership for each channel (WL_{Bin}). Its value was constant for all age groups.

Tab. 1. The parameter settings (window lengths) used for detection curve smoothing and the delay in transition resolution for step-like changes of the sleep stage for sampling frequency 256 Hz.

PCA (weeks)	31-38	>40
WL_{Mean}	80	5
WL_{Mean}	400	240
WL_{Bin}	100	100
Delay [sec]	156	93

IV. Results

The following picture shows the results of application of the described methods to neonatal EEG record. Above is the compressed EEG signal (80 min); below are the temporal profiles, under them are the curves corresponding to the steps 1-5 from Fig. 3. At the bottom is the final detection curve.

Artefacts cause the problems in the automatic EEG analysis. We show a simple method for artefact detection and elimination. The moving artefacts are classified into classes with highest value of amplitude feature. If we cut off the last classes exhibiting the highest amplitude values in temporal profile, and if we process the profiles without such grapholeements, the artefacts are eliminated and the quality of detection curve is improved. An example is shown in Fig. 4. In the original EEG there are amplitude artefacts in the

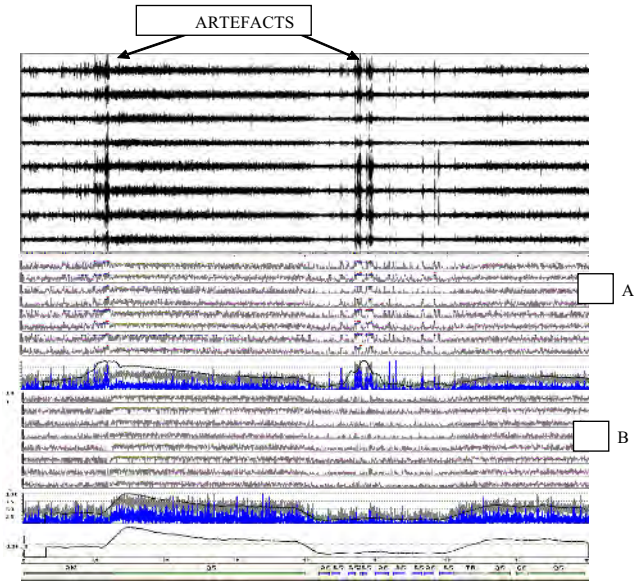

Fig. 4. Elimination of the artefacts by cutting the number of classes in the profile. The last three classes of total 14 containing artefacts were eliminated. They are not present in relevant profiles (B). A-original profiles, 14 classes. B-artefacts elimination, only 10 classes processed.

upper part of the picture. Below (4A) is the temporal profile with uncorrected class membership (14 classes). The artefacts signaled the false detection curve increase. If we use only the parts of the profile with the class membership less than 11, the noisy part of the profile (with the highest class membership containing artefacts) is eliminated (4B).

The results of computerized analysis compared with the visual evaluation are presented in Tab. 2. In most cases there was a good agreement. In some individual cases, the above mentioned artefact correction must be used. Two records of 32 postconception age neonates exhibit no visible changes in the detection curve.

Tab. 2. The three groups of neonates and the agreement with the visual evaluation. In the table the numbers of cases are presented.

PCA (weeks)	31-33	36-38	>40	Total / %
Number of records	10	13	17	40 [100,0%]
Agreement with expert	8	13	12	33 [82,5%]
Correction of artefacts	0	0	5	5 [12,5%]
Not possible to evaluate	2	0	0	2 [5,0%]

V. Discussion

Adaptive segmentation parameters

In all analyzed graphs the same adaptive segmentation parameters were used (window length 256 samples, segmentation threshold 0.5, and minimum length of segments 128 samples).

Optimal number of classes

The optimal number of classes was estimated with Bezdek´s criterium of validity for fuzzy c-means algorithm [10]. The optimal values were in the range of 12-18 classes both for term and preterm newborns.

Parameters for profiles processing

The only optional parameters for temporal profiles were the window lengths for detection curve creating and smoothing. The parameters were kept fixed during all experiments. It was very interesting (and it corresponds to our knowledge of the brain maturation), that we have to use two different sets of parameters for fullterm and preterm neonates. As soon as we selected the parameters, their values were kept constant within both groups.

The resolution of stages

The transition from one sleep stage to another is continuous, it does not occur abruptly. There is a question with what delay we are able to detect the step like changes in the detection curve. It depends on the width of relevant windows and it can be expressed as Delay = WL_{Bin}*WL_{Smooth}. Tab. 1 shows the values for the sampling frequency 256 Hz. The delay affects the initial part of the detection curve processing, and also the transition from one stage to another (Fig. 5).

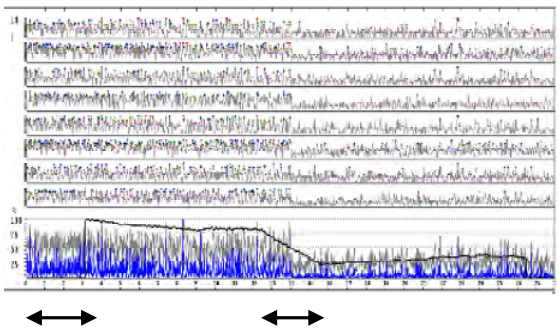

Fig. 5. The delays in stages resolution in the beginning of the signal and during the step-like change of sleep stage. 28 min, delay is 3 minutes (sampling frequency 128 Hz), window lengths are WL_{Bin} 100 samples and WL_{Smooth} is 240 samples.

VI. Conclusions

The examples proved a good ability of proposed methodology to model the sleep microstructure for groups of children of a different age ranging from 31 to 40 weeks of PCA, even for the cases, where the sleep transition was not evident in the original EEG records. The best results were observed for the newborns of 36-38 weeks of PCA. The older children (40 weeks) exhibited the structure of EEG stages too, but because of their activity, the EEG was more contaminated by movement artefacts. Nevertheless, the QS could be detected very reliably and also the transitions from QS to AS and vice versa were clearly visible. The age of children (the brain maturation) was reflected in values of parameters necessary for successful distinction of the sleep stages in the detection curve: there were two stable sets of parameters, one set for fullterms and another set for preterms. If the EEG analysis did not prove to be distinctive with the use of relevant parameter set, the consultation with the physician disclosed, that the EEG graph of the neonate was visually described as immature. The part of the methodology is also the extraction of quantitative parameters (segment boundaries detected by adaptive segmentation, features describing each segment) which reflect the differences between quiet and active sleep and related neonatal brain maturation.

Abstract — **The initial results of *in vivo* ^{23}Na magnetic resonance imaging (MRI) of the human torso at 3-Tesla using an 8-channel dual tuned ^{23}Na and ^{1}H transmit/receive coil for various body applications are presented. We are able to obtain ^{23}Na images of the human torso with 0.3 cm spatial resolution and ~ 20 SNR in ~15 min. These images were acquired with imaging parameters optimized under specific absorption rate limit for human scans. Because a trans-membrane sodium gradient is critical for cell survival, the ability to perform ^{23}Na MRI of the torso in clinical settings would be useful to non-invasively detect and diagnose a number of diseases of the liver, gallbladder, pancreas, kidney, spleen and other body organs.**

Keywords — **sodium, MRI, in vivo, SAR**

I. Introduction

Non-invasive sodium (^{23}Na) MRI has the ability to advance MR imaging beyond the routinely used proton (^{1}H) MRI because it can provide profound information about tissue physiology and metabolism at the cellular level. The motivation of ^{23}Na MRI is based on the fact that in certain diseased state, there is an increase in tissue [Na^+] due to interstitial and/or cytotoxic edema. Interstitial edema is caused by inflammation and vascular changes, and results in increased relative extracellular space where the Na^+ concentration is ~10 times higher than the intracellular concentration. Cytotoxic edema is caused by plasma membrane disruption and improper functioning of the Na^+-K^+ pump, and results in increased intracellular [Na^+]. The impact of ^{23}Na MRI has been overshadowed by existing technical difficulties when performing ^{23}Na MR scans. These difficulties arise from the inherent biological and MR properties of the ^{23}Na nucleus. Tissue ^{23}Na MR signal is ~10^{-4}-times weaker than the water signal because of its lower tissue concentration and MR receptivity compared to ^{1}H. In addition, ^{23}Na has very short transverse relaxation time (T_2: ~10 ms) which results in significant signal loss from excitation to imaging data acquisition. These properties of ^{23}Na translate to long image data acquisition times, limited spatial resolution and low signal-to-noise ratio (SNR).

Some of the areas that could be improved upon for obtaining better quality ^{23}Na MRI include: 1) increased main magnetic field strength 2) efficient RF coil design, and 3) pulse sequence and imaging protocol optimization. Our goal in this work was to enhance the quality of ^{23}Na MRI of the human torso using a 3-Tesla Siemens MR scanner and an 8-channel phase-arrayed dual tuned ^{23}Na and ^{1}H transmit (Tx)/receive (Rx) coil. A gradient-echo imaging sequence, commonly available on all clinical scanners, was optimized for the best possible combination of SNR, spatial resolution, and scan time without exceeding the US Food and Drug Administration (FDA) recommended specific absorption rate (SAR).

II. Methods

A. Coil design

The dual tuned ^{23}Na/^{1}H coil design for developing ^{23}Na imaging on Siemens 3T TIM Trio scanner was adapted from Lanz *et al*. [1]. The coil array consisted of two identical top and bottom plates (30 x 30 cm^2) as shown in Figure 1. The top plate was slightly curved to fit the curvature of the human torso. Each plate consisted of one ^{23}Na Tx loop and four ^{23}Na Rx elements that covered a field-of-view (FOV) of 20 x 24 cm^2. The two large Tx loops provided a relatively homogenous radio-frequency (RF) excitation and deep penetration, and the eight Rx elements provided a high filling-factor and SNR. Each coil plate also consisted a ^{1}H

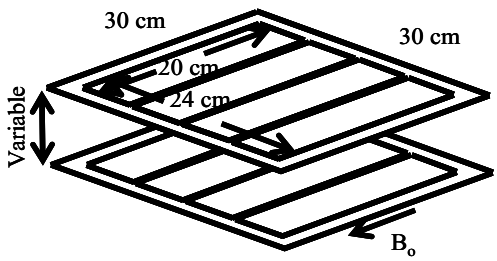

Fig. 1: Design of a dual tuned 8-channel ^{23}Na and ^{1}H Torso Coil.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 138–141, 2009
www.springerlink.com

Tx/Rx loop arranged around the ^{23}Na Rx arrays for ^{1}H MRI for co-registration purposes without having to use the inbuilt body coil. The flexibility to use the inbuilt body coil, when the 8-channel dual tuned ^{23}Na/^{1}H coil is plugged-in, was made possible by cable traps and detuning units. A number of low noise pre-amplifiers were also incorporated to reduce noise in the image.

Two sets of polyethylene tubes (Φ = 6 mm) filled with 150 mM NaCl were placed around the top and bottom ^{23}Na Rx elements covering 20 x 24 cm^2. These tubes served as fiduciary markers for co- registration purposes, signal intensity normalization and RF inhomogeneity correction.

B. Pulse sequence optimization

A 10 L plastic carboy filled with 50 mM sodium chloride (NaCl) was used for pulse sequence development and protocol optimization. A modified 3D gradient-echo sequence was used for acquiring trans-axial ^{23}Na images with the 8-channel dual tuned ^{23}Na/^{1}H coil. A very short echo time (TE) was used to minimize signal loss due to transverse relaxation. The short TE was achieved by using asymmetric echoes combined with volumetric interpolation. The minimum allowed receiver bandwidth (BW) was used to reduce the noise level. RF transmitter was calibrated by measuring ^{23}Na signal intensity as a function of transmitter voltage and a flip angle that matched the Ernst angle condition was used for achieving maximum SNR. Use of a short repetition time (TR) allowed collection of large number of signal averages over a reasonable time period. Elliptical acquisition was applied to further improve the SNR and to maintain the spatial resolution while reducing imaging time.

The 10 L phantom was imaged using both the 8-channel dual tuned ^{23}Na/^{1}H coil and the scanner's in-built body coil for SNR comparisons in the ^{1}H images. Trans-axial ^{1}H images were acquired using Half Fourier Acquisition Single Shot Turbo Spin Echo (HASTE) sequence with clinically approved and optimized parameters. The center of the slices for both ^{23}Na and ^{1}H images were matched for co-registration and further quantification.

Shimming of the magnet was done using the water ^{1}H signal prior to acquiring any MR images. An automatic 3D field map technique and manual shimming was employed to achieve the minimum full width half maximum (FWHM) for signal in frequency domain over the entire volume to improve SNR.

C. Specific Absorption Rate (SAR) evaluation of the coil for patient safety

SAR for the 8-channel dual tuned ^{23}Na/^{1}H coil was characterized using the FDA recognized 'Calorimetric Method' described in the National Electrical Manufacturers Association (NEMA) Standards [2]. The SAR measurements were performed at both ^{23}Na and ^{1}H frequencies using the optimized pulse sequence and imaging parameters as to be used for *in vivo* human imaging. The same phantom was used as used for pulse sequence optimization. 50 mM NaCl in the filling solution yielded a coil loading equivalent to that of a human. The phantom also contained 0.5 mM Omniscan Gadodiamide *(Nycomed Inc, Princeton, NJ)* to shorten the ^{1}H relaxation times. The phantom was wrapped in two layers of plastic sheet to avoid heat loss. A Digi-sense standard temperature controller with Type-T high temperature thermocouple probe *(Barnant Co., Barrinton, IL)* was used to measure the temperature of the phantom filler material. Accuracy of this temperature measuring device was 0.1 ˚C over -200 to 400 ˚C.

The phantom was equilibrated with the surrounding temperatures in the magnet bore for at least 2 hrs with fan in the scanner turned on. The initial temperature of the phantom (T_i) was noted using the temperature sensor. The phantom was then placed at the iso-center of the magnet for scanning. ^{23}Na and ^{1}H MRI sequences were run repeatedly for ~ 1 hr each to achieve a significant increase in temperature. The final temperature (T_f) of the phantom was noted after completing each of the ^{23}Na and ^{1}H scans. The energy, E (in joules), absorbed by the phantom of mass, M (in kilograms), and specific heat, c (in joules/ kg °C), was calculated using the equation: $E = M \times c \times (T_f - T_i)$. The average power, P (in watts), during the total scan time, τ (in seconds) was calculated using the equation: $P = E/\tau$. The SAR was calculated using the equation: SAR = P /M.

D. Feasibility studies for in vivo imaging

In vivo 3D ^{23}Na images of healthy volunteers were acquired using the 8-channel dual tuned ^{23}Na/^{1}H coil after obtaining informed consent. The subjects were positioned supine on the bottom plate of the coil with liver positioned in the centre of the coil. The curved top plate was placed at the top of the torso and aligned with the bottom plate using laser markers. No respiratory or cardiac gating was used.

3D trans-axial ^{23}Na images were acquired with the following optimized parameters: pulse sequence: FLASH, TR = 12 ms, TE = 2.81 ms, number of transits = 128, BW = 130 Hz/px, flip angle = 50°, data matrix = 128 ×128, FOV = 40 × 40 cm^2, number of slices = 12, slice thickness = 20 mm. Total imaging time was 14.15 min.

3D multi-slice ^{1}H images were acquired using the dual tuned ^{23}Na/^{1}H coil without moving the patient for anatomical comparison. The following imaging parameters were used: pulse sequence: HASTE, TR = 1000 ms, TE =

105 ms, number of transits = 1, slice orientation =trans-axial, data matrix = 512 × 512, FOV = 40 × 40 cm^2, number of slices = 24, slice thickness = 8 mm, and slice gap = 2 mm. Total imaging time was 1.25 min.

SNR for all images was estimated by dividing the average signal in a given region of interest (ROI) with the standard deviation of the background noise.

III. Results

^{1}H MR images of the 10 L NaCl phantom collected using the HASTE imaging sequence with the 8-channel $^{23}Na/^{1}H$ coil and the in-built body ^{1}H coil are compared in Figure 2. The 8-channel dual-tuned $^{23}Na/^{1}H$ coil gave approximately two times better average SNR than the in-built body coil. The 8-channel $^{23}Na/^{1}H$ coil also provided better shimming compared to the body coil with both automatic 3D phase mapping technique and manual adjustments of shim currents. ^{23}Na images of the same phantom collected using the 8-channel $^{23}Na/^{1}H$ coil with 3D FLASH imaging sequence and the optimized imaging parameters had an average SNR of ~20.

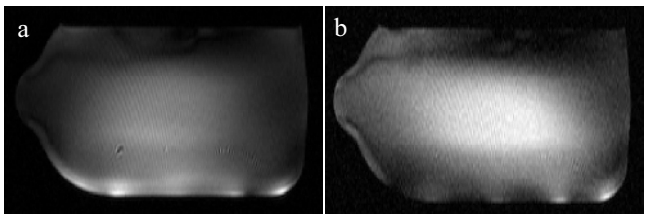

Fig. 2: Proton images of 10 L NaCl phantom acquired with (a) dual tuned 8-channel $^{23}Na/^{1}H$ coil and (b) in-built body coil for SNR comparisons

SAR measurements using the FDA recognized NEMA Standards "Calorimetric Method" showed that the 8-channel $^{23}Na/^{1}H$ coil produced a temperature increase of 1.1 °C during ^{23}Na MRI and 1.0 °C during ^{1}H MRI over one hour. These temperature changes correspond to an SAR of 1.1 W/kg at ^{23}Na frequency and 1.2 W/kg at ^{1}H frequency. The accuracy of the thermocouple used for measuring the phantom temperature was ±0.1°C. This accuracy introduced approximately 10% error in the SAR measurements. These experimentally determined SAR values are approximately one-fourth of the maximum safe SAR of 4 W/kg recommended by FDA for torso and head MRI.

The feasibility of acquiring ^{23}Na images of the human torso with the 8-channel $^{23}Na/^{1}H$ coil is shown in Figure 3. A series of representative trans-axial ^{23}Na and the corresponding ^{1}H images of the torso are shown in the figure. The left and right ventricles and the septum of the heart can be seen in the first slice of the ^{23}Na images. The ventricles appear hyper-intense in ^{23}Na MRI due to high $[Na^+]$ in the blood. The liver can be seen in slices 2-5 with relatively homogeneous signal intensity. The gallbladder is seen as a hyper-intense feature between the liver lobes in slices 5 and 6. The kidneys in the last three slices appear hyper-intense because of high $[Na^+]$ in the medulla. The vertebral canal and spine also show hyper-intense signal in all the slices due to high $[Na^+]$ in the cerebral spinal fluid. The in-plane resolution of the ^{23}Na images was 3.1 × 3.1 mm^2 and the average SNR in the image was ~ 20. The corresponding ^{1}H images collected for anatomical comparison had a resolution of 0.08 x 0.08 cm^2.

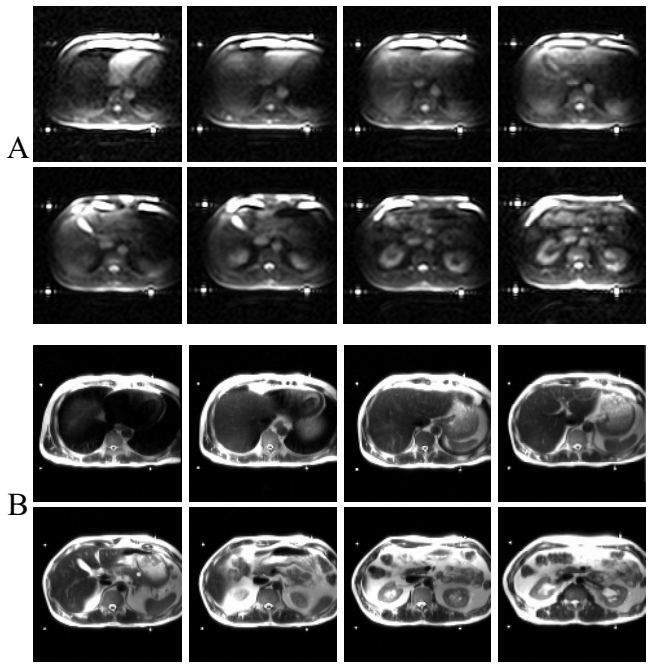

Fig. 3: Selected trans-axial ^{23}Na images (A) and the corresponding ^{1}H image (B) of a healthy volunteer acquired on the 3-T system using the 8-channel dual tuned $^{23}Na/^{1}H$ coil.

IV. Discussion

The ability to obtain *in vivo* ^{23}Na images of the torso at 3T using the 8-channel $^{23}Na/^{1}H$ coil appear very promising. These images were acquired in >15 minutes, a time period acceptable for clinical imaging. The images had reasonably good resolution and SNR considering that the ^{23}Na signal in tissue is ~10^{-4}-times weaker than the water ^{1}H signal. 3D imaging of the whole volume was employed for better coverage and for shorter imaging time since it aided in

reducing the TE considerably by allowing the use of a non-selective RF excitation pulse. The various changes made to the pulse sequence included the use of an asymmetric k-space sampling combined with volumetric interpolation, use of minimum allowed receiver BW, a flip angle that matched the Ernst angle condition and a short TR with large number of signal averages. The optimizations were done to the modified 3D GE pulse sequence to obtain ^{23}Na images with a maximum SNR.

For *in vivo* human imaging, the FDA recommends that the SAR should not exceed 8 W/kg in any gram of tissue (head or torso) and 4 W/kg averaged over the whole body. SAR is directly related to the square of RF amplitude (B_1). B_1 is inversely proportional to the gyro-magnetic ratio of the concerned nuclei. Therefore a ^{23}Na pulse would require four times more RF power than a ^{1}H nucleus. But SAR is also directly proportional to the square of frequency (ω^2). Due to a lower ω for ^{23}Na than ^{1}H, the SAR values computed for ^{23}Na and ^{1}H are almost identical [3]. The results of our SAR measurements show that the SAR values for ^{23}Na and ^{1}H MRI were 1.1 ± 1 and 1.2 ± 1 Watts/kg, respectively. These values are approximately one-fourth of the maximum safe SAR of 4 W/kg recommended by FDA. The heat deposition is expected to be less than 1.1-1.2 W/kg during *in vivo* ^{23}Na MRI experiments because of heat dissipation by blood flow and perfusion.

Though the efficient coil design with eight receive-elements allowed us to image a large torso region in all directions with optimum SNR, a significant B_1 inhomogeneity artifact was present in the images because the sensitivity of a coil decreases as a function of distance from the coil elements. There was an exponential drop in the signal intensity towards the centre of the image which made the central liver region appear darker (Figure 3). We plan to overcome this problem by applying RF field inhomogeneity corrections using fiduciary markers and a reference placed near the torso.

There are numerous possible applications of *in vivo* ^{23}Na MRI in the abdominal region. ^{23}Na MRI could be useful for detecting and assessing ischemic damage which results in an increase in intracellular [Na^+] [4]. It could aid in the diagnosis of hepatitis and cirrhosis which produce changes in intracellular [Na^+] and extracellular matrix structure [5]. ^{23}Na MRI may also prove useful for distinguishing between benign and malignant tumor since rapidly proliferating tumor cells are shown to have a high intracellular [Na^+] [6]. This technique could also be used for monitoring response to cancer therapy. ^{23}Na MRI is expected to be useful for the diagnosis of many acute and chronic renal diseases because the kidneys play a key role in maintaining the sodium homeostasis of the body. Thus, the feasibility of high-quality ^{23}Na MRI demonstrated here encourages us to develop ^{23}Na MRI for a wide range of clinical applications.

V. Conclusions

With 8-channel ^{23}Na/^{1}H coil and optimized imaging parameters, ^{23}Na MR images can be acquired with an in-plane spatial resolution of 0.3 cm and an SNR of ~20 within 15 min at 3T without exceeding the SAR limit for human imaging. The obtained ^{23}Na images allow clear delineation between different abdominal organs and their sub-regions. It is likely that this technique can yield useful information to study normal and abnormal physiology because of the great physiological significance of trans-membrane sodium gradient. The future area of development of ^{23}Na MRI would be focused on evaluating the use of the technique for disease diagnosis and monitoring therapy response.

Abstract — **An MR technique has been developed to administer controlled radiofrequency (RF) hyperthermia (HT) to treat sc-implanted tumors using an MR scanner and its components. The method uses the ^{1}H chemical shift of TmDOTA^{-} to monitor tumor temeprature non-invasively. The desired HT temeprature is achieved and maintained using a feedback loop mechanism that uses a proportional-derivative (PD) controller. The RF HT techqinue has been able to heat the tumor from 33 to 45 ˚C in ~ 10 min and was able to mainatain the tumor temeprature within ±0.2 °C of the target temperature. Simultaneous monitoring of the metabolic changes with RF HT using multinuclear MRS techniques showed a significant increase in the $[Na_i]^+$ as measured by TQF ^{23}Na MRS and a significant decrease in cellular bio-energetics and pH as measured by ^{31}P MRS.**

Keywords — **RF hyperthermia, MRI, sodium, pH, cellular energy**

I. Introduction

Radiofrequency (RF) hyperthermia (HT) in combination with radiotherapy or chemotherapy has been proved to be useful for treating some human cancers. In HT therapy, the temperature of a tumor is raised by few degrees (~ 42 - 45 ˚C) above the normal body temperature. HT can cause changes in cellular membrane permeability and ion exchange processes that could play a key role in cellular damage and death [1,2]. A magnetic resonance (MR) spectrometer that is equipped with RF system to excite spins enables an in-magnet HT application with simultaneous non-invasive temperature monitoring and control. Combining RF HT with multinuclear MR measurements enables investigation of metabolic and physiological effects of HT treatment on tumors.

Our goal in this work were: a) to develop a robust non-invasive method for delivering in-magnet controlled RF HT to subcutaneously- (sc-) implanted tumors using the same RF volume coil as used for MR data collection, and incorporate this RF HT technique with ^{23}Na and ^{31}P MR spectroscopy (MRS) data collection and b) to apply the developed controlled HT technique to monitor the effects of HT on total and intracellular Na^+ measured by single-quantum (SQ) and multiple-quantum-filtered (MQF) ^{23}Na MRS, and cellular energy status (ATP/P_i), and intra- and extra-cellular pH, (pH_i and pH_e, respectively) by ^{31}P MRS in sc-implanted 9L-glioma in rats.

II. Methods

A. In-magnet controlled RF HT during ^{23}Na and ^{31}P MRS

All MR experiments were performed on a Varian 9.4-T, 31 cm diameter horizontal bore scanner. A 20 mm diameter slotted tube resonator dual tuned to 400 MHz for ^{1}H, and either 106 MHz for ^{23}Na or 163 MHz for ^{31}P was used for MR data collection and heating. Initial development and testing was performed on a 2 ml bottle containing 2 mM TmDOTA^{-}, 10 mM sodium phosphate and 0.9% NaCl in 6% agarose gel. The temperature of the sample was derived from the ^{1}H chemical shift of TmDOTA^{-}. RF heating was irradiated at 400 MHz during ^{23}Na or ^{31}P MRS data collection. The phantom was initially heated at different constant RF power levels to obtain open loop temperature curves. These curves were used to model in-magnet RF heating in a simulation program designed to evaluate the optimum values for the proportional (K_p), integral (K_i) and derivative (K_d) constants for the proportional-intigral-derivative PID controller. The simulation program was developed in Simulink, Matlab 7.0 *(Math Works, MA)*. As shown in Fig 1 the program used a feedback loop mechanism to adjust the RF power, *u(t)*, based on the error between the target temperature and the current sample temperature, *e(t)*, using the following equation:

$$u(t+1) = u(t) + K_p e(t) + K_d \frac{de(t)}{dt} + K_i \int e(t)dt \qquad (1)$$

The following criteria were used for choosing the optimal values for K_p, K_i and K_d: (a) a rise time of >10-15 min to reach the target temperature, (b) a maximum overshoot of 0.5 °C, and (c) a maximum settling time of 5 min after achieving the target temperature.

After optimizing the PID controller with computer simulations, the controller was implemented on the Varian MR scanner and tested using the same phantom and dual tuned volume coil as used for the open loop curves. ^{1}H and

www.springerlink.com

^{23}Na or ^{31}P spectra were continuously collected during the heating experiment. The RF power was set to a maximum of 33 watts and modulated between 0 to 4095 DAC (digital-to-analog) units. The PID controller constants were set to the optimal values as determined from simulation results.

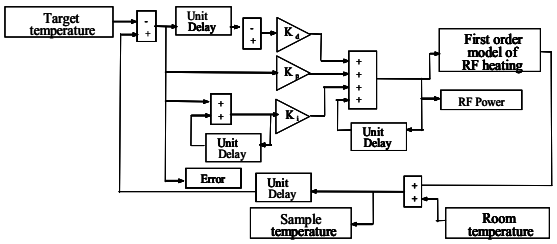

Fig 1 Block diagram of a PID controller for maintaining tumor temperature during RF HT

B. Controlled Hyperthermia with MR Thermometry and Metabolic Measurements

The above in-magnet controlled RF HT technique combined with ^{23}Na and ^{31}P MRS data collection was applied to investigate the effects of HT (45° for 30 min) on [Na_t^+] and [Na_i^+], cellular energy status (ATP/P_i), pH_i and pH_e in sc-implanted 9L tumors before, during and after HT treatment.

9L glioma cells (4 x 10^6) were subcutaneously implanted and grown in Fisher rats that were 6 weeks of age (70-135 g). The tumors were grown to ~2 cc before they were used for MR experiments. A nephrectomy was performed to avoid renal clearance of $TmDOTA^-$ during imaging experiments. A jugular vein was cannulated through a midline neck incision to inject 3-4 ml of 100 mM $TmDOTA^-$ prior to the MR experiments. A rectal fiber-optic probe (FOP) was inserted to monitor core body temperature. The rat was positioned on the cradle and the tumor was placed inside the 20 mm diameter slotted tube resonator through a copper tape placed above the coil to avoid contamination from muscles around the tumor. A pneumatic pillow sensor *(SA Instruments Inc., NY)* was placed under the animal for monitoring respiration during the MR experiments. The whole set up with the cradle was then positioned inside the horizontal bore magnet. The animal core body temperature was maintained at ~35 °C by blowing warm air with a commercial hair dryer into the magnet bore.

The protocols for ^{23}Na and ^{31}P MR data collection during in-magnet controlled RF HT experiments are shown in Fig 2. After baseline data collection, the RF power was turned on at 400 MHz during ^{23}Na or ^{31}P data collection. The target temperature was set to 45 °C and the PID controller was set to the optimal values determined from computer simulations. The RF heating was turned off after 30 min of HT and the tumor temperature was allowed to return to the baseline temperature. The heating and cooling rate constants were estimated using exponential fitting equations using PSI Plot *(Poly Software International, UT)*. The thermal dose at 43 ˚C *(tdm_{43})* in degree-minutes (°C min) was calculated from the time interval, Δt, initial temperature, T_0, and the average temperature, T_{av}, during Δt [3].

a. Effect of HT on SQ and MQF ^{23}Na MRS

A 1 ml vial containing 500 mM NaCl and 2.5 mM $TmDOTP^{5-}$ in 10 % agarose gel was placed inside the dual tuned ^{1}H/^{23}Na coil and used as a SQ and TQF ^{23}Na signal reference. $TmDOTP^{5-}$ was used to shift the reference ^{23}Na signal away from the tumor signal and agarose was used to generate a TQF ^{23}Na signal from the reference. ^{23}Na MRS data were collected at 106 MHz using a 170 μs excitation pulse followed by an acquisition of 1,000 data points over a spectral width of 5 kHz. The data collection time for a SQ ^{23}Na spectrum was 13 sec and that for a TQF ^{23}Na spectrum was 1 min and 24 sec.

^{23}Na SQ and TQF spectra were transferred to and processed with NMR Utility Transform Software (*NUTS-Acorn NMR, CA*). ^{23}Na free-induction decays (FIDs) were

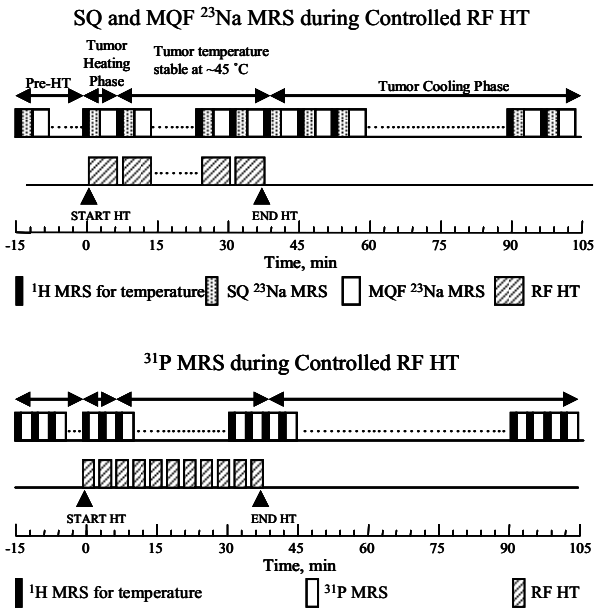

Fig 2 Experimental protocols for SQ and MQF ^{23}Na (top) and ^{31}P (bottom) MRS data collection during controlled RF HT

baseline corrected and multiplied by a single exponential corresponding to 10 Hz line broadening and Fourier transformed. The signal intensities in ^{23}Na SQ and TQF tumor and reference peaks were determined by integration.

b. Effect of HT on pH_i, pH_e and cellular energy status

^{31}P MRS experiments were performed on separate group of rats. Effects of HT on pH_i, pH_e and cellular energy status (ATP/P_i) in 9L-glioma were examined before, during, and after HT treatment.

The animals were prepared for ^{31}P MRS experiments in a similar manner as described previously except a solution containing 75 mM 3-aminopropylphosphonate (3-APP) and 100 mM $TmDOTA^-$ was infused through the jugular vein. ^{31}P signal from 3-APP was used for monitoring the pH_e. A 1 ml vial containing 100 mM methyl-phosphonic acid (MPA) was placed inside the dual tuned $^1H/^{31}P$ coil and used as a ^{31}P signal reference. The protocol for ^{31}P MRS data collection during controlled RF HT and temperature monitoring was similar to that used for ^{23}Na experiments as shown in Fig 2. ^{31}P MRS data was collected at 165 MHz using a 100 μs excitation pulse followed by an acquisition of 4,000 data points over a spectral width of 20 kHz. The total data collection time for each ^{31}P spectrum was 1 min and 11 s.

After data acquisition, four sets of ^{31}P spectra were added together to obtain a better SNR and quantification. ^{31}P FIDs were baseline corrected and multiplied by a single exponential corresponding to 25 Hz line broadening and Fourier transformed. The various signal intensities from the corresponding peaks on ^{31}P spectra were determined by integration. pH_i was estimated using the chemical shift of P_i signal referenced to α-ATP signal [4]. pH_e was calculated from the shift of 3-APP signal referenced to α-ATP.

III. Results

The PID based temperature controller simulation yielded optimal values K_p = 1000, K_d = 1000, and K_i = 0. The controlled RF HT technique was able to heat the phantom from 30 to 45 °C in ~10 min and maintain the phantom temperature at 45.0 ± 0.1 °C for over 60 minutes.

The feasibility of controlling and maintaining the temperature in sc-implanted tumors using the PID controller is shown in Fig 3. The tumor temperature was raised from 33.7 to 45.0 °C in about 10-15 minutes. After the target temperature was achieved, the RF heating power was adjusted automatically as per Eq. 1 to maintain the tumor temperature at 45.0 °C. The RF power varied between 4095 and 2717 DAC units during heating. The rise time for heating the tumor was slightly longer than that for the phantom due to heat dissipation by blood. In spite of this, the PID controller was able to maintain the tumor temperature at 44.9° ± 0.2 °C. After 30 minutes of HT, the RF power was turned off and the tumor returned to its baseline temperature (33.4 °C) in ~ 1 hr. The average cooling rate constant was estimated to be 16.9 ± 3.4 min. The tumor tdm_{43} was estimated to be 57 ± 2 min. The rectal temperature was 35 ± 1 °C throughout the experiment including during the HT treatment.

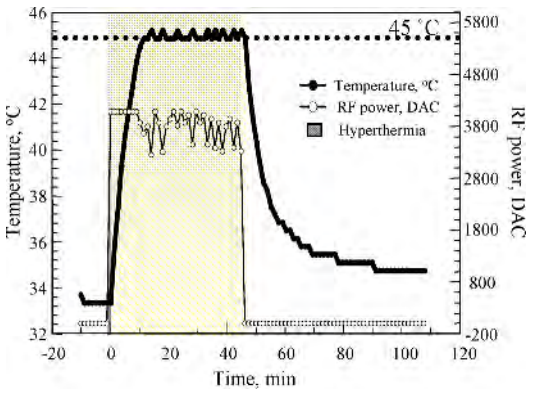

Fig 3 Changes in heating RF power level and tumor temperatures during controlled HT with the PID controller

Relative changes in SQ and TQF ^{23}Na signal intensity averaged for all the tumors (n = 5) are shown in Fig 4A. Controlled RF HT produced a gradual increase in both SQ and TQF ^{23}Na SI. There was a 30-40 % increase in TQF ^{23}Na SI compared to only a 12% increase in SQ ^{23}Na SI. TQF ^{23}Na SI continued to increase even after the heating was stopped and tumor temperature returned to the baseline value.

Effects of HT in pH_i and pH_e, and relative ATP/P_i from ^{31}P spectra averaged for all the tumors are shown in Fig 4B and C respectively. Prior to HT, the tumor pH_i and pH_e were 7.08 ± 0.10 and 6.89 ± 0.05, respectively. This trans-membrane pH gradient in the tumor is opposite to that seen in normal tissues which have a pH_i of 7.1 and a pH_e of 7.3-7.4. As the tumor temperature increased with the onset of HT, pH_i decreased by ~0.2 units ($p \leq 0.05$) but then returned back to the normal value within 15 minutes during HT. pH_i remained at the baseline value during the remaining experimental period including the post HT period. pH_e decreased by ~0.15 units ($p \leq 0.05$) with onset of HT, but 10-12 min after the decrease in pH_i. pH_e remained decreased during the HT period but gradually returned back to the baseline value (6.9 ± 0.1) when the

heating was turned off. ATP/P_i decreased by 40% ($p \leq 0.05$) during HT and remained depressed after HT.

IV. Discussion

We have been able to develop an in-magnet controlled RF HT technique using the following features: 1) RF HT was delivered using the same RF coil and MR system hardware as used for exciting the nuclear spins. 2) The tumor temperature was monitored from the ^{1}H chemical shifts of $TmDOTA^-$, which are 50-100 times more sensitive to temperature than water ^{1}H signal. 3) The tumor temperature was maintained within ±0.2 °C of the target temperature with an integrated PD controller based RF heating technique 4) ^{23}Na MRS or ^{31}P MRS data were collected consecutively with ^{1}H MRS data collection during controlled RF HT for monitoring the metabolic and physiological effects of the treatment. Among all the NMR parameters that were simultaneously monitored with RF HT in the sc-implanted tumors, Na_i^+ signal intensity and cellular bioenergetics were the most sensitive to temperature. The dramatic increase in TQF ^{23}Na SI suggests that HT causes an increase in [Na_i^+]. The initial increase in [Na_i^+] during HT may be a metabolic response to heating. This increase may result from 1) a decrease in the activity of Na^+/K^+-ATPase due to reduced cellular ATP levels or 2) an increase in the activity of Na^+/H^+ antiporter which helps maintain pH_i. The continued late increase in [Na_i^+] after HT may result from cellular membrane damage leading to potential cell death.

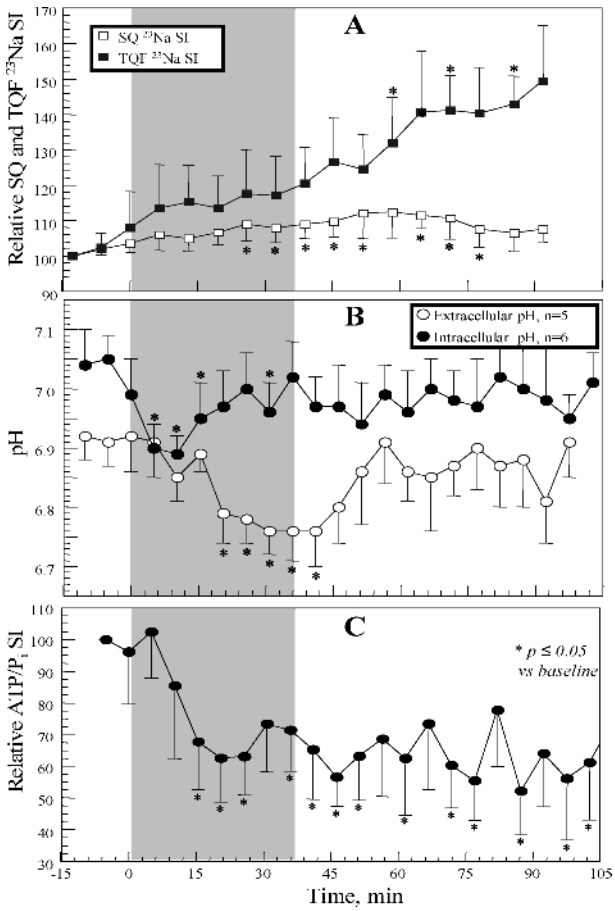

Fig 4 Effekts of HT on A) Na_i^+ as measured from SQ and Na_i^+ as measured from TQF ^{23}Na signal intensity, B) pH_i and pH_e and C) ATP/P_i measured from ^{31}P MRS

Decrease in the ATP/P_i suggests a compromised cellular energy metabolism which could reduce the activity of Na^+/K^+-ATPase and lead to an increase in [Na_i^+]. The decrease in pH_i can also increase the activity of Na^+/H^+ antiporter to maintain cellular pH homeostasis. This explains the initial drop in pH_i followed by its recovery during HT and a consecutive decrease in pH_e. In summary, the data presented show that HT causes a marked increase in [Na_i^+] in sc-implanted 9L glioma due to both a decrease in cellular energy status and increased acid production.

V. Conclusions

The above presented PD based RF HT technique, using an MR scanner for both RF HT application and MR data acquisition provides a robust non-invasive method for delivering controlled RF HT to sc-implanted tumors in-magnet using the same RF volume coil as used for MR data collection. Simultaneous measurements of sodium and cellular energetics during HT treatment show that ^{23}Na and ^{31}P will prove very useful for monitoring therapy responses during HT treatment. The *in vivo* tumor data presented show that HT causes a dramatic increase in [Na_i^+] due to significant decreases in cellular ATP and pH.

Abstract — **In this paper, we present a series of algorithms for dealing with artifacts in electroencephalograms (EEG), electrooculograms (EOG) and electromyograms (EMG). The aim is to apply artifact correction whenever possible in order to lose a minimum of data, and to identify the remaining artifacts so as not take them into account during the sleep stage classification. Nine procedures were implemented to minimize cardiac interference and slow ondulations, and to detect muscle artifacts, failing electrode, 50/60Hz main interference, saturations, highlights abrupt transitions, EOG interferences and artifacts in EOG. Detection methods were developed in the time domain as well as in the frequency domain, using adjustable parameters. A database of 20 excerpts of polysomnographic sleep recordings scored in artifacts by an expert was available for developing (excerpts 1 to 10) and testing (excerpts 11 to 20) the automatic artifact detection algorithms. We obtained a global agreement rate of 96.06%, with sensitivity and specificity of 83.67% and 96.47% respectively.**

Keywords — **Artifacts processing, EEG, EOG, EMG, ECG.**

I. Introduction

While trying to automatically classify sleep stages, one is generally faced with the problem of artifacts. Indeed, artifacts contained in the analyzed polysomnographic signals introduce spurious components during features extraction, which lead to incorrect interpretation of the results [1]. Dealing with artifacts is therefore mandatory before any other classification operation.

In the literature, three main approaches have been proposed to detect and correct them. The first approach is based on autoregressive modeling [2, 3, 4] and is used for two purposes: (i) estimating the recorded EEG and identifies transient events like muscle or movement artifacts by locating the abrupt variations of the parameters; (ii) removing artifact from the EEG by estimating the parameters of the mathematical model that describe the recorded EEG as an overlap of the real EEG and the artifact interference.

The second approach uses standard voltage thresholds (overflow check) [4-5]. While these thresholds can sometimes be fixed (e.g 50µV), it is univocally accepted that using values related to the energy distribution of the signal in the frequency or time domain is preferable since voltage levels can strongly vary between subjects and recordings.

Finally, some authors investigated the use of independent component analysis (ICA) to remove the artifacts [6-7]. Unfortunately, their methods often required many EEG channels and implied to visually select the origin of the interference among estimated sources.

In the present study, we introduce algorithms for processing artifacts on EEG, EOG and EMG which are suitable for automatic sleep stages classification. The strategy is to imitate human behavior by locating the short duration artifacts so as to ignore them during the feature extraction stage of sleep stage classification.

However, cardiac interferences and slow undulations (e.g caused by breath interferences or by sweat) could not be processed using this strategy because these artifacts can last several hours. This is why we also developed two artifact correction algorithms in order to minimize the loss of data.

Nine procedures were finally implemented to remove cardiac interference and slow ondulations, and to detect muscle artifacts, failing electrode, 50/60Hz main interference, saturations, highlights abrupt transitions, EOG interferences and artifacts in EOG.

The performances of the algorithms were evaluated on a database of 20 polysomnographic sleep recordings scored in artifacts by an expert.

II. Materials and methods

A. Data

Data used in this study were recorded at the Sleep Laboratory of the André Vésale hospital (Montigny-le-Tilleul, Belgium). They are composed of 20 excerpts of 15 minutes-long polysomnographic (PSG) sleep recordings carried out during the night. The recordings were taken from 20 patients (15 males and 5 females aged between 31 and 73) with different pathologies (dysomnia, restless legs syndrome, insomnia, apnoea/hypopnoea syndrome). The sampling rates were 50, 100 and 200Hz. The 20 excerpts were visually examined by an expert to identify the various artifacts. Then they were separated into two groups for devel-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 146–150, 2009
www.springerlink.com

oping (excerpts 1 to 10) and testing (excerpts 11 to 20) the automatic artifact detection algorithms.

B. Artifacts detection/correction processes

Two procedures were developed to minimize cardiac interference and slow ondulations (*P1-P2*) and seven other procedures were implemented to indentify the remaining short artifacts (*P3-P9*). These detection algorithms operate on fixed length epochs (1.25 second by default). They are mainly binary: if any of the parameters exceeds the corresponding threshold, the epoch is marked as an artifact. As the signal energy distribution in the frequency or time domain varies strongly between subjects, we have chosen thresholds relative to the statistical properties of the considered signal. For example:

$$threshold = mean(EEG) + k * std(EEG)$$

where k is a factor of proportionality and *std* is the standard deviation.

The various procedures are the following (for more details, see *http://tcts.fpms.ac.be/publications/techreports/DEA_sd.pdf*):

P1. Cardiac interference detection and correction on EEG (Atf_cardE) and on EOG (Atf_cardO). The basis of the method for removing cardiac interference was presented in [8]. It is based on a modification of the independent component analysis algorithm which gives promising results while only using a single-channel EEG (or EOG) and the ECG.

P2. Slow ondulations detection and correction on EEG (Atf_ondE) and on EOG (Atf_ondO). Slow ondulation artifacts are generally due to breathing or sweating. Their frequencies are lower than those of the slowest waves of the sleep (rhythm delta). Therefore, their extraction can be realized by a simple filtering, with cut-off frequency adjusted to the smallest frequency of the delta band.

P3. Saturations detection on EEG (Atf_satE), on EOG (Atf_satO) and on EMG (Atf_satM). The basic idea of this procedure is to locate epochs where the EEG signal remains at its maximal value of saturation during a sufficient time.

P4. Unusual increase of EEG detection (Atf_highE). These artifacts can for example be caused by EOG interferences. If the amplitude of the EEG signal exceeds a first threshold for any of the epochs, the onset and the offset of the artifact are researched. These are defined as the instant after which the amplitude of the EEG becomes lower than a second threshold (lower than the first threshold). Then the corresponding epochs are marked as artifact epochs.

*P5. Failing electrode detection on EEG (Atf_noE) and on EOG (Atf_noO).*This procedure locates the relatively constant amplitude (near to zero) of the signals EEG or EOG. Such artifacts are sometimes obtained at the end of the nights when the electrodes are disconnected.

P6. Highlights abrupt transitions detection on EEG (Atf_transE). Highlights abrupt transitions such as spikes are identified by locating slopes above some threshold. Let

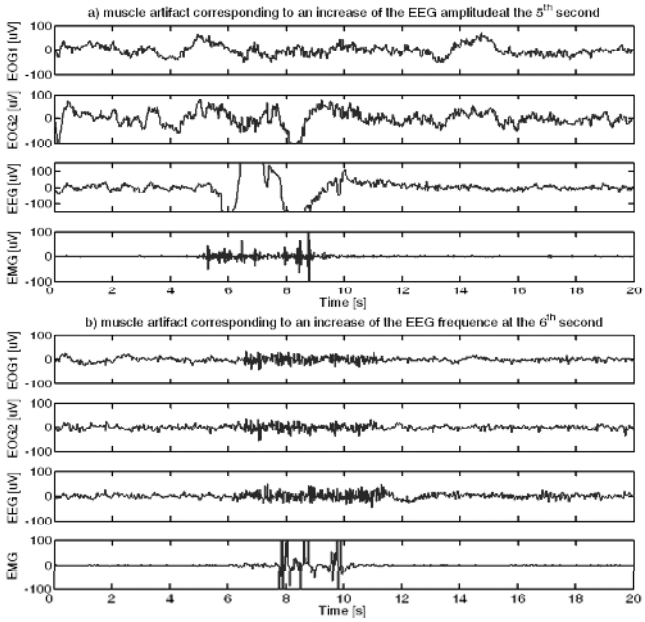

Fig. 1 Examples of muscle or movement artifacts

us note that epileptic spikes are not actually artifacts (since they have no artificial origin), but they can nonetheless obstruct the sleep stage classification. This is why we identified them as the artifacts.

P7. 50/60Hz mains interferences detection on EEG (Atf_50E). This interference network can easily be detected given the evident peak which takes place around 50Hz (or 60Hz) on the Fourier transform.

P8. Muscle or movement artifacts detection on EEG (Atf_mvtE). This algorithm detects temporary increase of muscular tone accompanied by disturbances on the EEG. These disturbances are of two types: they can be either a voltage increase as illustrated on Fig 1a. , or a change of rhythm of the EEG activity such as illustrated on Fig 1b.

P9. Detection of artifacts in EOG constituted of in-phase movements (Atf_phaseO). As the ocular movements are binocular and synchronous, the EOG recordings should appear in opposition of phase while placing electrodes on the lateral canthi and by using the same reference on the mastoid. The ocular artifacts are therefore easily identifiable since they correspond to in-phase movements of the EOG.

III. Results

A. Content of the artifact database

On the basis of the artifact scoring carried out by the expert, we first examined the content of the database in terms of short duration artifacts (Table 1).

Table 1 content of the artifact database based on the visual artifact scoring

Code	Type	Number of seconds	%
P3-a	Saturations of EEG (Atf_satE)	0	0
P3-b	Saturations of EOG (Atf_satO)	0	0
P3-c	Saturations of EMG (Atf_satM)	0	0
P4	Unusual increases of EEG (Atf_highE)	639,180	3,551
P5-a	Failing electrode on EEG (Atf_noE)	118,610	0,659
P5-b	Failing electrode on EOG (Atf_noO)	118,520	0,658
P6	Highlights abrupt transitions of EEG (Atf_transE)	46,790	0,260
P7	50/60Hz on EEG (Atf_50E)	23,980	0,133
P8	Muscle or movement artifacts on EEG (Atf_mvtE)	494,600	2,748
P9	artifacts in EOG (Atf_phaseO)	566,270	3,146
O-a	Other artifacts on EEG	129,73	0,72
O-b	Other artifacts on EOG	6,190	0,034
	All short artifacts on EEG	1014,930	5,639
	All short artifacts on EOG	690,980	3,839
	All short artifacts on EMG	0,000	0,000

The difference between the total duration of all short artifacts on EEG and the sum of durations of each type of artifact on this signal (P3-a+P4+P5a+P6+P7+P8) is due to the presence of multiple artifacts in some epochs.

As it can be seen, 5.64% of the total EEG recorded time contains artifacts. Among those, most frequent artifacts are "unusual increase of EEG" followed by "artifacts in EOG" and then "Muscle or movement artifacts".

No "saturation" artifact was found in the database. We therefore used other polysomnographic signals to tune the parameters of this procedure. These signals were not scored by the expert but simply examined visually by the authors.

B. Results of the minimization procedures

The ECG artifact removal procedure was previously tested on 10 excerpts of polysomnographic sleep recordings containing ECG artifacts and other typical artifacts [8]. It was shown that it is robust to various waveforms of cardiac interference and to the presence of other artifacts. Two hundred successive interference peaks of each of these excerpts were visually examined to compute the number of corrected peaks. We found a correction rate of 91.1%.

The removal of slow ondulations artifacts was only checked visually by the expert. It seems that the artifact can be well corrected without distorting the EEG, as it can be seen in Fig 2.

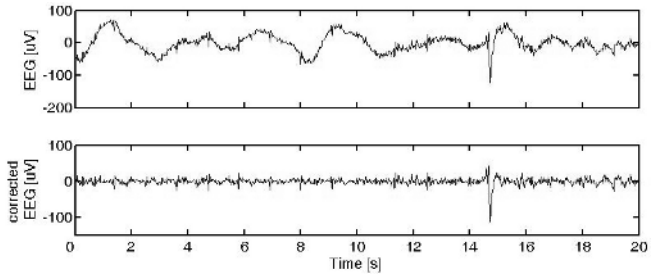

Fig. 2 Removal of slow ondulations artifacts on EEG

C. Results of the detection procedures

Concerning the short duration artifacts, the concordance between the expert scoring and the automatic detection procedures with the default thresholds, was examined as follows: 1) a true positive (TP) was counted when an artifact was automatically detected in an epoch also marked as an artifact by the expert, 2) a false positive (FP) when an artifact was automatically detected in an epoch classed as non-artifact by the expert, 3) a true negative (TN) when no artifact was detected neither automatically nor visually by the expert, 4) a false negative (FN) when no artifact was automatically detected in an epoch marked as artifact by the expert.

Then we computed the *agreement rate= (TP+TN)/(TP+TN+FP+FN)*, the *sensitivity=TP/(TP+FN)* and the *specificity=TN/(TN+FP)*.

The results obtained for each detection procedure on the central EEG are exposed in Fig 3, as well as the global results of the detection of any artifacts on this EEG. The results corresponding to the EOGs and the EMG are shown on Fig 4. If an artifact is not present (according to the expert) in the training database, the sensitivity figure has no sense. That is why we indicated it by an asterisk (*).

As it can be seen, the procedures corresponding to the more frequent artifacts (i.e. unusual increase of EEG, artifacts in phase on EOG and Muscle artifacts) are unfortunately those which have the lowest sensitivities. However, as a whole, the results show an acceptable agreement between our package of software and the human scoring with agreement rates of 92.18%, 95.98% and 100% respectively on the EEG, EOG and EMG. Without making distinction between the various signals, these results correspond to a

global agreement rate of 96.06%, a global sensitivity of 83.67% and a global specificity of 96.47%.

Finally, by varying the length of the analysis epoch from 1.25s to 1s, we observed that it introduced only little changes in the expert/software concordance (agreement rate = 96.46%, sensitivity = 82.33% and specificity =96.90%).

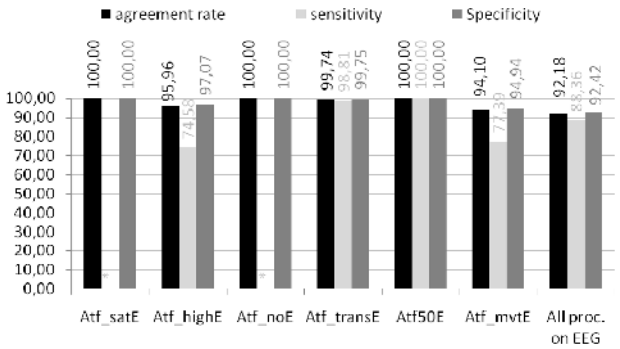

Fig. 3 Results of the detection procedure on the central EEG

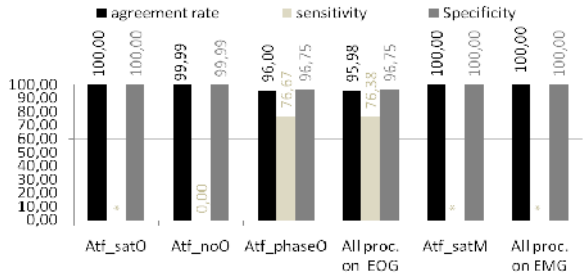

Fig. 4 Results of the detection procedure on the EEGs and on the EMG

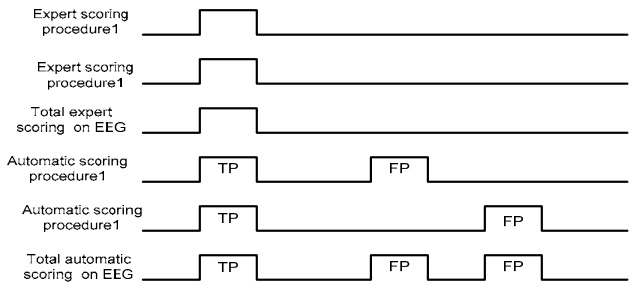

Fig. 5 Illustrative example of detection process

IV. Discussion

By looking at the Fig 3, one could be surprised of obtaining a total rate of agreement on the EEG of only 92.18% whereas each separate procedure has a higher agreement rate. Actually, this is due to the fact that false positives (FP) introduced by the various algorithms are not always located at the same place, while true positives (TP) are sometimes detected at the same epochs (fig 5). There is thus an increase in FP (proportionally to the number of TP) in the global detection on EEG. This explains why the total agreement rate is lower, while sensitivity is slightly modified and sensitivity is not affected. Fortunately, the number of epochs classified as non-artifact remains sufficient for feature extraction and sleep stage classification.

V. Conclusions

In conclusion, our findings showed that the proposed artifact minimization procedures and detection algorithms (although rather simple since they are mainly binary) are reliable in a context of classification in sleep stage classification. Indeed they give promising and repeatable results (agreement rate = 96.06%, sensitivity = 83.67% and specificity =96.47%) without requiring any human intervention.

The approach has however some limitations: (i) it is running on epochs of fixed length rather than locating the actual onset and offset of the artifacts. However using fixed length epochs dramatically simplifies the algorithm and the remaining part of signal is generally sufficient for the sleep stage classification. (ii) Although the parameters are calculated according to the statistical properties of the signal, their values (once determined) remain unchanged for all the duration of the recording. This can be can be inappropriate in sleep recording with fluctuation of tonicity level. The use of adaptive threshold rather than absolute threshold could then be investigated in future works.

Abstract — **Nowadays Medical Imaging has an increasing need in patient treatment ,not only it aids physicians in determining the correct diagnosis but also it reduces overall cost and speedup treatment plans .Medical Image Registration is a vital medical imaging application it aligns one image to another ,to obtain a registered image has the information content of both images .**

Our paper purpose is to provide a literature of Medical image registration methods based on Mutual Information, showing implementation techniques ,challenges ,and optimization approaches ,Mutual Information have been shown to be accurate and robust similarity measure at registering images specially for multimodal images taken from different imaging devices and/or modalities .

Keywords — **Image Registration, Image fusion, Mutual Information**

I. Introduction

Image Registration is the process of determining the optimal spatial transformation that brings at least two images into alignment with each other [1], Often in image processing, images must be spatially aligned in order to perform quantitative analyses of the images .Image registration applications grows daily ,it is used in computer vision, pattern recognition, target identification, remote sensing, and medicine (the focus of the current research).

*Transformation or warping function***:** This is the function used to warp the sensed image to take the geometry of the reference image. ***T (x A) = x B*** .

In choosing the transformation function ,and registration method or similarity metric ,we shall consider set of image characteristics such as [2] :

- Dimensionality 2D/3D .
- Transformation Domain (Global Vs Local).
- Transformation Type(Rigid-Affine-Curved-Projective).
- Subject of registration (Head-Knee-Heart-etc.).
- Image Modality(CT ,MR ,PET ,etc.).
- Extrinsic Vs Intrinsic features, in Extrinsic methods other objects are added to image to detect features like(using frames on patient brain),while Intrinsic methods extract and operates on image features like (edges, curves , Intensity values).

Fully automated algorithms based on Intensity similarity measures have been shown to be accurate and robust at registering images compared to feature based methods, Registration process works to find the optimal spatial and intensity transformations function so that the images are matched using a similarity measure between both images.

The choice of an image similarity measure depends on the nature of the images to be registered. Common examples of image similarity measures include Cross-Correlation, Mutual Information, Mean-square difference and Ratio Image Uniformity. Mutual Information and its variant, Normalized Mutual Information, are the most popular image similarity measures for registration of multimodality images. Cross correlation, Mean-square difference and Ratio Image Uniformity are commonly used for registration of images of the same modality.

Collignon [3],and Viola [4] proposed A widely used Intensity based similarity measure which is Mutual Information (MI). Registration based on mutual information is robust and data independent and could be used for a large class of mono-modality and multimodality images. This method requires estimating joint histogram of the two images. As a result, it requires an extremely high computation time. This is its main drawback ,another implementation challenges are local extrema ,and image noise which may a rise because of interpolation during registration process.

This paper illustrates Mutual Information based registration approach ,Section II, demonstrates methodology of Mutual Information technique(MI) ,concept ,properties ,and framework ,Section III discuss implementation issues and suggested optimization techniques, Section IV compares between some MI registration, finally our conclusion .

II. METHOD

A. Mutual Information image based Registration

Mutual information (MI) is usually used to measure the statistical dependence between two random variables, or the amount of information that one variable contains about the other. The method applies mutual information to measure the information redundancy between the intensities of corresponding Intensity in both images, which is assumed to be maximal if the images are geometrically aligned.

There exist many important technical issues to be solved about the method such as how to compute MI more accurately and how to obtain the maximization of MI. There are some implementation issues, for example, sub sampling, interpolation, outlier strategy. The combination of these computation techniques and searching strategy leads to a fast and accurate multi-modality image registration.

B. Entropy and Mutual Information

Let: X be a random variable (R.V) , P(X) be the probability distribution of X , p(x) be the probability density of X. Then The entropy of X, H(X) is defined by:

$$H(X) = -E_X[\ \log(P(X))\ ] \quad (1)$$

The joint entropy is a statistics that summarizes the degree of dependence of a RV X on an other RV Y. It is defined by:

$$H(X,Y) = -E_X\ [E_Y\ [\ \log(P(X,Y))\ ]\ ] \quad (2)$$

Entropy is a measure of randomness. The more random a variable is, the more entropy it will have.

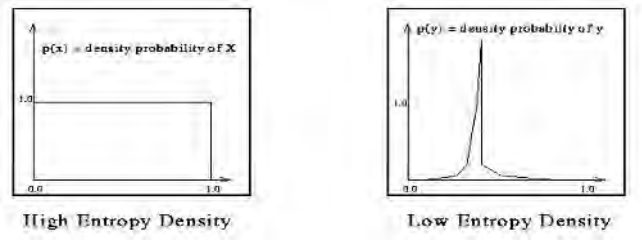

Fig.1 relation between Entropy ,and probability

The conditional entropy is a statistics that summarizes the randomness of Y given knowledge of X. It is defined by:

$$H(Y|X) = -E_X\ [E_Y\ [\ \log(P(Y|X))\ ]\ ] \quad (3)$$

Two random variables are considered to be independent if:

$$H(X,Y) = H(X) + H(Y) \quad (4)$$

The Mutual Information, MI, between two random variables X and Y is given by: [5]

$$MI(X,Y) = H(Y) - H(Y|X) = H(X) + H(Y) - H(X,Y) \quad (5)$$

Maximizing the mutual information is equivalent to minimizing the joint entropy . Advantage in using mutual information over joint entropy is it includes the individual input's entropy Works better than simply joint entropy in regions of image background (low contrast) .

C. Some Properties of Mutual Information[6]

- Mutual Information is symmetric: $I(X,Y) = I(Y,X)$ (6)
- $I(X,X) = H(X)$ (7)
- $I(X,Y) <= H(X)$, $I(X,Y) <= H(Y)$ (8)
  information each image contains about the other can not be greater than the information they contain about themselves.
- $I(X,Y) >= 0$ Cannot increase uncertainty in X by knowing Y ,If X,Y are independent then $I(X,Y)=0$ (9)

D. Normalized Mutual Information as a similarity measure

Mutual information depends on the overlapping region between registered images ,that a small overlapping area reduces the number of samples, which affects the probability distribution estimation. Image Registration can be seen as an optimization problem to find a cost function and then use an optimization method to get its minimum. Normalized mutual information is less sensitive to changes in overlapping region ,Its calculation is based on the joint histogram of the fixed and transformed moving images[7].

$$NMI(X,Y) = (H(X) + H(Y))\ /\ H(X,Y)\ . \quad (10)$$

Normalized measure proved better results for rigid registration of MR-CT and MR-PET images.

E. Mutual Information Registration framework

Image registration is performed on two or more images, The source or reference image is the image to which all the others will be registered., while The remaining images are referred to as target images. Registration problem is to find the optimal spatial and intensity transformations function so that the images are matched .

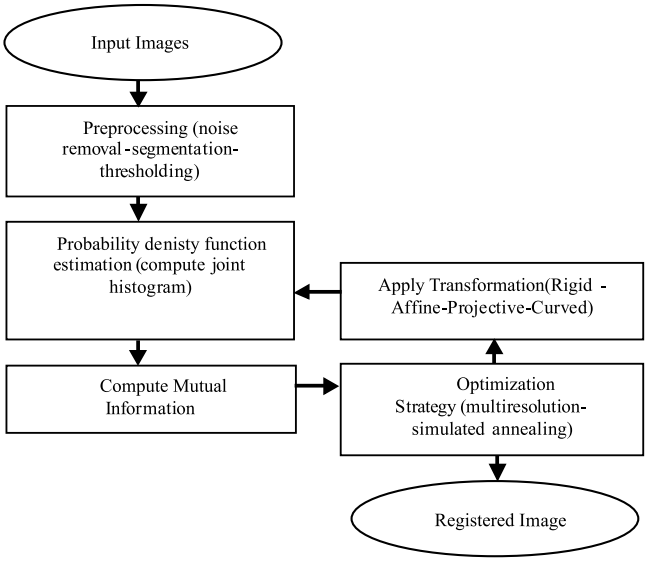

Fig.2 Mutual Information Registration Framework

III. Discussion

Mutual Information based registration use image gray values to create joint histogram between source and target images based on image nature we shall compromise between choosing suitable method to create joint histogram, generally mutual information proposed approaches may be classified into three approaches which are Probability Density Estimation ,Interpolation ,and Optimization approaches.

Probability Density Estimation

Computes the joint histogram h(X,Y) of images .Each entry is the number of times an intensity X in one image corresponds to an intensity Y in the other image, The discrete joint histogram does not allow the cost function to be explicitly differentiated, so it can only use non-gradient based optimization methods, such as Powell's method, to seek the minimum .a parzen-window based method is proposed to estimate the continuous joint histogram in order to make it possible to derive [7] . The distribution is approximated by a weighted sum of sample points Sx and Sy ,The weighting is a Gaussian window Interpolation.

$$P(x, y, Sx, Sy) = \frac{1}{N}\sum_{S} W(Dist(x, y; Sx, Sy)) \quad (11)$$

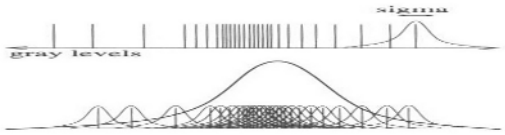

Fig.3 Parzen Window sub sampling

Interpolation

Interpolation is used to estimate gray values of one of the images at positions other than the grid points. grid lines for 2D images may be aligned along that dimension under certain geometric transformations. Therefore, fewer interpolations are needed to estimate the joint histogram of these two images than in the case that none of the grid planes are aligned. It is dependent on the image transformation. One of challenges is local extrema it impedes the registration optimization process. More importantly, they rule out registration accuracy.

Optimization

Generally Registration using mutual information is considered maximization problem ,Genetic algorithm(GA)is not suitable in our case because it does not avoid local maxima which may occur in Mutual information registration .

Current methods of multimodal image registration usually seek to maximize the similarity measure of mutual information (MI) between two images over their region of overlap Registration is achieved by adjustment of the relative position and orientation until the mutual information between the images is maximized .Additionally ,stochastic approximation may be used The main disadvantage of Mutual information is that it is known to be highly non-convex as a result a local maxima may occur .

Registration by maximization of mutual information

In it we seek an estimate of the transformation T that registers the reference image *u* and test image *v* by maximizing their mutual information.

$$T = \arg\max I(u(x), v(T(x))) \quad (12)$$

For optimization, a multi-resolution approach based on the Gaussian Pyramid representation may be used .Rough estimates of T can be found using down sampled images and treated as starting values for optimization at higher resolutions. Then the fine-tuning of the solution can be derived at the original image resolution [8].

local region-of-interest image registration

Mutual information-based methods may be used to improve local region-of-interest (ROI)image registration ,in some cases a diagnostician is more concerned with registration over specific (ROI). A main challenge when using small regions have limited statistics and thus poor estimates of entropies.

Maximization of Gradient Code of Mutual Information

Use pixel gradient information rather than pixel intensity, and simulated annealing to reduce next search space, combined with hill climbing method [9] .

Expectation Maximization Algorithm[10]

Solves registration of partial or missing data, by applying simultaneous segmentation and registration. is used to resolve this circular estimator, and proceeds as follows:

- E-step: compute the weights w (with an initial estimate of from the solution of smoothing
- M-step: estimate the model parameters, (rotation-translation).
- Repeat steps 1 and 2 until the difference between successive estimates of is below a specified threshold.
- The E-step is the segmentation stage, where pixels that do not have a corresponding match between source, and target images have a close to zero weight These pixels are given less consideration in the M-step which estimates the registration parameters. The EM algorithm allows for simultaneous segmentation and registration, and hence allows us to contend with missing data .

IV. Results

We applied Mutual Information based Registration using different techniques and applied it on different cases taken from different modalities , representing different objects of body ,the following table shows the error ,and time obtained for each case ,our results showed that Mutual information had proved better accuracy .

Mutual Information requires iterative technique ,and may have more than one iteration ,one of the disadvantages is local maxima which may occur in interpolation for example in second case had taken longer time and gave lower accuracy compared to Expectation maximization algorithm , optimization techniques applied to mutual information differ focused on increasing registration accuracy ,reduce time via sampling for example ,and try to avoid local maxima, one of the remarked causes of local maxima is noise ,and image has low resolution ,which tried to be solved in some techniques like Expectation Maximization algorithm to smooth intensity ,and segment regions of missing data or noise resident in images before applying registration phase .

Table 1 Experimental Results

Item	Mutual Information	Interpo-lation	Expectation maximiza-tion

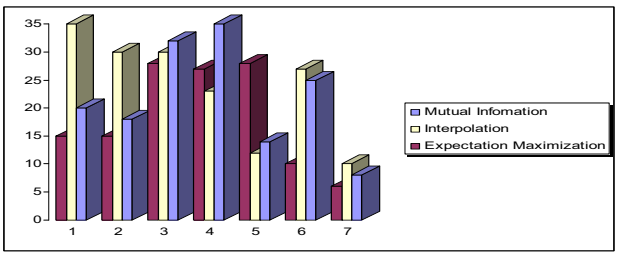

Fig.4 Comparison between time of 7 cases using Standard Mutual Information(MI), and using MI with Interpolation, and finally Information Expectation Maximization

V. Conclusion

Intensity based methods using mutual information as a similarity measure are robust accurate ,and invariant. Theoretically, these are the most flexible of registration methods, since they unlike all other methods do not start with reducing the grey valued image to relatively sparse extracted information, but use all of the available information throughout the registration process .An

increasing clinical call for accurate and retrospective registration, along with the development of ever-faster computers with large internal memories, have enabled full-image-content methods to be used in clinical practice.

A Feasibility Study of Commercially Available Audio Transducers in ABR Studies

A. De Silva, M. Schier

Sensory Neuroscience Laboratory, Faculty of Life & Social Sciences, Swinburne University of Technology, Melbourne, Australia

Abstract — **Among numerous sources of electrical interference, stimulus artifact produced by the audio transducer (typically headphones or earphones) affects the features of an auditory Brainstem Response (ABR). At high stimulus intensities, artifacts may create a serious problem because they extend into the time frame of the ABR. The stimulus artifact depends upon the type of transducer and the electrode arrangements used. At present, expensive and complex methods are being employed to eliminate this problem.**

This paper presents data recorded from a phantom head and human participants with two of the most common electrode arrangements to investigate the artifacts produced by different audio transducers. Additionally, the quality of the ABR produced by each transducer was studied through absolute latencies of wave I, II, III and V. Several commercially available audio transducers were tested, including supra-aural, circum-aural, ear-bud and in-ear transducer types with moving coil (dynamic) technology. For the point of comparison, standard TDH-49 and TDH-39 headphones for ABR studies were also used.

Our results indicate that in general, the artifact present in commercially available audio transducers is of a similar level to that with the standard headphones. The quality of the ABRs produced using these audio transducers at a high intensity level were found to be normal. However, with some responses, small aberrations were noticed. We thus describe a method to benchmark new audio devices before using them in practice.

Keywords — **Auditory brainstem response (ABR), audio transducer, stimulus artifact, phantom.**

I. Introduction

The Auditory Brainstem Response (ABR) consists of a series of potentials recorded from the human scalp generated by the brainstem in response to a brief auditory stimulation. This signal is used to assess the conduction through the auditory pathway to midbrain. Among different stimulus methods, the 'click' stimulus is widely used because of its broad frequency spectrum. The high frequencies affect the basal end of the cochlea and the low frequencies affect the apical end of the cochlea. Thus 'click' stimuli' provide ample information to the clinician to assess the functionality of the auditory pathway of a patient [1].

The normal ABR recording window is 15 ms with 10% of it dedicated to pre-stimulus time to record spontaneous electroencephalographic (EEG) activity. The amplitude of ABR potentials are in the range of tenths of a microvolt, and thus susceptible to electrical noise from other physiological signals and from external devices. To avoid contamination, care should be taken with the recording environment and with the equipment used. They should produce minimal noise to avoid interference with the ABR signal.

The major source of external noise at the point of stimulation is from the audio transducer which will result in a 'stimulus artifact'. Stimulus artifact is generated when the electromagnetic field produced by the audio transducer interacts with the electrodes placed on the scalp. The electrode and instrumentation which are fine tuned to pickup small ABRs could easily record this noise and suppress early components of the ABR.

In common clinical ABR measurements, headphones (that fit over the head) are used as the audio transducer, although in 1994 earphones (that fit into the ear) have been tested as a stimulation device by Yoshiko [2].

To minimize the impact of the stimulus artifact, two frequently applied methods are:

1. The use of mu-metal shielded headphones
2. The use of audio couplers, to create a distance between the head phone and the scalp electrodes [3]

Due to the cost and complexity of these methods, it is worthwhile to examine cheaper and less complicated audio transducers that will produce minimal stimulus artifacts with little or no impact on the ABR.

This paper compares results from several types of audio transducers to determine their suitability for use in ABR studies as substitutes for the more expensive and complicated transducers.

The testing includes two stages involving a phantom scalp on a realistic shaped head; and then using human participants. These two stages included two different electrode arrangements to find out the minimum impact of the magnetic field created.

II. Methods and equipment

A. Selection of audio transducers

Eight audio transducers of moving coil technology were tested in this study. Their specifications are summarised in

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 156–160, 2009
www.springerlink.com

Table 1. As the TDH-49 and TDH-39 headphones are commonly used in ABR recordings, they were considered as the standard for comparison purposes.

Table 1 Description of the audio transducers used

Model	Type	Description
TDH-49p	Supra-aural Headphones	Telephonics ™ (Audiometer)
TDH-39	Supra-aural Headphones	Telephonics™ Voyager 522
Qantas™	Earphones	Comfort kit (Entertainment)
Panasonic™	Earphones	RQ-E27V (Entertainment)

B. Experimental Design

The two approaches to measure the effect of stimulus artifact from audio transducers were carried out using:

1. A phantom head
2. Human participants

The phantom head was used to examine the actual stimulus artifact produced without the complication of any physiological potential or current sources. Then the same audio transducers were tested on human participants to analyse the total effect.

The amount of noise generated depends upon the position of electrodes with reference to the orientation of this potential. Therefore two electrode arrangements were tested for each audio transducer. One with non-inverting at the vertex (C_z), inverting at right earlobe (A_2), and ground at forehead (F_{pz}); the other with the inverting at right mastoid (M_2).

Four healthy human participants (two male and two female) were involved in this study with an age range of 24 – 26 years. The participants gave their written informed consent in accordance with University Human Experimentation Ethics requirements.

C. Equipment

A polystyrene phantom head was used with dimensions similar to an average human head. Electrodes were placed on this phantom scalp at the locations described in the previous section.

Simulating the inter-electrode impedances was the aim of constructing a conductive phantom scalp. A series combination of resistors and capacitors was used in between electrodes on the phantom scalp [8]. All the impedances were measured using GW Digital LCR meter at 100 Hz.

A gel-injected disk electrode was used at C_z and 3M® disposable electrodes were used at A_2, M_2 and F_{pz}. All these had silver chloride surfaces. PowerLab™ amplifiers and Chart-5 by ADInstruments™ was used to record data. Custom written Matlab® scripts were used for offline analysis.

D. Technical conditions

A rarefaction 'click stimulus' was used with a 0.1 ms pulse width (negative polarity) at a repetition frequency of 21.1 Hz. This rate was used to match the standard experimental protocol and to produce comparable data with Table 2 [3, 4].

ABRs were sampled at a frequency of 40 kHz with a band-pass filter of 10-5000 Hz. An intensity of 80 dB SPL was maintained for each audio transducer output, by adjusting the amplitude of the stimulus, regardless of the impedance of the audio transducer used.

E. Analysis methods

The human and phantom data were analysed according to the following criteria:

1. Comparison of the stimulus artifact end time (SAET) of each audio transducer with respect to measured ABR wave I. This will determine the extent of effect of stimulus artifact on ABR waves.
2. Comparison of absolute latency of waves I, II, III and V with published data to determine the quality of ABRs.
3. Comparison of the earlobe and mastoid electrode arrangements for SAET and ABR wave latencies to determine electrode arrangement with minimum impact.

III. Results

Impedance measurements obtained using the phantom and human scalp are tabulated in Table 3. This clearly indicates that the model used reflects the actual scalp conductive properties, thus data obtained from the phantom are comparable to human scalp data.

Table 3 Inter-electrode impedance measurements (at 100 Hz)

	Resistance (kΩ)	Capacitance (μF)	n
Phantom	3.1	3	16
Human scalp	3.0 ± 1.4	2.3 ± 0.9	32

Fig. 1 shows the ABRs obtained by a randomly selected participant using each audio transducer listed in Table 1. The bar under each recording shows the SAET. The SAET was determined by waiting until the value of the signal returned to within 1 standard deviation of the pre-stimulus baseline.

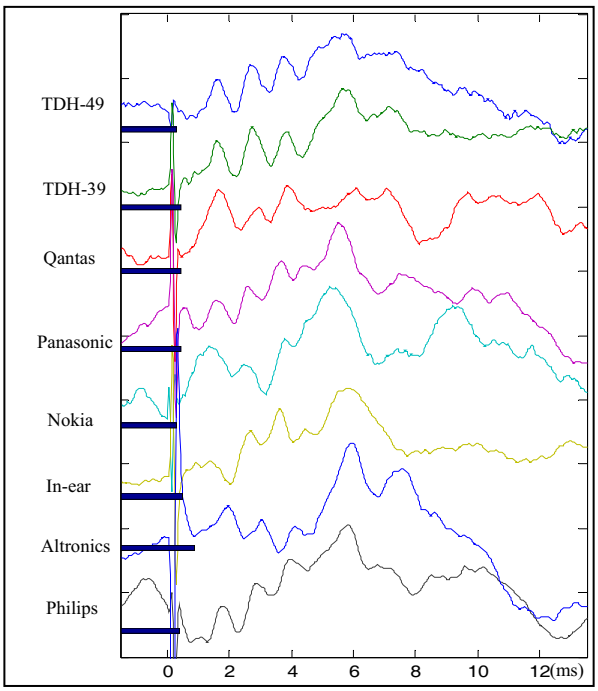

Fig. 1 ABRs of a selected participant using 8 different audio transducers (vertical axis) with the earlobe electrode arrangement. Each ABR shown is an average of 1024 epochs. The stimulus artifact is at t=0. The horizontal bars show the SAET for each audio transducer.

Fig. 2 illustrates the SAET obtained using the phantom and the participants with inverting electrode at earlobe. These values are categorized according to the audio transducer used on the vertical axis.

Fig. 3 shows the mean and the standard deviation of the absolute latencies of ABR waves I, II, III and V obtained from 4 participants, with inverting electrode at earlobe. The width of shaded vertical bars indicates the ranges in which each wave should occur. These ranges were determined using published data in Table 2.

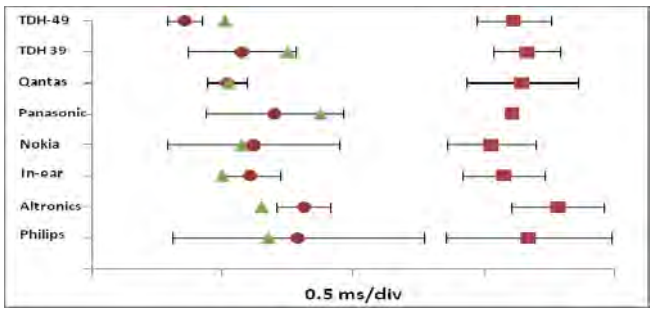

Fig. 2 SAET from the human scalp and the phantom with the ABR wave I from different audio transducers. Horizontal error bars show the standard deviation of SAET and wave I of human scalp. Earlobe electrode arrangement. All human data include an average of 4 participants.

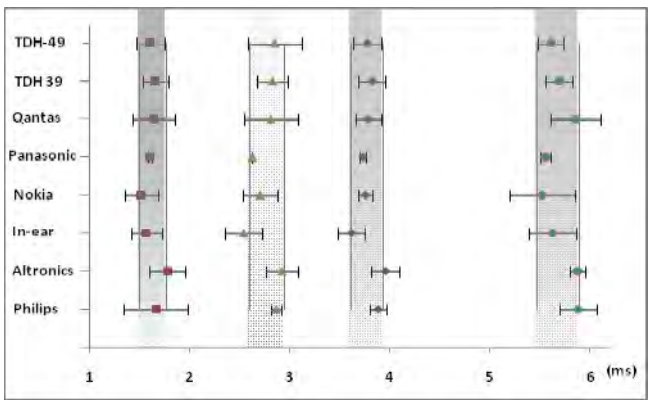

Fig. 3 Average absolute latency of wave I, II, III and V from 4 participants. Standard deviation is in horizontal error bars. Vertical grey bars represent the average range of published data for ABR waves at earlobe.

IV. Discussion

A. Separation of the stimulus artifact from ABR wave I

Due to the close proximity, prolonged stimulus artifacts can distort characteristics of the ABR wave I. Therefore the separation between stimulus artifact and onset of wave I is critical in choosing audio transducers.

Separation values in Table 4 are the time gaps between the highest of either phantom or average of human SAET and the onset of ABR wave I variation (using Fig. 2).

According to Table 4, all the introduced audio transducers are well above the standard TDH-39 except Philips transducer at the earlobe electrode arrangement. Qantas provides the best separation and Philips with a low 0.56 ms.

Table 4 Separation between the stimulus artifact and the ABR wave I

Audio transducer	Earlobe (ms)	Mastoid (ms)
TDH-49p	0.96	0.84
TDH-39	0.78	0.94
Qantas	0.91	0.86
Panasonic	0.71	0.60
Nokia	0.74	0.86
1.2M (in-ear)	0.81	0.68
Altronics	0.79	0.94
Philips	0.56	0.56

At the mastoid electrode arrangement, except for Panasonic, 1.2M (in-ear) and Philips transducers, the others are comparable with standard transducers.

As a whole, all separation values are acceptable as illustrated in Fig. 1, although, better clarity could be obtained by using different transducers at different electrode arrangements. Given the high variation in SAET of the Nokia and Philips devices, we would not recommend their usage for ABR recordings.

B. Quality of the ABR produced

The absolute latencies of ABR waves show little variation, and have almost constant values for a person at a specific sound intensity [1]. Therefore the quality of the ABR produced by each audio transducer could be determined by comparing absolute latencies of wave I, II, III and V with published data (Table 2) with similar sound intensities.

As shown in Fig. 3 the recorded latencies of all waves by the TDH-49 and TDH-39 (gold standard) transducers fall well within the expected range of values. Therefore, we conclude that the remaining values of the other transducers are valid.

Referring to Fig. 3, all the average values fall within published data ranges with little variations. A pattern to notice here is ABR waves always appear later for the Altronics (suggesting a time delay) and earlier for the 1.2M (in-ear) (suggesting an earlier arrival of sound at the eardrum due to proximity), but not enough to warrant latency correction.

With the mastoid electrode arrangement, measurement of standard latencies occurred for both Qantas and Panasonic earphones, but the Nokia produced wave II and III with a large variability in latency. The 1.2M (in-ear), Altronics and Philips produced similar results to the earlobe electrode arrangement.

In terms of quality of ABR wave latencies, both earlobe and mastoid electrode arrangements provided good results from all the introduced audio transducers, except the Nokia earphone at mastoid.

V. Conclusions

We conclude that, it is feasible to use most of the commercially available audio devices in ABR studies, but we recommend that a comparison of the new audio transducer with the gold standards should be carried out in the user's laboratory.

From the results of this study, we cannot recommend Philips headphones or Nokia earphones.

The other factor of consideration is that of sound intensity. In this study, the sound intensity used (80 dB SPL) is appropriate for diagnosis of neural disorders where a fully featured ABR is required. But, in the case of hearing screening, the participant should undergo recordings at different sound intensity levels. This may create further aberrations to the ABR wave form. Thus we recommend that those sound levels be analysed in this type use.

Acknowledgment

The authors thank the volunteers who participated for ABR recordings and Chris Anthony for technical assistance.

Abstract — **The purpose of the current study was to develop a magnetic resonance (MR)-compatible photoplethysmograph (PPG) system which could measure the raw PPG signal during MR image acquisition. The system consisted of an optic sensor which measured the optic signal, an optic cable which transmitted a near-infrared optic signal, a signal amplifier, and a filter for noise removal. To minimize interactive noise, only the optic cable and the optic sensor module were located inside the MR room; the signal amplifier and filter were located outside the MR room. The experiment verified that a reliable PPG signal can be obtained without deteriorating the MR image. Especially, it was possible to get a reliable PPG signal while acquiring MR images with EPI method which has been used for functional magnetic resonance imaging (fMRI) study. This system can simultaneously measure the response of the central nervous system using fMRI and that of the peripheral nervous system using the PPG.**

Keywords — **Photoplethysmograph, Magnetic resonance image, Optic sensor and cable**

I. Introduction

Compared with other physiological signals and imaging modalities, magnetic resonance (MR) imaging has outstanding spatial resolution, but has a shortcoming with respect to temporal resolution. Physiological signals, such as the electroencephalogram (EEG), the electrocardiogram (ECG), the galvanic skin response (GSR), the skin conductance response (SCR), and the photoplethysmograph (PPG), have excellent temporal resolution, but poor spatial resolution. To simultaneously achieve excellent temporal and spatial information, a number of studies regarding MR image acquisition with physiological signals are underway.

Recently, a reliable EEG signal measurement technique with MR acquisition has been introduced. During MR image acquisition, the main magnetic field, the gradient magnetic field, and the radio frequency (RF) pulse induce considerable noise on the EEG signal. To minimize induced noise, a carbon electrode was used instead of a Ag/AgCl electrode, and the electromagnetic field behind the leads was offset by twisting the leads. A study on induced noise removal by post-signal processing was carried out [1], and a real time noise removal algorithm was created [2]. A surface coil was used to minimize the effects of the RF pulse [3]. As the MR environment can affect physiological signals, physiological signal measuring instruments can distort MR images. To minimize the distortion of MR images, the length of the transmitter was minimized, the measuring instrument was shielded, and the use of metallic materials was minimized [4,5]. Based on these techniques, it was possible to perform functional magnetic resonance imaging (fMRI) and receive an EEG signal simultaneously. Through the use of this technique, it was possible to examine the mechanism by which the central nervous system (CNS) satisfies temporal and spatial resolution at the same time, and studies have been initiated which attempt to clarify the mutual relationship [6,7,8].

Studies are in progress which examine the mechanism whereby the CNS and the peripheral nervous system (PNS) simultaneously satisfy temporal and spatial resolution using fMRI and ECG, respectively, but are still in the beginning stages [9,10]. Investigations on the mutual relationships between the SCR, the GSR signal, and fMRI have been partially studied, but are insufficient to clearly examine both central and peripheral [11,12]. Thus, it is necessary to examine such mechanisms utilized by the CNS and PNS and to study the mutual relationships through the simultaneous measurement of fMRI and physiological signals.

The PPG signal can yield the information regarding the autonomic nerves among the peripheral nerves [13,14]. To minimize the interactive effects with MR, MR-compatible PPG or pulse oximeter system which uses fiber optic sensor and cable is commercially available [15,16,17]. However those systems are mainly used for patient monitoring and provide only numerical values of blood oxygen saturation and heart rate.

This study tried to develop the system that extracts raw PPG signal with fMRI under MR environment. In so doing, we sought to develop a technique which reliably and simultaneously measured the central and peripheral signals.

II. Methods

As shown in Fig. 1, this system consisted of an optic cable and an optic sensor module which were located inside the MR room, and a signal amplifier and filter which were located outside the MR room. The optic cable consisted of

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 161–164, 2009
www.springerlink.com

36 optic fibers, 1 mm in diameter, and divided into 18 fibers each, which sent and received the optic signal. After binding a bundle that combined each of the 18 optic fibers, the optic sensor module was built for measuring the PPG signal using a reflectance method with the sensor in contact with the skin. During measurement, the movement-induced noise was minimized by a band-type housing of contact between the optic sensor and the skin.

The light transmitter, which utilized an infrared (IR) LED, receiver, and amplifier, receives reflected light signal from the skin, and the filter was located outside the MR room. The IR LED in the transmitter used a 650 nm wavelength signal. The phototransistor was a signal receiver that used a non-inverting amplifier. To achieve optimal gain by preventing clipping phenomena, the amplification ratio could be varied up to 1,000 times. A 4th order low-pass filter was used for high frequency noise removal and base line drift was removed by a high-pass filter. This provided the possibility of measuring a main frequency range of 0.5-20Hz for the PPG signal. When the amplifier was located near the operating room, there was considerable electric noise. Thus, the hum was removed by the notch filter.

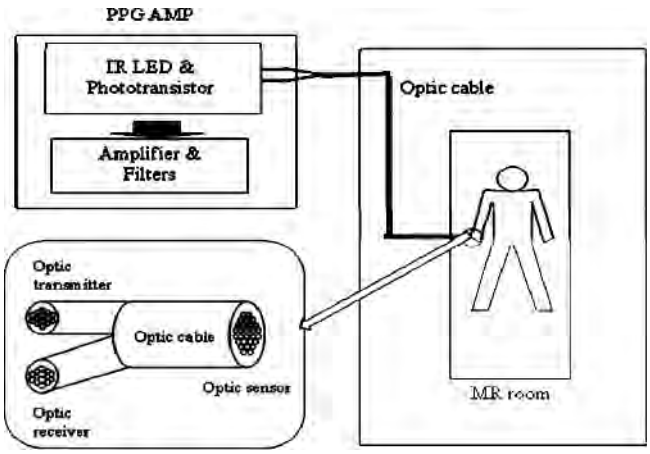

Fig. 1 Structure of a MR-compatible PPG system

The effect of the MR environment on the PPG signal was investigated by performing human subject experiments while measuring the PPG signal and MR image simultaneously. Images were acquired using a 3.0 Tesla MR system (Magnum 3.0, Medinus Inc., Korea) system with the fast spin echo (FSE) method and the following imaging parameters: TR/TE, 4400/96ms; field of view, 240mm; matrix size, 256×256; slice thickness, 3mm; and number of slices, 19. The PPG signal was also measured while acquiring images with the echo planar imaging (EPI) method which has been used for fMRI study using the following imaging parameters: TR/TE, 3000/96ms; field of view, 240mm; matrix size, 64×64; slice thickness, 3mm; and number of slices, 9. The PPG signal, at 300 samples/sec, was measured using a data acquisition board (DAQpad-6015, National Instruments, USA). The PPG signal was displayed, saved, and retrieved by using Labview (version 7.1) and Matlab (version 6.5) software.

III. Results

Two types of MR images were acquired by measuring the PPG signal with human subjects (Fig. 2). Figure 3 illustrates the measured PPG signal while performing MR image acquisition with the EPI method, which showed a slight noise, but a reliable signal.

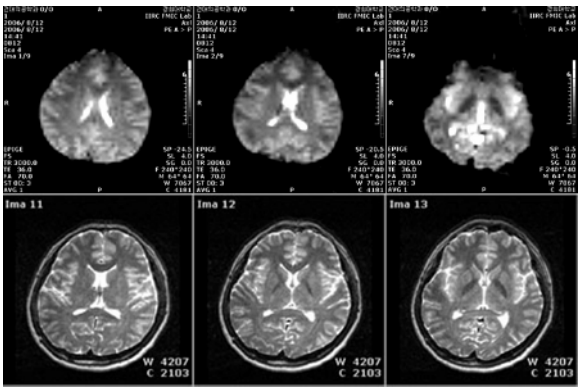

Fig. 2 MR images of the subject (upper, EPI sequence; lower, FSE sequence)

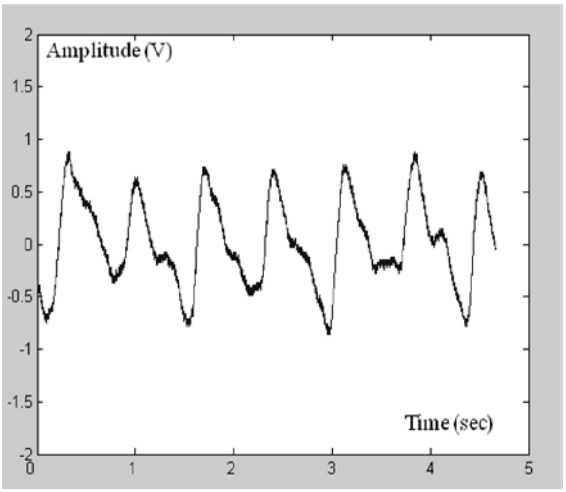

Fig. 3 Measured PPG signal during MR image acquisition with the EPI method

IV. Discussion

To prevent mutual interference between MR image acquisition and physiological signal measurement, sensors, cables, and amplifiers should not have an effect on MR images. Further, the main magnetic field, gradient magnet field, and RF pulse should not have an effect on physiological signals. Therefore, in the current study a MR-compatible PPG system was developed using an optic cable and an optic sensor to minimize the mutual interference between the MR image and the raw PPG signal [15,16,17].

When the physiological signal measuring instrument (i.e., the amplifier) was located inside the MR room, metallic material in the instrument had an effect on the MR image. A digital device, such as a microprocessor, induced RF noise, and induced noise had an effect on the MR image. Since the magnetic field and RF pulse of the MR system can cause a noise on the physiological signal measurement system, the instrument requires perfect shielding. To minimize the mutual interference effect in this study, the measuring instrument was located outside the MR room and only the optic cable and the optic sensor were located inside the MR room.

In general, the PPG amplifier used a 560-940nm wavelength IR LED, and the wavelength and intensity were selected for the specific application [18]. This study used a 650nm IR LED, which incurred the least amount of light loss by considering the distance between a subject in bed inside the MR room and the instrument outside the MR room. When a single optic fiber is used to transmit an optic signal, it is possible to cause a motion artifact on the PPG signal which is sensitive to movement. The amplitude and quality of the optic signal is increased by increasing the number of optic fibers [18]. Therefore, an optic cable with a maximum of 36 optic fibers was used in the current study by considering a penetrating hole across the MR room.

The results showed that the optic cable and the optic sensor did not have an effect on the MR image, but the measured PPG signal showed a slight noise. There is a possibility that MR environment such as strong magnetic field might induce the physiological changes of the subject and the signal might be slightly distorted, but there was not any published result about this problem. Therefore it could be concluded that the signal distortion was due to the complex effects of static magnet field, gradient magnetic field, and RF pulse. It will be necessary in future investigations to remove this induced noise.

The findings of this experiment verified that a reliable raw PPG signal could be obtained without deteriorating the MR image. Especially, it was possible to get a reliable PPG signal while acquiring MR images with EPI method which has been used for fMRI study. This system can simultaneously measure the response of the central nervous system using fMRI and that of the peripheral nervous system using the PPG.

A Study on the Cerebral Lateralization Index using Intensity of BOLD Signal of functional Magnetic Resonance Imaging

M.H. Choi, S.J. Lee, G.R. Tack, G.M. Eom, J.H. Jun, B. Lee and S.C. Chung*

Department of Biomedical Engineering, Research Institute of Biomedical Engineering,
College of Biomedical & Health Sciences, Konkuk University, Chungju, South Korea,

Abstract — **This study proposes a new cerebral lateralization index on the basis of neural activation intensity. Eight right-handed male college students (mean age 23.5 years) and ten right-handed male college students (the mean age - 25.1 years) participated in this study of visuospatial and verbal tasks, respectively. Functional brain images were taken from 3T MRI using the single-shot EPI method. A cerebral lateralization index based on neural activation area (i.e. number of activated voxels) and another based on neural activation intensity (i.e. intensity of BOLD) were calculated for both cognition tasks. The result of calculating a cerebral lateralization index based on neural activation area suggested that the right hemisphere is dominant during visuospatial tasks and the left hemisphere is dominant during verbal tasks. When a cerebral lateralization index was computed on the basis of the neural activation intensity, it was shown that the area of cerebral lateralization closely related to visuospatial tasks is the superior parietal lobe, and the area of cerebral lateralization closely related to verbal tasks is the inferior and middle frontal lobes. Since the proposed method can determine the dominance of the cerebrum by each area, it can be helpful to determine cerebral lateralization accurately and easily.**

Keywords — **Cerebral lateralization, BOLD, fMRI**

I. Introduction

There have been two major methods used to study the change in brain activation during cognitive tasks with the functional magnetic resonance imaging (fMRI). The first method measures the number of activated voxels based on blood oxygen level dependent (BOLD) signal and the other measures the neural activation intensity of activated voxels [1,2]. The former, which has been widely used, easily identifies the activated brain areas by using subtraction method designed to measure the number of activated voxels in response to cognitive activity. The latter measures the neural activation intensity of activated voxels, which is based on the assumption that an increase in the intensity reflects an increase in brain activation. This is because there is positive relationship between the intensity of BOLD signal and the magnitude of brain activation [2].

Generally, cerebral lateralization is calculated by the lateralization index (LI), which is based on neural activation area [3]. Calculation of LI is by the equation (LV-RV)/(LV+RV), where LV and RV are the number of activated voxels of the left and right hemisphere, respectively. When LI is positive, the left hemisphere is dominant, and when LI is negative, the right hemisphere is dominant. This method can determine which hemisphere is dominant, but it was difficult to calculate the regional LI of the cerebrum. For example, during visuospatial cognition tasks, neural activation occurs at proximal regions, including the cerebellum, the occipital lobe, and the parietal lobe. Since activated voxels are clustered, it is difficult to distinguish individual regions and difficult to calculate a regional LI [1].

This study tries to avoid the drawbacks of the existing cerebral LI calculation method, and proposes a new cerebral LI calculation method that uses the signal intensity of activated voxels (neural activation intensity) to calculate a regional LI.

II. Methods

Eight right-handed male college students (mean age, 23.5 years) and ten right-handed male college students (mean age, 25.1 years) participated in this fMRI study of visuospatial and verbal tasks, respectively. All subjects signed informed participation consent forms. All examinations were performed under the regulations of our Institutional Review Committee.

A total of 20 items for the visuospatial cognition task were selected from Korean versions of an intelligence test, an aptitude test, and a general aptitude battery (GATB) [4,5,6]. The selected items consisted of (1) selecting a figure that has the exact shape of a given diagram from among four examples and (2) finding the next one in a series of diagrams. A verbal cognition task (consisting of verbal analogy and antonym tasks) was developed. A total of 28 items were selected from Korean versions of an intelligence test and the GATB [4,6]. The verbal analogy testing required the subject to select one of a group of words with the same meaning as a given word. The verbal antonym testing required the subject to select a word that had a different meaning from among four words.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 165–168, 2009
www.springerlink.com

The experiment consisted of four blocks (8 min.); each block (2 min.) had both control (1 min.) and cognitive (1 min.) items. The control and cognitive tasks were presented using SuperLab 1.07 (Cedrus Co.). Items were projected onto a screen and subjects were instructed to provide the correct answers. In response to control tasks, subjects were instructed to press a button corresponding to the number (1, 2, 3, or 4) projected onto the screen. In the cognition task, subjects were asked to press a button to correctly identify the number of an item projected on the screen (visuospatial task, 5 trials per block; verbal task, 7 trials per block).

Imaging was conducted on a 3.0T ISOL Technology FORTE (ISOL Technology, Korea) equipped with whole-body gradients and a quadrature head coil. Single-shot echoplanar fMRI scans were acquired in 35 continuous slices, parallel with the AC-PC line. The parameters for fMRI included the following: the repetition time (TR) and echo time and (TE) were 3000 ms and 35 ms, respectively; flip angle, 60º; field of view, 240 mm; matrix size, 64 × 64; slice thickness, 4 mm; and in-plane resolution, 3.75 mm. T1-weighted anatomic images were obtained with a 3-D FLAIR sequence (TR, 280 ms; TE, 14 ms; flip angle, 60º; FOV, 240 mm; matrix size, 256 × 256; slice thickness, 4 mm).

The fMRI data were analyzed with SPM99 (Wellcome Department of Cognitive Neurology, London, UK). All functional images were realigned to the image taken proximate to the anatomical study by using affine transformation routines built into SPM99. The realigned scans were coregistered to the participant's anatomical images obtained within each session, and normalized to SPM99's template image that uses the space defined by the Montreal Neurologic Institute (MNI). Motion correction was done using Sinc interpolation. Time series data were filtered with a 240 s high-pass filter, to remove artifacts due to cardiorespiratory and other cyclical influences. The functional map was smoothed with a 7 mm isotropic Gaussian kernel prior to statistical analysis. Statistical analysis was done individually, and then as a group using the general linear model and the theory of Gaussian random fields implemented in SPM99. Using the subtraction procedure (cognition tasks – control tasks), activated areas in the brain during cognitive tasks were color-coded by *t*-score.

The cerebral lateralization index (LI) is calculated from the number of activated voxels by equation (1):

$$LI = (LV - RV) / (LV + RV) \quad (1)$$

where LV and RV are the number of activated voxels of the left and right hemisphere, respectively. By using small volume correction (SVC) among SPM methods, the number of activated voxels of each hemisphere is measured after assigning regions of the left and the right hemisphere.

On the basis of regional activated voxel intensity, the lateralization index using intensity (LII) is calculated by equation (2):

$$LII = (LI - RI) / (LI + RI) \times 100 \quad (2)$$

where LI and RI are the average intensity of activated voxels of the left and right regions, respectively. To observe the average intensity of BOLD signal at each activated region, the 5×5×5 region around the voxel that has the highest t-score (selection criteria) was selected.

For visuospatial tasks, three regions were selected as follows: the middle frontal lobe (MF), the superior parietal lobe (SP) and the occipital lobe (O). For verbal tasks, four regions were selected as follows: the middle frontal lobe (MF), the inferior frontal lobe (IF), the superior parietal lobe (SP) and the occipital lobe (O).

III. Results

Significant activation was observed in the cerebellum, occipital lobe, parietal lobe, and frontal lobe during the visuospatial tasks. Significant activation was observed in the cerebellum, occipital lobe, parietal lobe, temporal lobe, and frontal lobe during the verbal tasks.

The activated voxels are divided into the left and right hemisphere during visuospatial and verbal cognition tasks, the cerebral lateralization index (LI) based on equation (1) is calculated. During visuospatial tasks, the number of activated voxels of the right hemisphere showed significant increase compared with that of the left hemisphere (t = –9.057, df = 7, p = .001), and LI was negative, which means that the right hemisphere was dominant. During verbal tasks, the number of activated voxels of the left hemisphere showed significant increase compared with that of the right hemisphere (t = 6.498, df = 9, p = .001), and LI was positive, which means that the left hemisphere was dominant.

The lateralization index using intensity (LII) was calculated by equation (2) based on the intensity of activated voxels. Tables 1 and 2 show the intensity of activated voxels and LII of visuospatial and verbal tasks, respectively. As shown in Table 1, during visuospatial tasks, LII of all three regions was negative and the right region was dominant. But only at superior parietal lobes (SP) did the voxel signal intensity of the right region show a significant increase compared with that of the left region (t = –2.345, df = 7, p = .05). As shown in Table 2, during verbal tasks, LII of three regions, except the occipital lobe (O), were positive and the left region was dominant. But only at the middle frontal lobe (MF) (t = 4.559, df = 7, p = .003) and inferior frontal lobe (IF) (t = 4.689, df = 7, p = .002), did the voxel signal intensity of the left region show a significant increase com

pared with that of the right region. There is no activation for some subjects at selected regions; we did not include the calculation of LII in those cases, as shown in Table 2.

IV. Discussion

During visuospatial tasks, cerebellum, occipital lobe, parietal lobe, and frontal lobe are activated and it is well-known that especially the parietal lobe plays an important role [1,7]. For studies of verbal reasoning, verbal concept, and internal verbal generation, it is reported that cerebellum and occipital lobe and the inferior frontal lobe including Broca, parietal and temporal lobes, including Wernicke, play important roles in verbal cognition [8,9]. The activated cerebral regions during the cognition tasks of this study agree with previous results.

The number of activated voxels (activated area) has been used reliably to determine the dominant hemisphere during diverse cognition tasks. On the basis of these results for

cerebral lateralization, it is concluded that the right hemisphere is dominant for visuospatial tasks and the left hemisphere is dominant for verbal tasks, and these results agree with those of previous studies. However, there is a lack of information concerning in which region of the cerebrum this dominance occurs. Especially during the visuospatial tasks, since the cerebellum, the occipital lobe, and the parietal lobe regions are clustered, it is difficult to distinguish individual regions and it is difficult to calculate the regional LI.

This study showed that the new LII; which is based on the intensity of the activated voxels, can be used to overcome these limitations. On the basis of the LII calculation of the middle frontal lobe (MF), the superior parietal lobe (SP) and the occipital lobe (O) during visuospatial tasks, it can be concluded that all three regions showed negative values, which means that the right region is dominant, but there was statistical significance only at the superior parietal lobe (SP). This is convincing evidence that the superior parietal lobe is closely related with cerebral lateralization of visuospatial cognition. On the basis of the LII calculation of the middle frontal lobe (MF), the inferior frontal lobe (IF), the superior parietal lobe (SP) and the occipital lobe (O) during verbal tasks, it can be concluded that three regions, except the occipital lobe (O), were positive, which means that the left region is dominant. There was statistical significance only at the middle frontal lobe (MF) and the inferior frontal lobe (IF). This suggests strongly that the cerebral lateralization region for verbal tasks is the inferior frontal lobe, including the Broca region, and the middle frontal lobe is closely related with cerebral lateralization of verbal cognition tasks.

The BOLD signal intensity of specific regions in fMRI can be an index for the neuronal activation level. It is well known that the absolute magnitude of the change in MR signal (BOLD) has a nearly arbitrary relationship to the magnitude of brain activation [1,2]. Therefore, it is possible to calculate the amount of left and right neuronal activation using the magnitude of BOLD signals, and to calculate a regional LI from these values. Since the proposed LII was used to calculate the regional cerebral LI exactly and easily, this method could be used to help to understand human brain function.

A Comparison of Two Synchronization Measures for Neural Data

H. Perko, M. Hartmann and T. Kluge

Austrian Research Centers GmbH, Neuroinformatics, Vienna, Austria

Abstract — **In this paper we analyze the capability of two different signal synchronization measures to detect synchronized periodic signal components. We compare the periodic synchronization index (PSI), which was first introduced for the detection of epileptic seizures in EEG signals, with the widely known phase locking value (PLV). The PSI automatically detects the dominant periodic signal components utilizing Fourier series expansions and measures the synchronization between equivalent components in two signals. The PLV averages the difference between the analytic phases of two signals. Applying these two measures to synthetic data and EEG recordings we found clear advantages of the PSI over the PLV. Experiments with synthetic data and high signal to noise ratio (SNR) revealed no significant difference between the PSI and the PLV in their ability to detect small frequency deviations. However, in the presence of noise the detection performance of the PLV drops significantly. In particular, we found that the PLV relies on an SNR of nearly 3dB. In contrast, the performance with the PSI remained almost unchanged for SNR down to -4dB. This noise robustness of the PSI is due to the incorporation of harmonic oscillations resulting in an improved estimation of periodic signal components. When applied to the detection of early seizure phenomena in EEG data we found that the increase of the PSI at seizure onset is more pronounced and the variance of the measure during pre-ictal time periods is lower than for the PLV.**

Keywords — **signal synchronization, periodic synchronization index, phase locking value**

I. Introduction

Many studies in the field of neuroscience, epilepsy research and brain computer interfaces investigate changes in neural synchronization utilizing scalp EEG signals [1-4]. The majority of methods to measure neural synchronization are based on spectral representations as Fourier, Hilbert or Wavelet transform which are then used to derive synchronization measures as coherence or phase coupling. From a mathematical point of view these approaches are quite similar [5]. In practise however, the performance of a specific synchronization measure relies on the quality of the spectral representation and on the susceptibility to contaminating noise [6, 7]. In this paper we analyze the capability of two different signal synchronization measures to detect synchronized periodic signals contaminated by additive noise. In particular, we compare the periodic synchronization index (PSI), which we introduced for the detection of epileptic seizures in EEG signals [8, 9], with the widely known phase locking value (PLV) [10-13]. The PSI automatically detects the dominant periodic signal components utilizing Fourier series expansions and measures the synchronization between equivalent components in two signals. The PLV averages the difference between the analytic phases of two signals. Applying these two measures to synthetic data and EEG recordings, we found clear advantages of the PSI over the PLV. Experiments with synthetic data revealed a higher noise robustness of the PSI. When applied to the detection of early seizure phenomena in EEG data we found that the increase of the PSI at seizure onset is more pronounced and the variance of the measure during pre-ictal time periods is lower than for the PLV.

II. Method

To derive the PSI, we consider the signals $y_k[n]$ with channel index k and time index n. Our approach is based on the model that these signals are composed of periodic components $x_k[n]$ disturbed by additive noise $z_k[n]$, i.e. $y_k[n] = x_k[n] + z_k[n]$. The periodic components $x_k[n]$ with fundamental frequencies θ_k can be represented in terms of a Fourier series given by

$$x_k[n] = \sum_{m=1}^{M} \left(c_k[m]\, e^{j2\pi\theta_k mn} + c_k^*[m]\, e^{-j2\pi\theta_k mn} \right).$$

Our signal model is thus based on the assumption that there are periodic components hidden in additive noise. Since the periodic components are unknown, we have to estimate them from the observed signal $y_k[n]$. With the Fourier series representation, this is equivalent to an estimation of the fundamental frequencies θ_k and coefficients $c_k[m]$. To estimate these parameters we introduce the Fourier series

$$x_{k,\theta}[n] = \sum_{m=1}^{M} \left(c_{k,\theta}[m]\, e^{j2\pi\theta mn} + c_{k,\theta}^*[m]\, e^{-j2\pi\theta mn} \right),$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 169–173, 2009
www.springerlink.com

with a variable fundamental frequency θ and coefficients given by

$$c_{k,\theta}[m] = \sum_n y_k[n]\ e^{-j2\pi\theta mn}.$$

Using the coefficient vectors

$$\mathbf{c}_{k,\theta} = \left(c_{k,\theta}[1],...,c_{k,\theta}[M]\right)^T,$$

we define estimates for the fundamental frequencies as

$$\hat{\theta}_k = \arg\max_\theta \left\|\mathbf{c}_{k,\theta}\right\|.$$

With $\hat{\theta}_k$ a reasonable estimate of the Fourier coefficients is given by $c_k[m] \approx c_{k,\hat{\theta}_k}[m]$. The PSI is now[1]

$$S_{k,l} = \frac{\left|\left\langle \mathbf{c}_{k,\hat{\theta}_k}, \mathbf{c}_{l,\hat{\theta}_k} \right\rangle\right|}{\left\|\mathbf{c}_{k,\hat{\theta}_k}\right\| \ \left\|\mathbf{c}_{l,\hat{\theta}_k}\right\|}.$$

Note that both coefficient vectors ($\mathbf{c}_{k,\theta}$ and $\mathbf{c}_{l,\theta}$) are taken at the fundamental frequency $\hat{\theta}_k$ which maximizes $\left\|\mathbf{c}_{k,\theta}\right\|$ and is independent of l. Hence, the dominant periodic signal component of $x_k[n]$ is identified and the normalized inner product is taken at the corresponding fundamental frequency. Furthermore, note that $\arccos\left(S_{k,l}\right)$ can be interpreted as angle between the two coefficient vectors taken at $\hat{\theta}_k$. The PSI equals unity for two signals that are equal up to a constant factor and zero for signals with orthogonal coefficient vectors. In order to avoid numerical problems when the coefficients $\mathbf{c}_{l,\theta}$ are small for the fundamental frequency $\hat{\theta}_k$ we introduced the following regularization

$$\tilde{S}_{k,l} = (1+\alpha)\ \frac{\left|\left\langle \mathbf{c}_{k,\hat{\theta}_k}, \mathbf{c}_{l,\hat{\theta}_k} \right\rangle\right|}{\left\|\mathbf{c}_{k,\hat{\theta}_k}\right\| \ \left\|\mathbf{c}_{l,\hat{\theta}_k} + \alpha\ \mathbf{c}_{k,\hat{\theta}_k}\right\|},$$

[1] The inner product $\left\langle \mathbf{a}, \mathbf{b} \right\rangle$ is given by $\sum_{m=1}^{M} a_m b_m^*$ and the norm $\left\|\mathbf{a}\right\|$ is given by $\sqrt{\left\langle \mathbf{a}, \mathbf{a} \right\rangle}$.

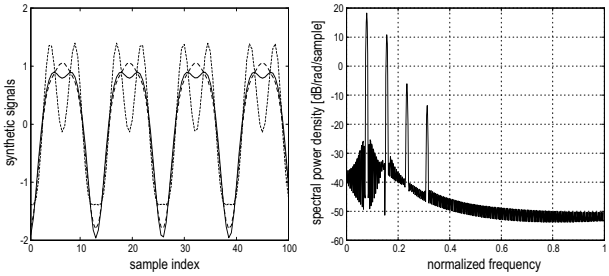

Fig. 1: Three realizations of synthetic signals and an example power spectrum consisting of a dominant fundamental component and three.

with a regularization factor α close to zero. Using that regularization, we still get $\tilde{S}_{k,l} = 1$ for $\mathbf{c}_{k,\theta} = \mathbf{c}_{l,\theta}$ and $\tilde{S}_{k,l} = 0$ for orthogonal coefficient vectors.

In this paper we compare the PSI to the widely known PLV. The PLV is based on the complex valued analytic signal [14] $a_k[n]$ associated to $x_k[n]$ and is defined as

$$P_{k,l} = \frac{1}{N}\left|\sum_n \frac{a_k[n]\ a_l^*[n]}{\left|a_k[n]\right|\ \left|a_l[n]\right|}\right|.$$

It measures the degree of similarity of the angles belonging to the analytic signals $a_k[n]$ and $a_l[n]$. It is easy to show, that for pure sinusoidal signals the PSI is equal to the PLV.

III. Results

A. Synthetic Signals

We analyzed our measure using synthetic signals with a duration of 12s and a sampling frequency of 256Hz. For the generation of these signals we use sinusoidals and applied a nonlinear transformation to yield

$$y_k[n] = \sum_{m=1}^{M} b_k[m]\ \sin^m\left(2\pi\theta_k n\right) + z_k[n].$$

The coefficients $b_k[m]$ where chosen as zero mean Gaussian random numbers and restricted to $\left|b_k[1]\right| > \left|b_k[m]\right|$ for $m > 1$. Three realizations of $x_k[n]$ and one example power spectrum are shown in Fig. 1. For this example, we used $M = 4$, hence the power spectrum shown in the right part consists of a dominant fundamental component and three harmonics.

In a first experiment we analyzed the capability of the PSI and the PLV to detect small frequency deviations in noiseless signals. For this reason, we generated two signals $y_1[n]$ and $y_2[n]$ without noise ($z_1[n] = z_2[n] = 0$). The fundamental frequency of $y_1[n]$ was fixed to 10Hz whereas that of $y_2[n]$ varied between 10Hz and 11Hz. The resulting PSI (dark gray curve) and PLV (light gray curve) for this experiment are shown in the upper left part of Fig. 2. Both measures start to decrease for very small frequency deviations and are close to zero for deviations of approximately 0.04Hz. The periodic peaks seen for increased frequency deviations in both PSI and PLV are due to suboptimal estimation of signal spectra coming from the use of time-limited signals. We found that the maximum PSI and PLV values for frequency deviations above 0.04Hz are below 0.18 and a reasonable detection of frequency shifts in noiseless signals can be done with both measures.

In our next experiment, we analyzed the robustness of the PSI and the PLV in the presence of noise. First, we measured the PSI and the PLV of signals $y_1[n]$ and $y_2[n]$ consisting of identical periodic components disturbed by additive white Gaussian noise. The mean values obtained from 2000 realizations for a SNR of -2dB are depicted in the upper right part of Fig. 2. It can be seen that the PSI value for zero frequency deviation is decreased to 0.85 while the corresponding PLV value dropped to 0.25. Hence, the PLV for two non-synchronized signals with small freqeuncy deviations is identical to the PLV of two synchronized signals in the presence of noise. The PSI also decreases in the presence of noise but the drop is much less pronounced than for the PLV such that a non-synchronized signal can be easily separated from a synchronized signal in the presence of noise. To further analyze the noise robustness of the PSI and the PLV we tried to detect the synchronized periodic components using a fix threshold of 0.5. This threshold value would be appropriate for the noiseless case (cf. left part of Fig. 2). Furthermore, it would be an intuitive value in the usual situations where no information on the SNR is available. The false negative rate for this experiment calculated from 2000 realizations is shown in the lower left of Fig. 2. For the PSI (dark gray curve) an SNR of approximately -4dB was sufficient to achieve a false negative rate of zero. In contrast, an SNR of nearly 3dB was needed for the PLV (light gray curve). Similar results where obtained for a wide range of thresholds.

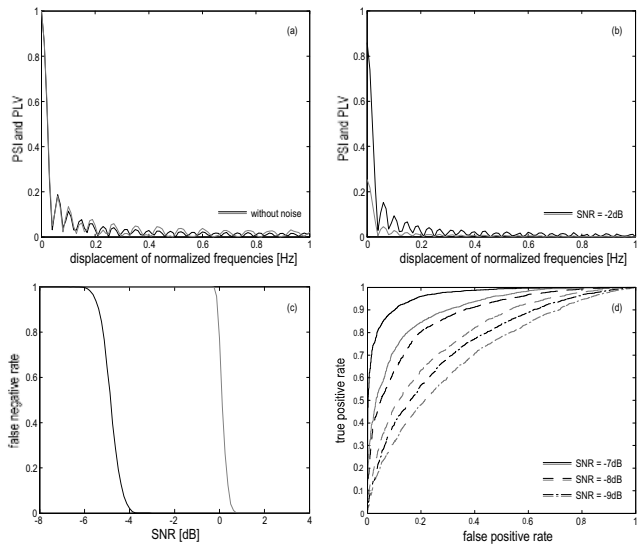

Fig. 2: Mean PSI (dark gray curve) and PLV (light gray curve) values for frequency shifted signal pairs without (a) and with noise (b). False negative rate for the detection of synchronized noisy signals obtained with the PSI and the PLV (c). ROC for the detection of synchronized signal pairs (d).

In a third experiment, we analyze the capability of the PSI and the PLV to distinguish between signal pairs without deviation of fundamental frequencies and signal pairs with a frequency shift of 1Hz, both in the presence of noise. In contrast to our previous experiment, we varied the detection threshold to capture the best possible detection performance for a given SNR. The receiver operating characteristic[2] (ROC) for this experiment is depicted in the lower right part of Fig. 2. The dark gray curves show the ROC obtained with the PSI and the light gray curves represent the ROC obtained with the PLV for SNR of -9dB, -8dB and -7dB. Each curve was derived from 2000 signal realizations. For any false negative fraction between 0 and 1, the PSI led to a higher true positive fraction compared to the PLV. Note that although the PSI outperformed the PLV, reasonable detection accuracy for low SNR could be reached with both measures. This accuracy however relies on the choice of a detection threshold appropriate for a certain SNR. Unfortunately, the SNR of a real life signal is rarely known and difficult to estimate.

B. Brain Signals

Fig. 3 compares the PSI and the PLV calculated from EEG data obtained from a patient with temporal lobe epilepsy. We used 15 minutes of data recorded from electrodes according to the international 10–20 system. A vertical dashed line marks the onset of the epileptic

[2]The ROC shows the fraction of true positives vs. the fraction of false positives as the detection threshold varies.

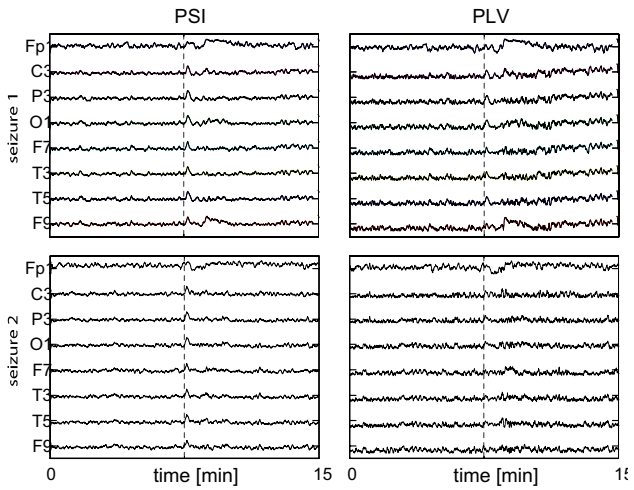

Fig. 3: PSI and PLV of electrode F3 vs. all other electrodes of the left hemisphere for two seizures. Results for seizure one are shown in the upper part and results for seizure 2 are shown in the lower part.

seizures. The upper plots and the lower plots of the figure correspond to two different seizures, respectively. The PSI and the PLV are shown for electrodes in the left hemisphere relative to electrode F3. The left hemisphere includes the seizure onset and propagation zone for this patient. For the calculation of PSI we optimized the number of harmonics experimentally. It turned out, that the optimal number of harmonics is three (used for results in Fig. 3) and that it can be chosen from three to five without large loss of performance. The example of Fig. 3 clearly shows that the PSI rises with approximately the same latency to the seizure onset as the PLV but the early signs of the upcoming seizure are much clearer. This is particularly pronounced in the second seizure shown in the lower part of Fig. 3. Whereas the PSI shows a unique peak in many channels, only small or no increases are seen for the PLV for this seizure. In addition to this well pronounced peak at seizure onset, the PSI shows a smaller variance during the inter-ictal period. This is especially important for automatic seizure detection that needs to distinguish the ictal from the inter-ictal period.

IV. Conclusions

In this paper we compared the capability of the PSI and the PLV to detect synchronized periodic signal components disturbed by different levels of additive noise. Our experiments with noiseless synthetic data revealed that both measures are sensitive to these components. In the presence of noise, the performance obtained with the PSI remained almost unchanged for an SNR down to -2dB and a reasonable detection is still possible with an SNR of -4dB. In contrast to the PSI, the detection performance drops significantly for noisy data when applying the PLV. In particular, we found that the PLV relies on an SNR of nearly 3dB. When applied to the detection of early seizure phenomena in EEG data we found that the increase of the PSI at seizure onset is more pronounced and the variance of the measure during pre-ictal time periods is lower than for the PLV.

Aknowlegdement

We are grateful to K. Schindler (Department of Neurology, Inselspital, Bern University Hospital, and University of Bern, Switzerland) for providing the EEG-data and his medical advice.

Abstract — **The classification of protein structures is essential for their function determination in bioinformatics. In this work, we use PDB files to extract descriptors based on structural characteristics of the protein, enriched with the biological features of the primary and secondary structure elements. Then we apply C4.5 algorithm and 10-fold-cross-validation decision trees to select the most appropriate descriptor features for protein classification based on the SCOP hierarchy. Empirical tests are provided for the usefulness and contribution of the different protein descriptor features to the decision tree classification precision. We propose a novel approach by transforming the hierarchical SCOP classification problem into a bottom - up classification flow. The results show that this approach provides much higher performances (it is much faster) than other algorithms with comparable accuracy: about 80% accuracy for DOMAIN recognition and 84% for SUPERFAMILY recognition.**

Keywords — **Protein Classification, SCOP, Decision Trees, C4.5**

I. Introduction

Proteins play vital structural and functional role in every living cell in the living organisms. The knowledge of the protein function is of great significance in many biochemical researches, especially in those researches that are trying to develop drugs for diseases. Nowadays there are very strong indications which confirm that protein function is strongly influenced by its structure. Therefore, it is reasonable to believe that proteins with a similar structure might have a similar function [1].

The classification of proteins based on their structure can play an important role in the deduction or discovery of protein structure and therefore, function prediction. Many classification schemes have been developed in order to describe the different kinds of similarity between proteins. Among the other classification schemes, SCOP (Structural Classification of Proteins) [2] has been accepted as the most relevant and the most reliable classification hierarchy [3]. This is due to the fact that SCOP strictly builds its classification decisions based on visual observations made by experts in the area. Also SCOP builds its classification hierarchy in such manner that brings to front the structural and functional relationships between protein structures. Although SCOP is highly reliable and precise system, it has one negative drawback. Namely, due to its manual classification methods, the dynamic of classification of new proteins in SCOP can't follow the dynamic of discovering novel protein structures (32.000 proteins classified in SCOP vs. 51.000 protein entries in PDB till 2008). This clearly brings to front the necessity of a system which will classify proteins in a precise and reliable manner as SCOP does, but in an automated fashion. Automated classification schemes have the advantage that the view of the protein universe can be updated frequently to include newly-discovered protein structures in a timely manner.

Some structure alignment methods are used in automating the classification process. These methods, like CE [5], DALI [7], MAMMOTH [6] etc. are used to detect and highlight distant homology relations between protein structures. In general these methods are very precise and efficient and they have high degree of successful mapping of existing structures in new proteins. Having in mind that structure alignment methods are quite cost expensive, the speed of classification with these methods is always questioned. For example CE takes 209 days [5] to classify 11000 novel protein structures. The classification approach used in our work took 5 hours in order to classify 9994 proteins.

There are numerous research approaches that combine sequence and structure alignment of the proteins. SCOPmap [8] is a system that uses a pipelined architecture for the classification. SCOPmap uses four sequence alignment methods: BLAST, PSI-BLAST, RPS-BLAST and COMPASS [10] and two structure alignment methods: VAST and DaliLite [9]. This pipelined approach brings to front high complexity of the classification process. FastSCOP [9] is another, more efficient system than SCOPmap which is based on 3D-BLAST [11] and MAMMOTH. 3D-BLAST is structure alignment method that is used as a preprocessing filter for MAMMOTH and it produces the top 10 scores. Afterwards, these top 10 results are used by MAMMOTH in order to find the most similar protein structure with the query structure. Although fastSCOP possesses

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 174–178, 2009
www.springerlink.com

high precision, the used combination of methods eventually in future will produce increasing classification complexity.

Instead of using the alignment methods, in some researches the classification based on the mapping of the protein structure in the descriptor spaces can be found. In [13] protein descriptor is formed by first producing distance matrix. The distance matrix is treated as image and local distance histograms are computed thus giving local protein features. Additionally the descriptor has global protein features. The whole descriptor dimension is 33, consisted from 24 local features and 9 global features. This protein descriptor afterwards is used for protein classification into the SCOP hierarchy based on the E-predict algorithm [13]. In [1] protein descriptor is generated solely from the protein sequence information in order to avoid complex structure comparison. The protein descriptor gives information for the number of different amino acids, the hydrophobicity, the polarity, the Van der Waals volume, the polarizability and for the secondary structures in the protein structure. With this protein descriptor, proteins are classified hierarchically into the SCOP hierarchy with Naive Bayes and boosted C4.5 methods [1]. The results from approaches described in [1] [13] will be compared with the results obtained from our work.

In this work, we propose novel classification logic that is based on generated protein descriptors in combination with C4.5 decision tree classification algorithm. As a classification scheme, the SCOP classification hierarchy is used. The classification flow is based on a bottom-up classification according to the SCOP hierarchy. The implemented classification logic is original and new due to the fact that according to the related work there were no protein classification approaches which use similar classification architecture. The implemented system introduces tremendous speed up compared with the structure alignment algorithms. It is ~816 times faster than CE [5] and ~68 times faster than MAMMOTH [9]. It is less correct than fastSCOP which has accuracy of 98% for the SUPERFAMILY level compared with our 84%. However, our algorithm is ~70 times faster.

In section 2 we present the system architecture and the used research methods. Section 3 presents the experimental results, while the section 4 concludes the paper.

II. System Architecture and Research Methods

The system has three main features. First, the system is based, and it uses the SCOP classification scheme. Second, it uses 3D protein descriptor [13] which transforms the protein tertiary structure into N-dimensional feature vector, and additionally gives some other protein structural features. And finally, as a classification algorithm decision trees trained with C4.5 are used.

This classification logic is based on the fact that the SCOP classification hierarchy is tree–like hierarchy, providing only one parent node for every child node in the hierarchy. According to this fact, if we know the DOMAIN of the protein, then we know the upper SCOP levels (the whole hierarchy) for that protein. Basically this classification flow is by all means very much similar to the classical top – down approach, except that the starting point is changed. Instead of starting the classification from the root, it is started from the leafs.

Chronologically the system is consisted of two phases: training phase and testing or classification phase. The training or offline data flow takes into consideration the knowledge given in the SCOP hierarchical database to build predicative classification flow for each SCOP hierarchy level. The training procedure can be divided in two general processes. The first one is the descriptor extraction (shown on figure 1) and data set generation process. Descriptors consisting of 450 features (416 of them describe the protein's geometry, while 34 of them give information for the primary and secondary protein structure) are generated for each protein forming a training set for the C4.5 decision tree algorithm. This descriptor relies on the geometric 3D structure of the proteins. After triangulation, normalization and voxelization of the 3D protein structures, the Spherical Trace Transform is applied to them to produce geometry - based descriptors, which are completely rotation invariant.

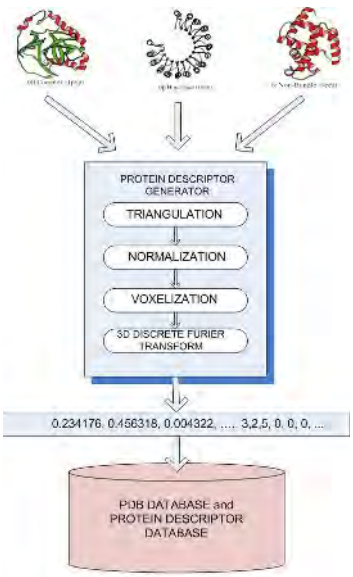

Fig. 1 Protein descriptor generation process

The second process is the process of forming and training of the decision trees for the bottom-up classifier. Decision trees are built for each level of the SCOP hierarchy, providing separate trees for classification in CLASS, FOLD, SUPERFAMILY, FAMILY and DOMAIN. In order to satisfy the bottom-up classification logic, additional level-specific decision trees for determination of DOMAIN are built. In this way, there are CLASS specific, FOLD specific, SUPERFAMILY specific and FAMILY specific decision trees for determination of DOMAIN. Also, additional decision trees are built for determination of one-level up SCOP levels (CLASS specific decision trees for FOLD determination etc.). These decision trees are afterwards used in the classification process of novel proteins.

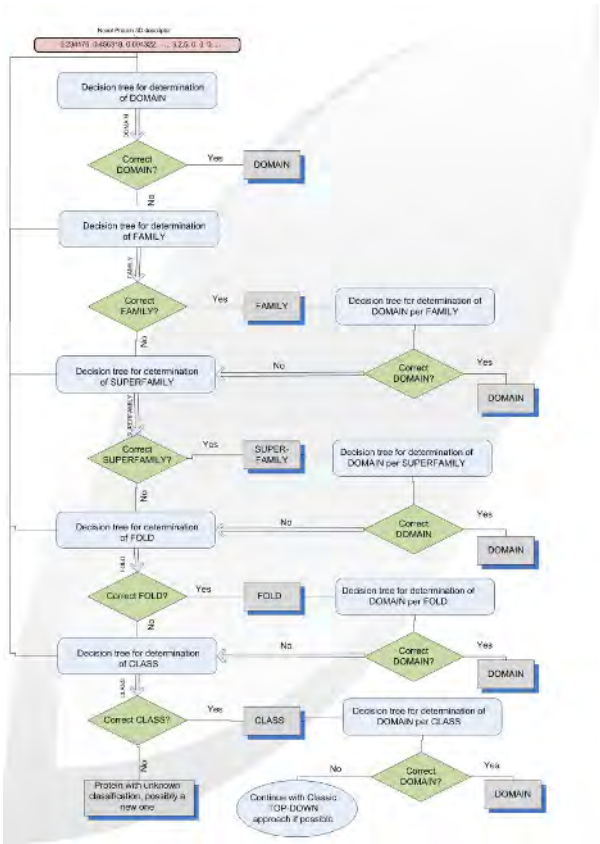

Fig. 2 Bottom-up classification approach

The classification or online data flow takes the unknown protein structure as query through the classification flow to generate new knowledge. The classification phase of new protein structures is shown on figure 2. As can be seen from the figure 2, new protein structure is preceded to the decision tree for determination of DOMAIN. If the protein is classified into the correct DOMAIN, then the classification process stops because we know the whole classification hierarchy of this protein, otherwise the protein is being proceeded to the classifier into the higher level of the hierarchy, in this case the decision tree for determination of FAMILY. If the classified FAMILY is correct, than the rest of the levels of the hierarchy for the protein are known, except the DOMAIN remains unknown. Therefore, the new protein is being preceded to the decision tree for determination of DOMAIN, trained only with instances from the predicted FAMILY. If the classified FAMILY is mistaken, the classifier continues one level up into the hierarchy, in this case it continues with predicting the SUPERFAMILY level of the new protein. This step is also the next step if the FAMILY specific decision tree mistakes the protein DOMAIN. Otherwise the classification is finished.

The process of protein classification continues with the backward recursion explained in the previous paragraph until it reaches the top level of the hierarchy, the CLASS. If there is no success in recognizing the correct protein DOMAIN, then the protein is announced as a protein with unknown SCOP classification, possibly a new one SCOP hierarchy.

III. Implementation, Experiments and Evaluation Results

The main GUI and the system logic were made with C#.NET. For implementation of the C4.5 algorithm, the WEKA API was used. The protein descriptor generation was made with C++. The SCOP hierarchy from the last two versions SCOP1.71 and SCOP 1.73 was downloaded and integrated into Oracle 10g database. The experiments were obtained on an Intel Core 2 machine with 2.2GHz and 2GB of RAM.

In the training phase, 73642 out of 75930 classified proteins from SCOP v1.71 were used for training the decision trees. Instead of having one decision tree for each level of the SCOP hierarchy, ensemble of decision trees is used for each level of the SCOP hierarchy. The idea for ensemble of trees came as a result of the huge memory requirements of the approach with one tree per level. The number of trees per ensemble in one level and number of output classes per tree in each level is presented in Table 1.

In the test phase proteins from the latest version of SCOP at the moment, SCOP v1.73, were taken. The test set consisted of 9994 proteins. We use only one condition for choosing these proteins. They have to belong to DOMAIN's which exist in the previous version of SCOP, SCOP v1.71, and the proteins from SCOP v1.71 which are classified in these DOMAIN's have to be classified into the same DOMAIN's in the SCOP v1.73.

Table 1. Number of trees per ensemble in one level and number of output classes per tree in each l

Level	Classes per tree	Num of trees per level
CLASS	11	1
FOLD	256	5
SUPERFAM	169	12
FAMILY	341	11
DOMAIN	659	14

Table 2. Results of the classification with the bottom-up approach

Level	Correct Classif.	Incorr. Classif.	Accuracy
CLASS	8817	1117	88,223%
FOLD	8460	1534	84,651%
SUPFAM	8364	1630	83,690%
FAMILY	8066	1928	80,708%
DOMAIN	7934	2060	79,388%

The classification results are shown in Table 2. The classification time was 6 hours, approximately. For example it is ~816 times faster than CE [5] and ~68 times faster than MAMMOTH [9]. As can be seen from the obtained results, the precision of the classification is satisfying. In [13] the precision is approximately 72% for 100% recall for protein DOMAIN prediction and 79,77% for 90% recall of the test set for DOMAIN prediction. In our work, the last percentage is 79,3876%. In [1] the best classification accuracy for protein CLASS recognition is 84% with boosted C4.5 classifier, and in our approach this percentage is 88,223%. When it comes to protein FOLD recognition in [13] the precision is 92% for SCOP v1.69 when E-predict is used as a classification algorithm. When NN (Nearest Neighbors) is used then the precision is ~92% when 1-NN is used, 91% when 3-NN and 5-NN are used as classifiers. If C4.5 decision tree is used as classifier the precision for FOLD prediction in [13] is 82%. The precision in our system is 84,651% for the FOLD level. There is no prediction of SUPERFAMILY, FAMILY and CLASS in [13] and SUPERFAMILY, FAMILY and DOMAIN in [1]. From this point of view our system has comparable accuracy and produces classification results for the whole SCOP hierarchy. However, fastSCOP [9] predicts the protein SUPERFAMILY with 98% accuracy compared with 84% accuracy in our work. On the other hand, our approach classifies proteins nearly ~70 times faster then fastSCOP thus providing much higher efficiency.

IV. Conclusion

The objective of this paper was to make empirical tests of the usefulness and the contribution of the different protein features to the decision tree classification precision and the usefulness of the bottom-up classification approach. It is evident that this approach which uses protein descriptor and decision tree algorithm for classification introduces high level of efficiency which can be concluded from the time taken to classify a protein and the percent of correctly classified proteins. The provided comparison with some other relevant works proves the satisfying results obtained with this work.

For the time being, our system can recognize the existing DOMAIN features in a novel protein but it cannot tell us if the novel protein belongs to new, yet no existing category. In future, there will be attempts to solve the problems explained here.

Abstract — **Independent component analysis (ICA) is the dominant method to resolve blind source separation (BSS) problem. In this article we conducted experiments to evaluate the separation performance of ICA for acoustic signals. Experiments results show that if we can find appropriate placement of microphones, applying ICA to hearing prostheses as pre-processing can help the wearer hear more clear sounds.**

Keywords — **Independent Component Analysis (ICA), Acoustic Signals Separation, Hearing Prostheses.**

I. Introduction

With the influence of disease, tumor, exposure to noise, and aging process, many adults and children suffer from hearing loss [1]. These people usually require a hearing-aid, and some of them even wear a cochlear implant. These hearing prostheses both use microphones to record and amplify sounds, so environmental noise is one of the main reasons which will lower their performance [2-4]. The addition of adaptive filters typically can improve this situation [5-6]. However, for environmental noise whose spectrum overlaps the desired signal, it cannot be suppressed simply by a filter. Therefore, how to extract the desired components from mixed signals is an important issue in hearing applications, which refers to the *blind source separation* (*BSS*) problem [7-8].

BSS is an approach taken to estimate source signals from only observed mixed signals without a priori information about source signals and mixing environment [7-8]. *Independent component analysis* (*ICA*) is the dominant method for performing BSS. ICA is originally developed to deal with problems that are closely related to the *cocktail-party problem* as shown in Figure 1 [9]. Consider a cocktail party where many people are talking at the same time. If a microphone is present then its output is a mixture of voices. When given such a mixture, ICA looks for hidden statistically independent and non-gaussian components. ICA has wide range of applicability, such as biomedical signals analysis, speech signals separation, telecommunications, and finial data analysis [8, 10-12]. In this article we first describe the formal ICA definition and the usage for separating acoustic signals. Then, we conduct experiments in a soundproof room to evaluate the separation performance of ICA.

