   f. Renal abnormalities
      i. Aplastic/dysplastic/hypoplastic kidneys
      ii. Horseshoe kidneys

iii. Ureteral duplications
iv. Megaureter
v. Hydronephrosis
vi. Cystic diverticula
vii. Vesicovaginal fistula

g. Genital abnormalities
i. Hypospadias
ii. Labial hypoplasia

h. Cutaneous abnormalities
i. Hemangiomas
ii. Hirsutism

i. Auditory abnormalities
i. Conductive hearing loss
ii. Neurosensory hearing loss

j. Neuroendocrine abnormalities
i. Altered hypothalamic-pituitary-adrenocortical axis-heightened stress response
ii. Abnormal thyroid function

k. Other abnormalities: include virtually any malformation

4. Alcohol-related neurodevelopmental disorder (ARND)
a. Structural CNS abnormalities associated with in utero alcohol exposure
i. Microcephaly
ii. Microencephaly
iii. Decreased size of cerebrum, cerebellum, basal ganglia, diencephalons
iv. Partial or complete agenesis of the corpus callosum
v. Neuroglial heterotopia
vi. Dendritic neuronal abnormalities
vii. Holoprosencephaly sequence
viii. Anencephaly
ix. Porencephaly
x. Ventricular enlargement
xi. Dandy–Walker malformation

b. Neurologic abnormalities associated with in utero alcohol exposure
i. Impaired fine motor skills
ii. Deficits in balance
iii. Poor tandem gait
iv. Neurosensory hearing loss
v. Poor hand–eye coordination
vi. Hypotonia

c. Neurobehavioral abnormalities associated with in utero alcohol exposure
i. Learning disabilities
ii. Decreased IQ scores
iii. Mental retardation
iv. Attention deficit/hyperactivity disorder
v. Poor impulse control
vi. Problems in memory, attention, or judgment
vii. Problems in social perception
viii. Deficits in higher level receptive or expressive language
ix. Poor capacity for abstraction or metacognition
x. Autism
xi. Adult mental illness
a) Alcohol or drug dependence
b) Psychotic disorders
c) Avoidant, antisocial, or dependent personality disorder
d) Depression
e) Suicide
xii. Alcohol or drug dependence
xiii. Psychotic disorders
xiv. Avoidant, antisocial, or dependent personality disorder
xv. Depression
xvi. Suicide

5. Neonatal alcohol withdrawal signs
a. Hypoglycemia
b. Irritability
c. Tremors
d. Seizures
e. Autonomic dysregulation, including temperature instability
f. Blood pressure abnormalities
i. Hypotension
ii. Hypertension
g. Excessive glucocorticoid release
h. Altered behavioral state organization

6. Medical risks for women who drink alcohol (Bradley et al. 1998)
a. Increased mortality and breast cancer in women who drink more than two drinks daily.
b. Increased menstrual symptoms, hypertension, and stroke in women with higher levels of alcohol consumption.
c. Increased infertility and spontaneous abortion in women who drink heavily.
d. Adverse fetal effects after variable amounts of alcohol consumption, making any alcohol use during pregnancy potentially harmful.

Diagnostic Investigations

1. Diagnosis of FAS based on clinical features in the setting of maternal alcohol use
2. Radiography for skeletal abnormalities
3. Neuroimaging in FASD (Norman et al. 2009)
   a. MRI imagings for CNS abnormalities
      i. Overall reduction in brain volume
      ii. CNS disorganization
      iii. Structural abnormalities
         a) Corpus callosum
         b) Cerebellum
         c) Caudate
         d) Hippocampus
   b. Neuroimaging techniques
      i. Regional increases in cortical thickness and gray matter volume
      ii. Decreased volume and disorganization of white matter in individuals
   c. Functional imaging studies: functional and neurochemical differences in those prenatally exposed to alcohol
4. Echocardiography for cardiovascular anomalies
5. Ultrasound for renal abnormalities
6. Neurologic and neurobehavioral evaluations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: high if the mother abuses alcohol during the pregnancy
   b. Patient's offspring: high if the affected woman abuses alcohol during her pregnancy
2. Prenatal diagnosis
   a. Low maternal serum alpha-fetoprotein and low pregnancy-specific β_1-glycoprotein observed in one report possibly reflecting primary or secondary effects of ethanol abuse in pregnancy and possibly useful in predicting fetal alcohol syndrome.
   b. Prenatal ultrasound examination recommended for pregnant women who drink to detect fetal growth retardation and various birth defects associated with in utero alcohol exposure.
3. Management (Thackray and Tifft 2001)
   a. Beneficial effects of early diagnosis of FAS on medical intervention of affected infants and children.
   b. Management of issues (medical and surgical interventions) regarding specific birth defects.
   c. Implementation of resource programs for developmental delay, functional abilities, speech abilities, and social/behavioral interactions.
   d. Appropriate interventions with educational evaluation and support and community resources such as The National Organization on Fetal Alcohol Syndrome (NOFAS).
   e. Evaluate and manage the siblings who also have FAS.
   f. Prevention of alcohol-induced fetal brain damage (AAP 2000).
      i. Abstinence recommended for pregnant women and for those planning pregnancy since there is no known safe amount of alcohol consumption during pregnancy.
      ii. High-quality educational programs regarding the deleterious effects of alcohol on the unborn child.
      iii. High awareness of FAS and ARND and their prevention by health care professionals.
      iv. Appropriate support services including prevention of recurrence for parents and children diagnosed as having FAS or ARND.

Fetal Hydantoin Syndrome

Fetal hydantoin syndrome is by far the best-characterized malformation complexes induced by anticonvulsant drugs used to treat maternal epilepsy.

Genetics/Basic Defects

1. Cause: maternal exposure to hydantoin anticonvulsant
2. Effect of prenatal exposure to hydantoin
   a. Fetal hydantoin syndrome in 11% of cases
   b. Fetal hydantoin effect in an additional 31% of cases
3. Teratogenicity of hydantoin
   a. Mediated not by the parent compound but by toxic intermediary metabolites that are produced during the biotransformation of the parent compound
   b. Epoxide (oxidative intermediates): the primary teratogenic agent of phenytoin
      i. Thought to occur before the formation of the dihydrodiol metabolite in a reaction catalyzed by the enzyme epoxide hydrolase
      ii. Highly reactive and capable of covalently binding to embryonic or fetal nucleic acids, which at critical periods of embryogenesis, are theoretically capable of disrupting normal development

Clinical Features

1. Eleven percent of infants exposed prenatally to hydantoin classified as having the fetal hydantoin syndrome
2. Presence of variable patterns of malformations
3. Classic features
   a. Growth and development
      i. Developmental delay
      ii. Mild to moderate mental retardation
      iii. Prenatal and postnatal growth deficiencies
      iv. Microcephaly
   b. Craniofacial anomalies
      i. Ridging of the metopic suture
      ii. Broad and low nasal bridge
      iii. Ocular defects
         a) Hypertelorism
         b) Ptosis
         c) Strabismus
         d) Wide epicanthal folds
         e) Congenital glaucoma
         f) Retinoschisis
         g) Nasolacrimal duct deformity and agenesis
         h) Coloboma of the iris and choroid
      iv. Short upturned nose
      v. Low-set ears
      vi. Wide mouth with prominent lips
      vii. Cleft lip and/or palate
   c. Limb defects
      i. Hypoplasia of distal phalanges and nails (most characteristic feature)
      ii. A finger-like thumb
      iii. Hyperphalangism
      iv. Adactyly/absent nails
      v. Acheiria (congenital absence of one or two hands)
      vi. Positional limb defects
         a) Calcaneovalgus deformity
         b) Pes cavus
      vii. Abnormal palmar creases

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_92,
© Springer Science+Business Media, LLC 2012

4. Less frequently observed abnormalities
   a. Neck webbing
   b. Cardiovascular anomalies
      i. Aortic coarctation
      ii. Patent ductus arteriosus
      iii. Septal defects
   c. Gastrointestinal abnormalities
      i. Pyloric stenosis
      ii. Duodenal atresia
   d. Renal defects
   e. Genital abnormalities in males
      i. Hypospadias
      ii. Bifid or shawl scrotum
   f. Hernias
      i. Diaphragmatic hernia
      ii. Umbilical hernia
      iii. Inguinal hernias
   g. Other skeletal anomalies
      i. Spinal anomalies
         a) Scoliosis
         b) Segmentation defects of vertebral bodies
      ii. Rib and sternal anomalies
   h. Occasional tumor association
      i. Neuroblastoma
      ii. Melanotic neuroectodermal tumor of infancy
   i. Single umbilical artery

Diagnostic Investigations

1. Radiography for skeletal defects
2. Echocardiography for associated congenital heart defect
3. Renal ultrasound for renal defects
4. Developmental evaluation

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: minimal in the absence of maternal exposure to hydantoin during pregnancy
   b. Patient's offspring: minimal in the absence of maternal exposure to hydantoin during pregnancy
2. Prenatal diagnosis: prenatal ultrasound examination recommended for pregnant women who take hydantoin anticonvulsant to detect fetal growth retardation and various birth defects associated with in utero hydantoin exposure
3. Management
   a. Management of issues (medical and surgical interventions) regarding specific birth defects
   b. Implementation of resource programs for developmental delay, functional abilities, speech abilities, and social/behavioral interactions
   c. Appropriate interventions with educational evaluation and support
   d. Avoid hydantoin anticonvulsant during pregnancy

Fibrodysplasia Ossificans Progressiva

Fibrodysplasia ossificans progressiva (FOP), an extremely rare and catastrophic genetic disorder of progressive heterotopic ossification, is the most disabling condition of extraskeletal ossification known to mankind. It is also known as myositis ossificans progressiva. The incidence of FOP was estimated to be approximately 1 in 1.64 million (Connor and Evans 1982b).

Synonyms and Related Disorders

Myositis ossificans progressiva

Genetics/Basic Defects

1. Inheritance
   a. Usually sporadic in occurrence: very few affected individuals have children because of the devastating nature of the disease
   b. Autosomal dominant inheritance
      i. Complete penetrance
      ii. Variable expression
2. Cause (Shore et al. 2006)
   a. FOP is caused by a recurrent heterozygous mutation (c.617G>A; p.R206H) of codon 206 in the glycine-serine (GS) activation domain of activin receptor 1A (ACVR1)/activin-like kinase (ALK2), a highly conserved BMP type I receptor, in all sporadic and familial cases of classically affected individuals worldwide, making this one of the most highly specific disease-causing mutations in the human genome.
   b. Chromosomal locus for the *FOP* gene: 2q23-24 by genome-wide linkage analysis.
3. Presence of two skeletons in patients with FOP (Mahboubi et al. 2001)
   a. A normotopic bone formation during embryogenesis
      i. Grossly normal normotopic skeleton
      ii. Exceptions
         a) Segmentation defects in the cervical spine
         b) Malformation of the great toes at birth due to shortening of the first metatarsal and proximal phalanx
         c) Monophalangic great toes due to synostosis: the earliest phenotypic feature of fibrodysplasia ossificans progressiva
   b. A heterotopic bone formation following birth
      i. Usually beginning in the first decade of life
      ii. Progressing in characteristic anatomic patterns
      iii. Typically involving upper back and neck
      iv. Heralded by large painful swellings of highly vascular fibroproliferative tissue involving ligaments, tendons, and skeletal muscle, often following minor trauma
      v. Early swelling regresses spontaneously but often matures to true heterotopic bone
4. Pathogenesis:
   a. p.R206H mutation in the *ACVR1* gene enhances ACVR1 activation and disrupts the highly conserved BMP signaling pathway (Groppe et al. 2007)
   b. When triggered by an inflammatory stimulus, some normal-functioning connective tissue may metamorphose into heterotopic bone (Kaplan et al. 2008)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_93,
© Springer Science+Business Media, LLC 2012

5. Precipitating factors for ectopic ossification (Kocyigit et al. 2001)
   a. Biopsies
   b. Intramuscular injections
   c. Dental therapy
   d. Prolonged pressure on the body, such as tight clothing
   e. Aggressive physical therapy
   f. Falls
   g. Injuries
   h. Exacerbation of bone formation common in response to surgery and other tissue trauma

Clinical Features

1. Appears to be normal at birth except for tell-tale malformations of the great toes (Kaplan et al. 2005)
2. Extraskeletal abnormalities (100%)
   a. Progressive widespread heterotopic ossification of muscles, tendons, ligaments, aponeurosis, and fascia. The heterotopic bony masses lead to progressive immobility/disability (100%)
   b. Onset: about 4 years of age in majority of patients
   c. Typical course of lesional progression at any site (Mahboubi et al. 2001)
      i. Early lesions during the first few weeks: characterized by pain, erythema, swelling, warmth, and tenderness
      ii. Intermediate lesions after several weeks
         a) Swelling beginning to subside
         b) Decrease in pain, tenderness, and erythema
      iii. Late lesions after approximately 12 weeks
         a) Disappearance of swelling
         b) A hard, non-tender lesion remains. It is roentgenographically a new area of heterotopic ossification
   d. Characteristic anatomical progression of heterotopic bone formation (Mahboubi et al. 2001)
      i. Typical earliest involvement: dorsal, axial, cranial, and proximal regions of the body
      ii. Later involvement: ventral, appendicular, caudal, and distal regions of the body
   e. Proximal medial tibial osteochondromas (>90%)
   f. Variation in size of soft tissue nodules involving the neck and back: often the first indication of heterotopic ossification in a child
   g. Progressive ankylosis
      i. Shoulder joints
      ii. Elbow joints
      iii. Hip joints
      iv. Knee joints
      v. Neck (>90%): painful swelling or stiffness of the neck in most patients
      vi. Spine
         a) Leading to complete fusion
         b) Mimicking ankylosing spondylitis
         c) Pain and stiffness of the spine present in most patients
      vii. Muscles of mastication
         a) Leading to limited mouth opening
         b) Inability to feed orally
         c) Poor oral hygiene
         d) Subsequent cachexia
   h. Severe restrictive pulmonary disease
      i. Causes
         a) Scoliosis of the thoracolumbar spine
         b) Ankylosis of costovertebral joints
         c) Ossification of the chest wall with resultant dependence on diaphragm for respiration
      ii. Severely reduced lung volume
      iii. Constrictive airway dysfunction developing over time
      iv. Recurrent pulmonary infections secondary to ineffective cough: a common cause of death in the third or fourth decade
   i. Eventual confinement to wheelchair
3. Congenital malformation (microdactylia) of the great toes (>95%) and thumbs (50%)
   a. Association with congenital great toe malformation
      i. Mainly short big toes with single phalanx (a cartilaginous anlage of the first metatarsal and proximal phalanx) present at birth
      ii. An important early diagnostic clue
   b. Shortened thumbs
   c. Clinodactyly of the fifth fingers
4. Other features
   a. Patients with FOP are prone to fractures with poor outcome
   b. Occasional baldness
   c. Conductive hearing loss (~50%) secondary to calcification and fusion of the ligaments, tendons, and bones of the middle ear
   d. Markedly reduced reproductive fitness

e. Life-threatening complications caused by thoracic insufficiency syndrome (95%) due to:
   i. Costovertebral malformations with orthotopic ankylosis of the costovertebral joints
   ii. Ossification of intercostals muscles, paravertebral muscles, and aponeuroses
   iii. Progressive spinal deformity
      a) Kyphoscoliosis
      b) Thoracic kyphosis
   iv. Pneumonia
   v. Right-sided congestive heart failure
f. Reduced life span but most patients survive to adulthood

5. Natural history
   a. Mobility becomes more restricted as the disease advances.
   b. A life-long rigid immobility caused by the progressive metamorphosis of skeletal muscle and soft connective tissue into a second skeleton of heterotopic bone.
   c. Typically confined to bed or wheelchair by early 30s.
6. Diagnostic criteria (Kartal-Kaess et al. 2010)
   a. Major characteristics
      i. Congenital malformation of the great toes (earliest phenotypic feature)
      ii. Progressive extraskeletal bone formation (episodic, begin during childhood)
      iii. Heterozygous *ACVR1* mutation
   b. Other features
      i. Early stage lesions associated with soft tissue swellings and inflammation in characteristic anatomic patterns
      ii. Predictable regional pattern of heterotopic ossification
      iii. Cervical spine fusions
      iv. Short/broad femoral necks
      v. Osteochondromas
      vi. Conductive hearing loss
7. Differential diagnosis of heterotopic ossification (Kartal-Kaess et al. 2010)
   a. Progressive osseous heteroplasia (Shore and Kaplan 2005)
      i. Presence of cutaneous ossification
      ii. Absence of congenital malformations of the skeleton
      iii. Absence of inflammatory tumor-like swellings
      iv. Asymmetric mosaic distribution of lesions
      v. Absence of predictable regional patterns of heterotopic ossification
      vi. Presence of dominance of intramembranous rather than endochondral ossification
      vii. Inherited only paternally
      viii. Carries inactivating mutations of the *GNAS* gene, a gene that is regulated through genomic imprinting and allele-specific gene expression
   b. Posttraumatic: myositis ossificans circumscripta
   c. Neurogenic
      i. After head trauma or spinal cord injury
      ii. After long coma
   d. Postsurgical: after total joint arthroplasties
   e. Reactive
      i. Bizarre parosteal osteochondromatous proliferation
      ii. Florid reactive periostitis
      iii. Subungual exostosis
   f. Neoplasms
      i. Sarcoma
      ii. Malignant fibrous histiocytoma
   g. Degenerative processes

Diagnostic Investigations

1. Radiography (Bridges et al. 1994)
   a. Extraskeletal ossification
      i. Progressive widespread heterotopic ossification of muscles, tendons, ligaments, and fascia
      ii. Ankylosis
         a) Shoulder joints
         b) Elbow joints
         c) Hip joints: prevent ability to ambulate
         d) Knee joints
         e) Muscles of mastication
   b. Phalangeal abnormalities
      i. Characteristically affecting the great toes
         a) Shortened first digits
         b) Delta-shaped proximal phalanges
         c) Often monophalangism with absence of the interphalangeal joint of the great toes
      ii. Shortened thumbs
      iii. Clinodactyly of the fifth fingers

   c. Less common congenital malformations
      i. Small vertebral bodies and enlarged pedicles in early childhood
      ii. Variable degrees of vertebral fusion, especially apophysial joint fusion in late childhood
      iii. Short, broad femoral necks
      iv. Ossification of ligamentous insertions producing exostoses of the proximal tibia
      v. Delay in skeletal maturation
      vi. Enchondroma formation
      vii. Association with synovial chondromatosis
2. Bone scintigraphy (radionuclide imaging) (Tulchinsky 2007)
   a. A very sensitive technique for new bone formation in FOP
   b. Reveals multiple foci of increased uptake in connective tissue at characteristic locations, in combination with pathognomonic microdactyly of the great toes (or thumbs): highly specific
3. CT scan
   a. Useful for diagnosis because CT scan is very sensitive for calcification.
   b. Soft tissue swelling in the fascial planes and muscle in the early course of FOP.
   c. Evidence of soft tissue calcification, typically in the form of shell seen within days to a few weeks.
   d. Calcification appearing as spicules in the soft tissue or in thin planes along the fascia often encircling muscle.
   e. Able to delineate the presence or absence of bone destruction, differentiating FOP from invasive processes such as infection and tumor.
4. MRI: a sensitive imaging technique for soft tissue abnormalities but not particularly useful for diagnosis
5. Ultrasonography to demonstrate echogenic and shadowing mass
6. Audiography: mixed-type hearing loss with prominent conductive component
7. Histopathology (Mahboubi et al. 2001)
   a. Earliest finding: an intense perivascular lymphocytic infiltration
   b. Followed by death of skeletal muscle and replacement by a highly vascular fibroproliferative soft tissue, which rapidly progresses through an endochondral process to form heterotopic bone
8. Molecular genetic diagnosis: mutational screening of *ACVR1* gene
   a. Detection of a specific heterozygous mutation (c.617G>A; p.R206H) in the activin A type I receptor gene (*ACVR1*) in all classically affected individuals
   b. Detection of a variant FOP phenotype (c.983G>A; p.G328E) (Carvalho et al. 2010)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected or has gonadal mosaicism
   b. Patient's offspring: 50%
2. Prenatal diagnosis: possible by molecular genetic testing of the *ACVR1* gene on fetal DNA obtained from amniocentesis or CVS for fetuses at 50% risk for FOP if a clinically diagnosed relative has an identified disease-causing *ACVR1* gene alteration
3. Management (Kocyigit et al. 2001)
   a. No effective treatment available
   b. FOP can often be recognized in children with or without previously affected family members at birth or in early years before the onset of heterotopic ossifications because of the presence of shortening of the great toe and short thumbs
   c. Early recognition allows protection of the child from injuries
      i. Avoid multiple biopsies, trauma, intramuscular injections, and dysfunctional IV catheters to prevent precipitating the heterotopic ossification and exacerbating the disease
      ii. Prevention of influenza-like illnesses
      iii. Minimal soft tissue trauma during routine dental care may precipitate permanent ankylosis of the jaw
   d. Physical therapy in general not recommended as stretching of the soft tissues around a joint can lead to a painful flare-up
   e. Steroids, nonsteroid anti-inflammatory agents, disodium etidronate, warfarin, and radiotherapy
      i. Used to halt the progression of disease
      ii. Without proven benefit
   f. Isotretinoin
      i. Principle based on its ability to inhibit differentiation of mesenchymal tissue into cartilage and bone

ii. Questionable benefit to decrease the incidence of heterotopic ossification at uninvolved anatomical sites

g. Etidronate (aminobisphosphonates)
   i. Blocks ectopic calcification and is approved by Food and Drug Administration for treatment of postoperative heterotopic ossification
   ii. Short-term effect of bone metabolism shows diminished bone turnover rate
   iii. Long-term effect on ectopic calcification is unchanged in most cases with few exceptions

h. Primary therapy for the debilitating disease: supportive care
   i. Active range-of-motion exercises encouraged if the movements are comfortable
   ii. Available adaptations or modifications prescribed to a disabled patient with FOP to achieve functional independence in the home and community
      a) Shoes
      b) Canes
      c) Wheelchairs

i. Surgery
   i. Nearly always contraindicated since new heterotopic ossification occurs at the operative site
   ii. Surgical removal of heterotopic bone
      a) Ineffective
      b) Leading to catastrophic exacerbation of the disease
   iii. Existence of intercurrent problems occasionally requiring surgery

j. Anesthesia
   i. Presenting numerous difficulties to the anesthesiologist including cervical spine ankylosis and restrictive pulmonary disease
   ii. Avoid tissue trauma in the form of local anesthetic injections
   iii. Presence of anatomical airway abnormalities
   iv. Alternative methods preferred
      a) Nebulized lidocaine
      b) IV sedation
      c) Nasotracheal intubation
   v. Proper positioning and padding perioperatively
   vi. Vigorous chest physiotherapy and pulmonary toilet postoperatively

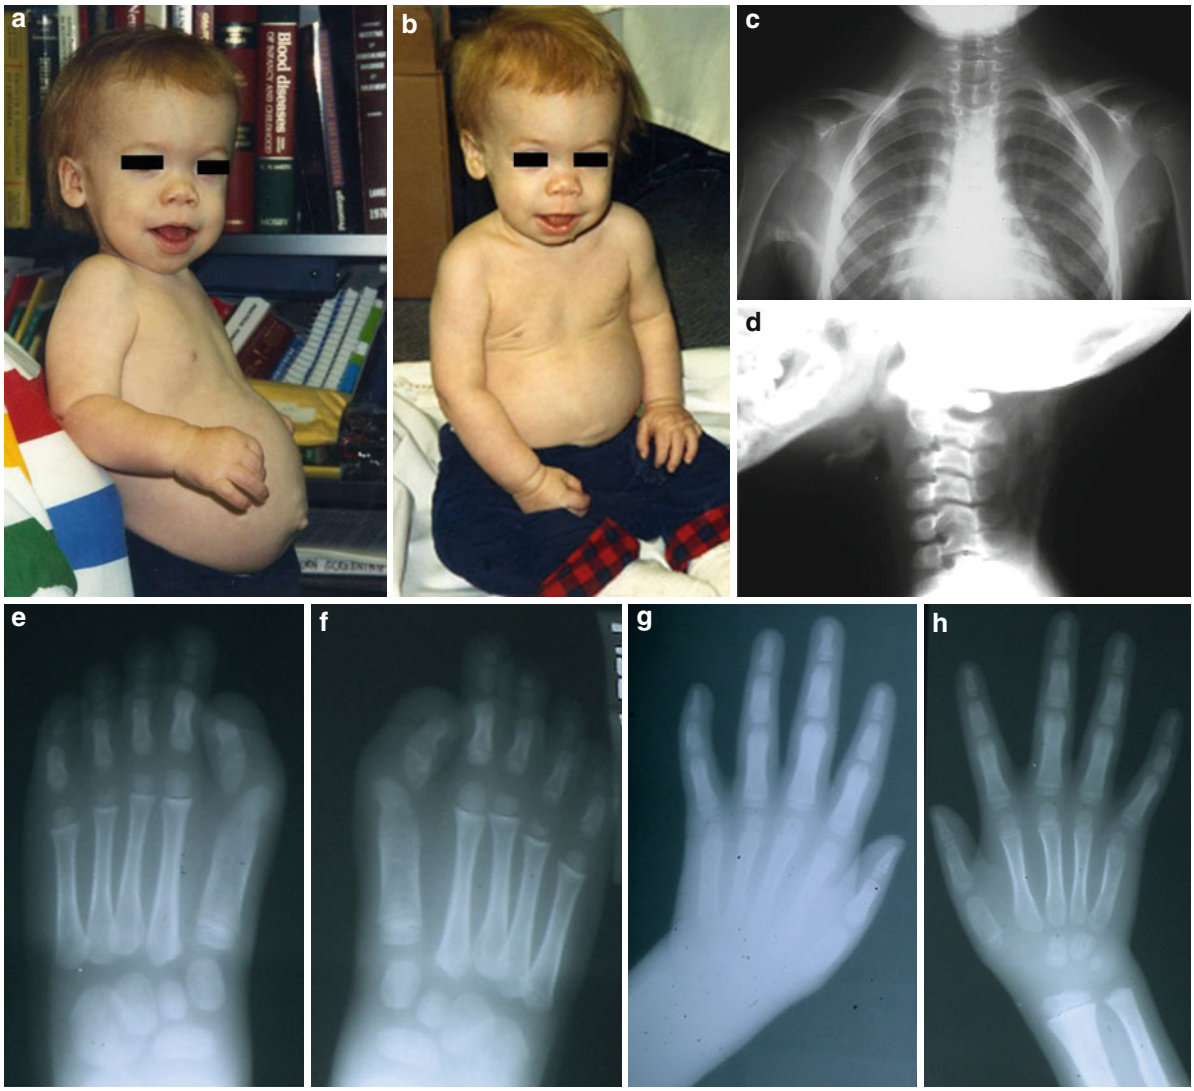

Fig. 1 (**a**–**h**) A boy with fibrodysplasia ossificans progressiva showing a stiff neck, a narrow chest, and inability to raise arms upward due to ossification of the soft tissues on the back of the neck, the lateral chest wall, and the axillary region, illustrated by the neck, chest, and pelvic radiographs. The radiographs of both feet showed shortened first toes and hallux valgus with delta-shaped proximal phalanges, monophalangism with absence of the interphalangeal joint of the great toes. The radiographs of both hands showed shortening of the first metacarpals and the middle phalanx of the fifth fingers with clinodactyly

Fig. 2 A 14-year-old girl was seen because of swelling and pain on the upper thigh, especially on the *left*. The pelvic radiograph showed extensive heterotopic calcifications on the inner upper thighs, worse on the *left*. Her father was also affected

Finlay–Marks Syndrome

In 1978, Finlay and Marks described the association of scalp defect, malformed ears, and absence of nipples in a family. The association is also known as scalp-ear-nipple syndrome.

Synonyms and Related Disorders

Scalp-ear-nipple syndrome

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant in most reports
   b. Severe autosomal recessive form: two children from an inbred Arab family with features suggestive of scalp-ear-nipple syndrome (Al-Gazali et al. 2007)
2. Lymphoid enhancer factor-1 (*Lef-1*), identified as a candidate gene for scalp-ear-nipple syndrome (van Steensel et al. 1999)
   a. *Lef-1*: an HMG-domain DNA-binding protein expressed in the neural crest, mesencephalon, tooth germs, and other sites during embryogenesis
   b. Homozygous deficiency of this gene causing postnatal lethality in mice
   c. Mutant mice lacking teeth, mammary glands, whiskers, and hair
   d. Lack of hair, missing teeth, and aplasia of breast tissue suggest that *Lef-1* may be a candidate gene for scalp-ear-nipple syndrome

Clinical Features

1. Scalp abnormalities (Edwards et al. 1994; Taniai et al. 2004)
   a. Raised firm nodules over the scalp in the occipital region, not covered by hairs
   b. The areas: raw at birth and heal during childhood
   c. Crumpled scalp over occipital region
2. External ear abnormalities
   a. Hypoplastic tragus, antitragus, and lobule
   b. Over-folding of the superior helix
   c. Flattening of the antihelix
3. Athelia (absent breasts and nipples)
   a. Rudimentary or absent nipples
   b. Breast hypoplasia or aplasia
4. Other reported features
   a. Ectodermal dysplasia features
      i. Dental anomalies
         a) Widely spaced teeth
         b) Missing secondary teeth
         c) Neonatal teeth
      ii. Reduction of axillary apocrine secretion and axillary hair growth
      iii. Hypohidrosis
      iv. Nail dysplasia
   b. Aplasia cutis vertices
   c. Renal hypoplasia
   d. Hypospadias
   e. Pyeloureteral duplication
   f. Cataract
   g. Coloboma of the iris
   h. Hypertension
   i. Diabetes mellitus
   j. Partial syndactyly

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_94,
© Springer Science+Business Media, LLC 2012

5. Hypotonia and developmental delay in severe autosomal recessive form

Diagnostic Investigations

1. No specific laboratory tests available
2. Histology of scalp defect resembling aplasia cutis congenita (Finlay and Marks 1978)
   a. An excess of normal-appearing connective tissue
   b. Lack pilosebaceous elements
3. Renal sonography for renal hypoplasia
4. Diagnosis primarily by clinical features

Genetic Counseling

1. Recurrence risk
   a. Autosomal dominant
      i. Patient's sib: low unless a parent is affected
      ii. Patient's offspring: 50%
   b. Autosomal recessive
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis: not been reported
3. Management: primarily supportive

Fig. 1 A 7-month-old boy with Finlay–Marks syndrome showing absence of nipples and abnormal ears. He also had scanty eyebrows and eyelashes, neonatal teeth, which were extracted, nasolacrimal duct stenosis, and lumpy scalp on the occiput region

Floppy Infant

A floppy infant is an infant with poor muscle tone affecting the limbs, trunk, and the craniofacial musculature. The causes are numerous (heterogeneous etiologies) and the workup in many instances can be complex. The task of evaluating infants with hypotonia is difficult and complex.

Synonyms and Related Disorders

Congenital hypotonia

Genetics/Basic Defects

1. Heterogeneous causes of hypotonia (Prasad and Prasad 2003; Igarash 2004)
   a. Chromosome disorders: central hypotonia
      i. Aneuploidy: e.g., Down syndrome (one of the most frequently encountered cause of neonatal hypotonia)
      ii. Microdeletions: e.g., Prader–Willi syndrome (neonatal hypotonia, feeding problems, and failure to thrive with later onset of hyperphagia and obesity)
      iii. Subtelomeric cryptic deletions (relatively new category of disorders that account for unexplained mental retardation): e.g., terminal 22q13.3 deletion syndrome (neonatal hypotonia can be a prominent feature)
   b. CNS malformations/encephalopathies (associated with profound neonatal hypotonia)
      i. Congenital CNS malformations
         a) Lissencephaly
         b) Holoprosencephaly
      ii. Acquired CNS disorders
         a) Birth trauma
         b) Hypoxic–ischemic encephalopathy
         c) Spinal cord injury
   c. Disorders affecting anterior horn cells and peripheral nerves
      i. Spinal muscular atrophy (SMA1) (Werdnig–Hoffman disease): generalized weakness, often spares the diaphragm, facial muscles, pelvis, and sphincters
      ii. Charcot–Marie–Tooth disease
         a) CMT1A
         b) CMT4E (congenital hypomyelination syndrome)
         c) Dejerine–Sottas syndrome (CMT3)
   d. Neuromuscular junction disorders
      i. Transient myasthenic syndrome
      ii. Hypermagnesemia of the newborn
      iii. Infantile botulism
      iv. Congenital myasthenic syndromes (neuromuscular junction disorders): bulbar, oculomotor muscles exhibit greater degree of involvement (neonatal hypotonia, easy fatigability, recurrent aspiration, feeding difficulty, cyanosis, and apnea)
         a) Congenital myasthenic with episodic apnea
         b) Slow-channel and fast-channel syndromes
         c) Endplate cholinesterase deficiency
   e. Congenital muscular dystrophies (CMD) and myopathies: hypoactive reflexes. For example,
      i. Classical congenital muscular dystrophy
      ii. Fukuyama muscular dystrophy
      iii. Walker–Warburg syndrome

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_95,
© Springer Science+Business Media, LLC 2012

iv. Muscle-eye-brain disease
v. Ullrich congenital muscular dystrophy
vi. Bethlem myopathy
vii. Rigid spine-muscular dystrophy (SEPN1 selenoprotein deficiency)
viii. Congenital myotonic dystrophy
a) Triplet repeat CTG expansion of the *DMPK* and *SIX5* genes
b) Abnormal splicing of chloride channels mRNA leading to the myotonia

f. Congenital myopathies: prominent weakness. For example,
i. Central core myopathy
ii. Nemaline myopathy
iii. Myotubular (centronuclear) myopathy
iv. Multicore myopathy
v. Congenital myopathy with fiber type disproportion

g. Metabolic disorders/myopathies: proximal musculature weakness. For example,
i. Acid maltase deficiency (Pompe disease)
ii. Pyruvate dehydrogenase complex deficiency
iii. Pyruvate carboxylase deficiency
iv. Respiratory chain defects (mitochondrial disorder)
v. Zellweger syndrome
vi. Smith–Lemli–Opitz syndrome
vii. Congenital disorders of glycosylation
viii. Phosphomannomutase-2 deficiency

h. Combined CNS and motor unit disorder
i. Metachromatic leukodystrophy
ii. Giant axonal neuropathy
iii. Familial dysautonomia
iv. Mitochondrial encephalopathy
v. Congenital muscular dystrophies

i. Congenital hypotonia with a favorable outcome (benign congenital hypotonia): characterized by an early neonatal onset and a benign clinical course: No longer considered as a specific diagnostic entity

j. Acute and systemic diseases especially in the newborn period
i. Sepsis
ii. Congestive heart failure

k. Chronic
i. Hypothyroidism
ii. Connective tissue disorder

2. Localization of hypotonia in the floppy infant (Bodensteiner 2008)
a. Supraspinal/suprasegmental hypotonia in which deep tendon reflexes are preserved:
i. Central hypotonia caused by brain lesions
a) Sepsis
b) Congenital heart failure
c) Hypoxic–ischemic encephalopathy
ii. Syndromic central hypotonia caused by brainstem lesions (extensive list of etiologic possibilities associated with constellation of dysmorphic features)
iii. Nonsyndromic central hypotonia
a) Cerebral dysgenesis (developmental anomalies of the brain).
b) Grossly normal brain by MRI includes myelination within normal range, normal development (essential hypotonia), delayed myelination, motor delay only (usually catch up to peers in tone and development by school age), developmental delay (may later be diagnosed as nonsyndromic mental retardation, frequently labeled as autistic), or global developmental delay (usually do not catch up intellectually and cognitively to peer by school age).
iv. Central hypotonia caused by craniocervical junction lesions
a) Spinal cord injury (critically ill infant with severe hypotonia at first and the nature of the injury is not usually suspected until the development of the hyperactive reflexes and the lack of the expected maturation of the corticospinal tract influences on the motor unit).
b) Chiari I malformation (may be an isolated finding that may cause hypotonia early on by compression of the lower brainstem at the level of the foramen magnum).
c) Chiari II malformation (usually associated with spina bifida and easily suspected).

b. Segmental or motor unit hypotonia in which deep tendon reflexes are depressed or lost
i. Anterior horn cell (spinal muscular atrophy)
ii. Peripheral nerve (hereditary motor sensory neuropathy)

iii. Neuromuscular junction
  a) Myasthenia gravis
  b) Congenital myasthenic syndromes
  c) Botulism
iv. Muscle
  a) Congenital myopathies
  b) Metabolic myopathies
  c) Neonatal presentation of muscular dystrophy

Clinical Features

1. Hypotonia (decreased or loss of muscle tone)
   a. Full abduction and external rotation of the legs.
   b. Flaccid extension of the arms.
   c. Prominent head lag on pull to sit (normally diminished or absent by about 2 months of age): "Pull to sit" maneuver tests axial tone of the neck and back and appendicular tone of the shoulder and arms and also tests strength to some extent. Normal response from the infant being tested is to resist the pull on the arms and shoulder.
   d. Scarf sign: produced by grasping the supine infant's hand and pulling it across the chest and bring the baby's elbow well beyond the baby's chin and the midline of the chest before encountering the resistance. The maneuver tests the appendicular tone in the shoulder and is somewhat sensitive to the gestational age of the infant, the degree of laxity of the ligaments, and the state of alertness of the child.
   e. Shoulder suspension test: produced by picking the infant up holding under the infant's arms and observe the tendency of the hypotonic infant to slip through the examiner's hands. The maneuver tests the appendicular tone but also gives some indication of head control (axial) as well as strength.
   f. Ventral suspension test: produced by lifting off the infant from the table by examiner's one hand under the infant's chest and abdomen and observe the hypotonic infant unable to lift the head above the horizontal plane and unable to flex the arms and legs.
2. Central hypotonia (disorders of central nervous system that cause decreased tone by interrupting pathways involved in the modulation) with following general characteristics:
   a. Hypotonia
   b. Obtundation
   c. Neonatal seizures
   d. Hyperactive deep tendon reflexes
   e. Neonatal encephalopathy
   f. Clinical or neuroimaging evidence for hypoxia–ischemia
3. Peripheral hypotonia (disorders of the motor unit)
   a. General characteristics
      i. Hypotonia (absence of features of central hypotonia)
      ii. Areflexia or diminished reflexes
      iii. Convincing weakness
      iv. Decreased antigravity limb movements
      v. Weak cry
      vi. Weak suck
      vii. Fasciculations
      viii. External ophthalmoplegia
      ix. Alert look
      x. Arthrogryposis
   b. Anterior horn cell disease
      i. SMA: the most common serious cause of hypotonia in the infant and child
      ii. Very few conditions other than SMA that would result in widespread denervation on EMG in the clinical setting of hypotonia and weakness in infancy
      iii. Muscle biopsy no longer necessary to make the diagnosis of SMA in the clinical situation
   c. Peripheral nerve diseases, such as CMT, rarely cause hypotonia in infancy
   d. Neuromuscular junction disease
      i. Not a common cause of hypotonia in infancy
      ii. The only category of motor unit disease in which the reflexes may be preserved
      iii. Neonatal myasthenia gravis
        a) Uncommon cause of hypotonia in infancy in recent years
        b) Caused by antibodies to the acetylcholine receptor (AchR) which are passively transferred to the infant by the mother who has autoimmune myasthenia gravis
      iv. Congenital myasthenic syndromes
        a) Much more common cause of hypotonia in infancy

b) Caused by genetic defects of neuromuscular transmission resulting in a decrease in the safety margin in neuromuscular transmission
c) Manifest clinically by easy fatigability and weakness to variable degree depending on the severity of the defect in transmission
d) Diagnosis based on fatigue with exercise
e) Affected infants may be very sensitive to neuromuscular blocking agents and may respond to AchE antagonists

v. Selected congenital myasthenic syndromes
a) AchR deficiency: early onset, variable severity, ptosis, extraocular palsy, and involvement of bulbar, arm, and legs.
b) Slow-channel syndrome: selective severe weakness of neck, wrist, and finger extensor, variable onset and severity, and common, often progressive ventilatory problems.
c) Fast-channel syndrome: variable onset and severity and may respond to AchE inhibitors.
d) Endplate rapsyn deficiency: early onset with hypotonia, respiratory failure, apnea, and arthrogryposis.
e) Congenital myasthenia syndrome with episodic apnea: early respiratory failure, episodic apnea, improvement with age, and may respond to AchE inhibitors.
f) Endplate acetylcholinesterase deficiency: ophthalmoparesis, severe axial musculature weakness, slow papillary responses.

e. Abnormalities of muscle structure or function
i. A major cause of motor unit hypotonia, second only to SMA in overall frequency
ii. Congenital myopathies
a) More likely than Duchenne muscular dystrophy as a cause of hypotonia in the first year
b) Comprised of a group of muscle diseases that typically only slowly progressive over time, although present at birth with variable severity
c) Classical congenital myopathies (central core disease, nemaline myopathy, centronuclear myopathy)
d) Other well-established congenital myopathies (multicore, congenital myopathy with fiber-type disproportion (CFTD, reducing body, fingerprint, cytoplasmic body)
e) Congenital muscular dystrophies (CMD): CMD is an important subgroup of congenital myopathies. The conditions are usually present at birth, often quite severe with muscle weakness, wasting, respiratory difficulty, and contractures, with variable involvement of brain, eyes, and other tissues. Muscle biopsies show dystrophic muscle with muscle fiber necrosis and regeneration with replacement of muscle with fibrous and fatty connective tissue. The CMD is typically subdivided into two categories: those with brain involvement (syndromic CMD, comprised of merosin-deficient CMD, CMD with partial merosin deficiency, CMD 1C, CMD with ITGA7 mutations, CMD with spine rigidity) and those without brain involvement (nonsyndromic CMD, comprised of Fukuyama CMD, muscle-eye-brain disease, Walker–Warburg syndrome 2, congenital muscular dystrophy)

iii. Central core disease
a) Variable presentation
b) Somatic abnormalities
c) Characteristic malignant hyperthermia
d) Occasional cardiomyopathy

iv. Nemaline myopathy
a) Variable presentation
b) Somatic abnormalities (infantile)
c) Muscle wasting
d) Ocular muscle weakness
e) Adult onset of pain/cramp
f) Rare cardiomyopathy

v. Centronuclear (myotubular) myopathy
a) Variable presentation
b) Somatic abnormalities (infantile)
c) Muscle wasting
d) Ocular muscle weakness with ptosis

vi. Multicore myopathy
a) Mild early presentation
b) Somatic abnormalities

c) Ocular muscle weakness with ptosis
d) Malignant hyperthermia reported
e) Cardiomyopathy reported

vii. Congenital myopathy with fiber-type disproportion (CFTD)
a) Variable presentation
b) Muscle wasting
c) Somatic abnormalities
d) Stiffness
e) Mental retardation

viii. Reducing body myopathy (X-linked)
a) Variable presentation
b) Somatic abnormalities
c) Ocular muscle weakness with ptosis
d) Cardiomyopathy reported

ix. Fingerprint body myopathy
a) Mild early presentation
b) Muscle wasting
c) Somatic abnormalities
d) Mental retardation

x. Cytoplasmic inclusion body myopathy
a) Early, moderate to severe onset
b) Somatic abnormalities
c) Cardiomyopathy

xi. Merosin-deficient DMD
a) Severe manifestation
b) Hypotonia
c) Global weakness
d) Contractures
e) Scoliosis
f) Inability to walk
g) Normal intelligence
h) Abnormal white matter signal (MRI)

xii. CMD with partial merosin deficiency
a) Milder manifestation
b) Ability to walk in most cases
c) Cardiomyopathy
d) Contractures of elbow, knees, and fingers
e) Normal intelligence
f) Normal MRI of the brain

xiii. CMD type 1C
a) Severe weakness
b) Global involvement
c) Contractures of elbow, knees, fingers
d) Cardiomyopathy
e) Normal intelligence
f) Normal MRI of the brain

xiv. CMD with ITGA7 mutation
a) Proximal muscle weakness
b) Torticolis
c) Congenital hip dislocation

xv. CMD with spine rigidity
a) Rigid spine, elbows, hips, and ankles
b) Progressive sleep hypoventilation

xvi. Ullrich CMD
a) Global weakness with contractures
b) Distal hyperextensibility
c) Calf atrophy
d) Normal intelligence

xvii. Fukuyama CMD
a) Severe generalized weakness
b) Contractures
c) Cobblestone lissencephaly

xviii. Muscle-eye-brain disease
a) Mild presentation early (ability to walk in some cases but lose walking by age 20)
b) Eye malformations (without cataracts)
c) Hydrocephalus
d) White matter abnormality (MRI)
e) Cobblestone lissencephaly

xix. Walker–Warburg syndrome
a) Severe generalized weakness
b) Contractures at elbows only
c) Lissencephaly
d) Dandy–Walker malformation or cerebellar hypoplasia, flat pons (MRI)
e) Early demise

xx. CMD 1D
a) Global delay
b) Proximal weakness greater than distal weakness
c) Muscle hypertrophy
d) Facial sparing
e) White matter changes (MRI)

4. Differentiating congenital hypotonia of central versus peripheral origin (Harris 2008)
a. Weakness
i. Central: mild to moderate
ii. Peripheral: significant (“paralytic”)
b. Deep tendon reflexes
i. Central: decreased or increased
ii. Peripheral: absent
c. Placing reactions
i. Central: sluggish or slow
ii. Peripheral: absent

d. Motor delays
   i. Central: present
   ii. Peripheral: present
e. Antigravity movements in prone and supine
   i. Central: some but less than a typical infant
   ii. Peripheral: often absent
f. Pull to sit
   i. Central: some head lag (more so than typical infant)
   ii. Peripheral: marked head lag
g. Cognition/affect
   i. Central: delayed
   ii. Peripheral: typical
h. Ability to "build up" tone, e.g., tapping under knees with infant in supine to assist them in holding hips in adduction
   i. Central: present
   ii. Peripheral: absent

5. Pattern of muscle weakness and localization in the floppy infant (Prasad and Prasad 2003)
   a. Central nervous system
      i. Corresponding disorders
         a) Chromosome disorders
         b) Inborn errors of metabolism
         c) Cerebral dysgenesis
         d) Cerebral/spinal cord trauma
      ii. Pattern of weakness and involvement
         a) Central hypotonia
         b) More prominent axial weakness
         c) Hyperactive reflexes
   b. Motor neuron
      i. Corresponding disorders (SMA)
      ii. Pattern of weakness and involvement (generalized weakness, often sparing diaphragm, facial muscles, pelvis, and sphincters)
   c. Nerve
      i. Corresponding disorders: peripheral neuropathies
      ii. Pattern of weakness and involvement (weakness with wasting involving distal muscle)
   d. Neuromuscular junction
      i. Corresponding disorders
         a) Myasthenia syndrome
         b) Infantile botulism
      ii. Pattern of weakness and involvement (weakness with greater involvement of bulbar and oculomotor muscles)
   e. Muscle
      i. Corresponding disorders
         a) Congenital myopathies
         b) Metabolic myopathies
         c) CMD
         d) Congenital myotonic dystrophy
      ii. Pattern of weakness and involvement
         a) Prominent weakness
         b) Proximal musculature
         c) Hypoactive reflexes
         d) Joint contractures
6. Congenital hypotonia with a favorable outcome (benign congenital hypotonia)
   a. No longer considered as a specific diagnostic entity
   b. The term applied to a group of patients in whom a specific diagnosis cannot be made despite best effort in workup
   c. Common features
      i. Generalized hypotonia since birth
      ii. Mild delayed or normal developmental milestones
      iii. Active movement with preserved reflexes
      iv. Significant joint laxity or hypermobility
      v. Normal investigations (muscle enzymes, EMG, nerve conduction studies, muscle biopsy)
      vi. Favorable outcome common
7. Other diagnostic features
   a. Areflexia, decreased limb movement, and demonstration of denervation on EMG suggest anterior horn cell disorders such as SMA type I.
   b. Decreased conduction velocities on nerve conduction test suggest a demyelinating neuropathies such as Charcot–Marie–Tooth (CMT) type 2 (also known as Dejerine–Sottas disease), congenital hypomyelinating neuropathy (CMT 4E), other subtypes of CMT4.
   c. Demonstration of cerebral myelin abnormalities and peripheral demyelination suggest Pelizaeus–Merzbacher disease or other known leukodystrophies such as Krabbe disease.
   d. Pompe disease (acid maltase deficiency).
      i. Can easily mistaken for a primary myopathy in the first year
      ii. Major differential clinical features
         a) A large heart
         b) Firm skeletal muscles secondary to glycogen stored in the muscle fibers
         c) Distinctive EMG findings

8. Differential diagnosis of hypotonia based on specific associated features (Dubowitz 1985)
   a. Hypotonia and respiratory difficulties
      i. Muscular disorders
         a) Spinal muscular atrophy
         b) Myotonic dystrophy
         c) Myotubular myopathy (especially X-linked form)
         d) Nemaline myopathy
         e) Congenital muscular dystrophy
         f) Other
      ii. Nonmuscular disorders
         a) Intracranial hemorrhage
         b) Intracranial ischemia
   b. Hypotonia and facial weakness: muscular disorders
      i. Congenital myotonic dystrophy
      ii. Myotubular myopathy
      iii. Congenital muscular dystrophy
      iv. Congenital facial diplegia syndrome
   c. Hypotonia and swallowing difficulty
      i. Muscular disorders
         a) Spinal muscular atrophy
         b) Myotubular myopathy
         c) Myotonic dystrophy
         d) Myasthenia gravis (neonatal)
      ii. Nonmuscular disorders
         a) Prader–Willi syndrome
         b) Intracranial hemorrhage
         c) Intracranial ischemia
   d. Hypotonia and ptosis/ophthalmoplegia: muscular disorders
      i. Myotubular myopathy
      ii. Mitochondrial myopathy
      iii. Myotonic dystrophy
      iv. Congenital muscular dystrophy
      v. Myasthenia gravis
   e. Hypotonia and arthrogryposis
      i. Muscular disorders
         a) Congenital muscular dystrophy
         b) Myotonic dystrophy
         c) Congenital fiber-type disproportion
         d) Denervation syndromes
      ii. Nonmuscular disorders
         a) Oligohydramnios
         b) Bicornuate uterus
         c) Renal agenesis
   f. Hypotonia and CNS dysfunction/convulsions
      i. Hypoxic–ischemic encephalopathy
      ii. Intracranial hemorrhage
      iii. Intracranial ischemia
      iv. Organic acidurias
      v. Mitochondrial encephalopathies
      vi. Zellweger disease
      vii. Other rare metabolic disorders

Diagnostic Investigations

1. A stepwise approach to the evaluation of a neonate with hypotonia (modified from Paro-Panjan and Neubauer 2004)
   a. Step 1 comprised of history taking and physical examination
      i. Family history
         a) Drug or teratogen exposure
         b) Breech presentation
         c) Reduced fetal movements
         d) Polyhydramnios
         e) Maternal diseases such as diabetes and epilepsy
         f) Parental age
         g) Neuromuscular disease
         h) Affected siblings
      ii. Prenatal history
         a) Decreased fetal movement
         b) Abnormal ultrasonographic findings such as hydrocephalus or polyhydramnios
         c) Possible evidence for hypoxic–ischemic insult, either in utero or during birth: detail perinatal birth trauma, birth anoxia, delivery complications, low APGAR scores (lower scores for tone, reflexes, and respiratory effort) and onset of hypotonia
      iii. Neonatal history
         a) A shortened umbilical cord and abnormal fetal presentation: reflects poor fetal movement or immobility.
         b) Infants requiring ventilator assistance soon after birth to maintain respiration in addition to hypotonia: suggest the presence of significant muscle weakness.
         c) In addition to hypotonia, infants with severe CNS abnormalities develop signs of impairment in level of consciousness, feeding difficulties, seizures, apneas, abnormal posturing,

abnormalities of ocular movements and of brain stem reflexes.
d) Presence of congenital malformations in other organ systems, deformations, and craniofacial dysmorphic features: need to establish a syndromic diagnosis.
iv. Postnatal history
v. Clinical and neurological examinations
b. Step 2 comprised of neurological imaging tests: important to determine whether there is evidence for a cerebral lesion contributing to hypotonia
i. Computed tomography (CT)
ii. Magnetic resonance imaging (MRI)
c. Step 3 comprised careful search of dysmorphology databases
d. Step 4 comprised of karyotyping with fluorescence in situ hybridization (FISH) for chromosome anomalies
e. Step 5 comprised of biochemical investigations for inborn errors of metabolism
f. Step 6 comprised of other specific studies
i. Specific nerve and muscle investigations
a) Serum kinase levels
b) Electromyography
c) Nerve conduction velocities
ii. DNA markers
a) Spinal muscular atrophy
b) Congenital myotonic dystrophy
c) Duchenne muscular dystrophy
iii. Muscle and nerve biopsy with mitochondrial enzymes

2. Initial workup of the floppy infant based on clinical presentation, localization, and diagnostic yield (Prasad and Prasad 2003)
a. Clinical history and physical examination
i. Central hypotonia
a) Hypotonia
b) Obtundation
c) Seizures
d) Hyperactive deep tendon reflexes
ii. Disorders of the lower motor unit
a) Hypotonia
b) Weakness
c) Areflexia
d) Fasciculations
e) Weak cry
f) Weak suck
g) External ophthalmoplegia
h) Alert look
i) Arthrogryposis
b. Multidisciplinary assessment including pedigree/family history and targeted investigations
i. CT/MRI, EEG, infection screen (CSF, blood)
a) Birth trauma
b) Hypoxic–ischemic encephalopathy
c) Sepsis
d) Cerebral dysgenesis
ii. Genetic studies (karyotyping, FISH, methylation studies, mutation analysis)
a) Chromosomal rearrangements
b) Prader–Willi syndrome
c) Congenital myotonic dystrophy
d) Subtelomeric deletions
iii. Creatine kinase assay, electrophysiology, nerve conduction studies, EMG
a) Nerve biopsy and/or direct mutation analysis (inherited neuropathies, disorders of neuromuscular junction)
b) Muscle biopsy followed by DNA-based mutation analysis when available (congenital muscular dystrophy, congenital myopathies)

3. Investigation scheme in the floppy infant with multisystem involvement (Prasad and Prasad 2003)
a. Cranial MRI, echocardiography, abdominal ultrasound, ophthalmic examinations for infants with hypotonia plus manifestations.
i. CNS obtundation
ii. Abnormal odors
iii. Seizures
iv. Craniofacial dysmorphisms
v. Cataracts
vi. Hepatomegaly
vii. Renal cysts
viii. Retinopathy
ix. Arthrogryposis
x. Lipodystrophy
b. Plasma lactate levels, mt DNA mutations, DNA depletion studies, respiratory chain analysis (muscle), DNA-based mutation analysis for mitochondrial and "energy deficient" encephalopathies (e.g., congenital lactic acidosis).
c. Plasma ammonia, amino acids (blood, urine), urine organic acids, blood acylcarnitine profile, plasma uric acid, urinary sulfites, enzyme assays in skin fibroblasts for

aminoacidopathies, organic acidemias, sulfite oxidate/molybdenum cofactor deficiency.
   d. Lysosomal enzyme assay in WBC, skin biopsy (EM for inclusion), skin fibroblast culture + enzyme assays for lysosomal disorders (e.g., Pompe disease).
   e. Phytanic acid, plasma VLCFA for peroxisomal disorders (e.g., Zellweger syndrome).
   f. Isoimmune electrophoresis for transferrin for congenital disorders of glycosylation.
   g. 7-dehydrocholesterol for Smith–Lemli–Opitz syndrome.
4. Cytogenetic analyses: for floppy infants with dysmorphic features and/or multiple congenital anomalies
   a. Aneuploidy disorders such as Down syndrome
   b. Microdeletion disorders such as Prader–Willi syndrome
      i. Methylation patterns study to determine the presence of PWS
      ii. FISH and mutation analysis to identify the class of mutation
   c. Subtelomeric deletion disorders: easily detected using in situ hybridization using chromosomal telomeric probes
5. Molecular analyses: genetic testing aid significantly in timely diagnosis for a critically ill newborn and allow for anticipation of medical interventions by the multidisciplinary team caring for the infant
   a. Chromosomal microarray studies
   b. Mutation or deletion analysis of the survival motor neuron gene (*SMN*) for SMA
      i. All patients with SMA have deletions or mutations of *SMN1* (also known as SMN_t, the telomeric copy of *SMN* gene). Homozygous deletion of exon 7 in the telomeric survival motor neuron gene found in 95% of SMA type I patients
      ii. The major phenotype determinant is the presence of the number of copies of *SMN2* (also known as SMN_c, the centromeric copy of *SMN* gene)
         a) One copy: likely to produce SMA1
         b) No copy of SMA1: likely results in spontaneous abortion or fetal wastage
         c) Five or six copies: likely allow normal survival with little or no progressive weakness
   c. Mutation analysis in CMT hereditary motor sensory neuropathies
      i. CMT 1A: mutations in the peripheral myelin protein-22 gene
      ii. CMT 1B: mutation in the myelin protein zero gene
      iii. CMT 2B: mutation in the RAS-associated protein RAB7
      iv. CMT 4A: mutation in the ganglioside-induced differentiation-associated protein-1 gene
      v. CMT-X1: mutation in the connexin-32 gene
   d. Mutation analysis for disorders of neuromuscular junction (congenital myasthenic syndromes)
      i. Congenital myasthenia with episodic apnea
      ii. Slow-channel and fast-channel syndrome
      iii. Endplate cholinesterase deficiency
   e. Mutation analysis for disorders with prominent muscle involvement
      i. Bethlem myopathy
      ii. Triplet repeat CTG expansion of the DM protein kinase mutations (>37)
      iii. Congenital DM protein kinase repeat expansion (>750)
   f. Gene sequencing, mutation analysis, or mutation scanning
      i. Dystrophinopathies
      ii. Muscular dystrophies
      iii. Myopathies
   g. mtDNA mutation analysis or mutation analysis in nuclear gene for mitochondrial disorders
6. Electrophysiological studies
   a. Needle electromyogram (EMG)
      i. Neurogenic changes
         a) Spontaneous fibrillation at rest
         b) Long duration polyphasic motor unit potentials
         c) Decreased interference pattern
      ii. Myopathic changes: consider muscle biopsy
         a) Low amplitude, short duration polyphasic
         b) Normal interference pattern
      iii. Myopathy plus muscle irritability (large amplitude of CMAPs, increased insertional activity) should consider Pompe disease (acid maltase enzyme assay)
      iv. Demonstration of denervation on EMG (large amplitude of CMAPs, fasciculation, positive sharp wave) should prompt

investigation for anterior horn cell disorders (proceed to SMA genetic test, SMN type I and type II copy number)

b. Motor and sensory nerve conduction studies (NCS): Decreased nerve conduction velocities on NCS suggest a demyelinating neuropathy

7. Pathologic studies of muscles (muscle biopsy):
   a. The most useful test in the diagnosis of motor unit hypotonia
   b. Used much less often today with the availability of specific gene test for many of the conditions under consideration
   c. A sequential scheme for the proper use of the muscle biopsy
      i. Nonspecific myopathy: consider myotonic, dystrophinopathy, and other congenital myopathy
      ii. Characteristic pathology
         a) Central core disease
         b) Nemaline rod myopathy
         c) Centronuclear myopathy
      iii. Dystrophic muscle
         a) Brain involvement: consider muscle-eye-brain disease, Fukuyama congenital muscular dystrophy, and Walker–Warberg syndrome
         b) Without brain involvement: consider histoimmunological stain for merosin-deficient and merosin-positive muscular dystrophies
   d. SMA: extensive large grouped atrophy involving both type I and type II fibers and scattered clusters of enlarged type I fibers
   e. Congenital muscular dystrophy: considerable variations in fiber size with extensive fatty infiltration
   f. Glycogen storage disease: vacuolar myopathy with muscle fibers containing type vacuoles of varying sizes
   g. Central nuclear myopathy: presence of central nucleus in the majority of muscle
   h. Central core myopathy: deficient oxidative enzyme in the center of many fibers
   i. Nemaline myopathy: muscle fibers with thickened striations and aggregates of rod bodies
   j. Congenital fiber-type disproportions: increased number of small lightly stained type I fibers and reduced number of larger darkly stained type II fibers
8. Biochemical studies
   a. Muscle enzymes (creatine kinase)
      i. Rarely helpful in workup of a floppy infant
      ii. Elevated in:
         a) Congenital muscular dystrophies
         b) Some forms of congenital myopathies
   b. Inborn errors of metabolism screening
      i. Categories of biochemical defects
         a) Toxic encephalopathies
         b) Energy deficient encephalopathies
         c) Disorders affecting intracellular processing of complex molecules
      ii. Blood ammonia
         a) Urea cycle defects
         b) Organic acidemias
         c) Fatty acid oxidation disorders
      iii. Lactate (blood, urine, CSF)
         a) Carbohydrate metabolism disorders
         b) Mitochondrial disease
      iv. Blood and urine quantitative analysis of amino acids for aminoacidopathies
      v. Blood organic acid and acylcarnitine profiles using tandem mass spectrometry
         a) Organic acidemias
         b) Fatty acid oxidation defects
      vi. Plasma very long chain fatty acids (VLCFA) for peroxisomal disorders
      vii. Transferrin (low in glycosylation disorders)
      viii. Blood 7-dehydrocholesterol (elevated in Smith–Lemli–Opitz syndrome)
9. Cranial ultrasound or CT studies (Rumack 1985): to detect CNS lesions causing infantile hypotonia
   a. Hypoxic–ischemic encephalopathy
      i. Fetal or neonatal hypoxia
      ii. Sudden infant death syndrome
      iii. Infarction from other causes
   b. Neonatal intracranial hemorrhage
      i. Subependymal hemorrhage (premature infants)
      ii. Subarachnoid hemorrhage or atypical intracranial hemorrhage (term infants)
   c. Intracranial infection
      i. Prenatal
         a) Cytomegalovirus
         b) Toxoplasmosis
         c) Herpes
         d) Rubella
      ii. Neonatal and infant: bacterial

d. Trauma
   i. Subdural hematoma
   ii. Epidural hematoma
   iii. Parenchymal hemorrhage or edema
10. Cranial CT/MRI studies
   a. Structural malformations
   b. Altered signals
      i. White matter: Laminin deficiency
      ii. Basal ganglia: mitochondrial cytopathies
      iii. Brain stem and cerebellar abnormalities
         a) Joubert syndrome
         b) Pontocerebellar hypoplasia

Genetic Counseling

1. Recurrence risk: depends on underline etiology
   a. Patient's sib
      i. Autosomal recessive (e.g., spinal muscular atrophy, congenital muscular dystrophy): 25%
      ii. Autosomal dominant (e.g., congenital myotonic dystrophy): not increased unless a parent is affected
      iii. X-linked recessive (e.g., severe infantile form of myotubular myopathy): 50% of male sibs affected if the mother is a carrier
      iv. Mitochondrial: All sibs are at risk of being affected if the mother has the mitochondrial DNA mutation
      v. Chromosomal: increased risk, especially a parent is a translocation carrier
   b. Patient's offspring
      i. Autosomal recessive: not increased unless the spouse is also a carrier
      ii. Autosomal dominant: 50%
      iii. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal
      iv. Mitochondrial:
         a) Offspring of males with a mtDNA mutation are not at risk
         b) All offspring of females with a mtDNA mutation are at risk of inheriting the mutation
         c) A female harboring a heteroplasmic mtDNA point mutation may transmit a variable amount of mutant mtDNA to her offspring, resulting in considerable clinical variability among sibs within the same nuclear family (Poulton and Turnbull 2000; Chinnery 2006)
      v. Chromosomal: an increased risk
2. Prenatal diagnosis: not reported to date
3. Management (Pediatric Care Online 2008)
   a. Supportive treatment in most causes of hypotonia
   b. Multidisciplinary team approach for coordination of interventions
   c. Infantile progressive spinal muscular atrophy
      i. Physical therapy
      ii. Respiratory therapy
      iii. Nutritional support as needed
      iv. Scoliosis treatments: e.g.,
         a) Body jacket
         b) Molded back support
         c) Surgery
         d) Motorized wheelchair for children with type II at approximately 2–3 years of age
   d. Peripheral nerve disorders: bracing for children with foot drop
   e. Neuromuscular junction disorders: hospitalization, with respiratory and nutritional support as needed
      i. Passively acquired autoimmune myasthenia gravis (transient neonatal myasthenia): give pyridostigmine until asymptomatic, then taper over 1–2 weeks
      ii. Acquired autoimmune myasthenia gravis (juvenile myasthenia)
         a) Anticholinesterase drugs
         b) Immunosuppressive treatment
         c) Intravenous γ-globulin
         d) Corticosteroids
         e) Thymectomy
      iii. Nonautoimmune myasthenic syndromes (congenital myasthenia gravis)
         a) Anticholinesterase inhibitors
         b) Corticosteroids
         c) Diaminopyridine (experimental)
      iv. Infantile botulism: antibotulism immune globulin may be therapeutic
   f. Myopathies
      i. Infantile form of myotonic dystrophy–type hypotonia
         a) Assisted ventilation as indicated
         b) Gastrostomy tube feedings as indicated

ii. Glycogen storage disease: consider enzyme replacement therapy (prognosis dismal without such therapy)

Fragile X Syndrome

Fragile X syndrome is the most common form of heritable mental retardation affecting approximately 1 in 1,250 males and 1 in 2,000 females (Webb 1989). The prevalence appears to be 1 in 4,000–6,000 males and 1 in 8,000–10,000 females. Martin and Bell first documented X-linked mental retardation in 1943. Subsequent identification of a fragile site on the long arm of the X chromosome (Lubs 1969), discovery of cell culture medium-dependent fragile site, and recognition of a unique constellation of physical features served to distinguish fragile X syndrome from other X-linked mental retardation syndromes.