Fig. 1 Illustration of cocktail-party problem

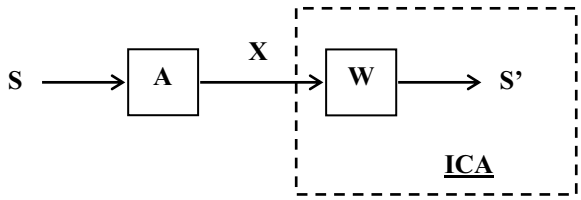

Fig. 2 Illustration of ICA formulation

II. Formal ICA Definition [7-8, 10, 12]

Given a set of observed signals $\mathbf{X} = (x_1, x_2, \ldots, x_m)^T$, which is a m-dimensional random variables. Assume that they are mixtures generated by linear combination of independent components $\mathbf{X} = \mathbf{AS}$, where $\mathbf{S} = (s_1, s_2, \ldots, s_n)^T$ is a set of source signals and $\mathbf{A}$ is a $m \times n$ mixing matrix. Both matrix $\mathbf{A}$ and signal set $\mathbf{S}$ are unknown. ICA is aimed to estimate $\mathbf{S}$ and $\mathbf{A}$, and obtains an $n \times m$ de-mixing matrix $\mathbf{W}$ where $\mathbf{S} \approx \mathbf{S'} = \mathbf{WX}$. Figure 2 illustrates the ICA formulation. It should be noted that sources are assumed be statistically independent and non-gaussian in ICA. In general the best de-mixing matrix $\mathbf{W}$ cannot be found, and ICA will make source components as independent as possible.

www.springerlink.com

III. ICA FOR ACOUSTIC SIGNALS SEPARATION

Conventional ICA is originally developed for the cocktail-party problem, but it is actually not well suit for separating mixed acoustic signals. One major problem is that conventional ICA assumes sources are linear mixing. However, in the real case sounds recorded by microphones are convolutive signals, because the mixing environment is noisy and reverberant. Thus, the observed signals **X** should be redefined as $\mathbf{X}(t) = \mathbf{A}(t)\mathbf{S}(t) = \sum_{k=-\infty}^{k=\infty} a(k)s(t-k)$, where t is the time index. It also make BSS problem of acoustic signals become to solve the de-convolution problem. Methods based on ICA for convolutive signals can perform in time-domain or frequency-domain [13]. Time-domain ICA is computational intensive due to computing many convolutions, such as [11-12, 14]. Frequency-domain ICA, such as [2-3, 9, 15], usually applies windowed Fourier transform to transfer mixed signals to frequency-domain, and does separation in each frequency bin individually. It may be more time efficient, but the derived permutation and scaling problems must be well resolved. In our experiment we select three ICA for comparison, two belong to time-domain and one is frequency-domain. Besides, although using ICA can separate mixed signals to original sources, the amplitude of separated signals may not equal to corresponding sources. If we want to apply ICA to real hearing prostheses, these separated signals must be scaled appropriately, in order to meet the volume of original sources.

In addition, noted that using ICA we need at least two recorded signals. Because the velocity of acoustic signals transferred in the air is really slow, there must be time-delay differences between different microphones from the same sources. Conventional ICA assumes sources are mixed instantaneously. That is, when the sampling rate or the distance between microphones is increasing, the *spatial aliasing effect* may degrade the separating performance. Intuitively that putting microphones near to each other can prevent the spatial aliasing effect. However, ICA requires more distinct mixed signals to get better separating results, which leads to put microphones apart. In our experiment we will compare the separating performance for different placements and distances between microphones.

IV. EXPERIMENTAL RESULTS

Figure 3 shows our experimental allocation in a soundproof room. Two sources, one speech and one noise, are produced by two loudspeakers. Two microphones are used to record mixing sounds, and then ICA is applied to separate the speech signal. In order to deal with the spatial aliasing effect, we add an artificial pulse into the speech source. This pulse will be visible in two recorded signals but at different timestamps. We then shift one recorded signals to make pulses align with the same timestamps, which will satisfy the assumption of ICA. Three ICA methods including FastICA, InfomaxICA, and Murata et al. [15] are applied for signals separation. FastICA and InfomaxICA belong to time-domain, and Murata et al. [15] is a frequency-domain ICA. Separated signals are scaled to have the same *average RMS* (*root-mean-square*) values as mixing sounds. As for the measurement we calculate the *improved segmental signal-to-noise ratio* (*SNR*), which equals the difference between segmental SNR of signals before and after separating. Larger segmental SNR indicates the separated speech signal is clearer.

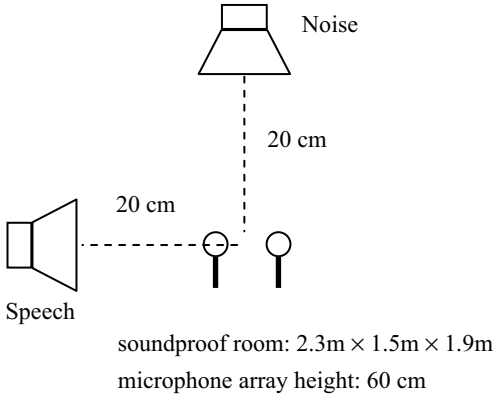

Fig. 3 The experimental allocation in the soundproof room

Three experiments are conducted in this article: the distance between microphones, the SNR between sources, and the placement of loudspeakers. According to Table 1, the improved segmental SNR is basically increasing when the distance between microphones increases. This result is predictable due to the principle of ICA, which requires more distinct mixed signals to get better separating performance. When we various the input SNR of sources, we will find that the segmental SNR is apparently improved only if the input SNR is non-positive. This is because speech signal has already quite clear in the mixed signals if the input SNR ≥ 5, the potential improvement can be achieved using ICA will be limited. About the third experiments, we place loudspeakers at different angles as shown in Figure 4. Results of this experiment are irregular, but in most cases the improved segmental SNR becomes larger when two loudspeakers are put opposite, such as 135°, 180°, or 225°. This situation is similar to that of in the first experiment. When two sources are produced farther from each other, two mi-

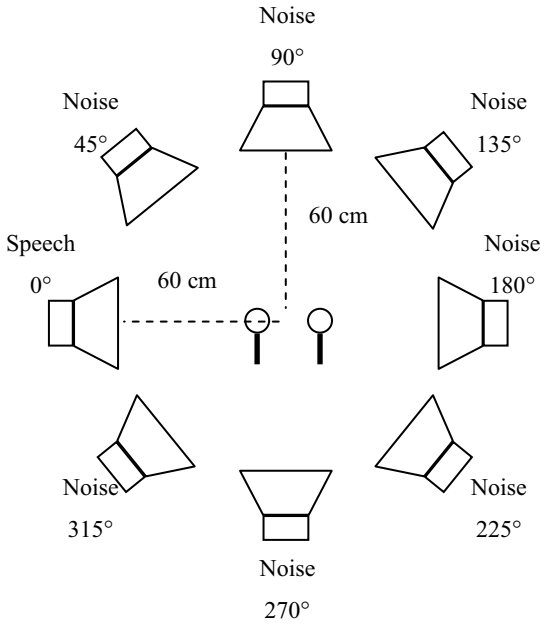

Fig. 4 The placement of loudspeakers at different angles

crophones will record more distinct mixed signals, which benefit ICA doing separation.

Comparing separating performances achieved by three ICA methods, we find that InfomaxICA performs inferior to other two methods. In addition, after applying ICA we almost obtain positive improved segmental SNR values, which indicate the volume of noise is definitely suppressed in the separated speech signals. Therefore, we believe applying ICA to real hearing prostheses will help the wearer hear more clear sounds.

V. Conclusions

In this paper we conducted experiments to evaluate the separation performance of ICA. Experimental results show that although using ICA cannot perfectly extract the speech signal, the volume of noise is definitely suppressed. Factors such as input SNR and placements of microphones and sources also affect the separating performance of ICA. We expect that after finding an appropriate placement of hardware, ICA will be a useful technique to be used in real hearing prostheses.

Age-Related Changes in Specific Harmonic Indices of Pressure Pulse Waveform

Sheng-Hung Wang[1], Tse-Lin Hsu[2], Ming-Yie Jan[2], Yuh-Ying Lin Wang[3] and Wei-Kung Wang[1,2]

[1]Department of Electrical Engineering, National Taiwan University, Taiwan

Abstract — **The central elastic arteries and the peripheral muscular arteries are different in their responses to aging. Aorta stiffens in much larger extent with age than peripheral arteries do. Peripheral blood pressure indices such as pulse pressure (PP) or augmentation index (AI) were preferred as surrogates in assessing arterial stiffness for clinical convenience. AI and PP both increase progressively with age.**

In this study, we present a harmonic based pulse waveform analysis method which may give similar result about central pressure as augmentation index. This method avoids the extra but necessary manipulations such as flow measuring, 4th derivative of pressure wave in determining the inflection point, the second systolic peak for augmentation index calculating, all these manipulations can introduce error. The non-invasive peripheral pulse waveforms copied from published reports for several ageing studies were analyzed. The mean pulse height *A0* and the harmonic proportion of the 1st harmonic *C1* increased but the harmonic proportion of the 3rd harmonic *C3* and the harmonic proportion of the 4th harmonic *C4* decreased with ageing. Aging had no significant effect on the harmonic proportion of the 2nd harmonic *C2*. Among all these harmonic indices, *A0*, the mean pulse pressure increased dramatically since the 6th decade.

These results suggest that A0 is related to aorta stiffen or PP sensitive. The gradual increasing of C1 and gradual decreasing of C3 and C4 by ageing suggest that C1, C3 and C4 could be similar to AI; it corresponds to the pressure pulse waveform affected from ageing.

The harmonic indices could be clinically useful in non-invasive cardio risk assessing for the elderly patients.

Keywords — **Ageing, Augmentation Index, Harmonic Analysis, Blood Pressure Pulse Waveform, Biosignal Processing**

I. Introduction

With the advancement of health care the average age of death is increased every year. The issue of gerontology is more and more important with the ageing population. It has been noted that aorta stiffens in much larger extent with age than peripheral arteries [1] [2]. It is convenient to assess arterial stiffness in clinic by peripheral blood pressure indices such as pulse pressure (PP) or augmentation index (AI) which both increase progressively with age [3].

However to calculate AI value needs to measure pressure and flow velocity at the same time [4] or 4th derivative of the measured pressure wave [5] [6] to determine the second systolic peak or the inflection point. The previous method needs extra flow measuring; and the latter one may give erroneous results sometimes [7] [8].

In this study, we analyze the pulse waveform from the published report of ageing effect. The pulse waveform was described by the harmonic proportions together with the mean pulse height where the harmonic proportions equal the amplitude of each harmonic divided by mean pulse height [9] [10]. The change of harmonics with ageing is expected.

II. Method

A. The data source

The data source is scanned from the report of Kelly et al. 1989 as shown in figure 1 [5]. Radial pulse waveforms were collected from 420 normal subjects who were 2-91 years old (207 men and 213 women) of whom 82 were smokers. Each pulse waveform is average of 40-70 individual pulse. Amplitude is showed in uncalibrated voltage (mV) units which can be translated into pressure unit (mm Hg) from the Millar preamplifier box as 1 mV to 1 mm Hg.

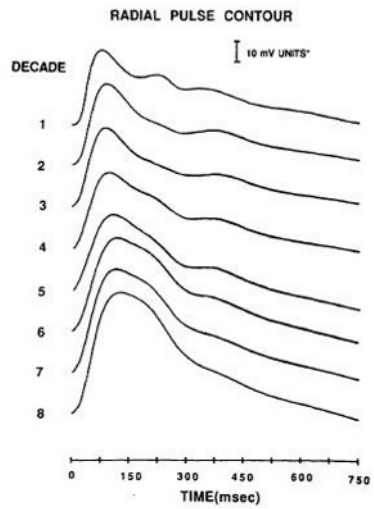

Fig. 1 Pulse waveform of 1 to 8 decades from 420 subjects

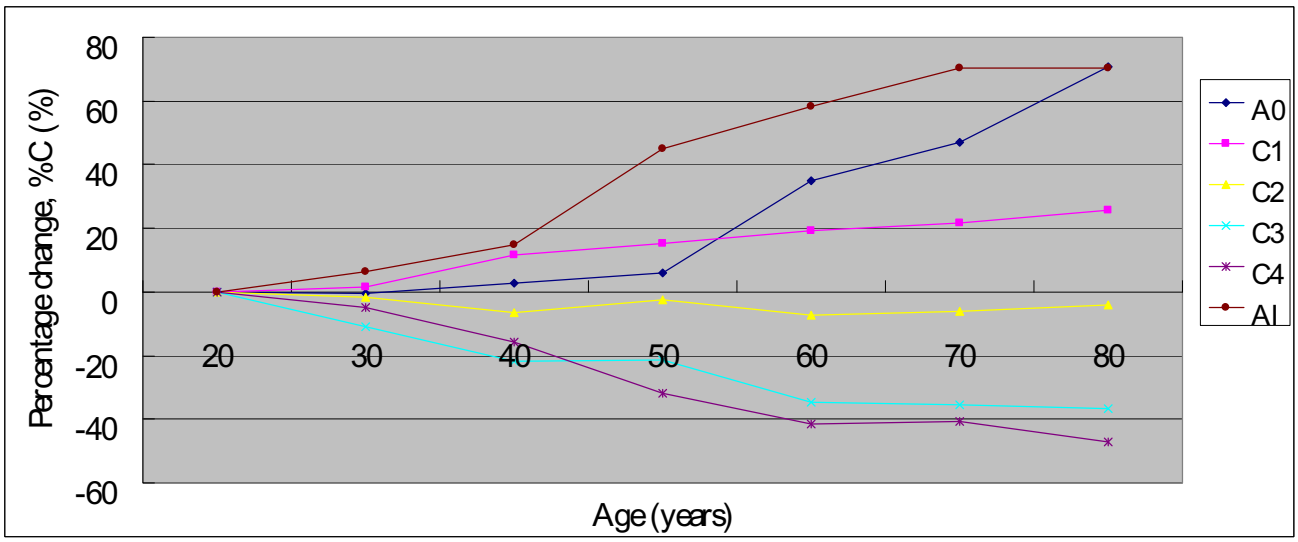

Fig. 2 Percent changes of pressure pulse harmonic proportions and AI with ageing

B. Digitalization and Analysis

Each pulse is scanned form the data source and is digitalized into 1068 points on the same time interval by the program "MATLAB". The digitalized pulse waveform was adjusted with the slope to make the start and the end point at the same height. The adjusted data are Fourier transformed into frequency domain. In this study, we only focused on the change in the first four harmonics and compute the harmonic proportion *Cn* as a pattern instead of the amplitude *An* of the nth harmonic. *Cn* was defined as *Cn = An/A0*, where *A0* is the mean value of pulse pressure.

The pulse waveform of the 2nd decade of age was used as control. The other ages such as 3rd, 4th, 5^{rh}, 6th, 7th and 8th decade were presented as the percentage changes $\%C^{Cn}$ in the harmonic proportion of the n^{th} harmonic between the spectrums of each decade of age and control,

$$(\%C^{Cn}) = 100 \times \frac{Cn,test - Cn,cont}{Cn,cont}, \qquad (1)$$

where Cn,cont is the harmonic proportion of the nth harmonic of the control, Cn,test is the harmonic proportion of the nth harmonic of the testing pulse waveform under aging.

The percent change $\%C^{A0}$ of the mean pulse pressure was presented as

$$(\%C^{A0}) = 100 \times \frac{A0,test - A0,cont}{A0,cont}, \qquad (2)$$

where A0,cont is the mean pulse pressure of the control, A0,test is the mean pulse pressure of the testing pulse wave form under aging.

The percent change $\%C^{AI}$ of the augmentation index was presented as

$$(\%C^{AI}) = 100 \times \frac{AI,test - AI,cont}{AI,cont}, \qquad (3)$$

where AI,cont is the augmentation index of the control, AI,test is the augmentation index of the testing pulse waveform under aging which was intercepted from the data source directly.

III. Result

The calculated data of the 2nd decade of age as the control is showed on table 1. The testing data is based on the control.

Figure 2 is the result of the testing harmonic proportion of 3rd to 8th decade of age which is compared with that of the control. The mean pulse pressure *A0* and the harmonic proportion of the 1st harmonic *C1* increased with ageing. The harmonic proportion of the 3rd harmonic *C3* and the

Table 1 data of 2nd decade of age (the control)

A0 (mm Hg)	C1	C2	C3	C4	AI (%)
14.3	77.8	52.1	38.1	21.5	3

Table 2 Averaged percent changes of %C and AI on 3rd- 4th, 5rh- 6th and 7th -8th decade

Age (yr)	% C^{A0} (%)	%C^{C1} (%)	%C^{C2} (%)	%C^{C3} (%)	%C^{C4} (%)	%C^{AI} (%)
30-40	1.25	6.46	-4.02	-16.5	-12.3	10.5
50-60	20.5	17.1	-4.80	-28.1	-47.7	51.7
70-80	58.9	23.7	-5.12	-36.1	-46.8	70.3

harmonic proportion of the 4th harmonic *C4* decreased but no significant change on the harmonic proportion of the 2nd harmonic *C2* with ageing. Among all these harmonic indices *A0* increased conspicuously at the 6th decade.

Table 2 averaged the percent change of AI, *A0* and harmonic proportions of harmonic 1 to 4 into three age groups. Averaged *A0* on age group between the 7th to 8th decades is about 2.8 times of the value on age group between the 5th and 6th decades. But the percent changes of C1, C2, C3, C4 and AI on age group between the 7th to 8th decades are only 1 to 1.4 times of the value on age range between the 5th and 6th decades. Averaged *A0* on age group between the 5th to 6th decades is about 16 times of the value on age group between the 3rd and 4th decades. But the percent changes of C1, C2, C3, C4 and AI on age group between the 5td to 6th decades are only 1 to 4 times of the value on age group between the 3rd and 4th decades.

IV. Discussion

From the results of this study, the mean pulse pressure, A0, is changed noticeably with ageing. Ageing could cause the increase of aorta stiffen and the pulse pressure. A0 may be an index that related to aorta stiffen or PP sensitive. The gradual increasing of C1 and gradual decreasing of C3 and C4 by ageing suggest that C1, C3 and C4 could be similar to AI which corresponds to the pressure pulse waveform affected from ageing. These harmonic indexes all have high correlation coefficient to augmentation index (C1: R=0.96; C3: R=-0.93; C4: R=-0.92) but use an easier algorithm. Only we need to do is to get the pulse waveform from the subject non-invasively and use Fourier transform for these pulse waveform. This analysis leaves out the measurement of blood flow and avoids the errors caused by the determination of the shoulder of pressure pulse. We could easily estimate the change of pulse waveform by harmonic analysis method. The harmonic indices could be clinically useful in not only geriatric hypertension research but also cardiovascular drugs development.

V. Conclusions

In this study we present an assessment of the change on the pulse waveform by harmonic analysis method. The harmonic index provides the similar result as augmentation index without the measurement of blood flow. The harmonic indices could be clinically useful in non-invasive cardio risk assessing for the elderly patients.

Abstract — **The paper describes the pre-processing and subsequent segmentation of NMR images of the human head in the region of temporomandibular joint in several slices. Image obtained by means of the tomograph used are of very low resolution and contrast, and their processing may prove to be difficult. A suitable algorithm was found, which consists in pre-processing the image by a smoothing filter, sharpening, and the four-phase level set segmentation. This method segments the image on the basis of the intensity of regions and is thus suitable for processing the above-mentioned NMR images, in which there are no sharp edges. The method also has some filtering capability. It is described by partial differential equations that have been transformed into corresponding difference equations, which are solved numerically. In the next stage, segmented slices of temporomandibular joint will be used to create a multidimensional model. A spatial model gives a better idea of the situation, structure and properties of tissues in the scanned part of patient's body. Multidimensional modeling mainly represents a change in describing input NMR data. The segmented regions need to be transformed from discrete to vector description i. e. the outer geometry of objects needs to be described mathematically.**

Keywords — **NMR imaging, image segmentation**

I. Introduction

NMR images serve the purpose of following the development and quantitative measurement of tissues. Segmentation can be applied to images and subsequent evaluation of the parameters of individual regions such as circuit, area or volume in case images from several slices are available. The present paper is concerned with the segmentation of images of the human head in the temporomandibular joint region. Available were 12 slices of the human head, with 2 test images being chosen for the experiment with the selected segmentation method. Image segmentation in several slices can be used for subsequently constructing a multidimensional model of the selected part of image.

Processing the NMR images obtained is difficult since they are of low resolution (the human head in the image is 256x256 pixels) and not very high contrast. The images need to be processed properly and then segmented by an appropriate method [1]. Fig. 1 gives an example of such an NMR test image and a detail of the temporomandibular joint that has been segmented.

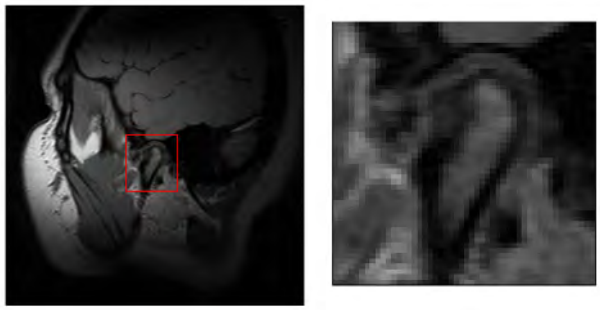

Fig. 1 NMR image of human head, slice with visible temporomandibular joint

The goal of segmentation is to find the temporomandibular joint in the NMR images. Prior to the segmentation itself, the image was focused and then smoothed with a simple averaging mask. The method chosen for segmentation was the four-phase level set method, which searches for regions of similar intensity in the image. This approach is of much advantage in NMR images since there are no sharp transitions here between the regions sought. The result of segmentation is an image with four levels of brightness, which correspond to the mean intensity value of the regions of original image. The segmented image can be further processed. The regions can be measured at random and a quantitative description can be obtained or the individual slices can be used to construct a multidimensional model of the selected part of image.

II. Multiphase level set segmentation

The multiphase level set for image segmentation is a generalization of an active contour model without edges based on 2-phase segmentation developed by T. Chan and L. Vese [2]. It is based on minimizing the energy given by energy functional:

$$F_n(\mathbf{c},\mathbf{\Phi}) = \sum_{1\le I\le n=2^m} \int_\Omega \left(u_0(x,y)-c_I\right)^2 \chi_I \mathrm{d}x\mathrm{d}y + \sum_{1\le i\le m} \nu \int_\Omega \left|\nabla H(\Phi_i)\right|, \quad (1)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 186–189, 2009
www.springerlink.com

where n is the number of phases (different intensity recognition), m is number of level set functions, u_0 is the observed image as intensity function of x and y, $\mathbf{c}$ is a constant vector of averages, where $c_I = mean(u_0)$ in the class I, χ_I is a characteristic function associated with phase Ω_i, $\nu > 0$ is a fixed parameter to weight the different term (length functional) in the energy, H is the Heaviside function $H(z)$, equal to 1 if $z \geq 0$ and to 0 if $z < 0$. $\mathbf{\Phi}$ is a vector of level set functions.

The boundary of region is given by the zero level set of a scalar Lipschitz continuous function Φ (called level set function). A typical example of level set function is given by the signed distance function to the curve of boundary. In figures 2 and 3 we can see the principle of region classification by the Heaviside function. There are two initial level set functions, Φ_1 and Φ_2, and their zero levels (boundaries of regions). Clearly, we will need only the $\log_2 n$ level set functions for the recognition of n segments with complex topologies.

In our case for $n = 4$ (and therefore $m = 2$) we obtain the 4-phase energy given by:

$$\begin{aligned} F_4(\mathbf{c},\mathbf{\Phi}) = & \int_\Omega (u_0 - c_{11})^2 H(\Phi_1) H(\Phi_2)\,dxdy \\ & + \int_\Omega (u_0 - c_{10})^2 H(\Phi_1)(1 - H(\Phi_2))\,dxdy \\ & + \int_\Omega (u_0 - c_{01})^2 (1 - H(\Phi_1)) H(\Phi_2)\,dxdy \\ & + \int_\Omega (u_0 - c_{00})^2 (1 - H(\Phi_1))(1 - H(\Phi_2))\,dxdy \\ & + \nu \int_\Omega |\nabla H(\Phi_1)| + \nu \int_\Omega |\nabla H(\Phi_2)|, \end{aligned} \tag{2}$$

where $\mathbf{c} = (c_{11}, c_{10}, c_{01}, c_{00})$ is a constant vector and $\mathbf{\Phi} = (\Phi_1, \Phi_2)$.

We can express the output image function u as:

$$\begin{aligned} u = & c_{11} H(\Phi_1) H(\Phi_2) + c_{10} H(\Phi_1)(1 - H(\Phi_2)) \\ & + c_{01}(1 - H(\Phi_1)) H(\Phi_2) \\ & + c_{00}(1 - H(\Phi_1))(1 - H(\Phi_2)). \end{aligned} \tag{3}$$

By minimizing the energy functional (2) with respect to $\mathbf{c}$ and $\mathbf{\Phi}$ we obtain the Euler-Lagrange equations:

$$\begin{aligned} \frac{\partial \Phi_1}{\partial t} = & \delta_\varepsilon(\Phi_1)\left\{\nu \operatorname{div}\left(\frac{\nabla \Phi_1}{|\nabla \Phi_1|}\right)\right. \\ & - \left[\left((u_0 - c_{11})^2 - (u_0 - c_{01})^2\right) H(\Phi_2)\right. \\ & \left.\left. + \left((u_0 - c_{10})^2 - (u_0 - c_{00})^2\right)(1 - H(\Phi_2))\right]\right\}, \end{aligned} \tag{4}$$

$$\begin{aligned} \frac{\partial \Phi_2}{\partial t} = & \delta_\varepsilon(\Phi_2)\left\{\nu \operatorname{div}\left(\frac{\nabla \Phi_2}{|\nabla \Phi_2|}\right)\right. \\ & - \left[\left((u_0 - c_{11})^2 - (u_0 - c_{10})^2\right) H(\Phi_1)\right. \\ & \left.\left. + \left((u_0 - c_{01})^2 - (u_0 - c_{00})^2\right)(1 - H(\Phi_1))\right]\right\}, \end{aligned} \tag{5}$$

where t is a artificial time, δ_ε is the Dirac function (derivation of Heaviside function). By applying the finite differences scheme we will give the numerical approximations of Euler-Lagrange equations for iterative process implementation.

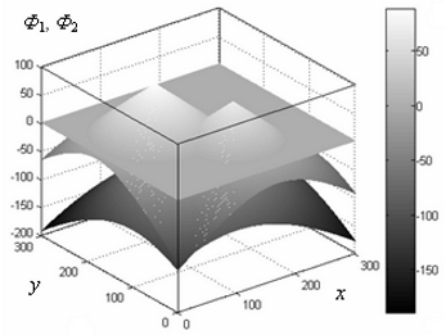

Fig. 2 Two initial level set functions and zero level

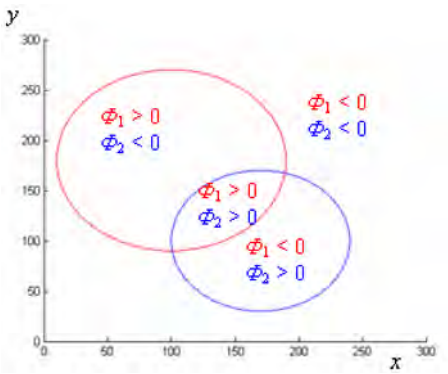

Fig. 3 Zero-cross levels and regions classification by level set functions signs

III. Implementation

In view of the image properties, the segmentation can be performed after an appropriate pre-processing. The first to be performed was convolution, with subsequent sharpening mask to enhance the contrast:

$$H = \frac{1}{(\alpha+1)}\begin{bmatrix} -\alpha & \alpha-1 & -\alpha \\ \alpha-1 & \alpha+5 & \alpha-1 \\ -\alpha & \alpha-1 & -\alpha \end{bmatrix}, \quad (6)$$

where the coefficient α determines the form of the Laplace filter used; the suitable value 0.001 was established experimentally.

The next step consists in smoothing the focused image. For this purpose, the simplest 3rd - order averaging mask was used:

$$H = \frac{1}{9}\begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}. \quad (7)$$

The pre-processed image was further subjected to the above-mentioned four-phase level set segmentation. Partial differential equations were transformed into corresponding difference equations, which are solved in iterations. The number of iterations was controlled by following the derivatives of energy function, which via successive segmentation of regions with similar intensities converged to zero.

IV. Experimental results

The result of segmentation is shown on the example of two NMR images in Figs. 4 and 5. These are two slices of the human head in the region of temporomandibular joint. At the top of the figures we can see a slice of the original image and the result of the segmentation of pre-processed image with the contours of segmented regions marked out. In the bottom of the figures the segmented image by four-phase segmentation is given. The intensity of each region is given by the mean intensity value of individual pixels in the respective region of the original image.

Table 1 Parameters of segmentation with Celeron 1.4 GHz, 768 MB RAM and Windows XP, Matlab 7.0.1

Image	Number of iterations	Duration [s]
A	14	Bold
B	12	Regular

V. 3D modeling

The aim of the next work is creation of 3D model of tissue from segmented 2D slices. This process consists of three steps [3]:

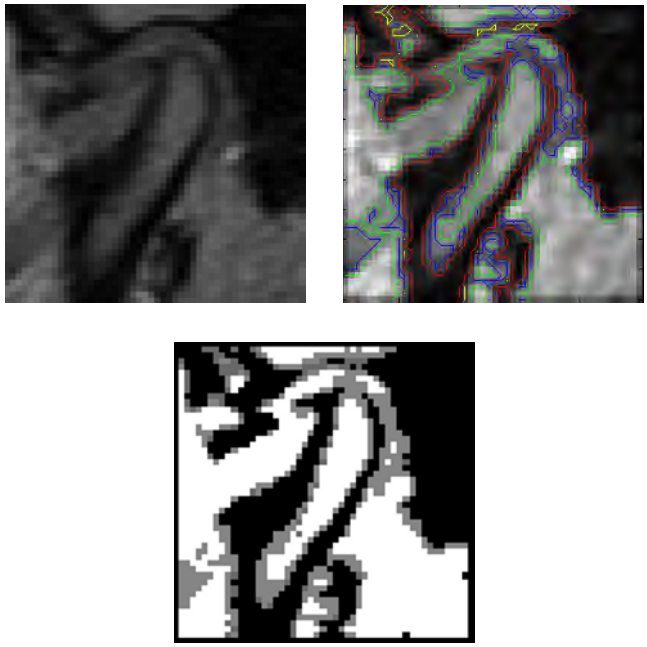

Fig. 4 Image A segmentation

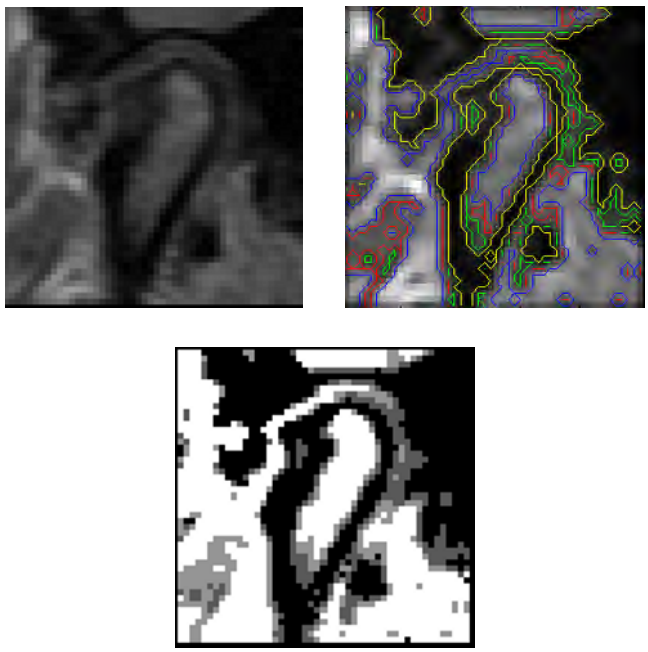

Fig. 5 Image B segmentation

1. Change of the data description – from discrete to vectorial description by the most used “Marching cubes” method for fully automated creation of geometrical models

2. Smoothing – e.g. by Laplace operator, because the changing of description cause that the geometrical model is stratified
3. Decimation – elimination of small triangles with maximal geometry preservation for surface simplification.

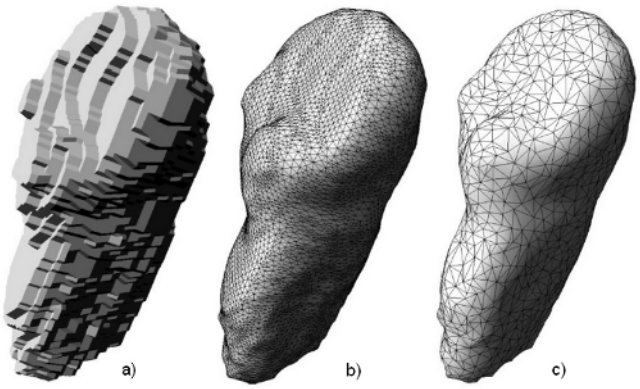

Fig. 6 Process of 3D creation (tooth), a) example of "Marching cubes" model, b) smoothed model, c) decimated model [3]

VI. Conclusions

The paper describes the application of a modern segmentation method with a suitable combination of pre-processing of NMR image of the human head. The images used are of low contrast and low resolution. The region of temporomandibular joint that was the subject of segmentation is of a mere 60 x 60 pixels, which makes precise processing difficult.

The output of the algorithm used is an image made up of regions with four levels of gray. These levels correspond to the mean values of pixel intensities of the original image. Segmenting the temporomandibular joint in several slices by the above-given method can be used, for example, to construct a three-dimensional model. Using the multiphase segmentation method, a more precise model can be obtained because by means of several levels of two-dimensional slice the resultant model can be approximated with greater precision.

Abstract — **The paper describes the pre-processing and subsequent segmentation of NMR images of growing tissue cultures. Images obtained by the NMR technique give three separately growing cultures. The aim of the work was to follow the speed of their development. Images obtained by means of the NMR device used are of very low resolution and contrast and there are no sharp edges between regions. Processing such images may prove to be quite difficult. A suitable algorithm was found, which consists of the pre-processing of the image and subsequent multiphase level set segmentation. The proposed method segments the image based on the intensity of the regions sought, and is suitable for working with NMR images in which there are no sharp edges. The method is described by partial differential equations that were transformed into corresponding difference equations solved numerically. Processing the detected images and measuring the sequence of NMR data give a graph of the growth development of the tissue cultures examined in comparison with manual measurement of their content.**

Keywords — **NMR imaging, image segmentation.**

I. Introduction

MRI is useful to obtain the number of hydrogen nuclei in biology tissue or to follow growing of cultures. There was provided examination by MR techniques [1] for rate of growth considering, rising of percentage of protons and cluster's shape of somatic germ. These measurements were part of research for hypothesis verification about increase percentage of water in process of tissue culture growth in case of cadmium contamination. In this case we put into tomograph operating area the measured tissue, choose the right slicing plane and measure MR image in this plane. The image is weighted by spin density and pixel intensity is equal to number of proton nucleus in chosen slice. MR image is a map of protons distribution in measured cluster of growing tissue culture [2].

The same technique was used for growth characterizing of early spruce germs contaminated by lead and zinc. There was computed intensity integral characterizing the number of protons in growing cluster and there were specified the changes of this value during the growth from MR images.

For measurement was used the spin-echo method because in contrast to gradient-echo technique the influence of the base magnetic field non-homogeneity is eliminated and images have better signal to noise ratio. The signal to noise ratio depends on the chosen width of slice. With thinner slices is the number of nucleus which generates signal smaller and the signal to noise ratio decreases. However the minimum width of slice is useful for tissue cultures imaging. The optimum width 2 mm was found. We must choose a size of image with a view to size of the tissue clusters and to size of operating probe. To improve the signal to noise ration we can repeat the measurement and average the results but it is more time-consuming. It is impossible to repeat the measurements quickly with regard to time of relaxation of water ($T_1 \approx 2$ s, $T_2 \approx 80$ ms). It is appropriate to choose the repetition cycle equal to spin-grid time of relaxation $T_R \approx T_1$. In our case for size of image 256x256 pixels is measurement time 256 x T_R.

There was placed small flask filed by deionized water for tomograph parameters instability suppression during long-term measurement. Obtained intensities of each image were scaling according to intensity of water in the flask (fig. 1).

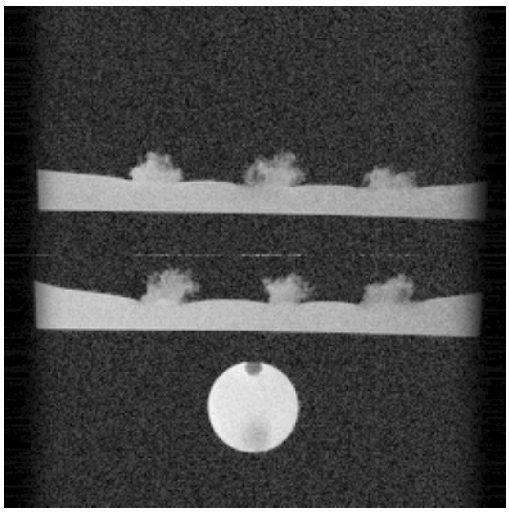

Fig. 1 Example of obtained image with 6 clusters and small flask filed by water for checking and scaling the image, at the top are the clusters contaminated by Zn, at the bottom are the clusters contaminated by Pb

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 190–193, 2009
www.springerlink.com

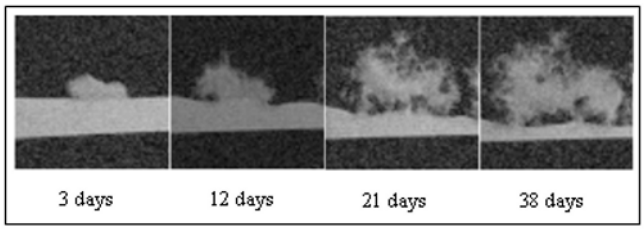

Fig. 2 Example of one cluster growth which is contaminated by lead 1000 mg/l

For described experiments was used MR tomograph with horizontal magnet (magnetic field 4.7 T) and operating area with diameter of 120 mm. Active shield gradient coils generate the maximal gradient field 180 mT/m.

At the first the data were processed in MAREVISI software where was achieved the manual computation of cluster surface from diffusion image and intensity integral of clusters from images weighted by spin density. Further the images weighted by spin density were filtered by wavelet transformation and segmented by region level set method. From segmented clusters was computed their surface and intensity integral too. Both methods were compared.

II. Measurement methods

The integral of image data could be established by two approaches. The first of them is sum of intensities in chosen part of image containing contaminated clusters divided by count of pixels

$$I_i = \frac{x_{\max} y_{\max}}{M.N} \sum_{1}^{M} \sum_{1}^{N} s_i \,, \tag{1}$$

where I_i is intensity integral, $x_{\max}$ a $y_{\max}$ are maximum dimensions of image in axis x and y.

The second approach utilizes properties of Fourier transformation and relation between MR image and interferential image which consist of obtained complex data. This relation could be described by following equation [3]:

$$s_i\left(k_x, k_y\right) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \rho_i\left(x, y\right).\mathrm{e}^{-2\pi\left(k_x x + k_y y\right)} \mathrm{d}x\mathrm{d}y, \tag{2}$$

where k_x and k_y are axis in measured interferential image called spatial frequency, $\rho_i(x,y)$ is distribution of spin density in MR image. For $k_x = k_y = 0$ we obtain:

$$s_i\left(0,0\right) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \rho\left(x, y\right) \mathrm{d}x\mathrm{d}y = I_i \,. \tag{3}$$

Number of the protons nucleus in measured sample is proportional to integral I_i which is equal to intensity of interferential image in zero point, i.e. for $k_x = k_y = 0$. Integral of MR image after DFT could be computed by this equation:

$$I_i = \frac{x_{\max} y_{\max}}{M.N} s_i\left(0,0\right). \tag{4}$$

The results of both methods are identical and the error is less than 1%. This approach is useful in case measurement of one tissue cluster.

For the results verification were the images filtered by means of wavelet transformation and consequently segmented by four-phase level set method. In fig. 3 is shown the example of processed image by described approach. The surface and intensity integral is then computed only from bounded clusters and due to the result is not devaluated by noise around clusters. The results are compared in the next chapter.

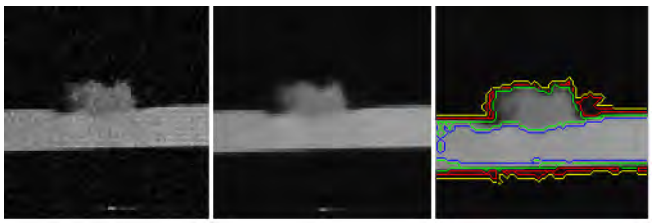

Fig. 3 Example of the image processing, on the left is the original image, in the middle is the wavelet transform filtered image and on the right is the segmented cluster by four-phase level set segmentation (green curve)

III. Results

Relation between intensity of cluster (thereby relative number of protons) and time of growth is for various Zn and Pb contaminations shown in fig. 4 and fig. 5. Clearly, the proton concentration in cluster of tissue culture grows all the time independently on tissue culture growth capability. The capability of growth dramatically decreases after 14 – 20 days to minimum. Relation between number of protons in tissue culture with contamination Zn or Pb and level of concentration by this element is shown in fig. 6 and fig. 7. We can find a concentration in which the percentage of protons is the highest all the time of growing. With zinc contamination is the optimal concentration 250 mg/l and for lead is the concentration 50 mg/l. In diffusion images are the clusters more precisely bounded and the evaluation of cluster surface is more accurately. It does not reflect a concentration of proton nucleus and the results are different from intensity integral measurement. The cluster's surfaces were evaluated from images weighted by spin density by wavelet filtration method and consequential region four-phase level set segmentation.

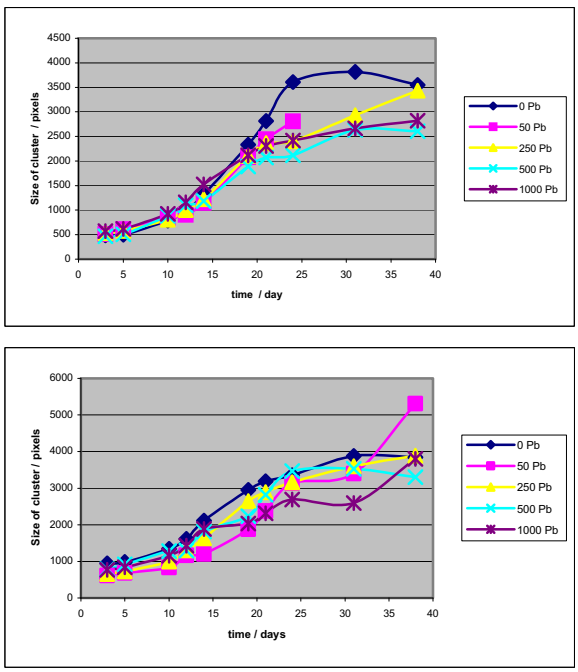

Fig. 9 Measurement of cluster size for various Pb concentrations, on the top is the result of the manual method, on the bottom is the result of the segmented image processing

IV. Conclusions

The MRI technique is useful for observing of the growth of the spruce germs and for verification of the hypothesis of increasing amount of water in the growing tissue cultures with various metal contaminations thereby their faster elutriation. The basic measurements and data processing by two different methods were taken. The aim of this work was the surface and the intensity integral measurement in time. Firstly the data were manually processed in the MAREVISI software by measuring of the cluster's surface in the diffusion images and then by the measuring of the intensity integral in the images weighted by the spin density. Further the images weighted by the spin density were processed by the wavelet transformation and segmented by the four-phase level set method and both monitored values were obtained in the Matlab. Both methods gives similar results thereby the measurement was verified.

Abstract — **Accurate detection of myocardium is much important in diagnosis of heart diseases. In this study, we proposed the myocardial detection method by combining level set method in 2D image and 3D NURBS approximation. We first extracted epi- and endocardial walls by level set method in 2D image. Calculation cost was reduced by the processing on the slice. In this extraction, we used a near-circular shape of left ventricle and set the initial circle in the myocardial region surrounding the endocardium. We then approximated these extracted walls with 3D NURBS (Non-uniformed rational B-spline) model. Here, we used third-order B-spline basis function. In our study, we applied the method to MRI T1-weighted heart images of 10 subjects (5 normal subjects and 5 patients with apical hypertrophic cardiomyopathy). The pixel size was 1.62 ×1.62 mm, and the slice interval and the number of slices were 6.62 mm and 18, respectively. Evaluation of our method was done by comparing with manual detection by two cardiologists. As a result, the accuracy of endocardial detection was about the same as or less than the difference between cardiologists. While on the other hand, that of epicardial detection was larger than the difference between cardiologists. We inferred that epicaridial contour is clearer than endocardial one. Average of detection error by the method combining level set method and NURBS approximation (endocardium: 2.58 mm / epicardium: 2.71 mm) was smaller or almost same as only level set method (2.77 mm / 2.51 mm). However, as for variance of the error, combining method (0.58 mm / 0.59 mm) was smaller than only level set method (1.07 mm / 1.06 mm). These results show that NURBS approximation suppressed the variation of the detection accuracy.**

Keywords — **level set method, NURBS approximation, myocardial wall thickness.**

I. Introduction

In recent years, cardiac disease has become one of the most common causes of death. Therefore, quantitative evaluation of myocardial function is much important in diagnosis including disease prevention. We have already proposed the method to extract the left ventricle (LV) of apical hypertrophic cardiomyopathy and made wall thickness map from cardiac magnetic resonance imaging (MRI)[1]. However, in the method, we used the slice-based method and linear approximation between slices for obtaining myocardial volume. In this study, we extended the method by introducing the NURBS (Non-uniformed rational B-spline) model considering 3-D shape.

Some reports applying the NURBS model to heart images can be found. Segars et al.[2] developed realistic heart phantom which is patient-based and flexible geometry-based phantom to create a realistic whole body model. Then they make polygon surfaces fit the points extracted from the surfaces of heart structures for each time frame and smoothed. 4-D NURBS surfaces were fit through these surfaces. Same research group Tsui[3] also investigated the effects of upward creep and respiratory motion in myocardial SPECT by using NURBS modeling the above phantom. Tustison et al. [4] used NURBS for biventricular deformation estimated from tagged cardiac MRI based on four model types with Cartesian or Non-Cartesian NURBS assigned by cylindrical or prolate spheroidal parameter.

Lee et al.[5] developed hybrid male and female newborn phantoms to take advantages of both stylized and voxel phantoms. NURBS surfaces was adopted to replace limited mathematical surface equations of stylized phantoms, and the voxel phantom was utilized as its realistic anatomical framework. In the method we have already proposed, it has a problem that the error due to local misdetected contours gives the nonsmooth map of final result. In this study, to suppress local misdetection on slice level, we introduced NURBS model reflecting 3-D structral myocardial shape to the previous method.

II. Methods

In this study, MRI images were acquired using a Philips GyroscanNT. T1 images (256 × 256 pixels) at LV end-diastolic were obtained under synchronization with the electrocardiogram at echo time 40 ms to cover the whole heart region. The pixel size of the images was 1.62 × 1.62 mm2 and the slice thickness was 5 mm. The slice interval and the number of slices were 6.62 mm and 18, respectively. Short axial slices were acquired through the heart,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 194–197, 2009
www.springerlink.com

perpendicular to the line connecting the cardiac apex and base.

We first detected the contours of endcardium and epicardium on the axial slice by level set method. And then, we constructed 3-D curved-surfaces on each myocardium by NURBS approximation. By applying NURBS, the misdetection by the level-set method in slice-based processing can be absorbed. We subsequently described about cardiac wall detection, NURBS fitting and image registration in detail. We finally show the constructing the bull's eys map for easy visual understanding.

A. Cardiac Wall Detection

The level set function we used is the model introduced by Malladi et al.[6] that considers curvature. We chose this model because it is considered that myocardial walls have smooth contours. In MRI images, we manually set the initial circle of the level set in the myocardial region to obtain the endocardial and epicardial walls because the LV has a near-circular shape in the MRI short-axis cardiac images. We then applied the level set method to contour detection.

Application and an example of an extracted result by this processing are shown in Fig. 1.

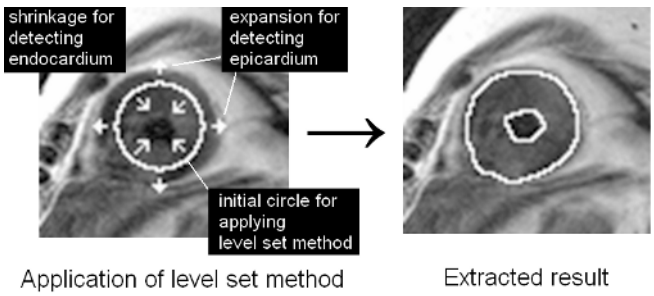

Fig. 1 Extraction of myocardial walls by level set method

We implemented 2-D image processing because we can stably extract myocardial contours. Namely, we can determine the number of times to update the level set function, after-mentioned, on every slice even if there are variations in image contrast between slices. This method uses a dynamic contour model that iteratively deforms the contour, beginning from the initial contour, to increase the gradient of the pixel values. The surface is presented as an equipollent level of the function $\phi^t(x,y)$. Zero crossover points form the contour by updating $\phi^t(x,y)$. The equation is described as follows, when the boundary surface at the time $t+\delta t$ is defined as $\phi^{t+\delta t}(x,y)$.

$$\phi^{t+\delta t}(x,y) = \phi^t(x,y) - \delta t(1-\varepsilon\kappa)V(x,y)\nabla\phi^t(x,y) \tag{1}$$

Here, δt and κ are the time interval and curvature, respectively. We set ε at 0.5.

$$\varepsilon = \nabla\cdot\frac{\nabla\phi}{|\nabla\phi|} = \frac{\phi_{xx}\phi_y^2 - 2\phi_y\phi_x\phi_{xy} + \phi_{yy}\phi_x^2}{(\phi_x^2+\phi_y^2)^{3/2}} \tag{2}$$

The function $V(x,y)$ in the right-hand side of (1) is the function that adjusts the growth of the border surface. In this study, we used the velocity function:

$$V(x,y) = -\frac{1}{1+\nabla(G_\sigma * I(x,y))} \tag{3}$$

, where $I(x,y)$ are pixel values at arbitrary coordinates (x, y) and G_σ is the Gaussian smoothing filter whose standard deviation is σ. Here, we give the following equation as the initial function $\phi_0(x,y)$:

$$\begin{cases} \phi_0(x,y) = (x-x_0)^2 + (y-y_0)^2 - r_0^2 \\ \qquad\qquad \text{(for endocardium detection)} \\ \phi_0(x,y) = -(x-x_0)^2 - (y-y_0)^2 + r_0^2 \\ \qquad\qquad \text{(for epicardium detection)} \end{cases} \tag{4}$$

Updating in Eq.(1) was stopped when the variation of summation of $\phi(x,y)$ in an enclosed region by the border was at the minimum.

NURBS Fitting

3-D NURBS surface of degree p in the u direction and degree q in the v direction is defined as a piecewise ratio of B-spline polynomials by the folloing equation. In this study, we set both parameters p and q at 3.

NURBS function, $S(u,v)$, can be described with next equation.

$$\begin{aligned} S(u,v) &\equiv (x(u,v), y(u,v), z(u,v)) \\ &= \frac{\sum_{i=0}^{n}\sum_{j=0}^{m} N_{i,p}(u)N_{j,q}(v)\omega_{ij}P_{ij}}{\sum_{i=0}^{n}\sum_{j=0}^{m} N_{i,p}(u)N_{j,q}(v)\omega_{ij}} \\ &\qquad (0\le u\le 1,\ 0\le v\le 1) \end{aligned} \tag{5}$$

P_{ij} represent the control points defining the surface, ω_{ij} are weights determining a point's influence on the shape of the surface, and $N_{ip}(u)$ and $N_{iq}(v)$ are the nonrational B-spline basis functions defined on the knot vectors.

$$U = [\underbrace{0,\ldots,0}_{p+1}, u_{p+1}\cdots u_n, \underbrace{1,\cdots,1}_{p+1}]$$
$$V = [\underbrace{0,\ldots,0}_{q+1}, u_{q+1}\cdots u_m, \underbrace{1,\cdots,1}_{q+1}] \quad (6)$$

B-spline basis functions are calculated using the Cox-deBoor reccurence relation described in following equations.

$$N_{i,0}(t) = \begin{cases} 1 & (t_i \le t < t_{i+1}) \\ 0 & (t < t_i, t_{i+1} \le t) \end{cases}$$
$$N_{i,m} = \frac{t - t_i}{t_{i+m} - t_i} N_{i,m-1} + \frac{t_{i+m+1} - t}{t_{i+m+1} - t_{i+1}} N_{i+1,m-1} \quad (7)$$

In this study, we acquired points on the myocardial contour by searching radially from the center which is the intersection of LV-long axis and each short-axis slice. We then calculated control points, P_{ij}, from the points on the myocardial contour. NURBS surface was obtained by using control points in Eq.(5). We showed the example of 3-D NURBS surface constructed from the MRI myocardial contours obtained in cardiac wall detection in Fig. 2. This figure was drawn by using the software, Real INTAGE (KGT Inc.).

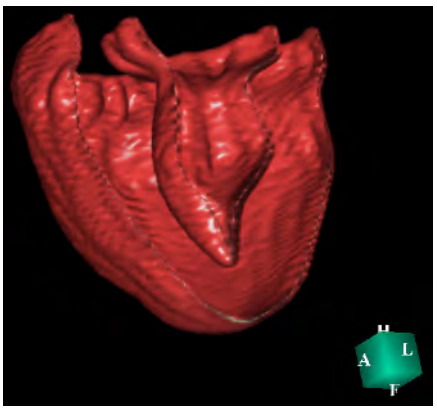

Fig. 2 Application the NURBS model to endocardium and epicardium detected from MRI images

B. Calculation of wall thickness

We will describe about the method to calculate blood flow volume per unit LV myocardial volume and the method for constructing bull's map. We calculated myocardial volume by using wall thickness. It is defined by the distance between the points of endocardium, $P_{end}(u,v)$, and epicardium, $P_{epi}(u,v)$, whose u and v are same in

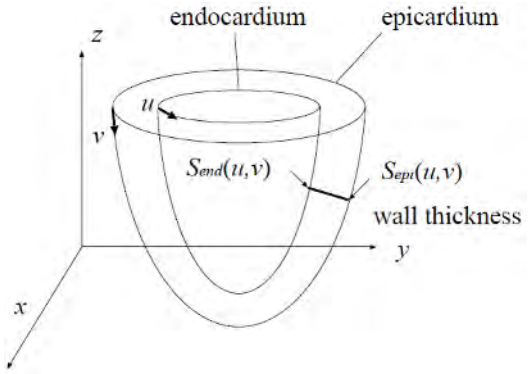

Fig. 3 Definition of myocardial wall thickness

MRI images as shown in Fig. 3. This wall thickness, $W(u,v)$, is described by following equation.

$$V(u,v) = \left\| P_{end}(u,v) - P_{epi}(u,v) \right\| \quad (8)$$

III. Results and Discussions

We applied our method to 5 normal cases and 5 APH cases.

In this study, we show the average map of 5 normal cases in Fig. 4 and 5. Figure 4 is the bull's eye map based on wall thickness extracted by level set method. And Fig. 5 is the map extracted by both level set method and NURBS approximation. We compared the detected myocardial walls with the results manually-extraction by two cardiologists to examine the performance of NURBS approximation. Here, NURBS surface was resliced at the original short-axis slices.

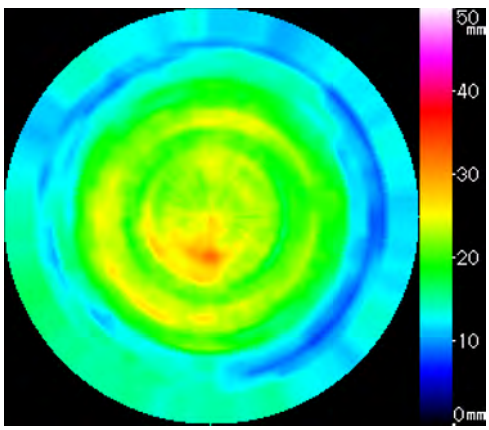

Fig. 4 Bull's eye map based on wall thickness extracted by level set method

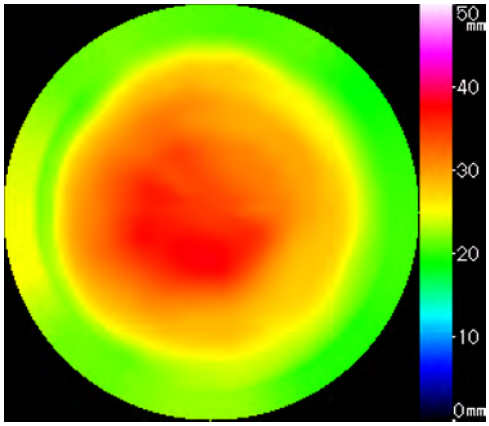

Fig. 5 Bull's eye map based on wall thickness extracted by both level set method and NURBS approximation.

In Fig.4 shows some striping because 3D myocardial shape is not considered. 3D NURBS approximation eliminates these striping. In Table.1, we can see that standard deviation of error decreases by adding NURBS approximation into level set method. These results show that NURBS approximation suppressed the variation of the detection on the slice level. Our method shows relatively good performance for endocardium detection. While on the other hand, that of epicardium detection was larger than the difference between cardiologists, namely the method is inferior in epicardium detection.

Table. 1 Detection error of myocardial wall

	endocardium (mm)	epicardium (mm)
Level set method (LSM)	2.51 ± 1.06	2.77 ± 1.07
Combined method (LSM + NURBS)	2.71 ± 0.59	2.58 ± 0.58
the difference of two cardiologists	3.44 ± 1.57	2.00 ± 0.71

IV. Conclusions

In this study, we proposed the method combining level set method and NURBS approximation for myocardial detection and calculation of wall thickness.

We first extracted epi- and endocardial walls by level set method in 2D image. Calculation cost was reduced by the processing on the slice. In this extraction, we used a near-circular shape of left ventricle and set the initial circle in the myocardial region surrounding the endocardium. We then approximated these extracted walls with 3D NURBS (Non-uniformed rational B-spline) model. In our study, we applied the method to MRI T1-weighted heart images of 10 subjects (5 normal subjects and 5 patients with apical hypertrophic cardiomyopathy). Evaluation of our method was done by comparing with manual detection by two cardiologists. As a result, the accuracy of endocardial detection was about the same as or less than the difference between cardiologists. While on the other hand, that of epicardial detection was larger than the difference between cardiologists. Bull's eye maps of wall thickness also show that NURBS approximation suppressed the variation of the detection.

Abstract — **Glaucoma is a common cause of blindness. Wireless, continuous monitoring of intraocular pressure (IOP) is an important, unsolved goal in managing glaucoma. An IOP monitoring system incorporated into a glaucoma drainage implant (GDI) overcomes the design complexity with incorporating a similar system in a more confined space within the eye. The device consists of a micro-electro-mechanical systems (MEMS) based capacitive pressure sensor combined with an inductor printed directly onto a polyimide printed circuit board (PCB). The device is designed to be placed onto the external plate of a therapeutic GDI. The resonance frequency changes as a function of IOP and is tracked remotely using a spectrum analyzer. A theoretical model for the reader antenna was developed to enable maximal inductive coupling with the IOP sensor implant, including modeling of high frequency effects. Pressure chamber tests indicate that the device has adequate sensitivity in the IOP range with excellent reproducibility over time. Additionally, we show that sensor sensitivity does not change significantly after encapsulation with polydimethylsiloxane (PDMS) to protect the device from the aqueous environment. *In vitro* experiments showed that the signal measured wirelessly through sheep corneal tissue was adequate indicating potential for using the system in human subjects.**

Keywords — **Glaucoma, intraocular pressure, glaucoma drainage implant, micro-electro-mechanical systems (MEMS), and capacitive pressure sensor**

I. Introduction

The most commonly used technique, and current gold standard for intraocular pressure (IOP) measurement is applanation tonometry. In addition to requiring topical anesthetic and a skilled operator, a major disadvantage of applanation tonometry is that it is influenced by many variables, thereby providing only a surrogate measure of true IOP. Additionally, diurnal measurements are difficult to obtain, particularly overnight.

Remote continuous monitoring of IOP has long been desired by clinicians and the development of such technology has the prospect of revolutionizing glaucoma care. Several groups have described an active remote measuring device that can be incorporated into the haptic region of an intraocular lens (IOL). [1-3] IOL's are universally used to replace the natural lens in cataract surgery and are in direct contact with the aqueous humor inside the anterior chamber, thus providing an accurate measurement of IOP. However, the IOL has size and weight constraints requiring the implant to be miniaturized and therefore requiring on-chip circuitry to process signals (i.e. active telemetry). Whilst active devices are accurate and sensitive, their complexity and manufacturing price are potentially major obstacles to a wide spread use.

In another approach, Leonardi et al [4] described an indirect method in which a micro strain gauge is embedded into a soft contact lens that allows measurement of changes in corneal curvature which correlates with IOP. However, the correlation between corneal curvature and IOP is not universally accepted.

A glaucoma drainage implant (GDI) is a device implanted to enable lowering of IOP in severe glaucoma cases. The explant plate of a GDI which is implanted under the conjunctiva is directly connected to the anterior chamber of the eye via a tube. The plate provides a larger surface area compared to an IOL allowing greater flexibility in design. A passive telemetry approach is suitable in such a case. This reduces the fabrication complexity making the device low cost and simple to fabricate. In addition, there are no active parts in the system making it desirable for implantation.

A feasibility study (beyond the scope of this paper) was done to verify that the explant plate of a GDI is a suitable location to incorporate an IOP measuring system. In this paper an IOP monitoring device is designed and implemented onto the explant plate of a Molteno GDI. In addition, an optimal design for the reader antenna to maximize coupling between itself and the sensor implant is proposed. This paper focuses on the Molteno GDI, however this method can be adapted to other GDI's available on the market.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 198–201, 2009
www.springerlink.com

II. Materials and Methods

A. Sensor implant

The sensor implant is designed to be placed onto the explant plate of the Molteno GDI (Molteno Ophthalmic Limited - New Zealand) as shown in Figure 1.

Figure 1: The IOP sensor implant placed on the explant plate of a Molteno GDI.

The IOP sensor implant consists of a MEMS capacitive pressure sensor (Microfab Bremen – Germany) and planar inductor printed directly onto a flexible, biocompatible polyimide printed circuit board (PCB) (Entech Electronics – Australia) to complete the parallel resonant circuit.

The planar sensor inductor and capacitive pressure sensor were both characterized using the Vector Impedance Meter (VIM) (Model 4815A Hewlett Packard). The sensor implant was encapsulated with biomaterial polydimethylsiloxane (PDMS) to protect against aqueous environment. All PDMS coatings were prepared from a Sylgard® Brand 184 Silicone Elastomere Kit.

B. Wireless communication

The wireless communication between the sensor implant and external reader antenna is an important determinant in implantable systems. When the sensor implant is brought near the vicinity of the external reader antenna a portion of the RF energy is absorbed by the sensor implant, creating a 'dip' in the signal as observed on the spectrum analyzer. The greater 'dip' signifies a greater coupling between the reader antenna and sensor implant.

The sensor implant is placed inside a pressure chamber connected to an inflation cuff at one end and a sphygmomanometer at the other. The sensor implant is separated from the reader antenna by a 4 mm thick non-conducting PDMS layer. The pressure was varied in the desired IOP range (5-50 mmHg) using the inflation cuff and the shift in the resonance peak was recorded. Experiments were repeated using explanted sheep scleral and corneal tissue to determine if wireless communication was possible through biological tissue.

C. Reader antenna design

Reader antenna design involves maximizing its read range by optimizing its coupling with the sensor implant. The coupling coefficient k is given by the following expression.[5 6]

$$k = \frac{M}{\sqrt{L_1 L_2}}$$

Where, M is the mutual inductance, L_1 and L_2 are the inductance of sensor and reader inductor coils respectively. In order to obtain the best system characteristics, the value of k should be designed for unity.

The inductances L_1 and L_2 can be directly determined from the VIM and M is calculated by the solution provided by Zierhofer et al. [7]. In order to determine the optimal reader antenna size for a specified read range the M between the two spiral coil geometries given by the expression below needs to maximized.[8]

$$M = \frac{\mu_o \pi N_1 N_2 (ab)^2}{2\left(a^2 + r^2\right)^{3/2}} \quad (2)$$

Where a, b are the radius of the reader and sensor coils respectively. N_1, N_2 the number of turns in reader and sensor coil respectively, 'r' is the distance between the two coils. The above equation can be reduced to

$$a = \sqrt{2}r \quad (3)$$

To validate the described model by experimentation, four planar inductors of different size, inductance and number of turns were printed directly onto a PCB. Their properties are listed in Table 1. The experimental setup consists of a LC

Table 1 Antenna coil properties

	Coil A	Coil B	Coil C	Coil D
Number of turns	18	15	7	15
Inductance (μH)	2.14	4.45	2.5	1.75
Self Resonating Frequency (MHz)	63	49	73	102
Diameter (mm)	9.4	32.51	32.5	16.76

resonant circuit comprising of a planar sensor inductor (L) and a 22 pF chip capacitor (C) mounted onto a vernier calipers separated from the reader antenna. The reader antenna is connected to a spectrum analyzer. To determine the maximum read range, the distance between the reader antenna and LC resonant circuit was increased until no further 'dip' in the signal was observed. The above experiment is then repeated using the sensor implant in place of the LC resonant circuit.

III. Results and discussion

A. Sensitivity of the sensor implant in the IOP range

VIM results showed the quality factor (Q) of the capacitive pressure sensor to be quite low at the resonant frequency of the sensor implant (8.71 @ 38.61 MHz) as compared to the maximum Q of 57.29 @ 10MHz.

Pressure chamber tests were repeated randomly (50 iterations) over a period of one week, the results are shown in Figure 2. The current resolution of the sensor implant in the IOP range is 10 mmHg. The resolution of the current system is limited by the sensitivity and Q of the MEMS capacitive sensor.

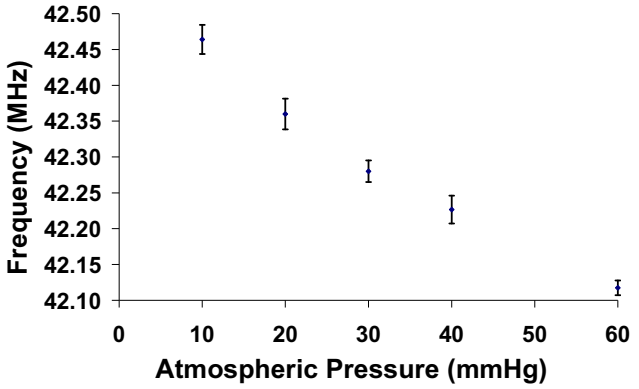

Figure 2: The resonance frequency response of the IOP sensor implant. The error bars indicate the standard deviation.

In vitro experiments were carried out by substituting the PDMS barrier with explanted sheep corneal and scleral tissue in aqueous environment. The results showed that the signal measured was adequate, indicating potential for using such a system in human subjects.

B. Reader antenna performance

Experimental results showing coupling between the reader antenna and LC resonant circuit represented by the 'dip' height are presented in Figure 3. The theoretical coupling coefficient k between the reader antenna and sensor implant is shown in Figure 4. The theoretical model closely follows the trend from the experimental results (Figure 3).

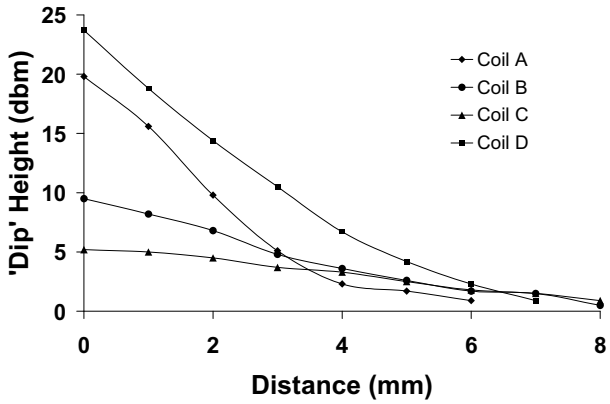

Figure 3: Experimental evaluation of reader coil geometries at varying distances from the LC resonant circuit. The better coupling results in a greater 'dip' height which decreases with increasing distance from the LC resonating circuit.

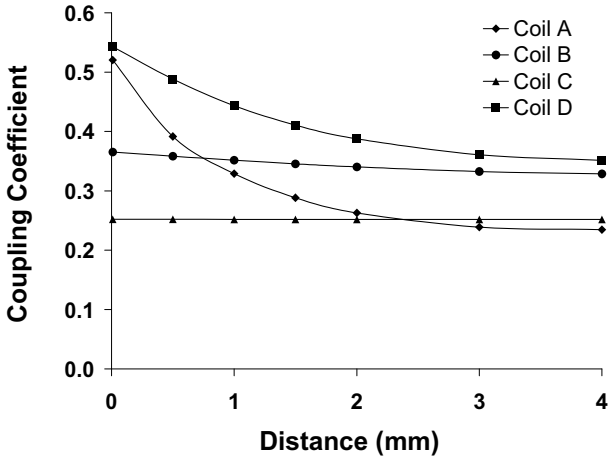

Figure 4: Theoretical coupling coefficients of reader coils at varying distances from the IOP sensor implant calculated from (3).

A summary of results showing the performance of each reader coil with the LC resonant circuit and sensor implant are presented in Table 2. The maximum read range between the reader antenna and sensor implant is greatly attenuated due to its low Q as compared to a high Q LC resonant circuit. The effect of self resonating frequency (SRF) on the reader coil performance is evident when coupled with the sensor implant. The SRF is the frequency beyond which the inductor starts to behave as a capacitor. Although coil B gives a maximum read range of 10 mm with the LC reso-

Table 2: Summary of results

	Coil A	Coil B	Coil C	Coil D
Theoretical read range (mm) (3)	4	10	10	6
Experimental range - LC circuit (mm)	6	8	8	7
Experimental range – sensor implant (mm)	3	0	0	4

nant circuit it produces zero 'dip' when coupled with the sensor implant. This is due to a) low Q of the sensor implant, b) the SRF of coil B is in close proximity to the resonant frequency of the sensor implant.

Coil D gave the maximum read range of 4 mm with the sensor implant. This result is anticipated due to a number of reasons a) its SRF is at least twice the resonant frequency of the sensor implant b) the number of turns are maximized to increase mutual inductance, which is directly proportional to k, c) coil D is larger than the sensor implant allowing for lateral and angular misalignments.

C. Encapsulation of sensor with PDMS

The results from encapsulating the capacitive pressure sensor with biomaterial PDMS as obtained from the VIM show that the sensitivity of the sensor does not change significantly upon encapsulation. The minor offset due to the influence of the silicone coating can be compensated by calibration of each sensor after encapsulation. The average sensitivity of the sensor in the IOP range determined over several repeated measurements was determined to be 1.167x10-3 pF/mmHg.

IV. Conclusion

An IOP sensor implant comprising of a MEMS based capacitive pressure sensor and planar inductor was designed to be incorporated into the explant plate of a Molteno GDI. The IOP sensor implant has been shown to have reasonable resolution (10 mmHg) in the IOP range such a resolution can be able to differentiate between normal and high IOP. In addition, the sensor implant showed excellent repeatability over time. Better resolution of small differences in IOP will be desirable in future iterations. In addition, sensor sensitivity was not significantly affected by encapsulation with PDMS bio-coating.

The reader antenna is designed to maximize its coupling with the sensor implant. Theoretical models are proposed to predict the coupling of the reader antenna coils with a resonant circuit of interest including its optimal size for a specified read range. We found the theoretical predictions closely followed experimental results. Signals from the sensor implant were measured though 4 mm thick PDMS bio-material and though explanted sheep scleral and corneal tissue indicating high potential for using the system in human subjects.

The IOP monitoring system incorporated into a GDI overcomes the design complexity and associated costs of incorporating such a system in an IOL. Such a device will open new perspectives, not only in the management of glaucoma, but also in basic research for mechanisms of glaucoma.

Abstract — **Liver and liver tumor segmentations are very important for a contemporary planning system of liver surgery. However, both liver and liver tumor segmentations are a grand challenge in clinics. In this paper, we proposed an integrated paradigm with fuzzy c-means (FCM) and level set method for computerized liver tumor segmentation. An innovation in this paper is to interface the initial segmentations from FCM and the fine delineation with level set method by morphological operations. The results in real medical images confirm the effectiveness of such integrated paradigm for liver tumor segmentation.**

Keywords — **liver tumor segmentation, fuzzy c-means, level set methods, medical image processing**

I. Introduction

Information and computer technologies exhibit great impact on liver tumor treatment. For instance, by them, the physicians are now possible to inspect liver components and plan liver surgery in an augmented reality. To this goal, one of essential steps is to capture the profile of internal components of human body and reconstruct them accurately. Medical imaging modalities, including computed tomography (CT) and magnetic resonance imaging (MRI), are among the most popular ones in this field. Take the CT for example. Their results have been applied to computerized planning system of liver tumor treatment in various publications [1-2].

In conventional planning systems of liver surgery, the physicians have to inspect a series of CT images and analyze liver components by hand. Obviously, it is not an easy job. Segmentation is a field of technology oriented to computerized distinguishing of anatomical structure and tissue types in medical images. It leads to the useful information like spatial distributions as well as pathological regions of physiological organs in medical image. Thus, for a contemporary planning system, one of essential components is for accurate liver segmentation, in particular hepatic vessels and liver tumors.

The underlying object of image segmentation is to separate the regions of interest from their background and from other components. A typical paradigm of image segmentation can be achieved by either allocating the homogeneous pixels or identifying the boundaries among different image regions [3]. The former often takes advantage of pixel intensities directly, while the latter depends on intensity gradients. Other than intensity information, it is possible to segment image by utilizing model templates and evolving them to matching the interested objects. In addition, various soft computing methods have been applied to image segmentation too. However, it is noteworthy that, till now, there is yet no universal method for image segmentation. The specific application and the available resources usually determine the individual method's strengths and weaknesses.

Among the state-of-the-art methods, active contours or deformable models are among the most popular ones for image segmentation. The idea behind them is quite straightforward. The user specifies an initial guess, and then let the contour or the model evolve by itself. If the initial model is parametrically expressed, it operates as snakes [3]. In contrast, the level set methods do not follow the parametric model, and hereby own better adaptability. But the level set methods, without the parametric form, often suffer from a few refractory problems, for example, boundary leakage and excessive computation [4]. Thus a good initialization is very important in level set methods for image segmentation.

In reference [5], the authors utilized a fast marching approach to propagate the initial seed point outwards, and followed by a level set method to fine tune the results. In this paper, we proposed to initialize the level set evolution by the segmentations from fuzzy c-means (FCM), which has gained esteem in medical image segmentation. In other words, an integrated technique was presented in this paper for liver tumor segmentation from CT scans. The first part is based on the unsupervised clustering by FCM, whose results are then selected out for a series of morphological operations. The final part is by an enhanced level set method for fine delineation of liver tumors.

II. Initial segmentation by FCM

Segmentation is a classical topic in the field of medical image processing and analysis. Suppose a medical image as u_0: $\Omega \to R^2$. Image segmentation is to find out the optimal subset u_i: Ω_i so that $\Omega = \bigcup \Omega_i$ and u_i has a nearly-constant property within each Ω_i. It is hereby possible to segment a medical image based on its pixel intensities or variational boundaries. For the latter case, image segmentation may be formulated as $\Omega = \bigcup \Omega_i \bigcup \Gamma_j$, where Γ_j is the boundary separating Ω_i. However, due to the intrinsic noises and discontinuities, neither of them is universally robust [7]. As a consequence, an integrated technique was proposed in this paper to utilize FCM, based on image intensity information, for initial segmentation and the level set method for object refinement by the variation information of image boundaries.

FCM has been widely utilized for medical image segmentation. In essence, it originates from the classical *k*-means algorithm. However, in the *k*-means algorithm, every image pixel is limited to one and only one of *k* clusters, which is not true in medical image segmentation. Generally speaking, each pixel in a medical image should be attributed to the superimposition of different human organs. In other words, it is usually not appropriate to assign an image pixel to a specific organ or organ component only. In stead, FCM utilizes a membership function μ_{ij} to indicate the belongingness of the *j*th object to the *i*th cluster. Its results are hereby more justifiable in medicine.

The objective function of FCM is:

$$J = \sum_{j=1}^{N}\sum_{i=1}^{c} \mu_{ij}^{m} \left\| x_j - v_i \right\|^2 \tag{1}$$

where μ_{ij} represents the membership of pixel x_j in the *i*th cluster, v_i is the *i*th cluster center, and m (m>1) is a constant controlling the fuzziness of the resulting segmentation. The membership functions are subject to the constraints $\sum_{i=1}^{c} \mu_{ij} = 1$, $0 \le \mu_{ij} \le 1$ and $\sum_{j=1}^{N} \mu_{ij} > 0$. In accordance with the following (2)-(3), the membership functions μ_{ij} and the centroids v_i are updated iteration by iteration respectively:

$$\mu_{ij} = \frac{\left\| x_j - v_i \right\|^{-2/(m-1)}}{\sum_{k=1}^{c} \left\| x_j - v_k \right\|^{-2/(m-1)}} \tag{2}$$

$$v_i = \frac{\sum_{j=1}^{N} \mu_{ij}^{m} x_j}{\sum_{j=1}^{N} \mu_{ij}^{m}} \tag{3}$$

The system is optimized when the pixels close to their cluster's centroid are assigned high membership values, and low membership values are assigned to the pixels far away from that centroid.

The performance of FCM for medical image segmentation relies on the prefixed cluster number and the initial clusters substantially. It has been found in our practice that the random initialization was not robust enough for liver tumor segmentation in CT scans. Other investigators ever successfully carried out the optimal initialization by histogram analysis for brain segmentation in MRI [7]. But it is found that there is merely tiny but variable discrepancy between the liver's and liver tumors' histogram in CT images. In our experiment, we experientially designated the initial cluster centroids by averaging the histogram of the CT image.

III. Tumor delineation by level set methods

The level set method, proposed by Osher and Sethian, is a versatile tool for tracing the interfaces that may separate an image Ω into different parts. The main idea behind it is to characterize the interface function $\Gamma(t)$ by a Lipschitz function Φ:

$$\begin{cases} \phi(t,x,y) > 0 & (x,y)\ is\ inside\ \Gamma(t) \\ \phi(t,x,y) = 0 & (x,y)\ is\ at\ \Gamma(t) \\ \phi(t,x,y) < 0 & (x,y)\ is\ outside\ \Gamma(t) \end{cases} \tag{4}$$

In other words, the interface $\Gamma(t)$ is implicitly solved as the zero-level curve of the function $\Phi(t, x, y)$ at time t. In general, $\Gamma(t)$ evolves in accordance with the following nonlinear partial differential equation (PDE):

$$\begin{aligned} &\frac{\partial \phi}{\partial t} + F \cdot \left| \nabla \phi \right| = 0 \\ &\phi(0,x,y) = \phi_0(x,y) \end{aligned} \tag{5}$$

where F is a velocity field normal to the curve $\Gamma(t)$, and the set $\{(x, y)|\ (\Phi_0(x, y))=0\}$ is the initial contour. A few limitations have been recognized in standard level set methods too. The first of all, the evolution of level set functions has to be reinitialized periodically in order to guarantee the solutions' stability and usability. Otherwise, it often confronts with the threats of boundary leakage. On the other hand, standard level set methods are carried out on the entire image domain. Nevertheless, in terms of image segmentation, merely the zero-level level set is interested eventually. In other words, it is meaningful if the computation is limited within a narrow band near the zero level.

In this paper, we follow the approach proposed in reference [6] for a distance preserving level set evolution. In the first side, the authors revised the level set model as:

$$\frac{\partial \phi}{\partial t} = \mu[\nabla \phi - div(\frac{\nabla \phi}{|\nabla \phi|})] + \lambda \cdot \delta(\phi) \cdot div(g \frac{\nabla \phi}{|\nabla \phi|}) + v \cdot g \cdot \delta(\phi) \quad (6)$$

where μ>0 is the weight of the internal energy term, which controls the smoothness of level set curve; λ>0 and v are constants controlling external contraction; g is the edge indicator function as in (11) ; δ is the univariate Dirac function. In practice, δ is regularized as:

$$\delta_\varepsilon(x) = \begin{cases} 0 & |x| > \varepsilon \\ \dfrac{1+\cos(\pi \cdot x / \varepsilon)}{2} & |x| \le \varepsilon \end{cases} \quad (7)$$

The distance preserving level set model eliminates the iterative reinitialization in standard level set method. Another benefit of such model is allowing a more general initialization but not the signed distance function. The authors proposed an efficient bi-value region-based initialization. Given an arbitrary region Ω_0 in an image, the initial level sets may be simply defined as:

$$\phi_0(x,y) = \begin{cases} -c & (x,y)\ is\ inside\ \Omega_0 \\ c & Otherwise \end{cases} \quad (8)$$

where c should be a constant larger than ε in (7). The initial region Ω_0 may come from manual region of interest or computer algorithms, for example, thresholding, region growing, and so on.

IV. Interfacing by Morphological Operations

It is desired in this paper to combine the advantages of fuzzy clustering and level set method for image segmentation. On one hand, each cluster by FCM, theoretically speaking, represents a significant object in that image. On the other hand, the different initialization strategies do impose effects on the final performance of level set segmentation. Intuitively, the initial segmentation by FCM may serve as the initial guess for level set evolution.

However, it is noteworthy that, unlike the original medical image, whose pixels are color intensities, the clusters by FCM are a series of membership functions to their centroids. The process of converting them to a grayscale image will amplify noise effects, and thus will not be suitable to initiate level set evolution directly. Meanwhile, as FCM pays most attention on intensity information only, the results inevitably suffer from image noise and background inhomogeneity. In other words, the initial segmentation by FCM is discrete and diverse, which is a great challenge to the following level set evolution. In this paper, we suggested to process the initial FCM segmentations by morphological operations, which involve a few simple graphic instructions only.

In essence, a morphological operation modifies an image based on the predefined rules and templates. The state of any image pixel is determined by its template-defined neighborhood. In general, morphological operations run very fast because they merely involve simple computation. For instance, the template is often defined as a matrix with elements 0 and 1. The template shape such as disk or diamond is approximated by the elements 1. In terms of morphological operations, merely max and min are utilized to expand or shrink the regions in the image. Take image shrinkage for example. The value of each pixel is the minimum among that pixel and its neighboring pixels.

The underlying object of morphological operations here is to filter out the objects in FCM clusters due to noises but preserve the genuine image components. In our practice, it is observed that most of noises are discrete and diverse. So morphological operations should firstly shrink and remove the small objects in FCM segmentation, and then expand and recover the interested objects. In this paper, it is desired to detect and delineate liver tumors in CT scans. Although liver tumors are amorphous, they are nearly round in most cases. So a disk-like template was empirically defined in our experiments.

Three real liver CT images, all of which were deemed with tumors, were randomly selected out for tumor detection and delineation. The first two images in Fig. 1 were from the Department of Surgery, National University Hospital, Singapore. The others were adopted from the 3D Liver Tumor Segmentation Challenge 2008 [8]. It is evidenced in Fig. 1 that the results by FCM may reflect the rough locations and extents of liver tumors in an unsupervised manner. Nevertheless, with the increasing of noises and artifacts, the initial segmentation by FCM turns to misleading gradually, as shown in Fig. 1(a).

Fig. 1(b) illustrates the effects of morphological operations on liver tumor delineation. It is initialized by FCM segmentation and finalized by level set evolution. No matter by visual inspection or numerical comparison, the latter results are obviously more robust and credible.

V. Conclusions

In this paper, we presented an integrated system for computerized liver tumor segmentation. In the first part, the method of FCM was adopted for initial segmentation and liver tumor detection; the second part was based on mor

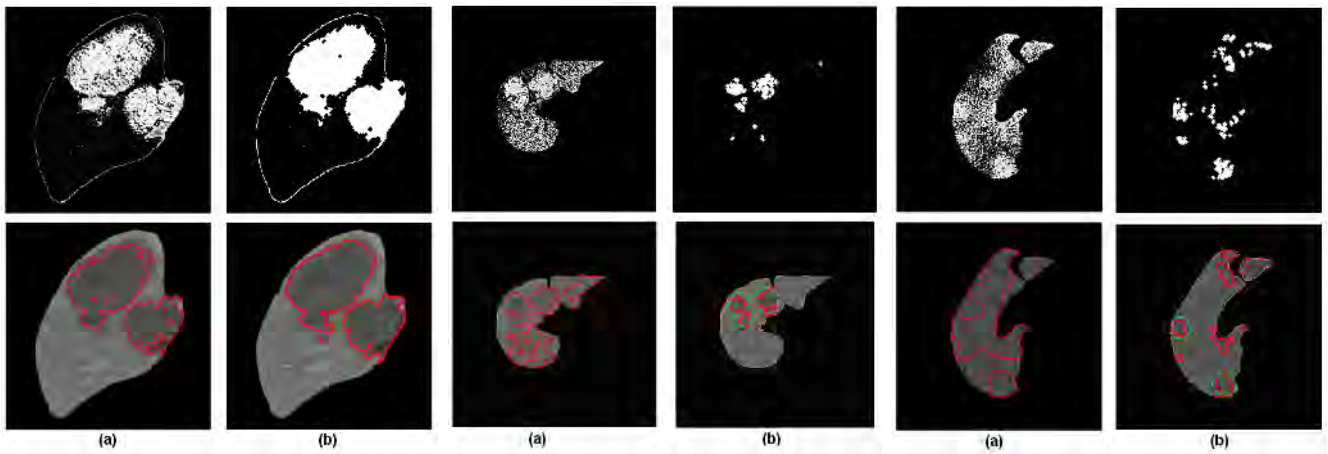

Fig. 1 Interfacing FCM and level sets by morphological operations
(Red line: computerized delineation by level set evolution; Green dash line: manual delineation from reference [14])

phological operations for segmentation refinement; the final part was a level set method for fine delineation of liver tumors. In the experiments by various methods, it was observed that the performance of thresholding and the method proposed in this paper was better than that of others. However, it is eventually difficult to find out a set of effective thresholds due to the intensity variety of liver tumors. In contrast, FCM separates different objects in an unsupervised manner. Thus it is able to detect liver tumors regardless of intensity variety.

As aforementioned, the results of liver tumor segmentation are oriented to an integrated surgical planning system for liver tumor treatment by radio-frequency (RF) ablation. Their accuracy and reliability are of vital importance: if false positive, it incurs the risk of impairing good hepatic tissues; if false negative, it will confront with the risk of leaving liver tumors without treatment. So, up to now, it is yet unlikely that a fully automated method or system is reliable enough for surgical planning system for liver tumor treatment. Instead of attending a fully automated segmentation method, our methods and systems are essentially in a semi-automated manner.

In summary, the complexity of liver tumor segmentation is far more challenging than expected. As illustrated in our experiments, neither intensities nor morphological features are robust enough for computerized segmentation and recognition. In addition, our current work merely focused on the segmentation of tumors from the liver. But how to segment the liver out from abdominal CT scans is a problem with equivalent difficulty (www.sliver07.org). In a word, there are many steps before we are able to set up a high-fidelity model for surgical planning of liver tumor ablation.

Abstract — **Dealing with large numbers of image data is considered as a compulsory routine for medical imaging researchers. With the growing number of medical image data, the effective management and interactive processing of imaging data become essential necessity. The scenario poses a challenge to researcher community on how to construct effective data management and processing systems, in order to promote collaboration, maintain data integrity and circumvent resource redundancy. In this paper, we present a Medical Image Computing Toolbox (MICT) for Matlab® as a extension to Picture Archive and Communication System (PACS). MICT is oriented to providing interactive images processing and archiving service to medical researchers. In a nutshell, MICT is desired to be a cost effective and enriched collaboration solution for medical image sharing, processing and analysis in research communities.**

Keywords — **Medical Image Computing, Picture Archive and Communication System (PACS), Computed Tomography (CT)**

I. Introduction

With the growing number of medical image data, the effective management of imaging data becomes more and more important. This scenario poses many challenges to medical image researchers. It is in some sense an answer to the popularity of Picture Archive and Communication Systems (PACS) [1-3]. Moreover, there are more and more open-source PACS and simple extensions for image processing [4-5]. All of them evidence the essential needs of researchers to have an effective image management system. Such kind of systems should be able to provide integration, archiving, distribution and presentation of medical images.

As a matter of fact, there have been several long-standing PACS and DICOM toolboxes. Most of them are open source and freely downloadable. Some merely fulfill the basic functionality [1-2], some are powerful enough with PACS image management and DICOM image viewer [3-5], and some have their source codes of them opened for academic research [6-7]. However, all of them have limited capability for effective image processing and analysis only.

The presented medical image computing toolbox (MICT) for Matlab® in this paper originates from our earlier works, Virtual Spinal Workstation (VSW), for managing and processing over 8,000 computed tomography (CT) images. In essence, VSW is a program developed for studying spine diseases, including spine segmentation and virtualization. MICT is a progressing project aimed to not only manage large volumes of image data but also have competence to process and analyze them. Its underlying goal is to provide a cost effective, collaboration enriched, research-centric medical image management and processing toolbox for academic researchers.

The rest of this paper is organized as follows. Section II provides the overall infrastructure of MICT, design considerations and implementation details. We give an exemplified application of MICT for medical image studies in Section III. The final parts, Section IV and V, cover discussions and concluding remarks on system performance, future works and possible improvement.

II. Infrastructure and design Considerations

Currently MICT has three component modules, namely: (1) An image pre-processing module for extraction, conversion and classification of DICOM images based on their meta information. (2) Several image processing modules include image viewer, annotation tools and segmentation tools. (3) A database module is in charge of image archiving, process enquiry and data retrieval. All of them are programmed, compiled and running in Matlab®. In addition, their infrastructures have been shown in Fig. 1 with a color of deep blue. Three blocks colored in olive green belong to a PACS system. Finally, the block colored in light blue refers to the communication layer that mediates communication between MICT and the PACS system.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 206–209, 2009
www.springerlink.com

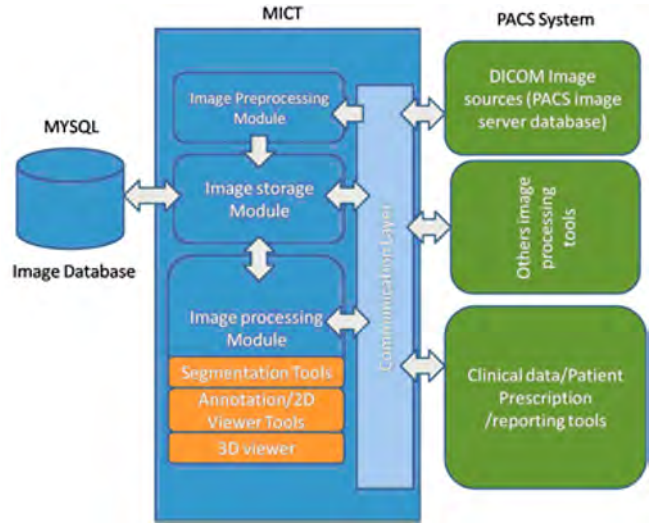

Fig.1. Overall architecture of MICT consisting of three different modules: 1) image pre-processing module; 2) image archiving module; and 3) image processing module.

A. Image Preprocessing Module

This module is in charge of carrying out image preprocessing before an image is archived into the database. It consists of classification, extraction and conversion of DICOM CT or MRI images. The component of classification is on the top of whole process. It scans DICOM meta information, which is abided together with the images, to classify and categorize CT or MRI images. Our module fully utilizes the DICOM tools available at Matlab® to acquire DICOM meta information. After that, the component of classification fetches all relevant images together, for example, from a same patient, due to a same scan. Furthermore, the preprocessing module continues to group all images with similar physician studies into a same group of each patient in sequence.

B. Image Processing Module

The image processing module includes image viewer, annotation tool, segmentation tool, and volume virtualization. It acts as an extension module or application where its application tools provide image processing functionality to academic researchers. All of them are developed with Matlab® and fully utilized the image processing and statistical toolboxes of Matlab®. To minimize user intervention, the image processing module is integrated and resided in the graphic user interface (GUI) layer of database management.

The annotation tool utilizes GUI drawing toolkit to place an annotation mask on top of an image. Conventional annotation masks have been implemented till now, for example, circle, rectangle, text and freehand drawing. In addition, the annotation may be interactively modified and saved as regions of interest (ROI) into image database. Such interactive annotation is necessary for computerized medical image segmentation, annotation and classification. Anyway, accurate annotation by hands is time-consuming and error-prone, while computerized processing is not robust and reliable yet. As a matter of fact, a common computer-aided medical image processing procedure may be described as follows: one or more researchers are required to provide the representative images as training set for computer programs. Thus they have to annotate and edit ROI carefully. During performance evaluation, the researchers may monitor the results of computer programs and modify them manually. The enhanced results may serve as the new training set to improve computer programs. Fig. 2 shows the integrative GUI including data management, image viewer, and interactive annotation tools.

Currently, MICT have been equipped with two automatic segmentation tools, that is, a tool for spinal cord segmentation and the other for active contour segmentation. The tool for spinal cord segmentation in this paper is a knowledge-based program [8]. It utilizes a few clinical knowledge and experience to allocate spine cord. For instance, the spinal cord resides inside the spinal column and above lamina, which has relatively high density compared with other tissues. After potential spinal cord location being indentified, a region growing method is applied to find spinal cord boundary.

C. Database Management Module

Database management module is in charge of data storage, processes enquiry and image retrieval in a text-based manner. In essence, this module includes two parts: 1) a relational database which controls, organizes, stores and retrieves various images and associated meta information; 2) an interface between that database and Matlab® modules. Our current design is built on MySQL® database management system. MySQL® provides open source interfaces and supports Open Database Connectivity (ODBC). In our current system, MySQL® acts as an agent to manage image data and various relevant information. The contents are reachable via standard SQL statement. At present, there are four major tables, named in accordance with their usage: patient ID; DICOM meta information; image data table; processed image data Table.

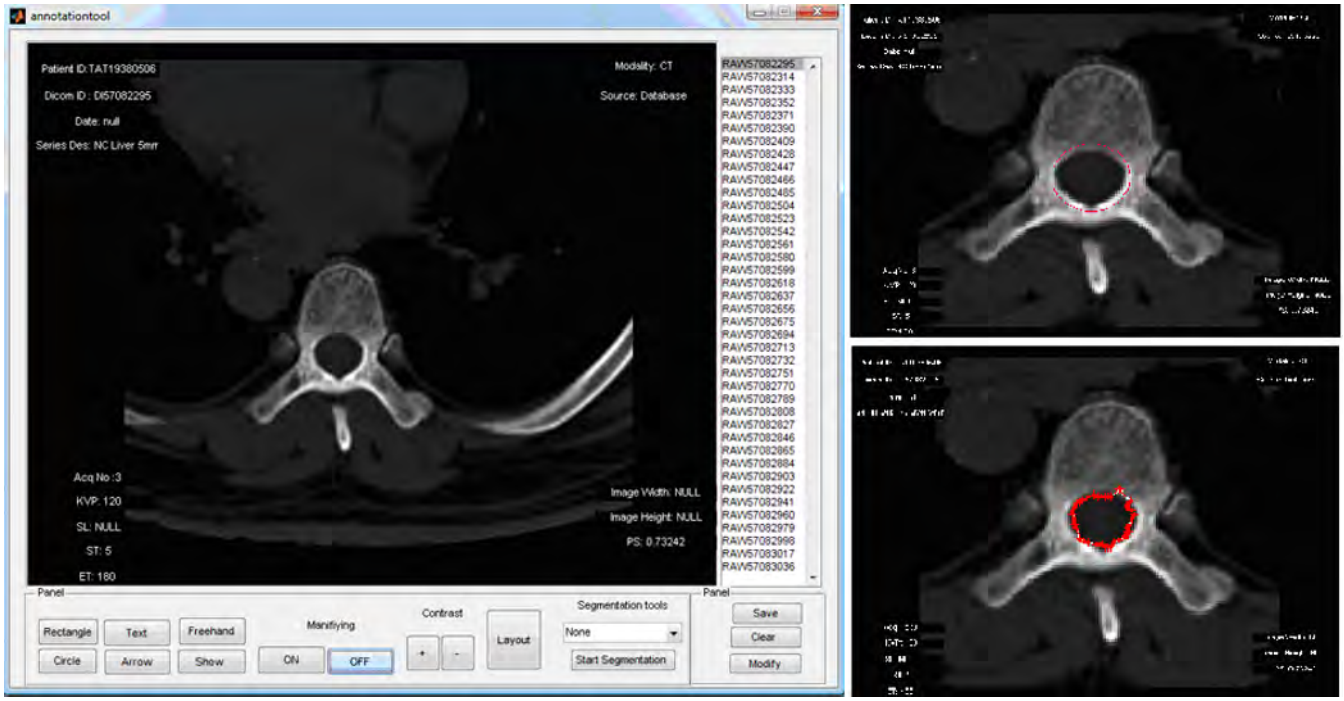

Fig.2. The integrative GUI allows image management, interactive annotation and modification.

III. Example Application: Interactive Image Processing, Analysis and Management

MICT leads itself to various academic researches and applications. The potential applications include image analysis workstation, machine learning and training workstation, image-based teaching and performance evaluation tools. To demonstrate the competence of MICT, we present our experience in this section of using it in the previously-reported VSW project. The first phase is medical imaging. In the second phase, the researchers need to annotate those collected medical images, where an interactive GUI is often of great help. The third phase is computerized analysis. In the fourth phase, the researchers check the performance of computer programs. In VSW project, we successfully dealt with a dataset of 8,000 CT images from 100 patients or so. The overall process is illustrated in Fig. 3.

All of three modules of MICT were used in that project, including CT image archiving, interactive image segmentation and text-based image management.

1) Image preprocessing module: It was used to get representative dataset. The module read DICOM meta information and classified CT images. The meta information was identified as the key reference to categorize types of spine column and segments (Fig.4).

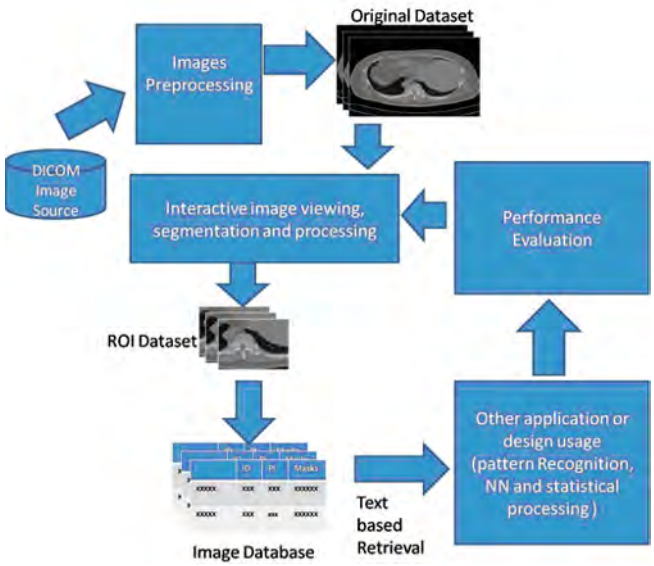

Fig.3. Overall process flow of MICT Example application that promotes interactive image processing and data management.

2) Image processing module: It was used for segmentation and performance evaluation. This module provided the interactive GUI to ease segmentation. A scalable rectan-

gle was used to manually define the ROI. The segmentation algorithms were then used to refine those ROI. During performance evaluation, the interactive annotation tool was applied to further refine those ROI. It was helpful to collect robust and reliable medical image segmentation.

3) Data management module: It was used to collaborate to manage both original and analytical results. The relational database and the text-based retrieve made image and result management particularly easy. Such kind of open infrastructure caters to the needs of academic researchers.

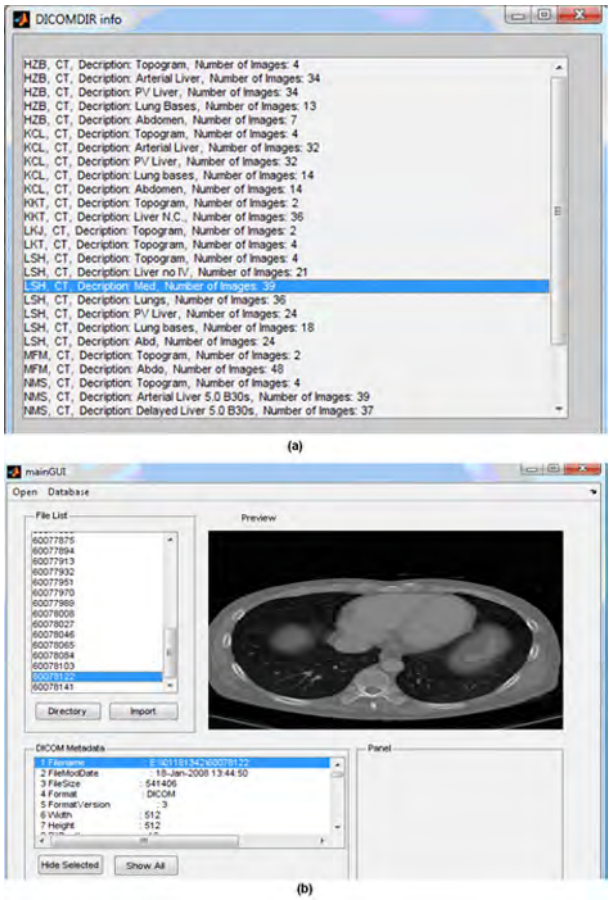

Fig.4. Image pre-processing module is designed able to read DICOM header information and conduct image classification.

IV. DISCUSSION AND CONCLUSION

In previous section, we demonstrated that how MICT provide a cost effective and enriched collaboration solution for image management, processing and analysis. In particular, MICT has been used in VSW project and successfully archived and processed over 8000 CT scans so far. MICT made it easy to process and analyze those medical images. Its interactive annotation module allowed the researchers to focus on their core studies.

MICT is written, compiled and running in Matlab®. It makes full use of the built-in toolkits such as image processing, database, statistics, GUI and other toolkit libraries. All of them guarantee the compatibility of MICT. Furthermore, it is also friendly to the third-party modules written in Matlab®.

MICT is a progressing project. There are still many points to be improved. Some of them are:

1) Cross platform deployment: The demonstrated MICT is just a prototype. It currently runs in Matlab® only. But we desire to make it a cross platform component-based toolbox, for example, supporting various PACS systems. In addition, it should be friendly to third-party components. As a consequence, we will evolve MICT to Java®.
2) Content-based image retrieval: It is desired to provide the language-like environment for image archiving and management. Currently, MICT runs in a content-based manner. It is still far away from language-like archiving and management.
3) Intelligent analysis module: The ability of performing intelligent analysis, such as statistical analysis and data mining, would be interesting to most academic researchers. A GUI for intelligent image analysis will be developed in future works.

An Intelligent Implantable Wireless Shunting System for Hydrocephalus Patients

A. Alkharabsheh, L. Momani, N. Al-Zu'bi and W. Al-Nuaimy

Department of Electrical Engineering and Electronics, University of Liverpool, Liverpool, UK

Abstract — **Hydrocephalus is a neurological disorder whereby the cerebro-spinal fluid surrounding the brain is improperly drained, causing severe pain and swelling of the head. Existing treatments rely on passive implantable shunts with differential pressure valves; these have many limitations, and life-threatening complications often arise. In addition, the inability of such devices to autonomously and spontaneously adapt to the needs of the patients results in frequent hospital visits and shunt revisions.**

This paper proposes replacing the passive valve with a mechatronic valve and an intelligent microcontroller that wirelessly communicates with a hand-held device that would have a GUI and an RF interface to communicate with the patient and the implantable shunt respectively. This would deliver a personalised treatment that would aim to eventually reduce or eliminate the shunt dependence. This system would also enable a physician to monitor and modify the treatment parameters wirelessly, thus reducing, if not eliminating, the need for shunt revision operations.

To manage the shunt, four methods were investigated, simulated and compared. As a result a method was selected based on performance. This method involves an implantable pressure sensor and intelligent software, which will cooperate in monitoring and determining vital parameters that will help in determining a decision regarding the optimal valve schedule. The decision will be either modifying the schedule or contacting the external device for consultation.

Initial results are presented, demonstrating different valve regulation scenarios and the wireless interaction between the external and implanted sub-systems. Also presented are important parameters from the ICP data that would help in optimising system resources. To conclude, an intelligent shunting system is seen as the future in hydrocephalus treatment, potentially reducing significantly hospitalisation periods and shunt revisions. Furthermore, a new technique was investigated that would help to circumvent the problem of updating software using read-only memories.

Keywords — **Hydrocephalus, shunt, mechatronic valve, wireless programming.**

I. Introduction

A. Hydrocephalus

Hydrocephalus comes from the Greek word 'hydro' meaning water and 'cephalie', meaning brain. Human brains constantly produce and absorb about a pint of CSF every day. The brain keeps a delicate balance between the amounts of CSF it produces and the amount that is absorbed. Hydrocephalus is a result of disruption in this balance and this is caused by the inability of CSF to drain away into the bloodstream. The number of people who develop hydrocephalus or who are currently living with it is difficult to establish since there are no national registry or database of people with the condition. However, experts estimate that hydrocephalus affects approximately 1 in every 500 children [1].

Since the 1960s the usual treatment for hydrocephalus is to insert a shunting device in the patient's CSF system [2]. Shunting controls the pressure by draining excess CSF from the ventricle of the brain to other areas of the body, so preventing the condition from becoming worse. A shunt is simply a device which diverts the accumulated CSF around the obstructed pathways and returns it to the bloodstream. It consists of a flexible tube with a valve to control the rate of drainage and prevent back-flow.

The valves used are typically mechanical, opening when the differential pressures across the valves exceed some predetermined threshold. This passive operation causes many problems such as overdraining and underdraining. Overdraining occurs when the shunt allows CSF to drain from the ventricles more quickly than it is produced. This Overdraining can cause the ventricles to collapse, tearing blood vessels and causing headache, hemorrhage (subdural hematoma), or slit-like ventricles (slit ventricle syndrome). Underdraining occurs when CSF is not removed quickly enough and the symptoms of hydrocephalus recur. These problems may have dramatic effects on the patients such as brain damage.

Also, current shunts cannot handle real-time patient discomfort and emergency situations, thus satisfying less than 50% of patients [3]. In addition, some complications can lead to other problems, the most common being shunt blockage, as a result the patient's life and cognitive faculties are placed at risk. There hasn't been a significant improvement in the level of blockages in recent years. The rate of shunt blockages is highest in the first year after insertion, when it can be in the order of 20-30% - decreasing to approximately 5% per year [4]. Currently, shunt blockage cannot be detected without invasively revising the shunt. Whilst symptoms and additional investigations such as CT scan, plain X-rays and a shunt tap may be decisive, a definitive diagnosis is sometimes only possible through surgery

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 210–214, 2009
www.springerlink.com

[5]. Furthermore, shunts are subject to other problems that sometimes require them to be revised, such as cracked and disconnected catheters. The longer the shunt system is in place, the more prone it is to some form of structural degradation [6].

All these problems and more urged the need for a shunt that responds to the dynamic needs of the patients and at the same time that can achieve a gradual weaning of the patient off the shunt, wherever possible. A further need is for the shunt to be able to carry out a self-diagnostic test, monitoring of all implantable components, detecting shunt malfunctions such as shunt blockage and disconnected catheters in an autonomous way. In order to develop such a shunt, a mechatronic valve which is electrically controlled by software, and that communicates wirelessly with the physician, is needed

B. Proposed Intelligent Shunting

In this paper we present an intelligent implantable wireless shunting system for hydrocephalus patients with features that help in reducing or eliminating the problems with current shunts. This shunting system would consist of hard and soft components. The overall system is shown in Figure 1. The implanted hardware components would mainly consist of a microcontroller, electronic valve [7], ICP sensor and transceiver. This implantable shunting system would wirelessly communicate with a hand-held Windows Mobile-based device operated by the patient, or on the patient's behalf by a clinician or guardian. This device would have a graphical user interface and an RF interface to communicate

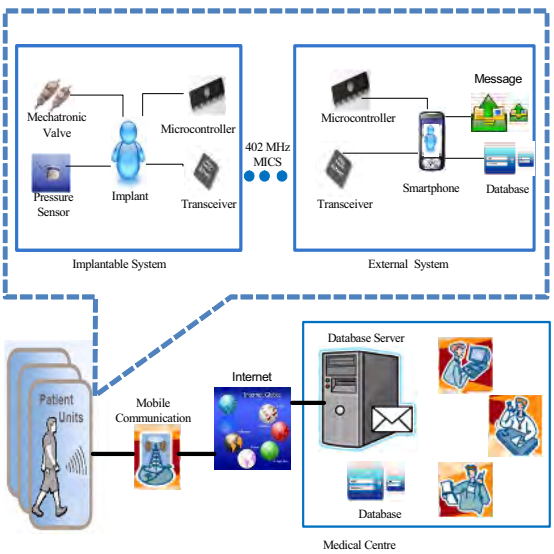

Fig. 1: Overall shunting system.

with the user and the implantable wireless e-shunt respectively.

The main tasks of the implantable embedded software are summarised below. One of the tasks would involve receiving ICP data from the sensor, analysing it and regulating the valve accordingly.

Another task would be wirelessly receiving modifications from the physician through the external patient device. Such modification might be ICP management parameters such as pressure threshold, valve schedule, etc. On the other hand, the implantable shunting system would send a report either on regular basis or upon request to the physician through the external device. Such reports would consist of information that is useful in understanding this particular patient case , thus might help in achieving shunt weaning on the long run, and in understanding of hydrocephalus which help other hydrocephalus patients. The implantable embedded code would handle self testing of the implanted shunt components such as the valve, ICP sensor, microcontroller and transceiver. This task is would be mainly detecting any shunt malfunctions such as valve blockage or disconnected catheters, that would use to verify the shunt is not blockage and fully functional. One of the important tasks that make this proposed system unique is dealing with the emergency case. In an emergency situation, the implantable shunting system would receive requests either from patient or physician through the external patient device to open/close valve or collect ICP readings instantaneously. As the result of monitoring the shunt components, the implantable system might request help when facing problem in meaning valve open, whereas ICP still high which is mean ICP not responding to the opening and closing of the valve due to valve malfunction.

II. Materials and Method

Two sources for ICP data were used to test the design of shunting software. One is a real data collected at 125Hz sampling rate [8]. The other source is a model of the simulated ICP data for hydrocephalus patients. To reach the optimal design of the implanted embedded software, four scenarios of designing the implantable code have been investigated and simulated.

A. Fixed-Time Schedule Scenario

In this scenario, the implanted shunt system would consist of a mechatronic valve, a microcontroller and an RF transceiver. The valve would permit fluid flow only based on a fixed time schedule i.e. would open at specific times for certain periods irrespective of ICP. The implanted valve

manager would be changed remotely by a physician, who determines at what time during the day or night the shunt is opened or closed.

The problem of such scenario is a mismatch between what is required and what is delivered. This mismatch would cause serious drawbacks e.g. overflow, underflow. In addition, it cannot handle real-time patient satisfaction and emergency situations e.g. headache, sneezing because the dynamic nature of ICP for the same patient. This scenario has been simulated and tested using real ICP data. Figure 2 illustrates the problems of using such approach i.e. overdraining and underdraining.

B. Fixe-Time Schedule Scenario with Pressure Sensor

This scenario differs from the previous one is utilising implanted pressure sensor. The sensor would be used to collect ICP data, and then these readings would be sent wirelessly via the RF transceiver to the external patient device. This data would help the physician modify the fixed time schedule in order to be more suitable for the patient. The new fixed schedule is uploaded remotely to the implanted shunting system.

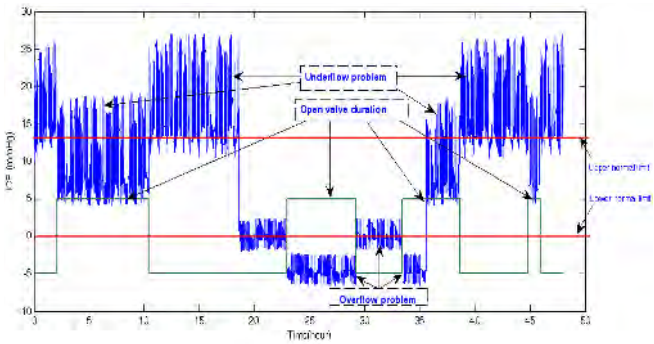

Fig. 2: Fixed schedule problems.

C. Closed Loop Scenario

A close loop shunt would consist of a mechatronic valve, microcontroller and pressure sensor. In this scenario the valve would be instantaneously managed (opened or closed) according to the measured ICP. Where the collected ICP would be analysed by the implantable software on the microcontroller to decide whether it is an appropriate time to open or close the valve. Many but not all problems can be solved by using such scenario e.g. overflow, underflow. Figure 3 illustrates the resulted ICP waveform for closed loop shunting system. Thus the collected ICP would be utilised only within implanted shunting system. Such data would not reach the physician since there is no mean for sending it outside the patient's body.

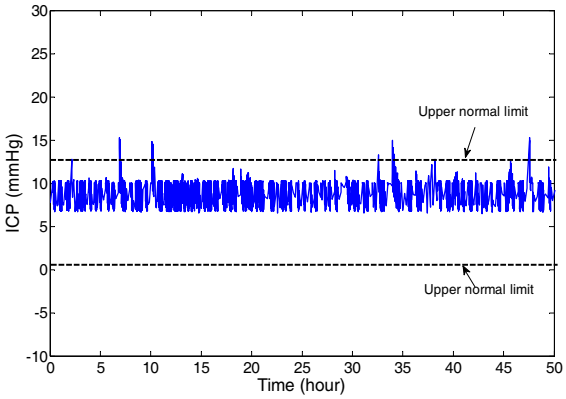

Fig. 3: The resulted ICP waveform for closed loop shunting.

D. Dynamic Shunting System Scenario

In this scenario, the implanted shunt system includes the mechatronic valve, microcontroller, RF transceiver, ICP sensor and smart software. As a result of investigated the previous scenarios, their drawbacks would be eliminated if the shunting system perform the following tasks.

1. ICP analysis: the ICP readings would be analysed to figure out some important parameters such as ICP waveform components. These parameters would be useful in autonomously modifying the valve schedule internally.
2. Self testing: this task involves testing all implanted shunt components for example, ICP readings collected when valve is open would be analysed and parameters are calculated to help in detecting shunt malfunction such as shunt blockage or disconnected catheter. Also this task would work on checking the capacity of the implanted battery and the functioning of ICP sensor.
3. Emergency call: this task is responsible for all emergency cases that might be happen during shunt operation. For example, it would send a signal to inform the external device when shunt malfunctions is detected. On the other hand, it will handle any emergency signals received from the physician through the external device to open/close the valve or to request ICP readings.
4. Updating task: the implantable ICP sensor and the smart software would cooperate in monitoring and determining vital parameters that would help in modifying and optimising the valve schedule.
5. Report generating: this task involves generating ICP information report consisting of ICP waveform components, valve status, real ICP readings and their corre-

sponding time, mean ICP and self shunt testing result. This report would be stored in implanted memory and a copy of this report would be sent remotely to the physician through the external device regularly or upon request. Thus, such report would be useful tool for the physician to decide any modification on the valve schedule. Also, it would be helpful in understanding hydrocephalus in general.

6. ICP compression: a peak detection algorithm has been designed and tested to overcome the problem of the implantable memory size limitation. By this algorithm, only the peaks (upper, lower) of the ICP waveform would store. Where it was noticed that the output waveform of such algorithm give a good estimation of the original waveform.
7. Wireless updating: an algorithm was designed and tested to enable the physician through the external device wirelessly modifying different implanted parameters such as valve schedule, ICP threshold value. Such algorithm rarely mention in literatures especially for implanted microcontroller. A self learning packet technique has been used in this algorithm to access the implanted memory address of each parameter needed to modify. This packet made up of packet length, patient identification, packet identification and the modified parameters value with their addresses, shown in Figure 4(b).
8. The power consumption algorithm has been designed and tested to minimise power consumption needed for the implanted shunt. A sleeping mode for the implantable microcontroller and RF transceiver is used to reduce the power needed for these components more than 90%. A wake up signal from physician through external device would be used to wake up these components when it is needed.

Most of these tasks are built using assembly and C language. MSP430 development kits shown in Figure 4(a) used to test these tasks. A packet format shown in Figure 4(b) manipulated between two kits through transceivers.

III. Result and discussion

The results of simulating a fixed-time schedule are presented in Figure 2. It can be noticed that mismatch between what is required and what is delivered by such shunt. The simulation results of closed loop shunting system shown in Figure 3 illustrates the efficacy of the closed loop shunt in keeping the ICP within the normal range. On the other hand, other current shunt problems such as difficulty of shunt malfunction detection, is not solved in closed loop shunt.

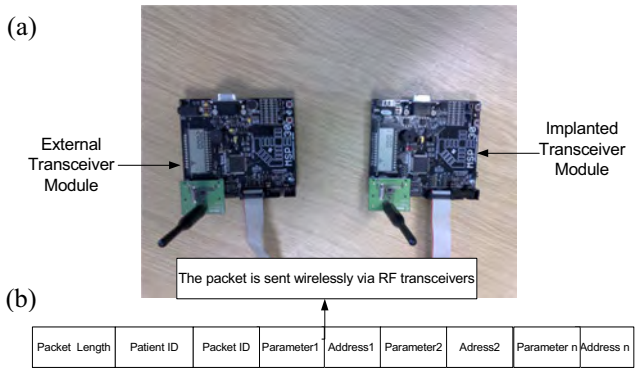

Fig. 4: Hardware and software tools for software testing. (a) MSP430 microcontrollers with RF transceivers, (b) packet format.

These problems could be solved by using a dynamic shunting system having a degree of "intelligence". One of the most difficult challenges of using an implantable microcontroller in medical applications is how to access, modify and replace the implanted program. An updating algorithm is used to remotely modify some parameters which are embedded into the microcontroller via RF transceivers. A peak detection algorithm of ICP waveform is utilised by which the size of ICP data is reduced by 93%, thus overcoming the implantable memory size limitation.

IV. Conclusion

An innovative, intelligent implantable wireless shunting system was introduced in this paper for the treatment of hydrocephalus. We attempted to replace the passive mechanical shunt with a dynamic shunt that maximizes the potential quality of life for each patient, reduces hospitalisation periods and shunt revisions. Furthermore, a new technique was investigated that would help to circumvent the problem of updating software remotely through RF transceiver.

Intelligent Diagnosis of Liver Diseases from Ultrasonic Liver Images: Neural Network Approach

P.T. Karule[1], S.V. Dudul[2]

[1]Department of Electronics and Communication Engineering, YCCE, Nagpur, INDIA
[2]Department of P.G.Studies in Applied Electronics, SGB Amravati University, INDIA

Abstract — **The main objective of this study is to develop an optimal neural network based DSS, which is aimed at precise and reliable diagnosis of chronic active hepatitis (CAH) and cirrhosis (CRH). Multilayer perceptron (MLP) neural network is designed scrupulously for classification of these diseases. The neural network is trained by eight quantified texture features, which were extracted from five different region of interests (ROIs) uniformly distributed in each B-mode ultrasonic image of normal liver (NL), CAH and CRH. The proposed MLP NN classifier is the most efficient learning machine that is able to classify all three cases of diffused liver with average classification accuracy of 96.55%; 6 cases of cirrhosis out of 7 (6/7), all 7 cases of chronic active hepatitis (7/7) and all 15 cases of normal liver (15/15). The advantage of proposed MLP NN based Decision Support System (DSS) is its hardware compactness and computational simplicity.**

Keywords — **Chronic Active Hepatitis, Cirrhosis, Liver diseases, Decision Support System, Multi Layer Perceptron, Ultrasound imaging**

I. Introduction

Medical diagnosis is quite difficult and complex visual task, which is mostly done reliably only by expert doctors. An important application of artificial neural network is medical diagnosis. Chronic infection with hepatitis virus (HV) has been a major health problem and is associated with over 10,000 deaths a year in the United States [1]. In the early stages, HV tends to be asymptomatic and can be detected only through screening. Ultrasonography is a widely used medical imaging technique. It is the safest method used for imaging of human organs or their functions. The attenuation of sound wave or difference in acoustic impedance in the organ yield complicated texture on the ultrasound B-mode images. For the diagnosis of diffuse liver diseases ultrasonography is commonly used, but visual criteria provide low diagnostic accuracy, and it depends on the ability radiologist. To solve the problem, tissue characterization with ultrasound has become important topic of research. For quantitative image analysis many feature parameters have been proposed and used in developing automatic diagnosis system [2]-[4]. The several quantitative features are used in diagnosis by ultrasonography. K. Ogawa [5, 7] developed a classification method which used an artificial neural network to diagnose diffuse liver diseases. Another work [6]-[13] presents the classifier for diagnosis of normal liver (NL), chronic active hepatitis (CAH) and cirrhosis (CRH) more accurately.

Quantitative tissue characterization technique (QTCT) is gaining more acceptance and appreciation from the ultrasound diagnosis community. It has the potential to significantly assist radiologists to use this system for second opinion . The grey scale ultrasound images provide significant contribution to the diagnosis of liver diseases, however at the resolution it is difficult to diagnose active hepatitis and cirrhosis from normal liver [10, 11]. A pattern recognition system can be considered in two stages, the first stage is feature extraction and the second is classification [12].

This paper presents new optimal designed MLPNN based decision support system for diagnosis of diffused liver diseases from the ultrasound images.

II. Material and methods

A. Data acquisition

Ultrasound images used in our research were obtained on Sony (US) model ALOKA-SSD-4000 ultrasonic machine with a 2-5 MHz multi frequency convex abdominal transducer. All images were of 640 × 480 pixels with 8-bit depth. Ultrasound images for different liver cases taken from patients with known histology and accurately diagnosed by expert radiologist from Midas Institute of Gastroenterology, Nagpur, INDIA. Three set of images have been taken: normal liver, chronic active hepatitis and cirrhosis with 22, 10 and 10 images respectively.

System outline: Fig. 1 shows the overall sketch of the proposed system; our approach is divided in three parts. First step is selection of region of interest (ROI). Second step is texture feature extraction from ROI and create a database. Third step is use neural network for classification of these images in one of the categories i.e. normal liver, chronic active hepatitis and cirrhosis

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 215–218, 2009
www.springerlink.com

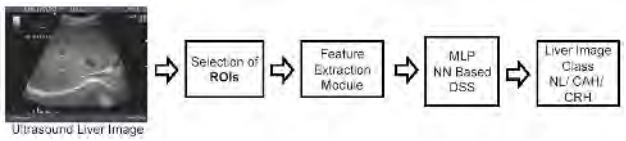

Fig. 1 Overall scheme for classification of liver image

Defining the region of interest (ROI): Selection of ROI is one of the first and the most important step in the process. In order to accurately identify and quantify regions, they should be as free as possible from the effect of the imaging system. For example their depth and location in the beam should be such that the effects of the side lobes and the beam diffraction, acoustic shadowing be a minimum. The important thing in selecting ROI position is not to include major vascular structures in the ROI. In the system we freely choose any of five regions of interest (ROIs) from the given liver image. The four ROIs were located to overlap half of each ROI with the"Center ROI". Fig. 2 shows the location of five ROIs. Each ROI is 32 x 32 pixels about 1 x 1 cm^2 in size.

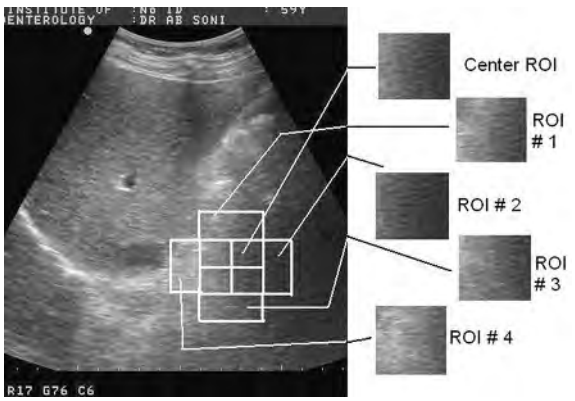

Fig. 2 Location of five ROIs of 32 x 32 pixels

Texture analysis of liver: Texture contains important information, which is used by human for the interpretation and the analysis of many types of images. Texture refers to the spatial interrelationship and arrangements of the basic elements of an image. The Grey Level Difference Method (GLDM) is very powerful for statistical texture description in medical imaging.

The texture features are extracted within the 32 x 32 pixels ROIs selected in the liver region by the method introduced by Haralick et al. [9]. The following parameters were calculated from the ROI: variance (V), coefficient of variation (CV), annular Fourier power spectrum (AFP) and longitudinal Fourier power spectrum (LFP). These parameters have been used in the diagnostic system [7] for chronic hepatitis with an artificial neural network. K. Ogawa et al.[5] also added three more parameters for the diagnosis of CAH and Cirrhosis: variation of the mean (VM) and the parameters ASM and CON derived from a co-occurrence matrix. VM was calculated from five ROIs, that is, the "center ROI" and the other four ROIs generated by this system around the "center ROI". The parameters ASM and CON were calculated from only the "center ROI".

The following are definitions of the parameters, where N (=32) is the size of the ROIs and *f(i,j)* is the density of a pixel in an ROI and $\hat{f}(I,J)$ is the Fourier power spectrum of *f(i,j).*We have selected one more parameter entropy (ent), calculated from the gray level co-occurrence matrix.

1) Variance (V):

$$V = \frac{1}{N^2}\sum_{i=1}^{N}\sum_{i=1}^{N}(f(i,j)-m)^2, \tag{1}$$

Where

$$m = \frac{1}{N^2}\sum_{i=1}^{N}\sum_{i=1}^{N}f(i,j), \tag{2}$$

2) Coefficient of variation:

$$CV = \frac{\sqrt{V}}{m} \tag{3}$$

3) Annular Fourier Power Spectrum (AFP):

$$AFP = \sum_{R=2}^{4}\left(\sum_{R^2\le I^2+J^2<(R+1)^2}\left(\frac{\hat{f}(I,J)}{R}\right)\right), \tag{4}$$

Where $R = \sqrt{I^2+J^2}$

4) Longitudinal Fourier Power Spectrum (LFP):

$$LPF = \sum_{J=3}^{5}\sum_{I=1}^{N}\hat{f}(I,J) \tag{5}$$

5) Variation of mean (VM)

$$VM = \frac{1}{5}\sum_{k=1}^{5}(m_k - m_0)^2, \tag{6}$$

Where m_k is the mean value of k-th AOI and

$$m_0 = \frac{1}{5}\sum_{j=1}^{5}m_j \tag{7}$$

6) Angular Second Moment (ASM):

These parameters are extracted form gray level co-occurrence matrix (GLCM) obtained from selected ROI. This was on the estimation of the second order joint conditional probability of one gray level a to another gray level b with inter-sample distance d and the given direction by angle θ. Gray level co-occurrence matrix (GLCM) is a repeated spatial pattern. This is obtained by computation of a number of co-occurrence matrices, which essentially measure the number of times a pair of pixels at some defined separation have a given pair of intensities. The normal

GLCM is given as C (a, b; d, θ). For calculating ASM from GLCM C (a, b; 1, 0º) we have:

$$C(a,b;1,0^0)=\frac{1}{T(1,0^0)}cardinaly\begin{Bmatrix}[(k,l),(m,n)]\\ \in AOI:|k-m|=1,\\ l=n,\\ f(k,i)=a,\\ f(m,n)=b\end{Bmatrix} \quad (8)$$

$$ASM=\sum_{a=0}^{M-1}\sum_{b=0}^{M-1}C(a,b;1,0^0)^2 \quad (9)$$

7) Contrast (con):

$$con=\sum_{a=0}^{M-1}\sum_{b=0}^{M-1}(a-b)^2C(a,b;1,90^0) \quad (10)$$

8) Entropy (ent):

$$ent=-\sum_{a,b\in G}c(a,b)*\log[c(a,b)] \quad (11)$$

The eight features mentioned above are extracted from five ROIs of each image. The descriptive statistics of eight extracted features are shown in Table 1. These texture features are used by neural network as input parameters for classification.

Table 1 Descriptive statistics of features of ultrasonic images

Sr. No.	Features	Minimum	Maximum	Mean	Std. deviation
1	V	0.002	0.030	0.006	0.005
2	CV	0.110	1.265	0.271	0.240
3	VM	0.003	0.329	0.083	0.071
4	LFP	0.000	0.239	0.037	0.047
5	AFP	0.000	0.151	0.039	0.037
6	ASM	0.167	6.382	1.613	2.313
7	con	0.098	0.559	0.252	0.098
8	ent	0.148	6.969	1.958	2.386

B. Design of MLP NN classifier

Artificial neural network (ANN), which has been successfully applied in many fields on medical imaging [29, 32], is easy for less experienced doctors to make a correct diagnosis by generalizing new inspections from past experience. We construct a fully connected neural network as shown in Fig. 3, which is a conventional three-layer feed-forward neural network with 8 input units, 3 hidden units and 3 output units. The network is trained by using the well known backpropagation (BP) algorithm [31]. After establishing the relationship function between the inputs and outputs, we can apply the ANN to the doctors' practical routine inspection to test the generation ability of ANN.

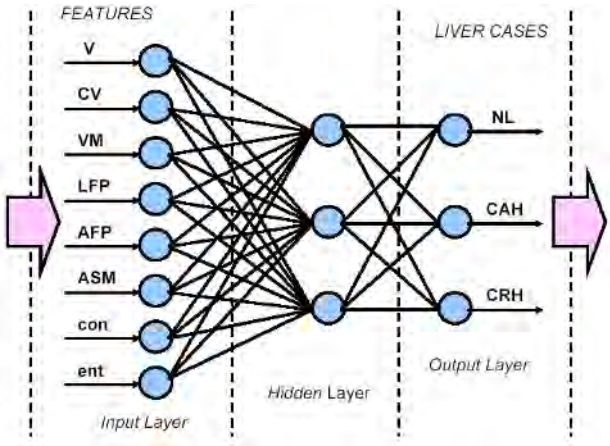

Fig. 3 MLP NN model for Classification

Table 2 Optimal Parameters of MLP NN DSS

S.N.	Parameter	Hidden Layer#1	Output Layer
1	Processing Elements	3	3
2	Transfer Function	Linear Tanh	Linear Tanh
3	Learning rule	DeltaBarDelta	DeltaBarDelta

Table 2 indicates optimal parameters used for MLP NN based DSS.

Performance measure: The learning and generalization ability of the estimated neural network based decision support system is assessed on the basis of certain performance measures such as MSE and confusion matrix [31]. Nevertheless, for DSS the confusion matrix is the most crucial parameter.

MSE (Mean Square Error): The MSE is defined by Eq. (12) as follows:

$$MSE=\frac{\sum_{j=0}^{P}\sum_{i=0}^{N}\left(d_{ij}-y_{ij}\right)^2}{N.P} \quad (12)$$

where P = number of output neurons, N = number of exemplars in the dataset, y_{ij} = network output for exemplar i at neuron j, d_{ij} = desired output for exemplar i at neuron j.

C. Data partitioning

These 42 sets of 8 features each are then used as inputs to the neural networks for the classification of liver disease. Different spit-ratios are used for training-testing exemplars. The percentage of exemplars used for training the NN was varied from 10% to 90% with corresponding 90% to 10% variation in exemplars used for testing. It is observed that with only first 30 % samples (1:13) used for training and the next 70 % samples (14:42) for testing, the classifier is seen to deliver optimal performance with respect to the MSE and classification accu-

racy. This also confirms the remarkable learning ability of the MLP NN as a classifier comprising of the lone hidden layer. The following Table 3 highlights the data partition schemes employed in order to design a classifier.

Table 3 No. of exemplars in training and testing data set

Sr. No.	Data Sets	No. Of Exemplars	Cirrhosis	Chronic Active	Normal
1	Training Set (30%)	13 (1:13)	3	3	7
2	Testing Set (70%)	29 (14:42)	7	7	15

The confusion matrix MLP NN based classifier for the testing data set with 70% samples is shown in Table 4. The average classification accuracy achieved is 96.55%.

Table 4 Confusion matrix for MLP NN based DSS

Output / Desired	Cirrhosis	Chronic Active	Normal
Cirrhosis	6	0	0
Chronic Active	1	7	0
Normal	0	0	15
Classification accuracy	85.71%	100%	100%

Table 5 displays the important performance measures of MLP NN classifier MSE and Classification accuracy.

Table 5 Performance measures of MLP NN based DSS

Performance Parameter	Cirrhosis	Chronic Active	Normal
MSE	0.03450	0.04942	0.01580
Classification accuracy	85.71%	100%	100%

III. Conclusions

After rigorous and careful experimentation optimal model of MLP was selected. MLP NN with 8 input PEs, one hidden layer with 3 PEs, and an output layer with 3 output PEs. The results on testing data set show that MLP NN classifier is able to classify the three cases of diffused liver diseases with average accuracy of 96.55%. In testing phase, 85.71% (6/7) cirrhosis, 100% (7/7) chronic active hepatitis and 100% (15/15) cases of normal liver were classified correctly.

The results also indicate that proposed MLP NN based classifier can provide a valuable ‘‘second opinion’’ tool for the radiologists in the diagnosis of liver diseases from ultrasound images, thus improving the diagnosis accuracy, and reducing the needed validation time.

Acknowledgment

The author would like to thank the doctors of Midas Institute of Gastroenterology, Nagpur, INDIA, for providing the ultrasound images of diffused liver of patients admitted at their hospital for our study.

Abstract — **Heart Rate Variability (HRV) is a sophisticated measure of an important and fundamental aspect of an individual's physiology. Heart rate variability (HRV) measurement is an important tool in cardiac diagnosis that can provide clinicians and researchers with a 24-hour noninvasive measure of autonomic nervous system activity. Heart Rate Variability is analyzed in two ways, either over time (Time Domain) or in terms of the frequency of changes in heart rate (Frequency Domain). Preliminarily studying on the different effects of sleep on HRV signal can be useful for finding out the function of autonomic nervous system (ANS) on heart rate. In this paper, we consider a HRV signal for one normal person in different sleep stages: stage1, stage2, stage3 and REM. Therefore, we use FFT on HRV signal and show differences in various stages. In addition, we evaluate these differences in quantitative and qualitative. This model can be used as a basic one for developing models to generate artificial HRV signal.**

Keywords — **autonomic nervous system, HRV, sleep, stage, signals.**

I. INTRODUCTIONT

The electrocardiogram (ECG) signal is one of the most obvious effects of the human heart operation. The oscillation between systole and diastole states of the heart is reflected in the heart rate (HR). The surface ECG is the recorded potential difference between two electrodes placed on the surface of the skin at pre-defined points. The largest amplitude of a single cycle of the normal ECG is referred to as the R-wave manifesting the depolarization process of the ventricle. The time between successive R-waves is referred to as an RR-interval, and an RR tachogram is then a series of RR-intervals. The development of a dynamical model for the generation of ECG signals with appropriate HRV spectra is a subject that has been widely investigated. Such a model will provide a useful tool to analyse the effects of various physiological conditions on the profiles of the ECG. The model-generated ECG signals with various characteristics can also be used as signal sources for the assessment of diagnostic ECG signal processing devices. Now, in co strutting a comprehensive model for generating ECG signals there are two steps. Step one is producing the artificial RR-tachogram with HRV spectrum similar to experimental data—the RR-tachogram shows where the R-waves of the ECG are actually placed. And step two is constructing the actual shape of the ECG. Using Gaussian functions method for generating ECG model can be also considered too [8].

Here, we develop a new model based on modifying the original Zeeman model to produce the RR-tachogram signal, which now incorporates the effects of sympathetic and parasympathetic activities to generate the appropriate significant peaks in the power spectrum of the HRV. By using a neural network approach based upon a modified McSharry model, the actual shape of the ECG in a single cycle can be successfully re-produced by using our model generated power spectrum of RR time intervals.

II. ECG AND HRV MORPHOLOGY

In any heart operation there are a number of important events. The successive atrial depolarization/repolarization and ventricular depolarization/repolarization occurs with every heartbeat. These are associated with the peaks and valleys of the ECG signal, which are traditionally labeled P, Q, R, S, and T (see Fig. 1). The P-wave is caused by depolarization of the atrium prior to atrial contraction. The QRS-complex is caused by ventricular depolarization prior to ventricular contraction. The largest amplitude signal (i.e. R-wave) is located here. The T-wave is caused by ventricular repolarization which lets the heart be prepared for the next cycle. Atrial repolarization occurs within ventricular depolarization, but its waveform is masked by the large amplitude QRS-complex. The HR, which is the inverse of the RR-interval, directly affects the blood

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 219–222, 2009
www.springerlink.com

pressure. The autonomic nerve system (ANS) is responsible for short-term regulation of the blood pressure. The ANS is a part of the central nervous system (CNS). The ANS uses two subsystems—the sympathetic and parasympathetic systems. The HR may be increased by sympathetic activity or decreased by parasympathetic (vagal) activity. The balance between the effects of the sympathetic and parasympathetic systems is referred to as the sympathovagal balance and is believed to be reflected in the beat-to beat changes of the cardiac cycle (McSharry et al., 2002). Spectral analysis of HRV is a useful method to investigate the effects of sympathetic and parasympathetic activities on heart rate (HR). The afferent nerves provide the feedback information to the CNS. The sympathetic system is active during stressful conditions, which can increase the HR up to 180 beats per minute (bpm). When sympathetic activity increases after a latent period of up to 5 s, a linearly dependent increment in HR begins and reaches its steady state after about 30 s. This affects the low frequency (LF) component (0.04–0.15 Hz) in the power spectrum of the HRV, and slightly alters the high frequency (HF) component (0.15–0.4 Hz). The parasympathetic activity can decrease the HR down to 60bpm.

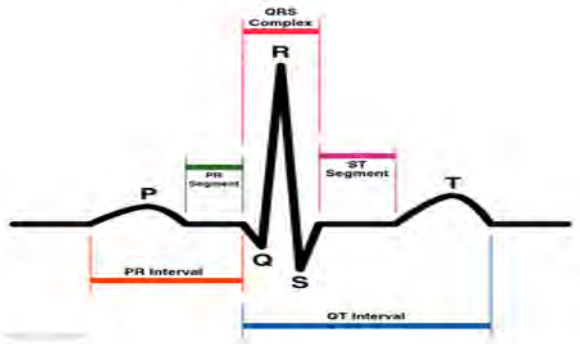

Fig. 1. A single cycle of a typical ECG signal with the important points labeled—i.e. P, Q, R, S and T.

The parasympathetic system is active during rest conditions. There is a linear relationship between decreasing the HR and the parasympathetic activity level, without any considerable latency. This affects only the HF in the power spectrum of the HRV. The power in the HF section of the power spectrum can be considered as a measure for parasympathetic activity. Now our proposed model will artificially produce a typical power spectrum as shown in Fig. 2, but for different sicknesses the model also has the capability to alter both the magnitudes, and central frequencies, of the peaks of the power spectrum to reflect different illnesses.

III. Sleep

Sleep is a dynamic state of consciousness characterized by rapid variations in the activity of the autonomic nervous system. The understanding of autonomic activity during sleep is based on observations of the heart rate and blood pressure variability. However, conflicting results exist about the neural mechanisms responsible for heart rate variability (HRV) during sleep. Zemaityte and colleagues [1] found that the heart rate decreased and the respiratory sinus a rhythmia increased during sleep. On the other hand, two other studies [2, 3] revealed high sympathetic activity during deep sleep. Thus the complete understanding of the autonomic activity during sleep is still elusive. Moreover, there are five different sleep stages and the HRV varies differently with these stages of sleep [4]. The comparison of HRV during different sleep stages is outside the scope of this paper. The causes of heart rate variability have been widely researched because of its ability to predict heart attack and survivability after an attack. The power spectral density (PSD) of the heart rate has been found to vary with the rate of respiration, changes in the blood pressure, as well psychosocial conditions such as anxiety and stress [5, 6]. All these phenomena are in turn related to the activity of the autonomic nervous system. The objective of this project was to understand how sleep affects the body in terms of what is already understood about the heart rate PSD. Also there are some disorders in sleep cycle which don't remove, they can be sign of some diseases such as angry, lack of confuses, etc. some of disorders which we can point to is on the stage of going to sleep and the second is the last of sleep. So if they don't cure, they can make some serious problems.

IV. Methods

In this paper we use developed zeeman model for generating HRV signal in different stages of sleep. As we want to point to the model, see [7]

$$\begin{aligned} \varepsilon \dot{x} &= -(x^3 + ax + b), \\ \delta \dot{a} &= -2x - 2a, \\ \delta \dot{b} &= -a - 1. \end{aligned} \tag{1}$$

where x (which can be negative) is related to the length of the heart muscle fiber, e is a positive scalar, b is a parameter representing an electrochemical control, and parameter a is related to the tension in the muscle fiber.

It is easy to see that the frequency of the oscillation in this model now depends upon the value of δ.

Now we consider the chronoscopic modulations of HR by relating the parameter δ to the four states of sympathetic and parasympathetic activity levels, e.g., s1, s2, p1 and p2. For simplicity, we assume that the states of sympathetic and parasympathetic activities are sinusoidal and can be modeled by the equations given below [7]:

$$\begin{aligned} \ddot{s}_1 &= -\omega_1^2 s_1, \\ \ddot{s}_2 &= -\omega_2^2 s_2, \\ \ddot{p}_1 &= -\omega_3^2 p_1, \\ \ddot{p}_2 &= -\omega_4^2 p_2. \end{aligned} \tag{2}$$

Now we can relate the parameter δ to the states of sympathetic and parasympathetic activity by the following equations[7]:

$$\begin{aligned} s_1 &= c_1 \sin(\omega_1 t + \theta_1) + A_1 \\ s_2 &= c_2 \sin(\omega_2 t + \theta_2) + A_2 \\ p_1 &= c_3 \sin(\omega_3 t + \theta_3) + A_3 \\ p_2 &= c_4 \sin(\omega_4 t + \theta_4) + A_4 \end{aligned} \tag{3}$$

$$\begin{aligned} q_1 &= s_1 + s_2 \\ q_2 &= p_1 + p_2 \end{aligned}$$

$$\begin{aligned} Q &= q_1 - q_2 \\ \delta &= 1/h(Q) \end{aligned}$$

The parameter δ determines the HR, and the function h and the coupling factors (c1, c2, c3 and c4) determine how the sympathetic and parasympathetic activities alter the HR.
Although the function h (q) (in (3)) is nonlinear, it can be approximated with either piecewise linear modules (as we will do in this paper) or with a neural network (currently research in progress by the authors). Finally, the parameters $\omega_1, \omega_2, \omega_3$ and ω_4 are the angular frequencies for the sinusoidal variations of the sympathetic and parasympathetic.
It is important to pay attention that we get a PSG test from one healthy person which dos not have any problems in sleep and cardiac cycle. In our test, we can get stage 1, 2, 3 and REM from the sample.
By considering these parameters in different stages of sleep we can see some various changes on them. We can see the parameters which are specify for sleep stages, these results are in table 1.

Table1- Coupling parameter in different stages

	stage 1	Stage 2	Stage 3	Stage R
C_1	0.001	0.001	0.1	1
C_2	1	1	1	1
C_3	0.4	0.4	0.4	0.01
C_4	0.25	0.3	0.7	1.2
A_1	0.3	0.3	0.4	0.5
A_2	0.75	0.75	0.8	0.9
A_3	0.1	0.1	0.1	0.01
A_4	0.8	0.8	1	1.5

V. Conclusion

As regards heart operation, it is well-known (see Braunwald et al., 2004) that HRV is used to evaluate vagal and sympathetic influences on the sinus node and to identify patients at risk for a cardiovascular event or death. So the major contribution of this study is to present an improved model that is able to produce a more comprehensive simulation of a realistic ECG than is observed in practice. So, based upon the original Zeeman model of 1972a, we have proposed a new model to generate the heart-rate time-series in different stages of sleep. In this model, considering the effects of sympathetic and parasympathetic activities on the VLF, LF and HF components in the HRV power spectrum. We can show all differences in four stages as a PSD in one shape. (See Fig2)
The model presented here has some important advantages over existing models. Compared to the original Zeeman model, model has the improved ability to generate signals that better resemble those recorded in practice. And importantly, is its ability to show various changes in stages. Also we can use this model in the pacemakers which will use in future. In addition we can use it for controlling in artificial gate of heart.

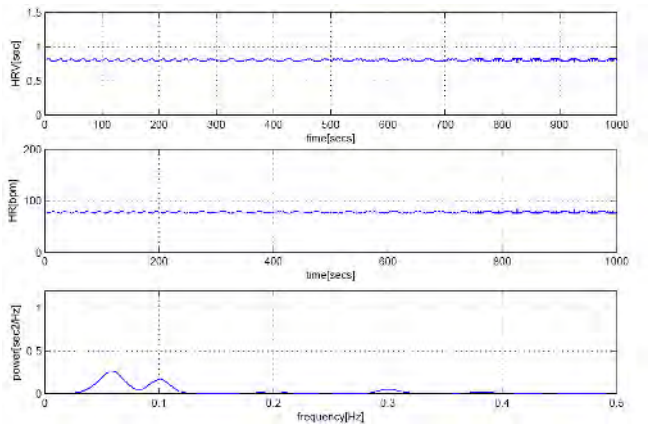

Fig2-HRV, HR, PSD of combined stage1, 2, 3 & REM of sleep

Abstract — **Methods for measuring the hematocrit level of whole blood includes measuring transmittance light at multiple wavelengths within the visible and infrared spectrum, calculating light transmittance at each of the multiple wavelengths, performing a comparison in a change in light transmittance between the multiple wavelengths, and comparison to total hematocrit value. A system for measuring total hematocrit of whole blood may include discrete LEDs for light source in the range of 430 nm to 950 nm, one photo detector, data processing circuitry, and/or a display unit. We constructed a simplified system and probe, design with LEDs and a photodiode was placed at the other side of the finger, we compare the results of the system with hematocrit levels measured by centrifuge that using blood sample drawn from 120 patients. From our analysis, the wavelengths between 700 nm to 950 nm are insensitivity to hematocrit levels, and between 470 nm to 610 nm are sensitivity to hematocrit levels. The potential optimal wavelengths for light transmittance hematocrit measuring system are in the range of 700 nm-900 nm and 470 nm-610 nm. Then, we used two potential optimal LEDs wavelengths at 585 nm and 875nm for linear algorithm to design of the noninvasive hematocrit measuring system, from the acquired information the system able to predict the hematocrit value to obtained 90% of the 120 data is given an error less than 25%.**

Keywords — **light, Transmittance, Hematocrit**

I. Introduction

Blood hematocrit refers to the packed red blood cell (RCB) volume of the whole blood sample. Blood is made up of [1] red and white blood cells and plasma. Hematocrit can be measured by various methods, but the blood drawn from a finger stick is often used for hematocrit testing. The blood fills a small tube, which is then spun in a small centrifuge. As the tube spins, is the red blood cell go to the bottom of the tube, the white blood cells cover the red in a thin layer, and the liquid plasma rises to the top. The spin tube is examined for the line that divides the red cell column is measured as a percent of the total blood column. The higher column of red cells the higher of hematocrit level. With regard to the determination of the hematocrit via optical means, it is well known that the transmission of the light through red blood cells is complicated by scattering components from plasma. The scattering from plasma vary from person to person. There by complicating the determination of hematocrit, but some wavelength possible for optical hematocrit [2-5] monitoring. The optical method is advantage the traditional for faster, real time and no finger stick similarly pulse oximeter [6-9]. The most method collected the blood sample and used spectro-photometer for optical blood constitutes transmittance spectrum. The large and heavy of spectrophotometer and puncture to drawn blood sample is disadvantage method to use direct with patients. In this present study we constructed the simplified system to measure the transmittance spectra across the finger. The LEDs was used as the light source and a photo diode was place another side to detect the light intensity. The information from this study is base to consideration the optimal wavelength for real-time optical hematocrit monitoring.

II. Detailed description of the investigate

The methods provide an optical and probe to determining the transmittance spectra from finger. The 25 LEDs used as the light source in difference wavelength in the range of 430 nm to 950 nm and a photo diode was placed at the other side of the finger. Figure (1) the experiment system and probe. The photo diode was placed other side for visible light and infrared detection. Figure (2) the hematocrit at 0% and 100% oxygen saturation. Figure (3) a given of light transmitted through a finger proportional to the intensity. The transmittance (T) and absorbance (A) from Beer's law able write to equation (1) and equation (2).

$$T = \frac{I}{Io} = e^{-\varepsilon(\lambda)cd} \tag{1}$$

$$A = 2 - \log(\%T) \tag{2}$$

Where I_0 is the intensity of the incident light, I is the intensity of transmittance light, d is the optical path length, c is the concentration of the substance and ε (λ) is the extinction coefficient at a given wavelength.

A. Noise reduction

The reduce method for thermal noise and ambient light or any other common mode noise. Fig (4) shown when LED turn on the measures of light transmittance of finger plus thermal noise plus ambient light. After that, when LED turns off there is no measure of transmittivity or reflected light from the finger. But, thermal noise and ambient light still exist and may be measured during LED turn off. The result of signal when LED turn off may then be subtracted from the result of signal when LED turn on to reduce effect of thermal noise and ambient light and other common mode noise that may be interfere with the measurement.

$$I_{LEDon} = Ifinger + Iambient + Ithermal + Iother$$
$$I_{LEDoff} = Iambient + Ithermal + Iother$$
$$I_{finger} = I_{LEDon} - I_{LEDoff}$$

Fig. 4 Noise reduction of Light Transmittance passed the finger

From fig (4) after reduce thermal noise and ambient light and any noise may be interfere during measurement, to calculates the result of light transmittance from the corrected LEDs turn on signal passed the finger equation (1) can be normalize percentage of light as follows to equation (3).

$$T_{(\lambda)\%} = \frac{I_{finger}}{I_{reference}} \qquad (3)$$

$T_{(\lambda)\%}$ is the percentage of light transmittance passed the finger after normalize, I_{finger} is the light transmittance from light source (LED) passed the finger to photo diode when the finger tip in the probe (I), $I_{reference}$ is the light transmittance from LED to photo diode in the probe without the finger tip that mean 100% of light transmittance (I_0).

B. Hematocrit monitoring equations

From [10] wavelength in the range of 470 nm to 610 nm are sensitivity to hematocrit level and wavelength in the range of 700 nm to 900 nm are insensitivity to hematocrit level. From fig (2) we chose two wavelengths are insensitivity to Oxygen saturation at 585 nm and 875 nm that are potential to calculate the hematocrit value. Fig (3) graphs from 22 patients' (Men 10, hematocrit 27% = 5, hematocrit 30 % = 5 and Women 12 hematocrit 27% = 6, hematocrit 30 % = 6) data collected of light transmittance at the finger tip from our system and compare to hematocrit value with blood drawn and centrifugation method. From fig (3) shown the wavelength 585 nm is sensitivity to hematocrit level and wavelength 875 nm is insensitivity to hematocrit level. From Fig (4) light transmittance at the finger from LED to photo diode can be writing to equation (4) and equation (5). We normalize the light transmittance to equation (6) and equation (7). Equation (8), Equation (9) showed the extinction coefficient of oxyhemoglobin and deoxyhemoglobin are equal at wavelengths 585 nm and 875

nm and able write to new constant K. Equation (10) H_{bO} is the oxyhemoglobin, H_b is the Deoxyhemoglobin, the total hemoglobin (tHb) of whole bloods that summation of H_{bO} and H_b is Hematocrit (Hct). Apply Equation (9) and Equation (10), summation H_{bO} and H_b with new constant K to Equation (11). Equation (12) to eliminate exponential term by applies natural logarithm. Equation (13) finds the difference intensity of light transmittance wavelengths is sensitivity and insensitivity to hematocrit value. Equation (14) showed the algorithm to measure the hematocrit value by light transmittance from two wavelengths method that the difference intensity of light transmittance at two wavelengths divides by constant K.

Equation (4) shown light transmittance at 585 nm is sensitivity to hematocrit level.

$$I_{585} = I_0 e^{-(aHbO + bHb + RBC + Plasma + Nail + Tissue + Pigmentation)} \quad (4)$$

Equation (5) shown light transmittance at 875 nm is insensitivity to hematocrtit level

$$I_{875} = I_0 e^{-(RBC + Plasma + Nail + Tissue + Pigmentation)} \quad (5)$$

Equation (6) normalizes the light transmittance by device with $I_{reference}$ (I_0) for sensitivity to hematocrit wavelengths.

$$T_{585} = \frac{I}{I_0} = e^{-(aHbO + bHb + RBC + Plasma + Nail + Tissue + Pigmentation)} \quad (6)$$

Equation (7) normalizes the light transmittance by device with $I_{reference}$ (I_0) for insensitivity to hematocrit wavelengths.

$$T_{875} = \frac{I}{I_0} = e^{-(RBC + Plasma + Nail + Tissue + Pigmentation)} \quad (7)$$

Equation (8) finds the difference of light transmittance at wavelength at 585 nm and 875 nm

$$T_{585} - T_{875} = e^{-(aH_{bO} + bH_b)} \quad (8)$$

Equation (9) extinction coefficient of oxyhemoglobin and deoxyhemoglobin very small, estimate equal to new constant K.

$$a = b = K \quad (9)$$

Equation (10) summation of total hemoglobin (H_{bO} and H_b) is hematocrit.

$$H_{bO} + H_b = Hct \quad (10)$$

Equation (11) applies with equation (9) and equation (10).

$$T_{585} - T_{875} = e^{-K(Hct)} \quad (11)$$

Equation (12) takes logarithm to eliminate exponential term.

$$KHct = \ln(T_{585}) - \ln(T_{875}) \quad (12)$$

Equation (13) finds the difference of light transmittance at two wavelengths (585 nm and 875 nm).

$$\Delta T = \ln(T_{585}) - \ln(T_{875}) \quad (13)$$

Equation (14) the hematocrit value is the difference of light transmittance at two wavelengths divides by the constant K.

$$Hct = \frac{\Delta T}{K} \quad (14)$$

Equation (15) the relationship between Hct and tHb is as follows.

$$tHb(\frac{g}{dL}) = 0.33 \times Hct(\%) \quad (15)$$

Figure (5) shown the system process of the light transmittance by two wavelengths method after press start the machine will collected the important data and to

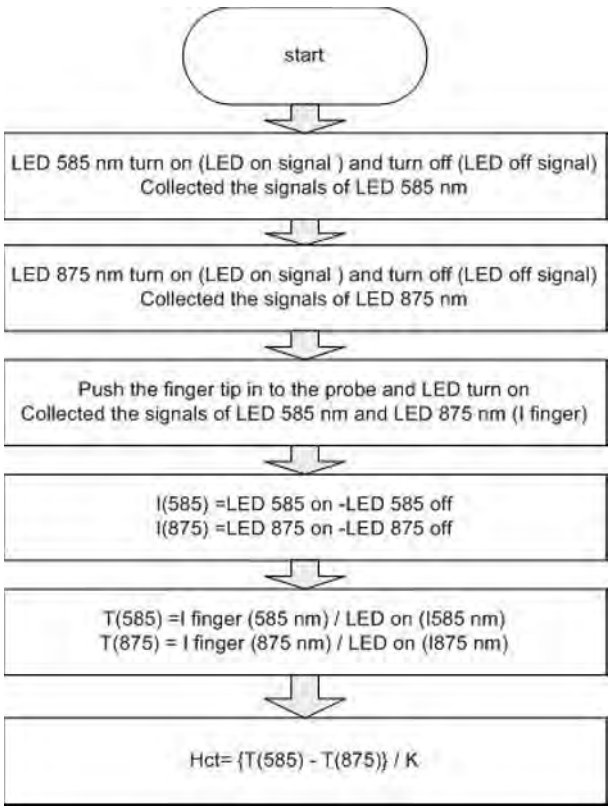

Fig. 5 The process flowchart of the system

eliminate noise (Fig 4) and follow by equation (3) to calculate the correct light intensity and finally to predicted the hematocrit value by equation (14)

C. Trial 1

This experiment used the hematocrit values measured by IEC Micro-MB centrifuge (International Equipment Company, measure the hematocrit value by blood drawn and centrifugation, compare with two wavelengths light transmittance method (Equation (14). We collected the hematocrit value with 60 patients (men); by the experiment we can find the constant K (0.0047) with equation (16).

$$K = \frac{\Delta T}{Hct} \tag{16}$$

After that we apply the constant K to equation (14), Table 1 shown the result and error from trial 1.

D. Trial 2

We collected the hematocrit value by blood drawn and centrifugation method and our system (equation 14) again with 60 patients (women), result of trial 2 shown in table 1.

Table 1 centrifugation Hematocrit value and Transmittance method.

No.	Measured (%)	Trial 1	Error (%)	Trial 2	Error (%)

18	43	42.636	-0.4	41.298	-2.0

III. Conclusions

The system and probe in this experiment as shown in Fig (1) and the process flowchart in Fig (5) can be obtained the optical transmittance by two wavelengths method, when chose the wavelengths 585 nm is sensitivity to hematocrit level and 875 nm is insensitivity to hematocrit level and both wavelengths are insensitivity to oxygen saturation in the linear equation (14) when used the average K (0.0047) value by blood sample drawn from the finger and centrifugation method to measure the hematocrit level from 120 patients. The table 1 and Fig (6) to compare of the hematocrit value reference from centrifugation and light transmittance by two wave lengths method can be predicted the hematocrit value to obtained 90% of the data is given an error less than 25%.

Abstract — **Either Fractional Brownian motion (FBM) or fractional Gaussian noise (FGN), depending on characteristic of real signal, usually provides a useful model to describe biomedical signals. Its discrete counterpart of the FBM or FGN, referred to as the discrete-time FBM (DFBM) or discrete-time FGN (DFGN), is used to analyze them in practical applications. This class of signals possesses long-term correlation and 1/*f*-type spectral behavior. In general, these signals appear to be irregular property in macroscopic view. However, in physiological signals they maybe exist certain regularity or rhythm in microscopic view in order to achieve the purpose of synergia. To find out these phenomena, the wavelet transform is invoked to decompose these signals and extract possible hidden characteristics. In this study, we first calculate fractal dimension of the electromyogram (EMG) of external urethral sphincter (EUS) to determine where the voiding phase is. Then sample a piece of signal during voiding phase to further investigate regularity or rhythm. Results indicate that certain regularity or rhythm indeed exists in irregular appearance.**

Keywords — **Discrete-Time fractional Brownian motion, discrete-time fractional Gaussian noise, wavelet transform, electromyogram, rhythm.**

I. Introduction

Many physiological signals can be modeled as either DFBM or DFGN [1], [2]. These two models are easily described by one parameter, called Hurst parameter (*H*), which has finite interval $(0,1)$. Hurst parameter is related to fractal dimension by $D=2-H$, which is a useful tool for the systems that demonstrate long-term correlations and 1/*f*-type spectral behavior. When the Hurst parameter estimated, its corresponding fractal dimension can be obtained. Among estimators for estimating Hurst parameter, maximum likelihood estimator (MLE) [1] is optimal. However, its computational complexity is high and difficult to execution. In particular, the problem is more apparent as the length of dataset is large. For this reason, we use an approximate MLE [3] to estimate Hurst parameter. This method is relatively quick and has acceptable accuracy.

Time-frequency analysis [4] is a frequently used tool in biomedical field. When describing periodic signals, Fourier transform is widely used. This method can capture periodic characteristic. In order to grasp irregularity of signals, a full-time interval is divided into a number of small, equal-time intervals. These intervals then are individually analyzed using the Fourier transform. The approach provides extra time information except frequency. It is well-known as the short-time Fourier transform (STFT). However, there is still a problem with this method. The time interval cannot be adjusted. If high frequencies exist, they cannot be discovered when time interval is short. In this situation, wavelets [5], [6] are invoked to improve this problem. It can keep track of time and frequency information very well. Moreover, wavelets can detect hidden information and extract important features. This function is a very useful tool for biomedical signals.

Physiological signals generally come from a very complex system. Signals generated from this system are usually irregular and fluctuating over time. However, some regular features maybe exist behind these phenomena. These regular components may facilitate tissues or organs effectively to implement functions themselves. Without their assistance, their responsibility may not complete and even failure. In order to investigate whether rhythm exists in physiological system, the EMG of EUS in female Wistar rats are invoked. The waveform of EMG exhibiting statistical self-similarity can be modeled as DFGN. Its accumulative signal can be viewed as DFBM. The fractal dimension of signal will assist us to judge when voiding phases happen during micturition. Wavelet transform will help us further analyze these phenomena and detect hidden information. Rhythm generally happens at low frequency band. Besides, an average power is also invoked to identify the difference during micturition.

II. Materials and Methods

The experiments were carried out on female Wistar rats anesthetized with urethane [7]. The EMG of EUS and cystometrogram (CMG) of bladder with an infusion rate of

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 227–230, 2009
www.springerlink.com

0.123 ml/min using saline solutions were recorded simultaneously at two different temperatures: room and cold temperature (6-8^{o} C). In this work, only the EMG of EUS is adopted for identifying muscular responses at two temperatures. The sampling rate was 500 points/s (time resolution as 0.002 s).

The time series of EMG are analyzed as follows. The processing window size was N=1024 points (2.048 s, frequency resolution as 0.4883 Hz). The total window size were 8192 points (16.384 s) for room temperature and 16384 points (32.768 s) for cold temperature. The first 1024 points was collected as the first window. Shifted by 64 points to the right, the second window was obtained and analyzed. These steps were repeated until the last window was gathered. The total windows were 113 for room temperature and 241 for cold temperature. For each window, fractal dimension, average power, power spectral density (PSD) via the fast Fourier transform (FFT) was executed. Although, the FFT is not suitable for estimating the PSD of DFGN, which possesses long-term correlation and 1/f-type spectral behavior, but appropriate for identifying the frequencies with periodic signals. In general, rhythm happens at low frequencies. In order to avert the interference of high frequency components and capture hidden information, the signals analyzed were decomposed into 3 levels via wavelet transform using Daubechies-2 filter coefficients [6]. Afterwards, we reconstructed signal from its corresponding approximated signal at each level. The original signal was labeled as Level 0, and reconstructed signal as Level j $(1 \le j \le 3)$ for other level. Each signal was calculated the PSD via the FFT. Their time-frequency diagrams were displayed to illustrate signal's phenomena during micturition. For the purpose of clearness, unimportant frequencies, where the PSDs were lower than 1 for room temperature and 0.35 for cold one, were suppressed.

III. Results

The results at two temperatures show that the collected signals roughly are classified as three possible outcomes as illustrated in Figures 1-3.

Figure 1 shows that the time interval (about 6-12 s) with fractal dimension below 1.5 can be suggested as voiding phase. It is reasonable because the fractal dimension between 1 and 1.5 indicates positive correlation on signal, while the one between 1.5 and 2 indicates negative correlation on signal. When voiding, coordination is important for animals. The activity of time series during voiding is obvious, but the time interval between filling and voiding phase is not apparent. The same is for the time interval between voiding

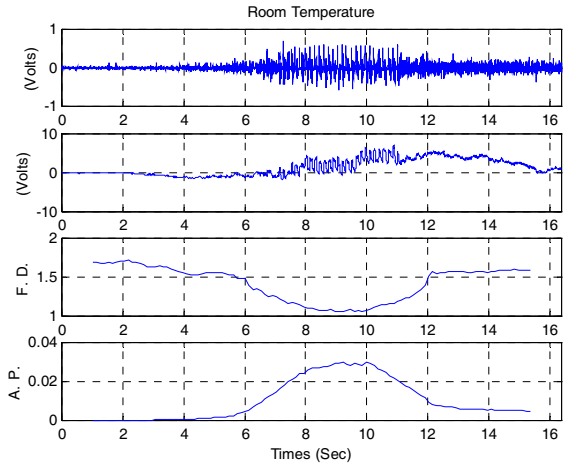

Fig. 1 From top to bottom: Original signal, accumulative signal, fractal dimension (F. D.), and average power (A. P.) at room temperature.

and next filling phase. On the other hand, average power also says that voiding phase needs more power to facilitate emptying. The average power is at least 0.01 during voiding. It is reasonable that the power needed after voiding is larger than filling phase. The extra power can be viewed as recovery or transient power. Moreover, certain rhythm exists at accumulative signal during voiding. It will be discovered via the FFT as illustrated in this section.

Figures 2 and 3 are both coming from cold temperature. In Figure 2, the voiding phase is not easy to discover from time series, whereas accumulative signal is easier than original one. According to the same line, the time interval with fractal dimension below 1.5 can be suggested as voiding phase. When the figure is zoomed in, the time series also roughly

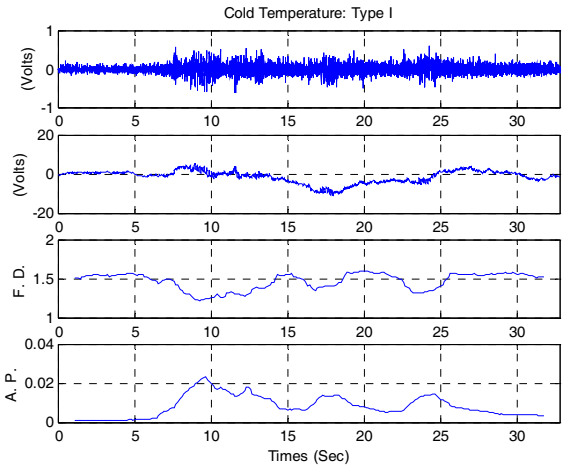

Fig. 2 From top to bottom: Original signal with Type I, accumulative signal, fractal dimension (F. D.), and average power (A. P.) at cold temperature.

displays certain rhythm, but cannot be decided without other indicator. Here fractal dimension helps us to explain importance of coordination among muscles. Likewise, average power during voiding is at least larger than 0.01. Here average power is a good auxiliary tool.

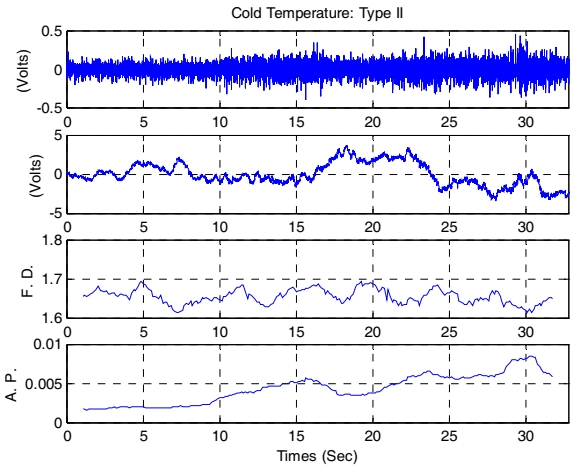

Fig. 3 From top to bottom: Original signal with Type II, accumulative signal, fractal dimension (F. D.), and average power (A. P.) at cold temperature.

In Figure 3, all fractal dimensions are larger than 1.5 and average power is lower than 0.01. We cannot discover any voiding response from the EMG of EUS. This phenomenon can be explained as incontinence. That is to say, cold-water stimulation can destroy coordination among muscles. It is interesting that signal with Type I still preserves intermittent voiding phases, but signal with Type II not. It can be explained that the rats of Type I possess robust physiological mechanism to self-organize, which can resist larger external stimulation. However, the rats of Type II lack of the ability to self-organization, because they have ordinary mechanism, not robust one.

From time series of Figures 1 and 2, it is implied that certain rhythm exists. In order to detect it, we resort to the FFT. The results show that rhythm indeed exists during voiding only if the physiological function of EUS is not damaged completely. Figures 4-6 illustrate the phenomena as follows:

Figure 4 shows that the main frequency is 6.8359 Hz and happens between 8.192 and 10.752 s. The second one is 6.3477 Hz and happens at two time intervals: 7.936-8.704 s and 10.24-11.008 s. In general, the signals on both sides of main frequency include other non-rhythmic signals, which must affect the estimate of PSD. Therefore, the main frequency can be viewed as the one of real rhythm. Rhythm will help the process during micturition.

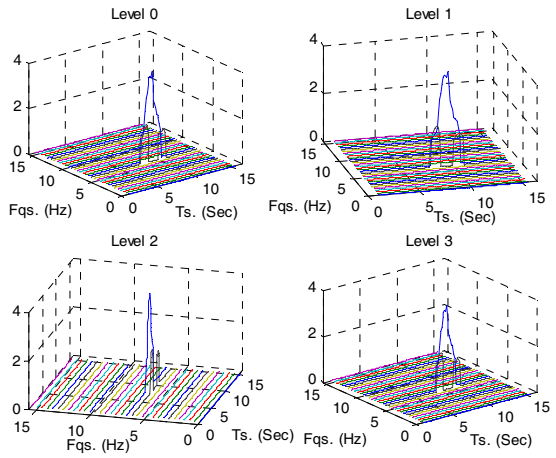

Fig. 4 From top to bottom and left to right: Original signal, reconstructed signal via Level 1, reconstructed signal via Level 2, and reconstructed signal via Level 3 at room temperature.

It is observed from Figure 5 that there exist five frequencies with PSD larger than 0.35. They are 5.8594 (third), 6.3477 (main frequency), 6.8359 (second), 7.3242 (fourth) and 7.8125 (fifth) Hz. The main frequency happens at two time intervals: 8.576-10.88 s and 23.296-24.576 s. The second one happens at two time intervals: 8.32-8.96 s and 10.624-11.008 s. The third one happens at 9.728-10.368 and 17.536-17.92 s. The fourth one happens between 11.776 and 12.672 s. The fifth one happens at 11.136 s. As mentioned before, the signals on both sides of main frequency are affected by other non-rhythmic signals. These rhythmic regions suggest us where voiding phases occur.

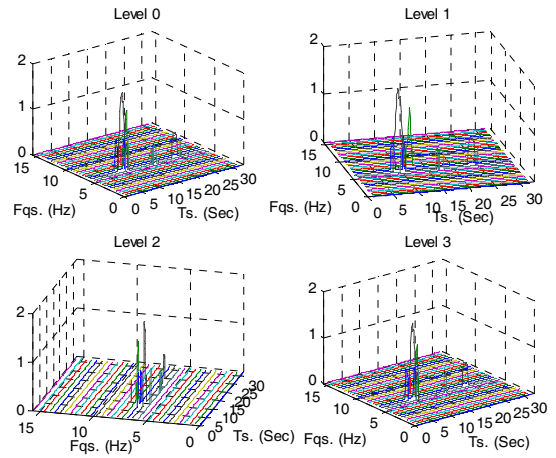

Fig. 5 From top to bottom and left to right: Original signal with Type I, reconstructed signal via Level 1, reconstructed signal via Level 2, and reconstructed signal via Level 3 at cold temperature.

In addition, the value also tells us that the main frequency at cold temperature is slight lower one-step frequency resolution than one at room temperature. These five obvious frequencies suggest us that rhythm still exists even though under cold-water stimulation for robust rats.

Figure 6 shows that no rhythm happens in signal with Type II at cold temperature. This suggests that physiological function with this type of rats is worse than one with Type I.

For revealing the rhythm on signal, one time interval with rhythm is extracted from full-time interval under room temperature. This interval of signal first is processed via wavelet transform and reconstructed them using approximated signal. Then it is processed via the FFT. The result shows in Figure 7. It is obvious from this figure that rhythm occurs during voiding phase and its main frequency is 6.8359 Hz.

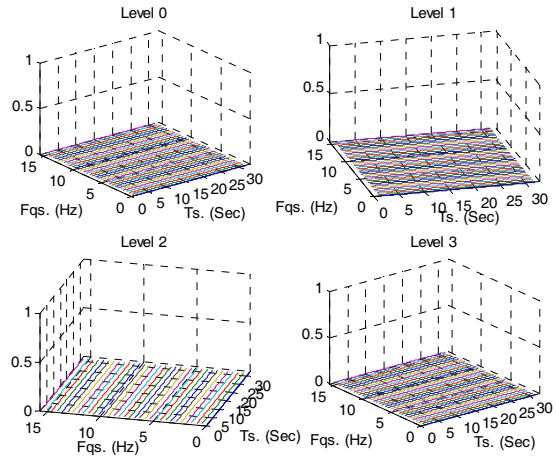

Fig. 6 From top to bottom and left to right: Original signal with Type II, reconstructed signal via Level 1, reconstructed signal via Level 2, and reconstructed signal via Level 3 at cold temperature.

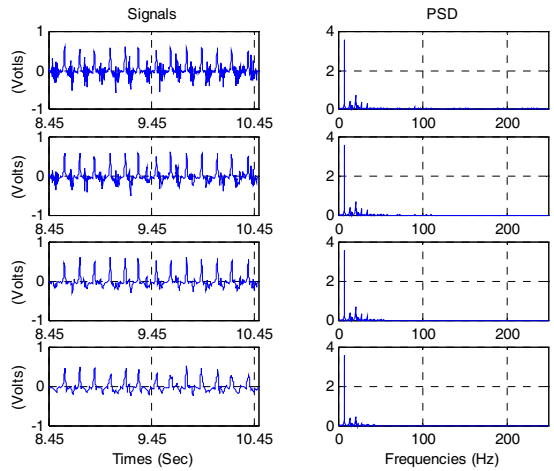

Fig. 7 From top to bottom and left to right: Original signal, its corresponding PSD, reconstructed signal via Level 1, its corresponding PSD, reconstructed signal via Level 2, its corresponding PSD, and reconstructed signal via Level 3, its corresponding PSD at one time interval at room temperature.

IV. Conclusion

Micturition is abnormal when muscles or nerves problem may be present and interfere with the ability of bladder to hold or release urine normally. In this study, it is suggested that nerves are numbed at cold-water stimulation more or less according to animal's physiological condition. Numbed nerves will result in coordination problem among muscles. Healthy animal should at least have one voiding phase and only one at best. Under cold-water stimulation, animal with robust mechanism exist many voiding phases, but rhythm still exist to facilitate micturition. Nevertheless, animal with bad function will result in incontinence. Results show that rhythm plays an important role during micturition. It facilitates the bladder to empty. In addition, hybrid methods usually provide some meaningful explanations.

Abstract — **Heart rate variability (HRV) refers to the regulation of the sinoatrial node, the natural pacemaker of the heart by the sympathetic and parasympathetic branches of the autonomic nervous system. HRV analysis is an important tool to observe the heart's ability to respond to normal regulatory impulses that affect its rhythm. Like many bio-signals, HRV signals are non-linear in nature. Higher order spectral analysis (HOS) is known to be a good tool for the analysis of non-linear systems and provides good noise immunity. A computer-based arrhythmia detection system of cardiac states is very useful in diagnostics and disease management. In this work, we studied the identification of the HRV signals using features derived from HOS. These features were fed to the support vector machine (SVM) for classification. Our proposed system can classify the normal and other four classes of arrhythmia with an average accuracy of more than 85%.**

I. Introduction

Electrocardiogram (ECG), a time varying signal that concerns the electrical manifestation of the heart muscle activity is an important tool in diagnosing the condition of the heart [1]. Heart rate variability, which is the changes of beat rate of heart over time, reflects the autonomic control of the cardiovascular system [2]. It is a simple, noninvasive technique which provides an indicator of the dynamic interaction and balance between the sympathetic nervous system and the parasympathetic nervous system. These signals are not linear in nature and hence, analysis using nonlinear methods can unveil the hidden information in the signal. A detailed review of HRV analysis that includes both linear and non-linear approaches is discussed [3].

An automated method for classification of cardiac abnormalities is proposed based on higher order spectra analysis of HRV. Higher order spectra (HOS) are spectral representations of moments and cumulants and can be defined for deterministic signals and random processes. They have been used to detect deviations from Gaussianity and identify non-linear systems [4].

II. Materials and Methodology

ECG data for the analysis was obtained from Kasturba Medical Hospital, Manipal, India arrhythmia database. Prior to recording, the ECG signals were processed to remove noise due to power line interference, respiration, muscle tremors, spikes etc. The R peaks of ECG were detected using Tompkins's algorithm [5]. The ECG signal is used to classify cardiac arrhythmias into 5 classes, namely, *normal sinus rhythm (NSR*), *premature ventricular contraction (PVC)*, *complete heart block (CHB)*, *type III-sick sinus syndrome (SSS-III)* and *complete heart failure (CHF)*. The number of dataset chosen for each of the five classes is given in Table 1. Each dataset consists of around 10,000 samples and the sampling frequency of the data is 320 Hz. The interval between two successive QRS complexes is defined as the RR interval ($t_{r\text{-}r}$ seconds) and the heart rate (beats per minute) is given as:

$$HR=60/t_{r\text{-}r} \quad (1)$$

Table 1 Number of Datasets in each class.

Cardiac Class	No. of Datasets
NSR	183
PVC	37
CHB	42
SSS-III	43
CHF	25

III. HOS and its features

The HRV signal is analyzed using different higher order spectra (also known as polyspectra) that are spectral representations of higher order moments or cumulants of a signal. In particular, this paper studies features related to the third order statistics of the signal, namely the bispectrum. The Bispectrum is the Fourier Transform of the third order correlation of the signal and is given by

$$B(f_1,f_2) = E[X(f_1)X(f_2)X^*(f_1+f_2)] \quad (2)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 231–234, 2009
www.springerlink.com

Where X(f) is the Fourier transform of the signal x(nT) and E[.] stands for the expectation operation. In practice, the expectation operation is replaced by an estimate that is an average over an ensemble of realizations of a random signal. For deterministic signals, the relationship holds without an expectation operation with the third order correlation being a time-average. For deterministic sampled signals, X(f) is the discrete-time Fourier transform and in practice is computed as the discrete Fourier transform (DFT) at frequency samples using the FFT algorithm. The frequency f may be normalized by the Nyquist frequency to be between 0 and 1.

In our earlier study, we proposed the general patterns for different classes of arrhythmia. Bispectral entropies [6] were derived to characterize the regularity or irregularity of the HRV from bispectrum plots. The formulae for these bispectral entropies are as follows:

Normalized Bispectral Entropy (BE 1):

$$P_1 = -\sum_n p_n \log p_n \tag{3}$$

where $p_n = \dfrac{|B(f_1,f_2)|}{\sum_\Omega |B(f_1,f_2)|}$, Ω = the region as in figure 1.

Normalized Bispectral Squared Entropy (BE 2):

$$P_2 = -\sum_n q_n \log q_n \tag{4}$$

where $p_n = \dfrac{|B(f_1,f_2)|^2}{\sum_\Omega |B(f_1,f_2)|^2}$, Ω = the region as in figure 1.

The normalization in the equations above ensures that entropy is calculated for a parameter that lies between 0 and 1 (as required of a probability) and hence the entropies (P_1 and P_2) computed are also between 0 and 1.

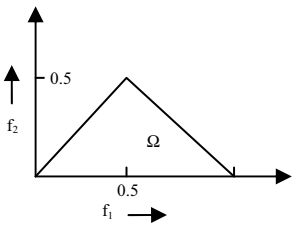

Figure 1 Non-redundant region of computation of the bispectrum for real signals. Features are calculated from this region. Frequencies are shown normalized by the Nyquist frequency.

In this study we also make use of features related to moments [7] and the weighted centre of bispectrum (WCOB) [8] to characterize these plots. The features related the moments of the plot are:

The sum of logarithmic amplitudes of the bispectrum:

$$H_1 = \sum_\Omega \log\left(\left|B\left(f_1,f_2\right)\right|\right) \tag{5}$$

The sum of logarit hmic amplitudes of diagonal elements in the bispectrum:

$$H_2 = \sum_\Omega \log\left(\left|B\left(f_k,f_k\right)\right|\right) \tag{6}$$

The first-order spectral moment of amplitudes of diagonal elements in the bispectrum:

$$H_3 = \sum_{k=1}^{N} k \log\left(\left|B\left(f_k,f_k\right)\right|\right) \tag{7}$$

These features (H_1-H_3) were used by Zhou et al [7] to classify mental tasks from EEG signals.

The definition of WCOB [8] is given by:

$$f_{1m} = \frac{\sum_\Omega iB(i,j)}{\sum_\Omega B(i,j)} \qquad f_{2m} = \frac{\sum_\Omega jB(i,j)}{\sum_\Omega B(i,j)} \tag{8}$$

where i, j are the frequency bin index in the non-redundant region.

Blocks of 1024 samples, corresponding to 256 seconds at the re-sampled rate of 4 samples/sec were used for computing the bispectrum. These blocks were taken from each HRV data record with an overlap of 512 point (i.e 50%).

IV. Support Vector Machine (SVM) Classifier

In this study a kernel-based classifier is adopted for classification of the cardiac abnormalities. Herein, the attribute vector is mapped to some new space. Despite the fact that classification is accomplished in a higher dimension space, any dot product between vectors involved in the optimization process can be implicitly computed in the low dimensional space [9].

For a training set of instance-label pairs $\left(x_i, y_i\right)$, $i = 0,...,l$ where $x_i \in R^n$ and $y_i = \{-1, 1\}$. If $\phi(.)$ is a non-linear operator mapping the attribute vector x to a higher dimensional space, the optimization problem for the new points $\phi(x)$ becomes

$$\min_{w,b,\xi} \quad \frac{1}{2} w^T w + C \sum_{i=1}^{l} \xi_i \quad \text{subject to the constraints}$$

$$y_i \left(w^T \varphi(x_i) + b \right) \geq 1 - \xi_i, \qquad \xi_i \geq 0 \tag{9}$$

where C>0 is the penalty parameter for the error term and ξ_i are a set of slack variables that are introduced when the training data is not completely separable by a hyper plane . The SVM finds a linear separating hyper plane with the maximal margin in this higher dimensional space. As in the linear case, the mapping appears in terms of the kernel function $K(x_i, x_j) = \phi(x_i)^T \phi(x_j)$. Despite the fact there are several kernels, typical choice for kernels are radial basis functions. The RBF kernel non-linearly maps samples into a higher dimensional space. There are several methods that can be used to extend a binary class SVM to multi-class SVM. In this work, we used the One against all method SVM to classify the five classes of HRV data [10].

V. Test vector generation

In order to measure and validate the performance of a classifier, there should be a sufficiently large set of the test data. When only a small database is available, different combinations of training and test sets can be used to generate more trials. In our experiment, we choose approximately two third of the data from each class of HRV signals for training and one third for testing. This experiment was repeated five times by choosing different combinations of training data and test data. Combinations of training and test data were randomly chosen. In each of these experiments, a new SVM model was generated and the test data sets did not overlap with the training data sets.

VI. Result

Table 2 shows the range of values for all the seven features for the five classes. The ANOVA test result of these HOS features are of very low p-value (i.e. p-value < 0.001).

For normal cases, heart rate varied continuously between 60bpm-80 bpm. The bispectrum entropies (P_1 and P_2) appear to be high due to higher variation in the heart rate. The mean value of P_1 is 0.719 while that of P_2 is 0.43. The mean values of moments H_1, H_2, H_3 are 2.81e5, 1.29e3 and 1.42e5 respectively. The WCOB mean values for f_{1m}, f_{2m} are 60 and 22.32 respectively. It may be that these values are related to the rate of breathing and its harmonics. And there may be a modulating effect on the heart rate variability due to the breathing pattern.

During PVC, there will be ectopic beats in the normal ECG signals. The mean entropies (P_1 and P_2) indicated in the Table 2 are correspondingly higher than the normal case due to higher variation. The mean values of moments H_1, H_2, H_3 are 2.81e5, 1.29e3 and 1.42e5 respectively. The WCOB mean values for f_{1m}, f_{2m} are 126.7 and 56.35 respectively.

Table 2 Results of ANOVA on various bispectral features. Entries in the columns correspond to mean and standard deviation. (all these features are of p-value < 0.001)

Features	Normal	PVC	CHB	SSS	CHF
P_1	0.719 ±0.086	0.824 ±0.063	0.710 ±0.022	0.780 ±0.091	0.605 ±0.129
P_2	0.430 ±0.146	0.542 ±0.181	0.428 ±0.150	0.420 ±0.255	0.187 ±0.140
H_1	2.81e5 ±5.82e4	3.64e5 ±4.55e4	1.79e5 ±4.23e4	4.64e5 ±3.40e4	2.02e5 ±5.43e4
H_2	1.29e3 ±2.31e2	1.60e3 ±1.74e2	8.94e2 ±1.66e2	1.98e3 ±1.22e2	9.74e2 ±2.18e2
H_3	1.42e5 ±3.04e4	1.90e5 ±2.39e4	8.94e4 ±2.15e4	2.38e5 ±1.87e4	1.02e5 ±2.89e4
f_{1m}	60.00 ±61.90	126.70 ±43.10	41.95 ±10.90	62.85 ±36.80	33.71 ±25.5
f_{2m}	22.32 ±31.40	56.35 ±36.80	12.91 ±4.28	31.05 ±23.2	10.50 ±9.89

Table 3 Percentage of classification accuracy for five different classes of arrhythmia with a SVM classifier.

Class	**NSR**	**PVC**	**CHB**	**SSS**	**CHF**	**Average**
Accuracy	87.93	74.00	80.00	98.46	88.57	85.79

In the case of CHB, the Atrio-ventricular node is unable to send electrical signals rhythmically to the ventricles and as a result the heart rate remains low. The bispectrum entropies (P_1 and P_2) indicated in the Table 2 are lower as compared to the normal subject due to the reduced beat to beat variation. The mean values of moments H_1, H_2, H_3 are 1.79e5, 8.94e2 and 8.94e4 respectively. The WCOB mean values for f_{1m}, f_{2m} are 41.95 and 12.91 respectively.

In SSS – III, there is a continuous variation of heart rate between bradycardia and tachycardia. The bispectrum entropies (P_1 and P_2) indicated in the Table 2 are comparable with the normal case due to the higher variation in the beat to beat. The mean values of moments H_1, H_2, H_3 are 4.64e5, 1.93e3, 2.38e5 and 8.94e4 respectively. The WCOB mean values for f_{1m}, f_{2m} are 62.85 and 31.05 respectively.

During CHF, the heart is unable to pump the blood (supply enough oxygen) to the different parts of the body. The mean bispectrum entropies (P_1 and P_2) are lower than the normal case due to the reduced beat to beat variation. The mean values of moments H_1, H_2, H_3 are 2.02e5, 9.74e2,

1.02e5 and 8.94e4 respectively. The WCOB mean values for f_{1m}, f_{2m} are 33.71 and 10.50 respectively.

Table 4 Result of Sensitivity (SENS) and Specificity (SPEC) for the SVM classifier. Entries to the left are the numbers of True negatives (TN) , False negatives (FN), True positive (TP) and False positives (FP).

TN	FN	TP	FP	SPEC	SENS
255	21	189	35	87.93%	90.00%

The result of classification efficiency is shown in Table 3. Our results show that, our proposed method can classify the unknown cardiac class with an efficiency of about 85%, sensitivity and specificity of 90% and 87.93% respectively (Table 4).

VII. Discussion

Different non-linear methods have been used to classify the cardiac classes using the heart rate signals [11-14]. In all these studies, different non-linear parameters namely correlation dimension, Lyapunov exponent, approximate entropy, fractal dimension, Hurst exponent and detrended fluctuation analysis have been used to identify the unknown class of the disease.

In this work, we have applied HOS as a non-linear tool to analyze cardiac signals. We have used the SVM and bispectral features to diagnose the different cardiac arrhythmia. Table 3 and 4 shows promising results of the application of HOS features for cardiac signals classification.

One of the major challenges in non-linear biosignal processing is the presence of intra-class variation. Another challenge is that there are overlaps among the derived features for various arrhythmias. Hence in our present work, we have used two bispectrum entropies and three features related to the moments and two weighted centre of bispectrum as descriptors to differentiate different arrhythmia. These features were then fed to the SVM classifier for automated classification. We achieve about 85% of classification accuracy with the current set of features. The accuracy may be further increased by extracting better features and taking more diverse training data.

VIII. Conclusion

The HRV signal can be used as reliable indicator of the cardiac diseases. In this work, we have extracted different HOS features from heart rate signals for automated classification. We have evaluated the effectiveness of different bispectrum entropies, moments and weighted centre of bispectrum as features for the classification of various cardiac abnormalities. Our proposed system utilizes combination of the different features with a SVM classifier and is able to identify the unknown cardiac class with a sensitivity and specificity of 90% and 87.9% respectively. The accuracy of our proposed system can be further increased by increasing the size of the training set, rigorous training, and better features.

Abstract — **Time varying magnetic fields can be used to transfer power across the skin to drive implantable biomedical devices without the use of percutaneous wires. However the coupling between the external and internal coils will vary according to orientation and posture. Other potential sources of power delivery variations arise from changes in circuit parameters and loading conditions. To maintain correct device function, the power delivered must be regulated to deal with these variations. This paper presents a TET system with a closed loop frequency based power regulation method to deliver the right amount of power to the load under variable coupling conditions. The system is capable of regulating power for axially aligned separations of up to 10mm and lateral displacements of up to 20mm when delivering 10W of power. The TET system was implanted in a sheep and the temperature of implanted components is less than 38.4 degrees over a 24 hour period.**

Keywords — **Magnetic field, coupling, Transcutaneous Energy Transfer (TET)**

I. Introduction

High power implantable biomedical devices such as cardiac assist devices and artificial heart pumps require electrical energy for operation. Presently this energy is provided by percutaneous leads from the implant to an external power supply [1]. This method of power delivery has the potential risk of infection associated with wires piercing through the skin. Transcutaneous Energy Transfer (TET) enables power transfer across the skin without direct electrical connectivity. This is implemented through a transcutaneous transformer where the primary and the secondary coils of the transformer are separated by the patient's skin providing two electrically isolated systems. A TET system is illustrated in figure 1. The electromagnetic field produced by the primary coil penetrates the skin and produces an induced voltage in the secondary coil which is then rectified to power the biomedical device.

Compared to percutaneous wires, TET systems become more complex to operate under variable coupling conditions as it result in a variation in power transfer [2]. One source of variation in coupling is due to posture changes of the patient causing variation in the alignment between the primary and the secondary coils. The typical separations between the internal and external coils are in the range of 10-20mm. If insufficient power is delivered to the load then the implanted device will not operate properly. If excessive power is delivered, then it must be dissipated as heat with the potential for causing tissue damage. Therefore it is important to deliver the right amount of power matching the load demand.

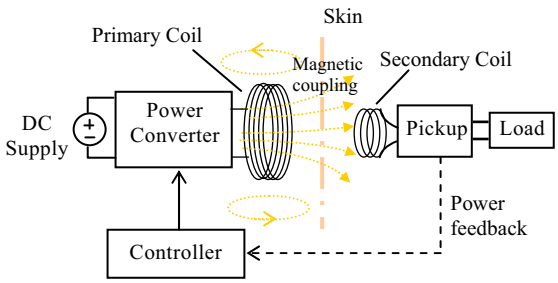

Fig. 1 Block diagram of a TET system

Power can be regulated either in the external or the implanted system. However, regulation in the implanted system results in dissipation of heat in the implanted circuitry [3]. Furthermore, it also increases the size and weight of the implanted circuitry therefore power regulation in the external system is preferred over the implanted system. There are two main methods of regulating power in TET systems, magnitude and frequency control methods. In the case of magnitude control, input voltage to the primary power converter is varied in order to vary the power delivered to the load. This method of control is very common in TET systems however it does not take into account the miss-match of the resonant frequency of the secondary resonant tank and the operating frequency of the external power converter. This miss-match in frequency reduces the power transferred to the load, consequently, a larger input voltage is required which results in a reduction in the overall power efficiency of the system. Frequency control involves varying the operating frequency of the primary power converter to vary the

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 235–239, 2009
www.springerlink.com

power delivered to the load. Depending on the actual power requirement of the pickup load, the operating frequency of the primary power converter is varied so the secondary prick-up is either tuned/detuned, thus the effective power delivered to the implantable load is regulated [4]. The system discussed in this paper uses frequency control to control power delivery to the load, and a Radio Frequency (RF) link is used to provide wireless feedback from the implanted circuit to the external frequency controller.

II. System Arcitechture

The TET system is designed to deliver power in the range of 5W to 25W. Figure 2 illustrates the architecture of the overall system. A DC voltage is supplied to the system with an external battery pack. A current fed push pull resonant converter is used to generate a high frequency sinusoidal current across the primary coil. The magnetic coupling between the primary and the secondary systems produces a sinusoidal voltage in the secondary coil which is rectified by the power conditioning circuit in the pickup to provide a stable DC output to the implanted load. As shown in figure 2, a DC inductor is added to the secondary pick up following the rectifier bridge in order to maximize the power transfer to the load. The DC inductor aids to sustain a continuous current flow in the pick up [5].

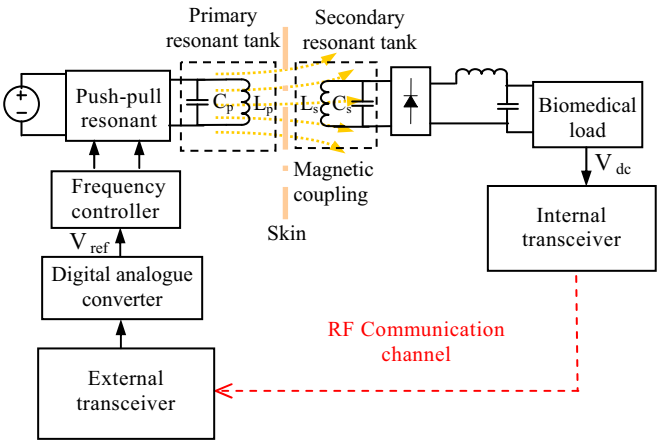

Fig. 2 System architecture

Two nRF24E1 Nordic transceivers are used for data communication. The DC output voltage of the pickup is detected and transmitted to the external transceiver. The external transceiver processes the data and adjusts the duty cycle of the output PWM signal in order to vary the reference voltage (V_{ref}) of the frequency control circuitry. The PWM signal is passed through a Digital to Analogue Converter (DAC), in order to obtain a variable reference voltage. This variable reference voltage is then used to vary the frequency of the primary resonant converter which in turn varies the power delivered to the implantable system. The response time of the system is approximately 360ms.

A. Frequency controller

The frequency controller employs a switched capacitor control method described in [7]. The controller varies the overall resonant frequency of the primary resonant tank in order to tune/detune to the secondary resonant frequency. The frequency of the primary circuit is adjusted by varying the effective capacitance of the primary resonant tank. This is illustrated in figure 3.

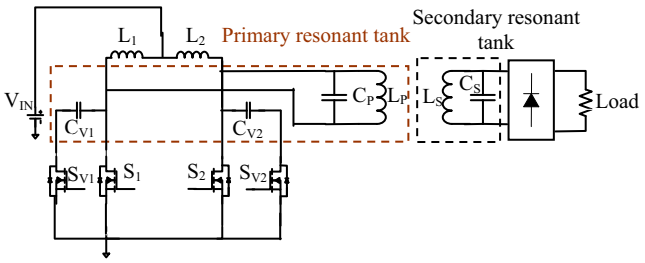

Fig. 3 System based of primary frequency control [4]

Inductor L_P, capacitor C_P and switching capacitors C_{V1} and C_{V2} form the resonant tank. The main switches S1 and S2 are switched on and off alternatively for half of each resonant period and changing the duty cycle of the detuning switch S_{V1} and S_{V2} varies the effective capacitances of C_{V1} and C_{V2} by changing the average charging or discharging period. This in turn will vary the operating frequency of the primary converter. Each C_{V1} and C_{V2} is involved in the resonance for half of each resonant period. The variation in reference voltage (V_{ref}) obtained from the DAC is used to vary the switching period of these capacitors. This method of frequency control maintains the zero voltage switching condition of the converter while managing the operating frequency. This helps to minimize the high frequency harmonics and power losses in the system. As shown in figure 3 the pickup circuitry is tuned to a fixed frequency using the constant parameters L_S and C_S. The operating frequency of the overall system is dependent on the primary resonant tank which can be varied by changing the equivalent resonant capacitance [6], therefore the tuning condition of the power pickup can be controlled.

III. Experimental Method

A prototype TET system was built and tested in a sheep. The internal coil and the resonant capacitor were Parylene coated and encapsulated with medical grade silicon to provide a biocompatible cover. The total weight of the implanted equipment was less than 100g. As illustrated by the cross sectional view in figure 4, thermistors were attached to the primary and the secondary coils to measure the temperature rise caused by the system in the surrounding tissue.

- Thermistor 1: Placed on top of primary
- Thermistor 2: Placed under the skin
- Thermistor 3: Placed on the muscle side
- Thermistor 4: 1cm from the secondary coil
- Thermistor 5: 2cm from the secondary coil
- Thermistor 6: Near the subcutaneous tissue near the exit of the wound.

Prior to experimentation, the thermistors were calibrated against a high precision FLUKE 16 Multimeter temperature sensor and a precision infrared thermometer.

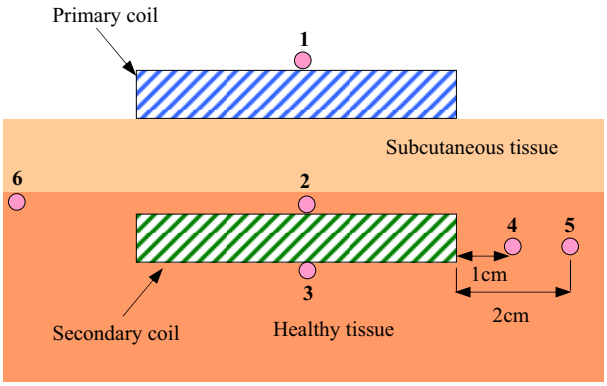

Fig. 4 The placement of the temperature sensors

Prior to the surgery all implantable components were sterilized using methanol gas. The sheep was put under isoflurane anesthesia and the right dorsal chest of the sheep was shaved. Iodine and disinfectant was applied over the skin to sterilize the area of surgery. Using aseptic techniques a 5 cm incision was made through the skin on the dorsal chest. A tunnel was created under the skin approximately 20 cm long and a terminal pocket created. The secondary coil and the thermistors were placed within this pocket. The thickness of the skin at this site was approximately 10mm. The secondary coil was then sutured in place and the power lead from the coil and leads of the thermistors were tunneled back to the incision site and exteriorised through the wound. The wound was stitched and Marcain was injected to the area of the wound. Iconic powder was also put on the site of the wound to reduce infection. Following the surgery the sheep transferred to a crate where it was kept over a three week period. The primary coil was placed directly above the secondary coil and held on the sheep using three loosely tied strings. A PowerLab ML820 data acquisition unit and Labchart software (ADInstruments, Sydney Australia) was used for continuous monitoring of the temperature, the output power to the load and the variation in input current of the system during power regulation. The data acquisition was carried out at a frequency of 10 samples per second.

IV. Experimental Results

Experimental results were obtained for delivering 10W of power to the load when the system was implanted in sheep. Figure 5 illustrates the closed loop controlled power delivered to the load over a period of 24 hours. The input voltage to the system was 23.5V. The controller is able to control the power to the load for axially aligned separations and lateral displacements between 10mm to 20mm. Beyond this range the coupling is too low for the controller to provide sufficient compensation, and delivered power will drop below the 10W set point. Evidence of inadequate coupling can be seen at intervals in Figure 5.Variation in input current reflects the controller working to compensate for changes in coupling using frequency variation between 163 kHz (fully detuned) and 173 kHz (fully tuned). When the coupling between the coils is good, the primary resonant tank is fully detuned in order to reduce the power transferred to the secondary. When the coils are experiencing poor coupling, the primary resonant tank is fully tuned to increase the power transfer between the coils.

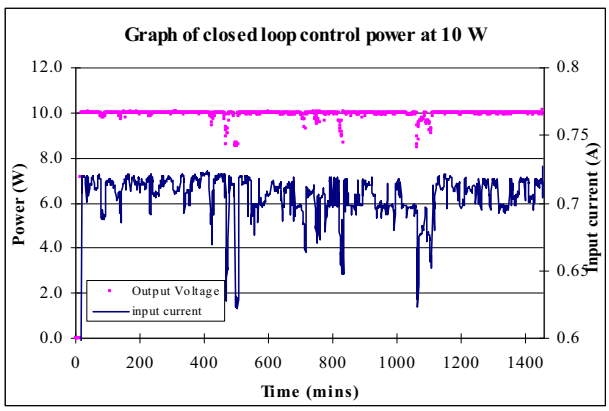

Fig. 5 Regulated power to the load and the input current to the system

Figure 6 shows the temperature recorded from the six thermistors. It takes approximately 20 minutes for the tem-

perature to reach a steady state after turn-on. The maximum temperature was observed in the thermistor placed under the secondary coil on the muscle side. The maximum temperature observed in this thermistor over the 24 hour period was 38.1^0C. The maximum temperature rise observed was 3.8^0C in the thermistor placed under the skin. The large variation in the primary coil temperature is due to the changes in current through the coil from the frequency control mechanism. When the system is in the fully tuned condition, the current in the primary coil is at a maximum to compensate for the poor coupling. The temperature rise in the thermistors 1cm and 2cm from the secondary coil is well below 2^0C.

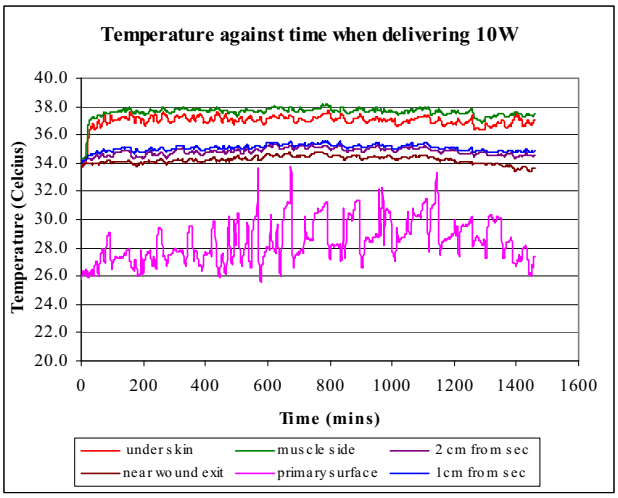

Fig. 6 Temperature profile of the thermistors

V. Discussion

Although the system performs well at delivering 10W over a 24 hour period, there are short intervals when this power level was not delivered. These intervals correspond to times when the coupling is too low for the controller to compensate. A variety of approaches can be taken to solve this problem. The first is to tighten the coupling limitations to prevent coupling deteriorating to beyond the equivalent limit of 20mm of axial separation. The second approach is to allow occasional power drops on the basis that an internal battery could cover these intervals, (patient alarms would activate if the problem persists). The third approach is to increase the controller tolerance to low coupling. The ability to tolerate misalignments of the frequency controlled system is mainly determined by the systems quality factor (Q value), which is defined by:

$$Q = \frac{R}{\omega L} \quad (1)$$

Where R is the load resistance, ω (2πf) is the system angular operating frequency, and L is the secondary coil inductance. A larger Q will enable the system to be more tolerant. This benefit is traded off against the need for a more sensitive and faster feedback response from the control system.

VI. Conclusions

We have successfully implemented a system that is capable of continuously delivering power to a load in a sheep. The results have been presented for delivering 10W of power to the load with closed loop frequency control technique for a period of 24 hours. The external coil was loosely secured to lie over the region of the internal coil and subjected to alignment variations from a non-compliant subject. The maximum temperature observed in this system is 38.1^0C on the thermistor placed on the muscle side under the primary coil. The maximum temperature rise was 3.8^0C on the thermistor placed under the skin.

Abstract — **A complexity measure is a mathematical tool for analyzing time-series data in many research fields. Various measures of complexity were developed to compare time series and distinguish whether input time-series data are regular, chaotic, and random behavior. This paper proposes a simple technique to measure fractal dimension (FD) values on the basis of zero-crossing function with detrending technique or is called modified zero-crossing rate (MZCR) function. The conventional method, namely, Higuchi's method has been selected to compare output accuracies. We used the functional Brownian motion (fBm) signal which can easily change its FD for assessing performances of the proposed method. During experiment, we tested the MZCR-based method to determine the FD values of the EEG signal of motor movements. The obtained results show that the complexity of fBm signal is measured in the form of a negative slope of log-log plot. The Hurst exponent and the FD values can be measured effectively.**

Keywords — **Complexity, fractal dimension, biomedical signal, modified zero-crossing rate, MZCR, Hurst exponent**

I. Introduction

Time-series data formed by sampling method based on the suitable rate of frequency. It can be measured as the complexity in order to show whether the data are regular, chaotic, or random behavior. Basically, we can measure irregularity of time-series data in terms of quantity's complexity. Especially, in the field of biomedical signal analysis, complexity of heartbeat signal (electrocardiogram; ECG) and brain signal (electroencephalogram; EEG) can be able to distinguish emotion, imagination, movement, and can be used for medical diagnosis purposes [1].

To determine the quantity's complexity, fractal dimension (FD) value is a one of indicative parameters which most widely used. Moreover, the FD value has been proved to be effective parameter in characterizing such biomedical signals. Fractal geometry is a mathematical tool for dealing with complex systems. A method of estimating FD has been widely used to describe objects in space, since it has been found useful for the analysis of biological data [2][3].

For related works, classical methods such as moment statistics and regression analysis, properties such as the Kolmogorov-Sinai entropy [4], the apparent entropy [5], and the existing methods in estimating FD value have been proposed to deal with the problem of pattern analysis of waveforms. The FD may convey information on spatial extent and self similarity and self affinity [6]. Unfortunately, although precise methods to determine the FD have already been proposed, their usefulness is severely limited since they are computer intensive and their evaluation is time consuming [7]. Recently, the FD is relatively intensive to data scaling and shows a strong correlation with the human movement of EEG data [8]. The time series with fractal nature are to be describable by the functions of fractional Brownian motion (fBm), for which the FD can easily be set. Waveform FD values indicate the complexity of a pattern or the quantity of information embodied in a waveform pattern in terms of morphology, spectra, and variance.

In this paper, we propose algorithm in which the FD value is on the basis of zero-crossing function with detrending technique or is called modified zero-crossing rate (MZCR) function. The proposed MZCR function is a simple technique in estimating FD and presents the fast computation time.

II. Method

A. Basic concept

On the assumption of a high value of the complexity of time-series data can be easily found by obtaining the high rate of zero-crossing point. It means that we can directly compute the complexity of time-series data on the basis of the zero-crossing rate function. Based on the general relationship of power law, during the locally computation period of input data, Δx, and time period, Δt, which can be defined by

$$f_z(\Delta x) \propto \Delta t^{\mu} \tag{1}$$

where $f_z(\cdot)$ is the MZCR function, μ is a scaling parameter.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 240–243, 2009
www.springerlink.com

B. MZCR function

The input time-series data are formed in the length of 2^n-point. To determine FD value by means of proposed method, there are three main steps of processing as follows:

Step 1: Zero-mean data by subtracted the mean value of locally sampled period from each value:

$$\hat{x}_n = x_n - \bar{x} \tag{2}$$

Step 2: Bride detrending by subtracted the regression line from each value. The zero-mean data, $\hat{x}_n$, is then locally detrended by subtracting the theoretical values, y_d, given by the regression:

$$\hat{y}_n = \hat{x}_n - y_d \tag{3}$$

Step 3: Zero-crossing rate (ZCR) determination, after that data were detrended we will use the zero-crossing rate function to determine the ZCR value which is defined by:

$$z_n = \frac{1}{L}\sum_{n=0}^{L-1} \Phi(\hat{y}_n \hat{y}_{n-1}) \tag{4}$$

where

$$\Phi(A) = \begin{cases} 1 & \text{if } A < 0 \\ 0 & \text{otherwise} \end{cases}$$

Finally, we can determine the scaling parameter by taking logarithmic function on both sides of Eq. (1). This computation is repeated over all possible interval lengths (in practice, we suggest minimum length 2^4-point and maximum length is 2^{n-1}-point.)

III. Assessment Conditions

A. Fractional Brownian motion (fBm)

Due to the fractional Brownian motions (fBms) take an important place among self-similar processes, fBms are selected to be input signal for assessing performance of the proposed method. The fBms are the only self-similar Gaussian processes with stationary increments, and they provide interesting models of self-similar processes [9]. General model of the fBm signal can be written as the following fractional differential equation [10] :

$$\frac{d^{H+1/2} B_H(t)}{dt^{H+1/2}} \propto w(t) \tag{5}$$

Where $w(t)$ is a white Gaussian function. The typical examples of two fBm signals of parameters H = 0.2 and H = 0.8 length 1,024 points generated by wavelet-based synthesis of Abry and Sellan's algorithm [11] are shown as Fig. 1. The Hurst exponent in the process, H, is related to the fractal dimension D:

$$H = E + 1 - D \tag{6}$$

where E is the Euclidean dimension (E = 0 for a point, 1 for a line, 2 for a surface). In this case, therefore, for one-dimensional signals:

$$H = 2 - D \tag{7}$$

B. Classical method

Since many methods were developed to determine FD value on time and frequency domains [7], we will select the method; namely, Higuchi's method [12] for comparison in this study because it has been proved to use in many research fields include in the biomedical engineering.

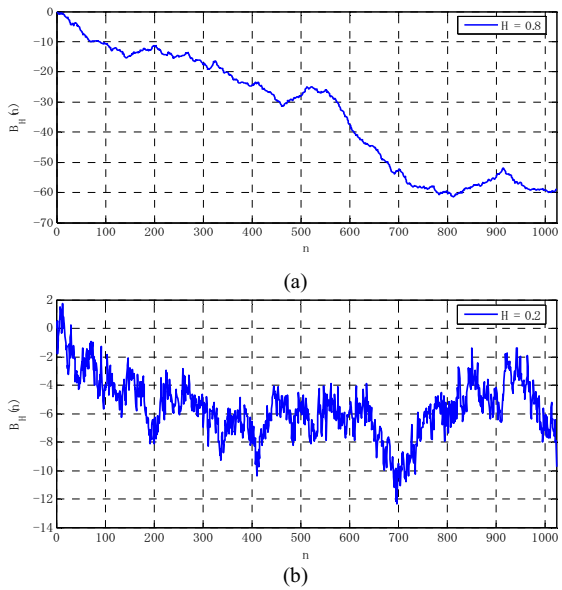

Fig. 1. Two fBm signals generated by different Hurst exponent values. (a) Parameter H=0.8. (b) Parameter H=0.2.

IV. Experiments

The fBm is also referred to as 1/*f*-like profile, since it can be generated from Gaussian random variables and its fractal dimension can easily be set. Therefore, fBm is used to be input signal for assessing in this experiment. Based on the

assumption of the given concept in the Eq. (1), we found that the estimation of H for one-dimensional data is in a negative form of a scaling parameter which can be expressed as the following definition:

$$H \approx -\mu \tag{8}$$

or,

$$\mu \equiv D - 2 \tag{9}$$

For all $n = 2^4, 2^5, \ldots, \log_2 L - 1$, where L is the total length of fBm. In Fig. 2 shows a log-log plot of MZCR function the H is a slope of regression line (dash line). During experiment, we fix step of H changing by 0.01 ranged from 0 to 1 with randomly repeat of five times for each step. Then, the mean-squared error (MSE) of the theoretical and estimated values, $\hat{D}$, can be computed by:

$$MSE = \sum \left(D - \hat{D}\right)^2 \tag{10}$$

MSE value will be used for showing output performance of our proposed method with the classical one. The comparison results and the results of different H (at the length of 1,024 points) are shown as Table 1 and 2, respectively. Table 1 also shows the average computation time which the methods were performed on a laptop CPU 1.66 GHz Pentium with memory of 1 GB.

Table 1 Comparison results of average MSE and computation time.

V. Discussions

The proposed MZCR function is the method to change the crossing lines over zero point. Fig. 5 shows a key process of the regression lines in determining ZCR values of

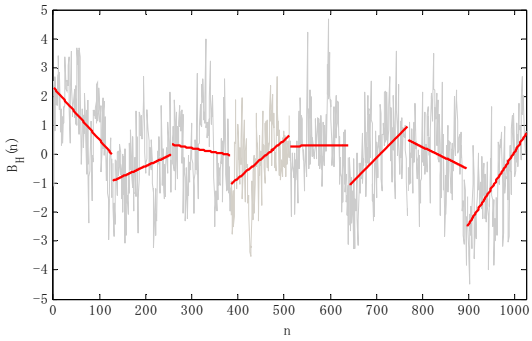

Fig. 5. Regression lines of detrending process in the length of 128 points.

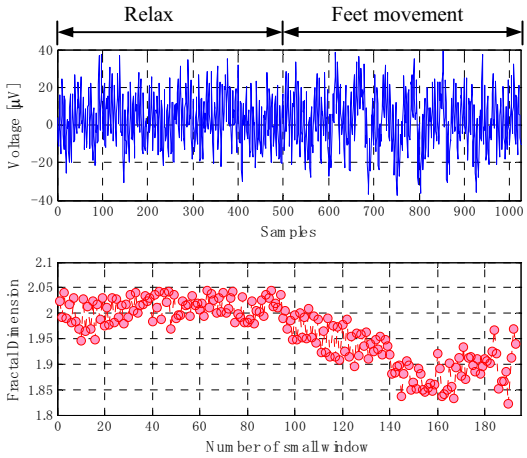

Fig. 6. Raw EEG data of feet movement and its FD waveform.

locally segmented data. If we do process the input data directly without bridge detrending the ZRC function does not play an important role, the results become out of accurate range. Based on the obtained results, we found that the Higuchi's method is more suited than our proposed method in case the length of data greater than 2^{12}-point. However, in practice, biomedical signal is mostly addressed with short-time analyzing, i.e., electroencephalogram (EEG) data were used as features [3][13]. The MZCR function presents the computation time faster than conventional method when the length of input time series less than 2^9 (512 points). To prove the assumption of the estimation method on the basis of MZCR function can be used effectively, the complexity of EEG data of feet movement was analyzed by using the MZCR function shown in Fig. 6. The electrodes were placed according to the 10-20 international system. FD values of recorded EEG data at C3 position were computed based on windowing size 256 points with the moving interval 4 points. The trajectory waveform of FD shows that the complexity during feet movement period less than relaxing period.

VI. Conclusions

In this paper, the complexity measure based on MZCR function is proposed. The proposed method estimates Hurst exponent in a negative slope of log-log plot, and the calculating procedure has three main steps. It is a simple technique for measuring complexity of time-series data in terms of fractal dimension value. The main challenge in estimating fractal dimension of time-series data is that the method can be employed accurately in a short-time analysis, and easy to implement. The proposed method in this paper can considerably be a one choice for such purpose.

The Automatic Sleep Stage Diagnosis Method by using SOM

Takamasa Shimada[1], Kazuhiro Tamura[1], Tadanori Fukami[2], Yoichi Saito[3]

[1] School of Information Environment, Tokyo Denki University, Japan
[2] Faculty of Engineering, Yamagata University, Japan
[3] Research Institute for EEG Analysis, Japan

Abstract — **In psychiatry, the sleep stage is one of the most important evidence for diagnosing mental disease. However, when doctor diagnose the sleep stage, much labor and skill are required, and a quantitative and objective method is required for more accurate diagnosis. For this reason, an automatic diagnosis system must be developed. In this paper, we propose an automatic sleep stage diagnosis method by using Self-Organizing Maps (SOM). Neighborhood learning of SOM makes input data which has similar feature output closely. This function is effective to understandable classifying of complex input data automatically. We didn't only applied SOM to EEG of normal subjects but also applied to EEG of subjects suffer from disease. The spectrum of characteristic waves in EEG of disease subjects is often different from it of normal subjects. So, it is difficult to classify EEG of disease subjects with the rule for normal subjects. On the other hand, SOM classifies the EEG with features which data include. And rules for classification are made automatically. So, even the EEG of disease subjects is able to be classified automatically. In our experiment, first, the features included in EEG were extracted and learned by the Elman-type feedback SOM on competitive layer. The EEG data were preprocessed and the spectrums at sixteen bands were calculated. Second, the spectrum data were inputted to the Elman-type feedback SOM and data were classified on competitive layer. Third, the data were diagnosed by doctor and the sleep stages were labeled. The data of stage wake were input to the learned Elman-type feedback SOM, and the neuron which fires mostly was decided. This neuron is called wake winner neuron (WWN). Finally, data for testing were inputted to the learned Elman-type feedback SOM and corresponding sleep stage was diagnosed by the distance from WWN to Best Matching Unit. Experimental results indicated that the proposed method is able to achieve sleep stage diagnosis along with doctor's diagnosis.**

Keywords — **EEG, Self-Organizing Maps, sleep stage.**

I. Introduction

In psychiatry, sleep staging is one of the most important means for diagnosis. The sleep staging of EEG, however, is liable to be subjective since it depends on the doctor's skill and requires much labor. An automatic diagnosis system must therefore be developed to reduce doctor's labor and realize quantitative diagnosis of sleep EEG.

For sleep staging by EEG analysis, it is especially important to detect the characteristic waves from EEG. Most conventional methods of diagnosing the sleep stage, however, use long-term spectrum analysis [1][2]. However, the spectrum of characteristic waves in EEG of disease subjects is often different from it of normal subjects. So, it is difficult to classify EEG of disease subjects with the rule for normal subjects. Moreover some methods are based on a kind of template matching. This also makes it difficult to cope with the large variation of EEG. So, the method of detecting the characteristic waves in EEG which is required in clinic must therefore be able to cope with fluctuations of pattern of frequency between individuals.

Recently, neural networks have been applied to various kinds of problems in many fields due to their ability to analyze complicated systems without accurate modeling in advance [3]. Especially, Self-Organizing Maps (SOM) has an ability of making classification rule automatically and classifying the data without teaching. Neighborhood learning of SOM makes input data, which has similar feature, output closely. This function is effective to understandable automatic classification of complex input data.

An Elman-type feedback SOM is a same type neural network as SOM. It has not only a function of SOM, but also a function of coping with temporal signal processing. For accurate sleep stage diagnosis, considering contextual information is important.

In this paper, we propose a new sleep stage diagnosing method using an Elman-type feedback SOM [4]. It is expected that the function of automatic making of classification rule is effective to classifying complex signal from human body and that even the EEG with disease subjects is able to be classified automatically.

II. Method

A. Self-Organizing Maps

The Self-Organizing Maps (SOM) is one of Neural Networks which was developed by T. Kohonen. SOM doesn't need to be taught by operator when it learn classification rule.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 245–248, 2009
www.springerlink.com

SOM consists of two layers, input layer and competitive layer. Input data are inputted to input layer of SOM. And the neuron which fires mostly on competitive layer (winner neuron) is decided. The weights of winner neuron and neighborhoods of it are increased. This learning process is repeated. Generally, if input data has more complex feature, the learning process is repeated more. This neighborhood learning of SOM makes input data, which has similar feature, output closely. This function is effective to understandable automatic classification of complex input data.

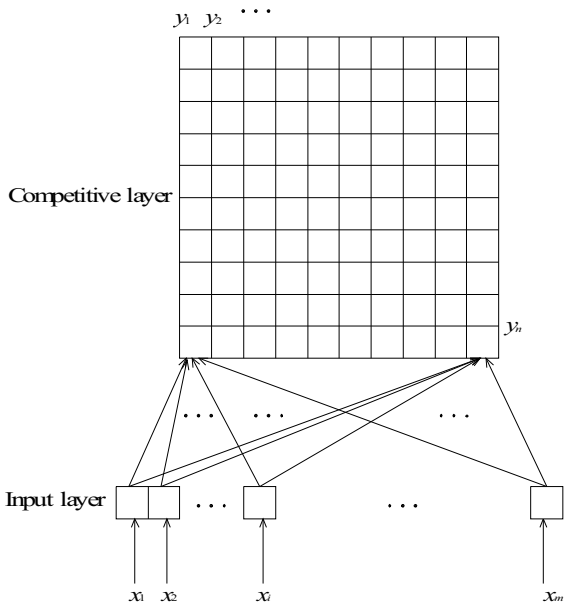

Fig. 1 SOM architecture.

B. An Elman-type feedback SOM

For achieving more accurate sleep stage diagnosis, considering contextual information is important. In clinical medicine, doctor uses the information of context for sleep stage diagnosis, because the state of short term EEG data often fluctuates from general EEG pattern of sleep stage in which subject is. So, the diagnosed sleep stage with short term EEG is improved by considering contextual information. In our experiment, an Elman-type feedback SOM was used for coping with contextual information.

An Elman-type feedback SOM is a model which has a feedback loop from competitive layer to input layer. There are context units at the middle of feedback loop. The number of context units is same with it of units of competitive layer and they are one-to-one correspondence. Each context unit always maintains a copy of the previous values of the corresponding unit in competitive layer. Thus the network can maintain a sort of previous state.

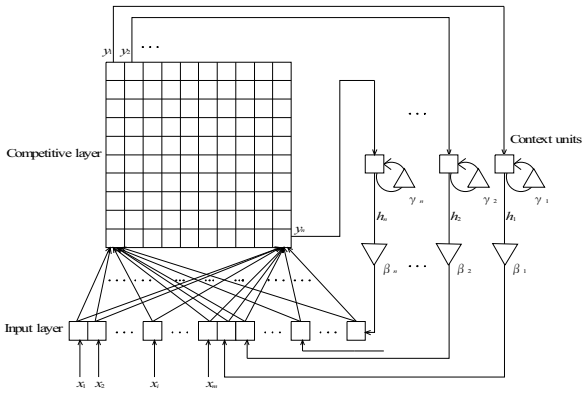

Fig. 2 Elman-type feedback SOM architecture. This architecture recognizes the contextual information of EEG.

C. Learning process

The training or testing data is generated as follows. First, the EEG data is sampled (at the rate of 200Hz) with a 2.56sec (512-point) hamming window. Its logarithmic power spectrum coefficients are calculated by FFT. In our experiment, the powers at 16 power bands were used for input data as shown in table 1.These 16 power bands were decided by considering the important spectrum range which are often used in clinical medicine for diagnosing sleep stages. Each power band of 16 power bands is corresponding to important spectrum range for diagnosing sleep stages as shown in Table 1. Generally, most of power spectrum of sleep EEG is included in this spectrum range (from zero to 100.0Hz).

Table 1 16 power bands corresponding to important spectrum range for diagnosing sleep stages

Name of bands	Spectrum range[Hz]
delta 0	0 - 1.17
delta 1	1.17 - 2.34
delta 2-3	2.34 - 4.30
theta 1	4.30 - 6.25
theta 2	6.25 - 8.20
alpha s	8.20 - 9.38
Alpha m	9.38 - 11.33
alpha f = omega 1	11.33 - 13.28
omega 2	13.28 - 15.23
beta 11	15.23 - 17.19
beta 12	17.19 - 19.14
beta 2	19.14 - 23.05
beta 3	23.05 - 26.95
gamma 1	26.95 - 39.45
gamma 2	39.45 - 60.16
gamma 3	60.16 - 100.0

These spectrum data were inputted to input layer of Elman-type feedback SOM. The clustering map was made on competitive layer automatically. The EEG data which have similar feature are classified closely on competitive layer by neighborhood learning of SOM.

The learning data were diagnosed by doctor and the sleep stages were labeled. The data of stage wake were inputted to the learned Elman-type feedback SOM, and the neuron which fires mostly was decided. This neuron is called wake winner neuron (WWN).

D. Testing process

Data for testing were inputted to the learned Elman-type feedback SOM, and the unit which fires mostly in competitive layer (BMU: Best Matching Unit) was searched.

The corresponding sleep stage to input data was diagnosed by the distance from WWN to BMU.

E. subjects

The number of subjects is four. And symptom of each subject is as described in Table 2. Twos of subjects are healthy and the others are suffering from disease.

Table 2 symptom of each subject

Subject	symptom
A	Healthy male, aged 16.
B	Healthy female, aged 39.
C	Epileptic mental disorder, female, aged 55. Power band of characteristic waves in EEG shift lower band
D	Epileptic mental disorder, female, aged 32.

III. Results

The test data of subjects A, B, C and D were applied to learned Elman-type feedback SOM, and results of diagnosis were decided by the distance from WWN to BMU. Results were acquired at each time and plotted them on the graphs. Figs 3, 4, 5 and 6 show the results of data of subjects A, B, C and D, respectively.

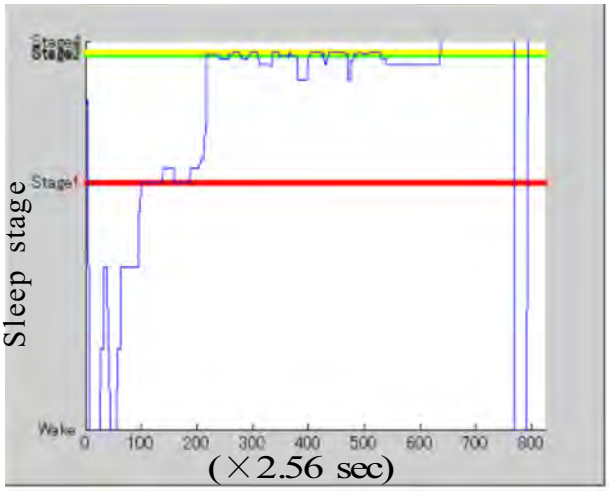

Fig. 3 The result of sleep stage diagnosis of data of subject A with Elman-type feedback SOM.

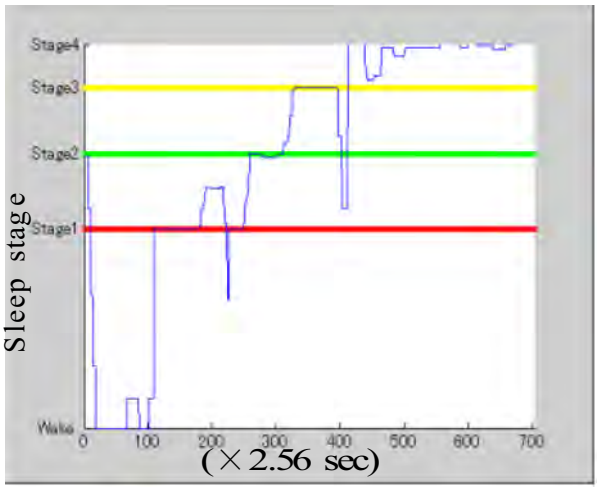

Fig. 4 The result of sleep stage diagnosis of data of subject B with Elman-type feedback SOM.

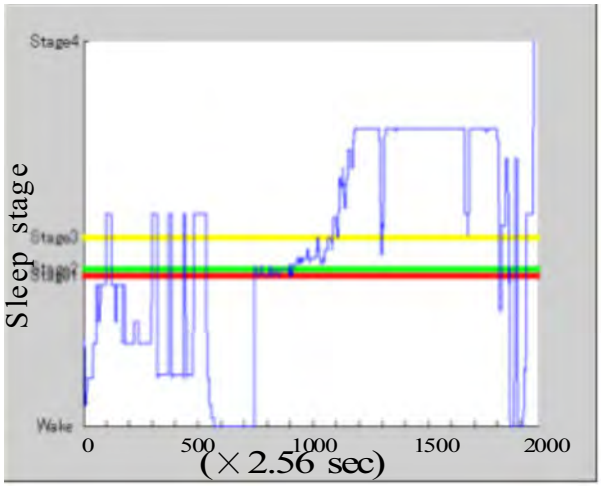

Fig. 5 The result of sleep stage diagnosis of data of subject C with Elman-type feedback SOM.

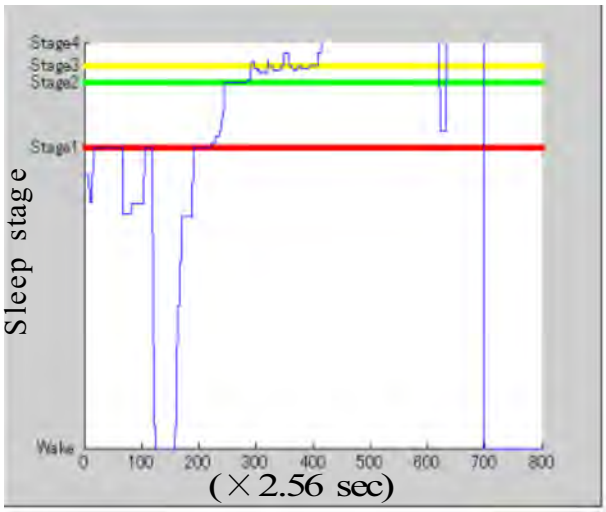

Fig. 6 The result of sleep stage diagnosis of data of subject D with Elman-type feedback SOM.

IV. Discussions

The correct rates of diagnosis were calculated by Equation (1).

$$\text{Correct rate} = \frac{\text{The number of correctly diagnosed period}}{\text{The total number of periods}} \times 100[\%] \quad (1)$$

Table 3 shows the correct rate of diagnosis with Elman-type feedback SOM.

Table 3 the correct rate of diagnosis with Elman-type feedback SOM

Subject	Correct rate[%]
A	70
B	89
C	81
D	85

The average correct rate of diagnosis with conventional SOM is 34.5%. On the other hand, the average correct rate of diagnosis with Elman-type feedback SOM is 81.3%. This result shows that the more accurate sleep stage diagnosis is achieved by considering contextual information with Elman-type feedback SOM.

Though the power bands of characteristic waves of subject C are different from that of normal subject, the high correct rate was achieved. This fact shows that Elman-type feedback SOM can cope with abnormal EEG of disease subjects with the function of automatic making of classification rules.

V. Conclusion

In this paper, we propose an automatic sleep stage diagnosis method by using Elman-type feedback SOM.

The data of four subjects including disease subjects whose power bands of characteristic waves are different from normal subjects were applied, and sleep stage were diagnosed.

Experimental results indicated that the proposed method is able to achieve sleep stage diagnosis along with doctor's diagnosis.

A Development of the EEG Telemetry System under Exercising

Noriyuki Dobashi[1], Kazushige Magatani[1]

[1] Department of Electrical and Electronic Engineering TOKAI University, Japan

Abstract — **Our purpose of the research is a development of the detecting method of EEG under exercising. Usually, measuring EEG is done in the quiet state. In case of the measuring EEG under exercising, a movement of the body causes vibration of electrodes and artifact for the EEG. Therefore, detection of the EEG under exercising is said to be difficult. So, we developed the measuring method of EEG under exercising by using our designed algorithm.**

In our previous system, measured signals were amplified by a system amplifier that was equipped with subject's body. And output of a system amplifier is connected to a personal computer with wire. In this condition, a subject could not move freely. In order to improve this problem, we developed telemetry system. In this system, we can obtain output from a system amplifier by wireless. So in our new system, a subject can move his/her body freely under measuring EEG.

Keywords — **Electroencephalogram (EEG), Acceleration censer, telemetry system**

I. Introduction

The mental state of a human under playing a game is one of important factors which decide a result of the game. We can assess the state of the athlete by bio-signals (e.g. heart rate, EMG, etc.). However, these signals can only express physical condition and cannot express mental condition. It is well known that EEG expresses mental condition. For example, human emotional factor can be estimated from frequency analysis of EEG. If a measuring EEG under exercising is possible, we can assess the mental condition of an athlete and the results of this assessment will be useful for mental training. Therefore, our objective of this study is a development of the remote sensing method of EEG under exercising. The relationship between frequency band of EEG and mental condition are shown the following.

δ- rhythm … Band:0.5~3[Hz]
→ Under unconsciousness and a deep sleep.
θ- rhythm … Band:4~7[Hz]
→ Shallow sleep and a relaxed state.
α- rhythm … Band:8~13[Hz]
→ While being devoted to meditation and concentration something, when mentally stable.
β- rhythm … Band:14~30[Hz]
→ Worries and strain and working promptly.

It is said that measuring EEG under exercising is difficult because of motion artifact. Actually, movement of the body causes vibration of EEG electrodes and, this vibration causes artifact for EEG. However, there is a close correlation between this artifact and acceleration of a subject's head, and no correlation between artifact and EEG. From these facts, we will be able to reduce artifact using adaptive filtering or ICA (Independent Component Analysis). Our developing system consists of the EEG and acceleration measuring system and the noise reduction system. One channel EEG signal and acceleration of subject's head are measured simultaneously, and these are frequency division multiplexed. Multiplexed signal is transmitted as radio frequency using frequency modulation in the EEG and acceleration measuring system. Received signal is de-multiplexed and digital filtered in order to obtain noise free EEG data in the noise reduction system. In this paper, we will talk about this system.

II. Methodology

II-I System hardware

Fig.1 shows a block diagram of our measurement system. Our system consists of an EEG amplifier, an acceleration sensor, a 16bit analog to digital converter and a personal computer. Our EEG amplifier is made of operational amplifier mainly. EEG amplifier amplifies The EEG about 2,000 times, and this signal is converted to the digital value after high pass (0.5Hz) and low pass (40Hz) filtered. Electrodes for EEG measurement are set on left earlobe (common), frontal pole (positive), vertex (negative). And EEG was measured under this bipolar condition. The position of EEG electrodes is shown in Fig.2. An acceleration sensor senses the head movement that will cause artifact of EEG. This acceleration output is amplified and high pass (0.5Hz) filtered and then converted to the digital value for the personal computer. This acceleration data is used for the reference signal of artifact, and a personal computer discriminates between EEG and noise from measured EEG data with artifact by using algorithm that we designed. Fig.3 shows the EEG amplifier of the system. Fig.4 shows an acceleration sensor unit (star precision ACB302). As mentioned earlier, our new system uses wireless system to transmit EEG and acceleration signals. Fig.5 shows a block

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 249–252, 2009
www.springerlink.com

diagram of our telemetry system. A surrounded area by dotted line in Fig.1 is the telemetry unit of our system. The details of this unit are shown in Fig.5. Wired connection between amplifiers that is equipped with subject's body and a personal computer disturbs the free exercise of the object. Therefore, amplified EEG data and acceleration data are transmitted to a personal computer by using telemetry system. So in our system, a subject can exercise freely.

Frequency modulation technique is used for the telemetry system, because this modulation has low noise characteristics. A carrier frequency of this telemeter is set about 80MHz. So, we can use a FM receiver on market as a receiver of our telemeter. This telemeter can transmit one signal. However, two kinds of signal (EEG and acceleration of head) are necessary in our system. So, the frequency division multiplexing technique is used to combine these signals in our system. As shown in Fig.5, EEG and acceleration data are frequency modulated by using 5kHz and 1kHz carrier frequency respectively. After frequency modulation, two modulated signals are combined to one signal by summing amplifier. This multiplexed signal is transmitted as 80MHz radio signal. A FM transmitter on market is used in this part. A FM receiver on market receives this signal. As shown in Fig.5, output of a FM receiver is frequency divided by filters and then separated signals are frequency demodulated and low pass filtered. And then EEG and acceleration data are obtained as transmitted data. Fig.6 shows the frequency division multiplexing system. Fig.6(a) is a multiplexing unit and Fig.6(b) is a de-multiplexing unit.

Fig.6 a) Modulation circuit.

b) Demodulation circuit.

II-II System software

We analyze digitized EEG and acceleration data of the head in a computer, and perform the noise removal. The most of noises of EEG under exercising are confirmed that

it is an acceleration origin of the head. We can reduce the noise of the acceleration origin using Adjustment Noise canceller as a digital filter.

Adjustment Noise canceller

The method of the adjustment noise cancellation is used for the noise removal, and this algorithm was developed by us. This method removes the noise element from the signal that contains the noise, and is one of the basic filters in the signal conditioning that takes out only the interested signal. In this theory, the noise source is assumed X(t), and the signal that we want to know is assumed S(t). We suppose that S(t) and X(t) have no correlation. Where, we define D(t) that is the liner summation of S(t) and X(t). Therefore, D(t) is expressed the following equation.

$$D(t)=aS(t)+bX(t)$$

And we suppose that D(t) and X(t) are observable. In our system, we have to discriminate between S(t)(real EEG signal under exercising) and X(t)(artifact) from D(t)(EEG with artifact). In our system, in order to obtain a coefficient "b", the variable "b' " is changed it's value step by step, and the correlation coefficient between D(t) and b'X(t) is calculated for each "b' ". From this procedure, we can obtain the "b' " that bring the highest value of correlation coefficient between D(t) and b'X(t). We regard this "b' " as the coefficient "b". And then interested signal S(t) is obtained. Fig.7 shows a principle of the adjustment noise cancellation.

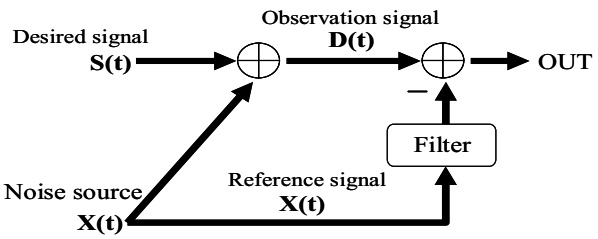

Fig.7 A principle of the adjustment noise cancellation.

III. Experiment

First, we measured the EEG at rest in this time. Second, we simulated the telemetry system with modulate and demodulate circuit of the Fig.6 a) and b). Electrodes for EEG measurement are set on left auricular (common), midline frontal (Fz), vertex (Cz). And EEG was measured under this bipolar condition.

IV. Results

Fig.8 shows an example of the EEG data that was measured under resting and their power spectrum. Fig.9(a) shows the EEG data with noise and Fig.9(b) shows the noise reduced EEG data by using adjustment noise canceller. Fig.9(c) also shows the power spectrum of noise reduced EEG data. As shown in Fig.8(b) and Fig.9(c), we can see that our developed noise canceller worked very well.

Simulated results of the telemetry system are shown in fig.10 and Fig.11. Fig.10 shows input data of multiplexing unit. Both Fig.10(a) and (b) are sinusoidal wave and these frequency are 10Hz and 40Hz respectively. Sinusoidal wave of 40Hz is inputted as “Data 1”and 10Hz is inputted as “Data 2” in Fig.5. Fig.11 shows the de-multiplexed data. Fig.11(a) is de-multiplexed “Data 2” and (b) is “Data 1”. As shown in these results, noise free de-multiplexed data were obtained. And we think that the developed data multiplexing unit worked perfect.

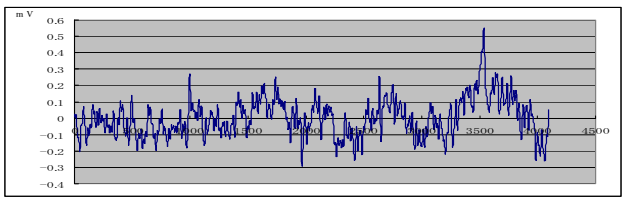

Fig.8 a) The EEG at rest of the time domain.

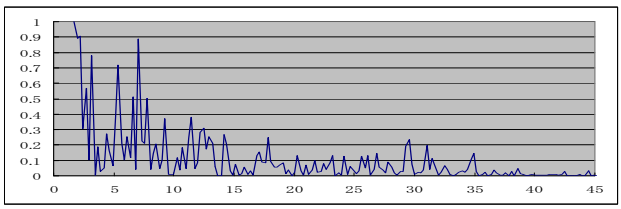

Fig.8 b) The EEG at rest of the FFT.

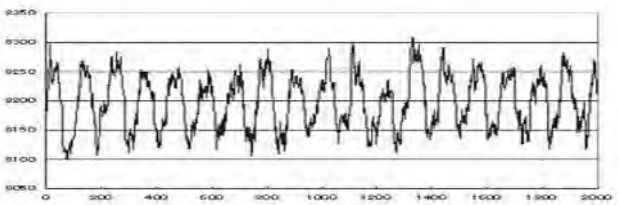

Fig.9 a) The EEG data with noise.

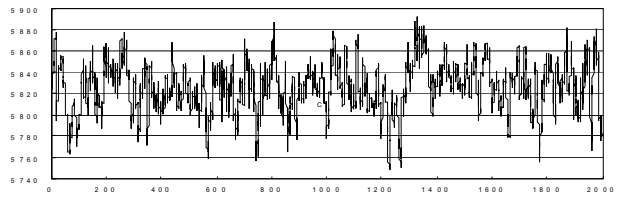

Fig.9 b) The noise reduced EEG data by using adjustment noise canceller.

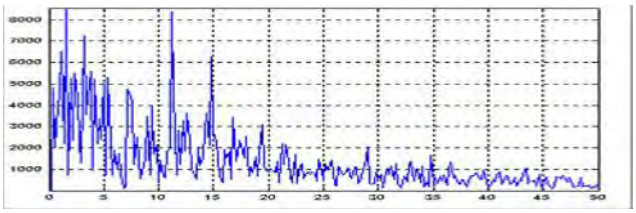

Fig.9 c) The power spectrum of noise reduced EEG data.

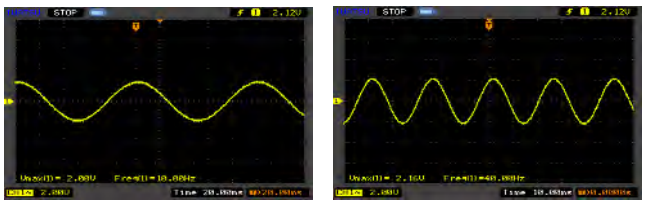

Fig.10 a) The wave pattern is input of the modulate circuit of 1 kHz (left). b) The wave pattern is input of the modulate circuit of 5 kHz (right).

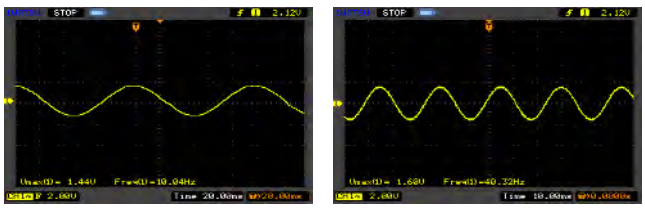

Fig.11 a) The wave pattern is the output of the demodulate circuit of 1 kHz (left). b) The wave pattern is the output of the demodulate circuit of 5 kHz (right).

V. Conclusions

In this paper, we talked about our EEG artifact reduction system and telemetry system. From experimental results, we can see that our artifact reduction system is able to reduce noise that includes measured EEG. And developed data multiplexing and de-multiplexing system worked perfect. Therefore, we concluded that if this system is completed, our EEG measurement system will be a valuable one for athletes.

Evaluation of Photic Stimulus Response Based on Comparison with the Normal Database in EEG Routine Examination

T. Fukami[1], F. Ishikawa[2], T. Shimada[3], B. Ishikawa[2] and Y. Saito[4]

[4] The Institute for EEG Analysis, Tokyo, Japan

Abstract — **The aim of our research is the evaluation of the photic driving response, a routine EEG examination for diagnosis. It is well-known the EEG responds not only to the fundamental frequency but also to all sub and higher harmonics of a stimulus. In this study, we propose a method for detecting and evaluating responses in screening data for individuals. This method consists of two comparisons based on statistical tests. One is an intraindividual comparison of the amplitudes between the EEG at rest and the photic stimulation (PS) response reflecting enhancement and suppression by PS, and the other is a comparison between data from an individual and a distribution of normals in the normal database. These tests were evaluated using the Z-value based on the Mann-Whitney U-test. The experiment was conducted using PS frequencies of 3, 6, 7, 10, 14 and 18Hz. We used the measured data at electrode O1 where PS appears the greatest. We measured EEGs from 130 normal subjects and 30 patients with any of schizophrenia, dementia and epilepsy. Normal data were divided into two groups, the first consisting of 100 data for database construction and the second of 30 data for test data. We evaluated amplitudes at a subharmonic frequency, the fundamental frequency, the second harmonic frequency, higher order harmonic frequencies less than 40Hz, and the alpha peak frequency. From the results of the comparison of patients and the normal database, frequencies with Z-values smaller than those of the normal database could be recognized. At the alpha peak frequency, patient data have higher Z-values than does the normal database though there were no significant differences for the subharmonics. Moreover, in the patient data, both the enhancement of harmonic components including the fundamental wave by PS and suppression of the alpha component were weak.**

Keywords — **electroencephalography(EEG), photic driving response, alpha suppression, Mann-Whitney U-test.**

I. Introduction

Photic stimulation (PS) is a commonly used stimulation in electroencephalogram (EEG) routine examinations. The PS response consists of the elicited rhythmic activity. Generally, three types of driving components are measured when PS is given to a human and they are diagnostically helpful. One is the fundamental driving for which the frequency is equivalent to the stimulus frequency (f_0), and the others are the harmonic driving and subharmonic driving for which the frequencies are nf_0 and $f_0/n\,(n \geq 2)$, respectively.

The effect of intermittent PS on the human EEG was first studied by Adrian and Matthews [1]. Numerous reports on human measurements were then presented. However, there have not been so many reports relating to an analyzing method for quantitative evaluation. Fukushima applied EEG-interval-spectrum-analysis to photic driving responses [2]. Drake et al introduced the quantitative measure of frequency times the duration of the driving response [3].

Regarding the analysis of clinical data, some researchers reported the relationship between normals and patients with a specific disease. Kikuchi et al analyzed EEG signals using the absolute power of harmonic responses to PS [4]. Jin et al compared PS responses between schizophrenics and normals[5]. However, the results in these studies were obtained by a statistical comparison between two groups such as a normal group and patient group. A comparison between groups is useless for diagnosis using data for individuals during screening. An analysis method using data for individuals aimed at diagnosis support has never been reported.

Therefore, in this study, we propose a method for evaluating data for individuals quantitatively.

II. Methods

EEG signals were recorded during a state of relaxed wakefulness with closed eyes. A multichannel EEG signal was acquired using a Nihon Koden polygraph (EEG-1100) with a 0.3s time constant, 60Hz high cut filter and 97.5nV quantization level. EEG signals were measured at 19 electrodes according to the International 10/20 system. Here, monopolar derivation with bilateral references to the corresponding earlobes was used.

The measurement of the photic driving response and a flowchart of our analysis are shown in Fig. 1. A cycle without PS (at rest) for 10s then with PS for 10s was re-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 253–256, 2009
www.springerlink.com

peated. The frequency of PS was varied in the order of 3, 6, 7, 10, 14 and 18Hz. The EEG signals were digitized at a sampling frequency of 200Hz. Photic pulse characteristics were as follows. The brightness of the flash stimulus was 30,000 cd/m^2, the light intensity was 4.0 lx/s, the pulse width was 2 ms, and the equipment was placed 30cm in front of the subjects. All data on subjects and patients in this paper were taken at Utsunomiya Hospital after informed consent.

Our method consists of two kinds of comparisons for evaluation of the PS response. One is a comparison of responses at rest and during PS as shown in Fig.1, and the other is a comparison of data for individuals (screening data) and a distribution of normals. The former comparison implies an index reflecting the enhancement or suppression by PS in intraindividual data and the latter comparison implies an index reflecting the position of the individual's data in the distribution of normal data.

In this study, we measured PS responses from 130 normal subjects (18-40 years old, ave.=23.8, s.d.=4.38) and 30 patients (36-89 years old, ave.=67.7, s.d.=12.8). Patients have a disease of any of schizophrenia, dementia and epilepsy. Normal data were divided into two groups; 100 data (18-40 years old, ave.=23.8, s.d.=4.89) for database construction and 30 data (20-27 years old, ave.=23.6, s.d.=1.97) for test data.

We first explain the former comparison shown in Fig.1.The EEG measurements at rest and with PS are repeated every 10 seconds alternately. In each period, the first 2s of data were discarded to avoid the effect of the orienting response and off-response due to the stimuli immediately. We need to construct a distribution consisting of plural samples when we perform a statistical test. In this study, a window having 100 sample points (0.5s) was slid from 2s after the onset of the cycle. The frequency analysis described below was performed in 16 sections for each cycle.

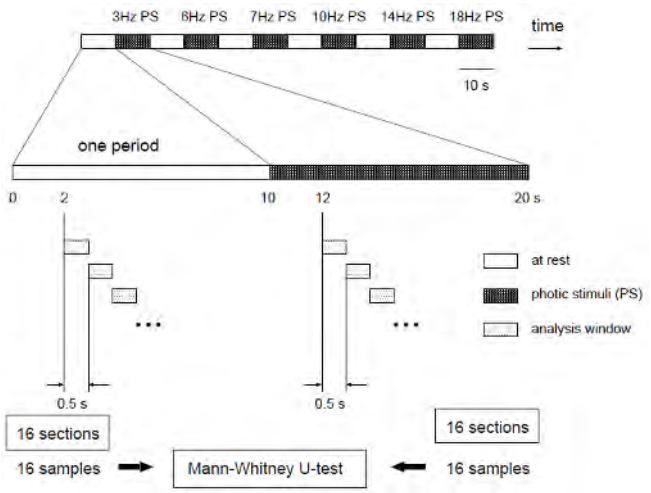

Fig.1 Analysis of EEG data

Generally, discrete Fourier transform (DFT) make it possible to calculate only the frequency components at integer multiples of the fundamental frequency, 2Hz in this study.

However, we need to estimate other frequency components which can not be calculated by limitation of DFT. We therefore used the method based on trapezoidal integral approximation of continuous Fourier transform. In this study, we performed the above calculation after elimination of bias (0Hz) component by subtraction of average in the analysis window. We then obtained the amplitude spectrum from 0 to 40Hz with 0.5Hz intervals by the following equation. This frequency analysis based on the Fourier transform was performed in 16 sections at rest and in 16 sections during PS. Amplitudes at these frequencies in each cycle were collected as a distribution of 16 samples.

The after-mentioned Mann-Whitney U-test was executed for the distributions before and during PS (16 vs. 16 samples) and the Z-value for each analysis frequency and each PS frequency was then calculated.

In the latter comparison, based on the Z-value for before and during PS response acquired in the former comparison, we introduced the rank among normal distributions in a database as the index. This index was expressed as a percentile rank such that a higher Z-value has a smaller rank.

In this study, we used the Mann-Whitney U-test, which is known as a statistical test for comparing non-parametric distributions, because we do not know if these distributions are necessarily specific distributions such as Gaussian or gamma distributions. This test is based on the Wilcoxon rank-sum test and a non-parametric test for assessing whether two sample sets of observations come from the same distribution. It is executed under the null hypothesis of samples from the same general population. We defined the rank-sum of two groups composed of amplitudes at rest and during PS after arranging data with higher rank (small ordinal number) for larger amplitude. We then executed the U-test.

General U-test prevents the Z-value from being less than zero. In our method, when the Z-value is negative, there is suppression due to PS, and when the Z-value is positive, there is enhancement due to PS. A zero Z-value indicates no change due to PS. In this study, we defined the thresholds for the judgment of significance as $|Z| = 1.96$ and 2.81. The thresholds correspond to $p<0.05$ and $p<0.005$. Under the condition of $|Z|>1.96$ or $|Z|>2.81$, we recognize a significant difference between the two distributions by judging that the null hypothesis is rejected. We finally show the results of applying this method to amplitudes at a subharmonic frequency (f/2), harmonic frequencies (2f, 3f, 4f, 5f) less than

40Hz and the alpha peak frequency (alpha peak) where the PS frequency (f) is the fundamental frequency. In this study, we used the measured data at electrode O1 where PS appears the greatest.

Judgment is performed by classifying the maximal Z-value mentioned above as one of five levels as follows. Five notations ((++),(+),N.S.,(-),(--)) are assigned depending on the Z-value. The notations "(++)" and "(--)" designate the cases satisfying $|Z|>2.81$ corresponding to $p<0.005$ and there being a very significant difference between the two amplitude distributions.The notations "(+)" and "(-)" indicate the cases satisfying $|Z|>1.96$ corresponding to $p<0.05$ and there being a significant difference between the two distributions. When $|Z|<1.96$, the notation N.S. indicates there is no significant difference between the distributions.

III. Results and Discussions

We evaluated amplitudes at a subharmonic frequency ($f_0/2$), the fundamental frequency (f_0), the second harmonic frequency ($2f_0$), higher order harmonic frequencies less than 40Hz, and the alpha peak frequency in this study.

We show the results for normal and patient groups, with 30 data used for each. In Table 1, we summarize the results for all combinations of PS frequency and analysis frequency based on the judgement corresponding to the averaged Z-value of 30 data. In this report, intraindividual evaluation is expressed in the row labeled "at rest vs. during PS" using the five levels in the U-test for subharmonics, the fundamental wave and harmonics less than 40Hz. For the alpha peak frequency, the frequency with maximal amplitude before PS was adopted.

Regarding the normal database comparison, evaluation of each subject data is difficult, so we showed the U-test results between 30 normals/patients and database (30 normal test data (patient data) vs. DB). This processing was performed by the U-test between two Z-value distributions, which is 30 samples vs. 100 samples for the normal database, and then classified the results into the five levels. For all PS frequencies, results for 30 normals and 30 patients are test are shown in Tables 1 and 2, respectively.

In the intraindividual test, a significant difference between at rest (before PS) and during PS can be recognized in the case that the PS frequency is greater than 6Hz. The significance is greater for high order harmonics more so than for the third harmonic in the case that the PS frequency is less than 7Hz. For PS with a frequency greater than 14Hz, a significant difference is seen for all harmonic frequencies, including the fundamental frequency, and Z-value is larger than that for a PS frequency less than 7Hz. There is no apparent difference for subharmonic and alpha peak frequencies.

Analysis results for data of the 30 patients are tabulated in Table 2. We can find significant differences were detected in similar cases to those of the normal test. However, enhancement by PS is smaller than that for the normal test.

In the comparison of the normal test and database data, there are no difference at all fundamental and harmonic frequencies for all PS frequencies. This result is appropriate because both test data and database data consist of normal subjects' data.

From the results of the comparison of patients and the normal database, frequencies with Z-values smaller than those of the normal database can be recognized. At the alpha peak frequency, patient data have higher Z-values

than does the normal database though there are no significant differences for the subharmonics. This means the amplitude at the alpha peak frequency is never enhanced more than the amplitude for the normal database is. It may be more accurate to say that the degree of alpha suppression by PS in patients is small compared with the normal database than to say there is enhancement by PS. These results indicate that both the enhancement of harmonic components including the fundamental wave by PS and suppression of the alpha component are weak.

IV. Conclusions

In this study, we proposed a method for the quantitative evaluation of the photic driving response for individual data.This method consists of two statistical processes. One is an evaluation of the enhancement or suppression by PS. The other is an evaluation of the position of the individual data in the distribution of normals. We calculated Z-values using the Mann-Whitney U-test, which is a statistical test for comparing nonparametric distributions. The experiment was conducted using PS frequencies of 3, 6, 7, 10, 14 and 18Hz. A subharmonic frequency, fundamental frequency, and higher harmonic frequencies less than 40Hz were categorized according to the above five levels. We constructed a normal database of 100 normal subjects' data.

We then applied this method to the data of 30 normals and 30 patients and presented the results in this study. For patients, Z-values at fundamental and harmonic frequencies are larger than those for normals and the degree of alpha suppression is smaller than that for normals.

We suggest that these insensitivities are new potential criteria for discriminating between normals and psychiatric and neurologic patients.

In future research, we plan to apply our method to many kinds of diseases.

A Speech Processor for Cochlear Implant using a Simple Dual Path Nonlinear Model of Basilar Membrane

K.H. Kim[1], S.J. Choi[1], J.H. Kim[2]

[1] Yonsei University/Biomedical Engineering, Wonju, South Korea
[2] Nurobiosys, Co., Seoul, South Korea

Abstract — **We present a novel speech processing strategy for cochlear implant (CI) based on active nonlinear characteristics of biological cochlea that contribute to hearing under noisy conditions. A simple dual path nonlinear model (SDPN) was developed to utilize the advantage of level-dependent frequency response characteristics in robust formant representation. The model was motivated from the function of basilar membrane so that level-dependent frequency response can be reproduced. Compared to dual resonance nonlinear model (DRNL) which has been proposed as an active nonlinear model of basilar membrane, the proposed model is much simpler and thus better suited to be incorporated in CI speech processor. We developed a CI speech processing strategy based on the SDPN for frequency decomposition and an adaptive envelope detector. It was verified from spectral analysis that the formants of speech is robustly represented after the frequency decomposition by the array of SDPN, compared to a linear bandpass filter array of conventional strategies. From acoustic simulation and hearing experiments on normal subjects, it was verified that the proposed strategy yielded enhanced syllable recognition under speech-shaped noise than the conventional strategy.**

I. Introduction

Cochlear implants (CIs) have been successfully used for the restoration of hearing function due to profound sensorineural hearing loss, by direct stimulation of spiral ganglions using electrical pulses generated by processing of incoming speech. In spite of great progress during more than two decades, there remain a lot of things to be done in order to achieve successful restoration of hearing under noisy environment, melody recognition, and the reduction of cognitive loads of the patients [1].

Several methods can be utilized for the improvement of CI. Among them, the development of novel speech processing strategy is very effective in that it does not require the change of current hardwares and can be adopted in already implanted devices by modification of embedded program. Speech processing strategy here means an algorithm used to generate electrical stimulation pulses based on the processing of incoming speech waveforms. More accurate imitation of normal auditory function is one of the most promising approaches among several directions in speech processing strategy development [1], [2]. It has been suggested that speech perception performance can be considerably improved by adopting an active nonlinear model of basilar membrane in cochlea, which is called dual resonance nonlinear (DRNL) model [2].

Spectral peaks of speech waveforms, which are called formants, are very important cues for speech perception. It is known that the information on formant frequencies are encoded in the population responses of the auditory nerve [3]. The improved speech perception enabled by active nonlinear model is due to robust representation of formants under noisy environments. We also have recently presented a detailed performance analysis of the DRNL-based CI speech processing strategy, focusing on the formant representation characteristics and enhanced vowel perception [2].

We propose a new active nonlinear model of frequency response of the basilar membrane, called simple dual path nonlinear (SDPN) model. The SDPN model was motivated from further simplification of the DRNL model, with the purpose of developing a CI speech processing strategy. Many building blocks and parameters of the DRNL model were not necessary to implement the level-dependent frequency response of the biological cochlea, because they were adopted for the detailed replication of experimental results. The proposed SDPN is much simpler than the DRNL, yet it can provide the level-dependent frequency response, which is beneficial for real-time processing with lower power consumption.

We developed a CI speech processing strategy based on the SDPN for frequency decomposition. It was verified from spectral analysis that the formants of speech is robustly represented after the frequency decomposition by the array of SDPN, compared to the linear bandpass filter array of conventional strategies. From acoustic simulation and hearing experiments on normal subjects, the proposed strategy was shown to provide enhanced syllable identification performance under speech-shaped noise, much better than the conventional strategy using fixed linear bandpass filter array and envelope detector.

II. Materials and Mehtods

A. Proposed speech processing strategy

Fig. 1 (a) shows the general structure of the speech processor for a CI. Incoming speech is decomposed into multiple frequency bands (stage 2 of Fig. 1 (a)), and then, relative strength of each subband is obtained from an envelope detector (stage 3) to be used to modulate the amplitudes of stimulus pulses after logarithmic compression. Most modern CI devices utilize this structure [4]. In the strategy proposed in this paper, each channel of the speech processor is made of an active nonlinear filter model of basilar membrane with variable response characteristic, instead a fixed linear bandpass filter employed in conventional CIs. The variable response characteristic originates from the input-dependent tuning property of basilar membrane resulting from active motility of outer hair cell (OHC), and this active nonlinear response property is known to contribute to robust representation of speech cues under noise [5].

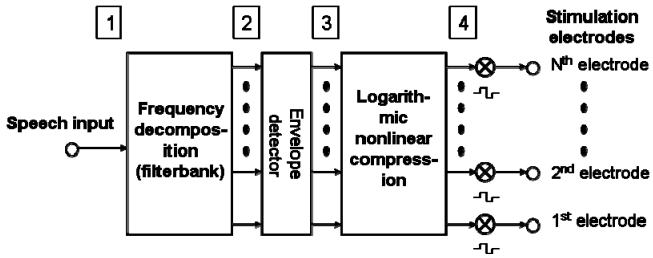

Fig. 1 General structure of the CI speech processing strategies.

Fig. 2 (a) illustrates a dual resonance nonlinear (DRNL) model, which was proposed as a numerical model of the basilar membrane response characteristic [6]. In the DRNL model, the output of each cochlear partition is represented as a summation of the outputs from a linear and a nonlinear pathway. The effective center frequencies of the linear and nonlinear pathways are slightly different. The DRNL model can replicate the frequency response of biological cochlea in that the level-dependent tuning and level-dependent gain properties could be successfully reproduced [6]. Because our aim here is only to utilize the advantages of the active nonlinear response and it is not necessary to replicate the biological cochlea in detail, we propose a new simplified model, which we call simplified dual path nonlinear (SDPN) model. The block diagram of the SDPN model is shown in Fig. 2 (b). While developing the SDPN model, we did not try to reproduce numerical details obtained from neurophysiological experiments. It was motivated by the purpose of implementing the level-dependent frequency response characteristics of biological cochlea.

As in the DRNL model, the incoming speech is given to two pathways. The linear pathway consists of a linear gain (fixed to 6 here) and a broad bandpass filter, which is called tail filter. The nonlinear pathway is made of a sharper bandpass filter, which is called tip filter, and a compressive nonlinearity that is employed to mimic the saturation property of the OHC. The nonlinearity is expressed as;

$$y = 2\arctan(15x) \quad (1)$$

Both the tail and tip filters are made of Butterworth bandpass filters (tail filter: 2nd order, tip filter: 4th order). The bandwidth of the tail filter is set to be three-times larger than that of the tip filter. In order to realize the variable response property, relative contribution of each pathway is controlled according to the input level (root-mean-square value) by the nonlinearity. The overall output from one channel of the frequency decomposition block is obtained by summing outputs from the two pathways. As we will show later in Results (Fig. 3), we can enable variable frequency response characteristics of biological cochlea with much lower computation cost than the DRNL model.

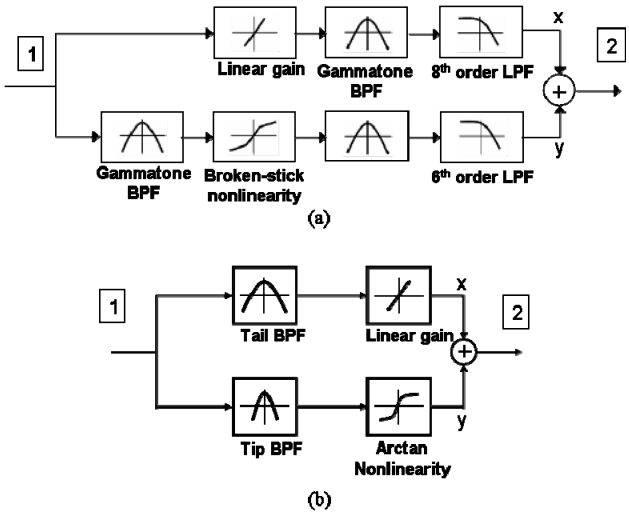

Fig. 2 (a) Block diagram of the DRNL model. (b) Block diagram of the proposed SDPN model.

B. Acoustic simulation

Acoustic simulation can provide an objective quantification of potential performance of a specific processing strategy and a reference to clinical tests, and thus it has been utilized for many studies on the development of novel speech processing strategies. The center frequencies of the channels were chosen according to the method of Loizou et al. [7], since this enables systematic computation of the filter bandwidths, and is used in current CI devices.

The method of acoustic simulation of conventional strategy was similar to that of Dorman et al [8]. After applying a linear bandpass filter array for frequency decomposition, an envelope detector consisting of a full-wave rectifier and a 4th order Butterworth lowpass filter (cutoff frequency: 400 Hz) was applied. The detected envelopes were used to modulate the sinusoids with frequencies same as the center frequencies listed in Table I. Finally, the amplitude-modulated sinusoids from all the channels were summed.

C. Hearing experiment

Ten normal-hearing subjects volunteered to participate in the hearing experiment (ages: 25.8 ± 4.08 years; six men, four women). The experiments were performed under two noise conditions: without any noise (i.e., SNR of ∞ dB) and with speech-shaped noise (SSN) of 2 dB signal-to-noise ratio (SNR). The number of channels was varied to 4, 8, and 12 channels.

Syllable identification tests were performed using multiple-choice tasks. Consonant-vowel-consonant-consonant (CVCV) disyllables were constructed mainly for the vowel perception performance test. Each speech token was fixed to the form of /sVda/, i.e., only the first vowel was changed while the others were fixed to /s/, /d/, and /a/. The first vowel was selected from /a/, /ə/, /o/, /u/, /i/, and /e/. Vowel-consonant-vowel (VCV) type monosyllables were also constructed. The vowels at the beginning and end were the same and fixed to /a/. The consonants between vowels were selected from /g/, /b/, /m/, /n/, /s/, and /j/.

The acoustic waveforms of speech tokens were generated by 16-bit mono analog-to-digital conversion at sampling rate of 22.050 kHz and stored as .wav files. The stored files were played by clicking icons displayed in a graphic user interface prepared for the experimental run. The speech tokens were presented binaurally using a headphone (Sennheiser HD25SP1) and a 16-bit sound card (SoundMAXTM integrated digital audio soundcard). A 5-min training session was given before the main experiment. If the subjects requested, the waveforms were played once more. After hearing each speech token, the subjects were requested to choose the presented syllable among six given examples as correctly as possible, and the percentage of correct answers was scored.

III. Result

A. Variable frequency response of the SDPN model

Fig. 3 shows the variable frequency response of the proposed SDPN model with 1500 Hz center frequency. When the input amplitude was low (35 dB sound pressure level (SPL)), the contribution of nonlinear pathway was relatively large so that overall response showed a sharp frequency selectivity determined by the tip filter. Peak gain was 9.44, and the full width at half maximum (FWHM) was 140.27 Hz. As the amplitude increases (85 dB SPL), the contribution of linear pathway became dominant, and thus, overall frequency response became broader (FWHM= 424.08 Hz). Meanwhile, the overall gain decreased due to the compressive nonlinearity (peak gain= 4.26). Hence we could achieve the goal of replicating the level-dependent frequency response characteristics of biological cochlea qualitatively. Compared to the DRNL model, the proposed simplified structure could be executed very quickly. For example, in order to process 1 s speech, the CPU time was 0.054 ± 0.012 s for the SDPN model while it took 1.33 ± 0.034 s for the DRNL (Average from 40 trials, Matlab implementation, 3.0 GHz Pentium 4 processor, 2 GB RAM). I.e., the processing time for the proposed model was only about 1/24.6 of the DRNL model.

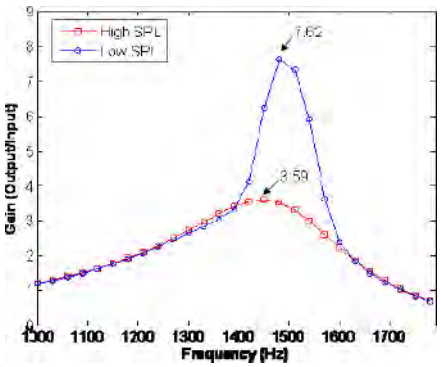

Fig. 3 Variable frequency response of the proposed SDPN model

B. Acoustic simulation and hearing experiment

The results of hearing experiments are shown in Fig. 7. The percentages of correct answers were plotted as functions of the number of channels for 4, 8, and 12 channels. For quiet conditions, the proposed strategy was better than the conventional strategy for all channel conditions. The superiority was statistically significant for 8 and 12 channel conditions (t-test, $p<0.05$ (uncorrected) for 4 channels, and $p<0.01$ for 8 and 12 channels). Under SSN of 2 dB SNR, the proposed strategy provided considerably better syllable identification for all channel conditions (t-test, $p<0.05$ (uncorrected) for 4 and 8 channels, and $p=0.06$ for 12 channels).

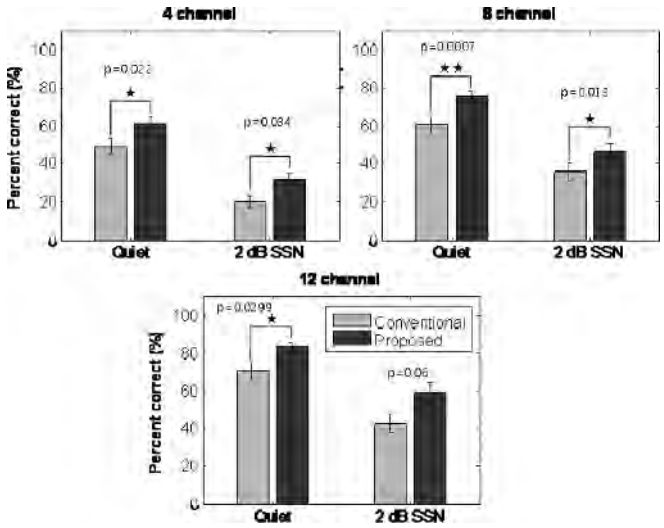

Fig. 4 Results of syllable identification tests

IV. Conclusions

In this paper, we proposed a simple active nonlinear model of biological cochlea and developed a novel speech processing strategy for CIs based on it. We showed that it is very useful for the robust representation of spectral cues to utilize the variable frequency response property originating from the function of biological cochlea.

Some previous experimental studies reported that the active, variable frequency response property of basilar membrane contributes significantly to the robust representation of formant information under noisy environments, and several numerical models were suggested to reproduce this property [5], [9]. For example, Deng and Geisler [5] proposed a nonlinear differential equation model with a variable damping term to simulate level-dependent compression effect, and successfully reconstructed the response characteristics of the biological cochlea that are beneficial for robust spectral cue representation under noise. This implies that the speech perception of CI recipients can be improved by adopting the active nonlinear response property, as was demonstrated by enhanced performances of the CI speech processors based on the DRNL model [2].

Although the DRNL model is one of the most efficient models considering computational costs, its purpose is to replicate detailed experimental results and many parameters are included so that it may still not be adequate for CI speech processor. Instead we proposed a simplified model for implementing variable frequency response. The proposed SDPN model consists of dual pathways just as the DRNL model, however, we did not make any attempt to reproduce experimental results quantitatively. Its advantage as a building block of the CI was verified by acoustic simulation and hearing experiment on normal subjects. Based on this result, we assume that the detailed imitation of the frequency response characteristics of the human cochlea is not essential for the purpose of the improvement of the CI speech perception performance, although it was suggested to use the DRNL model with parameters fitted to human basilar membrane [10]. Further verification is required to confirm this assumption.

In our SDPN model, the bandpass filters in linear and nonlinear pathways were implemented using Butterworth filter, which possesses maximally-flat frequency response. Thus, it may be possible to alleviate the 'picket fence effect' [10], i.e. the decrease of frequency response at the position of the boundaries between nearby channels, resulting from the sharp frequency response of the gamma-tone filter used in the DRNL model.

Mechanical and Biological Characterization of Pressureless Sintered Hydroxapatite-Polyetheretherketone Biocomposite

Chang Hengky[1], Bastari Kelsen[2], Saraswati[2], Philip Cheang[2]

[1] Nanyang Polytechnic, School of Engineering (Manufacturing), Biomedical Engineering Group , Singapore
[2] Nanyang Technological University, School of Chemical and Biomedical Engineering, Singapore

Abstract — **Bioactive particulate reinforced polymer composite comprising synthetic Hydroxyapatite (HA) and Polyetheretherketone (PEEK) has been fabricated by injection molding for load-bearing applications in these past few years. The limited degree of customization of injection molding process and the high cost of the mold fabrication and processing cost lead to the fabrication of HA-PEEK composites by pressureless sintering method. The aim of the project is prepared a HA-PEEK composite block from HA-PEEK powder blends using simple detachable cubic stainless steel mold in the furnace with specific temperature and duration. The resultant HA-PEEK composite block will be machine with CAD machining system to produce desired final shape and size of the implant device.**

The microstructural observations by scanning electron microscopy (SEM), mechanical testing and biological testing of the composites were performed. The averaged tensile and compressive strengths were around 15 MPa and 55 MPa respectively. On the other hand, biological tests showed very positive results which verified bioactivity, biocompatibility and non-toxicity of the composite with the formation of biological apatite layer deposited on the surface of the materials which is critical to establishing bonding between living tissue and biomaterials, without forming the fibrous tissue among them. These results suggested that pressureless sintered HA-PEEK biocomposites have the potential to replace injection molded composites in the load-bearing applications.

Keywords — **Hydroxyapatite; Polyetheretherketone; Biocomposites, Presureless Sintering, Biocompatibility.**

I. Introduction

In recent years, the fabrication of bioactive particulate reinforced polymer composites for orthopaedic implants has been receiving considerable attention from biomedical sector [[i]]. One of them is Hydroxyapatite-Polyetheretherketone (HA-PEEK) biocomposite that has been produced by injection molding in the past few years [1,2,3,4]. Injection molding process however has a few drawbacks. The mold and the machineries used in this process are very expensive, especially for highly specialised and customised implant products such as jaw bones implant, pelvic bone implant and augmentation implant. The other disadvantage of this method is that when the product's design changes, the mold also need to be changed. In other words, this method is not customizable and flexible. To overcome those problems, this research attempts to synthesize a general HA-PEEK biocomposite block using pressureless sintering method and followed by CNC machining for producing a desirable shape and size of implant. This method is considerably cheaper and more customizable than injection molding.

The concept of bioactive particulate reinforced polymer composite as bone analogue was introduced in the early 1980s by Bonfield et al [2]. Natural HA reinforced collagen found in the human bone is simulated by using synthetic HA reinforced polymer matrix. There are many bioactive HA-polymer composites which were developed using polymer matrices. And among the numerous choice of polymer matrices that have been widely promoted, PEEK and its composites have been highlighted as having the potential for such application.

In this study, the main objective is to produce HA-PEEK biocomposite using pressureless sintering method with equally good mechanical and biological properties as those obtained from injection molding and will be investigated on their mechanical and biological properties.

II. Experimental techniques

2.1 Chemicals and Materials

The Hydroxyapatite feedstock slurry suspension was synthesized by direct precipitation method using calcium hydroxide and orthophosporic acid (85%) as the starting materials and spray dried to obtain spherical HA powder [5]. The PEEK polymer used was PEEK™ (150XF) from Victrex plc.

2.2 Processing of HA-PEEK composite block

The HA powder was mixed with PEEK powder with certain composition to form biocomposite block by pressureless sintering method. As majority part of the project is fine tuning the process, the composition was limited to only 10 vol% HA. They were mixed together using horizontal ball mill to produce a homogeneous mixture of HA and PEEK in

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 261–264, 2009
www.springerlink.com

the duration of 8 hours. After milling process was finished, the powder mixture was placed in the stainless steel mold with dimension of 10 cm x 10 cm x 10 cm and then compacted by a manual hydraulic pressing machine with an applied load of 10 tons or equivalent to pressure of 10 MPa.

During sintering process, good control over heating rate, time, and temperature is required for reproducible results. Therefore in this study, those 3 parameters were varied to find the best fabricated biocomposite block. There are 7 samples obtained from the sintering process with different parameter values, shown in Table 1. They would be then compared to each other through Scanning Electron Microscopy observation, mechanical and biological testing.

Table 1 Different parameters used for the samples

Sample	Holding Temperature (ºC)	Holding Time (hours)	Heating Rate (ºC/min)
S1	300	5	1
S2	300	10	1
S3	350	10	1
S4	325	10	1
S5	325	15	1
S6	325	15	0.5
S7	325	15	0.1

2.3 Microstructural Observation using SEM

JEOL JSM-6700F SEM was used to analyze and observe the microstructure and surface morphology of the samples after sintering showing how well the encapsulation of the PEEK polymer to HA is and how even the distribution of the 2 components is. The sample needed to be trimmed first into an appropriate size of around 7 mm x 7 mm using cutting machines. The samples were coated with platinum for conduction path before SEM observation.

2.4 Mechanical Test

There are 2 types of mechanical tests that were done in this experiment; tensile test and compression test. The testing was carried out using Instron® 5582 at room temperature in accordance to ASTM638 for tensile testing and ASTM D695 for compression testing.

2.5 Biological Test

There are 2 biological tests conducted in this experiment: Simulated Body Fluid test and Cell Seeding test. All of these tests want to prove whether the biocomposite blocks produced earlier are bioactive, biocompatible and non-toxic to the human body.

2.5.1 Simulated Body Fluid (SBF) Test

Simulated Body Fluid is an acellular solution that has inorganic ion concentrations similar to those of human extracellular fluid or blood plasma, which can stimulate the formation of apatite layer on bioactive materials *in vitro* [6]. The ion concentrations of SBF in comparison with human blood plasma are given on Table 2.

Table 2 Comparison between ion concentrations of SBF and human blood plasma [6]

Ion	Concentration (mmol/litre)	
	Simulated body fluid (SBF)	Human blood plasma
Na^+	142.0	142.0
K^+	5.0	5.0
Mg^{2+}	1.5	1.5
Ca^{2+}	2.5	2.5
Cl^-	147.8	103.0
HCO_3^-	4.2	27.0
HPO_4^{2-}	1.0	1.0
SO_4^{2-}	0.5	0.5

The trimmed and polished biocomposite specimens obtained from the sintering process were immersed in 30 ml of SBF in the centrifuge tube for 0, 1, 4, 7, 14, 28 days at 37ºC where the temperature was maintained using a water bath. Upon removal from SBF, the specimens were dried in fume hood and were ready to be observed under SEM whether they have an apatite layer on their surface which indicates their potential for bonding with bone [7].

2.5.2 Cell Seeding

The trimmed and sterilized samples were put in the 6-well plate then 2 ml solution of cell and medium was poured onto the samples. They were then incubated for 24 hours at 37 ºC incubator to allow the cells to attach on the samples' surfaces. Samples were fixed before the cell morphology on the material could be observed using SEM.

III. Results and Discussions

3.1 Microstructural Observation

From Figure 1, it can be seen that surfaces of S1 and S2 which was sintered at 300ºC are not smooth and solid even though they are actually cut surfaces. The morphology of the powders still can be seen clearly suggesting that the samples had not been sintered well. However, there are some molten polymers that encapsulate some area of the HA powders.

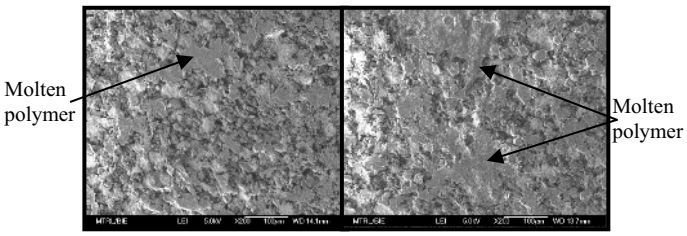

Figure 1 Comparison between cut surfaces of (a) S1 and (b) S2

Further observation of Figure 1 showed that the molten polymers, which look like some sort of layer, exist more in S2. This could be explained by the fact that holding time of S2 was longer than S1 which could give more time for the polymer to melt and encapsulate the HA powders.

From Figure 2 it clearly shows that S3 and S4 with holding temperature of 350ºC and 325ºC respectively have a very well-sintered surface which is smooth (not powdery) and solid if compared to S2 in Figure 1(b).

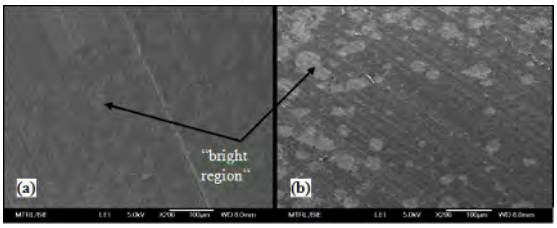

Figure 2 Comparison between cut surfaces of (a) S3 and (b) S4

Additionally from Figure 2, it also can be seen that specimen for S3, shows that the encapsulation of HA by the polymer is better than in S4. This can be observed from the obvious "bright region" on the surface of S4 while they are not clearly seen in S3. The bright region is the region of HA powder, while the dark region surrounding it is the PEEK polymer.

Therefore in conclusion, the higher the holding temperature of the process is, the better the encapsulation of HA by the PEEK polymer, resulting in better sintering.

3.2 Mechanical Test Results

Mechanical testing was only done to those samples which were well-sintered (S4 to S7).

3.2.1 Tensile Test Results

Each sample had 3 specimens tested using the machine, and the values obtained by the 3 specimens were averaged and shown in the chart Figure 3.

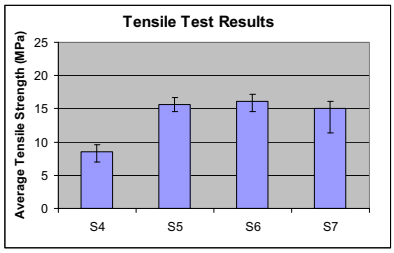

Figure 3 Chart of tensile test results of sample S4 to S7

From the tensile test results chart, it can be seen that only S4 has a lower tensile strength from the rest of the samples. The difference between S4 and the other 3 samples' parameters is the holding time. S4 was sintered at duration of 10 hours while the others 15 hours. Therefore, it can be concluded that holding time can determine the tensile strength of the composite. The longer the duration of the sintering could make a higher tensile strength. From the previous work done on mechanical properties of injection molded HA-PEEK biocomposite, tensile strength of 10 vol% HA – 90 vol% PEEK was 83.3 MPa which was within the cortical bone range of 50-150 MPa [i]. And taking 15 MPa as the average tensile strength value of pressureless sintered 10 vol% HA–90 vol% PEEK biocomposite block, the result is still way below the expected value.