In Verkerk et al. (1991) identified a single gene that was associated with symptoms of the disorder. The gene, known as fragile X mental retardation gene 1 (*FMR1*), exhibited a novel form of mutation, a sequence of three nucleotides (CGG) that was repeated many times in patients with fragile X syndrome.

Synonyms and Related Disorders

Fragile X mental retardation syndrome; Marker X syndrome; Martin-Bell syndrome; X-linked mental retardation and macroorchidism

Genetics/Basic Defects

1. Inheritance not conforming to usual rules governing X-linked traits
   a. Presence of asymptomatic transmitting males
   b. Presence of affected female carriers who inherited the gene
2. Caused by mutations in a trinucleotide $(CGG)_n$ repeat found in the coding region of the *FMR1* gene, mapped to Xq27.3
   a. Expanded CGG repeats >200 (full mutation): associated with fragile X syndrome.
   b. High repeat number (full mutation) leads to hypermethylation of an upstream promoter region and subsequent silencing (inactivating) of the *FMR1* gene.
   c. A small expansion (premutation) with approximately 50–200 CGG repeats: usually not associated with cognitive deficits.
   d. Expansion to a full mutation from the premutation in normal carriers occurs only when it is transmitted by a female.
   e. Presence of anticipation phenomenon.
3. The Sherman paradox (Laxova 1994)
   a. A perplexing and confusing fragile X pedigree pattern was discovered during mid-1980s by Sherman et al. who discovered the large discrepancy in risks for mental retardation within fragile X families containing transmitting males. This phenomenon was termed the "Sherman paradox" by Opitz (1986).
      i. 20% of males within fragile X families who carried the mutation are unaffected clinically and intellectually and became known as transmitting males.
      ii. An increasing risk of mental retardation in grandsons of normal transmitting males: a special form of genetic anticipation (the increase in disease severity through successive generations).
      iii. About a third of obligate carrier females are mentally impaired.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_96,
© Springer Science+Business Media, LLC 2012

iv. More than half of known carrier females are either mildly impaired or expressed the fragile site on one of their X chromosomes.

b. Possible explanations of the Sherman paradox.
   i. An unaffected transmitting male who inherits a premutation from his unaffected carrier mother, who has 50–200 repeats but probably a number closer to the lower end of the premutation range.
   ii. Offspring of a carrier mother with the number of repeats still within the premutation range, even if amplification occurs during oogenesis.
   iii. Transmission of the premutation to the daughters by the transmitting male. No amplification has occurred during spermatogenesis; hence, the daughters also have a premutation and are unaffected.
   iv. Amplification to more than 200 repeats occurs during oogenesis of the transmitting male's daughters whose sons will receive a ull mutation and be affected and their daughters may or may not be affected.

4. Genotypic–phenotypic correlations (Kaufmann and Reiss 1999)
   a. Fragile X full mutation and mental retardation with a wide spectrum of phenotypic effects in both sexes
      i. Mental retardation in 100% of males
      ii. Usually a milder form of retardation in 60% of females
   b. Large CGG amplification
      i. Associated with hypermethylation
      ii. Almost invariably correlated with the most severe fragile X phenotype
      iii. Seen in males with the full mutation pattern
   c. Premutation expansions that are not usually accompanied by methylation: minimal or no neurologic repercussion
   d. Correlation of methylation in *FMR1* expression and cognitive function
      i. Individuals with full mutation without methylation scored better than those with full mutation and complete methylation
      ii. Individuals with full mutation and partial methylation showed intermediate values
   e. Presence of the *FMR1* protein (FMRP) responsible for:
      i. Lack of neurologic abnormalities in individuals with premutation
      ii. Milder phenotype of males having full mutation without full methylation
5. Pathogenesis
   a. A consequence of the absence or deficit of the FMRP
   b. Absence of FMRP in the brain: the likely cause of mental retardation in patients with fragile X syndrome

Clinical Features

1. Affected males (Hagerman and Cronister 1996)
   a. CNS involvement
      i. Delayed developmental milestones
      ii. Mild to severe mental retardation
      iii. Difficulty with abstract thinking, sequential processing, mathematics, short-term memory, and visual motor coordination
      iv. Seizures
   b. Connective tissue dysplasia
      i. Hyperextensible finger joints
      ii. Double-jointed thumbs
      iii. Flat feet
      iv. High-arched palate
      v. Mitral valve prolapse (55%, diagnosed by echocardiography)
      vi. Dilatation of the ascending aorta
      vii. Inguinal hernia
      viii. Soft and velvet-like skin
   c. Typical facial features
      i. Long face
      ii. Prominent forehead
      iii. Prominent/long ears
      iv. Prominent jaw
   d. Other features
      i. Macroorchidism present in over 80% of adult fra(X) males
      ii. Pectus excavatum
      iii. Scoliosis
      iv. Strabismus
      v. Recurrent otitis media in early childhood
      vi. Reproduction documented but rare because of significant mental retardation

e. Behavior abnormalities
   i. Stereotyped with odd mannerisms (hand flapping/biting)
   ii. Tactile defensiveness
   iii. Poor eye contact (excessive shyness)
   iv. Attention-deficit/hyperactivity disorder
      a) Hyperactivity
      b) Temper tantrums
      c) Distractibility
      d) Mood lability
   v. Speech disorder
      a) Perseveration
      b) Litany speech
      c) Echolalia
   vi. Autism
   vii. Autistic-like features
   viii. Schizotypal personality disorder
   ix. Anxiety disorder
2. Females heterozygous for full mutation alleles
   a. Fifty percentage with cognitive deficits with learning disabilities, borderline IQ, or mental retardation
   b. Fifty percentage with normal intellectual function
3. Females heterozygous for premutation alleles (carriers) at risk for premature ovarian failure (early onset of menopause before age 40 years) (*FMR1*-related premature ovarian failure
4. Fragile X-associated tremor/ataxia syndrome (FXTAS) (Saul and Tarleton 2010)
   a. A definite diagnosis based on the following three observations
      i. Presence of FMR1 premutation
      ii. White matter lesions on MRI in the middle cerebellar peduncles and/or brain stem (the major neuroradiologic sign)
      iii. Presence of two major clinical signs
         a) Intention tremor
         b) Gait ataxia
   b. Other minor clinical criteria
      i. Parkinsonism
      ii. Moderate to severe working memory deficits
      iii. Executive cognitive function deficits
   c. A probable diagnosis: requires either one major neuroradiologic sign and one minor clinical sign or two major clinical signs
   d. A possible diagnosis: based on one minor neuroradiologic sign and one major clinical sign

Diagnostic Investigations

1. Pedigree analysis
2. Karyotyping of cells grown in folate- or thymidine-depleted cell culture media
   a. A "fragile" site on one of the X chromosomes (Xq27.3) that appeared as a constriction on the distal long arm in many patients
   b. Cells exhibiting fragile X chromosome: 5–50%
   c. Cytogenetic studies now rendered obsolete by direct DNA testing
3. Indications for molecular genetic testing (Park et al. 1994)
   a. Individuals of either sex with mental retardation, developmental delay, or autism
      i. Any physical or behavioral characteristics of fragile X syndrome
      ii. A family history of fragile X syndrome
      iii. Male or female relatives with undiagnosed mental retardation
   b. Individuals seeking reproductive counseling who have a family history of fragile X syndrome or undiagnosed mental retardation
   c. Fetus of a known carrier mother
   d. Patients with cytogenetic fragile X test result discordant with phenotype
      i. Patients with a strong clinical impression of being affected with or carrier of fragile X syndrome but had a negative or ambiguous cytogenetic test result
      ii. Patients with an atypical phenotype of fragile X syndrome but had a positive cytogenetic test result
4. Direct DNA analysis for point mutation or deletion in *FMR1* gene. Mutation analysis to determine the CGG repeat size by Southern blot hybridization and polymerase chain reaction (PCR): mutation detection rate >99% (commercially available)
5. Methylation analysis by Southern blot analysis to determine the *FMR1* methylation status
6. Types of *FMR1* repeat expansion mutations (Tarleton and Saul 1993; Saul and Tarleton 2010)
   a. Normal alleles: 5–40 CGG repeats
      i. Stably transmitted without any increase or decrease in repeat number

ii. In stable normal alleles, the CGG region is interrupted by an AGG triplet after every nine or ten CGG repeats. These AGG triplets are believed to maintain repeat integrity by preventing DNA strand slippage during replication
iii. Normal alleles with more than 35 CGG repeats are associated with increased risk of *FMR1*-related premature ovarian failure

b. Mutable normal alleles (intermediate alleles, also termed "gray zone"): broadly defined as 41–58 repeats (no consensus exists regarding the precise size)
c. Premutation alleles
i. 59–200 CGG repeats
ii. Methylation status of *FMR1*: Premutation alleles are usually unmethylated and FMRP production is normal
iii. Therefore, individuals (males or females) with permutation are clinically unaffected
iv. Do convey increased risk for FXTAS and POF, because of:
a) Potential repeat instability upon transmission of premutation alleles
b) Women with alleles in this range are considered to be at risk of having children affected with fragile X syndrome
d. Full mutation alleles
i. >200 CGG (several hundreds to several thousands) repeats. Expansion of the repeat more than 200 generally results in hypermethylation of both the CpG island and the CGG repeat within the *FMR1* gene
ii. Methylation status of *FMR1*: completely methylated
iii. Males: affected
iv. Females: affected in about 50% of cases; unaffected in about 50% of cases
e. Mosaicism
i. Number of CGG repeats varies between premutation and full mutation in different cell lines.
ii. Methylation status of *FMR1*: partially methylated (unmethylated in the premutation cell line and methylated in the full mutation cell line)
iii. Males: affected but may function higher than individuals with full mutation
iv. Females: highly variable clinical expression ranging from normal intellect to affected
f. Methylation mosaicism
i. Number of CGG repeats >200
ii. Methylation status of *FMR1* gene: partially methylated (mixture of methylated and unmethylated cell lines)
iii. Males: affected but may function higher than individuals with full mutation
iv. Females: highly variable clinical expression ranging from normal intellect to affected
g. Unmethylated full mutation
i. Number of CGG repeats >200
ii. Methylation status of *FMR1* gene: unmethylated
iii. Males: Nearly all are affected but may have high functioning mental retardation to low normal intellect
iv. Females: highly variable clinical expression ranging from normal intellect to affected

7. Immunocytochemical tests based on the direct detection of FMRP using monospecific antibodies. This FMRP detection assay is based on the presence of FMRP in cells from unaffected individuals and its absence in cells from patients with fragile X syndrome. This assay is proven to be a reliable alternative method to identify male patients with fragile X syndrome. The new test on hair roots is suitable for use in large screening programs among males. The immunocytochemical tests can also be used in patients with mosaic pattern, affected premutation males, and intragenic mutations
8. Molecular genetic testing
a. Targeted mutation analysis
i. PCR analysis
ii. Southern blot analysis
b. Methylation status
c. Sequence analysis
d. Deletion/duplication analysis
e. FISH analysis
f. X-chromosome inactivation

Genetic Counseling

1. Recurrence risk: Adequate genetic counseling depends on accurate diagnosis at the molecular level
   a. Individuals identified as noncarriers: The zero risk of transmitting fragile X syndrome to the next generation.
   b. Individuals identified as carriers: The risk of having children with fragile X syndrome depending on the sex of the carrier parent, the sex of the child, and the size of the CGG repeats.
      i. Premutation carrier males: considered "transmitting males." All daughters of transmitting males are unaffected premutation carriers. However, the grandsons and granddaughters of a transmitting male are at risk for developing fragile X syndrome.
      ii. All mothers of a child with *FMR1* full mutation (expansion >200 CGG trinucleotide repeats), considered carriers of an *FMR1* gene expansion (either full mutation or premutation and may be affected).
      iii. Females with premutation: an increased risk of passing on the full mutation and having offspring with the fragile X phenotype (the fragile X premutation can expand to the full mutation during maternal meiosis).
      iv. Carrier males who may reproduce: essentially zero risk of having male offspring with fragile X syndrome, since all their sons receive their Y chromosome [except in the rare instance of the fragile X chromosome coming into the family from the other source (mother)]. All the daughters of male carriers will have premutations regardless of the size of paternal amplifications and will not have fragile X syndrome. Only a few reports with premutation males have full mutation daughters.
   c. Females with full mutation: Her offspring, if they inherit the fragile X locus, all will have full mutation.
      i. All her sons will have fragile X syndrome.
      ii. About 50–60% of her daughters will have fragile X syndrome, exceeding the 35% applicable to all female carriers of the fragile X chromosome. Affected females generally have less severe intellectual disability than found in affected males.
   d. Males with full mutations.
      i. Mentally retarded
      ii. Generally do not reproduce
2. Risks to pregnant women with an expanded *FMR1* gene
   a. A repeat size of 40–59: safe (0% risk) with no fetal full mutations
   b. A repeat size of 60–80: low risk (14%) of full mutation in the fetus
   c. A repeat size of over 80–100: a significant increase in risk (89%) of developing full mutation in the fetus
   d. A repeat size of 100–200: 100% risk of developing full mutation in the fetus
3. Prenatal diagnosis by amniocentesis or CVS
   a. Available to at-risk pregnancies: requires prior confirmation of the presence of an expanded (or altered) *FMR1* allele in the family
   b. Prenatal diagnosis using direct DNA analysis to women discovered to be premutation carriers
   c. The limitation: inability to accurately predict phenotype in female fetuses with full mutation
   d. CVS: follow-up amniocentesis or testing using PCR, necessary to determine the size of the *FMR1* alleles in a methylation-independent manner
4. Preimplantation genetic diagnosis: available to at-risk pregnancies in which prior confirmation of the presence of an expanded (or altered) *FMR1* allele was identified in the family
5. Management
   a. Early intervention programs for developmental delay including speech and language therapies, physical therapy, and occupational therapy
   b. Behavioral interventions including psychopharmacological therapy
   c. Special educations
   d. Vocational planning
   e. Anticonvulsants for seizure control

f. Prophylactic antibiotics for surgical or dental procedures in patients with mitral valve prolapse
g. Orthopedic care for joint dislocations, flat feet, and scoliosis

Fig. 1 Two brothers with fragile X syndrome showing large ears, accompanied by their mother

Fig. 2 A pair of brothers with fragile X syndrome showing a long face with large ears

Fig. 3 Another pair of male siblings with fragile X syndrome

Fig. 4 A chromosome spread showing a fragile X chromosome (arrow)

Fig. 5 A large family affected by fragile X syndrome. The first boy (**a**, age 15) is the most affected one with CGG repeats of >1,500. He was not toilet trained until age 5 or 6 years. He never spoke until after auditory training. He may watch TV for 6–8 h straight and get agitated if someone approaches him. The brother (**b**, age 10) and sister (**c**, age 16) have CGG repeats of 1,200 and 600 respectively. Another sister (**d**) is a carrier with CGG repeats of 110 who has four children. The daughter (age 3, the first one from the left) has CGG repeats of 700. She has a long face with prominent ears, a high-arched palate, and flat feet. She suffers from hyperactivity, tactile/oral/olfactory defensiveness, gaze aversion, poor postural alignment, food cramming, hand biting, excessive drooling, poor self-regulation, and speech difficulties including echolalia. The other three children are normal with normal CGG repeats. The maternal grandmother has CGG repeats of 126

Fig. 6 A 66-year-old male with fragile X syndrome. The patient has mental retardation, a long face with large ears, and macroorchidism. Molecular analysis revealed CGG repeats of about 400

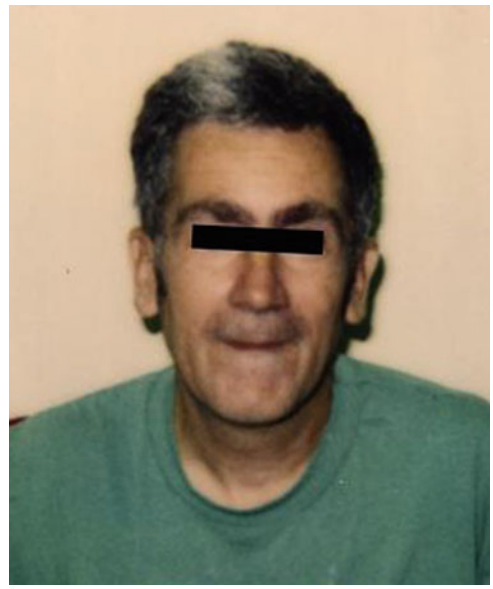

Fig. 7 A 46-year-old male with methylation mosaic fragile X syndrome (mixture of methylated full mutation allele of approximately 450 repeats in some cells and unmethylated premutation size allele of approximately 200 repeats in some cells). He is tall and has mental retardation, a long narrow face, slightly large ears, and macroorchidism

Fraser Syndrome

Fraser syndrome is a malformation syndrome characterized by cryptophthalmos ("hidden eye," a term coined by Zehender et al. 1872), cutaneous syndactyly, and anomalies of the genitourinary system. It was first described by Fraser in 1962. It is also known as cryptophthalmos-syndactyly syndrome, cryptophthalmos syndrome, or Fraser cryptophthalmos syndrome. Fraser syndrome occurs with a minimal estimated frequency of 0.43 per 100,000 liveborn infants and 11.06 per 1,000,000 stillbirths (Martínez-Frías et al. 1998).

Synonyms and Related Disorders

Cryptophthalmos with other malformations; Cryptophthalmos-syndactyly syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Caused by mutations in *FRAS1* and FRAS1-related extracellular matrix protein 2 (*FREM2*) genes
   a. *FRAS1* gene, encoding a putative extracellular matrix (ECM) protein, located on the long arm of chromosome 4 (4q21)
   b. *FREM2* gene located on the long arm of chromosome 13 (13q13.3)
3. Genotype–phenotype correlations (van Haelst et al. 2008)
   a. Patients with an *FRAS1* mutation
      i. More frequently skull ossification defects
      ii. Low insertion of the umbilical cord
   b. Mutations were identified in only 43% of the cases suggesting that other genes syntenic to murine genes causing blebbing may be responsible for Fraser syndrome as well
4. Familial cases (56%)
   a. Presence of consanguinity, estimated to be as high as 15%
   b. Multiple affected sibs born to the same parents (Slavotinek and Tifft 2002; Singh et al. 2007)
5. Three forms of cryptophthalmos, classified based on ophthalmic findings (Francois 1969)
   a. Complete (typical) cryptophthalmos
      i. The eyelids replaced by a sheet of skin running from forehead to cheek with absence or poor development of the eyebrow
      ii. Absence of the eyelashes or the gland structures
      iii. The elevated skin covering the globe moves when eye movements occur
      iv. The skin adherent to the underlying cornea
      v. Absence of the conjunctival sac
      vi. Microphthalmia usually present
      vii. Often associated with numerous congenital abnormalities, including anomalies of the head, ears, nose and genitalia, and syndactyly. This pattern of anomalies is termed Fraser syndrome (Ferri and Harvey 1999)
   b. Incomplete (atypical) cryptophthalmos
      i. Presence of rudimentary eyelids
      ii. Lateral placement of a small conjunctival sac
      iii. The palpebral aperture about one-third of normal length
      iv. Usually small globe, covered almost completely by the skin

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_97,
© Springer Science+Business Media, LLC 2012

   c. Abortive form or congenital symblepharon
      i. The upper eyelids, without a defined margin, covers and adherent to up to 75% of the upper cornea
      ii. Absence of punctum in the eyelid
      iii. Absence of the upper conjunctival fornix
      iv. Free part of the cornea often keratinized or opaque
      v. Globes: usually normal or small size
6. Pathogenesis (Ferri and Harvey 1999)
   a. Primary failure of differentiation during embryogenesis
   b. Compression of the amniochorionic band
   c. Intrauterine inflammation
   d. Failure of lid fold development
   e. Inactivation of glutamate receptor interacting protein 1 (GRIP1), a cytoplasmic multi-PDZ scaffolding protein, leads to the formation of subepidermal hemorrhagic blisters, renal agenesis, syndactyly or polydactyly, and permanent fusion of eyelids (cryptophthalmos), Fraser syndrome-like defects in mice (Takamiya et al. 2004)

Clinical Features

1. Intrafamilial clinical heterogeneity (Chattopadhyay et al. 1993; Slavotinek and Tifft 2002)
2. Eyes
   a. Cryptophthalmos (a developmental anomaly in which the skin is continuous over the eyeballs without any indication of the formation of eyelids): the most common feature of Fraser syndrome (84–93%)
      i. Bilateral (more common) or unilateral
      ii. Total or partial
   b. Microphthalmia
   c. Absent or malformed lacrimal ducts
   d. Ocular hypertelorism
   e. Coloboma of the upper eyelid
   f. Supernumerary eyebrows
   g. Blindness
3. Head: unusually low lateral hairline on temples extending to lateral eyebrow
4. Nose
   a. Hypoplastic and notched nares
   b. Broad nasal bridge
   c. Midline nasal cleavage
   d. Choanal atresia
5. Mouth
   a. Cleft lip
   b. Cleft palate
   c. High-arched palate
   d. Crowding of the teeth
6. Ears
   a. Malformation of middle and external ears (cup shaped and low set)
   b. Microtia
   c. Low-set ears
   d. Absent pinna
   e. Skin of the upper helix contiguous with scalp
   f. Conductive hearing loss
7. Laryngeal stenosis/atresia
8. Chest: widely spaced nipples
9. Lungs
   a. Lung hyperplasia (Stevens et al. 1994)
   b. Lung hypoplasia
10. Cardiac anomalies (Thapa and Bhattachakya 2008)
   a. Hypertrophy of the left ventricle
   b. A variant of Ebstein anomaly
   c. Coarctation of the aorta
   d. Atrial septal defect
   e. Interventricular communication
   f. Truncus arteriosus
   g. Ventricular septal defect
   h. Complex heart disease
   i. PDA
   j. Patent foramen ovale
   k. Dextrocardia
   l. Transposition of the great vessels
   m. Partial anomalous pulmonary venous connection
11. Gastrointestinal anomalies (Slavotinek and Tifft 2002)
   a. Imperforate anus
   b. Anal atresia and anal stenosis
   c. Rectal atresia
   d. Displaced anus
   e. Umbilical hernia
   f. Intestinal malrotation
   g. Colonic atresia
12. Urogenital anomalies
   a. Renal agenesis/hypoplasia
      i. Unilateral
      ii. Bilateral
      iii. Hypoplastic bladder

b. Male genital anomalies
   i. Small penis
   ii. Hypospadias
   iii. Cryptorchidism
c. Female genital anomalies
   i. Bicornuate uterus
   ii. Hypoplastic uterus
   iii. Vaginal atresia
   iv. Hypoplastic labia majora
   v. Clitoral enlargement

13. Limbs: syndactyly of the fingers (cutaneous in 54% of cases) and toes
14. CNS involvement
    a. Mental retardation
    b. Microcephaly
    c. Meningomyelocele
    d. Encephalocele
15. Natural history
    a. Stillborn: 25% of affected infants
    b. Additional 20% of affected infants die before 1 year of age
    c. Survival to 96 years of age reported (Impallomeni et al. 2006)
    d. Commonest causes of death
       i. CNS malformations
       ii. Laryngeal stenosis or atresia
       iii. Respiratory insufficiency
       iv. Obstructive uropathy or bilateral renal agenesis
16. Diagnostic criteria (Thomas et al. 1986): requires at least two major and one minor, or one major and four minor criteria for the diagnosis
    a. Major criteria
       i. Cryptophthalmos
       ii. Syndactyly
       iii. Abnormal genitalia
       iv. Sib with Fraser syndrome
    b. Minor criteria
       i. Congenital malformation of nose
       ii. Congenital malformation of ears
       iii. Congenital malformation of larynx
       iv. Cleft lip/palate
       v. Skeletal defects
       vi. Umbilical hernia
       vii. Renal agenesis
       viii. Mental retardation
17. Revised diagnostic criteria for Fraser syndrome (van Haelst et al. 2007): requires either three major, or two major and two minor, or one major and three minor diagnostic criteria present in a patient
    a. Major criteria
       i. Syndactyly
       ii. Cryptophthalmos spectrum
       iii. Urinary tract abnormalities
       iv. Ambiguous genitalia
       v. Laryngeal and tracheal anomalies
       vi. Positive family history
    b. Minor criteria
       i. Anorectal defects
       ii. Dysplastic ears
       iii. Skull ossification defects
       iv. Umbilical abnormalities
       v. Nasal anomalies

Diagnostic Investigations

1. Radiography
   a. Poor ossification of the calvarium
   b. Orbital structures
   c. Pulmonary hypoplasia
   d. Diastasis of the symphysis pubis
   e. Syndactyly
2. Renal ultrasound for renal anomalies
3. Hearing test
4. Molecular genetic testing (van Haelst et al. 2008; Shafeghati et al. 2008)
   a. Linkage analysis in consanguineous families indicated possible linkage to *FRAS1* and *FREM2* in 60% of the cases
   b. Mutation analysis identified 11 new mutations in *FRAS1* and one *FREM2* mutation

Genetic Counseling

1. Recurrence risk
   a. Patient's sibs: 25%
   b. Patient's offspring: recurrence risk not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis
   a. Prenatal diagnosis made in the follow-up of a pregnancy with a previous sibling having had the same syndrome (Feldman et al. 1985; Ramsing et al. 1990; Schauer et al. 1990; Fryns

et al. 1997; Berg et al. 2001; Rousseau et al. 2002; Vijayaraghavan et al. 2005)
   b. Prenatal diagnosis made in families with a negative history (Boyd et al. 1988; Serville et al. 1989; Maruotti et al. 2004)
   c. Prenatal ultrasonography
      i. Major findings
         a) Microphthalmia
         b) Syndactyly
         c) Ambiguous genitalia
      ii. Other findings
         a) Oligohydramnios
         b) Ear defects
         c) Renal abnormalities
         d) Uropathy
         e) Hyperechogenic lungs
         f) Laryngeal stenosis/atresia
         g) Ascites
         h) Intrauterine growth retardation
         i) Polyhydramnios
   d. Fetoscopy (Kabra et al. 2000)
3. Management
   a. Immediate ocular management: frequent use of artificial tears to maintain corneal luster and clarity (Dinno et al. 1974)
   b. Intubation or tracheotomy to provide an adequate airway when laryngeal atresia/stenosis is present. Final repair of the laryngeal stenosis is deferred until about 1–2 years of age when adequate thyroid cartilage development has occurred (Karas and Respler 1995)
   c. Surgical correction of associated anomalies
   d. Goals of reconstruction, considering the poor probability of restoring visual function (Ferri and Harvey 1999)
      i. To protect the cornea (if present) from infection and ulceration
      ii. To enhance cosmetic appearance
      iii. To preserve the globe
   e. Surgical treatment at a later age (Dibben et al. 1997)
      i. Reconstruction in partial cryptophthalmos
         a) Dissection of the eyelids from the cornea
         b) Reconstruction of the conjunctival fornices with buccal mucosa
         c) Repair the upper lid coloboma in a flap reconstruction using the inferior eyelid margin
      ii. Reconstruction without grafting in complete cryptophthalmos (Ferri and Harvey 1999)
   f. Surgical strategy for correction of cryptophthalmos (Saleh et al. 2009)
      i. The main indication for early surgery: presence or risk of corneal exposure in eyes with visual potential, as may occur in abortive cryptophthalmos
      ii. Surgery deferred for painless eyes with no potential for vision and where there is a low risk of corneal exposure. These include:
         a) Complete cryptophthalmos
         b) Incomplete cryptophthalmos with completely keratinized corneas
         c) Patients without corneal exposure

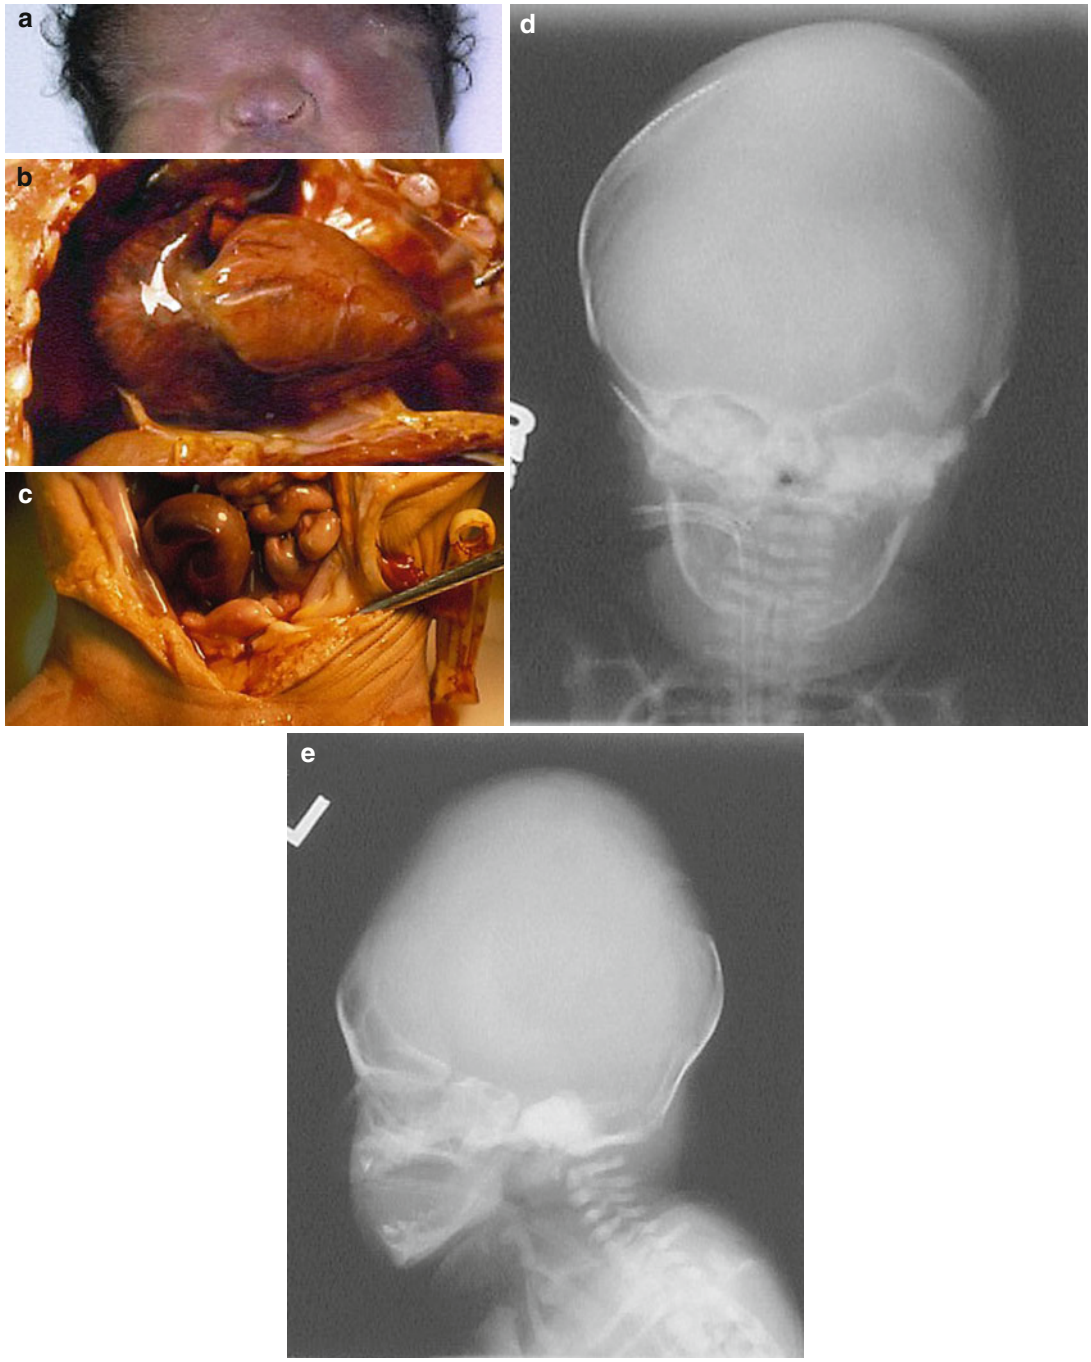

Fig. 1 (**a**–**e**) An infant with Fraser cryptophthalmos showing fused eyelids, lateral hair extending to lateral eyebrows, ocular hypertelorism, notched nares, and a tracheostomy site for management of laryngeal stenosis. Postmortem photos show lung hypoplasia, a small uterus, and clitoral hypertrophy. The skull radiographs show poorly ossified calvarium

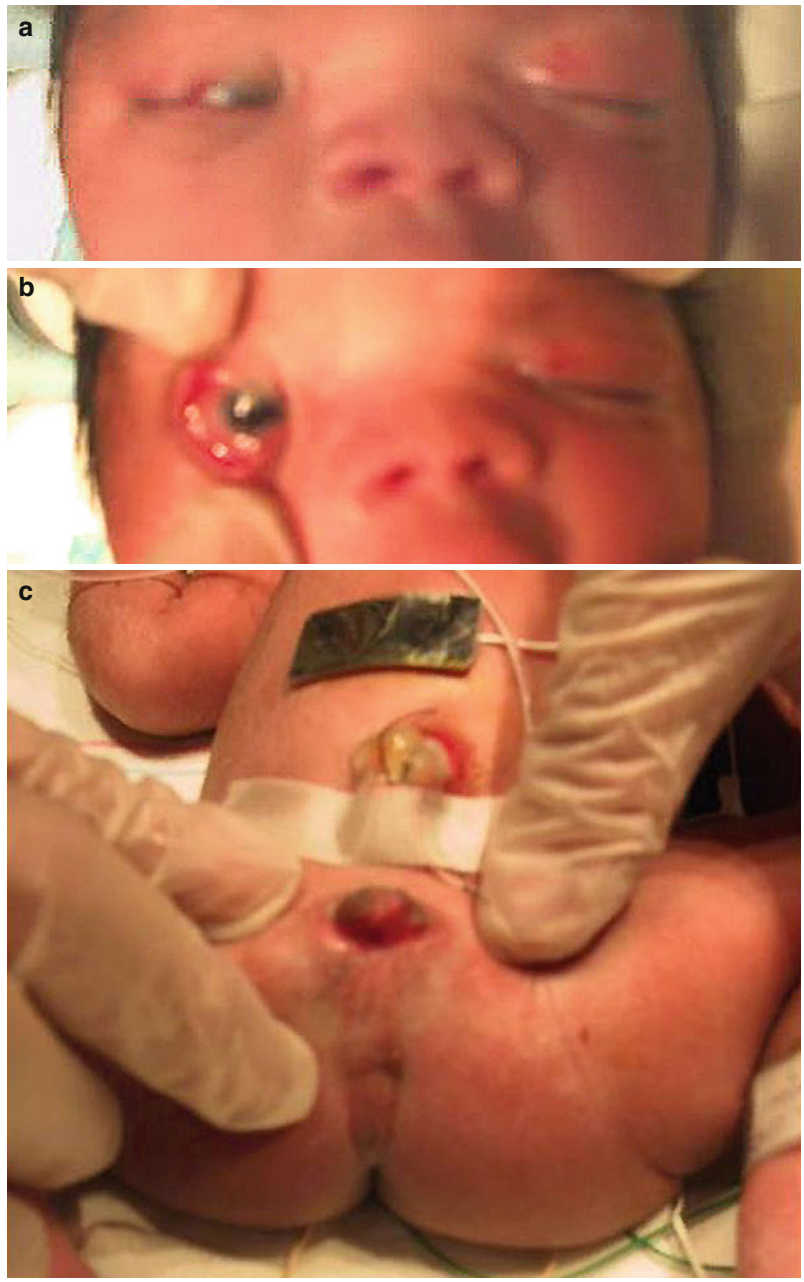

Fig. 2 (**a–c**) The sibling of the previous infant with Fraser syndrome showing microphthalmia, partial fusions of eyelids, ocular hypertelorism, genitourinary anomalies, and partial syndactyly of the toes. Variability of expression is illustrated in these two sibs

Freeman–Sheldon Syndrome

In 1938, Freeman and Sheldon described a syndrome characterized by a whistling face with a long philtrum, a puckered mouth, microstomia, H-shaped cutaneous dimpling on the chin, multiple joint contractures with camptodactyly, ulnar deviation of the fingers, bilateral talipes equinovarus, and kyphoscoliosis. Freeman–Sheldon syndrome (FSS) is the most severe of the distal arthrogryposes with the striking contractures of the orofacial muscles. The syndrome is also known as distal arthrogryposis (DA) type 2A, craniocarpotarsal dysplasia, or "whistling face" syndrome (Lev et al. 2000).

Synonyms and Related Disorders

Craniocarpotarsal dysplasia; "Whistling Face" syndrome

Genetics/Basic Defects

1. Caused by mutations in embryonic myosin heavy chain gene (*MYH3*) (Toydemir et al. 2006). Sheldon–Hall syndrome (SHS) is known to be caused by mutations in either *MYH3*, *TNNT2*, or *TNNT3* (Toydemir and Bamshad 2009)
2. Genetic heterogeneity (Lev et al. 2000)
   a. Autosomal dominant inheritance
      i. Usually with normal psychomotor development, although mild motor delay attributable to joint anomalies might be present
      ii. A variant of autosomal dominant inheritance, mapped to chromosome 11p15.5-pter (Krakowiak 1997)
   b. Autosomal recessive inheritance: severe developmental retardation reported in a few patients
3. Pathogenesis
   a. Considered a form of distal arthrogryposis
      i. Closely related to distal arthrogryposis type 1
         a) Similar limb phenotypes but distinguished only by differences in facial morphology
         b) Reports of families in which different individuals were diagnosed with distal arthrogryposis type 1 or Freeman–Sheldon syndrome
      ii. Proposed to classify Freeman–Sheldon syndrome as distal arthrogryposis type 2 (a distinct disorder from distal arthrogryposis type 1 with overlapping phenotypes) in a revised classification of distal arthrogryposis
   b. Primary brain anomalies suggested to explain many manifestations of the syndrome
   c. Also considered possibly a nonprogressive or slowly progressive myopathy (Vaněk et al. 1986)
4. Overlap of clinical characteristics of FSS with other DA syndromes suggests a shared etiology and/or pathogenesis (Stevenson et al. 2006)
   a. Several DAs can be caused by mutations in four genes that encode proteins of the troponin-tropomyosin complex of fast-twitch myofibers.
   b. Specifically, mutations in *TPM2*, *TNNT2* or *TNNT3*, and *MYH8* cause DA1, SHS, and trismus-pseudocamptodactyly (i.e., DA7), respectively.

Clinical Features

1. Variable clinical severity and phenotypic abnormalities (Marasovich et al. 1989)
2. Normal intelligence
3. "Whistling face" appearance
   a. Long philtrum
   b. Microstomia
   c. Puckered mouth
   d. Pursed lips
   e. H-shaped cutaneous dimpling on the chin
4. Musculoskeletal anomalies
   a. Multiple joint contractures
   b. Camptodactyly
   c. Ulnar deviation of fingers
   d. Windmill vane hand (bilateral ulnar deviation and contracture of fingers two to five at the metacarpophalangeal joints with adduction of thumbs)
   e. Normal hands in a few reports
   f. Bilateral talipes equinovarus
   g. Kyphoscoliosis
5. Growth retardation
6. Other craniofacial features
   a. Masklike rigid face
   b. Flat midface
   c. Deep-sunken eyes with hypertelorism
   d. Antimongoloid slant of the palpebral fissures
   e. Blepharophimosis
   f. Convergent strabismus
   g. Full cheeks
   h. Small nose
   i. Coloboma alae of the nose
   j. Micrognathia
   k. Cleft palate or high-arched palate
   l. Choanal atresia
   m. Low-set and malformed ears
   n. Hearing loss
7. Other features
   a. Nasal speech
   b. Short neck
   c. Inguinal hernia
   d. Cryptorchidism
   e. Spina bifida occulta
8. Complications
   a. Difficulty in swallowing attributed to the mouth deformity
   b. Pulmonary problems due to decreased thoracic expansion
9. Diagnostic criteria of Freeman–Sheldon syndrome (Stevenson et al. 2006)
   a. Presence of $\geq$2 of the major clinical manifestations of distal arthrogryposis (DA) plus the presence of a small pinched mouth, prominent nasolabial folds, and H-shaped dimpling of the chin
   b. Major manifestations of DA of the upper limbs
      i. Ulnar deviation of the wrists and fingers
      ii. Camptodactyly
      iii. Hypoplastic, and/or absent flexion creases, and/or overriding fingers at birth
   c. Major manifestations of DA of the lower limbs
      i. Talipes equinovarus
      ii. Calcaneovalgus deformities
      iii. A vertical talus
      iv. Metatarsus varus
10. Differential diagnosis of Sheldon–Hall syndrome (SHS) (Stevenson et al. 2006): Diagnostic criteria of SHS include:
    a. $\geq$2 of the major clinical manifestations of DA
    b. Deep nasolabial folds
    c. A small oral opening (but a larger oral opening than that of FSS)
    d. A small but protuberant chin (but lack an H-shaped dimpling of the chin)
    e. Webbing of the neck

Diagnostic Investigations

1. Radiography
   a. Skull
      i. Shallow anterior cranial fossa
      ii. Hypoplastic mandible
      iii. Small malar bones
   b. Ulnar deviation and flexion contractures of the fingers
   c. Talipes equinovarus
   d. Kyphoscoliosis
2. Polysomnography for sleep-disordered breathing
3. Muscle biopsy findings: structural changes predominantly involving type I fibers suggesting that the muscle lesion is a form of congenital fiber type disproportion (Duggar et al. 1989)
4. Molecular genetic testing of *MHY3* mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant inheritance: low unless a parent is affected
      ii. Autosomal recessive inheritance: 25%
      iii. Empirical risks for sibs of sporadic cases: 7%
   b. Patient's offspring
      i. Autosomal dominant inheritance: 50%
      ii. Autosomal recessive inheritance: low unless the spouse is affected
      iii. Empirical risk for children of sporadic case: 37%
2. Prenatal diagnosis
   a. Ultrasonography at 20 weeks of gestation in a fetus with a positive family history (Robbins-Furman et al. 1995)
      i. Bilateral equinovarus and abnormally positioned toes
      ii. Clenched hands with overlapping thumbs
      iii. An abnormally appearing mouth with pursing of the lips
   b. Molecular genetic diagnosis: If the family history is positive and the mutation is known in the family, prenatal molecular genetic diagnosis is possible by direct molecular testing of fetal DNA sample obtained from chorionic villus or amniotic fluid.
3. Management
   a. Tracheostomy required for severe upper airway narrowing (Robinson 1997)
   b. Management of anesthetic risks (Duggar et al. 1989)
      i. Risks primarily related to severe microstomia
      ii. Combinations of myopathic and skeletal abnormalities predisposing affected patients to significant postoperative respiratory difficulty
      iii. Awake endotracheal intubation or fiberoptic nasotracheal intubation in infants before induction of general anesthesia
   c. Functional and cosmetic correction of microstomia (Neumann and Coetzee 2009)
   d. Functional hand reconstruction for hand deformities
   e. Orthopedic correction of clubfeet and scoliosis

Fig. 4 A newborn with Freeman–Sheldon syndrome showing whistling appearance of the face, tight mouth opening, hypoplastic nasal alae, arthrogryposis of the hands and fingers with contractures and ulnar deviation of the wrists, and metatarsus adductus. Intrauterine growth retardation and Dandy–Walker malformation were detected prenatally by ultrasound

Friedreich Ataxia

During the period 1863–1877, Friedreich described the condition, now called Friedreich ataxia (FRDA), in nine members of three families. His initial report noted the following characteristics: age of onset around puberty and ataxia, dysarthria, sensory loss, muscle weakness, scoliosis, foot deformity, and cardiac symptoms.

FRDA is the commonest inherited ataxia (Harding 1984). Recent study based on molecular data suggests a carrier rate of 1 in 85 with a disease prevalence of 1 in 29,000 (Cossee et al. 1997).

Genetics/Basic Defects

1. An autosomal recessive disorder
2. The gene mutated in FRDA (FXN), mapped to 9q13-21.1, was initially called *X25* and later changed to *FRDA*
   a. FRDA: unique among trinucleotide repeat disorders in that it is autosomal recessive
   b. The repeat is intronic
   c. It is the only disease known to be the result of expansion of a GAA trinucleotide repeat
3. Frataxin, the encoded protein, is predicted to contain 210 amino acids. Frataxin has an N-terminal leader peptide that directs its subcellular localization to mitochondria
4. Intergenerational instability, premutations, and origin of mutations
   a. GAA repeat underlying FRDA: unstable in its transmission from parent to offspring as in other trinucleotide repeat disorders (Timchenko and Caskey 1996).
   b. Maternal transmission may result in a larger or smaller allele in offspring while paternal transmission always results in smaller allele (Monros et al. 1997; Pianese et al. 1997; Delatycki et al. 1998; De Michele et al. 1998). The size of the triplet repeat influences the direction of instability with smaller alleles more prone to increase in size and larger ones to decrease.
   c. Premutation alleles are prone to large expansion in one generation.
   d. Normal-sized alleles have a bimodal distribution.
      i. Small normal alleles (about 83%): between 6 and 12 repeats
      ii. Large normal alleles (about 17%): between 14 and 34 repeats
5. Genotype-phenotype correlation: not possible to predict the specific clinical outcome in any individual based on genotype (Bidichandani and Delatycki 2009)
   a. Variability in individuals with FRDA may be caused by:
      i. Genetic background (e.g., Acadian individuals)
      ii. Somatic heterogeneity of the GAA expansion
      iii. Other unidentified factors
   b. GAA repeat size in homozygotes for pathogenic GAA repeat expansions
      i. Statistically significant correlations with:
         a) Age of onset
         b) Presence of leg muscle weakness and/or wasting
         c) Duration until wheelchair use
         d) Prevalence of cardiomyopathy, pes cavus, and scoliosis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_99,
© Springer Science+Business Media, LLC 2012

ii. Individuals with late-onset FRDA (LOFA): frequently exhibit fewer than 500 GAA repeats in at least one of the expanded alleles
iii. Individuals with very-late-onset FRDA (VLOFA): usually have fewer than 300 GAA repeats in at least one of the expanded alleles
iv. Cardiomyopathy: more frequently seen with longer GAA repeat alleles
v. Diabetes mellitus or abnormal glucose tolerance: does not show a clear-cut correlation with the size of the GAA expansion

c. Spastic paraparesis without ataxia: may be seen in those with smaller expanded alleles or in association with the G130V missense mutation
d. Compound heterozygotes for an expansion and a point mutation
i. Most compound heterozygotes are clinically indistinguishable from typical individuals with FRDA with homozygous GAA expansions.
ii. Compound heterozygotes for an expansion and a borderline "mutable" allele. Individuals with somatically unstable borderline alleles present with LOFA/VLOFA, mild and gradually progressive disease, and normal reflexes/hyperreflexia.

6. Pathophysiology (Chawla 2008)
a. Major pathophysiologic finding: "dying back phenomena" of axons, beginning in the periphery with ultimate loss of neurons and a secondary gliosis
b. Primary sites of changes in spinal cord and spinal roots resulting in loss of large myelinated axons in peripheral nerves, which increases with age and disease duration
c. Unmyelinated fibers in sensory roots and peripheral sensory nerves are spared

Clinical Features

1. Diagnostic criteria for FRDA (Geoffroy et al. 1976)
a. Primary (essential for diagnosis)
i. Onset before the end of puberty (never after the age of 20 years)
ii. Progressive ataxia of gait
iii. Dysarthria
iv. Loss of joint position or vibration sense
v. Absent tendon reflexes in the legs
vi. Muscle weakness
b. Secondary
i. Extensor plantar responses
ii. Pes cavus
iii. Scoliosis
iv. Cardiomyopathy

2. Diagnostic criteria for FRDA (Harding 1981)
a. Primary (essential for diagnosis)
i. Age of onset of symptoms before the age of 25 years
ii. Progressive unremitting ataxia of limbs and of gait
iii. Absence of knee and ankle jerks
b. Secondary
i. Dysarthria
ii. Extensor plantar responses
c. Additional: If secondary criteria are absent, the following have to be present:
i. An affected sib fulfilling primary and secondary criteria
ii. Median motor nerve conduction velocities of greater than 40 m/s thus excluding cases of type I hereditary motor and sensory neuropathy

3. Typical and atypical FRDA (Harding 1981)
a. Typical: cases meeting above criteria
b. Atypical: cases not meeting above criteria

4. Cardinal features
a. Progressive gait and limb ataxia
b. Absent lower limb reflexes
c. Extensor plantar responses
d. Dysarthria
e. Reduction in or loss of vibration sense and proprioception (sensory modalities mediated by posterior column neurons)

5. Common but nonessential features
a. Cardiomyopathy
b. Scoliosis
c. Foot deformity

Diagnostic Investigations

1. Molecular genetic testing (Chawla 2008; Bidichandani and Delatycki 2009)
a. GAA triplet repeat expansion in intron 1 of the *FXN* gene with four classes of alleles (Sharma et al. 2004)

i. Normal alleles: 5–33 GAA repeats
   a) Short normal: <12 GAA repeats (>80%)
   b) Long normal: 12–33 GAA repeats (approximately 15%)
ii. Premutation (mutable normal) alleles: 34–65 pure, uninterrupted, GAA repeats
   a) Not associated with FRDA but may expand during parental transmission, resulting in disease-causing alleles.
   b) Expansion of premutation alleles, sometimes more than tenfold the original size, has been observed in both paternal and maternal transmission.
iii. Disease-causing expanded (full penetrance) alleles: 66–1,700 GAA repeats
iv. Borderline alleles: 44–66 uninterrupted GAA repeats

2. Clinical laboratory testing
   i. Targeted mutation analysis
      a) Homozygous GAA expansion in *FXN* (96%)
      b) Heterozygous GAA expansion in *FXN*
   ii. Sequence analysis: heterozygous point mutation in *FXN*
      a) Approximately 4% of patients are compound heterozygotes for a GAA expansion in the disease-causing range in one *FXN* allele and another inactivating *FXN* gene mutation in the other allele.
      b) No affected individuals with inactivating point mutations in both *FXN* alleles reported to date
3. Echocardiography: reveals symmetric, concentric ventricular hypertrophy, although asymmetric septal hypertrophy may be present
4. Brainstem auditory evoked responses: typically displaying absent waves III and IV with preservation of wave I, suggestive of involvement of central auditory pathways
5. Visual evoked potentials: absent or delayed latency and reduced amplitude of the p100 wave in two thirds of patients
6. Somatosensory evoked potentials
   a. Delayed central conduction time (N13a/N20, N13b/N20)
   b. Dispersed potentials at the sensory cortex
   c. Abnormal central motor conduction
7. Magnetic resonance imaging of the brain and spinal cord: consistently shows atrophy of the cervical spinal cord with minimal evidence of cerebellar atrophy
8. Nerve conduction studies
   a. Absent sensory nerve action potentials
   b. Absent spinal somatosensory evoked potentials, although these may be reduced or even normal early in the disease course (Harding 1984)
   c. Motor nerve conduction velocities are reduced to a lesser extent than sensory nerve action potentials.
9. Histological studies
   a. Loss of myelinated fibers of the dorsal columns and the corticospinal tracts in lower cervical cord (Weil stain)
   b. Milder involvement of spinocerebellar tracts
   c. Compact fibrillary gliosis in the affected tract on hematoxylin and eosin (H&E) stain but no breakdown products or macrophages, reflecting the very slow rate of degeneration and death of fibers
   d. Shrinkage and eventual disappearance of neurons associated with proliferation of capsular cells in the dorsal spinal ganglia (H&E)
   e. Nearly devoid of large myelinated fibers in the posterior roots
   f. Degeneration and loss of cells of the Clarke column within the thoracic spinal cord

Genetic Counseling

1. Ability to diagnose FRDA by molecular means with a high sensitivity and specificity
   a. Clinically typical patients
      i. A specific and rapid diagnosis can be made in most patients and in the 4% compound heterozygous for a point mutation.
      ii. The presence of one expanded allele indicates that the diagnosis is likely.
   b. Clinically atypical patients can be diagnosed to have or not to have FRDA by:
      i. GAA repeat study
      ii. Mutation analysis for point mutations
   c. Carrier testing
      i. Available for relatives of affected and their partners
      ii. There is a small possibility that a point mutation may be present.

d. For a subject with FRDA who has a carrier partner, there is a 1:2 risk of having an affected child. The a priori risk for a person with FRDA having a child with the condition is approximately 1:200 unless there is consanguinity.
e. If the partner of a carrier does not have an expanded allele, the chance that they carry a point mutation is about 1:5,000 (taking a FRDA carrier rate of 1:100 and that 2% of mutations are point mutations). Therefore, the risk of this couple having a child with FRDA is about 1:20,000 which is only about twice the background risk of the general population.

2. Recurrence risk (Bidichandani and Delatycki 2009)
   a. Patient's sib
      i. Both parents carry a full penetrance allele, or one parent carries a full penetrance allele, and the other parent carries another deleterious *FXN* gene mutation.
         a) At conception: each sib of an affected individual has a 25% chance of being affected, a 50% chance of being an asymptomatic carrier, and a 25% chance of being unaffected and not a carrier.
         b) Once an at-risk sib is known to be clinically unaffected, the risk of his/her being a carrier is 2/3.
         c) The wide range in age of onset and variable intergenerational instability of the GAA expansion dictate the use of caution in diagnosing an at-risk sib as unaffected.
      ii. One parent carries a full penetrance allele or another deleterious *FXN* gene mutation, and the other parent carries a mutable normal (premutation) allele.
         a) At conception: each sib of a proband whose parent is a carrier of a mutable normal (premutation) allele has a 25% chance of inheriting both parental mutations.
         b) Since the mutable normal (premutation) allele may remain unchanged or undergo minimal change (i.e., not expand to produce a full penetrance allele), the sibs have less than 25% chance of being affected.
         c) Each sib also has a 50% chance of being an asymptomatic carrier of one of the parental alleles and a 25% chance of being unaffected and having two normal alleles.
   b. Patient's offspring
      i. All offspring inherit one mutant allele from the affected parent.
      ii. Offspring have a 50% chance of being affected only if the reproductive partner of the proband is a carrier of a full penetrance allele or another deleterious *FXN* gene mutation.
      iii. If the reproductive partner of the proband carries a mutable normal (premutation) allele, the risk to each offspring of developing FRDA is less than 50%.
3. Prenatal diagnosis (Bidichandani and Delatycki 2009)
   a. Possible for pregnancies at 25% risk provided both disease-causing alleles of an affected family member must be identified before prenatal testing can be performed
      i. Amniocentesis
      ii. Chorionic villus sampling
   b. Preimplantation genetic diagnosis: available for families in which the disease-causing mutations have been identified in an affected family member
4. Management
   a. Supporting measures (Bidichandani and Delatycki 2009)
      i. Prostheses, walking aids, and wheelchairs for mobility
      ii. Orthopedic interventions for scoliosis and foot deformities
      iii. Speech, occupational, and physical therapy
      iv. Hearing aids
      v. Pharmacologic agents for spasticity
      vi. Dietary modifications and placement of a nasogastric tube or gastrostomy for dysphagia
      vii. Antiarrhythmic agents
      viii. Anti–cardiac failure medications
      ix. Anticoagulants and pacemaker insertion for cardiac disease
      x. Oral hypoglycemic agents or insulin for diabetes mellitus
      xi. Antispasmodics for bladder dysfunction
      xii. Psychological support
   b. Currently, no treatments have been proven to delay, prevent, or reverse the inexorable decline that occurs in this condition. However, several

pharmaceutical agents are undergoing clinical assessment (Delatycki 2009).

c. Treatment with intermediate- and high-dose idebenone had beneficial effects on neurological symptoms (Schulz et al. 2009).
d. Improvement in both cardiac hypertrophy and neurological symptoms among patients with FRDA treated with idebenone (Meier and Buyse 2009)

Fig. 1 This 22-year-old man was seen for progressive muscle weakness and progressive ataxia. The patient began noticing the problem while running during football practice in high school. In the last 6 months, he has had trouble swallowing, especially liquids, and trouble speaking. At present, he walks with a cane with ataxic gait. There was a significant thigh muscle mass loss. His deep tendon reflexes are absent. Friedreich ataxia DNA test showed that the patient is homozygous for the GAA repeat expansion mutation which confirms the clinical diagnosis of Friedreich ataxia type I (FRDA1) with X25 allele 1 of 400 GAA repeats and X25 allele 2 of 400 GAA repeats

Fig. 2 The patient stands with a cane and need to support standing with hand support on the wall

Frontonasal Dysplasia

Frontonasal dysplasia is a developmental field defect of craniofacial region characterized by hypertelorism and varying degrees of median nasal clefting. In 1967, DeMeyer first described the malformation complex "median cleft face syndrome" to emphasize the key midface defects. Since then, several terms have been introduced: frontonasal dysplasia, frontonasal syndrome, frontonasal dysostosis, and craniofrontonasal dysplasia (currently recognized as a syndrome distinct from frontonasal dysplasia) (Dubey and Garap 2000).

Synonyms and Related Disorders

Frontonasal malformation; Frontorhiny; Median facial cleft syndrome

Genetics/Basic Defects

1. Inheritance
   a. Sporadic in most cases.
   b. Rare autosomal dominant inheritance with variable expression.
   c. Recessive mutations in the homeobox gene *ALX3* cause a recurrent pattern of frontonasal malformation (Twigg et al. 2009).
   d. Rare autosomal recessive inheritance: disruption of *ALX1* causes autosomal-recessive *ALX*-related frontonasal dysplasia (Uz et al. 2010).
   e. Rare X-linked dominant inheritance.
2. Rare association with chromosome anomalies
   a. Partial trisomy 2q and partial monosomy 7q from a balanced maternal t(2;7)(q31;q36) (Chen et al. 1992)
   b. 22q11 microdeletion (Stratton and Payne 1997)
   c. Reciprocal translocation t(15;22)(q22;q13) (Fryns et al. 1993)
   d. Complex translocation involving chromosomes 3, 7, and 11 (Stevens and Qumsiyeh 1995)
3. Rare variants of frontonasal dysplasia/malformation with variable inheritance patterns
4. Embryologically classified as a developmental field defect (Sedano and Gorlin 1986)
5. Extreme variable phenotypic expression
6. Pathogenesis (Twigg et al. 2009)
   a. Formation of the human face is an exquisitely orchestrated developmental process involving multiple tissue swellings (the frontonasal, medial and lateral nasal, and maxillary and mandibular prominences) derived from the neural crest (Moore and Persaud 2007).
   b. During a critical period between 4 and 8 weeks of human fetal development, these processes must undergo cell proliferation and tissue fusion to form the orbital, nasal, and oral structures (Yoon et al. 2000; Moore and Persaud 2007).
   c. Disturbance to this developmental sequence causes frontonasal malformation, a very heterogeneous group of disorders characterized by combinations of hypertelorism, abnormal nasal configuration, and oral, palatal, or facial clefting, sometimes associated with facial asymmetry, skin tags, ocular or cerebral malformations, widow's peak, and anterior cranium bifidum (DeMeyer 1967; Sedano et al. 1970; Sedano and Gorlin 1986; van der Meulen and Vaandrager 1989; Guinon-Almeida et al. 1996; Tan and Mulliken 1997; Losee et al. 2004).