3.2.2 Compression Test Results

From the chart in figure 4, it can be seen that all of the 4 samples have quite similar average values, around 55 MPa.

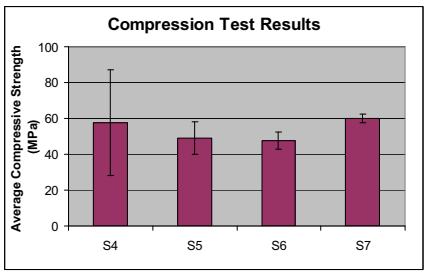

Figure 4 Chart of compression test results of sample S4 to S7

From the previous work done on injection molded HA-PEEK biocomposite, compressive strength of 10 vol% HA – 90 vol% PEEK was 125 ± 3.5 MPa which was in the lower limit of cortical bone (i.e. 106-215 MPa) [i]. And in this case taking 55 MPa as the average compressive strength value of pressureless sintered biocomposite block, the result is also still way below the expected value.

From the same previous work done, it is known that injection molding was using a pressure higher than 10 MPa

(injection pressure: 14MPa, follow-up pressure: 8-12 MPa) and this could be the reason. In addition, by only using a pressure of 10 MPa, the density achieved by the compaction process was far below the theoretical value. The theoretical value of the composite is 1.464 g/cm^3 while the density obtained after compaction is 0.67 g/cm^3 which is only 45.53% from the theoretical value.

3.3 Biological Test Results

Similar to mechanical test, biological tests were done only to those samples which were well-sintered (S4 to S7), which is Simulated Body Fluid (SBF) test and Cell Seeding test.

3.3.1 SBF test results

It is commonly believed that when artificial bioactive materials are implanted in the body, there will be spontaneously formation of biological apatite layer deposited on the surface of the materials which is critical to establishing bonding between living tissue and biomaterials, without forming the fibrous tissue among them [7].

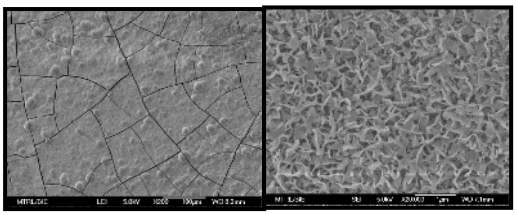

Figure 5 SEM results of SBF test for S4 with (a) magnification of 200 after 14 days upon immersion in SBF and (b) high magnification of S4 surface of the precipitated apatite layer after 28 days immersion in SBF

Figure 5 shows a layer formed in the surface of S4 upon immersion in SBF fluid after 14 days. This layer is an apatite layer which is actually precipitated crystals that had been confirmed as apatite through phase and composition analysis done in earlier report [7].

3.3.2 Cell Seeding Test Results

Bone is a connective tissue that contains different bone cells. And osteoblast, which was used in this experiment, is one type of bone cells (bone-forming cell). Hence, detection of these bone cells getting attached and becoming confluent on a material is one in-vitro technique to show the biocompability of the material [9].

Figure 6 shows the attachment of the osteoblast on top of control sample of S4 surface with their 'arm-like' structures. These results conclude that the biocomposite samples are biocompatible to the human body.

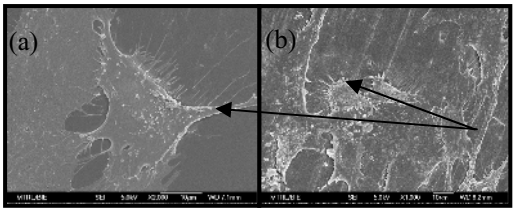

Figure 6 SEM micrograph of cell seeding control (a) and sample S4 (b)

IV. Conclusions

From the results obtained in this study, it can be said that pressureless sintering has the potential to replace injection molding in order to reduce cost, increase flexibility and yet still achieve similar results.

Mechanical test of the biocomposite obtained from the pressureless sintering were evidently below expectation. It was perhaps caused by several limitations inherent to the equipments used in the experiment. However the biological tests were extremely positive which verified that pressureless sintered HA-PEEK biocomposite blocks with composition of 10 vol% of HA were actually bioactive, biocompatible and non-toxic to the human body.

Computerized Cephalometric Line Tracing Technique on X-ray Images

C. Sinthanayothin

National Electronics and Computer Technology Center, National Science and Technology Development Agency, Pathumthani, Thailand

Abstract — **Cephalometric radiography analysis is an important diagnostic tool in orthodontics and cranio-maxillofacial surgery. Conventionally, cephalometric variables are measured manually on X-ray film. The clinician need to trace all the lines to show skull, teeth and jaw structures by themselves, which is inconvenient and time consuming. 2D cephalometric analysis can analyze in both lateral and frontal (PA) x-ray images. Therefore, this paper presents the method on producing the digital cephalometric tracing lines on x-ray images. The cephalometric tracing lines can lead to the measurement of the skull both in lateral and PA views in both bones and soft tissue sections and also can lead to the diagnostic of abnormalities of skull, face and teeth as well. Especially, PA view can use for analysis on symmetry of the skull. The computerized cephalometric lines tracing method combines with 4 steps. Firstly, the x-ray images are processed via adaptive, local, contrast enhancement. Secondly, the landmarks are defined by the dentists on both lateral and PA x-ray images. Next the cephalometric tracing lines are automatic generated by using the deformable template registration and cubic spline fitting techniques. Finally, the tracing lines are smoothed by put all lines into bitmap data which an interpolation technique is applied when the tracing lines are zooming. In this study, 10 laterals and 10 PA x-ray images are tested by this technique and the result shows very well drawing comparing to the manual method. Also the tracing lines are satisfied by the clinicians as a smoothed lines and curves. The cephalometric tracing lines will aid the future orthodontic and orthognathic analysis, diagnostic and planning in the next step.**

Keywords — **Cephalometric Line Tracing, Lateral, PA**

I. Introduction

Cephalometric analysis has been applied as tools in orthodontic diagnoses as well as cranio-maxillofacial surgery. The measurement of skull, jaw and soft tissue is simply called Cephalometric analysis where "cephalo" means head and "metric" comes from measurement. The cephalometric measurement in x-ray film can be done by locating the standard landmarks which is world wide well know for many years and continue developing for diagnostic for more than 50 abnormalities. Two-dimensional cephalometric measurements from lateral and/or frontal cephalograms were widely studied for diagnostic of abnormalities of skull bone and tissue and could be a tool that leads to an appropriated treatment planning by clinician. Currently, dentists perform orthodontic planning by initially taking the X-ray pictures of lateral and PA and then drawing the structure of surface, jaws, and teeth. At the same time the distance and angles are measured and calculated by using the stationary which taking a large amount of work and time. However, the software for cephalometric analysis are available such as OrisCeph Rx3 [1], OnyxCeph [2], Dolphine [3], Quick Ceph [4], Dr.Ceph (FYI) [5] and etc. [6-8]. Also group of researcher in Thailand have developed the software for cephalometric analysis called CephSmile [9] as well. Also many researchers are developed an automatic drawing of the cephalometric line tracing such as the review work by Leonardi [10] that the systems described in the literature are not accurate enough to allow their use for clinical purposes as errors in landmark detection were greater than those expected with manual tracing. Therefore, this paper proposes the technique on producing the digital cephalometric tracing lines on x-ray images. The method combines with 4 steps. First, contrast the x-ray images by local contrast enhancement technique. Second, define the landmarks by the dentists. Next draw the cephalometric line tracing which can be done by using the deformable template and cubic spline fitting. Finally, the tracing lines are smoothed. The cephalometric tracing lines can be use for both orthodontic and orthognathic planning in the next step.

II. Methodology

The method on producing the digital cephalometric tracing lines on x-ray images can lead to the measurement of the skull both in lateral and PA views in both bones and soft tissue sections and also can lead to the diagnostic of abnormalities of skull, face and teeth as well. Especially, PA view can use for analysis on symmetry of the skull. The method combines with 4 steps are as follow:

A. Radiographic Image Enhancement using "Local Contrast Enhancement" technique.

Most of x-ray images in this work are loss of detail and create of artifacts especially the digital image that taken from the x-ray film that placed on the view box or scanned as can be seen in figure 1. Therefore x-ray image is necessary pre-processed in order to perform the clearer image,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 265–269, 2009
www.springerlink.com

Fig 1: Original x-ray images of PA and Lateral views.

Fig 2: X-ray images with local contrast enhancement.

which the local contrast enhancement technique has been applied in this paper [11]. For the local contrast enhancement technique, let the intensity, *f*, of the picture elements (pixels) of an $N \times N$ digital image be indexed by (i,j) $1 \le i, j \le N$. Consider a subimage of size $M \times M$ centered on (i, j), in this paper $M=49$. Denote the mean and standard deviation of the intensity within W by $\langle f \rangle_W$ and $\sigma_W(f)$ respectively. The objectivity for this method is to define a point transformation dependent on W such that the distribution is localized around the mean of the intensity and covers the entire intensity range. The implicit assumption is that W is large enough to contain a statistically representative distribution of the local variation of grey levels, yet small enough to be unaffected by the gradual change of contrast between the centre and the periphery of the x-ray image. The adaptive contrast enhancement transformation is defined by

$$f(i,j) \to g(i,j) = 255 \frac{[\psi_w(f) - \psi_w(f_{\min})]}{[\psi_w(f_{\max}) - \psi_w(f_{\min})]} \quad (1)$$

Where the sigmoidal function was

$$\psi_w(f) = \left[1 + \exp\left[\frac{< f >_w - f}{\sigma_w}\right]\right]^{-1} \quad (2)$$

While f_{max} and f_{min} are the maximum and minimum values of intensity within the whole image with

$$< f >_{W(i,j)} = \frac{1}{M^2} \sum_{(k,l) \in W(i,j)} f(k,l) \quad (3)$$

$$\sigma_W^2(f) = \frac{1}{M^2} \sum_{(k,l) \in (i,j)} \left(f(k,l) - < f >_w\right)^2 \quad (4)$$

The result of local contrast enhancement technique can be seen in figure 2.

B. Cephalometric Landmarks on Lateral and PA Views.

The method in this paper could be able to draw the cephalometric line tracing of skull and face in both bones and soft surface sections on both lateral and PA images by using the landmarks defined by the dentists. Therefore, the landmarks need to be located by the clinician following the guideline in a step by step, 79 reference points for lateral view and 57 reference points for PA view as shown in figure 3. Some landmarks can be generated automatically or the ruler can appeared as a guideline for locating the reference point. The program also provides tools that allow users to mark the correct points with ease as well.

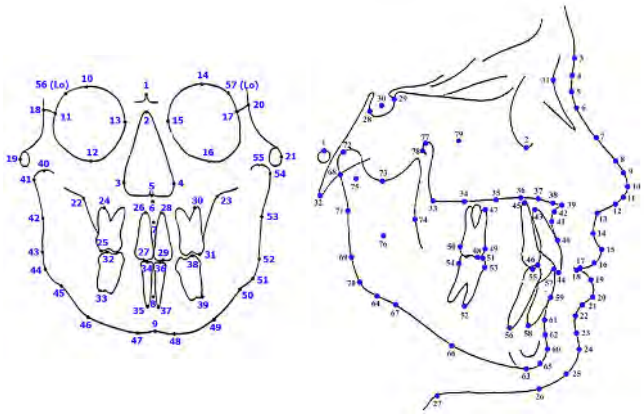

Fig 3: Reference points: 57 points for PA and 79 points for Lateral View.

C. Cephalometric Line Tracing on Lateral and PA Views

In this paper, there are 2 methods for cephalometric line tracing on lateral and PA views. Firstly, cephalometric line tracing using deformable template is described. Secondly, the cephalometric line tracing using cubic spline technique is explained. One technique will be applied at a time depends on the characteristic of the reference points.

C.1Cephalometric Line Tracing using Deformable Template

Cephalometric line tracing using deformable template can be applied when the tracing line has a unique shape such as tooth, circle and etc. This specific shape line can be matched with a few reference points. Therefore, the template of specific shape must be prepared as can be seen in figure 4.

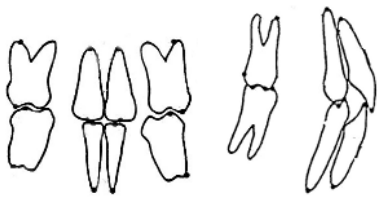

Fig 4: Templates with difference shapes.

Once the templates have been prepared, then the template is fitted to a few reference points. In this paper shows the example of tooth template matching with 2 reference points on x-ray image as shown in figure 5. The template matching can be done by determine the vector of two reference points on template and x-ray image respectively. Then the angle between two vectors has been calculated using dot product for template rotation. Next the distance of each vector indicates the size of template on x-ray image. Last the middle of the vector on x-ray image indicates the position that the template needs to be translated.

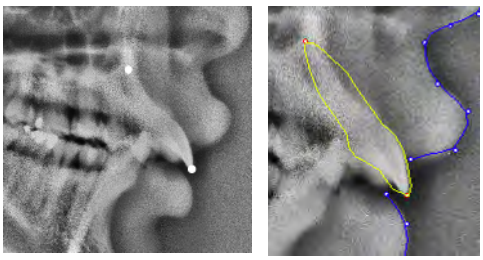

Fig 5: Tooth template matching with 2 reference points on x-ray image.

Equation 5, 6 and 7 shows the translation, rotation and scaling matrixes of template's coordinates on x-ray image.

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} d_x \\ d_y \end{bmatrix} \tag{5}$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \tag{6}$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} s_x & 0 \\ 0 & s_y \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \tag{7}$$

C.2 Cephalometric Line Tracing using Cubic Spline

Cubic spline technique is used for drawing curve along the reference points. The spline is obtained by calculating the second derivatives of the interpolating function at the tabulated points based on the formulation given in "Numerical Recipes in C". [12] One dimensional cubic spline fitting can be explained as in Eq. (8) – Eq.(13). With this method, a series of unique cubic polynomials is fitted between each of the data points with the condition that the curve obtained be continuous and appears smooth. This spline consists of weights attached to a flat surface at the points to be connected. A flexible line is then bent across each of these weights, resulting in a smooth curve.

$$G(x) = \begin{cases} g_1(x) & \text{if} \quad x_1 \le x < x_2 \\ g_2(x) & \text{if} \quad x_2 \le x < x_3 \\ \vdots & \\ g_{n-1}(x) & \text{if} \quad x_{n-1} \le x < x_n \end{cases} \tag{8}$$

Where g_i is a 3rd degree polynomial defined by

$$g_i(x) = a_i(x - x_i)^3 + b_i(x - x_i)^2 + c_i(x - x_i) + d_i \tag{9}$$

for $i = 1, 2, \ldots, n\text{-}1$.

Since the piecewise function $G(x)$ will interpolate all of the data points, we can conclude that

$$G(x_i) = y_i \tag{10}$$

for $i = 1, 2, \ldots, n\text{-}1$. Since $x_i \in [x_i, x_{i+1}]$, $y_i = g_i(x_i)$

The coefficients a_i, b_i, c_i, and d_i in (9) are determined from the first and second derivatives of the n-1 equations of $g_i(x)$. The routine must ensure that $g_i(x), g_i'(x)$ and $g_i''(x)$ are equal at the interior node points for adjacent segments. Substituting a variable S_i for the $g_i''(x_i)$ and y_i for $s_i(x_i)$ will reduce the number of equations and simplify the tasks.

Given the spacing between successive data points is

$$h_i = x_i - x_{i-1} \tag{11}$$

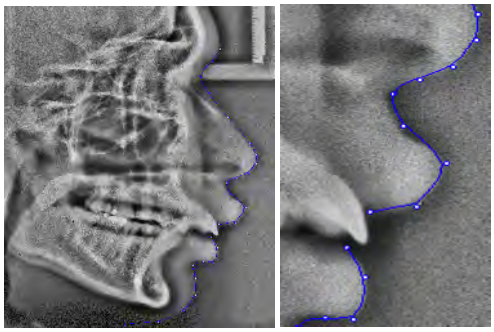
Finally, the variables a_i, b_i, c_i and d_i in (9), or termed the weights of each n-1 equations, will be

$$\begin{aligned} a_i &= \frac{S_{i+1} - S_i}{6h} \\ b_i &= \frac{S_i}{2} \\ c_i &= \frac{y_{i+1} - y_i}{h} - \left(\frac{S_{i+1} + 2S_i}{6}\right)h \\ d_i &= y_i \end{aligned} \tag{12}$$

When substituting these weights in (9), its 1st and 2nd derivatives, and including the condition of natural spline where 2nd derivative is equal to zero at the endpoints ($S_1 = Sn = 0$), the system can be determined in matrix equation as follows

$$\begin{bmatrix} 4 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 1 & 4 & 1 & \cdots & 0 & 0 & 0 \\ 0 & 1 & 4 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 4 & 1 & 0 \\ 0 & 0 & 0 & \cdots & 1 & 4 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 1 & 4 \end{bmatrix} \begin{bmatrix} S_2 \\ S_3 \\ S_4 \\ \vdots \\ S_{n-3} \\ S_{n-2} \\ S_{n-1} \end{bmatrix} = \frac{6}{h^2} \begin{bmatrix} y_1 - 2y_2 + y_3 \\ y_2 - 2y_3 + y_4 \\ y_3 - 2y_4 + y_5 \\ \vdots \\ y_{n-4} - 2y_{n-3} + y_{n-2} \\ y_{n-3} - 2y_{n-2} + y_{n-1} \\ y_{n-2} - 2y_{n-1} + y_n \end{bmatrix} \quad (13)$$

Therefore, Eq. (13)[13] is used to find the interpolation values in all dimensions. In this paper, a data point is equivalent to the number of reference points. The result of fitting the cephalometric line with cubic-spline interpolation can be seen as in figure 6.



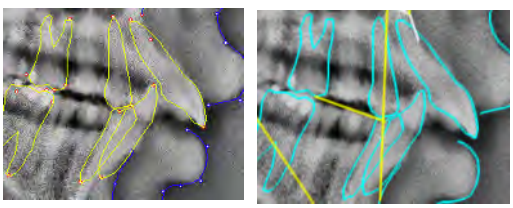


Fig 6: Tracing cephalometric line with cubic spline.

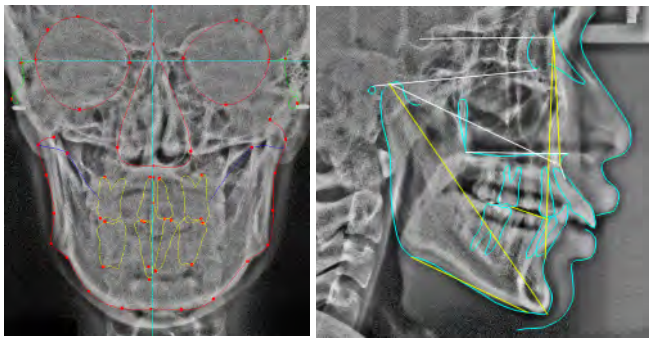
D. Cephalometric Line Smoothening

Cephalometric tracing lines are automatic generated by using the deformable template registration and cubic spline fitting techniques as mention above. However, the lines are not smooth when zoom into specific area as can be seen in figure 7(A). Therefore cephalometric line smoothening technique has been proposed by transform the window/canvas coordinates of the tracing lines into bitmap coordinates. Then the program will draw lines on bitmap instead of canvas and apply image interpolation when the user zooms into the specific area of x-ray image. The result of cephalometric line smoothening technique shows as figure 7(B) which the user zooms into the specific area.



(A) On Canvas (B) On bitmap plus interpolation

Fig 7: Cephalometric lines.

III. Result

The result of cephalometric line tracing on both PA and Lateral x-ray images can be displayed as figure 8(A) and 8(B) respectively. This method has been tested on 10 PA and 10 Lateral x-ray images and found that cephalometric lines showed the similar result depends on the coordinate of reference points.

(A) PA View (B) Lateral View

Fig 8: Cephalometric line tracing result.

IV. Conclusion

The result of the computerized cephalometric line tracing technique on x-ray images is reasonable and acceptable by collaboration clinicians. Since the tracing lines from computerized are similar to a hand drawing but more convenient and less time consuming. Therefore, this method can perform automatic drawing of the significant traces of face, skull, and teeth by using the reference points. The cephalometric analysis with different types of analysis, such as Mahidol Analysis, Down Analysis, Steiner Analysis, Tweed Analysis, Jaraback Analysis, Harvold Analysis, Rickette Analysis, and McNamara Analysis can be performed in the near future in order to show the structural problems on skulls, face, and teeth.

Brain Activation in Response to Disgustful Face Images with Different Backgrounds

Takamasa Shimada[1], Hideto Ono[1], Tadanori Fukami[2], Yoichi Saito[3]

[1] School of Information Environment, Tokyo Denki University, Japan
[2] Faculty of Engineering, Yamagata University, Japan
[3] Research Institute for EEG Analysis, Japan

Abstract — **Previous studies have demonstrated that the stimulus of a fearful and disgustful face images lead to activation of neural responses in the medial temporal lobe. In particular, it was reported that seeing disgustful face image activated the insula area of brain. In these studies, no background images were used with facial stimuli. However, normal day-to-day images always have a background. Moreover, background images are considered important in art forms (painting, photography, and movies, etc.) for eliciting effective expressions. We assessed the effect of background images on brain activation by using functional magnetic resonance imaging (fMRI). During fMRI scanning, face images with background images were presented repeatedly to 8 healthy right-handed males. Facial stimuli comprised 5 photographs of a disgustful face selected from the Paul Ekman's database (Ekman and Friesen 1976). The background images comprised 2 photographs—one is worms and the other is a flower garden. It is thought that disgustful face images coincide with worms background image on the point of impression. After scanning, the subjects rated the impression created by the images on the Plutchik scale. Significant effects of the image of the disgustful face against the worms background minus that against the flower garden were assessed using a t-test and displayed as statistical parametric maps (SPMs) using SPM2 software. The results demonstrated activation of the right insula, and the image of the disgustful face against the worms background created a more disgustful impression than that against the flower garden. Therefore, the image of the face and the background together create the overall impression. The difference in the activation of the insula is possibly induced by the creation of this overall impression. This demonstrates the importance of background images in forming an impression of face images.**

Keywords — **Face image, background image, functional magnetic resonance imaging.**

I. Introduction

In recent years, many studies have been conducted in an attempt to clarify the neural systems involved in emotional perception. Previous studies have demonstrated that the stimulus of a fearful and disgustful face images lead to activation of neural responses in the medial temporal lobe. Previous studies have suggested the involvement of the limbic system in emotional perception. The relationship between emotional perception and the hippocampus was shown by Papez et al. [1]. In particular, it was reported that seeing disgustful face image activated the insula area of brain.

One of the concepts of emotion, called Plutchik's psychoevolutionary theory of basic emotions, was suggested by Plutchik et al. [2]. These postulated basic emotions are acceptance, anger, anticipation, disgust, joy, fear, sadness, and surprise.

In many art forms (painting, photography, movies, etc.), background images are thought to be very important for enhancing the effect of the subject.

In most of the recent studies on anthropomorphic user interfaces [3][4], only a face image is used and background images are either not used or are considered unimportant. However, in daily conversations with individuals, the absence of a background is unnatural. It is expected that adding a background to face images will be useful in producing emotional effects. However, the mechanism through which background images affect face images has not been cleared. In addition, there are few studies on brain functions in the field of computer interface technology.

An objective evaluation method is important for evaluating the effect of background images on humans. In particular, clarifying the relation between background images and the activation of the brain is thought to be a key for such an objective estimation. However, the mechanism by which information related to background images is processed in the brain has not been investigated.

In this research, we attempted to elucidate this mechanism by using an fMRI scanner to detect brain activation induced by images that include not only a face image but also background images. In our research, the subjects were shown face images with background images. We focused on the brain activation and impression change induced by the different combinations of facial expressions and background images, which were further analyzed. Two background images were used for the experiment. One image induced the same type of emotional effect as the face images, whereas the other image induced a different type of emotional effect from the face images. The effect on brain acti-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 270–273, 2009
www.springerlink.com

vation was analyzed by means of the fMRI scanner. This experiment analyzed the relation between emotions and brain activation induced by images. Moreover, the effect induced only by background images was also analyzed by means of a questionnaire and the fMRI scanner.

II. Method

A. Experimental paradigm

The face images used in our experiment expressed disgust. The five face images used were selected from Paul Ekman's database (Ekman & Friesen, 1976). These images comprise two male and three female images.

The face image was superimposed on the background image. Two types of background images were used—one depicted worms; the other, a flower garden.

We selected two background images to investigate whether the emotional effect of the face images with one background is consistent with that elicited by the face images with another background.

Figs. 1 and 2 are samples of the face image with a background image of worms and a flower garden, respectively. It is believed that face images expressing disgust correspond to a background depicting worms; however, face images expressing disgust are in contradiction with a background depicting a flower garden.

In this experiment, we focused only on the changes in brain activity resulting from disgust; subsequently, we focused on changes in the insula areas, which are associated with the emotion of disgust.

During the fMRI scanning, the subjects, who were asked to wear earplugs, lay on the bed of the fMRI scanner. The total scanning time was 5 min per subject, and the scanning was carried out in blocks of 10 s wherein a face image along with the background image of either worms or a flower garden was repeatedly presented to the subject. The face presentation block was preceded and followed by a 10s block of a crosshair cursor, as seen in Fig. 3. During the 10-s face block, the stimulus of one face image (with a background image) of either a male or female was presented 5 times (stimulus duration, 200 ms; interstimulus interval, 1800 ms) because repeated stimulation is assumed to enhance corresponding cortical activation [5][6].

The combination of the face and background images was randomly selected for every 10s face block; however, the number of images with the worms and flower garden backgrounds was counterbalanced. In addition, the number of face images of a particular person with both the backgrounds was counterbalanced.

B. Questionnaire

In order to assess the difference in the psychological effects caused by different background images, the subjects were required to rate their impressions by using a questionnaire based on Plutchik's eight basic emotional categories. The subjects were required to rate the intensity of their impression of each category of emotion on a scale of 0 to 6 (seven levels). A rating of 0 implied that the subject did not feel anything for that particular category, and a rating of 6 implied that the subject experienced that emotion very strongly (maximum intensity). The subjects answered the questionnaire immediately after the fMRI scanning.

Fig. 1 Sample of a face image expressing disgust with the background image of worms

Fig. 2 Sample of a face image expressing disgust with the background image of flower garden

C. Subjects

The subjects were 8 healthy right-handed male adults (mean age is 21.8 years, standard deviation is 0.97). All the subjects provided written informed consent for participation in the experiment. In all the paradigms, the subjects, who

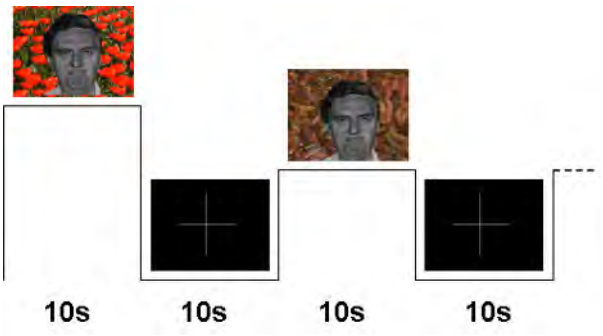

Fig. 3 Schematic diagram of the experimental paradigm

were monitored through a window, were forbidden to move, except when the task required them to do so.

D. Image Acquisition and Analysis

In this experiment, gradient-echo echo-planar magnetic resonance (MR) images were developed using a 1.5 Tesla Hitach Stratis II System at the Applied Superconductivity Research Laboratory, Tokyo Denki University, Chiba, Japan. T2*-weighted time-series images depicting the blood oxygenation level-dependent (BOLD) contrast were developed using a gradient-echo echo-planar imaging (EPI) sequence (TR, 4,600 ms; TE, 74.2 ms; inter-TR time, 400 ms; total scanning time, 5.00 min; flip angle, 90°; field of view (FOV), 22.5 cm × 22.5 cm; slice thickness, 4.0 mm; slice gap, 1.0 mm; voxel, 3.52 × 3.52 × 5 mm). In all, 28 axial contiguous slices covering the entire brain were collected.

The developed data were analyzed using the statistical parametric mapping (SPM) technique (using SPM2 from the Wellcome Department of Cognitive Neurology, London, UK) implemented in Matlab (Mathworks Inc., Sherborn, MA, USA). The analysis involved the following steps: correction for head movements between the scans, realignment of the functional images acquired from each subject to the first image using rigid body transformation. A mean image was created using the realigned volumes. The high-resolution, T1-weighted anatomical images were coregistered to this mean (T2*) image to ensure that the functional and anatomical images were spatially aligned. The anatomical images were then normalized into the standard space [7] by matching them to a standardized Montreal Neurological Institute (MNI) template (Montreal Neurological Institute, Quebec, Canada), using both linear and nonlinear 3D transformation [8][9]. The transformation parameters determined here were also applied to the functional images. Finally, these normalized images were smoothed with a 12 mm (full width at half maximum) isotropic Gaussian kernel to accommodate intersubject differences in anatomy and to permit the application of Gaussian random field theory to provide corrected statistical inference [8][9]. The SPMs {Z} for the contrasts were generated and thresholded at a voxel-wise P value of 0.01.

III. Results

The differences in the activation between the conditions of viewing face images expressing disgust with the background image of either worms or a flower garden (disgustful face images with the worms background minus those with the flower garden background) were analyzed. The results are shown in Fig. 4. The difference in activation was detected in the insula of the right hemisphere of the brain.

The results of questionnaire shown that the intensity of the impression was stronger for the basic emotional categories of disgust when the worms background was used than when the flower garden background was used.

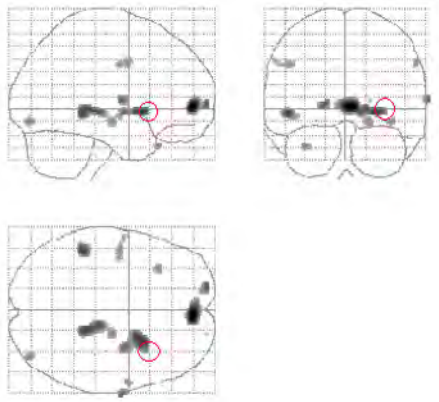

Fig. 4 Results of the difference in activity between the case of the disgustful face images with the worms background and that of the disgust images with the flower garden background (worms minus flower garden)

IV. Discussion

In our research, we attempted to reveal the effect of combining the background image with disgustful face images. As a result, stronger activity was detected in the insula area when the worms background image was used than when the flower garden background image was used.

The area in which activation was detected coincide with the areas in which activation was observed in a previous study in which subjects were shown disgustful faces.

The results of the questionnaire revealed that the subjects formed a stronger impression of disgust when they saw disgustful face images with the worms background than when they saw disgust images with the background image

of a flower garden. This reveals that the impression of disgust was enhanced by using the image with a worms background because this image corresponds with the image of a disgustful face.

In the abovementioned experiment, the background images comprised images of worms and a flower garden. Even if these images are shown to the subject without the face image, it is believed that the images will have their own emotional effects on humans. The average results of the ratings for the images with the backgrounds of worms and a flower garden indicate that the impression of disgust is stronger when the worms background is used than when the background with a flower garden is used. This may imply that the difference in the activation of the brain between the condition in which face images with the worms background are presented and that in which face images with the background of a flower garden are presented is caused merely by adding the activation in the case of the background image to that in the case of the disgustful face image.

We investigated this point by performing an additional experiment. In this experiment, the paradigm was the same but the face image was removed.

The results are shown in Fig. 5. In this experiment, the difference in activation was not detected in the insula area. This experiment showed that the background image had little effect on activity in the insula, although it considerably influenced the activation resulting from the stimuli of disgustful face images.

V. Conclusions

We investigated the effect of combining disgustful face images and background images to study the activation of the brain by using fMRI.

As a result, stronger activation was detected in the insula area when the worms background image was used than when the background image of a flower garden was used. It is believed that this difference in brain activity relates to the degree of disgust impression induced by the images. The results of the questionnaire revealed that the impression of disgust induced by the disgustful face image with the worms background image was stronger than that induced by the disgustful face image with the background of a flower garden.

In addition, the effect of the background image was investigated qualitatively. The difference in activation in the insula area was compared; no difference in activation was detected in the insula area. An image of worms creates an impression of disgust but may not involve biological processing.

Further, these results reveal that although the background image has little effect in activating the insula area, it considerably influences the activation resulting from the stimuli of the disgustful face images. These results indicate the probability of their application to the objective estimation of the emotional effect that the images have.

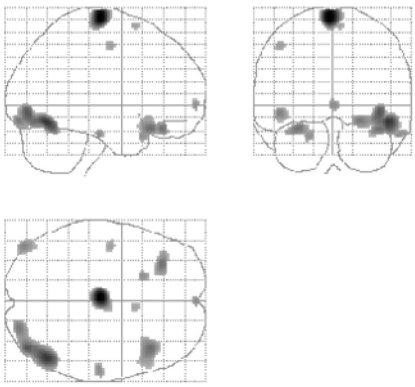

Fig. 5 The results of the difference in activation between the cases of the two background images (worms minus the flower garden)

Abstract — **Retinal blood vessels are significant anatomical structures in ophthalmic images. Automatic segmentation of blood vessels is one of the important steps in computer aided diagnosis system for the detection of diseases such as Diabetic Retinopathy that affect human retina. We propose a method for the segmentation of retinal blood vessels using Spatial Gabor filters as they can be tuned to the specific frequency and orientation. A new parameter is defined to facilitate filtering at different scales to detect the vessels of varying thicknesses. The method is tested on forty colour retinal images of DRIVE (Digital Retinal Images for Vessel Extraction) database with manual segmentations as ground truth. An overall accuracy of 84.22% is achieved for segmentation of retinal blood vessels.**

Keywords — **Colour Retinal Image, Vessel Segmentation, Gabor filter, Diabetic Retinopathy.**

I. Introduction

Diabetic retinopathy is a disorder of the retinal vasculature that eventually develops to some degree in nearly all patients with long-standing diabetes mellitus [1]. It is estimated that by the year 2010 the world diabetic population will be doubled, reaching an estimated 221 million [2]. The timely diagnosis and referral for management of diabetic retinopathy can prevent 98% of severe visual loss. Colour retinal images are widely used for detection and diagnosis of Diabetic retinopathy. In computer assisted diagnosis the automatic segmentation of the vasculature in retinal images helps in characterizing the detected lesions and in identifying false positives [3]. The performance of automatic detection of pathologies like microaneurysms and hemorrhages may be improved if regions containing vasculature can be excluded from the analysis. Another important application of automatic retinal vessel segmentation is in the registration of retinal images of the same patient taken at different times [4]. The registered images are useful in monitoring the progression of certain diseases.

In the literature [5] it is reported that many retinal vascular segmentation techniques utilize the information such as contrast that exists between the retinal blood vessel and surrounding background and all vessels are connected and originates from the same point that is the optic disc. Four techniques used for vessel detection are classified as filter based methods, tracking of vessels, classifiers based methods and morphological methods. In filter based methods the cross-sectional gray-level profile of a typical retinal vessel matches the Gaussian shape and the vasculature is piecewise linear and may be represented by a series of connected line segments [6]. These methods employ a two-dimensional linear structural element that has a Gaussian cross-profile section, rotated into different angles to identify the cross-profile of the blood vessel. Tracking methods [7] [8] use a model to track the vessels starting at given points and individual segments are identified using a search procedure which keeps track of the center of the vessel and makes some decisions about the future path of the vessel based on certain vessel properties. Classifier-based methods use a two-step approach [9]. They start with a segmentation step often by employing one of the mentioned matched filter-based methods and next the regions are classified according to many features. In the next step neural networks classifier is constructed using selected features by the sequential forward selection method with the training data to detect vessel pixels. Morphological image processing exploits features of the vasculature shape that are known a priori, such as it being piecewise linear and connected. The use of mathematical morphology for segmentation of blood vessels is explained in [10] [11]. These approaches works well on normal retinal images with uniform contrast but suffers in the presence of noise due to pathologies within the retina of eye.

In our work the vessel segmentation is performed using Gabor filter. Gabor filters have been widely applied to image processing and computer vision application problems such as face recognition and texture segmentation, strokes in character recognition and roads in satellite image analysis [12][13]. A few papers have already reported work on segmentation of vessels using Gabor filters [14] [15]. But still there is a scope of improvement as they fail to detect vessels of different widths. Also detection process becomes much more complicated when lesions and other pathological changes affect the retinal images. We focus to develop a much robust and fast method of retinal blood vessel segmentation using Gabor filter and introduce new parameter

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 274–276, 2009
www.springerlink.com

for designing filter of different scales that facilitates the detection of vessels of varying width.

II. Segmentation of blood vessels

The detection of blood vessels is an important step in automated retinal image processing system as the colour of hemorrhages and microaneurysms is similar to the colour of blood vessels and appear darker than the background. The blood vessels appear most contrasted in the green channel of the RGB colour space because of that only the green component is retained for the segmentation of vessels using Gabor filter. Figure 1 shows digital colour fundus image and green channel image.

Fig. 1 Digital colour Retinal image and its green channel image

A. Spatial Gabor filter

The 2D Gabor filters are a set of orientation and frequency sensitive band pass filters which have the optimal localization in both the frequency and space domains. Thus they are suitable for extracting orientation dependent frequency contents of the patterns [13]. The spatial Gabor filter kernels are sinusoids modulated by a Gaussian window, the real part of which is expressed by

$$g(x,y)=\exp\left[-\frac{1}{2}\left(\frac{x_p^2}{\sigma_x^2}+\frac{y_p^2}{\sigma_y^2}\right)\right]\cos(2\pi fx) \quad (1)$$

Where,

$$x_p = x\cos\theta + y\sin\theta$$

$$y_p = -x\sin\theta + y\cos\theta$$

θ : Orientation of the filter, an angle of zero gives a filter that responds to vertical features.

f : Central frequency of pass band.

σ_x : Standard deviation of Gaussian in x direction along the filter that determines the bandwidth of the filter.

σ_y : Standard deviation of Gaussian across the filter that control the orientation selectivity of the filter.

The parameters are to be derived by taking into account the size of the lines or curvilinear structures to be detected. To produce a single peak response on the center of a line of width t, the gabor filter kernel is rotated in different orientations with the parameters set as follows

$f = 1/t$,

$\sigma_x = t*k_x$, k_x is scale factor relative to σ_x

$\sigma_y = 0.5\sigma_x$,

k_x is required so that the shapes of the filters are invariant to the scale. The widths of the vessels are found to lie within a range of 2-14 pixels (40-200 μm). Thus for the values of k_x = 0.4 and t = 11, Figure 2 shows the Gabor filter spatial frequency responses at different orientations (60^0,120^0 and 180^0) on the retinal image in Figure 1.

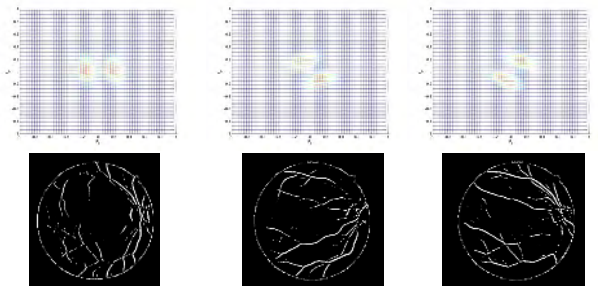

Fig. 2 Orientation of Gabor filter at 180^0, 60^0 and 120^0 (first row) applied to retinal image and corresponding response output (second row)

B. Blood vessel segmentation

Only six Gabor filter banks with different orientations (0 to 180 with interval of thirty degrees) are used to convolve with the image for fast extraction of vessels. The magnitude of each response is retained and combined to generate the result image. Figure 3 show the result of vessel segmentation using Gabor filter. Parameter are set to t=11 in Figure 3(c) and t=12 in Figure 3(d). It can be seen that at t=11 along with the thick vessels the thin vessels are also detected with true positive rate of 0.8347 and false positive rate of 0.21. With t=12 the true positive rate comes down to 0.7258, it can be seen in the Figure 3(d) that only thick vessels are segmented.

III. Experiment results

The image data required for the research work is obtained from publicly available DRIVE (Digital Retinal Im-

ages for Vessel Extraction) database and also from the Department of Ophthalmology, KMC, Manipal using Sony FF450IR digital fundus camera and stored in 24-bit colour compressed JPEG format with 768×576 pixel resolution.

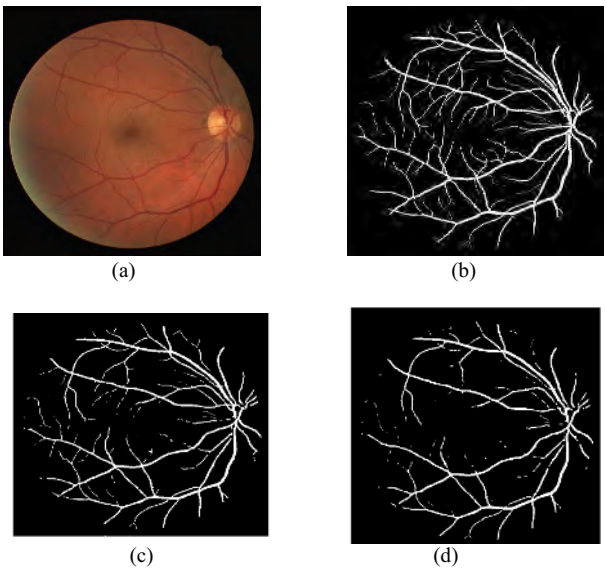

Fig. 3 Segmentation of blood vessels. (a) 19_test colour image from DRIVE database; (b) Manual segmentation of vessel; (c) Segmentation with t=11; (d) Segmentation with t=12.

It is reported in the literature that matched filter method of extraction provides an accuracy of 91% on drive database. We have implemented the matched filter for comparison with our method and found that the accuracy depends on threshold selected and applied to the filtered image the same is not the case with Gabor filter. It is also found that the matched filter method works well on normal retinal images but it suffers when an image with pathologies is considered. The proposed method is capable of segmenting retinal blood vessels of varying thickness. We tested our method on DRIVE database and obtained an accuracy of 84.22%.

IV. Conclusions

In this paper, we presented a method to detect vessels of varying thickness using Gabor filters of different scales and orientation and found that it provide better way of extracting vessels in retinal images. We also tested the method on retinal images containing lesions and varying local contrast and it gives a reasonable good result. It is hoped that automated segmentation of vessel technique can detect the signs of diabetic retinopathy in the early stage, monitor the progression of disease, minimize the examination time and assist the ophthalmologist for a better treatment plan.

Automated Detection of Optic Disc and Exudates in Retinal Images

P.C. Siddalingaswamy[1], K. Gopalakrishna Prabhu[2]

[1] Department of Computer Science & Engineering, Manipal Institute of Technology, Manipal, India

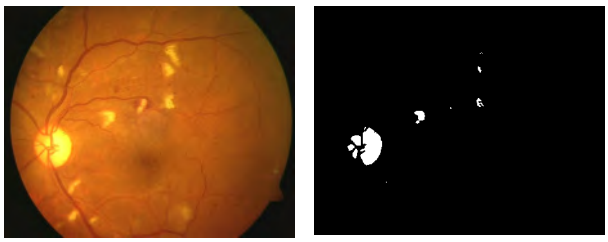
Abstract — **Digital colour retinal images are used by the ophthalmologists for the detection of many eye related diseases such as Diabetic retinopathy. These images are generated in large number during the mass screening of the disease and may result in biased observation due to fatigue. Automated retinal image processing system could save workload of the ophthalmologists and also assist them to extract the normal and abnormal structures in retinal images and help in grading the severity of the disease. In this paper we present a method for automatic detection of optic disc followed by classification of hard exudates pixels in retinal image. Optic disc localization is achieved by iterative threshold method to identify initial set of candidate regions followed by connected component analysis to locate the actual optic disc. Exudates are detected using k means clustering algorithm. The algorithm is evaluated against a carefully selected database of 100 color retinal images at different stages of diabetic retinopathy. The methods achieve a sensitivity of 92% for the optic disc and 86% for the detection of exudates.**

Keywords — **Diabetic retinopathy, Optic disc, Exudates, clustering.**

I. Introduction

Diabetic retinopathy causes changes in the retina, which is the most important tissue of the eye [1]. There are different kinds of abnormal lesions caused by diabetic retinopathy in a diabetic's eye such as microaneurysm, hard exudates, soft exudates and hemorrhages that affect the normal vision. The timely diagnosis and referral for management of diabetic retinopathy can prevent 98% of severe visual loss. Mass screening of Diabetic retinopathy is conducted for the early detection of this disease, wherein the retinal images are captured using standard digital colour fundus camera resulting in large number of retinal images that need to be examined by ophthalmologists. Automating the preliminary detection of the disease during mass screening can reduce the workload of the ophthalmologists. This approach involves digital fundus image analysis by computer for an immediate classification of retinopathy without the need for specialist opinions. In computer assisted diagnosis automatic detection of normal features in the fundus images like blood vessels, optic disc and fovea helps in characterizing the detected lesions and in identifying false positives.

Optic disc and hard exudates are the brightest features in the colour retinal image. It is found that the optic disc is the brightest part in the normal fundus image that can be seen as a pale, round or vertically slightly oval disc. It is the entrance region of blood vessels and optic nerves to the retina and its detection is essential since it often works as a landmark and reference for the other features in the fundus image and in correct classification of exudates [2]. The optic disc was located by the largest region that consists of pixels with the highest gray levels in [3]. The area with the highest intensity variation of adjacent pixels was identified as optic disc in [4]. Even the geometrical relationship between optic disc and blood vessels was utilized in the identification of optic disc [4]. In [5] region growing algorithm was used for detecting hard exudates. They report 80.21% sensitivity and 70.66% specificity for detecting overall retinopathy. In [6] red free fundus images are divided into sub-blocks and use artificial neural networks for classifying the sub blocks as having exudates or not. They report 88.4% sensitivity and 83.5% specificity for detecting retinopathy as a whole and 93.1% sensitivity and 93.1% specificity for hard exudates.



In this paper we propose detection of optic disc by detected using iterative threshold method followed by correctly identifying optic disc out of many candidate regions. Exudates are detected using k means clustering algorithm to classify exudate and non exudate pixels.

II. Methods

A. Optic Disc detection

In retinal images it has been observed that the green component of the RGB colour space contains the maximum data that can be used for efficient thresholding of the optic disc. The optic disc is observed to be brighter than other features in the normal retina. Optimal thresholding is applied to segment the brightest areas in the image. It is a method based on approximation of the histogram of an image using a weighted sum of two or more probability densities with normal distribution. The threshold is set as the closest gray level corresponding to the minimum probability between the maximum of two or more normal distribution. It is observed that it resulted in maximization of

www.springerlink.com

(a) (b)

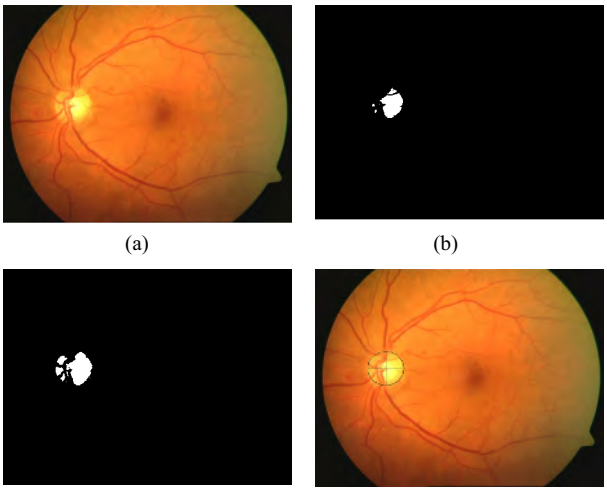

Fig. 1 Result of optimal thresholding. (a) Colour retinal image affected with diabetic retinopathy. (b) Distributed bright connected components in the threshold image.

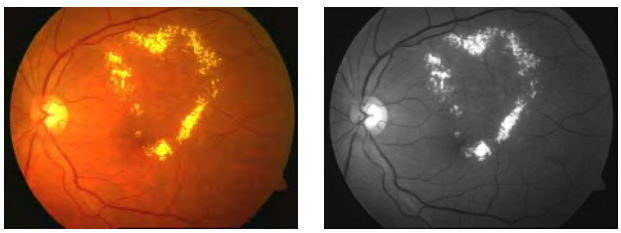
gray level variance between object and background. The result of optimal thresholding is as shown in the Figure 1.

A data structure is used to find the total number of connected components in the threshold image. The component having the maximum number of pixels is assumed to be having the Optic cup part of the optic disc and it is considered to be the primary region of interest. The mean of this region is computed in terms of x and y coordinates. The maximum length of optic disc can be 100 pixels, only the components whose mean coordinates are within 50 to 60 pixels distance from the mean coordinates of the largest component are considered to be parts of the optic disc. The extent of the Optic disc in horizontal and vertical directions is computed by finding the overall minimum and maximum x and y coordinates among all the components that are considered as a part of optic disc. If this region is greater than 80 pixels in width and 90 pixels in height, an ellipse is drawn using the x and y coordinates so obtained. Otherwise the threshold is decremented by one and applied to the initial image. But this time the threshold is applied only in the vicinity of the mean x and y coordinates computed earlier so as to avoid misclassifying large exudates as a part of the optic disc. The above process is repeated until an optimum size of the optic disc has been obtained. The Figure 2 shows the result of optic disc segmentation.

B. Hard Exudates detection

Hard exudates are considered to be bright intensity regions in the retinal images. It is found from the literature that the green layer contains the most information on the brightness and structure of exudates. The image is smoothed and elimination of Also fundus images are characterized by uneven illumination that is, the center region of a fundus image is usually highly illuminated while the illumination decreases closer to the edge of the fundus. In other words, objects of the fundus (lesions and blood vessels) are differently illuminated in different locations of the image due to the non-uniform illumination. Median filter is applied to the



(a) (b)

(c) (d)

Fig. 2 Detection of optic disc (a) Colour retinal image (b) - (c) optic disc detection phase (e) Detected optic disc marked by ellipse

retinal image and the filtered image is subtracted from original green channel image to eliminate intensity variation. Figure 3 shows intensity image in which lesion areas are properly highlighted. The darker background features and brighter lesion features can be clearly seen.

Fig. 3 Digital colour retinal image and Image after illumination correction

K means clustering technique have been used to automatically determine clusters without prior thresholds. The set of data within the cluster are more similar to each other the data from other clusters in the specific features. Each cluster has its own cluster center in the feature space. An important measurement of similarity for data is distance between cluster centers and between points inside one cluster. Here the distance measure is the difference in the intensity values between two pixels in the intensity difference image. Since we are interested in exudates and non exudates regions the number of clusters will be two. Exudates cluster will be located in the higher intensity range and background cluster in the lower intensity range. The maximum and minimum intensity levels in the intensity difference image calculated are termed as *min* and *max* respectively and

forms initial cluster centers. Intensity difference is taken as distance measure and it is used to find distance between pixels and initial cluster centers resulting in two clusters and the cluster centers are updated. The process is repeated iteratively there is not much variation in the values of cluster centers. Figure 4 shows the result of application of k means clustering method to the intensity image in Figure 3.

Fig. 4 Detected exudates

III. Results

The image data required for the research work is obtained from the "Lasers and Diagnostics", Department of Ophthalmology, Kasturba Medical College, Manipal. The colour fundus images are of dimension 768×576 pixels captured from Sony FF450IR digital fundus camera. Each fundus image comprises of a red, green, and blue grayscale image combined to form a three dimensional color image. The green plane was used in the algorithms due to the greater distribution of intensity through the image. The algorithm is evaluated against a carefully selected database of 100 color retinal images at different stages of diabetic retinopathy. Optic disc is located with the sensitivity of 92%. It failed in eight of the testing images, because of presence of large area of lesions around the optic disk. For the detection of hard exudates the optic disc is masked to avoid misclassification. The proposed clustering method detected the hard exudates with 86% sensitivity.

IV. Conclusion

The algorithms for the automatic and robust extraction of features in color retinal images were developed in this paper. Optimal iterative threshold method followed by connected component analysis is proposed to identify the optic disc. Clustering method was used for identifying hard exudates in a digital colour retinal image. The algorithm performed better on variety of input retinal images, which show the relative simplicity and robustness of the proposed algorithm. This is a first step toward the development of automated retinal analysis system and it is hoped that a fully automated system can detect the signs of diabetic retinopathy in the early stage, monitor the progression of disease, minimize the examination time and assist the ophthalmologist for a better treatment plan.

Acknowledgment

The authors would like to express their gratitude to the Department of Ophthalmology, Kasturba Medical College, Manipal for providing the necessary images and clinical details needed for the research work.

Abstract — **Ultraviolet rays have been widely used in providing antimicrobial environment in hospitals and also in certain sterilization procedures related to water treatment. The scope of the paper is to investigate the design of an ultraviolet sterilization unit developed to work in conjunction with a fluid dispenser for dispensing fluids in measured quantities periodically. Common problems associated with contamination of fluids in these dispensers have been carefully investigated to qualitatively document the requirements of the system. The most important part of this study has been focused on the qualitative assessment of the antimicrobial effects at various parts of the dispenser and also the variations of the antimicrobial effects at various depths of the fluid contained in the dispenser. We have designed a protocol to study the efficiency of the system and in order to have a real picture of the antimicrobial effects of ultraviolet radiation at various depths. To implement this protocol, we have designed an implantable array which is capable of containing microorganisms in sealed Petri dishes to be immersed in the fluid contained in the dispenser. Studies on the microbial growth conducted periodically under the influence of ultraviolet radiation of a known intensity provide a qualitative picture on the antimicrobial effects of ultraviolet rays at various depths. Thus it is possible to qualitatively analyze each sample for documenting antimicrobial effect. This study provides a good understanding on the intensity of the ultraviolet radiation required for providing a perfect antimicrobial environment and also other factors that are critical in the design of the system as a whole for dispensing fluids in biological applications.**

Keywords — **Ultraviolet rays, Antimicrobial effects, Fluid dispenser, Biological applications, Sterilization procedures**

I. Introduction

Purification and sterilization of water is considered important for all biological applications. Some of the conventional methods referred in practice are as briefly discussed [1]. Filtration of the water is considered very important before any sterilization procedures and a wide variety of filters are available for filtration of water. Filters remove sand, clay and other matter as well as organisms by means of a small pore size.

Filtration and sterilization is achieved by passing water usually through iodine exchange resins. In this method, when negatively charged contaminants contact the iodine resin, iodine is instantly released and kills the microorganisms without large quantities of iodine being in the solution. Boiling water is considered the most reliable and often the cheapest. Ideally, boiling the water for 5 minutes is considered safe in killing the microorganisms [2]. Alternatively, sterilization using chlorine and silver-based tablets can destroy most bacteria's when used correctly, but these are less effective for viruses and cysts.

In recent years, the ultraviolet (UV) sterilization is gaining popularity as a reliable sterilization method and is environmental-friendly too [1]. UV disinfection technology is of growing interest in the water industry since it was demonstrated that UV radiation is very effective against certain pathogenic micro-organisms of importance for the safety of drinking water [3]. In most of the sterilization equipments, the light source is a low-pressure mercury lamp emitting UV in the wavelength of 253.7 nm and this source is referred to as UVC [4]. Ultraviolet rays have been a known mutagen at the cellular level and it is used in a variety of applications, such as food, air and water purification.

II. Ultraviolet rays in sterilization

A. Germicidal Mechanisms of Ultraviolet Rays

The germicidal mechanism of UVC light has the ability to alter deoxyribonucleic acid (DNA) code, which, in turn, disrupts an organism's ability to replicate [5]. Absorption of UV energy by nuclei in DNA is primary lethal mechanism for the destruction of microorganisms. The antimicrobial effect is dependent on both the time of exposure and the intensity of the UVC ray. However, the UVC sterilization will not be effective if the bacterial or mold spores are hidden or not in the direct path of the rays. Organisms that are large enough to be seen are usually too resistant to be killed by practical UVC exposure. The radiation dose of UVC energy is measured in microwatts per centimeter square

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 280–283, 2009
www.springerlink.com

(μW/cm²). With the known wavelength of 253.7nm, it has been found that intensities from 2500 μW/cm to 26,400μW/cm² are effective against various bacterial organisms. For mold spores, intensities ranging from 11,000μW/cm² to 220,000μW/cm² are effective. Though most of common viruses, such as influenza, poliovirus and viruses of infectious hepatitis, are susceptible to intensities less than 10,000μW/cm², some of the viruses such as tobacco mosaic virus seen in plants are susceptible to UVC rays at very high intensity (440,000μW/cm²) [6].

B. Sterilization in Hospitals and Clinics

UVC rays are very widely used in sterilization procedures in hospital and clinics. UVC light (100-280 nm) has been reported to be very effective in decontamination of hospital-related surfaces, such as unpainted/painted aluminum (bed railings), stainless steel (operating tables), and scrubs (laboratory coats) [7]. It has been reported that UVC lighting is an alternative to laminar airflow in the operating room and that it may be an effective way for lowering the number of environmental bacteria. It is also believed that this method can possibly lower the infection rates by killing the bacteria in the environment rather than simply reducing the number at the operative site [8]. As infections represent a major problem in dialysis treatment, dialyzing rooms need be kept antibacterial to the extent possible. It has been reported that 15-watt UVC lamps installed for every 13.5m² on the ceiling for the purpose of the room disinfection used for 16 hours nightly after working hours provide an antimicrobial environment even in areas which were not directly exposed to the UVC radiations [9].

C. Sterilization in Water Purification System

Transmission of pathogens through drinking water is a well-known problem, which affects highly industrialized countries and also countries with low hygienic standards. Chlorination of drinking water was introduced to the water supply in the beginning of the 19th century in order to stop the spreading of pathogens. Disinfection of drinking water with chlorine has undoubtedly contributed to the reduction of typhoid fever mortality in many countries. Despite the worldwide use of chlorine for disinfection of drinking water, other safe methods of disinfection had gained popularity [10]. Ultraviolet disinfection technology is of growing interest in the water industry ever since it was found very effective against common pathogenic micro-organisms in water [3]. Ultraviolet disinfection systems are commonly incorporated into drinking water production facilities because of their broad-spectrum antimicrobial capabilities, and the minimal disinfection by-product formation that generally accompanies their use [11].

D. Ultraviolet Sterilization for Clinical Applications

Filtered water free from microorganisms and chemicals disinfectants is an absolute requirement for the preparation of solutions for certain biological applications in medicine. The process of reverse osmosis is an invaluable technology to provide filtered water free from pathogens. Since water filtered through the process of reverse osmosis is free from chemical disinfectants, it serves as the ideal solvent for the preparation of biochemical solutions used in biological applications. This paper will discuss briefly the various parts of the ultraviolet sterilization system developed for providing the solvent required for preparation of biochemical solutions used in biological applications.

III. Architecture of the System

The architecture of the system essentially consist of ultraviolet radiation chamber, fluid dispensing chamber, embedded adjustable profile, fluid inlet and outlet system and a microcontroller module. The block diagram of the architecture is shown below.

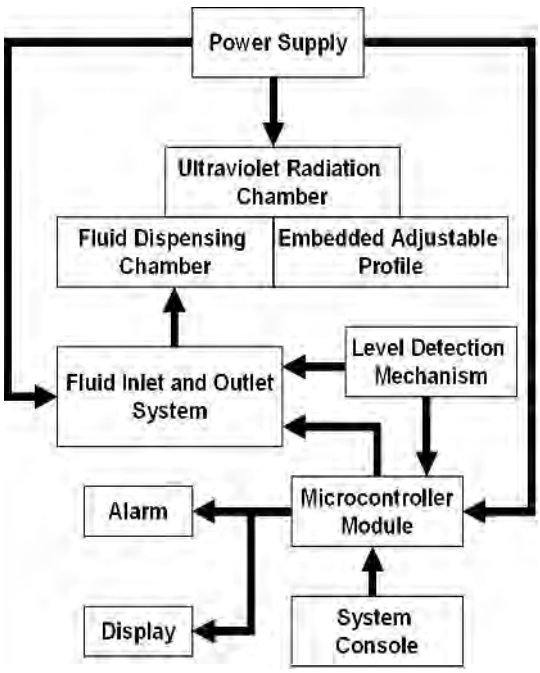

Fig. 1 Block Diagram of the Architecture

A. Ultraviolet Radiation Chamber

In order to provide an antimicrobial environment in the chamber, an ultraviolet radiation chamber was built. The ultraviolet radiation chamber has two ultraviolet lamps installed to provide maximal sterilization throughout the whole fluid dispensing chamber. The ultraviolet radiation module used in our system is shown in Fig. 2.

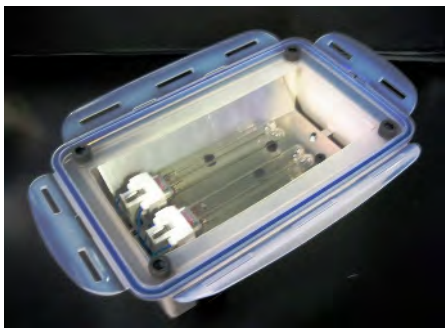

Fig. 2 Ultraviolet Radiation Module

B. Fluid Dispensing Chamber

The material used for building the chamber has to be a medically approved material for biological applications. Medical grade stainless steel and food-grade polyethylene often meet the requirements. In our preliminary studies, we have made use of food-grade polyethylene to build the fluid dispensing chamber. This chamber has been designed to hold the measured volume of fluid stored for dispensing which is eventually used to prepare biochemical solution for the biological applications.

C. Embedded Adjustable Profile

Qualitative studies had been made using the embedded adjustable profile capable of holding the sealed Petri dishes at various positions in the fluid dispensing chamber.

Fig. 3 Adjustable Profile in Chamber

This adjustable profile had been indigenously fabricated in such a way that it could be well accommodated within the chamber. The embedded adjustable profile along with the fluid dispensing chamber is shown in Fig. 3.

D. Fluid Inlet and Outlet System

The system is installed with two solenoid pinch valves that controlled the filling and dispensing of the fluid into and also out of the fluid dispensing chamber. Volume of the fluid is measured precisely by the level detection mechanism. A microcontroller module interfaces a level detection module to control the fluid inlet and outlet system.

E. Microcontroller Module

The architecture is built around PIC18F4520 microcontroller containing five ports. The ports are configured to support some of the modules such as display interface, keyboard interface, activation of the pinch valves and the level detection mechanism. The implementation of the microcontroller allows integration of the different modules of the system.

IV. Qualitative Studies on Ultraviolet Irradiation

The object of this study is to qualitatively evaluate the antimicrobial effects of the UV radiation. In order to assess the effects, we have constructed the adjustable profile capable of holding the sealed Petri dishes at various positions in the fluid dispensing chamber. The sealed Petri dishes within the chamber contain the required environment for bacterial growth. In our studies, we have used Lysogeny broth (LB) agar for the bacteria to multiply and we have conducted studies using this medium extensively. With the help of this set-up, it was possible to conduct studies on the bacterial colonies after exposure to UV radiations at various positions inside the fluid dispensing chamber. Studies were conducted for various exposure durations to assess the antimicrobial effects of UV radiations on the bacterial colonies positioned at various levels of the fluid dispensing chamber.

V. Results and Discussion

Preliminary studies of ultraviolet radiations had clearly demonstrated the effects of ultraviolet on the bacterial colonies at various depths within the fluid dispensing chamber. These studies have provided a clear picture on the effects of the ultraviolet rays of a known intensity and its capability to provide an antimicrobial environment deep inside the fluid

dispensing chamber. Fig. 4 shows the growth of the bacterial without ultraviolet radiation in an incubator retained as a control for our studies. Fig. 5 shows the absence of bacterial growth in the agar medium after exposure. The Petri dish was maintained within the fluid dispensing chamber at level two, which is approximately the middle portion of the chamber. Fig. 6 shows the absence of bacterial growth in the agar medium after exposure. The Petri dish was maintained within the fluid dispensing chamber at level three, which is approximately the bottom portion of the chamber.

Fig. 4 Control Petri Dish

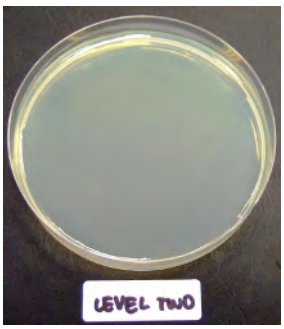

Fig. 5 Petri Dish at Level Two

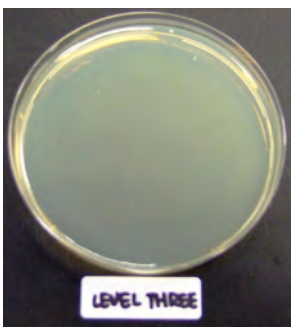

Fig. 6 Petri Dish at Level Three

VI. Conclusion

Preliminary studies conducted on the newly developed Ultraviolet Sterilization System have demonstrated the antimicrobial effects of the ultraviolet radiations as seen in Fig. 5 and Fig. 6. Theses studies were conducted with E.Coli bacterial strains to qualitatively document the antimicrobial effects of UVC at various depths. This system was built indigenously for providing a measured quantity of solvent for the preparation of biochemical solution for certain biological applications.

From e-health to Personalised Medicine

N. Pangher

ITALTBS SpA, Trieste,Italy

Abstract — **The research agenda of the TBS group is aiming at offering a complete solution for the management of molecular medicine in the standard care environment. The impact of the different –omics (genomics, proteomics, metabolomics,….) is already representing a very important part of the research effort in medicine and is expected to modify dramatically the model of delivery of healthcare service. The TBS group is facing this challenge through a R&D effort in order to transform its Clinical Information System into a complete suite for the management of clinical research and care pathways, supporting a completely personalised approach. The IT suite allows research to integrate the Electronic Clinical Records with data from technologies such as DNA and protein microarrays, data from diagnostic and molecular imaging, and workflow management solution. In this paper we will discuss the results from the participation to different European and national research projects, sharing this development aim. We provided the IT integration suite for projects for the identification of therapy-relevant mutations of tumor suppressor genes in colon cancer (MATCH EU project), for the genetic base for the impact of metabolic diseases on cardiovascular risk (MULTIKNOWLEDGE EU project) and for the identification of biomarkers for Parkinson disease (SYMPAR project in Italy).**

Keywords — **Bioinformatics, e-health, personalized medicine, Electronic Medical Records, health risk profiles.**

I. Introduction

The mantra in healthcare services in the past years has been quality through formalization and standardization of processes. Accreditation, Evidence Based Medicine, Best practices, Risk management: processes are described, guidelines established, outcomes defined as targets. The quality revolution has become the daily bread for most industrial sectors: we expect fully functional products wherever we obtain them and services that are effective independent of the particular person involved. At the same level we pretend from our healthcare provider to deliver the best possible service independent of the location and the professional that are treating us: the great effort towards a standardization of the quality of healthcare is not yet completed, but we are facing a changing scenario. The impact of molecular medicine is going to impact dramatically on the service delivery models: personalization of treatment will have a strong scientific background. Treatment will be based on our molecular make up: genomics, transcriptomics, proteomics, metabolomics will become the tools of the day. Advanced diagnostic will result not only in a more tailored treatment, but will allow the identification of risk profiles that will be essential to design improved prevention protocols, aiming at remaining healthy and not only cure or manage diseases. The personalization of the treatment process will also be based on the availability of new tissues and organs that will be obtained through the most advanced applications of tissue engineering: regenerative medicine, based on extensive exploitation of stem cells, will allow the repair and substitution of defective organs. But again the compatibility of the new tissues and organs will have to be tailored to the characteristics of the single human being, Engineered stem cells will be used to set up tissue banks: the patient himself will be one of the sources of these new tissues.

While we have still not achieved the target of the standardization of healthcare services, a discontinuity in the complexity of healthcare is appearing: good quality healthcare will require a very personalized approach, starting from diagnostic systems based on "-omics" analysis and molecular imaging through targeted drugs, new compatible tissues and organs, gene therapy and drug delivery solutions. Prevention will be based not only on more general rules, but will also depend on our actual predisposition to diseases.

This trend is impacting the development of IT solutions for the healthcare sector: workflow systems allowing supporting healthcare processes are not widely available and suddenly IT systems will have to abandon a "few sizes fit all" approach to present solutions systems that will allow the setting up of prevention , treatment and disease management processes ecompassing all kind of environments, data sources and knowledge basis. IT solution will have to allow continuity of prevention and care, collecting data from different sources ranging from home-based monitors to sequencing technologies to PET scanners. Treatment options should range from diet and exercise prescriptions to the design of viral vectors for gene therapies to the production of stem cells for organ replacement.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 284–286, 2009
www.springerlink.com

II. Research strategy

A. The Match Project

The MATCH project entitled the development of an automatic diagnosis system that aimed to support treatment of colon cancer diseases by discovering mutations that occurs to tumour suppressor genes (TSGs) and contributes to the development of cancerous tumours. The colon cancer automated diagnosis system is a computer based platform that addresses doctors, biologists, cancer researchers and pharmaceutical companies. The project goal was to perform medical integration between medicine and molecular biology by developing a framework where colon cancer diseases will be efficiently handled. Through this integration real time conclusion can be drawn for early diagnosis and more effective colon cancer treatment. The constitution of the system is based on a) colon cancer clinical data and b) biological information that will be derived by data mining techniques from genomic and proteomic sources.

B. The Multiknowledge Project

MULTI-KNOWLEDGE starts from the data processing needs of a network of Medical Research Centres, in Europe and USA, Partners in the Project and co-operating in researches related to the link between metabolic diseases and cardiovascular risks. These needs are mostly related to the integration of three main sources of information: clinical data (EHR), patient-specific genomic and proteomic data (in particular data produced through Micro-arrays technology), and demographic data.

MULTI-KNOWLEDGE has created an intelligent workflow environment for multi-national multiprofessional research consortia aiming at cooperatively mining, modelling, visualizing biomedical data under a single common perspective.

This will allow retrieval and analysis of millions of data through bio-informatics tools, with the intent of improving medical knowledge discovery and understanding through integration of biomedical information.

Critical and difficult issues addressed are the management of data that are heterogeneous in nature (continuous and categorical, with different order of magnitude, different degree of precision, etc.), origin (statistical programs, manual introduction from an operator, etc.), and coming from different data achieving environments (from the clinical setting to the molecular biology lab). The MULTI-KNOWLEDGE architecture and set of tools have been tested for the development of a structured system to integrate data in a single informative system committed to cardiovascular risk assessment. Therefore this project will also contribute to establish guidelines and operating procedures to manage and combine data coming from protein arrays and make them easily available for the imputation of study algorithms.

C. The Sympar Project

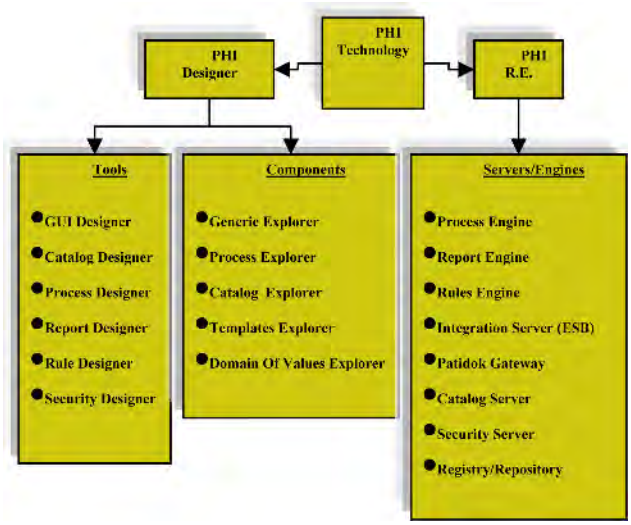
The target of the project is to develop an informatic system for research in the biomarkers and treatment of Parkinson's Disease (PD), the second most common progressive neurodegenerative disorder in western countries.

We are testing how an integrated IT solution can support researchers in identifying molecular biomarkers of the disease. These biomarkers will be used for early diagnosis in pre-symptomatic individuals and to follow at the molecular level the response to old and new therapies.

Our IT solution is based on the following elements:

1) A data repository where all data relevant to patient health are stored. Data will consist on routine medical records, brain-imaging data, filmed records of behavioural assessments, gene expression profiles from peripheral tissue.
2) A workflow engine: medical and research procedures should be standardized. The IT system should support users in collecting medical data and in following laboratory protocols. The system should help the user both in identifying and classifying patients, and in activating medical and research procedures.
3) An access to the external knowledge base: a unique interface to access literature, external scientific databases, specialised healthcare resources.

III. The toolbox



During the development of these different solutions,, we have identified the need to set up a unique toolbox to develop IT solutions addressing the needs of biomedical research and healthcare services tackling the issues of a the need of integrating different knowledge sources, biomedical instruments and personalised treatment options. We have realised this toolbox baptized PHI technology.

PHI Technology is divided in two separate parts called PHI Designer and PHI Runtime Environment (PHI RE). The PHI Designer is used to generate healthcare applications named PHI Solutions, deployed and executed upon the PHI RE runtime environment.

PHI Designer and PHI RE share a common Reference Information Model (PHI RIM), fully extensible and customizable, derived from the international standard HL7 RIM (www.hl7.org). PHI RIM stores the metadata catalog, de-

scribing objects' attributes, services, events, vocabularies and ontologies. Applications, named "solutions", are designed and executed upon the RIM.

The physical database (PHI RIM DB) is invisible to designers and applications; its conceptual and physical model is derived from the RIM, that makes it an open database, based on the most popular international healthcare standard. Its mixture of Entity-Relationship and Entity-Attribute-Value physical structures makes it extremely flexible and performing.

The PHI Designer is intended to assist you with developing easy to use and intuitive reusable applications for your daily work with information. Finally, the PHI Technology provides you with a runtime environment independent from underlying operating systems, named PHI RE, based on J2EE (Java 2 Enterprise Edition) and open standards, where you can deploy your applications once you have designed them with the PHI Designer. Servers and Engines can be seen as being nearly synonyms.

The main purpose of the PHI RE is to enable the applications exchange and reusability among partners and customers, making it as easy as a plug-and-play setup.

PHI RE is mainly composed by Servers and Engines, which are, finally, J2EE components developed in JBoss SEAM framework, which are deployed in JBOSS Application Server.

Both PHI Designer and PHI RE are reliable and scalable: you can install the whole PHI Technology either on a personal computer or in a network of distributed servers, in single node configuration as well as in a cluster configuration for high availability.

IV. Conclusions

The need of IT solutions for the management of biomedical research and personalized medicine tretments will be a major issue: these tools will b enecessary to navigate in the sea of informationa dn find the correct personalize route.

Quantitative Biological Models as Dynamic, User-Generated Online Content

J.R. Lawson, C.M. Lloyd, T. Yu and P.F. Nielsen

Auckland Bioengineering Institute, The University of Auckland, Auckland, New Zealand

Abstract — **Quantitative models of biological systems are dynamic entities, with modelers continually tweaking parameters and equations as new data becomes available. This dynamic quality is not well represented in the current framework of peer-reviewed publications, as modelers are required to take a 'one-dimensional snapshot' of their model in a particular state of development.**

The CellML team is developing new software for the CellML Model Repository that treats models as dynamic code, by providing server-side storage of models within a version control system, rather than as static entities within a relational database. Version control systems are designed to allow a community to collaborate on the same code in parallel and to provide comprehensive revision histories for every file within the repository.

Because CellML 1.1 espouses a modular architecture for model description, it is possible to create a library of modular components corresponding to particular biological processes or entities, which can then be combined to create more complex models. For this to be possible, each component needs to be annotated with a set of metadata that describes its provenance, a detailed revision history and semantic information from ontologies. A high level of collaboration is also essential to leverage domain-specific knowledge about the components of a large model from a number of researchers.

By treating quantitative biological models as dynamic, user-generated content, and providing facilities for the expert modeling community to participate in the creation and curation of a free, open-access model repository, the the next-generation CellML Model Repository will provide a powerful tool for collaboration and will revolutionise the way cellular models are developed, used, reused and integrated into larger systems.

Keywords — **databases, e-science, CellML, quantitative modeling**

I. Introduction

Quantitative models of biological systems are dynamic entities, with modelers continually tweaking parameters and equations as new data becomes available. This dynamic quality is not well represented in the current framework of peer-reviewed publications, as modelers are required to take a 'one-dimensional snapshot' of their model in a particular state of development.

The glut of data about biological systems can present a challenge to the ability of individual researchers or groups to manage and utilize their knowledge of these systems. One solution to this challenge is to encode this information into structured systems of knowledge, and the resulting models are rapidly becoming integral to many fields of biology. The sheer volume and rate of production of new data is stressing the traditional scientific publication process because it cannot keep up [1], and because the print medium is simply not appropriate in many cases. The internet must be leveraged to disseminate data as it is collected and incorporated into models, and to facilitate the mass collaborative initiatives required to merge these models into ever larger, more complex systems.

II. Limitations of the Conventional Scientific Publishing System

The ability of researchers to describe a quantitative biological model within a conventional printed academic publication is limited. As these models become more complex and detailed, this limitation has begun to hamper the ability of other researchers to work with these models. At best, this issue limits the critical second stage of peer-review: reproduction of experiments described in publications by the scientific community. If a model cannot be easily reproduced because it is inadequately described in the literature, not only is its validity questioned, but a barrier is created to the construction of complex models of biological systems, which are commonly built by combining smaller models. The greater levels of transparency required by this field of research will be difficult to provide by merely extending print-based the publication model. At present, publications that discuss quantitative models take can take one of several forms:

- Model equations and parameters are often interspersed throughout the paper, with salient discussions on each. This format can be frustrating to researchers attempting to reproduce a model, as the primary emphasis is often on the commentary describing why particular values were chosen or how equations were derived, rather than providing a complete description. Furthermore, descriptions of these models are frequently missing important parameters and initial conditions.
- Supplemental datasheets published with the article define the model by listing equations and parameters. This information provides a more concise, and often

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 287–290, 2009
www.springerlink.com

more complete, description of the model, although typographical errors still present a persistent barrier to model reproduction.

- Alternatively, the predictions and outputs of a model are simply discussed, without any real attention to how the model is constructed. These articles tend to be reviews or short format publications in journals such as *Science.* This approach is sometimes extended by providing links to the author's website, which either elaborates in the form of a listing of equations and parameters, or provides a download of the original model code. Providing 'external supplemental data' can be useful, but again, typographical errors can be an issue. This can be quite effective, although the fact that the model is not officially part of the publication, and thus not subject to the same oversight and peer review, gives no guarantee that the available model is the identical to the one used to produce the outputs shown and discussed in the publication. Making model code available in a widely accepted and utilised language such as MATLAB is helpful, but more often the model code is only available in obscure formats specific to small, in-house software packages developed by the authors or their colleagues.
- Some publishing groups, such as PLoS, Nature and BMC are actively moving towards requiring model authors to deposit a copy of their model in an open-access, recognised, online repository, in the same manner that most journals now require authors to deposit novel DNA sequence information or protein structures in a database (such as GenBank [2] or PDB [3], respectively) as a prerequisite to publication. This is an ideal solution to removing the barriers to transparency and reproduction presented above, but it involves a significant shift in the scientific publishing paradigm that has existed to date.

III. Storing models in online version control systems

CellML [4] is an XML-based format designed to allow description of quantitative models based on ordinary differential equations and systems of differential algebraic equations and to facilitate wide dissemination and reuse of these models. The CellML Model Repository [5] is an online resource that provides free, open access to CellML models. Currently Physiome Model Repository (PMR) software underlying this repository allows limited interaction with the models it stores; they can be associated with documentation and metadata and or organized thin a primitive versioning system.

The CellML team is developing new software (PMR2) for the CellML Model Repository that dispenses with the concept of quantitative biological models as static snapshots of knowledge and treats them as dynamic, software-like entities by providing server-side storage of models within a Mercurial, distributed version control system (DVCS). DVCS are designed to allow a community to collaborate on the same code in parallel and to provide comprehensive revision histories for every file within the repository. This concept of model development is drawn from the open source software development. Programmers are able to build large systems by drawing on libraries of pre-existing code, and online communities such as Sourceforge form around these efforts to discuss implementation.

Comprehensive revision histories which define provenance and the rationale of each and every addition to and modification of a piece of code are fundamental to any open source initiative because information about who did what and when provides the foundation for collaboration. PMR2 can support the signing of changesets with cryptographic signatures using the GPG plugin provided by Mercurial, ensuring the integrity of the information within and proper attribution to the author who signed the changeset. Changing the data without breaking the checksum and signature is extremely difficult without the original signature key that was used to sign the model.

Storing models within a DVCS allows collaborative software development methods to be used in model construction: rollbacks, branching, merging of branches and parallel revisions to the same code are all possible. Powerful access control systems can also be implemented to allow modelers to control who is able to see and interact with their work.

The PMR2 software and associated systems for online publishing are described in detail by Yu et al. [6]

IV. Modularity and model reuse

Complex systems in engineering are almost always constructed as hierarchical systems of modular components [7]. Such modularity can be seen in human engineered systems but also in biology [8]. Models should be designed with reuse in mind and implemented in formats which facilitate their combination into the kinds of hierarchical systems familiar to engineers.

Such methodology leverages ‘black-box’ abstraction and allows for separation of concerns. For example, a disparate group of researchers may be collaborating on the construction of a system: one may be responsible for organizing the top level hierarchy, while others may be responsible for lower level subcomponents or hierarchies. If the compo-

nents of the system are constructed in a sufficiently modular fashion, the researcher organizing the hierarchy needs to know very little about how they actually work – only their input and output. Terkildsen et al. [9] demonstrate this in a recent article discussing their use of the CellML standard to integrate multiple models, [10,11,12] each describing discrete but interrelated systems within a rat cardiac myocyte; the result was a model of excitation-contraction coupling. Similarly, descriptions of systems involving multiple cell types can be created from pre-existing models. Sachse et al. [13] recently used a model of the interaction between cardiac myocytes and fibroblasts as a platform to develop and number of novel hypotheses about the role of fibroblasts in cellular electric coupling within the heart. The model of the cardiac myocyte used in this work was a curated, (but unpublished through official channels,) form of the influential Pandit 2001 model [10], downloaded from the CellML Model Repository.

Because CellML 1.1 espouses a modular architecture for model description, it is possible to create a library of modular components corresponding to particular biological processes or entities, which can then be combined to create more complex models [14]. For this to be possible, each component needs to be annotated with a set of metadata that describes its provenance, a detailed revision history and semantic information from ontologies. A high level of collaboration is also essential to leverage domain-specific knowledge about the components of a large model from a number of researchers.

The CellML project seeks to provide the tools and infrastructure for both creating these libraries of components and disseminating them over the internet. PMR2 will provide a framework for users to reuse, review and modify pre-existing components, create new components, to collaborate securely and privately with any number of other users and to rapidly share and their work public. Methods for composing models from such libraries of components and practical applications of such have been described in the literature [15] and best practice approaches are beginning to be developed [16]. Further, the requirement within the synthetic biology community for a library of 'virtual parts' representing Standard Biological Parts [17], or 'Biobricks' which can be slotted together and simulated for rapid prototyping has been voiced repeatedly [18].

Implementing models as dynamic, online content opens up possibilities for programmatic interaction and processing, which represents a considerable development in the field of computational biology. The BioCoDa [19] project is working to create libraries of CellML models of biochemical reactions which source parameter values from databases that hold kinetic parameters. This will allow these models to dynamically update themselves as new information becomes available in the database. Description Logics [20] can be used to define rules to impose constraints on models to assure their biological validity. Assertions may be made about how particular processes act or how entities are related in a biological system; if a model violates these assertions it can be denoted as biologically invalid. In concert with comprehensive ontologies describing biological systems, these rules can also be used to automate the model building process. A modeler might define what parts of a system he wants to represent and where to draw the information from. This model could then be simulated and the results checked against databases containing wetlab experimental data about how the system should behave. Key to these possibilities is the digital representation and hyperaccessible nature of CellML models.

V. The Role of Online Communities

The possibilities presented by internet-based scientific collaboration do not end at simply building models: linking elements of models to online content through metadata promises to do for descriptions of biological systems what hyperlinking has done for basic text. For example, curation is essential to the integrity of any large repository of information. This is currently done primarily by small groups of highly skilled experts, but the job of curating every single entry in a repository or database is beginning to overwhelm curators of large datasets. This suggests a new job for current curation experts as 'meta-curators,' checking the validity of curation done by the community. A number of recent initiatives, such as the WikiPathways [21] and GeneWiki [22] projects, are taking such an approach to the challenging of organizing large datasets. Academic analysis has revealed that the community-sourced 'anyone-can-edit' Wikipedia online encyclopedia is in fact as trustworthy as Encyclopedia Brittannica; the Wikipedia system also involves a small group of 'Wikipedians' who take an active role in cleaning up and standardizing public contributions [23]. While the formal scientific review and publication process will likely remain in place for some time to come, many elements of peer review are amenable to online fora. Additionally, annotation with quality community-generated commentary and analysis can add significant value to a piece of research.

VI. Conclusions

The rise of 21st century communications technologies is profoundly affecting the way the science of quantitative computational biology is practiced through digitization,

decentralization and democratization. By treating quantitative biological models as dynamic, user-generated content, and providing facilities for the expert modeling community to participate in the creation and curation of a free, open-access model repository, the next-generation CellML Model Repository will provide a powerful tool for collaboration and will revolutionize the way cellular models are developed, used, reused and integrated into larger systems.

Development of Soft Tissue Stiffness Measuring Device for Minimally Invasive Surgery by using Sensing Cum Actuating Method

M.-S. Ju[1], H.-M. Vong[1], C.-C.K. Lin[2] and S.-F. Ling[3]

[1] Dept. of Mechanical Engineering, National Cheng Kung University, Taiwan
[2]Dept. of Neurology, Medical Center, National Cheng Kung University, Taiwan
[3]School of Mechanical & Aerospace Engineering, Nanyang Technological University, Singapore

Abstract — **Surgeon's perception of palpation is limited in a minimally invasive surgery so devices for *in situ* quantification of soft tissue stiffness are necessary. A PZT-driven miniaturized cantilever served as actuator and sensor simultaneously was developed. By using the sensing cum actuating method, the mechanical impedance functions of soft tissues can be measured. Bioviscoelastic materials silicone rubber and dissected porcine livers under room temperature or in frozen state were utilized to test the performance of the device. The frozen porcine liver was employed to simulate liver cirrhosis. The results showed that the dissipative modulus around the resonant frequency might be utilized to quantify the stiffness of the cancerous and normal liver structure. The application of the device to robot-assisted surgery was discussed.**

Keywords — **Soft tissue stiffness, sensing-cum-actuating, minimally invasive surgery, mechanical impedance, electrical impedance.**

I. Introduction

Minimally invasive surgery (**MIS**), also known as endoscopic surgery, is a new and popular surgical operation. Surgical equipments such as endoscope, grasper and blade can be inserted through small incisions rather than making a large incision to provide access to the operation site. Distinct advantages of this technique are: reduction of trauma, milder inflammation, reduced postoperative pain and fast recovery. However, reduced dexterity, restricted field of vision and lack of tactile feedback are main drawbacks of MIS. Liver cirrhosis is one of the most deadly diseases in Taiwan. Surgeons usually rely on palpation to assess the boundary of abnormality of liver tissues during surgery. However, this information is no longer available in MIS. It is believed that in-situ estimation of soft tissue's mechanical property may improve quality of MIS such as image-guided laparoscopic liver operation.

Recently, new techniques and instruments have been appeared for *in-vivo* determination of tissue properties. Dynamic testing methods such as indentation probes [1], compression techniques [2], rotary shear applicators [3] or aspiration [4] have been developed. However, all these methods need at least an actuator and a sensor to measure the dynamic response, i.e. applying force or torque and measuring displacement or velocity of the tissue simultaneously. The requirement makes the miniaturization of theses testing systems a challenge technical problem. Recently, Ling et al. [5] propose a new dynamic testing method- sensing cum actuating(SCA) in which the mechanical impedance of soft viscoelastic materials can be measured by detecting input electrical current and voltage of an activated electro-mechanical actuator without employing any traditional force and displacement sensors.

The goals of this study were three-folds: First was to develop a PZT-based miniaturized stiffness measuring device based on SCA method. Second was to test the system on biomaterials and in vitro tests of porcine livers. Third was to develop a method for quantify stiffness of liver from their electrical and mechanical impedances. Feasibility of the method for MIS of liver will be discussed.

II. Methods

Fig. 1 shows the PZT-based soft tissue measurement system designed in this work. The outer diameter of the pen holder was 10mm and the PZT- coated cantilever and the ring base were machined from a brass cylinder to avoid the fracture at the root of the cantilever. Dimension of the brass cantilever was 6.5mm × 2.0mm × 0.1mm and 5.0mm × 2.0mm × 0.2mm for the PZT. The height of stinger was 3mm to prevent direct contact between cantilever surface and specimen.

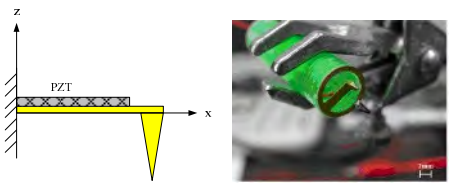

Fig.1 Schematic diagram of the PZT-coated cantilever (left) and the assembly of the pen-like soft tissue measurement device (right)

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 291–295, 2009
www.springerlink.com

The experimental setup shown in Fig. 2 consisted of a function generator to provide swept sinusoidal signals to the power amplifier to drive the PZT and a current amplifier to measure the potential induced from the direct piezoelectric effect. The potential, E, and current, I, were acquired simultaneously into the PC and real-time fast Fourier transforms were performed and the electrical impedance, $Z_e(\omega)=E(j\omega)/I(j\omega)$, $j=\sqrt{-1}$ was computed.

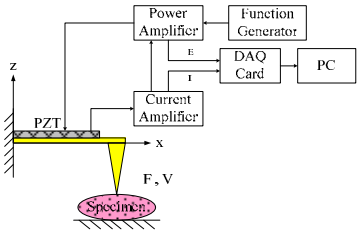

Fig. 2 Experimental setup of the soft tissue stiffness measurement system

From the two-port model (Fig. 3) of the system relationship between the input port (electrical) variables and the output port (mechanical) variables was given by:

$$\begin{bmatrix} E(j\omega) \\ I(j\omega) \end{bmatrix} = \begin{bmatrix} t_{11}(j\omega) & t_{12}(j\omega) \\ t_{21}(j\omega) & t_{22}(j\omega) \end{bmatrix} \begin{bmatrix} F(j\omega) \\ V(j\omega) \end{bmatrix} \tag{1}$$

where t_{ij}, i,j = 1, 2 were elements of the transduction matrix, $\mathbf{T}(j\omega)$, of the system and $F(j\omega)$ and $V(j\omega)$ were Fourier transform of the force and velocity at the output port. If $\mathbf{T}(j\omega)$ and $Z_e(j\omega)$ were known, the mechanical impedance, defined as $Z_m(j\omega)=F(j\omega)/V(j\omega)$ of the biological specimen at the contact point could be computed as

$$Z_m(j\omega) = \frac{F}{V} = \frac{t_{22}Z_e - t_{12}}{t_{11} - t_{21}Z_e} \tag{2}$$

To determine elements of the matrix **T** one could mechanically constrain the output port of the device to obtain the first column or free it to obtain the second column. The other approach was to add different masses on the stinger and solve a linear algebraic equation. In this study, due to the miniaturization, it was difficult to calibrate the transduction matrix experimentally. An alternative method suggested in [6] was employed in which finite element simulations were adopted. After the transduction matrix was calibrated, the mechanical impedance, Z_m, could be estimated. If no internal energy was generated or dissipated in the system the determinant of the matrix **T** should be unity.

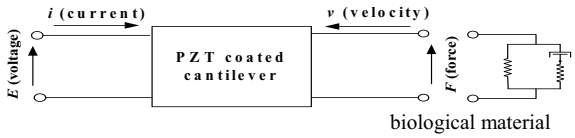

Fig. 3 Two-port model of the sensing-cum-actuating measurement system

All the finite element analyses were performed by using software package ANSYS. First, modal analysis of the PZT-coated cantilever was performed and next harmonic analyses of the PZT-coated cantilever were conducted to obtain the frequency response of the system. For simplification, the stinger was modeled as an equivalent rectangle mass. Element Solid 5 was used to model the PZT layer and element Solid 45 for modeling the brass cantilever and adhesive layer (Loctite-3880). The material properties of the probe can be found in [8]. Fig. 4 showed the finite element mesh of the composite cantilever beam. After a convergent test, the element size was set to 0.13mm and the output port was located at 6mm from the clamped end. Two simulations were performed to obtain the transduction matrix. In the first case, a spring with a spring constant of 1,000 N/m was connected to the stinger and the frequency response functions E_1, I_1, F_1, V_1, were computed from the harmonic analysis. In the second case, the spring constant was changed to 5,000 N/m and the corresponding frequency response functions were: E_2, I_2, F_2, V_2. The transduction matrix T can then be calculated by:

$$\mathbf{T} = \begin{bmatrix} \dfrac{E_1V_2 - E_2V_1}{F_1V_2 - F_2V_1} & \dfrac{E_1F_2 - E_2F_1}{F_2V_1 - F_1V_2} \\ \dfrac{I_1V_2 - I_2V_1}{F_1V_2 - F_2V_1} & \dfrac{I_1F_2 - I_2F_1}{F_2V_1 - F_1V_2} \end{bmatrix} \tag{3}$$

In the experiments, four specimens were utilized to evaluate the applicability of the soft tissue stiffness measurement system. There were two silicon gels (SC-725, PDMS) and two biological soft tissues (fresh and frozen porcine liver unfrozen for 20 minutes at room temperature) To simulate the application of the stiffness measurement system in robotic assisted surgery or traditional surgery, the porcine liver was measured by either holding the device by hand or by clamped on a fixture. The driving signal for PZT was swept sinusoidal with frequency ranged from 10Hz to 3.0 kHz and amplitude of 40 Volts. The initial indentation depth was set at 1 mm. Each sample was tested for five trials and the mean electrical impedances are computed. Then the mechanical impedance was computed by using the transduction matrix obtained from the aforementioned FEM simulations. The frozen porcine liver was employed to simulate cirrhotic liver tissyes.

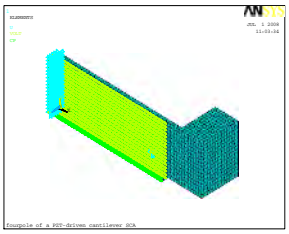

Fig. 4 Finite element model of the PZT-coated cantilever

III. Results

The measured electrical impedances of the four specimens, from fixture clamped test, were compared in Fig. 5. Within 10 Hz to 2 kHz (not shown), the difference between specimens was insignificant but around 2,250 Hz, except PDMS, there were resonant frequencies (valley) for SC-725, normal liver and frozen liver. PDMS was so stiff that no resonant frequency can be found. There was a local maximum higher than the resonant frequency. The difference between the local maximum and the resonant was defined as the peak-to-peak value of electrical impedance. The mean peak-to-peak values of SC-725, normal liver and frozen liver were: 0.478×10^4, 1.391×10^4 and 0.132×10^4 Ω respectively. The peak-to-peak value increased with the compliance of specimens.

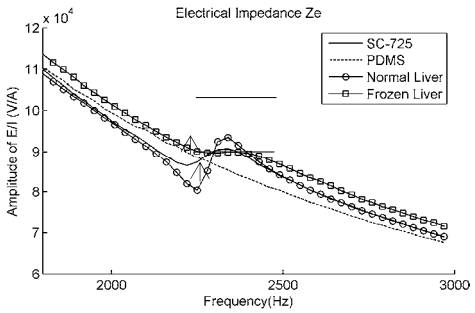

Fig. 5 Comparison of specimen electrical impedances, resonant frequency of each sample indicated by arrow and peak-to-peak value of normal liver is defined

In Fig. 6 the effects of holding the device on electrical impedance were compared. The peak-to-peak values of the hand-held tested samples were less than those of the clamped tested samples. For the normal porcine liver, the reduction of peak-to-peak value was about 74.2% by hand-held test.

In Fig. 7, the measured electrical impedance of the device was compared with the impedance computed from finite element simulations. The peak-to-peak value of the

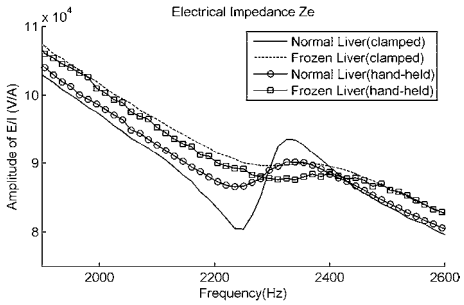

Fig. 6 Effects of holding the stiffness device on measured electrical impedance

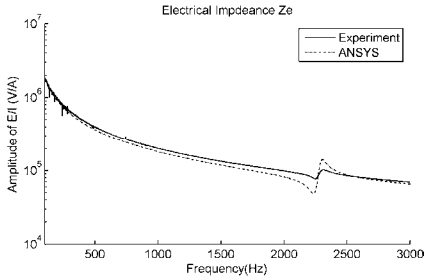

Fig. 7 Comparison of measured and simulated electrical impedance when tip was fixed

measured electrical impedance was less than that of the simulated and the resonant frequency of the simulated electrical impedance was lower than that of the measured electrical impedance.

In Fig. 8 the mechanical impedances of the porcine livers under different testing conditions were compared. In general, the magnitude decreased with the frequency from 1400 Hz to 2200Hz and it increased with the frequency for frequency higher than 2400 Hz. Similar to the electrical impedance, the peak-to-peak value around the resonant frequency for the liver under room temperature can be read from the figure as: 0.07145 Ns/m for the clamped test and 0.037 Ns/m for the hand-held test. For the frozen liver, it was

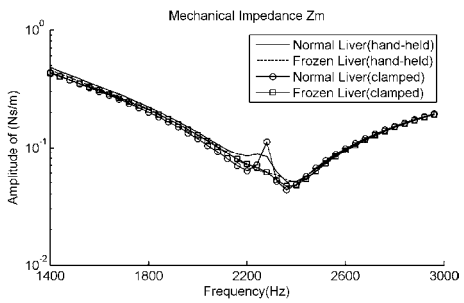

Fig. 8 Mechanical impedances of normal liver and frozen liver under different holding conditions

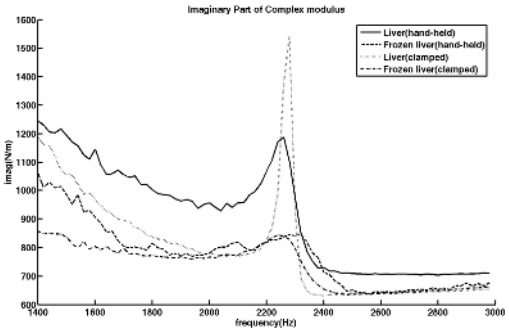

Fig. 9 The imaginary part of the complex modulus of stiffness of the porcine livers tested under different conditions

difficult to define the peak-to-peak values for both test conditions.

Fig. 9 showed the imaginary modulus of the liver samples under room temperature had a peaks around the resonant frequency for both handheld and clamped tests.

IV. Discussion

From the electrical impedance results, one may observe that the samples can be qualitatively separated into two groups: the soft materials (porcine liver at room temperature and SC-725) and the stiff materials (frozen porcine liver and PDMS).

In a previous work, we found that the apparent Young's moduli of the specimens were ordered as: liver < SC-725 < frozen liver < PDMS. The peak-to-peak values of the electrical impedance of the liver and SC-725 seemed to be inversely proportional to the apparent Young's modulus. For PDMS there is no peak-to-peak value. This may due to the stiffness of PDMS was higher than the mini cantilever and around the resonant frequency the beam deflection was small and the current induced by direct piezoelectric effect was small. On the other hand, the fresh porcine liver (at room temperature) and the silicone rubber SC-725 were less stiff than the mini cantilever so at the resonant frequency the beam deflection was large so did the current and thus the impedance decreases for same input voltage.

In this work, the finite-element method was employed to compute the transduction matrix. However, there were errors between the computed electrical impedance and the measured one. The error might come from the uncertainty in modeling the adhesive layer and the damping model of the mini cantilever. Further improvement on structural damping of the beam model might reduce the amplitude error. Unlike the experimental approach, the determinant of the transduction matrix was very close to one.

Unlike the electrical impedances, the mechanical impedances of the porcine liver specimens had a minimum around 2,500 Hz. Physically it means that, at this frequency, the same amplitude of sinusoidal force could result in higher amplitude of sinusoidal velocity signal. The peak-to-peak value of the liver tested under clamped test was larger than that of the hand-held test. The difference might be that the initial depth of hand-held test was higher than that of the clamped test (1 mm). It is well known that soft tissue like liver has a stress-strain curve consisted of three regions: toe, linear and nonlinear. The apparent Young's modulus at the toe region is much less than that of the linear region. It is very easy for the hand-held test to enter into the linear region and yield higher stiffness.

From the complex modulus of stiffness ($F(j\omega)/X(j\omega)$) of the porcine livers, one may observe that the real part or the storage modulus decreases with the frequency monotonically although, around 2,250 Hz small variations can be observed for liver tested at room temperature. However, significant variations of the imaginary part or the dissipation modulus can be found around the same frequency. It reveals that the porcine livers at room temperature had a higher damping or more like fluid than the frozen liver. The imaginary modulus at resonant frequency might be used as quantitative index for assessing the stiffness of cancerous liver tissue.

In this work, through the in vitro experiments the performance of the soft tissue stiffness measurement has been tested. The next stage is to design a system suitable for *in vivo* experiments by considering the control of initial indentation and the sterilization of the probe and the integration with robotic assisted surgery.

V. Conclusions

In this work, the sensing-cum-actuating method was adopted to develop a PZT-based soft tissue stiffness measurement system. In vitro tests on porcine livers revealed that the dissipative modulus computed from the mechanical impedance could quantify the stiffness of normal and pathological tissues.

A Novel Method to Describe and Share Complex Mathematical Models of Cellular Physiology

D.P. Nickerson and M.L. Buist

Division of Bioengineering, National University of Singapore, Singapore

Abstract — **With improved experimental techniques and computational power we have seen an explosion in the complexity of mathematical models of cellular physiology. Modern lumped parameter models integrating cellular electrophysiology, mechanics, and mitochondrial energetics can easily consist of many tens of coupled differential equations requiring hundreds of parameters. The reward of this increase in complexity is improved biophysical realism and an increase in the predictive qualities of the models. One of the most significant challenges with such models is being able to completely describe the model in such a manner that the authors can share the model with collaborators and, potentially, the scientific community at large.**

In this work we have developed methods and tools for the specification of the complete description of mathematical models of cellular physiology using established community standards combined with some emerging and proposed standards. We term the complete description of the cellular model a 'reference description'. Such a description includes everything from the mathematical equations, parameter definitions, numerical simulations, graphical outputs, and post-processing of simulation outputs. All of these are grouped into a hierarchy of tasks which define the overall reference description structure and provide the documentation glue to enable the presentation of a complete story of the model development and application.

Our reference description framework is based primarily on the CellML project, using annotated CellML models as the basis of the model description. Being based on CellML allows the underlying mathematical model to be shared with the community using standard CellML tools, and allows tools capable of interpreting the annotations to present the complete reference description in various manners.

Keywords — **CellML, mathematical model description, Physiome Project, electrophysiology, bioinformatics.**

I. Introduction

We have witnessed a dramatic increase in the complexity of mathematical models of cellular physiology in recent years. Due to an increased availability of experimental data and computational power, model authors are now able to create biophysically based models of cellular physiology incorporating finer and finer details. Recent models contain multiple compartments and the transportation kinetics between them, as well as combining several different aspects of cellular function into single models. The Cortassa *et al.* [1] model, for example, includes cellular electrophysiology, calcium dynamics, mechanical behavior, and mitochondrial bioenergetics, defined using fifty differential equations and more than 100 supporting algebraic expressions (c.f., the four differential equations in the classic Hodgkin and Huxley [2] model).

When dealing with such complicated mathematical models, it becomes very difficult to share the model with collaborators or the scientific community at large. Traditional peer reviewed journal articles restrict how much detail can be presented and require the translation of the model implementation into a format suitable for the particular journal. Such translation is an error prone process leaving much room for typographical mistakes when translating complex models. To address this deficiency, standard model encoding formats have been applied to the sharing and archiving of mathematical models of cellular physiology. The most notable standards being SBML [3, 4, http://sbml.org/] and CellML [5, 6, http://www.cellml.org/].

Both SBML and CellML address similar requirements for a machine readable and software independent model encoding format, but they each approach the issue from a quite different perspective. SBML developments have traditionally focused on representing models of biochemical pathways, whereas CellML has placed emphasis on representing related mathematical equations. These different approaches has resulted in two quite different model encoding standards, although there is some degree of compatibility between them – the mathematics can be translated from one to the other, but the biological concepts represented by a model may not be so easily translated in an automated fashion.

Using these model encoding standards, it is possible to define mathematical models of cellular physiology in a machine readable and software agnostic format. Models encoded in these standard formats can then be exchanged between scientists with confidence. The only potential loss of information in such an exchange is the "correctness" with which the tools used by each scientist interpret the model encoding [for a discussion of this problem, see 7]. While these standards provide for the specification of the mathematical models, further information is required in order to completely define the application of mathematical models

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 296–298, 2009
www.springerlink.com

in various scenarios. It is this additional information that is the subject of this manuscript.

II. Methods

In this work, we utilize CellML for encoding mathematical models. The discussion below applies equally as well to SBML. Metadata is used to provide additional, context dependent data about the mathematical model. In CellML the data represented are the definition of the mathematical equations. This work also falls under the IUPS Physiome Project (http://www.physiomeproject.org/) and as such it is desirable that this work should be able to extend to types of mathematical models and spatial scales other than those discussed below.

A. CellML

CellML is an XML-based model encoding standard that utilizes MathML (http://www.w3.org/Math/) to define mathematical equations and custom XML elements to define the variables used in the equations. CellML includes capabilities to define abstract hierarchies of mathematical components which can be connected together to form larger models of complete systems. These components can be defined locally within a model or imported from external models. Given the generic nature of CellML, it is applicable to a wide range of mathematical models covering the full spectrum of computational physiology [8–12].

The CellML project provides a freely accessible model repository (http://www.cellml.org/models/) as a valuable community resource [13]. With over 350 models in the repository, this provides an excellent demonstration of the range of models capable of being described using CellML. There are also several tools now available capable of utilizing CellML [for a recent review, see 14].

B. CellML Metadata

The CellML community is currently developing several metadata standards that greatly enhance model descriptions. The CellML Metadata specification (http://www.cellml.org/specifications/metadata/) provides a standard framework for the annotation of mathematical models with common data. This includes annotations such as model authorship, modification history, literature citations, biological constituents, human readable descriptions, *etc*. Such metadata provides the core description of the model allowing biological significance to be inferred.

The CellML Simulation Metadata specification (http://www.cellml.org/specifications/metadata/simulations/) aims to provide a standard framework for the description of specific numerical simulations. This provides for the instantiation of mathematical models into specific computational simulations. CellML Graphing Metadata (http://www.cellml.org/specifications/metadata/graphs/) defines a framework for the specification of particular observations to be extracted from simulation results. Graphing metadata also provides a mechanism for the association of external data with specific simulation observations. External data may consist of the experimental data from which the model was derived or the data used to validate the model. For the case of validating simulation tools rather than the mathematical models, the external data could be curated simulation output against which simulation tools can be tested. This therefore provides a quantitative validation of new simulation tools as opposed to the largely qualitative validation currently used [7].

All three of these metadata specifications leverage upon the Resource Description Framework (RDF, http://www.w3.org/RDF/) in their specification, providing a powerful technology for the annotation of models with no specific requirements on the serialized format of the model encoding. This therefore makes it straightforward to annotate models serialized in XML documents stored on the local computer, models stored remotely on the Internet as XML documents, or even models stored in remote databases.

C. Reference Descriptions of Cellular Physiology Models

We have previously described an approach to annotating mathematical models of cellular physiology using the metadata standards described above [15, 16]. This approach makes extensive use of graphing and simulation metadata in order to completely define simulation observations in terms of the mathematical models, their parameterization, and the numerical methods used in performing the computational simulations.

We envision these simulation observations forming the basis of journal articles submitted for peer review, allowing the articles to focus on the novel developments or observations being presented rather than devoting much of the article content to a description of the mathematical model. From the model reference description, web-friendly presentations can be generated, as illustrated in Nickerson *et al*. [15, http://www.bioeng.nus.edu.sg/compbiolab/p2/], which provide a complete description of the mathematical models and all associated annotations. Such presentations of the models allow for significantly more detail to be provided in regard to the development and implementation of the models. In addition, as they are generated directly from the model implementation, there is no longer the possibility of

translation errors when translating model implementations into journal articles.

III. Discussion

Annotated mathematical model descriptions using the community standards being developed by the CellML project provide the technology for completely describing the development of mathematical models. Supporting data, such as literature citations or experimental observations, can easily be incorporated into such model descriptions to substantiate modeling assumptions and justify parameter choices. Model authors using this framework are able to provide human-friendly presentations of model reference descriptions as supplements to peer reviewed journal articles. Providing such supplements as part of a curated web repository provides assurance to the scientific community that the reference description will be available as well as some degree of support in terms of the validity of the model encoding. This leaves the journal article able to focus on the novel aspects of the model development and outcomes rather than needing to devote a large portion of each article to basic model development and validation.

Work is currently underway to develop interactive presentations of the model reference descriptions to ensure relevant information is readily available to the various user communities. Such presentation environments must be sufficiently flexible to accommodate the different types of "views" users may desire from the underlying reference description. For example, following the presentation mode developed in Nickerson *et al*. [15] we are developing a more mathematically oriented view as well as a biologically focused view.

Abstract — **The activity of generating bibliographic data and the storage of the article (PDF) are usually separate activities. Desktop journal reference management software have been developed to manage bibliographic data but the PDF files are usually managed separately or added on later as a special feature. Based on a strategy used in tagging of MP3 files, a web based application in which the bibliographic data is embedded to the PDF has been developed. Such a paradigm shift allows highly efficient web applications to be developed for management of citations, bibliographic data and documents.**

Keywords — **reference, management, bibliographic, data, software**

I. Introduction

Life science research has undergone rapid expansion in both scope and depth in the recent years. The phenomenal growth is reflected by the exponential increase in the number of citations indexed by Medline in the last ten years. Shown in Fig. 1 is the citation collection in Medline on February 21, 2008, grouped according to publishing years of indexed citations [1]. As shown in the graph, there has been an exponential growth in the number of life science journal articles published from 2000 to 2006.

Rapid growth in life science research is only possible if the information on the field is readily accessible. Realizing the importance of open access information, the US government has required publications originated from research funded by National Institute of Health to be made publically available [2]. Shortly after the introduction of the bill, the European Commission poposed a similar recommendation which enable public access of publications that arise from EC funded research [3].

Traditionally, citations for peer-reviewed publications are managed as a list independent from the corresponding collection of electronic articles (mostly as PDF) [4]. In this new era of research where information can be freely accessed, the old way of managing references and full text articles as separate objects need to be reconsidered. In this article, we will introduce a new paradigm of managing the bibliographic data together with the corresponding electronic article (PDF) as a single object. This new approach allows for more versatile management of academic papers and increases the efficiency of research collaboration.

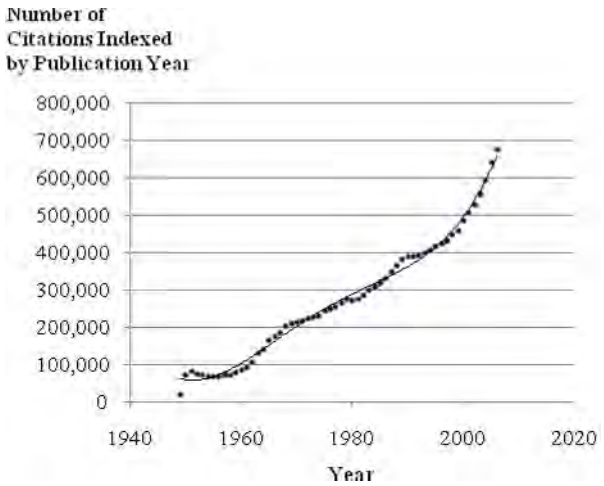

Fig. 1 Citations available in Medline as of February 21, 2008, sorted according to years the original articles were published. Data for citations published in year 2007 is incomplete and hence omitted.

II. Old paradigm

A. Embedded Metadata

In 2004, James Howison and Abby Goodrum from Syracuse University demonstrated the importance of metadata for effective management of music files [4]. Metadata refers to machine-readable information which describes content of a file, in a way labels describe contents of can foods. Examples of music metadata include song title, artist, and genre. Metadata facilitates management of music files by allowing users to sort and group the files according to various fields without having to run the files.

Music metadata can be directly stored in music files. The advantage of embedding metadata to a file is that whenever the file is moved or transferred, its metadata goes along with the file. According to Howison and Goodrum, it is the tight coupling of music metadata to music files which makes management of the files "the best personal informa-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 299–301, 2009
www.springerlink.com

tion management experience available to individuals today [4]".

B. Metadata in Academic Papers

Bibliographic data is basically metadata for academic papers which is used to identify specific publications. References cited in academic papers allow authors to substantiate their arguments and enable readers to access sources of information.

Contrary to music files, bibliographic data is not usually embedded onto PDF of academic papers; it is separately obtained from a database and managed independent of PDF. The consequence is evident: a PDF cannot be identified without firstly opening the file. This makes management of PDF troublesome.

One can use file names to identify a PDF but file names alone do not usually provide sufficient information for the file because of the limitation in number of characters a file name can hold. Furthermore, publishers usually name their PDF in a way nonsensical to readers which makes identification of the file even more difficult.

The process of reference management involves collecting references from multiple sources, obtain the PDFs from publishers, organize the references and cite relevant ones while writing papers.

After obtaining a list of references from multiple sources (often from references found in research papers), a researcher will need to download PDF from journal database. Usually, researchers use Digital Object Identifier (DOI) to retrieve PDF. DOI is a link which points a reference to its publisher's website. The PDF is saved on local drive but because bibliographic data is not embedded in PDF, the PDF cannot be easily tracked. For some, it might be easier to download the same article again using DOI [4]. As convenient as it might be, DOI is not a replacement of actual PDF for a variety of reasons. Firstly, the publishers' website that DOI links to always require users to login. Secondly, collaborators will need to repeat the same process of downloading the PDF which makes the process inefficient, given that the effort done by other collaborators is lost.

Reference managers help to ease the problem to some extent. Although reference management can be done manually but for a more organized approach, researchers use reference managers such as Endnote, Refworks, and WizFolio. Reference managers contain tools for researchers to collect references, obtain PDFs, organize and insert citations into documents. Reference managers can be broadly classified into two major groups according to the way they are accessed: desktop and web-based reference managers.

Most desktop reference managers link references and PDF stored on hard drive via shortcuts. Whenever PDF is moved or transferred, bibliographic data is not transferred together. The recipient will need to repeat the process of searching for bibliographic data; all the effort done by previous users is lost. On the other hand, most web-based reference managers do not allow users to upload PDF and hence do not assist in management of the documents.

III. New paradigm

Since bibliographic data is an integral for PDF management, we propose that the two should be managed as one object using soft embedment.

Soft embedment refers to embedment of metadata to a file using a file wrapper. As opposed to hard embedment (as in music files), the wrapper is not physically tied to PDF but is linked to PDF via software pointers.

In order for soft embedment to work, there must be a new platform which redefines the linkage between PDF and references. The new platform links both PDF and bibliographic data together. Whenever an item is moved or transferred, both PDF and corresponding bibliographic data are moved together as one item. The power of internet which connects users together can be harnessed and the independence of the web from users' operating system can be leveraged to bring management of references and files to a whole new level.

By applying concepts in the new paradigm, we have developed a web based application [5] that allows users to store both the bibliographic data and PDFs together as single object. Whenever an item is shared, both metadata and PDF can be shared together. By allowing sharing of both bibliographic data and PDF as a single entity we believe research efficiency is improved because effort done by previous collaborators is shared.

IV. Conclusion

Bibliographic data and PDFs for journal articles have long been managed as separate entities. Because of this practice, scattered PDFs are impossible to identify unless one opens the files. Management of PDFs is therefore convoluted especially when sharing is concerned. Although PDFs allow embedment of some bibliographic data, its current file system severely limits the amount of bibliographic data that can be stored in the file. It is proposed that soft-embedment can be used to embed bibliographic data onto PDF. This allows for more efficient and manipulation of journal reference articles.

Abstract — **There is electromyogram(EMG) as one of biological signals generated along with motions of the human body. This EMG has information corresponding to condition of power, tenderness of motions and motion level. Therefore, it is thought that it is useful biological information for analyzing person's motions. Recently, researches on this EMG have been actively done. For instance, it is used as a control signal of electrical arms, because EMG can be gathered from the remaining muscle about upper-extremity amputee. In addition, the pointing device that uses EMG has been developed. In general, EMG is measured from a part with comparatively big muscular fibers such as arms and shoulders. There is a problem that placing and removing the electrode is inconvenient when EMG is measured by placing the electrode in the arm and the shoulder. Therefore, if we can recognize wrist motions using EMG which is measured from the wrist, the range of application will extend furthermore. Currently, we have constructed a wrist motion recognition system which recognizes the wrist motion of 7 types as an object by using the technique named Simple-FLDA as a feature extraction technique. However, motions with low recognition accuracy were observed, and it was found that the difference of the recognition accuracy is significant at each motion and subject. Because EMG is highly individual and its repeatability is low. Therefore, it is necessary to deal with these problems. In this paper, we try the construction of a system that can learn by giving incremental data to achieve an online tuning. The improvement of the algorithm of Simple-FLDA that incremental learning becomes possible was tried as a technique for the construction of online tuning system. As a recognition experimental result, we can confirm the rising of the recognition accuracy by incremental learning.**

Keywords — **EMG, incremental learning, Simple-FLDA, Incremental Simple-FLDA**

I. Introduction

There is ElectroMyoGram(EMG) as one of biological signals generated along with motions of the human body. This EMG has information corresponding to condition of power, tenderness of motions and motion level. Therefore, it is thought that it is useful biological information for analyzing person's motions. However, there is a problem where the individual variation of EMG is large and its repeatability is low [1].

Recently, researches on this EMG have been actively done. For instance, it is used as a control signal of electrical arms, because EMG can be gathered from the remaining muscle about upper-extremity amputee [2,3]. In addition, the pointing device that uses EMG was developed [4]. In general, EMG is measured from a part with comparatively big muscular fibers such as arms and shoulders. There is a problem that placing and removing the electrode is inconvenient when EMG is measured by placing the electrode in the arm and the shoulder. Therefore, if we can recognize wrist motions using EMG which is measured from the wrist, the range of application will extend furthermore.

In this research, we aim toward the development of a device of wristwatch type that consolidates operation interface of various equipments. In particular, as an early stage, we propose a wrist motion recognition system which recognizes the wrist motions of 7 types as an object by using the technique named Simple-FLDA as a feature extraction technique [5,6,7]. Simple-FLDA is an approximation algorithm that calculates eigenvectors sequentially by an easy iterative calculation without the use of matrix calculation in the linear discriminant analysis. The verification experiments are carried out using this system. As a result, motions with low recognition accuracy were observed, and it was found that the difference of the recognition accuracy is significant at each motion and subject. As these reasons, we think that the difference between individual EMGs is related. To achieve the construction of the system that has the high general versatility, it is necessary that the system adapt to users.

In this paper, we try the construction of a system that can learn by giving incremental data to achieve an online tuning. The improvement of the algorithm of Simple-FLDA was tried as a technique for the construction of online tuning system. This improved algorithm that is called Incremental Simple-FLDA can perform an incremental learning by updating eigenvectors.

The rest of this paper is organized as follows. We describe a constructed system configuration and techniques used in this system in section 2. Section 3 explains about experimental details, experimental result, and discussion. Finally we conclude this paper with comments and remarks on future work in section 4.

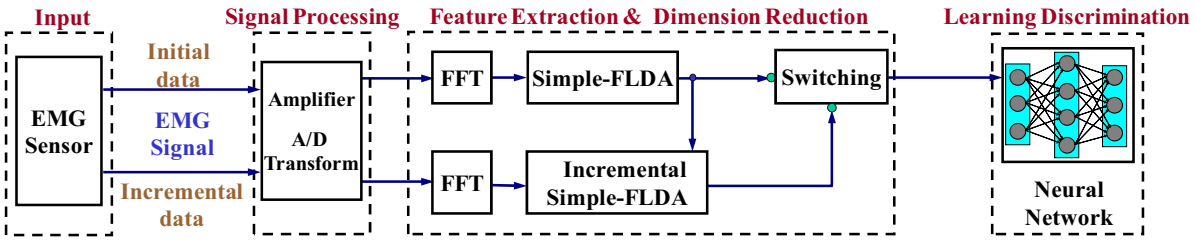

Fig.1 : Configuration of EMG recognition system

II. Icremental learning system

A. System configuration

The construction of an EMG pattern recognition system that we propose in this paper is shown in Fig1. The system consists of an input part, a signal processing part, a feature extraction & dimension reduction part, and a learning discrimination part.

In the input part, EMG is measured form the wrist by the electrode in four poles. In this paper, we use the surface electrode in consideration of practical application. Furthermore, because its treatment is easy, a dry-type electrode is adopted though surface electrodes are divided into the wet-type (used electrolysis cream) and dry-type (non-used electrolysis cream). The electrode is attached from the aspect of convenience in the wrist though it is necessary to place in flexor carpi radialis muscle and flexor carpi ulnaris muscle that can strongly measure EMG in high accuracy. The motions of the wrist at this time are set in seven states of the neutral, up, down, right, left, inside and outside as shown in Fig. 2, and measured in each state. In general, it was reported that from a few Hz to 2 kHz frequency of the EMG were important [9]. In this research, we have extracted the signal between 70Hz and 2 kHz from the measured EMG to avoid the influence of the commercial frequency noise (70Hz) in the signal processing part. Then, the extracted signal is converted to the digital signal by the A/D conversion. Next, we execute the fast Fourier transform(FFT) to the signal in the feature extraction & the dimension reduction part. Moreover, the eigenvectors are obtained using Simple-FLDA to spectra made by FFT. At the same time, the reduction in the dimension is carried out by doing this processing. Finally, wrist motions are discriminated using the eigenvectors by a classifier such as a neural network(NN) in the learning discrimination part.

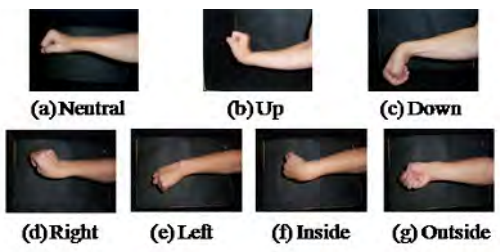

Fig.2 : Wrist motion patterns

When an incremental data was input, the eigenvectors are updated by using Incremental Simple-FLDA. Similarly, NN recognizes motions by using the updated eigenvectors. Thus, this system is expected to adjust to an individual by the influence of the incremental data. Therefore, feature extraction and dimension reduction is performed by using Simple-FLDA when the input EMG is the initial data. When the input EMG is the incremental data, the eigenvector that the influence of incremental data was considered is updated by using Incremental Simple-FLDA. Furthermore, the weights of NN are updated by using the updated eigenvectors at the same time. Next, we explain techniques named Simple-FLDA and Incremental Simple-FLDA.

B. Simple-FLDA

The fisher linear discriminant analysis is one of techniques of discriminant analysis. This technique can find eigenvectors that achieve maximization of variance between classes and minimization of variance in each class at the same time. However, matrix calculation cost becomes huge and a calculation time becomes very long. Simple-FLDA (Simple Fisher Linear Discriminant Analysis) is an algorithm from which eigenvectors are found without using matrix calculation, and by using the repetition calculation of an approximation algorithm. The Simple-FLDA is an approximated algorithm that achieves maximization of the variance between classes and minimization of the variance in each class at the same time. First, the maximization of the variance between classes as a description of this algorithm is described. First of all, a set of vectors to use is defined as follows.

$$V = \{v_1, v_2, \cdots v_m\} \quad (1)$$

The mean value of all data is assumed to be zero. The mean vector $\bar{h}_j$ of the data of each class is calculated. The following calculations are carried out by using this $\bar{h}_j$.

$$y_n = (\alpha_n^k)^T h_j \tag{2}$$

$$f(y_n, h_j) = \begin{cases} h_j & if \quad y_n \geq 0 \\ -h_j & otherwise \end{cases} \tag{3}$$

where α_n^k is an approximated vector of the *n*-th eigenvector, and *k* shows an index of repetition of the calculation. The threshold function (3) is summed using every mean vector. It can converge to the eigenvector that maximizes the variance between classes by these formulas. eq. (2) can be replaced by another form. Next, we describe the algorithm of the minimization of variance in each class. The vector x_j s have zero mean in the class. The positional relation between data x_j and an arbitrary vector assumed to be α_n^k is considered. The direction where x_j is projected and vector length is minimized is the orthogonal direction to x_j. Therefore, direction b_j where the direction component of x_j was removed from α_n^k can be expressed by the following eq. (4).

$$b_j = a_n^k - (\hat{x}_j \cdot a_n^k)\hat{x}_j \tag{4}$$

$$\hat{x} = \frac{x_j}{\|x_j\|} \tag{5}$$

This is the same as Schmidt orthogonalization procedure. An actual quantity is obtained by normalization of the vector length of b_j as follows.

$$f_i(b_j, x_j) = \frac{\|x_j\|}{\|b_j\|} b_j \tag{6}$$

The averaging is carried out by using all input vectors in each class during the repetition calculation. In other words, the influence of a component that the norm of a vector is large in this eq. (6) is significant. Therefore, it is hoped that it converges to a direction to minimize the variance in each class. The repetition calculation is shown by the following formulas.

$$f_n^k = \sum_{i=1}^{c} N_i f(y_n, h_i) + \sum_{i=1}^{c} \sum_{j=1}^{N_i} f_i(b_j, x_j) \tag{7}$$

$$a_n^{k+1} = \frac{f_n^k}{\|f_n^k\|} \tag{8}$$

where *c* is the number of classes and N_i shows the number of data in class *i*. N_i in the first term is used for equalizing the number of data in both terms. Thus, an arbitrary vector is converged to the eigenvector by achieving maximization of the variance between classes and minimization of the variance in each class at the same time.

C. Incremental Simple-FLDA

Incremental Simple-FLDA enables to update the eigenvector obtained by Simple-FLDA according to incremental data. First of all, incremental data is defined as v_{m+1} and the last mean value is assumed to be $\bar{v}$. Furthermore, the mean vector of the data of each class is shown $\bar{h}_j$ and *m* is the number of all data until last time. The calculation shown in eq. (9) is executed, a new mean $\bar{v}'$ is found.

$$\bar{v}' = \frac{1}{m+1}(m\bar{v} + v_{m+1}) \tag{9}$$

Next, new class mean vector $\bar{h}_j'$ is calculated in eq. (10)

$$h_j' = \frac{1}{M+1}(Mh_j + (v_{m+1} - \bar{v}')) \tag{10}$$

where *M* is the number of data in each class. The mean vector of the class $\bar{h}_j'$ where v_{m+1} belongs is updated. Next, we introduce the following threshold functions as well as the case of Simple-FLDA.

$$y_n = (\alpha_n)^T h_j' \tag{11}$$

$$f(y_n, h_j') = \begin{cases} h_j' & if \quad y_n \geq 0 \\ -h_j' & otherwise \end{cases} \tag{12}$$

where α_n shows a *n*-th eigenvector calculated last time. Moreover, we carry out the orthogonalization by using as well as the case of Simple-FLDA and the new orthogonal vector b_j' is obtained.

$$b_j' = a_n - (\hat{x}_j' \cdot a_n)\hat{x}_j' \tag{13}$$

$$\hat{x}' = \frac{x_j'}{\|x_j'\|} \tag{14}$$

where x_j' have zero mean in the class where v_{m+1} belongs. The normalization of b_j' is done in eq. (15)

$$f_i(b_j', x_j') = \frac{\|x_j'\|}{\|b_j'\|} b_j' \tag{15}$$

The new eigenvector α_n' is obtained by using $f(y_n, \bar{h}_j')$ and $f_i(b_j', x_j')$ in the following eq. (16)

$$\alpha_n' = \frac{1}{m+1}\left(\frac{f(y_n, h_j') + f_i(b_j', x_j')}{\|f(y_n, h_j') + f_i(b_j', x_j')\|}\right) + \frac{m}{m+1}\alpha_n \tag{16}$$

Finally, the previous eigenvector α_n' is removed from the new data and the mean vector in each class by using Gram-Schmidt orthogonalization. The eigenvector is sequentially updated by repeating these calculations.

III. Incremental learning experiment

A. Experimental details

In this section, incremental learning experiments are conducted by using the EMG recognition system to verify the effectiveness of incremental learning. This system obtains the eigenvectors using Simple-FLDA in the initial state and

using Incremental Simple-FLDA in the incremental learning. In this experiment, EMG that is measured different person is used as the initial data and the incremental data. Because, it is necessary that the system adapts to user by using user's incremental data. Thus, EMG of subject A(male: 30 years old) and subject B(male: 22 years old) are used as initial data and incremental data, respectively. Moreover, we use EMG of subject B as the evaluation data. Therefore, it is expected that the recognition accuracy in the initial state is extremely low. This system can increase the recognition accuracy using incremental data.

As a comparison experiment, we tried the incremental learning experiment by using the eigenvectors that are not updated with the incremental data, which means eigenvectors in the initial state. The number of initial data, incremental data, and evaluation data are 70(7 classes x 10 trials) in each.

B. Experimental result

The incremental learning experimental result is shown in Fig.3. The horizontal axis is the number of incremental data, and the vertical axis is recognition accuracy. In the graph, the lines labeled "Inc. SFLDA" and "Non Inc. SFLDA" are ones obtained by the Incremental Simple-FLDA and the method that the eigenvectors are not updated, respectively.

The recognition accuracy in the initial state is about 41%. In previous study, when the initial learning and the evaluation are performed using same person's data, the recognition accuracy is obtained about 90%. Therefore, this result is extremely low. This is because the initial leaning data and evaluation data are different person's ones. In the incremental learning, the recognition accuracy increases gradually according to the number of incremental data in each case. However, the recognition accuracy is obtained by using the Incremental Simple-FLDA is higher than the case when the eigenvector is not updated. As a result, the Incremental Simple-FLDA is effective in incremental learning in EMG recognition. However, more high recognition accuracy is required to use in actual environment. Thus, it is necessary to improve further this system.

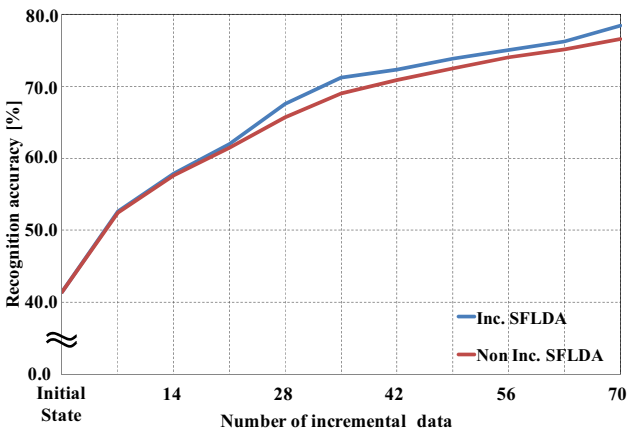

Fig.3 : Recognition accuracy in the incremental learning experiment

IV. Conclusions

In this paper, we constructed the online tuning system that built incremental learning function into the wrist motion recognition system that used wrist EMG. As the method, we proposed Incremental Simple-FLDA that gave the incremental learning function to the algorithm of Simple-FLDA. The construction of the online tuning system was tried by doing incremental learning with this algorithm. Moreover, the recognition experiment was carried out with this system. As a result, we can confirm the effectiveness of proposed system. However, further improvement is necessary to develop the various equipments using this system. In the future, we aim at the completion of the system.

Abstract — **Metal artifact is a significant problem in computed tomography (CT). Degradation of the quality of an image is a direct consequence of the metal artifacts in the image data. A number of papers and articles have been published regarding the subjects. However, none of the approach can be employed to incorporate in commercial CT scanners. Besides, all of the methods, to the best of our knowledge, are performed in the reconstruction process which means the CT images are created at the same time as the metal artifact removal process. In this research, we assume that the CT images with metal artifacts are given and we have no control over the reconstruction approach.**

Hence, we propose a new method to automatically remove metal artifacts in dental CT images in the post-processing steps. The proposed technique consists of two main steps. First, the local entropy thresholding scheme is employed to automatically segment out the dental region in a CT image. Then, the Label filtering technique is used to remove isolated pixels, which are the metal artifacts, by using the concept of connected pixel labeling.

The algorithm has been tested on thirty sets of the dental CT scanned images. The experimental results are compared with hand-labeled dental images and are evaluated in terms of accuracy, sensitivity and specificity. The numerical results showing sensitivity, specificity, and accuracy are 87.89%, 99.54%, and 99.21% respectively. The experiments demonstrate the robustness and effectiveness of the proposed algorithm. The algorithm provides promising performance in detecting and removing metal artifacts from dental CT images. Therefore, automatic artifact removal can greatly help with the 3-D Visualization of CT images.

I. Introduction

At present, computed tomography streak artifacts caused by metallic objects remain a challenge for the automatic processing of image data. A three-dimensional assessment of the bone architecture needs to be available for the planning of surgical placement of dental implants. Therefore, automatic artifact removal can greatly help with the 3-D object reconstruction process as shown in Fig.1.

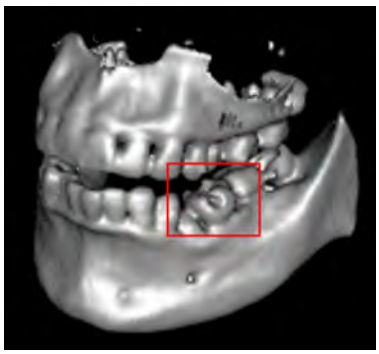

Fig.1. 3-D Visualization of CT Images

II. The Proposed Algorithm

Dental CT is a three-dimensional (3-D) scan from a large set of 2-D X-ray images which can be used for dental and maxillofacial applications. A 3-D object is generated from a series of 2-D images by selecting regions of interest. Then only regions of interest are used to generate a 3-D shape. In our case, dental bones, possessing brighter gray-scale intensities compared to other tissues, are our regions of interest. A user or dentist has to select an appropriate threshold to segment out the dental bones. Therefore, automatic threshold selection can greatly help with the 3-D object reconstruction process.

In this paper, we propose a new method for automatic segmentation, which is based on entropic thresholding scheme. While a traditional co-occurrence matrix specifies only the transition within an image on horizontal and vertical directions, in this work we embrace the transition of the gray-scale value between the current layer and its prior layer as well as the current layer and its next layer into our co-occurrence matrix. The proposed method can be used to automatically select an appropriate threshold range in dental CT images as shown in Fig.2.

The proposed technique consists of two main steps. First, the local entropy thresholding scheme is employed to automatically segment out the dental region in a CT image. Then, the Label filtering technique is used to remove iso-

lated pixels, which are the metal artifacts, by using the concept of connected pixel labeling.

A. Entropy Thresholding

Our test data are the dental CT (Computed Tomography) scan images which consist of different cross-section images as shown in Fig.3.and Fig.4.

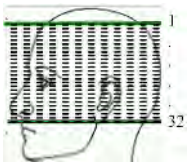

Fig.3. Position of CT slices from top to bottom

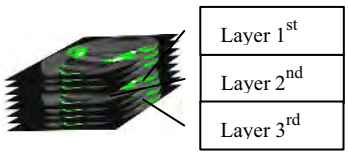

Fig.4. Examples from layer number

Because image pixel intensities are not independent of each other, an entropic-based thresholding technique is employed. Specifically, we implement a Multi-layer Entropy method which can preserve the structure details of an image. Our definition of a co-occurrence matrix is based on the idea that the neighboring layers should affect the threshold value. Hence, we define a new definition for a co-occurrence matrix by including the transition of the gray-scale value between the current layer and its prior layer as well as the current layer and its next layer into our co-occurrence matrix illustrated in Fig 6.

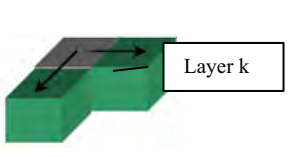

Fig.5. right and bottom of pixel in a co-occurrence matrix

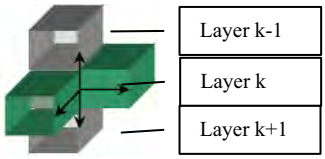

Fig.6. the prior and the next layers in a co-occurrence matrix

Let **F** be the set of images. Each image has dimension of P×Q. Let t_{ij} be an element in a co-occurrence matrix depending upon the ways in which the gray level i follows gray level j

$$t_{ij} = \sum_{x=1}^{P} \sum_{y=1}^{Q} \delta \begin{cases} (F_k(x,y) = i) \text{ and } (F_k(x,y+1) = j) & \text{or} \\ (F_k(x,y) = i) \text{ and } (F_k(x+1,y) = j) & \text{or} \\ (F_k(x,y) = i) \text{ and } (F_{k-1}(x,y) = j) & \text{or} \\ (F_k(x,y) = i) \text{ and } (F_{k+1}(x,y) = j) & \end{cases}$$

Where $\delta = 1$

$$, \delta = 0 \quad otherwise. \tag{1}$$

where F_k denotes the k[th] slice in the image set, **F**

The total number of occurrences, t_{ij}, divided by the total number of pixels, P×Q, defines a joint probability, p_{ij}, which can be written as

$$p_{ij} = \frac{t_{ij}}{\sum_i \sum_j t_{ij}} \tag{2}$$

If $s, 0 \le s \le L-1$ is a threshold. Then s can partition the co-occurrence matrix into 4 quadrants, namely A, B, C, and D shown in Fig.7.

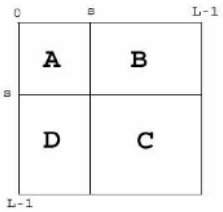

Fig.7. an example of blocking of co-occurrence matrix

Let us define the following quantities:

$$P_A = \sum_{i=0}^{s} \sum_{j=0}^{s} p_{ij} \quad , \quad P_{ij}^{A} = \frac{t_{ij}}{\sum_{i=0}^{s} \sum_{j=0}^{s} t_{ij}} \tag{3}$$

for $0 \le i \le s, 0 \le j \le s$

$$P_C = \sum_{i=s+1}^{L-1}\sum_{j=s+1}^{L-1} p_{ij}, \qquad P_{ij}^{C} = \frac{t_{ij}}{\sum_{i=s+1}^{L-1}\sum_{j=s+1}^{L-1} t_{ij}} \quad \text{for } s+1 \le i \le L-1, s+1 \le j \le L-1 \tag{4}$$

$$H_A^{(2)}(s) = -\frac{1}{2}\sum_{i=0}^{s}\sum_{j=0}^{s} P_{ij}^{A} \log_2 P_{ij}^{A} \tag{5}$$

$$H_C^{(2)}(s) = -\frac{1}{2}\sum_{i=s+1}^{L-1}\sum_{j=s+1}^{L-1} P_{ij}^{C} \log_2 P_{ij}^{C} \tag{6}$$

Where $H_A^{(2)}(s)$ *and* $H_C^{(2)}(s)$ represent the local entropy of the background and foreground respectively. Since two of the quadrants shown in Fig.5, B and D, contain information about edges and noise alone, they are ignored in the calculation. Because the quadrants, which contain the object and the background, A and C, are considered to be independent distributions, the probability values in each case must be normalized in order for each of the quadrants to have a total probability equal 1. The gray level corresponding to the maximum of $H_A^{(2)}(s) + H_C^{(2)}(s)$ give the optimal threshold for object-background classification.

$$S_{opt} = \arg\max_{s}\left[H_A^{(2)}(s) + H_C^{(2)}(s)\right] \tag{7}$$

For the given original image shown in Fig. 8. The result after Multi-layer entropy thresholding shows in Fig. 10. For comparison purpose, the local entropic result is illustrated in Fig.9 where the metal artifacts have been segmented out in the amount greater than those in Fig. 9.

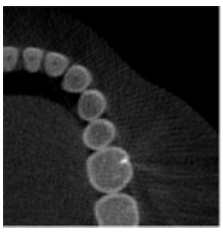

Fig.8. original Image

Fig.9. Resulted image after Local Entropic Thresholding

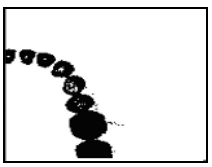

Fig.10. Resulted image after the integration of the prior-layer and the next-layer relationship

B. Connected Component Labeling

Connected component labeling or labeling filtering is used to remove some misclassified pixels in image as shown in Fig. 10. Label filtering is used to remove isolated pixels by using the concept of connected pixels labeling. The Label filtering tries to isolate the individual objects by using the eight-connected neighborhood. The result after label filtering shows in Fig. 11.

Fig.11. Resulted image after connected component labeling

III. Experiment and Results

On Pentium 4, CPU 2.0 GHz, using MATLAB version R2006b, the computational time of the whole algorithm takes approximately a few minutes for each sets of the dental CT scanned images. We used the thirty sets of the dental CT scanned images. The dental images and dental ground truth data are obtained from the National Metal and Materials Technology Center (MTEC), Advanced Dental Technology Center (ADTEC) and hand-labeled.

The performance of the metal artifact removal algorithm is conventionally measured using accuracy sensitivity and specificity. The definitions of the three indices are follows:

Table 1 Calculations of Accuracy

	Reference Test Results		
		+	-
New Test Results	+	TP	FP
	-	FN	TN

$$Sensitivity = \frac{TP}{TP + FN} \tag{8}$$

$$Specificity = \frac{TN}{TN + FP} \tag{9}$$

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{10}$$

where TP=number of true positive specimens
FP=number of false positive specimens

FN=number of false negative specimens
TN=number of true negative specimens

The algorithm has been tested on thirty sets of the dental CT scanned images. The experimental results are compared with hand-labeled dental images and are evaluated in terms of accuracy, sensitivity and specificity. The numerical results showing sensitivity, specificity, and accuracy are 87.89%, 99.54%, and 99.21% respectively, and show on Table 2. The experiments demonstrate the robustness and effectiveness of the proposed algorithm. The algorithm provides promising performance in detecting and removing metal artifacts from dental CT images.

IV. Conclusions

Multi-layer Entropic Thresholding and Label Filtering Technique methods for metal artifact removal on dental CT scanned image are presented in this paper. We define a new definition for a co-occurrence matrix which can both preserve the structure within an image and at the same time can present the connection between adjacent images. The approach can be applied to automatically indicate an appropriate thresholding range in dental CT images. The algorithm provides promising performance in detecting and removing metal artifacts from dental CT images. Therefore, automatic artifact removal can greatly help with the 3-D Visualization of CT images.

Abstract — **Cochlear implant provides opportunity for profoundly hearing impairment patient to have a chance to hear sound again. However, the limited number of electrodes is in sufficient to provide enough hearing resolution for hearing impaired people, especially for application in tonal language and music. Virtual channel technology opens up the possibility to increase the hearing resolution under the limited electrodes available and improve and quality for tonal language and music. In this paper, vocoder implementation of a new speech strategy based on virtual channel technology is used to study the improvement. The test result shows improved understanding and quality with virtual channels over the traditional strategies, ex. CIS, especially for mandarin and music.**

Keywords — **Cochlear Implant, Current Steering, Virtual Channel, Vocoder, Speech Strategy.**

I. Introduction

Cochlear implant (CI) helps people with profoundly hearing impairment to recover partial hearing through electrical stimulating the hearing nerves. The mechanism is to pick up sound by a microphone and a speech processor turns the input sound to frequency representations fit to the tonotopic organization of human cochlea and generates electrical current to implanted electrode array to stimulate the corresponding hearing nerves [1], [2]. Current available commercial CI devices provide 12~24 electrodes but the limited number of electrodes cannot fully cover the whole auditory nerve fibers and are not sufficient for satisfactory stimulation quality.

Current steering is designed to improve the stimulation resolution without increasing the originally implanted electrode count. By controlling the input currents of adjacent electrodes in a suitable manner simultaneously, intermediate channels, virtual channels, between the electrodes can be generated [3], [4]. This can increase the perceptual channels over the limited electrodes and improve the listening quality, especially for tonal language and music. To benefit from the virtual channels, new speech strategies are required to exploit this effect.

In this paper, new speech strategy based on virtual channel technology is designed and a vocoder is developed to realize the new strategy to study the improvement of performance.

II. Methods

A. Spectrum representations in CI

To give an impression how a CI user may perceive the sound, a spectrum comparison in Fig. 1 shows the difference between original signal and the stimulation channels in CI. Because of the tonotopic organization of human cochlea, the locations along the basilar membrane represent the corresponding frequencies. In Fig. 1, the upper one is an example spectrum of the original signal and the lower two are the stimulation channels in CI. The bottom squares represent the electrodes in an electrode array and eight electrodes are present in this example.

It can be observed that in most commercial CI devices, the limited number of electrodes does not allow for satisfactory tracing of spectrum variation, resulting in inconsistent perception and thus compromised understanding. Virtual channels allow intermediate channels between adjacent electrodes can be generated, the stimulation channels similar to the original signal which can provide better stimulation results for CI users and better hearing quality. This can be compared by the peak positions from the figure (arrows)

B. New speech strategy and vocoder

In this study, we proposed a new speech strategy based on virtual channel technology for better efficacy. To assess the performance, an adapted vocoder is developed using National Instrument LABVIEW programming environment [7]. Fig. 2 provides the block diagram of the vocoder, including new speech strategy and the sound synthesis. In the simulation, digitized sound data stored in disk is used as input directly. Two main paths in the new strategy are processed according to the input sound data. Spectrum processing analyzes the spectrum information by using FFT and then selects the peak signal between adjacent electrodes. This will be used to locate the virtual channels. Magnitude

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 310–313, 2009
www.springerlink.com

processing analyzes the magnitude of the spectral band between adjacent electrodes and then nonlinear maps to the CI user's dynamic range. This will be used to set the magnitude of the virtual channels stimulation.

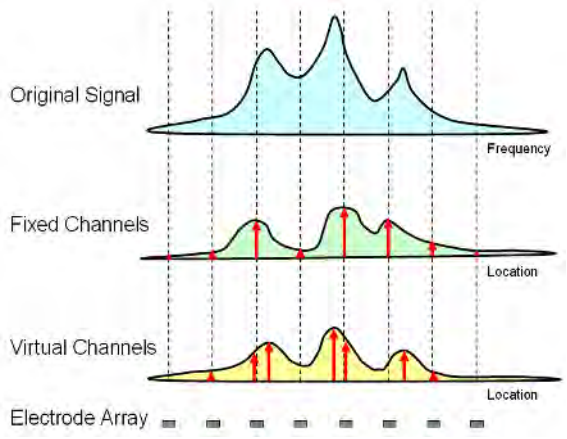

Fig.1 Spectrum comparison between original signal and the CI channels. The arrows represent the stimulation channels by the electrodes.

After processed by the new speech strategy, noise and pure tonal carrier are used to synthesize the sound to emulate the hearing of CI users [8].A band pass filter (BPF) control module is used to control the bandwidth of synthesis BPF. By adjusting the bandwidth of synthesis BPF, The current spread from the electrodes or virtual channels can be represented. This makes the outputs from the vocoder closer to the hearing of CI users.

C. Test materials

To assess the performance of the new speech strategy, Mandarin and music were selected in this study. For Mandarin source, a phrase including four different tone words is used : "ton(/) shi(\) ten(-)ya(/)". For music source, a clip of music played by a violin is used. All test materials are sampled at 16kHz and the signal bandwidth is 8kHz according to Nyquist-Shannon sampling theorem which covers the typical hearing frequen cy range of CI users.

The configuration of HiFocus electrode array from Advanced Bionics Corporation [9] was used in this experiment. There are 16 electrodes, representing 16 fixed channels generated by traditional strategy and 15 virtual channels between 15 electrode pairs. The mapping between frequencies and the corresponding electrodes are listed in Table 1 [10].

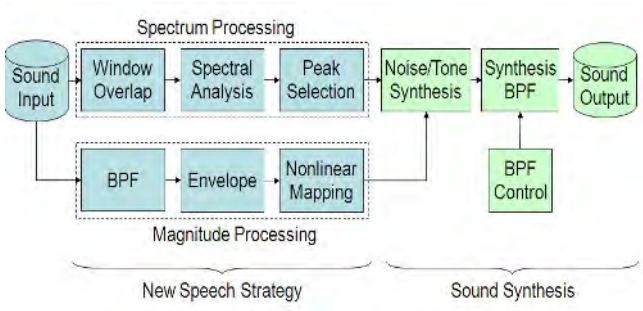

Fig. 2 Block diagram of the vocoder, including new speech strategy and sound synthesis.

Table 1 Mapping between frequencies and corresponding electrodes

Electrode ID	1	2	3	4
Frequency (Hz)	333	455	540	642
Electrode ID	5	6	7	8
Frequency (Hz)	762	906	1076	1278
Electrode ID	9	10	11	12
Frequency (Hz)	1518	1803	2142	2544
Electrode ID	13	14	15	16
Frequency (Hz)	3022	3590	4264	6665

III. Results

Fig. 3 shows the waveform and spectrum of the test Mandarin phrase."ton(/) shi(\) ten(-) ya(/)". A typical Chinese word is usually composed of consonant, vowel and

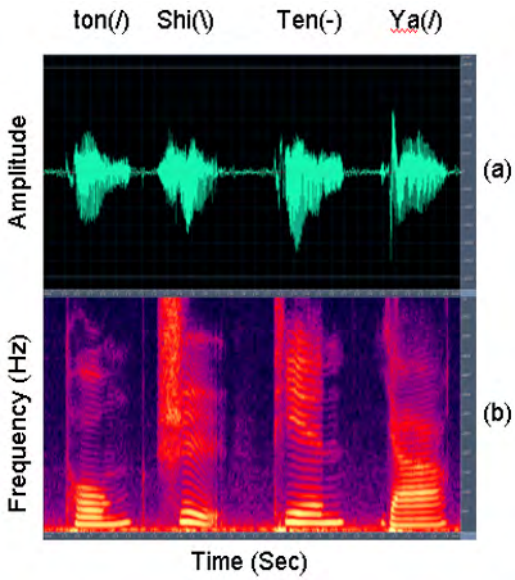

Fig. 3 The original test Mandarin phrase sample: ton(/) shi(\) ten(-) ya(/). (a) Speech waveform. (b) Corresponding spectrum.

tonal information. In the spectrum representation (Fig. 3b), it is observed clearly that the four words comprise the consonant and vowel while the second word is more obvious. The tones are different between words. The rising tone of the first word is associated with a rising frequency while the falling tone of the second word is associated with a falling frequency and so on. This tonal information is important to the understanding of Mandarin and any other tonal language, such like Cantonese. So how to maintain the tonal information for CI users using tonal language is crucial.

Fig. 4 shows the spectral comparison of the synthesized sounds by using traditional fixed channel strategy and new strategy based on virtual channel. As Fig. 1 show, the spectrum is composed of fixed frequency components as the electrode located for the fixed channel strategy (Fig. 4a). The tonal information is lost and sounded like flat tone for all words. This makes the understanding more difficult.

Observing the spectrum of the tonal synthesized sound (Fig. 4b), the frequency variation between adjacent electrodes, the stimulation sites can be adjusted and the frequency perceived will follow accordingly. In the perceptual test, the signal from the virtual channel strategy sounded much clearer and more natural than the traditional approach. Fig. 4c shows the spectrum using noise synthesis. By controlling the bandwidth of synthesis BPF, the synthesized sound can be made easier to understand. Since tonal carrier is a very narrow band noise signal, the spectral spread of tonal synthesis is narrower and more concentrated than that of noise synthesis and can be observed by comparing Fig. 4b and 4c, especially in the high frequency region.

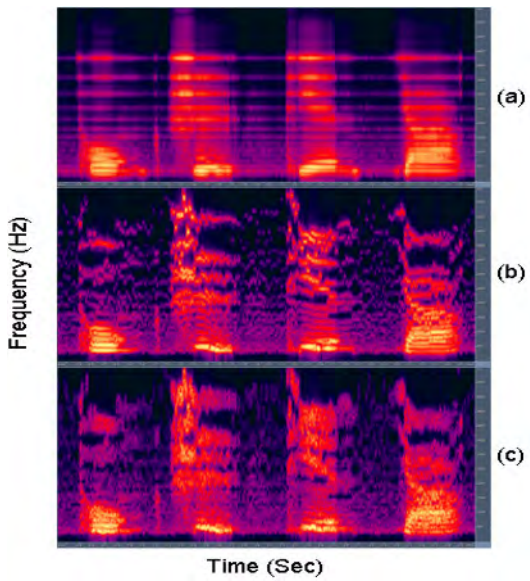

Fig. 4 Spectral comparison of the synthesized sounds. (a) Spectrum of the tonal synthesized sound using traditional fixed channel speech strategy. (b) Spectrum of the tonal synthesized sound using new speech strategy. (c) Spectrum of the noisy synthesized sound using new speech strategy.

IV. Discussion

Traditional fixed channel strategy performs well for non-tonal language now, however the fixed approach of stimulation cannot trace the frequency variation for tonal language. The proposed new speech strategy preserves the main spectral information since the main peaks of the spectrum between each electrode pairs are selected for stimulation and adopts the virtual channel technology to trace the frequency variation. So the simulation result reveals that the new speech strategy is superior to the traditional strategy. In addition to the preservation of tonal information, the consonant also sounded more natural than traditional approach. Since the consonant is a noise like signal, the peaks are also distributed randomly. Using the virtual channel technology, the signal spectrum can be represented easily and therefore sounds more natural. The simulation result shows that the new strategy also performs better than the traditional approach.

V. Conclusions

This paper presented a new speech strategy based on virtual channel technology to improve the understanding of tonal language. The acoustic simulation showed that it is superior to the traditional strategy. For the music listening, the new strategy also performed better but there is still room for improvement.

The vocoder implementation can help to develop a new strategy without involving CI users which can simplify the development effort and reduce the development time. The new CI strategy can therefore be improved based on the result of the vocoder simulation. Systematic perceptual experiment will be performed to validate the new speech strategy in the future.

Towards a 3D Real Time Renal Calculi Tracking for Extracorporeal Shock Wave Lithotripsy

I. Manousakas, J.J. Li

Department of Biomedical Engineering, I-Shou University, Kaohsiung County, Taiwan

Abstract — **Extracorporeal shock wave lithotripsy can fragment renal stones so that they can pass out during urination. Breathing can induce motion of the kidneys which results in reduced efficiency of the treatment. This study attempts to evaluate if a three dimensional method of stone tracking could be possible with existing hardware and software components. A gelatin phantom was imaged with ultrasound to create a three dimensional volume image. Subsequently, two dimensional images acquired in parallel and perpendicular directions to the scans that produced the volume image were registered within the image volume. It is shown that data reduction methods and optimized software can achieve processing times suitable for real time processing.**

Keywords — **ESWL, renal stone, image analysis.**

I. Introduction

Extracorporeal shock wave lithotripsy (ESWL) is the preferred method of treatment for renal calculi. It is a non invasive treatment and has been already in routine clinical practice for many years. During treatment, the stone formation is commutated to small fragments by exposing the stone to focused shock waves. The fragments, if they are of small size, can spontaneously pass out during urination. The most common practice is that the stone is localized using fluoroscopy. The focal area of the shock wave generator is positioned in such way that it will coincide with the stone location. It is usually a painful procedure and has complications such as hematuria and injuries at other healthy tissues near the treated area. Renal function may be reduced and most of it is recovered after a period of time. Internal injuries are caused because of reasons such as focus area that is larger than the size of the stone, breathing induced motion of the organs in the abdomen including the kidneys, involuntary movements of the patient, non-accurate localization, overtreatment and so on. Moreover, fluoroscopy with its radiation nature is not the ideal choice for localization purposes and ultrasound is now available for the majority of the commercial systems. Nevertheless, it is seldom used because requires more training for the technicians and doctors and also more time during treatment for the stone localization.

During the recent years, methods for automatic renal stone tracking have been proposed based in ultrasound imaging 1-3. These methods use stone positioning information from the images to reposition the shock wave focal area in real time. The benefits of such tracking methods are such as: smaller stone fragments, reduced treatment time, reduced injuries to healthy tissues, reduced pain and less radiation exposure for the patient. The efficiency that could be achieved is commented by other independent researchers 4.

The main reasons why these treatment methods are not yet accepted and widely used today are that the methods are difficult to use and there are possibilities of erroneous tracking of other structures that may look like stones to the system's image analysis software. These problems mostly arise from the nature of the two dimensional ultrasound imaging that is used with these systems. For a perfect stone tracking the stone should be visible in the image at all times. This could only be achieved if the imaging plane is perfectly aligned with the stone motion. Repositioning the patient on the system may improve the alignment but this needs some time and the cumbersome procedure may have to be repeated through a treatment. As somebody could imagine, such treatments are not welcome by doctors or patients. Moreover, if the alignment is poor and the stone gets out of the imaging plane, the software has difficulty in deciding whether to track something else or stop and wait for the stone to reappear at a close position.

While three dimensional ultrasound imaging systems could certainly solve the above mentioned problems, are of high cost and not supported by any software system for stone tracking. In the research presented here, a method that uses pseudo three dimensional imaging is used in conjunction with classical two dimensional imaging. This method, although in an initial state, shows the potential of a three dimensional method. A study with a phantom shows that real time processing with current computer technology is possible.

II. Materials and methods

The method presented here uses a three dimensional image composed from individually acquired slices. This image volume acts as a reference for registration of subsequently

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 314–317, 2009
www.springerlink.com

acquired images. The study was performed using a simplified gelatin phantom.

A. Phantom Model

A simplified kidney stone phantom was used in this study for collection of ultrasound images. The phantom was structured as a kidney with a clearly visible stone formation in the calyx and was constructed with widely available materials for a single use. The kidney tissue was mimicked using material used for gelatin based desserts. Various other materials, like agar, could have been used but with no difference to the results. Since these materials are usually looking transparent in the ultrasound images, scattering materials are usually added, such as graphite powder. A more easy to prepare method that we have been using for some time is the addition of a small portion of common wheat flour that is firstly diluted with cold water and then added to the hot gelatin solution as the last preparation step before pouring into a mold. As could be expected a more irregular grain is produced in the image that could be claimed to be more realistic for a tissue mimicking phantom. The exact proportions of the added materials and water are not critical to this study and could be altered to produce phantoms of various sound impedances, if that was necessary. The stone model was mimicked with a small irregular natural stone positioned within a small balloon full of water. This balloon was first fixed at a position within the mold and then the gelatin was poured around. The phantom was used after refrigeration for one day which reduces the air bubbles that may present during manufacturing.

B. Ultrasound Imaging

The constructed phantom was placed inside a water tank lined with materials to reduce reflections. A commercial ultrasound imaging system was used for this study (Sonos 500, Hewlett Packard). Ultrasound imaging was performed for the constructed phantom at 2.5 MHz and at the maximum depth of 12 cm. The ultrasound probe was mounted on a XYZ positioning system and a small front part of the probe was immersed in the water. A drawing of the experiment's configuration is shown in Fig. 1. The whole phantom volume was imaged using two different probe directions. The space between successive slices was 1 mm. In a clinical case, a free hand three dimensional ultrasound imaging of the kidney could be acquired within a short time period during hold breath.

During a treatment, the morphology of the kidney in the image is not expected to be strongly altered and therefore this image volume could be used as a reference. Within this volume the position of the stone under treatment should be identified by a system user. A subsequently acquired two dimensional image of the same area could be registered to this volume.

C. Image Analysis

Software was written in both Matlab® (ver. 2007a, The MathWorks, Inc, USA) and Visual C++® (Visual studio 2005, Microsoft, USA) for performance comparison. The software was used on a Windows XP® based PC with an Intel Pentium D® 930 CPU at 3GHz having 4Gbytes of memory. The Intel's Integrated Performance Primitives software library (ver. 5.3, Intel, USA) was used to increase performance of the C++ program.

In a basic three dimensional stone tracking method, the task would be to follow an already identified target through time and space. The available processing time for a realistic tracking system could be equal or less to the frame rate of the ultrasound system. Often this is about 15 frames per second, allowing about 66 ms for image analysis and the necessary motion of the system until the next image becomes available.

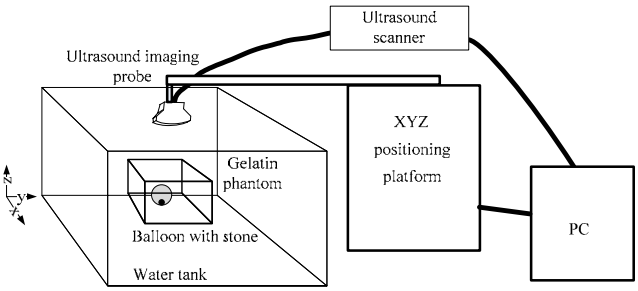

Fig. 1 Drawing of the configuration for the phantom experiments.

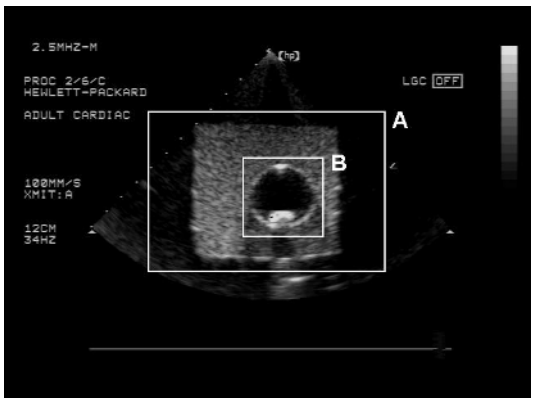

Fig. 2 Ultrasound image of the phantom. The region marked A depicts the 3D ROI for the registration and the region B depicts the 2D template size.

The proposed approach relates the tracking performance to the software's ability to register the most recent acquired two dimensional image to the three dimensional image that was initially acquired. The difference between the displacement of the stone position in the 3D and 2D images and the current position of the system represents the required motion for the systems shock wave focal area positioning motors.

D. Algorithm

Image registration was performed between each of the 2D images and each of the individual slices inside the acquired three dimensional volumes. Normalized correlation coefficients were computed for the image registration 5. The images were acquired as 640x480 pixel images, see Fig. 2. Each time, a template region from the two dimensional image of size 100x100 pixels (2D template) was related to regions of interest (3D ROIs) of size 290x200 pixels on each slice in the three dimensional volume image. Tests were also performed with the same images after been resized to a 1:3 and 1:5 ratio. When the images had different resolutions, the data were interpolated to produce more slices and result in a volume with the same resolution in all axes. The relative position of the 3D ROIs and the 2D templates are shown in Fig. 3. In the first case the 2D templates were extracted from the volume image, so they are at the same direction. In the second case, the 3D ROIs and the 2D templates were acquired in a perpendicular to the volume scans direction. The number of 3D ROIs images and 2D templates used in the parallel scans case were 42 and 20 respectively and for the perpendicular scans case 45 and 20 respectively. The sizes of the 3D ROIs and the 2D templates were selected so that to contain the whole balloon area.

III. Results

In Fig. 4 the results from the registration are shown. Each line in the graphs show the values achieved when a specific 2D template is compared with all the 3D ROIs. The normalized correlation coefficient is in the range between zero and one. The ideal experiment in the parallel scans case, Fig. 4(a), shows that there is always a distinct peak of maximum height. When we perform resizing (1:5), distinct peaks still exist but with lower values. In the perpendicular scans case were the acquisition directions differ, the peaks are lower and when also using resizing, the peaks are even lower.

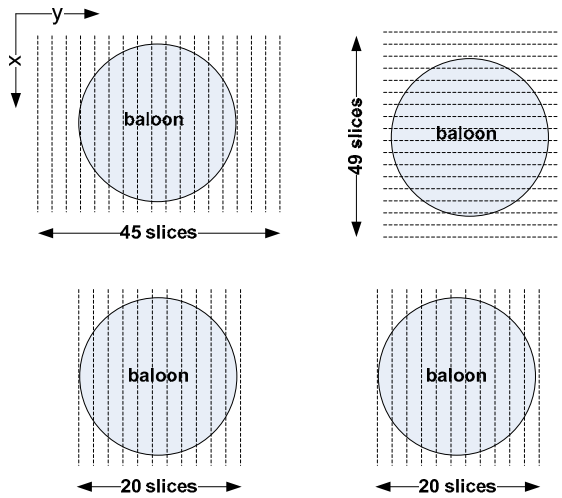

Fig. 3 The relative direction between the 3D ROIs (top row) and the 2D templates (bottom row) for the parallel scans case (left column) and the perpendicular scans case (right column). The dashed lines depict the direction that the scans cut the balloon.

The processing times for the experiments in (ms) are shown in Table I. These times represent the time needed for a single 2D template to a 3D ROI registration.

IV. Discussion

The results shown in Fig. 4 show that registration of the phantom images is ideal when the direction of both the 3D ROI and the 2D template are the same and the images are practically the same. Furthermore, stronger values are achieved when the images are of the original size. The lines in the graphs also show that there are two distinct peaks within an area of higher values. The higher value areas depict the balloon area where higher similarity exists as compared to the further away area. As the balloon with the stone was constructed as a very symmetrical structure, two peaks appear in the graphs representing positions with similar appearance on the left and on the right of the stone. In a real case, tracking would be sufficient when the shock waves' focal area is positioned so that intersects with the calyx. Therefore, small errors could be of small importance. The relative directions of the 2D templates and the 3D ROIs may reduce the correlation coefficient but do not affect drastically the registration results. In a clinical case, it is more likely that all the 2D and 3D scans would be parallel. Even so, reasons such as movement of the patient or fan shape 3D image acquisition are expected to cause reduction of the correlation coefficient.

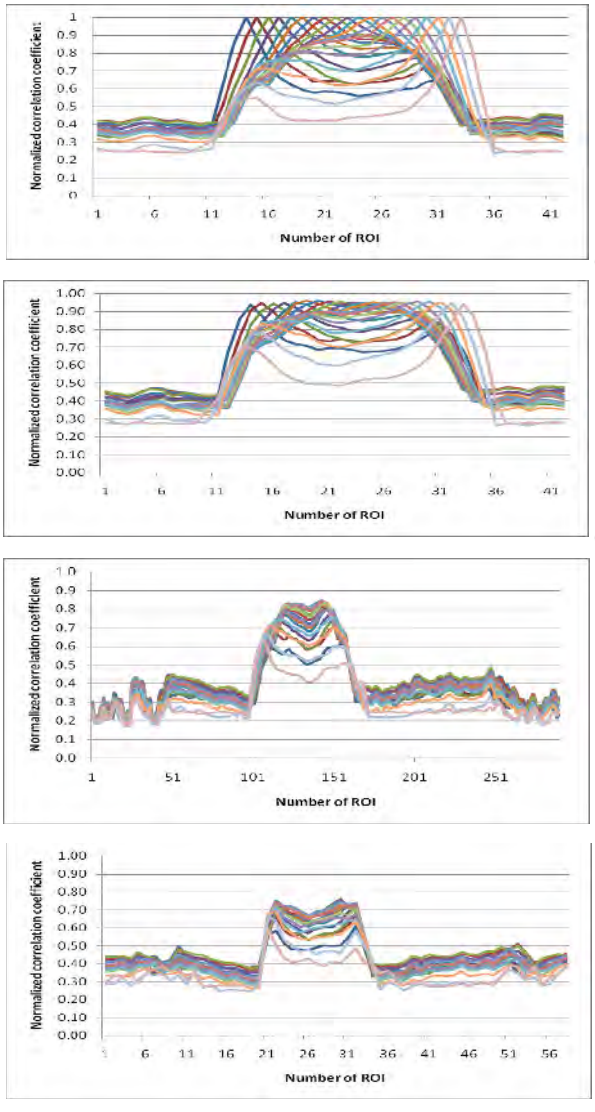

Fig. 4 Crosscorelation figures for (a) parallel scans case with original size, (b) parallel scans case with resize 1:5, (c) perpendicular scans case with original size, (d) perpendicular scans case with resize 1:5.

The time needed for processing shows that processing is time consuming with non specific software like Matlab®. This software is often used for prototyping but for a real time application is not recommended. Some difference in processing time is noticed between the parallel and perpendicular scans cases due to the different data sizes. Nevertheless, the shortest time achieved for a single slice to slice registration using the original sized data was 9.7 ms and is also very long for a real time application. Reduction of the dataset using resizing or skipping individual slices, or any other appropriate method, is highly recommended. As an example, a 1:5 resizing of the data and registration between a whole 42 slices volume would require 42 times 0.28ms which is about 12 ms. Such processing time is within the time available for a real time stone tracking. Further in-vitro and in-vivo studies are necessary to verify the applicability of the method in clinical conditions.

V. Conclusion

Using a simplified kidney stone phantom we have shown that three dimensional stone tracking could be achieved using a normalized correlation coefficient method. The time required for the proposed method is within the range of real time processing.

Table 1 Single registration processing time (ms)

Resize ratio	1:1	1:3	1:5
Parallel scans case using Matlab®	230	15.9	5.9
Perpendicular scans case using Matlab®	120	12.6	5.2
Parallel scans case using the Intel® library	9.7	0.65	0.28

A Novel Multivariate Analysis Method for Bio-Signal Processing

H.H. Lin[1], S.H. Change[1], Y.J. Chiou[1], J.H. Lin[2], T.C. Hsiao[1]

[1] Institute of Computer Science/Institute of Biomedical Engineering, National Chiao Tung University, Taiwan
[2] Department of Electronic Engineering, Kun Shan University, Taiwan

Abstract — **Often, multivariate analysis is wildly used to process "signal information", which includes spectrum analysis, bio-signal processing and etc. In general, Least Squares (LS) and PLS fall into overfitting problem with ill-posed condition, which means the future selections make the training data have better adaptability, but the quality of the prediction would be poor, compared with the testing data. However, the goal of these models is to have consistent prediction between testing and training data. Therefore, in this study, we present a novel MVA model, Partial Regularized Least Squares, which applies regularization algorithm (entropy regularization), to Partial Least Square (PLS) method to cope with the problem mentioned above.**

In this paper, we briefly introduce the conventional methods and also clearly define the model, PRLS. Then, the new approach is applied to several real world cases and the outcomes demonstrate that while calibrating data with noises, PRLS shows better noise reduction performance and lower time complexity than cross-validation (CV) technique and original PLS method which indicates that PRLS is capable of processing "Bio-signal". Finally, in the future we expect utilizing another two regularization techniques instead of the one in the paper to identify the performance differentiations.

Keywords — **Multivariate Analysis, Partial Regularize Least Squares, Noise reduction-**

I. Introduction

Multivariate analysis technique is of great importance in signal processing field, such as application in spectrum analysis [1], bio-signal and image processing [2,3]and pattern reorganization [4]. Typically, MVA can be classified into two categories: regression analysis and iterative method. In regression analysis, Least Square (LS) and Partial Least Square (PLS) are the most commonly used method. Also, the iterative method, which is well known as artificial neural network (ANN), uses Multilayer perceptron [5] as its main model. Although, both regression and iterative methods have their unique properties and are suitable for different applications, some researches in the past have demonstrated that integrating these two techniques shows significant impact on the analyzing data and verify with real case data [7, 8].

Chen (1991) presented by using the regression strategy, orthogonal least squares (OLS), to construct a ANN, radial basis function network (RBFN) [9]. Moreover, Hsiao (1998) suggested that PLS can be implemented in multilayer architecture as back-propagation (BP) network [10]. However, LS criterion in certain condition is prone to overfitting. If data are highly noisy, results may still fit into noise. Regularization is one of the techniques to overcoming the overfitting problem. Chen (1996) applied regularization techniques to his algorithm, which is regularized orthogonal least squares learning algorithm for radial basis function networks (ROLS based on RBFN) [11], and the prediction results demonstrate better generalization performance than the original non-regularized method. Therefore, follow the concept of ROLS based on RBFN, we develop a novel calibration model called Partial Regularized Least Square (PRLS) to overcome the overfitting problem that Hisoa's algorithm encountered.

II. Methods and materials

Before specifying the PRLS algorithm, we briefly describe the basic principle of PLS and its implementation in ANN architecture.

PLS regression is a widely used multivariate analysis method and is particularly useful when we need to predict a set of dependent variables from a large set of independent variables. The independent variable matrix X_{msn} and dependent variable matrix Y_{nxl} can be both decomposed into a matrix with corresponding weight matrix:

$$\begin{aligned}\mathbf{X}_{nxm} &= \mathbf{X}^{(1)} + \mathbf{X}^{(2)} + \ldots + \mathbf{X}^{(a)} + E \\ &= \hat{u}_1 \hat{p}_1^{\mathrm{T}} + \hat{u}_2 \hat{p}_2^{\mathrm{T}} + \ldots \hat{u}_a \hat{p}_a^{\mathrm{T}} + E \\ &= \mathbf{U}_{nxa}\mathbf{P}_{axm}^{\mathrm{T}}\end{aligned} \quad (1)$$

$$\begin{aligned}\mathbf{Y}_{nx1} &= \mathbf{Y}^{(1)} + \mathbf{Y}^{(2)} + \ldots + \mathbf{Y}^{(a)} + F \\ &= \hat{v}_1 \hat{q}_1 + \hat{v}_2 \hat{q}_2 + \ldots + \hat{v}_a \hat{q}_a + F \\ &= \mathbf{V}_{nxa}\mathbf{Q}_{ax1}\end{aligned} \quad (2)$$

- *Partial Least Squares (PLS)*

Fig. 1 shows the schema of PLS algorithm.

By performing the algorithm in Fig. 1, $||E_{nxm}||$ and $||F_{nxl}||$ are minimized regressively and when number of iterations

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 318–322, 2009
www.springerlink.com

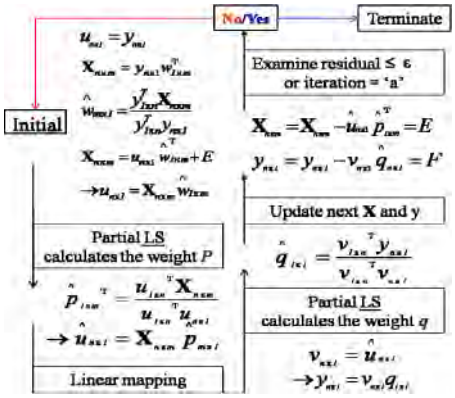

Fig. 1 PLS algorithm

equals to a certain value "a" or the "examine residual" is less or equal than a certain value ε, the process terminates. The best generalized result would be found out.

Fig. 2 illustrates the implementation of PLS in multi-layer architecture as BP network. Hsiao's contribution is to provide possible findings for the constituents within the convergent weight matrix and is a more effective method for the necessary number of hidden nodes in BP.

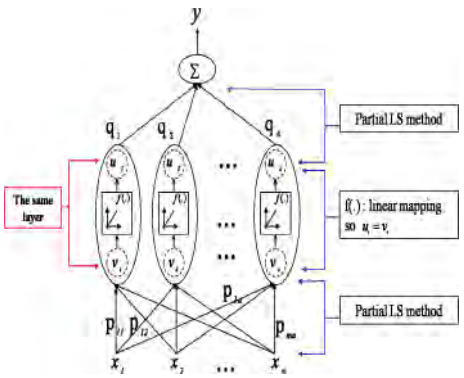

Fig. 2 Three layer PLS architecture

- *Regularization*

Generally, regularization is used to prevent overfitting and to minimize the error function of residual. Essentially it involves adding some multiple of a positive definite matrix to an ill-conditioned matrix so that the sum is no longer ill-conditioned and is equivalent to simple weight-decay in gradient descent methods. The symbols, A[u] > 0 and B[u] > 0, are two positive functions of u, so that u can be determined by either minimizing A[u] or B[u]. To summarized, regularization uses Lagrange Multipliers combines with quadratic constraint to minimize the weighted sum A[u] + λB[u] and lead to a adequate solution for u.

- *Partial Regularized Least Squares (PRLS)*

In general PLS calibration only minimizes the residual ||Enxm|| and ||Fnxl|| during the processing of decomposing independent and dependent matrices. In ideal situation, the calibration will approximate the desired output minimum. In most cases, undesired information always hide behind the real world data which we called "nosie" will interfere the prediction. However, in some circumstances, PLS calibration may suffer from overfitting problem by the undesired noises within the data. As mentioned earlier, to prevent overfitting, we introduce regularization, entropy regularization, concept into PLS and rewrite the error criterion of PLS as:

$$E_e = E_D + \lambda E_{\tilde{R}} = E^T E + \lambda q^T q, \lambda \geq 0 \quad (3)$$

(Where q is weighting vector which inferences the output directly)

Fig. 3 demonstrates the schema of PRLS algorithm.

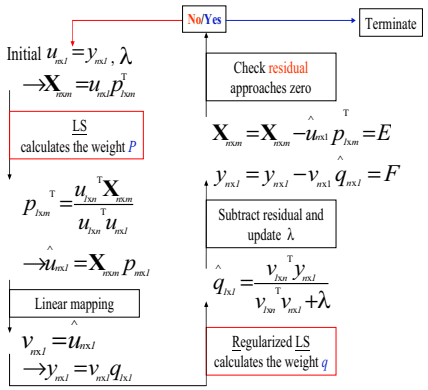

Fig. 3 PRLS algorithm flow chart

In Fig. 3, we can see that PLS are used in two different phases, however, only the later one, which calculates the weight q, influences the output directly. Hence, we only apply regularization into the second PLS phases.

Apart from integrating regularization into the original PLS, we also adjust the three-layer PLS architecture with regularization method (Fig. 4).

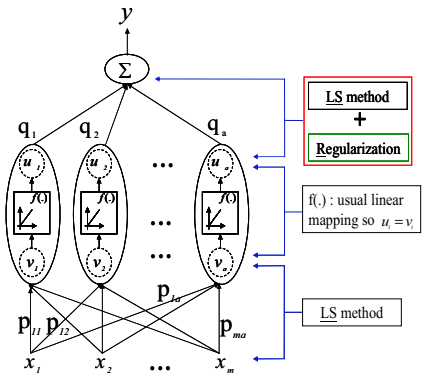

Fig. 4 PRLS three layer calibration system

III. Results

In the previous work, the PRLS algorithm has been proved have better performance than PLS with the simulation data - sigmoid and polynomial function and imitative spectrum data under SCSP (self calibration and self prediction) and CV (cross-validation). In this study, we apply PRLS method to the real data, sound and blood glucose to illustrate the performance of PRLS.

- **Sound file - Power-station ambience**

In the experiments, ex-99 data are used to predict the 100 data in the sound data - power-station-ambience. Followings are the results of the experiment.

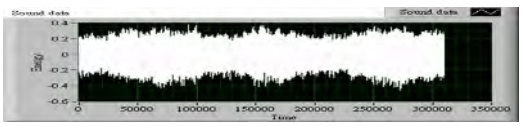

Fig.5-1 Power station ambience source data

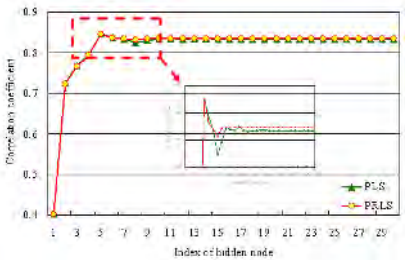

Fig.5-2 Correlation coefficient as a function of index of hidden node under SCSP

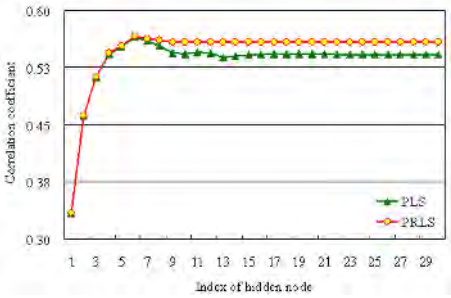

Fig.5-3 Correlation coefficient as a function of index of hidden node under CV

Table 1 Optimal CV results for power station ambience prediction data

	PLS	PRLS
Correlation coefficient	0.5646	0.5658
RMSE	0.0415	0.0411
Adequate iteration	6	6

- **Blood glucose data**

Diabetes mellitus is one of the most common diseases in the present day, we can analysis the blood glucose data and further control when the density is irregular. In the experiment, we select 37 data sets to evidence our purpose. Fig.6-1 shows blood glucose data with noise. Fig6-2 – Fig.6-7are the results of calibration under SCSP and CV.

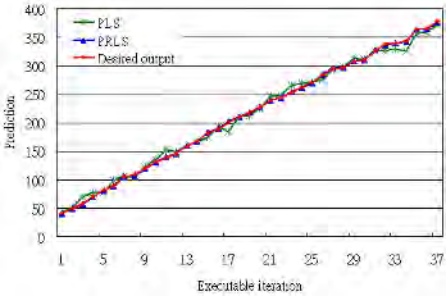

Fig.6-4 Network mapping constructed by PRLS and PLS algorithm under SCSP

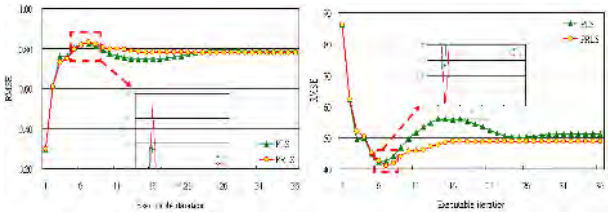

Fig.6-5 Correlation coefficient as a function of executable iteration under CV. Fig. 6-6 RMSE as a function of executable iteration under CV

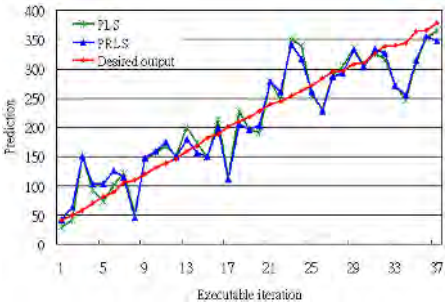

Fig. 6-7 Network mapping constructed by PRLS and PLS algorithm under CV

Table 2 Optimal CV results for blood glucose data

	PLS	PRLS
Correlation coefficient	0.8240	0.8320
RMSE	42.280	40.993
Adequate iteration	6	7

IV. Discussion

Table 3 is drawn from the results of our experiments. It is hoped that the prediction results are in high correlation coefficient, small RMSE and consumes little computation which means, the height of correlation coefficient always keeps high, slope of RMSE is not abrupt and the time complexity could be as low as possible. From the table, it clearly shows that PRLS has better performance than other methods.

Table 3 Compilation of real experimental results

Condition / Criterion	SCP		CV	
	PLS	PRLS	PLS	PRLS
Correlation Coefficient				
RMSE				
Time complexity	O(n)		$O(n^2)$	

V. Conclusions

In this study, we accomplish integrating regularization method, entropy regularization, into PLS algorithm called PRLS as a brand new MVA technique. PRLS illustrates better calibration result than the original method.

Despites manipulating PRLS with simulation data, PRLS method is successfully applied to real world problems – sound and blood glucose in this study. PRLS illustrates better calibration results both in performance and time complexity than the original method when calibrating data with large undesired noise. The result demonstrates that PRLS is suitable for analyzing bio-signal, which particularly has a lot of noise within the raw data.

Furthermore, we would like to extend our work by using another two regularization techniques (gradient based regularization and square-error based regularization) to enhance multivariate analysis technique.

Multi-Wavelength Diffuse Reflectance Plots for Mapping Various Chromophores in Human Skin for Non-Invasive Diagnosis

Shanthi Prince and S. Malarvizhi

[1] Department of Electronics and Communication Engineering, SRM University,
SRM Nagar -603203, Tamil Nadu, Chennai, India.

Abstract — **Optical techniques have the potential for performing in vivo diagnosis on tissue. Spectral characteristics of the components provide useful information to identify the components, because different chromophores have different spectroscopic responses to electromagnetic waves of a certain energy band.**

The basis for this mapping method arise from the differences in the spectra obtained from the normal and diseased tissue owing to the multiple physiological changes associated with increased vasculature, cellularity, oxygen consumption and edema in tumour. Different skin and sub-surface tissues have distinct or unique reflectance pattern which help us differentiate normal and cancerous tissues.

An optical fibre spectrometer is set up for this purpose, which is safe, portable and very affordable relative to other techniques. The method involves exposure of skin surface to white light produced by an incandescent source. These back scattered photons emerging from various layers of tissue are detected by spectrometer resulting in tissue surface emission profile.

For the present study, three different skin diseases - warts, moles and vitiligo are chosen. The spectral data from the scan is presented as a multi-wavelength plot. Further, ratio analysis is carried out in which, the relative spectral intensity changes are quantified and the spectral shape changes are enhanced and more easily visualized on the spectral curves, thus assisting in differentiating the part which is affected by disease visually.

The unique information obtained from the multi-wavelength reflectance plots makes it suitable for a variety of clinical applications, such as therapeutic monitoring, lesion characterization and risk assessment.

Keywords — **Multi-wavelength, diffuse reflectance, chromophores, ratio-analysis, non-invasive.**

I. Introduction

Advances in the understanding of light transport through turbid media during the 1990s led to the development of technologies based on diffuse optical spectroscopy and diffuse optical imaging [1] [2]. There has recently been significant interest in developing optical spectroscopy as a tool to augment the current protocols for cancer diagnosis [3], as it has the capability to probe changes in the biochemical composition of tissue that accompany disease progression. A non-invasive tool for skin disease diagnosis would be a useful clinical adjunct. The purpose of this study is to determine whether visible/near-infrared spectroscopy can be used to non-invasively characterize skin diseases.

Many benign skin diseases resemble malignancies upon visual examination. As a consequence, histopathological analysis of skin biopsies remains the standard for confirmation of a diagnosis. Visible/near-infrared (IR) spectroscopy may be that tool which could be utilized for characterization of skin diseases prior to biopsy.

A variety of materials in skin, absorbs mid-IR light (>2500 nm), thus providing an insight into skin biochemistry. But, if the sample thickness is greater than 10-15μm, mid-IR light is completely absorbed. Therefore, the diagnostic potential of mid-IR spectroscopy in-vivo is limited, In contrast, near-IR light is scattered to a much greater extent than it is absorbed, making tissues relatively transparent to near-IR light, thus allowing the examination of much larger volumes of tissue [4] and the potential for in-vivo studies.

The near-IR region is often sub-divided into the short (680-1100 nm) and long (1100-2500 nm) near-IR wavelengths, based upon the technology required to analyze light in these wavelength regions. At shorter near-IR wavelengths, oxy- and deoxyhemoglobin, myoglobin and cytochromes dominate the spectra, and their absorptions are indicative of regional blood flow and oxygen consumption.

The purpose of this study is to determine whether the information obtained from visible/near-IR spectroscopy for a variety of skin diseases will enable us to characterize the tissues based on chromophore mapping and be used as a diagnostic tool.

II. Materials and Methods

Optical spectrum from the tissue yield diagnostic information based on the biochemical composition and structure of the tissue. Different skin and sub-surface tissues have distinct or unique reflectance pattern which help us differentiate normal and cancerous tissues [5].

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 323–326, 2009
www.springerlink.com

Light reflected from a surface consists of specularly reflected and diffusely reflected components. The intensity of the specular component is largely determined by the surface properties of the sample and is generally not of analytical utility. The intensity of the diffuse component, which includes the contributions from the absorbance of light by the specimen and the scattering of light by the specimen and the substrate, can be used to determine the concentration of the indicator species [6].

The schematic diagram of the visible/near-infrared (IR) spectroscopy system is shown in Fig.1. It consists of Tungsten Halogen Light Source (LS-1) which is a versatile white-light source optimized for the VIS-NIR (360-2500nm) and the spectrometer (USB4000) [7]. The spectrometer consists of 3648 element detector with shutter, high speed electronics and interface capabilities. The USB4000 is responsive from 360-1100nm.

Acquisition of visible/near-IR data is straightforward. White light from a tungsten halogen lamp is brought to the skin via a reflectance probe (R400). The reflectance probe consists of bundle of seven optical fibers. Six illumination fibers and one read fiber – each of which is 400µm in diameter. The fiber ends are coupled in such a manner that the 6-fiber leg (the illumination leg) is connected to the light source and the single fiber leg is connected to the spectrometer. The light penetrates the skin, and water, hemoglobin species, cytochromes, lipids and proteins absorb this light at specific frequencies. The remaining light is scattered by the skin, with some light being scattered back to the fiber optic probe. The light is collected by the probe and transmitted back to the spectrometer for analysis.

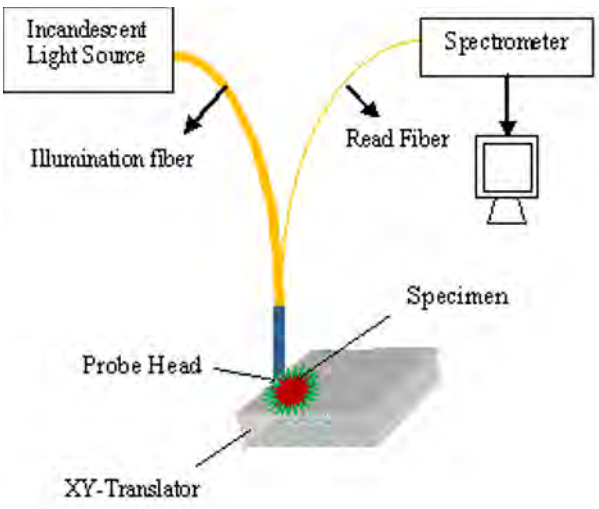

Fig.1 The schematic diagram of Visible/near-infrared (IR) spectroscopy system based on diffused reflectance

III. Aquisition of spectra and analysis

For the present study, three different skin diseases - warts, moles and vitiligo are chosen. Warts are small skin growths caused by viral infections. There over 100 types of human papilloma virus (HPV). Some warts share characteristics with other skin disorders such as molluscum contagiosum (a different type of viral skin infection), seborrhoeic keratosis (benign skin tumor) and squamous cell carcinoma (skin cancer). It is important to distinguish and diagnose.

Mole (nevus) is a pigmented spot on the outer layer of the skin epidermis. Most moles are benign, but typical moles (dysplastic nevi) may develop into malignant melanoma, a potentially fatal form of skin cancer. Congenital nevi are more likely to become cancerous.

Vitiligo is a zero melanin skin condition . The characteristics of this disease are the acquired sudden loss of the inherited skin color. The loss of the skin color yields white patches of various sizes, which can be localized anywhere on the body. However, not all white skin patches are vitiligo. There are other conditions and diseases that are associated with white skin called leucoderma. Clearly, it seems mandatory to make the correct diagnose.

Malignant Melanoma (MM) is another skin cancer which can be very dangerous if not recognized early. These tumors can develop in existing moles but they can also arise totally new as pigmented as well as non-pigmented tumors. Early recognition and excision are important for the outcome. The observation that melanoma is more frequent in patients with vitiligo originates from a study which included 623 Caucasian patients with melanoma of the Oncology Clinic at the Department of Dermatology at the University of Hamburg/Germany [8]. Some individuals with melanoma develop patches of white skin in the vicinity of their melanoma or after their tumor had been excised. In this context it seems important that these white patches are not vitiligo. This skin shows a very different molecular biology and biochemistry compared to true vitiligo [9].

Each reflectance spectrum is acquired by an Ocean Optics USB4000 spectrometer with a spectral resolution of 3.7nm. Spectra are acquired and recorded in the360 -1100 nm ranges using the system described in the previous section.

Firstly, white light is directed into a portion of the skin afflicted with the skin disease, the diffusely reflected light is collected, thereby producing a condition spectrum. Next, the same light is directed into a control skin portion of the patient which is not afflicted with the skin disease. A spectrum is taken of an unaffected skin portion as a control from each patient.

Prior to obtaining the readings, the subject's skin and the end of the probe are cleansed with 70% alcohol. The fiber optic probe is then positioned 1.0 mm from the measure-

ment site and data acquired. A plot of the amount of light backscattered at each wavelength (the spectrum) is computed. Measurements are rapid, non-destructive and non-invasive

The ratio technique is used to aid spectra interpretation. In the ratio analysis technique, the lesional spectra are divided by the corresponding spectra of the normal neighboring skin. In this way, the relative spectral intensity changes are quantified and the spectral shape changes are enhanced and more easily visualized on the spectral curves. As a consequence, these differences can be used to identify or diagnose a skin disease by comparing the visible/near-IR spectrum of a control region to a spectrum taken of the region of interest.

For the present study, spectrum is obtained from wart, mole and vitiligo skin. Also, for each case a control spectrum is obtained. The control spectrum and the disease spectrum is compared at wavelengths corresponding to visible/ near-IR absorption by oxyhemoglobin, deoxyhemoglobin, water, proteins, lipids or combinations thereof.

IV. Results and Discussion

As mentioned above, three different skin abnormalities are studied viz. wart, mole and vitiligo regions. Fig. 2 shows the plot of the original reflectance spectra of wart and the control skin along with the reflectance ratio between the wart region and the normal skin. The wart region shows very low reflectance but the shapes of the two curves are visually same.

By obtaining the ratio spectrum we observe that there is a valley around 610nm which is unique to wart and which cannot be discerned by only looking at the original spectrum. The values of the ratio plot are higher in the lower and higher wavelengths, except for the visible region.

Fig. 3 shows the spectra of mole and the control skin along with the reflectance ratio plot. Except for a slight decrease in the reflected intensity for the mole region nothing specific can be obtained from the original spectra.

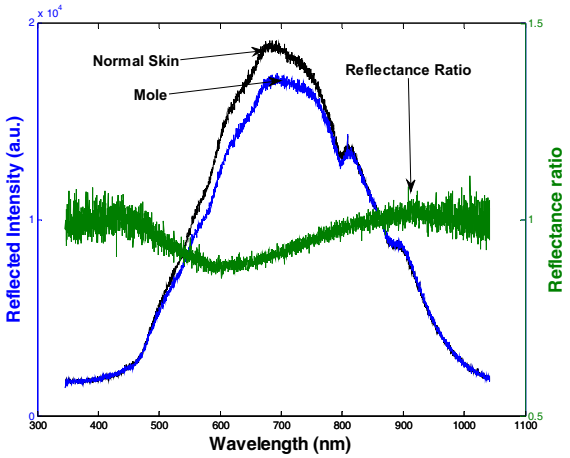

Fig.3 Reflected Intensity and Reflectance ratio spectra for the mole and the normal skin

By observing the reflectance ratio plot we find a valley at around 580nm which is specific to that particular mole type. The ratio value is more or less equa1 to 1, indicating that there is a close resemblance of mole to the control spectra.

Fig. 4 shows the reflectance spectra of vitiligo and the control skin. The absolute value of the ratio spectrum is larger than 1, indicating that the reflected intensity for a

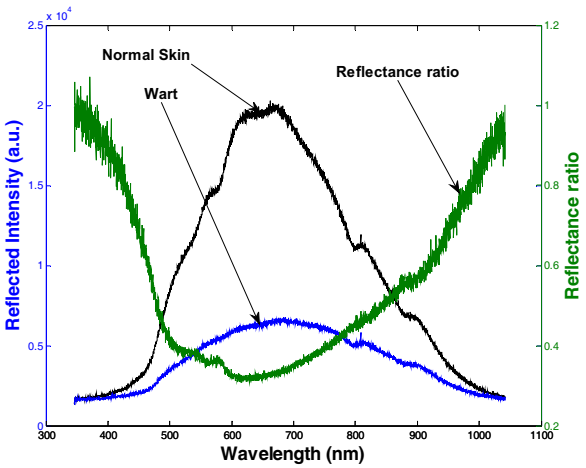

Fig.2 Reflected Intensity and Reflectance ratio spectra for the wart and the normal skin

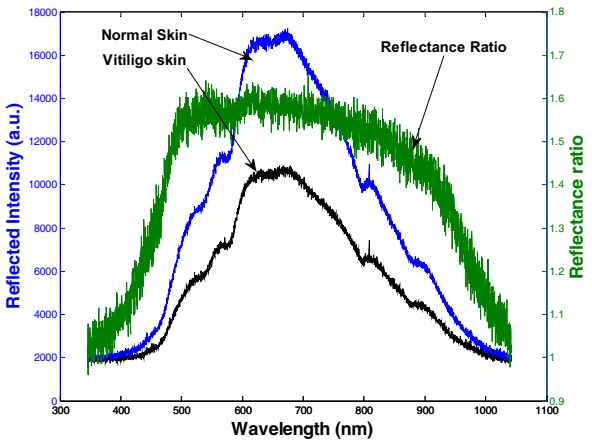

Fig.4 Reflected Intensity and Reflectance ratio spectra for the vitiligo and the normal skin

vitiligo skin is higher than that for the normal skin. Since vitiligo corresponds to region of zero-melanin skin it has little absorption and hence maximum reflectance. The ratios with values less than 1 indicate that the lesional reflectance is lower than the surrounding normal skin. The numerical ratio values quantify this difference as a function of wavelength.

Fig.5 shows the three dimensional multi-wavelength reflectance plots along the region of wart. As seen in the Fig. 2 the intensity is much lower when compared to the neighboring control skin. This plot along with the reflectance ratio plots will aid in the visible-NIR spectroscopy to be used as a diagnostic tool for detecting various skin pathologies.

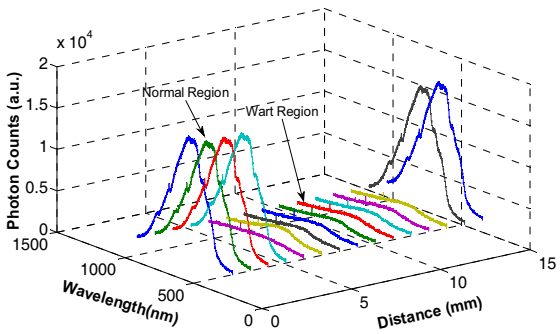

Fig.5 Multi-wavelength reflectance plot along the wart region

The visible/near-IR spectra of different skins presented here exhibit strong absorption bands from water and a number of weak, but consistent, absorption bands arising from oxy- and deoxy- hemoglobin, lipids and proteins. However, visual examination of spectra did not show distinct differences in these spectral features that could be used to distinguish between spectra of skin diseases and healthy skin.

V. Conclusions

The spectrum depends on the depth and the type of chromophore contained in the inclusion. An increase in the concentration of a given molecule may produce different contrast, independently of the depth, depending on the characteristics of the skin layer where this change occurs.

Each peak in the spectrum can be assigned to a specific compound found in the skin. Visually, strong absorption bands arising from OH groups of water dominate the spectrum. However, much information is present in the weaker spectral features. For instance, the relatively strong absorption feature at 550 nm arises from hemoglobin species and provides information relating to the oxygenation status of tissues. Further information on tissue oxygenation can be obtained from analysis of a weak absorption feature at 760 nm, arising from deoxyhemoglobin.

Information on tissue architecture/optical properties can be obtained from the spectra. Changes in tissue architecture/optical properties may affect the basic nature of the interaction of light with the tissue. For example, changes in the character of the epidermis (i.e. dehydration) may result in more scattering of light from the surface, reducing penetration of light into the skin in a wavelength dependant manner. Also, different tumor densities may result in more scattering of light from the surface. Such phenomena would be manifest in spectra as changes in the slope of the spectral curves, especially in the 400-780 nm regions.

Abstract — **A new system is developed for the diagnosis of diabetic retinopathy. It is developed with the help of slit lamp biomicroscopic retinal images. The results are compared with digital fundus image using image processing techniques. The slit lamp, offering users both space savings and cost advantages. By using slit lamp biomicroscopic equipment with an ordinary camera, users can reduce the cost more than 30 times compared to digital fundus camera. The fundus examination was performed on human volunteers with a hand held contact or non-contact lens (90D).The lens providing an extremely wide field of view and better image resolution. The slit lamp equipment is used to examine, treat (with a laser), and photograph (with a camera) of the retina. A digital camera is permitted to capture the image and store this image by using slit lamp, each photograph have small potion of the entire retinal image. The individual slit lamp biomicroscopic fundus images are aligned and blended with block matching algorithm to develop an entire retinal image same as the fundus camera image and detect optic disk, blood vessel ratio from the images. This image can be used for the diagnosis of diabetic retinopathy.**

Keywords — **Block matching algorithm, Sum of squared difference, Diabetic retinopathy, Optic disk, Blood vessel ratio.**

I. Introduction

The retina is a light sensitive tissue at the back of the eye. When light enters the eye, the retina changes the light into nerve signals. The retina then sends these signals along the optic nerve to the brain. Without retina eye cannot communicate with the brain, making vision impossible.

Fundus cameras provide wide field, high quality images of posterior segment structures including the optic disc macula and blood vessels [1]. However, the slit lamp biomicroscope, the workhorse for ophthalmic diagnosis and treatment is easy and it is now often equipped with camera attachments to permit image capture for documentation, storage, and transmission. In many cases, image quality may be low, in part attributable to a narrow field of view and specular reflections arising from the cornea, sclera, and hand held lens.The cost of fundus camera is very high compared to slit lamp camera and this is the motivation of this work. Digital retinal cameras are now being used in a variety of conditions to obtain images of the retina to detect diseases such as; glaucoma, diabetic retinopathy, hypertensive retinopathy and age related macular degeneration.

The main parts for the slit lamp images consist of slit lamp equipment, digital camera and 90D lens, without using 90D lens we can capture only the front portion of the eye [2]. The slit lamp images from the slit lamp camera is combined by using Block Matching Algorithm with a typical criteria used is Sum of Squared Difference (SSD) in terms of cross correlation operations [3]. Diabetic retinopathy is the leading cause of blindness in the Western working age population. Screening for retinopathy in known diabetics can save eyesight but involves manual procedures which involve expense and time [4].In this work, detect the arteries to vein ratio of main blood vessels from the fundus image and the combined slit lamp image then compare the values between these two images. The diabetic level, both for these two set of images are determined and compared with clinical data.

II. Proposed system

The fundus photographs were taken with a fundus camera during mass screening. These photographs were then scanned by a flat-bed scanner and saved as a 24-bit true color JPG file of 512x512 pixels. The slit lamp images of the same person is taken with a slit lamp camera and saved as a JPG file of size 512x512 pixels. The basic block diagram to describe the methodology is shown in Fig (1).

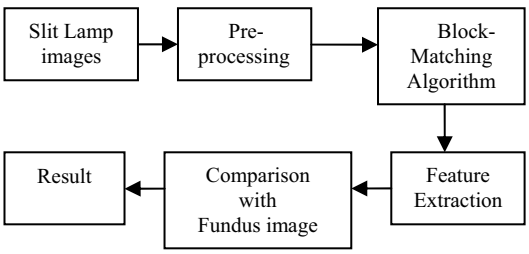

Fig (1) Block diagram of methodology

A. Slit Lamp Image

The slit lamp biomicroscopic images are small portions of the entire retinal fundus image; this is shown below in Fig (2).

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 327–330, 2009
www.springerlink.com

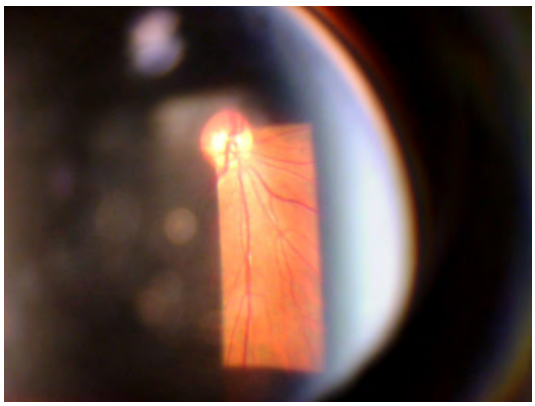

Fig (2) Slit Lamp Biomicroscopic image

B. Pre-processing

Pre-processing of the slit lamp image is done to improve the visual quality and reducing the amount of noise appearing in the image. RGB color coordinate is not required for this purpose; color system of the original image was converted to RGB components. Applied histogram equalization [5] to B component only and combined to three color coordinate, which is converted to grayscale image. The resultant image is shown below in Fig (3),

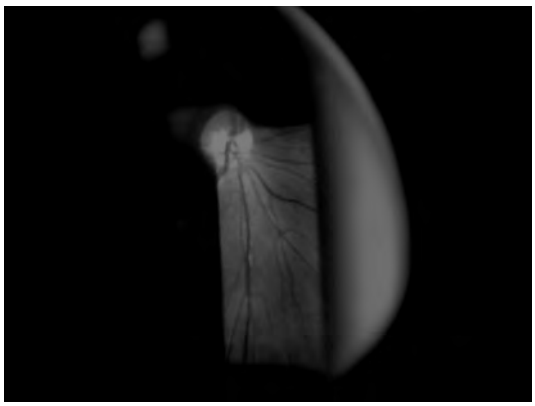

Fig (3) Pre-processed image

C. Block Matching Algorithm

In this paper, The block based method is to determine the position of a given block *g* from the current block *f*. Let *g(k,l)* denotes the luminance value of the block *g* of size (a x b) at the point *(k,l)* and *f(k,l)* denotes the luminance value of the current block *f* of size (c x d) at the point *(k,l)*.

The common used optimal block based algorithm is the Full Search Block Matching Algorithm (FS) which compares the current block *f* to all of the candidate blocks , and selects the motion vector corresponding to the candidate block, which yields the best criterion function value [6]. In this paper, we compare only the boundaries of current block *f* to the boundaries of the candidate blocks to optimizing the algorithm. Typical criteria used is the sum of squared differences (SSD),

$$SSD(x,y)=\sum_{l=0}^{n-1}\sum_{k=0}^{m-1}(f(k+x,l+y)-g(k,l))^2 \quad (1)$$

The motion vector (mv_x , mv_y) is measured from the position of the minimum in (1). The original fundus image from digital fundus camera and the resultant combined slit lamp fundus image are shown in Fig (4) and (5).

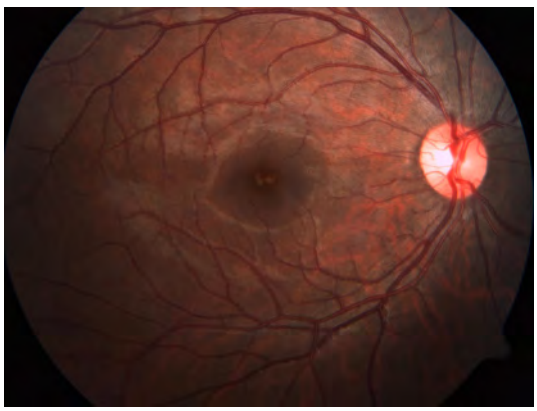

Fig (4) Original Fundus image

The combined slit lamp image is shown below,

Fig (5) Combined slit lamp image

D. Optic Disk Detection

Optic disk is the brightest part in the normal fundus image, which can be seen as a pale, round or vertically oval disk. It is the entrance region of blood vessels and optic nerves of the retina. The optic disk was identified by the area with the highest variation in intensity of adjacent pixels. First convert the color image into gray level image; enhance this image by using histogram equalization, then apply morphological closing followed by opening to suppress most of the vasculature information [7]. The structuring element is a disc lager than the largest vessel cross-section. Finally we got a bright area as plausible optic disk candidate. This is shown in Fig (6).

Fig (6) Optic Disk

E. Ratio of blood vessel width

Blood vessels appear as networks of either deep or orange-red filaments that originate with in the optic disk and are progressively diminishing width. Information about blood vessels in retinal images can be used in grading disease severity.

The normal ratio of the diameter of the main venule to the main arteriole in the retinal vascular system is about 3:2. This value is standardized by ophthalmologists all over the world [8]. In a diseased retina, one that is affected by diabetic, ratio of the diameter of the main venule to the main arteriole increases above 1.5 and can go up to 2. Due to blockages in the vessels and change in the blood sugar levels caused by diabetes, there will be a change in the diameters of the blood vessels. The diameter of arteries will decrease and that of veins increases. By detecting this change in the blood vessel diameter ratio increase, it can diagnose diabetic as early as possible [9].

Ratio of blood vessel width is estimated using concentric circle method. The centre of the optic disk is found by binary matrix calculations [10]. The next step is to find the ratio of the widths of the blood vessels. The centre of the optical disk is used to draw concentric circles of uniformly increasing radius. Traveling along the circles, the sudden intensity changes are noted, which are used to identify the width of the veins and arteries.

F. Comparison with fundus image

Image data base consist of 11 images from both digital fundus camera and slit lamp camera of diabetic retinopathy with clinical details. All images are classified in to four categories like normal, mild, moderate and severe. The comparison between fundus image and slit lamp image is shown in Table 1.

- Error Calculation

Calculating the error between fundus image and slit lamp image by using equation (2) given below,

$$\text{Error in \%} = \frac{|A-B|}{A} \times 100 \qquad (2)$$

Where A is the blood vessel ratio of fundus image and B is the blood vessel ratio of slit lamp image

Table: 1. Comparison between fundus image and slit lamp image.

No.	Blood vessel ratio (fundus image) (A)	Diabetic Stage of fundus image	Blood vessel ratio (slit lamp image) (B)	Diabetic Stage of slit lamp image	Error (%)
1	1.6667	moderate	1.7333	moderate	4.00
2	1.4981	normal	1.5618	mild	4.25
3	1.4688	normal	1.5321	mild	4.30
4	1.9704	severe	2.0461	severe	3.84
5	1.6144	moderate	1.6819	moderate	4.18
6	1.7934	moderate	1.8648	moderate	3.98
7	2.0680	severe	2.1441	severe	3.68
8	1.5685	mild	1.6345	moderate	4.21
9	1.5695	mild	1.6357	moderate	4.22
10	1.9264	severe	2.0008	severe	3.86
11	1.4684	normal	1.5316	mild	4.30

III. Conclusions

On the basis of slit lamp image information, can combine the slit lamp images and detect diabetic retinopathy. The error between slit lamp image and fundus image is small in terms of blood vessel ratio, hence in the detection of diabetics, the results are matched with clinical data. Although the

present work is focused on diabetic retinopathy in terms of blood vessel ratio, it is extensible to the detection of diseases based on retinal condition.

Tracing of Central Serous Retinopathy from Retinal Fundus Images

J. David[1], A. Sukesh Kumar[2] and V. Viji[1]

[1] College of Engineering, Trivandrum, India
[2] College of Engineering, Trivandrum, India

Abstract — **The Fundus images of retina of human eye can provide valuable information about human health. In this respect, one can systematically assess digital retinal photographs, to predict various diseases. This eliminates the need for manual assessment of ophthalmic images in diagnostic practices. This work studies how the changes in the retina caused by Central Serous Retinopathy (CSR) can be detected from color fundus images using image-processing techniques. Localization of the leakage area is usually accomplished by Fluorescein angiography. The proposed work is motivated by severe discomfort occurring to certain patients by the injection of fluorescein dye and also the increase in occurrence of CSR now days. This paper presents a novel segmentation algorithm for automatic detection of leakage site in color fundus images of retina. Wavelet transform method is used for denoising in the preprocessing stage. Contrast Enhancement method is employed for non-uniform illumination compensation and enhancement. The work determines CSR by the localization of leakage pinpoint in terms of pixel co-ordinates and calculates the area of the leakage site from normal color fundus images itself.**

Keywords — **Central Serous Retinopathy, Fundus Imaging, Wavelet Analysis, Watershed Algorithm, Neural Network Classification.**

I. Introduction

Central serous Retinopathy (CSR) [1] is a serous macular detachment that usually affects young people and it leads to visual prognosis in most patients. It may also develop as a chronic or progressive disease with widespread decompensation of the Retinal Pigment Epithelium (RPE) and severe vision loss. Localization of the leakage site is crucial in the treatment of CSR. It is usually accomplished by Fluorescein angiography (FA). Despite the widespread acceptance of FA, its application has been restricted because of the possibility of severe complication and the discomfort to patients, as well as the time needed to perform the test. A normal fundoscopy of the eye also reveals the features of CSR. However, the images obtained through the normal fundoscopy are not as specific as Angiogram and they cannot be used as an efficient method for the analysis of CSR. A computer assisted diagnosis system can effectively employ Image Processing techniques to detect specifically the leakage area of CSR without taking the angiogram of the patient. The major structures of the retina such as Optic disk and Macula are detected during the work using Image Processing Techniques. This work describes image analysis methods for the automatic recognition of leakage area from color fundus image. A comparative study of the Angiogram and the color fundus images is done. The error between the coordinates of detected leakage point from color fundus and the angiogram leakage point is calculated. From the set of parameters, the images are distributed into two different groups, mild and severe. Neural network is used effectively in data classification.

II. Proposed System

The fundus photographs were taken with a fundus camera. The angiogram images of the patients are also taken by the injection of the fluorescein dye. These photographs were then scanned by a flatbed scanner and saved as a 24-bit true color JPG file of 576x768 pixels. Both the images of the same patient are taken and collected as a database for the comparison purpose. The block diagram of the proposed system is shown in figure (1). The image files are analyzed using the algorithms described in the following section: 1. Detection of optic disc 2. Detection of Fovea. 3. Detection of leakage site and the corresponding pixel co-ordinates. 3. Calculation of area of the leakage site. 4. Classification of images using Neural Network.

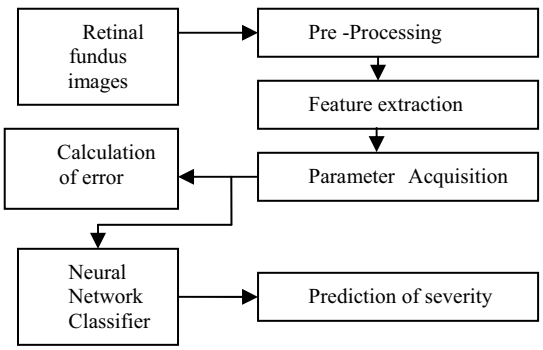

Fig (1) Block diagram of the proposed system

III. Pre-processing

A. Method

Pre-processing is used to improve the visual quality of the fundus image and it helps in color normalization [2]. It helps in highlighting the features that are used in image segmentation. Two typical techniques used are filtering and contrast enhancing. Filtering is used for enhancing the quality of images. It helps in sharpening blurry images. Images having low contrast can result from inadequate illumination, wrong lens aperture. Contrast enhancement increases the dynamic range of an image. For the image, local contrast enhancement [3] gave a superior result compared to contrast stretching transformation and histogram equalization. The results are shown in Fig (2) a. and b.

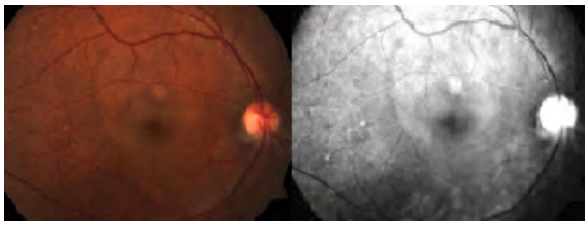

Fig (2) a. Original image Fig (2) b. Contrast Enhanced image

B. De-Noising.

De-Noising is done by wavelet analysis using wavelet toolbox, as shown in Fig (3). The advanced stationary wavelet analysis [4] is employed. The basic idea is to average many slightly different discrete wavelet analyses.

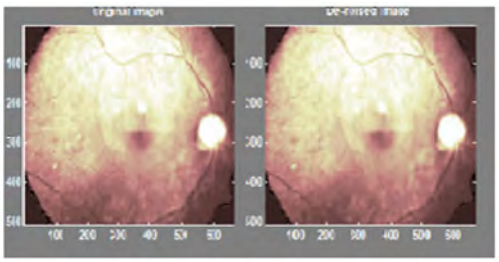

Fig (3) Denoising using wavelet analysis.

IV. Detection of optic disc

Optic disk is the entrance region of blood vessels and optic nerves to the retina and it often works as a landmark and reference for other features in the retinal fundus image [5]. Its detection is the first step in understanding fundus images. It determines approximately the localization of the macula, which is of great importance, as leakage area is more prominent there.

An area threshold is used to localize the optic disc. A best fitting circle is drawn for determining the boundary. The centre point and hence the diameter of the optic disk (ODD) is thus defined. The Optic disk detection is significant for the work because the centre point of the Optic disk is taken as the reference point for locating pixel co-ordinates of the leakage point. The result is shown in Fig (4).

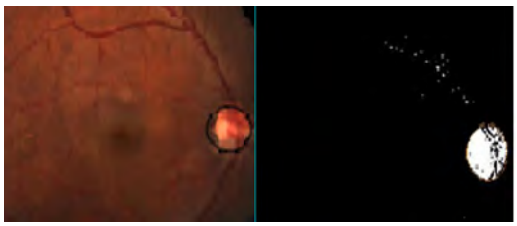

Fig (4) Optic Disc located

V. Detection of fovea

The macula is localized by finding the darkest pixel in the coarse resolution image following a geometric criterion.

The gradient is calculated and certain morphological operations are done to recognize the fovea, as shown in Fig (5). The candidate region of fovea is defined as an area of circle, which forms 2ODD [6], shown in Fig (6). Location of fovea is significant because, for the classification scheme, the distance of the leakage point co-ordinates from the fovea is to be measured as it determines whether Laser Photocoagulation is necessary for the patient or not.

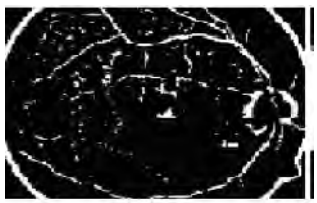

Fig (5) Gradient calculated and fovea recognized

Fig (6) Fovea located

VI. Detection of leakage area.

It is the green channel that the leakage area appears more contrasted. We first identify the candidate regions; these are regions that mostly contain the leakage area. Then morphological techniques [7] are applied in order to find the exact contours.

A. The Segmentation Paradigm

The information on objects of interest are extracted from the images. Image Segmentation [8] plays a crucial role in medical imaging by facilitating the delineation of regions of interest. Watershed transform [9] is the technique employed for the purpose. The principle of the watershed technique is to transform the gradient of a gray level image in a topographic surface. A watershed is obtained which is the boundary between the two minima influence zone. The real image is often noisy and leads to over-segmentation. So in order to avoid that, the advanced Gradient and Marker Controlled algorithm is employed. The watershed transform gives good segmentation results if topographical relief and markers are suitably chosen for different type of images. [10] The minima and maxima of a function are calculated by SKIZ algorithm [11].

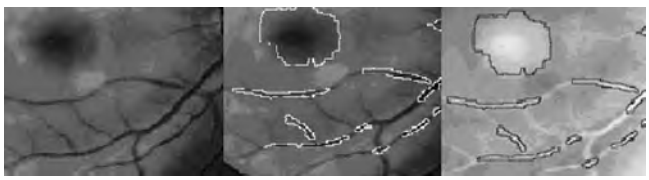

Fig (7) a. Original image Fig (7) b. Watershed of the image. Fig (7) c. Ridgelines

VII. Parameter acquisition

A. Area of the Leakage site

As the disease progresses, the area of the leakage site increases. It indicates the severity of the disease, as increase in leakage area means the RPE leak is more prominent. Leakage area is estimated by taking the ratio of No. of pixels in the leakage site to that of total pixels in the image.

B. Measurement of the distance of leakage site from fovea

The leakage point is defined by the particular pixel coordinate of the region. The co-ordinate distance is measured with respect to centre of OD and fovea [12]. If the RPE leak region is less than $1/4^{th}$ of ODD distance from fovea, the disease is mild and can wait for 4 months without any treatment. If it is greater than $1/4^{th}$ of ODD, then Laser Photocoagulation is needed.

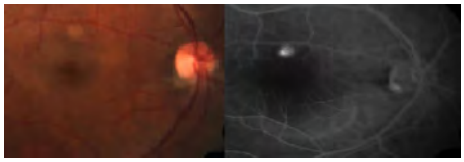

Fig (8) a. Color fundus image Fig (8) b. Angiogram image

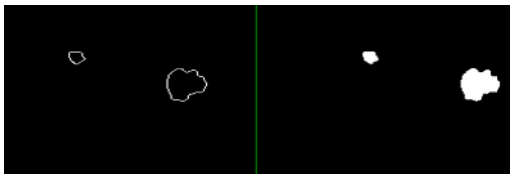

Fig (9) Leakage point detected from color fundus image.

Image database consists of 20 images. For each image, area of leakage site and the distance from fovea are measured.

Table 1 shows the pixel co-ordinates with respect to optic disk from both color fundus images and angiogram images. The pixel co-ordinates represent the leakage pinpoint. The distance of the leakage co-ordinate from the reference point. i.e., from the centre of optic disk is also calculated.

Error percentage of Coordinates is measured by least square method.

Table 1. Calculation of error between leakage point pixel co-ordinates of color fundus image and Angiogram images

Co-ordinates Angio	Co-ordinates Fundus	Error %	Dist: From Ref: Angio(*X*)	Dist from Ref: Fundus(*Y*)	Error %
178,145	174,151	2.81	132	128	3.03

$$\text{Error percentage of distance} = \frac{|X - Y|}{X} \times 100\ \% \qquad (1)$$

where X and Y are distance from reference point to leakage site for angiogram and fundus images respectively.

VIII. Neural network classifier

In this work, Back Propagation Network [13] is used for the classification scheme. The network is used to classify the images according to various disease conditions. All the images are distributed into two categories as severe and mild according to the parameter values. Table 2 shows the distribution of the parameters with CSR conditions.

Table 2. Classification of images based on disease conditions.

No.	Area of Leakage site(A)	OD diameter (D)	Distance from Fovea(d)	Stages Of Disease
1	0.0361	84	76.94	mild
2	0.0362	89	51.00	mild
3	0.0678	82	29.21	severe
4	0.0523	91	46.52	severe
5	0.0852	79	23.01	severe
6	0.0961	89	56.12	severe
7	0.0361	78	21.82	mild
8	0.0511	93	98.31	mild
9	0.1321	86	32.63	mild
10	0.0932	84	19.82	severe
11	0.0756	82	78.52	severe
12	0.0462	83	63.52	mild
13	0.0382	87	21.63	mild
14	0.0621	83	19.86	severe
15	0.0500	77	21.36	mild
16	0.0112	93	82.37	mild
17	0.0718	92	63.00	severe
18	0.0819	84	49.58	severe
19	0.0911	82	23.12	severe
20	0.1667	85	73.06	mild

IX. Conclusion

In this paper, an image-processing technique is proposed, which can play a major role in the diagnosis of CSR. A comparative analysis of the detected leakage area from Color Fundus images and Angiogram images is done. The accuracy is determined by the calculated error percentage between the two, and it is found that the error is small.

A Confidence Measure for Real-time Eye Movement Detection in Video-oculography

S.M.H. Jansen[1], H. Kingma[2] and R.L.M. Peeters[1]

[1] Department of Mathematics, MICC, Maastricht University, The Netherlands
[2] Division of Balance Disorders, Department of ENT, University Hospital Maastricht, The Netherlands

Abstract — **Video-oculography (VOG) is a frequently used clinical technique to detect eye movements. In this research, head mounted small video-cameras and IR-illumination are employed to image the eye. The need for algorithms to extract the eye movements automatically from the video recordings is high. Many algorithms have been developed. However, to our knowledge, none of the current algorithms, is in all cases accurate and provides an indication when detection fails. While many doctors draw their conclusions based on occasional erroneous measurement outcomes too, this can result in a wrong diagnosis. This research presents the design and implementation of a robust, real-time and high-precision eye movement detection algorithm for VOG. But most importantly, for this algorithm a confidence measure is introduced to express the quality of a measurement and to indicate when detection fails. This confidence measure allows doctors in a clinical setting to see if the outcome of a measurement is reliable.**

Keywords — **Eye movement detection, video-oculography, confidence measure, pupil detection, reliability**

I. Introduction

Medical studies of eye movement are important in the area of balance disorders and dizziness. For example, studying nystagmus (rapid, involuntary motion of the eyeball) frequently allows localization of pathology in the CNS. Nystagmus can occur with and without visual fixation. Therefore, detection of nystagmus or eye movements in general, is required in the dark and in the light.

Various methods have been developed to examine human gaze direction or to detect eye movement. However, the remaining problems in these methods are simplicity of measurement, detection accuracy and the patient's comfort. E.g., electro-oculography (EOG) [1] is affected by environmental electrical noise and drift. In the corneal reflection method [2], the accuracy is strongly affected by head movement. The main drawback of the scleral search coil technique [3], is the need for a patient to wear a relatively large contact lens, causing irritation to the eye and limiting the examination time to a maximum of about 30 minutes.

In the nineties, clinical Video Eye Trackers (c-VET) were developed. The c-Vet can be described as a goggle with infrared illumination, where small cameras have been attached to the goggle. With this construction it is possible to record a series of images (movie) while the relative position of the head and the camera remain constant. The need for algorithms to extract the eye movements automatically from the video recordings is high. However, this is not an easy task as IR-illumination results in a relatively poor image contrast. Furthermore, a part of the pupil can be covered by the eyelid, by eyelashes or reflections. Also the pupil continuously changes in size and shape. Another design issue is that the algorithm has to perform in real-time, because direct feedback with the patient is desirable.

Many algorithms have been developed, some with analytical methods and others with neural networks. However, to our knowledge, none of the current algorithms is in all cases accurate and provides an indication when detection fails. While many doctors draw their conclusions based on occasional erroneous measurement outcomes too, this can result in a wrong diagnosis.

This research presents the design and implementation of a real-time high-precision eye movement detection algorithm for VOG in combination with a confidence measure to express the reliability of the detection. By this, clinical application will gain substantial reliability.

II. Algorithm design

While the pupil is much darker than the rest of the eye, it can be detected 'easily', and is therefore a perfect marker to determine the eye movement. Because the shape and the size of the pupil vary continuously, it is necessary to determine one point in the pupil that is constant on the same position of the eye ball: the center of the pupil.

Before starting with complex time consuming calculations to find the exact center of the pupil, it is suitable to design a quick and less time consuming algorithm to approximate the location of the center of the pupil and to determine a region of interest (ROI). Consequently, applying complex calculations in the ROI is less time consuming than applying the same calculations in the original image.

A. Rough localization of the pupil center

By taking horizontal lines through an image recording by the c-VET, see Figure 1, a corresponding gray value pattern can be obtained. All points with a gray value lower than a certain threshold are considered to be part of the pupil.

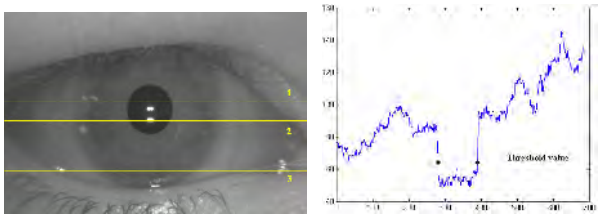

Fig. 1 Horizontal line through the pupil with corresponding RGB pattern

This threshold value is for each recording different, mainly caused by different positioning of the c-Vet. Setting this threshold by hand before every recording is time-consuming and error-sensitive. Therefore, a method was developed to determine the threshold automatically. An RGB histogram of the first image (Figure 2) is made. The small peak on the left side represents the RGB values of the pupil. By performing a local minimum search after this peak, the threshold is determined.

To approximate the center of the pupil, the method of Teiwes [4] is used. Teiwes method determines circles through points on the edge of the pupil. The left and right borders of the pupil are detected by comparing the gray value of points on horizontal lines in the image with the threshold. The center of the pupil is calculated by using the points on the left and right border of two horizontal lines, see Figure 3.

By taking the median of the outcomes for 50 randomly chosen combinations of two horizontal lines through the pupil, the center of the pupil is determined.

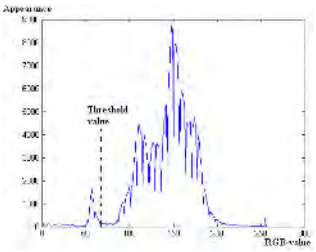

Fig. 2 Using a histogram of the RGB-values to find the threshold value

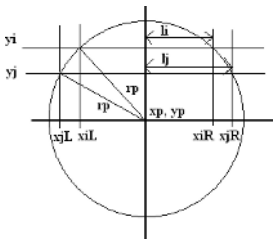

Fig. 3 Approximation of the pupil center by Teiwes method

B. Determining a region of interest

With the approximation of the pupil center point, one is able to place a window around this point, see Figure 4.

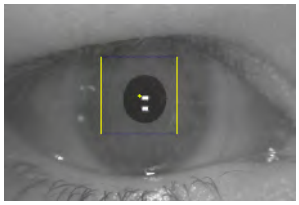

Fig. 4 A window is placed around the approximated pupil center

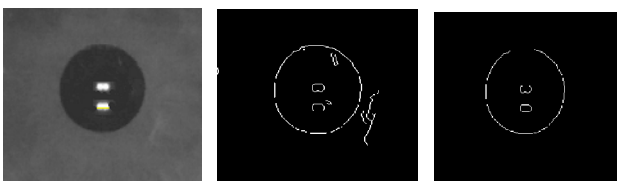
The window size is chosen in such a way that, in all practical situations, the pupil will fit in the window. Taking the resolution of the images into account, this led to a window size of 210x210 pixels, the ROI, which is much smaller than the original image (680x460).



C. Edge detection

Within this ROI, an edge detection algorithm is applied. After several analyses on a dataset with artificially created pupil images, the Canny Edge Detector [5] is decided to be the most suitable edge detector for this situation.

To avoid the selection of noise, detection with a high threshold is applied. Also the 8-directional connection method is used to further delete noise, see Figure 5.

Unfortunately, a high threshold makes that a part of the pupil edge remains undetected. In Section II D it is discussed how to reconstruct the boundary of the pupil.

Even when edge detection with a high threshold is applied, the white reflections caused by the IR-light source are

(a) **(b)** **(c)**

Fig. 5 At the region of interest, displayed in (a), edge detection is applied with a low threshold in (b) and with a high threshold in (c)

still selected as edges. However, they can be filtered out with a simple analytical method. As can be seen in Figure 2, the small peak on the right represents the RGB-values of the reflections. If one or more adjacent pixels have such a high RGB-value, the edge point is deleted.

During the experiments, patients will lose their concentration and eyelids and lashes will cover a part of the pupil. This disturbs the edge detection process, see Figure 6.

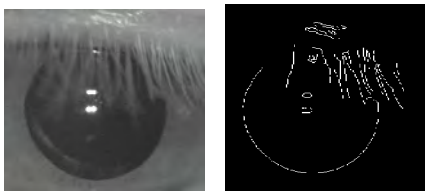


Fig. 6 Eyelashes disturb the process of edge detection

Kong and Zhang proposed an accurate method for eyelash detection [6]. In this method, as implemented, edge detection is applied to detect separable eyelashes, and intensity variances are used to recognize multiple eyelashes.

D. Reconstruction of the pupil shape

With the set of edge points found by the algorithm, it is possible to reconstruct the complete edge of the pupil by applying a stable direct least squares ellipse fit [7]. In Figure 7, an example of ellipse fitting is given.

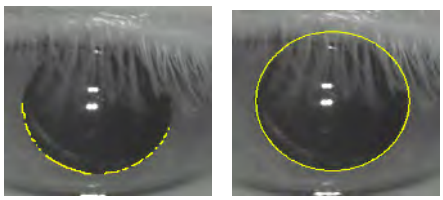

Fig. 7 Reconstruction of the pupil shape with least squares ellipse fitting

E. Feasibility check

When only a few edge points are detected and those edge points lie on one side of the pupil, it can happen that the algorithm returns an inadequate ellipse fit, see Figure 8.
A method was developed to detect those wrong ellipses. In an experimental set up, the relation between the shape and angle of the pupil and ellipse fit of two successive frames was studied. From the experiments it followed that an ellipse is generally accurately computed correct if:

- The rotation angle of the ellipse differs no more than 6.88 degrees from the previous ellipse.

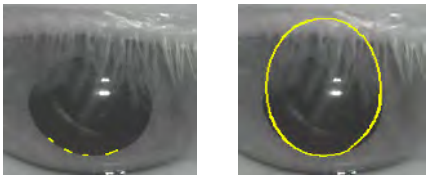

Fig. 8 Ellipse fit can fail when there are not enough edge points or the distribution of the edge points on the pupil border is not suitable

- The ratio of the two axis lengths of the ellipse differs no more than 0.1 from the ratio for the previous ellipse.

If one or both conditions are not met, a minimization procedure is started to compute an ellipse that fits the conditions and minimizes the average distance from the ellipse to the edge points. Note that this process will only work, if the data of the previous ellipse is correct. Therefore, it is necessary that, in the beginning of the measurement, the eyes of a patient are wide open. If the algorithm detects at least 10 stable pupils in a row, this procedure is started.

III. Confidence measure

Many authors, e.g. [8, 9], have described an algorithm to find the pupil center in images. However, to our knowledge, none of these authors paid attention to the reliability of the outcome of such a measurement. In many cases, the average error of the algorithm was given, but none of the authors gave information about what happens in situations when the measurement is wrong. In some situations it is impossible, even for humans, to detect the exact pupil center. In other situations the detection process is hampered by many eyelashes and it is not unlikely that the algorithm makes an error in the exact location of the pupil center. In those situations, doctors would like to know that the measurement has failed. This will help to prevent them to draw conclusions based on an erroneous measurement.

The proposed algorithm, described in the previous section is designed in such a way that it will be possible to design a confidence measure which makes use of data from the pupil detection algorithm. Some aspects of the algorithm contain information on the likelihood that pupil detection will fail.

First, the quality of the image is assessed by determining the number of pixels that contain noise, as found by the edge detection algorithm. Second, the number of pixels with eyelashes that have been filtered out are used. More eyelashes will decrease the reliability of the measurement. A third aspect concerns the number of detected edge points. More such points increase the confidence of the measurement. Another feature is the distribution of the edge points on the pupil boundary. It is better that a few edge points are

located on all sides of the pupil border than many edge points all on one side of the pupil. Therefore, the size of the largest gap between the edge points is used for the confidence measure. The last information that is derived from the algorithm concerns consistency. If the ellipse fit does not differ much from the previous ellipse, it is considered more reliable. Summarizing, the design of the confidence measure takes the following features into account.

- Number of pixels in ROI containing noise
- Number of pixels in ROI containing eyelashes
- Number of edge points that is found
- Largest gap between edge points
- Difference in angle with the previous ellipse fit
- Difference in axis ratio with the previous ellipse fit

To express the relation of these features with the outcome and accuracy of a measurement, certain weights have to be assigned to each feature. In this research it was chosen to train a neural network to assess these weights.

IV. Experimental results

A. Test environment

To design the confidence measure and to validate the algorithm, a dataset of 50.000 images was created. This dataset exists of 25.000 images where the pupil center can be easily detected by humans (part A) and 25.000 images where it is harder or (almost) impossible to locate the exact pupil center by visualization (part B). In all images, the location of the (expected) pupil center was annotated by human experts. Also the Helmholtz coordinates of the pupil center in the images are determined using the scleral search coil technique simultaneously with the c-Vet recordings. Patients with conjugate eye movements of the left and right eye wore a contact lens in one eye during the experiments. The recording of the eye without the contact lens was used for the dataset. Patients were tested on saccadic and persuit eye movements and the head impulse test was performed.

B. Performance of the algorithm

To express the quality of the algorithm, the pupil centers found by the algorithm are compared with the experts annotated pupil centers and with the outcome of the scleral search coil technique. In Figure 9, the performance of the algorithm on images of part A and B are shown.

The average error in the detected pupil location in the images in part A is 1.7 pixels, with a maximum error of 14 pixels. The average error in the images of part B is 3.3 pixels with a maximum of 22 pixels.

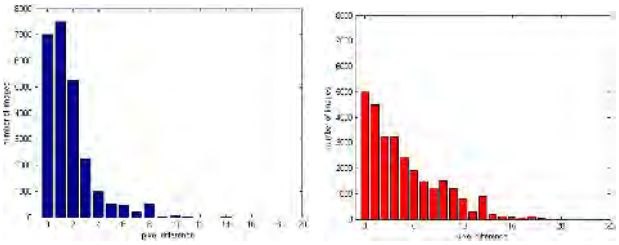

Fig. 9 Performance of the algorithm on part A and part B of the dataset

C. Performance of the confidence measure

For the confidence measure, a neural network was trained with 6 input parameters, as described in Section III, and 1 output parameter, the error of the pupil center. The idea is that the neural network predicts the accuracy of the pupil center algorithm. The result of the neural network was validated with a test set, see Table 1.

Table 1 Result of confidence measure in relation with real error (in %).

10+	0.0	0.0	0.0	0.0	0.0	0.0	0.4	0.0	0.3	4.3	6.7	28.6

V. Conclusions

Tests have shown that the algorithm of this paper can find the pupil center in images that are not extremely hampered by eyelashes and eyelids with a high accuracy. On images where the pupil is covered by many eyelashes, a pupil center is found with lower accuracy. When the accuracy can not be guaranteed, this is well expressed by the confidence measure. If the confidence measure expresses a high accuracy, a doctor can rely on the measurement. Otherwise, he needs to be on his guard.

Development of Active Guide-wire for Cardiac Catheterization by Using Ionic Polymer-Metal Composites

B.K. Fang[1], M.S. Ju[2] and C.C.K. Lin[3]

[1, 2] Dept. of Mech. Engineering, National Cheng Kung University, Tainan 701, Taiwan

Abstract — **Due to the inconvenience in passing bifurcated blood vessels via changing curvature of guide-wires during surgery, active catheter or guide-wire systems are developed recently. For lightweight and large bending deformation, the ionic polymer metal composites (IPMCs) have been employed in many biomedical applications. For controlling an IPMC-based active cardiac guide-wire system, the goal of this research is to develop methods that can actuate an IPMC and detect its deformation without extra sensors. The method is to parallel a reference IPMC with an actuated IPMC. Then a mixed driving signal that consisted of high and low frequencies was applied to drive the IPMCs. The low frequency signal makes the IPMC to deform and change its surface electrical resistance, while the high frequency signal retains the deformation information. By utilizing a lock-in amplifier to demodulate the high frequency signal, the deformation can be measured. When low frequency actuation signal is absent, the sensing signal follows the deformation well. However, when sinusoidal or square wave actuation signals of frequency 0.1Hz was applied transient error appeared. The error may due to the mismatch of electric resistances and capacitances between the actuation and reference IPMCs. However, when the frequency of actuating signal was reduced to 0.01Hz, the transient error disappeared. For practical applications like catheter guide wire, a low frequency actuation signal induces a large deformation so the method might be feasible for simultaneously sensing and actuating an IPMC.**

Keywords — **Ionic polymer-metal composites (IPMC), actuator, active catheter, control, guide wire.**

I. Introduction

For diagnosing or treating coronary heart diseases, cardiac catheterization is a common procedure (Fig. 1). To improve the inconvenience in changing guide-wires during surgery to pass bifurcated blood vessels, there have been many studies on active catheter or guide-wire systems, which can tune the tip-curvature of guide-wire or catheter in real-time [1-4].

Due to lightweight, large bending deformation, biocompatibility and low power consumption, ionic polymer metal composites (IPMCs) have high potential for many biomedical applications. The IPMC is a proton exchange membrane (PEM) plated with platinum or gold on both surfaces and typically working in a hydrated condition. When a electric potential is applied on the electrode pair, the hydrophilic cations within the IPMC migrate to the cathode of potential and make an unsymmetrical swelling of PEM. Then the IPMC bends toward the anode. In the reverse way, bending of the IPMC also induces a transient electric potential which can be utilized as a sensing signal. Therefore, the characteristics of IPMC are similar to piezoelectric materials which can be served as an actuator and a sensor [5-7].

In general, an actuated IPMC has nonlinear and time-variant behaviors, e.g. hysteresis and back relaxation, which deteriorate precision of the control system. To solve these problems, using feedback control schemes are common strategies [8, 9]. For position or force controls, the feedback signals are mostly measured by using bulky sensors, e.g. laser displacement sensor, CCD camera and load cell. For this reason, the applications of feedback control are restrictive for bulky size of system. Therefore integrating a sensory function into the actuated IPMC without using extra sensors is an important subject in this area.

In this research, the ultimate goal is to develop an IPMC-based active cardiac guide wire system (Fig. 1). In previous work, a position feedback control scheme was applied to actuate an IPMC [10]. For implementing the control scheme to our application, the next objective is to combine position sensing method with the actuation of IPMC.

The goal of this study is to develop a sensor-free system to measure the tip position and to actuate the IPMC simultaneously.

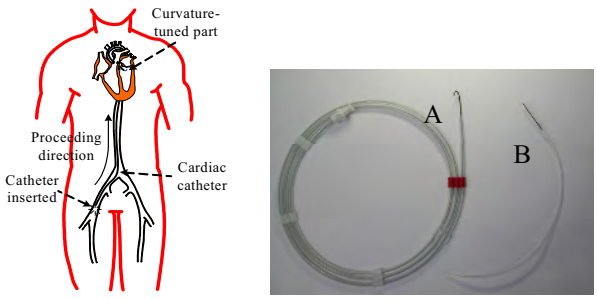

Fig. 1 Sketch of cardiac catheterization with active guide-wire. A-traditional guide-wire, B-IPMC based active guide wire

www.springerlink.com

II. METHODS

Depending on its size, the bandwidth of an IPMC is generally lower than several hundred Hzs, so a driving voltage of several thousand Hzs does not actuate an IPMC [10, 11]. In this study, a driving signal, V_{dm}, that consisted of a low frequency (0.01~10Hz) actuating signal, V_{act}, and a high frequency (5kHz) carrier signal, V_{car}, was used to actuate the IPMC and to measure the deformation, simultaneously(Eq. 1). In Eq. (1), v_{act}, v_{car} are amplitudes, and ω_{act}, ω_{car} are frequencies. With V_{dm}, the deformation of the IPMC follows the waveform of V_{act}, and V_{car} carries the deformation signal due to the changes of surface resistances.

$$V_{dm} = V_{act} + V_{car} = v_{act}\sin(\omega_{act}t) + v_{car}\sin(\omega_{car}t) \quad (1)$$

To eliminate the noise from environments, a fixed reference IPMC connected parallel with the actuated IPMC was employed (Fig. 2). The equivalent circuit shown in Fig. 3 is similar to a Wheatstone bridge circuit, in which V_{a1} and V_{a2} are voltage signals, R_a, R_b, R_{am}, and R_{bm} are electrical resistances, C_p and C_{pm} are capacitances. The sensing signal $V_{aa}(t)$ from the connected IPMCs can be written as

$$V_{aa}(t) = V_{a1} - V_{a2} = \left(\frac{R_b + 1/C_p s}{R_a + R_b + 1/C_p s} - \frac{R_{bm} + 1/C_{pm} s}{R_{am} + R_{bm} + 1/C_{pm} s} \right) V_{dm} \quad (2)$$

Because V_{act} in V_{dm} could be treated as a low frequency noise in $V_{aa}(t)$, the high frequency band signals in V_{a1} and V_{a2} are first separated by using a high-pass filter. Eq. (2) can then be further simplified as:

$$V_{aa}'(t) = \left(\frac{R_b}{(R_a + R_b)} - \frac{R_{bm}}{(R_{am} + R_{bm})} \right) \left(v_{car}\sin(\omega_{car}t) \right) \quad (3)$$

Furthermore, multiply Eq. (3) by $v_c\sin(\omega_c t)$ and expend yield:

$$V_{aa}''(t) = \left(v_{car}\sin(\omega_{car}t) \right) V_{aa}'(t)$$
$$= \frac{v_{car}^2}{2} \left(\frac{R_b}{(R_a + R_b)} - \frac{R_{bm}}{(R_{am} + R_{bm})} \right) \left(1 - \cos(2\omega_{car}t) \right) \quad (4)$$

The high frequency band $\cos(2\omega_c t)$ in $V_{aa}''(t)$ can be eliminated by using a low-pass filter to yield the demodulated sensing signal $V_{sen}(t)$. $V_{sen}(t)$ is related to the amplitude of carrier signal and electrode resistances by:

$$V_{sen}(t) = \frac{v_{car}^2}{2} \left(\frac{R_b}{(R_a + R_b)} - \frac{R_{bm}}{(R_{am} + R_{bm})} \right) \quad (5)$$

The surface resistances of the actuated IPMC, after deformation, can be written as:

$$\begin{cases} R_a = R_{a0} + \Delta R_a \\ R_b = R_{b0} + \Delta R_b \end{cases} \quad (6)$$

where R_{a0}, R_{b0} are initial resistance of the IPMC, and ΔR_a, ΔR_b are changes of resistances due to deformation. R_{a0}, R_{b0}, R_{am}, R_{bm} are equal to a constant R_i. Substitute Eq. (6) into Eq. (5) and simplify it to yield:

$$V_{sen}(t) \approx \frac{v_{car}^2}{8} \frac{\Delta R_b - \Delta R_a}{R_i} \quad (7)$$

where ΔR_a, ΔR_b are assumed much smaller than R_i. Eq. (7) showed that $V_{sen}(t)$ is proportional to the difference between variations of resistance at the compression and tension surface of the ated IPMC.

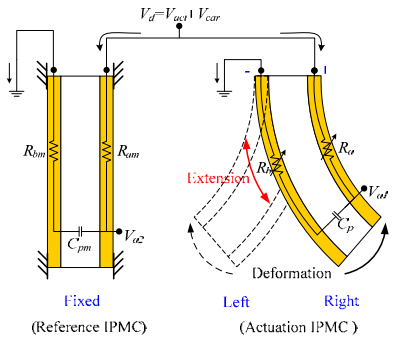

Fig. 2 Parallel connection between the reference and the actuated IPMC

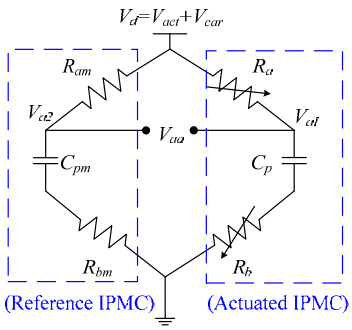

Fig. 3 Equivalent circuit of reference IPMC paralleled with reference IPMC

Two encapsulated IPMCs and an experimental setup were implemented to verify the feasibility of the proposed method. Dimension of the two IPMCs are 30mm in length, 5mm in width, 0.2mm in thickness (Fig. 4). The values of electrical resistances are close to 10Ω, and the values of

capacitances are 1.8mF. The sensing method was realized by using an analog circuit (Fig. 5). In the experimental setup a laser displacement sensor is utilized to detect the deformation of the actuated IPMC at the end, and an electromagnetic shaker controlled by the displacement feedback is used to deform the IPMC for actuation-free tests (Fig. 6).

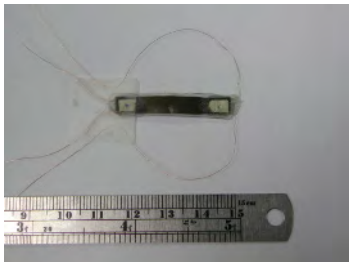

Fig. 4 Sample of IPMC manufactured in this study

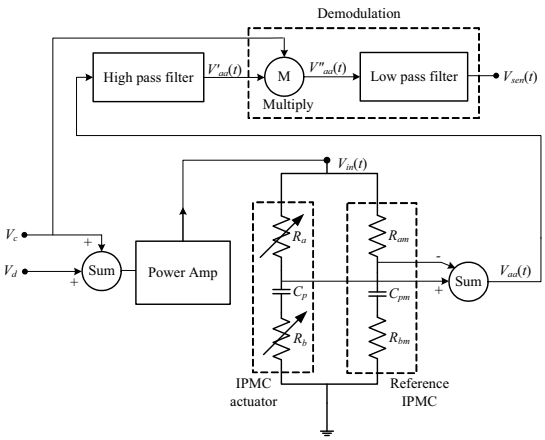

Fig. 5 Diagram of the sensing circuit

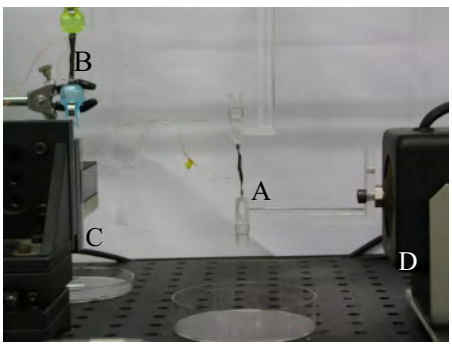

Fig. 6 Experimental setup. A-actuated IPMC, B-reference IPMC, C-Laser displacement sensor, D-electromagnetic shaker

III. Results and Discussions

Typical testing results are depicted in Fig. 7. A tip displacement of amplitude 2mm deformed by the shaker induced a sensing signal of amplitude 5mV even though the waveforms are slightly different. A 4th-order polynomial was fitted to the relationship between sensing signals and deformations (Fig. 8). From the results, sensing deformation of IPMC with the method proposed in this study was achieved successfully.

However, while applying a 0.1Hz low frequency actuating signal into the driving signal and restricting the displacement of the actuated IPMC, the sensing signal was coupled with noise that increased with the amplitude of actuating signal (Fig. 9). This may due to the electric resistances and capacitances of the reference and actuated IPMCs are not equal exactly, so the transient error was exhibited to the sensing signal. Comparing results of actuating signals with frequencies of 0.1Hz and 0.01Hz, the noise for the 0.01Hz actuation is much smaller than that of the 0.1Hz (Fig. 10). It indicates that deformation of actuated IPMC can be measured by current method if the actuating frequency is lower than 0.01Hz.

For an actuated IPMC, the longer DC actuating time induces the larger deformation [12]. So the sensing approach proposed in this study might be feasible for an IPMC despite the limitation of low actuating frequency.

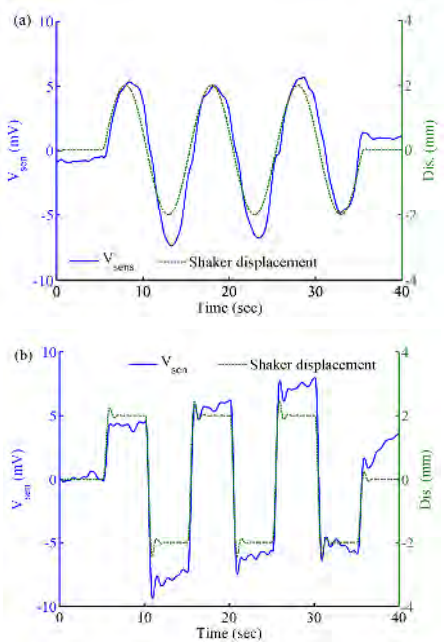

Fig. 7 Sensing signals in response to deformation induced by the shaker, sinusoidal (a) and square wave (b)

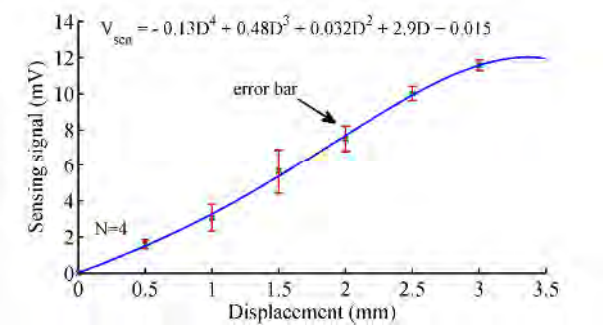

Fig. 8 Relationship between deformation and sensing signal

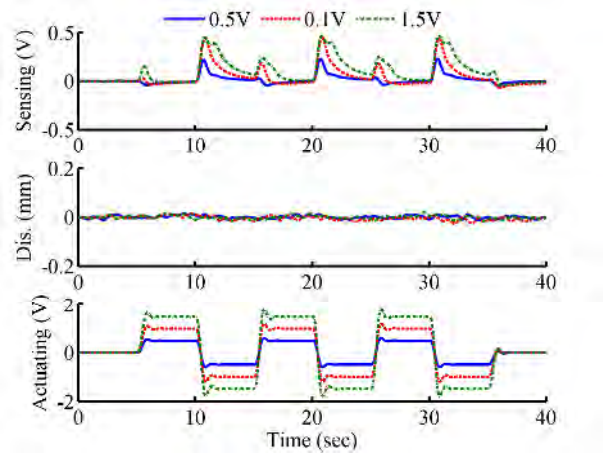

Fig. 9 Sensing signals in response to 0.1Hz square-wave actuating signals of different amplitudes

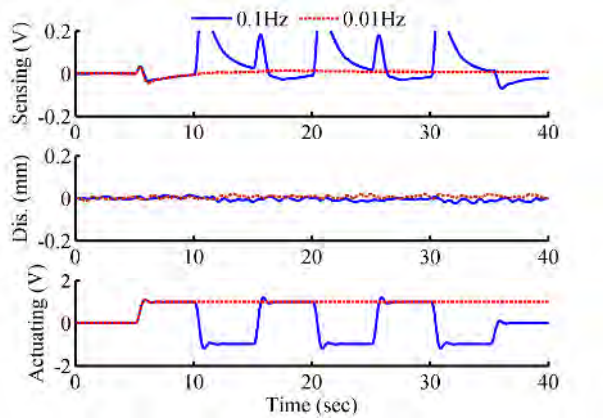

Fig. 10 Comparison between low (0.01Hz) and high (0.1Hz) frequency actuating results

IV. Conclusions

A method of sensing deformation and actuating of IPMC simultaneously was developed and tested. The results revealed that the method can be applied for IPMC at low frequency of 0.01Hz. For further development, the degree of deformation of IPMC is much concerned than the frequency of manipulation. The developed method might be feasible for a large deformed IPMC induced by DC actuating signal.

Design and Development of an Interactive Proteomic Website

*K. Xin Hui[1], C. Zheng Wei[2], Sze Siu Kwan[3] and R. Raja[4]

[1,2&4] Biomedical Informatics Engineering, Temasek Polytechnic, Singapore
[3] Asst. Professor, SCBS, Nanyang Technological University, Singapore.

Abstract — **The interactive proteomic core facility website was done with Apache, PHP & MySQL. This website aims to allow researchers to submit information about their samples via a webpage and at the same time, provides clear and accurate cost of the experiment. This would minimize information mix up and provides a platform for them to manage their expenses better. The server program would process the information sent and return a generated code about their sample. The end results would be stored into our database and our servers would email users to download the results from our servers. Users would have to register first before they could start using our services and a tutorial (FAQ) is provided to facilitate the users. This website would increase the efficiency of work done, reducing the trouble on both sides. User now can submit entry anytime at anywhere and the staff can manage the submission better from the lab. The staff will also gain a much more manageable system for them to trace or perform any calculation. Errors like missing forms; unreadable handwriting and etc will be reduced to the minimum.**

Keywords — **Proteomics, information processing, database.**

I. Introduction

Proteomic is a study of protein's structures and function. As we know protein is essential for all living organisms because they are the main component of the physiological metabolic pathway of cells. [1] Protein is a very complex structure form by many peptides or amino acids, thus identifying them are not an easy task.

At Nanyang Technology University (NTU)'s proteomics facility, they are equipped with a high-tech proteomic facility mass spectrometry lab which can carry out protein test like "Protein Identification", "Mass Weight determination" and "Chromatography-mass Spectrometry (LC-MS)". With these services protein can be easily analysis in the lab with some specialist machines.

Most proteomic researcher does not have these equipments to carry test on their own. So they have to send all samples to the proteomic facility. A better platform is needed to interact between researcher and service provider, hence an interactive proteomic website needed to be create to handle sending and receiving data or information.

II. Flow Chart

Module [2]-[18]	Principle
PHP	- Open Source - Used to write our webpage and to create website functions such as login and user profile update - Highly flexible: able to use together with JavaScript, HTML & any database systems - Widely supported by many online communities and reference materials
MySQL	- Open Source - Database for our system - Used to store information and to be used with the website
Apache Server	- Open Source - The program makes the system into a website server - Highly customizable: able to configure to suit the website's demand - Widely used; internet companies such as Google & Yahoo! uses Apache
MySQL Navicat Lite 8.0	- Free to use - Used to edit, create and maintain MySQL database - Able to remote connect via Server's IP address - Fast & easy to use
Adobe Dreamweaver CS3	- To create websites - Easier to develop websites with Dreamweaver as there are many inbuilt functions - Able to view our websites as we create it - Also enable us to connect to the database
Macromedia Fireworks 8	- Used hand in hand with Flash 8 - To create images for the website and also for the flash animations - To edit some of the image background to transparent in order to prevent white background to overlap other words or images.
Macromedia Flash 8	- To create flash web links - Makes the website more colorful with nicer looking buttons

Work Flow

The work flow for the development of this website project can be grouped into seven stages.

First Stage: Defining the Concept

At this stage the project is defined. The project scope is discussed and it is designed with the needs and demands of the end users in mind

Second Stage: Initialization

The initialization stage begins by deciding on the technology used. Firstly, a research was done on the available options. This includes researching on the software used to code the website and the type of programming language used. It was decided on PHP, MySQL and Apache because it was cheaper and widely supported. The necessary software was then installed.

Third Stage: Design

At this stage, the layout for the website was decided. Essential functions for this website were also decided at this stage. It is important to decide on those that are relevant, suitable and practical so as to suit the demands and the ease of use.

Fourth Stage: Development & Debugging

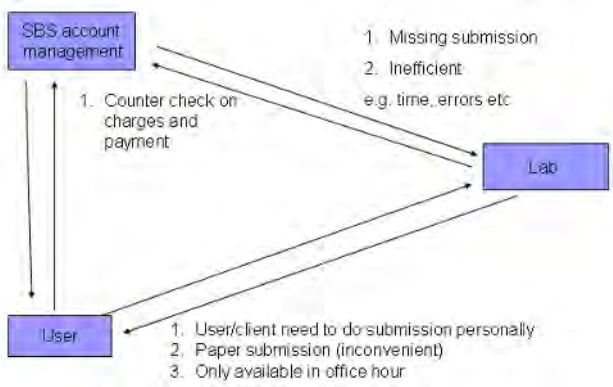
At this stage, we begin the coding of the website. Developing under local host, it was to minimize the number of error and bugs that are persistent on the system before posting on the server. Common bugs and errors that were usually spotted were incomplete database queries and white space. As the project continues, there were changes made to the design. Certain planned functions were either removed or improved on.

Fifth Stage: Finalizing the Concept

The prototype was shown. During this stage, a third party's point of view is essential to this project, due to the fact that they are the target users. Their comments and ideas are incorporated into making this website better.

Sixth Stage: Development & Debugging (live)

This is a repeat of the fourth stage. On the other hand, at this stage, it is tested first on local host and then tested on the live server.

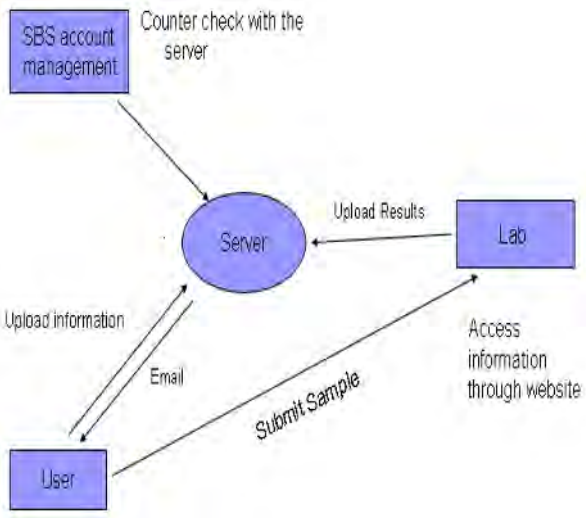


Final Stage: Launch

The completed programme is launched to the server.

III. Results

In the diagram on the right show the old system that is practice by the proteomic facility lab. There are many inconvenient causes by this system.



With this system, the three parties which are the lab, the SBS account management and user (researcher) need to meet up personally with each other in order to get the work-done.

With this system, error and problem usually occur as stated in the diagram for all three parties.

With this new interactive proteomic website is setup (server) shown in the diagram on the right, we can solve the above problem and simplify the procedure of the whole process.

The website (server) acts as a main brain of the system. All the information is send directly to the server with is 24/7 operated. System is automated which help to cut down time and cost needed compare to the old system.

Features

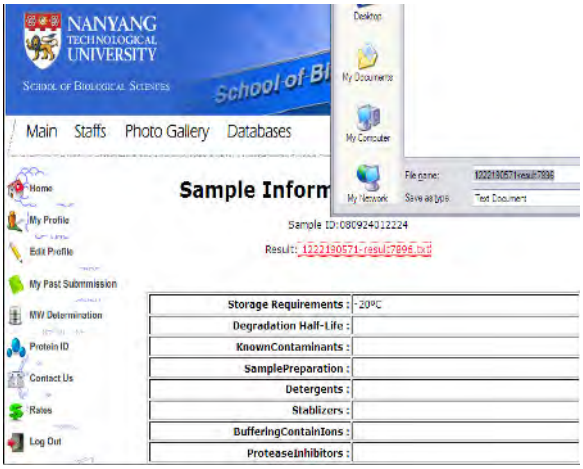
Admin

Admin home page which includes

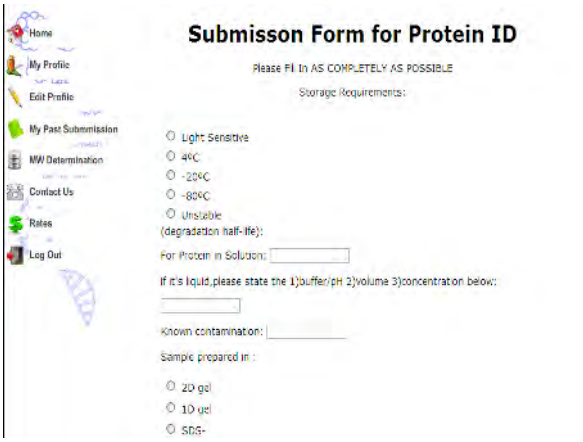
- Search for sample using the search bar
- Sign up new admin
- View incomplete submission/filter completed submission
- View mass weight/protein id/user's detail with more information
- Update payment

Admin can

- Upload results to the web for the user to download
- Sent email to notify user



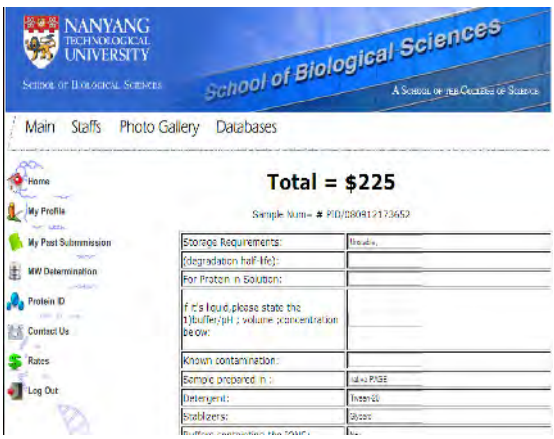
User can



- Download the result after they login their account

User

Submission and calculation



User can

Submit their sample information form (mass weight/ protein id)

- Cost calculation of the service will be done
- Detail will be show for and edit before confirmation

Records

User can view

- Sample reference no.
- Status (Complete/Incomplete)
- Cost
- Payment (Paid/Pending)
- Full detail by clicking "View"

User also can

Update file (image or text) by clicking "Update File"

IV. Discussion & Conclusion

Minimize human related errors

- Computerized forms removes unreadable handwriting
- Inbuilt program prevents important fields from not filling up
- Makes data analyzing faster and efficient as there's little need to call back to double confirm

Saves cost

- The manpower in the lab can be redeployed to other areas, reducing unused manpower

Convenient

- Reduces the number of unnecessary trips down to the lab. Example: a researcher would have to make multiple trips if he could not submit his form as the staff is missing or he would have to make a advance appointment to arrange a time to come down to the lab.
- Reduce the demand of sending emails or making phone calls to arrange appointments or sample pick up
- Digitalized database of received forms makes it possible to make back up and to change address of business easily

Acknowledgment

We acknowledge with thanks the management of NTU & Temasek Polytechnic for the opportunity provided to create, design and develop an interactive proteomic website for mass spectrophotometric analysis.

A New Interaction Modality for the Visualization of 3D Models of Human Organ

L.T. De Paolis[1,3], M. Pulimeno[2] and G. Aloisio[1,3]

[1] Department of Innovation Engineering, Salento University, Lecce, Italy
[2] ISUFI, Salento University, Lecce, Italy
[3] SPACI Consortium, Italy

Abstract — **The developed system is the first prototype of a virtual interface designed to avoid contact with the computer so that the surgeon is able to visualize models of the patient's organs more effectively during surgical procedure. In particular, the surgeon will be able to rotate, to translate and to zoom in on 3D models of the patient's organs simply by moving his finger in free space; in addition, it is possible to choose to visualize all of the organs or only some of them. All of the interactions with the models happen in real-time using the virtual interface which appears as a touch-screen suspended in free space in a position chosen by the user when the application is started up. Finger movements are detected by means of an optical tracking system and are used to simulate touch with the interface and to interact by pressing the buttons present on the virtual screen.**

Keywords — **User Interface, Image Processing, Tracking System.**

I. Introduction

The visualization of 3D models of the patient's body emerges as a priority in surgery both in pre-operative planning and during surgical procedures.

Current input devices tether the user to the system by restrictive cabling or gloves.

The use of a computer in the operating room requires the introduction of new modalities of interaction designed in order to replace the standard ones and to enable a non-contact doctor-computer interaction.

Gesture tracking systems provide a natural and intuitive means of interacting with the environment in an equipment-free and non-intrusive manner. Greater flexibility of action is provided since no wired components or markers need to be introduced into the system.

In this work we present a new interface, based on the use of an optical tracking system, which interprets the user's gestures in real-time for the navigation and manipulation of 3D models of the human body.

The tracked movements of the finger provide a more natural and less-restrictive way of manipulating 3D models created using patient's medical images.

Various gesture-based interfaces have been developed; some of these are used in medical applications.

Grätzel et al. [1] presented a non-contact mouse for surgeon-computer interaction in order to replace standard computer mouse functions with hand gestures.

Wachs et al. [2] presented "Gestix", a vision-based hand gesture capture and recognition system for navigation and manipulation of images in an electronic medical record database.

GoMonkey [3] is an interactive, real time gesture-based control system for projected output that combines conventional PC hardware with a pair of stereo tracking cameras, gesture recognition software and customized content management system.

O'Hagan and Zelinsky [4] presented a prototype interface based on tracking system where a finger is used as a pointing and selection device. The focus of the discussion is how the system can be made to perform robustly in real-time.

O'Hagan et al. [5] implemented a gesture interface for navigation and object manipulation in the virtual environment.

II. Technologies used

In the developed system we have utilized OpenSceneGraph for the construction of the graphic environment and 3D Slicer for building the 3D models starting from the real patient's medical images.

OpenSceneGraph [6] is an open source high performance 3D graphics toolkit used by application developers in fields such as visual simulation, computer games, virtual reality, scientific visualization and modeling. The toolkit is a C++ library and is available on multiple platforms including Windows, Linux, IRIX and Solaris.

3D Slicer [7] is a multi-platform open-source software package for visualization and image analysis, aimed at computer scientists and clinical researchers.

The platform provides functionality for segmentation, registration and three-dimensional visualization of multi-modal image data, as well as advanced image analysis algo-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 348–350, 2009
www.springerlink.com

rithms for diffusion tensor imaging, functional magnetic resonance imaging and image-guided therapy.

Standard image file formats are supported, and the application integrates interface capabilities with biomedical research software and image informatics frameworks.

The optical tracking system used in this application is the Polaris Vicra of the NDI. The Polaris Vicra [8] is an optical system that tracks both active and passive markers and provides precise, real-time spatial measurements of the location and orientation of an object or tool within a defined coordinate system.

The system tracks wired active tools with infra-red light-emitting diodes and wireless passive tools with passive reflective spheres. With passive and active markers, the position sensor receives light from marker reflections and marker emissions, respectively.

The Polaris Vicra uses a position sensor to detect infra-red-emitting or retro-reflective markers affixed to a tool or object; based on the information received from the markers, the position sensor is able to determine position and orientation of tools within a specific measurement volume.

The system is able to track up to 6 tools (maximum 1 active wireless) with a maximum of 32 passive markers in view and the maximum update rate is 20 Hz.

The systems can be used in a variety of surgical applications, delivering accurate, flexible, and reliable measurement solutions that are easily customized for specific applications.

III. The Developed Application

The developed system is the first prototype of a virtual interface designed to avoid contact with the computer so that the surgeon can visualize models of the patient's organs more effectively during the surgical procedure.

A 3D model of the abdominal area, reconstructed from CT images, is shown in Figure 1 using the user interface of the 3D Slicer software.

In order to build the 3D model from the CT images some segmentation and classification algorithms were utilized.

The Fast Marching algorithm was used for the image segmentation; some fiducial points were chosen in the interest area and used in the growing phase.

After a first semi-automatic segmentation, a manual segmentation was carried out.

All of the interactions with the models happen in real-time using the virtual interface which appears as a touch-screen suspended in free space in a position chosen by the user when the application is started up.

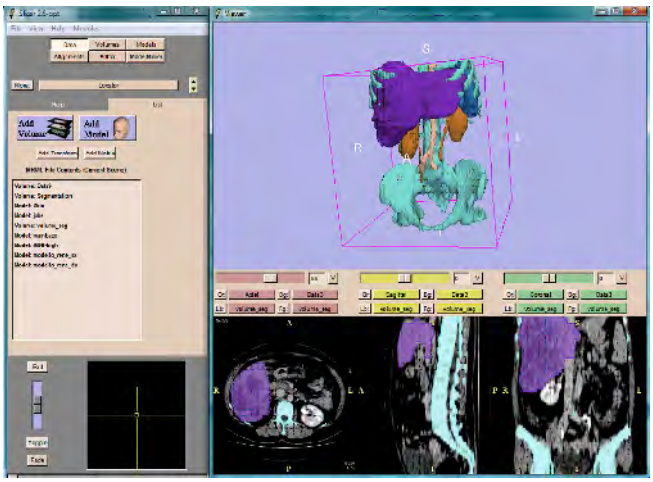

Fig. 1 User interface of 3D Slicer with the reconstructed model

Finger movements are detected by means of an optical tracking system (the Polaris Vicra) and are used to simulate touch with the interface where some buttons are located.

The interaction with the virtual screen happens by pressing these buttons, which make it possible to visualize the different organs present in the built 3D model (buttons on the right) and to choose the possible operations allowed on the selected model (buttons on the left).

For this reason, when using this graphical interface, the surgeon is able to rotate, to translate and to zoom in on the 3D models of the patient's organs simply by moving his finger in free space; in addition, he can select the visualization of all of the organs or only some of them.

In figure 2 the interaction with the user interface by means of the tracking system is shown.

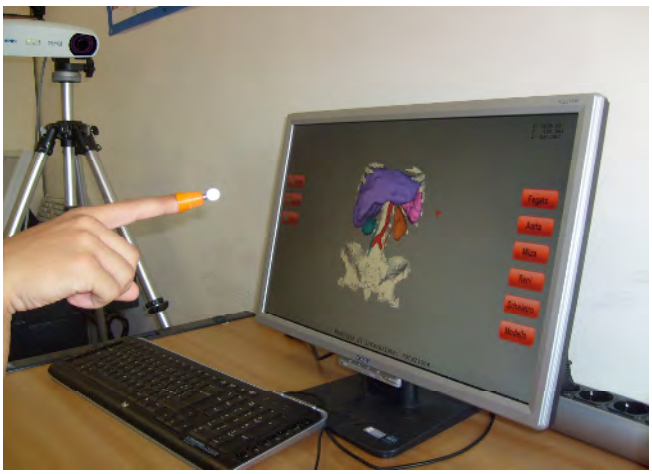

Fig. 2 The interaction with the virtual user interface

IV. Conclusions and future work

The described application is the first prototype of a virtual interface which provides a very simple form of interaction for navigation and manipulation of 3D virtual models of the human body.

The virtual interface created provides an interaction modality with models of the human body, a modality which is similar to the traditional one which uses a touch screen, but in this interface there is no contact with the screen and the user's finger moves through open space.

By means of an optical tracking system, the position of the finger tip, where an IR reflector is located, is detected and utilized first to define the four vertexes of the virtual interface and then to manage the interaction with this.

The optical tracker is already in use in computer aided systems and, for this reason, the developed interface can easily be integrated in the operation room.

Taking into account a possible use of the optical tracker in the operating room during surgical procedures, the problem of possible undesired interferences due to the detection of false markers (phantom markers) will be evaluated.

The introduction of other functionalities of interaction with the models is in progress, after further investigation and consideration of surgeons' requirements.

Performance Analysis of Support Vector Machine (SVM) for Optimization of Fuzzy Based Epilepsy Risk Level Classifications from EEG Signal Parameters

R. Harikumar[1], A. Keerthi Vasan[2], M. Logesh Kumar[3]

[1]Professor, Bannari Amman Institute of Technology, Sathyamangalam, India
[2,3]U.G students, ECE, Bannari Amman Institute of Technology, Sathyamangalam, India

Abstract — **In this paper, we investigate the optimization of fuzzy outputs in the classification of epilepsy risk levels from EEG (Electroencephalogram) signals. The fuzzy techniques are applied as a first level classifier to classify the risk levels of epilepsy based on extracted parameters which include parameters like energy, variance, peaks, sharp spike waves, duration, events and covariance from the EEG signals of the patient. Support Vector Machine (SVM) may be identified as a post classifier on the classified data to obtain the optimized risk level that characterizes the patient's epilepsy risk level. Epileptic seizures result from a sudden electrical disturbance to the brain. Approximately one in every 100 persons will experience a seizure at some time in their life. Some times seizures may go unnoticed, depending on their presentation which may be confused with other events, such as a stroke, which can also cause falls or migraines. Unfortunately, the occurrence of an epileptic seizure seems unpredictable and its process is very little understood The Performance Index (PI) and Quality Value (QV) are calculated for the above methods. A group of twenty patients with known epilepsy findings are used in this study. High PI such as 98.5% was obtained at QV's of 22.94, for SVM optimization when compared to the value of 40% and 6.25 through fuzzy techniques respectively. We find that the SVM Method out performs Fuzzy Techniques in optimizing the epilepsy risk levels. In India number of persons are suffering from Epilepsy are increasing every year. The complexity involved in the diagnosis and therapy is to be cost effective in nature. This paper is intended to synthesis a cost effective SVM mechanism to classify the epilepsy risk level of patients.**

Keywords — **Epilepsy, EEG signals, fuzzy techniques, performance Index, Quality Value.**

I. Introduction

Support Vector Machine (SVM) is an important machine learning technique which involves creating a function from a set of labeled trained data. People attacked by epilepsy [2] are unnoticed and this leads to other events such as a stroke, which also causes falls or migraines. In India number of persons suffering from epilepsy is increasing per year. The complexity involved in the diagnosis and therapy is to be cost effective in nature. Airports, amusement parks, and shopping malls are just a few of the places where computers are used to diagnosis a person's Epilepsy risk levels if a life threatening condition occurs. In some situation there is not always a trained doctor's and neuro scientists on hand. This project work is intended to synthesis a cost effective SVM mechanism to classify the epilepsy risk level of the patients and to mimic a doctor's and neuro scientist's diagnosis.

The EEG (Electroencephalogram) signals of 20 patients are collected from Sri Ramakrishna Hospitals at Coimbatore and their risk level of epilepsy is identified after converting the EEG signals to code patterns by fuzzy systems. This type of classification helped doctor's and neuro surgeons in giving appropriate therapeutic measures to the patients. This paper helps to save a patient's life when a life threatening condition occurs. This scientific paper is carried in order to save a patient's life and also to create public awareness among people about the risk ness of epilepsy.

II. Methodology

Support Vector Machine (SVM) is used for pattern classification and non linear regression like multilayer perceptrons and Radial Basis Function networks. SVM is now regarded as important example of 'Kernel Methods'. The main idea of SVM is to construct a hyper plane as the decision surface in such a way that the margin of separation between positive and negative examples is minimized. The SVM is an approximate implementation of method of structural minimization. In SVM we investigate the optimization of fuzzy outputs in the classification of Epilepsy Risk Levels from EEG (Electroencephalogram) signals. The fuzzy techniques are applied as a first level classifier to classify the risk levels of epilepsy based on extracted parameters like energy, variance, peaks, sharp and spike waves, duration, events and covariance from the EEG signals of the patient.

The block diagram of epilepsy classifier is shown in figure1. This is accomplished as:

1. Fuzzy classification for epilepsy risk level at each channel from EEG signals and its parameters.
2. Each channel results are optimized, since they are at different risk levels.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 351–354, 2009
www.springerlink.com

3. Performance of fuzzy classification before and after the SVM optimization methods is analyzed.

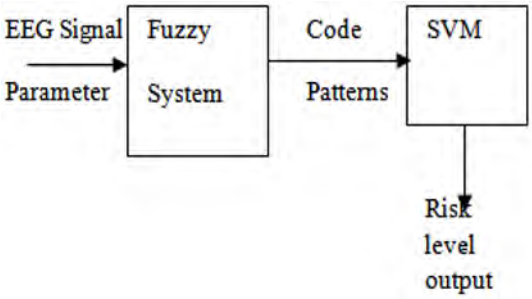

Fig 1 SVM- Fuzzy Classification System

The following tasks are carried out to classify the risk levels by SVM which are,

1. First a simplest case is analyzed with hyper plane as decision function with the known linear data.
2. A non linear classification is done for the codes obtained from a particular patient by using quadratic discrimination.
3. Then the k-means [8][5] clustering is performed for large data with different sets of clusters with centroid for each.
4. The centroid obtained is mapped by the kernel function for obtaining a proper shape.
5. A linear separation is obtained by using SVM with kernel and k-means clustering

In fuzzy techniques [3] more suboptimal solutions are arrived. These solutions are to be optimized to arrive a better solution for identifying patient's epilepsy risk level. . Due to the low value of performance index (40%), quality value (6.25) it is necessary to optimize the output of the fuzzy systems. Hence we are moving to SVM classification which gives a performance index of 98% and a quality value of 22.94. For optimization of fuzzy outputs the Support Vector Machine (SVM) method is identified.

The following solutions constrain steps are followed:

Step 1: The linearization and convergence is done using Quadratic Optimization [7][4]. The primal minimization problem is transformed into its dual optimization problem of maximizing the dual lagrangian L_D with respect to α_i:

$$\text{Max } L_D = \sum_{i=1}^{l} \alpha_i - \frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} \alpha_i \alpha_j y_i y_j (X_i \cdot X_j) \quad (1)$$

Subject to

$$\sum_{i=1}^{l} \alpha_i y_i = 0 \quad (2)$$

$$\alpha i \geq 0 \; \forall \; i = 1, ..., l \quad (3)$$

Step 2: The optimal separating hyper plane is constructed by solving the quadratic programming problem defined by (1)-(3). In this solution, those points have non-zero Lagrangian multipliers ($\alpha_i > 0$) are termed support vectors.

Step 3: Support vectors lie closest to the decision boundary. Consequently, the optimal hyper plane is only determined by the support vectors in the training data.

Step 4: The k-means [8][5] clustering is done for the given set of data. The k-means function will form a group of clusters according to the condition given in step2 and step3. Suppose for a group of 3 clusters, k-means function will randomly choose 3 centre points from the given set. Each centre point will acquire the values that are present around them.

Step 5: Now there will be six centre points three from each epochs and then the SVM training process is done by the Kernel methods. Thus, only the kernel function is used in the training algorithm, and one does not need to know the explicit form of ∅. Some of the commonly used kernel [10] functions are:

Polynomial function: $K(X, Y) = (X^T Y - 1)^d$

Radial Basis Function: $k(xi, xj) = \exp\left\{ \frac{-|xi - xj|^2}{(2 \cdot \sigma)^2} \right\}$

Sigmoid function: $K(X, Y) = \tanh(kX^T Y - \theta)$

III. Radial Basis Function Kernel

The hyper plane and support vectors are used to separate linearly separable and non-linearly separable data. In this project we used, Radial Basis Kernel function (RBF) [4] for this non-linear classification. RBF is a curve fitting approximation in higher dimensional space. According to this learning it is equivalent to finding a surface in multi dimensional space that provides a best fit by utilizing the training data and generalization is equivalent to use of this multidimensional surface to interpolate the test data. It draws up on a traditional strict interpolation in multidimensional space. Thus RBF provides a set of the testing data which acts as a "basis" for input patterns when expanded into hidden space. From the set of RBF testing values the Mean Square Error (MSE) and Average MSE is performed and error values are calculated. The tool used in this study is mat lab v7.2.

An important factor for the choice of a classification method for a given problem is the available a-priori knowledge. During the last few years support vector machines

(SVM) have shown to be widely applicable and successful particular in cases where a-priori knowledge consists of labeled learning data. If more knowledge is available, it is reasonable to incorporate and model this knowledge within the classification results or to require less training data. Therefore, much active research is dealing with adapting the general SVM methodology to cases where additional a-priori knowledge is available. We have focused on the common case where variability of data can be modeled by transformations which leave the class membership unchanged. If these transformations can be modeled by mathematical groups of transformations one can incorporate this knowledge independently of the classifier during the feature extraction stage by group integration, normalization etc. this leads to variant features, on which any classification algorithm can be applied.