Clinical Features

1. Pure frontonasal dysplasia (Dubey and Garap 2000)
   a. Variable mental retardation
   b. Inheritance pattern
      i. Sporadic in majority of cases
      ii. Familial transmission in few cases
   c. Cranium bifidum occultum
   d. CNS anomalies
      i. Frontal cephalocele
      ii. Meningocele/meningoencephalocele
      iii. Agenesis of the corpus callosum
      iv. Mild holoprosencephaly
      v. Hydrocephalus
   e. Nasal anomalies
      i. Mild colobomas of the nostril
      ii. Flattening of the nose with widely separated nares
      iii. A broad nasal root
      iv. Broad nasal tip
      v. Notching or clefting of alae nasi (cleft nose)
      vi. Nasal tag
   f. Ocular anomalies
      i. Hypertelorism
      ii. Epicanthal folds
      iii. Narrowing of the palpebral fissures
      iv. Accessory nasal eyelid tissue with secondary displacement of inferior puncti colobomas
      v. Epibulbar dermoids
      vi. Upper eyelid colobomas
      vii. Microphthalmia
      viii. Vitreoretinal degeneration with retinal detachment
      ix. Congenital cataracts
   g. Facial anomalies
      i. Widow's peak configuration of the anterior hairline in the forehead
      ii. Median cleft of upper lip
      iii. Median cleft palate
      iv. Preauricular tag
      v. Absent tragus
      vi. Low-set ears
   h. Other anomalies
      i. Conductive deafness
      ii. Hypoplastic frontal sinuses
      iii. Cardiac anomalies, especially tetralogy of Fallot
      iv. Limb anomalies
         a) Clinodactyly
         b) Polydactyly
         c) Syndactyly
         d) Tibial hypoplasia
      v. Umbilical hernia
      vi. Cryptorchidism
2. Autosomal-recessive frontonasal dysplasia in two distinct families (Uz et al. 2010)
   a. Bilateral extreme microphthalmia
   b. Bilateral oblique facial cleft
   c. Complete cleft palate
   d. Hypertelorism
   e. Wide nasal bridge with hypoplasia of the ala nasi
   f. Low-set, posteriorly rotated ears
3. Other syndromes associated with frontonasal dysplasia or frontonasal malformation (Martinelli et al. 2002)
   a. Autosomal dominant form of frontonasal dysplasia with vertebral anomalies
   b. Acromelic frontonasal dysplasia
      i. Autosomal recessive disorder
      ii. Similar frontonasal "dysplasia"
      iii. Rare agenesis of the corpus callosum
      iv. Tibial hypoplasia
      v. Polydactyly (duplicated hallux)
   c. Craniofrontonasal dysplasia
      i. Possible X-linked disorder
      ii. Rare mental retardation
      iii. Hypertelorism
      iv. Craniosynostosis
      v. Facial asymmetry
      vi. Broad nasal root
      vii. Bifid nasal tip
      viii. Syndactyly of toes and fingers
      ix. Split nails
      x. Broad first toe
   d. Acrocallosal syndrome
      i. Autosomal dominant or autosomal recessive disorder
      ii. Severe mental retardation
      iii. Hypertelorism
      iv. Hypoplastic or absent corpus callosum
      v. Prominent forehead
      vi. Small nose
      vii. Broad nasal bridge
      viii. Normal nasal tip
      ix. Cardiac defects
      x. Postaxial polydactyly of hands and feet

xi. Preaxial polydactyly of feet
xii. Syndactyly of toes
xiii. Clinodactyly
e. Oral-facial-digital syndrome
i. X-linked disorder
ii. Variable mental retardation
iii. Agenesis of the corpus callosum
iv. Median cleft lip and palate
v. Lobated/bifid tongue
vi. Clinodactyly
vii. Syndactyly
viii. Polydactyly
f. Oculo-auriculo-frontonasal dysplasia
i. Frontonasal dysplasia
ii. Ocular dermoids
iii. Eyelid colobomata
iv. Preauricular tags
g. Fronto-facio-nasal dysplasia
i. Autosomal recessive disorder
ii. Frontonasal dysplasia
iii. Ocular dermoids
iv. Preauricular tags
v. Cerebral lipoma
h. Acro-fronto-facio-nasal dysplasia I
i. Autosomal recessive disorder
ii. Frontonasal dysplasia
iii. Macrostomia
iv. Broad and notched nasal tip
v. Fibular hypoplasia
vi. Polydactyly
vii. Short stature
i. Acro-fronto-facio-nasal dysplasia II
i. Autosomal recessive disorder
ii. Frontonasal dysplasia
iii. Microcephaly
iv. Nasal midline groove with blind dimples
v. Broad thumbs
vi. Syndactyly
j. Greig acrocephalopolysyndactyly
i. Autosomal dominant disorder
ii. Mild mental retardation
iii. Mild features of frontonasal dysplasia
iv. Macrocephaly
v. Broad nasal root
vi. Normal nasal tip
vii. Postaxial polydactyly of hands
viii. Preaxial polysyndactyly of feet
ix. Broad thumbs and halluces
x. Syndactyly
k. Meinecke frontonasal dysplasia-cardiac defects
i. Frontonasal dysplasia
ii. Microcephaly
iii. Cardiac defects, especially tetralogy of Fallot
4. Prognosis depending on severity of defects
a. Normal intelligence in most patients
b. Mental retardation affecting 12% of cases without CNS abnormalities
c. Up to 50% of cases with mental retardation complicated by agenesis of the corpus callosum

Diagnostic Investigations

1. Radiography, CT, and MRI of the brain
a. Anterior cranium bifidum
b. Agenesis of the corpus callosum
c. Lipoma of the corpus callosum
d. Arhinencephaly
e. Hydrocephalus
2. Chromosome analysis for chromosome etiology
3. Molecular genetic diagnosis of *ALX1* and *ALX3* mutations: not available clinically

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Autosomal dominant disorder: not increased in de novo case unless a parent is affected
ii. Autosomal recessive disorder: 25%
iii. X-linked dominant disorder: 50% when the mother is a carrier
iv. Chromosome disorder: not increased in a de novo case; risk of unbalanced segregation from a carrier parent
b. Patient's offspring
i. Autosomal dominant disorder: 50%
ii. Autosomal recessive disorder: not increased unless the spouse is a carrier
iii. X-linked dominant disorder: 50%
iv. Chromosome disorder: not surviving to reproductive age
2. Prenatal diagnosis
a. Ultrasonography (Martinelli et al. 2002)
i. Hypertelorism
ii. Frontonasal cephalocele

iii. Agenesis of the corpus callosum
iv. Median cleft lip

b. 3-D ultrasonography: increasingly helpful in identifying facial features (Johnstone et al. 2008)
c. Amniocentesis for associated chromosome anomaly

3. Management
   a. Speech therapy
   b. Maxillofacial surgeries for functional and cosmetic improvement
      i. Cleft lip/palate
      ii. Hypertelorism
      iii. Nose
   c. Psychosocial and/or psychiatric support

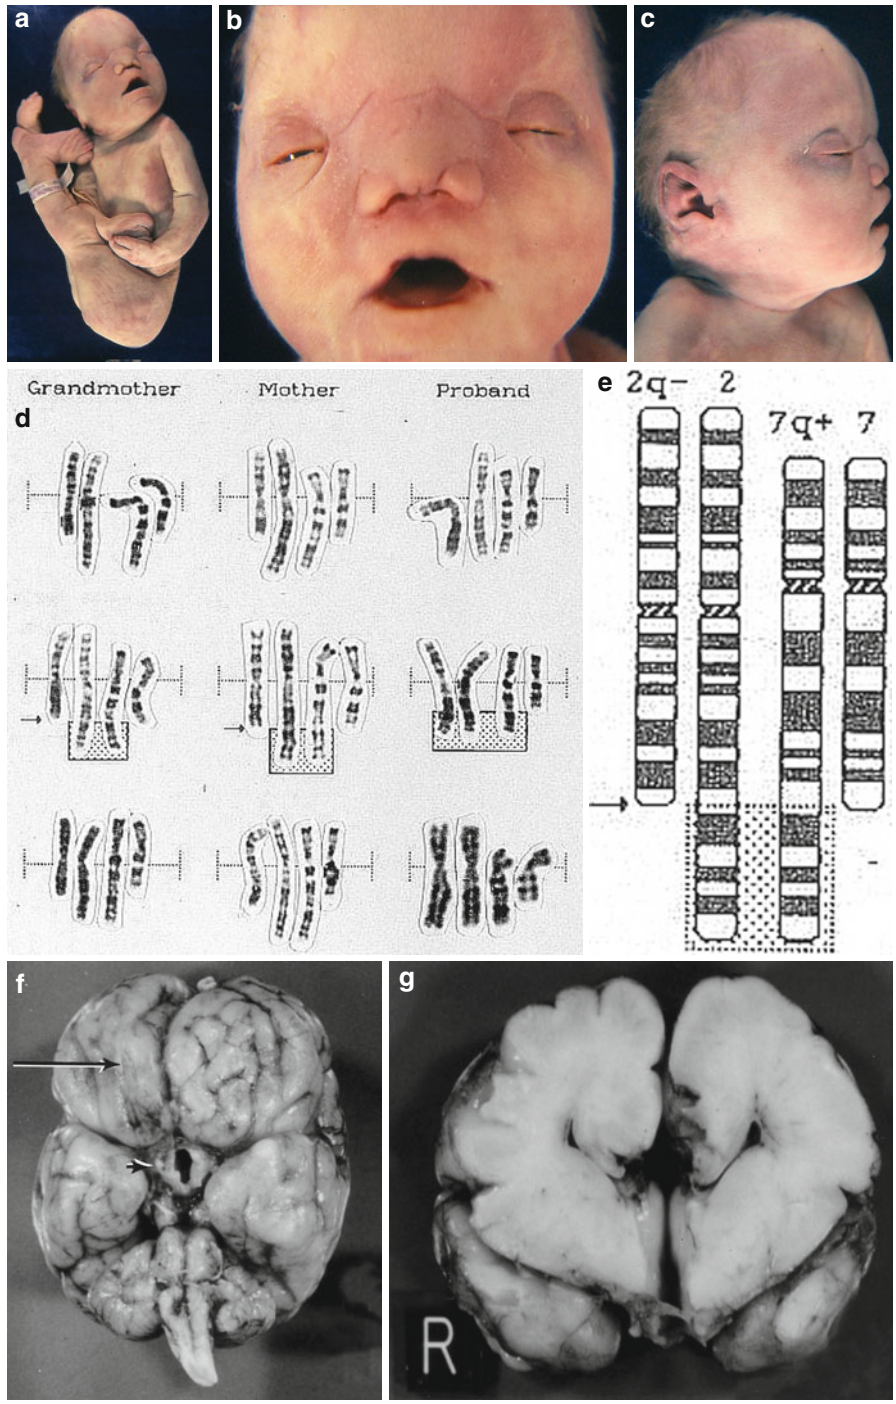

Fig. 2 (**a**–**g**) A newborn with frontonasal dysplasia and arrhinencephaly resulting from unbalanced segregation of a maternal t(2;7)(q31;q36). The patient had partial trisomy 2q and partial monosomy 7q, iris coloboma, tetralogy of Fallot, and limb anomalies

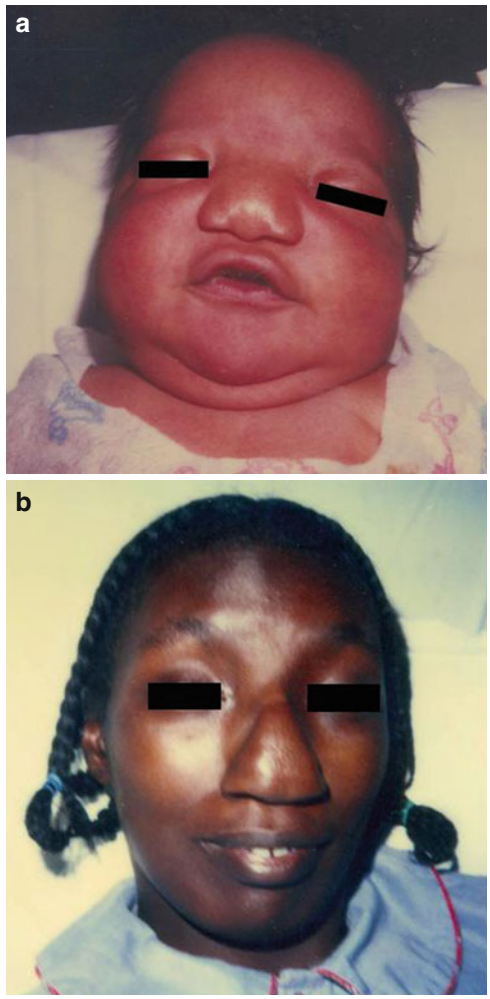

Fig. 3 (**a**, **b**) A mother and a child with frontonasal dysplasia showing hypertelorism and broad and notched nasal tip

Fig. 4 A 2-year-old girl with frontonasal dysplasia

Galactosemia

Classic galactosemia (G/G) is an autosomal recessive disorder of galactose metabolism, caused by a deficiency of galactose-1-phosphate uridyl transferase. The incidence is estimated to be 1 in 30,000–1 in 60,000 births, based on the results of newborn screening programs.

Synonyms and Related Disorders

Classic galactosemia; Galactose-1-phosphate uridyltransferase deficiency

Genetics/Basic Defects

1. Inheritance: autosomal recessive. (Leslie 2003)
2. Cause: deficiency of galactose-1-phosphate uridyl transferase (GALT)
3. Galactose metabolism (Arn 2003)
   a. D-galactose
      i. Galactose: an important sugar in human nutrition, especially during childhood.
      ii. Milk: major source of galactose, which contains lactose, a disaccharide of glucose and galactose.
      iii. Liver: the primary site of galactose metabolism.
      iv. Individuals have the capacity to metabolize large quantities of galactose under normal circumstances.
   b. Normal individuals
      i. Lactase (present in the small intestine): metabolizes galactose to glucose and galactose.
      ii. The resulting glucose and galactose is then absorbed via the portal system to the liver.
      iii. In the liver, a series of four reactions converts galactose to glucose-1-phosphate.
      iv. Glucose-1-phosphate can be metabolized to glucose, CO_2, pyruvate, or glycogen depending on prevailing metabolic conditions.
      v. Inborn errors have been described in all of the enzymes of the pathway.
   c. Affected individuals: Deficiency of the enzyme galactose-1-phosphate uridyl transferase (GALT) causes classic galactosemia.
4. Galactose-1-phosphate uridyl transferase
   a. The gene for GALT is mapped on chromosome 9p13.
   b. GALT is second enzyme in the Leloir pathway, catalyzing conversion of galactose-1-phosphate and UDP glucose to UDP galactose and glucose-1-phosphate.
   c. Essential in human infants who consume lactose as their primary carbohydrate source.
   d. Near total absence of GALT activity in infants with classical galactosemia.
   e. A deficiency causes elevated levels of galactose-1-phosphate and galactitol in body tissues.
5. Endogenous production of galactose may be responsible for the long-term effects, such as cognitive dysfunction and gonadal dysfunction in female patients
6. Duarte (D) allele (Beutler 1991)
   a. Very common
   b. Defined biochemically by:
      i. Reduced enzyme activity
      ii. An isoform distinguishable by gel electrophoresis and isoelectric focusing
   c. Heterozygous Duarte variants (D/N)
      i. Observed in about 11% of Caucasian subjects
      ii. Have about 75% of normal GALT activity

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_101,
© Springer Science+Business Media, LLC 2012

d. Homozygotes for the Duarte variant (D/D)
   i. Have approximately one half (50%) of normal transferase activity
   ii. Mimic carriers for galactosemia
e. Infants with a galactosemia allele and a Duarte allele (D/G)
   i. Have 1 quarter (25%) of normal enzyme activity
   ii. Have reduced capacity to metabolize galactose with abnormal accumulation of galactose-1-phsphate in the red cells
   iii. Phenotypically normal with no ill effect

7. Genotype–phenotype correlations (Elsas II 2003).
   a. Q188R mutations (prevalent in 70% of Caucasians): a poorer outcome in homozygous state associated with essentially no enzyme activity (Elsas et al. 1995)
   b. Duarte variant (N314D)
      i. Homozygous state (D/D or N314D/N314D) with erythrocyte GALT enzyme activity reduced by only 50%
      ii. Compound heterozygotes (D/G or N314D/Q188R)
         a) Relatively benign in most infants
         b) May or may not require dietary intervention
   c. Los Angels (LA) variant with identical N314D missense mutation but has normal erythrocyte GALT activity
   d. S135L allele
      i. Prevalent in Africa
      ii. A good prognosis if therapy is initiated in the neonatal period without neonatal hepatotoxicity and chronic problems
   e. K285N allele
      i. Prevalent in Southern Germany, Austria, and Croatia
      ii. A poor prognosis for neurological and cognitive dysfunction in either the homozygous state or compound heterozygous state with Q188R

Clinical Features

1. Onset of symptoms
   a. May present by the end of the first week of life
   b. May die or develop cataracts, hepatomegaly, cirrhosis, and mental retardation in late-detected cases
2. Neonatal toxicity syndrome
   a. Exposure to dietary galactose in infants with classical galactosemia results in acute deterioration of multiple organ systems, including the following:
      i. Liver dysfunction
         a) Jaundice
         b) Hepatomegaly
      ii. Coagulopathy
      iii. Poor feeding and weight loss
      iv. Vomiting and diarrhea
      v. Lethargy and hypotonia
      vi. Renal tubular dysfunction
      vii. Cerebral edema (encephalopathy)
      viii. Vitreous hemorrhage
      ix. *Escherichia coli* (or other gram-negative) sepsis: consider diagnosis of galactosemia since a high frequency of neonatal death appears to be caused by *E. coli* sepsis (Levy et al. 1977)
   b. Withdrawal of dietary galactose results in reversal of neonatal toxicity syndrome and reducing mortality and morbidity in the early weeks of life.
3. Cataracts
   a. Resulting from accumulation of galactitol within the lens
   b. Seen in infants with classical GALT-deficient galactosemia (and also in galactokinase deficiency)
      i. The ocular hallmark of untreated or late-detected patients
      ii. Severity of lens involvement dependent on the severity of galactosemia and the age at commencement of therapy
   c. Reoccur in older patients who have poor dietary compliance
   d. May be prevented by dietary restriction of galactose
4. Premature ovarian failure
   a. Despite the high prevalence of premature ovarian failure and subsequent infertility in galactosemic women, spontaneous pregnancies occur and may not be as rare as is generally assumed (Gubbels et al. 2008)
   b. Hypergonadotropic hypogonadism occurring almost universally (>90%) in females with classical GALT deficiency
   c. The rapidity and severity of the ovarian failure vary widely among individuals

d. Clinical manifestations
   i. Delayed puberty
   ii. Primary amenorrhea
   iii. Secondary amenorrhea
   iv. Oligomenorrhea
5. Chronic brain effects
   a. Specific deficits
      i. Developmental speech dyspraxia and tremor
      ii. Globally decreased IQ and/or learning disability
   b. Uncertainty as to:
      i. Whether these deficits are initiated in early development, perhaps even prenatally, and unmasked, as more complex brain function is required
      ii. Whether these deficits represent true neurodegenerative processes compounded by dietary exposure and endogenous production of "intoxicants"
      iii. Longitudinal assessment of intellectual achievement in patients with classic galactosemia (Schadewaldt et al. 2010):
         a) Confirms the presence of reduced cognitive ability in classical galactosemia
         b) Presents evidence for an absence of substantial galactosemia-induced aggravation of this impairment with increasing age, at least in patients from 4 to 40 years of age
         c) Remains to be clarified whether a reduction of cognitive function in galactosemia may be initiated by an in utero toxicity of endogenously formed galactose and which role such a process may play in the development of intellectual deficiencies that are later maintained throughout life
6. Prognosis
   a. A life-threatening disorder if untreated.
   b. Currently, affected infants are treated before becoming ill because of newborn screening in most states.
7. Differential diagnosis (Elsas II 2003)
   a. Galactokinase (GALK) deficiency
      i. An autosomal recessive disorder
      ii. Considered in patients with cataracts and galactosemia but otherwise healthy
      iii. Cataracts
         a) The main clinical feature
         b) Due to accumulation of galactitol
      iv. Pseudotumor cerebri
         a) Described in several cases
         b) Considered to be a true consequence of the disorder
      v. These features resolve when a galactose-restricted diet is introduced
      vi. Diagnosis made by detection of reduced galactokinase activity
      vii. Caused by mutations in the *GALK1* gene
   b. UDP-galactose 4-epimerase (GALE) deficiency
      i. An autosomal recessive disorder
      ii. Considered in patients with liver disease, sensorineural deafness, failure to thrive, and elevated galactose-1-phosphate but normal GALT activity
      iii. Response to the removal of galactose from their diets
      iv. Diagnosis made by detection of reduced UDP-galactose 4-epimerase activity
      v. Caused by mutations in the *GALE* gene
   c. Neonatal hepatotoxicity
      i. Infectious diseases (sepsis)
      ii. Obstructive biliary disease
         a) Progressive familial intrahepatic cholestasis (Byler disease)
         b) Metabolic diseases such as Niemann–Pick disease, type C and Wilson disease

Diagnostic Investigations

1. Newborn screening programs in most states (Leslie 2003)
   a. An almost 100% detection of affected infants in states that include testing for galactosemia in their newborn screening programs
   b. Prevention of needless deaths associated with galactosemia, resulting from limiting diagnostic measures to infants who develop symptoms
   c. A positive (i.e., abnormal) screening, followed by a quantitative erythrocyte GALT analysis
2. Liver dysfunction
   a. Bilirubin determination.
      i. Initial unconjugated hyperbilirubinemia
      ii. Later conjugated hyperbilirubinemia
   b. Abnormal liver function tests.
   c. Abnormal clotting.
   d. Raised plasma amino acids, particularly phenylalanine, tyrosine, and methionine. Raised

phenylalanine may result in a false positive neonatal screening test for phenylketonuria.

3. Renal tubular dysfunction
   a. Metabolic acidosis
   b. Urinalysis
      i. Galactosuria
         a) The presence of reducing substances or galactose in the urine is neither sensitive nor specific.
         b) Small quantities of galactose commonly found in the urine of any patient with liver disease.
      ii. Albuminuria
         a) Present in the initial stage
         b) Quick disappearance of albuminuria after eliminating lactose-containing formula from the diet
      iii. Aminoaciduria in the later stage
4. Abnormal carbohydrate metabolism
   a. Increased plasma galactose
   b. Increased red cell galactose-1-phosphate
   c. Increased urine and blood galactitol
5. Testing for hemolytic anemia
6. Study for septicemia, especially *Escherichia coli*
7. Slit lamp examination for cataract assessment
8. Computerized tomography and magnetic resonance imaging
   a. Abnormalities on brain imaging: common in classical galactosemia
   b. Patients with late neurologic disease
      i. Abnormal white matter
      ii. Ventricular enlargement
      iii. Diffuse cortical atrophy with basal ganglia and brainstem involvement
      iv. Cerebellar atrophy
      v. Failure of normal myelination
9. Endocrine investigations for hypergonadotropic hypogonadism
   a. Raised follicle-stimulating hormone
   b. Raised luteinizing hormone
   c. Initially normal estradiol concentration with high gonadotropin levels, indicating continued follicular development, but fall as ovarian failure progresses
10. Increased urinary galactitol excretion
11. Beutler test
    a. A fluorescent spot test for galactose-1-phosphate uridyl transferase activity
    b. Now widely used for the diagnosis of galactosemia
    c. False negative resulting from recent blood transfusions (within 3 months)
    d. False positive resulting from glucose-6-phosphate dehydrogenase deficiency
12. Red blood cell galactose-1-phosphate
    a. Concentration always raised in classical galactosemia
    b. Not significantly affected by blood transfusions
13. Biochemical confirmation of the diagnosis
    a. Red blood cell galactose-1-phosphate uridyl transferase assay
       i. A quantitative assay to confirm the diagnosis (virtual absence of the enzyme activity in classical (G/G) galactosemia)
       ii. Also identifies variants with residual enzyme activity
       iii. False negative results due to blood transfusion within 3 months
    b. A GALT isoelectric-focusing electrophoresis test to distinguish variant forms such as the Duarte defect
14. DNA analysis: *GALT* genotyping for providing specific molecular diagnosis
    a. Classic (G/G) galactosemia
       i. Mutation analysis for the six common *GALT* galactosemia (G) mutations
          a) Q188R mutation: the most common *GALT* allele in whites
          b) S135L: the most common allele in blacks
          c) K285N
          d) L195P
          e) Y209C
          f) F171S
       ii. *GALT* sequence analysis to detect private mutations under the following two conditions:
          a) Both disease-causing mutations not detected by mutation analysis
          b) Diagnosis of galactosemia confirmed by biochemical testing
    b. Mutation analysis for Duarte variant (D/G) galactosemia identified by biochemical testing of the patient and both parents
       i. Identification of Duarte allele (N314D) by mutation analysis
       ii. Identification of G allele by mutation analysis or sequence analysis

15. Carrier testing
    a. Measuring GALT activity: about 50% of control values in carriers
    b. Molecular genetic testing for carriers available to family members, provided *GALT* mutation(s) has/have been identified in the proband

Genetic Counseling

1. Recurrence risk
    a. Patient's sib
        i. A proband with G/G galactosemia
            a) Given the parents are G/N and G/N: a 25% chance of being affected with G/G galactosemia for each sib
            b) Given the parents are D/G and G/N: a 25% chance of being affected with G/G galactosemia and a 25% chance of being affected with D/G galactosemia for each sib
        ii. A proband with D/G galactosemia, given the parents are D/N and G/N: a 25% chance of being affected with D/G galactosemia for each sib
    b. Patient's offspring:
        i. Patient with G/G galactosemia and the normal spouse with N/N: All offspring are carriers.
        ii. Patient with G/G galactosemia and the carrier spouse for a G allele (N/G): a 50% chance of having G/G galactosemia.
        iii. Patient with G/G galactosemia and the carrier spouse for a G allele (D/G): a 50% chance of having G/G galactosemia and a 50% chance of having D/G galactosemia.
2. Prenatal diagnosis possible for fetuses at a 25% risk for classical galactosemia
    a. Galactose-1-phosphate uridyl transferase assay in cultured amniotic fluid cells or in chorionic villus biopsies.
    b. Galactitol estimation in amniotic fluid supernatant.
    c. Mutation analysis of DNA extracted from amniocytes or chorionic villus samples if the genotype of the index case has been characterized.
    d. Prenatal diagnosis of a treatable condition, such as classic galactosemia, may be controversial if the prenatal testing is being considered for the purpose of pregnancy termination rather than early diagnosis.
    e. Preimplantation genetic diagnosis: may be available for families in which the disease-causing mutations have been identified.
3. Management (Arn 2003; Elsas II 2003)
    a. Dietary intervention.
        i. Lactose-galactose-restricted diet
            a) Restrict milk, the principal source of lactose, and products made from milk
            b) Breast milk and cows' milk contraindicated
        ii. Milk substitutes
            a) Use a formula free of bioavailable lactose (e.g., Isomil or Prosobee)
            b) Casein hydrolysate (Alimentum, Nutramigen, and Pregestimil): not recommended because they contain small amounts of bioavailable lactose
        iii. Difficult to totally eliminate galactose since it is present in a wide variety of food, such as infant foods, fruits, and vegetables
        iv. Older patients tolerating lactose much better than children, but recommend restrict milk intake throughout life
        v. Calcium supplements if calcium intake does not meet the recommended daily allowance
        vi. May prevent cataracts, hepatomegaly, liver cirrhosis, mental retardation, and other symptoms
        vii. Effect of dietary restrictions during pregnancy on the long-term complications of an affected fetus: unknown
        viii. Individuals with homozygous Duarte variant without symptoms: do not require treatment (Ficicioglu et al. 2008)
        ix. Management of D/G or N344D/Q188R compound heterozygotes
            a) Decision to treat should be based on the demonstration of abnormal biochemical indices.
            b) No dietary therapy is instituted if the blood galactose and/or galactose-1-phosphate do not rise above 12 mg/dL within 4 h following such ingestion, and there are no clinical signs associated with galactosemia.

c) Dietary therapy should probably be given if there is a greater accumulation of galactose or of galactose-1-phosphate.
d) There is possible benefit of dietary intervention to individuals with variant forms of galactosemia with residual GALT activity in the range of 5–20%: for prevention of cataracts, ataxia, dyspraxic speech, and cognitive deficits.

b. Vitamin K and fresh-frozen plasma to correct clotting abnormalities.
c. Pharmacologic treatment.
   i. An appropriate intravenous antibiotic for gram-negative sepsis.
   ii. Many medications, particularly tablets, contain lactose, and this should be considered when prescribing; however, the amount of galactose is often insignificant when given over a short period.
d. Treat unconjugated hyperbilirubinemia with phototherapy or exchange transfusion to infants who may be at an increased risk of kernicterus if albumin levels are particularly low secondary to liver disease.
e. Parental feeding if the infant is too sick to tolerate enteral feeding for more than 1 or 2 days, unless there is significant liver disease or thrombocytopenia.
f. Treat the following long-term problems in older children and adults with classical galactosemia, despite early and adequate therapy.
   i. Cataracts
   ii. Speech defects
   iii. Poor growth
   iv. Poor intellectual function
   v. Neurological deficits, predominantly extrapyramidal findings with ataxia
   vi. Ovarian failure
g. Physical/speech therapy.
   i. Speech therapy for speech delay or verbal dyspraxia (Nelson 1995)
   ii. Regular assessment of development and cognitive function using standardized tests recommended (Walter et al. 1999)
h. Other therapies/evaluations.
   i. Monitoring of red cell galactose-1-phosphate available for assessing dietary compliance, though despite dietary adherence, these levels never decline to normal
   ii. Ophthalmologic examination for cataract assessment to be made at the time of diagnosis, every 6 months until age 3 years, and then annually (Walter et al. 1999)
   iii. Referral to a pediatric endocrinologist by the time a female patient is 10 years (Walter et al. 1999)
i. Emerging therapies.
   i. None with trial data.
   ii. Environment, GALT genotype, and epigenetic pathway of galactose metabolism probably all contribute to outcome.
   iii. In the absence of new therapies emerging from pathogenetic studies, attempts to enhance GALT activities may prove of value (Holton 1996; Elsas and Lai 1998).

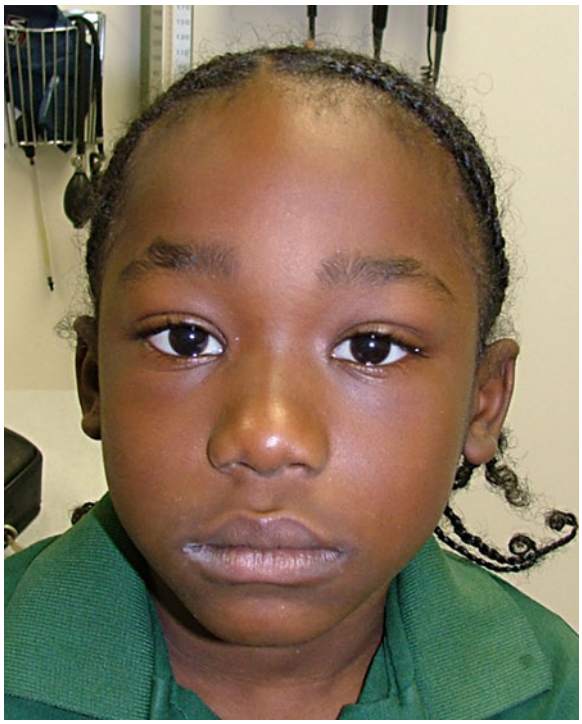

Fig. 1 A 5-year-old boy with classical galactosemia. The initial clinical presentation was at 12 days of age with unconjugated hyperbilirubinemia, presence of reducing substance in the urine, and *E. coli* sepsis. The patient was found to have posterior stellate lens opacities OU. He was found to have deficient galactose-1-phosphate uridyl transferase activity of 0.3 (normal range: 17–37 UMOL/HR/G HGB). Galactokinase was within normal limits. The patient was put on galactose-free diet and has been growing well

Fig. 2 A 2-month-old girl with D/G compound heterozygote. The newborn screening revealed total blood galactose (Gal + Gal-1-phosphate) level of 33.4 mg/dL (normal, <15.0) and blood galactose (without Gal-1-phosphate) level of 3.7 mg/dL. Enzyme assay for uridyl transferase was 41.3 μm (normal, >40.0). DNA analysis showed one copy of the N314D (Duarte galactosemia) variant and one copy of the Q188R (classical galactosemia) mutation. The patient is currently on Isomil and growing well

Gastroschisis

Gastroschisis (Greek for belly cleft) is a congenital paraumbilical wall defect characterized by the protrusion of the intestines uncovered by the peritoneum. It represents one of the most common congenital malformations requiring multidisciplinary neonatal intensive care, with an incidence of approximately 1 in 3,300 births that seems to be increasing (Alvarez and Burd 2007).

Genetics/Basic Defects

1. Precise etiology unknown
2. Inheritance
   a. Isolated occurrence in most cases
   b. Rare autosomal dominant inheritance
3. Pathogenesis and risk factors Sharp et al. (2000); Fillingham and Rankin 2008; Lammer et al. 2008; Rasmussen and Frias 2008)
   a. Pathogenesis
      i. Most commonly quoted: Hoyme's vascular disruption theory with disruption occurring in the omphalomesenteric artery (Hoyme et al. 1983)
      ii. More recent proposed pathogenesis
         a) Consequence of abnormal folding of the body wall (Feldkamp et al. 2007)
         b) Disruption of endothelial oxide synthase pathway (its relationship to vasculogenesis) by environmental exposures or by genetic variation may represent one pathogenetic model for gastroschisis (Lammer et al. 2008).
   b. Risk factors
      i. Vascular insult
         a) Association of maternal smoking and maternal cocaine use with an increased incidence of gastroschisis
         b) The association of intestinal atresia and gastroschisis
      ii. Premature atrophy or abnormal persistence of the right umbilical vein
      iii. In utero rupture of a hernia of the umbilical cord
      iv. Young maternal age (<20 years of age): the most striking epidemiological association with gastroschisis (20–25%)
      v. Primiparous mothers
      vi. Socially disadvantaged mothers
      vii. Use of vasoactive drugs (e.g., decongestant pseudoephedrine) early in pregnancy
      viii. Use of aspirin and decongestants
      ix. Recreational drug use (particularly the use of more than one drug)
      x. Low socioeconomic status
      xi. Maternal nutrition
      xii. Living in close proximity to landfill sites
      xiii. Other novel risk factors
         a) Prior history of gynecological infection/disease
         b) Change of paternity
         c) Paternal age
4. Rare syndrome association
   a. Omphalocele-exstrophy-imperforate anus-spinal defects (OEIS)
   b. Amniotic band syndrome
   c. Limb-body wall complex

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_102,
© Springer Science+Business Media, LLC 2012

5. Rare association with chromosome abnormalities
   a. Trisomy 21
   b. Trisomy 13

Clinical Features

1. Herniation of abdominal contents
   a. Through a small abdominal wall defect
      i. Lateral to the insertion of the umbilical cord
      ii. Most often to the right side of the umbilical cord
   b. Without covering sac
   c. The herniated viscera floating freely in the amniotic cavity
   d. Rare extrusion of the liver
   e. Dilatation of bowel loops due to partial lymphatic and venous obstruction when they are mechanically compressed against the sidewall of the defect
   f. Massive dilatation of the bowel secondary to volvulus, atresia, and ischemia
2. The incidence of associated anomalies relatively infrequent except associated gastrointestinal anomalies (10–20%)
   a. Intestinal stenosis/atresia, often related to:
      i. Intrauterine volvulus
      ii. Strangulation of the blood supply to the extruded segment of intestine at the extremely tight abdominal wall defect
   b. Adhesions
   c. Malabsorption
   d. Meckel diverticulum
   e. Protein-loosing enteropathy
   f. Midgut volvulus
   g. Necrosis
   h. Severe short gut syndrome
   i. Hypoperistalsis
3. Prognosis and complications
   a. Oligohydramnios
      i. Associated with a high incidence of intrauterine growth retardation which occurs in up to 60% of affected fetuses
      ii. Possible secondary effects of severe oligohydramnios
         a) Pulmonary hypoplasia
         b) Limb compression
         c) Cord compression
   b. Polyhydramnios probably associated with reduced bowel motility or bowel obstruction
   c. Fetal distress during labor
   d. IUGR
   e. Small for gestational age
   f. Prematurity
   g. Sepsis
   h. Bowel damage
   i. Cardiac anomalies
   j. Non-gastrointestinal-associated anomalies including occasional occurrence of amyoplasia and arthrogryposis
   k. Problems with absorptive and motility functions
   l. Intraoperative complications
   m. Greater than 90% survival rate (Baerg et al. 2003)
   n. Higher mortality rate (50%) associated with herniation of the liver
   o. Rare reports of spontaneous resolution of gastroschisis and closure of the anterior abdominal wall defect
4. Outcomes in neonates with gastroschisis in US children's hospitals (Lao et al. 2010)
   a. Critical comorbidities and procedures
      i. Cardiovascular defects (15%)
      ii. Pulmonary conditions (5%)
      iii. Intestinal atresia (11%)
      iv. Intestinal resection (12.5%)
      v. Ostomy formation (8.3%)
   b. Factors associated with mortality
      i. Large bowel resection (odds ratio 8.26)
      ii. Congenital circulatory disease (odds ratio 5.62)
      iii. Pulmonary disease (odds ratio 8.22)
      iv. Sepsis (odds ratio 3.87)
   c. Factors associated with sepsis
      i. Intestinal ostomy (odds ratio 2.94)
      ii. Respiratory failure (odds ratio 2.48)
      iii. Congenital circulatory anomalies (odds ratio 1.58)
      iv. Necrotizing enterocolitis (odds ratio 4.38)
5. Differential diagnosis (Nichol et al. 2008)
   a. Omphalocele
      i. Characterized by its involvement of the cord insertion and surrounding membrane.
      ii. The distinction is important given the higher risk for chromosomal and other anomalies in omphalocele.
      iii. The rare finding of a ruptured omphalocele may be very difficult to distinguish from a gastroschisis in utero.

b. Limb-body wall and body-wall complex
   i. Both may involve defects of the ventral body wall, often large and asymmetric, and often involving multiple organs including the liver.
   ii. The lack of a free-floating umbilical cord and scoliosis, with or without limb defects, will suggest this diagnosis.
c. Amniotic band syndrome
   i. Amniotic band syndrome is often difficult to distinguish from body-wall complex.
   ii. Frequently, will also involve severe anomalies of the craniofacial area.
   iii. Like limb-body wall complex, may involve adhesion to the placenta.

Diagnostic Investigations

1. Routine blood work
2. Chromosome analysis rarely indicated (incidence of chromosomal anomalies <5%)
3. Abdominal radiography
4. Abdominal ultrasound
5. Gastrointestinal investigations to rule out gastroesophageal reflux, abnormal intestinal absorption and motility, and Hirschsprung disease
6. Echocardiography

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: The sibling recurrence risk is estimated to be 3.5% (familial occurrence of gastroschisis has been reported) (Torfs and Curry 1993) unless a parent is affected with an autosomal dominant disorder.
   b. Patient's offspring: The offspring recurrence risk is not increased unless the patient is affected with an autosomal dominant disorder.
2. Prenatal diagnosis
   a. Elevated maternal serum alpha-fetoprotein (MSAFP): MSAFP levels are greater in gastroschisis than in omphalocele.
   b. Prenatal ultrasonography
      i. Demonstration of a mass adjacent to the anterior ventral wall representing the herniated viscera
      ii. Herniation almost always exits through the right rather than the left lower quadrant.
      iii. Cord vessels observed to the left of the exiting bowel
      iv. Dilated bowel loops within or outside the abdomen observed when the abdominal wall defect is small
      v. Possible evisceration of stomach
      vi. Possible evisceration of the urinary bladder with secondary hydronephrosis
      vii. Polyhydramnios associated with bowel obstruction
   c. Amniocentesis
      i. Elevated amniotic fluid alpha-fetoprotein
      ii. Positive acetylcholinesterase
      iii. Chromosome analysis
3. Management
   a. Counseling of parents (Hunter and Soothill 2002)
      i. Inform 5–10% incidence of fetal or neonatal death
      ii. Inform long-term digestion problems associated with short gut syndrome
   b. No clear evidence indicating early cesarean section improves the outcome
   c. Endotracheal intubation for respiratory distress in neonates
   d. Avoid hypothermia, hypovolemia, and sepsis
   e. Fluid and electrolyte balance to prevent metabolic acidosis commonly observed as a result of poor perfusion related to hypovolemia
   f. Insertion of an orogastric tube
      i. To prevent air swallowing
      ii. To aspirate intestinal contents
   g. Parenteral antibiotics
   h. Surgical repair: primary repair versus staged repair with silastic silo
   i. Total parenteral nutritional support for prolonged adynamic ileus
   j. Potential need for organ transplantation (Mian et al. 2008)

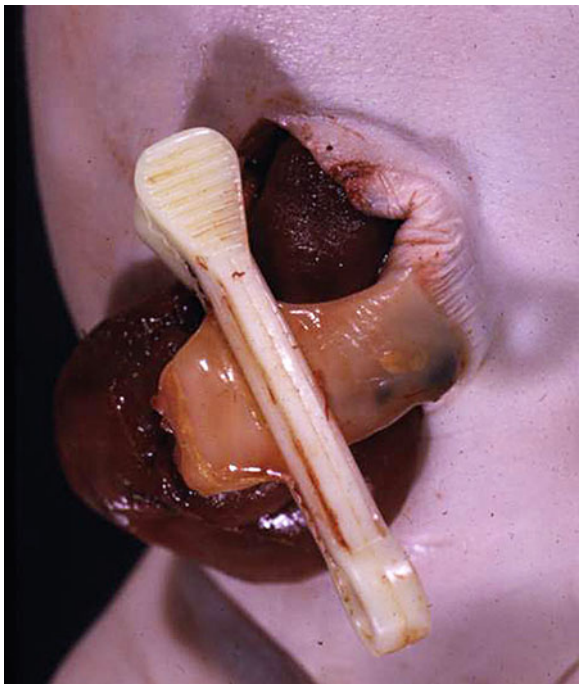

Fig. 1 A premature neonate had herniation of gastric antrum, small intestine, and colon through the gastroschisis, right of intact umbilicus. There was malrotation of the intestine

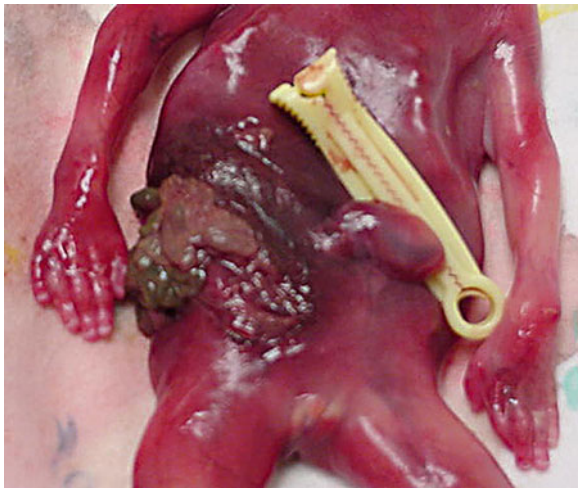

Fig. 2 A stillborn with gastroschisis showing herniation of abdominal contents

Gaucher Disease

Gaucherdisease is the most common lysosomal storage disease and the most common genetic disorder among Ashkenazi Jews. The disease incidence in the Ashkenazi population in Israel is 1 in 7,750 to 1 in 10,000. The disease frequency in the Caucasian population is approximately 1 in 50,000 live births (Grabowski 2000).

Synonyms and Related Disorders

Acid beta-glucocerebrosidase deficiency; Gaucher disease type 1 (non-neuropathic type); Gaucher disease type 2 (acute neuropathic type); Gaucher disease type 3 (chronic neuropathic type); Gaucher disease type 4 (cardiovascular type); Glucocerebrosidase deficiency; Perinatal lethal Gaucher disease (collodion type)

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive
   b. The gene encoding β-glucocerebrosidase (acid β-glucosidase) mapped to 1q21
2. Caused by mutation in the glucocerebrosidase (*GBA*) gene that results in deficiency of β-glucocerebrosidase activity
   a. Over 200 different mutations reported.
   b. Four common mutations (N370S, L444P, 84GG, IVS2 + 1).
      i. Account for about 90% of the disease-causing alleles in the Ashkenazi Jewish population.
      ii. Account for 50–60% of the disease-causing alleles in the non-Jewish population.
      iii. Presence of the common N370S precludes neuronopathic involvement, also in combination with severe L444P.
   c. Other rare mutations and unique mutations: worldwide differences in genetic mutations.
   d. Genetic heterogeneity results in phenotypic heterogeneity: phenotypic presentation of the same mutation may vary in a wide spectrum: this difference is most possibly related with ethnicity, genetic background, and environmental and nutritional factors (Harmanci and Bayraktar 2008).
3. Consequences of deficient β-glucocerebrosidase activity (Charrow et al. 1998)
   a. Accumulation of glucocerebroside in the lysosomes of monocyte-derived macrophages in the reticuloendothelial system.
   b. Resulting hypersplenism produces progressive anemia and thrombocytopenia.
   c. Accumulation of glucocerebroside in bone marrow resulting in:
      i. Osteopenia
      ii. Lytic bone lesions
      iii. Pathologic fractures
      iv. Chronic bone pain
      v. Acute episodes of excruciating "bone crisis"
      vi. Bone infarct
      vii. Osteonecrosis

Clinical Features

1. Notable for marked phenotypic variability
2. Type 1 (non-neuronopathic type)
   a. Adult or chronic form: the most common form

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_103,
© Springer Science+Business Media, LLC 2012

b. Representing about 85% of cases with Gaucher disease
c. Wide range of age of onset and rate of progression
   i. Ranging from disability in toddlers to asymptomatic disease in octogenarians
   ii. The mean age at diagnosis: 21 years
d. Skeletal involvement (Charrow et al. 1998)
   i. Clinical or radiographic evidence of bone disease in 70–100% of patients with type 1 Gaucher disease.
   ii. May be the most debilitating and disabling aspect of type 1 Gaucher disease, leading to:
      a) Bone marrow infiltration by Gaucher cells
      b) Failure of remodeling
      c) Osteopenia
      d) Focal lytic or sclerotic lesions
      e) Osteonecrosis
      f) Osteomyelitis and bone crisis
      g) Chronic bone pain
      h) Pathologic fractures
e. Hepatosplenomegaly
   i. Enlarged spleen with resultant hypersplenism associated with pancytopenia.
   ii. Infarction of the spleen resulting in acute abdominal pain.
   iii. Rare acute surgical emergencies because of splenic rupture.
   iv. Hepatomegaly common but cirrhosis and hepatic failure rare.
f. Pancytopenia
   i. Anemia secondary to the following cause:
      a) Hemolysis secondary to hypersplenism
      b) Hemodilution such as pregnancy
      c) Splenic sequestration
      d) Depressed erythropoiesis due to bone marrow failure from Gaucher cell infiltration or medullary infarction (in advanced cases, particularly postsplenectomy)
   ii. Leukopenia
      a) Commonly noted
      b) Rarely severe enough to contribute to recurrent infections
      c) Risk of infection compounded by chemotactic defects in leukopenic patients
   iii. Thrombocytopenia
      a) Resulting from hypersplenism, splenic pooling of platelets, or marrow infiltration of Gaucher cells or infarction.
      b) Associated with easy bruising or overt bleeding, particularly with trauma, surgery, or pregnancy.
      c) The risk of bleeding increases when there are concomitant clotting abnormalities.
g. Pulmonary disease
   i. Interstitial lung disease
   ii. Alveolar/lobar consolidation
   iii. Pulmonary hypertension
   iv. Hepatopulmonary syndrome
      a) Dyspnea
      b) Cyanosis with digital clubbing
      c) Liver dysfunction
h. Cholelithiasis in adult patients (32%)
i. Cardiac and renal complications rarely encountered
j. Neurological complications secondary to bone disease
   i. Severe osteopenia with vertebral compression.
   ii. Emboli following long bone fracture.
   iii. Coagulopathy secondary to hematomyelia.
   iv. Parkinsonian features in a few patients: uncertain cause-and-effect relationship or just a coincidence.
k. Absence of primary central nervous system disease

3. Type 2 (acute neuronopathic type)
   a. Infantile form: the rarest and most severe form of the disease
   b. Representing about 10% of cases with Gaucher disease
   c. Onset before age 2 years, mostly symptomatic by age 6 months
   d. Normal at birth
   e. Development of hepatosplenomegaly
   f. Regression of developmental milestones
   g. Arrest of growth
   h. Bulbar signs
      i. Stridor
      ii. Squint
      iii. Swallowing difficulty
   i. Pyramidal signs
      i. Opisthotonus
      ii. Head retroflexion
      iii. Spasticity
      iv. Trismus
   j. Oculomotor abnormalities
      i. Oculomotor apraxia
      ii. Saccadic initiation failure

iii. Opticokinetic nystagmus
iv. Strabismus

k. Collodion baby phenotype (congenital ichthyosis) in some neonates
l. Perinatal lethal Gaucher disease: a subset of type 2 or a specific clinical entity (Mignot et al. 2003)
i. Lethality of a homozygous null mutation reported
ii. Non-neurological involvement
a) Nonimmune hydrops fetalis
b) Prematurity
c) Fetal demise or death usually occurring within 2 days to 3 months
d) Hepatosplenomegaly (92%)
e) Thrombocytopenia (38%) associated with purpura (22%)
f) Anemia (10%)
g) Neonatal ichthyosis/collodion baby phenotype (41%)
h) Bone marrow invasion by Gaucher cells, a constant finding at autopsy
iii. Neurological involvement
a) Neurologic signs overlapping with classical type 2 Gaucher disease.
b) Hypokinesia (43%) with facial dysmorphology.
c) Contractures of distal joints (club foot, camptodactyly) (30%).
m. Universally progressive and fatal, succumb to apnea or aspiration by age 2–4 years

4. Type 3 (chronic neuronopathic type)
a. Juvenile form: presenting in childhood or early adulthood
b. Observed primarily in a cluster of cases from Sweden (Norrbottenian type) but may occur in other ethnic groups
c. Hepatosplenomegaly
d. Anemia
e. Thrombocytopenia
f. Bony involvement
g. Pulmonary infiltrates and esophageal varices associated with liver cirrhosis
h. Neurologic disease
i. Supranuclear gaze palsy
ii. Seizures in some patients
a) Generalized tonic-clonic seizures
b) Progressive myoclonic epilepsy
iii. Advanced stage
a) Dementia
b) Ataxia
i. Lifespan extending into the third to fourth decade

5. Type 4 (cardiovascular type)
a. Calcification of the aortic and mitral valves
b. Mild splenomegaly
c. Corneal opacities
d. Supranuclear ophthalmoplegia

Diagnostic Investigations

1. General clinical laboratory blood tests (Charrow et al. 1998)
a. Hemoglobin concentration for anemia.
b. Platelet count for thrombocytopenia.
c. Liver enzymes for liver disease.
d. Iron, ferritin, and total iron-binding capacity for coexistent iron deficiency or iron overload.
e. Prothrombin time and activated partial thromboplastin time for:
i. Clotting defects associated with liver disease.
ii. Factors IX and Factor X deficiency with Gaucher disease.
iii. Factor XI deficiency that may cosegregate with Gaucher disease among Ashkenazi Jewish population.
f. Alkaline phosphatase, serum calcium, phosphorous, and 24-h urinary calcium for markers of bone involvement and defects in calcium absorption and metabolism.
g. Total and direct bilirubin, and total protein and albumin for monitoring liver function.
h. Serum protein electrophoresis and serum immunoelectrophoresis for detecting monoclonal gammopathies that may be more common in adult patients with Gaucher disease than in the general population.
i. Plasma chitotriosidase (markedly elevated in plasma).

2. Abdominal ultrasound
a. Assessing organ volume and parenchymal abnormalities
b. Gallstone detection

3. Brainstem auditory evoked response (BAER) for abnormal wave form in type 2 and type 3
4. Bone densitometry for quantitative assessment of osteopenia

5. Radiography (Wenstrup et al. 2002)
   a. Erlenmeyer flask deformity
      i. Common but not pathognomonic finding.
      ii. Deformity resulting from the impairment of remodeling of the metaphyseal region of tubular bones.
      iii. Manifesting as a flaring of the distal lateral aspects of the femur and proximal tibia.
   b. Lytic lesions
   c. Osteosclerosis due to aberrant remodeling after bone infarction with deposition of calcium
   d. Generalized osteopenia
      i. Nearly universal in children and adults with Gaucher disease.
      ii. Associated with increased risk of bone fractures.
   e. Osteonecrosis (avascular necrosis)
      i. Believed to be secondary to chronic infarction.
      ii. Affecting primarily the femoral head, proximal humerus, and vertebral bodies.
      iii. Resulting in fracture and joint collapse.
   f. Fractures
   g. Bone marrow infiltration
6. MRI
   a. Extent of marrow involvement
   b. Fibrosis and/or infarction
   c. Cerebral atrophy
7. Bone marrow aspiration (Pastores and Hughes 2011)
   a. Presence of lipid-engorged macrophages ("Gaucher cells").
      i. Fibrillary, "crumpled silk" appearance to the cytoplasm.
      ii. Eccentrically placed nucleus.
      iii. Stained positively with periodic acid-Schiff (PAS) reagent.
   b. Not a mandatory test since the bone marrow findings are nonspecific changes and not reliable.
8. Assay of acid β-glucocerebrosidase enzyme activity in peripheral blood leukocytes, lymphoblasts, cultured fibroblasts, amniocytes, and chorionic villi samples (Pastores and Hughes 2011)
   a. The most efficient and confirmatory diagnostic test.
   b. Affected individuals: 0–15% of normal activity.
   c. Individuals with type 1 Gaucher disease: 10–15% of normal activity.
   d. Individuals with type 2 Gaucher disease: $\leq$10% of normal value.
   e. Unreliable for carrier detection since the values overlap in carriers and noncarriers.
9. Molecular genetic testing to identify two disease-causing alleles providing additional confirmation of the diagnosis (Pastores and Hughes 2011)
   a. Targeted mutation analysis
   b. Sequence analysis

Genetic Counseling

1. Recurrence risk (Pastores and Hughes 2011)
   a. Patient's parents
      i. Heterozygotes (carrying a single copy of a disease-causing mutation in the *GBA* gene) in most instances
      ii. Asymptomatic
      iii. A homozygous parent possible.
         a) High carrier frequency in certain population (approximately 1 in 18 in Ashkenazi Jews population)
         b) Variable phenotype with the N370S/N370S genotype
   b. Patient's sib
      i. 25% affected, given the parents are carriers.
      ii. 50% affected when one of the parents is a homozygote and the other a heterozygote.
   c. Patient's offspring
      i. When the spouse is not a carrier: all offspring obligate heterozygotes.
      ii. When the spouse is a carrier: 50% of offspring affected and 50% of offspring carriers.
2. Prenatal diagnosis
   a. Prenatal ultrasound findings in perinatal lethal Gaucher disease (Rowlands and Murray 1997)
      i. Nonimmune hydrops fetalis
      ii. Hepatosplenomegaly
      iii. Abnormal fetal movements, posture, and tone
   b. Available to pregnancies at increased risk
      i. Highly useful to predict non-neuronopathic disease with assurance.
      ii. Overall difficulty in predicting disease progression adding complexity.

c. Analysis of β-glucocerebrosidase enzymatic activity (0–15% of normal), performed on fetal cells obtained by:
   i. CVS cells
   ii. Amniocytes
d. Mutation analysis of the *GBA* gene when the disease-causing *GBA* mutations have been identified in both parents or a prior affected sibling, performed on fetal cells obtained by:
   i. CVS cells
   ii. Amniocytes
e. Preimplantation genetic diagnosis (PGD) (Altarescu et al. 2010)
   i. In the case of type 1 Gaucher disease, PGD might be considered because it obviates the ethical dilemma of pregnancy termination should the fetus be affected.
   ii. PGD is possible for at-risk pregnancies provided the disease-causing mutations have been previously identified in the family.

3. Management (Pastores and Barnett 2003)
   a. Symptomatic care
      i. Partial or total splenectomy
         a) For patients who have massive splenomegaly with significant infarction and persistent severe thrombocytopenia with high risk of bleeding.
         b) Enzyme replacement therapy alleviates hypersplenism and eliminates the need for splenectomy.
      ii. Transfusion of blood products for severe anemia and bleeding
      iii. Analgesics for bone pain
      iv. Joint replacement surgery to relieve bone pain and restore joint function
      v. Oral bisphosphonates suggested in patients with Gaucher disease and low bone density
   b. Therapy to reduce glucosylceramide accumulation
      i. Bone marrow transplantation
      ii. Enzyme replacement therapy
      iii. Substrate reduction therapy
      iv. Gene therapy
   c. Bone marrow transplantation
      i. Corrects metabolic defect
      ii. Improves blood counts
      iii. Reduces increased liver volume
      iv. Stabilizes bone disease and neurologic disease in a few patients
      v. Limited use in patients with type 1 and type 3 Gaucher disease because of the morbidity and mortality associated with the bone marrow transplantation
      vi. Useful concomitant therapy for patients with chronic neurological Gaucher disease and progressive disease on enzyme replacement therapy
   d. Enzyme replacement therapy (ERT) (Charrow 2009)
      i. Efficacy using alglucerase and imiglucerase (Bembi et al. 2002).
         a) For treating the visceral and hematological aspects of Gaucher disease: improvement in hematologic parameters, normalization of bone marrow fat content, and improved bone mineral content and quality of life.
         b) Treatment responses seen within months.
         c) Effective for halting or reversing the skeletal pathology of Gaucher disease.
         d) The optimal dosage and the response time of ERT for treating the skeletal system, particularly for pediatric patients, are not well defined.
      ii. Intravenous infusions of purified macrophage-targeted human β-glucocerebrosidase.
         a) Alglucerase (Ceredase, Genzyme Corporation), derived from human placenta
         b) Imiglucerase (Cerezyme, Genzyme Corporation), derived from recombinant DNA production methods
      iii. Treatment results (visceral aspects of type 1 and type 3 Gaucher disease).
         a) Breakdown of stored glucocerebroside.
         b) Reduction in liver and spleen size.
         c) Amelioration or resolution of anemia and thrombocytopenia.
         d) Decreased bone pain.
         e) Increased bone mineralization.
         f) Remodeling over a period of several years.
         g) Improved health-related quality of life.

h) IgG antibodies to alglucerase reported to develop in approximately 13% of patients. These antibodies have little clinical effect and diminish with continued therapy in most circumstances. However, the presence of antibodies could be associated with an increased risk of hypersensitivity reactions (Charrow et al. 1998).

iv. Treatment in patients with type 2 Gaucher disease (Charrow et al. 1998).
   a) Limited and disappointing: unaltered ultimate fatal course.
   b) Therapy at birth given to an infant, identified prenatally, failed to alter the inevitable neurologic outcome.
   c) Currently not recommended to treat patients with type 2 Gaucher disease.

v. Currently, no hard data available to show the efficacy of enzyme therapy for reversing existing or rapidly progressing CNS disease in type 3 patients with Gaucher disease.

vi. Effect of enzyme therapy on the cardiac, valvular, and hydrocephalic manifestations of type 4 patients remains unknown.

vii. ERT is a lifelong treatment since withdrawal of therapy inevitably leads to progression of Gaucher disease and the (sometimes rapid) loss of the progress made with ERT.

e. Substrate reduction therapy
   i. Miglustat, a formulation aimed at restoring metabolic homeostasis by limiting the amount of substrate precursor synthesized to a level that can be effectively cleared by the mutant enzyme with residual hydrolytic activity.
   ii. Additional controlled longitudinal studies needed to be undertaken with a larger number of patients not only to determine the biochemical but also clinical long-term outcomes of patients with type 1 Gaucher disease on miglustat therapy (Ficicioglu 2008).

f. The future of Gaucher disease therapy (Harmanci and Bayraktar 2008)
   i. Gene therapy
      a) Neither ERT nor SRT has achieved excellent results in terms of neurological and pulmonary involvement due to problems such as inability to pass through the blood–brain barrier.
      b) Possibility of administration and incorporation of a healthy genome replacing a deficient genome.
      c) In early animal models of gene therapy, the vectors responsible for "infecting" a healthy genome were viruses (adeno-associated virus, leutivirus, and retrovirus). These studies showed promising results for the future (Kim et al. 2004; Enquist et al. 2006; McEachern et al. 2006).
      d) The advantage of gene therapy: its widespread infection of specific targeted cells in the body substantially increasing the enzyme levels to a considerable level.
   ii. Chaperone treatment
      a) Imino sugars: ability to increase the strength of the target enzyme (glucocerebrosidase) (Sawkar et al. 2002).
      b) These chemicals increase the half-life of the enzyme by inhibiting its degradation and by providing stabilization.
      c) Although this option currently does not seem to offer a monotherapy option, chaperones might be an option for combination treatment strategies.

Fig. 1 A 3-year-old African-American female with Gaucher disease showing hepatosplenomegaly. She had history of "large belly" since she was 6–12 months of age, anemia (hemoglobin of 8.7 g%), and thrombocytopenia (73,000). She had an elevated total acid phosphatase of 29 U/L (2.3–5.0), a very low leukocyte beta-glucocerebrosidase of 0.01 U (0.08–0.35), and "Gaucher cells" in the bone marrow

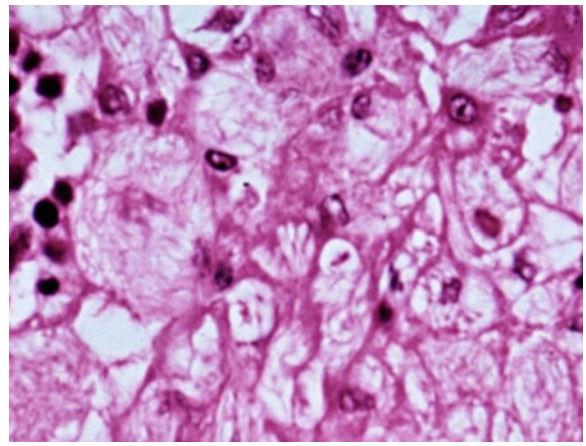

Fig. 2 Bone marrow smear from another patient with Gaucher disease showing extensive infiltration by Gaucher cells (H&E stain)

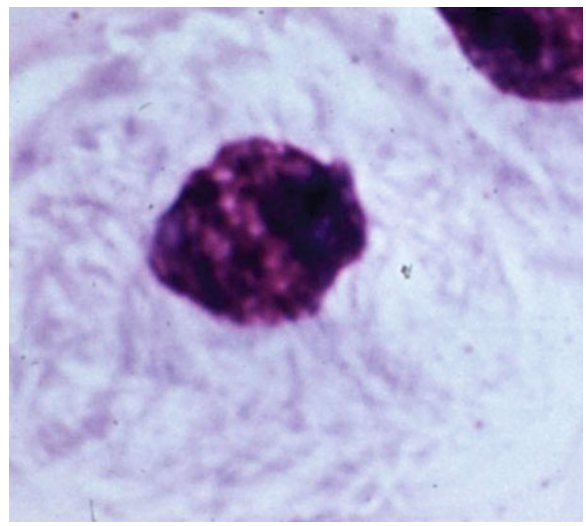

Fig. 3 Higher magnification of bone marrow smear showing a Gaucher cell (Wright-Giemsa stains)

Generalized Arterial Calcification of Infancy

General arterial calcification of infancy is a rare and usually fatal disease. The condition is also called idiopathic arterial calcification of infancy.

Synonyms and Related Disorders

Idiopathic infantile arterial calcification; Infantile occlusive arteriopathy

Genetics/Basic Defects

1. Inheritance: autosomal recessive.
2. Cause (Rutsch et al. 2008).
   a. Loss-of-function mutations in *ENPP1* gene (located on chromosome 6q22–q23) that inactivate ectonucleotide pyrophosphatase/phosphodiesterase 1 (*ENPP1*).
      i. This cell-surface enzyme generates inorganic pyrophosphate, a solute that regulates cell differentiation and serves as an essential physiologic inhibitor of calcification.
      ii. *ENPP1* coding region mutations are associated with generalized arterial calcification of infancy in ≈75% of subjects.
      iii. This mutation was recently found to also cause autosomal-recessive hypophosphatemic rickets (Lorenz-Depiereux et al. 2010).
   b. Plasma cell membrane glycoprotein-1 (PC-1) deficiency.
      i. Associated with human infantile arterial calcification, especially with periarticular calcification.
      ii. May explain the sharing of certain phenotypic features between some infantile arterial calcification patients and PC-1-deficient mice.
3. Basic defects.
   a. Possibly a defect of elastic fiber.
      i. Occurrence of calcification particularly in the internal elastic lamina.
      ii. Material with the staining properties of mucopolysaccharide accumulates around the elastic fibers.
   b. Fundamental lesions.
      i. A remarkable predilection for mineralization around the internal elastica laminae of medium- to large-sized arteries.
      ii. Narrowing of the arterial lumen due to a marked intimal proliferation.
   c. Pathogenesis.
      i. Incompletely understood.
      ii. Involves calcification (calcium hydroxyapatite deposition) in the internal elastic lamina of large- and medium-sized arteries, associated with a stenosing, fibroproliferative medial smooth muscle cell-mediated process, maximal in the area of the internal elastic lamina.
      iii. Relates to decreased levels of plasma and urinary inorganic pyrophosphate whose role is to inhibit hydroxyapatite crystal deposition in bone and cartilage.

Clinical Features

1. Stormy clinical course.
2. Infant usually thrive normally right after birth.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_104,
© Springer Science+Business Media, LLC 2012

3. Thereafter, following symptoms develop rapidly.
   a. Poor feeding.
   b. Vomiting.
   c. Respiratory distress.
      i. Tachypnea.
      ii. Tachycardia.
      iii. Cyanosis.
   d. Hypertension (Van Dyck et al. 1989).
   e. Myocardial infarctions.
   f. Progressive congestive cardiac failure.
4. Prognosis.
   a. Death (sudden death or unexpected infant death).
      i. Usually occurring during early infancy secondary to coronary insufficiency.
      ii. 85% of cases dying before 6 months of age (Byard 1996).
      iii. Causes of death.
         a) Vascular occlusion due to extensive calcification of the arterial media associated with intimal proliferation.
         b) Other complications of obstructive arteriopathy including renal artery stenosis.
         c) Ischemic myocardial ischemia/cardiomyopathy resulting in refractory heart failure.
   b. Rare regression of calcification and prolonged survival (Ciana et al. 2006): Once the severe circulatory problems of infancy are overcome, disease prognosis may be better than previously thought.

Diagnostic Investigations

1. Blood workup.
   a. Normal calcium levels.
   b. Normal phosphate levels.
2. Radiography.
   a. Demonstration of the calcified arteries, leading to possible diagnosis of the condition during life.
   b. Extensive vascular calcification.
      i. Upper and lower limbs.
      ii. Neck.
      iii. Subclavicular fossae.
      iv. Axillae.
   c. Periarticular calcification and stippled calcification of the epiphyseal cartilage.
   d. Cardiac enlargement.
3. ECG changes suggesting.
   a. Coronary occlusion.
   b. Myocardial infarct.
4. Echocardiography to demonstrate coronary calcification.
5. Aortogram showing striking obliterations of the peripheral vessels.
6. Biopsies of peripheral arteries showing extensive intimal mineralization.
7. Postmortem gross pathological findings usually limited to the cardiovascular system.
   a. An enlarged heart.
   b. Focal calcifications of coronary arteries and other peripheral arteries.
   c. Pale or mottled areas of the myocardium or other viscera indicative of infarction.
8. Histopathology.
   a. Extensive mineralization (calcium hydroxyapatite deposition) of arteries.
      i. Usually noted around the internal elastic lamina of the medium-sized arteries.
      ii. Often accompanied by a marked intimal hyperplasia causing luminal narrowing.
      iii. Tends to be most severe in the coronary arteries.
         a) Resulting in myocardial ischemia and infarction.
         b) Death usually attributable to myocardial infarction or heart failure.
   b. Involvement of a variety of arteries.
      i. Aorta.
      ii. Pulmonary arteries.
      iii. Carotid arteries.
      iv. Iliac arteries.
      v. Femoral arteries.
      vi. Visceral arteries.
      vii. Limb arteries.
      viii. Vessels of the brain usually not affected.
   c. Cardiac abnormalities.
      i. Left or biventricular hypertrophy.
      ii. Fibrointimal thickening.
      iii. Calcification of the coronary arteries.
      iv. Endocardial fibroelastosis.
      v. Widespread ischemic myocardial damage.

   d. Generalized arterial calcification of infancy generally indistinguishable from the following conditions.
      i. Metastatic calcification of arteries secondary to advanced renal disease.
      ii. Arterial lesions in hypervitaminosis D or secondary to other toxic agents.
      iii. Hyperparathyroidism of pregnancy.
9. Molecular genetic diagnosis: not yet available clinically (only available in a few research laboratories) (Cheng et al. 2005; Dlamini et al. 2009).

Genetic Counseling

1. Recurrence risk.
   a. Patient's sib: 25%.
   b. Patient's offspring.
      i. Not surviving to reproductive age in majority of patients.
      ii. Low recurrence risk for those who survive.
2. Prenatal diagnosis.
   a. Fetal ultrasonography and radiography to detect calcium hydroxyapatite deposits (echogenic walls of arterial vessels).
      i. Presence of mitralic echogenic foci in the 14th week of gestation (Ciana et al. 2006).
      ii. Echogenic great arteries at 29 weeks of gestation (Reitter et al. 2009).
   b. Fetal echocardiography (Nagar et al. 2003).
      i. Fetal nonimmune hydrops.
      ii. Increased echo (calcific type) density of walls of the fetal aorta, pulmonary arteries, coronary arteries, within the lumen of the heart, and other arterial walls.
      iii. Poor focal contraction of the heart, as a result of the expected accompanying cardiac ischemia due to coronary artery narrowing.
      iv. Dilated cardiac chambers.
      v. Pericardial effusion.
      vi. Hypertrophic cardiomyopathy.
   c. Prenatal diagnosis.
      i. Reference ranges for the disease-related enzymes in amniocytes or fibroblast cultures from CVS have not been established.
      ii. Molecular genetic diagnosis: Prenatal diagnosis may be possible in at-risk families, provided disease-causing mutations have been identified previously.
3. Management.
   a. Therapy with diphosphonates (nonhydrolyzable analogs of inorganic pyrophosphate) (Van Dyck et al. 1989).
      i. Function of diphosphonates.
         a) Simple chemical compounds containing phosphate-carbon-phosphate bonds.
         b) Inhibit the precipitation of several calcium salts in vitro.
         c) Block the conversion of amorphous calcium phosphate into crystalline hydroxyapatite.
         d) Partially converting apatite crystals into a colloidal state with treatment of large amounts of certain diphosphonates.
      ii. Effective in some patients.
         a) Some apparent reduction of calcification.
         b) Usually with persistence of ischemic effects of intimal fibroproliferation.
         c) Except for the p.P305T mutation, which was universally lethal when present on both alleles, the identified *ENPP1* mutations per se have no discernable effect on survival. However, survival seems to be associated with hypophosphatemia linked with hyperphosphaturia and also with bisphosphonate treatment (Rutsch et al. 2008).
         d) Case report by Ramjan et al. 2009: Low-dose disodium pamidronate (0.1 mg/kg per week for 4 weeks), which commenced on the seventh day after birth and was changed to oral risedronate sodium (1 mg/kg per week as a single dose) at 4 weeks of age. Complete resolution of arterial calcification was seen by 3 months of age. Treatment with bisphosphonates is ongoing but is planned to be discontinued at 3 years of age. The child has remained healthy and developmentally normal.
   b. Management of arterial hypertension.
      i. May be refractory to conventional medical therapy.
      ii. Prostaglandin E_1 infusion.

c. Management of myocardial infarctions.
d. In utero diphosphonate etidronate therapy (Stuart et al. 1990; Bellah et al. 1992).
   i. Apparent radiographic and ultrasonographic improvement in the degree of vascular calcification.
   ii. Unable to prevent the lethal progression of intimal vascular occlusive disease.

Fig. 1 Postmortem picture of a neonate (twin B) with generalized arterial calcification showing ischemic changes of the right arm. The pregnancy was complicated by polyhydramnios. At 2 weeks of age, he was noted to have intercostal retraction and tachypnea with distended abdomen and hepatomegaly

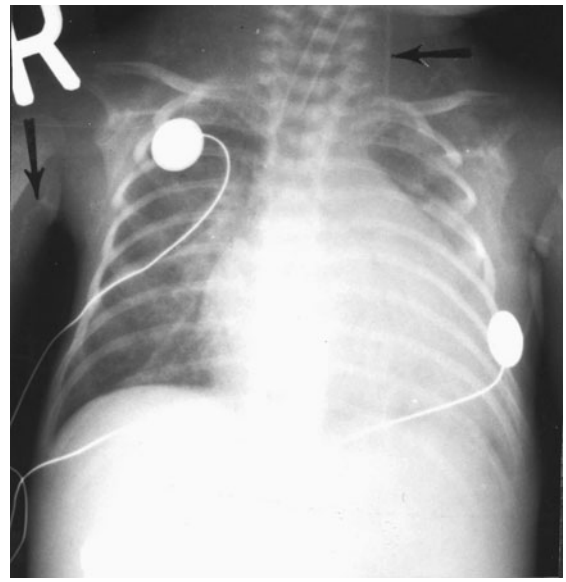

Fig. 2 Radiograph examinations showed extensive vascular calcification extending down the upper and lower limbs, neck, supraclavicular fossae, and axillae. Radiograph here shows an enlarged heart and linear calcification (*arrows*) of the carotid and brachial arteries

Fig. 3 Gross view of vessels, especially the renal arteries, intercostalis, and iliacs, which were hard with mineralization of vessel walls

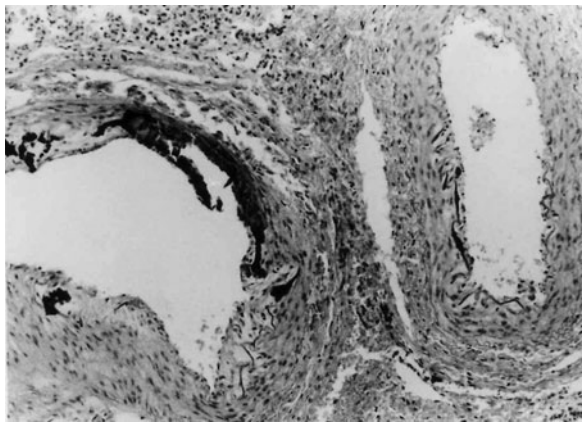

Fig. 4 Artery on the right shows the earliest type of lesion with mild intimal hyperplasia, mild fragmentation, and early mineralization of internal elastic lamina. Artery on the left shows a more advanced lesion with moderate intimal proliferation, moderate fragmentation of internal elastica lamina, and heavy mineralization in and around elastic fibers

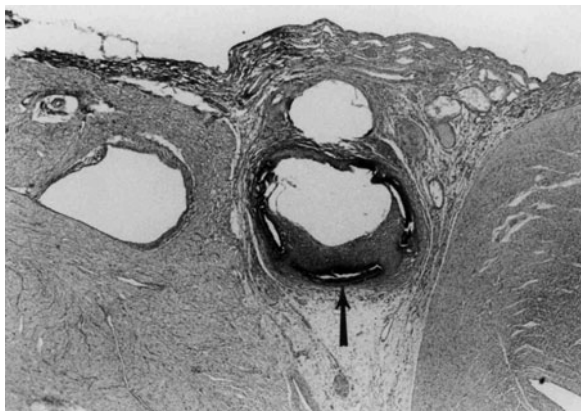

Fig. 5 Advanced mineralization in and around internal elastica lamina (coronary artery)

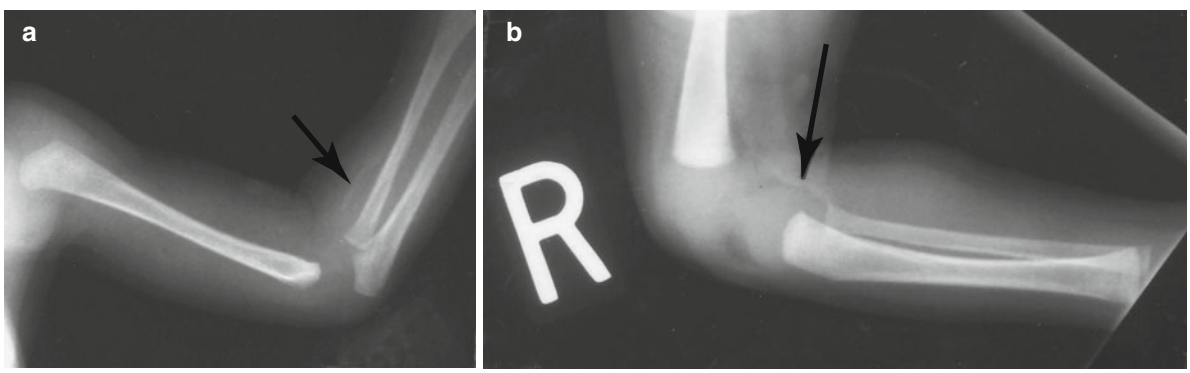

Fig. 6 (**a, b**) Radiographs of twin B show linear calcification (*arrow*) of the radial artery (*upper*) and popliteal artery (*lower*). At 35 days of age, the twin suffered a cardiac arrest and expired shortly thereafter. No autopsy was performed

Genitopatellar Syndrome

In 1988, Goldblatt et al. first reported a 4-year-old boy with hypoplastic patellae, mental retardation, scrotal hypoplasia, skeletal deformities, renal anomalies, flattened nasal bridge, and short stature. Later in 2000, Cormier-Daire et al. reported seven patients with genital anomalies (scrotal hypoplasia and cryptorchidism in the boys and clitoral hypertrophy in the girls), facial dysmorphism, renal anomalies, absent patella, and severe mental retardation in the two survivors. The condition is now known as genitopatellar syndrome.

Synonyms and Related Disorders

Absent patellar, facial dysmorphism, mental retardation, renal anomalies, and scrotal hypoplasia

Genetics/Basic Defects

1. An autosomal recessive inheritance of this condition was proposed (Cormier-Daire et al. 2000).
2. Normal karyotypes and normal array based comparative genome hybridization (aCGH) in all except one case of ovotestes and XY sex reversal in a female with an interstitial 9q33.3–q34.1 deletion encompassing *NR5A1* and *LMX1B* causing features of genitopatellar syndrome (Schlaubitz et al. 2007).
3. No molecular etiology has been identified (Abdul-Rahman et al. 2006; Schlaubitz et al. 2007): Mutations of *LMX1B*, *TBX4*, *WNT4*, and *WNT7A* genes, consistent with nail–patella syndrome, small patella syndrome, and defects in Müllerian ducts and limb development, respectively, were excluded.

Clinical Features

1. Genital anomalies
   a. Males
      i. Scrotal hypoplasia
      ii. Cryptorchidism
      iii. Small penis
   b. Females
      i. Prominent clitoris and labia minora
      ii. Hypoplastic clitoris and labia minora
2. Absent/hypoplastic patella
3. Arthrogryposis
   a. Knees
      i. Flexion contractures
      ii. Skin dimples at the knee
   b. Flexion contractures or dislocation/subluxation of the hips
4. Other skeletal anomalies
   a. Brachydactyly of the upper limbs
   b. Clubfeet
   c. Hypoplasia of pelvic bones
5. Distinctive craniofacial features
   a. Microcephaly
   b. Abnormal skull shape
   c. Hypertelorism
   d. Midfacial hypoplasia
   e. A large, broad nose with a high nasal bridge
   f. Micrognathia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_105,
© Springer Science+Business Media, LLC 2012

6. CNS anomalies
   a. Severe psychomotor retardation
   b. Hypotonia
   c. Swallowing and feeding difficulties during neonatal period
   d. Absence of corpus callosum
   e. Colpocephaly
7. Congenital heart defects
   a. VSD
   b. ASD
   c. PDA
   d. PFO
   e. Abnormal aortic arch
8. Renal anomalies
   a. Multicystic kidneys
   b. Hydronephrosis
   c. Large fused kidney
   d. Vesicoureteral reflux
9. Anal atresia or ventral displacement of the anus
10. Mild manifestations of ectodermal dysplasia
    a. Sparse scalp hair
    b. Delayed tooth eruption
11. Severe respiratory problems
    a. Apnea
    b. Pulmonary hypoplasia
12. Hearing loss
13. Differential diagnosis (Lam et al. 2009)
    a. Nail–patella syndrome
       i. Nail dysplasia
       ii. Absent/hypoplastic patella
       iii. Elbow synostosis
       iv. Presence of iliac horns
       v. Nephropathy (glomerular basement membrane)
       vi. Open-angle glaucoma
    b. Short patella syndrome
       i. Caused by *TBX4* gene mutations
       ii. Absent/hypoplastic patella
       iii. Knee contractures
    c. Subtelomeric 1q deletion syndrome causing patellar hypoplasia and limb deformities, features overlapping with genitopatellar syndrome.

Diagnostic Investigations

1. Cranial ultrasound and MRI to detect CNS malformations
2. Radiography for skeletal anomalies and absent patella (for older child)
3. Renal ultrasound for renal anomalies
4. MRI of the patella to ascertain absence of the patella

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a 25% recurrence risk
   b. Patient's offspring: recurrence risk not increased unless the spouse is a carrier
2. Prenatal diagnosis: has not been accomplished
3. Management: supportive

Fig. 1 The neonate was a twin A of dizygotic twins, delivered at 29 weeks via emergency C section secondary to suspected chorioamnionitis. The baby was noted to have no scrotal sac with nonpalpable testes. He was noted to have abnormal positioning of the legs with contractures of the hips and the knees and clubfeet. He was also noted to have an imperforate anus with intestinal malrotation which were repaired. Renal ultrasound showed bilateral hydronephrosis

Fig. 2 Craniofacial features were characterized by coarse face, flat occiput, bitemporal narrowing, and a deep crease across the nasal bridge. The neck was short. There were proximal interphalangeal contractures of the digits two to four on both hands, a single flexion crease on the fifth digit. Transverse palmar creases were present bilaterally. MRI of the brain showed absence of the corpus callosum with delayed myelination, prominent DSF spaces in the frontal region, and mega cisterna magna. Chromosome analysis and microarray analysis were normal

Fig. 3 Showed knee dimples with flexion contractures, popliteal webbing, and talipes equinovarus

Fig. 4 Dimples on both knees shown by *black arrows*

Fig. 5 External genitalia showed scrotal hypoplasia and bilateral cryptorchidism

Fig. 6 This photo showed scrotal hypoplasia and imperforate anus

Fig. 7 MRI of the knee showed absence of the patella

Giant Congenital Melanocytic Nevi

Giant congenital melanocytic nevi (GCMN) or giant congenital nevi are rare, congenital, disfiguring lesions present at birth with a risk of degeneration to malignant melanoma (Watt et al. 2004) and may be associated with neurocutaneous melanosis (HCM) (Hale et al. 2005; Ka et al. 2005). The incidence of giant-sized congenital melanocytic nevi greater than 20 cm in diameter was estimated as approximately 1 in 20,000 live births. The larger bathing-trunk variety occurs approximately 1 in 500,000 live births (Castilla et al. 1981).

Synonyms and Related Disorders

Giant congenital nevi

Genetics/Basic Defects

1. GCMN generally occurs in isolation, but rare familial occurrence (Voigtländer and Jung 1974; Hecht et al. 1981; De Wijn et al. 2009) points to a genetic background.
2. Genetic basis of giant nevi.
   a. Concept of paradominant inheritance.
      i. Heterozygous individuals carrying the mutation are phenotypically normal, and the trait would only manifest itself when heterozygosity was lost at an early developmental stage.
      ii. Would explain why lesions occur in a mosaic pattern, occur sporadically, and do not show any consistent pattern of Mendelian inheritance.
      iii. Discordance for giant pigmented nevi in monozygotic twins was reported.
   b. Nevi harboring the BRAFE600 mutation undergo cell cycle arrest and senescence, thus preventing the development of malignancy in these lesions.
   c. Using single-strand conformational polymorphism and sequencing analysis, BRAF and N-ras oncogene mutations were found to be extremely common in individuals with congenital nevi, which could explain the higher risk of developing cutaneous melanoma.
   d. Reports on chromosome abnormalities in GCMNs: infrequent.
      i. Two balanced translocations involving the BRAF gene and one deletion of the long arm of chromosome 6 out of 27 GCMNs (Dessars et al. 2008).
      ii. 22% of mitoses with polyploid and 4% with chromosome rearrangements involving 1p, 12q, and 19p from a single GCMN (Heimann et al. 1993).
   e. The pattern of inheritance (De Wijn et al. 2009).
      i. Likely not Mendelian.
      ii. Discordance in identical twins and the segmental distribution of lesions suggest a postzygotic mutation.
      iii. A polygenic paradominant inheritance best explains the clinically observed transmission pattern.
      iv. Candidate genes include those influencing neural crest development and melanocyte proliferation.
3. Embryological origin of congenital melanocytic nevus.
   a. Not well understood

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_106,
© Springer Science+Business Media, LLC 2012

b. Hypothesis
   i. Giant congenital nevi develop between the 5th and 25th weeks of gestation.
   ii. Dysregulated growth of melanoblasts occurs secondary to morphogenic errors in neuroectodermal development, resulting in dysregulated migration of melanoblasts from the neural crest to the skin and leptomeninges.

Clinical Features

1. Congenital melanocytic nevi
   a. Definition: benign proliferation of cutaneous melanocytes, clinically apparent at birth or becomes so within the first postnatal weeks.
   b. Incidence: affects approximately 1% of all newborns
   c. Characteristics: vary in size, macroscopic appearance, and histology as a group
   d. Classification of congenital melanocytic nevi based on final size of the nevi:
      i. Small: less than 1.5 cm in diameter
      ii. Intermediate: 1.5–20 cm in diameter
      iii. Giant or large (also called garment or bathing trunk nevi: measuring more than 20 cm in diameter).
2. Giant congenital nevi: classified based on the percentage of body area affected (a congenital nevi covering 1% body surface area in the face and neck and 2% elsewhere on the body)
3. Clinical manifestations of giant congenital nevi
   a. Onset: flat, brown, or brownish-black patches but with increasing age may become elevated and develop a mottled appearance and nodular surface.
   b. Appear darker at birth than a few weeks later.
   c. Found most commonly on the trunk, followed by the limbs and the head.
   d. Giant nevi: almost always confined to the skin but, rarely, invade underlying fascia and muscle.
   e. Most giant CMN involve the trunk and have a predominant bathing suit distribution.
   f. Associated abnormalities (De Wijn et al. 2009).
      i. Neurocutaneous melanosis (Arneja and Gosain 2005)
         a) Characterized by presence of benign or malignant melanocytic proliferations in the CNS in association with a giant CMN or three or more smaller melanocytic nevi (Kadonaga and Frieden 1991).
         b) Signs and symptoms of symptomatic neurocutaneous melanosis (hydrocephalus, seizures, developmental delay, cranial nerve palsies, or a tethered spinal cord) (Foster et al. 2001).
         c) Almost all children with neurocutaneous melanosis have giant nevi on the head, neck, or dorsal spine.
      ii. Structural brain abnormalities
         a) Dandy-Walker malformation
         b) Hemimegalencephalopathy
         c) Meningohydroencephalocele
         d) Lissencephaly
         e) Microcephaly
         f) Spina bifida oculta
      iii. Polydactyly
      iv. Linear epidermal nevus syndrome
      v. Segmental neurofibromatosis
      vi. Encephalocraniocutaneous lipomatosis
      vii. General lipomatosis
      viii. Placental nevomelanocytosis
      ix. Hirschsprung disease
      x. Hypotrophy of the underlying bone or subcutaneous fat (limb hypoplasia)
      xi. Ear deformities
      xii. Angiomas
4. Prognosis
   a. Usually disfiguring.
   b. The lifetime risk for development of malignant melanoma in giant congenital nevi: approximately 4–42% (about a 14-fold increased risk of developing cutaneous and extracutaneous melanoma) (Trozak et al. 1975; Baader et al. 1992).
   c. Giant nevi on the scalp in a posterior axial location and those with surrounding satellite nevi are at greatest risk of malignant transformation.
5. Neonatal malignant melanoma (Leech et al. 2004)
   a. Extremely rare
   b. Develops within a giant congenital nevus or preexisting nevus
   c. Can occur de novo on apparently normal skin
   d. Arises from maternal malignant melanoma via placental metastases
   e. May metastasize or spread locally

f. Notoriously difficult to diagnose in children, especially neonates
   i. Clinical indicators such as changes in color, size, shape, rapid growth rate, nodularity, and even ulceration may occur in benignly evolving GCNs.
   ii. Histologic features accepted as evidence of malignancy in an adult, such as mitotic activity, nuclear pleomorphism, and pagetoid melanocytic proliferation, may also be present in benign lesions in infants.
   iii. Morphologic findings of melanocytic lesions from frozen tissue specimen cannot be confidently interpreted.

Diagnostic Investigations

1. Biopsies
   a. Probably only useful in clarifying the nature of pathological changes that occur in discrete areas of these nevi.
   b. Sampling of multiple areas required when there is a question of malignant change.
2. Magnetic resonance imaging (MRI)
   a. Highly sensitive in detecting melanin, which produces short T1 and T2 relaxation times due to interactions of unpaired electrons in the stable free radicals of melanin with the protons of free water.
   b. Can delineate the extent of underlying soft tissue involvement and assist in preoperative planning.
   c. Neither the location nor the size of the nevus appears to correlate completely with the presence or absence of MRI abnormalities suggestive of CNS melanosis.
   d. Foci of melanosis generally became more difficult to detect on follow-up images, which may be related to changes in the signal intensity of the brain that accompany myelination.
   e. Recommend MR imaging in addition to ongoing developmental and neurological evaluations to help identify individuals who are at greater risk for CNS disease, as well as encourage MR imaging for those with giant nevi in the lumbosacral region.
3. Positron emission tomography (Makosz et al. 2004)
   a. To detect occult primary melanoma as well as melanoma metastases within the nevi
   b. May play an important role in long-term monitoring and management of these patients
4. Dermoscopy (episcopy, dermatoscopy, skin surface microscopy, epiluminescence microscopy): allows in vivo visualization of anatomical pigmented structures in the epidermis, dermoepidermal junction, and superficial papillary dermis not usually seen by the naked eye (Lodha et al. 2003).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: increased but exact risk not known
   b. Patient's offspring: increased but exact risk not known
2. Prenatal diagnosis: not reported but possible by fetoscopy (an invasive procedure)
3. Management
   a. Early and complete surgical excision is recommended because of an increased lifetime risk of malignancy.
   b. The surgical and reconstructive options for congenital melanocytic nevus are varied depending on the size and location of the nevus (Pearson et al. 2005).
      i. Laser treatment: the results for congenital nevus have been unsuccessful because the deeper portions of the nevi are unaffected by the laser.
      ii. Dermabrasion.
         a) Plagued by recurrence if performed too superficially and hypertrophic scar if performed too deep.
         b) Produces uneven changes in the pigmentation of the skin because the melanocytic cells are found at varying depths in the dermis; dermabrasion produces uneven changes in the pigmentation of the skin.
         c) Dermabrasion has been abandoned for the treatment of nevi.
      iii. Excision.
         a) Excision followed by primary closure: a frequently used technique
         b) Caution not to distort important structures such as oral commissure, eyelids, and eyebrows

iv. Stage excision.
   a) Consider when the resultant wound is too large to close or places excessive tension along the closure, increasing the risk of wound dehiscence
   b) An outpatient procedure involving less postoperative care and expense

v. Skin grafting.
   a) A useful tool in the management of medium to large congenital nevi.
   b) Avoid split-thickness skin grafting because of the potential for an unsightly donor site and a greater need for inpatient care or a more complicated outpatient experience.
   c) Consider full-thickness grafts to allow for an acceptable donor site and less postoperative care.
   d) Considered in areas of the body of lesser esthetic importance.

vi. Tissue expansion.
   a) Commonly used when a nevus is too large for primary closure: serial excision will produce residual deformity on the adjacent structures, or skin grafting will produce an undesirable esthetic result.
   b) The ability to replace tissue with like tissue, such as hair-bearing scalp with hair-bearing scalp, typically allows an acceptable esthetic result.
   c) The drawbacks include multiple operations (placement followed by removal and advancement), difficulty in expanding axial portions of the body, the weekly clinical visits for expansion, discomfort for the child during the expansion process, and the esthetic deformity produced during the expansion process.

vii. Cultured epithelial autograft.
   a) Represents another reconstructive option
   b) Requires a tissue sample from the patient, several weeks for cellular production, and final placement
   c) Cultured epithelia autograft's application to giant congenital nevi: natural as in the burn treatment of large total body surface area burn
   d) Can be used for giant nevi that preclude the use of tissue expansion or skin grafting secondary to lack of donor site availability
   e) Definite shortcomings: including expense, time required for manufacturing of the graft (less of a limiting factor in children with nevi), and durability
   f) Preferred procedure to split-thickness skin grafting because no donor site morbidity exists, decreased blood loss occurs, a greater area of excision with resultant faster removal of a nevus can be accomplished, and the durability of the cultured epithelia autograft compares favorably with a split-thickness graft

viii. Enzymatically separated epidermal grafting (Kishi et al. 2009).
   a) A useful method for the treatment of GCMN
   b) Easy to perform
   c) Cosmetically satisfactory results

Fig. 2 (**a**–**d**) A neonate with a bathing-trunk nevus, extending from mid-trunk to knees, with a large unevenly pigmented lesion of the back, buttocks, and upper extremities as well as several nodules and a large hypertrophic area over the sacrum

Glucose-6-Phosphate Dehydrogenase Deficiency

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common human enzyme defect, affecting more than 400 million people worldwide, especially in tropical Africa, the Middle East, tropical and subtropical Asia, some areas of the Mediterranean, and Papua New Guinea. The gene frequencies are estimated to be as high as 5–25% in these areas (Luzzatto et al. 2001).

Genetics/Basic Defects

1. Caused by mutations in the G6PD gene (mapped to Xq28 region) (Luzzatto 2006).
   a. About 140 mutations have been described.
   b. Most mutations are single missense point mutations, entailing single amino acid replacements in the G6PD protein.
   c. Few exceptions
      i. Small deletions (of one to eight amino acids)
      ii. Presence of two mutations (rather than one)
2. Inheritance
   a. X-linked recessive in terms of clinical expression
      i. Not truly recessive since heterozygous females can even develop severe hemolytic attacks
      ii. Coexistence in female heterozygotes of two-cell populations, G6PD(+) and G6PD(−), secondary to X-chromosome inactivation
      iii. Homozygous females not rare in many populations with high frequency of G6PD deficiency
   b. Codominant in terms of biochemical characteristics of electrophoretic variants segregating in a pedigree
3. Genetic heterogeneity (Luzzatto et al. 2001)
   a. Diverse biochemical characteristics
      i. Presence of about 400 different variants
      ii. Many allelic mutations in the G6PD gene causing these variants
      iii. Presence of several structural mutants without enzyme deficiency
   b. Heterogeneous molecular characteristics
      i. Some variants with different names proved to be identical.
      ii. Some variants thought to be homogeneous proved to be heterogeneous.
   c. Different mutations responsible for:
      i. Chronic hemolytic anemia: less common
      ii. Episodic hemolysis: more frequently seen
   d. Diverse clinical manifestations, to a large extent, explainable by the genetic heterogeneity
4. Pathogenesis
   a. G6PD
      i. A central enzyme in the pentose phosphate shunt of glucose metabolism
      ii. Catalyzes glucose-6-phosphate (G6P) to 6-phosphogluconic acid (6PG)
      iii. Reduces nicotinamide adenine dinucleotide phosphate (NADP) to the reduced form of NADP (NADPH)
   b. NADPH: converts glutathione disulfide (GSSG) to reduced glutathione (GSH)
   c. Reduced glutathione GSH
      i. Inactivates hydrogen peroxides (H_2O_2)
      ii. Protects protein sulfhydryl groups from oxidation
      iii. Neutralizes agents that threaten to oxidize either hemoglobin or components of the red cell membrane.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_107,
© Springer Science+Business Media, LLC 2012

   d. In the absence of G6PD
      i. Red cell membrane and hemoglobin damaged by oxidant exposure
      ii. Leading to rapid hemolysis
5. Hemolysis secondary to inability of G6PD-deficient red cells to withstand the oxidative damage produced, directly or indirectly, by the triggering agents (Luzzatto et al. 2001).
   a. Drugs
   b. Infections
   c. Ingestion of fava beans with life-threatening manifestations especially favism in children
6. G6PD deficiency conferring resistance against *Plasmodium falciparum* malaria based on (Luzzatto et al. 2001)
   a. Prevalence of G6PD deficiency and the past and present endemicity of *Plasmodium falciparum* malaria
   b. The high prevalence in malaria-endemic areas of G6PD mutants
   c. Heterozygote advantage

Clinical Features

1. History
   a. Asymptomatic in the vast majority of G6PD-deficient individuals without being aware of their genetic abnormality
   b. No positive history of acute intravascular hemolytic crises without exposure to oxidant stress
   c. Neonatal jaundice
   d. Chronic hemolytic anemia
      i. An insidious decrease in hemoglobin
      ii. Observed in certain variant enzymes
   e. Required a careful investigation to establish the history of exposure to inciting agents
2. Common clinical manifestations
   a. Neonatal jaundice: may cause permanent neurologic damage or death in some severe cases
   b. Episodes of acute hemolytic anemia
      i. Drug-induced hemolysis
      ii. Infection-induced hemolysis
      iii. Favism: occurrence of acute hemolysis after ingestion of broad beans (*Vicia faba*)
      iv. Chronic nonspherocytic hemolytic anemia
      v. Associated with hemoglobinuria since red cell destruction in these acute hemolytic events is largely intravascular
      vi. Concomitance with a variety of clinical situations, including diabetic ketoacidosis, hypoglycemia, myocardial infarction with pericardial tamponade, and strenuous exercise
   c. Symptoms and signs of acute hemolytic crisis
      i. Headache
      ii. Lethargy
      iii. Pallor
      iv. Jaundice
      v. Red, clear urine
3. Symptoms and signs of chronic hemolytic crisis
   a. Pallor
   b. Jaundice
   c. Severe chronic hemolysis observed in a rare subset of G6PD-deficient patients
4. Drugs responsible for hemolysis (Cappellini and Fiorelli 2008)
   a. Antimalarials
      i. Definite association (primaquine, pamaquine)
      ii. Possible association (chloroquine)
      iii. Doubtful association (quinacrine, quinine)
   b. Sulfonamides
      i. Definite association (sulfanilamide, sulfacetamide, sulfapyridine, sulfamethoxazole)
      ii. Possible association (sulfadimidine, sulfasalazine, glyburide)
      iii. Doubtful association (sulfoxone, sulfadiazine, sulfisoxazole)
   c. Sulfones: definite association (dapsone)
   d. Nitrofurantoin: definite association (nitrofurantoin)
   e. Antipyretic/analgesic
      i. Definite association (acetanilid)
      ii. Possible association (aspirin)
      iii. Doubtful association (acetaminophen, phenacetin)
   f. Other drugs
      i. Definite association (nalidixic acid, niridazole, methylene blue, phenazopyridine, sepirin)
      ii. Possible association (ciprofloxacin, chloramphenicol, vitamin K analogs, ascorbic acid, p-aminosalicylic acid)
      iii. Doubtful association (PAS, doxorbicin, probenecid, dimercaprol)
   g. Other chemicals
      i. Definite association (naphthalene, trinitrotoluene)

a) Development of kernicterus after exposure to naphthalene in the glucose-6-phosphate dehydrogenase Mediterranean polymorphic variant (revealed by mutation analysis) (de Gurrola et al. 2008).
b) As the use of naphthalene in stored clothes is a common practice, glucose-6-phosphate dehydrogenase testing in neonatal screening could prevent severe clinical consequences.

ii. Possible association (*Acalypha indica*)

5. Types of G6PD deficiency (Segel et al. 2002)
   a. X-minus variety
      i. Most common type seen in the USA
      ii. An X-linked condition primarily affecting African-American males
      iii. Females affected if homozygous for G6PD deficiency or if unfavorable random X-chromosome inactivation resulting in a large proportion of deficient red cells.
   b. Mediterranean variety
      i. Develops severe hemolysis when exposed to oxidant drugs
      ii. Characterized by enzyme deficiency in red cells of all ages, including reticulocytes, and shows no evidence of spontaneous recovery.
   c. Other varieties
      i. Develops chronic hemolytic anemia without external oxidant exposure
      ii. Susceptible to develop cholelithiasis because of heightened bilirubin turnover
      iii. Complaints of abdominal pain or fatty food intolerance

Diagnostic Investigations

1. Acute hemolysis (Segel et al. 2002)
   a. Precipitous anemia
      i. A fall in hemoglobin
      ii. A fall in hematocrit
      iii. Subsequent rise in reticulocyte percentage
   b. Elevated bilirubin, particularly the indirect fraction
   c. Reduced haptoglobin as it binds free hemoglobin and is removed from the circulation
   d. Hemoglobinemia +/− hemoglobinuria
2. Diagnosis of G6PD deficiency (Frank 2005; Kaplan and Hammerman 2010)
   a. Rapid fluorescent screening spot test detecting the generation of NADPH (reduced NADP) from NADP
      i. The test is positive if the blood spot fails to fluoresce under ultraviolet light (NADPH fluoresces intensely when activated by long-wave UV light; fluorescence under UV light source is normal and indicates G6PD activity).
      ii. Useful in identifying totally deficient individuals with <20% residual activity
      iii. Could erroneously classify as normal males and females with partial deficiency (20–60% residual enzyme activity)
      iv. Not helpful in identifying most heterozygotes with intermediate levels of G6PD activity
   b. Quantitative analysis of G6PD activity by assessing NADPH formation spectrophotometrically
      i. G6PD-deficient male hemizygotes and female homozygotes: usually <50% normal activity, frequently <20%, and often undetectable (Luzzatto 2006).
      ii. Heterozygous females may have intermediate activity, but this may range from normal to deficient and many female heterozygotes with partial enzyme activity will not be detected.
      iii. Falsely obtaining normal test results during or immediately after an acute hemolytic event
   c. In field research, where quick screening of a large number of patients is needed, other tests have been used; however, they require definitive testing to confirm an abnormal result (Iwai et al. 2003; Jalloh et al. 2004).
   d. Tests based on polymerase chain reaction detect specific mutations and are used for
      i. Population screening
      ii. Family studies
      iii. Prenatal diagnosis
3. Direct DNA analysis
   a. Sequence analysis (analysis of the entire coding region)
   b. Targeted mutation analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib (if the mother is a carrier)
      i. 50% of male siblings affected

   ii. 50% of female siblings carriers (some female heterozygotes may be affected)
  b. Patient's offspring
   i. 100% of female offspring carriers (some female heterozygotes may be affected)
   ii. 50% of female offspring affected (homozygotes) if the spouse is a carrier
   iii. Male offspring not affected unless the spouse is a carrier
2. Prenatal diagnosis: may be possible in at-risk families, provided disease-causing mutations have been identified previously
3. Management
  a. Prevent or remove precipitating agents
  b. Phototherapy for neonatal hyperbilirubinemia
  c. Supportive transfusion
  d. Exchange transfusion to prevent kernicterus
  e. Hemodialysis may be necessary if there is acute renal failure.

Fig. 1 (**a**, **b**) A 1-month-old and a 2-month-old boys with G6PD deficiency who are asymptomatic. The newborn screenings of both boys identified one (hemizygous) copy of the double mutations (G202A; A376G)

Fig. 2 An 8-week-old girl with G6PD deficiency who is asymptomatic. The newborn screening identified compound heterozygote consisting of one copy of the double mutation (G202A; A376G) and one copy of the A378G mutation. This phenotype is seen only in females since this is an X-linked disorder

Fig. 3 A 1-month-old boy with G6PD deficiency who is asymptomatic. The newborn screening revealed G6PD of 3.8 (10.8–16.2 U/g Hb). Molecular analysis showed one copy of A376G mutation

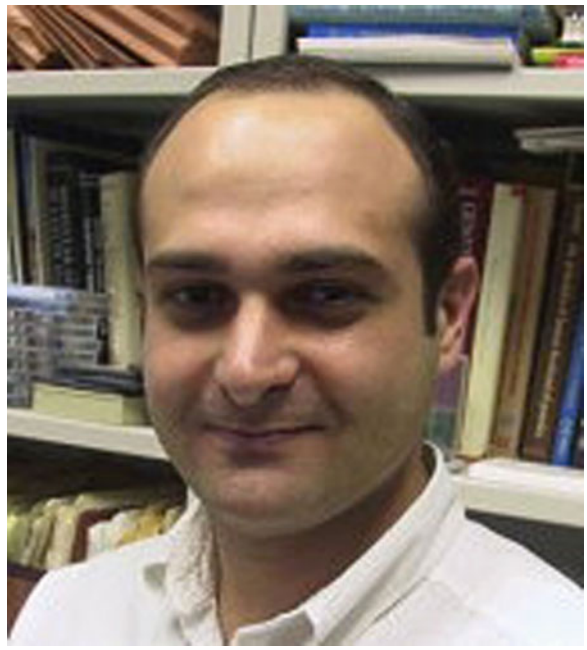

Fig. 4 A patient of Mediterranean ancestry with G6PD deficiency. He has had a history of hemolytic anemia crisis after ingestion of fava bean

Fig. 5 Fava beans

Glycogen Storage Disease, Type II

Type II glycogen storage disease (GSD), also known as Pompe disease, is an autosomal recessive disorder caused by deficiency of the lysosomal enzyme acid α-glucosidase (acid maltase). Incidence is estimated at 1 in 50,000 in most populations, implying a carrier frequency of 1 in 100 (Kleijer et al. 1995).

Synonyms and Related Disorders

Acid maltase deficiency; Glycogenosis type II; Pompe disease

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Kleijer et al. 1995)
2. Caused by deficiency of acid maltase (acid α-glucosidase), leading to the pathological accumulation of glycogen in lysosomes, predominantly in the skeletal muscle, heart, and liver.
   a. Virtual absence of α-glucosidase activity in infantile form (Pompe disease)
   b. Considerable residual enzyme activity in the great majority of patients with the adolescent or adult form
3. Identification of various mutations in the α-glucosidase (*GAA*) gene (mapped on 17q23–25), leading to the disease
   a. Types of mutations
      i. Point mutations
      ii. Deletions
      iii. Insertions
   b. Compound heterozygotes in most patients
   c. Relatively common mutations among European patients
      i. The single base pair deletion ΔT525 causing premature termination at nucleotide 658–660
      ii. Deletion of exon 18
4. Genotype-phenotype correlation
   a. The nature of the mutation is generally considered a good predictor of a clinical phenotype.
   b. Homozygosity for either Δexon 18 or ΔT525 mutation or compound heterozygosity for these two mutations results in a severe infantile form of GSDII.
   c. Combination of either of these mutations with leaky IVS1t-13 g mutation results in the majority of cases in the adult phenotype.
   d. A splicing defect (IVS6 t-22 g) results in a removal of exon 6, and insertion of 21 nucleotides of the intronic sequence defined the juvenile phenotype in a compound heterozygote patient who carries a silent second allele. Homozygosity for the same splicing defect resulted in a milder adult phenotype.
   e. Growing number of cases in recent years where the genotype does not match the phenotype.
5. Pathophysiology (American Association of Neuromuscular and Electrodiagnostic Medicine 2009)
   a. Mutations in both copies of the GAA gene lead to varying degrees of GAA deficiency.
      i. Infantile-onset form: either totally or virtually absent acid α-glucosidase enzyme activity in skin fibroblasts
      ii. Late-onset form: some residual enzyme activity (1 ∼ 40%) in skin fibroblasts in most affected children and adults

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_108,
© Springer Science+Business Media, LLC 2012

b. Primary defect.
   i. Progressive intralysosomal storage of glycogen
   ii. Recognition of the role of dysfunctional autophagy in the disease process

Clinical Features

1. Infantile form (Raben et al. 2002).
   a. Classical infantile form
      i. Onset within first weeks or months of life or even at birth.
      ii. Characterized by complete or near complete deficiency of α-glucosidase.
      iii. Poor feeding (difficulty sucking and swallowing) and failure to thrive, early complaints.
      iv. Cyanosis and attacks of dyspnea beginning early.
      v. Frequent respiratory infections.
      vi. Delayed motor milestones.
      vii. Cardiomyopathy (hypertrophic) (∼95%): the important finding suggesting diagnosis.
         a) Marked cardiomegaly
         b) Congestive heart failure
      viii. Striking hypotonia.
         a) Increasing generalized weakness
         b) Affecting bulbar musculature
         c) Without muscle atrophy
      ix. Macroglossia (∼62%).
      x. Moderate hepatomegaly (∼82%).
      xi. Calf hypertrophy.
      xii. Depressed or absent reflexes due to glycogen accumulation in spinal motor neurons.
      xiii. Impaired alertness.
      xiv. Accumulation of glycogen in the lysosomes rapidly disrupts cellular function in the most severe form.
         a) Rapidly disrupts cellular function.
         b) Leading to intractable cardiorespiratory failure.
         c) Most patients die by 1 year of age.
   b. Nonclassical infantile form
      i. Onset in infancy
      ii. Slower progression
      iii. Involving primarily skeletal muscle with minimal or no cardiac involvement (without cardiomegaly)
      iv. May present with delayed motor milestones if onset is in early preschool age
      v. May present with a decrease in motor skills if onset is later in childhood
      vi. Usually demonstrates progressive proximal weakness with different degrees of respiratory muscle involvement
      vii. Presence of respiratory complications often contributing to early death
2. Juvenile form.
   a. Juvenile onset (first decade)
   b. Characterized by presence of reduced but residual α-glucosidase activity
   c. Clinical boundaries between juvenile and adult forms not precisely defined
   d. Clinical manifestations
      i. Predominantly skeletal muscle weakness with respiratory muscle involvement and mild hepatomegaly.
      ii. Cardiac involvement: absent or mild.
         a) Arrhythmia
         b) Mild ventricular dysfunction
      iii. Death results from respiratory failure after a course lasting several years.
3. Adult form.
   a. Onset: second to sixth decades
   b. Characterized by higher levels of residual α-glucosidase activity
   c. Slower progression of the skeletal muscle weakness
      i. Upper arms
      ii. Pectoral muscles
      iii. Asymmetry of affected muscle groups
      iv. Limb-girdle weakness, a prominent finding
      v. Respiratory muscle involvement (weakness of the diaphragm) (about 33%): a hallmark of the disease
      vi. Little or no cardiac abnormality
   d. Acute respiratory failure
4. Differential diagnosis of infantile-onset Pompe disease (with respect to shared signs and symptoms) (Kishnani et al. 2006).
   a. Acute Werdnig-Hoffman disease (spinal muscular atrophy I)
      i. Hypotonia
      ii. Progressive proximal myopathy
      iii. Absent reflexes
   b. Hypothyroidism
      i. Hypotonia
      ii. Macroglossia

c. Endocardial fibroelastosis
   i. Breathlessness
   ii. Feeding difficulties
   iii. Cardiomegaly
   iv. Heart failure
d. Myocarditis: cardiomegaly
e. Congenital muscular dystrophy
   i. Severe hypotonia
   ii. Severe muscle weakness
f. Glycogen storage diseases: IIIa (Debrancher deficiency/Cori or Forbes disease) and IV (branching enzyme deficiency/Anderson disease)
   i. Cardiomegaly
   ii. Myopathy
   iii. Elevated creatine kinase (CK)
g. Mitochondrial/respiratory chain disorders
   i. Hepatomegaly
   ii. Muscle weakness
   iii. Cardiomegaly
   iv. Elevated creatine kinase (CK)
h. Danon disease
   i. Cardiomegaly
   ii. Cardiomyopathy
   iii. Myopathy
   iv. Vacuolar glycogen storage
i. Idiopathic hypertrophic cardiomyopathy: biventricular hypertrophy
j. Peroxisomal disorders
   i. Hypotonia
   ii. Hepatomegaly

5. Differential diagnosis of late-onset Pompe disease (Kishnani et al. 2006; American Association of Neuromuscular and Electrodiagnostic Medicine 2009): Heterogeneity of presentation can mimic other neuromuscular disorders, and the differential diagnosis includes a broad range of myopathies, as well as motor neuron and neuromuscular junction disorders (Kishnani et al. 2006).
   a. Dystrophies
      i. Limb-girdle muscular dystrophy: progressive muscle weakness in the pelvis, legs, and shoulders (shared signs and symptoms)
      ii. Dystrophinopathies (Duchenne and Becker muscular dystrophy): progressive proximal muscle weakness, respiratory impairment, difficulty walking, and elevated creatine kinase (CK) (shared signs and symptoms)
      iii. Myofibrillar myopathy
      iv. Myotonic dystrophy type 2
      v. Scapuloperoneal syndromes: progressive muscle weakness behind the knees and around the shoulder blades (shared signs and symptoms)
      vi. Danon disease: hypertrophic cardiomyopathy, skeletal muscle myopathy, and vacuolar glycogen storage (shared signs and symptoms)
      vii. X-linked myopathy with excessive autophagy
      viii. Facioscapulohumeral muscular dystrophy
      ix. Rigid spine syndrome: spinal rigidity and lower back pain (shared signs and symptoms)
   b. Inflammatory myopathies
      i. Polymyositis: unexplained muscle weakness (shared signs and symptoms)
      ii. Inclusion body myositis
   c. Congenital myopathies
      i. Nemaline rod myopathy
      ii. Central core and multiminicore myopathy
      iii. Centronuclear myopathy
      iv. Hyaline body myopathy
      v. Other congenital myopathies
   d. Other metabolic myopathies
      i. Glycogen storage diseases (debranching enzyme deficiency (IIIa), branching enzyme deficiency (IV), McArdle disease (V), and muscle phosphofructokinase deficiency (VII)): hypotonia, hepatomegaly, muscle weakness, and elevated creatine kinase (CK)
      ii. Mitochondrial myopathy: hypotonia, hyperreflexia, hepatomegaly, and some forms with hypertrophic cardiomyopathy, muscle weakness, and elevated creatine kinase (CK)
      iii. Lipid disorder myopathies
   e. Motor neuron disorders
      i. Spinal muscular atrophy types II and III: asymmetrical muscle weakness and atrophy of voluntary muscles (shared signs and symptoms)
      ii. Kennedy disease
      iii. Amyotrophic lateral sclerosis
   f. Neuromuscular junction disorders
      i. Myasthenia gravis: generalized muscle weakness (shared signs and symptoms)

ii. Congenital myasthenic syndromes
iii. Lambert-Eaton syndrome
g. Rheumatoid arthritis: stiffness/pain upon exertion (shared signs and symptoms)

Diagnostic Investigations

1. Elevated serum creatine kinase in most patients
2. Elevated serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactic dehydrogenase (LDH)
3. Radiography: tremendous cardiomegaly
4. EKG: can readily observe the signs of cardiac glycogenosis (indicators of relative myocardial ischemia)
   a. Very large QRS complex in all leads
   b. Short P-R interval: pathognomonic of infantile Pompe disease
   c. Left axis deviation or absence of the normal right axis deviation (presence of biventricular hypertrophy)
   d. Inverted T wave
   e. ST segment depression
5. Echocardiography: biventricular hypertrophy without outflow obstruction
6. EMG
   a. Infantile form: nonspecific myopathic changes or normal finding
   b. Adult form
      i. Pseudomyotonia
      ii. High-frequency discharges
      iii. Fibrillations
7. Muscle biopsy
   a. Presence of vacuoles that stain positive for glycogen (PAS) as well as for the lysosomal enzyme acid phosphatase
   b. A typical lacework appearance of histologic sections from the myocardium resulting from deposition of stored material in the cardiac fibrils
   c. Electron microscopy
      i. Membrane-bound glycogen
      ii. Glycogen accumulation within the lysosome
8. Glycogen accumulation
   a. Infantile form
      i. Muscle
      ii. Liver
      iii. Motor nuclei in the brain stem
      iv. Anterior horn cells of the spinal cord
      v. Placenta
         a) Amniotic storage cells identified and shown histochemically to contain glycogen
         b) Pathognomonic accumulation of lysosomal glycogen in the placenta by electron microscopy in the second trimester
         c) Confirmation of the prenatal diagnosis made by enzyme assay
      vi. Other tissues
         a) Endothelial cells
         b) Kidneys
         c) Skin
   b. Adult form: not seen in the heart, liver, or brain
9. Diagnostic enzymatic test: deficient acid maltase in leukocytes, muscle, and skin fibroblasts
10. DNA analysis by targeted mutation analysis
11. Newborn screening by determining the total α-glucosidase in plasma or dried blood spots (Umapathysivam et al. 2001; Chien et al. 2009)
12. Heterozygote detection
    a. Reduced α-glucosidase activity: not reliable
    b. DNA-based detection more appropriate and definitive within families

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier in which cases 50% of offspring will be affected and 50% will be carriers
2. Prenatal diagnosis (Phupong et al. 2004)
   a. Rapid prenatal diagnosis by electron microscopy of uncultured amniocytes
   b. Deficient activity of lysosomal acid α-glucosidase in cultured amniocytes or CVS
   c. Electron microscopic study of chorionic villus biopsies for the pregnancy at risk: fibrocytes with typical vacuoles filled with glycogen
   d. Mutation analysis on amniocytes or CVS: 100% reliable prediction of the genetic status of the fetus, including heterozygosity (Kleijer et al. 1995)
3. Management
   a. Supportive therapy to manage symptoms and minimize complications whenever possible

i. Respiratory therapy
ii. Physical therapy (Case and Kishnani 2006)
iii. Dietary therapy
iv. Infection prevention
v. A high-protein diet to improve muscle function
vi. Ventilator support

b. Administration of purified α-glucosidase not effective
c. Bone marrow transplantation presumably to provide enzyme secreted by the normal cells continuously
   i. Results not promising
   ii. Transitory engraftment of the haploidentical transplant
   iii. No enzyme detected in muscle cells
   iv. Patient died of complications of the transplant
d. Enzyme replacement therapy (ERT)
   i. ERT with recombinant human α-glucosidase from rabbit milk in Pompe patients in an open-label study
      a) Intended to directly address the underlying metabolic defect via intravenous infusions of recombinant human GAA (rhGAA) enzyme
      b) The enzyme generally well tolerated
      c) Normalization of muscle α-glucosidase activity
      d) Improved tissue morphology and motor and cardiac function
      e) Significantly decreased left ventricular mass index
      f) Recommend early treatment (before irreversible damage) and follow-up of long-term effects
      g) Anti-rhGAA antibody may limit the efficacy of the treatment
      h) Extensive muscle damage may be unrefractive to therapy
   ii. Infantile-onset Pompe disease (Klinge et al. 2005; Kishnani et al. 2006, 2007): significantly prolongs survival, decreases cardiomegaly, and improves cardiac and skeletal muscle function
   iii. Late-onset Pompe disease (Bernstein et al. 2010): Gastrointestinal symptoms resolved within the first 6 months of ERT with recombinant human alglucosidase alpha (rhGAA). Patients gained weight and remain symptom free, two for over 4 years.
e. Gene therapy aiming at providing a permanent endogenous source of enzyme for the affected tissues: not available currently

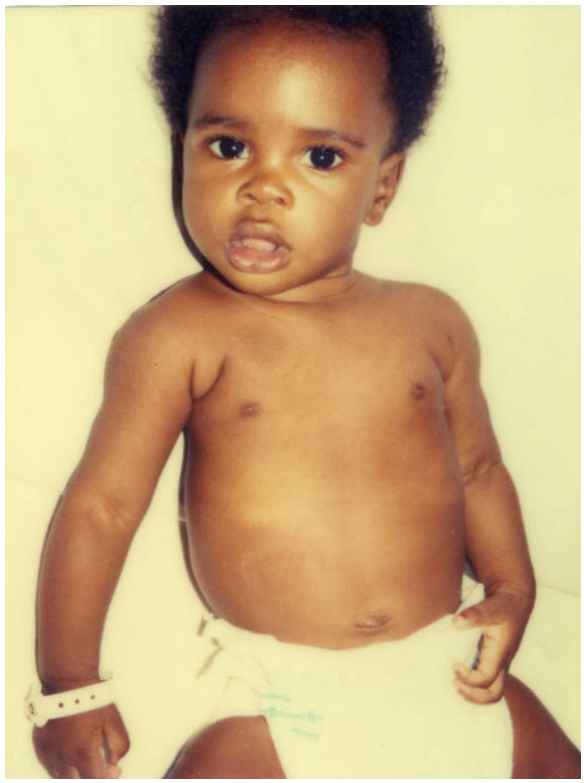

Fig. 1 An infant with massive cardiomegaly and hypotonia. Diagnosis of Pompe disease was confirmed by deficient acid maltase in the leukocytes

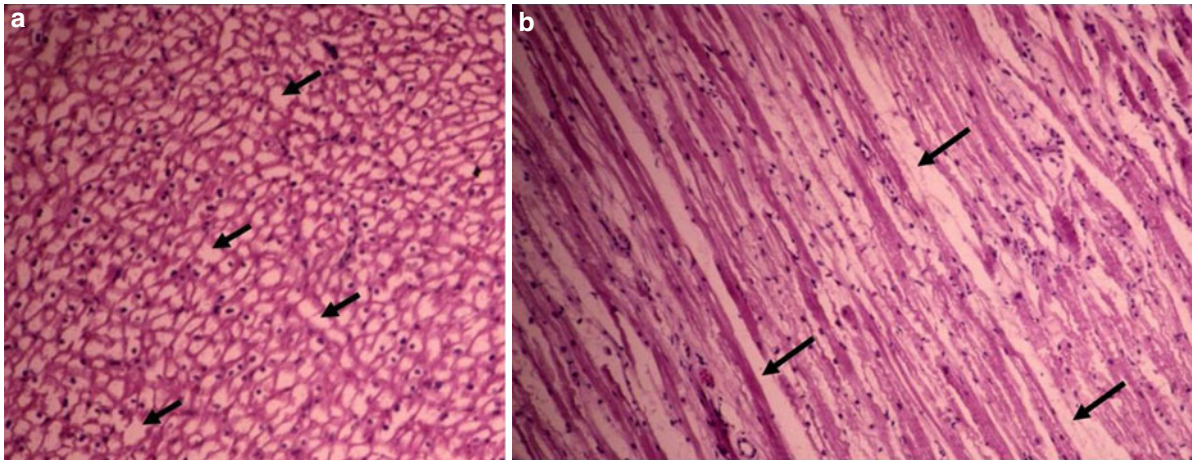

Fig. 2 Different patient with Pompe disease. (**a**) Myocardium. Note numerous vacuolated fibers (*arrows*) due to glycogen accumulation. HE, ×40. (**b**) Smooth muscle from GI tract. Note clear areas represent glycogen deposition (*arrows*)

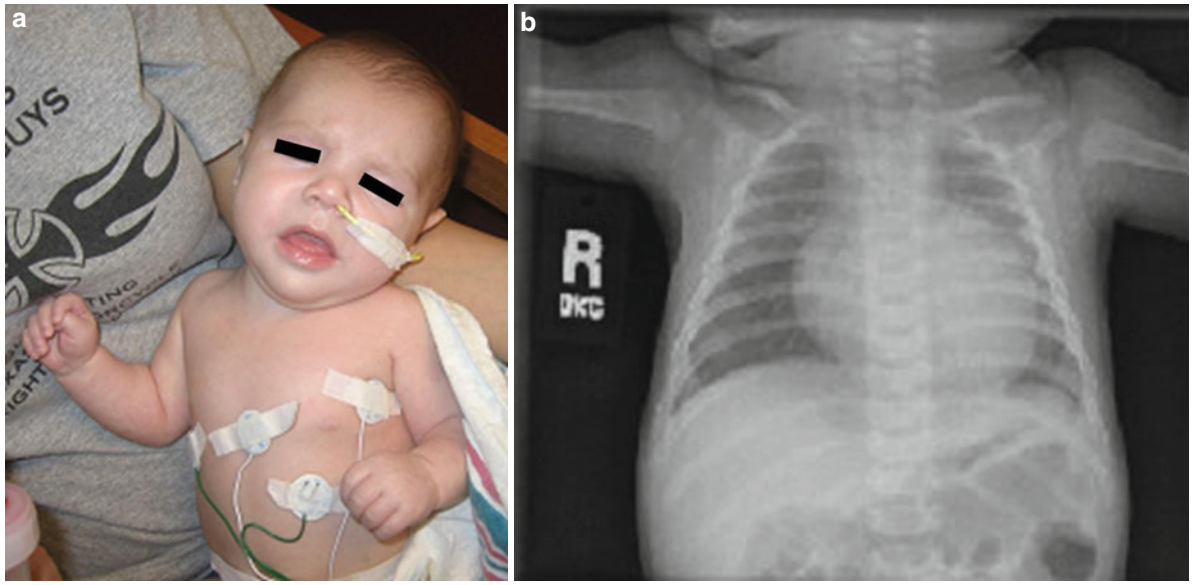

Fig. 3 (**a**, **b**) A 23-month-old boy was seen because of respiratory distress and heart failure. A chest X-ray showed a large globular-shaped heart. An echocardiogram showed a hypertrophic cardiomyopathy. He was noted to be hypotonic and had an enlarged liver. Muscle biopsy showed excessive glycogen storage with glycogen content 5.6% (control: 0.94 +/− 0.55% wet weight). Muscle α-glucosidase was deficient (0.01; control: 0.42 +/− 0.2 micromol/min/g of tissue). Muscle neutral α-glucosidase was 0.05 (control: 0.12 +/− 0.6 micromol/min/g of tissue). Blood acid α-glucosidase was 1.3 (control: 10.0–49.0 pmol/punch/h). Blood neutral α-glucosidase was 52.3 (control: 23.8–132.6 pmol/punch/h). Urine Hex4 was 34.1 (control for <6 month: <19 nmol/mol creatinine). Mutation analysis revealed c.1846 G > A (exon 13) and c.2608 C > A (exon 18). The c.2608CA mutation is a nonsense mutation that results in a premature termination codon, a reported disease causing mutation. The c.1846 G > A mutation has not been previously reported as a mutation causing Pompe disease or a known polymorphism, but has been seen once in the Duke University laboratory, in the homozygous state as the only mutation in a patient with Pompe disease. This patient received 1 dose of enzyme replacement therapy and tolerated his first dose of Myozyme well

Goldenhar Syndrome

In 1952, Goldenhar described a pair of monozygotic twins discordant for hemifacial microsomia, mandibular hypoplasia, auricular malformations, and epibulbar dermoids. Gorlin et al. later in 1963 coined the term "oculoauriculovertebral dysplasia" to describe patients with mandibular hypoplasia, microtia, epibulbar dermoids, and vertebral anomalies. The presence of vertebral anomalies and epibulbar dermoids delineates the so-called Goldenhar syndrome. Oculoauriculovertebral spectrum (OAVS) is a relatively common disorder affecting approximately 1 in 5,600 live births.