It is noted that one of main assumptions of SVM is that all samples in the training set are independent and identically distributed (i.i.d), however, in many practical engineering applications, the obtained training data is often contaminated by noise. Further, some samples in the training data set are misplaced on the wrong side by accident. These known as outliers. In this case, the standard SVM training algorithm will make decision boundary deviate severely from the optimal hyper plane, such that, the SVM is very sensitive to noise, and especially those outliers that are close to decision boundary. This makes the standard SVM no longer sparse, that is, the number of support vectors increases significantly due to outliers. In this project, we present a general method that follows the main idea of SVM using adaptive margin for each data point to formulate the minimization problem, which uses the RBF kernel trick. It is noted that the classification functions obtained by minimizing MSE are not sensitive to outliers in the training set. The reason that classical MSE is immune to outliers is that it is an average algorithm. A particular sample in the training set only contributes little to the final result. The effect of outliers can be eliminated by taking average on samples. That is why the average technique is a simple yet effective tool to tackle outliers.

In order to avoid outliers we utilized the RBF kernel functions and also decision functions for determining the margin of each classes. Since we are analyzing twenty epilepsy patients through leave one out methods and ten fold cross validation. Based on the MSE value and Average MSE values of SVM models the classifications of epilepsy risk levels are validated. The following fig 2 depicts the training and testing MSE of SVM models. The out liers problem is solved through Average MSE method which is shown in figure 3

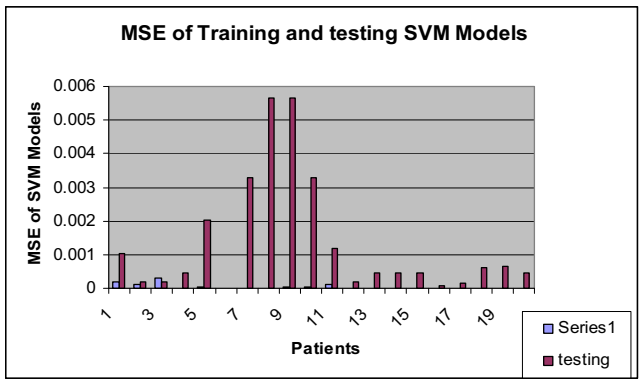

Fig 2 MSE of Training and Testing of SVM Models

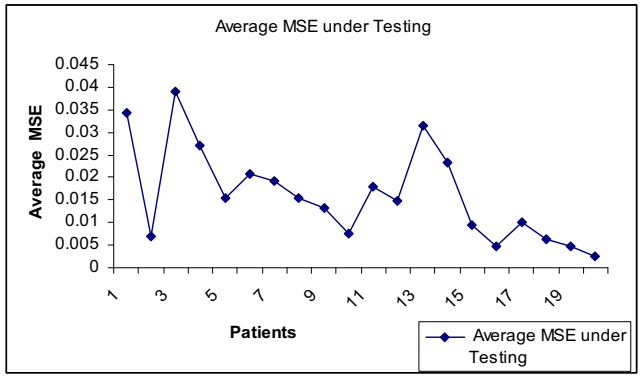

Fig 3 Average MSE under Testing of SVM Models

IV. Test Results

In SVM the performance classification is about 97.39% which is very high when compared with Fuzzy logic which is 50% only. The sensitivity and selectivity of SVM is also more when compared to the latter. The missed classification

Table 1: Comparison Results of Classifiers Taken As Average of All Ten Patients

Parameters	Fuzzy Techniques Without Optimization	Optimization With SVM Technique
Perfect Classification (%)	50	97.39
Missed Classification (%)	20	1.458
Performance Index (%)	40	97.07
Sensitivity	83.33	98.59
Specificity	71.42	98.52
Quality Value	6.25	22.94

of SVM is 1.458% but it is about 20% in Fuzzy Network and the value of PI in SVM is 97.07 and 40 in Fuzzy.

V. Conclusion

This Project investigates the performance of SVM in optimizing the epilepsy risk level of epileptic patients from EEG signals. The parameters derived from the EEG signal are stored as data sets. Then the fuzzy technique is used to obtain the risk level from each epoch at every EEG channel. The objective was to classify perfect risk levels with high rate of classification, a short delay from onset, and a low false alarm rate. Though it is impossible to obtain a perfect performance in all these conditions, some compromises have been made. As a high false alarm rate ruins the effectiveness of the system, a low false-alarm rate is most important. SVM optimization techniques are used to optimize the risk level by incorporating the above goals. The classification rate of epilepsy risk level of above 98% is possible in our method. The missed classification is almost 1.458 for a short delay of 2.031 seconds. The number of cases from the present twenty patients has to be increased for better testing of the system. From this method we can infer the occurrence of High-risk level frequency and the possible medication to the patients. Also optimizing each region's data separately can solve the focal epilepsy problem. The future research is in the direction of a comparison of SVM between heuristic MLP and Elman neural network optimization models.

Acknowledgement

The authors wish to express their sincere appreciation to the Management Principal of Bannari Amman Institute of Technology, Sathyamangalam for their support. We wish to express our sincere thanks to Dr.Asokan, Neurologist, Sri Ramakrishna Hospitals, Coimbatore for providing us EEG signals of the patient.

Abstract — **Cold plasma generated at the atmospheric pressure has been applied to disinfect microorganisms such as bacteria and yeast cells in biomedical research. Especially, due to its low temperature condition, the heat-sensitive medical device can be easily sterilized by the cold plasma treatment. In recent years, the effects of plasma on mammalian cells have arisen as a new issue. Generally, plasma is known to induce intensity dependent necrotic cell death. In this research, we investigate the feasibility of cold plasma treatment for cancer therapy by conducting comparative study of plasma effects on normal and cancer cells. We select THLE-2 (human liver normal cell) and SK-Hep1 (human liver metathetic cancer cell) as our target cells. Two types of cells have different onset plasma conditions for the necrosis, which may be explained by difference in electrical properties of these two cell types. Based on this work, a feasibility of the novel selective cancer therapy is tested.**

Keywords — **Cold plasma, Cancer therapy, Biomedical engineering**

I. Introduction

Plasma is generated by ionizing the neutral gas molecules, resulting in the mixture of energetic particles, including electrons and ions. Generally, the low pressure plasma is well characterized over many years and applied particularly in semiconductor industry applications. In recent years, new technique has been developed to generate plasma at the atmospheric pressure. The temperature of the nonthermal atmospheric plasmas, so called the cold plasmas, is at the minimum around the room temperature. When the substrate is treated by the cold plasma, it induces chemical reactions due to the active radicals even at the low temperature. Also, the vacuum system is not required in the cold plasma, making it possible to be used in many applications, for examples, plasma waterproofing of textiles [1].

In biomedical engineering, cold plasma is used to sterilize medical equipments, especially heat-sensitive devices [2, 3]. Membranes of bacteria and yeast cells are broken by radicals mechanically and chemically. In addition, in a few years, the plasma effects on mammalian cells have been studied [4, 5]. In this research, we investigate the difference in plasma effects on the human liver normal and cancer cells. This study could evaluate the feasibility for the cancer therapy using cold plasma.

II. Materials and Matheds

A. Target cells and sample preparation

We select THLE-2 (human liver normal cell) and SK-Hep1 (human liver metathetic cancer cell) cell lines as the target cells. THLE-2 cells are cultured in the complete media (BEGM + 1% antibiotics + 10% Fetal Bovine Serum (FBS)). SK-Hep1 cells are also cultured the recommended complete media (DMEM + 1% antibiotics + 10% FBS). Cells are seeded on the slide glasses to prepare the experiment. After culturing two types of cells at the same coverage, the cells are rinsed twice by Phosphate Buffered Saline (DPBS) solution for the sample preparation.

B. Experimental setup

We use jet type plasma device which consists of a single pin electrode of 360 μm in radius as shown in Fig. 1. Helium (99.99% purity) gas flows at 2 lpm through the 3 mm diameter pyrex tube. When 50 kHz AC voltage (950 ~ 1200 V) is applied to the pin electrode, the plasma is generated by the electric discharge. The sample is placed on the substrate about 15 mm below the device and treated by the plasma at a certain applied voltage and exposure time.

C. Experimental procedure and imaging

The intensity of the generated plasma depends on the distance (d) between the pin electrode and the slide glass, gas flow rate (r), the applied voltage (V) and frequency (f), and liquid thickness on the sample (l). To prevent cells from being dehydrated, we add DPBS solution on the slide glass to 0.15 mm thickness (l). We set the parameters same during the plasma experiment except the applied voltage: f = 50 kHz, r = 2 lpm, d = 15 mm, l = 0.15 mm, and V = 950 ~ 1200 V. After loading a sample on the center of the substrate, we have plasma treatment on cells and the exposure time ranges 30 ~ 120 sec.

www.springerlink.com

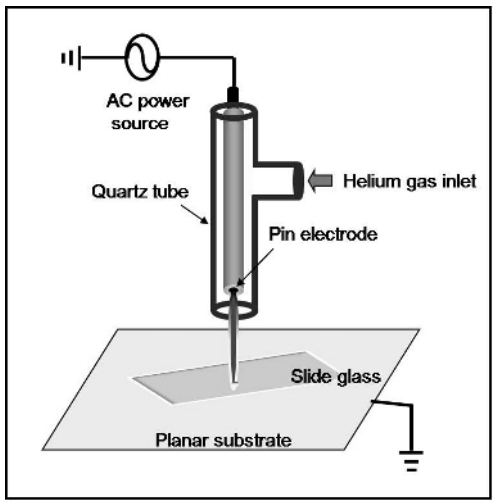

Fig. 1 Schematic drawling of pin-type plasma jet device

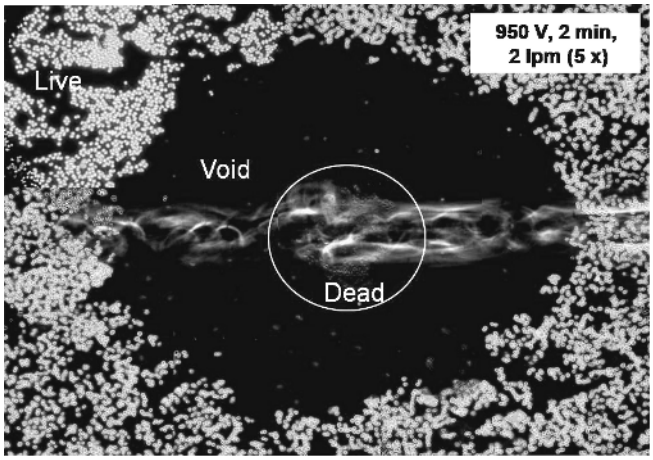

Fig. 2 A microscopic image of plasma-treated SK-Hep1 cells at V= 950 V, t = 120 sec and r = 2 lpm. Green and red dots are live and dead cells, respectively

The plasma treated sample is stained with the dye (ethidium homodimer 5 ul + calcine 2.5 ul + DPBS 5 ml for the live/dead assay. In imaging processes, the live and dead cells are stained in green and red colors, respectively.

III. Results

A. Characteristics of the plasma treated cells

At short exposure times and low applied voltages, both types of cells, THLE-2 and SK-Hep1 are live and their morphologies are unchanged, compared to the control cells. Over the onset plasma condition of necrosis, however, we observe the plasma treated area. The typical plasma treated area shows two different circular zone, void and dead zone, as shown in Fig. 2. In the dead zone, the necrotic cell death occurs while there are no cells in the donut-like void zone. The cells seem to be detached or lysed in the void zone. We find out the higher the applied voltage is, the larger the plasma treated zone is. Considering that the diameter of the plasma jet gets longer as the applied voltage increases, this result is given from the change of plasma beam diameter. Also, higher intensity of plasma in large voltage conditions gives more influence to the cells.

B. Differences in plasma effects on both types of cells

After we perform experiments for THLE-2 and SK-Hep1 cells with the same plasma condition, which is described in the section 2, except fixing t = 120 sec, we compare sample viabilities of both cells. The sample viability is defined by N/N_0 times 100 %, where N is the number of surviving samples and N_0 is the number of total samples. THLE-2 has the sample viability over 60 % in all of plasma conditions. While, the sample viability of SK-Hep1 is much lower than that of THLE-2. It is below 50 % over V = 950 V. At the highest voltage of 1200 V, SK-Hep1 samples completely have necrosis. Therefore the necrosis-onset voltage of SK-Hep1 is lower than that of THLE-2.

C. Differences in electrical properties of both types of cells

We measure the total capacitance of the system, including air, DPBS solution, cells and slide glass. We find that the capacitance of THLE-2 system is higher than that of SK-Hep1 system, suggesting that SK-Hep1 cells could be more conductive in electricity.

IV. Disccusions

In the necrotic sample, we observe the phase separation into void and dead zones. We propose that this feature results from the spatial characteristics of the pin-type plasma device. Generally, pin-type plasma has Gaussian distribution in the plasma density, which is maximum at the center of plasma [6]. Thus, at the center of the plasma treated region, necrosis could occur due to the strong intensity of plasma. Cell detachment could occur around the boundary region, resulting in a void.

On the other hand, we see that the sharp boundary line between non-plasma-treated and plasma-treated regions. This result implies that we can have plasma treatment on cells with a high-precision. This high-precision removal of cancer cells could be applied to the direct cancer therapy

without excessive damage of surrounding normal cells in biomedical application.

Even at the same plasma condition, samples have a distribution in both of survival and necrosis. This could result from the fluctuation of cell coverage. Basically, plasma effects on cells could rely on the cell coverage. Because cells are dielectric materials, the difference in cell coverage could give rise to the difference in the plasma condition. We maintain the same coverage of THLE-2 and SK-Hep1 cells. However, there could be a fluctuation in the cell coverage. To estimate this effect, we can study the dependence of plasma effects on cell coverage.

In the results of capacitance measurement, SK-Hep1 cells could be more conductive in electricity than THLE-2 cells. The higher conductivity of a sample is, the stronger intensity of plasma is. Thus, even at the same plasma condition, the generated plasma in SK-Hep1 system is stronger than that in THLE-2 system. This result could give rise to the difference in the onset voltages of necrosis between normal and cancer cells. Using this difference in plasma effects on THLE-2 and SK-Hep1 cells, we may apply this device to a novel cancer therapy, which kills cancer cells selectively without damages of normal cells.

V. Conculsions

We perform a comparative study of plasma effects on human liver normal and cancer cells for the feasibility of cancer therapy using cold plasma. In necrotic plasma conditions, the local area of cells can be treated by plasma with a high-precision. On the other hand, the total capacitance of normal cell system is larger than that of cancer cell system. This difference in electrical properties of cells could result in the difference in onset voltages of necrosis between normal and cancer cells. Based on the results of this research, we may provide a novel method of cancer treatment to biomedical field.

Space State Approach to Study the Effect of Sodium over Cytosolic Calcium Profile

Shivendra Tewari and K.R. Pardasani

Department of Mathematics, M.A.N.I.T., Bhopal, INDIA

Abstract — **Calcium is known to play an important role in signal transduction, synaptic plasticity, gene expression, muscle contraction etc. A number of researchers have studied Cytosolic calcium diffusion but none have studied the effect of sodium over Cytosolic calcium profile. Here in this paper we have developed a mathematical model which incorporates all the important parameters like permeability coefficient, calcium flux, sodium flux, external sodium, external calcium etc. Thus we can study dynamically changing calcium with respect to dynamically changing sodium. Further, we have used Space State approach for the simulation of the proposed model which is a novel technique in itself developed in the later part of the twentieth century.**

Keywords — **Cytosolic calcium, permeability coefficient, sodium flux, calcium flux.**

I. Introduction

Intracellular calcium is known to regulate a number of processes [1]. One of the most important process is the process of signal transduction. Calcium acts as a switch in the process of signal transduction while converting electrical signal into a chemical signal. Calcium helps in the mechanism of exocytosis by combining with synaptotagmin to release neurotransmitters [2]. There are a number of parameters that affect its mobility and concentration like channels, pumps, leaks etc. Further, Reuter and Seitz found that calcium extrusion in heart muscles is caused by the electrochemical sodium gradient across the plasma membrane. Blaustein also observed that the sodium gradient across the plasma membrane influences the intracellular calcium concentration in a large variety of cells via a counter transport of Na^+ for Ca^{2+}. The dependence of Na^+ – Ca^{2+} electrochemical gradient has been studied by Sheu and Fozzard for sheep ventricular muscle and Purkinje strands. Thus, there is enough evidence that Na^+ is an important parameter to be considered when modeling cytosolic [Ca^{2+}] concentration. Matsuoka *et al.* also found that Na^+ – Ca^{2+} is the major mechanism by which cytoplasmic Ca^{2+} is extruded from cardiac myocytes [3, 4, 5, 6]. The mathematical models proposed so far have not incorporated the effect of Na^+ in their models [1, 7, 8]. Thus in this model we have incorporated the effect of dynamically changing Na^+ over dynamically changing Ca^{2+}. In this mathematical model we have incorporated Ca^{2+} influx, Na^+ influx, Na^+ / Ca^{2+} exchange pump. Since we have used Space State approach [9] to simulate the given model, we needed to linearise the given model. The results showed the effect of Na^+ / Ca^{2+} exchange over intracellular Ca^{2+} and intracellular Na^+.

II. The Mathematical Model

The mathematical model consists of a Ca^{2+} flux, Na^+ flux and a Na^+ / Ca^{2+} exchange pump. The influx of Ca^{2+} and Na^+ currents is modeled using the famous *Goldman-Hodgkin-Katz* (GHK) current equation [10] while the third parameter Na^+ / Ca^{2+} exchange pump is modeled using the free energy principle [11]. We have assumed a cytosol of radius 5 μm and thickness 7 nm. The proposed mathematical model can be framed using the following system of ordinary differential equations:

$$\frac{d[Ca^{2+}]}{dt} = -\sigma_{Ca} - \sigma_{NCX}$$
$$\frac{d[Na^{+}]}{dt} = -\sigma_{Na} - \overline{\sigma}_{NCX} \tag{1}$$

Along with the initial conditions,

$$[Ca^{2+}] = 0.1\mu M$$
$$[Na^{+}] = 12mM$$

A. Ca^{2+} and Na^+ currents

The influx of Ca^{2+} and Na^+ is modeled using the GHK equation:

$$I_S = \frac{P_S z_S^2 (\frac{V_m F^2}{RT})([S]_i - [S]_o exp(-\frac{(z_S V_m F)}{RT}))}{(1 - exp(-\frac{z_S V_m F}{RT}))} \tag{2}$$

here, 'S' is any ion in this case Ca^{2+} or Na^+. All the parameters have their usual meanings and have values as stated in Table 1. The value of permeability constant of Ca^{2+} and Na^+ is determined from the fact that conductance or permeability is equal to $\frac{D}{L}$ where D is the diffusion coeffi-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 358–361, 2009
www.springerlink.com

cient and L is the thickness of the membrane [10]. The diffusion coefficients were taken as from Stryer *et al.* [12] and membrane thickness is taken to be 7 nm [10]. Further, the inward current was taken to be negative and is converted into Molar / second using the faradays constant and using the fact that 1 L = 10^{15} μm^3 before being substituted in equation (1).

$$\sigma_{Ca} = \frac{-I_{Ca}}{z_{Ca}FV}$$

where, all the parameters have their usual meanings and V is the volume of the cytosol. Similarly, we can calculate the net flux of Na^+ ions from the Na^+ channel.

B. Na^+ / Ca^{2+} exchange

The Na^+ / Ca^{2+} exchange pump is known as the most important mechanism of Ca^{2+} extrusion [6]. This exchange is modeled by equating the electrochemical gradient of both the ions,

$$\Delta_{Ca} = RT\log(\frac{Ca_i}{Ca_o}) + z_{Ca}FV_m \tag{3}$$

Similarly, we can frame for electrochemical gradient of Na^+ (Δ_{Na}). The pump is assumed to be electrogenic in nature as one Ca^{2+} leaves the cytosol for intake of three Na^+ ions. Thus,

$$\Delta_{Ca} = 3\Delta_{Na} \tag{4}$$

Using equation 4 and solving we can obtain the required relation for Na^+ / Ca^{2+} exchange, given in the following equation:

$$\sigma_{NCX} = Ca_o(\frac{Na_i}{Na_o})^3 \exp(\frac{FV_m}{RT})$$
$$\bar{\sigma}_{NCX} = Na_o(\frac{Ca_i}{Ca_o})^{1/3} \exp(-\frac{FV_m}{RT}) \tag{5}$$

Before solving equation (1) by Space State technique the equations were linearised. For our convenience we write 'u' in lieu of Ca^{2+} and 'v' in lieu of Na^+. Further, the equations were transformed into matrix equations after using a number of transformations:

$$\frac{du}{dt} = au - b - a'v$$
$$\frac{dv}{dt} = cv - d + c'u \tag{6}$$

where, $a = \dfrac{2P_{Ca}FV_m \exp(\frac{2FV_m}{RT})}{RT(1-\exp(\frac{2FV_m}{RT})}$

$$b = \frac{2P_{Ca}FV_m u_{out}}{RT(1-\exp(\frac{2FV_m}{RT}))}, a' = \frac{u_{out}}{v_{out}}\exp(\frac{FV_m}{RT})$$
$$c = \frac{P_{Na}FV_m \exp(\frac{FV_m}{RT})}{(1-\exp(\frac{FV_m}{RT}))}, d = \frac{P_{Na}FV_m v_{out}}{(1-\exp(\frac{FV_m}{RT}))}$$
$$c' = \frac{v_{out}}{u_{out}}\exp(-\frac{FV_m}{RT})$$

Using another transformation of

$$\bar{u} = u\exp(\frac{2FV_m}{RT}) - u_{out}$$
$$\bar{v} = v\exp(\frac{FV_m}{RT}) - v_{out} \tag{7}$$

Using equation (7) in equations (6) it is reduced to

$$\frac{d}{dt}\begin{bmatrix}\bar{u}\\ \bar{v}\end{bmatrix} = \begin{bmatrix} -\frac{u_{out}}{v_{out}}\exp(2\varepsilon) & \frac{2P_{Ca}\exp(2\varepsilon)}{1-\exp(2\varepsilon)} \\ \frac{P_{Na}\varepsilon\exp(\varepsilon)}{1-\exp(\varepsilon)} & -\frac{v_{out}}{u_{out}}\exp(-2\varepsilon)\end{bmatrix}\begin{bmatrix}\bar{u}\\ \bar{v}\end{bmatrix} - \begin{bmatrix} u_{out} \\ -v_{out}/\exp(2\varepsilon)\end{bmatrix} \tag{8}$$

here, ε is a dimensionless quantity equal to FV_m/RT. If we use matrix notations and use another transformation then equation (8) can be reduced to the form which is readily solvable by the method of Space State,

$$\frac{dY}{dt} = AY \tag{9}$$

where,

$$Y = AX + C, X = \begin{bmatrix}\bar{u}\\ \bar{v}\end{bmatrix}, C = \begin{bmatrix} u_{out} \\ -v_{out}/\exp(2\varepsilon)\end{bmatrix},$$
$$A = \begin{bmatrix} -\frac{u_{out}}{v_{out}}\exp(2\varepsilon) & \frac{2P_{Ca}\exp(2\varepsilon)}{1-\exp(2\varepsilon)} \\ \frac{P_{Na}\varepsilon\exp(\varepsilon)}{1-\exp(\varepsilon)} & -\frac{v_{out}}{u_{out}}\exp(-2\varepsilon)\end{bmatrix}$$

with initial conditions,

$$Y(0) = \begin{bmatrix} 0.002 \\ 74.361 \end{bmatrix} \quad (10)$$

Solving equation (9 – 10) with help of space state technique and using inverse transformations, we have,

$$u(t) = 256.41(0.002 - 0.00005(-37.18 - 37.31(Sinh(kt)$$
$$+74.36(Cosh(kt) - 0.012(Sinh(kt)))) + 0.012(-0.002($$
$$-0.002 - 0.004(Sinh(kt)) + 0.002(Cosh(kt)$$
$$+0.0002(Sinh(kt)))))$$
$$v(t) = 16(0.145 - 0.0002(-37.18 - 37.31(Sinh(kt)))$$
$$+74.36(Cosh(kt) - 0.0118(Sinh(kt))))$$
$$-18589.7(-0.002 - 0.004(Sinh(kt))$$
$$+0.002(Cosh(kt) + 0.0002(Sinh(kt)))))$$

here, k is the eigen value of matrix A which has two values:

$$k_1 = -1.00579$$
$$k_2 = 0.99253$$

That is $k_1 \approx k_2 \approx k \approx 1$

III. Results and Discussion

This section comprises of the results and conclusion obtained from our methodology and hypothesis. The parameters used for simulation are as stated in Table 1

Table 1 Values of the parameters used

Parameter	Symbol	Value
Faraday's Constant	F	96487 Coulombs / moles
Membrane Potential	V_m	-70 mV
Real Gas Constant	R	8.314 J per Kelvin mole
Temperature	T	293 K
External Calcium Concentration	u_{out}	2 mM
External Sodium Concentration	v_{out}	145 mM
Ca^{2+} diffusion coefficient	D_{Ca}	250 μm^2/second
Na^+ diffusion coefficient	D_{Na}	480 μm^2/second
Membrane thickness	L	7 nm
Ca^{2+} permeability	P_{Ca}	3.3 x 10^{-2}metre / second
Na^+ permeability	P_{Na}	6.4 x 10^{-2}metre / second

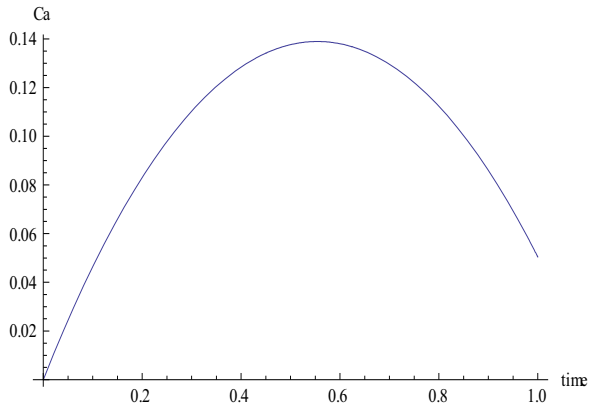

Fig. 1shows the plot of Ca^{2+} against time

In figure 1, the impact of Na^+ / Ca^{2+} exchange is shown on the temporal scale. Ca^{2+} is shown on the mM scale and time is shown on the second scale. It is evident from the figure when Ca^{2+} concentration rises above a certain level it triggers Na^+ / Ca^{2+} exchange protein and initializes the extrusion of Ca^{2+} for intake of Na^+ ions. As soon as, Na^+ / Ca^{2+} exchange is triggered the rising of Ca^{2+} stops and it starts decaying.

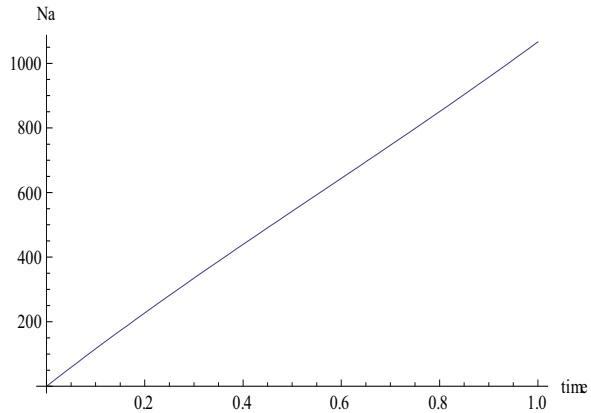

Fig. 2 shows the plot of Na^+ against time

In figure 2, the increasing Na^+ is plotted against time. Intracellular Na^+ is in the units of mM and time is on the scale of seconds. Since, there is no parameter in equation 1 to regulate intracellular concentration, therefore, Na^+ concentration goes on increasing. But that is not the case in reality as there is a Na^+ / K^+ ATPase which extrudes excess Na^+ from inside the cytosol [13]. Further, the Na^+ / Ca^{2+} exchange functions both ways when the Ca^{2+} is high it exchanges intracellular Ca^{2+} for extracellular Na^+ and when Na^+ is high it exchanges intracellular Na^+ for extracellular

Ca^{2+} [14]. The numerical results and graphs are obtained using Mathematica 6.0.

Since the model proposed needed to be a linear one we have to drop the non-linear terms and hence the Na^{+} concentration is not decreasing. On the other hand, this paper helps us to observe the apparent effect of Na^{+} / Ca^{2+} exchange over intracellular Ca^{2+} concentration while keeping the model a simple one. Further, the use of space state technique simplifies the solution and gives an analytic solution. In a similar manner, we can incorporate more parameters in this model to have a more realistic model which can be used either for simulation of cytosolic diffusion or excitation contraction coupling problem.

Abstract — **Magnetic resonance (MR) spectroscopy is a valuable method for the noninvasive investigation of metabolic processes. Although brain ATP studies can be found in multi-voxel ^{31}P MR spectroscopy, previous studies of intracellular brain pH was conducted in single-voxel ^{31}P MR spectroscopy. The purpose of this study was to explore the feasibility of mapping brain ATP and brain pH by using multivoxel ^{31}P MR spectroscopy. Phantom studies were carried out by using a GE 3T scanner firstly. Many available sequences were tested using phantom and the 2D PRESSCSI sequence was selected because of better signal to noise ratio. TR was 1000 msec and TE 144 msec with 128 scan averages. The acquisition matrix was 16 x 16 phase encodings over a 24-cm FOV. Slice thickness was 10 mm. Then a healthy volunteer from MR research team was studied. Data were processed offline using the SAGE/IDL software. Baseline and phase corrections were performed. Multivoxel spectra and brain ATP map were analyzed. Brain pH values were calculated from the difference in chemical shifts between inorganic phosphate (Pi) and phosphocreatine (PCr) resonances. Color scaling map was generated using MatLab software. Multivoxel ^{31}P spectra were obtained for phantom and the healthy volunteer. PCr map was obtained in phantom. At this moment, peaks of PCr were not homogeneous in phantom studies. There was noise for multivoxel ^{31}P spectra in volunteer study. Phosphomonoester (PME) peak, P*i* peak, phosphodiester (PDE) peak, PCr peak, γATP peak, αATP peak, and βATP peak can be identified. Preliminary brain ATP map and brain pH map were generated in the volunteer. It is feasible to map brain ATP and brain pH using multivoxel ^{31}P MR spectroscopy. However, endeavors should be made to improve quality of multivoxel ^{31}P MR spectroscopy.**

Keywords — **MR spectroscopy, brain pH mapping, brain ATP mapping**

I. Introduction

Magnetic resonance (MR) spectroscopy is a valuable method for the noninvasive investigation of metabolic processes. Many fundamental physiological, biochemical and metabolic events in human body can be evaluated by using MR spectroscopy. Single voxel MR spectroscopy has been an important tool to investigate metabolites in the regions of brain, prostate, muscle, etc. However, the drawback of single voxel technique is obvious in terms of anatomical coverage and small structure, compared with multivoxel MR spectroscopy. Multivoxel MR spectroscopy is a welcome change over previous single voxel method [1-5].

Brain energy metabolism can be assessed by using ^{31}P MRS to measure changes in the intracellular pH and relative concentrations of adenosinetriphosphate (ATP), phosphocreatine (PCr), and inorganic phosphate (P*i*) [6]. Intracellular pH values can be calculated from the difference in chemical shifts between P*i* and PCr resonances [7-11]. Mitochondrial activities can be evidenced by measuring ATP peaks. Brain pH study will be beneficial for diagnosis and treatment of many diseases, such as brain tumor, brain infarction, neurodegenerative diseases, and so on. Although brain ATP studies can be found in multi-voxel ^{31}P MR spectroscopy, previous studies of intracellular brain pH was conducted in single-voxel ^{31}P MR spectroscopy.

To our knowledge, mapping brain pH using multivoxel ^{31}P MR spectroscopy has not been published. The hypothesis of this study was that if multivoxel ^{31}P MR spectroscopy could be used to measure brain metabolites directly, we should be able to generate brain pH map indirectly. In order to enhance visual observation, brain pH map could be enhanced by color scaling. Therefore, the purpose of this study was to explore the feasibility of mapping brain ATP and brain pH by using multivoxel ^{31}P MR spectroscopy. We report our preliminary results in a sense of encouraging our future endeavors.

II. Materials and Methods

Phantom studies were carried out at first in this study. Phantom was a sphere filled with physiological metabolites of brain, including phosphocreatine (GE Braino). Then a healthy volunteer from MR research team was studied. All procedures were approved by the research committee at the Toronto Western Hospital. The studies were performed on a 3-T GE scanner (General Electric Medical Systems, Milwaukee, WI). The scout images were obtained with a gradient echo sequence. Many available sequences were tested using

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 362–365, 2009
www.springerlink.com

phantom. The 2D PRESSCSI sequence is the best sequence for multivoxel ^{31}P MR spectroscopy concerning signal to noise ratio. The 2D PRESSCSI sequence was utilized for both ^{1}H scans with a standard head coil and ^{31}P scans with a GE service coil. TR was 1000 msec and TE 144 msec with 128 scan averages. A single PRESS volume of interest was prescribed graphically. The acquisition matrix was 16 x 16 phase encodings over a 24-cm FOV. Slice thickness was 10 mm. Before ^{31}P scan, a ^{1}H MRS pre-scan was performed to obtain shimming values. The ^{1}H pre-scan was performed using first and automatic shimming. Shimming values of ^{1}H MRS scan in x, y, z directions were copied to ^{31}P MRS scans. The standard head coil was unplugged when ^{31}P scan was performed.

Data were processed offline using the SAGE/IDL software. Baseline and phase corrections were performed. Multivoxel spectra, phantom PCr map, and brain ATP map were generated using SAGE/IDL software.

Because of noise spectra in the volunteer, brain pH values were roughly calculated from the difference in chemical shifts between P*i* and PCr resonances using the following standard formula [7-10]:

$$\mathrm{pH} = 6.77 + \log\{(A - 3.29)/(5.68 - A)\} \quad (1)$$

where A = chemical shift difference in parts per million between P*i* and PCr. Color scaling map was generated using MatLab software.

III. Results

Multivoxel ^{31}P spectra were obtained for phantom and the healthy volunteer. However, the peaks of PCr were heterogeneous in phantom study (Figure 1). From the data of this scan, a corresponding PCr map could be generated by SAGE/IDL software (Figure 2).

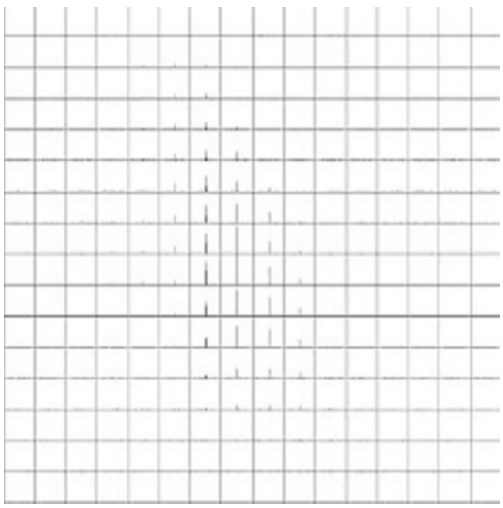

Fig. 1. Multivoxel ^{31}P MR spectroscopy of phantom obtained by the 2D PRESSCSI sequence. The heterogeneous PCr peaks were observed.

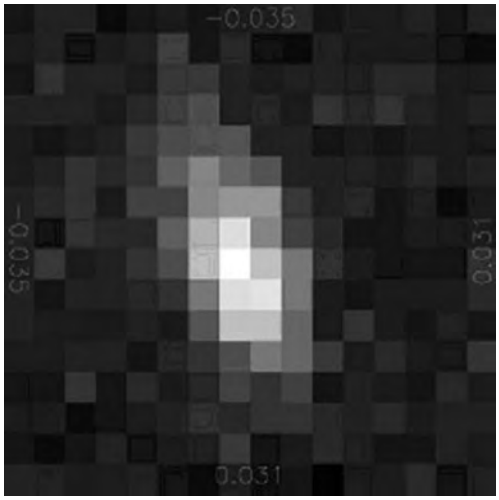

Fig. 2. PCr map generated by the data of Figure 1.

At this moment, there was noise for multivoxel ^{31}P spectra in volunteer study. A cumulated spectra from the multivoxel ^{31}P MR spectroscopy is shown in Figure 3. Roughly, phosphomonoester (PME) peak, inorganic phosphate (P*i*) peak, phosphodiester (PDE) peak, phosphocreatine (PCr) peak, γATP peak, αATP peak, and βATP peak could be identified. The individual spectra were with similar quality. From the data of same scan, corresponding metabolite maps could be generated by SAGE/IDL software. Figure 4 shows a brain γATP map as an example.

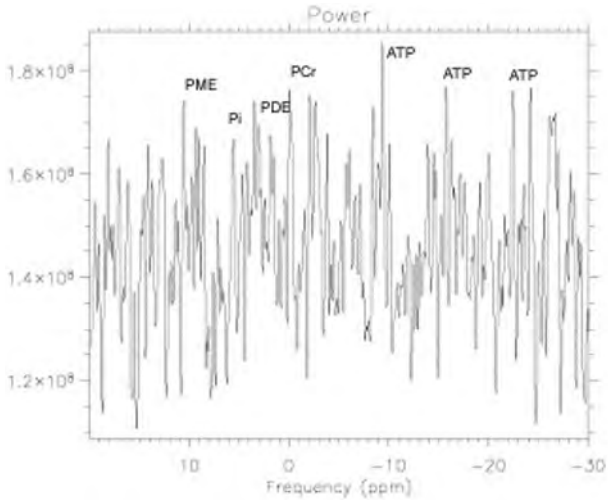

Fig. 3. Cumulated spectra of multivoxel ^{31}P MR spectroscopy in vivo. Although there was too much noise, brain metabolites could be identified.

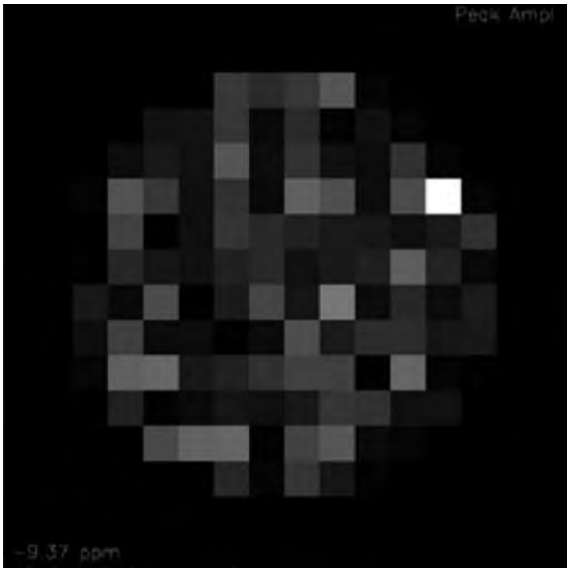

Fig. 4. γATP map generated by SAGE/IDL software from same data of Figure 3.

Figure 5 shows the results of rough brain pH calculation based on multivoxel ^{31}P data of the volunteer scan. The lowest value was 7.01 and the highest value was 7.24. From the values of Figure 5, a color scaling map was generated using MatLab software (Figure 6). Red color represents higher pH value and blue color represents lower pH value. Although the brain pH map might be just preliminary, we did obtain the brain pH map.

IV. Discussion

What multivoxel ^{31}P MR spectroscopy measures at this time is limited in quality, but it does provide a window to noninvasively measure small structure of brain tissue. The advantage of using multivoxel ^{31}P MR spectroscopy over single voxel arises from its capability of offering metabolite information in spacing distribution, and continuous spectra to be obtained from tissue in real-time. By generating color map using multivoxel ^{31}P MR spectroscopy, evaluation of physiological or pathological information becomes much easy. Mapping brain metabolites has received increasing interest and could be utilized in other organs and tissue of human body [12-14].

Although our results of generating brain ATP map and brain pH map are preliminary, bright future could be expected in terms of technique improving. At this moment, MR hardware and software are not perfect so that our brain ATP map and brain pH map might just be at their earliest stage. But we did obtain our preliminary maps based on previous outcomes. What we should endeavor in the future is finding better hardware and software to improve homogeneity of magnetic filed and perfect shimming for multivoxel ^{31}P MR spectroscopy. More sensitive detection techniques and better post-processing should also be taken into account. As long as source signals of multivoxel ^{31}P MR spectroscopy are accurate, the corresponding maps are just visual enhancement. We are confident of that brain ATP map and brain pH map will be feasible in the near future. Accurate metabolite information for small region of organ tissue will be available for studies of gene expression, identifying progenitor cells, early detection of various diseases, differential diagnosis of diseases, etc [15-17].

V. Conclusions

This study was conducted to prove the possibility of mapping brain ATP and brain pH by using multivoxel ^{31}P MR spectroscopy. We report our preliminary results in a sense of encouraging our future endeavors.

Abstract — **A brain-computer interface (BCI) is a new communication channel between the human brain and a digital computer. Furthermore a BCI enables communication without using any muscle activity for a subject. The ambitious goal of a BCI is finally the restoration of movements, communication and environmental control for handicapped people. However, in more recent research also BCI control in combination with Virtual Environments (VE) gains more and more interest. Within this study we present experiments combining BCI systems and control VE for navigation and control purposes just by thoughts. A comparison of the applicability and reliability of different BCI types based on event related potentials (P300 approach) will be presented.**

BCI experiments for navigation in VR were conducted so far with (i) synchronous BCI and (ii) asynchronous BCI systems. A synchronous BCI analyzes the EEG patterns in a predefined time window and has 2-3 degrees of freedom. A asynchronous BCI analyzes the EEG signal continuously and if a specific event is detected then a control signal is generated. This study is focused on a BCI system that can be realized for Virtual Reality (VR) control with a high degree of freedom and high information transfer rate. Therefore a P300 based human computer interface has been developed in a VR implementation of a smart home for controlling. the environment (television, music, telephone calls) and navigation control in the house.

Results show that the new P300 based BCI system allows a very reliable control of the VR system. Of special importance is the possibility to select very rapidly the specific command out of many different choices. This eliminates the usage of decision trees as previously done with BCI systems.

Keywords — **Brain-Computer Interface, P300, evoked potential, Virtual Environment**

I. Introduction

An EEG based Brain-Computer Interface (BCI) measures and analyzes the electrical brain activity (EEG) in order to control external devices. A BCI can be seen as novel and additional communication channel for humans. In contrast to other communication channels a BCI does not need using any muscle activity from the subject. BCIs are based on slow cortical potentials [1], EEG oscillations in the alpha and beta band [2, 3, 4], the P300 response [5] or steady-state visual evoked potentials (SSVEP) [6]. BCI systems are used mainly for moving a cursor on a computer screen, controlling external devices or for spelling purposes [2, 3, 5].

BCI systems based on slow cortical potentials or oscillatory EEG components with 1-5 degrees of freedom were realized up to now. However, high information transfer rates were reached based on 2 degrees of freedom as otherwise the accuracy of the BCI systems dropped down. SSVEP based systems allow selecting up to 12 different targets and are limited by the number of distinct frequency responses that can be analyzed in the EEG. P300 response based BCIs typically used a matrix of 36 characters for spelling applications [5]. The underlying phenomenon of a P300 speller is the P300 component of the EEG which is induced if an unlikely event occurs. The subject has the task to concentrate himself on a specific letter he wants to select [5, 7, 8]. When the character flashes on, a P300 is induced and the maximum in the EEG amplitude is reached typically 300 ms after the flash onset. Several repetitions are needed to perform EEG data averaging for increase the signal to noise ratio and accuracy of the system. The P300 signal response is more pronounced in the single character speller than in the row/column speller and therefore easier to detect [7, 8].

II. Methods

Three subjects participated in the experiments. EEG from 8 electrode positions located over the parietal and occipital areas was measured. The sampling frequency was set to 256 Hz and EEG was digitally bandpass filtered between 0.1 to 30 Hz. Then a hardware interrupt driven device driver was used to read the biosignal data with a buffersize of 1 (time interval ~ 4ms) into Simulink which runs under the MATLAB environment [4]. Within Simulink the signal processing and feature extraction (see [5] for details) and the paradigm presentations are performed. The paradigm module controls the flashing sequence of the symbols. In this work, a smart home VR realization should be controlled with the BCI. Therefore the subjects were trained firstly in spelling characters and numbers based on their P300 EEG response. Therefore, the characters of the English alphabet (A, B,…Z) and Arabic numbers (1, 2,…9) were arranged in

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 366–369, 2009
www.springerlink.com

a 6 x 6 matrix on a computer screen. Then the characters were highlighted in a random order and the subject had the task to concentrate on the specific character he/she wanted to spell. All experiments were undertaken in 2 modi: (i) the row/column speller – all items of one row or column are highlighted at the same time, (ii) the single character speller – only one character is highlighted. For the single character speller each character was highlighted 15 times. For the row/column speller each row and each column was also highlighted 15 times. This results in a speed up of 3 for the row/column speller. Another important parameter in the P300 experiment is the flash time (character is highlighted) and the dark time (time between 2 highlights). Both times should be as short as possible to reach a high communication speed, but must be long enough so that the subject can react on the flash and that the single P300 responses are not overlapping.

At the beginning of the experiment the BCI system was trained based on the P300 response of 42 characters of each subject with 15 flashes per character (about 40 minutes training time). All 3 subjects needed between 3 and 10 flashes (mean 5.2) per character to reach an accuracy of 95 % for the single character speller and between 4 and 11 flashes (mean 5.4) for the Row/Column speller. This resulted in a maximum information transfer rate of 84 bits/s for the single character speller and 65 bits/s for the row column speller. Figure 1 yields the a typical P300 response to the target letters.

Then the P300 based BCI system was connected to a Virtual Reality (VR) system. A virtual 3D representation of a smart home with different control elements was developed as shown in Figure 2.

Figure 2: Virtual representation of a smart home

In the experiment it should be possible for a subject to switch on and off the light, to open and close the doors and windows, to control the TV set, to use the phone, to play music, to operate a video camera at the entrance, to walk around in the house and to move him/herself to a specific location in the smart home. Therefore special control masks for the BCI system were developed containing all the different necessary commands. In total 7 control masks were created: a light mask, a music mask, a phone mask, a temperature mask, a TV mask (see Figure 3), a move mask and a go to mask (see Figure 4).

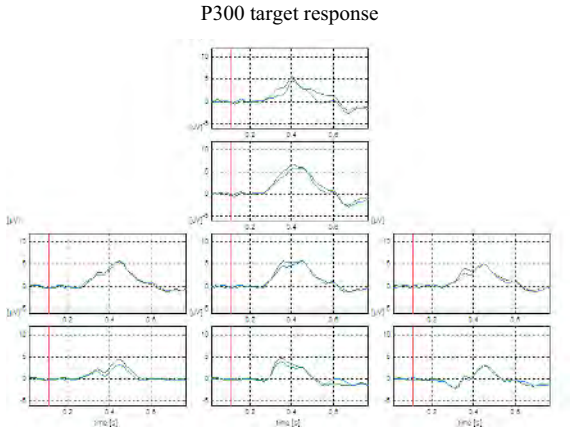

Figure 1: Typical averaged P300 responses for a single character flasher. The graphs represent the P300 responses from electrode positions Fz, Cz, P3, Pz, P4, Fp1, Oz and Fp2 (from upper left to lower right). The red vertical bar represents the occurrence of the target letter. Amplitudes on the y-axis are given in [µV] and the x-axis represents the time from 100 ms before target occurrence to 700ms after target occurrence.

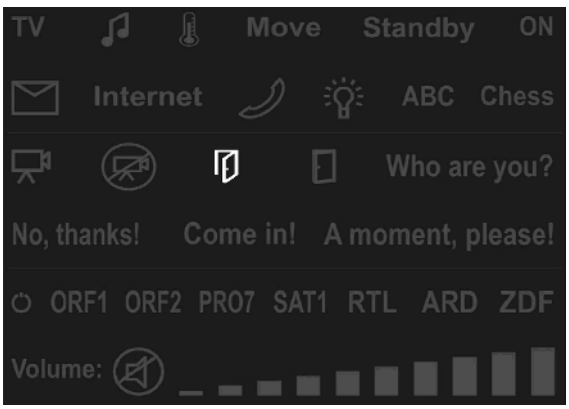

Figure 3: Control mask with the main menu in the first 2 rows, the icons for the camera, door control and questions in the 3rd and 4th row and the TV control in the last 2 rows.

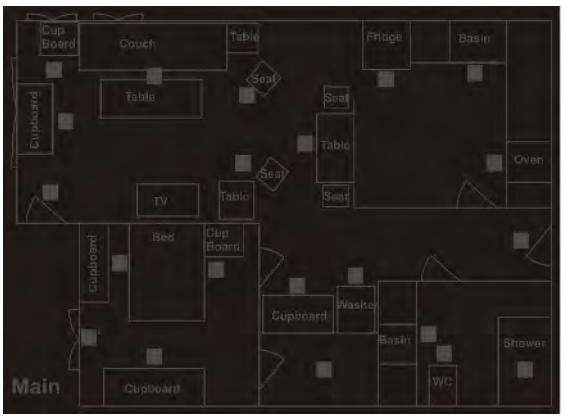

Figure 4: Control mask for going to a specific position in the smart home (bird view).

III. Results

Table 1 shows the results of the 3 subjects for the 3 parts of the experiment and for the 7 control masks. Interestingly, the light, the phone and the temperature mask were controlled by 100 % accuracy. The Go to mask was controlled with 94.4 % accuracy. The worst results were achieved for the TV mask with only 83.3 % accuracy.

Table 2 shows the number of symbols for each mask and the resulting probability that a specific symbol flashes up. If more symbols are displayed on one mask then the probability of occurrence is smaller and this results in a higher P300 response which should be easier to detect. The flashes column shows the total number of flashes per mask until a decision is made. The translation time per character that is longer if more symbols are on the mask.

Table 1. Accuracy of the BCI system for each part and control mask of the experiment for all subjects.

Mask	Part1	Part2	Part3	Total
Light	100%	100%	100%	100%
Music	-	89,63%	-	89,63%
Phone	-	100%	-	100%
Temperature	100%	-	-	100%
TV	83,3%	-	-	83,3%
Move	88,87%	-	93,3%	91,1%
Go to	100%	-	88,87%	94,43%

Table 2. Number of symbols, occurrence probability per symbol, number of flashes per mask (e.g. 25 x 15 = 375) and conversion time per character for each mask.

Mask	Symbols	Probability [%]	Flashes	Time per character [s]
Light	25	4	375	33,75
Music	50	2	750	67,50
Phone	30	3.3	450	40,50
Temperature	38	2.6	570	51,30
TV	40	2.5	600	54,00
Move	13	7.7	195	17,55
Go to	22	4.5	330	29,70

IV. Discussion & conclusion

The P300 based BCI system was successfully used to control a smart home environment with accuracy between 83 and 100 % depending on the mask type. The difference in accuracy can be explained by the arrangement of the icons.

However, the experiment yielded 2 important new facts: (i) instead of displaying characters and numbers to the subject also different icons can be used, (ii) the BCI system must not be trained on each individual character. The BCI system was trained with EEG data of the spelling experiment and the subject specific information was used also for the smart home control. This allows using icons for many different tasks without prior time consuming and boring training of the subject on each individual icon. This reduces the training time in contrast to other BCI implementations were hours or even weeks of training are needed [1, 2, 3]. This reduction in training time might be important for locked-in and ALS patients who have problems with the concentration over longer time periods. The P300 concept works also better if more items are presented in the control mask as the P300 response is more pronounced if the likelihood that the target character is highlighted drops down [4]. This results of course in a lower information transfer rate, but enables to control almost any device with such a BCI system. Especially applications which require reliable decisions are highly supported. Therefore the P300 based BCI system enables an optimal way for the smart home control. The virtual smart home acts in such experiments as a testing installation for real smart homes. Also wheelchair control, which many authors identify as their target application, can be realized with this type of BCI system in a goal oriented way. In a goal oriented BCI approach it is then not necessary e.g. to move a robotic hand by thinking about hand or foot movements and controlling right, left, up, down commands. Humans just think “I want to grasp the glass” and the real command is initiated by this type of BCI implementation.

A P300 based BCI system is optimally suited to control smart home applications with high accuracy and high reliability. Such a system can serve as a easy reconfigurable and therefore cheap testing environment for real smart homes for handicapped people.

Abstract — **This paper emphasizes on a FPGA Implementation of Fuzzy PD&PID Controller in biomedical application. A novel approach aims to identify and design a simple robust Fuzzy PD&PID Controller system with minimum number of fuzzy rules for the diabetic patients as a single injection process through the blood glucose level from Photo plethysmogram is discussed. VLSI system is simulated and analyzed then FPGA system is synthesized and implemented using VHDL.A simulation of VLSI design of the above automatic controller is analyzed. In this process insulin is administrated through an infusion pump as a single injection. The pump is controlled by the automatic control Fuzzy PD Controller which is more efficient compared to the conventional PD Controller.**

Keywords — **blood glucose level, Photo plethysmogram, FPGA, Fuzzy PD&PID Controller.**

I. Introduction

The motto of this paper is to identify a proper methodology for the infusion process of insulin to diabetic patients using an automated Fuzzy logic controller. FPGA Implementation of the above automatic controller is analyzed by using VHDL. In this process insulin is administrated through an infusion pump as a single injection. The pump is controlled by the automatic control Fuzzy PD& PID Controller which is more efficient compared to the conventional PD&PID Controller. In case of non- linear inputs, Fuzzy PD &PID Controller performs better compared to the conventional controller.

The task organization for obtaining FPGA Implementation of Fuzzy PD&PID Controller is as follows:

1. Measurement of Blood glucose level using Photo plethysmography method which is explained in ref [6],[8]
2. Design of Fuzzy PD controller (2x1) based on error and error rate as inputs and output signal to control the movement of infusion pump.
3. Performance study of conventional PD&PID controller with Fuzzy PD&PID controller.
4. VLSI Design and Simulation of Fuzzy PD &PID Controller are analyzed.
5. FPGA Implementation of Fuzzy PD&PID Controller is analyzed.

The FPGA architecture is designed such that its very simple and occupies less memory ,so that our system can also be adaptable in low level FPGA's.

II. Materials and Methodology

A logical system, which is much closer to the spirit of human thinking and natural language than the traditional logic system is called a Fuzzy logic. Here the Fuzzy Controller is considered as new approchement between the conventional mathematical control and human like decision making. The Fuzzy controller has to be provided with a predefined range of control parameters or sense of fields. The determination of these sets is normally carried out by initially providing the system with a set of data manually fed by the operator. The Fuzzy system can be further enhanced by the adaptive control where the time constant and gain are varied to self tune the controller at various operating point.

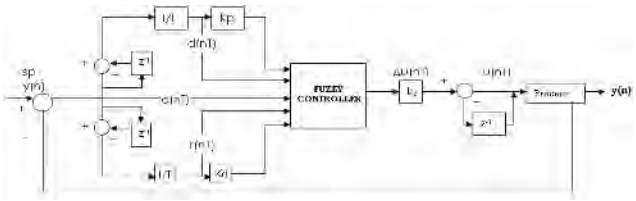

Fig.1 Fuzzy PD controller system

The Figure 1 depicts the Fuzzy PD Controller with Y(nT) is the output of photoglucometer (Photo plethysmography) which is compared with set point (sp), the error and rate of error are calculated and they are given as an input to the Fuzzy inference system which consists of fuzzifier, rule base and defuzzification, which produces the control input Δu(nT). The input u (nT) of the plant is calculated which act as the position control of an insulin pump. Photo-glucometer is an instrument that uses IR radiation (850 nm) from a source, a sensor, amplifier and an output display unit to give the blood sugar of a diabetic patient. The IR radiation when incident on the skin a part of it is transmitted reflected and absorbed by the skin. The transmitted ray is sensed by the sensor and the output of sensor is applied and it is displayed.

III. Analysis of fuzzy PD controller

Fuzzy logic control technique has found many successful industrial applications and demonstrated significant performance improvements. In standard procedure the design consist of three main parts Fuzzification, Fuzzy logic rule base, and Defuzzification[1].

A. Mathematical analysis

Ackerman et al (1965) used a two compartment model to represent the dynamics of glucose and insulin concentration in the blood system. The blood Glucose dynamics of an individual can be written as

$$\dot{x_1} = -m_1 x_1 - m_2 x_2 + p(t) \quad (1)$$

$$\dot{x_2} = -m_3 x_2 + m_4 x_1 + u(t) \quad (2)$$

where $\dot{x_1}$ represents blood glucose level deviations, $\dot{x_2}$ denotes the net blood glycemic harmonic level, p(t) represents the input rate of infusion of glucose, u(t) denotes the input rates of infusion of insulin and m_1,m_2,and m_3 and m_4 are parameters. The photo glucometer output levels are shown in table1.

Table 1 Photo Glucometer Output Levels

Sl No.	Blood Glucose Level (mg/dl)	Photo Glucometer Output (V)	Control levels
1.	50	8	Lower point
2.	100	9	Set point
3.	200	10	Upper point

For severe diabetes we shall take m4 to have the value of Zero. We are considering a group of diabetics with no insulin secretion whose blood glucose level is 200 mg/dl while fasting. Based on the observation we derived the following insulin injection needed for the group in a single injection process in the time duration of 30 min. The above case needs 2950 micro units/ml insulin at a single stroke of injection.

B. Design of Fuzzy PD controller

The conventional continuous time PD control law is described by

$$u(t) = k_p^c e(t) + k_d^c e(t) \quad (3)$$

Where k and k are the proportionality derivative gains of the controller and e(t) is the error signal defined by

$$e(t) = sp(t) - y(t) \quad (4)$$

Sp (t) is the set point and y (t) is the system output

In fuzzification step we employ two inputs ,the error signal e(nT) ,and the rate of change of error signal r(nT), with only one control output u(nT). Both the error and the rate have two membership values, positive and negative while the output has three; positive, negative and zero. Based on the membership functions, the fuzzy control rules that we used are the following

Fr1: IF error = ep AND rate = rp THEN output = oz
Fr2: IF error = ep AND rate = rn THEN output =op
Fr3: IF error = en AND rate = rp THEN output =on
Fr4: IF error = ep AND rate = rn THEN output = oz

Here the output is the fuzzy control action Δu (nT), ep means error positive and oz means output zero etc., In the defuzzification center of mass formula is employed

$$\Delta u(nT) = \frac{rp \times oz + rn \times op + en \times on + en \times oz}{rp + rn + en + en} \quad (13)$$

We use op = 2; on = -3; z=0

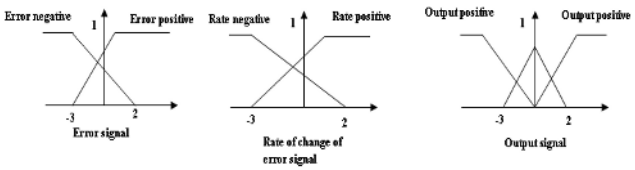

Fig.2 The membership function of e (nT), r (nT) and u (nT)

C. Design of Fuzzy PID controller

The Fuzzy PID controller is designed similar to that of PD controller and it has seven fuzzy control rules.

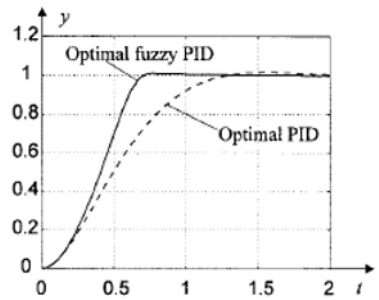

Fig.3 Step responses of optimal PID and optimal fuzzy PID controller

The simulation results of the design shows that the Fuzzy PID controller performs better than conventional PID controller.

IV. VLSI DESIGN OF FUZZY PROCESSOR

VLSI architecture is designed to implement the fuzzy based controller for insulin pumps in diabetic neuropathy patients. This implementation aims at improvement of speed and efficiency of the system. This can be done by incorporating parallel computing system to the architecture. In the design of Fuzzy PD&PID controller there are two inputs, the error signal, error rate and the output is the control signal for the insulin pump. The design we decided to develop was that of a low cost, high performance fuzzy processor with 5 inputs and a single control output.

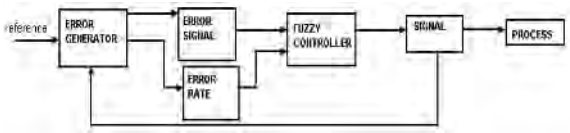

Fig.4: VLSI architecture of fuzzy controller

As shown in the block diagram the controller has an error generator, fuzzy controller, output control signal and the process of infusion being carried on by the insulin pump in a single injection process. In this work the fuzzy architecture is implemented and simulated using VHDL which is IEEE standard language for both simulation and synthesis. VLSI system is incorporated using VHDL Design unit called PROCESS. Atypical test bench is created using VHDL by which simulation of online testing is carried out.

V. FPGA IMPLEMENTATION OF FUZZY CONTROLLERS

Field Programmable Gate Arrays (FPGAs) represent reconfigurable computing technology, they are processors which can be programmed with a design, and then reprogrammed (or reconfigured) with virtually limitless designs as the designer's needs change.FPGA Generic Design Flow has three steps. They are Design Entry, Implementation, and Design verification. Design Entry is created by design files using a schematic editor or hardware description language. Design Implementation on FPGA has partition, place, and route to create bit-stream file. Design verification by using simulator to check function, other software determines max clock frequency.

In this paper the Xilinx Spartan-3 family of FPGA is used. Xilinx Spartan-3 features are low cost, high performance logic solution for high-volume, consumer-oriented applications. Table.2 & 3 shows the for the Device utilization summary for output membership function of Fuzzy PD & PID controllers synthesis process respectively. It shows

Table 2 Device Utilization Summary for Fuzzy PD controller output

that only less part of the resources are utilized for the FPGA synthesis process.

Densities up to 74,880 logic cells, Select IO™ signaling Up to 784 I/O pins, 622 Mb/s data transfer rate per I/O, 18 single-ended signal standards, Eight differential I/O standards including LVDS, RSDS. Logic resources are abundant logic cells with shift register capability. Wide, fast multiplexers, Fast look-ahead carry logic, Dedicated 18 x 18 multipliers, JTAG logic compatible with IEEE 1149.1/1532,

Select RAM™ hierarchical memory, Up to 1,872 Kbits of total block RAM, Up to 520 Kbits of total distributed RAM, Digital Clock Manager (up to four DCMs), Clock skew elimination, Frequency synthesis, High resolution phase shifting, Eight global clock lines and abundant routing. By using the RTL schematic internal components also can be analyzed.

VI. Results and discussion

The Implementation result shows that the Fuzzy PD controller has Minimum input arrival time before clock is 2.951 ns; Maximum output required time after clock is 7.078ns. The Fuzzy PID controller has Minimum period is 5.512ns (Maximum Frequency: 181.429MHz), Minimum input arrival time before clock is 6.657ns, Maximum output required time after clock is 6.141ns.The FPGA system is very simple in architecture and higher in performance with less power dissipation.FPGA Fuzzy control system, which is capable of processing under different input conditions.

The architecture is simulated with various values of error and error rate values. The initial conditions for the overall control systems have the following natural values. For the fuzzy control action $\Delta U(0) = 0$; for the system output y (0) =0and for the original error and rate signals e(0)=r (the set point) and r(0)=r respectively. For our diabetic pump which is a second order system [4], the transfer function is $H(S) = \frac{1}{s^2 + s + 1}$. we remark that the Fuzzy PD controller designed above has a self-timing control capability i.e., when the tracking error e(nT) keeps increasing, the term d(nT)=[e(nT)+e(nT-T)]/T becomes larger. In this case the fuzzy control action $\Delta u(nT)$ also keeps increasingly accordingly, which will continuously reduce the tracking error. Under the steady-state condition $|d(nT)| = 0$, we found that the control performance of the Fuzzy PD controller in VLSI Simulation is also as good as, if not better than the conventional controller.

VII. Conclusion

This paper discusses about the treatment of diabetic neuropathic patients using an automated Fuzzy PD&PID Controller system by FPGA. This system is designed by VLSI System and Implemented using FPGA technology. The control system consists of photoglucometer and an insulin pump. The simulation results have shown that this PD Controller overrides the conventional controller in handling non-linear inputs. In this paper it is assumed that the patient is continuously attached to the infusion pump and the blood glucose level is monitored at regular intervals. The VHDL code is implemented in FPGA and tested for its performance.

Abstract — **Place cells are located in the hippocampus of the brain and play an important role for spatial navigation. In this study neural spike activity of freely moving rats along with the position of the rats was acquired. The study was performed to investigate if position reconstruction is possible if the rat is freely moving in open arenas of different sizes based on neural recordings from CA1 and subiculum regions.**

The neural spike activity was measured using tetrodes from 6 chronically implanted rats in CA1 and subiculum regions. The position of the rats was monitored using a video tracking system .In the encoding step spike activity features of the place cells and position information from the rats were used to train a computer system. In the decoding step, the position was estimated from the neural spiking activity. Different reconstruction methods were implemented: (i) Bayesian 1-step and (ii) Bayesian 2-step. The results show, that the reconstruction methods are able to determine the position of the rat in 2-dimensional open space from cell activity measured in the CA1 and subiculum regions. Better accuracies were achieved for CA1 regions because the firing fields show more localized spots. Higher accuracies are achieved with a higher number of place cells and higher firing rates.

Keywords — **place cells, hippocampus, online position reconstruction, Bayesian 2-step method**

I. Introduction

Cells with spatially modulated firing rates have been found in almost all areas of the hippocampus and in some surrounding areas. Such place cells (PC) encode an internal representation of an animal's position in its environment. The background firing rate of a PC is very low (0.1 Hz), but when an animal enters the receptive field of the neuron, its firing rate rapidly increases (up to ~ 5- 15 Hz) [1,2]. The location inducing the increased cell activity is called the firing field (FF) or place field (PF) of the particular neuron. However, also other sensory cues can influence place cell activity, but visual and motion-related cues are the most relevant [3].

Recently place cells were also used to reconstruct the foraging path of rats by investigating the firing field patterns [1, 5]. In an encoding stage the place cell spiking activity together with video tracking information is used to train a computer system on the data. In a decoding stage only the spike activity is used to reconstruct the path of the animal. In this study it was of interest to test if position reconstruction is also possible in open environments in contrast to the linear arenas used in previous studies [5]. The reconstruction was tested in square arenas with different side length (0,5m, 0,7m, 0,1m, 1m) and a square arena with a smaller square barrier inside (outer square: 1m x 1m, inner square: 0,6 x 0,6m). Two different algorithms based on Bayesian methods were implemented after a Template matching approach was ruled out for reconstruction.

II. Material and methods

A. Neural spike and video data acquisition

Action potential data were measured from 6 rats from CA1 or subiculum by the Instituto de Neurociencias de Alicante (Universidad Miguel Hernández-CSIC, UMH), Institute of Cognitive Neuroscience (University College London, UCL) and Center for Neural Systems, Memory and Aging (University of Arizona, UA). The rats were connected to the recording system via a head stage pre-amplifier. From 1 to 8 tetrodes were used for the recordings. Each data channel was amplified up to 40,000 times and a sampling frequency of 48,000 Hz was used. For tracking purpose small infrared light-emitting diodes were attached to the rat's head and a video camera system was mounted above the experimental arena. The number of recorded cells, the recording region and the arena sizes and shapes are shown in Table 1. The sampling frequency for the position-tracking signal was 50 Hz (*UMH, UA*) and 46.875 Hz (*UCL*).

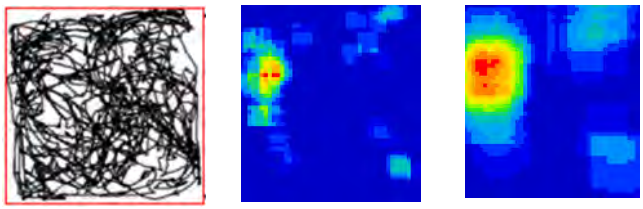

Table 1: Recording information of the 6 rats.

Rat #	1	2	3	4	5	6
No. of cells	5	26	9	6	4	11
Hippocampal region	CA1	CA1	CA1	CA1	Subiculum	Subiculum
Test field side length [m]	0,7	0,8	0,5	1	1	1
Test field shape

www.springerlink.com

B. Dwell Time and Firing Rate

In the first step the recorded spike activity was used as input for the cluster cutting. The cluster cutting was performed manually to separate neuronal activity picked up by the electrodes into single cell activity. In a second step firing rate maps were created. Therefore the arena was divided into small subsets of space and class labels were assigned to these subsets (pixels). Then the firing rate for each pixel was calculated by counting the number of spikes in each class. The test fields were divided into 64x64 classes, leading to an edge length for each class of 1.09 cm (rat 1), 1.25 cm (rat 2), 0.78 cm (rat 3) and 1.56 cm (rats 4, 5, 6). Figure 1A shows the movement trajectory of a rat obtained from the video tracking system for one full experiment with one rat.

A B C

Figure 1: A: arena divided into 64 fields, the cells are firing with a specific rate at each position. B: movement trajectories of the rat recorded with the video tracking system seen from top. C, D: firing maps of 1 neuron with different smoothing factors (5x5 and 10x10 Kernel).

The average firing rate of a cell *i* for each position $\boldsymbol{x}$ is described by the firing rate distribution, i.e. a vector of firing rates per cell *i*: $f(x) = (f_1(x), f_2(x), ..., f_N(x))$. In the training step, the firing rate maps *f(x)* are calculated for the whole population of *N* recorded cells and for every single position $\boldsymbol{x}$. The average firing rates are calculated from the total number of spikes collected for a cell while the rat was at position *S(x),* divided by the total amount of time the rat spent there *V(x).*

$$f(x) = \frac{S(x)}{V(x) \cdot \Delta t} \tag{1}$$

Δt is the time interval of the position tracking system.

The firing rate distribution is independent of how often the rat populates a certain position, it rather describes the tendency of a cell to fire at a given position $\boldsymbol{x}$ as shown in Figure 1B for one neuron.

C. Position reconstruction algorithms

First firing rates of all cells within a sliding time window are compared with the firing rate vectors of each class that were setup in the training phase. Depending on the algorithm, a matching class number is returned which identifies the reconstructed position. To calculate the reconstruction error, the reconstructed position can be compared to the position known from the position tracking data. Then the time window is moved to the next reconstruction position.

For position reconstruction the two algorithms were implemented that were already tested in linear arenas: (i) Bayesian 1-step and (ii) Bayesian 2-step with continuity constraint. For the analysis all datasets were divided into three equally long parts. Training was performed on two thirds of the recordings; the other third was used for the testing and reconstruction.

Bayesian method (1-step)

When the rat moves to specific positions then certain spike trains are produced as response to the sensory stimuli The probability of observing a number of spikes $n = (n_1, n_2, ..., n_N)$ given the stimulus $\boldsymbol{x}$ is $P(n \mid x)$. The probability of a stimulus (rat at position $\boldsymbol{x}$) to occur is defined as $P(x)$. The joint distribution

$$P(n, x) = P(n \mid x) \cdot P(x) \tag{2}$$

measures the likelihood of observing both a stimulus $\boldsymbol{x}$ and a spike train n.

For the reconstruction, the observation of a number of spikes n found in the measured data occur with a probability of $P(n)$. The likelihood of observing both stimulus and spikes is finally given by [5]

$$P(x \mid n) = C(\tau, n) \cdot P(x) \cdot \left(\prod_{i=1}^{N} f_i(x)^{n_i} \right) \cdot \exp\left(-\tau \cdot \sum_{i=1}^{N} f_i(x) \right) \tag{3}$$

Were $C(\tau, n)$ is a normalization factor and τ is the length of the time window. In this study the normalization factor $C(\tau, n)$ was set to 1.

The most probable position will be regarded as the animal's position:

$$\hat{x}_{Bayes,1-step} = \arg\max_{x} P(x \mid n) \tag{4}$$

Bayesian method with continuity constraint (2-step)

A continuity constraint can improve the accuracy of reconstruction. Sudden jumps in the reconstruction are observed by the low instantaneous firing rates of the recorded place cells. If not enough cells are firing then there is a lack of information. However the firing information is needed for the position reconstruction. The continuity constraint incorporates the reconstructed position from the preceding

time step as well as the current speed information. Based on the 1-step Bayesian method the reconstructed position at the preceding time step $t-1$ is also used to calculate the reconstructed position at time *t:*

$$P(x_t \mid n_t, x_{t-1}) = k \cdot P(x_t \mid n_t) \cdot P(x_{t-1} \mid x_t) \quad (5)$$

For more on this approach and details see [5].

III. Results

Figure 2 shows the reconstruction results computed with the Bayesian 2-Step algorithm of rat 3. Data from seconds 160 to 480 were used to train the algorithm and the interval 0 to 160 was used to test the method. The figure shows that the reconstructed path follows the real path very well in many data points of the recording. The mean reconstruction error of rat 3 was 9.5 cm. Figure 2 shows clearly erratic jumps of the reconstructed path in both x- and y-coordinates. If the reconstruction is only performed for time intervals where a minimum number of spikes (4 spikes in reconstruction window) are present the accuracy is increased as shown by the grey thin line in Figure 2B. In this case the mean error is 8 cm. Interesting is the erratic jump around second 51 were the running speed (Figure 2C) was almost 0.

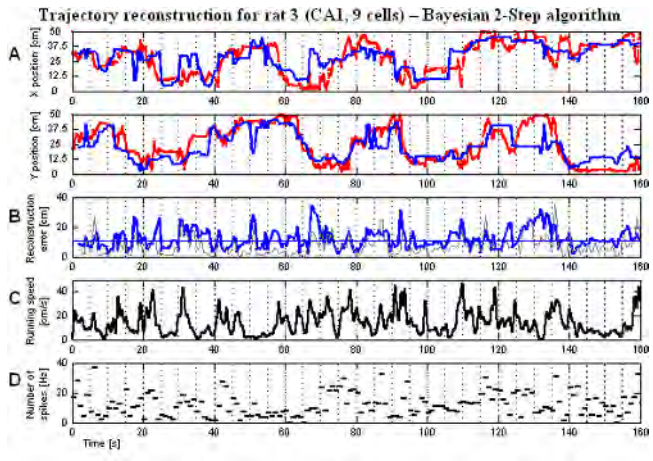

Figure 2: Reconstruction results for rat 3. A: Real (red) and reconstructed x- and y-positions. B: Reconstruction error (thick line), reconstruction error weighted by the instant place cell firing rate (thin line) and median error of the whole recording (horizontal line). C: Running speed. D: Firing rate of all neurons.

The two reconstruction algorithms were tested on all 6 rats by using a 3 x 3 fold cross-validation technique. Additionally, the Bayesian 2-step algorithm was trained and tested on 100 % of the data to test the theoretically achievable accuracy. In Figure 3 one example of CA1 cells and one example for subiculum cells are shown. Rat 3 reached a minimum error of 9.4 cm for a reconstruction window of 4 seconds using CA1 neurons. Rat 6 reached 26 cm with subicular units. For all rats the Bayesian 2-step (100 % training) version performed obviously best.

The horizontal dotted line at 5cm in each graph displays the intrinsic tracking error, which is defined as the average uncertainty in position tracking, due to the size of the diode (LED) arrays, the distance of the diodes above the rat's head and variations in posture [6].

IV. Discussion

The reconstruction algorithms for neural spike trains were implemented and applied to hippocampal place cell activity. The goal was to reconstruct the position of the rats just by investigating the spike activity as accurate as possible and therefore to minimize the reconstruction error. The best performance was found for the Bayesian 2-Step algorithm. The reason is that the algorithm considers also the previous position of the rat and does not allow large jumps from one reconstruction point to the next one. The Bayesian 1-Step algorithm performed less accurate but it is very interesting to see the results because it is only based on the current reconstruction window.

Despite subicular units tend to be more stable than CA1 cells, the results show that position reconstruction is more accurate with CA1 units. However, it is also interesting that subicular units contain enough information for the reconstruction. This can also be seen from the place field density plots, where the place fields of subicular units are much more blurred than place fields of CA1 units. Distinct place fields in combination with a high number of cells guarantee good reconstruction results. But it must be noted that only 2 data-sets from the subiculum and 4 data-sets from CA1 regions were investigated. The investigation of more data-sets is necessary to proof that.

Theoretically the reconstruction error is inversely proportional to the square root of the number of cells. This has been confirmed by the data analysis of all 6 rats as well as in other publications [5,7]. Interesting is that for 3 rats (1, 2, 3) the reconstruction error was below 20 cm with less than 10 place cells. Wilson [7] reported an error of 33 cm with 10 cells and Zhang [5] of 25 or 11 cm for 10 cells. This shows that with even a few cells the reconstruction can already be performed. But important is to consider the different arena sizes.

Erratic jumps occur also when the animal stops running. This has two reasons: (i) the firing rate is modulated by speed and therefore lower and (ii) the animal received food

rewards to move around in the arena and therefore the eating can produce artifacts in the neural data recorded. Zhang also suggests biological reasons for the erratic jumps like the rat is looking around or planning the next move. As already mentioned in the results section, minimizing the reconstruction to points where the firing rate is above a certain threshold only punctually yields to better reconstruction results. It does not reduce the overall error rate, because the positions that have not been reconstructed have to be interpolated. This estimation leads to reconstruction errors for the interpolated positions again, and increases the error rate.

Next steps in this research will include the investigation of grid cells as well as the realization of real-time reconstruction hardware and software setup.

Heart Rate Variability Response to Stressful Event in Healthy Subjects

Chih-Yuan Chuang, Wei-Ru Han and Shuenn-Tsong Young

Institute of Biomedical Engineering, National Yang-Ming University, Taipei, Taiwan

Abstract — **The purpose of this study was to investigate the autonomic nervous system function in healthy subject under stress event by analyzing heart rate variability (HRV). The participants were eight graduate students exposed to a cognitive stress task involving preparation for an oral presentation. Measurements of subjective tension, muscle bound level and electrocardiograms of 5 minutes were obtained at 30 minutes before oral presentation as pretest and at 30 minutes after oral presentation as posttest. R-R intervals of electrocardiogram were calculated, and the R-R intervals' tracks were analyzed using power spectral analysis to quantify the frequency domain properties of HRV. The results showed that subjective tension, muscle bound level and heart rate were significantly higher in pretest and normalized high frequency power of HRV was significantly lower in pretest, compared with posttest. These findings suggest that stress event will reduce cardiovascular parasympathetic nervous responsiveness and increase sympathetic nervous responsiveness and subjective tension. The normalized high frequency power of HRV can response the affective state under stress event. This psychophysiology measurement will be used for detect human affective state and stress management.**

Keywords — **Autonomic nervous system, Heart rate variability, Stress, Tension**

I. Introduction

Mental stress can cause psychosomatic and other types of disease. Quantitative evaluation of stress is very important for disease prevention and treatment.

Heart rate variability (HRV) is the variation in the time interval between heartbeats, from beat to beat. It is controlled by autonomic nervous system including the sympathetic nervous system (SNS) and the parasympathetic nervous system (PNS). Generally, the SNS activity increases heart rate and the PNS activity decreases heart rate [1]. Frequency-domain analysis of HRV can obtain the HRV spectrum which is a noninvasive tool for the evaluation of autonomic regulation of the heart. HRV spectrum can be categorized into high-frequency (HF 0.15-0.40Hz) and low-frequency (LF 0.04-0.15Hz) components. The HF component is equivalent to the respiratory sinus arrhythmia (RSA) and is generally assumed to represent parasympathetic control of heart. The LF component is jointly contributed by both sympathetic and parasympathetic nerves. The ratio LF/HF is considered to reflect sympathetic modulation.

A reduction of HRV has been associated with several cardiologic diseases, especially lethal arrhythmic complications after an acute myocardial infarction [2]. Therefore, HRV is often used as a predictor of disease risk [3]. A reduced HRV is also associated with psychosocial factors such as stress, anxiety, and panic disorder [4]. It is suggested as a good tool to estimate the strength of psychological effects [5].

Previous studies reported that the HF component of HRV significantly increased during relaxation training, and the cardiac parasympathetic tone also increased associating with relaxation response [6].

The purpose of this study was to investigate the autonomic nervous system function and subjective tension in healthy subject under stress event. We hypothesized those participants who are exposed to a cognitive stress task will demonstrate significant higher tension, higher muscle-bound level and lower arousal of parasympathetic nervous system compared to finish stress task.

II. Methods

A. Experimental Protocol

The participants were recruited from Institute of Biomedical Engineering, Nation Yang Ming University. Total of 8 healthy graduate students, aged 22-32 without symptoms or histories of cardiovascular or other diseases were recruited in this study. The participants were exposed to a cognitive stress task involving preparation for one-hour oral presentation. The presentations were related to participants' research topics.

Measurement of subjective tension, muscle-bound level and electrocardiogram (ECG) of 5 minutes were obtained at 30 minutes before oral presentation as pretest and at 30 minutes after oral presentation as posttest (Fig. 1). Instantaneous ECG recordings were taken for 5 min while each subject sat quietly and breathed normally.

ECG recordings were obtained by Biopac ECG-100C, digitalized using a 14-bit analog-to-digital converter (NI USB-6009, National Instruments) with a sampling rate of 1024 Hz, and stored on a personal computer for off-line analysis.

www.springerlink.com

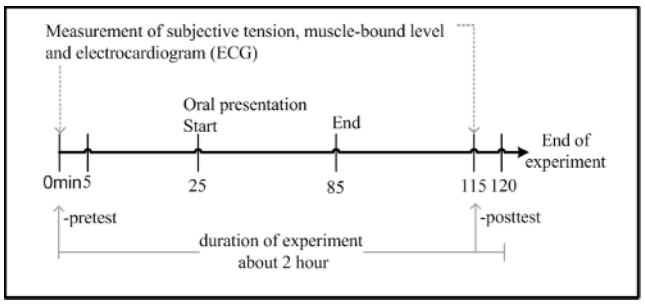

Fig. 1 Experiment procedure

Participants also rated their subjective tension and muscle-bound level on five-point scales which ranged from "very little"(1) to "very much"(5).

B. Data Analysis

The HRV analysis of ECG signals was performed with a standard procedure [3]. The R point of each valid QRS complex was defined as the time point of each heart beat, and the interval between two R points (R-R interval) was calaculated. Frequency-domain analysis of HRV was also performed using the nonparametric method of Fourier transform. For the ECG of 5 minutes, the R-R intervals were linearly interpolated to produce a continuous track by 3Hz resample rate, and the track was analyzed by Fourier transform with a hamming window to have the power sectrum of HRV. The HRV power spectrum was subsequently quantified into various frequency-domain indices as total power, LF (0.04-0.15 Hz) and HF (0.15-0.40 Hz) power, LF and HF in normalized units (LF%, HF %), and ratio of LF to HF (LF/HF).

Statistical data analysis was performed using software SPSS 15.0. Data were expressed as mean and standard error (SE). Comparisons of the HRV indices and subjective tension between pretest and posttest were performed with the Mann-Whitney U-test. Significant levels were assumed at $p<0.05$.

III. Results

The study data consisted of 8 male healthy graduate students. Each participant was evaluated within two times.

Quantitative measurements of HRV indices from the the 8 pariticipants showed that the pretest had significantly lower %HF power of HRV and significantly higher heart rate compared with the posttest ($P<0.05$)(Table 1). However, mean HF, LF, %LF power, total power and L/H ratio were no significant differ between pretest and posttest.

Table 1 Heart Rate and Heart Rate Variability indices

	Pretest (M±SE)	Posttest (M±SE)	p value
HR	96.38±6.49	80.96±5.04	0.011
HF(ms2)	267.62±154.73	215.04±69.69	0.483
LF(ms2)	874.15±296.56	649.18±239.30	0.262
%HF	20.51±4.45	31.34±6.66	0.035
%LF	84.40±4.10	73.15±7.0	0.068
LF/HF	6.21±1.70	4.37±1.51	0.262
TP	2589.96±1534.29	1307.83±350.46	0.888

Values are presented as means ± SE; HR: heart rate, LF: low-frequency power, HF: high-frequency power, LF/HF: ratio of LF to HF, and LF%: normalized LF in normalized units (nu) of heart rate variability; P values: vs. pretest by Mann-Whitney U-test.

The assessments of subjective tension were changed in the levels on the five-point scales (Table 2). The mean value of tension and muscle-bound level in pretest were significant higher than those in posttest ($p<0.05$).

Table 2 Subject assessment of tension, muscle-bound

	Pretest (M±SE)	Posttest (M±SE)	p *value*
Tension level	3.87±0.64	1.62±0.74	0.009
Muscle bound level	2.62±0.74	1.5±0.75	0.024

Values are presented as means ± SE; P values: vs. pretest by Mann-Whitney U-test.

IV. Discussion

In the present study, we reliably described the measurable changes in subjective tension in response to the preparation for an oral presentation. The tension and muscle-bound level were significant higher at preparation time compared with those at time after finishing the oral presentation.

The high frequency component of the HRV has been reported to reflect the activity of vagal parasympathetic nerve, and the LF/HF ratio to reflect the activity of sympathetic nervous system [7]. Mental stress will change the balance of the activities between sympathetic and parasympathetic nervous system. The present study found the LF and LF/HF

ratio were higher during pretest compared with posttest. Low frequency component reflected the activities of sympathetic nervous system, preparation for an oral presentation task might activate sympathetic nervous system. On the other hand, the preparation for an oral presentation task caused significant increase of heart rate and decrease of normalized high frequency power of HRV. These results regarding HRV support the findings of previous studies [8]. The high frequency component of HRV was reduced during stress tasks. Therefore, these results suggest that the mental stress task can decrease the parasympathetic nervous activity and the %HF power may be sensitive to stress elicitation and reduction.

In conclusion, the %HF power of HRV can response the affective state under stress event. This psychophysiology measurement will be used for detect human affective state and stress management.

Automatic Quantitative Analysis of Myocardial Perfusion MRI

C. Li and Y. Sun

Department of Electrical & Computer Engineering, National University of Singapore, Singapore

Abstract — **In this paper, we propose an automatic analysis method to facilitate the quantitative evaluation of myocardial perfusion MR images. We first extract the perfusion parameters from the intensity-time curve and combine them in a color image, in which myocardial ischemia is relatively easy to detect. Then we use the appropriate parameter maps to segment the myocardium by evolving level set functions. The experimental results show that the proposed method succeeds in extracting parameters and segmenting the myocardium.**

Keywords — **myocardial perfusion MRI, parameter map, level set, image segmentation, temporal information**

I. Introduction

Segmentation is an important step in MR image analysis. Due to the low contrast and complicated background in myocardial perfusion MR images, most of the popular segmentation techniques based on single frames either are not robust enough or require manual initialization.

Several methods incorporating temporal information into myocardium segmentation have been proposed. Stegmann et al. proposed a motion-compensation method using active appearance model with cluster analysis [1]. This method is learning-based and requires training sets provided by medical doctors. Spreeuwers et al. proposed a boundary correction method using perfusion information, assuming that a rough segmentation has been provided [2]. In [3], Adluru et al. use the temporal variance image to locate the heart, select reference frame, and initialize the segmentation. They then independently obtain the myocardium masks in several frames adjacent to the reference frame and threshold the sum of these masks to generate the myocardium boundary. Although better than using one frame for segmentation, this method relies too much on the image quality of the chosen frames. Recently, Schöllhuber classifies the myocardium and the background according to the intensity-time curve and then converts the segmentation problem into a shortest path problem [4]. Because the classifier does not consider any spatial information, the myocardial boundaries are often not smooth and hence need refinement.

Here we propose a method that first extracts the perfusion parameters and then automatically segments the myocardium using the parameter maps. The final results can be shown in a color image that combines the extracted perfusion parameters as well as the myocardium mask.

The rest of this paper is organized as follows: In section II, we introduce the temporal characteristics of myocardial perfusion MRI. Our method for parameter extraction is described in section III. Section IV presents the experimental results, and we conclude the paper with section V.

II. Background

First-pass myocardial perfusion MR images are scanned immediately after the injection of a contrast agent. Fig.1 displays four representative frames of a typical first-pass myocardial perfusion sequence, while Fig.2 plots the intensity-time curves of pixels from different tissues. As can be seen, the intensity of the right ventricle (RV) increases due to the wash-in of the contrast agent, followed by the left ventricle (LV), and then the myocardium. In contrast, the intensity-time curve of the background is like noise during the entire perfusion period.

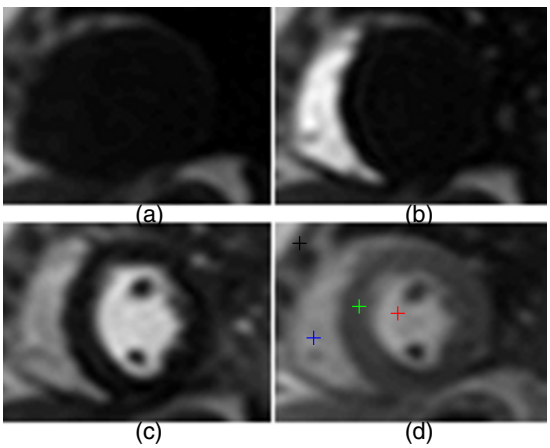

Fig. 1 Myocardial perfusion MR images: (a) the 5th frame, (b) the 15th frame, (c) the 20th frame, (d) the 40th frame

The intensities of pixels from the same tissue usually vary in a similar way, i.e., they follow the same intensity-time curve model. Such a model can be characterized by several perfusion parameters such as *maximum upslope*, *peak*, and *absolute time to peak* (refer to III-*B* for defini-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 381–385, 2009
www.springerlink.com

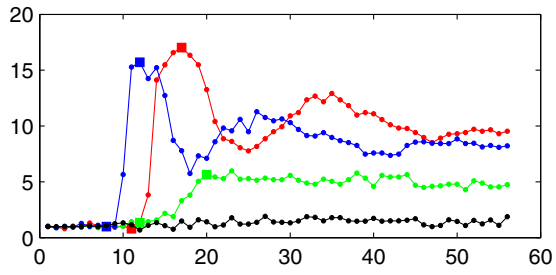

Fig. 2 Intensity-time curves of RV (blue), LV (red), myocardium (green), and background (black). The positions of these pixels are shown in Fig. 1 in corresponding colors

tions), etc. It is reasonable to use these distinctive parameters for myocardium segmentation.

III. Methodolagy

Our method consists of three steps. First, an image registration algorithm is used to compensate for patient motion. Second, we calculate perfusion parameters including *maximum upslope*, *peak*, and *absolute time to peak,* based on the intensity-time curve of each pixel; a combination of these parameters is displayed in a color parameter map for visualization. Finally, automatic detection of the myocardial boundaries is achieved by applying a region based level set method with shape priors using appropriate parameter maps.

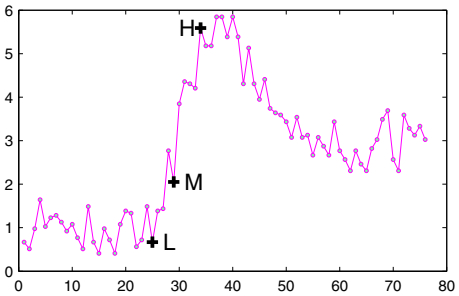

Fig. 3 Intensity-time curve of a myocardium pixel

A. Registration

Before applying registration, a reference frame is automatically selected and the LV mask is detected. To achieve this, we first find a range of frames with good contrast by assessing temporal intensity variation. For each selected frame, a binary image is obtained by thresholding. Then we remove small connected components, and look among remaining components for the one being least eccentric, most circular, and most convex. The winner corresponds to the LV mask, and its frame number is the reference frame number. We then apply a rigid registration algorithm to register the time series to the reference frame [5].

B. Parameter extraction

Fig.3 shows the intensity-time curve of a myocardium pixel. When calculating the *maximum upslope*, *absolute time to peak*, and *peak*, it is crucial to determine the start instant and the end instant of the wash-in phase. Due to the image noise and the limitations of motion compensation, the local gradient during the wash-in phase is not always positive, and the intensity at the end of the wash-in phase is not always the global maximum. These issues make the parameter extraction step more challenging.

For each intensity-time curve, we first normalize it with respect to the average intensity of the first four frames. Then we generate a smooth curve by applying a moving average filter in the time domain. After that, we estimate the center M and the average local gradient Δh of the wash-in phase, using the smoothed curve.

Let L and H denote frame indices of the start and the end of the wash-in phase, respectively. Let N denote the total number of frames, and let $I(n)$ denote the pixel intensity in the n^{th} frame. Then H is defined as the smallest frame number n that satisfies the following conditions.

$$\begin{cases} M < n < N-2 \\ I(n) > I(n+1) \\ I(k) < I(n) + (k-n) \times \Delta h,\ k = n+2, n+3, \ldots, N \end{cases} \quad (1)$$

Similarly, L is defined as the largest frame number n that satisfies:

$$\begin{cases} 2 < n < M \\ I(n) < I(n-1) \\ I(k) > I(n) - (n-k) \times \Delta h,\ k = 1,2,\ldots,n-2 \end{cases} \quad (2)$$

Next we use a small window sliding from L to H to calculate the local upslope, and select the maximum of them to be the *maximum upslope*; the *peak* is calculated by $I(H) - I(L)$; and the *absolute time to peak* is given by H.

By using each parameter as one color channel, an RGB color map is generated. All the parameters are normalized for better contrast. To prevent the background from dominating the normalization, in the final results, we only show the parameter map of the myocardium for visualization.

C. Myocardium segmentation

To segment the myocardium of the LV, we need to detect two boundaries: the endocardial boundary between the myocardium and the LV blood pool, and the epicardial boundary between the myocardium and the background. In our method, we first segment the endocardium and then segment the epicardium based on the segmentation results of the endocardium.

As shown in Fig.2, the intensity of the LV blood pool increases faster than that of the myocardium during the wash-in of the contrast agent. In addition, the *maximum upslope* is less sensitive to the choices of L and H than the other two parameters. Therefore, we use the *maximum upslope* map (see Fig.5 (a)) to segment the endocardium.

The epicardium is more difficult to segment than the endocardium due to the complicated background. In the *maximum upslope* map shown in Fig.5 (a), the RV is brighter than the myocardium while many other areas of the background are darker than the myocardium. This makes it hard to estimate the intensity distribution model of pixels outside the epicardium. The *peak* map also has similar problem since the *peak* of the RV is larger than that of the myocardium (see Fig.2). As shown in Fig.5 (b), the intensities of the RV and the background are similar in the *absolute time to peak* map. Therefore, we chose to use the *absolute time to peak* map for epicardium segmentation.

The energy functional is defined as:

$$E = \lambda_1 E_{region} + \lambda_2 E_{shape} + \lambda_3 E_{length} + \lambda_4 E_{penalizing}, \quad (3)$$

where λ_1, λ_2, λ_3, and λ_4 are constant parameters balancing different energy terms.

Assuming that the intensities of the background and the foreground follow Gaussian distributions, we use the stochastic region model [6] for E_{region}. In each iteration, we fix the contour and estimate the Gaussian intensity models for the inside and outside of the contour, respectively, as $M_i\left(\overline{I_i}, \sigma_i\right)$ and $M_o\left(\overline{I_o}, \sigma_o\right)$. The region term is given by

$$E_{region} = \iint_{in(c)} \left(-\ln M_i\right) dxdy + \iint_{out(c)} \left(-\ln M_o\right) dxdy .$$

Based on the assumption that the shape of myocardium is close to an ellipse, we use the shape prior term E_{shape} to incorporate such prior knowledge [6, 7], and define the shape energy term as

$$E_{shape} = \iint D^p \delta_x \left|\nabla \phi(x, y)\right| dxdy ,$$

where D is the normalized distance to the estimated ellipse.

When estimating the ellipse, we first generate the convex hull of the contour, and then calculate the distance d of each point on the contour to the convex hull. According to this distance, we assign a weight of $w = \exp\left(-d^2/2\right)$ to each point, such that the points close to the papillary muscles contribute less in estimating the ellipse. Finally we estimate the ellipse using weighted least square fitting [8].

Fig.4 shows the estimated ellipse and the force vectors at five contour points for endocardium segmentation. In order to keep the LV cavity pixels inside the evolving contour, we set $D=0$ for pixels outside the estimated ellipse. As a result, the black arrows in Fig. 4 will not take effect.

For endocardium segmentation, we set $p=4$ for less penalty on the pixels near the estimated ellipse, thus maintaining the shape of the LV. For epicardium segmentation, we set $p=2$, and penalize both sides of the estimated ellipse to make the boundary resemble an ellipse.

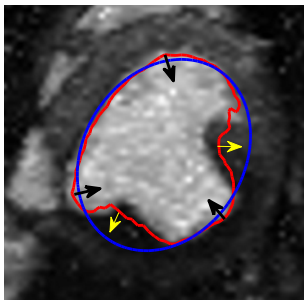

Fig. 4 Ellipse fitting: The red curve is the current contour; the blue curve is the estimated ellipse; and the arrows indicate the force vectors resulting from the shape term at five selected points on the contour

E_{length} in (3) controls the smoothness of the contour:

$$E_{length} = \iint \delta_x \left|\nabla \phi(x, y)\right| dxdy .$$

The penalizing term $E_{penalizing}$ in (3) helps avoid re-initialization [9] and is defined as

$$E_{penalizing} = \iint \frac{1}{2}\left(\left|\nabla \phi\right| - 1\right)^2 dxdy .$$

We use the LV mask in III-*A* as the initial contour for endocardium segmentation. After the energy functional converges, we expand the resulting endocardial contour outwards by 5 pixels to obtain the initial contour for epicardium segmentation.

IV. Results

We tested the proposed method on two animal data sets and four patient data sets. The automatic quantitative analysis tool succeeds in generating the parameter maps and automatically segmenting the myocardium.

Fig.5 (a)-(c) show the *maximum upslope* map, the *absolute time to peak* map, and the segmentation results of one animal data set. As shown, although the myocardial boundaries, especially the epicardial boundary, are not clear in the reference frame, these two boundaries are easy to detect in the *maximum upslope* map and the *absolute time to peak* map, respectively. Segmentation results of one animal data set and 3 patient data sets are shown in Fig.6, demonstrating the effectiveness and accuracy of the proposed method.

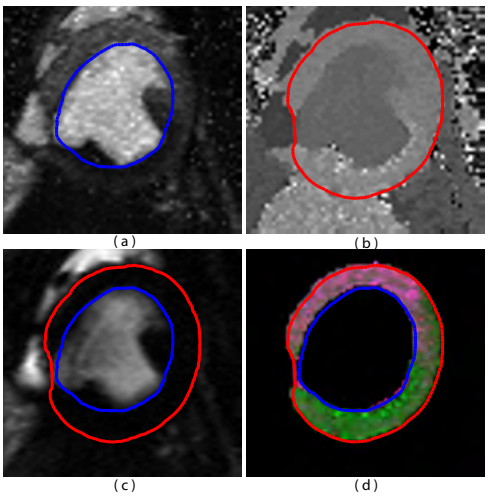

Fig. 5 Segmentation results and parameter maps: (a) the *maximum upslope* map, (b) the *absolute time to peak* map, (c) the reference frame with segmentation results overlaid, and (d) the final color parameter map

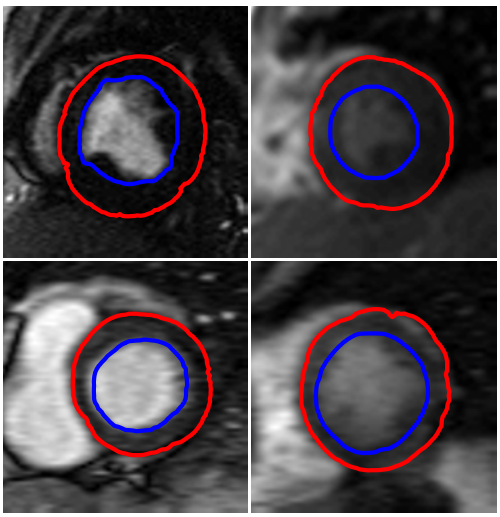

Fig. 6 Segmentation results of one animal and three patient data sets

Ischemic myocardium usually demonstrates delayed wash-in and lack of increase in intensity, which results in larger *absolute time to peak* and smaller *maximum upslope*. Fig.5 (d) shows the color parameter map of an animal data set, in which a bright green area in the LV free wall indicates a myocardial perfusion defect (ischemia).

V. Conclusions

In this paper, we presented an automatic quantitative analysis tool for first-pass myocardial perfusion MRI. By combining distinct perfusion parameters including *maximum upslope, peak* and *absolute time to peak* that are extracted from the intensity-time curves, in a single color map, the ischemic tissues can be easily identified. By using the appropriate corresponding parameter map for segmenting the endo and epicardium, the myocardial boundaries can be detected using a level set based method with an elliptical shape prior. Our experimental results with real patient data sets show that the proposed method can successfully generate parameter maps and segment the myocardium.

Visualization of Articular Cartilage Using Magnetic Resonance Imaging Data

C.L. Poh[1] and K. Sheah[2]

[1] Nanyang Technological University/Division of Bioengineering, Singapore
[2] Singapore General Hospital/Department of Diagnostic Radiology, Singapore

Abstract — **Osteoarthritis (OA) is a common disease, with the majority of people over 65 showing radiographic evidence of the disease. To carry out effective diagnosis and treatment, it is necessary to understand the progression of cartilage loss and to study the effectiveness of therapeutic interventions. Hence, it is important to have accurate and fast diagnosis of the disease. Magnetic Resonance Imaging (MRI) is the most widely used non-invasive tool to assess intra articular soft tissues, and cartilage in particular. MRI allows detailed, multi-planar analysis of the joint anatomy, as well as cartilage and underlying bone, with the ability to view articular surfaces at any angle. In addition to anatomical information, MR $T_{1\rho}/T_2$ mapping are potentially useful parameters in detecting early biochemical and biophysical changes in the articular cartilage. However, the presence of both anatomical and $T_{1\rho}/T_2$ mapping data results in a large amount of multi-dimensional dataset. Consequently, clinicians have to study more data, which is a time consuming process. New visualization techniques are required to aid clinicians to visualize the large amount of data. In this paper, we present a visualization interface to study articular cartilage using MR data. This interface allows studying of OA using both anatomical images and T_2 mapping data. The interface includes semi-automatic segmentation of cartilage using localized thresholding; and visualization of the averaged T_2 mapping data at various regions of the cartilage in 2D/3D using a radii search method. Our results suggest that the visualization technique allows clinicians to study both anatomical images and T_2 mapping data in a more efficient manner.**

I. Introduction

Many adults suffer from Osteoarthritis (OA), with the majority of people over 65 showing radiographic evidence of the disease [1]. To carry out effective diagnosis and treatment, it is necessary to understand the progression of cartilage loss and to study the effectiveness of therapeutic interventions. Hence, it is important to have accurate and fast diagnosis of OA. In this context, the use of Magnetic Resonance Imaging (MRI) has gained significant support. MRI allows detailed, multi-planar analysis of the joint anatomy, as well as cartilage and underlying bone status, with the ability to view articular surfaces at any angle. MRI is becoming the recognized imaging method for accurate visualization of cartilage morphology and thickness depiction.

Early detection of cartilage disorder is important to predict the progression of OA, and to determine the appropriate timing for treatment. MR images have been used to provide high-resolution anatomical information to detect degenerated cartilage [2]. However, using MR anatomical images alone is unlikely to show early degeneration of cartilage [3]. In addition to anatomical information, $T_{1\rho}/T_2$ mapping are potential parameters in detecting early biochemical and biophysical changes in the articular cartilage [4-6]. $T_{1\rho}/T_2$ mapping could provide the functional information of the articular cartilage. Loss of proteoglycans in the extracellular matrix (ECM) is an initiating event in early OA [4-5]. Previous studies indicate that T_2 of articular cartilage is only sensitive to the collagen content in the ECM and T_2 is less sensitive to loss of proteoglycans [4-5]. On the other hand, $T_{1\rho}$ relaxation time is sensitive to changes in the proteoglycans content of cartilage and $T_{1\rho}$ decreases linearly with changes in the proteoglycans content of cartilage [4]. T_2 mapping has been shown to have the potential in detecting localized degeneration of cartilage [6]. It has been shown that aging is associated with an asymptomatic increase in T_2 of the transitional zone of articular cartilage [6].

The presence of both anatomical and $T_{1\rho}/T_2$ mapping data results in large amount of multi-dimensional dataset. Consequently, clinicians have to study more data to make a diagnosis, which increases the time needed. Hence, new visualization techniques are required to aid clinicians to study the large amount of data.

In this paper we present a visualization interface to study articular cartilage using MR data. This interface allows studying of the OA disease using both anatomical images and T_2 mapping data. The interface developed in this paper includes (i) semi-automatic segmentation of cartilage using localized thresholding, and (ii) visualization of the averaged T_2 mapping data at various regions of the cartilage in 2D/3D using a radii search method. To demonstrate the interface, 3T MR knee datasets (i.e. T_2 weighted images and T_2 mapping data) of patients with varying degree of OA were studied.

II. Methods

Fig. 1 shows the schema of the software interface. Referring to the figure, both anatomical and functional images are read by the program. Once all the images are input into the program, the user will first perform segmentation. This can be carried out manually or semi-automatically. For manual segmentation, the user will click a number of points along the boundary of the cartilage. The points will then be connected using a B-Spline function to form the boundary of the cartilage. For semi-automatic segmentation, the user will define a Region of Interest (RoI) to first localize the cartilage. A semi-automatic segmentation program [7] is then used to delineate the cartilage using the anatomical images. The semi-automatic segmentation program uses a radii search technique which based on a threshold method to identify the boundaries of the cartilage. Using the cartilage delineated by the segmentation program, an image mask is produced. The mask is used to delineate the T_2 mapping data of cartilage. The T_2 mapping data of the cartilage is color coded to show the variation of the T_2 values.

It is important to visualize the T_2 values so that the clinician can easily identify abnormality. It has been shown that the T_2 values vary along the cartilage in the direction from the subcondral bone towards the surface of the cartilage [6]. T_2 values at the surface of the cartilage tend to be higher than the T_2 values at the interface of the cartilage and subcondral bone [6].

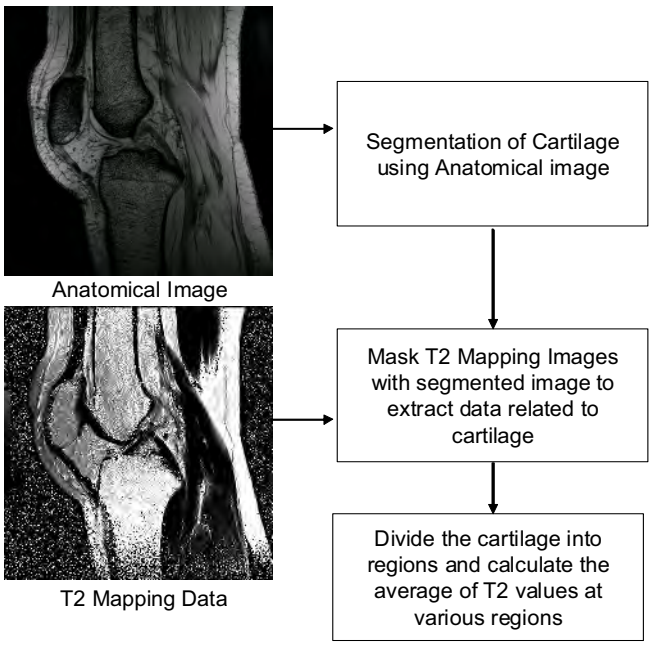

Fig. 1. Schema of the visualization software interface.

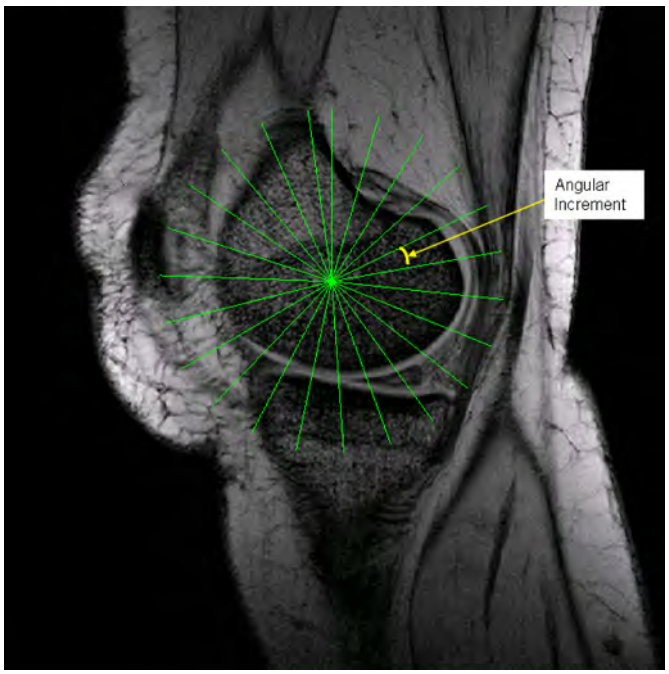

Fig. 2. Dividing cartilage into different regions.

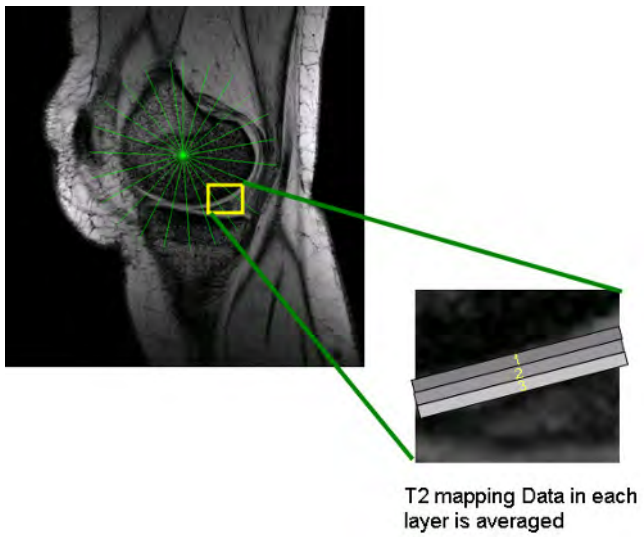

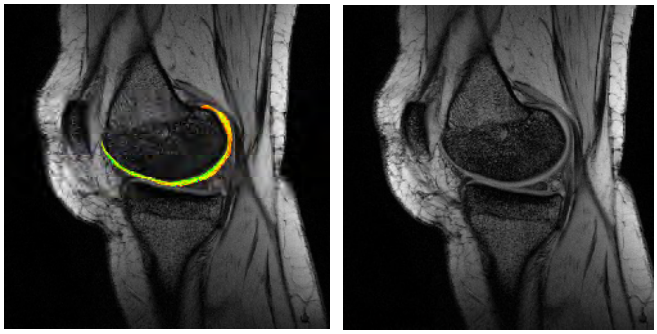

Fig. 3. Dividing each cartilage region into 3 layers.

Average $T_{1\rho}$ and T_2 values can be quantified from several pixels of the selected Regions of interest or from every pixel of different layers. In our approach, the cartilage is first divided into regions based on a radii division (refer to Fig. 2). Based on pre-defined angular increment, the regions are

(a) (b)

Fig. 4. (a) Color coded T2 mapping data of the femoral cartilage overlapped with the corresponding anatomical image. (b) Using the Toggling function, the T2 mapping data can be removed so that the structural details of the cartilage can be studied.

divided. The value of the angular increment will determine the number of regions that will be obtained (i.e. a small angular increment will divide the cartilage into more regions). Once the cartilage is divided into regions, the cartilage within each region is divided into 3 layers (see Fig. 3). Dividing cartilage into superficial, mid and deeper layers is required due to topographic variation in cartilage orientation. In particular, the superficial layer of cartilage has been shown to be easily separable from the underlying cartilage [8]. Cartilage repair techniques vary according to the width and depth of cartilage defect seen on arthroscopy. Hence, this technique allows surveillance and follow-up of cartilage defects and repair over time. The average of the T_2 values in each layer at different sampling points is calculated and plotted in a 2D/3D contour plot.

In this technique, we assume that the thickness of different cartilage layers is uniform, while it is known that the laminar architecture of cartilage varies depending on the type and location of the joint. However, the parameter being measured is the rate of change of cartilage T_2 properties over time. Hence, a consistently reproducible and robust method of cartilage segmentation is clinically adequate. Depiction of microscopic transition points between the cartilage layers is currently beyond the resolution of clinical scanners (given limitations of imaging time).

A. Toggling

Toggling of images is considered by radiologists as an important functionality when viewing both anatomical and functional images. Consequently, a toggling function is developed. The anatomical images are used as the base and the color coded $T_{1\rho}/T_2$ images are overlay onto the anatomical images. Only the regions of the cartilage of the $T_{1\rho}/T_2$ images that have been segmented are overlay onto the corresponding anatomical images. This toggling function is controlled using a radio button.

III. Results

To demonstrate the interface, two sets of MR images are used. Each set of MR data comprises anatomical and T_2 mapping data. One set of the data is a normal knee whereas the other set of data is a knee showing thinning cartilage. The interface developed was used to visualize the two sets of MR data.

Fig. 4 shows an example result of the toggling between the anatomical image and T_2 mapping data. Using the interface, it is possible to view both anatomical and T_2 mapping data interactively. This function was performed by clicking a radio button. As a result, it is possible to view the details of the cartilage and surrounding tissues using the high resolution anatomical image and studying the functional information of the cartilage using the T_2 data, as opposed to viewing two images (anatomical and T_2 mapping) separately.

Fig. 5 shows an example plot of the calculated T_2 mapping values from one image slice of a normal knee and a knee with thinning articular cartilage. Referring to the figure, the contour shows the variation in the T_2 values at different regions of the cartilage. The vertical axis of the plot is the three different layers of the cartilage (from the subcondral bone to the surface of the cartilage) and the horizontal axis is the different regions along the cartilage. The plots show that the overall T_2 values of the knee with thinning cartilage are larger as compared to the T_2 values of the normal knee. The plots also show that the thinning cartilage has more variation in the T_2 data. The 3D contour plot enables the user to visualize the change in the T_2 values. Using the 3D contour plot, the user is able to rotate and to enlarge the plot while studying the data. These plots were generated automatically once the segmentation was performed. The trend of the cartilage T_2 values were visualized in the plots.

IV. Discussions

Using the visualization interface, it is possible to visualize both anatomical and functional images in a more efficient manner. The interface enables the clinician to delineate the cartilage and focus on the study of the T_2 values of the cartilage. The segmentation method allows faster segmentation of the cartilage to be carried out interactively. This enables more images to be studied in a shorter time. The plotting of T_2 values using the contour plot enables the clinician to study the change in T_2 values throughout the whole cartilage.

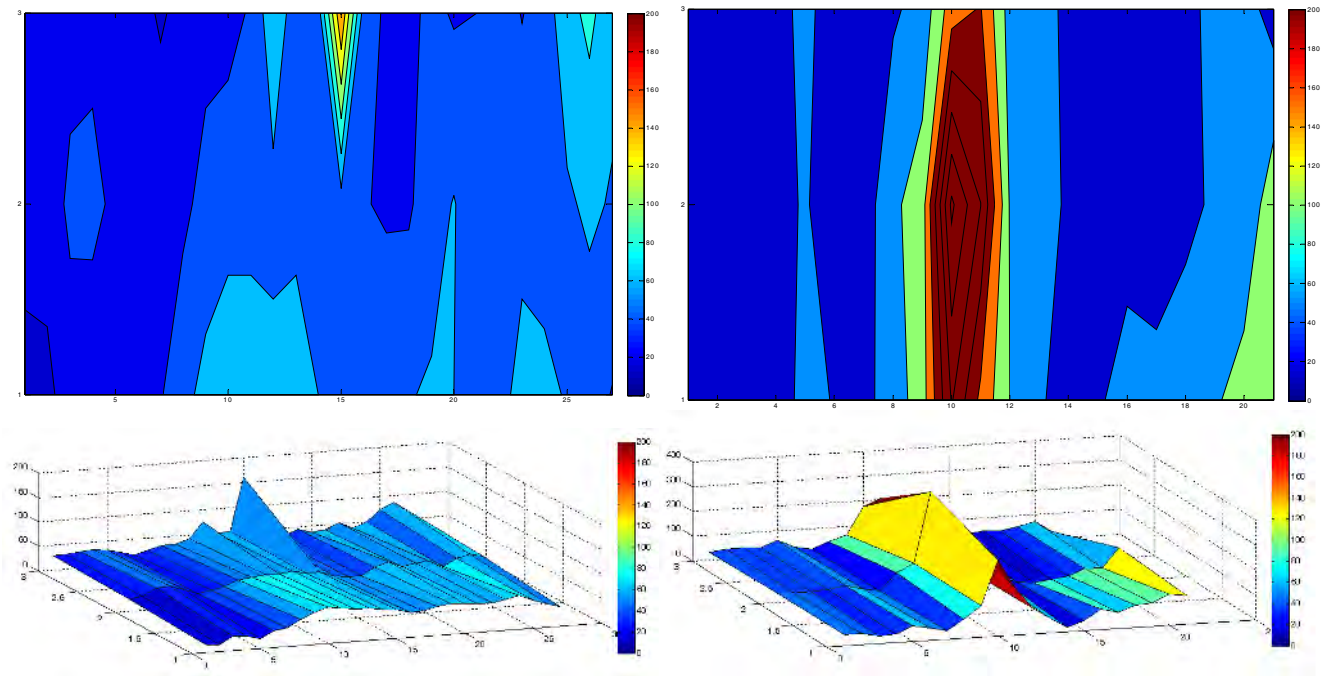

Fig. 5. Contour plots of T_2 mapping data for one image slice of cartilage. (i) Left - from a normal knee. (ii) Right – from a knee showing thinning cartilage.

Combining the anatomical and functional information may enhance our ability to detect early cartilage degeneration, and to distinguish between different stages of degeneration. Future work includes using the interface to perform longitudinal clinical studies of the T_2 and $T_{1\rho}$ mapping to further understand the characteristics of the changes in T_2 and $T_{1\rho}$ at the different stages of OA.

A Chaotic Detection Method for Steady-State Visual Evoked Potentials

X.Q. Li and Z.D. Deng*

State Key Laboratory of Intelligent Technology and Systems
Tsinghua National Laboratory for Information Science and Technology
Department of Computer Science, Tsinghua University, Beijing 100084, China

Abstract — **This paper investigates the application of chaotic detection theory to brain-computer interfaces (BCI) technology. We present a chaotic oscillator array (COA)-based method using the steady-state visual evoked potential (SSVEP) paradigm. The presented chaotic oscillator array model is used for electroencephalogram (EEG) signal feature extraction, which works based on the phase transition characteristics of the chaotic oscillator. The dynamic characteristics of Duffing system and the corresponding bifurcation process are discussed in detail. We define a quantitative measure to characterize the response in dynamic behaviors of COA considering the trajectory divergence degree in phase space. The learning vector quantization networks (LVQ) is viewed as classification model in our method. Different response patterns of COA can be clustered and mapped with predefined BCI commands through a well-trained LVQ model. The experimental results show the feasibility of the proposed method.**

Keywords — **Chaotic detection, Learning Vector Quantization Networks (LVQ), Brain-computer interface (BCI), electroencephalogram (EEG).**

I. Introduction

Brain-computer interface (BCI) is the system that uses brain activity to control external devices such as robots, computers, switches, wheelchairs, or neuroprosthetic extensions [1]. It provides a new approach to restoring communication and control to people with severe motor disorders. In recent years, BCI researches based on noninvasive scalp electrencephalography (EEG) have become an active research area. Event-related potentials, mu and beta rhythms, event-related synchronization and desynchronization, slow cortical potentials, and visual evoked potentials (VEPs) are commonly used signals in EEG-based BCIs [2]. Among which, the VEP-based BCI has the advantages of requiring less training and having less influence from individual difference and is receiving increasing research interest.

The spectrum method is extensively adopted in SSVEP-based BCI research and it obtains remarkable achievement [1-3]. However, the uncertainty principle in signal processing field places intrinsic limitation in further improvement of information transfer rate (ITR) through spectrum method. To be more concrete, the frequency resolution of a time domain limited signal can only reach the level of the reciprocal of the length of the signal segment. That is to say the high frequency resolution and short signal length can't be realized simultaneously. Because of this, a tradeoff must be taken between response speed and the number of selections in a single trial. This problem emerges as one of the obstacles hindering further improvement of the ITR of current SSVEP-based BCIs.

Chaotic detection theory is a newly developed method for weak signal detection [4]. It detects the changes of a weak signal by identifying the transformation of the phase state of chaotic oscillator from chaotic to large-scale periodic when the weak external signal is applied [5]. In this paper, we present a new framework for SSVEP-based BCI research based on chaotic detection. The proposed method can reach a much more high frequency resolution with required time resolution than traditional spectrum method, and thus provides a promising solution for designing a new SSVEP-base BCI system of high ITR.

The rest of this paper is organized as follows. First, the Duffing chaotic oscillator is introduced and the fundamental principle of chaotic detection is discussed. Then in section III, a chaotic oscillators array (COA) model is constructed for EEG feature extraction and the quantitative term of TDI for measuring the response in dynamic behavior of COA is given. Also a LVQ model is introduced and employed as classifier. Furthermore, the experimental results are given in section 4. Finally, we draw conclusions.

II. Fundamental principle

Chaos describes the complex behaviors of a nonlinear deterministic systems abound in our life. Chaotic oscillator acts as a chaotic attractor and has the characteristic of the sensitivity of to its parameters. Based on this property, chaotic oscillator detection has developed to a useful weak signal detection theory and been extensively studied in the past few years [4-6].

The Duffing equation is one of the classic non-linear system and is chosen for modeling chaotic oscillator in our study, which can be formulated as,

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 390–394, 2009
www.springerlink.com

$$\frac{1}{\omega^2}\ddot{x}_\tau(\tau)+\frac{f}{\omega}\dot{x}_\tau(\tau)-x_\tau(\tau)+x^3{}_\tau(\tau)=\gamma\cos(\omega\tau) \quad (1)$$

where $\gamma\cos(\omega t)$ denotes the periodic driving force, f the damping ratio, and $-x+x^3$ the nonlinear recovery force.

The state equations are given by

$$\begin{aligned}\dot{x}&=\omega y\\ \dot{y}&=\omega[-fy+x-x^3+\gamma\cos(\omega\tau)]\end{aligned} \quad (2)$$

To study the dynamic behaviors of (2), we fix $f=0.5$ and let γ increase gradually starting from 0. As γ is small, for example, $\gamma=0.25$, the phase trajectories form an attractor in the meaning of Poincaré map. They perform periodic oscillation around one of the two focus points. When γ increases above a certain threshold γ_b, periodic-doubling bifurcations appear and the system gets into chaotic state. This transition happens rapidly and the system will continues to keep chaotic state within a large scope of γ until reach another threshold γ_c. Here a very short intermittent chaotic state happens and then the system goes fast into the large-scale periodic state. The thresholds γ_b and γ_c can be determined using the Melnikov method in combination with tests [7].

To detect weak signals buried in noise, we introduce the mixed signal *Input* to chaos oscillator as illustrated in (3),

$$\begin{aligned}\dot{x}&=\omega_0 y\\ \dot{y}&=\omega_0[-fy+x-x^3+\gamma_c\cos(\omega_0\tau)+Input]\end{aligned} \quad (3)$$

where

$$\begin{aligned}Input&=s(\tau)+N(\tau)\\ &=a\cos((\omega_0+\Delta\omega)\tau+\varphi)+N(\tau)\end{aligned}$$

ω_0 is the driving frequency (or reference frequency). $\Delta\omega$ the frequency difference. φ the primary phase difference. $N(\tau)$ the noise.

Now we can see that the total periodic force of the Duffing oscillator is

$$\begin{aligned}A(\tau)&=\gamma_c\cos(\omega_0\tau)+a\cos((\omega_0+\Delta\omega)\tau+\varphi)\\ &=\gamma(\tau)\cos(\omega_0\tau+\theta(\tau))\end{aligned}$$

where

$$\gamma(\tau)=\sqrt{\gamma_c{}^2+2\gamma_c a\cos(\Delta\omega\tau+\varphi)+a^2} \quad (4)$$

$$\theta(\tau)=\arctan\frac{a\sin(\Delta\omega\tau+\varphi)}{\gamma_c+a\cos(\Delta\omega\tau+\varphi)} \quad (5)$$

From (4) we can see that if $\Delta\omega=0$,i.e. $\omega=\omega_0$, only the phase difference can affect the system state. If $\pi-\arccos(a/2\gamma_c)\le\varphi\le\pi+\arccos(a/2\gamma_c)$, $\gamma\le\gamma_c$, the system remains in chaotic motion. Otherwise the state of chaotic oscillator will be changed into periodic state.

If $\Delta\omega$ exits, $\gamma(\tau)$ will be periodically less than or more than the critical value γ_c within the scope between γ_c-a and γ_c+a, the cycle time T_Δ is $2\pi/\Delta\omega$. As $\gamma(\tau)$ approaches γ_c-a, the oscillator is in chaotic motion. The system changes to periodic state as $\gamma(\tau)$ approaches γ_c+a. This is why the intermittent chaotic phenomenon takes place [8]. It has been pointed out in [5] that when $|\Delta\omega/\omega_0|\le 0.03$, the regular intermittent chaos state can be easily identified and the theoretical value of $T_\Delta(2\pi/\Delta\omega)$ accurately coincides with the experimental results. Otherwise the regular intermittent chaos is difficult to maintain and the state of chaotic oscillator remains in chaos state.

From the analysis above, we can see that a single Duffing oscillator is only sensitive to signals, the frequency of which is very close to the oscillator's driving frequency. In another word, a specific oscillator is only responsible for detection of a very narrow frequency extent. The immunity of chaotic oscillator to other components, including noise and frequency components with frequency difference $|\Delta\omega/\omega_0|>0.03$, has been testified in [4].

III. Method

A. Feature Extractions

In this study, a chaotic oscillators array (COA) based EEG feature extraction model is proposed. It works based on a chaotic oscillators array composed of R chaotic oscillators. The driving frequencies of each member are tuned corresponding to the frequencies of each stimulus in the SSVEP experimental environment. When the subject is asked to gaze at one of the flash stimuli encoding a specific command, a trigger is given and the recorded sampling EEG signals by scalp electrodes are provided with the chaotic oscillators array and feed into all the R chaotic oscillators in parallel.

As can be seen from (4) and (5), if $\Delta\omega = 0$, the phase difference plays an important role in the system state. Only when φ fall into an appropriate range of $\varphi < \pi - \arccos(a/2\gamma_c)$ or $\varphi > \pi + \arccos(a/2\gamma_c)$, the expected phase transition can be guaranteed. So in our COA-based feature extraction method, the phase difference is fixed at $\varphi = 0$ by a proper phase shift $\Delta\varphi$ at the start of feeding of EEG signal. Now (4) is changed to $\gamma(\tau) = \sqrt{\gamma_c^2 + 2\gamma_c a\cos(\Delta\omega\tau) + a^2}$, and each chaotic oscillator in COA will response to a narrow band of frequencies centered in it's driving frequency.

According to the basic principle of an SSVEP-based BCI, large areas of the visual cortex are allocated to process the center of our visual field, so the amplitude of SSVEP increases enormously as the stimulus is moved closer to the central visual field. Different SSVEP can be produced by directly looking at one of a number of frequency coded stimuli [2].

When a stimulus target is selected by subject through changing his/her gaze direction, the SSVEP of the related frequency is induced and the corresponding member of COA will be activated once the condition $\gamma \le \gamma_c$ is satisfied. This motivates the phase state of this chaotic oscillator to be transformed from the chaotic state to the large-scale periodic state while the other members of COA remain in chaotic state. Thus the user intent can be identified.

All BCI research programs share the same goal of rapid and accurate communication. Unfortunately, a limitation in frequency resolution handicaps the further improvement of ITR through traditional spectrum method. For instance, if the frequency band of 1~10Hz is used and the sliding window is 2s, the frequency resolution can reach 0.5Hz using the short-time Fourier transform analysis method, and thus only 20 frequencies can be used to configure the flash buttons in SSVEP-based BCI research.

In this COA-based feature extraction method, the driving frequencies of the member of the chaotic oscillator array can be arranged based on the frequency selectivity condition of $|\Delta\omega/\omega_0| \le 0.03$ as discussed above. For a working frequency band of 1~10Hz, an equal-ratio array can be used for driving frequencies arrangement. i.e.

$$\omega_1 = 1, \omega_2 = 1.06, \cdots, \omega_k = 1.06\omega_{k-1}, \cdots, \omega_K = 10.286$$
$$(K = 41)$$

Up to 41 frequencies can be used in the COA-based method to configure the splash stimuli given the sliding window length of 2s. Thus more selections can be provided by the COA-based feature extraction method than traditional spectrum method with the same time resolution.

B. Trajectory Divergence Degree Measure

In our SSVEP-based BCI scheme, the responses in phase state of each member of COA are characterized through a quantitative measure to produce a feature vector for further classification. In this section, we define a descriptive term named trajectory divergence index (TDI) to characterize, in phase map, the dynamic behavior of the chaotic oscillator. It calculates the average distance of initially adjacent trajectories after certain steps of evolvement.

Let $Y_i = (y_i(1), \cdots y_i(m)) \in R^m, (i = 1, 2, \cdots, N)$ be the points in m-dimension phase space and the trajectory of the chaotic oscillator is formed by joining the points $\{Y_1, Y_2, \cdots, Y_N\}$ up continuously. For each point Y_i, we can find its nearest neighbor $Y_{\hat{i}}$ as follows,

$$\hat{i} = \{j \mid \min_j \|Y_i - Y_j\|, |i - j| > P, j \in (1, 2, \cdots, N)\}$$

where $\|Y_i - Y_j\| = \sum_{k=1}^{m} |y_i(k) - y_j(k)|$ and P is used to eliminate the false nearest neighbor that located continuously in the same trajectory segment. The calculation of P is the same as the average period in the estimating of Lyapunov index [9].

Then the trajectory divergence index of the dynamic behavior of a chaotic oscillator in certain phase state can be calculated as

$$TDI = \frac{1}{N}\sum_{i=1}^{N} \ln(\|Y_{i+d} - Y_{\hat{i}+d}\|) \quad (6)$$

where d is the discrete time step after which the divergence of trajectories is measured. It can be determined through a cross-validation process.

C. LVQ Classification

The Learning Vector Quantization Networks (LVQ) is a supervised neural network model based on competitive learning using winner-take-all Hebbian approach [10]. For our R-dimension chaotic oscillator array, which comprises R individual chaotic oscillators with different driving frequencies, a LVQ neural network is constructed with R neurons in each of its three layers. A set of training pairs $\{x^\mu, y^\mu\}$ are used to train the parameters of LVQ model,

where $x^{\mu} = (x_1^{\mu}, x_2^{\mu}, \cdots, x_R^{\mu})$, x_i^{μ} is the trajectory divergence index (TDI) of the ith member of COA when the EEG signal from the μth trial in SSVEP experiment is applied. The target output vector y^{μ} is constructed beforehand with a specific configuration of one 1 and $R-1$ 0s to represent uniquely the μth stimulus or alternatively the μth BCI command.

In the evaluating stage, when a new pattern of COA response, coded using the trajectory divergence index (TDI), is presented to the well trained LVQ model, the classification process is performed by detecting regularities and correlations between input and training patterns, and a proper output vector is given out.

IV. Experimental results

The experiments were carried out using EEG data of three different subjects provided by the Department of Biomedical Engineering in Tsinghua University [2]. The subjects are referred to as s1, s2, and s3 in the following text.

Three virtual buttons flashed at different repetition rates (11Hz, 12Hz, 13Hz), composing a frequency-coded stimulator. The subjects were asked to gaze at the target attentively, ignoring the other buttons in the operation. The attention duration of a single trial was asked to keep for no less than 2s. A COA model with three chaotic oscillators was constructed for this experiment and the driving frequencies of each member were set according to the flashing frequencies of the three stimuli.

According to the feature extraction algorithm described in section III, whenever a trial was taken the EEG signal recorded was applied to each member of the chaotic oscillator array in parallel. The responses in dynamic behavior of the COA were measured using the quantitative measure of the trajectory divergence index. The feature vectors were produced and classified by the LVQ model. The experimental results are listed in Table 1.

Table 1 Extracted feature vectors and classification results

Subject	Task	Feature Vector			Classification results
s1	1	-0.19882	0.87386	0.83011	1
	2	0.16304	-0.91172	-0.21528	2
	3	1.1536	0.87043	-1.3062	3
s2	1	-1.034	0.92112	-0.055455	1
	2	0.88419	-0.60986	0.27625	2
	3	1.0849	1.3031	-0.32175	3
s3	1	-1.245	-0.20017	-0.27617	1
	2	0.50466	0.98019	1.7361	1
	3	0.36226	1.1399	-0.95068	3

We can see from the experimental results above that the presented feature extraction and classification method can correctly recognize the gaze target of the subject except for task 2 of subject s3.

V. Conclusion

In this paper, we propose a chaotic detection method for EEG feature extraction in BCI research. The theoretical basis is discussed and the COA-based BCI scheme including feature extraction, quantification and classification is presented. The advantages of the chaotic detection based BCI method in frequency resolution make it a promising solution for SSVEP-based BCI research. The experimental results using real EEG signal show the feasibility of the proposed method.

Speckle Reduction of Echocardiograms via Wavelet Shrinkage of Ultrasonic RF Signals

K. Nakayama, W. Ohyama, T. Wakabayashi, F. Kimura, S. Tsuruoka[1] and K. Sekioka[2]

[1] Graduate School of Engineering, Mie University, Tsu, Japan
[2] Sekioka Clinic, Minami–Ise, Japan

Abstract — **We propose a new speckle reduction algorithm for clinical echocardiograms. The proposed method employs Wavelet Shrinkage to reduce the noise on an ultrasonic signal. In the wavelet shrinkage, at first, original ultrasonic signal is decomposed into wavelet coefficients by multiresolution decomposition using orthogonal wavelet. A threshold of which objective is suppression of noise component is estimated on the resultant complex wavelet coefficient. Wavelet coefficients corresponding to noise are eliminated by soft–thresholding. The noise reduction by the wavelet shrinkage can remove specific frequency components. In this study, we employed the RI-Spline wavelet that was proposed as a shift-invariant mother wavelet. We conducted experiments using clinical ultrasonic signals to evaluate the noise reduction performance of the proposed method. Ten clinical subjects were used in the experiments. The experimental results show that the algorithm provides superior performance on speckle and noise reduction compared to that of existing speckle reduction method.**

Keywords — **Echocardiogram, Ultrasound, Wavelet Shrinkage, Speckle Reduction.**

I. Introduction

An echocardiograph has built its strong position in today's diagnosis of the cardiovascular system as an indispensable imaging device. Its frequently usage is a result from its multifold advantages in cardiovascular performance assessment. Using an echocardiograph provides us noninvasive, low–cost, portable and real–time assessments of heart.

However, echocardiograms contain certain amount of speckles and noise due to the inherent property of ultrasound. These speckles and noise not only degrade the image quality of echocardiograms but make clinical diagnosis based on echocardiography difficult. To obtain enough quality of images, doctors or ultrasonologists should adjust several parameters like dynamic range or time gain compensation using a control panel of ultrasonic equipment. Though speckles and random noise appearing in the heart chamber can be removed by eliminating small amplitude using the reject–level control, the homogeneous influence of the reject–level control to the all ultrasonic signal also removes meaning appearance in myocardium. To improve clinical diagnosis, automatic reducing speckles and enhancing image quality are required.

Several methods intending to improve image quality of echocardiograms have been proposed. Zong *et.al* [1] proposed an algorithm for speckle reduction and contrast enhancement of echocardiograms. They applied a multi-scale wavelet shrinkage to eliminate noise and employed a nonlinear processing of feature energy to enhance contrast of images. Yue *et.al* [2] proposed a multiscale wavelet diffusion method for speckle suppression and edge enhancement. These methods subjected two–dimensional echocardiograms acquired using a ultrasonic diagnosis equipment. This means that these methods behave as a post–process which follows image generation process in an echocardiograph so that they oversimplify the images.

In contrast to these two–dimensional echocardiogram based methods, we propose a new noise reduction method subjecting the radio–frequency (RF) signal of ultrasound. The method employs Discrete Wavelet Transform (DWT) where the Real–Imaginary Spline Wavelet (RI–Spline wavelet)[3] is used as a mother wavelet. For noise reduction, Wavelet Shrinkage [4] is widely used by its simple usage. However, since the ordinary DWT has a problem of which the translation invariance is lacking, artifacts is generated. The RI–Spline wavelet has been developed to overcome this problem of DWT.

The paper is organized as follows. In section II, the proposed speckle reduction method is described. In this section, we explain how the method suppresses the speckle in ultrasonic RF signals. Availability of the proposed noise reduction method is observed and evaluated in section III. And finally, we conclude the paper in section IV.

II. Speckle Reduction of Echocardiogram

In this section, we explain our proposed noise reduction method employing the DWT with RI–Spline wavelet on the ultrasonic RF signals.

A. Ultrasonic Data Acquisition

Fig.1 illustrates the system used for ultrasonic RF data acquisition. An ultrasonic transducer placed on the chest transmits pulsed ultrasonic toward the heart, and receives the backscattered ultrasonic. The transducer coverts the received ultrasound to electric signal $y(t)$.

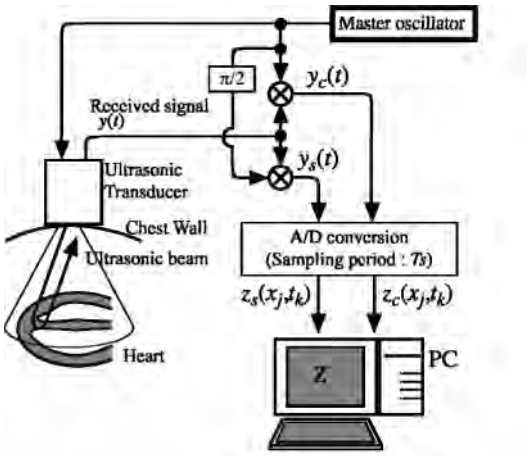

Fig. 1 Data acquisition system

The electric signal $y(t)$ is quadrature demodulated and-then A/D conveted to be imported to PC as discrete ultrasonic signal $\boldsymbol{Z} = \{\boldsymbol{z}(n,m)\}$. The ultrasonic signal $\boldsymbol{z}(n,m)$ is expressed as follows,

$$\boldsymbol{z}(n,m) = z_s(n,m) + jz_c(n,m) \tag{1}$$

where z_s and z_c denote the sine and cosine components obtained by the orthogonal demodulation. n and m denote the radial and angular indices of the B–scan sector image samples, respectively. The location of the sampling point indicated by (n,m) is defined as,

$x_n = nc_0T_s,$

$$\psi_m = m\Delta\psi, \tag{2}$$

where x_n and ψ_m denote the distance and angle from ultrasonic transducer. The constant C_0 is sound velocity in human body, i.e. 1530 [m/s]. T_s and $\Delta\psi$ are sampling period and angle interval, respectively.

Fig.2 illustrates an example of acquired ultrasonic data and an ultrasonic B–scan image generated from the ultrasonic data. In the figure, the signals located on the lower part exhibit original ultrasonic signal $\boldsymbol{Z}$ on the scan–lines A and B, which are displayed by the white lines in the image.

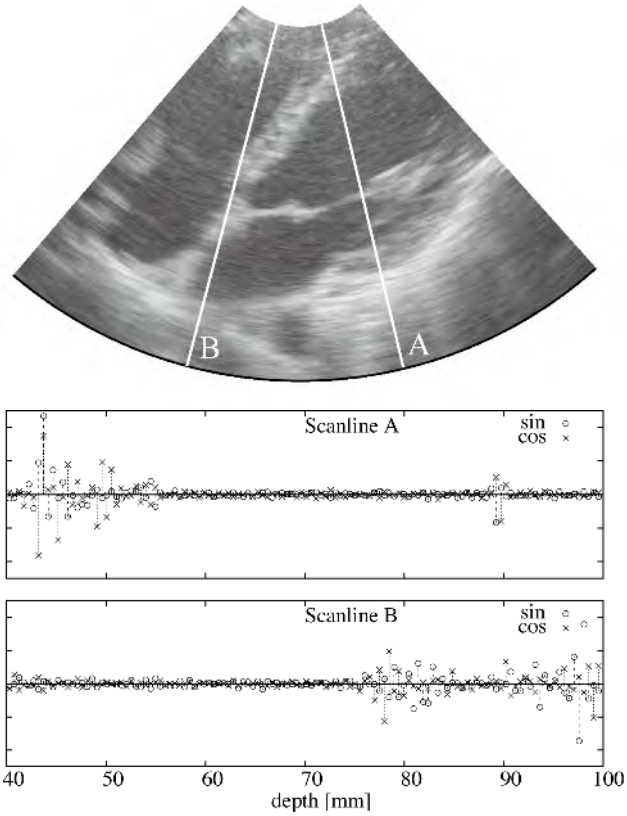

Fig. 2 Example of acquired ultrasonic data (lower) and ultrasonic image generated from the data (upper)

B. Noise Reduction by Wavelet Shrinkage

The noise reduction process in the proposed method consists of three main stages. In the first stage, the original ultrasonic signal is decomposed into complex wavelet coefficients by Complex Multi–Resolution Analysis (CMRA) with RI–Spline wavelet. In the next stage, Soft–Thresholding is applied on the wavelet coefficients to eliminate the noise components. And finally, de–noised ultrasonic signal is synthesized from the wavelet coefficients after Soft–Thresholding. Using the CMRA, a wavelet coefficient is expressed as a pair of coefficient. The each of them is corresponding to the real and imaginary parts of synthetic wavelet:

$$d^r_{k,l}\psi^r_{k,l}(t) + d^i_{k,l}\psi^i_{k,l}(t) \tag{3}$$

This equation denotes the synthetic wavelet on the level k and shift l.