Synonyms and Related Disorders

Hemifacial microsomia; Oculoauriculovertebral spectrum

Genetics/Basic Defects

1. The term, "Oculoauriculovertebral dysplasia spectrum," suggested to represent an etiologically diverse spectrum of congenital anomalies
   a. Oculoauriculovertebral dysplasia
   b. Facioauriculovertebral syndrome (Goldenhar-Gorlin syndrome)
   c. Hemifacial microsomia (second most common facial anomaly, second only to cleft lip and palate) (Sze et al. 2002)
   d. Hemifacial microtia
   e. Otomandibular dysostosis
   f. Original Goldenhar syndrome
   g. Goldenhar-Gorlin syndrome
   h. Anomalies of the first and second branchial arches
2. Congenital anomalies
   a. Usually unilateral
   b. Primarily right sided
   c. More common in monozygous twins usually with one affected
3. Causes: unknown but likely heterogeneous
   a. Usually sporadic occurrence
   b. Maternal teratogenic exposures
      i. Retinoic acid
      ii. Thalidomide
      iii. Primidone
      iv. Cocaine
   c. Presumed vascular disruption
   d. Maternal diabetes
   e. Discordant occurrence in monozygotic twins: arising from a disturbance of blastogenesis leading to malformations
   f. Autosomal dominant inheritance (Guizar-Vazquez et al. 1978; Zankl and Zang 1979; Sanchez-Corona et al. 1982; Oliveira et al. 1989; Orstavik et al. 1990; Gupta and Patton 1995; Tasse et al. 2007; Vendramini-Pittoli and Kokitsu-Nakata 2009)
   g. Autosomal recessive inheritance (Ellwood et al. 1968; Konigsmark et al. 1972; Schmid et al. 1985; Strisciuglio et al. 1986)
   h. Associated chromosome abnormalities
      i. Del(5p)
      ii. Monosomy 6q
      iii. Trisomy 7
      iv. Dup(7q)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_109,
© Springer Science+Business Media, LLC 2012

v. Dup(8q)
vi. Trisomy 9 (mosaic)
vii. Del(18q)
viii. Der(18)
ix. R(21)
x. Del(22)(q13.31)
xi. Dup(22)(q11.2q13.1)
xii. Trisomy 22 (mosaic)
xiii. 47,XXY
xiv. 49,XXXXY

4. Pathogenesis: unknown but likely heterogeneous
   a. Interference with vascular supply and focal hemorrhage in the developing first and second branchial arch region
   b. Impaired interaction of cranial neural crest cells with branchial arch mesenchyme
   c. A disorder of blastogenesis
5. Hypothesis: candidate genes for OAVS, particularly in familial cases
   a. Homeobox genes, especially of the MSX class
      i. *Msx* critical for the differentiation of first branchial arch ectoderm-mesenchyme leading to various craniofacial structures
      ii. Strongly expressed in cephalic neural crest cells prior to migration of the cells that contribute extensively to craniofacial development
   b. Encompasses previous partial pathogenetic explanations for OAVS, including neurocristopathy and developmental field defects, and represents a unifying concept regarding the wide spectrum of involvement in OAVS
   c. Mutations that result in partial loss of function of these genes could explain incomplete penetrance and clinical variability occurring in individuals with different genetic backgrounds.

Clinical Features

1. Major clinical features
   a. Ocular manifestations
      i. Epibulbar dermoids or lipodermoid (Goldenhar syndrome)
      ii. Unilateral microphthalmia
      iii. Upper eyelid coloboma
      iv. Strabismus
      v. Diminished visual acuity
      vi. Tilted optic disc
      vii. Optic nerve hypoplasia
      viii. Tortuous retinal vessels
      ix. Macular hypoplasia and heterotropia
      x. Microphthalmia
      xi. Anophthalmia
   b. Ear anomalies
      i. Microtia
      ii. Preauricular tags and/or pits
      iii. Middle ear anomaly
      iv. Inner ear defects
      v. Variable deafness
   c. Vertebral defects
      i. Hemivertebrae
      ii. Hypoplasia of vertebrae, usually cervical
      iii. Abnormal ribs
   d. Hemifacial microsomia
      i. Unilateral microtia
      ii. Ipsilateral hypoplasia of malar, maxillary, and mandibular region, especially temporomandibular joint
      iii. Ipsilateral macrostomia
      iv. Ipsilateral hypoplasia of the facial musculature
2. Other associated features
   a. Craniofacial features
      i. Cranial nerve palsy
      ii. Cleft lip/palate
      iii. Malfunction of soft palate
      iv. Decreased parotid secretion
      v. Anomalies in function or structure of the tongue
      vi. Low scalp hairline
      vii. Branchial cleft remnants in anterior-lateral neck
   b. CNS anomalies
      i. Hydrocephaly
      ii. Microcephaly
      iii. Plagiocephaly
      iv. Frontal/occipital encephalocele
      v. Cranial bifidum
      vi. Lipoma
      vii. Dermoid cyst
      viii. Arnold-Chiari malformation
      ix. Lissencephaly
      x. Holoprosencephaly/arhinencephaly
      xi. Arachnoid cyst
   c. Congenital heart diseases (5–58% depending on ascertainment of cases)

i. Tetralogy of Fallot (with or without right aortic arch) and VSD (account for over half of the cases with congenital heart diseases)
ii. Pulmonary stenosis
iii. Patent ductus arteriosus
iv. Coarctation of aorta
v. Total atrioventricular canal defect
vi. ASD
vii. Transposition of great vessel
viii. Rare isolation of the left innominate artery infradiaphragmatic total anomalous pulmonary venous connection
ix. Wolf-Parkinson-White syndrome

d. Respiratory tract anomalies
i. Laryngeal anomaly
ii. Incomplete lobulation of the lung
iii. Pulmonary hypoplasia to aplasia
iv. Sequestration
v. Focal tracheomalacia due to extrinsic vascular compression
vi. Obstructive sleep apnea

e. Gastrointestinal anomalies
i. Esophageal atresia
ii. Tracheoesophageal fistula
iii. Diaphragmatic hernia
iv. Imperforate anus

f. Renal anomalies
i. Renal agenesis
ii. Hydronephrosis
iii. Ectopic kidney
iv. Double ureter
v. Hydroureter

g. Prenatal growth deficiency
h. Normal intelligence in most cases

Diagnostic Investigations

1. Radiography
a. Platybasia/occipitalization of atlas
b. Hypoplasia of the mandibular-maxillary bones
c. Fused vertebrae, especially cervical
d. Segmentation anomaly of the vertebra
e. Hemivertebrae
f. Klippel-Feil anomaly
g. Rib anomalies
h. Aplasia of radius/thumb
i. Spina bifida

2. Echocardiography: variable and nonspecific findings because cardiovascular abnormalities are complex in most cases

Genetic Counseling

1. Recurrence risk: depending on the etiology and the mode of inheritance
a. Patient's sib
i. Isolated: empiric recurrence risk of 2%
ii. Autosomal dominant inheritance: recurrence risk not increased unless a parent is affected, in which case the recurrence risk is 50%
iii. Autosomal recessive inheritance: 25% of siblings affected, 50% of siblings carriers, and 25% of siblings normal

b. Patient's offspring
i. Isolated: unknown
ii. Autosomal dominant inheritance: 50%
iii. Autosomal recessive inheritance: recurrence risk not increased unless the spouse is also a carrier, in which case the recurrence risk is 50%

2. Prenatal diagnosis by ultrasonography
a. Hemifacial microsomia
b. Microphthalmia or anophthalmia
c. Cleft lip/palate
d. Unilateral facial cleft with macrostomia
e. Unilateral ear hypoplasia
f. Unilateral preauricular tag
g. Hemiatrophy of the nose
h. Hyposegmentation of the unilateral lung
i. Single umbilical artery
j. Imperforate anus
k. Polyhydramnios

3. Management
a. Surgical removal of epibulbar dermoids, if needed.
b. Manage associated conductive hearing loss.
c. Cleft lip/palate repair.
d. Combined surgical-orthodontic approach for dental occlusion.
e. Traditional osteotomies, followed by acute orthopedic movement and osseous fixation for adult patients with maxillomandibular hypoplasia, facial asymmetry, congenital micrognathia, and hemifacial microsomia.
f. Alternative procedure: distraction osteogenesis.

g. Assess cervical spine for instability before undergoing any general surgery. C1–C2 fusion or occipitocervical fusion may be needed (Kaymak et al. 2002).
h. Anesthesia: anticipate airway obstruction and difficulty in tracheal incubation, resulting from a combination of micrognathia, unilateral mandibular hypoplasia, and vertebral anomalies including vertebral fusion and odontoid elongation.

Gorlin Syndrome

Nevoid basal cell carcinoma syndrome (NBCCS), also known as Gorlin syndrome, was first reported by Jarisch and White in 1894 who described a patient with multiple basal cell carcinomas, scoliosis, and learning disability. Howell and Caro in 1959 were the first to associate the basal cell nevus with other multiple cutaneous cancer and associated developmental anomalies. The spectrum of disease associated with this syndrome, comprising the principal triad of multiple basal cell nevi, jaw keratocysts, and skeletal anomalies, was described in detail by Gorlin and Goltz in 1960. A spectrum of other neurological, ophthalmic, endocrine, and genital manifestations are now known to be variably associated with this triad (Manfredi et al. 2004). The prevalence is estimated to be 1 in 60,000 persons (Cohen 1999).

Synonyms and Related Disorders

Gorlin-Goltz syndrome; Multiple basal cell nevi; Nevoid basal cell carcinoma syndrome; Odontogenic keratocysts and skeletal anomales

Genetics/Basic Defects

1. An autosomal dominant disorder with complete penetrance and variable expressivity (Bare et al. 1992; Bonifas et al. 1994).
2. The gene responsible has been localized to chromosome 9q22.1-q31 (Farndon et al. 1992; Compton et al. 1994).
3. Causes:
   a. Between 50% and 85% of patients with GS harbor germ line mutations in the only susceptibility gene identified to date, *PTCH1*, a key component in the Sonic Hedgehog signaling pathway:
      i. Caused by mutations in the human homolog of the Drosophila patched gene, *PTCH* (Johnson et al. 1996)
      ii. *PTCH*: a tumor suppressor gene, encoding a transmembrane glycoprotein that acts as an antagonist in the Hedgehog signaling pathway (Bak et al. 2003)
   b. A microdeletion at 9q22.3 involving a deletion of *PTCH* gene in a few cases (Shimkets et al. 1996; Sasaki et al. 2000; Olivieri et al. 2003; Midro et al. 2004; Boonen et al. 2005; Yamamoto et al. 2009).
   c. SUFU, another component in this pathway, is known to be involved in susceptibility to medulloblastoma but has never been reported in Gorlin syndrome patients to date. A *SUFU* germ line splicing mutation (c.1022þ1G > A) has been identified for the first time in a family that was *PTCH1*-negative and who had signs and symptoms of Gorlin syndrome, including medulloblastoma (Pastorino et al. 2009).
4. Odontogenic keratocysts (Agaram et al. 2004).
   a. A distinctive odontogenic cyst with a potential for aggressive behavior, local recurrence, and an association with nevoid basal cell carcinoma syndrome
   b. A significant number of odontogenic keratocysts show clonal loss of heterozygosity of common tumor suppressor genes

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_110,
© Springer Science+Business Media, LLC 2012

c. Presence of clonal deletion mutations of genomic DNA in these cysts supports the hypothesis that they are neoplastic rather than developmental in origin

Clinical Features

1. Clinical features
   a. An increasing number of basal cell nevi:
      i. Mostly appearing from the age of puberty onwards
      ii. Having tendency to develop into basal cell carcinomas of the skin
      iii. Most commonly in sun-exposed areas
   b. Dermal pits of the palms and soles:
      i. Particularly useful in diagnosis
      ii. Pits more pronounced when the hands and feet are soaked in warm water for up to 10 min, appearing as white "punched-out" or pink "pinpricked" lesions
   c. Keratocysts of the jaws
   d. Skeletal anomalies:
      i. Spine and rib anomalies:
         a) Bifid ribs
         b) Thoracic and cervical vertebral anomalies
         c) Scoliosis
         d) Spina bifida
         e) Osteoporosis
         f) Short fourth metacarpals
      ii. Abnormal craniofacial configurations:
         a) Macrocephaly
         b) Frontal, parietal, and temporal bossing
         c) Hypertelorism
         d) Broad nasal bridge
         e) Maxillary retrognathia
         f) Mandibular prognathism
         g) Increased gonion angle
         h) Increased facial height
   e. Intracranial calcifications (Dahl et al. 1976; Donatsky et al. 1976; Kimonis et al. 1997; Evans et al. 1993):
      i. Falx cerebri
      ii. Falx cerebelli
      iii. Petroclinoid ligament
      iv. Dura
      v. Pia
      vi. Choroid plexus
   f. Other features:
      i. Sensitive to ultraviolet and ionizing radiation
      ii. Occasional abnormalities (Evans et al. 1993; Kimonis et al. 1997)
         a) Dental agenesis
         b) Cleft palate and lip
         c) Mental deficiency
         d) Agenesis of corpus callosum
         e) Vermian dysgenesis
         f) Anosmia
         g) Hydrocephalus
         h) Cataract
         i) Coloboma of iris
         j) Retinal atrophy
         k) Glaucoma
         l) Strabismus
         m) Mandibular coronoid process hyperplasia
         n) Arachnodactyly
         o) Polydactyly
         p) Renal anomalies
         q) Other neoplasms such as medulloblastoma, meningioma, fibroma, lipomata, melanoma, neurofibromata of skin, cardiac fibromas, eyelid carcinomas, breast cancer, lung cancer, lymphoid leukemia, non-Hodgkin's lymphoma, ovarian dermoid, lymphomesenteric cysts, and hepatic mesenchymal tumors
2. Diagnostic criteria for nevoid basal cell carcinoma syndrome (Evans et al. 1993; Evans and Farndon 2010; Kimonis et al. 2004): A diagnosis can be made when two major, or one major and two minor criteria are fulfilled:
   a. Major criteria:
      i. Multiple (>2) basal cell carcinomas (BCC) or one BCC under the age of 20 years, or >10 basal cell nevi
      ii. Any odontogenic keratocyst histologically or observed on orthopantogram as an area of translucency or polyostotic bone cyst
      iii. Palmar or plantar pits (three or more)
      iv. Ectopic calcification: lamellar (sheetlike) falx calcification or evidence of early calcification in an individual younger than 20 years
      v. First degree relatives with NBCCS
   b. Minor criteria:
      i. Congenital skeletal anomaly: bifid, fused, splayed, or missing ribs, or bifid, wedged, or fused vertebra

ii. Occipital-frontal circumference >97 percentile (macrocephaly), with frontal bossing
iii. Cardiac or ovarian fibromas
iv. Childhood medulloblastoma (primitive neuroectodermal tumor)
v. Lymphomesenteric or pleural cysts
vi. Congenital malformation: cleft lip and/or palate, polydactyly, eye anomaly (cataract, coloboma, microphthalmia)

Diagnostic Investigations

1. Family history:
   a. Brain tumors
   b. Female organ tumors
2. Medical and dental history:
   a. Removal of jaw cysts
   b. Abscesses
   c. Skin lesions
3. Physical examination:
   a. Mandibular and maxillary swelling
   b. Head circumference
   c. Head shape
   d. Skin basal cell nevi
   e. Pits on the palms and soles
4. Radiographic studies:
   a. Skull radiography for detection of calcified cerebral falx
   b. Jaw radiography for detection of maxillary and mandibular cystic lesions
   c. Chest radiography for rib and vertebral anomalies
5. MRI of the brain to detect meningiomas or medulloblastomas at an early age
6. Ovarian ultrasonography for detection of ovarian cysts or fibromas
7. Echocardiograms to evaluate cardiac fibromas
8. Cytogenetic analysis to detect rare interstitial 9q deletion associated with clinical features of NBCCS and additional features such as severe developmental delay or short stature
9. Molecular genetic testing (Evans and Farndon 2010):
   a. Sequence analysis of exons 2-23 with intron-exon junctions and one of the splice forms of exon 1 to detect *PTCH1* gene mutation (Marsh et al. 2005; Klein et al. 2005)
   b. Deletion testing to detect exonic and whole *PTCH1* gene deletions

Genetic Counseling

1. Recurrence risk:
   a. Patient's sib:
      i. An affected parent: a 50% risk
      ii. Unaffected parents: a low risk
   b. Patient's offspring: a 50% risk
2. Prenatal diagnosis:
   a. Ultrasonography:
      i. Hydrocephalus
      ii. Macrocephaly
      iii. Cleft lip and palate
      iv. Intracardiac tumor
      v. Fetal hydrops
      vi. Fetal chylothorax
   b. Molecular genetic testing available, provided the disease-causing allele of an affected family member has been identified, by analyzing DNA extracted from fetal cells obtained by:
      i. CVS
      ii. Amniocentesis
3. Management:
   a. Surgical excision of keratocysts identified early in life
   b. Basal cell carcinomas:
      i. Complete eradication of aggressive BCCs; surgical excision supplemented by cryotherapy, laser treatment for early lesion, and photodynamic therapy
      ii. Preserve normal tissue to prevent disfigurement
   c. Surgical excision of ovarian fibromas

Fig. 1 (**a**, **b**) An 11-year-old boy and his father both have Gorlin syndrome. The boy had multiple odontogenic cysts removed from his jaw. Craniofacial CT scan showed extensive dural and choroid plexus calcifications and abnormal enlargement of subarachnoid space in the left frontal and anterior temporal regions. He was noted to have macrocephaly, forehead bossing, and plantar pits. His father had his multiple odontogenic cysts removed at 16 years of age. In addition, he has several soft subcutaneous tissue masses in his fingers and his right foot. The patient is heterozygous for a duplication of a single "A" nucleotide in exon 2 of the *PTCH* gene. The normal sequence with the base that is duplicated in braces is "TTGTT(A)CATTCA." This mutation is denoted c.278dupA at the cDNA level or p Tyr93Stop (Y93X). The c.278DupA mutation results in the replacement of a Tyrosine codon with a Stop codon at position 93

Fig. 2 CT scan of jaw shows multiple odontogenic cysts

Fig. 4 A small subcutaneous nodule seen in the dorsal aspect of the foot of the father

Fig. 3 A small subcutaneous nodule seen in the index fingers of the father

Greig Cephalopolysyndactyly Syndrome

Greig cephalopolysyndactyly (GCPS) syndrome is named after David Middleton Greig for his 1926 description of a patient with unusual head shape, hypertelorism, and limb anomalies. It is a rare, pleiotropic, multiple congenital anomaly syndrome characterized by the primary clinical triad of polysyndactyly, macrocephaly, and hypertelorism.

Synonyms and Related Disorders

Cephalopolysyndactyly; Polysyndactyly with peculiar skull shape

Genetics/Basic Defects

1. Inheritance: Autosomal dominant with high penetrance in majority of cases.
2. Caused by mutations in the transcription factor *GLI3* on chromosome 7p13 resulting in functional haploinsufficiency of *GLI3*. The mutations include:
   a. Point mutations
   b. Frameshift mutations
   c. Translocation mutations
   d. Deletion mutations
   e. Insertion mutations
3. Allelic to the Pallister-Hall syndrome (PHS) and one form of the acrocallosal syndrome:
   a. Severe GCPS phenotype is likely caused by deletion of contiguous genes and substantially overlaps with the mild end of the acrocallosal syndrome (an autosomal recessive disorder characterized by pre- or postaxial polydactyly, syndactyly, agenesis corpus callosum, ocular hypertelorism, macrocephaly, moderate to severe mental retardation, intracerebral cysts, seizures, and umbilical and inguinal hernias).
   b. *GLI3* mutations can also cause PHS, postaxial polydactyly type A, and other *GLI3* morphopathies. GCPS and PHS are likely allelic with distinct modes of pathogenesis.
4. Phenotypes caused by mutations in GLI3 are diverse, discrete, variable, and pleiotropic. The mutations in GLI3 that cause PHS and GCPS correlate with the phenotypes on two levels:
   a. Many types of inactivating mutations cause GCPS.
   b. Whereas PHS is caused almost exclusively by truncation mutations in the middle third of the gene.
5. Mutations in genes other than *GLI*: possible in some patients with a GCPS phenotype.

Clinical Features

1. The primary clinical triad.
   a. Macrocephaly
   b. Hypertelorism
   c. Polysyndactyly
2. Variable clinical manifestations
3. Developmental history:
   a. Feeding problems/failure to thrive
   b. Developmental delay, seizures, and psychomotor retardation: more likely in a child with rare CNS malformations or uncommon hydrocephalus and more common in individuals with large (>300 kb) deletions that encompass *GLI3*

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_111,
© Springer Science+Business Media, LLC 2012

4. Craniofacial features: highly variable
   a. Significant hypertelorism (increased interpupillary distance) with or without telecanthus (increased inner canthal distance) in some patients
   b. Macrocephaly, not typically associated with CNS anomalies, such as hydrocephalus and seizures
5. Digital anomalies:
   a. Polydactyly:
      i. Classically described as preaxial.
      ii. May occur in any limb.
      iii. Postaxial may be more common than preaxial.
      iv. Most common finding: postaxial polydactyly of the hands and preaxial polydactyly of the feet.
      v. Severity varies widely among individuals and among limbs in the same individual. This can vary from an apparently normal extremity, through subtle broadening of the thumb or hallux, tiny postaxial nubbins, to partially bifid digits, hypoplastic supernumerary digits, fully formed supernumerary digits, and higher order polydactyly.
   b. Cutaneous syndactyly: highly variable.
      i. Absent in many patients
      ii. Mild partial cutaneous syndactyly of a few digits in some patients
      iii. The spectrum continues through to complete cutaneous syndactyly of all digits, not unlike that seen in patients with Apert syndrome.
6. Less common anomalies:
   a. Craniosynostosis: very few patients.
   b. Mental retardation: not common.
   c. Agenesis of the corpus callosum.
   d. Umbilical and diaphragmatic hernias.
   e. Risk of cognitive impairment appears to be associated with the GCPS-contiguous gene syndrome.
7. Diagnostic criteria (Johnston et al. 2005):
   a. Presumptive diagnosis: a proband with:
      i. Preaxial polydactyly
      ii. Syndactyly of toes 1–3 or fingers 3–4
      iii. Ocular hypertelorism
      iv. Macrocephaly
   b. Firm diagnosis:
      i. Presence of an affected first-degree relative whom the diagnosis has been independently established
      ii. A proband who has features of GCPS and a mutation in *GLI3*
   c. Cautions in applying above diagnostic criteria:
      i. Clinical criteria: useful but not sufficiently specific to warrant a "firm" diagnosis on clinical grounds alone
      ii. A small but significant fraction of individuals with features of GCPS do not have mutations in *GLI3*.
      iii. Features of GCPS are seen in many other syndromes.
8. Diagnostic criteria (combined clinical-molecular definition for the syndrome) (Biesecker 2008)
   a. A presumptive diagnosis with the classic triad:
      i. Preaxial polydactyly with cutaneous syndactyly of at least one limb
      ii. Hypertelorism
      iii. Macrocephaly
   b. Definitive diagnosis:
      i. A phenotype consistent with GCPS but which may not manifest all three attributes listed above
      ii. Presence of a *GLI3* mutation
9. Additional definitive diagnostic criteria: persons with a GCPS-consistent phenotype who are related to a definitively diagnosed family member in a pattern consistent with autosomal dominant inheritance
10. Prognosis:
    a. A mild form: excellent general health and normal longevity reported in several large families
    b. Slight increase in the incidence of developmental delay or cognitive impairment
    c. Worse prognosis in patients with large deletions that include *GLI3*
11. Differential diagnosis:
    a. Preaxial polydactyly type IV
    b. GCPS contiguous gene syndrome
    c. Acrocallosal syndrome (ACLS):
       i. Inherited in an autosomal recessive manner.
       ii. Pre- or postaxial polydactyly.
       iii. Syndactyly.
       iv. Agenesis of the corpus callosum (rare in GCPS).
       v. Ocular hypertelorism.
       vi. Macrocephaly.
       vii. Moderate to severe mental retardation.
       viii. Intracerebral cysts.

ix. Seizures.
x. Umbilical and inguinal hernias.
xi. The milder end of the ACLS phenotype can overlap with the severe end of the GCPS phenotype caused by interstitial deletions of 7p13 that delete *GLI3* and additional neighboring genes.
xii. Frequency of consanguinity, sibling recurrences with unaffected parents, and preliminary mapping data suggest that ACLS can be a disorder distinct from severe GCPS.

d. Gorlin syndrome
e. Carpenter syndrome
f. Teebi syndrome

Diagnostic Investigations

1. Radiographic studies of digital anomalies
2. CNS imaging studies:
   a. For individuals showing signs of increased intracranial pressure, developmental delay, loss of milestones, or seizures
   b. To evaluate hydrocephalus or other CNS abnormalities
3. Chromosome analysis: performed either as a first test, or in all patients who have GCPS but no mutation was found by sequencing:
   a. Detection of visible pure chromosomal deletions involving 7p13 or a deletion combined with a translocation
   b. Detection of familial translocation: a risk for offspring with unbalanced translocations in addition to their risk of having a child with GCPS
4. Molecular genetic testing:
   a. Indications:
      i. Confirmatory diagnostic testing
      ii. Prenatal diagnosis
   b. FISH analysis: Using hybridization of the labeled BAC clone to metaphase spreads detects deletions in the estimated 5–10% of individuals with large deletions.
   c. Comparative genomic hybridization (CGH):
      i. An array of *GLI3* is available on a limited clinical basis.
      ii. CGH array would be expected to detect a deletion that encompasses more than one target on the array.
   d. Other methodologies:
      i. Loss-of-heterozygosity (LOH) analysis to detect large deletions
      ii. Sequencing of the *GLI3* coding exons or scanning with denaturing high-performance liquid chromatography (DHPLC), single-strand conformation polymorphism (SSCP), or other conformation detection methods: an appropriate first screen for patients with typical GCPS
      iii. Quantitative PCR

Genetic Counseling

1. Recurrence risk:
   a. Patient's sib:
      i. De novo cases: recurrence risk low
      ii. Fifty percent of siblings affected if one of the parents is affected
      iii. No instances of germline mosaicism reported, but it remains a possibility
      iv. Proband with an unbalanced structural chromosome constitution:
         a) Neither parents with a structural chromosome rearrangement: risk to sibs negligible
         b) A parent with a balanced structural chromosome rearrangement: risk to sibs increases and depends upon the specific chromosome rearrangement
   b. Patient's offspring
      i. Fifty percent risk of inheriting the mutation and having an affected offspring: Since intrafamilial variability is generally low, affected offspring are expected to have clinical findings similar to those of the parent.
      ii. Offspring of an individual with a balanced or unbalanced chromosomal rearrangement: at risk of having a similar or related rearrangement.
2. Prenatal diagnosis:
   a. Ultrasound studies in pregnancies at 50% risk may detect the following findings:
      i. Polydactyly
      ii. Ma
      iii. CNS malformations such as hydrocephalus
   b. Chromosome analysis of fetal cells in at-risk families with a parent having a cytogenetically visible 7p13 deletion or a balanced chromosomal rearrangement.

c. Molecular genetic testing: Antenatal molecular diagnosis is technically straightforward to perform.
d. Preimplantation genetic diagnosis (PGD): may be available for families in which the disease-causing mutation or chromosome abnormality has been identified in an affected family.

3. Management:
   a. Symptomatic treatment with plastic or orthopedic surgery indicated for significant limb malformations
   b. Surgical repair:
      i. Preaxial polydactyly of the thumbs: a higher priority for surgical correction than postaxial polydactyly of the hand or polydactyly of the foot because of the importance of the thumbs for prehensile grasp
      ii. Severe syndactyly of the fingers
      iii. Surgical correction of the feet for orthopedic complications, cosmetic benefits, and easier fitting of shoes

Fig. 1 (**a**, **b**) A 34-year-old patient with typical facial features characterized by macrocephaly and hypertelorism. He also has mental retardation and seizure disorder. The hands show postaxial polydactyly and complete cutaneous syndactyly of digits 2–5 with fusion of nails. The feet show a partially duplicated hallux with cutaneous syndactyly of several digits

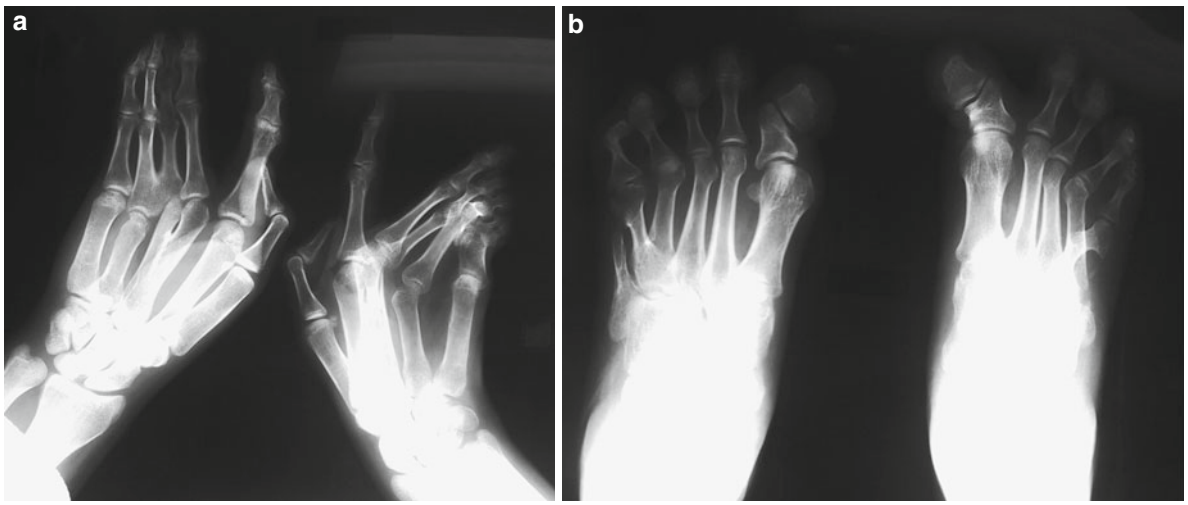

Fig. 2 (**a**, **b**) Radiographs of the same patient. The hands show six phalanges with partial fusion of the third and fourth metacarpals and partial fusion of the fourth and fifth proximal phalanges. The feet shows a partially duplicated hallux

Fig. 3 (**a**–**c**) Another patient with macrocephaly, ocular hypertelorism, and a partially duplicated great hallux

Hallermann-Streiff Syndrome

Hallermann-Streiff syndrome was independently described by Hallermann in 1948 and Streiff in 1950. The syndrome is characterized by proportionate short stature, craniofacial dysostoses consisting of skeletal, ophthalmologic, and cutaneous defects.

Synonyms and Related Disorders

Francois dyscephalic syndrome

Genetics/Basic Defects

1. Sporadic in virtually all cases
2. Inheritance pattern unknown

Clinical Features

1. Characteristic craniofacial features
   a. Dyscephaly (malformation of the cranium and bones of the face) (89–90%)
      i. Calvarium
         a) Brachycephaly
         b) Thin calvarium
         c) Delayed closure of fontanelles
         d) Wide cranial sutures
      ii. Cranial base
         a) Platybasia
         b) Depressed sella
         c) Elevated anterior cranial fossa
      iii. Parrotlike face
         a) A beaked nose
         b) Hypoplastic mandible
   b. Hypotrichosis (80–82%)
      i. Alopecia
         a) Characteristic sutural alopecia (hair loss following the lines of the cranial sutures)
         b) Frontal alopecia
         c) Alopecia at the scalp margins
      ii. Hypotrichosis involving the eye-brows and eyelashes
      iii. Brittle and sparse scalp hair
   c. Cutaneous atrophy (68–70%)
      i. Face
      ii. Scalp
   d. Ocular abnormalities
      i. Congenital cataracts (81–90%)
      ii. Microphthalmos (78–83%)
      iii. Nystagmus
      iv. Strabismus
      v. Glaucoma
      vi. Blue sclerae
      vii. Fundal anomalies
      viii. Conjunctival defects
      ix. Corneal abnormalities
      x. Down slanting palpebral fissures
      xi. Intraocular hypertension
      xii. Lower lid coloboma
      xiii. Iris atrophy
      xiv. Persistent pupillary membrane
      xv. Enophthalmos
      xvi. Bilateral retinal detachments (Haque et al. 2009)
      xvii. Epicanthal folds
   e. Mouth
      i. Microstomia
      ii. Narrow/high-arched palate

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_112,
© Springer Science+Business Media, LLC 2012

iii. Dental abnormalities (80–85%)
a) Natal teeth
b) Partial anodontia/hypoplasia
c) Persistent deciduous teeth
d) Irregular implantation of the teeth
e) Anterior open bite

2. Musculoskeletal abnormalities
a. Proportionate short stature (45–69%)
b. Syndactyly
c. Lordosis
d. Scoliosis
e. Spina bifida
f. Winged scapulae
g. Hyperextensible joints including temporomandibular joints
h. Hip dislocation
i. Periodic osteoporosis

3. Other abnormalities
a. Mild to severe mental retardation (15%)
b. Calcified falx cerebri
c. Neurologic abnormalities
i. Neurofibromatosis
ii. Epilepsy
d. Genital anomalies (10–12%)
i. Hypogenitalism
ii. Cryptorchidism
iii. Hypospadias
iv. Subseptate uterus
v. Clitoral hypertrophy
e. Cardiac defects (2–9%)
i. Pulmonic stenosis
ii. Atrial septal defect
iii. Ventricular septal defect
iv. Patent ductus arteriosus
v. Tetralogy of Fallot
f. Endocrinological abnormalities
i. Immune deficiency
ii. Hypoparathyroidism
iii. Hypothyroidism
iv. Hypopituitarism
g. Ear anomalies (9%)
h. Hematopoietic abnormalities (7%)
i. Pulmonary anomalies (3%)
i. Obstructive sleep apnea
ii. Tracheomalacia
iii. Recurrent pulmonary infections
iv. Cor pulmonale
j. Gastrointestinal abnormalities (3%)
k. Muscular hypotrophy (3%)
l. Hepatic anomalies (2%)
m. Renal anomalies (1–2%): bilateral duplication of renal collecting system

4. Prognosis
a. Some patients succumb in infancy to respiratory infections and pulmonary insufficiency, possibly related to airway obstruction and abnormal compliance
b. Majority of patients with a normal life span

5. Diagnostic criteria
a. Major features
i. Dyscephaly with beak nose and mandibular hypoplasia
ii. Dental abnormalities
iii. Proportional short stature
iv. Hypotrichosis
v. Cutaneous atrophy
vi. Microphthalmia
vii. Congenital cataracts
b. Minor features
i. Narrow/high-arched palate
ii. Ocular features
a) Blue sclera
b) Antimongoloid palpebral fissures
c) Synechiae irides
d) Choroid atrophy
iii. Hypoplastic genitalia
iv. Musculoskeletal features
a) Elevated scapulae
b) Scoliosis
c) Lordosis
d) Hyperextensible joints
v. Mental retardation

Diagnostic Investigations

1. Radiography (Christian et al. 1991)
a. Skull
i. A large, poorly ossified skull
ii. Delayed closure of fontanelles with persistent wide sutures
iii. Presence of Wormian bones
iv. Brachycephaly
v. Platybasia
vi. Depressed sella turcica

vii. Frontal or parietal bossing
viii. Small orbits
ix. Disproportion between the large cranial vault and the small facial skeleton
x. Midfacial hypoplasia
a) Hypoplastic mandibular ramus
b) Possible absent condyles
c) Anteriorly displaced temporomandibular joint
d) Hypoplastic malar bones
xi. A birdlike nose
xii. Micrognathia
xiii. Dental anomalies
a) Presence of natal teeth
b) Retained decidual teeth
c) Partial anodontia
d) Supernumerary and hypoplastic teeth
e) Anterior open bite malocclusion

b. Long bones
i. Thin/gracile
ii. Retarded bone age

c. Other skeletal anomalies
i. Scaphocephaly
ii. Cervical vertebral anomalies
iii. Mild platyspondyly
iv. Scoliosis
v. Lordosis
vi. Elevated scapulae
vii. Hip dislocation
viii. Spina bifida
ix. Syndactyly

2. Overnight polysomnography to confirm obstructive sleep apnea
3. Endocrine evaluation for hypothyroidism, hypoparathyroidism, or hypopituitarism
4. Chromosome study: no diagnostic cytogenetic characteristics

Genetic Counseling

1. Recurrence risk
a. Patient's sib: not increased
b. Patient's offspring: not increased
2. Prenatal diagnosis: not been reported
3. Management
a. Surgery
i. Repair of cardiovascular defect
ii. Ophthalmological procedure (cataracts removal)
iii. Rhinoplasty
iv. Facial augmentation
v. Dental surgery (Patterson et al. 1982)
a) General restorative dentistry
b) Orthodontic palatal expansion
c) Realignment of the dental arches
vi. Mandibular advancement

b. General anesthesia and airway management
i. Difficult laryngoscopy and endotracheal intubation secondary to micrognathia, microstomia, and serious upper airway compromise
ii. Brittle and easily broken natal teeth during laryngoscopy
iii. Orotracheal intubation precluded by anterior placement or absence of the temporomandibular joints
iv. Difficult nasotracheal intubation secondary to hypoplastic nose and deviated nasal septum
v. Consider preoperative tracheotomy or prepare for emergency tracheotomy

c. Long-term nasal continuous positive airway pressure therapy for obstructive sleep apnea (Ryan et al. 1990)
d. Management for endocrine problem if present

Harlequin Ichthyosis

Harlequin ichthyosis is a rare severe scaling disorder and the most devastating congenital ichthyosis, which manifests in utero and is often fatal early in life.

Synonyms and Related Disorders

Congenital ichthyosis of harlequin type; Harlequin fetus

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. *ABCA12* gene
   a. Located on chromosome 2q34
   b. Consists of 53 exons and codes a 2595 amino acid protein member of the adenosine triphosphate (ATP)–binding cassette transporter family (Lefévre et al. 2003; Akiyama et al. 2005; Kelsell et al. 2005)
3. Caused by loss-of-function mutations in *ABCA12* (Akiyama and Shimizu 2008; Akiyama 2010)
   a. Truncation mutations: most mutations
      i. Nonsense mutations
      ii. Frameshift mutations (deletion/insertion mutations)
      iii. Splice site mutations
   b. Missense mutations
   c. Exon deletion
   d. Single amino acid deletions
4. Novel homozygous mutation p.R287X resulted from complete paternal isodisomy (Castiglia et al. 2009)
   a. Non-mosaic chromosome 2 trisomy from chorionic villus karyotyping while postnatal peripheral blood karyotype was normal female.
   b. These findings indicate that trisomic rescue is one step of the mutational cascade leading to reduction to homozygosity for the *ABCA12* mutation in the embryo.
5. Pathomechanisms of ichthyosis involving *ABCA12* mutations (Akiyama 2010): several morphologic abnormalities including abnormal lamellar granules in the keratinocyte granular layer and a lack of extracellular lipid lamellae within the stratum corneum observed in harlequin ichthyosis (Akiyama et al. 2005)
   a. Lack of *ABCA12* function subsequently leads to disruption of lamellar granule lipid transport in the upper keratinizing epidermal cells resulting in malformation of the intercellular lipid layers of the stratum corneum.
   b. Cultured epidermal keratinocytes from an harlequin ichthyosis patient carrying *ABCA12* mutations demonstrated defective glucosylceramide transport and this phenotype was recoverable by in vitro *ABCA12* corrective gene transfer.
   c. To date, intracytoplasmic glucosylceramide transport has been studied using cultured keratinocytes from a total of three patients harboring *ABCA12* mutations (Akiyama et al. 2005, 2006, 2007).
      i. One patient was a homozygote for a splice site mutation c.3295-2A > G.
      ii. Another patient was a compound heterozygote for p.Ser387Asn and p.Thr1387del.
      iii. Only one heterozygous mutation p.Ile1494Thr was identified in the other patient.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_113,
© Springer Science+Business Media, LLC 2012

iv. Cultured keratinocytes from all the three patients showed apparently disturbed glucosylceramide transport, although this assay is not quantitative.

6. Report of a male with harlequin ichthyosis with a de novo deletion of the long arm of chromosome 18 [46,XY,del(18)(q21.3)] suggesting the possible gene localization within the deleted region

Clinical Features

1. Major clinical features
   a. Large, thick, and yellowish armor-like plaques (platelike scales) with reddish, moist, oozing fissures and cracks, covering the whole body
   b. Severe ectropion (complete eversion of the non-keratinizing mucosa of the eyelids with occlusion of the eyes)
   c. Eclabium (eversion of the non-keratinizing mucosa of the lips)
   d. "Frog-like" grostesque appearance of the face
   e. Crumpled and flattened ears
   f. Flattened nasal tip with anteversion of the nares (nasal hypoplasia)
   g. Permanently opened mouth unable to suck properly
   h. Swollen extremities secondary to tight sausage-like encasement by the thickened stratum corneum
   i. Semiflexed rigid extremities (allowing little limb movement) with hypoplastic fingers
2. Minor clinical features
   a. Absent eyebrows and eyelashes
   b. Absent scalp hair
3. Associate anomalies
   a. Renal tubular defects
   b. Altered thymic structures
   c. Pulmonary hypoplasia
4. Natural history
   a. Restricted fetal movement caused by dense masses of hyperkeratotic scale
   b. Prematurity in most cases
   c. Perinatal death (usually in the first few weeks) secondary to:
      i. Respiratory compromise due to mechanical limitation of ribcage excursion
      ii. Sepsis
      iii. Hypothermia
      iv. Dehydration
      v. Malnutrition
      vi. Severe anemia
      vii. Renal failure
   d. Rare survivals
      i. Variable neurologic impairment
      ii. Short stature
      iii. Failure to thrive
      iv. At risk for severe keratitis due to ectropion of all eyelids

Diagnostic Investigations

1. Light microscopy findings
   a. Extraordinary compact orthohyperkeratosis (thickened orthokeratotic stratum corneum)
   b. Keratin plugs in hair follicles and sweat ducts
   c. Absent lamellar bodies and abundant vesicles in both the stratum granulosum and stratum corneum
   d. Abnormal lipid droplets and vacuoles in the cytoplasm of keratinized cells in the thick stratum corneum
2. Ultrastructural findings
   a. Abnormal lipid droplets and vacuoles in the cytoplasm of keratinized cells in the thick stratum corneum
   b. Absent normal lamellar granules in the cytoplasm of granular layer keratinocytes
   c. Lack of lamellar structure in the extracellular space between the first cornified cell and the granular cell
3. Biochemical analysis of skin samples: a defect of conversion from profilaggrin to filaggrin
4. Family history for evidence of consanguinity
5. Molecular genetic diagnosis by gene sequencing or deletion/duplication analysis of *ABCA12*

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: patient not surviving to reproductive age
2. Prenatal diagnosis possible in families at risk
   a. Ultrasonography (2D, 3D and 4D) at 18–24 weeks (Kudla and Timmerman, 2010).

i. Minimal fetal movement with stiff limbs in a semiflexed position
ii. Swollen limbs with hypoplastic fingers and toes and short phalanges
iii. Shriveled hands that do not open
iv. Characteristic facial features
  a) Flat face profile
  b) Open eyes
  c) Ectropion
  d) Cataracts
  e) Flat nose
  f) Thick lips
  g) Eclabium
  h) Absence of typical ear morphology (hypoplasia of the ears)
  i) Large open mouth
  j) Micrognathia
  k) Partitioned cystic formations in front of the eyes
v. Short neck
vi. Thick skin
vii. Choroid plexus cysts
viii. Short umbilical cord
ix. Hyperechogenic amniotic fluid
x. Absence of associated visceral anomalies

b. Amniocentesis: demonstration of clumping of keratinocyte cells in the amniotic fluid containing lipid droplets and amorphous electron dense material.
c. Electron microscopy of the fetal skin biopsy specimen from fetoscopy at 20–22 weeks.
  i. Abnormal vacuoles in keratinized cells
  ii. Abnormal lamellar granules in the hair canal
d. Molecular genetic testing: After identification of ABCA12 as the causative gene for harlequin ichthyosis, it is feasible to perform DNA-based prenatal diagnosis for harlequin ichthyosis by chorionic villus or amniotic fluid sampling (Akiyama et al. 2007; Yanagi et al. 2008) or preimplantation genetic diagnosis. Both disease-causing alleles of an affected family member must be identified before prenatal testing can be performed.

3. Management
a. Temperature control.
b. Electrolyte and fluid balance.
c. Adequate caloric intake.
d. Prevention of infection with antibiotics.
e. Topical steroids to reduce secondary inflammation.
f. Tretinoin creams or ointments or oral retinoid treatment to reduce the amount of scale. Early use of systemic retinoids promotes accelerated shedding of the hyperkeratotic plates, whereas continued use reduces scale and improves ectropion and eclabium (Harvey et al. 2010).
g. Pain management with anti-inflammatory drugs and morphine sulfate if necessary.
h. Ocular management.
  i. Intensive topical eye ointment
  ii. Treat keratitis promptly
  iii. Surgical management of the ectropion by skin-release surgery with autologous skin grafting in patients with severe exposure keratitis or cosmetically unacceptable ectropion
i. Careful handling to avoid hard friction and physical contract for prevention of blistering.

Fig. 1 (**a**–**d**) A newborn with harlequin ichthyosis, covered with yellowish plaques (severe hyperkeratosis) with moist fissures and cracks and grostesque appearance of face with ectropion, eclabium, a flat nose, crumpled/flat ears, and swollen/semiflexed rigid limbs

Hemophilia A

Hemophilia A is a congenital X chromosome–linked coagulation disorder characterized by deficiency in factor VIII clotting activity that results in prolonged oozing after injuries, tooth extractions, or surgery and delayed or recurrent bleeding prior to complete wound healing. It affects approximately 1 in 5,000–1 in 10,000 male births.

Synonyms and Related Disorders

Classic hemophilia

Genetics/Basic Defects

1. Inheritance (Hedner et al. 2000)
   a. An X-linked recessive disorder
   b. New mutations in approximately one third of patients
   c. Hemophilia A in females
      i. Rarely reported
      ii. Possible explanation
         a) Extreme skewing of X chromosome inactivation resulting in unusually low factor VIII levels in female hemophilia A carriers
         b) Rare individuals carrying a hemophilia A mutation associated with an X chromosome–autosome translocation or other cytogenetic abnormality, which may result in exclusive inactivation of the normal X chromosome
         c) Rare individuals carrying a hemophilia A mutation in the rearranged X-chromosome
2. Molecular genetics (Hedner et al. 2000)
   a. Caused by absent or decreased factor VIII (FVIII) procoagulant function, resulting from mutations in FVIII (*F8*) gene, mapped on chromosome Xq28.
   b. A unique rearrangement within the FVIII gene (intron 22 gene inversion), recently identified as a common, recurrent mechanism for hemophilia A.
      i. Accounting for approximately 45% of all severe hemophilia A patients.
      ii. The mutation almost always arises during a male meiosis.
      iii. The mother of an apparently new mutation patient with an identified gene inversion can generally be assumed to be a carrier, with the recombination event often identified in the maternal grandfather's allele.
   c. The remaining 55% of severe hemophilia patients are shown to have a more conventional molecular defect in the FVIII gene.
      i. Approximately 50% of patients with specific point mutations in exons or at splice junctions within the FVIII gene
      ii. Approximately 5% of patients with deletions which remove varying-sized segments of the FVIII gene
      iii. Rare small insertions and deletions
   d. Nearly all patients with mild or moderately severe hemophilia A have some residual level of FVIII activity, shown to have a point mutation within the FVIII coding sequence, resulting in a single amino acid substitution.
   e. Clinical severity of the hemophilia A phenotype correlates very closely with the amount of residual factor VIII activity.

Clinical Features

1. Clinical features suspecting a coagulation disorder (Hedner et al. 2000)
   a. Hemarthrosis, especially with mild or no antecedent trauma
   b. Deep muscle hematomas
   c. Intracranial bleeding in the absence of major trauma
   d. Cephalohematoma or intracranial bleeding at birth
   e. Prolonged oozing or renewed bleeding after initial bleeding stops following tooth extractions, mouth injury, or circumcision
   f. Prolonged bleeding or renewed bleeding following surgery or trauma
   g. Unexplained gastrointestinal bleeding or hematuria
   h. Menorrhagia, especially at menarche
   i. Prolonged nosebleeds, especially recurrent and bilateral
   j. Excessive bruising, especially with firm, subcutaneous hematomas
2. Severe hemophilia A (43% of hemophiliacs)
   a. Spontaneous bleeding
      i. Joints: the most frequent symptom
      ii. Other sites
         a) Kidneys
         b) Gastrointestinal tract
         c) Brain
   b. Without treatment
      i. Bleeding from minor mouth injuries and large "goose eggs" from minor head bumps during the toddler period
      ii. Rare intracranial bleeding resulting from head injuries
      iii. Almost always with subcutaneous hematomas
      iv. Frequency of bleeding
         a) Relating to the FVIII clotting activity
         b) Varying from two to five spontaneous bleeding episodes each month
         c) Bleeding episodes more frequent in childhood and adolescence than in adulthood
   c. Age of diagnosis
      i. Usually diagnosed during the first year of life
      ii. Relating to the FVIII clotting activity
3. Moderately severe hemophilia A (26% of hemophiliacs)
   a. Seldom with spontaneous bleeding
   b. Without treatment
      i. Prolonged or delayed oozing after relatively minor trauma
      ii. Frequency of bleeding
         a) Varying from once a month to once a year
         b) Bleeding episodes more frequent in childhood and adolescence than in adulthood
   c. Usually diagnosed before the age of 5–6 years
4. Mild hemophilia A (31% of hemophiliacs)
   a. Absent spontaneous bleeding
   b. Without treatment
      i. Occurrence of abnormal bleeding with surgery, tooth extraction, and major injuries
      ii. Frequency of bleeding
         a) Varying from once a year to once every 10 years
         b) Bleeding episodes more frequent in childhood and adolescence than in adulthood
   c. Often not diagnosed until later in life
5. Carrier females
   a. Risk of bleeding in approximately 10% of carrier females
   b. Mild symptoms
6. Complications of untreated bleeding
   a. Intracranial hemorrhage: the leading cause of death
   b. Chronic joint disease: the major cause of disability
7. Life expectancy: 60–70 years
8. Differential diagnosis
   a. Inherited bleeding disorders associated with a low factor VIII clotting activity
      i. Type 1 vWD (mild von Willebrand disease)
         a) An autosomal dominant disorder
         b) Predominant feature: mucous membrane bleeding
         c) Quantitative deficiency of von Willebrand factor (low vWF antigen, factor VIII clotting activity, and ristocetin cofactor activity) in 80% of patients
      ii. Type 2 vWD
         a) Quantitative deficiency of vWF with a decrease of the high molecular weight multimers
         b) Low normal to mildly decreased vWF antigen and factor VIII clotting activity
         c) Low functional vWF level in a ristocetin cofactor assay

iii. Type 2 N (Normandy) vWD
  a) An uncommon variant due to several missense mutations in the amino terminus of the vWF protein, resulting in defective binding of factor VIII to vWF
  b) Low factor VIII clotting activity usually showing autosomal recessive inheritance
  c) Indistinguishable clinically from mild hemophilia A, which can be differentiated with molecular genetic testing of the FVIII gene, molecular genetic testing of the vWF gene, or measuring binding of factor VIII to vWF using ELISA or column chromatography
iv. Type 3 vWD (severe von Willebrand disease)
  a) An autosomal recessive disorder
  b) Frequent episodes of mucous membrane bleeding and joint and muscle bleeding similar to hemophilia A
  c) <1% vWF level
  d) Two to eight FVIII clotting activity
v. Mild combined factor V and factor VIII deficiencies
  a) A rare autosomal recessive disorder
  b) Deficiency of a chaperone protein (ERGIC-53)

b. Acquired hemophilia A (Collins et al. 2010)
  i. A bleeding disorder caused by an autoantibody to factor VIII
  ii. Estimated incidence: 1.5/million/year
  iii. Predominantly affects older patients
  iv. Acute onset of severe and life-threatening bleeding or widespread subcutaneous bleeds
  v. Bleeding sites atypical of congenital hemophilia
  vi. Presence of underlying diseases and conditions
  vii. No personal or family history of bleeding
  viii. High mortality with both early and late deaths: estimated at between 9% and 22%
  ix. Prolonged aPTT (activated partial thromboplastin time) with a normal prothrombin time (PT)
  x. Mixing test: failure of normal plasma to correct the aPTT by more than 50% is usually taken as evidence that an inhibitor is present (Kasper 1991)

c. Other bleeding disorders with normal factor VIII clotting activity
  i. Hemophilia B
    a) An X-linked recessive disorder caused by mutations in the factor IX (FIX) gene
    b) Clinically indistinguishable from hemophilia A
    c) Diagnosis based on factor IX clotting activity of <30%
  ii. Factor XI deficiency
    a) An autosomal recessive disorder
    b) Homozygotes with factor XI coagulant activity of <1–15%
    c) Heterozygotes with factor XI coagulant activity of 25–75%
  iii. Factor XII, prekallekrein, or high-molecular-weight-kininogen deficiencies
    a) Do not cause clinical bleeding
    b) A prolonged PTT
  iv. Prothrombin (factor II) or factors V, X, or VII deficiencies
    a) Autosomal recessive disorders
    b) Clinical features: easy bruising and hematoma formation, epistaxis, menorrhagia, bleeding after trauma and surgery
    c) Diagnosis established by specific coagulation factor assays
  v. Fibrinogen disorders
    a) Afibrinogenemia: an autosomal recessive disorder characterized by prolonged bleeding from minor cuts due to the lack of fibrinogen to support platelet aggregation
    b) Hypofibrinogenemia: inherited either in an autosomal dominant or recessive fashion with mild to moderate bleeding symptoms or may be asymptomatic
    c) Dysfibrinogenemia: an autosomal dominant disorder with symptoms similar to hypofibrinogenemia
  vi. Factor XIII deficiency
    a) An autosomal recessive disorder
    b) Occurrence of umbilical stump bleeding in >80% of cases
    c) Intracranial bleeding occurring spontaneously or following minor trauma in 30% of cases
    d) Subcutaneous hematomas
    e) Muscle hematomas

f) Defective wound healing
g) Recurrent spontaneous abortion
h) Rare joint bleeding

vii. Platelet function disorders
a) General features: bleeding problems similar to thrombocytopenia (skin and mucous membrane bleeding, recurring epistaxis, gastrointestinal bleeding, menorrhagia, excessive bleeding during or immediately after trauma and surgery)
b) Bernard-Soulier syndrome: an autosomal recessive disorder involving the vWF receptor and platelet GPIb characterized by thrombocytopenia and large platelets
c) Glanzmann thrombasthenia: an autosomal recessive disorder involving the GPIIb-IIIa receptor necessary for platelet aggregation

Diagnostic Investigations

1. Coagulation screening test
   a. Prolonged partial thromboplastin time (PTT) in severe and moderately severe hemophilia A
   b. PTT often normal in mild hemophilia A
2. Coagulation factor assay for factor VIII clotting activity
   a. Normal range: 50–150%
   b. Low to low normal: above 35%
      i. Usually do not have bleeding
      ii. Bleeding can occur in association with mild von Willebrand disease
   c. Factor VIII clotting activity unreliable in the detection of carriers
   d. Diagnosis of hemophilia A established in patients with low FVIII clotting activity (<35%) in the presence of a normal von Willebrand factor (vWF) level
      i. Activity <1%: severe hemophilia A
      ii. Activity 1–5%: moderately severe hemophilia A
      iii. Activity 5–35%: mild hemophilia A
3. Hemophilia imaging (Maclachlan et al. 2009)
   a. Hemophilia arthropathies: radiography, ultrasound, MRI
   b. Intramuscular hemorrhage: MRI
   c. Soft tissue hemorrhage (pseudotumors): CT/MRI
   d. Intracranial hemorrhage: CT/MRI
   e. Complications secondary to administration of blood products (liver cirrhosis, liver failure, hepatocellular carcinoma): CT/MRI
4. Molecular genetic diagnosis (Brower and Thompson 2008)
   a. Targeted mutation analysis
      i. An *F8* intron 22-A gene inversion: accounts for nearly half of families with severe hemophilia A (Kaufman et al. 2006)
      ii. An F8 intron 1 gene inversion: accounts for 2–3% of severe hemophilia A
   b. Mutation scanning or sequence
      i. Seventy-five to ninety-eight percent mutation detection rate in individuals with hemophilia A who do not have one of the two common inversions
      ii. Gross gene alterations (including large deletions or insertions, frame shift and splice junction changes, and nonsense and missense mutations) of F8: account for approximately 50% of mutations detected in severe hemophilia A (Kemball-Cook et al. 1998; El-Maarri et al. 2005; Kaufman et al. 2006)
      iii. Missense mutations within the exons coding for the three A domains or the two C domains: account for most of the mutations detected in mild to moderately severe hemophilia A (Kemball-Cook et al. 1998; Kaufman et al. 2006)
   c. Deletion analysis
      i. Available clinically to detect exonic, multiexonic, or larger deletions in affected males
      ii. Also available for direct diagnosis in potential carrier females
   d. Indirect genetic linkage analysis (Ljung and Tedgård 2003)
      i. Using linked polymorphic markers (restriction fragment length polymorphisms, RFLP) to trace the inheritance of the hemophilia gene within a pedigree if mutation is not found
      ii. Limitation of linkage analysis
         a) Uninformative patterns of polymorphic markers
         b) Ethnic variation
         c) Linkage disequilibrium
         d) Need for participation of family members
         e) Not useful in sporadic families which constitute more than half of the hemophilia families

Genetic Counseling

1. Recurrence risk
   a. Obligatory carrier (Ljung and Tedgård 2003)
      i. A woman whose father has hemophilia
      ii. A woman who has given birth to two boys with hemophilia, excluding identical twins
      iii. A woman who has given birth to one son with hemophilia and a daughter who has a son with hemophilia
   b. Establish the genetic probability for carriership for women in a pedigree who are not genetic obligatory carriers based on:
      i. Pedigree data
      ii. Clotting factor (FVIII:C) analysis
   c. Patient's sib (sib of a male proband): risk to the sibs depending on the carrier status of the mother
      i. Mother is a carrier: a 50% risk of having a male sib with hemophilia A and a 50% risk of having a carrier female sib
      ii. Possibility of maternal germline mosaicism: a low recurrence risk of having a male sib with hemophilia A if the mother has a normal factor VIII clotting activity and no evidence of her carrying her son's FVIII disease-causing mutation in her leukocytes, unless she has germline mosaicism
   d. Patient's offspring
      i. No sons will inherit the mutant allele and therefore will not be affected with hemophilia A
      ii. All daughters will be carriers for hemophilia A
2. Prenatal diagnosis available to pregnancies of carrier women with hemophilia A
   a. Fetal karyotyping to determine male fetus (46,XY)
   b. DNA extracted from fetal cells by amniocentesis or CVS analyzed for:
      i. The known FVIII disease-causing mutation
      ii. The informative linked polymorphic markers
   c. Fetal blood sample obtained by percutaneous umbilical blood sampling (PUBS) for assay of factor VIII clotting activity if the disease-causing FVIII mutation is not known and if linkage testing is not informative
   d. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified in an affected family member
3. Management
   a. Prophylactic treatment using plasma-derived concentrate of coagulation factor in the past (Mannucci 2003)
      i. Preventing majority of bleeding episodes
      ii. Minimizing the impact of arthropathy
      iii. Complications
         a) Concentrates manufactured from plasma, pooled from thousands of donors, invariably contaminated with blood-borne viruses that caused posttransfusion hepatitis B and non-A non-B (hepatitis C) in practically all treated hemophiliacs
         b) Optimistic perception of hemophilia: benefits of concentrates seemed to outweigh hepatitis risks
         c) Tragedy: 60–80% of persons with severe hemophilia became infected with the human immunodeficiency virus (HIV) with contaminated concentrates in the early 1980s
   b. Infusion of plasma-derived or recombinant FVIII (Helixate, Kogenate, Recombinate, ReFacto) (Bhattacharyya et al. 2003; Vandendriessche et al. 2003)
      i. Markedly improves both the life expectancy and the quality of life of patients suffering from hemophilia A
      ii. Still at risk for life-threatening bleeding episodes and chronic joint damage
      iii. Side effect of clotting factor substitution therapy: develop neutralizing antibodies against FVIII, rendering further substitution ineffective (10–40% of cases)
   c. Promising new recombinant factor VIII products are in advanced stages of clinical trials, and studies are underway to address how to optimally use current resources to improve quality of life for individuals with severe hemophilia A (Powell 2009)
   d. Orthopedic management (Rodriguez-Merchan 2008)
      i. Hemarthrosis: arthrocentesis
      ii. Synovitis: synoviorthesis and synovectomy
      iii. Flexion contractures
         a) Tendon-lengthening procedures
         b) Supracondylar osteotomy to correct a fixed-knee contracture
         c) Implantation of an external fixator

iv. Hemophilic arthropathy
  a) Subchondral bone cysts: cheilectomy and curettage
  b) Alignment osteotomy
  c) Joint debridement
  d) Arthrodesis
  e) Joint prosthesis
  f) Total knee arthroplasty
  g) Total hip arthroplasty
v. Intramuscular hematomas: usually reabsorb without complication when hematological treatment is adequate
  a) Iliopsoas hematoma
  b) Compartment syndrome (fasciotomy)
  c) Pseudotumors
vi. Orthopedic surgery in patients with inhibitors: contemporary orthopedic and hematological advances such as recombinant activated factor VII (rFVIIa; NovoSeven®, Novo Nordisk, Bagsværd, Denmark) and activated prothrombin complex concentrates (aPCC; FEIBA, Baxter Corp, Deerfield, IL) enable major orthopedic operations to be performed on hemophilia patients with inhibitors, despite these patients having a higher risk of bleeding complications than patients with hemophilia who do not have inhibitors (Rodriguez-Merchan et al. 2007)

e. Obstetrical issues
  i. Asymptomatic carrier
    a) Uncommon intracranial hemorrhage in affected male fetuses (1–2%)
    b) Cesarean section reserved for complicated deliveries
  ii. Symptomatic carrier (baseline factor VIII clotting activity <35%)
    a) Somewhat protected by the natural rise of factor VIII clotting activity during pregnancy
    b) Delayed postpartum bleeding when factor VIII clotting activity returns to baseline within 48 h

f. Neonatal issues
  i. Early determination of the genetic status of male infants at risk
    a) Assay factor VIII clotting activity from a cord blood sample obtained by venipuncture of the umbilical vein
    b) Molecular genetic testing for the FVIII mutation identified in the family
  ii. Avoid circumcision in infants with a family history of hemophilia A, unless:
    a) Hemophilia A is excluded or
    b) Factor VIII concentrate is administered just prior and subsequent to the procedure to prevent delayed oozing and poor wound healing

g. Analysis of patients's DNA
  i. Permits identification of the gene lesions that cause hemophilia
  ii. Allows the disease to be controlled through carrier detection and prenatal diagnosis

h. Future gene therapy (Vandendriessche et al. 2003)
  i. Providing a cure for the disease
  ii. Providing constant, sustained FVIII synthesis in the patient
    a) Obviate the risk of spontaneous bleeding
    b) Obviate the need for repeated FVIII infusions
    c) Obviate the risk of viral infections associated with plasma-derived FVIII
  iii. Requires the use of a gene delivery system that is efficient, safe, nonimmunogenic, and allows for long-term gene expression
  iv. Must compare favorably with existing protein replacement therapies
  v. Initiation of several gene therapy phase I clinical trials in patients suffering from severe hemophilia A
    a) Fewer bleeding episodes reported in some patients
    b) Occasional detection of low levels of clotting factor activity

Fig. 2 An infant boy with hemophilia A who was found to have low factor VIII activity. The mother and maternal grandmother had histories of nosebleeds and prolonged bleeding after small cuts and bruise easily

Fig. 3 A 30-year-old man with hemophilia B

Hereditary Hearing Loss

Hearing loss can be divided into conductive, sensorineural, mixed, and central types (Gifford et al. 2009). Conductive hearing loss (CHL) results from interference with the mechanical transmission of sound through the external and middle ear. Sensorineural hearing loss (SNHL) results from a failure to transduce vibrations to neural impulses effectively within the cochlea or transmit these impulses down the vestibulocochlear nerve. Mixed hearing loss involves a combination of CHL and SNHL, usually due to damage throughout the middle ear and the inner ear. Central hearing loss refers to defects in the brainstem or higher processing centers of the brain. Both CHL and SNHL may be caused by a wide variety of congenital/hereditary and acquired factors.

Understanding genetic basis of hearing loss is important because almost 50% of profound hearing loss (affecting almost 1 in 1,000 newborns) is caused by genetic factors and more than 120 independent genes have been identified (Bayazit and Yilmaz 2006).

Genetics/Basic Defects

1. Causes of conductive hearing loss (Bayazit and Yilmaz 2006; Gifford et al. 2009; Hilgert et al. 2009)
   a. Congenital
      i. Microtia/atresia
      ii. Tympanic membrane abnormalities
      iii. Ossicular malformations
   b. Acquired
      i. Infections
         a) Acute otitis media
         b) Otitis externa
         c) Ossicular erosion
      ii. Otitis media with effusion
      iii. Foreign body including cerumen
      iv. Cholesteatoma
      v. Trauma
         a) Ossicular disruption
         b) Tympanic membrane perforation
2. Nonhereditary causes of sensorineural hearing loss (SNHL)
   a. In utero infections
      i. Cytomegalovirus: the most common environmental (nongenetic) cause of congenital hearing loss
      ii. Measles
      iii. Mumps
      iv. Rubella
      v. Varicella
      vi. Syphilis
   b. Anatomic abnormalities of the cochlea or temporal bone
   c. Exposure to ototoxic drugs during pregnancy
      i. Alcohol
      ii. Isotretinoin
      iii. Cisplatinum
   d. Hyperbilirubinemia
   e. Infections
   f. Trauma
      i. Physical
      ii. Acoustic
   g. Radiation therapy for head and neck tumors
3. Hereditary hearing loss: mutations and polymorphisms
   a. Recessive gene mutations
      i. Homozygosity
         a) Same mutation is present in both alleles

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_115,
© Springer Science+Business Media, LLC 2012

b) Having two identical alleles as a specific autosomal (or X chromosome in a female) gene locus
c) Can cause hearing impairment

ii. Heterozygosity
a) Having two different alleles as a specific autosomal (or X chromosome in a female) gene locus
b) "Compound heterozygote": both alleles have different disease-causing mutations; can cause hearing impairment
c) "Carrier": only one of the alleles has the disease-causing mutation and the other allele is normal; does not have hearing impairment

b. Dominant gene mutations
i. Presence of a mutation in only one of the alleles: enough for the individual to have the disease
ii. Penetrance in the dominant gene
a) Likelihood that a person carrying a particular mutant gene will have an altered phenotype
b) May differ in different individuals
c) Presence of a dominant mutation in the parents does not always mean that the siblings will always have hearing impairment
iii. Expression of a disease-causing gene
a) May cause differences in the phenotype
b) Expression may be one of the reason why the same genotype or mutations are manifested by different phenotypes in genetic hearing loss

c. Genetic polymorphism
i. Most polymorphisms have no detectable clinical effects
ii. If one of the alleles is mutated and the other allele has a polymorphism, the individual will probably not have hearing impairment

4. Genetic nonsyndromic hearing loss (NSHL): to date, there are 46 nonsyndromic deafness genes reported in the literature (Hilgert et al. 2009)
a. Autosomal dominant NSHL
i. Constitutes 18% of NSHL
ii. Affects almost 50% of the siblings
iii. Usually postlingual hearing loss except for DFNA3, DFNA6, DFNA8, DFNA12, DFNA19 and DFNA14
iv. *WFS1* gene mutations cause:
a) Autosomal dominant low-frequency SNHL
b) Wolfram syndrome (hearing loss, diabetes mellitus, diabetes insipidus, and optic atrophy)
v. *KCNQ4* gene mutations
a) Frequent cause of autosomal dominant NSHL
b) Missense mutations cause hearing loss beginning at a young age and affecting all frequencies
c) Deletion mutations cause a milder phenotype with later onset and affecting only the high frequencies
d) W276S mutation in *KCNQ4*: may be a mutational "hot spot" (van Camp et al. 2002)
vi. *COCH* gene mutations
a) Frequent mutations: P51S in Belgium and the Netherlands
b) Cause progressive hearing loss and vestibular impairment with late onset
vii. Dominant mutations in *GJB2* cause:
a) Autosomal dominant NSHL
b) Syndromic hearing loss associated with diverse skin disorders (include diffused palmoplantar keratoderma-hyperkeratosis, Vohwinkel syndrome and keratitis-ichthyosis-deafness [KID] syndrome) (Richard et al. 2002; de Zwart-Storm et al. 2008)
viii. *TECTA* gene mutations cause autosomal dominant mid-frequency HL and high-frequency HL

b. Autosomal recessive NSHL
i. Constitutes 80% of all NSHL cases
ii. Usually prelingual and severe hearing loss except for DFNB8 in which hearing loss is postlingual and rapidly progressive
iii. Affects almost 25% of siblings
iv. DFNB1 (Kelsell et al. 1997; Denoyelle et al. 1999): caused by a mutation in the *GJB2* gene on chromosome 13q12-13 that codes for a gap junction protein called connexin 26
a) *GJB2* mutations: the most frequent cause of autosomal recessive nonsyndromic

hearing loss in most world populations, frequent in the Caucasian, Jewish, and Asian populations (Morell et al. 1998; Abe et al. 2000)
b) 35delG mutation: most frequent in the majority of Caucasian populations and may account for up to 70% of all *GJB2* mutations (Snoeckx et al. 2005)
v. *SLC26A4* gene mutations
a) The second most frequent cause of autosomal NSHL
b) Associated phenotypic spectrum: ranges from Pendred syndrome at one extreme to isolated NSHL with enlarged vestibular aqueduct at the other (DFNB4 locus)
vi. *MYO15A* gene mutations
a) Cause congenital severe-to-profound hearing loss at the DFNB3 locus
b) All 28 identified mutations have been found by linkage analysis in consanguineous families, most of which originate from Pakistan
vii. *OTOF* gene mutations
a) Cause prelingual, profound autosomal recessive NSHL
b) Suggest as the major cause of auditory neuropathy
viii. *CDH23* gene mutations: cause both Usher syndrome type 1D and moderate-to-profound progressive autosomal recessive NSHL at the DFNB12 locus
ix. *TMC1* gene mutations
a) One of the more frequent causes of autosomal recessive NSHL in consanguineous populations
b) Characterized by prelingual severe-to-profound hearing loss

c. X-linked recessive NSHL
i. Constitutes 1–3% of all NSHL cases
ii. Usually prelingual hearing loss except for DFN6
iii. Frequently affects boys
iv. DFN2 and DFN4: mostly cause severe prelingual sensorineural hearing loss
v. *POU3F4* gene (at locus DFN3) mutations
a) Cause X-linked mixed or purely sensorineural HL
b) May be associated with Mondini dysplasia, cochlear hypoplasia and/or stapes fixation

d. Mitochondrial hearing loss
i. Mutations in mitochondrial genes: the majority are the cause of a broad spectrum of maternally inherited multisystem disorders
ii. A subset of genes causes NSHL by a currently unknown mechanism
a) *MT-RNR1*
b) *MT-TS1*

5. Genetic syndromic hearing loss
a. Usher syndrome
i. The most common cause of autosomal recessive syndromic hearing loss (Smith et al. 1994)
ii. Affects almost 50% of the blind and deaf people in the USA
iii. Mutations
a) USH1A-G
b) USH2A-C
c) USH3

b. Pendred syndrome
i. Almost 50% of families with *SLC26A4* (PDS) gene mutation on chromosome 7q21-q34
ii. The same mutation can also cause DFNB4 (Li et al. 1998)

c. Jervell and Lange-Nielsen syndrome: mutations in the following potassium channel genes
i. JLNS1 locus in the *KVLQT1* gene located on chromosome 11p15.5
ii. JLNS2 locus in the *KCNE1* (*IsK*) gene located on chromosome 21q22.2

d. Biotinidase deficiency: resulting from deficiency of an enzyme required for the normal recycling of the vitamin biotin

e. Waardenburg syndrome (WS): has four subgroups (Van Camp and Smith 2010)
i. Type I: *PAX3* on 2q35
ii. Type II: *MITF* on 3p14.1-p12.3; *SLUG* on 8q11
iii. Type III: *PAX3* on 2q35
iv. Type IV: *EDNRB* on 13q22; *EDN3* on 20q13.2-q13.3; *SOX10* on 22q13

f. Branchio-oto-renal (BOR) syndrome
i. *EYA1* gene mutation on chromosome 8q13.3 (in 50% of patients)
ii. Mutations on chromosome 1q31 may also cause this syndrome (Abdelhak et al. 1997)

g. Stickler syndrome
   i. The STL1 locus in the *COL2A1* gene located on chromosome 12q13.11-q13.2 is responsible for type 1
   ii. The STL2 locus in the *COL11A1* gene located on chromosome 1p21 is responsible for type 2
   iii. The STL3 locus in the *COL11A2* gene located on chromosome 6p21.3 is responsible for type 3
h. Treacher-Collins syndrome (TCOF): caused by *TCOF1* gene mutation on chromosome 5q32-q33.1
i. Alport syndrome
   i. X-linked (85%): *COL4A5* gene (Xq22) mutation is responsible
   ii. *COL4A3* and *COL4A4* (on 2q36-q37) mutation: responsive for the autosomal recessive and autosomal dominant types
      a) Autosomal recessive (15%)
      b) Autosomal dominant (rare)
j. Norrie disease
   i. Caused by *Norrin* gene mutation on Xp11.3
   ii. *Norrin* gene is considered to control vascularization in the cochlea and retina

6. Mitochondrial hearing loss
   a. Constitutes <1% of all HHL cases
   b. Only maternal DNA is transmitted to the child while paternal DNA is not
   c. All children are at risk of having hearing impairment when the mitochondrion of the mother possesses a disease-causing mutation
7. Heterogeneity of genetic hearing loss
   a. Genetic hearing loss: a heterogeneous condition although it is mostly caused by a mutation in a single gene (Hardisty et al. 1999)
   b. Syndromic, nonsyndromic, recessive, or dominant hearing loss may be caused by the same mutation in a single gene
   c. Recessive or dominant NSHL can be caused by connexin 26, connexin 31, and *MYO7A* mutations
   d. *COL11A2*, PDS, *MYO7A*, and connexin 26 mutations can cause syndromic or nonsyndromic hearing loss (De Leenheer et al. 2001; Tamagawa et al. 2002)

Clinical Features

1. Usher syndrome (Bayazit and Yilmaz 2006)
   a. The most common cause of autosomal recessive syndromic hearing loss (Smith et al. 1994)
   b. Almost 50% of the blind and deaf people in the USA have this syndrome
   c. Type 1
      i. Severe hearing loss and vestibular dysfunction
      ii. Retinitis pigmentosa (a progressive degeneration of the retina leading to loss of night vision, restriction of the visual fields, and blindness) starting in childhood
   d. Type 2
      i. Mild to moderate hearing loss
      ii. Normal vestibular function
      iii. Retinitis pigmentosa occurring after childhood
   e. Type 3
      i. Progressive hearing loss and vestibular dysfunction
      ii. Retinitis pigmentosa occurring any time in life
2. Pendred syndrome (Reardon et al. 1997)
   a. Severe congenital sensorineural hearing loss
   b. Euthyroid goiter
      i. Due to a specific defect in the organification of iodine
      ii. Can be demonstrated by the perchlorate test
   c. Labyrinthine bone abnormality like Mondini dysplasia seen in 86% of cases
   d. Vestibular dysfunction can occur
   e. Onset may be delayed and clinically unapparent
   f. Rarely associated with hypothyroidism
3. Jervell and Lange-Nielsen syndrome (Splawski et al. 1997)
   a. Congenital hearing loss
   b. Elongation of the QT interval on electrocochleography (QT > 440 ms)
   c. Syncope and sudden death due to a cardiac problem
4. Biotinidase deficiency: clinical manifestations within the first few months of life if untreated
   a. Skin rashes
   b. Seizures

c. Hair loss
d. Hypotonia
e. Vomiting
f. Acidosis
g. Seventy five percent of the affected infants develop hearing loss if untreated
h. Biotinidase deficiency is a completely preventable form of genetic deafness with supplementation of biotin

5. Waardenburg syndrome
   a. Sensorineural hearing loss
      i. Accounts for 1–2% of individuals with profound hearing loss
      ii. Can be bilateral or unilateral of varying severity
   b. Pigmentation abnormality in the skin and hair
   c. White forelock
   d. Dystrophia canthorum (lateral displacement of the inner canthi of the eyes)
   e. Pinched nose
   f. Heterochromia iridis (different iris colors)
   g. Gastrointestinal features
      i. Constipation
      ii. Hirschsprung disease
   h. Neural tube and limb defects
6. Branchio-oto-renal (BOR) Syndrome
   a. Conductive, sensorineural, or mixed hearing loss
      i. Some degree of hearing loss in almost 80% of gene carriers
      ii. Can be delayed in onset
   b. Branchial cleft cyst
   c. Auricle or external auditory canal abnormality
   d. Preauricular pits
   e. Renal abnormalities
      i. Renal dysplasia
      ii. Polycystic kidney
      iii. Malformation of the calyces
   f. Inner ear abnormalities
      i. Mondini dysplasia
      ii. Stapes fixation
7. Stickler syndrome
   a. Progressive sensorineural hearing loss
   b. Cleft palate
   c. Abnormal development of the epiphysis
   d. Vertebral abnormalities
   e. Osteoarthritis
8. Treacher-Collins syndrome
   a. Hearing loss
      i. Conductive in 55% of cases
      ii. Sensorineural hearing loss usually occurs at high frequencies
   b. Symmetric and hypoplastic zygoma
   c. Lower palpebral fissure
   d. Malformed and small ear
   e. Auditory pit
9. Alport syndrome
   a. Progressive bilateral hearing loss
      i. In almost 50% of cases
      ii. Usually begins in the second decade
      iii. Initially involves high-frequency hearing loss
   b. Renal disorder
      i. Glomerulonephritis
      ii. Hematuria
      iii. Renal failure
   c. Ocular abnormalities
      i. Cataract
      ii. Spherophakia
      iii. Retinal flecks
      iv. Anterior lenticonus
10. Norrie disease
    a. Progressive sensorineural hearing loss
    b. Eye disorders
       i. Pseudotumor
       ii. Retinal lesions
          a) Hyperplasia
          b) Hypoplasia
          c) Necrosis
       iii. Cataract
    c. Mental retardation
11. Mitochondrial mutations causing syndromic hearing loss may be associated with:
    a. Diabetes mellitus
    b. Neurologic disorder
    c. Progressive myoclonic epilepsy
    d. Ataxia
    e. External ophthalmoplegia
    f. Retinopathy
    g. Arrhythmia
12. Mitochondrial mutations causing nonsyndromic hearing loss may be associated with:
    a. Palmoplantar keratoderma
    b. Neurologic disorder

Diagnostic Investigations

1. Obtain family history (ACMG Statement 2002; Smith et al. 2010; Gifford et al. 2009)
   a. Pedigree
      i. Consanguinity
      ii. Paternity
      iii. Hearing status of the parents and siblings
   b. Ethnicity and country of origin
   c. Inheritance pattern of hearing loss
      i. Autosomal dominant
      ii. Autosomal recessive
      iii. X-linked
      iv. Mitochondrial
   d. Audiometric characteristics in any deaf and hearing-impaired family members
      i. Age of onset
      ii. Progression
      iii. Conductive hearing loss
      iv. Nonsyndromic hearing loss
      v. Auditory neuropathy
   e. Evidence of vestibular dysfunction
   f. Syndromic versus nonsyndromic features
2. Evaluate and inquire the following conditions in the patient and/or relatives:
   a. Visual anomalies
      i. Heterochromia iridis
      ii. Retinitis pigmentosa
      iii. Myopia
      iv. Retinal detachment
      v. Early cataracts
   b. Facial/cervical dysmorphology
      i. Synophrys
      ii. Dystopia canthorum
      iii. Preauricular pits
      iv. Aural atresia
      v. Branchial cysts
      vi. Cleft palate
      vii. Dental anomalies
   c. Endocrine abnormalities
      i. Thyromegaly
      ii. Diabetes
   d. Cardiac signs and symptoms
      i. Syncope
      ii. Sudden death
      iii. Arrhythmia
      iv. Prolonged QT interval
      v. Fainting spells
      vi. Congenital heart defect
   e. Renal abnormalities
      i. Hematuria
      ii. Proteinuria
      iii. Structural defects
   f. Integumentary changes
      i. Premature graying
      ii. White forelock
      iii. Abnormal pigmentation
      iv. Dry skin/keratoderma
3. Obtain patient history with respect to specific risk factors
   a. Intrauterine infections such as:
      i. Toxoplasmosis
      ii. Rubella
      iii. CMV
      iv. Herpes simplex
   b. Meningitis
   c. Extracorporeal membrane oxygenation (ECMO)
   d. History of hypoxia
   e. Prenatal alcohol exposure
   f. Exposure to ototoxic drugs
4. Perform physical examination
   a. Otologic examination
   b. Airway examination
   c. Documentation of dysmorphisms
   d. Neurologic evaluation including assessment of vestibular function in older patients
5. Laboratory tests/imagings (Grundfast et al. 2000; Parving 2007; Martini et al. 2009)
   a. Viral antibodies
      i. Rubella
      ii. CMV
      iii. HIV
      iv. Others
   b. Bacterial antibodies
      i. Syphilis
      ii. Toxoplasmosis
      iii. Others
   c. Thyroid studies for suspected Pendred syndrome
      i. TSH
      ii. T3
      iii. T4
      iv. Perchlorate test
   d. Urine analysis
      i. A positive proteinuria or hematuria can reflect Alport syndrome

ii. Viral cultural isolation
iii. Measurement of electrolyte levels
e. Electrocardiogram for suspected Jervell and Lange-Nielsen syndrome
f. Ophthalmologic examination including electroretinography and slit-lamp examination
g. Renal and cardiac ultrasonography
h. Radiographic testing
i. Bilateral acoustic neuromas: frequently detected radiographically in NF2
ii. Temporal Bone CT scan
a) Can help visualize cochlear abnormalities such as the Mondini deformity in Pendred (enlarged vestibular aqueduct) and Waardenburg syndrome
b) Can detect internal auditory canal aberrations associated with X-linked mixed hearing loss with stapes gusher and might reveal cochlear dysplasia
iii. MR imaging
a) With gadolinium enhancement: the study of choice in patients with a family history of NF2
b) Used when the hearing loss is progressive but the CT scan is normal
i. Cytogenetic testing: FISH for velocardiofacial/DiGeorge syndrome
j. Array CGH
k. Mutation analysis
i. Connexins
a) *GBJ2*
b) *GBJ6*
ii. Other relevant genes such as:
a) *WFS1*
b) *SLC26A4*

6. Universal newborn hearing screening
a. Evoked otoacoustic emission (OAE) testing: detects the evoked sound from the cochlea in response to clicks or tones
b. Auditory brain stem response (ABR, also known as BAER or BSER)
i. Measures the electroencephalographic waveform response from the vestibulocochlear nerve
ii. Has potential of detecting the following hearing losses:
a) Hearing loss due to auditory neuropathy, a condition to which the newborn intensive care unit population is particularly prone
b) Hearing loss resulting from middle and inner ear disorders
c. Combination of OAE and ABR

7. Other hearing tests to diagnosis and characterization of hearing loss
a. Tympanometry
i. External ear canal of individuals (except newborn) is sealed with probe tip
ii. Measure sound reflection by tympanic membrane while ear canal pressure is varied
iii. An effective assessment of middle ear pressure and function
b. Audiometry
i. Behavioral observation audiometry
a) Infant in a soundproof room is presented with warbled pure-tones, speech, or white and narrow-band noise through loudspeakers
b) Observe responses such as the auropalpebral reflex, startle responses, and head turning
ii. Visual reinforcement audiometry: child is seated between two speakers and conditioned to look toward the active speaker
iii. Play audiometry
a) Tones of varying frequencies are delivered through headphones or a bone vibrator
b) Child is conditioned to perform play activities, such as dropping a block or placing a peg in a board
iv. Conventional audiometry
a) Tones of varying frequencies are delivered through headphones or a bone vibrator
b) Child is instructed to raise a hand or push a button when a tone is heard
v. Pure-tone audiometry (air and bone conduction): involves determination of the lowest intensity at which an individual "hears" a pure tone
vi. Air conduction audiometry
a) Presents sounds through earphones
b) Threshold depends on the condition of the external ear canal, middle ear, and inner ear

vii. Bone conduction audiometry
  a) Presents sounds through a vibrator placed on the mastoid bone or forehead, thus bypassing the external and middle ears
  b) Thresholds depend on the condition of the inner ear
viii. Conditioned play audiometry
  a) Used to test children from age 2.5–5 years
  b) A complete frequency-specific audiogram for each ear can be obtained from a cooperative child
ix. Audioprofile
  a) Recording of several audiograms on a single graph
  b) These audiograms may be from one individual at different times, but more frequently they are from different members of the same family segregating deafness usually in an autosomal dominant fashion
  c) By plotting numerous audiograms with age on the same graph, the age-related progression of hearing loss can be appreciated within these families
  d) Often the composite picture is characteristic of specific genetic causes of autosomal dominant nonsyndromic hearing loss
  e) One of the most characteristic audioprofiles is associated with DFNA6/14/38 hearing loss caused by mutations in *WFS1*

8. Degree and effects of hearing loss (Bachmann and Arvedson 1998; Gifford et al. 2009)
  a. Normal hearing (no hearing loss) (0–15 dB loss): can detect all aspects of speech
  b. Minimal hearing loss (16–25 dB loss)
    i. May miss up to 10% of speech
    ii. May respond inappropriately
  c. Mild hearing loss (26–40 dB loss)
    i. May miss up to 50% of speech
    ii. May be labeled as "behavior problem" and "poor listener"
  d. Moderate hearing loss (41–55 dB loss)
    i. May miss 50–100% of speech
    ii. Speech quality likely to be poor
    iii. Limited vocabulary
    iv. Low self-esteem possible
  e. Moderate to severe hearing loss (56–70 dB loss)
    i. 100% of normal volume speech lost
    ii. Delayed speech and poor intelligibility
    iii. Social isolation likely
  f. Severe hearing loss (71–90 dB loss)
    i. Loud voices only heard within 12 in. of ear
    ii. Delayed speech and language if loss is prelingual
    iii. Declining speech abilities and atonal voice if loss is postlingual
  g. Profound hearing loss (>90 dB loss)
    i. Sound vibrations felt rather than heard
    ii. Visual cues primary for communication
    iii. Peer group of hearing-impaired children preferred
9. Triage/testing and triage paradigm (ACMG Statement 2002)
  a. If a form of syndromic deafness is suspected: perform gene-specific mutation screening
  b. If nonsyndromic deafness is suspected and the patient is a simplex case:
    i. CMV testing should be performed
      a) A negative test for CMV antibodies in early infancy may exclude CMV-related hearing loss
      b) A positive result must be interpreted with caution
    ii. *GJB2* (connexin 26) mutation screening by sequence analysis
      a) A negative test result does not exclude a genetic etiology
      b) A positive test result may make it possible to avoid other expensive and potentially invasive tests
  c. If nonsyndromic deafness is suspected and the patient is a multiplex case with other hearing impaired first-degree relatives: proceed directly to connexin 26 testing
  d. If nonsyndromic deafness is suspected and the pedigree suggests dominant inheritance: connexin-related deafness is not excluded and gene-specific mutation screening for other loci may be available
  e. If nonsyndromic deafness is suspected and the pedigree suggests mitochondrial DNA inheritance: testing for the A1555G mutation (associated with aminoglycoside-induced hearing loss) and the A7445G mutation, both of which are associated with some rare familial

cases of hearing loss, may be appropriate after common *GJB2* mutations are excluded

f. If nonsyndromic deafness is suspected and both parents are deaf:
   i. Connexin-related deafness will be strongly suspected (since mutations in *GJB2* are the most common cause of deafness in the United States and the vast majority of marriages between deaf individuals who produce deaf offspring are between individuals with *GJB2* mutations)
   ii. Possible to ascribe a genetic etiology to the hearing loss in many persons after triage/testing:
      a) For example, a child may be diagnosed with *GJB2*-related deafness
      b) If two clearly pathologic alleles are found, the cause of that child's deafness will be known with virtual certainty and can accurately predict the chance of recurrence in a subsequent child
   iii. Alternatively, mutation screening may be negative:
      a) A negative mutation screen must not be taken to mean that the deafness is not genetic: important to be conveyed to parents of deaf children who undergo genetic testing (Brunger et al. 2000)
      b) The probability that the deafness is genetic in patients with an unremarkable family history of deafness and a negative test result for connexin 26 will vary based on the number of hearing siblings. The proportional distribution of the different mutations in the connexin 26 locus also varies in different ethnic groups (Kenneson et al. 2002)

Genetic Counseling

1. Recurrence risk (Smith et al. 2010)
   a. Patient's sib
      i. Autosomal dominant hereditary hearing loss
         a) A 50% risk of inheriting the mutant allele if one of the proband's parents has a mutant allele
         b) Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable
      ii. Autosomal recessive hereditary hearing loss
         a) A 25% risk of being deaf
         b) A 50% risk of having normal hearing and being a carrier
         c) A 25% risk of having normal hearing and not being a carrier
         d) Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable
         e) For siblings with the identical *GJB2* genotype as the probands with severe-to-profound deafness: a 91% risk of having severe-to-profound deafness and a 9% risk of having mild-to-moderate deafness
         f) For siblings with the identical *GJB2* genotype as the proband with mild-to-moderate deafness: a 66% risk of having mild-to-moderate deafness and a 34% risk of having severe-to-profound deafness
      iii. X-linked hereditary hearing loss
         a) A carrier mother has a 50% risk of transmitting the deafness-causing mutation with each pregnancy: sons who inherit the mutation will be deaf; daughters who inherit the mutation are carriers and likely to have normal hearing
         b) A non-carrier mother: the risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism
         c) Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable
      iv. Mitochondrial disorders with hearing loss as a possible feature
         a) The risk to the sibs depends on the genetic status of the mother: the mother of a proband usually has the

mitochondrial mutation and may or may not have symptoms (note that the father is not at risk of having the disease-causing mtDNA mutation)
b) If the mother has the mitochondrial mutation, all sibs are at risk of inheriting it

b. Patient's offspring
i. Autosomal dominant hereditary hearing loss
a) A 50% risk of transmitting the mutant allele to each child
b) In case of an apparent de novo mutation in the proband (neither parent of a proband with an autosomal dominant condition has the deafness-causing mutation or clinical evidence of the disorder), explore possible nonmedical explanations (alternate paternity or maternity such as with assisted reproduction or undisclosed adoption)
c) Clinical severity and disease phenotype may differ between individuals with the same mutation, depending on the specific syndrome; thus, age of onset and/or disease progression may not be predictable
ii. Autosomal recessive hereditary hearing loss: all of the offspring are obligate carriers
iii. X-linked hereditary hearing loss: males with X-linked hereditary hearing loss will pass the deafness-causing mutation to all of their daughters and none of their sons
iv. Mitochondrial disorders with hearing loss as a possible feature
a) All offspring of females with an mtDNA mutation are at risk of inheriting the mutation
b) Offspring of males with a mtDNA mutation are not at risk

2. Prenatal diagnosis
a. Prenatal diagnosis for some forms of hereditary hearing loss is technically possible by analysis of DNA extracted from fetal cells obtained by:
i. Amniocentesis usually performed at approximately 15–18 weeks' gestation
ii. Chorionic villus sampling (CVS) at approximately 10–12 weeks' gestation
b. The deafness-causing allele(s) of a deaf family member must be identified before prenatal testing can be performed
c. Preimplantation genetic diagnosis (PGD): may be available for families in which the deafness-causing mutation(s) have been identified

3. Management
a. Multidisciplinary team consisting of:
i. An otolaryngologist
ii. An audiologist
iii. A clinical geneticist
iv. A pediatrician
v. An educator of the deaf
vi. A neurologist
vii. A pediatric ophthalmologist
b. Treatment
i. Determine the appropriate habilitation option such as:
a) Hearing aids
b) Vibrotactile devices
ii. Cochlear implantation: considered in children over age 12 months with severe-to-profound hearing loss
iii. Early auditory intervention through amplification, otologic surgery, or cochlear implantation is essential for optimal cognitive development in children with prelingual deafness

Hereditary Hemochromatosis

Hereditary hemochromatosis (HHC; *HFE* 1) is a common hereditary disorder of iron metabolism and the most common inherited autosomal recessive disorder in Caucasians with a prevalence of 1 in 300 to 1 in 500 individuals. It is characterized by inappropriately high iron absorption resulting in progressive iron overload.

Synonyms and Related Disorders

Hemochromatosis

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Cause: result of a single faulty *HFE* gene on chromosome 6p21.3 near the *HLA* complex that codes for a glycoprotein called HFE, which binds to the transferrin receptor and reduces its affinity for iron-bound transferrin, allowing cellular uptake of iron-based transferrin
3. Two common mutations (missense)
   a. C282Y.
      i. Accounts for most cases of HHC
      ii. Homozygotes for C282Y mutation (>80% cases world-wide) are at high risk for HHC.
      iii. Heterozygote for C282Y mutation.
         a) Have increased levels of transferrin saturation
         b) Rarely have organ damage
   b. H63D: Homozygotes for H63D (often has a potentiator, such as hepatitis C infection, β-thalassemia trait) are unlikely to develop HHC.
   c. C282Y/H63D (11% present phenotypically): Compound heterozygotes for C282Y/H63D have a milder form of HHC than C282Y homozygotes.
4. Other *HFE* mutations
   a. Missense mutations
      i. S65C: the third most common mutation
      ii. G93R
      iii. I105T
      iv. Q127H
      v. R330M
   b. Frameshift mutations
      i. P160ΔC
      ii. V68ΔT
   c. Nonsense mutations
   d. Spice site mutation
5. Clinical expression of the disease
   a. Homozygotes: affected clinically
   b. Heterozygotes
      i. Can have minor abnormalities of the parameters that reflect body iron status
      ii. Can develop significant iron overload only when other diseases that affect iron metabolism coexist, such as:
         a) Heterozygous β-thalassemia
         b) Hereditary spherocytosis
         c) Sporadic porphyria cutanea tarda
6. Hereditary hemochromatosis not attributable to mutations in *HFE*
   a. A subgroup of hereditary hemochromatosis indistinguishable from *HFE*-associated HHC
   b. Does not have mutations in *HFE*.
   c. The disease does not appear to be linked to the HLA complex.
   d. The genetic basis has not been defined.

7. Pathophysiology (Whittington and Kowdley, 2002)
   a. Inappropriately high intestinal iron absorption: the most important pathophysiological step in body iron loading
   b. Effects of mutations on iron absorption: central to the understanding of the pathological basis of hereditary hemochromatosis

Clinical Features

1. Variable clinical presentation
2. Median age at presentation of symptoms
   a. Fifty one years in males
   b. Female homozygotes
      i. Less likely to develop symptomatic disease
      ii. Median age: age 50
3. Asymptomatic: abnormal serum iron studies on routine screening
4. Early manifestations
   a. Often subtle
   b. Vague arthralgias
   c. Fatigue
   d. Lethargy
   e. Apathy
   f. Weight loss
5. Later manifestations as tissue iron progressively accumulates
   a. Discoloration of the skin
   b. Arthropathy
      i. Due to iron accumulation in joint tissues.
      ii. Arthritis with joint swelling most commonly involves:
         a) Metacarpophalangeal (MCP) joints
         b) Proximal interphalangeal joints
         c) Knees
         d) Feet
         e) Wrists
         f) Back
         g) Neck
      iii. Chondrocalcinosis.
         a) Involves the knees and wrists
         b) May be asymptomatic
      iv. Symptoms usually do not respond to iron removal.
   c. Liver involvement
      i. Abdominal pain associated with hepatomegaly
      ii. Hepatomegaly, the most common physical abnormality
      iii. Splenomegaly
      iv. Cirrhosis
      v. Portal hypertension
         a) Ascites
         b) Encephalopathy
      vi. Hepatocellular carcinoma in about 30% of cases
   d. Cardiac involvement
      i. Dilated cardiomyopathy
      ii. Arrhythmias
      iii. Cardiac failure
   e. Endocrine abnormalities
      i. Diabetes mellitus
      ii. Pituitary hypogonadism
         a) Decreased libido and impotence (testicular atrophy) in men
         b) Amenorrhea in women
      iii. Hypothyroidism
6. Suspect diagnosis from characteristic clinical manifestations
   a. Classical clinical triad of "bronzed cirrhosis with diabetes" in a middle-aged man:
      i. Diffuse hyperpigmentation (melanodermia), often with a metallic gray or "bronze" rather than a brown discoloration
      ii. Hepatomegaly, with the liver markedly enlarged, firm and sharp to palpation but without signs of hepatocellular insufficiency (no palmar erythema, no spider nevi, no bruises, normal prothrombin time) or of portal hypertension
      iii. Diabetes mellitus, often requiring insulin
   b. Presence of cardiomyopathy
   c. Diagnosis at this late stage: considered a diagnostic failure
7. Suspect diagnosis from earlier signs and symptoms
   a. Sex and age: Both young adults and older women are at risk.
   b. "Rule of three A's"
      i. Asthenia: unexplained chronic fatigue
      ii. Arthralgia
         a) A "painful" handshake: resulting from chronic arthritis of the second and third MCP joints.
         b) Other joints affected especially the knees and wrists.

c) Can also suffer from pseudogout (pyrophosphate arthropathy).
d) Arthritis greatly diminishes the quality of life.

iii. Aminotransferase (transaminases) elevation

8. Cause of death
   a. Liver failure
   b. Cancer
   c. Congestive heart failure
   d. Arrhythmia
9. Other conditions associated with significant iron overload
   a. Non-*HFE* hereditary hemochromatosis (Pietrangelo, 2010)
      i. Transferrin receptor 2 gene (*TFR2*, on 7q22) hemochromatosis
         a) Caucasian or non-Caucasian
         b) Male or female
         c) Thirty to forty years
         d) Cardiomyopathy
         e) Endocrinopathy
         f) Liver disease
         g) Elevated transferrin saturation (TS) and serum ferritin (SF)
      ii. Hemojuvelin (*HJV* on 1q21) or hepcidin gene (*HAMP*, on 19q13) juvenile hemochromatosis
         a) Caucasian or non-Caucasian
         b) Male or female
         c) Fifteen to twenty years
         d) Impotence/amenorrhea and/or cardiomegaly
         e) High TS and SF
      iii. Ferroportin disease (SLC40A1, on 2q32)
         a) Caucasian or non-Caucasian
         b) Male or female
         c) Ten to eighty years
         d) One patient with unexplained hyperferritinemia
         e) Unexplained elevation of SF and normal TS
   b. Secondary iron overload
      i. Iron-loading anemias (ineffective erythropoiesis, increased iron absorption, blood transfusions)
         a) β-thalassemia
         b) Congenital dyserythropoietic anemias
         c) Sideroblastic anemia
         d) Pyridoxine-responsive anemia
      ii. Hypoplastic anemias (blood transfusions)
         a) Aplastic anemia
         b) Myelodysplastic syndromes
         c) Pure red cell aplasia
      iii. Chronic hemolytic anemias (increased iron absorption)
         a) Spherocytosis
         b) Sickle cell anemia
         c) Pyruvate kinase deficiency
      iv. Parental iron overload
         a) Red blood cell transfusion
         b) Iron dextran injections
         c) Long-term hemolysis
      v. Neonatal hemochromatosis
      vi. Ceruloplasmin deficiency (aceruloplasminemia) (decreased ferroxidase activity)
      vii. Sub-Saharan iron overload (increased dietary iron, increased iron absorption)
      viii. Porphyria cutanea tarda (increased iron absorption)
      ix. Hepatic disorders
         a) Chronic viral hepatitis
         b) Alcoholic cirrhosis
         c) Portacaval shunts (increased iron absorption)

Diagnostic Investigations

1. Biochemical testing
   a. High serum ferritin levels
   b. High transferrin-iron saturation value: an early and reliable indicator for risk of iron overload/HFE-HHC
      i. A fasting transferrin-iron saturation of $\geq$60% for men and $\geq$50% for women on at least two occasions, in the absence of other known causes of elevated transferrin-iron saturation, is observed in about 80% of individuals with HFE-HHC and is considered suggestive of HFE-HHC.
      ii. A threshold transferrin-iron saturation of 45% is more sensitive for detecting HFE-HHC suggested by recent studies.
      iii. Some overlap occurs in serum transferrin-iron saturation among homozygotes and heterozygotes.

2. Radiography
   a. Arthropathy
      i. Squared-off bone ends and hook-like osteophytes in the MCP joints, particularly in the second and third MCP joints
      ii. Subchondral arthropathy
      iii. Chondrocalcinosis
3. MRI of the liver
   a. The most promising noninvasive technique for identification of HHC. High hepatic iron content causes:
      i. A decrease in signal intensity of the liver
      ii. A marked decrease in transverse (T_2) relaxation time
4. Liver biopsy to assess histologic hepatic iron stores
   a. Usually not indicated for diagnostic purposes in HFE-HHC.
   b. Recommended to C282Y homozygotes with a serum ferritin concentration of >1,000 ng/mL to determine if cirrhosis is present; those with a serum ferritin concentration <1,000 ng/mL need not undergo biopsy.
   c. Useful to determine hepatic iron overload, particularly in patients with presumed hemochromatosis who lack the common *HFE* mutations associated with HFE-HHC.
5. Molecular genetic testing (Kowdley et al. 2006)
   a. Mutation analysis for the disease-causing alleles in the *HFE* gene (C282Y and H63D)
      i. C282Y/C282Y homozygotes (60–90%)
      ii. C282Y/H63D compound heterozygotes (3–8%)
      iii. H63D/H63D homozygote (1%)
      iv. H63D/? (4%)
      v. C282Y/? (1%)
      vi. ?/? (6%)
   b. Testing strategy for a proband
      i. Mutation analysis warranted in adults with serum transferrin-ion saturation of >45%
      ii. Individuals with homozygous C282Y/C282Y or compound heterozygous C282Y/H63D: have genetic makeup to develop HFC-HHC
      iii. Individuals who are not C282Y homozygotes
         a) Generally represent a heterogeneous group.
         b) Many have liver disease unrelated to HFE-HHC or other metabolic syndromes.
         c) Some may have primary iron overload in a pattern identical to HFE-HHC.
         d) The next diagnostic step: perform liver biopsy with assessment of histology and measurement of hepatic iron concentration
   c. Carrier detection: identification of carriers and noncarriers in at-risk family members possible provided both *HFE* alleles have been identified in the proband
6. Screening for HHC
   a. HHC: a prime target for screening because of its high prevalence, morbidity, and mortality, as well as the benefits of early diagnosis and treatment
   b. Initial screening probe for HHC diagnosis
      i. Transferrin saturation
      ii. Unsaturated iron-binding capacity

Genetic Counseling

1. Recurrence risk (Kowdley et al. 2006)
   a. Patient's sib
      i. Twenty-five percent if both parents are HFE-HHC heterozygotes
      ii. Fifty percent if one parent is HFE-HHC heterozygotes and other parent HFE-HHC homozygote
   b. Patient's offspring: 5% risk to be affected due to the high carrier rate for *HFE* mutant alleles in the general population
      i. The risk that the partner of an individual with HFE-HHC is heterozygous for the C282Y allele is 1/9
      ii. Therefore, the risk to the offspring to be a homozygote for C282Y allele is $1/2 \times 1/9 = 1/18$ (about 5%)
2. Prenatal diagnosis
   a. Technically feasible when both parents carry identified *HFE* mutations
   b. Highly unusual to request prenatal diagnosis because HHC is an adult-onset, treatable disease
3. Management (Kowdley et al. 2006)
   a. Early diagnosis and treatment
      i. Can completely prevent the development of clinical complications
      ii. Offer patients a normal life expectancy

b. Treatment of iron overload
   i. Periodic phlebotomy
      a) Goal of therapy: to achieve and maintain a serum ferritin concentration of ≤50 ng/mL
      b) Usual therapy: removal of the excess iron by weekly phlebotomy until the serum ferritin concentration is ≤50 ng/mL
   ii. Dietary management
      a) Avoid medicinal iron
      b) Avoid mineral supplements
      c) Avoid excess vitamin C which increases intestinal absorption of inorganic iron
      d) Avoid uncooked shellfish or other seafood which can be contaminated with *V vulnificus* causing sepsis in patients with HHC
      e) Avoid alcohol consumption for patients with liver involvement
   iii. Iron chelation therapy: not recommended unless the patient has an elevated serum ferritin concentration and concomitant anemia that makes therapeutic phlebotomy impossible
c. Conventional therapies for diabetes, hepatic failure, and cardiac failure
d. Cirrhosis: screen for hepatocellular cancer
   i. Biannual abdominal ultrasound
   ii. Annual serum alpha-fetoprotein testing
e. Orthotopic liver transplantation for end-stage liver disease from decompensated cirrhosis
f. Surveillance of at-risk asymptomatic adults with C282Y homozygotes
   i. Monitor serum ferritin concentrations yearly starting in early adulthood
   ii. Initiate therapeutic phlebotomy when serum ferritin concentrations are elevated

Fig. 1 Father (40-year-old) and son (12-year-old) both carry heterozygous C282Y mutation. H63D and S65C were not detected. The father currently receives periodic phlebotomy with fasting transferrin-iron saturation level of 56% (15–50) and ferritin level of 1,238 ng/mL (20–345). The son is currently asymptomatic. Approximately 3–5% of patients with hereditary hemochromatosis have this genotype. The molecular results do not rule out the possibility of disease causing mutations in other regions of the *HFE* gene or in other as yet undefined genes

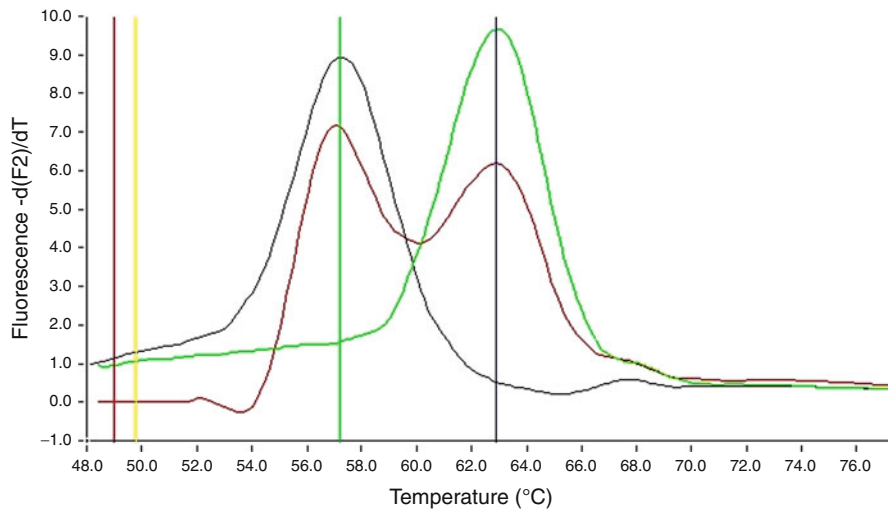

Fig. 2 Real-time PCR of HFE gene in another patient. The patient is homozygous for *C282Y* mutation, demonstrated by the green line (melting point (Tm) = 62.89)

Hereditary Multiple Exostoses

Hereditary multiple exostoses (HME) is a type of skeletal dysplasia characterized by osteochondral growths (osteochondromas) on the periphery of bones, comprised of bone surrounded by a cap of cartilage. The estimated prevalence is about 1 in 50,000 Caucasians (Schmale et al. 1994).

Synonyms and Related Disorders

Diaphysis aclasis; Hereditary multiple osteochondromas; Hereditary multiple osteochondromatosis; Multiple cartilaginous exostoses

Genetics/Basic Defects

1. Exostoses (Schmale et al. 1994)
   a. Result of dysplasia of the peripheral aspect of the growth plate
   b. The most common type of benign bone tumors
   c. Small exostoses may not be discovered because many do not cause symptoms
   d. Multiple lesions develop in individuals who have a hereditary type
2. Inheritance
   a. Autosomal dominant with nearly complete penetrance
   b. About 90% of patients have an affected parent.
   c. About 10% of patients result from a de novo gene mutation.
3. Genetic heterogeneity: Linkage analysis identified the following three genes associated with hereditary multiple exostoses:
   a. *EXT1* gene
      i. A ubiquitously expressed gene located on chromosome 8q24.1.
      ii. Normal gene product: exostosin 1.
      iii. Mutations in *EXT1* are responsible for about half of cases.
   b. *EXT2* gene
      i. A ubiquitously expressed gene located on chromosome 11p11-p12
      ii. Normal gene product: exostosin 2
      iii. Mutations in *EXT2* are responsible for about one third of cases.
   c. *EXT3* gene
      i. A gene located on chromosome 19p
      ii. Mutations in *EXT3* are implicated in a minority of cases
4. Loss of heterozygosity in the *EXT1* or *EXT2* implicated in causing osteochondromas, which are the most common bone tumors in children, characterized by cartilage-capped, bony excrescences (exostoses) arising from the metaphyseal ends of rapidly growing long bones
5. Deletion of *EXT1* gene and adjacent *TRPS1* gene (a gene located on chromosome 8 proximal to the *EXT1* gene) resulting in Langer–Giedion syndrome (trichorhinophalangeal syndrome, type II) in which multiple exostoses are distinguishing features

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_117,
© Springer Science+Business Media, LLC 2012

6. EXT genes
   a. Encode glycosyltransferases
   b. Catalyze heparin sulfate polymerization
7. Genotype-Phenotype correlations (Pannier and Legeai-Mallet 2008)
   a. More severe disease in individuals with *EXT1* mutations than *EXT2* mutations on the basis of short stature, skeletal deformity (shortened forearm or bowing, knee deformity) and function (elbow, forearm and knee range of motion) (Francannet et al. 2001; Porter et al. 2004).
   b. The risk of chondrosarcoma may also be higher in individuals with an *EXT1* mutation than in those with an *EXT2* mutation, but *EXT1* mutations are responsible for most cases of HME.

Clinical Features

1. Exostoses (cartilage-capped bony growths)
   a. Bony swellings (bumps) near the growing ends of the long bones: initially painless but later the majority of patients experiences pain
   b. Onset during childhood (often asymptomatic)
   c. Sites
      i. Humerus
      ii. Distal end of the femur
      iii. Proximal end of the tibia and fibula
      iv. Distal ends of the radius
      v. Ribs
      vi. Scapula
      vii. Ilium
   d. Types
      i. Pedunculated with a narrow pedicle
      ii. Sessile with a broad pedicle
   e. Size and number
      i. Grow in size and gradually ossify during skeletal development
      ii. Ceases with skeletal maturity (when the growth plates close at puberty) after which no new exostoses develop
2. Bowing
   a. Often occurs without exostoses
   b. Bowing of forearms: ulnar deviation of the wrist secondary to a bowing of the radius and shortening of the ulna
   c. Bowing of lower legs
3. Genu valgum
4. Deformities observed in children
   a. Most common deformities
      i. Disproportionate short stature (40%)
      ii. Limb length discrepancies
      iii. Valgus deformities of the knee and ankle
      iv. Asymmetry of the pectoral and pelvic girdles
      v. Bowing of the radius with ulnar subluxation of the carpus
      vi. Subluxation of the radial head
      vii. Relative shortening of the metatarsals, metacarpals, and phalanges
   b. Less common deformities
      i. Scoliosis
      ii. Coxa valga
      iii. Acetabular dysplasia
5. Prognosis and complications
   a. Normal life span
   b. Normal intelligence
   c. Cosmetic concern (one of the most common clinical complaints)
   d. Mechanical restriction of adjacent joint movements
   e. Adventitious bursa with bursitis
   f. Compression or displacement of the adjacent nerves (22%)
      i. Pain (one of the most common clinical complaints)
      ii. Sensory or motor deficits
   g. Compression or displacement of the adjacent vessels (11%)
   h. Spontaneous hemothorax as a result of rib exostoses (rare)
   i. Urinary or intestinal obstruction resulting from large pelvic exostoses (rare)
   j. Compression of spinal cord
      i. Very rare occurrence
      ii. Extremely serious complication
   k. Slipping of the adjacent tendons
   l. Fractures at the pedicle
   m. Malignant transformation of osteochondroma to osteochondrosarcoma (0.5–5%): the most important complication
      i. Rapid growth
      ii. Increasing pain
      iii. A bulky cartilage cap

6. Differential diagnosis (Pannier and Legeai-Mallet 2008)
   a. Metachondromatosis
      i. An autosomal-dominant disorder
      ii. In contrast to HME, the exostoses of metachondromatosis point toward the joints and frequently regress spontaneously
      iii. Exostoses do not result in shortening of affected long bones or produce bowing, joint deformity or subluxation as seen in HME
   b. Langer–Giedion syndrome
      i. A contiguous gene deletion syndrome involving *EXT1* and *TRPS1* genes (trichorhinophalangeal syndrome I)
      ii. Affected individuals have exostoses, mental retardation, craniofacial abnormalities (laterally protruding ears, broad nasal bridge and bulbous nose, sparse hair) and digital anomalies (cone-shaped epiphyses)
   c. 11p11.2 deletion syndrome (formerly known as Potocki–Shaffer syndrome) (Wu et al. 2000)
      i. A contiguous gene deletion syndrome involving *EXT2* and *ALX4* (homeobox) genes
      ii. Affected patients have multiple exostoses, an ossification defect of the skull (enlarged parietal foramina), craniofacial dysostosis, and mental retardation
   d. Enchondromatosis (Ollier disease)
      i. Enchondromas
         a) Common benign cartilage tumors of bone
         b) Can occur as solitary lesions or as multiple lesions in enchondromatosis, often with unilateral predominance
      ii. Usually a nonhereditary disorder
      iii. Association of hemangiomas is referred to as "Maffucci syndrome"
      iv. Risk of malignant transformation into chondrosarcomas (20–50%)

Diagnostic Investigations

1. Radiographic features.
   a. Pedunculated or sessile exostoses pointing away from the joint.
   b. Cortex of exostoses continuous with that of the underlying bone.
   c. Exostoses originated in the metaphysis in the long bones and migrate to the diaphysis as growth continues in the epiphysis.
   d. Cartilagenous cap.
      i. Usually radiolucent
      ii. Appearance of irregular zones of calcification after puberty
      iii. Extensive calcification with irregularities of the cap suggesting possibility of malignant change
   e. Exostoses prevent normal bone tabulation resulting in metaphyseal widening and growth retardation.
   f. Broad and barrel-shaped metaphyses without normal remodeling.
   g. Wrist.
      i. Shortening of the ulna
      ii. Bowing of the radius with subluxations of the inferior radioulnar joint
2. CT and MRI imagings: evaluate spinal cord compression from an osteochondroma (Roach et al. 2009).
   a. Presence of a risk of having a lesion within the spinal canal
   b. Potential occurrence of serious neurologic injury
3. Serial technetium bone scans: Increased radionucleotide uptake suggests malignancy.
4. Histology of exostosis.
   a. Core: cancellous bone
   b. Surrounding: cortical bone
   c. Apex: covered with a cap of hyaline cartilage
5. DNA analysis of mutations in the *EXT1*, *EXT2*, and *EXT3* genes available clinically for *EXT1* and *EXT2*.
   a. FISH on metaphase cells.
   b. Genomic microarray analysis.
   c. Screening of the entire coding region.
   d. A combination of sequence analysis and deletion analysis of the entire coding regions of both *EXT1* and *EXT2* detects mutations in 70–95% of affected individuals (Schmale et al. 2008).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Usually with 50% risk of inheriting the gene alteration, since most probands (about 90%)

have a parent with the altered gene and 95% risk of manifesting symptoms (penetrance)
   ii. Low risk if both parents are normal
   b. Patient's offspring: 50% risk of inheriting the mutant allele
2. Prenatal diagnosis: available clinically for pregnancies at risk
   a. Molecular genetic analysis on fetal DNA obtained from amniocentesis or CVS for *EXT1* or *EXT2* mutation, provided the disease-causing allele of an affected family member has been identified prior to prenatal diagnosis
   b. Preimplantation diagnosis using embryonic cells available to couples at 50% risk of having a child with hereditary multiple exostosis, provided the disease-causing mutation of the *EXT1* or *EXT2* gene has been identified in the affected parent
3. Management
   a. Exostoses without clinical problems required no therapy
   b. Surgical intervention of exostoses
      i. Simple excision of exostoses
         a) Painful lesion without bony deformity
         b) Slowing growth disturbance
         c) Improving cosmesis
      ii. Angular deformities
      iii. Pain due to irritation of skin, tendons, or nerves
      iv. Either epiphysiodesis of the longer leg or lengthening of the involved leg for leg length discrepancy greater than one inch
      v. Excision of the exostoses and corrective osteotomies for forearm deformity (pain and stiffness of the elbow and wrist are a common cause of disability)
   c. Sarcomatous degeneration
      i. Surgical resection
      ii. Adjuvant radiotherapy and chemotherapy for secondary osteosarcoma

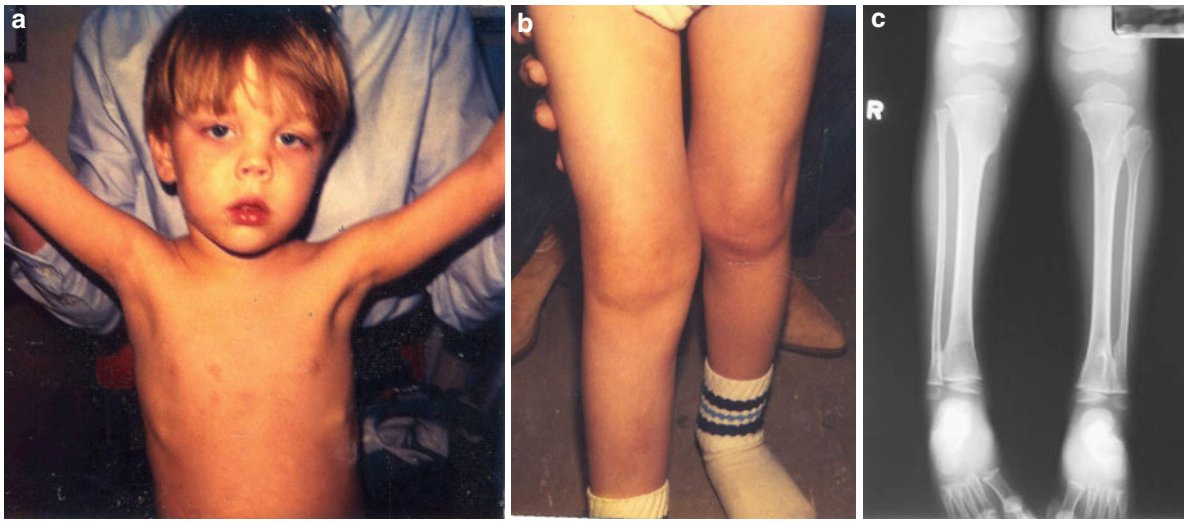

Fig. 1 (**a**–**c**) A boy with hereditary multiple exostoses showing bony growths on both sides of the ribs and the lower legs, illustrated by the radiograph

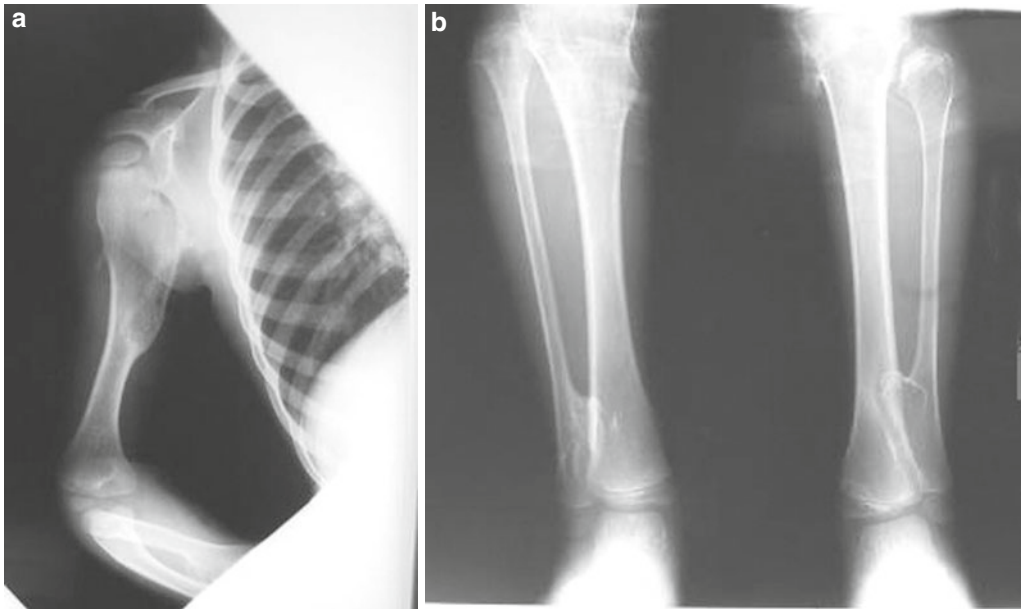

Fig. 2 (**a**, **b**) Radiographs of a 5-year-old boy with hereditary multiple exostoses showing multiple exostoses of the humerus, radius, tibia, and fibula

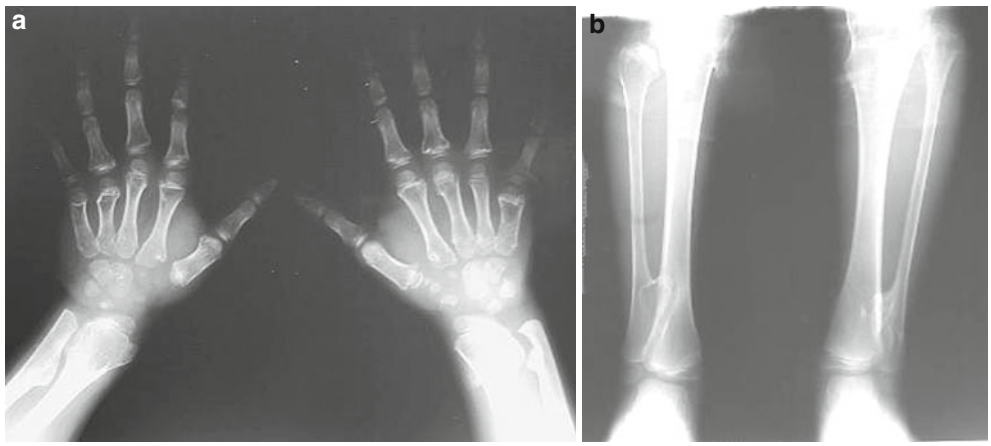

Fig. 3 (**a**, **b**) A 7-year-old boy with hereditary multiple exostoses showing more severe degree of multiple exostoses of the humerus, radius, tibia, and fibula

Fig. 4 (**a**–**c**) A 20-year-old female with hereditary multiple exostoses showing pedunculated exostosis on the left proximal tibia and fibula, exostosis on the shaft of the left fibula, and exostoses on the distal radius and ulna. She was discovered to have multiple exostoses since 1 year of age and has had multiple surgeries to remove multiple tumors from right femur, left tibia, and left fibula. Currently, she has bumps on the right distal femur, right proximal fibula, right distal tibia, left distal fibula, left distal forearm, right distal phalange of the right fifth finger, and left second toe. Her father is also affected

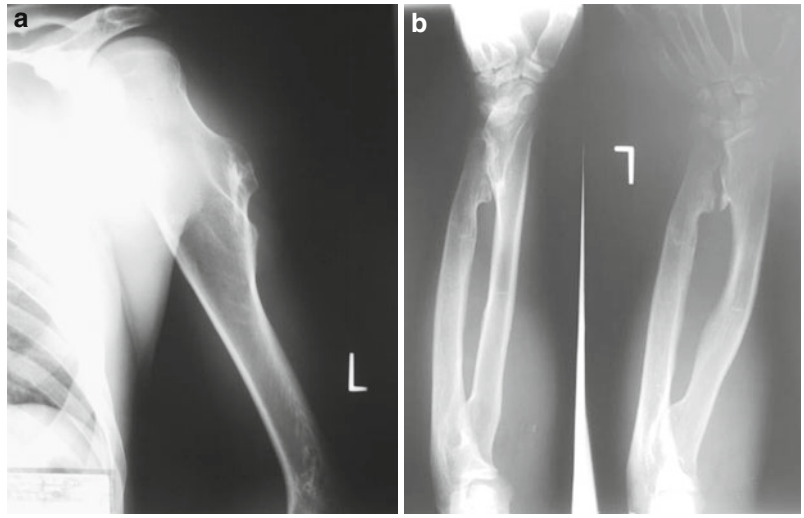

Fig. 5 (**a**, **b**) A 27-year-old male with hereditary multiple exostoses showing exostoses, ulnar shortening, and ulnar carpal drift

Fig. 6 (**a**–**c**) A 9-year-old girl with hereditary multiple exostoses showing typical radiographic features of both distal femurs

Herlyn-Werner-Wunderlich Syndrome

Herlyn-Werner-Wunderlich syndrome is a rare Müllerian anomaly consisting of a didelphic uterus, a hemivaginal septum, and ipsilateral renal agenesis. The diagnosis should be suspected in adolescent females with a pelvic mass and ipsilateral renal agenesis.

Synonyms and Related Disorders

Blind hemivagina with ispsilateral renal agenesis

Genetics/Basic Defects

1. Anatomical defect is caused by a failure of lateral fusion of Müllerian ducts (didelphic/septate uterus and double vagina) combined with a failure of vertical fusion between the Müllerian duct and the urogenital sinus (hemivaginal septum) ipsilateral to the side of the renal agenesis.
2. Various types of uterine anomalies secondary to nondevelopment or failure of fusion of the distal segments of the Müllerian ducts
   a. Hypoplasia/agenesis of the uterus
   b. Unicornuate uterus
   c. Didelphic uterus
   d. Bicornuate uterus
   e. Septate uterus
   f. Arcuate uterus
3. Various types of vaginal anomalies secondary to the different embryological origin of the upper two thirds of the vagina (originates from the Müllerian ducts of mesodermal origin) and the lower third of the vagina (originates from the urogenital sinus of endodermal origin): the anomaly may exist alone or in association with Müllerian anomalies.
   a. Hypoplasia/aplasia
   b. Duplication
   c. Septa
4. Close interrelationship between the urinary and reproductive systems during embryogenesis may explain the coexistence of urinary and reproductive tract abnormalities.
5. Specific association of a didelphic uterus, an obstructed hemivagina, and an ipsilateral renal agenesis is a rare malformation concomitantly involving both Müllerian and Wolffian ducts.
6. Mode of inheritance: unclear but Wiersma et al. (1976) had reported mother and daughter with uterus bicornis bicollis with partial vaginal septum and unilateral hematocolpos with ispsilateral renal agenesis, suggesting possible sex-limited autosomal dominant inheritance.