To accomplish the wavelet shrinkage using such complex coefficients, we should calculated the norm $n_{k,l}$ of the synthetic wavelet by follows:

$$n_{k,l} = \sqrt{\left(d^r_{k,l}\right)^2 + \left(d^i_{k,l}\right)^2}\,, \tag{4}$$

Where $d^r_{k,l}$ and $d^i_{k,l}$ denote the real and imaginary part of wavelet coefficient. The threshold for noise reduction is estimated on the level–1 (highest–frequency) wavelet coefficients. The noise magnitude in the signal is estimated using the following:

$$\delta = \frac{Median\left(\left|n_{-1,l} - Median\left(n_{-1,l}\right)\right|\right)}{0.6745}, \tag{5}$$

where, Median(nl) denote the median of $\left\{n_l \mid l = 1,2,3,\ldots,\frac{L}{2}\right\}$. Using estimated noise magnitude, we obtain the threshold,

$$\lambda = \delta\sqrt{2\ln L} \tag{6}$$

where L denotes the number of sampling point on one scan–line.

Obtained threshold is applied in the soft thresholding process following the CMRA. The soft thresholding process is defined as:

$$\dot{n}_l = \begin{cases} n_l - \lambda, & n_l \geq \lambda \\ 0, & n_l < \lambda \end{cases} \tag{7}$$

Prior to the reconstruction process, we should transform $\dot{n}_l$ to wavelet coefficients using:

$$\dot{d}^r_{k,l} = \frac{\dot{n}_{k,l}}{n_{k,l}} d^r_{k,l}$$
$$\dot{d}^i_{k,l} = \frac{\dot{n}_{k,l}}{n_{k,l}} d^i_{k,l} \tag{8}$$

III. Experiments and results

To demonstrate and evaluate the noise reduction performance of the proposed method, we conducted an experiment using clinical ultrasonic data. The set of test ultrasonic data were acquired using an ultrasonic diagnose system (Hitachi–Medical EUB–6500). One ultrasonic data is corresponding to one systolic and diastolic sequence of echocardiogram. Ten data sets were subjected to the experiment.

Fig.3 exhibits three examples of experimental result. The upper three images are ultrasonic images generated from original ultrasonic data. These examples contain a certain amount of speckle in both cavity and myocardium regions. The lower three are ultrasonic images generated with the proposed noise reduction. One can see that the speckles in cavity and myocardium regions are reduced and the contrast of images are enhanced.

Table 1 Image quality measure obtained in the evaluation experiment using different noise reduction method

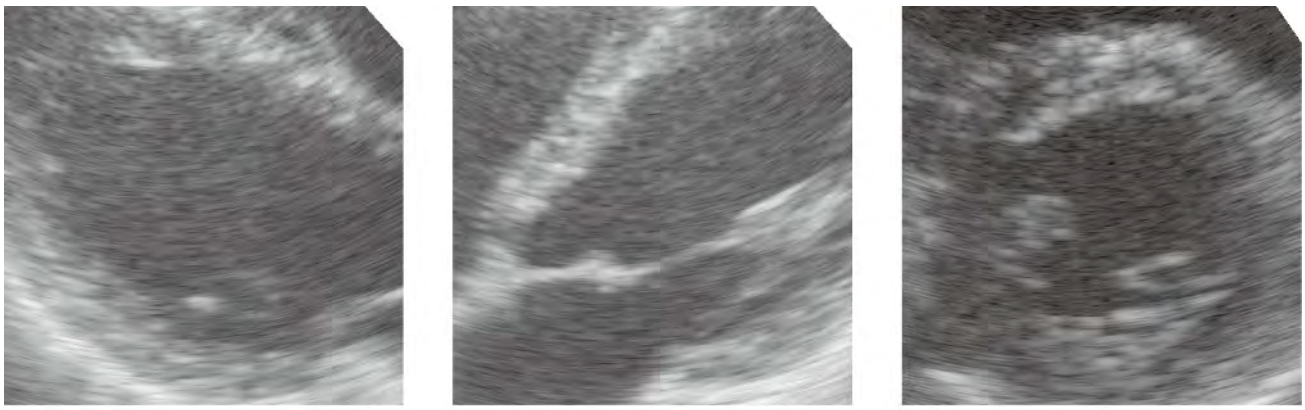
	Original	with noise reduction
SNR	4.22	5.11

To quantify the effectiveness of noise reduction, we conducted the following evaluation process. We evaluate the image quality using the following signal to noise ratio.

$$\mathrm{SNR} = \frac{\left|\bar{f}_m - \bar{f}_c\right|}{\sigma_B} \tag{9}$$

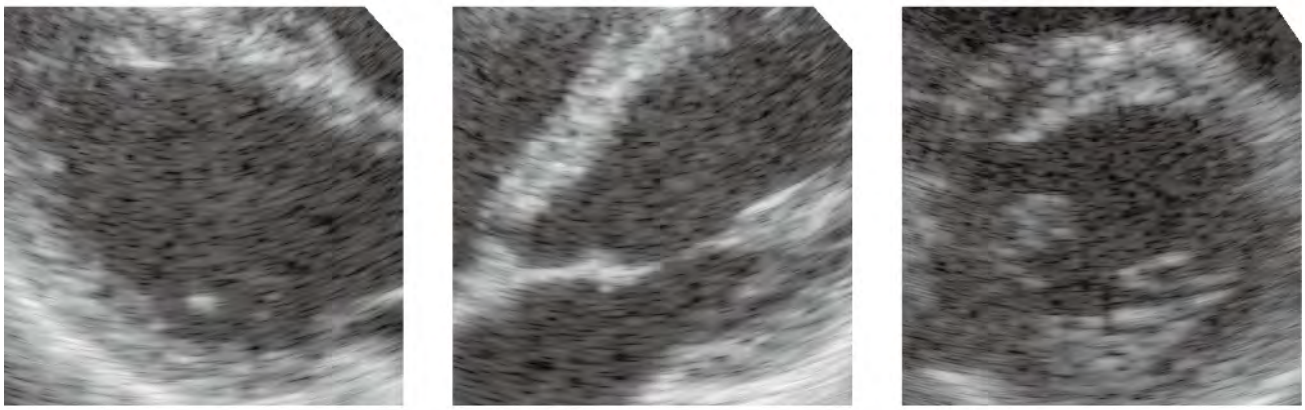
where, $\bar{f}_m$ and $\bar{f}_c$ denote the mean pixel value in the regions corresponding to myocardium and cavity, respectively. σ_B denotes the standard deviation of pixel value in the generated ultrasonic image calculated by:

$$\sigma_B = \sqrt{\frac{\omega_c\sigma_c^2 + \omega_m\sigma_m^2}{\omega_c + \omega_m}} \tag{10}$$



where, σ_c and σ_m denote the standard deviation of pixel value in the myocardium and cavity regions, and ω_m and ω_c denote the area (number of pixel) of myocardium and cavity, respectively. The myocardium and cavity regions are extracted manually on the generated ultrasonic images.

The evaluation experiment subjected ten ultrasonic images generated with and without the proposed noise reduction method. Table.1 shows the comparison between two methods. One can see that the SNR is improved by the proposed noise reduction method.



IV. Conclusions

We proposed a new noise reduction method for echocardiograms. The proposed method employs the wavelet shrinkage which using the RI–Spline wavelet as the analyzing wavelet.

The future research topics include (1) detailed comparisons among the proposed method and other noise reduction method for image quality, and (2) improvement of processing speed.

Advanced Pre-Surgery Planning by Animated Biomodels in Virtual Reality

T. Mallepree, D. Bergers

University of Duisburg-Essen, IPE-PP, Duisburg, Germany

Abstract — **Complex anatomies like the human nose are more difficult to understand from conventional two-dimensional anatomy images than from interactive virtual three-dimensional models of the individual human anatomy. The objective of the present study was to establish a procedure necessary to develop an animated three-dimensional virtual reality model of a complex anatomy like the human nose from high-resolution computerized-tomography scans. With high-resolution scans, accurate 3D reconstruction of the human nose was possible. A reconstructed triangulated .VRML model was separated in sagittal and coronal direction in order to realize a component based animation that provides navigation through the virtual environment. For a virtual reality representation a passive stereoscopic visualization system was used. Accurate three-dimensional virtual reality models of the human nose and its structures can enhance our understanding of anatomy and physiology of this complex part of the body. Thus, it supports accurate and faster surgical intervention planning.**

Keywords — **Pre-Surgery Planning, Biomodels, Virtual Reality**

I. Introduction

The success of a surgery can depend on a reliable pre-surgical plan. To elaborate a surgical plan for each individual patient, surgeons need revealing image information. Especially, complex anatomies are difficult to understand by two-dimensional (2D) gray-value images.

Currently, tomographic slice images are used for the presentation of medical image data. Standardized static three-dimensional (3D) visualizations are provided as surgical planning support [1,2,3,4]. However, there are major limitations: (a) The difficulty to recognize exact spatial relations between two or more objects and (b) the occlusion of relevant objects or parts thereof. Especially in minimally invasive surgery, the surgeon is confronted with difficult conditions during the surgical procedure. In contrast to common surgery, a direct insight to the specific area of interest is missing.

These drawbacks can be compensated by interactive 3D virtual reality (VR) visualizations. Nevertheless, navigating in 3D environments is time consuming and the viewer can lose sight of important objects or lose orientation [5]. Some of those disadvantages of both static visualizations and interactive environments can be avoided by using animations which effectively provide information in a limited and pre-defined time span.

We developed a process for generating animations in VR of complex anatomies for surgical intervention planning. A novel procedure was applied in order to support surgeons especially in minimally invasive surgery in gaining insight in the present situation. Finally, the process of surgical intervention planning could be accelerated in terms of setting-up a faster diagnosis and treatment plan.

II. Methods

High-resolution scans were used for an accurate 3D reconstruction of an exemplary nose model. The parameters were as follows: the image matrix was set to 512x512 pixels, the slice thickness was set to 1 mm and the slice increment to 0,5 mm. The scanned images were imported as .DICOM files into the 3D reconstruction software Mimics (Materialise's Interactive Medical Image Control System, Materialise NV, Leuven) (Fig. 1). The model was segmented by selecting different densities (Hounsfield Units) as threshold for extracting the model. Air appeared with a mean intensity of approximately -1024 Hounsfield units (HU), most tissue of the cavity was in the range of 20 HU to 130 HU, while cartilage and bone structures were much more dense (well above 800 HU). That operation was followed by the connected component analysis of region growing. The reconstructed model and its components (nasal conchae, nasal septum) were separated in sagittal and coronal direction in order to realize a component based animation. The triangulated mesh was enhanced by triangle reduction and smoothing in order to improve the surface quality and to reduce the file size. Then, the optimized model was imported as .VRML (Virtual Reality Modeling Language) file to CosmoWorlds (Silicon Graphics Inc.). After the setting of actors and frames, the software interpolated the frames in between. After setting the sequence, the animation had been defined directly by creating a JavaScript (Fig. 1). A script node was defined by at least one *EventIn* and one *EventOut* field. A necessary *TouchSensor* is linked by *Route* to *Script* (*EventIn*). Finally, that script is integrated by the use of an *URL* in order to control the .VRML file.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 399–401, 2009
www.springerlink.com

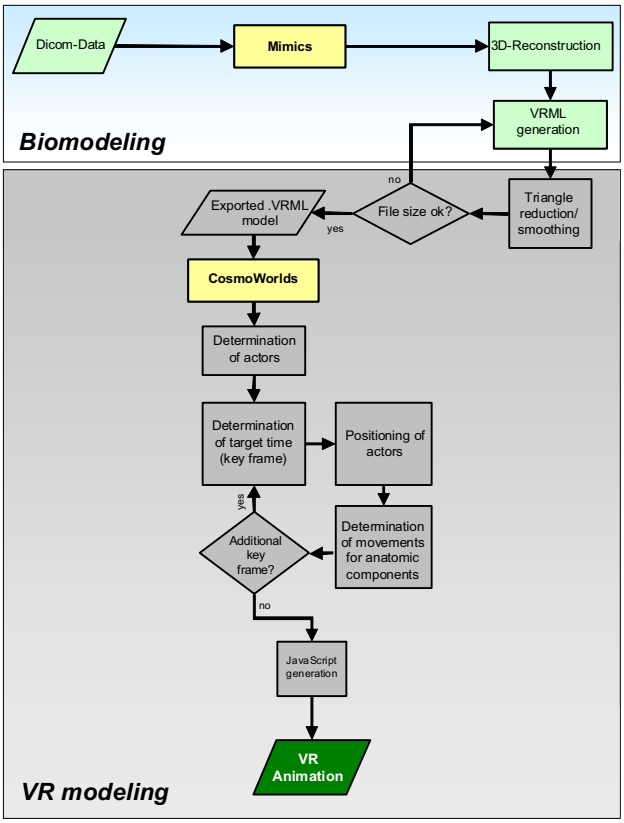

Fig. 1 VR animation process

The defined .VRML model was visualized in stereovision using the VR visualization software VRED (VREC GmbH, Darmstadt). Stereovision glasses were used to display the model in 3D.

III. Results

The generated nose model consisted of 59.000 triangles and its file size was defined to 2.400 Kbyte. The animation procedure generated, allowed interacting and exploring the 3D model from any geographical position. The representation of the applied procedure is depicted in Figure 2. It was possible to convert 2D image slices into a component based 3D animation in VR.

Table 1: Animation sequence

Sequence	Components	Plane
1	Complete nose	Coronal
2	Setum nasi (Sn)	Sagittal
3	Meatus nasi: inferior (Mni), medius (Mnm)	Coronal
4	Nasal cavitiy, nasal conchae	Sagittal

Components difficult to visualize as the nasi septum (Sn), concha inferior (Ci), concha media (Cm), concha superior (Cs), meatus nasi inferior (Mni), and meatus nasi medius (Mnm) had been displayed in animated sequence (Table 1).

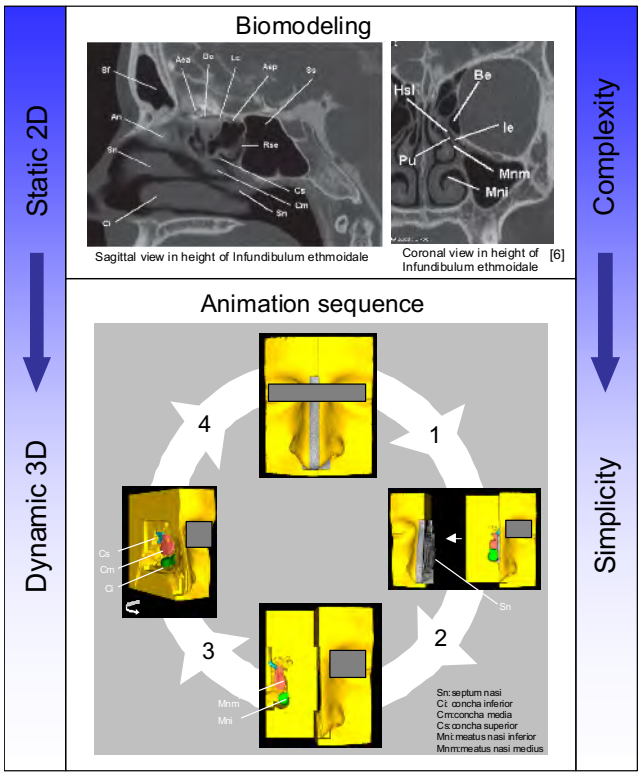

Fig. 2 Animated components

First, the animation procedure provided a coronal view on the nasal conchae. After the inspection of the nasal conchae and nasi septum, a sagittal view was given secondly to explore the nasal conchae in length. The user was enabled to change the given direction of view any time during the animation to start an individual exploration interactively.

IV. Conclusions

A procedure for creating animations of complex 3D biomodels like the human nose is shown. The complexity of 2D images is reduced by dynamic 3D animated component based parts of the human nose.

The current study aims to establish a process that can be used for the generation of animated anatomical models in order to provide surgeons with best possible image information for pre-surgery planning. Moreover, the introduced

procedure enables surgeons to communicate with each other even if they are located at different sites. That is possible both by analyzing the provided .VRML file in a standard internet browser that includes a .VRML plug-in.

An additional field of use can be seen in both medical teaching and patient information. Students would be enabled to examine complex anatomical structures interactively. They are guided by the animation to get to know specific sections difficult to find. Surgeons are enabled to communicate with patients especially in situations where deceases and treatments are difficult to explain by 2D gray-value images only. Pre-operative and post-operative situations can be discussed easily.

Overall, due to Hu [2] 3D visualizations play a significant role in planning surgeries reducing planning time as distinctive advantage over two-dimensional images by about 30 %. With the shown excerpt of our work, we are able to show that the procedure has the potential to be used as both a virtual planning and research instrument to reduce the time for understanding the morphology and physiology of complex parts of the body.

This is the first demonstration of a procedure for processing animated 3D VR models of the human nose within biomedical engineering.

Computerized Handwriting Analysis in Children with/without Motor Incoordination

S.H. Chang[1] and N.Y. Yu[2]

[1] Department of Occupational Therapy, I-Shou University, Kaohsiung County, Taiwan
[2] Department of Physical Therapy, I-Shou University, Kaohsiung County, Taiwan

Abstract — **We used computerized kinematic and kinetic analyses to determine the mechanism of handwriting deficit in children with developmental coordination disorder (DCD).**

Totally, 72 children (33 DCD and 39 non-DCD) with handwriting deficit and 22 children without handwriting deficit (normal control) were recruited. The speed that subjects learned to write an unfamiliar character (i.e., the speed of execution) was used to assess motor learning of handwriting. Three simple and 3 complex Chinese characters were written, and the changes in the velocity and pressure for corresponding strokes were observed.

In children with DCD, handwriting execution was markedly slower. They were able to speed up stroke movement to maintain stability (phasic strategy) in the writing of simple characters but not complex characters, and failed to use more pressure on the writing surface (tonic strategy) to stabilize movement.

In conclusion, the parameters in this study are linked to underlying perceptual-motor functions and can be used to characterize handwriting problems arising from motor incoordination.

Keywords — **motor learning, handwriting, developmental coordination disorder, kinematic analysis s.**

I. Introduction

In fine motor control of handwriting movement, the coordination of muscle movements and the regulation of pen speed and force are the key components of legible writing. In 1994, Marquardt et al. developed a computer controlled handwriting evaluation tool [1]. The procedure records the handwriting of the subject on a digital tablet, especially loops like ℓℓℓℓℓℓ. The movement is traced automatically and divided into segments corresponding to individual strokes. These strokes can be used as diagnostic measures of motor control.

Normal handwriting movement does not require continuous modification of motor output or use visual or kinesthetic feedback from the hand. This kind of movement is achieved using open-loop control. Learning to write a new letter uses closed-loop feedback control and requires a lot of practice [2]. In their study, normal adults were recruited to write two similar but unfamiliar letters 60 times. They used the number of acceleration peaks of every stroke segment to estimate the degree of movement automation.

To characterize fine motor skills in DCD, Smits-Engelsman et al. (2001) asked children to draw the flower-trail-drawing item of the Movement Assessment Battery for Children (M-ABC) test and found that serious handwriting problems are associated with fine motor deficits. They suggested that handwriting to children with motor deficits is a kind of stress that may enhance neuromotor noise—the noise being the result of random muscle fiber recruitment. Children can speed up stroke movement (phasic movement), or hold the pen more tightly (tonic movement) to provide stability, thereby filtering the neuromotor noise [3]. However, it is not known whether DCD children respond similarly, how phasic and tonic movements reduce enhanced noise, and whether simple and complex tasks differ? Most of the current studies on handwriting use the Western alphabet. Since Chinese and Western alphabets differ in form and since there are cultural differences, studies using the Western alphabet may not necessarily have implications for Chinese children with DCD.

Furthermore, there is still no published article on the mechanism of handwriting deficit in DCD involving computerized evaluation and use of Chinese characters. In this study, children with handwriting problems (with or without DCD) were compared to children without handwriting problems. Computerized handwriting movement analysis was utilized to analyze the motor and control sequence used in writing Chinese characters.

II. Methods

A. Subject Recruitment

From five public elementary schools, 1258 children in grade 1 or 2 were screened by the Beery-Buktenica Developmental Test of Visual-Motor Integration (VMI) (Beery, Buktenica, & Beery, 2004). A score lower than the mean minus 1.5 times standard deviation was the criterion for inclusion. School teachers who administered the Chinese Handwriting Evaluation Questionnaire (CHEQ) (Chang & Yu, 2005) selected 75 children with handwriting deficits and these were recruited into this study as the experimental

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 402–405, 2009
www.springerlink.com

group. In addition, 22 non-DCD children without a handwriting deficit were randomly recruited from the same pool as the experimental group.

B. Research Design

For measuring the motor learning of a handwriting task, we tested the proficiency of children to render an unfamiliar character with two rectangular angled strokes. To assess motor control during handwriting, we tested the ability of children to copy 3 simple and 3 complex Chinese characters. Differences in stroke velocity and pen-tip pressure for the same strokes were compared among the three groups.

C. Measures Used to Verify Motor Incoordination

DCD was diagnosed on the basis of results from the M-ABC test and Developmental Coordination Disorder Questionnaire (DCDQ) (Henderson & Sugden, 1992; Wilson, Kaplan, Crawford, Campbell, & Dewey, 2000). The DCDQ is a 17-item parent self-report questionnaire, which assists clinicians to identify children with motor problems. The total DCDQ score is the sum of the scores for each item. On the basis of the above selection criteria, DCD was diagnosed in 33 children and non-DCD in 39. Three children without either diagnosis were excluded.

D. Measuring Instruments

The handwriting tasks were performed on A4 size paper affixed to the surface of a 2-D digitizing tablet (444.0 x 435.5 x 37.0 mm, Wacom, Intuos 2, Japan) using a wireless electronic ball-point pen with pressure sensitive tip. The digitizer tablet also samples the axial pen force, with a maximum frequency of 200 Hz, a resolution of 2540 lines per inch, and a temporal accuracy of 1 ms.

E. Handwriting Tasks

(1). Test for Automated Handwriting

An A4-sized blank paper was placed on the digitizing tablet. The content of the page was arranged in 5 rows and 8 columns (40 grid cells), each cell being 18*18 mm. The subjects were instructed to write two rectangular characters (「 and 」) in the cells. The subjects were told that they could write at their own speed. They were required to write the character 40 times.

(2). Measuring the Control of Handwriting Movement

The content of the page was arranged in 6 rows and 6 columns (36 grid cells), each cell being 18*18 mm. The children were instructed to write three simple characters: "三" (san; composed of three horizontal strokes), "川" (chuan; composed of three vertical strokes), and "八" (ba; two slant strokes) and three complex characters "書" (shu; mostly horizontal strokes), "刪" (shan; mostly vertical strokes), and "參" (tsan; mostly slant strokes). All strokes of simple characters were compared with the 6 horizontal, 6 vertical, and 5 slant strokes of the respective complex characters.

G. Data Processing and Analysis

The data was processed and analyzed using a self-programmed MATLAB routine (The MathWorks, v 6.5, Natwick, MA, USA). The first (velocity) and second derivatives (acceleration) of each stroke were calculated (Marquardt and Mai, 1994). In the first experiment, the number of acceleration peaks per stroke movement was counted. In the second experiment, the mean stroke velocity and pen tip pressure of every stroke were measured. The following are the derived parameters processed from the registered coordinates and pen tip pressure.

1. Number of Corrective Movements (COMs): The number of vertical (or horizontal) acceleration peaks for every vertical (or horizontal) stroke was determined as an approximation of the number of corrective movements. It represents the level of automation. The number of COMs decreases as movement becomes automatic; otherwise movement is still deliberate. When movement is fully automated, the ideal number of COMs is 2 per vertical or horizontal stroke. Decrease in the number of COMs indicates a switch from closed feedback control to open loop control.
2. Inflection Point: To characterize the automation process, a hyperbolic tangent equation, generally used for the description of empirical data with a sigmoid-like distribution, was adopted to describe the change in the number of COMs:

$$Y = a \times \tanh(b \times n - c) + d \cdots\cdots \quad (1)$$

3. where Y is the number of COMs and n is the number of practice attempts. The coefficients a, b, c, and d are estimated by using a least-squares error method. The inflection point was obtained from c/b. It is the number of practice attempts required for the number of COMs to decrease to 50% of their initial value. It represents the speed needed to reach automation in handwriting.

Statistical Analysis

SPSS for Windows/PC (10.0) was used for the statistical analyses. In the handwriting automation experiments, the

DCD group was compared to the non-DCD group and children in the two experimental groups were compared to children in the control group. More than two comparisons were needed. For reducing the accumulation of type I error, one-way analysis of variance (ANOVA) was used to compare the differences among the three groups. The significance level was set at α=0.05. Significant ANOVA results were followed by Tukey's post hoc comparisons. In the comparison between simple and complex character tests, a two-way repeated measure ANOVA with Tukey's post hoc analysis was employed. The significance level was also set at α=0.05.

III. Results

A. Differences in Learning between the Control and Experimental Groups

An abrupt drop in the COM number to the inflection point indicated automated movement was achieved. Figure 1 shows the learning curve of a child in the DCD group tasked with writing the target letter. The inflection point indicates that automation was achieved after about 16 letters. The graph of the measured COM numbers is circles connected by dotted lines. The solid line is the fitted sigmoid curve. Figure 2 shows the learning curve of a child in the non-DCD group tasked with writing the target letter. Automation was observed after about 6 letters.

Table 1 lists the mean numbers of practice attempts (±SD) needed to learn to write the test letter automatically. The group factor was found to have a significant effect on the number of practice attempts needed to achieve automation ($F_{2,91}$=15.52, p<0.001). The result of *post-hoc* tests showed that the difference in this mean number between the DCD and non-DCD groups and between the DCD and control groups reached statistical significance. The difference between the non-DCD and control group was insignificant.

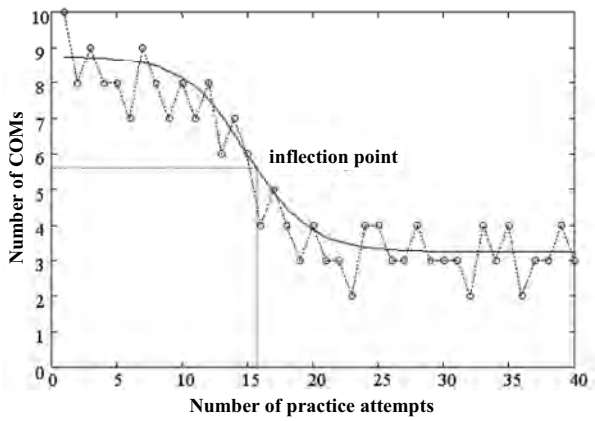

Figure 1: The learning curve of a DCD child in writing the target letter.

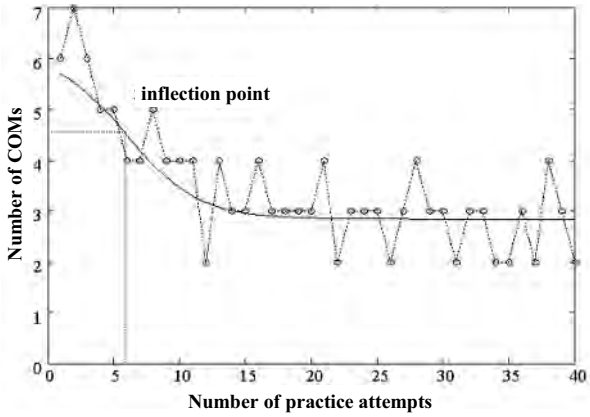

Figure 2: The learning curve of a non-DCD child in writing the target letter.

Table 1: Average number of practice attempts needed to achieve automation

Items \ Groups	DCD	n-DCD	Comparison
No of letters to automation	14.6 (7.9)	7.6 (5.1)	6.2 (5.2)

B. Movement Control in Handwriting

To assess the ability to control stroke movements, velocity changes occurring during the tasks of writing simple and complex characters were compared. Table 2 shows the mean and standard deviations of stroke velocity for the three groups. The repeated measures ANOVA showed that the mean stroke velocity significantly differed between the simple and complex character writing tasks. The velocity was much slower in writing a complex character than a simple character ($F_{1,91}$=129.81, p<0.001). The differences

Table 2: The mean and standard deviation of stroke velocity in writing simple and complex characters

Items \ Groups	DCD n=33	n-DCD n=39	Control n=22
Velocity in the simple task	5.90 (1.68)	5.58 (1.41)	4.85 (0.98)
Velocity in the complex task	4.07 (1.10)	4.34 (1.28)	4.79 (0.98)
Mean velocity	4.98 (1.64)	4.96 (1.40)	4.82 (1.00)

1. unit: cm/s

among the three groups were also significant ($F_{2,91}$=5.22, p=0.007). Furthermore, the two factors interacted, i.e., different groups exhibited different changes in stroke velocity ($F_{2,91}$=15.40, p<0.001). There were differences in stroke velocity among the three groups as well as a difference in the stroke velocity between writing simple and complex characters. The result of *post hoc* showed that, in the simple character test, the stroke velocity was higher in the DCD group than the non-DCD and control groups, but in the complex character test, it was much lower in the DCD group than the non-DCD and control groups.

IV. Discussion & conclusions

This study found that children with DCD needed to practice more to reduce the number of acceleration peaks needed to produce a single stroke. Learning to write a new letter automatically was much slower in DCD children than average children. Most previous studies also found children with DCD experience difficulty in achieving automation of motor skills. Motor learning was also found to be slower in DCD children than normally developed children [4]. The difficulties in motor learning are directly reflected by the problem of learning to write a new letter. Much more practice seems to be necessary for learning the letter.

In studying the learning of handwriting, Kharraz-Tavakol et al. (2000) found that mean corrective movements were reduced 34.5% after 30 practice attempts [2]. We found that a typical child achieves automation after only 6 attempts. On average, children with DCD needed to write the character more than 17 times to reach automation. Automation was defined in this study by a 50% reduction in the number of COMs. The children in our study were faster than those in the study of Kharraz-Tavakol et al. In comparing the target letters used in the two studies, ours was simpler than theirs "ل". There were only two turning points (changes in direction of movement) to complete the task of our study, while at least 4 turning points (changes in movement direction) were required to complete their task, i.e., "ل." In addition, Mergl et al. (1999) found that learning to write rectangular strokes automatically is faster than learning to make curvalinear strokes. Kharraz-Tavakol et al. (2000) found that motor planning subroutines for similar strokes can be practiced and used interchangeably. The two strokes used in the task of this study are geospatially similar, though rotated 90 degrees; therefore, motor planning subroutines can be used interchangeably, which might account for the faster learning in the setting of this study [2].

Smits-Engelsman et al. (2001) speculated that poor handwriting is part of a wider neuromotor condition characterized by faster and cruder movements, lack of inhibition of co-movements, and poor coordination of fine motor skills [3]. As expected, the DCD children in our study used a faster stroke velocity to write simple characters than did control children. However, there was no between-group difference in the stroke velocity used to write complex characters. Moreover, we also found the stroke speed of children with DCD was slowed as compared with control children by writing complex characters. The complexity of complex characters (i.e., involving strokes of many different lengths, directions, and turning points) may account for this slowing. Learning of complex procedures requires closed-loop control with more visual feedback to adjust the procedure. Most children with DCD have impaired visual feedback control and integration of the visual and motor systems [5]. When visual feedback is limited, the number of times the model characters are looked at increases, and so stroke velocity is significantly reduced.

The Development of Computer-assisted Assessment in Chinese Handwriting Performance

N.Y. Yu[1] and S.H. Chang[2]

[1] Department of Physical Therapy, I-Shou University, Kaohsiung County, Taiwan

Abstract — **This study investigated the utility of assessment for Chinese handwriting performance. In an attempt to computerize the existing Tseng Handwriting Problem Checklist (THPC), this study employed MATLAB to develop a set of computer programs entitled Chinese Handwriting Assessment Program (CHAP) to be used for the evaluation of handwriting performance.**

Through a template-matching approach, the program processed each character by using size adjustable standard models to calculate the 2-dimensional cross correlation coefficient of the template and its superimposed handwritten character. With the help of image processing, it could measure the size control, spacing, alignment, and the average resemblance between standard models and handwritten characters.

The results of CHAP's test-retest reliability showed that high correlation coefficients (from 0.809 to 0.939) all reached statistical significance. The results of correlation analyses between each CHAP and THPC item reached statistical significance. As these two assessment items for handwriting performance are required for objectivity and quantification, further development of CHAP is necessary.

Keywords — **Elementary education, evaluation methodologies, handwriting, computer application, image processing.**

I. Introduction

Children often have difficulties producing legible output both at the speed required to keep up in class or in the amount essential to complete their school work. Generally speaking, poor spacing between consecutive characters, deficient character formation, missing or extra strokes in a character, reversals, sloppiness, and slow writing speed are the problems most often encountered in children as they learn to write [1].

A sophisticated evaluation system should provide not only a score or list, but also an analysis of the problems found in a child's handwriting. Assessment of handwriting legibility involves a subjective examination of characters, numbers or sentences. However, the factors that contribute to legible handwriting are multi-factorial and complex. The test-retest reliability of these methods is still questionable [2][3].

Chinese characters are usually composed of more than two components and constructed primarily by pictographic component. Each component of a character is arranged within a square frame. Writing a Chinese character is similar to delineating an image. It requires harmonic, symmetry, and equilibrium structures for the completion of a character. More attention is necessary to assess neatness, proper stroke placement and alignment.

For a standardized Chinese handwriting performance assessment, Tseng has developed a set of items entitled the Tseng Handwriting Problem Checklist (THPC) used for the evaluation of handwriting in schoolchildren. She has studied the factorial validity of THPC and found that it an effective tool to assess a child's handwriting from 6 dimensions [1]. Chang has used THPC as the assessment tool for handwriting performance to explore the correlation between the latter and perception performance. Although the inter-rater reliability of the THPC reached up to r=0.96 (p=.0001), the advance training of the examiners required considerable time and effort [4].

In recent years, many researchers have used computer technology to analyze the relationship between handwriting and fine motor control while attempting to employ handwriting performance as an indicator for the evaluation of neural motor control [5][6]. Since the spatial layout of a Chinese character is square in nature, the application of image processing techniques may make standardized Chinese handwriting assessment possible. This study used the THPC and other handwriting evaluation tests to develop a new assessment of the neatness and legibility of handwriting for diagnostic purposes. Drawing from the related literature reviews it was determined that letter formation, spacing, size, alignment, and slant are the aspects most frequently adopted as criteria for evaluating the legibility of handwriting [7][8]. Thus, this research aimed to develop a set of computerized evaluations that involved assessments of spatial arrangement, character size control, neatness and legibility of handwriting scripts.

II. Methods

A. The development of the Chinese Handwriting Assessment Program (CHAP)

Since a handwriting performance evaluation requires models as standard for assessment, we first created the stan-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 406–410, 2009
www.springerlink.com

dard model in Kai-Shu font and saved it into a 1-bit image. Kai-Shu, known as standard regular, is the newest of the Chinese calligraphy styles. The test sheet written by the participants was scanned (Scanmaker E6, Microtek) with a 100 dpi and saved by 1-bit image.

The main function of the CHAP is to quantify the resemblance between pencil written and standard characters, to scale the character size and to measure spatial arrangement through an image processing algorithm. The program was written by MATLAB language (The MathWorks, v 6.5, MA). The program first loaded the handwritten samples and graphic files of standard models into the computer memory. Compared with the standard models, the pencil written characters revealed thinner strokes. The first step in image processing was to dilate each stroke in the image four times with a 3*3 matrix operator and then overlap five images (including the original image) into one image [9]. The step could thicken the strokes and produce the effect of gradient.

CHAP takes a template matching approach. This approach to identifying a character within an image cross correlates the image with a size adjustable template. The template is itself an image of a standard character. Where the template and the handwritten character being sought are similar, the cross correlation will be high. In the image identification process, the template may need to be scaled at each position to measure the size of the handwritten character. As shown on Figure 1, the template is centered at every pixel in the image and the cross correlation calculated. This forms a 2D array of correlation coefficients.

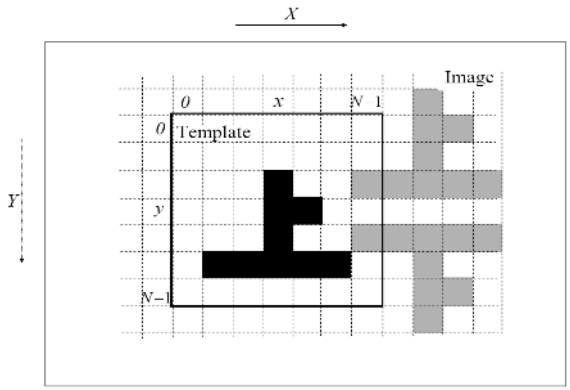

Figure 1. Template matching approach for localizing the handwritten characters. Black: Character in template. Gray: Handwritten character in image.

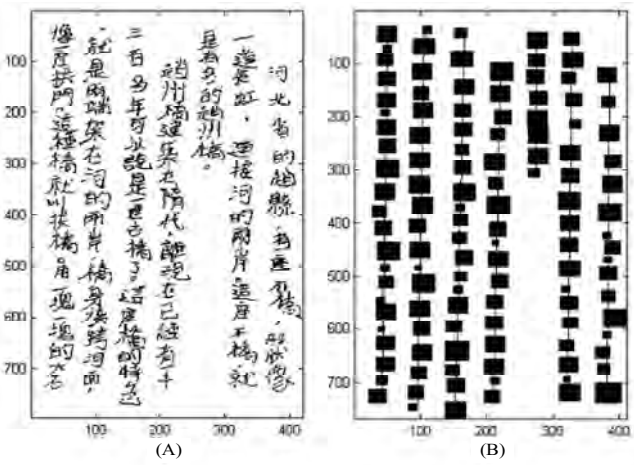
The form of the un-normalized correlation coefficient at position (X, Y) on the image is given by $r[X][Y] = \sum_{y=-N/2}^{y<N/2} \sum_{x=-N/2}^{x<N/2} \left(template[x+N/2][y+N/2] - \overline{template} \right) \left(image[X+x][Y+y] - \overline{image} \right)$ where $\overline{template}$ is the mean of the templates pixels and $\overline{image}$ is the mean of the image pixels under (covered by) the template.

The peaks in this cross correlation "surface" are the positions of the best matches in the image of the template. Using the above processes, we could identify the accurate coordinate position of each handwritten character. The correlation coefficient referred to the resemblance between handwritten and standard character. Subsequent to the identification of the position of each character, the spatial arrangement of characters could be quantified. Assume the coordinate positions of two characters next to each other were (*Xi, Yi*) and (X_{i+1}, Y_{i+1}). The distance between the two characters (inter-character distance) is $\sqrt{(X_{i+1} - X_i)^2 + (Y_{j+1} - Y_j)^2}$. For measuring the alignment control, the difference between X_i and the X coordinate value of each vertical middle line is the horizontal distance between the center of each character and the middle line. The shorter the distance was, the better the control of the linear alignment of handwritten characters.



The image processing program could calculate the number of characters written or skipped by the participants, the average/standard deviation of inter-character distance (for spacing control), the average/standard deviation of distance deviated from the mid-line (for alignment control), the average/standard deviation of resemblance with a standard model (for legibility), and the average/standard deviation of character size (for size control). Character sizes were divided into 34 levels ranging from 6*6, 8*8 ...to 72*72 (unit: pixel). Using millimeters as the unit, character sizes ranged from 1.52*1.52, 2.03*2.03 ...to 18.29*18.29 (unit: mm).

B. Reliability of Chinese handwriting assessment program (CHAP)

1. Participants: 20 fourth grade students (10 males and 10 females) were recruited to participate in the experiment.
2. Process: The participants were asked to copy a text selected for this research. The text included four paragraphs. Both the first two and last two paragraphs were printed on two separate papers as two handwriting samples. To counterbalance the arrangement, they were randomly assigned to write any one of the handwriting samples first. Hence, there was no fixed copy order.
3. Statistical analysis: SPSS for Windows/PC (SPSS Inc., Ver 10.0) was used for the statistical analyses. The first two and last two paragraphs were allocated into two groups of samples and respectively evaluated by CHAP. Pearson's correlation analysis was conducted to explore the reliability of this assessment program.

C. Comparison between CHAP and THPC

1. Participants: 66 third grade elementary schoolchildren (34 boys and 32 girls) were recruited into this study.
2. Experimental Procedures: The participating subjects copied the text on the test sheet in the regulated 10 minutes and were told to write in their most natural manner instead of at their fastest speed. The test sheet made in advance was not drawn with checks and lines. Instead, they were drawn with dotted lines of 1.4 cm width as the base for the students.
3. Assessment Tools: The tests for assessing the children's handwriting performance in this research included: a subjective handwriting performance assessment - THPC and computerized assessment program - CHAP.
   (1) Tseng Handwriting Problem Checklist (THPC)
   For the evaluation of Chinese handwriting performance, THPC includes 24 items for the assessment of legibility and handwriting behavior. The first through twelfth items assess handwriting legibility; the thirteenth through the twenty-fourth items involve the observation of handwriting behavior. This research only adopted scores from the first through twelfth items. Scoring was based on the frequency of mistakes. These twelve items included 6 categories of measurement for handwriting performance evaluation (interval, space relation, character size, form, reverse character and strokes).
   (2) Chinese Handwriting Assessment Program (CHAP)
   For this research, four parameters were computed by CHAP for the evaluation of handwriting performance. (1) The standard deviation of character size was utilized for assessing *the control of character size*. (2) The standard deviation of inter-character distance and (3) the average distance deviated from the mid-line were calculated to measure *the control of inter-character space and the straight line alignment*. (4) The average resemblance with the standard model was the indicator for neat and legible handwriting.
4. Validity Tests: Pearson's correlation analyses were conducted for the four parameters of the computer assessment with the corresponding items in THPC. Thus, based on the results of THPC, the significance of CHAP can be evaluated and validated.

◇Total characters written (including punctuation marks)	108	◇Total skipped characters	5
◇Average inter-character space (mm)	9.57	◇SD of inter-character space*	2.08
◇Average deviated distance from mid-line (Unit: mm)*	0.70	◇SD of deviated distance from mid-line	0.55
◇Average resemblance with standard model (0-1)*	0.551	◇SD of resemblance with standard model	0.09
◇Average character size (1-34)	18.90	◇SD of character size*	4.96

(C)

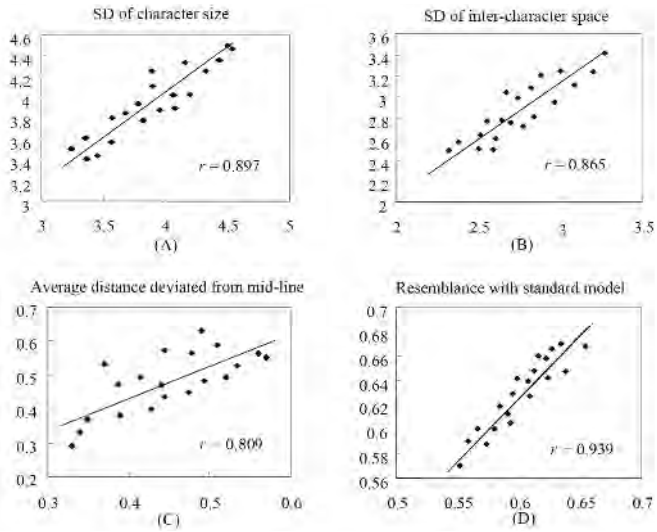

Figure 3. The correlation analyses for the test-retest reliability of CHAP. X- and Y-axes are the results of the first and the last two paragraphs of the same participants.

III. Results

A. Assessment Results and the Reliability of CHAP

Figure 2 is a demonstrative report of a CHAP assessment. It shows the handwritten scripts and the positioning process for quantitative assessment. Figure 3 is the CHAP assessment results for ten fourth grade students. The horizontal coordinate was the assessment result of the first two paragraphs of text and the vertical coordinate was that of the

last two paragraphs. It depicted four results of the correlation analyses: (a) the average inter-character space, (b) the average deviation from the mid-line, (c) the standard deviation of character size, and (d) the resemblance with the standard model. The result showed that correlation coefficients ranged from 0.809 to 0.939 and the *p* values were all less than 0.001, which reached statistical significance.

B. Comparison between THPC and CHAP

According to the results of statistical analysis, viewed from the perspective of CHAP, the correlation between CHAP and the corresponding items of THPC all reached statistical significance ($p < 0.001$). Putting the SD of character size ($r = -0.51$) aside, a strong strength of correlations between CHAP and the corresponding items of THPC was found (r=-0.77 in average distance deviated from the mid-line; r=-0.78 in SD of inter-character distance; r=0.82 in the resemblance with the standard model). An explanation for the negative correlation coefficients is that CHAP observed the deviated distance of the characters from the mid-line and the variance of inter-character distance, whereas in THPC, the neater the spatial arrangement, the higher the assessment scores. As for control of character size, positive results lead to higher evaluation scores in THPC. Thus, it also showed negative correlation.

IV. Discussions and conclusions

The results of this research showed that the CHAP could accurately identify the positions of characters and measure the size of each. Subsequent to the positioning of each character, their spatial arrangement can be successfully parameterized. Based on a set of objective standards, this study was a novel attempt to objectively assess handwriting performance with the help of computer technology. While the traditional evaluation of handwriting neatness and legibility is also based on a set of criteria, it depends on strenuous visual inspection and subjective judgment. Another achievement of CHAP was that it could assess the resemblance to each character to evaluate the neatness and legibility of handwriting. In the past, teachers only scored a student's tasks using their own judgment. When the development and implementation of related techniques mature, the computer is very likely to replace subjective assessments so as to make the assessment of neatness and legibility automatic and more objective.

The further implications of this study include the assessment of perceptual motor functions in children of developmental age. A child with a handwriting problem may have underlying developmental dysfunctions. In addition to academic performance, the measurement of size control and spatial arrangement in CHAP could be associated with the fine motor skills of children. For future studies, CHAP could be utilized for the off-line measurement of neuromotor control in children of developmental age or subjects with neuromuscular conditions. In addition, the approach proposed in this study might be applied to the evaluation of a machine method of coding a subjective rating scheme.

The correlation analyses between THPC and CHAP, among all items, only the one of THPC did not show strong correlation with the corresponding items in CHAP. As mentioned, THPC could complement an examination for the accuracy of handwriting scripts. However, with more objective or quantitative items, the CHAP appeared to be more suitable for an assessment of spatial arrangement.

This study revealed that the combination of CHAP and THPC may be complementary. The integration of CHAP and THPC can be applied to the study of handwriting problems and its remediation in children with special needs or low academic achievement. If the computer techniques and AI of the future reached a more mature level, children's handwriting tasks could be assessed in a more automatic method which could be as objective, rapid and accurate as a present-day computer scoring answer sheet system.

Novel Tools for Quantification of Brain Responses to Music Stimuli

O. Sourina[1], V.V. Kulish [2] and A. Sourin[3]

[1] Nanyang Technological University/School of Electrical and Electronic Engineering, Singapore
[2] Nanyang Technological University/School of Mechanical and Aerospace Engineering, Singapore
[3] Nanyang Technological University/School of Computer Engineering, Singapore

Abstract — **Therapeutic effect of music is known for long time. Music therapy can be used to improve the current patient's state or even prevent some deceases of psychosomatic origin. For decades, the basic research methods of music psychology mainly relied on survey with questionnaire or on observations of subjects. Investigating the effect of music through electroencephalograms (EEG) could be more precise and objective. In this paper, we describe fractal dimension model for quantification of brain responses to external stimuli. Human EEG evoked by music stimuli are analysed with the developed software. The proposed technique of processing EEG is based on the Rényi entropy – the concept of generalized entropy of a given probability distribution. It allows defining generalized fractal dimension of EEG. The experiments involved ten subjects, both male and female twenty years old university students. The EEGs were processed by the fractal dimension analysis tools. Analysis of fractal dimension values demonstrates that the method can be used to quantitatively distinguish between different states of the brain. Correlation between music, and subject's emotion and concentration was studied. Few hypotheses were validated.**

Keywords — **EEG, music therapy, brain response quantification, fractal dimension, emotions.**

I. Introduction

For decades, the basic research methods of music psychology is no different from other disciplines in social science domain, mainly relying on survey with questionnaire and attaining results through statistical approach, or otherwise through the observation of subjects. Investigating the effect of music through EEG was still new to the research community until recent times. Now, combination of the accomplishment of past study of music psychology with EEG-based research is already bearing fruit, as therapeutic effect of music is now widely recognized and music is used for treatment of neural abnormality or mental disorder. Modeling of brain activity with EEG signals is more precise and objective than survey, because the subject being surveyed might not be fully aware of his/her psychological and emotional status when answering questions. On the other hand, EEG signals would not be altered by the subject's own judgment. Therefore this approach would be more used in the coming years.

EEG signals are the records of electrical potential produced by the brain along with its activities. Quantification of responses of human brain to various external stimuli is a research area that can help to solve a mystery of the human brain. Researchers attempt to create tools and models to study and describe the behaviors and nature of EEG signal. The current methodology is to analyze real-time EEG readings in frequency domain. But there is a new trend for EEG signal processing as moving from linear Fast Fourier Transform (FFT) to non-linear Fractal Time Series analysis to study dynamic nature of EEG signals. The analysis of EEG data in fractal dimension domain is based on its geometric pattern, rather than frequency content.

In our works [1-3], we proposed to process EEG signals using fractal dimension model and implemented novel algorithm to process EEG signals evoked by odor stimuli. We studied brain responses to six basic olfactory stimuli given to the subjects in our experiments.

In this paper, we describe results of experiments with music used as external stimuli. The psychological effect of music measured in terms of EEG responses is studied. In this paper, we describe fractal dimension analysis model and apply it to analyze EEG evoked by music stimuli. We extend fractal dimension model with dynamic component and develop a novel algorithm and software system. The fractal dimension changing over time is visualized dynamically on the chosen EEG channels. The experiments are conducted with music used as the external stimulus, and the EEG response of the subjects, university students, are recorded and subjected to fractal dimension analysis. The analysis results are plotted graphically for intuitive investigation and visualized dynamically with the developed visualization software. Few hypotheses were validated.

In Section II, an introduction to fractal dimension analysis is given. Section III describes the experiment setting and analyzes experiments results. Section IV summarizes the outcomes of the project and provides recommendations for the future development.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 411–414, 2009
www.springerlink.com

II. Fractal analysis model description

Fractal dimension analysis can be generally applied to non-linear systems. It basically tells how many points lie in the set and how scattered they are or how "strange" is a geometric structure [4].

A common practice to distinguish among possible classes of time series is to determine their so-called correlation dimension. The correlation dimension, however, belongs to an infinite family of fractal dimensions [5]. Hence, there is a hope that the use of the whole family of fractal dimensions may prove to be advantageous in comparison with using only some of these dimensions.

The concept of generalized entropy of a probability distribution was introduced by Alfred Rényi [6]. Based on the moments of order q of the probability p_i, Rényi obtained the following expression for entropy

$$S_q = \frac{1}{q-1}\log\sum_{i=1}^{N} p_i^q \tag{1}$$

where q is not necessarily an integer and log denotes $\log_2$. Note that for $q \to 1$, Eq. (1) yields the well-known entropy of a discrete probability distribution [7]

$$S_1 = -\sum_{i=1}^{N} p_i \log p_i \tag{2}$$

The probability distribution of a given time series can be recovered by the following procedure. The total range of the signal is divided into N bins such that

$$N = \frac{V_{\max} - V_{\min}}{\delta V} \tag{3}$$

where $V_{\max}$ and $V_{\min}$ are the maximum and the minimum values of the signal achieved in the course of measurements, respectively; δV represents the sensitivity (uncertainty) of the measuring device. The probability that the signal falls into the ith bin of size δV is computed as

$$p_i = \lim_{N\to\infty} \frac{N_i}{N} \tag{4}$$

where N_i equals the number of times the signal falls into the ith bin. Alternatively, in the case of a time series, the same probability can be found from the ergodic theorem, that is

$$p_i = \lim_{T\to\infty} \frac{t_i}{T} \tag{5}$$

where t_i is the time spent by the signal in the ith bin during the total time span of measurements T.

Further, the generalized fractal dimensions of a given time series with the known probability distribution are defined as

$$D_q = \lim_{\delta V\to 0} \frac{1}{q-1} \frac{\log\sum_{i=1}^{N} p_i^q}{\log \delta V} \tag{6}$$

where the parameter q ranges from $-\infty$ to $+\infty$. Note that for a self-similar fractal time series with equal probabilities $p_i = 1/N$, the definition Eq. (6) gives $D_q = D_0$ for all values of q [8]. Note also that for a constant signal, all probabilities except one become equal to zero, whereas the remaining probability value equals unity. Consequently, for a constant signal, $D_q = D_0 = 0$. The fractal dimension

$$D_0 = -\frac{\log N}{\log \delta V} \tag{7}$$

is nothing else but the Hausdorff-Besicovitch dimension [8].

The correlation dimension, mentioned previously, is the fractal dimension with q = 2.

As $q \to 1$, Eq. (6) yields the so-called information dimension

$$D_1 = \lim_{\delta V\to 0} \frac{-\sum_{i=1}^{N} p_i \log p_i}{\log(1/\delta V)} \tag{8}$$

where the numerator is Shannon's entropy given by Eq. (2).

Note also that

$$D_\infty = \lim_{\delta V\to 0} \frac{\log p_{\max}}{\log \delta V} \tag{9}$$

and

$$D_{-\infty} = \lim_{\delta V\to 0} \frac{\log p_{\min}}{\log \delta V} \tag{10}$$

such that $D_{-\infty} \geq D_{\infty}$. In general, if a < b, $D_a \geq D_b$, such that D_q is a monotone non-increasing function of q [7]. For a given time series ("signal"), the function D_q, corresponding to the probability distribution of this signal, is called the fractal spectrum. Such a name is well-justified, because the fractal spectrum provides information about both frequencies and amplitudes of the signal.

This definition of fractal dimension covers a very large family corresponding to different q values. When $q = 0$, it is the Hausdorff-Besicovitch Dimension. When $q = 1$, it is so-called the information dimension; the entropy will become Shannon's entropy. The correlation dimension is the fractal dimension with $q = 2$.

As EEG signals are not stationary traces, but a dynamic and time varying measure, it is necessary to reveal the history of fractal dimension in time. Hence an algorithm is implemented to calculate a time-series dynamic fractal dimension data.

Thus, the introduction of fractal dimension analysis is to change the way of EEG signal analysis from frequency perspective to geometric or pattern-based perspective. The described equation for general fractal dimension model is for a sample set of fixed number of data entities *N,* or can be otherwise called a static model. But in real application, the samples set size would be accumulating all the time to accommodate incoming data. Therefore, we proposed and implemented novel algorithm to handle sample set of growing size or in this sense a dynamic one.

III. Experiments and Results

As human brain is processing in a tremendous speed, the real time EEG signal should be sampled in a reasonably high sampling frequency. In our project, the equipment used for EEG signal recording, called MINDSET24, records 256 EEG samples per second for every single channel. There are 24 channels in total covering the entire skeleton sculp.

We proposed and conducted experiments using different music stimuli. We had series of experiments spiritual (religious), hard rock music, classical music, and hip-hop music. The questionnaire was used to record emotional state of subjects to discover correlation between fractal dimension values and mental state induced by music.

The results of experiments were processed with the implemented dynamic fractal dimension algorithm and were visualized as graph changing over time/frequency. Fractal dimension changing over time can be also visualized with the developed Brain Visualization system. In Fig. 1, fractal dimension values are represented by changing in heights "sticks" showing which channels are active and how active they are during listening music. The subjects investigated in our experiments were the university students, both males and females 22-25 years old.

The results processing confirmed our hypothesis that it is possible to recognize happiness and sadness emotions by computing fractal dimension values. By processing the EEG during experiments it was also proved that fractal dimension model can be used to differ between concentration/relaxation states of the mind.

Hard Rock music showed the biggest fractal dimension values for all subjects throughout the whole experiment. It was also supported by the interview conducted during the experiment that such song gives the most disturbing effect.

The subjects were required to answer the survey questionnaires before and after the experiments.

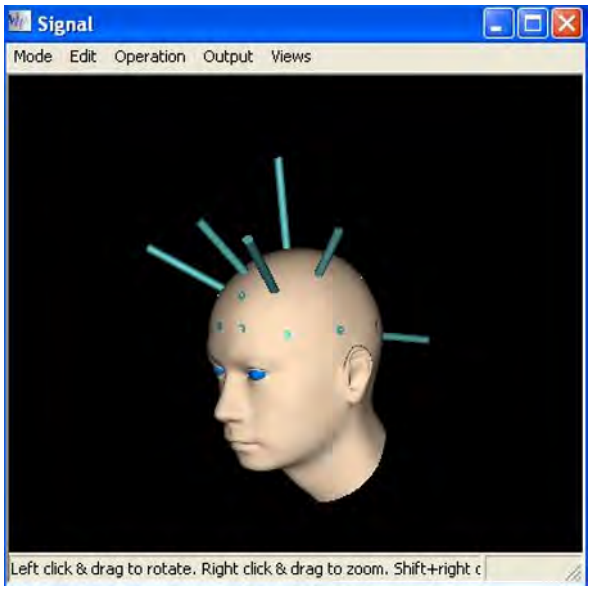

Fig. 1 Visualization of fractal dimension in 6 active channels with VisuBrain

The following questions were asked:

- Do you have any musical background?
- What genre of music do you like to listen?
- What emotion does the music evoke?
- Have you heard the song before?

The subjects were given the memory tests during experiments to assess their level of concentration when they were listening different types of music. The following observations were drawn after processing the results. Subjects generally performed better in the memory test while listening to the songs which induce feeling of happiness. Subjects

have the lowest score when they are listening to songs which they find disturbing or irritating. Jazz song was the most disturbing to the subjects, followed by hard rock song, except for one subject who named hard rock music as favorite. All the subjects indicated that classical songs make them feel happy and comfortable. Music which evoked positive emotions such as happiness, acceptance and pleasantly surprise resulted in subjects scoring better for the memory test. Music which brings negative emotions such as anger and distress generally resulted in the subjects performing their worst in the memory test.

After processing both EEG and survey questionnaires the following hypotheses have been confirmed:

- The subjects' concentration levels will show significant differences among different genres of songs.
- The subjects' EEG responses do not depend on gender of subjects.
- The subjects' EEG responses depend on music familiarity.
- Music which evokes positive emotions will results in better concentration as compared to music evoking negative emotions.
- The subjects' levels of concentration depend on their preferred genre of music.
- The subjects' EEG responses depend on music background of subjects. Subjects that took music clases have higher fractal dimension values in all experiments.

The following hypotheses have not been confirmed:

- Music which brings relaxation will result in the highest level of concentration.
- The subjects perform better on memory test while listening to any music.

Some other hypotheses were inconclusive.

IV. Conclusions

Music stimulus could be used for subject's concentration and to put subjects into different emotional states. In our experiments, the highest level of concentration was evoked by music that evokes positive emotions. Since concentration is relative to emotions, it is therefore reasonable to say that a person's emotional state can influence a person's level of concentration.

In our experiments, it was confirmed that it is possible recognize happiness and sadness emotions by computing fractal dimension values that could be used in development of music therapy applications. We believe that fractal dimension model can be used for quantification of brain responses to develop personally adaptive music therapy program. Further research and experiments should be carried out. The more conclusive results could be achieved in the case of more careful choice of subjects, regarding their musical affinities and cultural background.

This field of research is still relatively new, and there is still much to be done to improve on emotions quantification models and algorithms. The list of basic emotions to be studied should be extended as well.

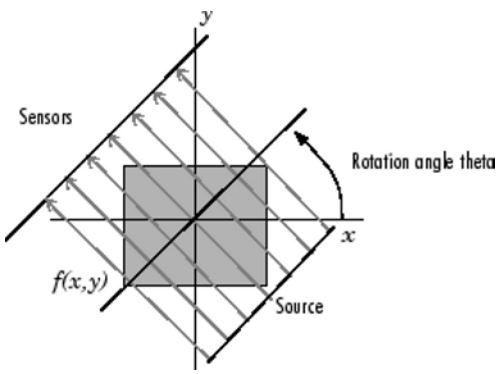
Abstract — **Biometric security systems are becoming more and more predominant these days and are rapidly replacing every other security sytem.Also,these are getting involved in and out of our daily life. In this scenario, these systems are expected to be highly intelligent and sophisticated in nature. Even small errors or mistakes may post huge security threats. This paper addresses the basic problem encountered by fingerprint recognition systems. The problem of inaccuracy caused due to improper placement of the finger on the scanner either intentionally or accidentally is dealt with using this algorithm. The algorithm is developed using the basic concepts of radon transform on the MATLAB platform. A misaligned fingerprint (image) in query is compared with the fingerprints (images) in the database by applying radon transform to correct the angle to match the fingerprints. Different images were tested using this algorithm and satisfactory results have been obtained in most of the cases. Experimental evaluation demonstrates an efficient performance of the proposed algorithm.**

Keywords — **Fingerprints, radon transform, misaligned, matching.**

I. Introduction



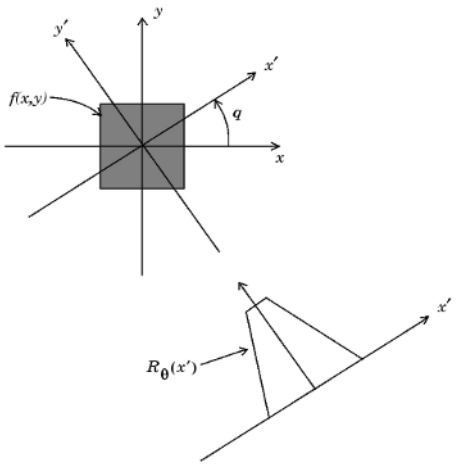
Biometrics can be defined as the study of methods for uniquely recognizing humans based upon one or more of their intrinsic physical(fingerprint, face recognition, iris, retina, palm-print, etc.) or behavioral traits.Biometric authentication has been receiving extensive attention over the past decade with increasing demands in automated and secure identification.

Fingerprint based biometric security systems are the oldest and widely used for authentication purposes because of their universality, uniqueness, performance and acceptability**.** A **fingerprint** is an impression of the friction ridges of all or any part of the finger. A friction ridge is a raised portion of the epidermis of the skin. These ridges are sometimes known as "dermal ridges" or "dermal papillae". The three basic patterns of fingerprint ridges are the arch, loop, and whorl. Traditional fingerprint recognition methods employ feature-based image matching, where minutiae [1] (i.e., ridge ending and ridge bifurcation) are extracted from the fingerprint image in the database and the input fingerprint image in query, followed by their pairings to recognize the valid fingerprint[2]. Even though fingerprint identification techniques are age old, there are still some problems associated with them.[3]

This paper is an attempt to address one such problem which is recognition of misaligned fingerprints using a new approach which makes use of the concepts of radon transforms and bilinear rotations.

II. Radon transform for fingerprints

Radon transform computes projections of an image matrix along specified directions. A projection of a two-dimensional function f(x,y) is a set of line integrals. The *radon* function available in MATLAB computes the line integrals from multiple sources along parallel paths, or beams, in a certain direction[4]. The beams are spaced 1 pixel unit apart. To represent an image, the radon function takes multiple, parallel-beam projections of the image from different angles by rotating the source around the center of the image. The following figure shows a single projection at a specified rotation angle.



Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 415–417, 2009
www.springerlink.com

Projections can be computed along any angle. In general, the Radon transform of f(x,y) is the line integral of f parallel to the y′-axis:

$$R_\theta(x') = \int_{-\infty}^{\infty} f(x'\cos\theta - y'\sin\theta,\ x'\sin\theta + y'\cos\theta)\, dy'$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

The following figure illustrates the geometry of the Radon transform.

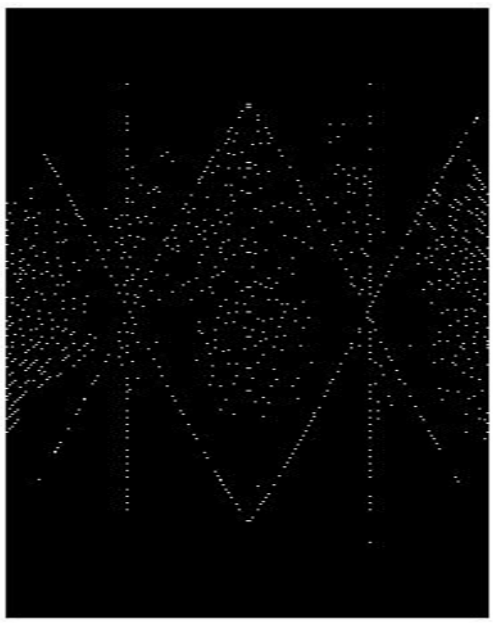
III. Procedure of Implementation

A. Image Rotation

This concept is applied to the original fingerprint and also to the fingerprint in query. The radon projections for the prints are taken in step increases of one degree from 0 to 180 degrees. Here, the main aim is to find out whether the finger print in query is identical to the original fingerprint or not. The image in query is rotated using the *imrotate* command in MATLAB making use of bilinear interpolation[6]. After each rotation the procedure of applying radon transform is repeated.

a. Normal fingerprint

b. Misaligned fingerprint under query

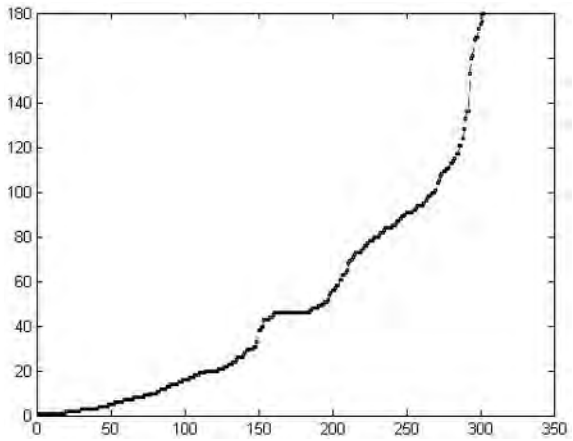


B. Computing the local maxima

As shown above the radon transform is applied on misaligned finger print. The radon coefficients are stored in a matrix. On this matrix we compute the extended-maxima transform, which is the regional maxima of the H-maxima transform. H is a nonnegative scalar.[7]

Regional maxima are connected components of pixels with the same intensity value t, whose external boundary pixels all have a value less than t. all this is implemented using the MATLAB function *imextendedmax (I,H).*

By default, *imextendedmax* in MATLAB uses 8-connected neighborhoods for 2-D images and 26-connected neighborhoods for 3-D images.



On applying this function to the misaligned fingerprint we get the following figure which is an implication of the local maxima points in the fingerprint.[8]

C. Calculating the angle of rotation

The rotation angle of the misaligned finger print, if it matches to that in the database is calculated[9]. This is implemented by taking all the angles of the local maxima points and sorting them in an array in the increasing order to find the smallest angle, which is the angle by which the

finger print is misaligned. We now plot this array to get the following graph which can also be used as a tool for matching the fingerprints.

Same finger prints results in similar graphs. Using the angle measured from this graph the image can be used for re-registration.

IV. Experimental results

The proposed algorithm has been tested with FVC 2000 2 A data base. This database consists of 100 different fingers, with 8 samples per finger, giving a total of 800 fingerprints. Substantial equal error rate(ERR) has been achieved .This algorithm worked well with both high resolution and low resolution images. The algorithm has been implemented in MATLAB v7.0 in a Intel dual core processor-2.99GHz,1gb RAM system and the time taken to achieve correct matching for one sample is around half minute. But still the algorithm is having good efficiency and reliability.

V. Conclusion

A novel technique to align and match two fingerprint images is proposed in this paper. The experiments presented in this paper demonstrate that this approach produces acceptable results even with low resolution images.Currently we are investigating the methods to reduce the time taken by the algorithm by minimizing the number of radon projections. This technique makes the biometric fingerprint detection system more intelligent and highly reliable. This algorithm finds its profound applications in the fields of forensic science, electronic voting machines and many more, where fool proof fingerprint recognition is required.

Abstract — **A novel capacitor-less amplitude demodulation receiver architecture is used in the design of a downlink transceiver for a wireless implantable glucose sensing biosystem. The transceiver system is composed of a high efficiency class E power amplifier utilized as an external transmitter and an implantable data detection receiver, communicating through an inductive link. Amplitude shift keying digital scheme is used to externally modulate the 2 MHz carrier frequency at a data rate of 2 kbps. Transmitter spectral power was measured at 1.51 mW during transmission in air and data was successfully decoded at an effective distance of 3 cm between antennas. Implantable receiver off-chip antenna is implemented using a ferrite core, wire wound coil. A low power, low area consumption implantable receiver module is produced in the research with internal receiver core area measuring at 64.8µm by 55.9µm. Average power dissipation is 1.15 mW at a 3.3V single rail power supply, the lowest to date. Power consumption was measured at both 10 pF and 100 pF load capacitances. Implantable receiver chip was designed and implemented using a TSMC 0.35µm mixed-signal 2P4M 3.3V/5V standard CMOS process.**

Keywords — **Low power, downlink transceiver, implantable systems, glucose sensing, inductive link.**

I. Introduction

Research in micro-dose drug delivery systems and a substantial and increasing diabetic population are pushing the field of implantable electronic devices.

Diabetic patients usually monitor glucose levels by a painful finger pricking process to obtain blood samples. This inefficient and excruciating procedure, especially when administered to aged people and children, has led to developments of glucose sensors that are non invasive or implanted subcutaneously [1].

Several factors have to be considered when designing implantable sensing systems. An implanted system needs an efficient power amplifier to transmit commands to the implanted module. One also needs to consider that magnetic coupling could interfere with the biological signals. Carefully designing the signal acquisition circuitry with high signal to noise ratio is a necessity. Distance and data transmission rate are key factors that affect the entire system architecture.

II. Overall System Architecture

Fig.1 shows the downlink transceiver system, composed of an external transmitter subsystem and an internal data demodulator subsystem. This external module will give command, power and data to the implantable module. This internal unit will recover power, demodulate the data and give command to the internal MCU. The internal module will have an off-chip implantable ferrite core antenna. The internal device receives data through RF telemetry, achieved by the amplitude modulation of the carrier frequency. The telemetry link is a transformer like coupled pair of coils previously used in implantable devices [2] [3].

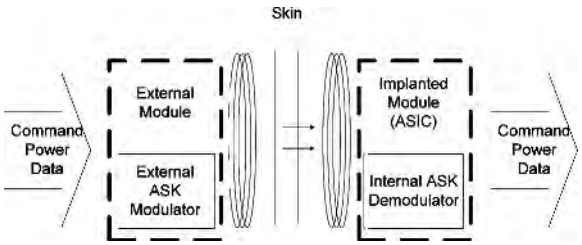

Fig. 1 Downlink transceiver system architecture displaying external and implantable subsystems.

III. Downlink Transceiver Prototype

The class E power amplifier was chosen as transmitter for its high efficiency and simplicity. The specific transmitter schematic used in this paper is shown in Fig. 2. Class E amplifiers, typically can operate at power losses at a factor of 2.3 times smaller compared to conventional class B or C at the same frequency and output power using the same transistor M1. This efficiency in the active device is necessary due to the very low coupling between transmitter and receiver coils with the implanted system receiving less than

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 418–421, 2009
www.springerlink.com

1% of the average emitted RF power. Research showed that RF technology is practical for clinical applications [2][3][4].

Carrier generator was implemented using a 2MHz crystal oscillator circuit. The selection for the 2MHz carrier frequency allows enough power to be transmitted to the receiver without much tissue heating and RF absorption while permitting tolerable miniaturization. The choice of the frequency must consider the attenuation of magnetic field intensity in non magnetic materials such as air and the power absorption of biological tissue with magnetic fields inducing eddy currents. For coil based coupling technique, the received signal is proportional to the transmission frequency; although the power attenuation rate of lower frequencies is less than that of higher frequency EM waves. A lower carrier frequency can produce a slow and detrimental data transmission rate; however a higher frequency can cause excessive heating and damage body tissue. 2 MHz is between hundreds of kilohertz and few megahertz, the suggested range by researchers for implantable devices or bio microsystems [3] [4] [5].

ASK modulation was chosen because it uses the simplest modulation circuitry, therefore implementation complexity is minimized. Acceptable signal to noise ratio (SNR) and modulating index is achievable through proper design. With efficient design, the quality of digital data transmission will be more than sufficient in most applications [6].

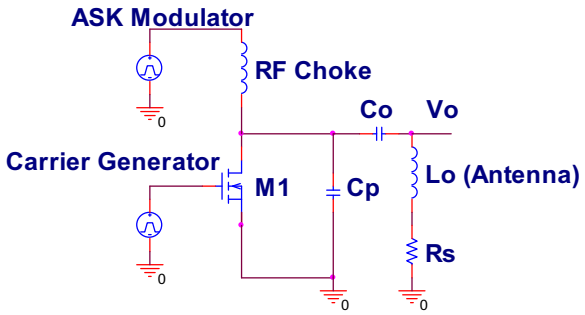

Fig. 2 External ASK modulator (transmitter) prototype schematic.

Fig. 3 shows the transmitter spectral power of 1.8 dBm or 1.51 mW measured at the 2 MHz center frequency. Using the Agilent 3585A Spectrum Analyzer up to a full range of 40 MHz, frequency harmonics were at least 20 dBm lower with respect to center frequency, guaranteeing transmission to be immune to harmonic distortions.

Fig. 4 shows the schematic of the ASK data demodulator circuit and is composed of three main blocks: the envelope detector, high pass filter and Schmitt trigger. The low pass filter (envelope detector) serves to extract the envelope from the 2 MHz carrier. Diode D1 is used to detect the peaks of the envelope while R1 and C1 determine the corner frequency of the detector. The high pass filter is a standard RC circuit composed of R2 and C2 and is necessary to remove the DC offset of the envelope and provide breakdown protection for the CMOS gate inputs of the Schmitt trigger [3].

Table 1 shows parameters for both external and implantable coil: LS–series inductance, LP–parallel inductance,

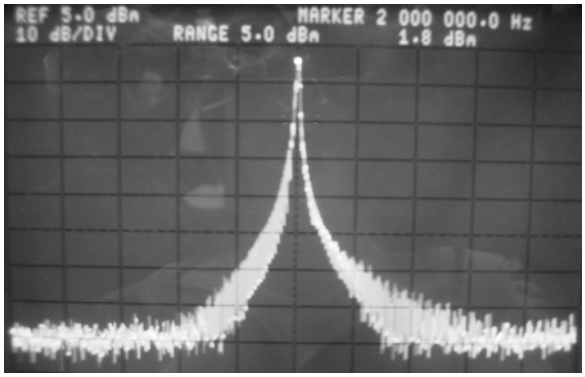

Fig. 3 External transmitter data modulated spectrum taken at 2 MHz center frequency.

CS–series capacitance, CP–parallel capacitance, RS–series resistance, RP–parallel resistance and Q–quality factor. These were measured using the 2-MHz model of Quadtech 7600 LCR meter. Successful data detection was seen at the receiver end of the downlink operation as proven in Fig. 5.

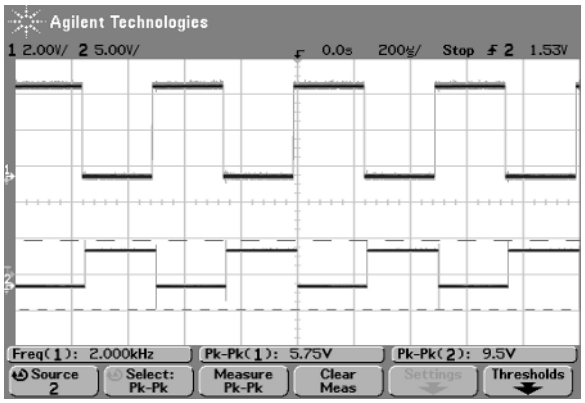

Fig. 5 Data modulating signal input to the class E transmitter (channel 1) and the data as decoded by the internal receiver (channel 2).

IV. Integrated Circuit Implementation

Previous implementations of the implantable receiver make use of passive components which resulted in large chip area consumption. For the integrated circuit implementation, the proposed architecture for the implantable receiver prototype was revised to allow for a smaller design. Actual voltage and noise levels were measured using the downlink transceiver prototype; MATLAB® was used to reconstruct the actual data measures. Ideal input levels were first created, and then a 6dB noise level was added, in accordance to the actual signal received. The reconstructed data was then written out as a SPICE file format VPWL function at a sampling rate of 8 MHz. This VPWL function was used as input stimulus to the transistor level post layout simulation using Hspice®, giving the internal receiver design a much more realistic stimulus than an ideal input [7].

A novel capacitor less internal receiver module in Fig. 6 was developed and largely referenced from [8]. This circuit features an input buffer stage, which effectively eliminates noise levels by forcefully pulling up logic 1 to VDD (3.3V) and logic 0 to GND (0V). Fig. 7 depicts the integrated circuit layout of the capacitor less internal receiver with dimensions of 64.8 µm by 55.9 µm.

The integrated circuit architecture of the internal data receiver is composed of an input buffer, envelope detector, Schmitt trigger and a load driver. Fig. 8 shows simulation results and the signal transformation waveforms as the input signal passes through each stage of data detection.

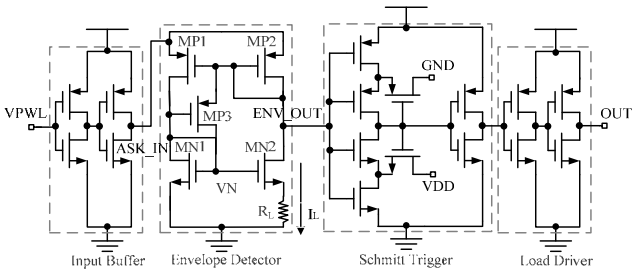

Fig. 6 Internal receiver integrated circuit design schematic.

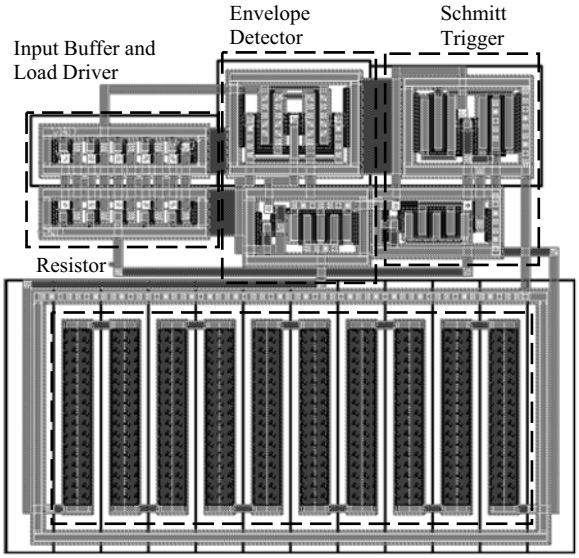

Fig. 7 Internal data receiver chip layout.

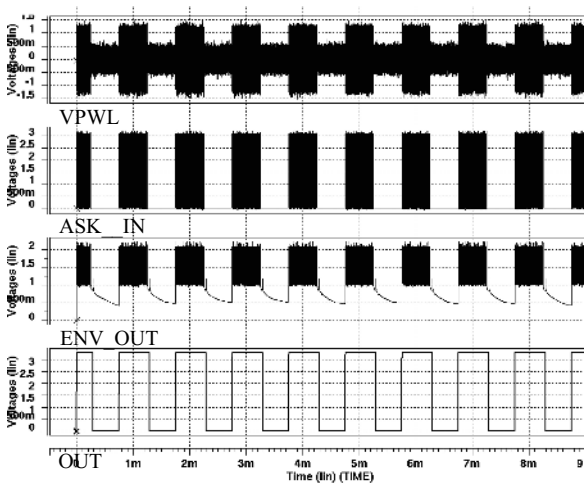

Fig. 8 Simulation results of the input signal as it passes through the different stages of demodulation.

The envelope detector not only extracts the ASK_IN signal envelope but the supply independent bias circuit also locks DC levels. Current through MP2 and MN1 are provided by MP3 upon start up. During envelope detection, PMOS MP3 effectively disappears as it only functions as a start up device. MP2 and MN1 are effectively modelled as diodes with their gates connected to the drain terminals.

The first cycle of envelope detection occurs when VN=ASK_IN-$V_{SD\ (MP1)}$. Initially VN<V_{TN}, so both MN1 and MN2 are cutoff, thus ENV_OUT is 0. As the ASK signal changes from logic "0" to logic "1" and when ASK_IN–ENV_OUT>V_{TP} and VN>V_{TN}, shifting all of MP1, MP2, MN1 and MN2 to saturation. This gives ENV_OUT=$V_{DS\ (MN2)}$ + $I_L \cdot R_L$. Where V_{TN} is the threshold voltage for NMOS, V_{TP} is for PMOS, VN is the gate voltage of both MN1 and MN2, I_L is the current passing through load resistor R_L and ENV_OUT is the output of the envelope detector.

As the ASK signal reverts back from logic high to logic low and if ASK_IN–ENV_OUT<V_{TP} and VN<V_{TN}, forcing MP1, MP2, MN1 and MN2 into cutoff. However ENV_OUT does not entirely go to zero as the Schmitt trigger input gates acts as loading capacitance to the envelope detector block. This gives a characteristic transient curve as the signal exponentially decays to 0V. The load driver, composed of cascaded inverters, serves to increase the signal driving capability of the circuit [8].

Table 2 Internal Receiver Specifications

Receiver Specifications	
Data Rate	2 Kbps
Input Frequency	2 MHz carrier
Input Voltage Level	Low Logic Level: 0.4V~0.6V High Logic Level: 1.1V~1.3V
Demodulator Output Logic Level	Low Logic Level: 0V High Logic Level: 3.3V
Power Supply	Single (3.3V)
Load Capacitance	10 pF, 100pF
Temperature	37
Power Consumption	1.15 mW

V. Results and conclusions

Successful data transmission and detection was exhibited at an effective air distance of 3cm between antenna cores. A discrete component prototype was used as a model for the integrated circuit design. This prototype uses an ASK modulated 2 MHz carrier frequency at a data rate of 2 Kbps. Class E transmitter spectral power was measured at 1.51 mW during transmission. After having measured the actual voltage received at the secondary coil, MATLAB® was used to digitally reconstruct the signal. This reconstructed voltage piece wise linear function was written into an Hspice® compatible file to serve as stimulus to the internal receiver integrated circuit design.

This research has addressed issues of designing biomedical circuits especially for implantable sensing systems. An internal receiver chip with average power consumption of 1.15 mW was developed. Such a low power consumption coupled with a small area, owing to the capacitor less design is ideal for implantable biochips. Furthermore, the design is not specific for glucose sensing, as it is well suited for other biochemical sensing or other implantable chip applications.

Advances in Automatic Sleep Analysis

B. Ahmed and R. Tafreshi

Texas A&M University at Qatar, Doha, Qatar

Abstract — **In this paper we investigate the innovative spectral analysis techniques that have been used in sleep analysis with some success. A comparative analysis of these proposed classification techniques have been presented and the findings discussed. The paper identifies the problems faced in interpreting published results and performs an accurate comparison of different proposed systems. Future strategies to improve the performance of sleep analysis algorithms and novel signal processing tools suitable for sleep analysis are proposed.**

Keywords — **sleep, EEG, automatic sleep analysis, sleep classfication.**

I. Introduction

The electroencephalogram (EEG) is extensively used to study sleep and sleep-related disorders. Research conducted over the past few decades has led to several approaches that identify and classify the various stages of sleep. Polysomnography (PSG), which measures breathing efforts, blood oxygen levels, brain electrical activity (EEG), electrocardiogram (ECG), electrooculogram (EOG), and muscle activity (EMG), is now the main diagnostic tool in sleep medicine.

Normal healthy sleep is organized into sequences of stages that typically cycle every 60-90 min. The R&K sleep scoring rules, proposed by Rechtschaffen & Kales, divided sleep into two phases called rapid eye movement (REM) and non-rapid eye movement (NREM) sleep on the basis of pattern changes in the EEG, EOG, and EMG [1]. The American Academy of Sleep Medicine (AASM) in its recent revision, subdivided NREM sleep into three stages; referred to by N1 through N3 [2].

Sleep researchers have been hindered in understanding the relationship between sleep disorders and other physiological conditions due to the unavailability of an accurate and robust automatic sleep analyzer. Till now data collected from polysomnography is visually screened by a trained sleep technologist that is both time-consuming and expensive. The automatic sleep staging systems commercially available are not reliable, requiring manual validation. These systems are also unable to detect transient events occurring at the microlevel. Clinicians are thus hesitant to take advantage of computerized polysomnography, including the potential capability of these systems; preferring visual classification by a sleep technologist.

II. Automatic sleep staging

The key to any automated sleep monitoring system is the accurate detection of the sleep stages and the microstructure. Sleep staging is based on the idea that a pattern is assumed to exist for a time interval until a new pattern emerges indicating changes in state. Since there is in fact a continuum from light sleep to deep sleep, the artificial demarcation of sleep stages is a simplification implemented to standardize analysis across reviewers and laboratories. The exact time of change of state is highly subjective and leaves room for varying interpretations of transitional epochs by scorers. Studies have shown inter-scorer agreement ranging from 67% to 91% depending on different scoring epoch lengths and number of readers [3]. Most data on inter-scorer agreement are based on the study of normal subjects [4].

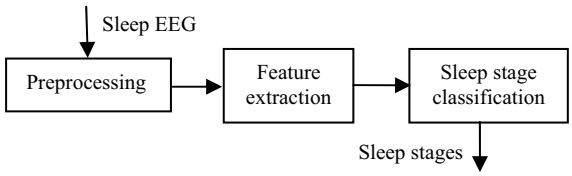

Fig. 1 : Block diagram of automatic sleep classifier

Automatic sleep analysis consists of a number of consecutive steps, as shown in Figure 1. Preprocessing reduces the vast amount of raw data to an amount which can be managed by statistical tools. It also removes artefacts in the EEG signal. Next features such as the amplitude or power of regular EEG waves (alpha, beta, theta and delta waves), in addition to specific patterns such as K-complexes and sleep spindles are extracted. Analysis is performed in short epochs, usually ranging from one to two seconds, to avoid loss of time resolution.

The final stage of the analysis is the combination of the extracted features and waveforms to a limited number of sleep stages. Rule-based logics are used to classify stages based upon features extracted from the EEG, which imitate visual inspection according to standards, such as the R&K and AASM rules. In systems used for clinical purposes the final results of the automatic sleep scoring have to come close to a visual AASM scoring. Most published studies on automatic sleep classifiers compare results from healthy subjects, with reliabilities between 70-90% [5].

www.springerlink.com

Some characteristic waves in sleep EEG which provide clues to the sleep stages are short-term and appear sporadically in the background waves. A method to detect them must, therefore, be able to take a large view of the EEG and recognize these isolated characteristic waves. However, most conventional techniques for diagnosing the sleep stages are based on long term spectral analysis and consequently not suited for detecting such transient characteristic waves.

III. Signal processing tools used

During the last few decades, different EEG signal processing techniques have been applied to develop an automated sleep stage classification system. Because the EEG, like other biological signals, is highly non-stationary, there have been limits to the information that can be obtained from simple spectral estimation techniques like the fast Fourier transform (FFT), leading to the use of more complex time-frequency analysis techniques.

A. Feature Extraction

Innovative spectral analysis techniques are being applied to the sleep EEG for sleep staging with some success. Features such as the normalized amplitude of frequency bands [6, 7] features derived from the autoregression and linear predictor coefficients, harmonic parameters, parameters of Hjorth sub-band energies [8] have all been used to identify the stages in sleep EEG on an epoch to epoch basis. An advantage of frequency measures is that they are not affected by the age- and gender-dependent EEG changes. They thus provide a uniform feature that requires minimal tailoring to specific cases. However as the frequency bands used are generally fixed, they can lead to misleading results in epochs with activity due to more than one characteristic waves.

Due to the non-stationary nature of the EEG signal, decomposition using time frequency analysis has become popular in automatic sleep stage classification. The discrete wavelet transform, matching pursuit, Gabor transform and the wavelet transform modulus maxima have all been used to characterize the sleep stages [9, 10]. As the EEG signal stems from a highly non-linear system, non-linear dynamic methods such as chaos theory and multifractal analysis have been also applied to derive EEG features [11, 12]. As it is difficult to adapt these features, these techniques are not completely successful in epochs with ambiguous properties due to the presence of multiple superimposed waves.

The choice of features in most systems is generally made based on heuristic reasons. To compensate, most systems use multiple features; each targeting different characteristic waves present in the sleep EEG, e.g. alpha, beta, slow wave sleep, sleep spindles and K-complexes. There is no analysis which compares the performance of all these features to verify their actual effectiveness in sleep classification.

B. Classification

A significant amount of work has been done in developing sleep staging systems based on linear and nonlinear classifiers, specifically artificial neural network (ANN) classifiers and fuzzy logic. This is because they do not require any classification rules, or complex domain knowledge. Neural networks have a learning ability that enables them to form their own structure based on training instances. This allows them more flexibility with differences in experts or subjects.

The sleep staging process has been modeled with different types of ANNs; such as a finite state machine [13], hybrid neuro-fuzzy system [14, 15], and feed-forward multilayer neural network [16-18]. Decision tree learning [19] and support vector machines (SVM) [20] have also been utilized in sleep classification.

However systems based on ANNs have problems as the R&K scoring rules are mainly based on marking events such as sleep spindles, K-complexes, rapid eye movement and slow delta waves rather than background signal activities. If no marking events are found in the sleep epochs, then the R&K rules apply smoothing to these epochs. This reduces the performance of neural network based systems as they are not event driven detectors. This has led to systems using rule-based systems for event detection which are being supported with neural network based classifiers.

Most of the methods discussed try to mimic the R&K rules, but run into problems as they are unable to take advantage of the additional information that can be extracted using signal processing tools. Adaptive systems, introduced now, allow the classes to develop intrinsically, based on the patterns present in the signal. Most of these systems use clustering and other modeling techniques to differentiate the signal into distinct classes. Feature extraction is separated from clustering to improve efficiency, and can even be done while recording. This allows repeated applications of the clustering process without repeating the segmentation and feature extraction, thus reducing the computational load of the system.

Separation of the sleep classes has been performed using repeated k-means clustering on sleep-related features extracted from EEG segments [4, 12, 21, 22], principal component analysis to develop 2D density plots [23] and Hidden Markov Models (HMM) to model the sleep stages as a mixture of different processes [24].

Table 1 Comparison table of sleep staging methods with testing results

Authors	features	classfier	subjects	accuracy
Vivaldi (2006)	PCA of spectum of subbands	clustering	1 healthy	
Saastamoinen (2006)	amplitude spectrum of subbands	rule based	1 healthy & 1 sleep apnea	
Huuponen (2003)	amplitude spectrum of subbands	rule-based	15 healthy	
Agarwal (2001)	amplitude, dominant frequency, FEW, spindles, theta-slow-wave index	clustering	12 healthy subjects	76.80%
Chao (2006)	FEW, NLEO, wavelet coefficients	adaptive clustering	1 healthy	
Schwaibold (2001)	periodic activity, spindles, K-complexes	ANN	8 OSA patients	31.5%-87.4%
Van Hese (2001)	Hjorth & harmonic parameters, relative band energy	clustering	1 healthy	
Hanaoka (2002)	zero-crossing, wave period, amplitude, duration, transient events	decision tree learning		40%-91.8%
Estrada (2004)	autoregression coefficients, harmonic parameters, Itakura distance	rule based		
Flexer (2002)	reflection coefficients, stochastic complexity	HMM	20 healthy	68%-82%
McGrogan (2001)	reflection coefficients	ANN	9 healthy, 3 disturbed	72.2%, 96%
Li (2005)	parameters from wavelet coefficients	rule-based	1 subject	
Song (2007)	wavelet transform modulus maxima	rule based		55.4%-97.7%
Ma (2005)	wavelet transform modulus maxima		6 subjects	
Ma (2006)	zerocrossing, signal asymmetry	multifractal analysis	4 subjects	
Kaplan (2001)	segmentation	clustering		
Huang (2003)	Lempel-Ziv complexity measure	ANN	6 healthy	90.83%
Gudmundsson (2005)	Hjorth parameters, power spectrum, amplitude and frequency distribution	SVM, ANN		81%
Kim (2000)	Frequency, chaos measures	ANN		
Principe (1989)	frequency band, spindle, K-complex	fuzzy logic	5 healthy	84.74%
Park (2000)	frequency band, LPC coefficients	ANN & rule-based	2 healthy	62.6%-95.4%

The high degree of adaptability to individual subject behavior afforded by clustering systems is attractive; however it does not guarantee a classification in accordance with AASM rules. It is possible for clustering to not identify all the relevant patterns and also introduce irrelevant patterns.

It is difficult to compare the performance of different proposed systems due to the lack of standardized uniform assessment criteria or a gold standard. The results presented in literature are usually highly individualistic and subjective as seen in Table 1; hence the quoted level of agreement between automatic systems and manual scoring cannot be generalized. Furthermore, most of the systems are developed using limited subject data and are generally restricted to healthy subjects. This leaves the performance of these systems open to interpretation when used on patients suffering from a range of disorders.

IV. Limitations in current systems

In spite of the extensive research aimed at automating sleep analysis, no standardized sleep analysis system has emerged with widespread acceptance in clinical settings. The performance of these systems is limited in situations which cannot be described by existing scoring rules and those with no marking events.

The limitations of the R&K rules, which were initially intended for use only as a reference, are well documented [25]. These rules are based on empirical observations of only young normal subjects and neglect the less understood micro-structure of sleep. These rules are not reliable for a robust and accurate computer analysis. Very little work has been done on understanding how the sleep structure changes in the wide range of disorders suffered. These are partly due to the high degree of variability between different EEGs leaving much room for subjective interpretation. There is a need for techniques which adapt to differences in subjects' physiological measures. They must take into account the considerable variability of data, both intra and inter-individual, and the inherent stochastic nature of the EEG.

Due to the absence of a wide training dataset in which includes subjects suffering from a range of disorders, their performance is accurate only in a subset of people. These algorithms are limited in their adaptability due to strong

inter-patient variability, which occur specifically due to artifacts in patients of different pathological conditions.

There is also limited published information on their reliability, with most of the studies using data collected from healthy subjects. There is limited clinical validation of these systems, specifically on patients with different disorders. Proposed improved sleep scoring systems must perform more reliably than that achieved through visual classification based on the new AASM scoring rules [2, 26].

There are still many unanswered questions about the microstructure of sleep which must be answered before automatic scoring can be successful. Part of the problem is due to the rigid epoch size used [27]. Epochs during transition phases have characteristics of at least two stages. Adaptive segmentation could increase the temporal resolution where errors often occur and increase inter-rater and man/machine agreements. However as sleep EEG typically consists of a number of superimposed phenomena, it might be necessary to use two different simultaneous epoch lengths to analyze the micro- and macro-structure of the signal.

There is also concern that these systems have developed in the absence of any professionally endorsed and uniform standards [28]. The strong dependence of clinicians on scoring rules has forced developers to design systems following these rules. This has compromised the quality of these systems and limited the information that they can provide. There is a need for clinicians and engineers to join forces and develop joint guidelines and performance criteria for automated sleep analysis systems.

Early Cancer Diagnosis by Image Processing Sensors Measuring the Conductive or Radiative Heat

G. Gavriloaia[1], A.M. Ghemigian[2] and A.E. Hurduc[3]

[1]University of Pitesti/Electronic and Computing Department, Pitesti, Romania
[2]Endocronological Institute of Bucharest, Bucharest, Romania
[3] Oncological Institute of Bucharest, Bucharest, Romania

Abstract — **The heat is one of the most important parameters of living beings. The tissues heat, generated at normal or diseases states, is lost to environment through several mechanisms: radiation, conduction, convection, evaporation, etc. Skin temperature is not the same on the entire body and a thermal body signature can be got. The temperature of neoplasic tissue is different up to 1.5 ^{0}C than the healthy tissue as a result of the specific metabolic rate. The infrared camera images show the heat transferred by radiation very quickly. A lot of factors disturb the conversion temperature-pixel intensity. A very sensitive sensor, a video camera showing its spatial position and a special computer fusion program were used for early cancer diagnosis.**

By using the high resolution maps, the diagnosis for about 78.4% of patients with thyroid cancer, and more than 89.6% from patients with breast cancer were right.

Keywords — **Bioheat, thermal imaging, cancer, radiation or conductive heat**

I. Introduction

Humans and animals in general, are usually in a thermal steady state with respect to their surroundings. The heat is one of the most important parameters of living beings. All our common activities rely on energy cost. Sleeping, for instance, needs 35 cal/m2 hr, and running 600 cal/m2 hr [1]. Approximately 80% of these costs are given by waste heat. Thermal physiology describes all body functions related to thermal energy given to or removed from a living body. Therefore, the body needs a temperature regulation, which keeps the temperature on a constant level, about 37 ^{0}C. There is equilibrium between outside of body and skin temperature. The sympathetic nerve fibers are involved in temperature regulation, and this is the autonomic nerve system function, it is a non-voluntary control. As a result of different situations, the core temperature may be increase (hyperthermia) or decrease (hypothermia). The skin temperature and the core temperature determine the regulation process [2], [3]. The temperature distribution on the human skin gives a thermal image, a thermal pattern of the body, with highly symmetrically distributed related to a symmetry axis situated in the median plane of the human body. In many situations, this pattern is not symmetric and hyperthermic or hypothermic areas appear. There is a strong link between these thermographic changes and diseases. Hyperthermic or hypothermic skin areas may be caused by increased or decrease blood flow, tumors, inflammation process, etc. Tumor vascularity particularly played a fundamental role in promoting cancer growth, invasion, and metastasis [1], [4]. Solid tumors rely on blood vessels to obtain necessary nutrients and oxygen [5]. New vessels also offer path way for tumor expansion; therefore, increase the opportunity for tumor cells to enter the blood or lymph circulation. Rapid and noninvasive imaging techniques may be a better alternative for assessing tumor vascularity. In medical applications, infrared imaging can produce reliable and valid results and it is based on the physics of heat radiation or conduction and the physiology of thermoregulation of the human body.

The final aim of the research is to find some clues in order to get an early cancer diagnosis. As a result of angiogenesis process, the skin projection of the certain tumors modifies the local area temperature. The temperature can be measured by many means: contact thermocouples, non-contact infrared thermocouples, resistance temperature detectors, thermistors, liquid crystal sensors, and microbolometers. All of them have advantages and disadvantages concerning to this medical application. The thermistor sensor is the cheapest and IR camera with microbolometres is the most expensive sensor. The problem, we are looking for, is in what way the measurement results by the two sensors are the same. The heat, generated in the region of interest, is spreaded through several mechanisms: radiation, conduction, convection, evaporation, breathing, etc. The contact thermistor sensor uses the conduction component of this mechanism, and IR camera, radiation one. Some aspects have to be taking in consideration. The thermistor sensor measures the heat with an infinite range of wavelengths, from theoretical point of view, and IR camera on 8-14 microns only. Human skin temperature is the product of heat dissipated from the vessels and organs within the body, and the effect of the environmental factors on heat loss or gain. There are a number of further influences which are controllable, such as cosmetics, alcohol intake or smok-

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 427–430, 2009
www.springerlink.com

ing. The radiated heat depends on a lot of parameters: skin emissivity, environment between cameras and the investigated area, other heat sources, etc. So, do the results reflect the same situation when the measurements are made by thermistor or IR camera?

II. Materials and Methods

The heat transfer by conduction from skin gives information more appropriate to reality and can be used to early cancer diagnosis, but up to now, only point temperature measurement has done. We used a very sensitive sensor, 0.04 ^{0}C temperature resolution, and a video camera showing the sensor spatial position. A special computer program was created for sensor and video camera data fusion. The investigated surface and a red circle showing the sensor position are displayed. When the successive temperatures values are appropriated, the circle becomes green. The temperature sensor is moved on the region of interest and a green patch appears. A computer program using the spatial adaptive spline functions assures 0.5 mm spatial resolution. The IR camera has about 1-3 mm spatial resolution and 0.1^{0}C as a temperature resolution of one microbolometer from the focal plane array.

From spectral point of view, the thermistor sensor covers almost entire frequencies range but IR camera 8-14 microns only. The amount of radiation energy E_o, emitted by a blackbody at an absolute temperature T, per unit time, per unit area of surface, per unit wavelength λ, is given by Planck's law, [6]:

$$E_\lambda = \varepsilon_\lambda E_{\lambda o} = \frac{\varepsilon_\lambda c_1}{\lambda^5\left[\exp\left(\frac{c_2}{\lambda T}\right)-1\right]} \tag{1}$$

where

$c_1 = 3.74310^8 \ \frac{watt\ \mu m}{m^2}$, $c_2 = 1.4387 \mu m K$, and ε_λ is the spectral hemispherical emittance [7]. On Fig. 1 is shown radiated energy for biomedical range, 32^{0}C – 40^{0}C. For entire temperature range, the blackbody emissive power is:

$$E_o = \int_0^\infty E_{\lambda o} d\lambda = \sigma T^4 \tag{2}$$

where $\sigma = 5.6710^{-8} \ \frac{watt}{m^2 K^4}$ Stefan-Boltzman constant.

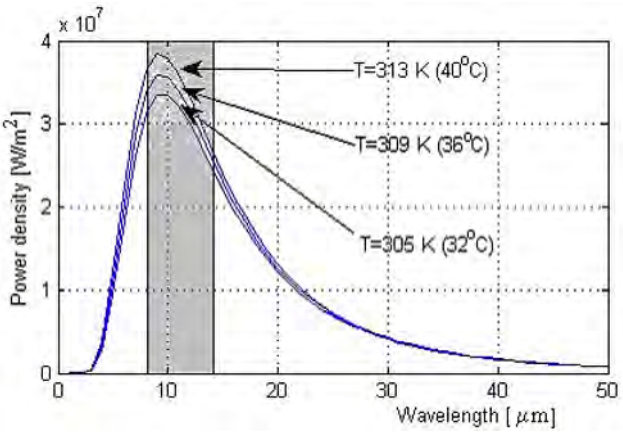

Fig. 1 The radiated energy versus medical temperature range

IR camera operates on a part of this spectrum, so we need to determine the fraction f_{12} of blackbody emissive power between two wavelengths by integration of Equation (1) and division by Equation (2):

$$f_{12} = \frac{\int_{\lambda_1}^{\lambda_2} \frac{c_1}{\lambda^5\left[\exp\left(\frac{c_2}{\lambda T}\right)-1\right]} d\lambda}{sT^4} \tag{3}$$

The fraction of blackbody emissive power on 8-14 microns band is about 6.5%, and this thing means the thermistor sensor gives more information about temperature. Its main disadvantage is concerning to large rise time, more than 2 s, but for our application it doesn't matter because the investigated skin area is at the steady state.

In this paper three sensors: video and IR cameras and a 2.5 mm diameter thermistor were used:.

The air temperature in the room used for thermal imaging was at about 22°C during the measurement process, [3], [8], [9]. The time required to achieve the adequate values from thermistor was 15 minutes.

III. Results

On the Fig. 2 an infrared image of a patient suffering of thyroid cancer is depicted. The abnormal thyroid aria, a rectangular one, is selected as region of interest, ROI. Most of the temperature pixels show values about 1.5 ^{0}C smaller than neighboring skin surfaces. The ROI temperature is measured by a microbolometer focal plane array. The microbolometers are very sensitive, but don't have the same characteristics. As a result, two adjacent microbolometers

give different results, about 0.1^0C, for two adjacent regions of the investigation object, and it is seen as a small noise. On the Fig. 3, the out signal of a horizontal line from the infrared camera is shown.

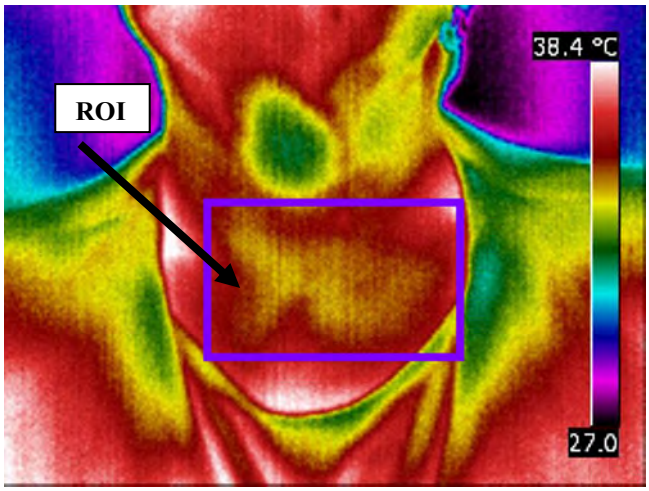

Fig. 2 IR image of a patient with cancer thyroid

In order to reduce this kind of noise a single sensor was used. The association between the sensor position on the patient skin and its temperature values is obtained by a data fusion computer program.

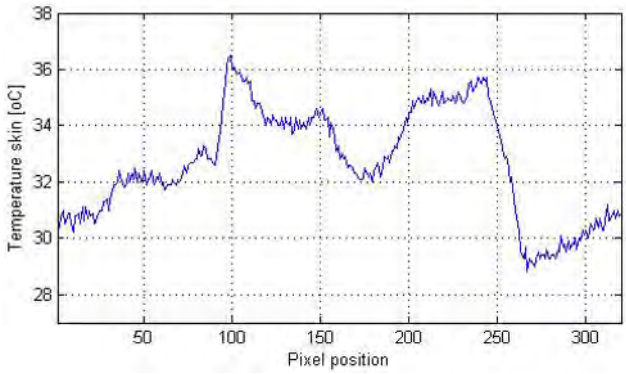

Fig. 3 The output signal from a micobolometer line of an IR camera

The temperature map of ROI, evaluated by the thermistor with 0.04^0C temperature resolution is shown on Fig. 4. Its spatial position was processed with a computer program using the spatial adaptive spline functions, assuring 0.5 mm as spatial resolution. The neoplasic tissue has a better contour.By looking on Fig. 5, a nonhomogenous thyroid aria can be seen. The 3D image shows many small warmer regions on The ROI, as a result nonuniform cell multiplications.

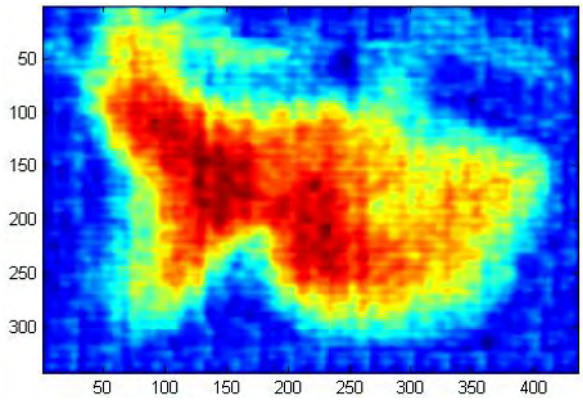

Fig. 4 The temperature map of ROI, the 2D case

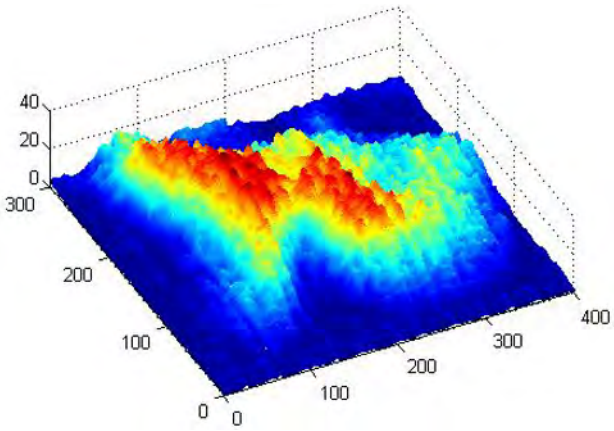

Fig. 5 The temperature map of ROI, the 3D case

Fig. 6 IR image of a patient with thyroid disorders but no cancer

The method was tested on patients with thyroid or breast cancer. On the maps of high resolution temperature, the ABCD (asymmetry, border, color, and differential structure)

method gives good results, [4]. On the Fig 3 and 4 the strong asymmetry and irregular border can be seen. Other patient, who suffers of thyroid disorders, but no cancer, the two lobes have a regular contour and the same shape.

A data base, containing 100 temperature maps for healthy people, was created before. As a result of direct comparison, the diagnoses were right for about 78.4% of patients with thyroid cancer and more than 89.6% from patients with breast cancer.

IV. Conclusions

A cheaper method for thyroid and breast cancer diagnosis was described. Rapid and noninvasive imaging techniques may be a better alternative for assessing the neoplasic tissue. The sensor, a quick thermistor, measures the radiative heat of the human skin and gives data for a map of ROI with high resolution temperatures. The map is generated by a computer program using data fusion and the spatial adaptive spline functions. The map of high resolution temperatures gives the possibility to do an early diagnosis by looking at the irregular shape of ROI and its structure. The results are pretty good and they can be improved in next future by the fractal analysis.

Abstract — **Aim: The study aimed to record and analyse saccadic eye movements of epileptic patients. The specific purpose was to determine and compare saccadic parameters of normal subjects with those of age-matched epileptic patients. The selected parameters were saccadic duration, latency, peak saccadic velocity and the main sequence relationship. Any possible relationship between these parameters and severity of epilepsy was also examined.**

Methodology: A microcontroller-based saccadic diagnostic system was indigenously designed and developed for the above purpose. It was used to elicit, record and analyse around 80 saccadic eye movement recordings from 53 normal subjects for a visual angle range of -60^0 to $+60^0$. These data have been analysed and the saccadic parameters were determined using MATLAB 2007. Saccadic detection was done using amplitude threshold and velocity threshold techniques and the results were compared. Saccadic eye movement data from 14 epileptics have been recorded. Saccadic parameters in respect of these data was calculated. Data collection from some more epileptics is under progress.

Salient results: The system was tested successfully on human subjects and its performance was found satisfactory as per the design requirements with a good feedback from the medical personnel who are presently using it.

Analysis of data collected revealed that the amplitude threshold technique was more efficient to detect a saccade in 97% determinations. The saccadic parameters and their relationships for normal subjects were found to be in good agreement with those reported in literature. The saccadic parameters showed a change in epileptics.

Conclusions and significance: Our saccadic diagnostic system could be of immense help to those working in the field of saccadic studies due to its simplicity, portability, ease of use and user-friendly features. Additional data to be collected from epileptics and similarly treated will provide concrete and meaningful information diagnosis.

Keywords — **Saccadic eye movements, saccadic stimulator, saccadic duration, skewness, peak saccadic velocity.**

I. Introduction

Measurement of eye movements plays a significant role in many areas of neurological and oculomotor research. There are different types of eye movements, namely, saccadic, smooth pursuit, vergence, and vestibulo ocular movements, associated with varying visual functions. Many techniques like electrooculography (EOG), photoelectric oculography have been developed over the past 30 years for tracking eye movements. These methods vary greatly in their resolution, range, and tolerance to head motion, ease of use, invasiveness, and cost [1]. Saccades are fast movements of the eyes, which are employed to position the images of objects of interest onto the fovea and have been studied. The motivation for using the Electrooculography (EOG) method in this study was to develop an unobtrusive, inexpensive and non-invasive way of recording saccadic eye movements with clinically acceptable accuracy.

Electrooculography is based on recording the potential between the cornea and the retina. This potential, in the range of 0.4 to 1.0mV is considered to be a result of a steady electrical dipole with a negative pole at the retina and a positive pole at the cornea. Surface recording electrodes are typically placed on the skin close to the eyes in horizontal and vertical planes to pick up the potential. The relationship between EOG output and horizontal angle of gaze is approximately linear for $\pm 30^0$ of eye movement. Through careful calibration, horizontal eye movements can be measured with a resolution of 1^0.

An attempt to quantitatively assess the saccadic movements of epileptics as compared with normal subjects is done in this study. The assessment is done in terms of the comparison of the saccadic parameters namely, saccadic duration, skewness, signal amplitude and peak saccadic velocity. Some changes in the saccadic parameters and their characteristics were observed in case of epileptic subjects.

II. Materials and Methods

The major subsystems of the saccadic diagnostic system [2] include the saccadic stimulator, EOG signal conditioner, RCM 3710-based data acquisition system and the Personal Computer-based analysis system as shown in figure 1.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 431–434, 2009
www.springerlink.com

Saccadic Stimulator

Each type of eye movement requires a specific stimulus [3]. A saccadic stimulator, designed and built around the microcontroller PIC 18F452, generates visual stimuli for triggering horizontal saccadic movements [4]. LEDs lit in various specific or random sequences from an array of LEDs stimulate eye movements of various angles.

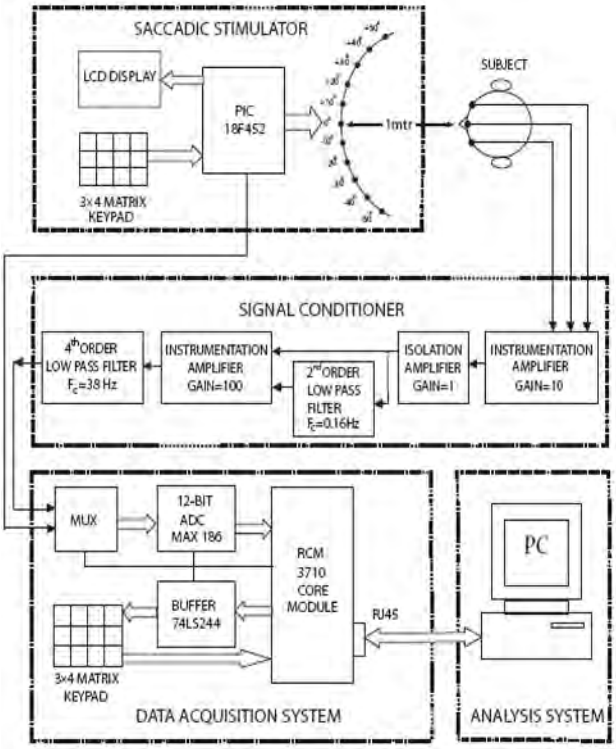

Fig. 1. Block diagram of the saccadic diagnostic system

Thirteen LEDs are mounted on a curvilinear wooden board of 1m radius subtending an angle of 120^0 at its centre. The array of lights is arranged in a horizontal plane covering a visual angle of $\pm 60^0$ in steps of $+10^0$. The distance between any two adjacent LEDs is about 17.5cm. Subject sits at a distance of 1m from the LED board. The stimulator consists of PIC 18F452 microcontroller, a 3X4 matrix keyboard and a 16X2 LCD module. PIC 18F452 controls the lighting sequence and duration of the LEDs through input/output ports configured as digital output lines, in accordance with the test selected by the user.

Signal Conditioner

The signal conditioner amplifies the EOG signal picked up by surface electrodes without significant distortion and is not affected by external noise/interference. The conventional EOG amplifiers suffer from DC drifts that result in amplifier saturation [5,6]. The designed system overcomes this problem by incorporating DC drift removal circuit. The other modules are Preamplifier, Isolation Amplifier, Voltage Amplifier and Low pass filter.

Preamplifier: The preamplifier is built around the instrumentation amplifier INA114 with high input impedance, good CMRR and excellent accuracy. This stage provides a gain of 10 and suitably raises the signal amplitude for isolation and subsequent analog processing.

Isolation amplifier: The electrical isolation of the subject is achieved by the isolation amplifier, ISO122 and a DC-DC converter combination to protect the subject from leakage currents.

DC drift removal circuit and Voltage amplifier: A second order low pass filter with a cut off frequency of 0.16 Hz is connected as shown in figure 1. The output of this filter consists of the low frequency DC drift components of the signal being amplified. It is continuously subtracted from the original signal using another instrumentation amplifier (INA114). This technique successfully eliminates the DC drift from the EOG signal. A gain of 100 is provided by this stage.

Low pass filter: The final stage of the signal conditioner is a fourth order Butterworth low pass filter with a cut off frequency of 38Hz. This filter minimizes out of band noise and reduces power line interference and unwanted EMG and EEG interference.

Data Acquisition System

The conditioned EOG signal from the signal conditioner and the sync signal from the saccadic stimulator are fed to the Rabbit core module through a multiplexer, which facilitates the channel selection. Analog signal from the selected channel is converted into digital form by an analog-to-digital converter MAX 186. The digital values are stored in the RAM of the core module. Acquisition parameters like sampling frequency, number of channels, input voltage range are set from the matrix keyboard. The program run by Rabbit core module is developed in Dynamic C. The data are subsequently transferred to the PC through LAN interface.

Experimental Procedure

EOG recordings from 53 normal and 14 epileptic subjects were collected at the department of Clinical Pharmacology & Therapeutics, Nizam's Institute of Medical Sciences, Hyderabad, India. All the subjects had normal or corrected-to-normal vision. Recordings were obtained in a

uniformly/adequately lit room in a noise-free environment with controlled temperature, to avoid distraction and increase the comfort level of the subject. Each subject was made to sit in a comfortable chair with height adjustment arrangement.

Two electrodes are placed on the left and right external canthi of the subject, to pick up the EOG signal. A ground electrode is placed on the middle of the forehead. A chin-rest is used to restrict the subject's head movement during recording. The height of the subject's chair was adjusted to ensure that the subject's eyes were in visual alignment with the stimulator. The subject was asked to look at the glowing LED, without moving the head. The saccadic stimulus pattern was then presented. When the subject looks at the glowing LEDs, EOG signal was acquired by the electrodes, processed in the signal conditioner and acquired by the data acquisition system. Then the digitized signal is further processed and the results are displayed on the PC.

III. Results and Discussions

The EOG data collected was first smoothened using the 3-point moving average technique. The saccades are then detected using the amplitude threshold technique, as this technique yielded better results compared to the velocity threshold technique. For the data collected from the normal and the epileptic subjects so far, the saccadic parameters namely, saccadic duration, skewness, signal amplitude and peak saccadic velocity were computed and compared.

Saccadic duration: Saccadic duration is the time taken to complete a saccade, that is, till the target is focused upon.

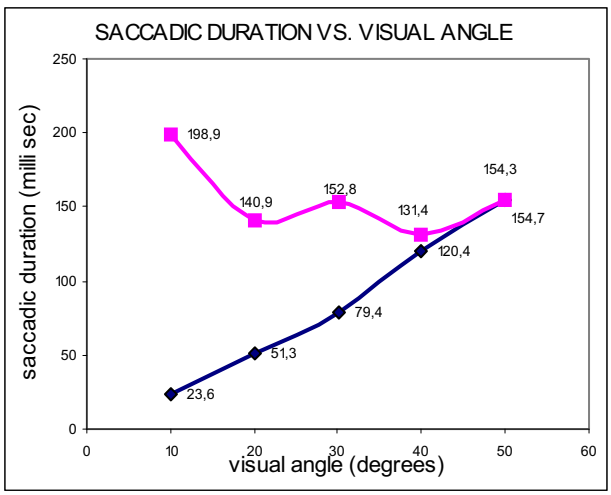

Fig. 2. Saccadic duration vs. visual angle for normal (lower graph) and epileptic (upper graph) subjects

As reported in literature [7], the saccadic duration for the normal subjects increased linearly with the visual angle (Figure 2, lower graph).

Skewness: Skewness, a measure of asymmetry of the saccadic profile, is taken as the ratio of the acceleration duration to the saccadic duration. Acceleration duration is the time lapse between the beginning of the saccade to the instant of peak velocity. The skewness values were quite different for normal and epileptic subjects as can be seen from Figure 3. The skewness showed a peak at a visual angle of 30^0 for the normal subjects (minimum 0.18 and maximum 0.85). But the variation for epileptic subjects was very less (minimum 0.27 and maximum 0.47).

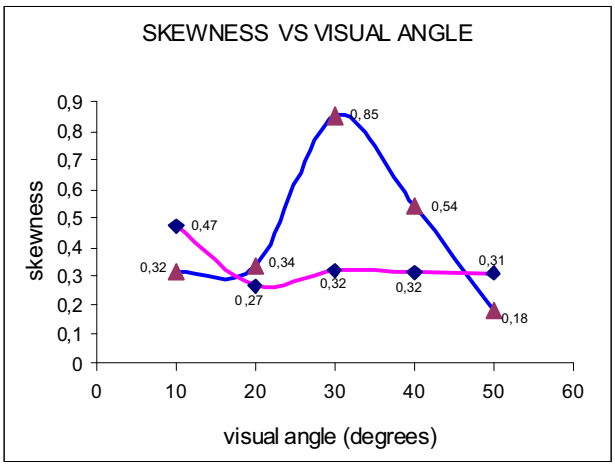

Fig. 3. Skewness vs. visual angle for normal (upper graph) and epileptic (lower graph) subjects

Signal amplitude: The signal amplitude is calculated as the difference between the amplitudes at the starting and the ending of the saccade. The mean of this parameter showed an almost linear increase with visual angle in both cases as can be seen from Table 1. The mean signal amplitude of epileptic subjects was observed to be higher than that of normal subjects.

Table 1 Mean signal amplitude of normal and epileptic subjects at various visual angles

S.No.	Visual angle	Mean signal amplitude (micro volts)	
		Normal subjects	Epileptic subjects
1	10	54.6	96.8
2	20	101.4	144.6
3	30	147.2	199.1
4	40	185.7	260.4
5	50	207.7	315.2

Peak saccadic velocity: The EOG data collected, which represents the eye position signal, is differentiated to yield saccadic velocity. Saccadic velocity is defined as the rate at which saccadic movement occurs.

For each visual angle, the mean peak velocity of each subject is determined from the velocity profile. The peak velocity at each visual angle is plotted as shown in Figure 4.

The peak velocity for normal and epileptic subjects showed a similar characteristic and it increased non-linearly with visual angle.

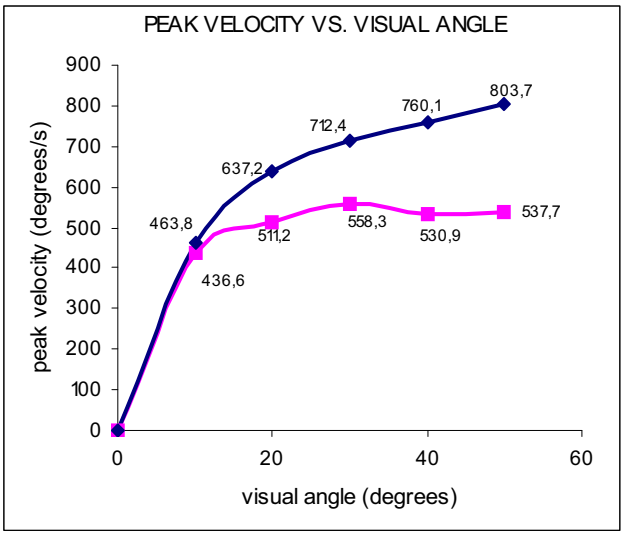

Fig. 4. Peak saccadic velocity vs. visual angle for normal (lower graph) and epileptic (upper graph) subjects

IV. Conclusions

A saccadic diagnostic system has been indigenously designed and developed for saccadic data acquisition and analysis. Its performance is found to be satisfactory and met the design specifications. The system is found to be reliable and user-friendly according to the feedback from the medical personnel. Saccadic parameters have been successfully extracted from the data collected from normal and epileptic subjects. The preliminary analysis showed that the saccadic parameters of normal and epileptic subjects are found to significantly different. More data from epileptic subjects is being collected to explore and possibly establish any relationship between the saccadic parameters and the severity of epilepsy.

Abstract — **The purpose of this study is to propose the ultrasonic-imaging guided focused ultrasound induced blood-brain barrier (BBB) disruption system design. This system comprises of a 270-kHz, 80-channel hemispherical ultrasound phased array, RF power amplifier, animal holder, and a clinical used ultrasound imager. Before animal treatment, we propose to use high-precision hydrophone and ultrasound imager coordinate transformation to achieve the alignment, focused ultrasound guidance, and treatment position targeting. During the treatment, Forty Sprague-Dawley rats were sonicated, and burst-mode ultrasonic energy was delivered in the presence of micro bubbles injected IV to disrupt the BBB. All Rats were skull-intact during the sonication, and different power output and duration durations were tested. Evans Blue dye was serves as an indicator to verify the BBB disruption in gross animal sectioning, and hematoxylin and eosin (H&E) staining was conducted for brain tissue damage analysis. Results showed that the designed hemispherical multiple channel phased array system under the ultrasonic imaging guidance can successfully disrupt BBB through intact skull at the targeting position. Safety parameter was characterized which ranges from 5 – 7.5 w of electrical power with the sonication duration of 30 – 180 s. The design provides the possibility toward using ultrasonic imaging to guide the focused ultrasound induced BBB disruption process for targeting drug delivery.**

Keywords — **Focused Ultrasound, Blood Brain Barrier, Burst mode, Delivery drug, Image-guided.**

I. Introduction

The blood brain barrier (BBB) structure serves as a natural protection in the brain from the invasion of virus attack or exogenous molecule entrance into parenchyma. However, the BBB is also regarded as a major challenge when intend-ing to deliver therapeutic agent into brain. At the neurosci-ence point of view, disrupting BBB can provide benefit on the application of brain drug delivery. Recently, it has been discovered that using focused ultrasound under the presence of ultrasound microbubbles can disrupt BBB. [1, 2]. More noticeably, since the ultrasonic energy can be tightly con-centrated, this approach enhances the BBB permeable re-gion locally. The BBB-permeable duration may retain sev-eral hours, which is sufficient for delivering molecules into parenchyma [ref].

Current ultrasound induced BBB disruption and brain drug delivered application relies on the guidance of magnetic-resonance imaging (MRI) [ref]. MRI guidance contains advantages including good anatomical image quality and the capability of utilizing MRI contrast agent to detect the BBB-disruptive region. However, there are also many challenges of this approach including the very-high complexity of the system integration between MRI and focused ultrasound apparatus, relatively high cost of MRI usage, and only semi-real-time when imaging the treatment process.

The purpose of this paper is to investigate the feasibility of using ultrasound to guide the focused ultrasound induced BBB disruption process. The potential of using ultrasonic imaging includes the (1) real-time imaging capability, (2) the lower-cost in imaging the treatment process, and (3) the its higher simplicity of integrating therapeutic and diagnostic ultrasound. The procedure of ultrasonic imaging guidance was proposed. A hemispherical ultrasound phased array was employed to generated concentrated energy. Animal experiments were conducted to in-vivo test the efficiency of the system, and the induced brain hemorrhage was also accessed and analyzed.

II. Methods

A. Focused Ultrasound transducer design

Figure 1 shows the design overview of the multiple-channel ultrasound phased array driving system. The hemispherical phased arrays were constructed in house. The phase array contained 80 round piezoelectric ceramic elements (center frequency = 270 kHz, -3 dB bandwidth =20 kHz; PZT-4, Huachen Inc., Chung-Li, Taiwan).Each element had a diameter and thickness of 25 and 7 mm respectively. The electric-to-acoustic efficiency of the PZT-4 element ranges from 15 to 20%, as measured by an acoustic power meter (Ohmic Instruments, Easton, Maryland,USA). The element was fixed in the hemispherical mold with an inner diameter of 250 mm and a curvature radius of 125

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 435–438, 2009
www.springerlink.com

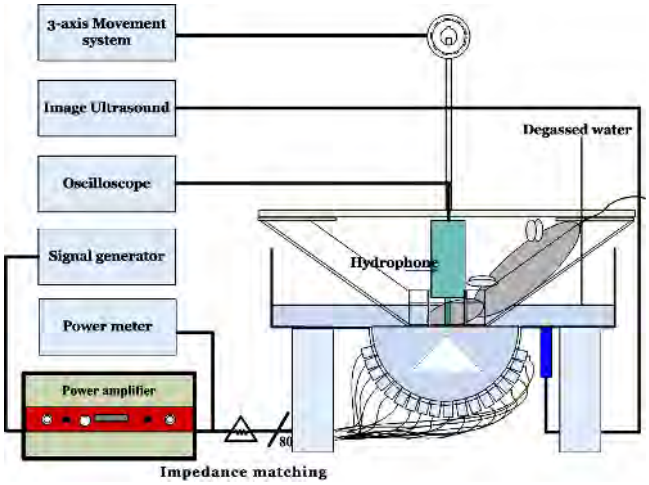

Fig. 1 Diagram showing the experimental setup

mm. Each element was equally spaced around the mold surface. All elements were sprayed with silicone-rubber and used with acrylic plastic housing.

B. Animal preparation

All animal procedures were approved by the institutional Animal Care and Use Committee of the Chang-Gung University. Adult male Sprague-Dawley rats were anesthetized by a mixture of ketamine and xylazine administered intravenously, and removed the animal skull area hair .An animal positioning device was designed for the *in-vivo* animal experiments. The hemispherical phased array was fixed at the bottom of a water tank filled with degassed water. A holder was designed to carry the animal with supine position, and this was moved by a three-axis precision-movement table (with a spatial resolution of 50μm).

C. Ultrasonic image guidance

A procedure of using diagnostic ultrasound to guide the treatment process was described below: (1) One needle hydrophone (Onda, Sunnyvalc, California,USA; calibration range: 50 kHz to 20MHz) was attached besides of the stereotactic animal holder (mounted on a 3-D high precision positioning stage) with the distance between animal brain and hydrophone been fixed and defined; (2) The peak pressure was searched by using the attached hydrophone. Once the peak pressure location been identified, the stage can easily move a definite distance to steer focal energy into animal brain; (3) One diagnostic ultrasound (Model T3000, Terason, MA, USA) was employed, and the imaging probe was mounted at the bottom of the water tank with the location also predefined; (4) The positioning table first move the animal to the top of the diagnostic imaging probe to acquire the image before the animal treatment; then move back the animal back to the focal spot and align the focal point to unilateral brain and then treated; (5) The positioning system then move the animal back to the top of the diagnostic probe and acquire the second image (i.e., imaging after treatment). Figure 2 shows the ultrasound imaging acquired during the process. Figure 2(a) shows the imaging acquired from step (3), and Fig. 2(b) and 2(c) shows the imaging acquired from step (5). In order to examine the procedure can acquire pre- and post-treatment imaging at the identical plane, two line markers were built (pointed in Fig. 2(b) by white arrows). The subtraction of pre- and post-treated brain in Fig. 2(d) shows that the line markers align well and whole process can guide precisely without position errors.

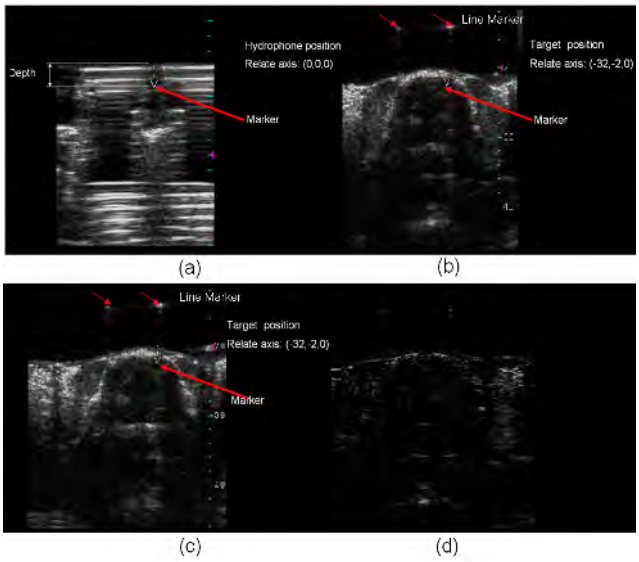

Fig. 2 Ultrasound image guided procedure; use marker and got the relation distance. (a) Needle hydrophone; (b) animal brain before treatment; (c) animal brain after treatment; (c) subtraction between before and after treatment

D. Parameter select

The animal brain was sonicated in the presence of an ultrasound microbubble-based contrast agent (SF_6 coated with mean diameters of 2-5 μm; SonoVue®, Bracco, Milan, Italy), which was injected intravenously prior to sonications. Each bolus injections contained the contrast agent at 2.5μl/kg for an individual sonication. Using the Burst-mode single output for sonication which with a burst length of 10 ms, a PRF of 1Hz. The delivered electrical powers ranged

from 2 to 90 W were tested, combined with the duration times from 30 to 180 s. TABLE I lists all parameters and the animal numbers been sonicated and examined.

Table 1 The number of animal experiments under different sonication parameters

		Electrical Power (W)									
		90	75	60	40	30	20	10	7.5	5	2
Duration (s)	180						1	1	1	3	3
	120	1	1	1	2	1	1	1	1	1	1
	60							1	3	14	1
	30	1	1		2	1	3	3	1	10	2

E. Histological and pathologic examinations

Evans blue was injected intravenously as a bolus immediately after sonication. According to the Evans blue dye the Brain sample BBB disruption area will be observed. All animals were sacrificed 2-3hours after sonication, and the brain sample were section with 10μm thickness. Representative sections were stained by hematoxylin and eosin (H&E) for cell damage, the system performers can be found.

The level of cell damage and hemorrhage were classified into four categories as Fig. 3. Level 0 was defined as a little necrosis phenomena. Level 1 was defined as some discontinuous form of bleeding phenomena. Level 2 was defined as some continuous form of bleeding phenomena. Level 3 was defined as some continuous bleeding and tissue injuring phenomena.

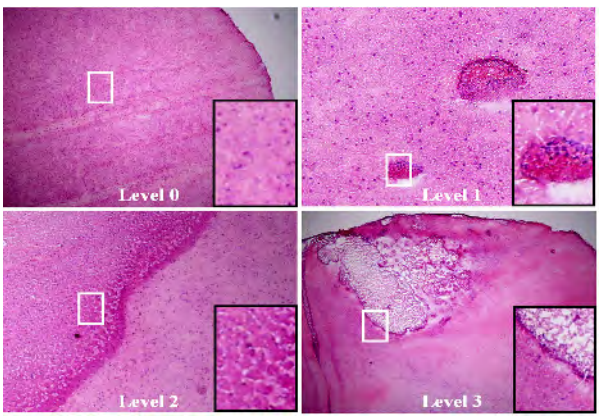

Fig. 3 Hematoxylin and eosin (H&E) cell damage level

III. Result

A. Focal ability of hemispherical phased array

The three-dimensional positioning system with the hydrophone was used to measure the hemispherical phase arrays transducer focusing. Figure 4 shows measured ultrasonic pressure distribution at the focal depth. The -3dB dimension of the pressure was estimated to be about 3 mm, demonstrated that the designed 80–channel hemispherical array contains excellent focusing ability and capable of delivering concentrated energy into animal brain.

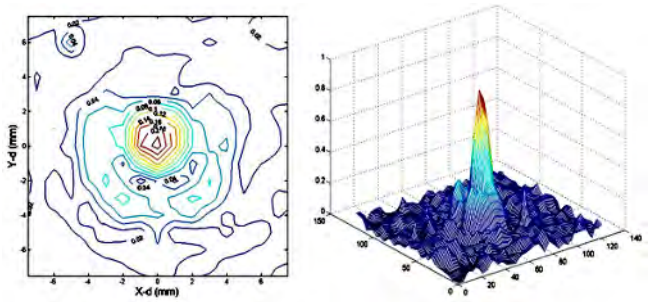

Fig. 4 Measured ultrasonic pressure distribution along the cross-sectional plane at the focal depth

B. In-vivo animal experiment

All animal was sacrificed and the BBB-disruption region was detected by the blue-stain in the brain tissues. Figure 5 shows different level of BBB disruption effect when different focused ultrasound powers were employed. When observing the power great then 5-W the BBB disruption was found. On the contrary, the hemorrhage was found when power output was greater then 10-W. This *in-vivo* animal experiment confirms the feasibility of using the design system to disrupt the BBB.

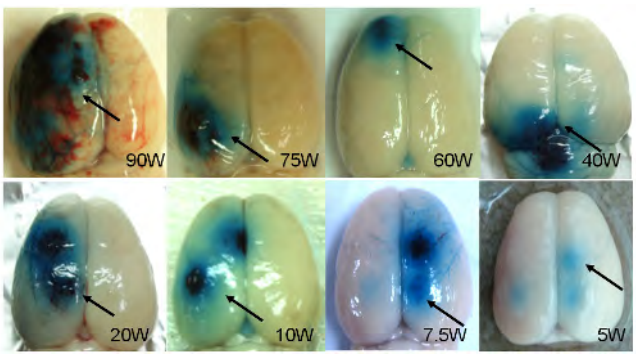

Fig. 5 Gross observation showing blue-dye deposition in animal brain under different acoustic parameters

Brian tissue damage was also examined. 2 W of power was found to be the lower threshold to produce BBB disruption. The power ranging from 2 – 7.5 W was considered to be safe since only a few of erythrocyte extravasations was detected (level 1). In the power range of 7.5 to 20 W, a few hemorrhagic damage can be found in brain tissues; For power larger than 20 W, Some tissue damage including tissue large scale hemorrhage and tissue necrosis were observed.

C. Conformal BBB disruption

Although the system feasibility parameter was found, sometimes the region of BBB disruption may not wide enough to cover the disease region. Figure 6 demonstrate one example showing the BBB-disruptive region can be well controlled and the affective region can be defined and constructed by multiple sonications.

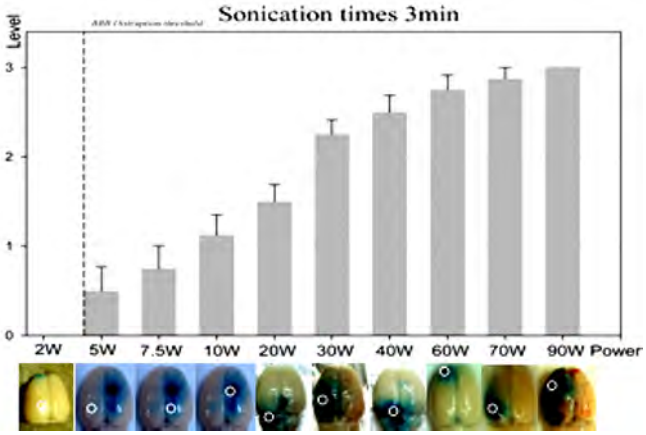

Fig. 5. Hemorrhage level occurred accompanying with sonication under different applied powers

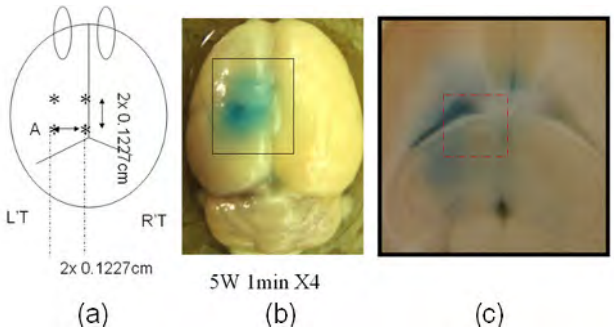

Fig. 7 BBB disruption to conform the designated regions. An example of using four sonication to confine a rectangular shape was shown. (a) Sonication plan; (b) Gross observation from brain surface; (c) gross observation 3 mm beneath brain surface. 5W of power were employed

IV. Conclusions

In this paper, we have proposed a successful integration to use diagnostic ultrasound imaging to guide the focused ultrasound induced BBB disruption procedure. The feasibility to use diagnostic ultrasound imaging to guide the brain drug delivery was confirmed. The system may be further improved to achieve the following aim points:

- Real-time monitor the focused-ultrasound induced BBB disruption process
- Design the phased array which confocal with he imaging probe to reduce the focal point identification process in each treatment.
- More comprehensive therapeutic transducer can be deigned such as increasing the element of the phased array for larger steering distance
- Increase the operating frequency of the imaging probe to gain the image resolution.