Clinical Features

1. Major complaints: the median age of presentation is 13 years. The condition is usually discovered at puberty shortly after menarche. The diagnosis is generally made only if the suspicion of the existence of this syndrome is raised.
   a. Abdominal pelvic mass due to hemihematocolpos resulting from retained longstanding, partially clotted menstrual blood in the obstructed hemivagina

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_118,
© Springer Science+Business Media, LLC 2012

   b. Recurrent and progressive pelvic pain
   c. Menstrual bleeding
   d. Menstrual irregularity
   e. Intraabdominal abscess
   f. Fever and vomiting can be the presenting symptoms
2. A didelphic uterus
   a. Characterized by two uterine bodies and two cervices
   b. Presence of a longitudinal vaginal septum in the majority of cases
3. Consequences of blood stasis and retrograde menstruation in the obstructed system
   a. Hematocolpos (a dilated hemivagina)
   b. Hematometros (a dilated uterine cavity)
   c. Hematosalpinx (bleeding/dilated fallopian tube)
4. Other vaginal anomalies
   a. Imperforate hymen variants
   b. Vaginal atresia
   c. Duplicated vagina
   d. Fused labia
5. Ipsilateral renal agenesis
6. Occasional gastrointestinal tract malformations
   a. Esophageal atresia
   b. Imperforate anus
7. Natural history if untreated
   a. Endometriosis
   b. Pelvic adhesions
   c. Pyosalpinx
   d. Pyocolpos
8. Unusual dichotomy in reproductive function
   a. Fertility not compromised with high spontaneous abortion rate (40%)
   b. No obstetric difficulties when a pregnancy is carried to term

Diagnostic Investigations

1. Abdominal examination finding of a suprapubic mass with tenderness to palpation
2. Pelvic and/or rectal examination findings of a paravaginal cystic mass
3. Abdominal and pelvic imagings
   a. Ultrasonography allows the correct diagnosis by showing uterovaginal duplication, hematocolpos or hematometrocolpos, and the absence of the ipsilateral kidney.
   b. Computed tomography scan
   c. Magnetic resonance imaging provides more detailed information regarding uterine morphology, the continuity with each vaginal channel (obstructed and nonobstructed), and the bloody nature of the contents.
4. Unilateral renal agenesis can be diagnosed prenatally. Female fetuses or neonates with renal malformations or multidysplastic kidneys need to be screened for genital malformations and to look for an obstructed Müllerian system. The uterine anomaly can be better detected in the neonatal period because the uterus is still under maternal hormonal stimulation and is characterized by a prominent myometrium and an echogenic endometrium. It is advisable that follow-up ultrasonographic examination of these asymptomatic patients be performed until the end of puberty.

Genetic Counseling

1. Recurrence risk: possible sex-limited autosomal dominant inheritance
   a. Patient's sib: recurrence risk not increased in female sibs unless the mother is affected
   b. Patient's offspring: a 50% risk for female offspring
2. Prenatal diagnosis: not yet reported
3. Management
   a. Operative management
      i. Vaginal septectomy with marsupialization and drainage of hematocolpos/hematometrocolpos to provide relief of pain and prevent further complications: a preferred surgical approach with a good long-term outcome
      ii. Salpingectomy for pyosalpinx if needed
   b. Errors in the surgical management can occur when the diagnosis is not suspected, and laparotomy to explore and resect the intra-abdominal mass is performed.
   c. Hemihysterectomy with or without salpingo-oophorectomy is rarely indicated and should be

avoided to provide the best chance for a successful reproductive outcome.

d. Post-operative considerations
   i. To achieve the goal of normal sexual relations and successful reproductive outcomes
   ii. Vaginal adenosis in the previously obstructed vagina

Fig. 1 A 13-year-old female was evaluated for vaginal bleeding and lower abdominal pain. Abdominal ultrasonography showed a very unusual appearance of the uterus with two horns which converge to form one lower uterine segment which then go into a prominent cervix where there was a large amount of fluid (blood) within the cervix and vagina

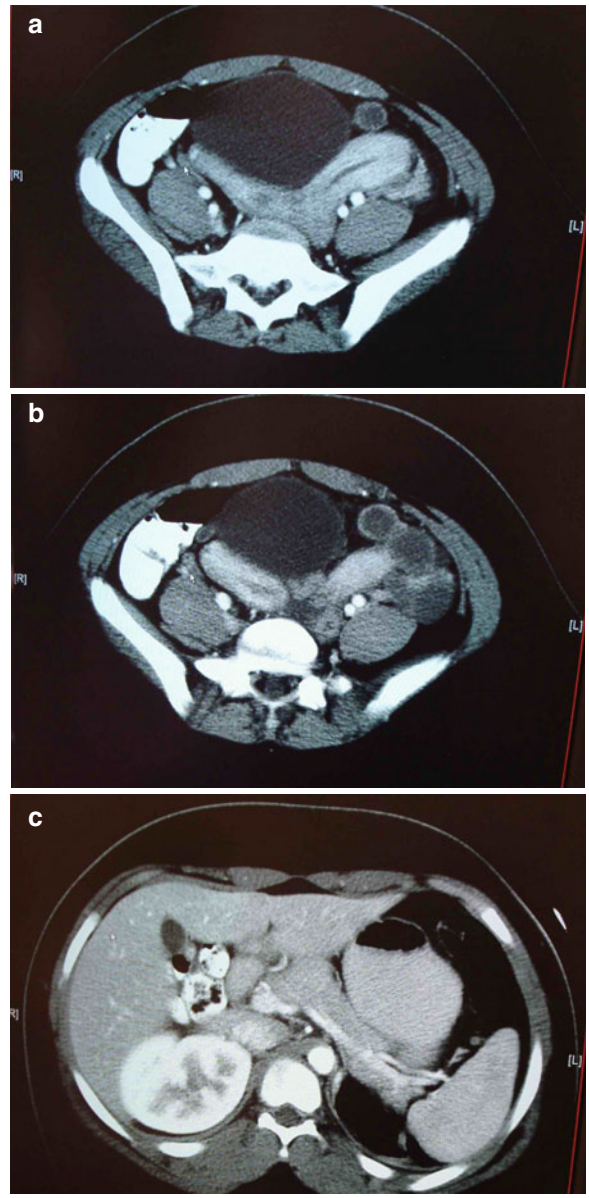

Fig. 2 (**a**–**c**) CT scan of the abdomen and pelvis showed congenital uterine anomaly likely didelphic uterus, absence of left kidney, and presence of hypertrophic right kidney

Holoprosencephaly

Holoprosencephaly (HPE) is a heterogeneous entity of CNS anomalies caused by the impaired midline cleavage of the embryonic forebrain. The incidence is estimated to be 1 in 16,000 live births and observed in 1 of 250 spontaneous abortions (Roessler and Muenke 2001).

Synonyms and Related Disorders

Arrhinencephaly; Cebocephaly; Ethmocephaly; Holoprosencephaly (alobar, lobar, semilobar); Holoprosencephaly facies syndrome; Premaxillary agenesis

Genetics/Basic Defects

1. Isolated and sporadic in most cases
2. Genetically heterogeneous, involving at least 12 loci on 11 chromosomes. There are at least five putative loci for HPE:
   a. *HPE1*
      i. Map locus: 21q22.3
      ii. Familial alobar holoprosencephaly
   b. *HPE2* (*SIX3*)
      i. Map locus: 2p21
      ii. Chromosome 2 form of holoprosencephaly, including midline cleft syndrome and DeMyer sequence
      iii. Caused by mutations in the homeobox-containing *SIX3* gene
   c. *HPE3* on 7q36-qter, characterized as the locus containing the human *sonic hedgehog* gene (*SHH*)
      i. Either loss-of-function mutation or disruption of one of the *sonic hedgehog* alleles at 7q36 (haploinsufficiency) shown to cause variable phenotype of holoprosencephaly
      ii. A broad spectrum of holoprosencephaly present in patients with de novo 7q, or with autosomal dominant holoprosencephaly having a linkage on 7q36
      iii. 7q deletion syndrome without typical holoprosencephaly in some patients
      iv. Interaction of partial trisomy 3p and partial monosomy 7q: invariably associated with severe forms of holoprosencephaly and facial dysmorphism. This delineates an autosomal imbalance syndrome or a dosage effect involving distal 3p duplication/terminal 7q deletion and dysmorphogenesis of the forebrain and midface.
   d. *HPE4* (TG-interacting factor, *TGIF*) on 18p11.3. Mutations of *TGIF* have been associated with holoprosencephaly and premaxillary agenesis.
   e. *HPE5* (*ZIC2*) on 13q32
3. SHH signaling pathway or the Nodal/TGF pathway (Cohen 2006; Bertolacini et al. 2010)
   a. *SHH* is the major gene implicated in holoprosencephaly (12.7% of HPE cases: 50% of overall point mutations and 38% of overall large deletions) (Dubourg et al. 2004)
   b. *ZIC2* is the second HPE gene by order of involvement (9.2% of HPE cases: 31% of overall point mutations and 38% of overall large deletions)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_119,
© Springer Science+Business Media, LLC 2012

c. Point mutations and large deletions in *SIX3* represent 3% and 1% of HPE cases, respectively. They are generally found in severe phenotypes (Pasquier et al. 2005).
d. Mutations in *TGIF* account for 1% of studied cases and large deletions for nearly 1% (Gripp et al. 2000).

4. *GLI2* mutations (Rahimov et al. 2006): nucleotide change and diverse phenotype
   a. 451A → G (Arg151Gly): holoprosencephaly-like phenotype
   b. 3,677C → T (Pro1226Leu): lobar HPE
   c. 1,809C → T (Pro604Ser)
      i. Anophthalmos
      ii. Branchial arch anomalies
      iii. CNS anomalies
   d. 3,348G → A (Met1116Ile)
      i. Heminasal aplasia
      ii. Orbital anomalies
5. *FAST1* (forkhead activin signal transducer 1) mutations: *FAST1* is the first human gene with mutations causing both midline defects (holoprosencephaly) and lateral defects (anomalies of cardiac looping) (Ouspenskaia et al. 2002)
6. Other known HPE-associated genes
   a. *PTCH*
      i. Patched mutations in humans result in haploinsufficiency.
      ii. A few of such mutations cause holoprosencephaly
      iii. Common in nevoid basal cell carcinoma syndrome and in isolated basal cell carcinomas
   b. *DHCR7*
      i. Mutations resulting in reduced serum cholesterol and accumulation of 7-dehydrocholesterol in autosomal recessive Smith–Lemli–Opitz syndrome
      ii. Four percent of cases with Smith–Lemli–Opitz syndrome have holoprosencephaly
   c. *DISP1*: Loss-of-function mutations may be associated with normal brain structure and development but facial features usually seen in conjunction with frank HPE (Roessler et al. 2009).
   d. *NODAL*: Mutations may result in HPE but are more commonly associated with cardiac and laterality defects (Roessler et al. 2009).
   e. *FOXH1* (part of the NODAL signaling pathway): Mutations may result in HPE or cardiac defects (Roessler et al. 2008)
   f. *FGF8*: A loss-of-function mutation has been described in three members of one family with a range of classic HPE-spectrum features (Araúz et al. 2010).
7. Subtypes of holoprosencephaly and the range of possible craniofacial features
   a. Alobar holoprosencephaly
      i. Cyclopia (a single eye or a partially divided eye in a single orbit with or without proboscis above the eye)
      ii. Ethmocephaly (extreme ocular hypotelorism with proboscis located between the eyes)
      iii. Cebocephaly (ocular hypotelorism with a single-nostril nose)
      iv. Premaxillary agenesis (ocular hypotelorism with median cleft lip and palate)
      v. Bilateral cleft lip
      vi. Ocular hypotelorism only
      vii. Anophthalmia or microphthalmia
      viii. Relatively normal facial appearance
   b. Semilobar holoprosencephaly
      i. Bilateral cleft lip with median process representing the philtrum-premaxilla anlage
      ii. Flat nasal bridge
      iii. Absent nasal septum
      iv. Flat nasal tip
      v. Midline cleft lip and/or palate
      vi. Ocular hypotelorism
      vii. Flat nose
      viii. Anophthalmia/microophthalmia
      ix. Relatively normal facial appearance
   c. Lobar holoprosencephaly
      i. Bilateral cleft lip with median process
      ii. Ocular hypotelorism
      iii. Flat nose
      iv. Relatively normal facial appearance
8. Causes
   a. Detectable chromosome abnormalities (24–45%)
      i. Numerical chromosomal abnormalities
         a) Trisomy 13 (most common)
         b) Trisomy 18
         c) Triploidy
         d) Mosaic trisomy 9
      ii. Structural chromosomal abnormalities: reported in virtually all chromosomes. The most frequent ones are as follows:
         a) Involving 13q [del(13q), r(13), dup(13q)]
         b) Del(18p)
         c) Del(7)(q36) (20%)

d) Dup(3)(p24-pter) (10%)
e) Del(2)(p21)
f) Del(21)(q22.3)
g) Del(22q11)
h) Partial monosomy 14q

b. Monogenic holoprosencephaly (18–25%)
i. Autosomal dominant
a) Pallister–Hall syndrome
b) Rubinstein–Taybi syndrome
c) Kallmann syndrome
d) Martin syndrome (with club foot and spinal anomalies)
e) Steinfeld syndrome (with congenital heart disease, absent gallbladder, renal dysplasia, and radial defects)
f) Ectrodactyly and hypertelorism
ii. Autosomal recessive
a) Meckel-Gruber syndrome
b) Smith–Lemli–Opitz syndrome
c) Pseudotrisomy 13 syndrome
d) XK aprosencephaly syndrome
e) Heterotaxy and holoprosencephaly
f) Genoa syndrome (with craniosynostosis)
g) Lambotte syndrome (with microcephaly, prenatal growth retardation, and hypertelorism)
h) Hydrolethalus syndrome (with hydrocephalus, polydactyly, and other anomalies)
i) Facial clefts and brachial amelia
iii. X-linked recessive (holoprosencephaly with fetal hypokinesia/akinesia)
c. Agnathia–otocephaly (10%)
d. Fronto-nasal dysplasia (6.7%)
e. Sirenomelia association
f. Holoprosencephaly, ectopia cordis, and embryonal neoplasms

9. Nongenetic risk factors (Johnson and Rasmussen 2010):
a. Maternal diabetes
i. One to two percent of newborn infants of diabetic mothers develop holoprosencephaly.
ii. The most commonly studied with the strongest association of the risk factor
b. Salicylates use, respiratory and sexually transmitted infections, and use of assisted reproductive technologies: identified in epidemiologic studies as possibly associated with increased risk of HPE
c. Quality of diet and use of multivitamin supplements: associated with a decreased risk
d. Retinoic acid
i. CNS anomalies, particularly hydrocephalus
ii. Holoprosencephaly
e. Ethyl alcohol
i. Holoprosencephaly/arhinencephaly
ii. Agnathic cyclopia
iii. Midline cerebral dysgenesis with hypothalamic–pituitary dysfunction
iv. Hydrocephalus
v. Agenesis of the corpus callosum and anterior commissure
f. Estrogen/progestin
g. Anticonvulsants
h. Low-calorie weight reduction diets
i. Prenatal infections
i. Cytomegalovirus
ii. Rubella
iii. Toxoplasma
j. Poverty
k. Previous pregnancy loss

Clinical Features

1. Variable expression, ranging from a small brain with a single cerebral ventricle and cyclopia to clinically unaffected carriers in familial holoprosencephaly
2. Face: Holoprosencephaly is often associated with distinct facial appearance (holoprosencephaly facies syndrome). The face predicts the brain approximately 80% of the time. In decreasing order of severity:
a. Absence of eye(s) (the most severe form)
b. Cyclopia
i. The most severe dysmorphism
ii. A median monophthalmia (a single midline eye)
iii. Synophthalmia (fusion of two eyes in a single midline orbit)
iv. Anophthalmia
v. Presence of a single median orbit (sine qua non for the diagnosis)
vi. Without or with proboscis (single or double protruding from the glabella, just above the median eye)

vii. Complete arhinia with no nose, no nasal bones
viii. Degree of facial dysmorphism strongly correlated with the severity of brain malformation (facial and the oculo-orbital phenotype reflect the underlying central nervous system pathology)

c. Ethmocephaly
i. Rarest type
ii. Close-set eyes (ocular hypotelorism) located in two separate orbits
iii. A median proboscis between the two eyes as a rudimentary tube-like nose
iv. Hypoplastic or absent median facial bones

d. Cebocephaly
i. Close-set eyes (ocular hypotelorism) into separate orbits
ii. A nose with a single nostril
iii. No cleft lip

e. Premaxillary agenesis
i. Close-set eyes (ocular hypotelorism)
ii. Median cleft lip and palate

3. Eyes
a. Anophthalmia
b. Microphthalmia
c. Cyclopia
d. Fused eyes
e. Coloboma
f. Hypotelorism
g. Bulging eyes
h. Other eye malformations
i. Fused lids
ii. Optic disk hypoplasia
iii. Cataract

4. Nose
a. Proboscis
b. Arhinia with or without proboscis
c. Flat nose
i. With proboscis
ii. Absent or nonpatent nares
iii. Other malformations

5. Mouth
a. Median cleft lip
b. Bilateral cleft lip
c. Unilateral cleft lip
d. Cleft palate alone
e. Cleft lip with cleft palate
f. Cleft lip alone
g. Cleft uvula
h. Microstomia
i. Macrostomia
j. Agnathia
k. Micrognathia

6. Ear
a. Fused ears
b. Other ear malformations

7. Neurodevelopmental deficits
a. Hoarse or "barking" voice, high-pitched crying
b. Major feeding problems with choking spells
c. Common growth delay
d. Seizures
e. Spasticity or floppy muscle tone
f. Brain-stem dysfunction with irregular breathing and heart rate and erratic body temperature control
g. Profound developmental delay with very limited expressive language and minimal attainment of motor skills
h. Behavioral problems

8. Endocrine disorders
a. Occasional diabetes insipidus with episodes of dehydration
b. Rare panhypopituitarism

9. Presence of microforms of holoprosencephaly in relatives of patients with holoprosencephaly
a. Microcephaly
b. Single central maxillary incisor
c. Ocular hypotelorism
d. Anosmia/hyposmia secondary to absent olfactory tracts and bulbs
e. Iris coloboma
f. Absent superior labial frenulum
g. Midface hypoplasia
h. Congenital nasal pyriform aperture stenosis
i. Developmental delay

10. Holoprosencephaly-agnathia spectrum (Kauvar et al. 2010)
a. Holoprosencephaly, the most common developmental disorder of the human forebrain, is occasionally associated with the spectrum of agnathia, or virtual absence of the mandible
b. This condition results in a constellation of structural cerebral and craniofacial abnormalities
c. The majority of these patients are female and have the most severe forms of HPE, with cyclopia present more frequently than is usually observed in cohorts of patients with HPE. Also,

many patients have additional clinical findings not typical in patients with classic HPE, particularly situs abnormalities

11. Prognosis
    a. Infants born with cyclopia, ethmocephaly, and cebocephaly: virtually all die within a week of birth
    b. Infants born with premaxillary agenesis, unilateral or bilateral cleft lip, or more normal facies
        i. Half of the patients die before 4–5 months.
        ii. Twenty to thirty percent of the patients live to 1 year of age. Longer survival is possible to at least 11 years.
    c. Cases diagnosed in utero will have an extremely poor neurologic development after birth.
    d. Causes of death most often due to brain-stem malfunction (unable to control the respiration and heart rate) aggravated by infections and other stresses

Diagnostic Investigations

1. Neuroimagings (MRI/CT of the brain)
    a. A single ventricle
    b. Absence of olfactory bulb and tracts
    c. Absence of corpus callosum
    d. Absence of inferior frontal and temporal regions
    e. Fused thalami
    f. Absence of optic nerve
    g. Incomplete anterior and posterior pituitary
    h. Normal brainstem and cerebellum
    i. Lack of ethmoid bone
2. Cytogenetic analysis (Bendavid et al. 2009)
    a. An essential diagnostic tool
    b. Initially, karyotype approach led to the identification of several recurrent chromosomal anomalies predicting different HPE loci
3. Molecular genetic diagnoses
    a. Subsequently, several genes were isolated from these critical HPE regions, but point mutations and deletions in these genes were found only in 25% of the genetic cases
    b. In order to identify other HPE genes, a more accurate investigation of the genome in HPE patients was necessary: If HPE is isolated and nonsyndromic, including sporadic cases, the study of the four major genes involved in the disease should be undertaken.
    c. To date, high-resolution cytogenetic techniques such as subtelomeric multiplex ligation-dependent probe amplification (MLPA) and microarray-based comparative genomic hybridization (array CGH) have enhanced chromosomal aberration analysis.
        i. A systematic search for gains or losses in the subtelomeres by MLPA
            a) Leads to identification of 4% more anomalies
            b) Rearrangements, deletions, or duplications must be verified by FISH on the karyotype of the proband and parents, so the identification of a cryptic-balanced translocation in a parent can change the approach to genetic counseling.
        ii. Array-CGH analysis
            a) A part of the molecular diagnosis algorithm to help clinicians get more disease markers for difficult HPE genetic counseling (Pineda-Alvarez et al. 2010)
            b) Indicates a high prevalence of genomic rearrangements in HPE (Bendavid et al. 2009)
            c) Detects a high frequency of submicroscopic anomalies with a yield of 25%, especially in severe forms and in fetuses
            d) Helpful in identification of unbalanced anomalies, as MLPA for subtelomeres, and leading secondarily to identification of parental cryptic-balanced translocations by FISH (Bendavid et al. 2009)
            e) Would allow identification of new HPE loci
4. Necropsy and anatomical classification (Demyer and Zeman 1963; Delezoide et al. 1990; Dubourg et al. 2007): Holoprosencephaly is generally classified into three major types and one milder subtype. The distinction among the following three types is not always clear.
    a. Alobar holoprosencephaly
        i. The most severe form
        ii. Complete failure of brain tissue to develop into the normal right and left cerebral hemispheres
        iii. The brain consisting of a single fused cerebral hemispheres located in the frontal region
        iv. Total absence of interhemispheric fissure and falx cerebri

v. The brain surface is smooth with sparse convolutional markings
vi. A single dilated ventricle communicating with a large dorsal cyst
vii. Absence of the third ventricle, neurohypophysis, and olfactory bulbs and tracts
viii. Absence of corpus callosum
ix. Fused thalami and basal ganglia
x. Migrational anomalies often present

b. Semilobar holoprosencephaly
i. The less severe form
ii. Rudimentary cerebral lobes. Only partial separation into two cerebral hemispheres; the hemispheres are not separated across the midline in the front part of the brain
iii. A single ventricle
iv. Olfactory bulbs and corpus callosum are usually absent.
v. Partial presence of the septum pellucidum and corpus callosum pending on the severity

c. Lobar holoprosencephaly
i. The least severe form
ii. Well-formed cerebral lobes that may be of normal size
iii. Virtual complete separation of the cerebral hemispheres
iv. Various degree of rostral and basilar non-separation
v. Absent, hypoplastic, or normal olfactory bulbs, tracts and corpus callosum
vi. Gray matter heterotopias and other associated migrational anomalies

d. Middle interhemispheric variant or syntelencephaly
i. Failure of separation of the posterior frontal and parietal lobes
ii. Callosal genu and splenium normally formed
iii. Absence of corpus callosum
iv. Hypothalamus and lentiform nuclei normally separated
v. Heterotopic gray matter

Genetic Counseling

1. Based on a rigorous clinical evaluation exploring family history, environmental factors, and associated features (Mercier et al. 2010)

2. Recurrence risk: depending on the basis for the actual condition
a. Patient's sib
i. Empirical estimate of 20% for holoprosencephaly, 15% for a microform, and 15% for normal phenotype
ii. Increased recurrence risk depending on the type of Mendelian inheritance (autosomal recessive and dominant conditions with holoprosencephaly). Existence of incomplete penetrance or an incomplete form or microform of holoprosencephaly makes the interpretation of familial occurrence difficult.
iii. Fifty percent recurrence risk of having affected siblings with variable clinical symptoms and severity if a parent is affected with holoprosencephaly
iv. Germline mosaicism in which apparently unaffected parents with negative family history having more than one affected child
v. Sibs of a child with a numeric chromosome abnormality: have a slightly increased risk of having a similar chromosome abnormality (depending on the specific abnormality and the age of the mother) with a similar or different phenotype.
vi. Increased in a case where a parent carries a chromosome translocation or other chromosome rearrangement

b. Patient's offspring
i. Severe cases of prosencephaly: not surviving to reproductive age
ii. Individuals with mild form or microform holoprosencephaly (with a gene mutation for the autosomal dominant nonsyndromic holoprosencephaly): 50% recurrence risk of having an affected child

3. Prenatal diagnosis
a. Prenatal ultrasonography: can detect CNS and facial abnormalities of severe HPE as early as the first trimester, but is less sensitive for detection of milder forms of HPE, such as lobar HPE
i. General characteristics
a) Polyhydramnios
b) Ocular hypotelorism
c) Cleft lip/palate
d) Arhinia

e) Cyclopia and proboscis: identifiable at the beginning of the ninth week of gestation by 2-D and 3-D ultrasonography
f) Absence of central falx
g) Demonstration of a single rudimentary cerebral ventricle

ii. Alobar holoprosencephaly
a) Single ventricle
b) Presence or absence of dorsal sac
c) Fused thalami
d) Absence of cavum septum pellucidum

iii. Semilobar holoprosencephaly
a) Single ventricles with rudimentary occipital horns
b) Presence or absence of dorsal sac
c) Fused thalami
d) Absence of cavum septum pellucidum

iv. Lobar holoprosencephaly
a) Almost divided ventricles except at frontal horns of lateral ventricles
b) Some enlargement of lateral ventricle
c) Flat roof of frontal horns in microtonal view
d) Wide communication between the frontal horns and the inferior third ventricles
e) Absence of dorsal sac
f) Divided thalami
g) Absence of cavum septum pellucidum

b. Fetal MRI: provides better characterization of brain malformations, but only later in the third trimester of pregnancy (Hahn and Barnes 2010; Mercier et al. 2010)

c. Cytogenetic analysis from CVS or amniocytes
i. Parent with a balanced chromosomal rearrangement
ii. Fetus with multiple anomalies including holoprosencephaly from prenatal ultrasonography

d. Prenatal diagnosis by molecular analysis on fetal DNA obtained from amniocentesis or CVS for the disease-causing mutation previously identified in the proband
i. Sequence analysis or deletion/duplication analysis
a) *SIX3*-related holoprosencephaly
b) *SHH*-related holoprosencephaly
c) *TGIF*-related holoprosencephaly
d) *ZIC2*-related holoprosencephaly
e) *GLI2*-related holoprosencephaly
f) *PTCH1*-related holoprosencephaly
g) *TRAPPC10*-related holoprosencephaly
h) *ZIC2*-related holoprosencephaly
ii. Pallister–Hall syndrome: mutation analysis for mutation panel GLI3 (2023delG and 2012delG)
iii. Rubinstein–Taybi syndrome: FISH analysis of the deletion of the *CREBBP* gene on chromosome 16 (16p13.3)
iv. Smith–Lemli–Opitz syndrome
a) Detection of two disease-causing mutations in the *DHCR7* gene previously identified in the proband
b) Abnormal concentration of 7-dehydrocholesterol levels

e. Preimplantation genetic diagnosis
i. May be available for families in which the disease-causing mutation has been identified
ii. Reported for sonic hedgehog mutation causing familial holoprosencephaly (Verlinsky et al. 2003)

4. Management
a. Care for common medical problems (Levy et al. 2010)
i. Hydrocephalus
ii. Seizures
iii. Motor impairment
iv. Oromotor dysfunction with risk of poor nutrition and aspiration
v. Chronic lung disease
vi. Gastroesophageal reflux
vii. Constipation
viii. Hypothalamic dysfunction with disturbed sleep–wake cycles and temperature dysregulation
ix. Endocrine dysfunction: Diabetes insipidus in particular is found in about 70% of children with classic HPE

b. Treatment strategies based on the types of brain malformations and associated anomalies
i. Lethal entity: no specific treatment available
ii. Nonlethal entity
a) Ventriculoperitoneal shunt for hydrocephalus
b) Cleft lip and palate repair if indicated
c) Monitoring of fluid and electrolyte intake in patients with diabetes insipidus
d) Hormone replacement therapy for pituitary dysfunction

c. Supportive
   i. Multidisciplinary team approach
   ii. Support and counseling of the parents
   iii. Seizure management
   iv. Gastrostomy tube placement and fundoplication for gastroesophageal reflux and vomiting

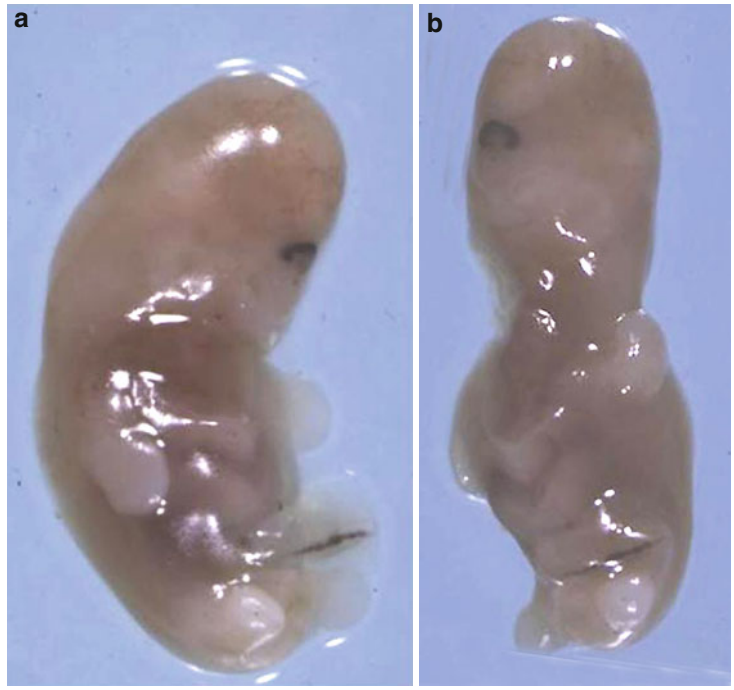

Fig. 1 (**a**, **b**) An aborted embryo with cyclopia

Fig. 2 A neonate with cyclopia. The infant had holoprosencephaly (arrhinencephaly), agenesis of olfactory and optic nerves, agenesis of pituitary, cor binoculare, left diaphragmatic hernia, bilobar spleen, agenesis of adrenal glands, and absence of right umbilical artery

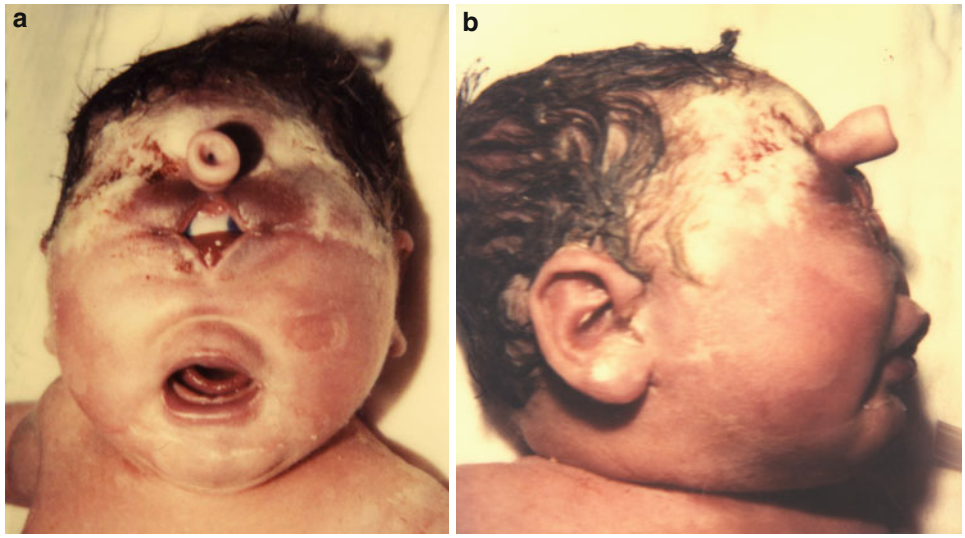

Fig. 3 (**a**, **b**) Another neonate with cyclopia

Fig. 4 An infant with ethmocephaly

Fig. 5 Postmortem brain with holoprosencephaly (dorsal view) showing a dilated single ventricle. The large dorsal cyst was ruptured during dissection, and the remnants of the membranous cyst wall are vaguely visible at the margins of the ventricle, especially on right side

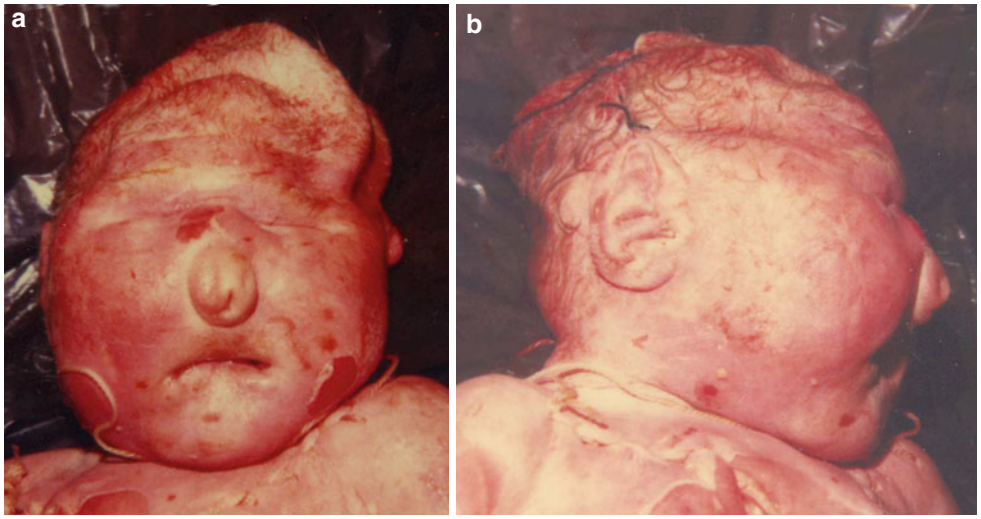

Fig. 6 (**a**, **b**) A neonate with cebocephaly

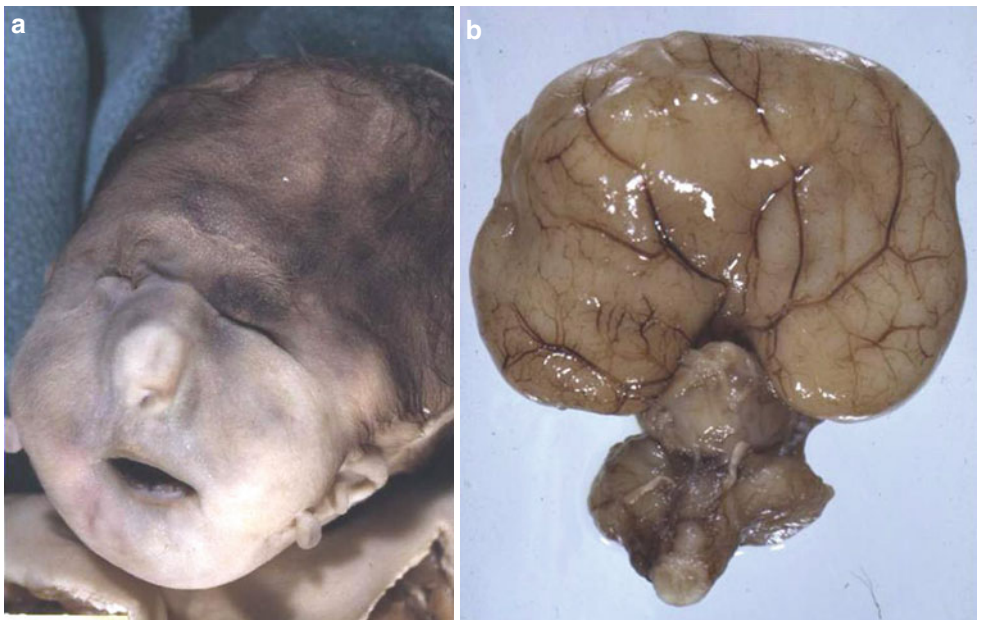

Fig. 7 (**a**, **b**) A premature neonate with cebocephaly. The infant had anophthalmia; bilateral nasal atresia; alobar holoprosencephaly (*ventral view*) with a 4.5 × 5.5 × 6.0 cm dorsal cyst (not shown), atresia of left external auditory canal with hypoplastic malformed auricle; agenesis of left lung; left kidney and left ureter; hypoplasia of left posterior cranial fossa and left cerebellum; multiple skin tags; hemivertebrae; and absence of right umbilical artery

Fig. 8 A neonate with cebocephaly and 48,XXY,+13

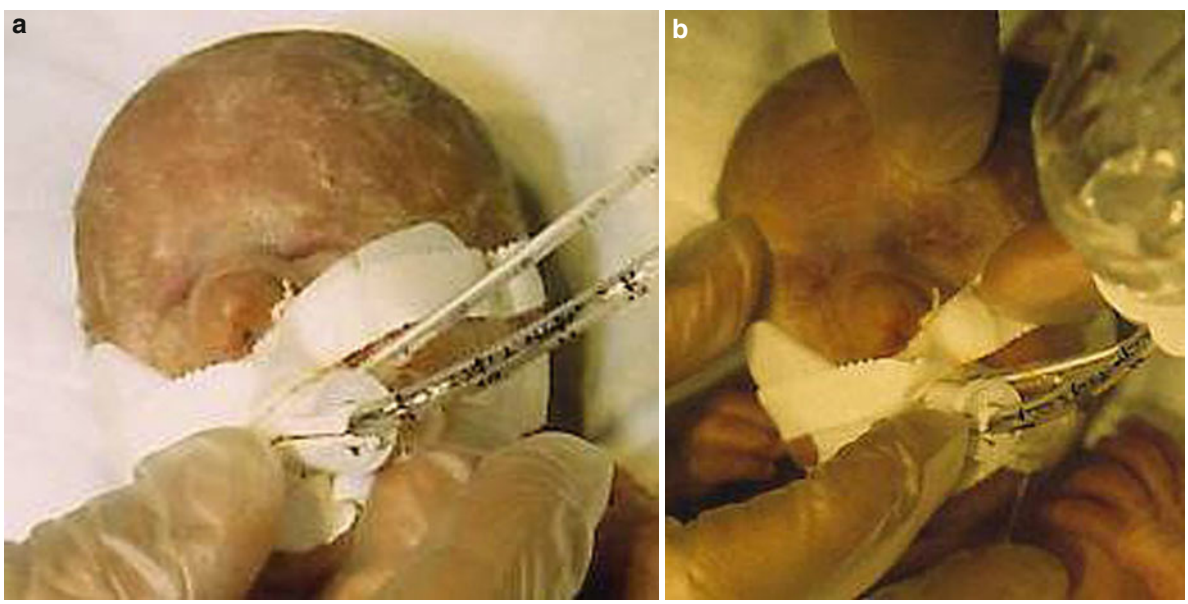

Fig. 9 (**a**, **b**) A newborn with trisomy 13 showing ocular hypotelorism and extreme microphthalmia

Fig. 10 (**a**, **b**) A neonate with trisomy 13 showing ethmocephaly, transverse reduction of the left forearm, and polydactyly of the right hand and both feet

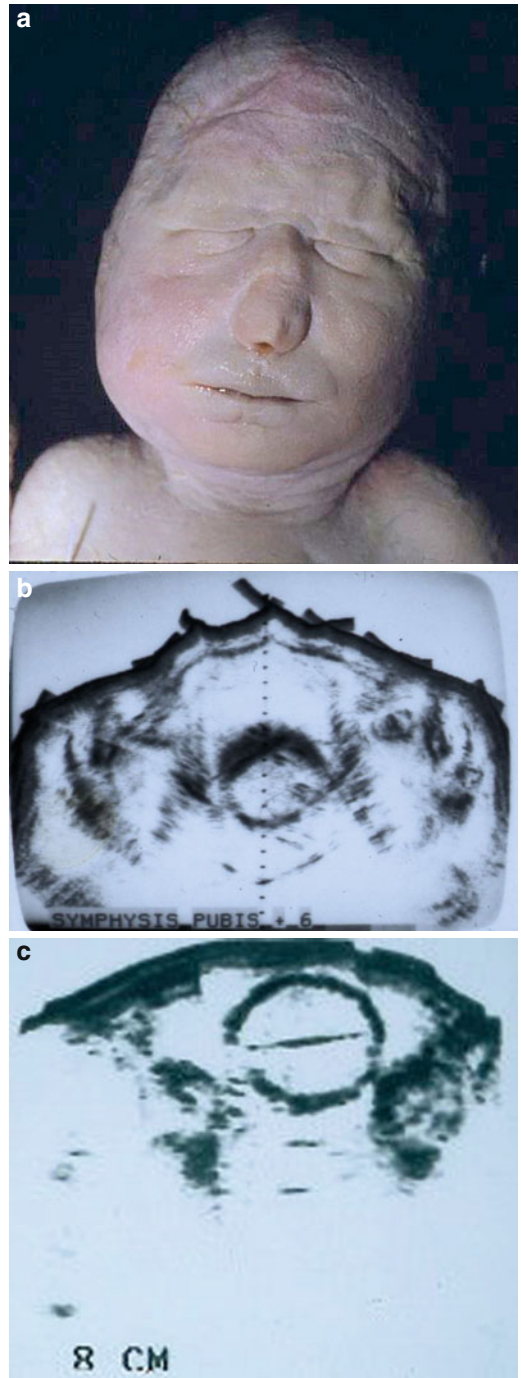

Fig. 11 (**a**–**c**) A neonate with trisomy 18 showing cebocephaly. The prenatal ultrasound showed fetal scalp edema, microcephaly, and holoprosencephaly (a normal brain ultrasound at the same gestation is illustrated here)

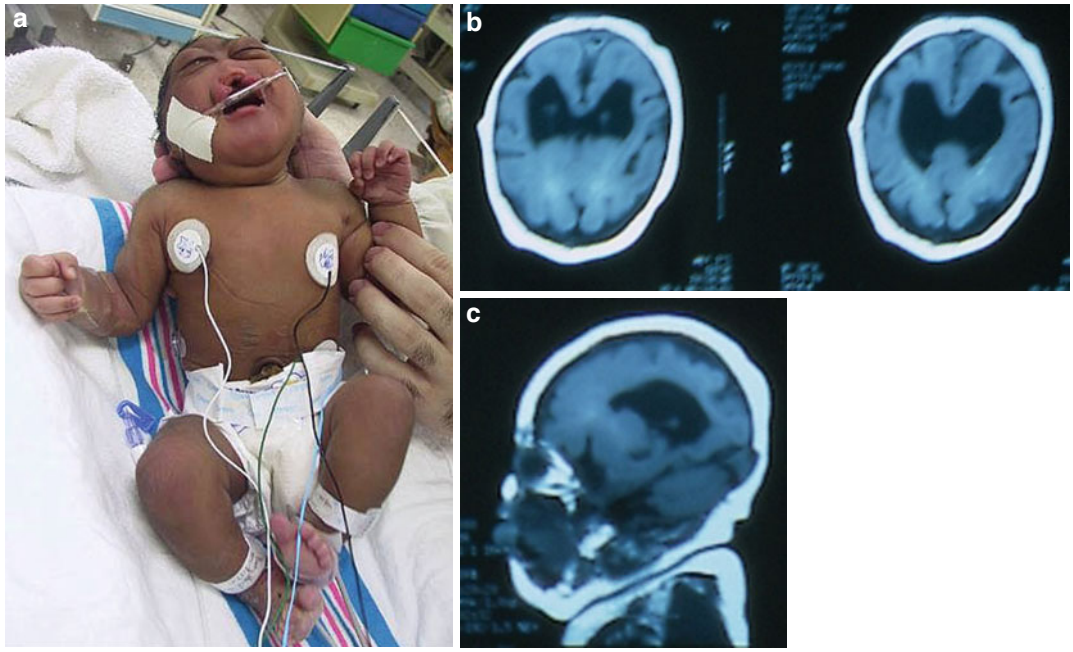

Fig. 12 (**a**–**c**) A neonate with semilobar holoprosencephaly illustrated by MRI of the brain

Fig. 13 (**a**–**d**) Front and lateral views of an infant with arrhinencephaly. The postmortem brain showed absence of olfactory tract and sulci and septum pellucidum and fused thalami

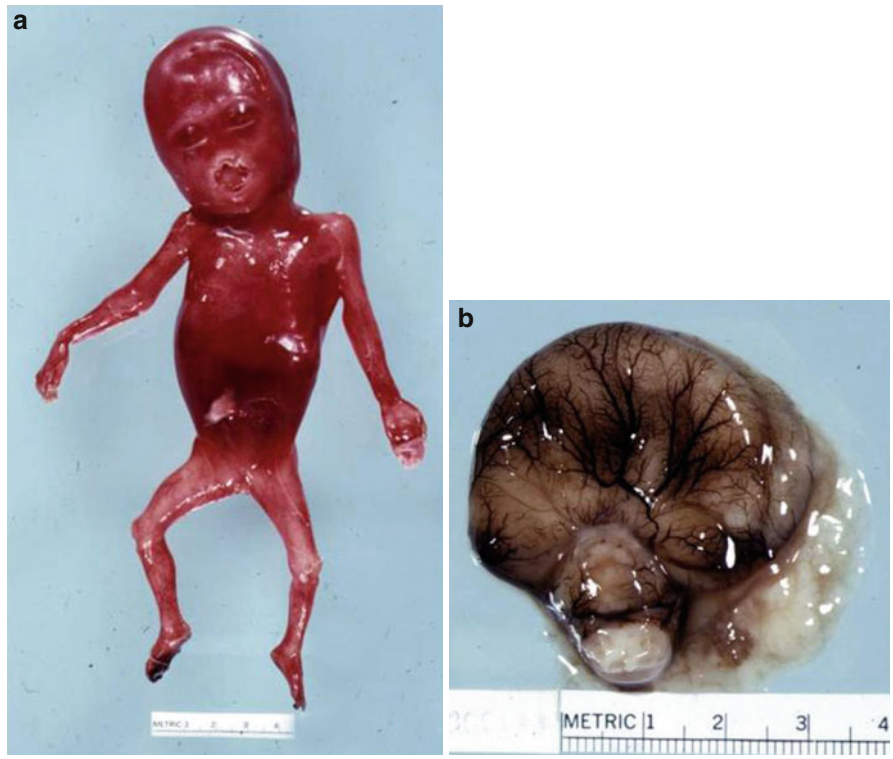

Fig. 14 (**a**, **b**) A fetus with premaxillary agenesis showing facial dysmorphism, including hypotelorism, absence of nose, median cleft lip and palate, and low-set ears. In addition, the fetus had 13 pairs of ribs and absence of uterus and left kidney. The pregnancy was terminated at 17 weeks gestation because of alobar holoprosencephaly detected by ultrasonography. The postmortem brain showed alobar prosencephaly with a cerebral vesicle. Gyri were not developed

Fig. 15 A newborn with sirenomelia associated with holoprosencephaly

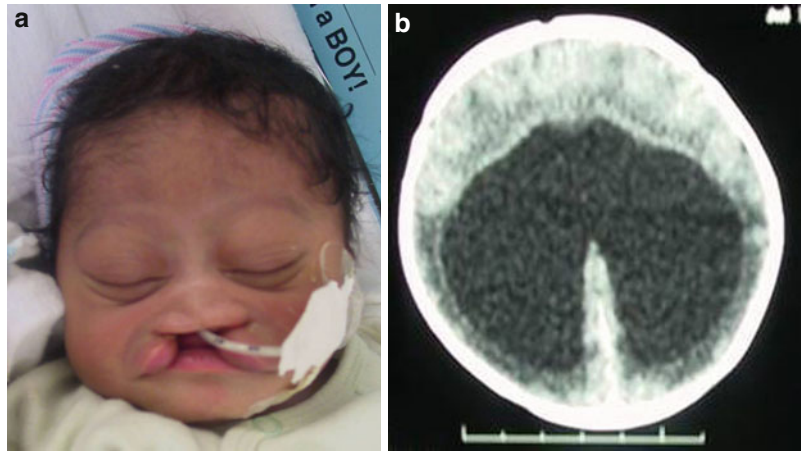

Fig. 16 (**a**, **b**) A neonate with premaxillary agenesis and holoprosencephaly illustrated by MRI of the brain

Fig. 17 (**a**–**c**) A child with premaxillary agenesis and upper limb defects

Fig. 18 (**a**–**d**) Four infants with premaxillary agenesis

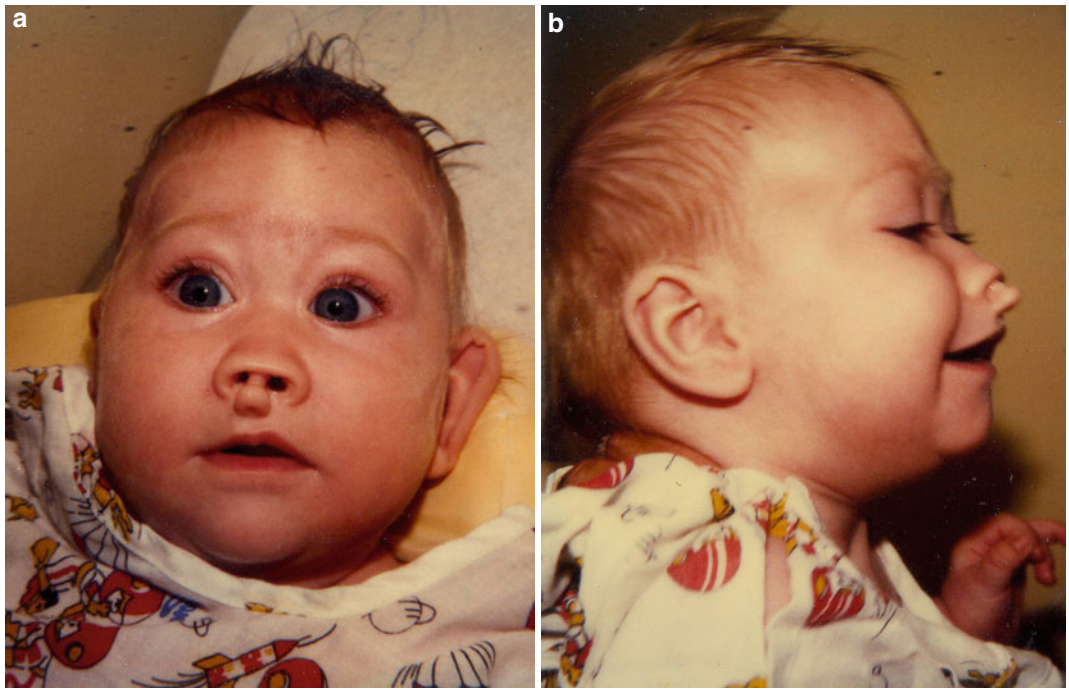

Fig. 19 (**a**, **b**) An infant with hypotelorism and duplicated nose

Fig. 20 (**a**, **b**) A girl with mild hypotelorism, antimongoloid slant, and a central incisor

Holt-Oram Syndrome

In 1960, Holt and Oram described a family in which nine members in four generations were affected by skeletal abnormalities of the upper limbs, cardiac malformations, and arrhythmias. The prevalence is about 1 in 100,000 live births. About 40–85% of cases are due to fresh mutation.

Synonyms and Related Disorders

Atrialdigital dysplasia; Heart-hand syndrome

Genetics/Basic Defects

1. An autosomal dominant disorder
   a. Complete penetrance
   b. Widely variable expression
2. Holt-Oram syndrome frequently linked to the gene *TBX5*, which is mapped to 12q24.1
3. Caused by mutations in the *TBX5* gene, a member of the T-box family that encodes a transcription factor (Huang 2002)
   a. Mutations predicted to create null alleles cause substantial abnormalities in both the limb and heart.
   b. Nonsense mutations of *TBX5* produce distinct phenotypes.
      i. One class of missense mutations: causes significant cardiac malformations but only minor skeletal abnormalities
      ii. Other class of nonsense mutations: causes extensive upper limb malformations but few significant cardiac abnormalities.
      iii. Several novel missense mutations in *TBX5* lead to functional haploinsufficiency and result in a reduced transcriptional activation of target genes, which is likely central to the pathogenesis of Holt-Oram syndrome (Boogerd et al. 2010)
4. Intrafamilial variations of the malformations: suggest that genetic background or modifier genes play an important role in the phenotypic expression of Holt-Oram syndrome (Huang 2002).
5. Hand-heart syndromes (syndromes with frequent association of congenital cardiac and upper limb malformations): genetically heterogeneous (Basson et al. 1995)
   a. Holt-Oram syndrome: the most common form
   b. Heart-hand syndrome type II (Tabatznik syndrome)
      i. Hypoplastic deltoids
      ii. Skeletal anomalies in the humeri, radii, ulnae, and thenar bones
      iii. Brachydactyly type D
      iv. Congenital cardiac arrhythmias (junctional rhythms and atrial fibrillation)
   c. Heart-hand syndrome type III
      i. Cardiac conduction defects (intraventricular delays and sick sinus syndrome)
      ii. Skeletal malformations limited to the hands and feet (brachydactyly type C)
   d. Autosomal dominant "partial phenocopy" conditions
      i. Familial atrial septal defects with conduction disease occurring without limb deformities
      ii. Familial limb malformations occurring without cardiac defects

Clinical Features

1. Preaxial radial ray abnormalities of the upper limb(s) (Newbury-Ecob et al. 1996)
   a. Almost always present
   b. Unilateral or bilateral
   c. Symmetric or asymmetric (left side more affected than the right side)
   d. Severe (phocomelia) to mild phenotype due to aplasia, hypoplasia, fusion, or anomalous development of involved bones
   e. Thumbs
      i. Aplasia
      ii. Hypoplasia
      iii. Triphalangeal
      iv. Syndactyly
      v. Long
      vi. Normal
   f. Fingers
      i. Clinodactyly
      ii. Brachydactyly
      iii. Hypoplasia
      iv. Absent
      v. Syndactyly
      vi. Normal
   g. Radial bones
      i. Hypoplasia
      ii. Aplasia
   h. Ulnar
      i. Hypoplasia
      ii. Aplasia
   i. Carpal bones
      i. Deformed
      ii. Extra
   j. Thenar bones: hypoplastic thenar eminence
   k. Humerus
      i. Hypoplasia
      ii. Abnormal head
      iii. Aplasia
      iv. Normal
   l. Clavicles
      i. Hypoplasia
      ii. Prominent acromioclavicular joint
      iii. Normal
   m. Thorax
      i. Pectus excavatum
      ii. Hypoplasia pectoralis major
   n. Limited supination
   o. Limited extension of the elbow
2. Cardiac anomaly (75% of cases)
   a. Structural defects
      i. Atrial septal defect (most common type, usually of secundum variety)
      ii. Ventricular septal defect
      iii. Pulmonary stenosis (including peripheral arterial)
      iv. Mitral valve prolapse
      v. Complex cardiac malformations (tetralogy of Fallot, hypoplastic left heart, endocardial cushion defects, truncus arteriosus)
   b. Cardiac conduction defects
      i. Paroxysmal tachycardia
      ii. Prolonged PR interval (ECG)
      iii. Wandering atrial pacemaker
      iv. Atrial ectopics
      v. Sinus bradycardia
      vi. Syncope
      vii. Sinus arrest
      viii. Atrioventricular block
      ix. Atrial fibrillation
3. Mild to no symptoms in children and young adult
   a. Recurrent respiratory infections
   b. Failure to thrive
4. Older adults
   a. Congestive heart failure
   b. Supraventricular arrhythmia, especially atrial fibrillation
5. Differential diagnosis (Huang 2002)
   a. Fanconi anemia syndrome
      i. Multiple congenital anomalies consisting of malformations of the thumbs, forearms, and heart
      ii. Progressive bone marrow failure with pancytopenia, typically in the first decade
      iii. An increased risk for myelodysplasia or acute myelogenous leukemia
      iv. Diagnosis based on detection of chromosomal breakage or rearrangement in the presence of diepoxybutane or mitomycin C
   b. Thrombocytopenia-absent radius
      i. Both radii always absent
      ii. Thumbs always present
      iii. Occasional phocomelia

iv. Possible involvement of lower limbs.
  a) Club foot
  b) Knee instability
v. Thrombocytopenia
  a) Present in infancy
  b) Generally improves with time
vi. Heart defect can be present

c. Heart-hand syndrome II (Tabatznik)
  i. Type D brachydactyly (shortening of the distal phalanx of the thumb with or without shortening of the fourth and fifth metacarpals)
  ii. Sloping shoulders
  iii. Short upper limbs
  iv. Bowing of the distal radii
  v. Absence of the styloid process of the ulna
  vi. Supraventricular tachycardia
  vii. Possible mild mental retardation and mild facial dysmorphism
d. Heart-hand syndrome III
  i. Type C brachydactyly (shortening of the middle phalanges)
  ii. An accessory wedged-shaped ossicles on the proximal phalanx of the index fingers
  iii. Sick sinus syndrome
e. Okihiro syndrome
  i. Duane syndrome
    a) A congenital eye-movement disorder resulting from abnormal development of cranial nerve VI
    b) Absence of abduction of the globe
    c) Narrowing of the palpebral fissure on adduction of the globe
  ii. Upper extremity reduction defects
  iii. Cardiac malformations
f. Long-thumb brachydactyly syndrome
  i. Elongation of the thumb distal to the proximal interphalangeal joint
  ii. Often associated with index finger brachydactyly and clinodactyly
  iii. Narrow shoulders
  iv. Secondary short clavicles
  v. Pectus excavatum
  vi. Occasional rhizomelic limb shortening
  vii. Frequent with cardiac conductive defect
g. VACTERL association
  i. Radial defect usually unilateral
  ii. Accompanied by other malformations such as imperforate anus and tracheoesophageal fistula, and congenital heart defect

Diagnostic Investigations

1. Radiography
  a. Phocomelia of the upper limbs
  b. Shortened humeri
  c. Shortened forearms
    i. Aplasia/hypoplasia of the radius
    ii. Hypoplastic ulna
    iii. Radioulnar synostosis
    iv. Humeral-ulnar synostosis
  d. Thumbs
    i. Absent thumbs
    ii. Triphalangeal thumbs
    iii. Clinodactyly
    iv. Syndactyly
    v. Absent first metacarpals
    vi. Hypoplastic thenar eminences
  e. First metacarpals
    i. Absent
    ii. Hypoplastic
  f. Fifth fingers
    i. Short middle phalanx
    ii. Clinodactyly
  g. Carpal bones
    i. Deformed
    ii. Extra carpals
    iii. Fused
    iv. Irregular
    v. Delayed formation
  h. Shoulders
    i. Deformed scapula and/or clavicle
    ii. Deformed head of the humerus
    iii. Accessory bones
  i. Deformed sternum
2. Echocardiography for structural cardiac defects
3. Electrocardiography for cardiac conduction defects (Bossert et al. 2002)
  a. Sinus arrest
  b. Various degrees of atrioventricular block
  c. Right bundle branch block
  d. Sinus node dysfunction
  e. Wandering pacemaker

   f. Bradycardia
   g. Atrial fibrillation/flutter
   h. Supraventricular tachycardia and WPW syndrome
   i. Premature ventricular complexes
4. Molecular genetic testing of *TBX5* by sequencing of entire coding region or mutation scanning

Genetic Counseling

1. Recurrence risk
   a. Probands
      i. Sixty to seventy percent have an affected parent
      ii. Thirty to forty percent have a de novo mutation
   b. Patient's sib: not increased unless a parent is affected in which case, there is 50% recurrence risk
   c. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Ultrasonography of Holt-Oram syndrome for fetuses at risk involving severe anomalies by demonstrating cardiac defect associated with upper limb defects, especially the radial ray defects
   b. Molecular genetic testing of *TBX5* of fetal DNA obtained from amniocentesis or CVS, provided the disease-causing mutation has been identified in the family
   c. Preimplantation genetic diagnosis
      i. May be available for families in which the disease-causing mutation has been identified
      ii. Reported for Glu69ter *TBX5* mutation causing Holt-Oram syndrome (McDermott et al. 2005)
3. Management
   a. A permanent pacemaker for advanced heart block
   b. Surgery for severe cardiac defect
   c. Prostheses for children with severe limb shortening
   d. Orthopedic management of severe limb defects

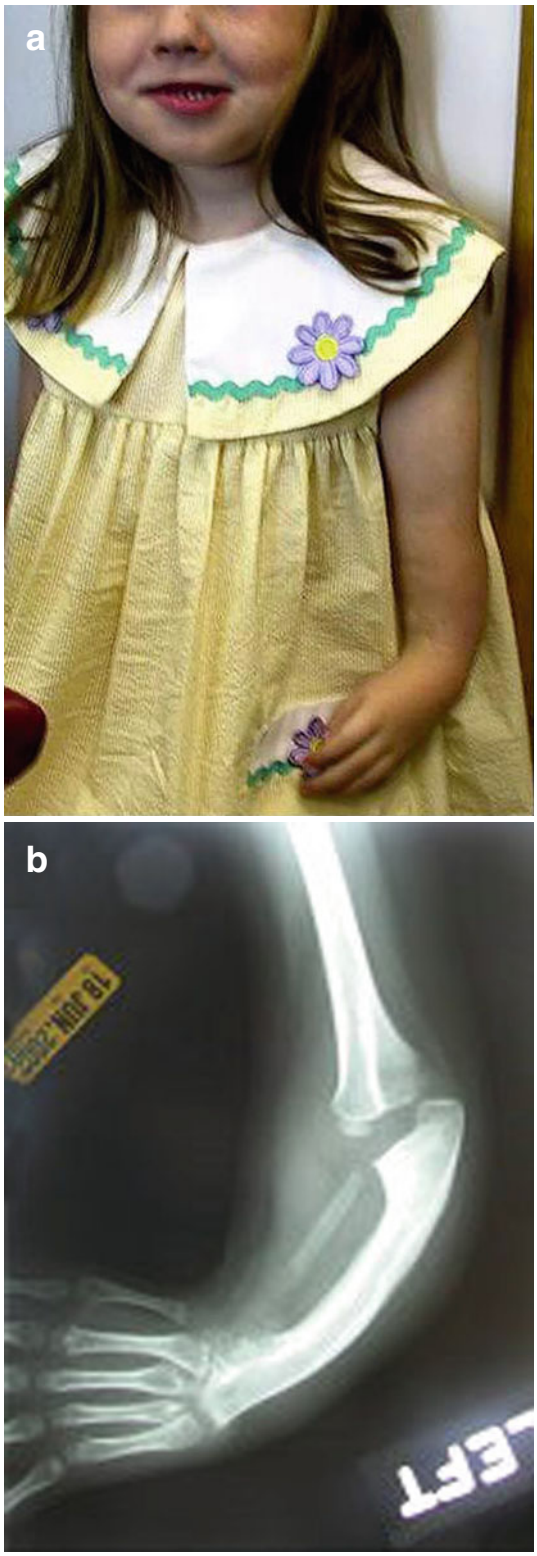

Fig. 3 (**a**, **b**) A child with Holt-Oram syndrome showing left club hand and hypoplastic radius, illustrated by radiography

Huntington Disease

Huntington disease (HD) is an autosomal dominant, progressive neurodegenerative disorder, typically characterized by a movement disorder, affecting middle-aged adults. It is the most frequent cause of genetic chorea with reported prevalence rates in North America and Europe ranging from 3 to 7 per 100,000 (Cardoso et al. 2006).