A Precise Deconvolution Procedure for Deriving a Fluorescence Decay Waveform of a Biomedical Sample

H. Shibata, M. Ohyanagi and T. Iwata

Graduate School of the University of Tokushima, Japan

Abstract — **We propose a simple and convenient method for measuring the wavelength dependency of the delay time of the response of a photomultiplier tube (PMT) by using a normal time-correlated single-photon-counting (TCSPC) instrument for use in a precise deconvolution procedure. In order to derive the delay time, we employed an algorithm that was used in a modified Gerchberg- Papoulis' band-extrapolation algorithm that we had already reported. Fundamental simulation results and basic experimental results are shown.**

Keywords — **fluorescence lifetime, time delay, photomultiplier tube, wavelength dependency, deconvolution.**

I. Introduction

In the field of biomedical engineering, to measure fluorescence decay waveforms or to obtain fluorescence lifetimes are important when shapes of fluorescence spectra for given two samples are similar with respect to each other. This is because the two samples might be distinguished qualitatively if there are differences in the values of fluorescence lifetimes. To obtain the value of the fluorescence lifetime itself is also important because it is one of the most fundamental material parameters to characterize the sample. However, to measure the fluorescence decay waveform becomes difficult when the value becomes small so as to be comparable with that of the pulse width of the excitation light.

In such a situation, the delay time of the response of a photomultiplier tube (PMT), depending on the kind of the material of the photocathode of the PMT and the applied voltage, should be a serious problem. This is because the peak wavelength of fluorescence emission is Stokes-shifted toward the longer wavelength in comparison with that of the excitation light and because the time delay of the response of the PMT depends on the wavelength [1-3]. The conventional deconvolution technique cannot be carried out precisely in the presence of the time delay.

In order to determine the wavelength dependency of the delay time of the response of the PMT and to obtain the accurate fluorescence lifetime values, we have to establish a precise deconvolution procedure. In the present article, we propose such a method, which is applicable to biomedical samples whose lifetimes are short as the same order as a pulse width of the excitation light. Our proposed method is based on an iterative Gerchberg-Papoulis algorithm that is usually used for a band-extrapolation procedure applicable for data obtained from a band-limited measurement system. This means that the normal time-correlated single-photon-counting (TCSPC) instrument in combination with a nanosecond-pulsewidth light source can be used without paying much attention.

We describe the principle of operation, how to determine various parameters, and show fundamental simulation and experimental results.

II. Principle of the Delay Time Estimation

We have already proposed a deconvolution procedure that is combined with a band-extrapolation technique to obtain a true fluorescence-decay waveform from a reference and a measured fluorescence-decay waveform that are both band-limited. To carry out the band-extrapolation procedure, we proposed two kinds of algorithms: (i) a method by use of an iterative Hilbert-transform technique in a frequency domain [4], and (ii) a method by use of the Gerchberg-Papoulis algorithm carried out in a frequency and a time domain alternatively [5]. We have confirmed that both algorithms are equivalent mathematically and that the convergence of the iteration becomes worse when there is a difference in time origins between the reference and the measured fluorescence-decay waveform. Without the difference, on the one hand, the fastest convergence to the true value is attained. By make use of this fact, we can estimate the time delay by introducing the time delay parameter t_d and by searching the t_d value that makes the convergence rate fastest.

As was described in the previous section, the peak wavelength of fluorescence is shifted toward the longer wavelength in comparison with that of the excitation light and the time delay of the response of the PMT depends on the wavelength. Then, we can estimate the wavelength dependency of the delay time of the response of a PMT as the following fashion: First we prepare several kinds of a narrow band-pass interference filters and a fluorescent sample whose emission spectrum is broad. And then we measure

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 439–443, 2009
www.springerlink.com

the reference and the fluorescence decay waveform at each transmission wavelength of the interference filter. Finally, we apply the deconvolution procedure for the corresponding data. Because the procedure is based on the band-extrapolation algorithm, we can use band-limited measurement instrument for measuring the reference and the fluorescence-decay waveform. This means that the normal time-correlated single-photon-counting (TCSPC) instrument in combination with a nanosecond-pulsewidth light source can be employed without paying much attention.

III. Parameters for use in the proposed procedure

The proposed deconvolution procedure has the following parameters that influence the final result: t_d : the delay time to be estimated, τ : fluorescence lifetime of the sample, W: the full width at the half maximum (FWHM) of the excitation light pulse, f_c: a cut-off frequency that is used in the iteration algorithm for band-extrapolation, N: the number of the iteration. In order to confirm the precision and accuracy of the proposed procedure, we carried out three kinds of numerical simulations. We put the pulse shape of the excitation light as a Gaussian with W=1.0ns and the waveform of the fluorescence decay as a single exponential function with the number of a peak count 10000. We superimposed Poisson noise on the decay waveform and put t_d=100 ps, f_c=1.0 GHz, and N=10000.

Figure 1 shows the absolute value of the averaged estimation errors $|\Delta t_d|$ over the true delay-time t_d=100ps as a function of τ (black circle) and the corresponding standard deviation of the errors (white triangle), where the number of trials was 50. From this result, we found that $|\Delta t_d|/t_d \le 0.6$ % can be obtained for $0.5 \le \tau \le 3.0$ ns. For the large value of τ , the value of the standard deviation in estimation is increased. This is because the decay rate of the signal component in the frequency domain becomes fast at the cut-off frequency f_c, which brings about a worse condition in the band extrapolation procedure.

Figure 2 shows the $|\Delta t_d|$ as a function of W (black circle) and the corresponding standard deviation (white triangle) of the errors, where the number of trials was 50 again. From this result, we found that $|\Delta t_d|/t_d \le 0.5$ % can be obtained for $0.5 \le W \le 1.3$ ns. For the large value of W, the value of the standard deviation in estimation is increased. This is based on the same reason as that described in Fig.1.

Figure 3 a plot of the $|\Delta t_d|$ versus $\Delta\tau_{res}$, where we introduced $\Delta\tau_{res}$ to taking into account of the wavelength dependency of the shape of the instrumental response func-

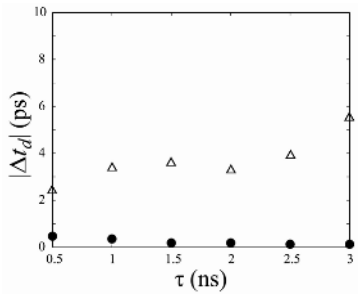

Fig. 1 $|\Delta t_d|$ as a function of τ (black circle) and its standard deviation (white triangle) in the estimation of the delay time t_d .

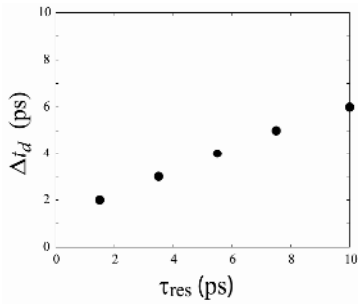

Fig. 3 A plot of $|\Delta t_d|$ versus $\Delta\tau_{res}$.

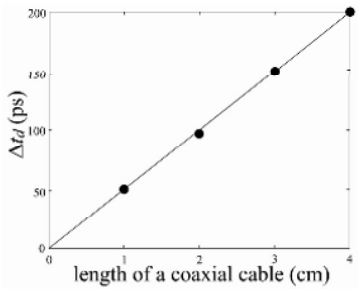

Fig. 4 A plot of Δt_d versus length of a coaxial cable.

tion of the measurement system representatively including that of the PMT. For such a purpose, we convolved the Gaussian function of W=1.0ns with a single exponential-decay function of a time constant $\Delta\tau_{res}$ as the excitation waveform. From this result, we can understand that $|\Delta t_d| \le 6\text{ps}$ when $\Delta\tau_{res} = 10\text{ps}$. The delay is introduced mainly by the numerical convolution procedure. The shape of the response function or the value of $\Delta\tau_{res}$ itself brings about less problem in estimating the value of t_d in a practical situation for the deconvolution procedure than the t_d does[7].

IV. Results and Discussion

A. Delay time estimation by use of a coaxial cable

In order to demonstrate that the proposed method works well in the real measurement system, we measured the delay time of a 50 Ω -coaxial cable (3C2V) by changing its physical length step by step. In the TCSPC instrument, we measured fluorescence decay curve of a business card at a wavelength 450 nm, whose fluorescence lifetime was around 0.9 ns. Then we varied the length of the coaxial cable relatively from 0 to 4.0 cm by 1.0 cm, which is used for connection between the PMT (1P28; applied voltage; -900V, Hamamatsu Photonics) and a high-speed pulse amplifier set before a time-to-amplitude converter (TAC). The measurement result is shown in Fig.4, which agrees well with the theoretical delay time of the coaxial cable 5 ps/mm.

B. Dependency of the delay time on the applied-voltage for the PMT

Next, we measured the dependency of the delay time on the applied voltage for the PMT. Using the TCSPC instrument, we measured fluorescence decay of the business card three times at a wavelength 450 nm as the manner in described in the previous section. Then the applied voltage for the PMT was varied from -800 V to -900 V by a step of 20 V. The result is shown in Fig.5. As is expected, the larger applied voltage results in the smaller delay time and the smaller variation in the estimation.

C. Wavelength dependency of the delay time of the response of the PMT

Next, we measured the wavelength dependency the delay time of the response of the PMT. Experimental setup is the same as above. For the selection of the wavelength, we used four interference filters in sequence: the center of transmission wavelength of which were 400 nm (VPF-25C-40-40000, Sigma Koki), 450, nm (VPF-25C-45-45000), 500 nm (VPF-25C-50-50000), and 550 nm (VPF-25C-50-55000). At each wavelength, seven measurements were carried out. The fluorescent sample used is the business card again, whose excitation spectrum and emission spectrum are shown in Fig.6, together with the normalized transmission spectra of the four interference filters. The applied voltage for the PMT (1P28) was fixed at -900V. From this result we can understand that the longer wavelength gives the longer delay time. The value of the delay time is around 20ps/50 nm at a wavelength between 400 and 450nm. Although literature values for proving correctness of our measurement have not been found, our measurement value seems reasonable by considering the type of the PMT, its applied voltage, and the literature values of other PMTs [1-3,6].

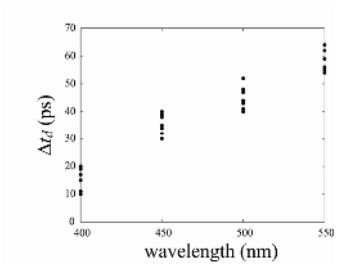

Fig. 7 Wavelength dependency of the delay time of the response of the PMT.

D. Deconvolution procedure by taking into consideration of the wavelength dependency of the time delay of the response of the PMT

In order to demonstrate the usefulness of the proposed procedure as a tool for deriving values of fluorescence lifetimes in analytical practice, we carried out numerical simulations in a comparative way with the normal curve-fitting method in a controllable condition. Figure 8(a) shows an artificial excitation profile: We assumed a Gaussian function with FWHM 0.5 ns, where data interval Δt and the number of total data point *NM* were 0.1 ns and 500, respectively. Figure 8(b) shows an assumed three-component exponential-fluorescence-decay waveform, where individual fluorescence lifetimes are τ_1 = 0.5 ns, τ_2 = 2.0 ns, and τ_3 = 6.0 ns with their amplitude ratios are $a_1 : a_2 : a_3$ = 12 : 4 : 1. Here, we put the delay time as t_d = 100.0 ps. Figure 8(c) shows a waveform obtained from a convolution integral of the waveform shown in Fig. 8(a) with that in 8(b), where a symbol ∗ stands for the convolution procedure. Figure 8(d) shows an instrumental function of the measurement system. We assumed it by a Gaussian function with FWHM 0.8 ns. Figure 8(e) shows a band-limited excitation profile, which is obtained from a convolution integral of Fig. 8(a) with 8(d). Then Poissonian noise was added on it. Figure 8(f) also shows a band-limited time-delayed fluorescence-decay-waveform with addition of Poissonian noise. For such simulated excitation and fluorescence-waveforms shown in Figs. 8(e) and 8(f), we tried to apply the normal Gauss-Newton curve-fitting method and the proposed deconvolution method separately.

For the fitting method, it is better to know the number of components *n* and the value of time delay t_d before procedure. When we set *n* and t_d as 3 and 100.0 ps, respectively, the estimated results were as follows: $\hat{\tau}_1$ = 0.51 ns, $\hat{\tau}_2$ = 2.01 ns, and $\hat{\tau}_3$ = 6.01 ns with their amplitude ratios $\hat{a}_1 : \hat{a}_2 : \hat{a}_3$ = 12.1 : 4. 0 : 1.0. Relative accuracy in estimating these parameter values over true ones was less than 2.0 %. Figure 8(g) shows the fitting result: A solid line shows the fitted curve and a dotted line shows the simulated waveform shown in Fig. 8(f). Figure 8(h) shows a plot of weighted residuals r_i of the fitted curve to the simulated one. From a test of goodness of fit, we found that the fitted curve could not be rejected with a significance level α = 0.05.

On the other hand, a solid line and a dashed line shown in Fig. 8(i) are the fluorescence decay waveform obtained from the proposed method and the true one shown in Fig. 8(b), respectively, where the derived delay time is $\hat{t}_d$ = 100.0 ps for σ = 1.0 GHz and *N* = 10000. The two curves are almost identical except small oscillating behavior on the tail. By applying the same curve fitting method for the derived fluorescence-decay waveform with considering the excitation profile as a delta function, we obtained the following estimates: $\hat{\tau}_1$ = 0.49 ns, $\hat{\tau}_2$ = 1.98 ns, and $\hat{\tau}_3$ = 5.95 ns with their amplitude ratios $\hat{a}_1 : \hat{a}_2 : \hat{a}_3$ = 11.8 : 4.0 : 1.0. The relative accuracy in estimating parameter values over the true ones was again less than 2.0 %. For an explicit comparison purpose, we show a convoluted waveform of the derived waveform with the excitation profile shown in Fig. 8(a) and the instrumental function shown in Fig. 8(d) by a solid line in Fig. 8(j). A dotted line in the same figure shows the simulated waveform shown in Fig. 8(f). Figure 8(k) shows a plot of weighted residuals. The proposed method gives an accurate decay waveform.

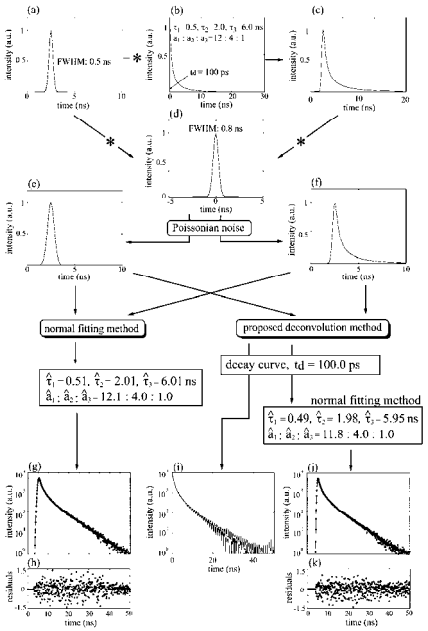

Fig. 8 Comparison of the proposed deconvolution method with the normal curve-fitting method. See text.

Although the proposed deconvolution procedure had the frequency-band-extrapolation stage, the relative accuracy in estimating the fluorescence lifetimes and amplitude ratios was almost the same as that of the normal fitting method. The fact that the normal fitting method worked quite well is quite reasonable in a sense because we knew the accurate mathematical model for the fitting in advance: the form of the mathematical function, the number of components, and the value of the delay time. In addition, the fitting procedure

works so as to cancel the waveform distortion due to band limitation, because both the excitation and the fluorescence waveform have distortion as the same manner at least mathematically. Although we can use the delay time as one of the estimating parameters in the fitting, to do so might be somewhat difficult in analytical practice. If we do not consider the delay time in the fitting, the residuals and uncertainty are increased. Also, if we do not know the number of components, the fitting procedure might be somewhat difficult. For a successful use of the fitting, determination of adequate initial values is important. On the other hand, the proposed method gave a fluorescence decay waveform directly with no information on such as the presence of the time delay and the number of components. In order to derive values of fluorescence lifetimes and amplitude ratios, however, we have to make an adequate mathematical model like the fitting method except the delay time. In this sense, the proposed method might be useful for making more precise model, especially when the fluorescence decay waveform is difficult to be expressed by a sum of exponential decay curves.

V. Conclusions

We have proposed a simple method for measuring the wavelength dependency of the delay time of the response of a photomultiplier tube (PMT) by using a normal time-correlated single-photon-counting (TCSPC) system for use in a precise deconvolution procedure. In order to derive the delay time, we employed an algorithm that was used in a modified Gerchberg-Papoulis' band-extrapolation algorithm that we had already reported. Fundamental simulation and basic experimental results were shown.

Laser Speckle Contrast Analysis Using Adaptive Window

H.-Y. Jin[1], N.V. Thakor[2], H.-C. Shin[1]

[1]Soongsil Univ., Seoul, Republic of Korea
[2]Johns Hopkins Univ., Baltimore, U.S.A.

Abstract — **This paper proposes a new image processing method for laser speckle, adaptive windowing laser speckle contrast analysis (aLASCA) that adaptively processes laser speckle images in the temporal and spatial direction. Conventional fixed window based LASCA has shortcoming in that it uses the same window size regardless of target areas. Inherently laser speckle contains undesired noise. Thus a large window is helpful for removing the noise but it results in low resolution of image. Otherwise a small window may detect small vascular but it has limits in noise removal. To overcome this trade-off, we newly introduce the concept of adaptive windowing to conventional laser speckle image analysis. We have compared conventional LASCA and its variants with the proposed method in terms of image quality and processing complexity**

Keywords — **Laser speckle contrast analysis(LASCA), adaptive window, Laser speckle, micro vessel.**

I. Introduction

The laser speckle technique has progressively become a emerging technique for real-time medical imaging [1]. A laser speckle is created when laser light illuminates an object, and the speckle contrast values are calculated from the time-varying statistics.

The laser speckle imaging (LSI) technique can detect vascular and blood flow changes in the underlying medium [2]. The detection of blood flow is an important in medical diagnosis. Using LSI, it is possible to observe of skin capillary flow and retinal flow in a noninvasive way. Also LSI is a relatively simple and inexpensive technique but it may support the investigation of complex interactions between neuronal activities and hemodynamic affairs [3].

Investigation of the spatiotemporal characteristics of blood flow is important in understanding the interest region of tissues. Various signal processing techniques for LSI exist but mostly they are based on laser speckle contrast analysis (LASCA). As variants, Spatial way[5], temporal way[6], spatial-temporal[7] and adaptive spatial mean filter[8] and temporal mean filter[2] have been studied to see micro vascular better.

Conventional fixed window based LASCA has shortcoming in that it uses the same window size regardless of target areas. Inherently LSI contains speckle noise. Thus a large window is helpful for removing the noise but it results in low resolution of image. Otherwise a small window may detect small vascular but it has limits in noise removal. To overcome this trade-off, we newly introduce the concept of adaptive windowing to conventional laser speckle image analysis. Adaptive windowing is applied to both spatial and temporal processing.

This paper is organized as follows. The experimental setup and techniques, laser speckle imaging of various LASCA and adaptive windowing LASCA are described in section II. In section III, the result images are presented Finally, section IV deals with the conclusion and observations.

II. Material and Method

A. Laser Speckle Imaging

A laser speckle is a random pattern that has a granular appearance produced by reflected light when a coherent laser illuminates an irregular course surface. Goodman [4] asserts that useful information can be attained by examining the statistical properties of laser speckle patterns defined after storing the granular image in a CCD camera.

Figure 1 shows the experimental setup used to obtain laser speckle images. When a He-Ne Laser (655nm) illumi-

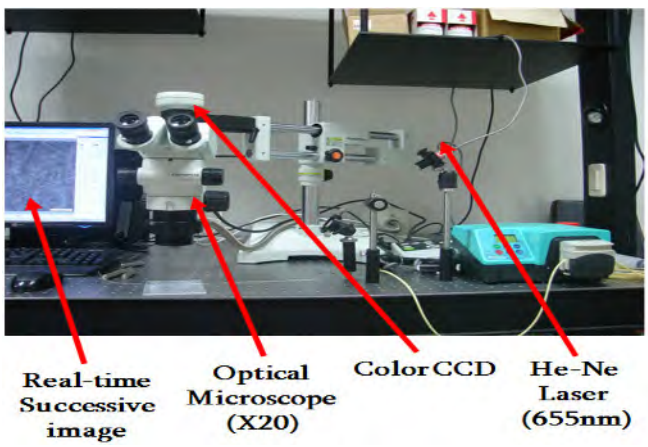

Fig. 1 Experimental setup

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 444–447, 2009
www.springerlink.com

nates the target region, the light is reflected by the surface of the object, and a microscope then magnifies the image. Finally, CCD camera captures the image and the images are stored in the computer. In this experiment, the 384×364 pixel images were stored and Matlab was used for simulation.

B. Speckle Contrast , K

The definition of the speckle contrast is

$$K=\frac{\sigma_s}{\langle I\rangle} \tag{1}$$

where K is the speckle contrast, σ_s is the spatial standard deviation, and $<I>$ is the spatial mean intensity of a window of pixels. The range of the contrast K is $0\le K\le 1$. The contrast value is low when an object moves quickly, whereas the value is high when an object moves slowly.

Applying this definition, vascular and non-vascular areas can be distinguished since the contrast is low where blood flow occurs, whereas it is high when no blood flow occurs.

C. Conventional LASCA based Techniques

LASCA based techniques can be divided into three categories: spatial, temporal, and spatial-temporal.

Generally, spatial LASCA is known as LASCA [5].

In spatial LASCA, (1) a square-shaped fixed $M\times M$ window is used around target pixel to calculate the contrast in eq.(1).

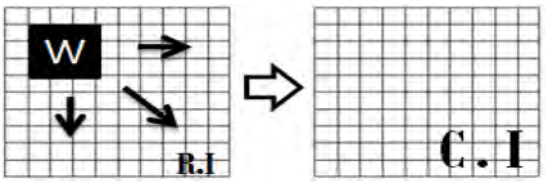

Fig. 2 LASCA operation

Figure.2 shows the spatial LASCA operation, where W is $M\times M$ window, R.I is the raw speckle image, and C.I is speckle contrast image. As the sliding window W is moving by one pixel, the contrast is calculated.

Figure.3 shows the temporal LASCA operation where n is the image frame number. Temporal LASCA can be defined according to equation (2) [6]

$$K_{tem}(i,j)=\sigma_{i,j,n}/<I_{i,j}>_n \tag{2}$$

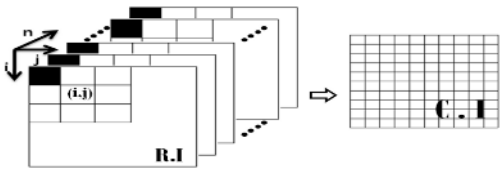

Fig. 3 Temporal LASCA operation

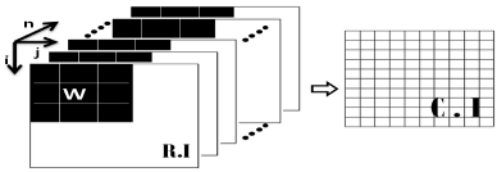

Fig. 4 mLSI operation

Figure.4 shows the mLSI operation which was proposed by H. Cheng [7]. In mLSI spatial and temporal LASCA are applied simultaneously and calculated by using eq.(3)

$$N_{mLSI}=[<I_{i,j}^2>_n-<I_{i,j}>_n^2]/<I_{i,j}>_n^2 \tag{3}$$

D. Proposed adaptive LASCA

The proposed method attempts to improve spatial and temporal resolution over the basic variable LASCA techniques. The key is that the window size for calculating speckle statistics adaptively changes.

The measure for applying variable-sized square windows is K, σ_K and σ_s where K is speckle contrast, σ_K is the variance of contrast, and σ_K is the variance of raw images.

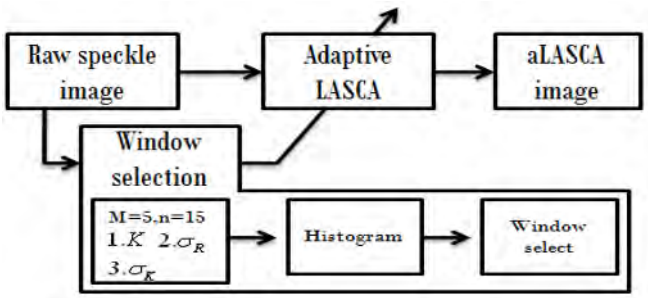

Fig. 5 Proposed aLASCA block diagram

Figure 5 is a block diagram of the proposed aLASCA. From the raw image, K, σ_K and σ_s are calculated using M=5, n=13. Then based on K, σ_K and σ_s, the adaptive

window M and the frame number n are determined by using Image Intensity Histogram. The window size and the frame number are adaptively changed among M = 3, 5, and 7, and n = 3, 5, 7, 9, 11, 13, and 15. aLASCA and $a_{temporal}$LASCA are obtained by applying the various M and n in each pixel to the raw speckle image. In this case, a_{spa}LASCA follows formula (1) and a_{tem}LASCA follows formula (2).

III. Results

A. Images using conventional LASCA techniques

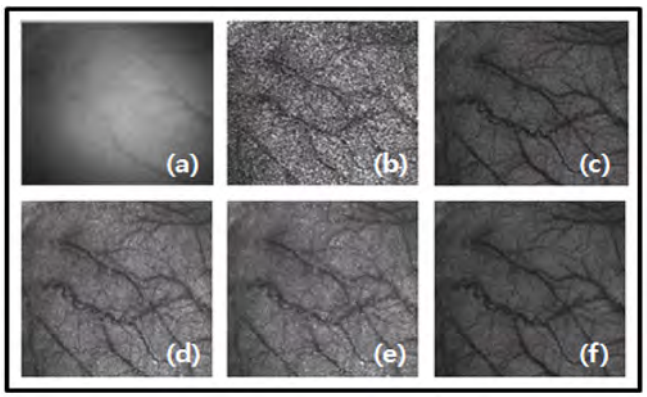

Fig. 6 Laser speckle images (a) the raw image, (b) the LASCA image, (c) the temporal LASCA image, (d) the mLSI image, (e) the sLASCA image, and (f) the tLASCA image

Figure 6 shows the conventional laser speckle images where M = 3 and n = 15 are applied to the 384×368 pixel raw image.

Every image has white spots, or speckle noise. Because many spots are concentrated in (d), (e), and (b), it is reasonable to assume that speckle noise occurred more frequently in spatial operation. Looking at (e) and (f), we can see that when the mean filter is used, noise is decreased. The image, however, is slightly blurred compared to (b) and (c). Moreover, noise is also decreased by using the temporal operation. Therefore, (f) is the best quality image in the sense of the noise reduction.

B. Adaptive LASCA

The most important part of LASCA imaging is to separate vascular areas from non-vascular areas. Adaptive LASCA increases resolution by applying small-sized windows to vascular areas and decreases error by using large-sized windows to non-vascular areas.

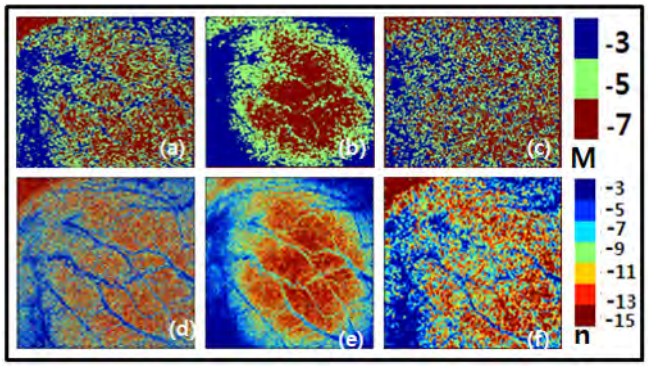

Fig. 7 Window distribution in spatial LASCA: (a) using Kspa (M = 5), (b) using variance of raw image (M = 5) (c) using variance of K (M = 5). Window distribution in temporal LASCA: (d) using Ktem (N = 15), (e) using variance of raw image (n=15), (f) using variance of K (M = 5).

Figure 7 shows the distribution of the adaptive windowing size. The vascular areas in (a) and (d) are the most remarkable in spatial and temporal processing, respectively. Thus, the window selection of adaptive LASCA follows the value of K.

Figure 8 shows adaptive LASCA images using window selection based on K. In (c), speckle noise with white spots is removed, although the occurrence of black spots is slightly increased in comparison to (a).

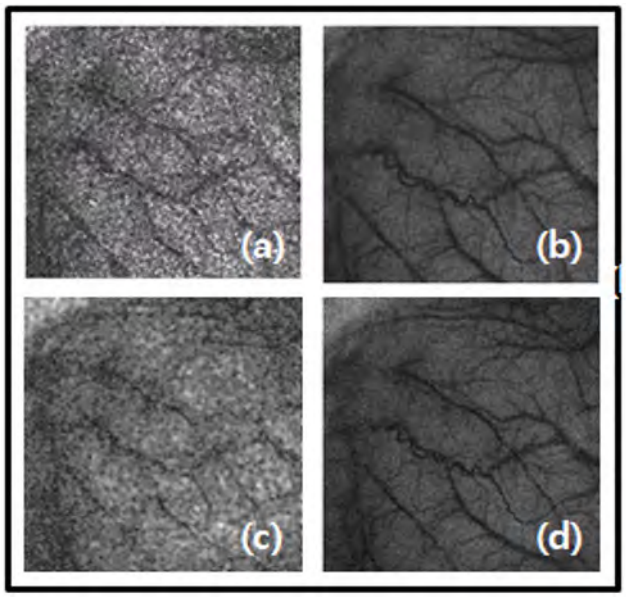

Fig. 8 Comparison of conventional and proposed methods (a) the LASCA image (b) the temporal LASCA image (c) the adaptive spatial LASCA image (d) the adaptive temporal LASCA image

A close examination of (d) reveals that the number of thinner vascular areas is less apparent than (b). However, there is little difference in quality between the two images.

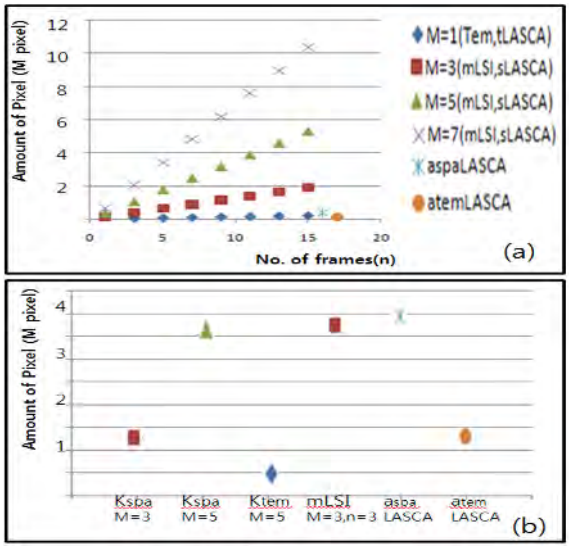

Fig. 9 Comparison of the computational cost (a) all of LASCA (b) LASCA similar to aLASCA

Figure 9 shows the comparison of the number of pixels involved in image processing. An examination of (a) reveals that mLSI uses a large amount of pixels so that the amount of computation is more than 10 times that of other procedures. Looking at (b), it can be recognized that a_{spa}LASCA is calculated with the similar or less amount of pixel to temporal LASCA (n = 3), spatial LASCA (M = 5), and mLSI (M = 5, n = 3).

a_{tem}LASCA has the same quantity of pixels as spatial LASCA (M = 3), and both procedures use the minimum number of pixels. By comparing Figure 6 (b) and Figure 8 (b), it can be seen that the quality of the image in Figure 8 (b) is better than the other with the same computation. Additionally, by comparing Figure 6 (c) and Figure 8 (b), it is apparent that the computation was reduced by 50% even though the image quality remained the same.

IV. Conclusions

We have proposed a new technique, spatial & temporal adaptive LASCA which uses the adaptive windowing size for calculating speckle statistics. We have compared conventional LASCA and its variants with the proposed aLASCA images through Matlab simulation. Based on the results, we expect that in a real-time LSI system, the adaptive LASCA technique will be advantageous.

Neural Decoding of Single and Multi-finger Movements Based on ML

H.-C. Shin[1], M. Schieber[2] and N. Thakor[3]

[1]Soongsil Univ./Dept. of Information and Communications, Rep. of Korea
[2]Univ. of Rochester/Dept. of Neuroscience, New York, U.S.A.
[3]Johns Hopkins Univ./Dept. of Biomedical Eng., Baltimore, U.S.A.

Abstract — **We present an optimal method for decoding the activity of primary motor cortex (M1) neurons in a non-human primate during finger movements. The method is based on the maximum likelihood (ML) inference. Each neuron's activation is first quantified by the change in firing rate before and after finger movement. We then estimate the probability density function of this activation given finger movement. Based on the ML criterion, we choose finger movements to maximize the likelihood. With as few as 20-25 randomly selected neurons, the proposed method decoded single finger movements with 99% accuracy. Since the training and decoding procedures in the proposed method are simple and computationally efficient, the method can be extended for real-time neuroprosthetic control of a dexterous hand.**

I. Introduction

Most neural systems incorporate large number of neurons to process sensory and motor information. The way the neural systems represent such information has been the subject of intense investigation. Understanding these neural population activities is very important for the development of neuroprosthetic control as well as for neural mechanisms [1][2]. For the neural control of external devices such as computer peripherals or prosthetic arms, we need to infer which movements are intended from neural population activities.

This is the so called *neural decoding* procedure. Although it has not been clearly explained how neuronal populations represent movements, it may be possible to infer which finger movements are active, assuming we have enough information on activities of neural populations. With the help of accurate decoding of movement, we should be able to generate a prosthetic movement or control signal. Many neural decoding methods have been developed and demonstrated in prosthetic control applications.

The population vector (PV) method was introduced in [3] where the population vector was obtained by combining weighted contributions from each neuron along its preferred direction. The PV method works well if the preferred directions are distributed uniformly in space [4]. Since this early work, many neural decoding algorithms have been developed. The simplest approach uses a linear estimator [5], which has been used effectively for real-time neural control of a 2D cursor in brain-computer interface research [6]. But this approach requires the use of data over a long time window [7]. One of the popular approach for neural decoding is to use artificial neural networks [8]-[9]. In addition Kalman filter based methods have been exploited for inferring hand position and velocity [7][10]. Recently probabilistic approaches such as maximum likelihood (ML) methods have provided promising results in decoding movements [11]-[13]. Moreover, in [14] the authors provide a neuron model that can realize the likelihood function for an optimal decoding of sensory information.

Here, we present a statistically optimal method, based on the ML inference, for decoding the activity of primary motor cortex (M1) neurons during single movements. Most conventional decoding schemes incorporate the absolute firing rate for quantifying neural activities and model it by a Poisson random process. For modeling of neuron discharge patterns, we quantified the activity of each neuron as the change in firing rate before and after finger movements. The mathematical modelling is done by using the Skellam distribution, which is the probability distribution of the difference of two random variables following Poisson distribution [15]. Then we inferred the finger movement for which the Skellam based likelihood function has a maximum. Based on ML criterion, we choose finger movements to maximize the likelihood. The investigations presented here involved experiments on primates performing 12 possible movement task involving flexion and extension of individual fingers. The methods and decoding accuracies are presented in the following sections. Data were collected from 115 task-related neurons in M1. Only with randomly selected $20-25$ neurons, the proposed method decoded single finger movements with 99% accuracy.

II. Maximum likelihood neural decoding of M1 neuronos

A. Data recording from m1 neurons

Most neural systems incorporate large number of neurons to process sensory and motor information. The way the neural systems represent such information has been the subject of intense investigation. Understanding these neural

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 448–451, 2009
www.springerlink.com

population activities is very important for the development of neuroprosthetic control as well as for neural mechanisms [1][2]. A male rhesus monkey (Macaca mulatta) was trained to perform visually cued individuated finger movements. There are 12 different types of the movements: flexion and extension of the right five fingers and wrist. Sitting in a primate chair, the monkey placed the right hand in a pistol-grip manipulandum which separated each finger into a different slot. At the end of each slot, each fingertip lay between two micro-switches. By flexing or extending a digit a few millimeters, the monkey closed the ventral or dosal switches, respectively. This pistol grip manipulandum was mounted, in turn, on an axis permitting flexion and extension wrist movements.

The monkey viewed a display on which each digit (or wrist) was represented by a row of five light emitting diodes (LEDs). When the monkey flexed or extended a digit, a microswitch was closed and the LEDs provided the feedback. We abbreviate each instructed movement with the number of the instructed digit (1=thumb through 5=little finger, w=wrist), and the first letter of the instructed direction (f =flexion and e =extension). For example, '$4e$' indicates instructed extension of the ring finger.

Data were recorded from 115 task-related neurons in the $\mathrm{M}1$ neurons of the monkey. The monkey performed all \$12\$ possible movements involving flexion and extension of a single digit or of the wrist. The neurons were recorded for \$7\$ trials of each type of finger movement.

B. Maximum likelihood neural decoding

Here, we describe the modified ML based neural decoding method for individuated finger movements. Let $r_n(m)$ be the neural activity, i.e., firing rate, of neuron n for single finger movement m among 12 possible choices. We then define the neural activation related with the movement by

$$x_n(m) = r_n(m) - r_n(0) \tag{1}$$

where $r_n(0)$ is the baseline activity of neuron n before finger movement. Therefore, $x_n(m)$ represents the activity change in neuron $x_n(m)$ before and after the instructed finger movement m. Note that $x_n(m)$ may have a negative value, unlike $r_n(m)$. Experimentally we observed the neural activities of some neurons to decrease for certain finger movements.

Now given the observed neural activations $x_1, x_2, ..., x_N$, we want to infer which finger is intended to move. ML decoding estimates an unknown parameter, m, so that the probability function $\Pr(x_1, x_2, ..., x_N | m)$ is maximized, i.e.,

$$\hat{m} = \arg\max_m \Pr(x_1, x_2, ..., x_N | m) \tag{2}$$

where N is the total number of neurons used for ML decoding. Obviously the challenging task in ML decoding is to estimate the probability function. To do this we consider two probabilistic models: Skellam and Gaussian distributions.

Literature has shown that the Poisson process provides a useful approximation of stochastic neural firing rate, although this assumes no dependence at all on preceding events [2]. When the firing rate $r_n(m)$ follows the Poisson process, the probability, $f_n(k|m)$, that k spikes will be in the interval of Δt given m movement equals

$$f_n(k|m) = e^{-\mu_n(m)\Delta t} \cdot \frac{(\mu_n(m)\Delta t)^k}{k!} \tag{3}$$

where $\mu_n(m)$ is the ensemble mean of $r_n(m)$, i.e., $\mu_n(m) = E[r_n(m)]$. Also the probability of the baseline activity, $f_n(k|m=0)$ is represented by (3) if we replace $\mu_n(m)$ with the ensemble mean of $r_n(0)$, $\mu_n(0)$.

Since we are interested in the difference of two rates as in (1), we need to get the probability of $x_n(m)$. This can be modeled by the Skellam distribution, which is the probability distribution of the difference of two random variables following Poisson distribution [15]. The Skellam probability, $h_n(x_n|m)$ of $x_n(m)$ can be obtained by cross-correlating two Poisson distributions

$$\begin{aligned} h_n(x_n|m) &= \sum_{q=-\infty}^{\infty} f_n(x_n+q|m) f_n(q|m=0) \\ &= \alpha_n(m) \cdot \sum_{q=-\infty}^{\infty} \frac{(\mu_n(m)\Delta t)^{q+x_n} (\mu_n(0)\Delta t)^q}{q!(x+q)!} \end{aligned} \tag{4}$$

where $\alpha_n(m) = e^{-(\mu_n(m)+\mu_n(0))^{\Delta t}}$. The above formulae have assumed that any term with a negative factorial is set to zero. Using the *modified Bessel function of the first kind* $I_x(z)$, (4) reduces to

$$h_n(x_n|m) = \alpha_n(m)\left(\frac{\mu_n(m)}{\mu_n(0)}\right)^{x_n/2} \cdot I_x\left(2\sqrt{\mu_n(m)\mu_n(0)\Delta t^2}\right) \quad (5)$$

Now we have the probability distribution of each neuron's activation, $x_n(m)$ given a finger movement m:

$$\Pr(x_n|m) = h_n(x_n|m)$$

To obtain $\Pr(x_1, x_2, \ldots, x_N|m)$, we assume that x_i and x_j are independent as in [14]. Although it is possible that the firing response of neurons i and j may be interdependent and correlated kind of convey the same meaning, we use the independence assumption because the neurons in our study were randomly chosen from different electrode positions and trials. Assuming x_i and x_j are independent, we have

$$\Pr(x_1, x_2, \ldots, x_N|m) = \prod_{n=1}^{N} h_n(x_n|m) \quad (6)$$

and finally based on (2) the finger movement is estimated by

$$\hat{m} = \arg\max_m \prod_{n=1}^{N} h_n(x_n|m) \quad (7)$$

Note that the only variables required to solve (\ref{eq:m2}) are $\mu_n(m)$ and $\mu_n(0)$, which can be estimated from training data sets.

Another choice for modeling the probability distribution of the neural activations is Gaussian. This is motivated by the fact that the Skellam distribution is bell-shaped and has a similar shape as the Gaussian.

The Gaussian-based probability function for each neuron's activation is given by

$$\Pr(x_n|m) = \frac{1}{\sqrt{2\pi}\sigma_n(m)} e^{-\frac{(x_n-\mu_n(m))^2}{2\pi\sigma_n^2(m)}} \quad (8)$$

where $\mu_n(m) = E[x_n(m)]$ and $\sigma_n^2(m) = E\left[\left(x_n(m)-\mu_n(m)\right)^2\right]$. Thus to estimate an unknown finger movement, all that we need are $\mu_n(m)$ and $\sigma_n^2(m)$, which can also be estimated from training data sets.

III. Experimental Results

Fig.1 shows the performance of the proposed decoding method compared to the conventional population vector decoding approach. The performance of the ML decoding was evaluated by randomly choosing N neurons and this random selection was repeated \$40\$ times. Thus, the success rate in Fig.1 is calculated over 2880 movements for each N. As can be seen in Fig.1, the ML decoding with Skellam modelling performed best. With as few as 20-25 randomly selected neurons, it achieved greater than 99% decoding accuracy. The ML decoding performance with Gaussian modeling was comparable to but slightly poorer than Skellam as the number of neurons is greater for a given decoding accuracy. For comparison purposes, the performance of conventional population vector method was also plotted but the decoding accuracy was only 65-70% even with up to 100 neurons.

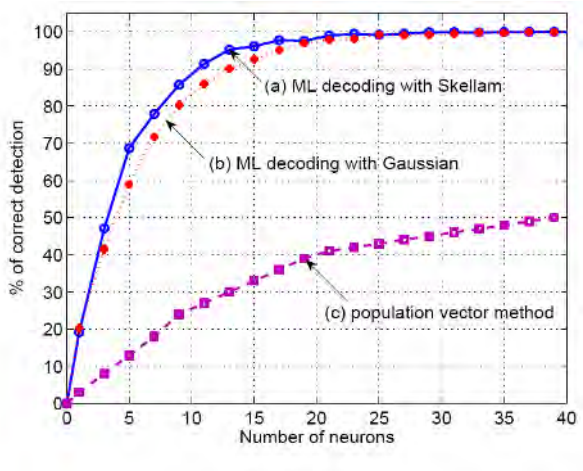

Fig. 1. Decoding accuracy

IV. Conclusions

We have described ML-based neural decoding results for single movements. The decoding was done by the newly introduced Skellam-based likelihood function model. Since the Skellam model considers neural activity both before and after finger movements, it can quantify task-related neural responses better than the conventional Poisson model, which considers the absolute firing rate itself.

Maximum Likelihood Method for Finger Motion Recognition from sEMG Signals

Kyoung-Jin Yu[1], Kab-Mun Cha[1] and Hyun-Chool Shin[1]

[1]Soongsil Univ., Seoul, Rep. of Korea

Abstract — **We provide a method could recognize finger flexing motions using a 4-channel surface EMG (electromyogram). Surface EMG is harmless to human body and easy to be acquired. But it could not be reflected activity of specific nerves or muscles as compared to the invasive EMG. Accordingly, it was so difficult to discriminate various motions using low number of electrodes. EMG data were obtained from 4 electrodes placed around the forearm. The motions we chosen are flexing of each 5 single fingers (thumb, index finger, middle finger, ring finger, and little fingers) and 3 hand motions like 'O.K. sign'. One object trained these motions enough and another one didn't. The proposed method uses the short-time entropy using windowing function as the criterion for detect activation moment of muscle. Overall information entropy was a measurement that could represent the pattern of muscle activity. Maximum likelihood estimation was used to determine motion models reconstructed with statistical properties of data. Results showed that this method could be useful for recognizing finger motions. The average accuracy was more than 95 %.**

Keywords — **surface EMG, finger flexing motion, pattern recognition, classification, neural signal processing**

I. Introduction

Surface EMG (sEMG) signal processing is commonly studied to control electronic devices for amputees. Pattern recognition is indispensable to this technology. As compared to the invasive type EMG that is suitable for checking each motor unit action potential (MUAP) on muscle fiber in small area, the non-invasive type sEMG is appropriate for recording muscle activity within a large skin area [1]. The main object of pattern recognition study has been the upper limb or hand, but each finger has also been studied recently. Many nerve tissues and muscles with individual functions are in the forearm; therefore, decoding an intentional motor command which is indirectly detected on the skin's surface is not simple. Many attempts to extract features and recognize patterns this way have been widely studied.

Englehart [2]-[3] used wavelet analysis and PCA analysis to classify two arm motions and two wrist motions. Later, Englehart used the absolute mean value, the zero crossing rate, and the wavelength to classify four arm and wrist motions. Momen [4] used RMS and FCMs to classify arm and wrist motions that had been selected by the subject. Hudgin [5] obtained an ensemble average of EMG signals, and used a neural network (NN) to classify four arm motions. Nishikawa [6] used the Gabor transform and absolute mean value to extract the feature and classify ten wrist and finger motions in real-time learning based on NN. Nagata [7] used absolute sum analysis, canonical component analysis, and minimum Euclidean distance to classify four wrist motions and five finger motions.

In this paper, we propose a new method to recognize the motion pattern of unknown sEMG signals. We obtained the sEMG signal when five fingers were flexed. To emphasize the uncertainty of bio-signal which likes the random variable, we figure out the information entropy by use of the probability of presence in the specified absolute sEMG range. With the collected entropies for training, we calculate approximate probability density functions using Gaussian distribution to improve the observed histogram of entropies.. Assuming statistical independence in each channel, we can find the likelihood functions of the each flexing motion then estimate motion which was really performed. We demonstrated a significant recognition accuracy by cross-validation.

II. sEMG recording

A signal acquisition device (Laxtha Inc. Poly-G-A), bipolar Ag-AgCl electrodes (Tyco Healthcare Ltd. Kendall ARBO H124SG), and snap electrodes (Laxtha Inc. SECS-4) were used. The EMG signal was observed at the sampling frequency of 256 Hz. This was 60 Hz and 120 Hz bandstop-filtered to reduce power line noise.

Two able-bodied subjects with no upper limb deficiencies participated in performing finger motions for this study. Subject A (a 23 year-old male) mastered the finger motions and learned about the acquisition system, but subject B (a 24 year-old male) practiced just fifteen minutes. Subjects were ordered to maintain normal speed and strength. However, they were not told specifically how to flex their fingers.

The sEMG signal was acquired with four channels on the left forearm (around the wrist) for three seconds. During the first 1.5 seconds, the subjects did not perform any motion — termed 'relaxation' — and waited for an acoustic alarm.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 452–455, 2009
www.springerlink.com

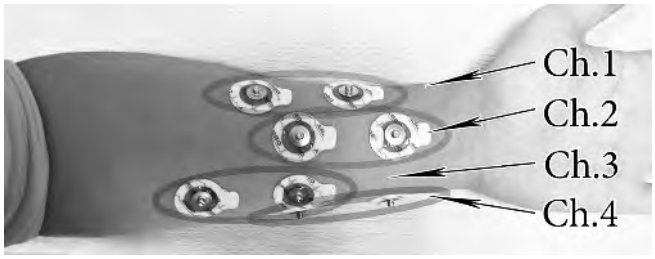

Fig. 1 Locating four channel electrodes for acquiring sEMG on the forearm

After 1.5 seconds, subject heard the alarm and then flexed a finger immediately. After 3 seconds, the sEMG signal recoding procedure ended. To avoid muscle fatigue and cramping, the subjects took a long rest between recording procedures.

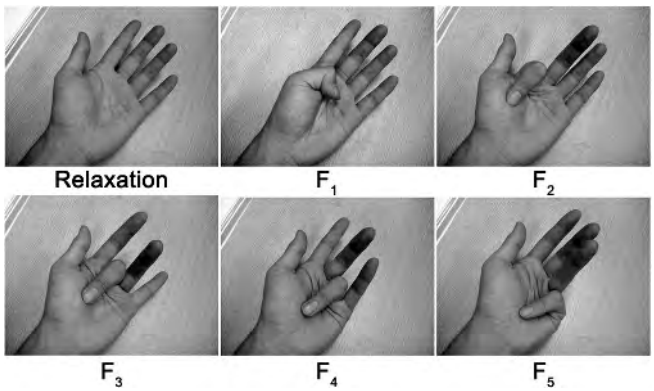

Fig. 2 Relaxation and each five-finger flexing motion (F_1—F_5)

III. Proposed Method

A. Preprocessing of sEMG signal

Let c and k be channel and motion indexes respectively. Here we consider 4 channels and 5 finger flexing motions. Then during F_k movement, the recorded raw sEMG from c^{th} channel can be denoted by $r_c^k[n]$ where n is a discrete time index.

Since the sEMG signal has both positive and negative levels, we take an absolute of $r_c^k[n]$

$$x_c^k[n] = \left| r_c^k[n] \right| , \tag{1}$$

i.e., Fig 3 shows the $r_2^3[n]$ and $x_2^3[n]$.

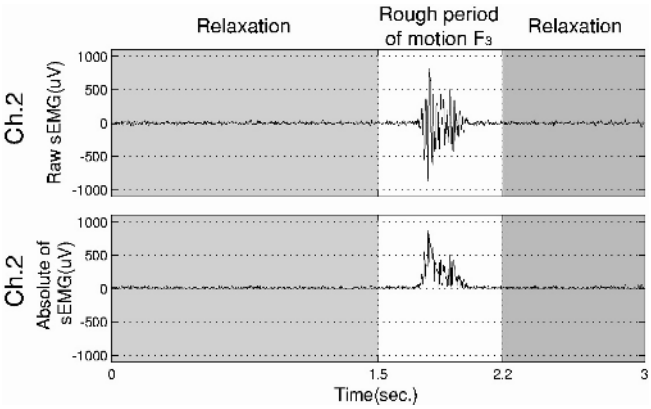

Fig. 3 Examples of raw sEMG signal and absolute of sEMG signal corresponding 2nd and 3rd channel during F_3 motion. The recorded samples that treated as signals are limited in 1.5~2.2 sec (brightened area).

B. Entropy based sEMG model

Entropy (information entropy, H) was used to present the characteristics of each EMG signal of finger flexing motions. Entropy is a sound measure that is able to reveal the uncertainty or variance of random variability as follows:

$$H(X) = -\sum_{m=1}^{M} p(x_m) \log_2 p(x_m) . \tag{2}$$

Here X represents discrete random variable, $p(x_m)$ means $\Pr(X = x_m)$ with $0 \le p(x_m) \le 1$ and $\sum_{m=1}^{M} p(x_m) = 1$.

The probability $p_c^k(m)$ is calculated by

$$p_c^k(m) \equiv \frac{\text{number of samples} \in I_m}{\text{number of total samples}} ,$$
$$I_m = \left\{ x_c^k[\cdot] \middle| \frac{x_{\max}(m-1)}{M} \le x_c^k[\cdot] < \frac{x_{\max} m}{M} \right\} , \tag{3}$$
$$m = 1, \ldots, M$$

where M determines the number of step. The parameter $x_{\max}$ is the maximum value that the signal acquisition device can represent; it is adjusted as follows: $x_{\max} = 1,050 \mu\text{V}$. However, this value can be modified to correspond to the subject's sEMG characteristics.

The information entropy of the sEMG signal $x_c^k[n]$ is

$$H_c^k = H\left(x_c^k[n]\right) = -\sum_{m=1}^{M} p_c^k(m) \log_2 p_c^k(m) . \tag{4}$$

Fig. 4 shows the histograms of H_c^k from 100 independent trials.

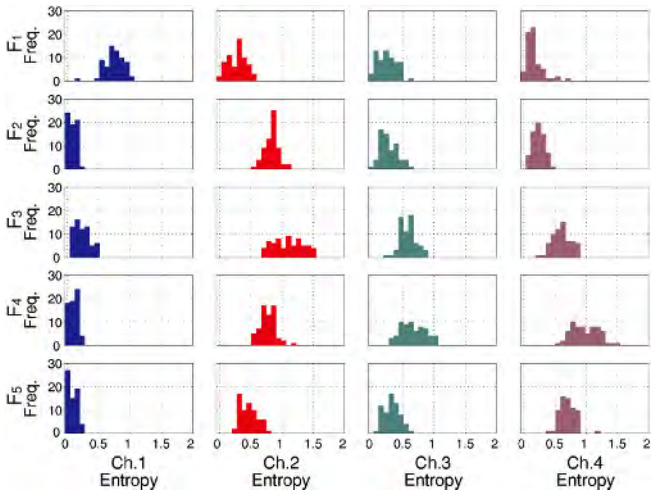

Fig. 4 Histograms of entropy of F_1 — F_5

With the training entropy data ${}^{l}H_c^k$ where $l = 1,..,L$, continuous function of t_c^k be:

$$f_{T_c^k}\left(t_c^k\right) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left[-\frac{1}{2\sigma^2}\left(t_c^k - \mu\right)^2\right], \quad \mu = \frac{1}{L}\sum_{l=1}^{L} {}^{l}H_c^k, \ \sigma^2 = \frac{1}{L}\sum_{l=1}^{L}\left(\mu - {}^{l}H_c^k\right)^2. \tag{5}$$

Here $f_{T_c^k}\left(t_c^k\right)$ is the approximate probability density function derived from the mean and variance of ${}^{l}H_c^k$. This is shown in Fig. 5.

The joint density function of t_c^k (entropy) on each channel when motion k is performed is

$$f_{T_c^k}\left(t_c^k \middle| \omega_k\right) \tag{6}$$

where ω_k is class k. Equation (6) also could be a likelihood function of multivariate probability density function. Furthermore, assuming the statistical independence in each channel's sEMG signal, the likelihood function $L(k)$ as follows:

$$L(k) = f_{T^k}\left(t^k \middle| \omega_k\right) = \prod_{c=1}^{4} f_{T_c^k}\left(t_c^k \middle| \omega_k\right). \tag{7}$$

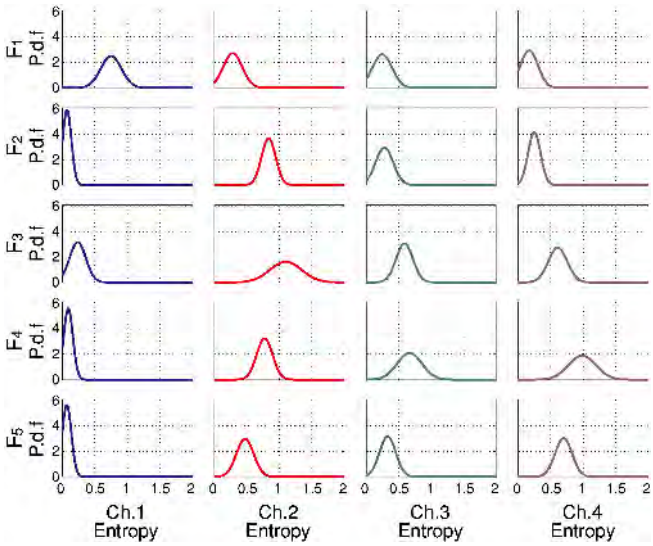

Fig. 5 Approximate probability density functions of F_1 — F_5

We find $\hat{k}$ which maximizes the logarithm for $L(k)$ as

$$\hat{k} = \arg\max_{k} \sum_{c=1}^{4} f_{T_c^k}\left(t_c^k \middle| \omega_k\right). \tag{8}$$

$\hat{k}$ means the estimated motion. Fig. 6 shows the likelihoods ($L(1)$ — $L(5)$) corresponding each motion.

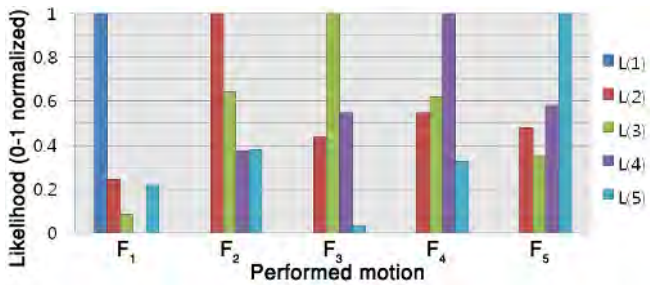

Fig. 6 Example of finding the maximum likelihood

IV. Experiments

A cross-validation was used to estimate the recognition rate. Alternating the ratio of the number of test data (J) and the number of total data, the range was about 0.02–0.95. Each experiment was done 100 times. All test data were excluded from the training data. Fig. 7 shows recognition accuracy when changing the ratio of the number of test data to the number of total data.

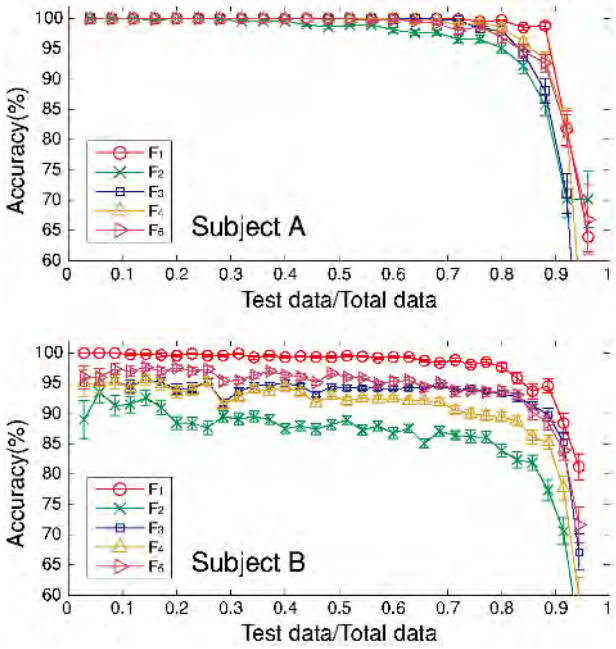

Fig. 7 Average recognition accuracy with gradual change of the ratio of training data to total data. (top: Subject A, bottom: Subject B)

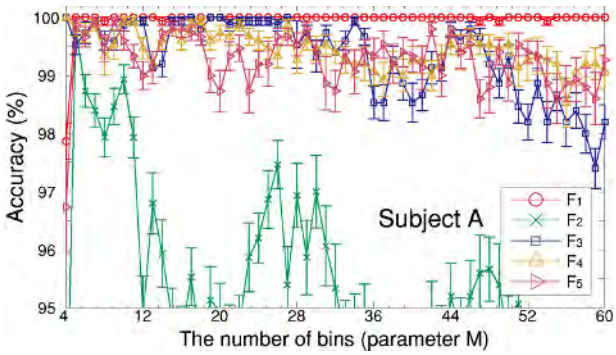

Fig. 8 Average recognition accuracy with gradual change of the number of bins in the range 4—60.(Subject A with total of 25 data)

The parameter M in equation (3) changes the entropy value H_c^k and also the accuracy of the proposed method. In the validation of data from subjects, the ratio of the number of test data to the number of total data was fixed at 0.4. As shown in Fig. 8, M was suitable in the 5–7 range.

V. Conclusions

We proposed a new method to classify finger flexing motions based on entropy and the maximum likelihood estimation method. The average recognition accuracy of subject A was 99.80%, and subject B's was 93.75%.

Cardiorespiratory Coordination in Rats is Influenced by Autonomic Blockade

M.M. Kabir[1], M.I. Beig[2], E. Nalivaiko[2], D. Abbott[1] and M. Baumert[1]

[1]School of Electrical and Electronic Engineering, University of Adelaide, Adelaide, SA 5005, Australia
[2]School of Biomedical Sciences, University of Newcastle, Callaghan, NSW 2308, Australia

Abstract — **Autonomic disturbance creates changes in the modulation of heart rate. In this study we analyzed the influence of sympathetic and vagal blockade on the interaction between cardiac and respiratory rhythms. In seven anaesthetized rats, electrocardiogram (ECG), and respiratory rate were recorded continuously before and after autonomic blockade with either methyl-scopolamine or atenolol. For the assessment of cardiorespiratory coordination, we analyzed the phase locking between heart rate, computed from the R-R intervals of body surface ECG, and respiratory rate, computed from impedance changes, using Hilbert transform. The procedure was carried out for different m:n coordination ratios where, m, is the number of heart beats and n, is the number of respiratory cycles. The changes in percentage of synchronization and duration of synchronized epochs before and after injection were assessed with one-way ANOVA. Sympathetic blockade with atenolol caused an increase (baseline: 0.49 ± 0.03s vs. blockade: 0.54 ± 0.06s) and vagal blockade with methyl-scopolamine caused a decrease (baseline: 0.49 ± 0.03s vs. blockade: 0.45 ± 0.08s) in the duration of synchronized epochs. Neither the overall percentage of synchronized epochs, (baseline: 10.76 ± 3.5% vs. blockade 9.44 ± 4.3%), nor the average locking ratio, 3:1, was significantly affected by autonomic blockade. In conclusion, the phase-locking between heart rhythm and respiration is modulated by both vagal and sympathetic efferences, in the opposite directions.**

Keywords — **sympathetic nervous system, vagal blockade, respiration, heart rate**

I. Introduction

The interaction between cardiac and respiratory oscillations can be studied through synchronization of these oscillators. Several studies have been undertaken on cardiorespiratory synchronization not only for subjects at rest [1,2,3], but also for subjects under the influence of anesthesia and drugs [4,5]. Synchronization is proven to be an intrinsic cardio-respiratory phenomenon and not just an artifact [6]. However, little is known about the physiological basis and the underlying mechanism responsible for the cardiorespiratory interaction.

The parasympathetic (vagal) system is known to have a great influence on heart rate [5] and heart rate variability [7], but its effect on cardiorespiratory coordination is yet to be revealed.

In this study we investigated the effect of sympathetic and vagal blockade on cardiorespiratory coordination in rats.

II. Methods

A. Animal preparation

Seven male Wistar Hooded rats, weighing 250-300 g (obtained from Flinders University, Bedford Park, South Australia), were used for this study. Experiments were conducted in accordance with the European Community Council Directive of 24 November 1986 (86/609/EEC), and were approved by the Flinders University Animal Welfare Committee. During the experiment, ECG, respiratory rate and blood pressure were recorded continuously before and after autonomic blockade with either methylscopolamine or atenolol. The signals were acquired using MacLab interface and Chart software (ADInstruments, Sydney, Australia).

B. Data analysis

Pre-processing: Custom made computer software developed under MATLAB® was used to extract the R-peaks from the recorded ECG signal using parabolic fitting. The RR intervals obtained from the time-points of the R-peaks were scanned for artifacts and, if necessary, manually edited. In order to obtain baseline values, we selected a 40 minute interval, starting 10 minutes prior to the blockade. For the analysis of synchronization during blockade, we selected 30 minute epochs each after vagal blockade with methyl-scopolamine and sympathetic nervous system blockade with atenolol, starting 5 minutes after the injection.

Respiration analysis: Respiratory signals consist of noisy, linear, nonlinear and non-stationary components. To extract the essential respiratory rhythm related components from the signal, we used empirical mode decomposition (EMD). EMD separates data into non-overlapping time-scale components. The multi-component signal is decomposed into a series of intrinsic mode functions (IMF) where each IMF represents a simple oscillatory mode embedded in the data [8]. The IMF that best matched the respiratory rhythm was selected for further analysis.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 456–459, 2009
www.springerlink.com

In order to determine the maximum and minimum points of each respiratory cycle, known as maxima and minima respectively, we calculated the derivative of the respiratory signal and considered those points that were equal to or very close to zero (window length: 0 - 0.2 mV). The average of the time series obtained from minima-to-minima intervals was used to calculate the average respiratory period.

Synchronization analysis: Synchronization between two periodic oscillators can be defined as the appearance of some relationship in the form of locking of their phases or adjustment of rhythms. We used Hilbert transform to calculate the phases of the cardiac and respiratory signals. If we denote the phase of heartbeat as Φ_c and respiratory signal as Φ_r and considering that the cardiovascular system completes m heartbeats in n respiratory cycles, then the condition for phase locking can be given as

$$\left|m\Phi_c - n\Phi_r\right| \le const \quad (1)$$

In other words, if the phase difference between the two oscillators was within a certain threshold value and remained stable for n respiratory cycles, the oscillators were considered synchronized. The cardiorespiratory synchrogram, CRS, provide a visual tool to detect synchronization. If t_k is the time of the kth R-peak, then the normalized relative phase of heart beat is

$$\Psi_n = \frac{1}{2\pi}\left(\phi(t_k) \bmod 2\pi m\right) \quad (2)$$

CRS is generated by plotting Ψ_n against t_k which, in case of m:n synchronization, results in m horizontal lines. In order to determine the values of m and n, we selected one value of n at a time and looked for coordinations at different values of m. The study was carried for the following m:n coordinations: n = 1: m = 2,…,7 and n = 2: m = 5,7,9,11,13. We used a threshold value of 0.035 for the phase difference as it was suggested by Cysarz et al. [9].

Statistical analysis: Statistical analysis was performed with GraphPad Prism® version 5.0. The differences before and after autonomic blockade were analyzed by one-way analysis of variance (ANOVA) for multiple measurements and Wilcoxon test for paired comparisons. Data are expressed as the mean±SD. For the analysis, $p < 0.05$ was considered statistically significant.

III. Results

A. Effect of autonomic blockade on heart rate

Methyl-scopolamine, which was used to block the parasympathetic nervous system, caused an increase in heart rate, while atenolol, used to block the sympathetic nervous system, caused a decrease in heart rate (Fig. 1). The differences were statistically significant, $p < 0.01$, and are summarized in Tab.1.

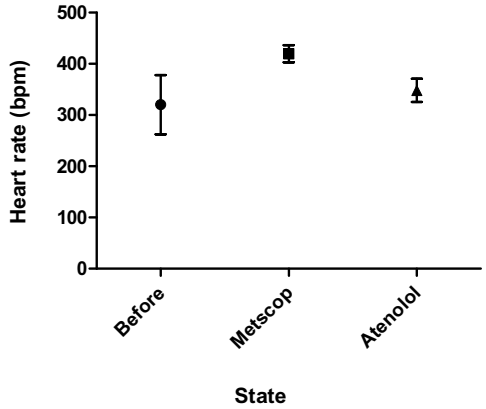

Fig. 1 Mean±SD of heart rate (beats per minute) obtained from seven rats prior and after injection of methyl-scopolamine (metscop) and atenolol

B. Effect of autonomic blockade on respiratory frequency

There was no significant effect (Fig. 2) of either atenolol or methyl-scopolamine on the respiratory frequency.

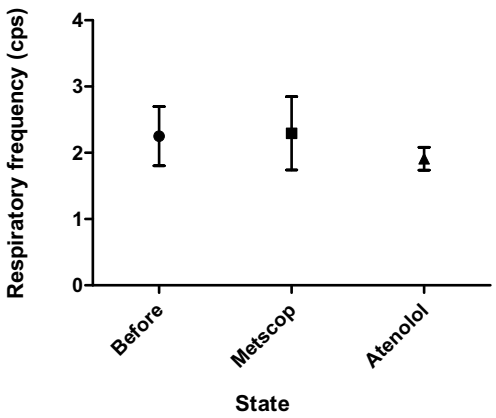

Fig. 2 Mean±SD of respiratory frequency (cycles per second) obtained from seven rats prior and after injection of methyl-scopolamine (metscop) and atenolol

C. Effect of autonomic blockade on average duration of synchronized epochs

The average duration of synchronized epochs was longer (Fig. 3) after injecting with atenolol (baseline: 0.49 ± 0.03s

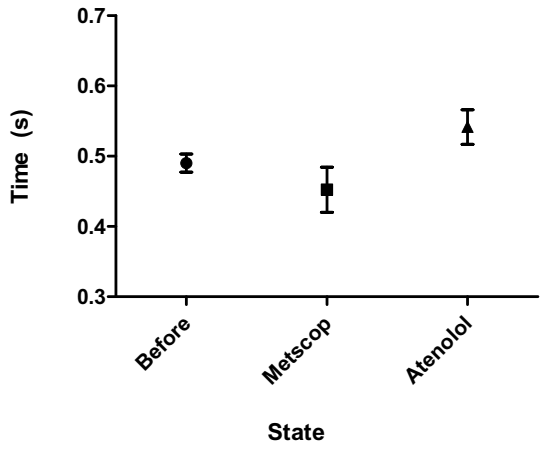

Fig. 3 Mean±SD of duration of synchronized epochs obtained from seven rats prior and after injection of methyl-scopolamine (metscop) and atenolol.

vs blockade: 0.54 ± 0.06s). On the other hand, injection of methylscopolamine caused a decrease in the average duration of synchronized epochs (baseline: 0.49 ± 0.03s vs blockade: 0.45 ± 0.08s). These effects were statistically significant.

D. Effect of autonomic blockade on percentage of synchronization

Vagal blockade caused a decrease while sympathetic blockade caused an increase in percentage of synchronization in six rats. In one rat, the percentage of synchronization was higher after vagal blockade. The results were not statistically significant. However, percentage of synchronization followed a similar trend (Fig. 4) after vagal blockade showing significant results in six rats.

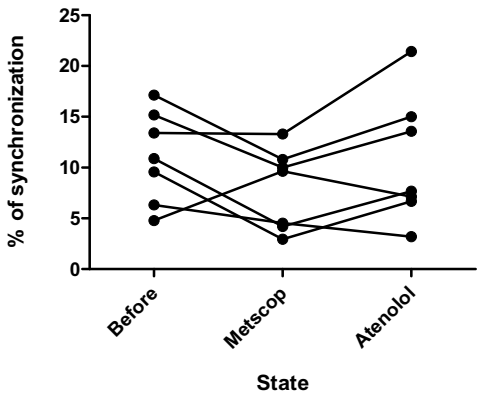

Fig. 4 Percentage of synchronization in seven rats prior and after injection of methyl-scopolamine (metscop) and atenolol.

Table 1 Total recording time (TRT), heart rate (HR), RR interval (RRint), respiratory frequency (RespFr), percentage of synchronization (PofSync) and duration of synchronized epochs (SyncDur) in seven rats represented as mean±SD as well as p-values of Wilcoxon test for paired comparisons

	Before	Metscop	Atenolol	p
TRT (min)	40.2 ± 4.5	30.5 ± 5.1	29.7 ± 4.3	-
HR (bpm)	320.1 ± 27.6	419.5 ± 16.9	347.9 ± 22.7	0.01
RRint (s)	0.18 ± 0.01	0.14 ± 0.01	0.17 ± 0.01	0.01
RespFr (cps)	2.25 ± 0.45	2.29 ± 0.56	1.91 ± 0.17	0.69
Pof Sync	11.04 ± 4.5	7.78 ± 4.1	10.81 ± 6.1	0.08
SyncDur (s)	0.49 ± 0.03	0.45 ± 0.08	0.54 ± 0.06	0.03

E. Effect of autonomic blockade on the average locking ratio

The cardiorespiratory coordination occurred for the phase-locking ratios of 2:1, 3:1, 4:1, 5:2 and 7:2. The 3:1 phase-locked state was frequently observed and was not significantly affected by autonomic blockade.

IV. Discussions

This is the first study to investigate the effect of autonomic blockade on cardiorespiratory coordination. Both sympathetic as well as vagal efferents affect cardiorespiratory coordination with opposite directions.

Our results show that autonomic blockade produces changes in heart rate. These findings are in accordance with the results reported earlier in the literature [5,7,10]. Contrary, no changes in the respiratory rate were observed. Consequently, heart rate rather than respiratory rate seems to be the predominant factor causing the phenomenon of phase locking between heart rate and respiration.

The reduction of cardiorespiratory coupling after vagal blockade is in line with the observation that vagal outflow to the sinus node of the heart is the predominant driver of respiratory sinus arrhythmia.

The increase of cardiorespiratory coordination after sympathetic blockade was unexpected. Possibly, sympathetic effects on heart rate disturb the respiratory sinus rhythm and a sympathetic blockade consequently increases the amount of observed phase locking between heart rate and respiration. Although the average duration of synchronized epochs and percentage of synchronization was found to increase with sympathetic blockade and decrease with vagal blockade, the change in percentage of synchronization did not

reach statistical significance. This is because one of the rats showed an opposite behavior compared to others, (see Fig. 4) whose results would otherwise considered being statistically significant.

V. Conclusions

Vagal and sympathetic blockade cause a respective decrease and increase in the duration of synchronized epochs and percentage of synchronization between heart rate and respiration in rats.

Abstract — **Although the use of transcranial direct current stimulation (tDCS), a noninvasive brain stimulation technique, has become popular in cognitive neuroscience research and clinical applications, there still exists limited knowledge on how to optimally use tDCS for the brain stimulation. To understand the underlying principles and effects of tDCS, finite element analysis (FEA) has been successfully applied due to its truly volumetric analysis and capability of incorporating the anisotropic tissue property. However, there are still many factors to be considered in stimulation: the influence of the white matter (WM) anisotropy is one of them which has not been considered in tDCS. In this study, we have examined the influence of the WM anisotropic conductivities on tDCS via high-resolution FE head models of the whole head. The effects of the WM anisotropy has been assessed by comparing the current density maps computed from the anisotropic FE model against those of the isotropic model using the similarity measures. The results show that there are significant differences caused by the tissue anisotropy, indicating that the anisotropic electrical conductivity is one of the critical factors to be considered during tDCS for accurate and effective stimulation of the brain.**

Keywords — **Transcranial direct current stimulation, Finite element analysis, White matter anisotropic conductivity**

I. Introduction

Transcranial direct current stimulation (tDCS) is a noninvasive brain stimulation technique that applies weak current electrical currents (normally 1-2 mA) to the brain using surface electrodes placed on the scalp to modulate membrane polarization and firing rates of cortical neurons. tDCS does not affect resting nerve neurons to fire, but the spontaneous firing rate of neurons is rather modulated by acting at the level of the membrane potentials [1]. Nitsche and Paulus [2] have reported that tDCS of the human motor cortex results in cortical excitability changes due to the tDCS polarity: the excitability of the underlying neurons increases when anodal tDCS is induced, whereas cathodal stimulation decreases it. The electrical stimulation of the brain by means of tDCS has been utilized as a promising therapeutic tool for the treatment of depression, stroke, Parkinson's disease, and epilepsy [1], [3].

Although the use of tDCS has become popular in cognitive neuroscience research and clinical applications, there still exists limited knowledge on how to optimally utilize tDCS for the brain stimulation. To understand the underlying principles and effects of tDCS, finite element analysis (FEA) has been successfully applied due to its truly volumetric analysis and capability of incorporating anisotropic electrical properties. Previous studies have used a simplified FE model consisting of three concentric spheres [4] and rather realistic head models [5], [6]. However, there still many factors to be considered in the brain stimulation: the influence of the white matter (WM) anisotropy is one of them which has not been considered fully in tDCS. To our best knowledge, only a couple of studies have reported the influence of its effects on tDCS in 2-D [7] and 3-D [8].

In this work, we have examined the influence of the WM anisotropic conductivities on tDCS via our high-resolution FE head models of the whole head (referred to as *wMeshes*) suitable for modeling the WM anisotropic property [9]. The effects of the WM anisotropic electrical conductivity tensors have been assessed by comparing current density maps computed from the anisotropic wMesh head model against those of the isotropic model. The results describe that there are significant differences caused by the tissue anisotropy, indicating that the WM anisotropic conductivity is one of the critical factors to be considered during tDCS for more precise and accurate simulation of the brain.

II. Methods

A. High-resolution FE head modeling

To construct a high-resolution FE model of the entire head, we utilized our adaptive FE meshing technique that generates the DT-MRI WM anisotropy-adaptive FE meshes [9]. The steps of our wMesh generation are briefly described as follows: i) To generate MRI content-adaptive FE meshes (cMesh), adaptive node sampling is done from a set of T_1-weighted MRIs as described in [10]. ii) A map of fractional anisotropy (FA) as an anisotropy feature map is computed using the eigenvalues of the diffusion tensor (DT)

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 460–464, 2009
www.springerlink.com

matrix derived from the measured DT-MRIs. iii) WM anisotropy-adaptive FE nodes in the WM tissues are extracted based on the spatial anisotropic density of the WM FA maps. iv) wMesh nodes are created by combining the cMesh nodes and WM nodes. v) wMeshes are generated using the Delaunay tessellation algorithm. The detailed methodology of generating wMesh is described in [9]. The wMesh models of the whole head is made up with 160,231 nodes and 1,009,447 tetrahedral elements with 1 mm^3 voxel resolution, consisting of five sub-regions including WM, gray matter, CSF, skull, and scalp.

B. Modeling tissue anisotropy conductivity

In the generation of the isotropic FE model, we used the isotropic electrical conductivity values according to each tissue type as follows: WM=0.14 S/m, gray matter=0.33, CSF=1.79, skull=0.0132, and scalp=0.33 [11], [12].

To generate the anisotropic wMesh model, we computed the anisotropic conductivity tensors in the WM regions with the anisotropy ratio of 1:10 as in [9]: We used the eigenvectors of the DTs from DT-MRIs [13] and eigenvalues from the volume constraint algorithm [11]. We incorporated the following anisotropic conductivities into the WM elements: WM=0.65 S/m (longitudinal) and 0.065 (transverse) based on the assumption that the conductivity value of the principal eigenvector is ten times larger than the values of the other two eigenvectors.

C. tDCS simulation

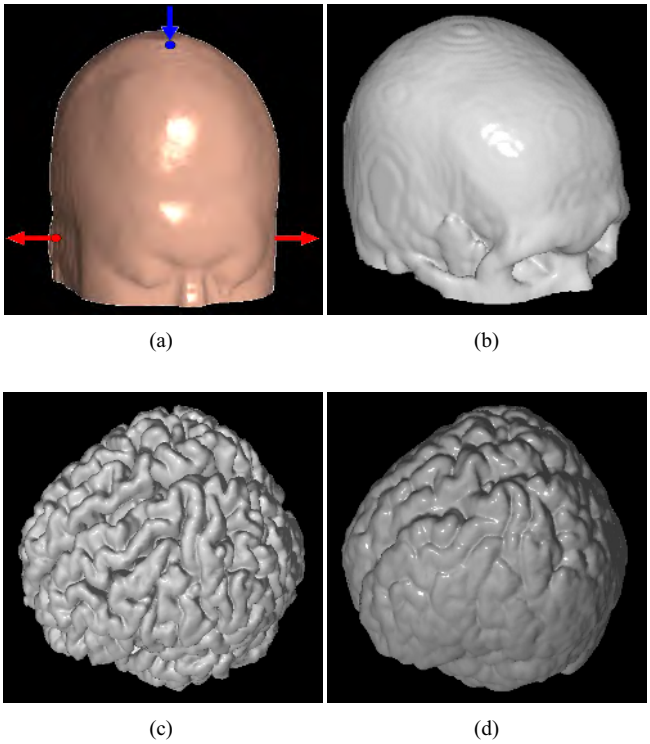
For the tDCS simulation, we used the three-electrode configuration [4] over the scalp to compute forward solutions. An anodal electrode was placed over the premotor cortex near Cz according to the electrode placement of the international 10/20 EEG system. We also set two cathodal electrodes over the mastoids bilaterally. The scalp electrodes were modeled as constant current electrodes where electrical current of +2 mA was injected through the anodal electrode and -1 mA for two cathodal electrodes. Then, the quasi-static Laplace equation was solved due to no internal sources as follows [3]:

$$\nabla \cdot (\sigma \nabla \Phi) = 0 \tag{1}$$

where Φ and σ represent the electrical potential and the electrical conductivity of the tissues respectively. The current density within the head, $\sigma\mathbf{E}$, was then calculated from the computed conductivity tensors and electrical fields, $\mathbf{E}$.

D. Numerical differences of the current densities: isotropic vs. anisotropic

To evaluate numerical differences of the current density maps from the isotropic and anisotropic head models, we used two similarity measures: linear correlation coefficient (CC) and residual errors (RE) [10]. We also examined the directions of current flows to visualize the effects of the WM anisotropic conductivities.



III. Results

Fig. 1 shows the results of 3-D surface rendered volumes according to each tissue type of the head segmented from the MRI data set. Fig. 1 (a) displays 3-D surface rendered scalp including the electrode montage for the computation of the current density. As can be seen in Fig. 1 (a), the blue and red arrows represent the anode and cathodes respectively. The 3-D outer skull, white matter, and gray matter volumes extracted are also visualized in Figs. 1 (b)-(d) respectively.

Fig. 2 displays a set of exemplary results of a transaxial DT-MRI from which anisotropic conductivity tensors are derived. A transaxial T_2-weighed MRI and corresponding FA map derived from the DT data are shown in Figs. 2 (a) and (b) respectively. As shown in Fig. 2 (b), the strong anisotropy is clearly observed in the corpus callosum and the pyramidal tracts. Fig. 2 (c) shows the color-coded FA. A region of interest (ROI), enclosing 30 x 30 pixels, is superimposed with a red box in Fig. 2 (c). In Fig. 2 (d), DT ellipsoids of the WM tissue overlaid on its corresponding T_1-weighed MRI are visualized. The directions of the principal tensor eigenvectors are shown according to the RGB sphere (i.e., red: mediolateral, green: anteroposterior, and blue: superoinferior direction).

Fig. 3 shows a set of results of the 3-D wMesh model covering the whole head through the five segmented subregions. The axial, sagittal, and coronal cutplanes of the wMesh head model are displayed in Figs. 3 (a)-(c) respectively. The anisotropy-adaptive meshes are clearly visible in the WM compartments. It is also seen that there are dense and adaptive meshes in the WM regions in accordance with the FA information of the WM tissues.

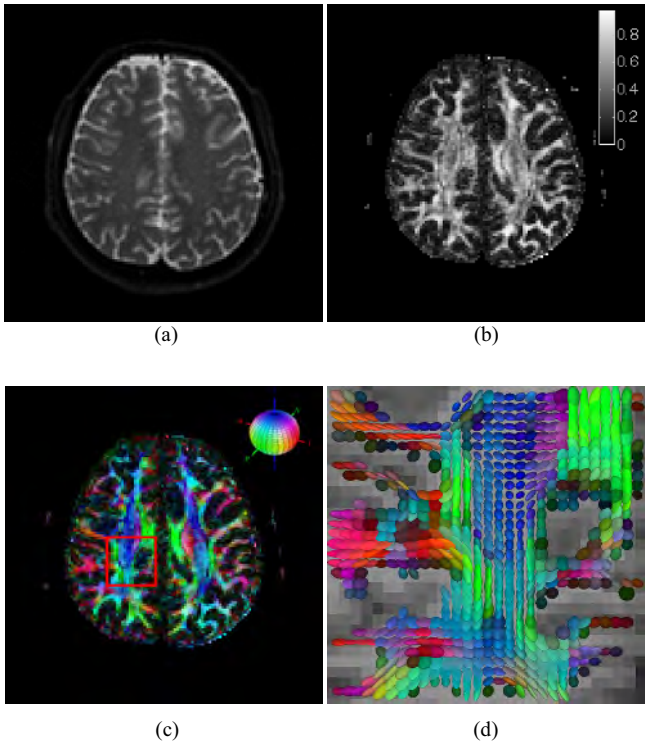


Fig. 4 shows an exemplary of the current density maps computed from the isotropic and anisotropic wMesh models due to the given three-electrode configuration shown in Fig. 1 (a). Figs. 4 (a) and (b) display the current density distributions in the coronal view from the isotropic and anisotropic wMesh models respectively. The resultant current densities were normalized by the maximum value of the current density for better visualization. We also set the color coding of

(a) (b)

(c) (d)

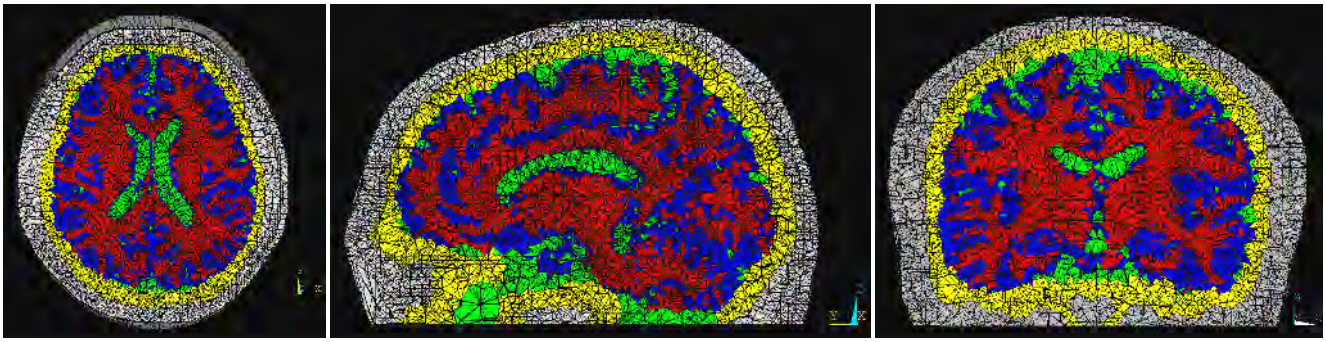
Fig. 2 (a) A transaxial T_2-weighed MR slice, (b) corresponding FA map derived from the DTs, (c) color-coded FA map according to the red-green-blue sphere (red: mediolateral, green: anteroposterior, and blue: superoinferior direction), and (d) color-coded white matter ellipsoids overlaid on the ROI T_1-weigted MRI.

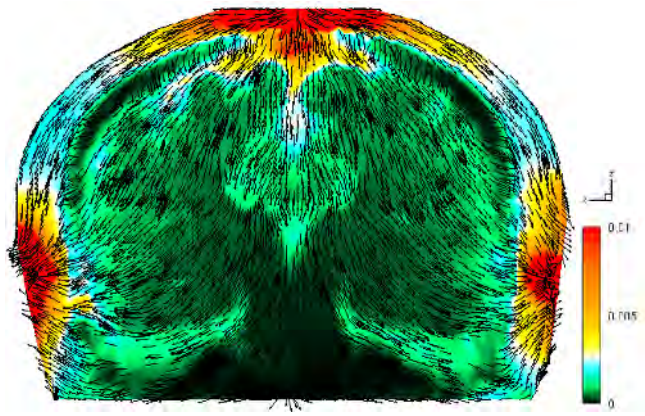
the current density distributions from 0 to 0.01 A/m^2. As observed in Fig. 4, much of the current was shunted through the skull. We found that the largest current density magnitude near the electrodes.



The effects of the skull and CSF compartments in current density distributions are also shown inside the brain due to its low and high electrical conductivity. The directions of the current flows are also plotted. In comparison to the isotropic model in Fig. 4 (a), the current vector lines in the anisotropic model in Fig. 4 (b) are relatively non-uniform and inhomogeneous due to the influences of the anisotropic conductivities according to the WM fiber directions. The results indicate that the WM anisotropic tensors strongly results in the errors of the current density magnitude and directions during tDCS. Note that the magnitudes of the current densities vary with the tissue electrical conductivities.

As mentioned above, we also assessed the numerical differences of the current density maps using CC and RE. The results produce CC=0.56/RE=0.53 (in WM), CC=0.94/RE=0.17 (in gray matter), and CC=0.99/RE=0.02 (skull), indicating that there are meaningful changes of the current densities between the isotropic and anisotropic head models.

IV. Disccusion and Conclusion



The goal of this work was to investigate the influence of the WM anisotropic conductivity on the effects of tDCS via high-resolution FE head models of the whole head. We have examined the effects of the WM anisotropy by comparing the computed current density maps from the anisotropic head model against those from the isotropic model. The results demonstrate that there are significant numerical differences in the current densities caused by the tissue anisotropy, indicating that the WM anisotropy produces significant variations of the current magnitudes and directions. Our study suggests that the inclusion of the WM anisotropic conductivity is one of the important factors to be considered for more precise analysis in the brain stimulation via tDCS.

There still remain several factors to be taken into account for more accurate brain stimulation via tDCS in this study. As for the electrodes, we modeled the electrodes as the point sources instead of pads available commercially. Modeling skull anisotropy should be considered, since the elec-

trical conductivities in the tangential directions are larger than those in the radial directions [8]. In deriving the WM anisotropic conductivity tensors, the eigenvalues could be derived from DT-MRIs directly as well [14]. The influences of the electrical anisotropy on the spatial focality and tissue safety via tDCS will be investigated using optimal electrode configurations. For the future works, we plan to involve the investigation of these factors for more precise analysis of tDCS.

Abstract — **It is generally thought that neuronal damage by cerebral ischemia is associated with extracellular concentrations of the excitatory amino acids. L-glutamate over production initiated the neuronal cell death in ischemic condition. Real time quantitative measurement of glutamate would be applicable to evaluate brain injury during or after surgery, as well as to demonstrate immediate function by Nimodipine, which is one of L-type calcium channel blocker.**

For in-vivo glutamate measurement, the eleven vessel occlusion (11VO) was prepared by using rat model. Changes in cerebral blood flow were monitored by laser-Doppler flowmetry simultaneously with cortical glutamate level by amperometric biosensor. Ten minute ischemia was initiated by pulling the snares on the common carotid arteries (CCAs) and the external carotid arteries (ECAs) while Nimodipine was dripped on the vicinity of burr hole for CBF probe during ischemic period.

In comparison with the Nimodipine-treatment and non-treatment group, peak concentration and the area under the curve (AUC) of glutamate release showed statistically significant difference between two groups. It is considered that decreased glutamate level in Nimodipine treated group is attributed to the neuroprotective effect by Nimodipine.

Keywords — **Glutamate, Nimodipine, 11 vessel occlusion model, neuroprotective effect, real time monitoring**

I. Introduction

It was generally accepted that glutamate was the principal excitatory neurotransmitter in the brain, and its excessive release might play a key role in neuronal death associated with a wide range of neurological disorders.[1] Various studies demonstrated the mechanism of excitotoxic cellular injury from the pharmacological effect to block the cascading injury process.[2-5] Nimodipine was a well known neural protective drug which was applied for the ischemic vascular disease and the ischemia after subarachnoid hemorrhage.[6] Many researchers suggested that calcium channel blocker could facilitate vasodilatation on small arteriole.[7-10] And it was reported that the L-type voltage-gated calcium channels blocker such as Nimodipine prevented calcium influx which induced apoptosis.[11] On the other hand, J.W. Lazarewicz et al. reported that Nimodipine could protected directly neurons in the rabbit brain by intracellular calcium antagonism rather than by inhibition of calcium influx.[12] Although many researchers reported about the calcium channel blockade, the role of Nimodipine on the presynaptic glutamate release was not fully understood.[13-16] A better understanding of these excitotoxic processes requires accurate assessment of the time course of changes in extracellular glutamate levels.

In this paper, we hypothesized that the calcium channel blocker, Nimodipine, could reduce the glutamate release because the same type calcium channel existed in both side of pre- and post-synaptic membrane. Therefore we performed real time monitoring about glutamate release to validate the Nimodipine effect during ischemic period.

II. Materials & methods

A. 11 VO model preparation

Male Sprague-Dawley rats (250-350 g), which had been allowed food and water, were anesthetized with chloral hydrate (0.4 g/kg i.p.). During the entire preparation, the body temperature was maintained at 37.1 ± 0.10°C with Homeothermic Blanket Control Unit (Harvard apparatus, Holliston, MA). On supine position, after midline vertical incision from cricoids cartilage to sternal border with platysma incision, the common carotid artery was defined at the between the sternocleidomastoid muscle and sternohyoid muscle. The occipital artery, ascending pharyngeal artery and superior thyroid artery of external carotid artery were occluded with bipolar electrocautery. The pterygopalatine artery of the internal carotid artery was found at the just medial of the tympanic bulla and coagulated. Before the occlusion of the basilar artery, a tracheostomy was made at the level of the 3-4th tracheal ring level, then the silastic tube (inner diameter: 1.8-2.1mm) was inserted and tied up with 4-0 black silk. After the retraction of the trachea, esophagus and both lounges coli muscles, there was the clivus which was drilled out with 3mm diameter size. The basilar artery was selected at the mid pontine groove at the inferior level of anterior cerebellar artery after the dura incision and arachnoid dissection, and then the basilar artery

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 465–467, 2009
www.springerlink.com

was coagulated permanently. We sealed the pore with bone wax to prevent the leakage of cerebrovascular fluid. At last, the carotid arteries were prepared for the ischemia induction. In order to safely expose the common carotid artery, model was prepared as followed. Carotid artery was dissected with caution not to injure vagus nerve and autonomic nervous chains. On ischemia induction, we had hanged the rubber ring on the common carotid artery and internal carotid artery at both sides, to make a flow down temporally, which enabled the vessel to restore the vascular patency upon the reperfusion.

B. Real time monitoring

Animals were placed in a stereotaxic head holder. The laser Doppler flow probe placed over the dura, was adjusted to avoid large blood vessels and record stable blood flows. EEG (electroencephalogram) electrodes were fixed bilaterally at the skull on the parietal cortex adjacent to the laser probe. Body temperature was maintained at 37.5±0.1°C by a rectal thermistor probe connected to a dual temperature controller, then coupled to the heating pad. The microdialysis electrode was purchased from Sycopel International Ltd. (Type: General 20-10-4-4, UK) The dialysis electrode was filled with phosphate buffer saline (PBS) to electropolymerize the O-phenylenediamine on the platinum electrode at 0.65V for 20min with Sycopel BD2000 potentiostat. And then fresh PBS containing glutamate oxidase was perfused in the dialysis electrode at a flow rate of 0.5μl/min. The dialysis electrode showed linear response in the concentration range of 50~450μM standard glutamate solution with a sensitivity of 0.22nA/μM. (R^2 coefficient of regression of 0.998) The Microdialysis electrode was inserted into motor cortex at coordinates A 1: L 4: V 4mm (from bregma and the dura) through a small incision in the dura.

Ten minute 11VO cerebral ischemia was initiated by pulling the snare on the common carotid arteries (CCAs) and external carotid arteries (ECAs). Snares were released and withdrawn after 10 min.

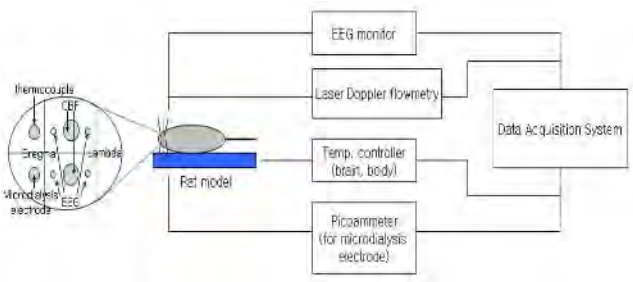

Fig. 1 The diagram of experimental setup for real-time glutamate monitoring system in 11 VO rat model. Zoomed image showed the coordinates for craniotomy

Nimodipine, which was diluted 20 times with normal saline, was dripped (0.025μg/100gm/min) on the vicinity of burr hole for CBF probe during ischemic period. The infusion syringe was protected from light source by thin aluminum foil.

III. Results & Discussion

The pattern of ischemia-evoked response in 11VO rat model was shown in Figure 2(a). As soon as the ischemia was induced, basic CBF declined rapidly to near zero levels, coincident with the development of a flat EEG. With a dialysis electrode, the elevation in glutamate release began approximately 100s after the onset of ischemia episode and continued to rise throughout the entire ischemic period. Then the glutamate level was rapidly declined to pre-ischemic levels during reperfusion. However, the elevation

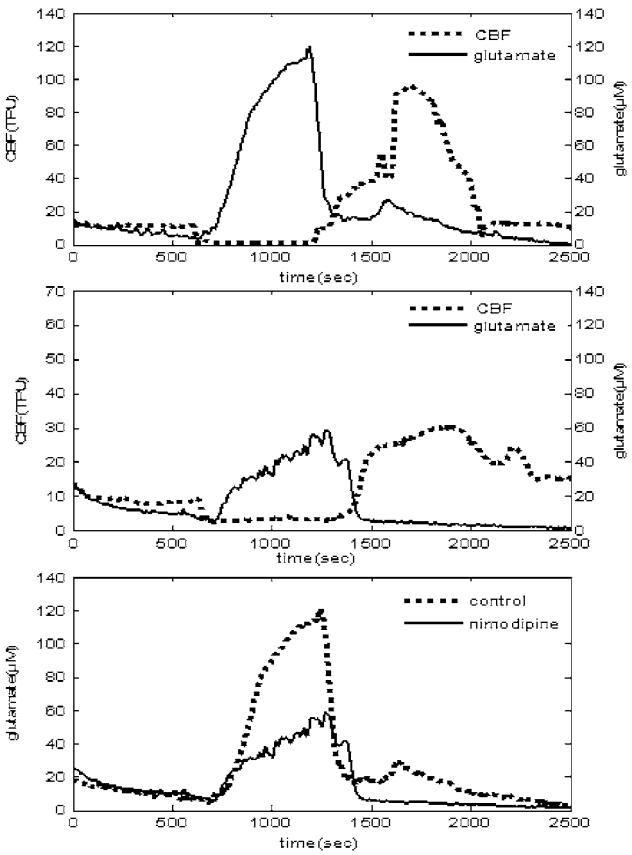

Fig. 2 (a) Real time measurement of glutamate and CBF on non-Nimodipine-treatment group (representative) (b) Real time measurement of glutamate and CBF in Nimodipine-treatment group (representative) (c) The comparison of glutamate dynamics between two groups

Table 1 Changes of glutamate concentration between non-treatment group and Nimodipine-treatment group in global ischemia induced by 11VO method

Changes of glutamate concentrations (n=4)	Control group (mean±S.E.M)	Nimodipine group (mean±S.E.M)	p-value
Maximum (in ischemic period)	129.67±3.64	70.77±0.85	p<0.001
Maximum (in reperfusion period)	136.75±2.02	81.3±3.11	p<0.001
Total amount	57657±3714	31154±1105	p<0.001

in glutamate release was suppressed in the Nimodipine-treatment group, as shown in Figure 2(b).

As shown in Table 1, the maximum change of glutamate concentration was 129.67± 3.64 μM in control group and 70.77± 0.85 μM (55%) in Nimodipine-treatment group during ischemic period. The maximum change of glutamate concentration was 136.75± 2.02 μM in control group and 81.3± 3.11 μM (59%) in Nimodipine-treatment group during reperfusion period. Total amount of glutamate release was 57657 ± 3714 in control group and 31151 ± 1105 (54%) in Nimodipine-treatment group.

IV. Conclusions

In this study, we examined the effects of Nimodipine on glutamate release in acute ischemic condition. In comparison with the Nimodipine-treatment and non-treatment group, peak concentration and the area under the curve (AUC) of glutamate release showed statistically significant difference between two groups. It was showed that the glutamate could be partially regulated by Nimodipine. (L-type calcium channel blocker), though glutamate release could not block completely. This fact indirectly supported that the exocytosis of glutamate was mediated by multiple types of calcium channels.[17]

It is considered that decreased glutamate level in Nimodipine treated group is attributed to the neuroprotective effect by Nimodipine. From this result, we demonstrated that Nimodipine could be applied to clinical condition in neurosurgical area which was performed the multiple clipping or carotid occlusion by continuous drug infusion during the ischemic period.

Abstract — **A windowed nonlinear energy operator (wNEO)-based algorithm is proposed to detect the first-arrival pulse of ultrasound transmission computed tomography (UTCT). In UTCT, the detection of first-arrival pulse is critical to derive imaging indices such as attenuation coefficients and time-of-flight (TOF). Currently, various algorithms utilizing a threshold, maximum, wavelet, etc. have been tested for the detection of the pulse, but each technique suffers from its own intrinsic limitations, failing in detecting the first-arrival pulse reliably. Especially the most widely used wavelet technique, which is also considered as the most effective technique to handle frequency-dependent attenuation, dispersion, and noise of ultrasound, often fails to detect the first-arrival pulse due to the inconsistency of ultrasound pulse shapes with respect to a best mother wavelet. Furthermore, the wavelet technique is impractical for real-time processing. In this work, we propose the use of wNEO for the first time to detect the first-arrival pulse and show its outperforming results in comparison to those conventional techniques through simulation and experimental data with a pair of 5MHz ultrasound transmit-receive transducers.**

Keywords — **Computed Tomography, NEO, Pulse Detection, Ultrasound Transmission**

I. Introduction

Ultrasound imaging system is an intensive research area due to its properties of non-ionizing radiation and abundant information contents. Typically, echo-mode imaging systems (EMIS) have been widely used as they provide images of internal tissues according to the differences in acoustic impedance. Recently, there is an increased activity in developing UTCT [1],[2], since it yields more accurate and quantitative information of objects. The main advantages of UTCT over the conventional EMIS are as following: (1) it provides more quantitative information of tissue characteristics [1]; (2) soft tissue differentiation is possible with the transmitted ultrasound [3]. One of the imaging complications in UTCT is the multi-path problem of the received pulses [1]: multiple pulses are received in one transducer. To mitigate this multi-path problem, it is critical to detect the first-arrival pulse (or we call it a 'snippet'). Also, in UTCT image indices such as the attenuation and TOF are typically derived from the snippet [1],[3].

In this paper, we propose the use of wNEO to detect the snippet for UTCT. Previously, NEO has been successfully applied for the detection of neural spikes [4] and QRS complexes [5]. In this work, we improve the conventional NEO via convolution with data specific windows to improve its performance. To assess the performance of wNEO, we have compared the technique against the various conventional pulse detection algorithms.

II. Methods

A. Conventional Pulse Detection Techniques

In this section, we describe the most commonly used methods for the detection of ultrasound pulses.

1) Three Times Noise Standard Deviation Method

The three times noise standard deviation (3xNSD) method is one of the threshold methods in which a snippet are detected through a threshold defined as three times standard deviation of noise. We have considered the first fifty samples of acquired signal as the noise for the calculation of noise standard deviation.

2) Maximum Peak Detection Method

The maximum peak detection method detects a snippet by picking up the maximum value of received ultrasonic pulses. After detecting the maximum peak value from a signal, a snippet is extracted with a fixed duration.

3) Wavelet-based Method

The wavelet-based method detects a best correlated position with a 'best mother wavelet.' The best mother wavelet is chosen by its similarity to the reference ultrasound signal which is obtained through water only signals.

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 468–471, 2009
www.springerlink.com

4) Pan-Tompkins Algorithm

The Pan-Tompkins algorithm is a most widely used and powerful detection method for the QRS detection [6]. We adopt this technique for the snippet detection and extraction.

5) Nonlinear Energy Operator

Kaiser has defined a nonlinear energy operator for the continuous and discrete time in [7]. For the discrete time case, NEO is defined as,

$$\Psi_d[x[n]] = x^2[n] - x[n+1]x[n-1] \quad (1)$$

where $x[n]$ is the sample of signal representing the oscillation.

$x[n]$ can be expressed again as,

$$x[n] = A\cos(\Omega n + \phi) \quad (2)$$

where A is amplitude, Ω the angular frequency, and ϕ initial phase.

Using Eq. (2) as the input of NEO, the output is rewritten as,

$$\Psi_d[x[n]] \approx A^2 \sin^2(\Omega n) \approx A^2\Omega^2 . \quad (3)$$

The energy of a simple oscillation is proportional the multiplication of the square of the amplitude and the square of the frequency [7]. Hence, Eq. (3) means the energy of $x[n]$ and therefore NEO is called the energy operator. Eq. (3) can also show that NEO is suitable for the detection of a discontinuity part or transient term because the output of NEO is sensitive to instantaneous amplitude and frequency.

B. Windowed Nonlinear Energy Operator for Detection

wNEO is the convolution of NEO with a time-domain window to reduce negative values and remove noise term, which is expressed as,

$$\Psi_w[x[n]] = \Psi_d[x[n]] * w[n] \quad (4)$$

where $w[n]$ represents the window and $*$ represents a convolution operator. In addition, wNEO can serve as $E[\Psi_d[\bullet]]$ [4].

The window type and width are important factors to achieve sufficient reduction of noise without losing much of its time resolution. Consequently, the factors have to be taken into account depending on the state of systems. In this paper, the Bartlett window function is chosen, of which its width is 30 (i.e., 300ns) under our experimental setting.

C. Experimental Setup

An experimental setup is designed as shown in Fig. 1, in which an object (agar gel containing a glass bar), immersed in the water tank, is horizontally scanned with a pair of ultrasonic transducers in the transmission mode. One of the transducers is set up as a transmitter and the other as a receiver. The transducer consists of 128 elements with its crystal size of 2×2mm and the center frequency of 5MHz. The signal is sampled at 100MHz. In total of 250 transmitted ultrasound signals are obtained in each scan.

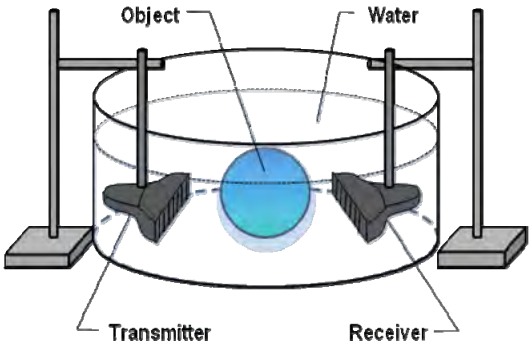

Fig. 1 Experimental Setup

III. Results and Discussion

For the validation of our proposed wNEO-based algorithm, we have manually examined every result derived from those algorithms. One set of result for detection accuracy and computation time is given in Table 1: (1) the detection accuracy of each technique is calculated by counting the correct results among 250 samples; (2) the computation time of individual method is the time to process all 250 signals.

Table 1 Detection Accuracy and Computation Time

Methods	Accuracy (%)	Computation Time (second)
3xNSD	91.6	0.16
Max Peak	80.4	0.23
Wavelet	89.4	4.82
Pan-Tompkins	93.6	1.02
NEO	92	0.18
wNEO	99.2	0.39

The 3xNSD technique achieves the best computation time and the reasonable level of accuracy rate among the applied techniques. Despite of the accuracy rate of 91.6%

comparable to the NEO result, the method however has a serious problem: it frequently detects noise as pulses in low SNR (see Fig. 2(a)).

The max peak detection algorithm shows the worst accuracy and high computation time. The method cannot detect the first-arrival pulse if the other pulses have a bigger maximum peak value than the first-arrival pulse (see Fig. 2(b)). In spite of its low accuracy, however, the detected pulse might reflect some frequency-dependent attenuation indices for UTCT, since most pulses detected by the maximum peak detection are usually located in the actual transmitted pulses. However, TOF cannot be correctly derived from this technique.

The wavelet-based technique results can be useful in the case that the waveforms are similar with a best mother wavelet but it often fails to detect a snippet due to the inconsistency of ultrasound pulse shapes caused by the nonlinear properties of ultrasound such as frequency-dependent attenuation and dispersion (see Fig. 2(c)). In addition, the wavelet-based method shows the longest computation time among those algorithms. As both of the accuracy rate and the computation time, the wavelet based method does not seem to be suitable for UTCT.

The Pan-Tompkins algorithm performs the second-highest accuracy rate whereas the computation time is the second-longest (see Fig. 2(d)). The computation time can be a disadvantage in our case because UTCT requires processing of huge amount of data.

The NEO-based method achieves reasonably high accuracy rate and the second-lowest computation time. NEO is capable of detecting the envelopes of signal based on energy [8], hence the envelope of ultrasonic waves can be emphasized because the ultrasonic waves have bigger energy than noise. However, through the term of multiplication sometimes it can also be sensitive to noise (see Fig. 2(e)). This disadvantage of NEO can be improved through the convolution with data specific windows.

Our proposed technique, wNEO which is an improved version of NEO, achieves the highest accuracy rate and the third-lowest computation time (see Fig. 2(f)). The convolution of NEO with data specific window achieves the decrease of noise sensitivity hence the accuracy rate improves. Although it also decreases the computation time a little, the technique can be applied in real-time.

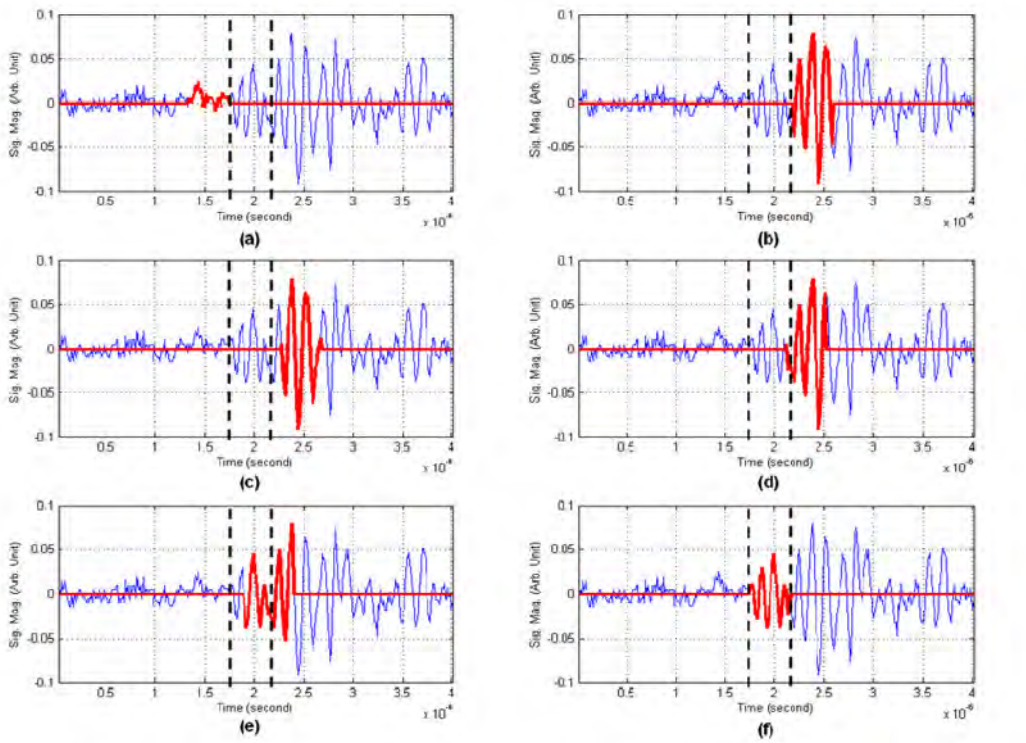

Fig. 2 A set of results for the first-arrival pulse detection using (a) 3xNSD, (b) maximum peak detection, (c) wavelet analysis, (d) Pan-Tompkins method, (e) NEO, and (f) wNEO. The true first-arrival pulse is indicated with the two dashed bars, the detected in red, and the original in blue.

IV. Conclusion

In this paper, we propose the wNEO-based first arrival time detection technique for UTCT. The technique achieves the best accuracy of detecting the first-arrival pulse and reasonable computation time for real-time processing of UTCT data.

Abstract—**This paper is to introduce dental model analysis software with facilitating functions to allow direct dental measurement along with simulation after dental alignment and extraction. Model analysis is one of the orthodontic analyses to assess dental alignment and dental space whether the teeth are at the appropriated positions and space for orthodontic treatment or dental extraction is in need. There are several model analysis researches done by local researchers done by tedious and time-consuming manual means while there are a few cases model analyses by using dental software but most using imported and expensive orthodontic software. There are very few local researches on the software to perform dental model analysis but none of them could perform direct dental measurement and dental simulation after dental alignment and extraction. This model analysis software could perform dental width and dental arches measurements which results have been applied for Bolton analysis, which calculate the dental ratios. User could perform dental model simulation after selecting individual teeth appeared on the dental simulation image. Further developments of this model analysis program will allow the measurement of dental curve widths and curve heights along with other measurements relating to dental model analyses.**

Keywords—**Dental Model Analysis, Bolton Analysis, Dental Widths, Dental Arches, Orthodontic Analyses.**

I. Introduction

Model analysis is a part of the orthodontic analyses to investigate the dental alignment if individual teeth are at proper alignment. There are several researches on dental model analyses by local Thai orthodontists including dental sizes [1], the predictions of dental curve widths and heights [2], the mandibular width comparisons before and after orthodontic treatments at the canine, the first premolar, and the first molar [3], average values of dental sizes from Thai people [4], relationships between the tooth sizes and dental curves for those Class I [5] as well as Class II patients [6], malocclusal analyses from dental models [7] and so on.

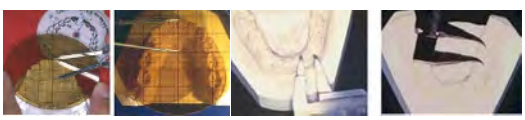

Fig. 1 Examples of Model Analyses by Manual Means [8] [9]

Fig.1 is showing dental width and dental curve analysis by manual that require dental width measurements by veneer [8] along with the dental curves by apply bronze wires [9], vulnerable to intrapersonal or interpersonal discrepancies and accuracy limit of measuring instruments.

There are software developments for dental model analysis to reduce analysis time, shorten the dental analysis procedure, and reduce the measurement discrepancies as orthodontic treatments became more popular. Cadant Ltd. has developed OrthoCAD for model analysis in 1999 [10] with patent approved in 2000 [11]. Geodigm Corp. has developed E-Models in 2001 with patent approved in 2003 [12]. For the case of 2D dental model analysis, Dolphin Imaging 10 from Dolphin Imaging Inc. invented a dental model analysis module with patent approved in 2007 [13].

There are a few local researches on model analysis software such as the 3D model analyzer by Eimtaveecharern in 2001[14] and 2D computerized orthodontic model analysis by Thongti-amporn in 2003 [15]. However neither of them fully met the orthodontists' requirements since [14] did not go into complicated model analysis as [15] while [15] used data from manual measurements instead of digital image measurements.

Therefore, this new research on dental model analysis software will have facilitated functions to cut down the procedure along with shortening the analysis time. Furthermore, the dental model analysis program has functions to simulate dental movement during orthodontic movement.

II. Linear and Angular Measurements

There are two major types of measurements for dental model analysis, linear measurements and angular measurements, which can be shown in details as follows:

A. Linear Measurements

Linear measurements could be divided into direct measurements and perpendicular measurements. Direct measurement is the linear measurement of distance between two points to be applied to for curve measurement shown in (1).

$$|ab| = \sum_{i=0}^{N-1} \sqrt{(x_{i+1} - x_i)^2 + (y_{i+1} - y_i)^2} \qquad (1)$$

Chwee Teck Lim, James C.H. Goh (Eds.): ICBME 2008, Proceedings 23, pp. 472–475, 2009
www.springerlink.com

Perpendicular measurement is the linear measurement of triangular height h to be calculated by applying Heron's Formula [16] shown in (2) with A as the distance opposite to a angle, B as the distance opposite to b angle and C as the distance opposite to c angle respectively.

$$h = (2/C) * \sqrt{S(S-A)(S-B)(S-C)}, S = (A+B+C)/2 \quad (2)$$

B. Angular Measurements

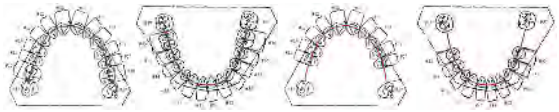
The angular measurement can be done by applying dot product on 2 vectors to calculate θ_{vec} as shown in (3) while the alternative is to measure θ_{Slope} as shown in (4).

$$\theta_{vec} = \cos^{-1}(|\vec{A} \bullet \vec{B}| / (|A||B|)) \quad (3)$$

$$\theta_{Slope} = \tan^{-1}((a_y - b_y)/(a_x - b_x)) \quad (4)$$

III. Dental Model Analysis

Dental model analysis is a part of orthodontic treatments to analyze dental model details including dental widths and curve lengths and assess if malocclusion exists along with the malocclusion severity by comparing results with the standard sets of measurements before deciding to either extract teeth to increase space or apply orthodontic treatments without extraction. This paper will mention only the analyses implemented in the model analysis software.



A. Bolton Analysis

Bolton analysis is the dental analysis to measure dental width of the individual teeth along with the comparisons between maxilla and mandibular sum of dental widths in percentage invented by Bolton in 1958 [17] for the following dental assessments:

1. When the dental ratios are not proportional with standard values, it would indicate where irregularity occurs
2. This analysis can be applied for orthodontic treatment and cephalometric analysis to indicate if orthodontists and craniofacial surgeons would either extract the teeth or perform cephalometric surgery along with dental stripes to correct dental positions and space.
3. This analysis can estimate overjet and overbite after orthodontic treatment.
4. Sum of 12 maxilla and 12 mandibular dental widths could be applied for malocclusion assessments.

Bolton ratios will be explained in details as follows:

1. Ratio of 12 teeth (B_1) is the ratio between the sum of 12 maxilla dental widths Mx_{12} from the first right molar (#16) to the first left molar (#26) shown in Fig. 2(A) and the sum of 12 mandibular dental widths Md_{12} from the first right molar (#46) to the first left molar (#36) shown in Fig. 2(B). If the first molars are missing, the end points would be at the last positions to measure the the second molar shown in Fig 2(C) for the maxilla and Fig 2(D) for mandibular and the ratio is shown in (5).

(A) (B) (C) (D)

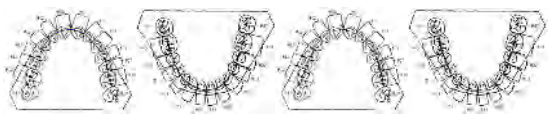


Fig. 2 Bolton Ratio of 12 Maxilla and 12 Mandibular Teeth

2. Ratio of 6 frontal teeth (B_2) is the ratio between the sum of 6 maxilla dental widths Mx_6 from the first right canine (#13) to the first left canine (#23) shown in Fig. 3(A) and the sum of 6 mandibular dental widths Md_6 from the first right canine (#13) to the first left canine (#23) shown in Fig. 3(B) from the first right to the first left canine shown in (6).
3. Ratio of 6 lateral teeth (B_3) is the ratio between the different sum of 12 teeth and 6 frontal teeth shown in Fig. 3(C) for maxilla and Fig. 3(D) for the mandibular and the ratio can be shown in (D) shown in (7).

$$B_1 = 100 Md_{12} / Mx_{12} \quad (5)$$

$$B_2 = 100 Md_6 / Mx_6 \quad (6)$$

$$B_3 = 100 Md_{6d} / Mx_{6d} = 100 \frac{Md_{12} - Md_6}{Mx_{12} - Mx_6} \quad (7)$$

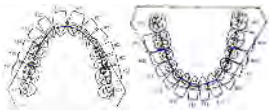
(A) (B) (C) (D)

Fig. 3 Bolton Ratio of 6 Maxilla and 6 Mandibular Teeth

B. Arch Length Analysis or Space Analysis

Arch length analysis is to assess the arch length discrepancy (ALD) by measuring the arch length (AL) within mesial surface area from the front of the first left molar to the front of the right molar to calculate the space available by applying (2) as shown in Fig. 4. The arch lengths will be compared with the space requirement measure from the sum

of dental width from the second right premolar (#15) to the second left premolar (#25) for maxilla and #45 to #35 for mandibular since these teeth are movable by applying brackets and dental wires. If arch length discrepancy (ALD) is negative, it implies that the space requirement is more than the corresponding space available (AL) so tooth extraction is a necessary measure to ensure positive arch length discrepancy before further orthodontic treatment.



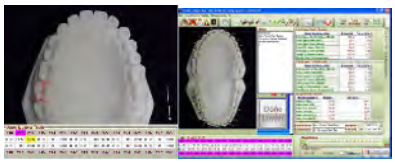


Fig. 4 Maxilla and Mandibular Arch Length

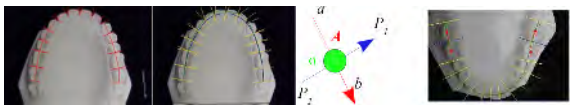
IV. Dental Model Analysis



(A) (B)

Fig. 5 Tooth Size Measurement by Mouse

Dental model analysis has been developed by using Borland C++ Builder 6 as a compiler and VCL components from TMS Software to develop software for dental model analysis. After opening the dental model image, user can define the dental widths of the maxilla by mouse, which can be skipped clicking right mouse button for the section without tooth as shown in Fig. 5 (A). After drawing the maxilla arch, user can define mandibular tooth sizes and draw the mandibular arch by following the same procedure as maxilla cases. Dental width sums along with the space requirement accumulated and the results along with the user interface of the model analysis program shown in Fig. 5(B).

After finishing tooth width definition on the maxilla as shown in Fig 6(A), user can draw the line divided individual teeth and dental arches from the dental width positions along with the averaged corresponding position as shown in Fig. 6(B) by applying cubic spline interpolation [18] along with averaging to smooth the dental curves. The Drawing of segmentation line $\vec{P_1P_2}$ with the length of K perpendicular to vector from the middle of one dental width to the neighbor dental width and crossed at point O can be shown in Fig. 6(C) with the results shown in Fig. 6(D). Calculation for the perpendicular line position can be expressed as equations from (8) to (11).

(A) (B) (C) (D)

Fig. 6 Drawing Dental Arches and Segmentation lines

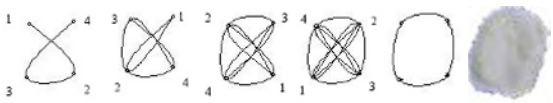
$$P_1 = (P_{1x}, P_{1y}) = (O_x + K_x, O_y - K_y) \quad (8)$$

$$P_2 = (P_{2x}, P_{2y}) = (O_x - K_x, O_y + K_y) \quad (9)$$

$$K_x = K(a_y - b_y) / \sqrt{(a_x - b_x)^2 + (a_y - b_y)^2} \quad (10)$$

$$K_y = K(a_x - b_x) / \sqrt{(a_x - b_x)^2 + (a_y - b_y)^2} \quad (11)$$

After finishing dental arch drawing, user could start dental segemntation by clicking four landmarks in clockwise or counter clockwise direction around each tooth to set up the dental boundary. After marking all 4 point, the cubic spline interpolation will be applied to draw the boundary section by section and the starting and ending point for cubic spline interpolation will be rotated to ensure a closed loop with suitable form along with segmented teeth shown in Fig. 7.



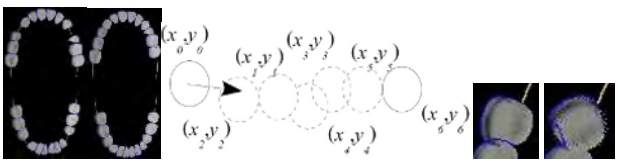


Fig. 7 Results after Drawing Dental Arches

After dental segmentation shown in Fig. 8 (A), user could simulate the dental movement by moving and rotating the individual teeth first and simulating the dental movement, according to (12) for translation with (x_0,y_0) for the starting position, (x_i,y_i) for the intermediate position, and (x_N,y_N) for the final position at step N. For the rotation case, the rotation angle θ will be according to (4) and the rotation mechanic will follow (13) with (x_0,y_0) as the starting position, (x_c,y_c) as rotation center. Results from translation movement can be expressed in Fig. 8(B) while the result from rotation can be seen in Fig. 8(C).

(A) (B) (C)

Fig. 8 Results before and after Dental Alignment along with translation and rotation of individual teeth

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} x_0 \\ y_0 \end{bmatrix} + \left(\frac{i}{N}\right)\begin{bmatrix} x_N - x_0 \\ y_N - y_0 \end{bmatrix} \quad (12)$$

$$\begin{bmatrix} x_i \\ y_i \end{bmatrix} = \begin{bmatrix} x_c \\ y_c \end{bmatrix} + [x_c - x_0, y_c - y_0]\begin{bmatrix} \sin(i\theta / N) \\ \cos(i\theta / N) \end{bmatrix} \quad (13)$$

V. Results

During software development period, there are several problems to be listed along with the solutions as follows:

1. Slow processing for drawing dental arches that can be solved by the following measurements.
   a) Separated drawing function, cubic spline algorithm and data saving to reduce code redundancy.
   b) Dynamic arrays with proper memory managements to prevent memory leak.
   c) Appropriated logics for drawing functions.
2. Applying bilinear interpolation to calculate pixel colors to fill missing pixels of individual tooth during rotation.
3. Further dental segmentation improvements are to apply gradient vector flow along with edge detection to push the dental boundary to be exactly on the dental edges.
4. Designing user interface to meet requirements has to stick with the dental model analysis results used by orthodontists. However, additional model views are in need to obtain more dental model analysis data.

VI. Conclusions

This dental model analysis software could perform Bolton analysis and dental arch analysis along with simulation of orthodontic treatments. However, further development of model analysis software to obtain the data and analyses in frontal and lateral views of dental models to complete the dental model analysis procedures.

Acknowledgment

The proposal of this paper is to mention about a dental model analysis module to be integrated as a part of software modules in the CephSmile V2.0 project to create the cephalometric analysis software for orthodontists.

We would like to thank National Electronics and Computer Technology Center for providing the grant for this project and orthodontists from Orthodontic Department, Faculty of Dentistry, Mahidol University for providing the photographic data of dental model along with other information relating to dental model analysis.

We appreciated Mr. Phanaphon Panjamanee for the contributions on image segmentation to simulate orthodontic treatment along with the dental arch drawing.

Abstract — **A method of classifying the precancerous cells from Papanicolaou smear images is proposed in this paper. The proposed method utilizes a set of simple features extracted from the two-dimensional Fourier transform of the cell images in order to avoid the problem of cell and nucleus segmentation. The features used to discriminate between the normal and the abnormal cells are calculated based on the mean, variance, and entropy obtained from the frequency components along the circle of radius r centered at the center of the spectrum and the frequency components along the radial line having an angle θ.**

The classification results achieved by five classifiers are compared in order to evaluate the utilization of the selected features in normal and abnormal cell classification using four-fold cross validation. The classifiers used in this research include Bayesian classifier, linear discriminant analysis (LDA), K-nearest neighbor (KNN) algorithms, artificial neural network (ANN), and support vector machine (SVM). The classification rates obtained from these classifiers show promising performances. The result from the support vector machine provides the best accuracy and the lowest false rate. It achieves more than 92% correct classification rate on a set of 276 cervical single-cell images containing 138 normal cells and 138 abnormal cells.

Keywords — **Cervical cell, Fourier transform, Image classification, Frequency spectra, Feature extraction.**

I. Introduction

Cervical cancer is the most common cancer among women. This type of cancer, however, has good prognosis if it is detected and treated in the early stage. In Thailand, the National Cervical Cancer Prevention and Control Program suggests that women aged 35-60 years should perform the screening by Papanicolaou smear or the so-called Pap smear every 5 years [1]. The major problem of the screening program is the lack of an expert cytotechnologist and a large number of slides per day. For the past thirty years, many researches have focused on creating the automatic system for Pap smear screening in order to help solving these problems.

Several previous works have been focused on finding the effective features for the automated screening system. Most of the proposed techniques employed the features which depend on the accurate segmentation of cytoplasm and nucleus. In [2], a set of single cell images were segmented into nucleus and cytoplasm. The features were calculated from characteristics of nucleus and cytoplasm. The method in [3] proposed the feature sets based on the texture of nucleus only. One of the techniques for extracting features from a cervical cell is the Malignancy Associated Changes (MACs) measurements [4, 5]. MACs are the changes of DNA distribution in nuclei due to the effect of malignancy which can be observed from nucleus texture alteration. The image database used in these works was a taken in high resolution. It was also taken from slides that were stained by the Feulgen-Thionin technique since it provided strong nuclear-cytoplasmic contrast which is suitable for automated cell classification system. However, such high quality cell images are not commonly used in the cervical cancer screening program.

To avoid the problem of cell and nucleus segmentation, several attempts have been focused on Pap smear classification using the feature sets derived from frequency domain. The method for classifying cervical cells based on the optical power spectrum using analog system was proposed [6]. The idea of utilizing the features from frequency spectrum was investigated by using Discrete Fourier Transform implemented on digital computer [7-11]. The advantage of this approach is that the accurate segmentation of cell and its nucleus is not needed. However, it should be noted that this approach was applied to the single cell image captured in high resolution only.

This paper proposes a new method to classify the normal cervical cells and the abnormal cells (precancerous cells) by using a set of simple features extracted from the Fourier transform of the low resolution cell images. This allows us to avoid the cell segmentation process and a high resolution image acquisition system. The results of classification by several classifiers are compared in order to evaluate the ability of the extracted features used in classification of normal and abnormal cells.

This paper is organized as follows. Section II describes the data set and methods applied in this research including feature extraction and classifiers. The classification results are shown and discussed in section III. The conclusion is drawn in section IV.

II. Materials and Methods

A. Data Description

The images of cervical cell are obtained from [12]. The examples of the images in this data set are shown in Fig 1. There are 276 single cell images consisting of:

- 138 normal cell images with 63 superficial cells and 75 intermediate cells, and
- 138 abnormal cell images with various degrees of abnormality. The abnormal data consists of 34 light dysplastic cells, 34 moderate dysplastic cells, 35 severe dysplastic cells, and 35 carcinoma in situ (CIS) cells.

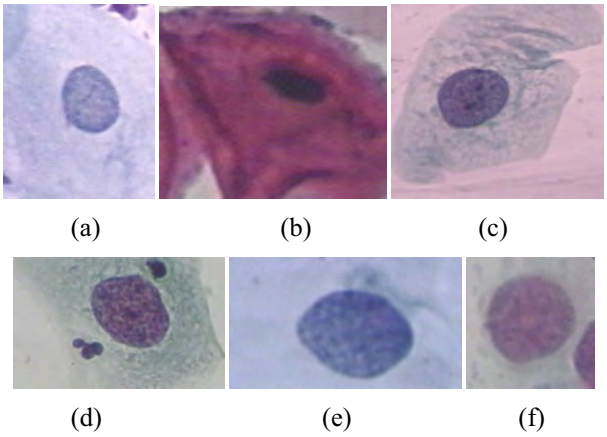

Fig. 1 Sample image of different cervical cell types (a) Normal intermediate cell, (b) Normal superficial cell, (c) Light dysplastic, (d) Moderate dysplastic, (e) Severe dysplastic, and (f) CIS

B. Fourier Transform-based Features

Each $M \times N$ cell image is transformed to the 2-D Fourier spectrum using the discrete Fourier transform defined by:

$$F(u,v) = \sum_{x=0}^{M-1}\sum_{y=0}^{N-1} f(x,y) e^{-j2\pi\left(\frac{ux}{M}+\frac{vy}{N}\right)} \quad (1)$$

for $u = 0,1,2,...,M-1$ and $v = 0,1,2,...,N-1$. The zero-frequency component is moved to the center of spectrum. Each component in the 2-D spectrum is transformed to the domain of polar coordinates, $F(r,\theta)$. This function is separated into two 1-D functions, i.e., the radial function $F(r)$, and the angular function $F(\theta)$. The radial function is defined as the frequency components along the circle of radius r centered at the center of the spectrum. The angular function is the frequency components along the radial line having an angle θ with respect to the u-axis. The radial and angular functions in frequency domain are illustrated in Fig 2.

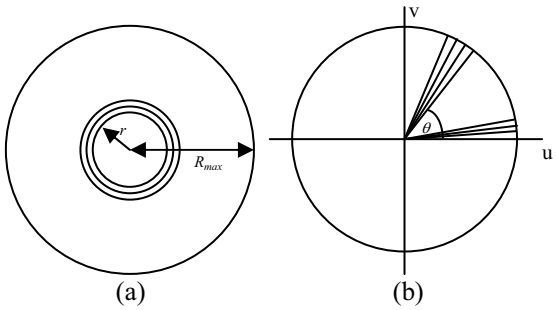

Fig. 2 Frequency spectrum in terms of (a) radial function, $F(r)$ and (b) angular function $F(\theta)$

The behavior of the frequency component at each pair of values of r and θ is represented by three statistical values, i.e., mean, variance, and entropy. The features used to discriminate between the normal and abnormal cells are calculated based on these values in the following equations:

Mean of $F(r)$ for any r :

$$\mu_r = \frac{1}{n_r}\sum_{i=1}^{n_r} F_i(r) \quad (2)$$

Variance of $F(r)$ for any r :

$$\sigma_r^2 = \frac{1}{n_r}\sum_{i=1}^{n_r}\left[F_i(r) - \mu(r)\right]^2 \quad (3)$$

Entropy of $F(r)$ for any r :

$$H_r = -\sum_{k=0}^{M-1} p_k(r)\cdot\log_2 p_k(r) \quad (4)$$

Mean of $F(\theta)$ for any θ :

$$\mu_\theta = \frac{1}{n_\theta}\sum_{j=1}^{n_\theta} F_j(\theta) \quad (5)$$

Variance of $F(\theta)$ for any θ :

$$\sigma_\theta^2 = \frac{1}{n_\theta}\sum_{j=1}^{n_\theta}\left[F_j(\theta) - \mu(\theta)\right]^2 \quad (6)$$

Entropy of $F(\theta)$ for any θ :

$$H_\theta = -\sum_{k=0}^{M-1} p_k(\theta)\cdot\log_2 p_k(\theta) \quad (7)$$

where n_r is the number of components in a circle of radius r. n_θ is the number of components along the radial line with angle θ. $p(r)$, $p(\theta)$ are the normalized histogram counts of the components of radius r and angle θ, respectively. M is the number of intensity levels in the frequency spectrum.

In total, 43 features are obtained by extracting the features in two ways: 1) calculating from the whole frequency spectrum and 2) calculating from subsections by dividing the spectrum into annular rings and radian wedges. The equations of each feature are defined below.

1. Features from whole frequency spectrum

Six features are extracted from the whole frequency spectrum in both radial and angular functions. The calculations are as follows:

Summation of mean of

$$F(r): f_1 = \sum_{r=1}^{R_{\max}} \mu_r \tag{8}$$

Average variance of

$$F(r): f_2 = \frac{1}{N_r} \sum_{r=1}^{R_{\max}} \sigma_r^2 \tag{9}$$

Average entropy of

$$F(r): f_3 = \frac{1}{N_r} \sum_{r=1}^{R_{\max}} H_r \tag{10}$$

Summation of mean of

$$F(\theta): f_4 = \sum_{\theta=0}^{2\pi} \mu_\theta \tag{11}$$

Average variance of

$$F(\theta): f_5 = \frac{1}{N_\theta} \sum_{\theta=0}^{2\pi} \sigma_\theta^2 \tag{12}$$

Average entropy of

$$F(\theta): f_6 = \frac{1}{N_\theta} \sum_{\theta=0}^{2\pi} H_\theta \tag{13}$$

where N_r is the total number of circles in the frequency image. N_θ is the total number of radial lines in the frequency image, and $R_{\max}$ is the maximum possible radius of a circle inscribed in the spectrum area.

2. Features from spectral subsections

In order to create spectral subsections, the frequency spectrum is divided in two manners, i.e., the annular ring and the radian wedge.

2.1 Annular ring subsection

Since the information of an image is mostly contained in a frequency component with small radius, the annular ring is then limited to the radius ranged from r=2 to 60% of $R_{\max}$. This area is divided into 5 annular rings with equal distance (Δr) between the adjacent rings.

A total of 25 features are obtained from the annular ring subsections. Each ring consists of 5 features as follows:

Summation of mean of the j^{th} ring:

$$f_7 = \sum_{r=r_j}^{r_j+\Delta r} \mu_r \tag{14}$$

Average variance of the j^{th} ring:

$$f_8 = \frac{1}{N_{rj}} \sum_{r=r_j}^{r_j+\Delta r} \sigma_r^2 \tag{15}$$

Average entropy of the j^{th} ring:,

$$f_9 = \frac{1}{N_{rj}} \sum_{r=r_j}^{r_j+\Delta r} H_r \tag{16}$$

Average variance of the product of the j^{th} ring:

$$f_{10} = \frac{1}{N_{rj}} \sum_{r=r_j}^{r_j+\Delta r} \sigma_{Fr}^2 \tag{17}$$

Average entropy of the product of the j^{th} ring:

$$f_{11} = \frac{1}{N_{rj}} \sum_{r=r_j}^{r_j+\Delta r} H_{Fr} \tag{18}$$

where N_{rj} is the total number of circles in the j^{th} ring. σ_{Fr}^2 is the variance of the function $r \cdot F(r)$. H_{Fr} is the entropy of the function $r \cdot F(r)$ and r_j is the inner radius of the j^{th} ring.

2.2 Radian wedge subsection:

The frequency spectrum between 0 and 180 degrees is divided into 4 equiangular $(\Delta\theta)$ subsections. Three features of each wedge-liked section are calculated by (19) to (21).

The calculation on these four subsections results in 12 wedge features.

Summation of mean of the k^{th} wedge:

$$f_{12} = \sum_{\theta=\theta_k}^{\theta_k+\Delta\theta} \mu_\theta \tag{19}$$

Average variance of the k^{th} wedge:

$$f_{13} = \frac{1}{N_{\theta k}} \sum_{\theta=\theta_k}^{\theta_k+\Delta\theta} \sigma_\theta^2 \tag{20}$$

Average entropy of the k^{th} wedge:

$$f_{14} = \frac{1}{N_{\theta k}} \sum_{\theta=\theta_k}^{\theta_k+\Delta\theta} H_\theta \tag{21}$$

where $N_{\theta k}$ is the total number of the radial lines in the k^{th} wedge, and θ_k is the left edge of the k^{th} wedge.

The total of 43 features values from radial and angular distributions are scaled to the range of [−1, 1] prior to the classification process.

C. Classification

Five classifiers including Bayesian classifier, linear discriminant analysis (LDA), K-nearest neighbor (KNN), artificial neural networks (ANN), and support vector machine (SVM), are investigated. The performance of 5 classifiers on discriminating the normal and abnormal cells is evaluated. In this research, 5 nearest neighbors are used for KNN. For ANN, we use three-layer backpropagation neural network which composed of 43 inputs in the input layer, 1 hidden layer with 20 neurons and 2 outputs in the output layers as suggested in [8]. For SVM, the exponential radial basis function (ERBF) kernel is chosen. After extensive trials, the best parameters for SVM in this research are the kernel spread parameter σ=0.8, the regularization parameter C=10^5, and ε = 0.1.

III. Experimental results and discussion

The classification results from each classifier are obtained using 4-fold cross validation. A total of 276 single cell images are separated into 2 groups, i.e., 68 images (one-fourth of the total images) are used as a test set. The rest of the images (208 images) are used as a training set. Due to space limitation, we cannot show all confusion matrices of the classifiers. The classification accuracy, the false positive and false negative rates are summarized in Table 1. The false positive rate (FP) is the proportion of normal cells (negative cases) that are incorrectly classified as abnormal cells (positive cases.) The false negative rate (FN) is the proportion of abnormal cells (positive cases) that are incorrectly classified as normal cells (negative cases.)

Considering the results in Table 1, the selected features provide good classification results even with a simple classifier such as Bayesian or LDA. The LDA give the lowest accuracy compared with other classifiers tested in this study. This may be because the data in this study is not linearly separable. KNN, ANN and SVM produce the classification rate higher than 90%. The best classification rate at 92.65% is obtained from SVM.

The false negative rate is important for cancer cell classification. If the abnormal cell is predicted as a normal cell, it will lead to undiagnosed abnormality which can progress to cancer. Even though the false negative rate of Bayesian is the lowest, the false positive rate is the highest. This could be because the Gaussian distribution of classes is not suitable for this dataset. Among all classifiers, SVM gives the optimum rates of both false positive and false negative of 7.35% for both parameters. SVM is the best classifier for this research.

Table 1 Classification results (%) from each classifier

	Classifier				
	Bayes	LDA	KNN	ANN	SVM
Accuracy	88.97	88.60	91.18	91.91	92.65
False positive	14.67	10.53	8.82	8.09	7.35
False negative	6.56	12.23	8.82	8.09	7.35

IV. Conclusion

This research proposed the method for classifying images of cervical cell by using a set of 43 simple features calculated from Fourier spectrum of the images. The images are classified into 2 classes, i.e., normal cervical cell and abnormal cells which are the cell that potentially progress to cancer. The classification rates obtained from 5 classifiers are quite good with the accuracy higher than 85%. The results show that Support Vector Machine provides the best result with 92.65% accurate and the false rates are 7.35% for both false positive and false negative. It is shown that the simple features from Fourier spectrum are usable in classification of the single cell image. For further development, the classification for non-isolated cells such as overlapping cells and cell cluster will be developed to avoid the cell isolation step.