Synonyms and Related Disorders

Huntington chorea

Genetics/Basic Defects

1. Caused by a mutation in the *IT15* gene, which is a 210-kb gene located near the tip of the short arm of chromosome 4 (4p16.3), resulting in the N-terminal region of huntingtin protein (Htt) (The Huntington's Disease Collaborative Research Group 1993; Cardoso 2009; Harris et al. 2009)
2. Patients with Huntington disease have an expanded and unstable trinucleotide CAG (cytosine-adenine-guanine) repeat in the *IT15* gene within exon 1 (Rubinsztein et al. 1996). Huntington disease is, therefore, considered one of the trinucleotide repeat disorders.
   a. Normal CAG repeat length in the *HD* gene: 35 or lower
   b. Expansions of 40 or more cause HD with complete penetrance.
   c. Individuals with 36–39 repeats may also develop HD but penetrance is incomplete (Rubinsztein et al. 1996).
   d. A CAG repeat range between 27 and 35: considered normal allele with particular risk for expansion into the HD range in the paternal germline (Ranen et al. 1995; Laccone et al. 1999)
   e. The number of CAG repeats
      i. Has significant implications for age at onset, disease severity, and stability of the gene between generations
      ii. Presence of a robust inverse correlation between the number of polyglutamine repeats and the age at disease onset so that longer repeat lengths are associated with earlier onset of Huntington disease (Shelbourne et al. 2007)
      iii. The number of CAG repeats, however, is not an absolute prediction of disease onset.
3. The nature of the genetic defect in the *HD* gene (Myers et al. 1998) explains many of the genetic features of the disorder, including:
   a. The variability in age at onset
   b. The tendency for juvenile disease to be inherited from fathers
      i. Merritt et al. (1969) first observed that a disproportionate number of cases with onset before the age of 21 had inherited the *HD* gene from affected fathers.
      ii. The observation of earlier ages at onset in successive generations, termed "anticipation," is seen in several of the trinucleotide repeat disorders including HD.
      iii. Meiotic instability of the *HD* repeat in paternal transmission explains the observation of anticipation in HD.
   c. The sporadic appearance of new mutations to HD

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_121,
© Springer Science+Business Media, LLC 2012

4. Pathophysiology (Roze et al. 2008)
   a. The expanded polyglutamine repeat alters the normal functions of Htt.
   b. The mutated protein, Exp-Htt, is itself toxic.
   c. Htt interacts with an array of proteins in neuronal cells
   d. One important characteristic of Huntington disease is the particular vulnerability of a particular brain region, the caudate–putamen, despite similar expression of the mutated protein in other brain areas.

Clinical Features

1. A triad of HD (Cardoso 2009; Harris et al. 2009)
   a. Movement disorder (Leigh et al. 1983; Carella et al. 1993; Jankovic and Ashizawa 1995; Reuter et al. 2000; Tan et al. 2000)
      i. Full spectrum of motor impairment
         a) Eye movement abnormalities
         b) Parkinsonian features
         c) Dystonia (particularly in juvenile HD)
         d) Myoclonus
         e) Tics
         f) Ataxia
         g) Dysarthria
         h) Dysphagia
         i) Spasticity with hyperreflexia and extensor plantar responses
      ii. Chorea: often superseded by dystonia or akineto-rigid parkinsonian features with progressing illness
      iii. Dystonia: found in more than 90% of patients with HD in one study (Louis et al. 1999) although rarely it becomes as prominent as in idiopathic dystonias
   b. Cognitive decline
      i. Universally go through cognitive decline, mental slowing, impaired problem-solving abilities, and other signs of a frontal dysexecutive syndrome, and they eventually become demented. These patients present with the prototype of so-called subcortical dementia (Lawrence et al. 1996; Kirkwood et al. 2001; Ho et al. 2003).
      ii. Cognitive decline also heralds the juvenile onset of HD (Ribai et al. 2007).
      iii. Asymptomatic carriers of the HD gene have decreased phonemic fluency (Larsson et al. 2008).
   c. Behavioral changes
      i. Universal and may occasionally antedate motor manifestations
      ii. Major depression is common, diagnosed in more than 40% of subjects, and responsible for increased suicide rates in HD
      iii. Broad spectrum of behavioral abnormalities (Caine and Shoulson 1983; Mendez 1994; Schoenfeld et al. 1984; Shiwach 1994; Rosenblatt and Leroi 2000; Rosenblatt et al. 2003; Guttman et al. 2003)
         a) Anxiety or panic attacks
         b) Obsessive compulsive symptoms
         c) Manic features
         d) Psychosis
         e) Irritability and aggressive behavior
         f) Sexual disinhibition
         g) Apathy
         h) In presymptomatic HD, significantly more psychiatric symptoms (specially depression, anxiety, and obsessive-compulsiveness) were reported than for the controls (Duffin et al. 2007)
         i) Similarly, psychiatric difficulties are indicators of juvenile HD onset (Ribai et al. 2007).
2. End-stage HD
   a. Relentlessly progressive course with death occurring 15–20 years after symptom onset with particularly rapid progression in the juvenile Westphal variant
   b. Typically rigid and akinetic, demented, and mute
   c. Immobility and dysphagia often lead to aspiration pneumonia, the most common cause of death in these patients (Marshall 2004; Sorensen and Fenger 1992; Lanska et al. 1988).
3. Differential diagnosis
   a. Choreoacanthocytosis: the most likely disorder to be confused
      i. Dementia
      ii. Involuntary movements
      iii. Caudate atrophy
      iv. Abnormal red blood cell morphology

v. Neuropathy
vi. Seizures
vii. Myopathy
viii. Elevated creatine phosphokinase
ix. Self-mutilation
x. An unusual eating dystonia

b. Different causes of chorea
i. Genetic causes
a) Huntington disease
b) Huntington disease–like illnesses
c) Neuroacanthocytosis
d) McLeod syndrome
e) Wilson disease
f) Benign hereditary chorea
g) Spinocerebellar atrophy types 2, 3, 17
h) Dentatorubropallidoluysian degeneration
i) Ataxia-telangiectasia
j) Ataxia associated with oculomotor apraxia
k) Neuroferritinopathy
l) Pantothenate kinase associated degeneration
m) Leigh disease and other mitochondriopathies
n) Lesch–Nyhan disease
o) Creutzfeldt–Jakob disease
p) Neuronal ceroid lipofuscinosis
q) Glutaric aciduria
r) Polycythemia vera
s) Celiac disease
t) Benign familial chorea
ii. Immunologic causes
a) Sydenham chorea
b) Systemic lupus erythematosus
c) Antiphospholipid antibody syndrome
iii. Drug-induced chorea
a) Amantadine
b) CNS stimulants (amphetamines, methylphenidate, cyproheptadine)
c) Anticholinergics
d) Anticonvulsants (carbamazepine, phenytoin)
e) Carbon monoxide
f) Cocaine
g) Dopamine agonists
h) Dopamine-receptor blockers
i) Estrogens
j) Ethanol
k) Levodopa
l) Levofloxacin
m) Lithium
n) Sympathomimetics
o) Theophylline
p) Tricyclic antidepressants
q) Carbamazepine
r) Drugs that cause tardive dyskinesia
s) Withdrawal emergent syndrome
iv. Infections
a) AIDS-related (toxoplasmosis, progressive multifocal leukoencephalopathy, HIV encephalitis)
b) Bacteria (diphtheria, scarlet fever, whooping cough)
c) Encephalities (B19 parvovirus, Japanese encephalitis, measles, mumps, West Nile river encephalitis, others)
d) Parasites (neurocysticercosis)
e) Protozoan (malaria, syphilis)
v. Endocrine-metabolic dysfunction
a) Adrenal insufficiency
b) Hyper/hypocalcemia
c) Hyper/hypoglycemia
d) Hypomagnesemia
e) Hypernatremia
f) Liver failure
vi. Vascular
a) Postpump chorea (cardiac surgery)
b) Stroke
c) Subdural hematoma
vii. Miscellaneous
a) Anoxic encephalopathy
b) Cerebral palsy
c) Kernicterus
d) Multiple sclerosis
e) Normal maturation (less than 12 months old)
f) Nutritional (e.g., B12 deficiency)
g) Posttraumatic (brain injury)
h) Chorea gravidarum hyperthyroidism
i) External pallidal atrophy
j) Pick disease
k) Paraneoplastic syndromes
l) Acute disseminated encephalo myelopathy
m) Multiple system atrophy

Diagnostic Investigations

1. A confirmed family history of Huntington disease combined with clinical manifestations: sufficient for diagnosis (Harris et al. 2009)
2. Neuroimaging (MRI and CT)
   a. Severe atrophy of the caudate nucleus in moderately disabled patients
   b. May be relatively normal in patients in the early stages
3. Pet scan: Atrophy of the caudate nucleus can be detected in a presymptomatic state by the finding of head of caudate hypometabolism
4. Neuropathological features
   a. Neuronal loss and gliosis in the cortex and striatum, particularly the caudate nucleus: the most prominent neuropathologic features (Roth et al. 2005)
   b. Neuronal injury occurs initially in the caudate tail, in the medial paraventricular caudate, and in the dorsal part of the putamen.
   c. Further neuronal loss and an increase in astrocytes can be observed in widespread cortical and subcortical regions as the neurodegenerative process progresses.
   d. Pathologic observation of affected striatum shows loss of GABAergic spiny projection neurons with preservation of the aspiny interneurons and large aspiny acetylcholinesterase-positive neurons.
   e. A decrease of important neurotransmitters and neuropeptides, such as γ-aminobutyric acid (GABA), calbindin, enkephalin, and substance P, as a result of selective loss of the medium spiny neurons
5. Three main types of genetic testing of HD
   a. To confirm or rule out disease
   b. Presymptomatic testing to determine the carrier status of an individual at genetic risk for inheriting the disease
      i. To assist in making decisions about marriage, procreation, or career
      ii. The emotional impact of the result can be difficult to anticipate and can evoke substantial adverse emotional reactions (Taylor and Myers 1997; Almqvist et al. 1999).
      iii. Appropriate pretest counseling is important to assist the at-risk individual in considering the risks and benefits of genetic testing for diseases such as HD for which available treatment does not justify testing
   c. Prenatal testing to determine the carrier status of a fetus

Genetic Counseling

1. Recurrence risk (Warby et al. 2010)
   a. Patient's sib
      i. A 50% risk if a parent is affected or has a CAG size of 40 or greater.
      ii. An estimated risk as high as 5% (50% × 10%) of inheriting a mutant allele (≥36 CAG repeats) if the father has an intermediated allele (Chong et al. 1997)
      iii. A sib who inherits an *HD* allele with reduced penetrance may or may not develop symptoms of HD.
   b. Patient's offspring
      i. A 50% risk of inheriting the disease-causing mutation from a parent with heterozygosity for the *HD* allele
      ii. A 100% risk of inheriting the disease-causing allele from a parent with homozygosity for CAG repeat expansion in the *HD* gene
2. Prenatal diagnosis (Warby et al. 2010)
   a. Prenatal diagnosis is possible for pregnancies at 50% risk by analyzing DNA extracted from fetal cells obtained by amniocentesis or CVS, provided the disease-causing allele in the affected parent or in an affected relative has been confirmed.
   b. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member.
3. Management (Harris et al. 2009)
   a. No definitive cure
   b. Limited therapeutic options currently
   c. Multidisciplinary team approach
      i. Medical
      ii. Social work
      iii. Physical therapy
   d. Selective serotonin reuptake inhibitors: effective in treating depression symptoms:
      i. Depression
      ii. Mania

iii. Delusions
iv. Paranoia
v. Chorea
vi. Other symptoms related to depression
  a) Rumination
  b) Perseveration
  c) Obsessive-compulsive disorder
  d) Suicide
vii. Mood stabilizers (valproate, carbamazepine, lamotrigine, or lithium) for bipolar disorders

e. Neuroleptic for delusions and paranoia symptoms as well as chorea
f. Atypical antipsychotics (risperidone, clozapine, olanzapine, and quetiapine): provide sufficient control of psychotic symptoms with a lower risk for extrapyramidal adverse effects and tardive dyskinesia.
g. Nutritional management
h. Palliative care in managing the latter stage of the disease
  i. Bedridden
  ii. Mute
  iii. Rigid
  iv. Dysphagia
  v. Aspiration

Fig. 1 The patient, a 42-year-old lady, was evaluated for increasing weakness of her legs over the past 1 year, dropping things out of her hands and increased balance difficulties. She was ambulatory but had difficulty going upstairs and on uneven surfaces. She later developed typical movement disorders, chorea, dystonia, cognitive decline, and behavioral changes. The family history was significant for affected family members (mother and two brothers). The diagnosis of Huntington disease was confirmed by the presence of over 40 CAG repeats

Hydrolethalus Syndrome

Hydrolethalus syndrome was coined by Salonen et al. in 1981 in patients with severe CNS malformations, hydrocephalus, micrognathia, cleft lip/palate, lung hypoplasia club foot, and polydactyly, distinguishable from the Meckel syndrome by the absence of polycystic kidneys (Salonen et al. 1981). The majority of cases were reported from Finland.

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Hydrolethalus syndrome locus: assigned to 11q23-q25 in Finnish families
3. *HYLS1* gene mutation
   a. Responsible for hydrolethalus syndrome in the Finnish population, HYLS1
   b. c.632A > G (D211G) mutation: the common mutation carried in the Finnish population

Clinical Features

1. A lethal condition: stillborn or died within a few hours of birth in majority of cases
2. Hydramnios
3. Severe midline CNS malformations
   a. A midline cerebral cleft: more common
   b. Absence of the corpus callosum
   c. Absence of septum pellucidum
   d. Hydrocephalus secondary to aqueductal stenosis
   e. Dorsal midline defect of the foramen magnum, forming a keyhole-shaped opening (occipitoschisis)
   f. Cerebellar heterotopias
   g. Brain stem malformations
   h. Cerebral gyral abnormalities
   i. Absent olfactory lobes
   j. Hypothalamic hamartomas
   k. Dandy-Walker malformation
4. Craniofacial features
   a. Microphthalmia
   b. Nasal anomalies
   c. Small mandible
   d. Cleft lip/palate
   e. Small tongue
   f. Low-set, malformed ears
5. Pulmonary anomalies
   a. Abnormal larynx, trachea, and bronchi
   b. Pulmonary hypoplasia/agenesis
   c. Defective lung lobulation
6. Congenital heart defects
   a. Ventricular septal defect
   b. Open foramen ovale
   c. Common atrioventricular canal
7. Renal anomalies
8. Duplex/bicornis uterus
9. A typical "keyhole" occipital bone defect
10. Polydactyly
    a. Hands: always postaxial
    b. Feet: almost always preaxial
11. Differential diagnosis
    a. Acrocallosal syndrome
       i. Macrocephaly
       ii. Craniofacial anomalies
       iii. Hallux duplication
       iv. Postaxial polydactyly
       v. Absence of corpus callosum
       vi. Mental retardation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_122,

b. Smith-Lemli-Opitz syndrome (severe form)
   i. Hydrocephalus
   ii. Cerebellar hypoplasia
   iii. Cardiac anomalies
   iv. Genital anomalies
   v. Polydactyly
c. Orofacialdigital syndrome, type VI
   i. Cerebellar anomalies
   ii. Hypertelorism
   iii. Micrognathia
   iv. Midline cleft lip
   v. Cleft palate
   vi. A small tongue with lingual nodules and multiple frenula
   vii. Laryngeal anomalies
   viii. Cardiac anomalies
   ix. Preaxial polysyndactyly of hands and feet
   x. Postaxial polysyndactyly of the feet
d. Pallister-Hall syndrome
   i. Hypertelorism
   ii. Micrognathia
   iii. Midline cleft lip
   iv. Cleft palate
   v. A small tongue with lingual nodules and multiple frenula
   vi. Laryngeal anomalies
   vii. Lung segmental anomalies
   viii. Cardiac anomalies
   ix. Postaxial polysyndactyly of the feet
e. Walker-Warburg syndrome
   i. Overlapping features
      a) Encephalocele
      b) Agenesis of midline brain structures
      c) Hydrocephalus
   ii. Features usually not seen
      a) Eye abnormalities
      b) Polydactyly

Diagnostic Investigations

1. Radiologic studies
   a. Skull
      i. Microcephaly
      ii. Occipital bone defect continuous with foramen magnum
      iii. A keyhole shaped defect at the base of skull
   b. Digital anomalies
      i. Postaxial polydactyly of the hands
      ii. Preaxial polydactyly or hallux duplication of the feet
2. Ultrasound or MRI of the brain for delineation of brain anomalies
3. Echocardiogram for delineation of congenital heart defects
4. Molecular genetic study: target mutation analysis of *HYLS1* gene (c.632A > G)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk: 25%
      ii. Unaffected sibs of a proband: two thirds chance of being heterozygotes
   b. Patient's offspring: a lethal entity not surviving to reproduction
2. Prenatal diagnosis
   a. Possible by prenatal ultrasonography in at-risk families
   b. Possible for pregnancies at risk when the disease-causing mutation in the family is known
3. Management
   a. Supporting care
   b. No treatment available for the underlying lethal disorder

Hydrops Fetalis

Hydrops fetalis is a condition in which fluid accumulates in the serous cavities and/or in the soft tissues of the fetus. It is classified as immune if there is an indication of a fetomaternal blood group incompatibility, otherwise classified as nonimmune. The incidence of nonimmune hydrops fetalis is estimated to be approximately 1 in 2,500 to 1 in 3,500 neonates.

Synonyms and Related Disorders

Hydrops fetalis syndrome; Immune hydrops; Nonimmune hydrops

Genetics/Basic Defects

1. Causes of immune hydrops (IH)
   a. Rh-D disease (approximately 90% of immune hydrops)
      i. Prior to 1960s, this is the most common cause (up to 80%) of all cases with hydrops fetalis. The incidence of rhesus isoimmunization has declined steadily because of the widespread use of anti-D gamma globulin. The majority of hydrops is now of the nonimmune type (Holzgreve et al. 1985).
      ii. Mother (Rh−), father (Rh+), and fetus (Rh+)
      iii. After sensitization, maternal Rh antibody (IgG anti-D) crosses the placenta and destroys the Rh-positive fetal red blood cells. It results in fetal anemia.
      iv. Previous pregnancy, including maternal-fetal blood mixing
      v. Previous abortion (spontaneous, missed, therapeutic)
      vi. First trimester bleeding
      vii. Trauma
      viii. Blood transfusion
   b. ABO incompatibility (rare, overall incidence about 1%)
      i. ABO incompatible pregnancies (about 20%) in which only 5% of these cases lead to hydrops
      ii. Mother (nearly always O+ with antibodies to A, B, or both)
      iii. Fetus (A, B, or AB)
   c. Other autoimmune causes (targeting other RBC antigens)
      i. Anti-Lewis antibodies: benign ("Lewis lives")
      ii. Anti-Kell antibodies (the second most common type accounting for about 10% of antibody mediated severe fetal anemia): mild to severe hydrops ("Kell kills")
      iii. Anti-Duffy antibodies: mild to severe hydrops ("Duffy dies")
2. Pathophysiology of immune hydrops
   a. Sensitization of the mother to an antigen (usually Rh-D)
      i. Presence of antigen on fetal RBC but not on mother's RBC
      ii. Primary response generally a maternal IgM anti-RBC response
   b. Production of IgG antibodies by the mother on the secondary exposure. The IgG antibodies can cross the placenta.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_123,
© Springer Science+Business Media, LLC 2012

c. Destruction of fetal RBC by maternal anti-fetal RBC antibodies
   i. A Coombs' positive process
   ii. Destruction most likely mediated by complement and macrophages
   iii. Jaundice frequently observed secondary to increased bilirubin production
d. Compensatory increase in fetal cardiac output due to decreased fetal hematocrit
e. Heart failure resulting from high cardiac output by the fetal heart
   i. Edema
   ii. Ascites
   iii. Circulatory failure with fetal death *in utero*

3. Conditions associated with nonimmune hydrops fetalis (NIHF). Nonimmune type now represents majority of hydrops fetalis after the practice of anti-D gammaglobulin prophylaxis since 1960s (Holzgreve et al. 1985).
   a. Cardiovascular disorders (5.3–26%, the most frequent underlying cause of NIHF) (Bukowski and Saade 2000)
      i. Tachyarrhythmia (supraventricular tachycardia, atrial flutter)
      ii. Bradyarrhythmias (complete heart block)
      iii. Congenital heart block
      iv. Hypoplastic left heart syndrome (31%)
      v. Endocardial cushion defects (13%)
      vi. Agenesis of the ductus venosus
      vii. Other anatomic defects of the heart
      viii. Premature closure of the ductus arteriosus
      ix. Generalized arterial calcification
      x. Cardiomyopathy
      xi. Myocarditis (Coxsackie virus or CMV)
      xii. Cardiac rhabdomyoma
      xiii. Intracardiac teratoma
   b. Chromosome abnormalities (7.5–77.8%, the second most frequent underlying causes of NIH)
      i. Trisomies
         a) Trisomy 21
         b) Trisomy 18
         c) Trisomy 13
      ii. Turner syndrome (most common chromosome anomaly)
      iii. Triploidies
      iv. Deletions
      v. Others
   c. Recognizable syndromes (2.2–27.6%)
      i. Skeletal dysplasias
         a) Thanatophoric dysplasia
         b) Arthrogryposis multiplex congenita
         c) Asphyxiating thoracic dystrophy
         d) Hypophosphatasia
         e) Osteogenesis imperfecta
         f) Achondrogenesis
         g) Saldino–Noonan syndrome
         h) McKusick–Kaufman syndrome
         i) Klippel–Trenaunay–Weber syndrome
         j) Conradi syndrome
         k) Other types of skeletal dysplasias
      ii. Metabolic diseases
         a) Mucopolysaccharidosis type IV Morquio disease (β-galactosidase deficiency)
         b) Mucopolysaccharidosis Type VII (β-glucuronidase deficiency)
         c) I-cell disease
         d) Niemann–Pick disease
         e) Gaucher disease
         f) Sialidosis
         g) Galactosialidosis
         h) Salla disease (Finnish type sialuria)
         i) Wolman disease
         j) Farber disease
         k) Carnitine deficiency
         l) Disorder of glycosylation (Léticée et al. 2010)
      iii. Other genetic syndromes
         a) Pena–Shokeir syndrome
         b) Neu–Laxova syndrome
         c) Recessive cystic hygroma
         d) Multiple pterygium syndrome
         e) Meckel syndrome
         f) Caudal regression syndrome
         g) Noonan syndrome
         h) Tuberous sclerosis
         i) Myotonic dystrophy
         j) X-linked dominant disorders with male lethality (e.g., hypomelanosis of Ito)
         k) Other single gene disorders
   d. Twin pregnancy (twin-twin transfusion syndrome) (3–8%)
   e. Hematologic disorders (10–27%)
      i. Intrinsic hemolysis
         a) α-thalassemia syndromes (Homozygous α-thalassemia-1 is the most common

cause of hydrops fetalis in Southeast Asia) (Lam et al. 1999)
b) G6PD deficiency
c) Pyruvate kinase deficiency
d) Glucosephosphate isomerase deficiency
e) Spectin abnormalities
ii. Extrinsic hemolysis (Kasabach–Merritt syndrome)
iii. Hemorrhage
a) Fetomaternal hemorrhage
b) Twin-twin transfusion syndrome
c) Fetal hemorrhage
iv. Fetal liver and bone marrow replacement syndromes
a) Transient myeloproliferative disorder
b) Congenital leukemia
v. Red cell aplasia and dyserythropoiesis
a) Parvovirus B19 infection
b) Blackfan–Diamond syndrome
c) Congenital dyserythropoiesis

f. Thoracic abnormalities (2.5–13%)
i. Diaphragmatic hernia
ii. Congenital cystic adenomatous malformation of the lung
iii. Extralobar pulmonary sequestration
iv. Congenital hydrothorax or chylothorax
v. Mediastinal teratoma
vi. Laryngeal atresia
vii. Pulmonary hypoplasia

g. Genitourinary malformations (2.5–3.5%)
i. Urethral obstruction
ii. Posterior urethral valves
iii. Neurogenic bladder with reflux
iv. Ureterocele
v. Prune-belly syndrome
vi. Upper urinary tract obstruction
vii. Renal dysplasia
viii. Cloacal malformations

h. Gastrointestinal anomalies
i. Jejunal atresia
ii. Midgut volvulus
iii. Malrotation of the intestine
iv. Duplication of the intestinal tract
v. Meconium peritonitis
vi. Gastroschisis
vii. Tracheoesophageal fistula

i. Hepatic diseases
i. Polycystic disease of the liver
ii. Hepatic fibrosis
iii. Cholestasis
iv. Biliary atresia
v. Hepatic vascular malformations
vi. Familial cirrhosis

j. Neurological abnormalities
i. Encephalocele
ii. Intracranial hemorrhage
iii. Cerebral aneurysm
iv. Intracranial arteriovenous malformation

k. Maternal diseases/complications
i. Medications (indomethacin taken to stop premature labor causing fetal ductus closure and secondary nonimmune hydrops fetalis)
ii. Mirror syndrome
a) Maternal edema
b) Preeclampsia
iii. Systemic diseases
a) Severe diabetes mellitus
b) Severe anemia
c) Hypoproteinemia
iv. Antepartum/postpartum hemorrhage
v. Theca lutein cysts development

l. Placenta-umbilical cord abnormalities
i. Chorioangioma
ii. Chorionic vein thrombosis
iii. Fetomaternal transfusion
iv. Placental and umbilical vein thrombosis
v. Umbilical cord torsion
vi. True cord knots
vii. Angiomyxoma of the umbilical cord
viii. Aneurysm of umbilical artery

m. Intrauterine infections (2–17.5%)
i. Viruses
a) Parvovirus B19
b) CMV
c) Rubella
d) Adenovirus
e) Enteroviruses
f) Coxsackie virus
g) Polio
h) Influenza B
i) Respiratory syncytial virus
j) Congenital hepatitis
k) Herpes simplex, type I
ii. Bacteria/spirochetes
a) *Treponema pallidum*
b) *Listeria monocytogenes*
c) *Leptospira interogans*

iii. Parasites
a) *Toxoplasma gondii*
b) *Trypanosoma cruzii*
iv. Other
a) Chlamydia
b) *Ureaplasma urealyticum*
n. Miscellaneous conditions
i. Congenital lymphedema
ii. Congenital hydrothorax or chylothorax
iii. Polysplenia syndrome
iv. Amniotic band syndrome
v. Congenital neuroblastoma
vi. Tuberous sclerosis
vii. Ovarian cyst torsion
viii. Fetal trauma
ix. Large fetal angioma
x. Sacrococcygeal teratoma
xi. Cloacal malformation
o. Idiopathic (without an identifiable cause)

4. Pathophysiology of nonimmune fetal hydrops
a. Cardiac failure directly involving the heart
i. Arrhythmias
ii. Malformations
iii. Myocarditis
iv. Infarction
v. Cardiomyopathy
b. Abnormal vascularization causing high output cardiac failure
i. Twin-twin transfusion syndrome
ii. Acardiac twinning
iii. Tumors
iv. AV fistulas
v. Placental vascular anomalies
c. Profound anemia
i. Hemolytic anemias
ii. Parvovirus B19 (fifth disease)
iii. Fetal-maternal hemorrhage
iv. Alpha-thalassemia, hemoglobin Bart's
v. G6PD deficiency
vi. Glucose-6-phosphate isomerase deficiency
vii. Pyruvate kinase deficiency
viii. Defects of red cell membrane
d. Decreased plasma oncotic pressure
i. Congenital nephrosis
ii. Hepatic necrosis
e. Fetal infections
i. Increased capillary permeability (anoxia due to congenital infection)
ii. Infection of erythroid progenitor cells (e.g., parvovirus B19)
iii. Myocarditis (e.g., adenovirus, Coxsackie virus)
iv. Hepatic destruction (e.g., syphilis)
f. Obstruction of venous return
i. Congenital cystic adenomatoid malformation
ii. Fetal closure or restriction in the size of the ductus arteriosus, foramen ovale or ductus venosus
iii. Diaphragmatic hernia
iv. Pulmonary sequestration
v. Tumors of the heart, lungs, abdomen or pelvis
vi. Umbilical cord lesions
g. Obstruction of lymphatic flow (e.g., Turner syndrome)

Clinical Features

1. Maternal history associated with hydropic infants
a. Previous history of hydrops
b. Severe maternal anemia
c. Associated polyhydramnios in at least 50% of hydropic fetuses
d. Size-date discrepancy
e. Twin gestation
f. Maternal diabetes mellitus
g. Maternal pregnancy induced hypertension/preeclampsia
h. Fetal arrhythmia
i. Placentomegaly
j. Positive antibody screen
k. Syphilis or other TORCH infections
2. Edema due to right-sided heart failure
a. Circulatory failure
b. Ascites
i. First sign of fetal hydrops caused by anemia
ii. Hypertension
iii. Hypoalbuminemia
iv. Prune belly secondary to marked fetal ascites
c. Pleural effusions
d. Pericardial effusions
e. Jaundice (hyperbilirubinemia)
3. Hemolysis with extramedullary hematopoiesis

4. Hepatosplenomegaly
   a. A hallmark for immune hydrops
   b. Absent in nonimmune hydrops fetalis
5. Fetal prognosis: presence of fetal hydrops often indicating fetal compromise with a significant risk of mobility and death
   a. Cardiovascular disorders
      i. Best prognosis among abnormalities underlying nonimmune hydrops
      ii. Cumulative survival rate: 29%
      iii. Treatment of tachycardia improves prognosis.
   b. Chromosome abnormalities: 2% survival rate
   c. Syndromes: 5% survival rate
   d. Fetal infections: 19% cumulative survival rate
   e. Thoracic lesions: one of the best cumulative prognosis, 26%
   f. Fetofetal transfusion syndrome: 20% survival rate
   g. Extremely poor prognosis
      i. Anemia secondary to parvovirus infection
      ii. Anemia resulting from fetomaternal hemorrhage
      iii. α-thalassemia: All fetuses with the Hb Bart's hydrops fetalis syndrome succumb to severe fetal hypoxia in utero during the third trimester of gestation or within hours after birth (Chui and Waye 1998).
   h. Good prognosis for psychomotor development in survivors with nonimmune hydrops fetalis (Haverkamp et al. 2000)
6. Morbidity (Bukowski and Saade 2000)
   a. Morbidity depending on the underlying disorder
   b. Short-term morbidity high (neonate requires difficult resuscitation, long and intensive hospitalization, and multiple invasive procedures)
   c. Relatively low long-term morbidity in NIHF in children diagnosed prenatally
7. Mortality
   a. Mortality rate: 50–98%
   b. Contribute to 3% of perinatal mortality
   c. Mortality depending on the underlying disorder

Diagnostic Investigations

1. Diagnostic evaluation of immune hydrops
   a. ABO and Rh typing and a serum antibody screen (positive indirect Coombs' test) for every pregnant woman as early as possible during each pregnancy
   b. Spectrophotometric estimation of bilirubin pigments in the amniotic fluid, obtained by amniocentesis in selected patients, to estimate the risk of severe hemolytic disease while the fetus is still in utero
   c. Direct Coombs' test on cord blood
      i. Nearly always positive in Rh-induced hemolytic disease of newborns (HDN)
      ii. Frequently but not always positive in ABO-induced HDN
   d. Usually increased cord blood bilirubin and decreased cord blood hemoglobin in severe HDN
2. Diagnostic evaluation of newborn babies with nonimmune hydrops (Carlton et al. 1989)
   a. Cardiovascular disorders
      i. Echocardiogram
      ii. Electrocardiogram
   b. Thoracic abnormalities
      i. Chest radiographs
      ii. Pleural fluid examination
   c. Hematologic disorders
      i. Complete blood cell count
      ii. Differential
      iii. Platelet count
      iv. Blood type
      v. Coombs' test
      vi. Blood smear for morphology
      vii. Hemoglobin electrophoresis
   d. Gastrointestinal abnormalities
      i. Abdominal radiographs
      ii. Abdominal ultrasound
      iii. Liver function tests
      iv. Peritoneal fluid examination
      v. Total protein
      vi. Albumin
   e. Renal malformations
      i. Urinalysis
      ii. BUN
      iii. Creatinine
   f. Genetics
      i. Chromosome analysis
      ii. Skeletal radiographs
   g. Congenital infections viral cultures or serology (Barron and Pass 1995)
      i. Parvovirus B19
         a) Maternal infection: specific IgM and IgG
         b) Fetal/neonatal infection: specific IgM, virus detection by PCR

ii. Syphilis
  a) Maternal infection: RPR or VDRL
  b) Fetal/neonatal infection: RPR or VDRL, dark-field examination of material from lesions
iii. CMV
  a) Maternal infection: CMV-IgM or IgG seroconversion
  b) Fetal/neonatal infection: isolation of virus from amniotic fluid, fetal, or neonatal body fluid
iv. HSV
  a) Maternal infection: HSV culture of lesion
  b) Fetal/neonatal infection: HSV culture of amniotic fluid, fetal tissue, or neonate
v. Toxoplasmosis
  a) Maternal infection: capture IgM, specific IgG
  b) Fetal/neonatal infection: capture IgM ELISA
vi. Rubella
  a) Maternal infection: specific IgM and IgG or proven exposure plus compatible illness
  b) Fetal/neonatal infection: isolation of virus from fetal or neonatal body fluid, rubella IgM

h. Autopsy indicated for stillbirth or perinatal death including examination of the placenta and babygram

Genetic Counseling

1. Recurrence risk
  a. Patient's sib
    i. Immune hydrops fetalis: will be affected unless sensitization is prevented
    ii. Nonimmune hydrops fetalis
      a) Sporadic: no increased risk
      b) Autosomal recessive disorder: 25%
      c) Autosomal dominant disorder: not increased unless a parent is affected
      d) Chromosome disorder: increased especially when a parent is a translocation carrier
  b. Patient's offspring
    i. Immune hydrops fetalis: recurrence risk not increased
    ii. Nonimmune hydrops fetalis
      a) Sporadic: no increased risk
      b) Autosomal recessive disorder: not increased unless the spouse is a carrier
      c) Autosomal dominant disorder: 50%
      d) Chromosome disorder: increased if the patient survives to reproductive age
2. Prenatal evaluation of immune hydrops fetalis
  a. Rh testing and ABO typing indicated for all pregnancies
  b. Positive maternal antibody screen (indirect Coombs test)
  c. Suspicious for immune hydrops
    i. Cord blood for testing of hemolysis and hematocrit
    ii. Amniocentesis for bilirubin
  d. Specific testing for antibodies in women with previous pregnancy losses
  e. Doppler ultrasonography
    i. Used to measure peak velocity of systolic blood flow in fetus
    ii. Increased peak systolic blood flow velocity in fetuses with anemia
    iii. Increased systolic velocity: 100% sensitive to fetal anemia
  f. Prenatal diagnosis of fetal Rh-D status by molecular analysis
3. Maternal evaluation of nonimmune hydrops fetalis (Holzgreve et al. 1985)
  a. Complete blood count and indices for hematological disorders
  b. Hemoglobin electrophoresis (α-thalassemia)
  c. Kleihauer–Betke stain for evidence of fetomaternal hemorrhage
  d. Maternal blood chemistry for fetal red cell enzyme deficiency
    i. Glucose-6-phosphate deficiency screen
    ii. Pyruvate kinase carrier status
  e. Infection screening
    i. Syphilis by VDRL
    ii. TORCH titers
    iii. Parvovirus titers
    iv. Group B streptococcus
    v. Listeria monocytogenes
  f. Autoantibody screen
    i. Systemic lupus erythematosus
    ii. Anti-Ro (anti-SS-A) and Anti-La (anti-SS-B) antibody titers for Sjogren syndrome
  g. Fetal echocardiography for presence of congenital heart defects

4. Prenatal ultrasonography
   a. Immune hydrops secondary to α-thalassemia (Tongsong et al. 1996)
      i. Hepatosplenomegaly (>95%)
      ii. Cardiomegaly (>95%)
      iii. Edematous placenta (>95%)
      iv. Ascites (>95%)
      v. Oligohydramnios (82%)
      vi. Subcutaneous edema (75%)
      vii. Decreased fetal movement (74%)
      viii. Cord edema (63%)
      ix. Enlarged umbilical vessel (62%)
      x. Pericardial/pleural effusion (15%)
   b. Nonimmune hydrops
      i. Fetal ascites
      ii. Fetal pleural effusion
      iii. Fetal pericardial effusion (the earliest finding)
      iv. Fetal skin thickening
      v. Maternal polyhydramnios
      vi. Placentomegaly, especially Rh disease or chorioangioma
      vii. Cystic hygroma as early as 13 weeks of gestation
5. Fetal evaluation of nonimmune hydrops fetalis
   a. Fetal echocardiography, M-mode, pulsed, and color flow Doppler
      i. Congenital heart defects
      ii. Fetal rhythmic abnormalities
      iii. Cardiac biometry
   b. Doppler flow velocity studies
      i. Umbilical artery
      ii. Middle cerebral artery
      iii. Tricuspid ejection velocity
   c. Amniocentesis
      i. Amniotic fluid index
      ii. Fetal karyotype (chromosome abnormality)
      iii. Amniotic fluid viral cultures
      iv. Alpha-fetoprotein (congenital nephrosis, sacrococcygeal teratomas)
      v. Isolation of CMV virus for identification of CMV DNA by PCR
      vi. Specific metabolic tests
         a) Tay–Sachs disease
         b) Gaucher disease
         c) GM_1 gangliosidosis
      vii. Metabolic disease screening panel
         a) Acid sphingomyelinase deficiency
         b) Deficient cholesterol esterification
         c) Acid β-glucosidase deficiency
         d) Acid β-galactosidase deficiency
         e) Acid sialidase deficiency
         f) Sialidase deficiency
         g) β-galactosidase deficiency
         h) Ceramidase deficiency
         i) Glucose phosphate isomerase deficiency
         j) N-acetylglucosamine phosphotransferase deficiency
      viii. Restriction endonucleases tests (e.g., thalassemias)
   d. Fetal blood sampling
      i. Rapid karyotype (chromosome abnormality)
      ii. Fetal complete blood count (fetal anemia)
      iii. Blood group and Coombs' test
      iv. Hemoglobin electrophoresis (α-thalassemia)
      v. Fetal plasma analysis for specific IgM (e.g., CMV-specific IgM antibody, PCR)
      vi. G6PD in male fetuses
      vii. Fetal plasma albumin (fetal hypoalbuminemia)
      viii. Metabolic testing
         a) Tay–Sachs disease
         b) Gaucher disease
         c) GM_1 gangliosidosis
   e. Fluid aspirated for biochemistry and viral screen
      i. Pleural effusion
      ii. Ascites
      iii. Amniotic fluid
   f. Placenta
      i. Morphology
      ii. Thickness
6. Management
   a. Immune hydrops fetalis
      i. Prevent sensitization by Rhogam or Rh immune globulin
      ii. Prevent fetal heart failure when mother has sensitization reaction
      iii. Fetal transfusion for fetal anemia via cordocentesis
      iv. Induction of labor
      v. Postpartum exchange blood transfusion to prevent kernicterus, the most feared complication of Rh-induced HDN
   b. Nonimmune hydrops fetalis
      i. Screen tests to detect couples at risk for having a fetus with the Hb Bart's hydrops fetalis by simple blood counts and hemoglobin electrophoresis

ii. Neonatal resuscitation
iii. Intrauterine or immediate post-delivery transfusions to babies (e.g., homozygous α-thalassemia, Parvovirus B19 infection)
iv. Fetal cardiac arrhythmias treated by transplacental antiarrhythmic therapy
v. Flecainide acetate for fetal supraventricular tachycardia with hydrops fetalis
vi. Continuous arteriovenous hemodilution for fluid overload in newborns with hydrops fetalis
vii. Pleurocentesis in utero to drain pleural effusion to minimize pulmonary hypoplasia
viii. Treatment of maternal infection (Barron and Pass 1995)
   a) Parvovirus B19: intrauterine transfusion
   b) Syphilis: IV penicillin
   c) CMV: No pharmaceutic regimens available for treatment of maternal and fetal CMV infections. Treatment with antiviral agents (ganciclovir, foscarnet) is limited to severe infections (CMV retinitis) in immunocompromised patients and not currently used in pregnancy.
   d) HSV: acyclovir warranted in disseminated disease; fetal effect unknown
   e) Toxoplasmosis: spiramycin and/or pyrimethamine, sulfadiazine, and folinic acid
ix. Fetal surgery attempted for congenital cystic adenomatoid malformation, pulmonary sequestration, fetal pleural effusions, and sacrococcygeal teratoma

Hyper-IgE Syndrome

Hyper-IgE syndrome (HIES) is a rare, hereditary multisystem disorder characterized clinically by hyperimmunoglobulinemia E, recurrent infections, and eczematoid dermatitis. In 1966, Job reported two patients with eczematous dermatitis, recurrent staphylococcal boils, hyperextensible joints, and distinctive coarse facies. In 1972, Buckley et al. expanded the clinical picture by adding elevated immunoglobulin E (IgE).

Synonyms and Related Disorders

Job syndrome

Genetics/Basic Defects

1. Inheritance (Erlewyn-Lajeunnesse 2000)
   a. Autosomal dominant with variable penetrance and expressivity
   b. Linkage to a region on chromosome 4q21demonstrated in several affected families
   c. An upregulating mutation in the interleukin-4 receptor gene on chromosome 16, demonstrated in some patients with hyper-IgE syndrome
   d. Autosomal recessive hyper-IgE syndrome: a similar but distinct syndrome reported by Renner et al. (2004)
2. Autosomal dominant hyper-IgE syndrome (AD-HIES): caused by dominant-negative mutations in signal transducer and activator of transcription 3 (*STAT3*) in most cases of autosomal dominant HIES (Holland et al. 2007; Minegishi et al. 2007; Jiao et al. 2008; Renner et al. 2008)
   a. Most cases are sporadic.
   b. When familial, all individuals carrying the mutation have the HIES phenotype.
3. Autosomal recessive hyper-IgE syndrome (AR-HIES) (Freeman and Holland 2009; Engelhardt et al. 2009)
   a. Homozygous mutation of *Tyk2* with a four nucleotide deletion resulting in a premature stop codon reported in one patient (Minegishi et al. 2006). This patient had the following common features of AR-HIES:
      i. Eczema
      ii. Viral infections
      iii. Recurrent sinopulmonary infections
      iv. Bacille Calmette–Guerin and *Salmonella* infections, classic for IL-12/IFN-gamma defects
   b. Mutations of Tyk2 have been absent in the other reported cases of AR-HIES (Woellner et al. 2007).
   c. Homozygous mutations (large deletions and point mutations) in the dedicator of cytokinesis 8 (*DOCK8*) identified recently in most patients with AR-HIES (Engelhardt et al. 2009)

Clinical Features

1. Classic triad (77%) (Grimbacher et al. 1999a; Erlewyn-Lajeunnesse 2000)
   a. Abscesses
   b. Pneumonia
   c. An elevated IgE

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_124,
© Springer Science+Business Media, LLC 2012

2. Skin manifestations
   a. Onset with distinctive neonatal rash
      i. Typically pruritic, secondary to intradermal mast cell histamine release triggered by the elevation of available IgE
      ii. Often lichenified
      iii. A distribution atypical for true atopic dermatitis
   b. Chronic eczema and dermatitis
   c. Skin infections
      i. Frequent presentation in infancy
         a) Furuncles
         b) Occasional "cold" abscesses
         c) Cellulitis
      ii. Multiple staphylococcal abscesses on the skin (furunculosis)
         a) Most common around the face
         b) Tender and warm to touch
      iii. Cold abscesses
         a) A large fluctuant mass that feels like a tumor or cyst
         b) Neither hot or tender
         c) Not associated with systemic symptoms, fever, or other signs of local or generalized inflammation
         d) Filled with pus that always grows *Staphylococcus aureus*
         e) Pathognomic to hyper-IgE syndrome
         f) Not essential to the diagnosis
   d. Skin abscesses
   e. Candidiasis
3. Infections
   a. Pulmonary infections
      i. Recurrent and severe
      ii. Most common infecting organism: *Staphylococcus aureus*
      iii. Chronic infections
         a) Sinusitis
         b) Discharging otitis media
         c) Otitis externa
         d) Mastoiditis
      iv. Long-term complications
         a) Bronchiectasis
         b) Bronchopleural fistulae
         c) Pneumatocele secondary to staphylococcal pneumonia
   b. Mucocutaneous candidiasis and fungal infection
      i. Chronic candidiasis (83%)
         a) Mucosa sites (oral moniliasis)
         b) Nail fungal infection and dystrophy secondary to *Candida albicans*
      ii. *Aspergillus* infection
      iii. Cryptococcal infection
   c. Other serious infections
      i. Skin, sinopulmonary, and bone infections: most common
      ii. Staphylococcus: the most frequently infecting organisms
      iii. Encapsulated organisms
         a) Haemophilus
         b) *Streptococcus pneumoniae*
      iv. Opportunistic infections: *Pneumocystis carinii*
4. Facial and dental abnormalities
   a. Characteristic coarse facies
      i. Frontal bossing
      ii. Wide alar base of the nose
      iii. Wide outer canthal distance
      iv. Rare craniosynostosis
      v. Midline facial defects
      vi. High-arched palate
   b. Red hair: uncommon finding
   c. Retained primary teeth (72%): failure or delay of shedding of the primary teeth secondary to lack of root resorption
5. Skeletal abnormalities
   a. Scoliosis (76%)
   b. Pathological fractures
      i. Secondary to minor trauma
      ii. Associated with osteopenia
      iii. Frequent recurrent fractures (57%)
      iv. Systemic infections at fracture sites
         a) Recurrent bacterial arthritis
         b) Staphylococcal osteomyelitis
   c. Generalized joint hyperextensibility (68%)
      i. Fingers
      ii. Wrists
      iii. Shoulders
      iv. Hips
      v. Knees
      vi. Genu valgum
6. Vascular features (Yavuz and Chee 2009): constitute one of the major clinical characteristics in HIES
   a. Types of vascular abnormalities
      i. Aneurysms (coronary, aortic, carotid, and cerebral)
      ii. Pseudoaneurysms
      iii. Congenital patent ductus venosus

iv. Superior vena cava syndrome
v. Vasculitides
vi. Vascular ectasia
vii. Thrombosis
viii. Others

b. May be congenital or acquired, in the veins and arteries, affecting both sexes
c. Can be seen in all subtypes of HIES
d. Can be fatal in children and adults
e. Limited pathological investigations revealed the presence of vasculitis.
f. Presence of hypereosinophilia, vasculitis, and defective angiogenesis in HIES may contribute to the formation of vascular abnormalities in HIES.

7. Association with isolated reports of autoimmune disease
   a. Systemic lupus erythematosus
   b. Dermatomyositis
   c. Membranoproliferative glomerulonephritis
8. Malignant changes
   a. Hodgkin disease
   b. Lymphoma
   c. Leukemias
   d. Cancers of the vulva, liver, and lung
9. Autosomal recessive hyper-IgE syndrome (AR-HIES) (Renner et al. 2004)
   a. Similar features
      i. Extremely elevated serum IgE
      ii. Severe eczema
      iii. Recurrent skin bacterial and viral infections as well as sinopulmonary infection
   b. Distinctive features
      i. Lack the somatic features, such as the characteristic facies, scoliosis, and the failure of baby teeth to exfoliate
      ii. Although pneumonias occur in AR-HIES, pneumatoceles do not form.
      iii. Has a much higher rate of cutaneous viral infections such as *Molluscum contagiosum*, Herpes simplex, and varicella infections
      iv. Has frequent neurologic disease, ranging from facial paralysis to hemiplegia, in some cases due to CNS vasculitis
      v. Mortality: high at a young age in AR-HIES with sepsis more frequent than in AD-HIES
      vi. Eosinophilia and elevated serum IgE: the most consistent laboratory findings and may be more dramatic than in AD-HIES
      vii. Autoimmune cytopenias may occur.

Diagnostic Investigations

1. Routine laboratory workup
   a. Grossly elevated serum polyclonal IgE: at least ten times normal (peak serum IgE >2,000 IU/mL)
   b. Accompanying eosinophilia
2. Radiographs, CT scan, and MRI imaging
   a. Pulmonary abnormalities
      i. Recurrent alveolar lung infections
      ii. Pneumatoceles
      iii. Occasional pneumothorax
   b. Skeletal abnormalities
      i. Full evaluations and monitor vigilantly for fractures after even minor trauma
      ii. Scoliosis
   c. CNS abnormalities on brain MRI (Freeman et al. 2007)
      i. Remarkably common and previously unrecognized aspect of HIES
      ii. Several patients with lacunar infarcts in addition to focal hyperintensities suggest possible small vessel disease.
3. Skin biopsy (Chamlin et al. 2002)
   a. An eosinophilic infiltrate similar to that seen in eosinophilic pustular folliculitis
   b. Spongiosis
   c. Perivascular dermatitis
4. Molecular genetic diagnosis
   a. AD-HIES: investigate *STAT3* mutations
   b. AR-HIES: investigate *DOCK8* mutations in patients with a phenotype of elevated IgE, eosinophilia, and recurrent skin boils, pneumonia, and viral infections (especially molluscum contagiosum and herpes) (Engelhardt et al. 2009)

Genetic Counseling

1. Recurrence risk
   a. Autosomal recessive inheritance
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier
   b. Autosomal dominant inheritance
      i. Patient's sib: not increased unless one of the parents is affected, in which case, there will be 50% risk of sibling affected
      ii. Patient's offspring: 50%

2. Prenatal diagnosis for AD-HIES (Freeman et al. 2010)
   a. Possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis or chorionic villus sampling (CVS):The disease-causing allele of an affected family member must be identified before prenatal testing can be performed.
   b. Preimplantation genetic diagnosis (PGD) may be available for families in which the disease-causing mutation has been identified previously.
3. Management (Erlewyn-Lajeunnesse 2000; Freeman and Holland 2009)
   a. Largely supportive
   b. Prompt treatment of infection with prolonged intravenous antibiotics
   c. Treatment of eczema and prevention of *S. aureus* abscesses are most successfully accomplished with antiseptics such as bathing in bleach (120 mL of bleach in tub of water for 15 min three times weekly) or swimming in chlorinated pools.
   d. Active suspicion of pneumonia is necessary because systemic symptoms of illness are often lacking.
   e. Antimicrobial prophylaxis
      i. Prevents recurrent sinopulmonary infections with trimethoprim–sulfamethoxazole, a frequent choice
      ii. Pneumonias should be treated aggressively to try to prevent parenchymal damage.
      iii. If pneumatocoeles and bronchiectasis are present, antimicrobial prophylaxis often needs to be broadened to cover Gram-negative bacteria and fungi.
      iv. Management of pneumatocoeles is complex, as these cysts when secondarily infected carry significant risk for morbidity and mortality; however, surgery is not without risk, as HIES patients may have trouble re-expanding their lungs and soilage of the pleural space can occur.
   f. Cimetidine, the histamine receptor-2 (H2) antagonist
      i. Shown to reverse the hyper-IgE syndrome neutrophil chemotactic defect in vitro
      ii. A single patient showed a clinical improvement on treatment with improved neutrophil chemotaxis in spite of a clinical relapse.
      iii. Another seven patients treated with H2 antagonist with benefit.
   g. Cyclosporine may be helpful.
   h. Bronchoscopy may help isolate causative pathogens and clear pus.
   i. Dental extraction of primary teeth
   j. Surgical intervention by incision and drainage of abscesses
   k. Chest tube drainage and lobectomy for complications of pneumonias
   l. Orthopedic cares for fractures and scoliosis
   m. Dermatitis
      i. Topical steroid
      ii. Topical antifungals
      iii. Emollient creams
   n. Isotretinoin used to improve dermatitis
   o. High-dose intravenous γ-globulin for patients with aberrant humoral immunity: Intravenous immunoglobulin (IVIG) may decrease the number of infections for some individuals and is the most frequent immunomodulator used.
   p. Invasive approach with plasmapheresis with temporary improvement of skin condition and free of infections
   q. Bone marrow transplantation: only hope of cure at present, likely not fully corrective
   r. A single report of a peripheral stem cell transplantation
      i. Serum IgE returned to normal
      ii. Disappearance of symptoms
      iii. Unfortunately, patient died of interstitial pneumonia
   s. Hematopoietic cell transplantation (Gatz et al. 2010)
      i. Curative in patients with AR-HIES
      ii. Should be considered early before life-threatening complications develop, which include malignancies

Fig. 1 (**a**–**d**) A 3-year-9-month-old patient with hyperimmunoglobulin E syndrome showing skin scars on his arm and bowing of the legs. Facial features included frontal bossing, wide alar basis of the nose, and wide outer canthal distance. He had history of recurrent pneumonias, otitis media, asthma, and fractures of the leg bones. At 2 years and 10 months of age, IgE was 15,610 ($\leq$93 KU/L). He is currently on intravenous immunoglobulin therapy with antibiotic prophylaxis

Fig. 2 A 13-year-old boy had a history of recurrent pneumonias, a right hip infection, and significant atopic dermatitis. Facial features included frontal bossing, wide alar basis of the nose, and wide outer canthal distance. Laboratory tests showed hyperimmunoglobulin E

Hypochondroplasia

Hypochondroplasia is a disproportionate short stature disorder resembling achondroplasia but with less severe phenotype.

Genetics/Basic Defects

1. Inheritance (Le Merrer et al. 1994).
   a. Autosomal dominant with full penetrance
   b. Sporadic in 90% of cases
   c. Observation of an increased paternal age effect at the time of conception, suggesting involvement of de novo mutations of paternal origin
   d. Presence of locus heterogeneity
2. Evidence supporting the view that hypochondroplasia and achondroplasia are allelic disorders (McKusick et al. 1973; Le Merrer et al. 1994)
   a. A remarkable inter- and intrafamilial variation in expression of hypochondroplasia with some cases resembling minor forms of achondroplasia
   b. Offspring of an achondroplastic parent and hypochondroplastic parent with severe neonatal achondroplasia resembling homozygous achondroplasia
   c. Similar histopathological aspects of the growth cartilage for the two disorders
3. Molecular defect.
   a. About 70% of affected individuals who are heterozygous for a mutation in the fibroblast growth factor receptor 3 (*FGFR3*) gene, which is mapped on chromosome 4p16.3 (Francomano 2005)
   b. *FGFR3* mutations reported in hypochondroplasia
      i. 1620C-A (Asn540Lys): two thirds of cases
      ii. 1620C-G (Asn540Lys): one third of cases
      iii. 1658A-C (Asn540Thr) and other *FGFR3* mutations: rare
   c. FGFR3 mutation reported in hypochondroplasia association with acanthosis nigricans (Castro-Feijóo et al. 2008) and acanthosis nigricans and hyperinsulinemia (Blomberg et al. 2010): p.Lys650Thr mutation
4. Hypochondroplasia-achondroplasia compound heterozygote
   a. Born to a hypochondroplastic parent and an achondroplastic parent
   b. The severity of the child: clinical and radiographic findings more severe than achondroplasia or hypochondroplasia alone but less severe than homozygous achondroplasia (Huggins et al. 1999)
   c. Demonstration of both the hypochondroplasia (Asn540Lys) and achondroplasia (Gly380Arg) mutations at the FGFR3 locus in a patient with the genetic compound

Clinical Features

1. Short stature (Francomano 2005)
   a. Evident by school age
   b. Adult height: 128–165 cm
2. Stocky build
3. Facial appearance
   a. Usually normal
   b. Mild macrocephaly may be present.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_125,
© Springer Science+Business Media, LLC 2012

4. Skeletal features
   a. General features: usually similar but milder to achondroplasia
   b. Limbs
      i. Disproportionately short compared with the length of the trunk
      ii. Shortening of the proximal (rhizomelia) or middle (mesomelia) segments of the extremities
      iii. Mild limitation of elbow extension
      iv. Broad and short hands and feet (brachydactyly)
      v. Absence of trident hand deformity
      vi. Bow legs (genu varum): usually mild
      vii. Adult onset osteoarthritis: less common
   c. Spine
      i. Scoliosis
      ii. Slight lumbar lordosis with a sacral tilt
5. Rare association with acanthosis nigricans
6. Medical complication
   a. Following complications: less frequent compared to achondroplasia
      i. Spinal stenosis with neurologic complications
      ii. Tibial bowing
      iii. Obstructive apnea
   b. Deficits in mental capacity and/or function: may be more prevalent than achondroplasia

Diagnostic Investigations

1. Radiography (Francomano 2005)
   a. The most common features
      i. Short proximal (rhizomelic) and/or middle (mesomelic) segments of the long bones with mild metaphyseal flare, especially femora and tibiae
      ii. Caudal narrowing or unchanged lumbar interpedicular distance
      iii. Mild to moderate brachydactyly
      iv. Short and broad femoral neck
      v. Squared and shortened ilia
   b. The less common but significant features
      i. Elongation of the distal fibula
      ii. Anterior-posterior shortening of the lumbar vertebrae
      iii. Dorsal concavity of the lumbar vertebral bodies
      iv. Shortening of the distal ulna
      v. Long ulnar styloid in adults
      vi. Prominence of muscle insertions on the long bones
      vii. Shallow "chevron" deformity of distal femur metaphysis
      viii. Low articulation of sacrum on pelvis with a horizontal orientation
      ix. Flattened acetabular roof
2. Molecular genetic testing
   a. Mutation analysis
      i. 1620C-A (Asn540Lys)
      ii. 1620C-G (Asn540Lys)
      iii. Other *FGFR3* mutations
   b. Sequence analysis of mutations in *FGFR3* exons 10, 13, and 15

Genetic Counseling

1. Recurrence risk (Francomano 2005)
   a. Patient's sib: an extremely low risk (<0.01%) of having an affected sib if parents are not affected (germline mosaicism has not been reported for hypochondroplasia)
   b. Patient's offspring
      i. 50% risk of having an affected offspring if the spouse is normal
      ii. If the spouse is an achondroplastic
         a) Twenty-five percent chance of having an affected offspring with hypochondroplasia
         b) Twenty-five percent chance of having an affected offspring with achondroplasia
         c) Twenty-five percent chance of having an affected offspring with achondroplasia-hypochondroplasia genetic compound
         d) Twenty-five percentchance of having a normal offspring
      iii. If the spouse also has hypochondroplasia or other dominant form of skeletal dysplasia: genetic counseling becoming more complicated due to the high incidence of genetic heterogeneity and the lack of medical literature addressing these circumstances
2. Prenatal diagnosis
   a. Prenatal diagnosis by amniocentesis or CVS for family with high-risk pregnancy with a parent who has hypochondroplasia

i. When the spouse is normal: testing for disease-causing FGFR3 mutation in the fetus
ii. When the spouse is affected with another dominantly inherited skeletal dysplasia caused by a known gene mutation: testing for the known mutation for that skeletal dysplasia and the mutation for the hypochondroplasia in the fetus

b. Prenatal diagnosis by ultrasonography, amniocentesis, or CVS in low-risk pregnancy without family history of affected individual
i. Ultrasonography: short limbs detected by routine ultrasound examination late in pregnancy
ii. DNA-based diagnosis of *FGFR3* mutations to confirm the diagnosis of hypochondroplasia

3. Management
a. Follow closely developmental milestones and signs of learning disability or mental retardation
b. Treatment of short stature
i. Trials of growth hormone therapy with mixed results
ii. Surgical limb lengthening for severe case of hypochondroplasia
a) An invasive procedure
b) Entails considerable disability and discomfort over a long period of time
c) Prefer postponement of the procedure until adolescence when the patient can make an informed decision

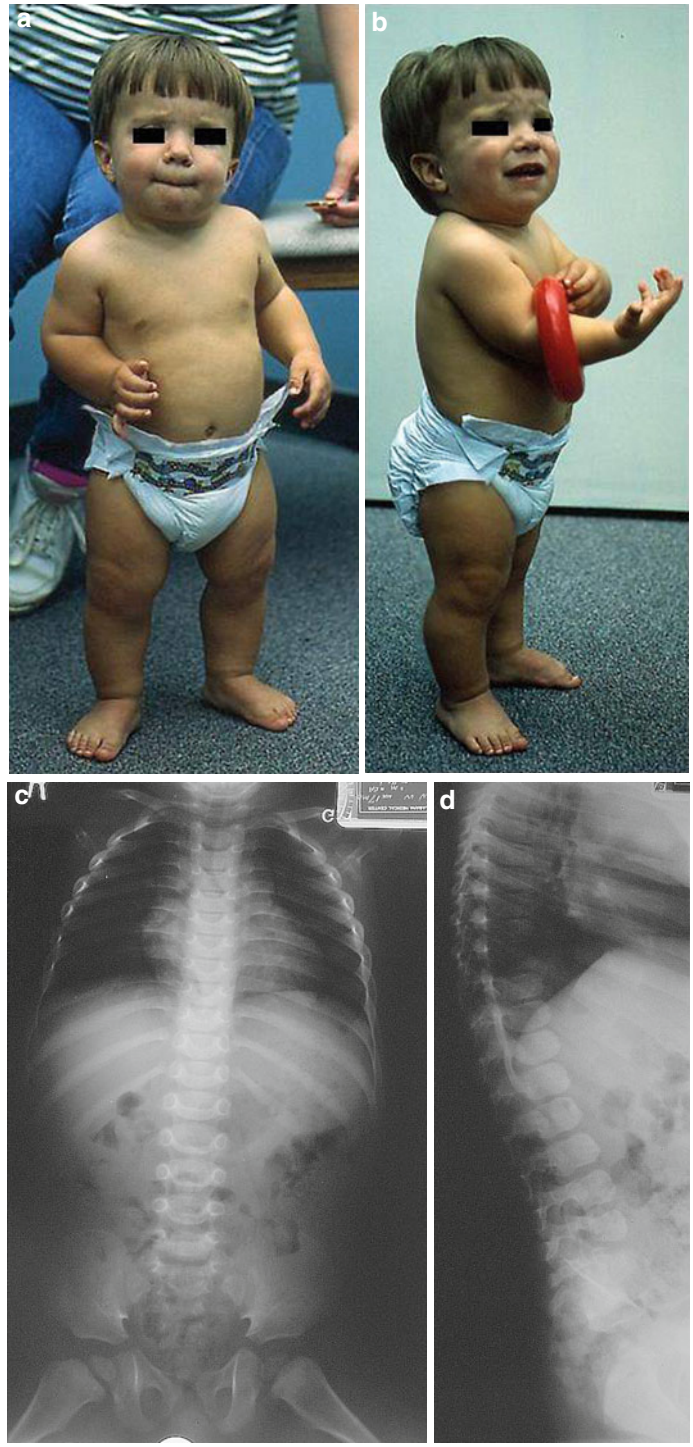

Fig. 1 (**a**–**d**) A young child affected with hypochondroplasia showing mild short stature and mild rhizomelic shortening of the extremities. Radiographs showed unchanged lumbar interpedicular distance

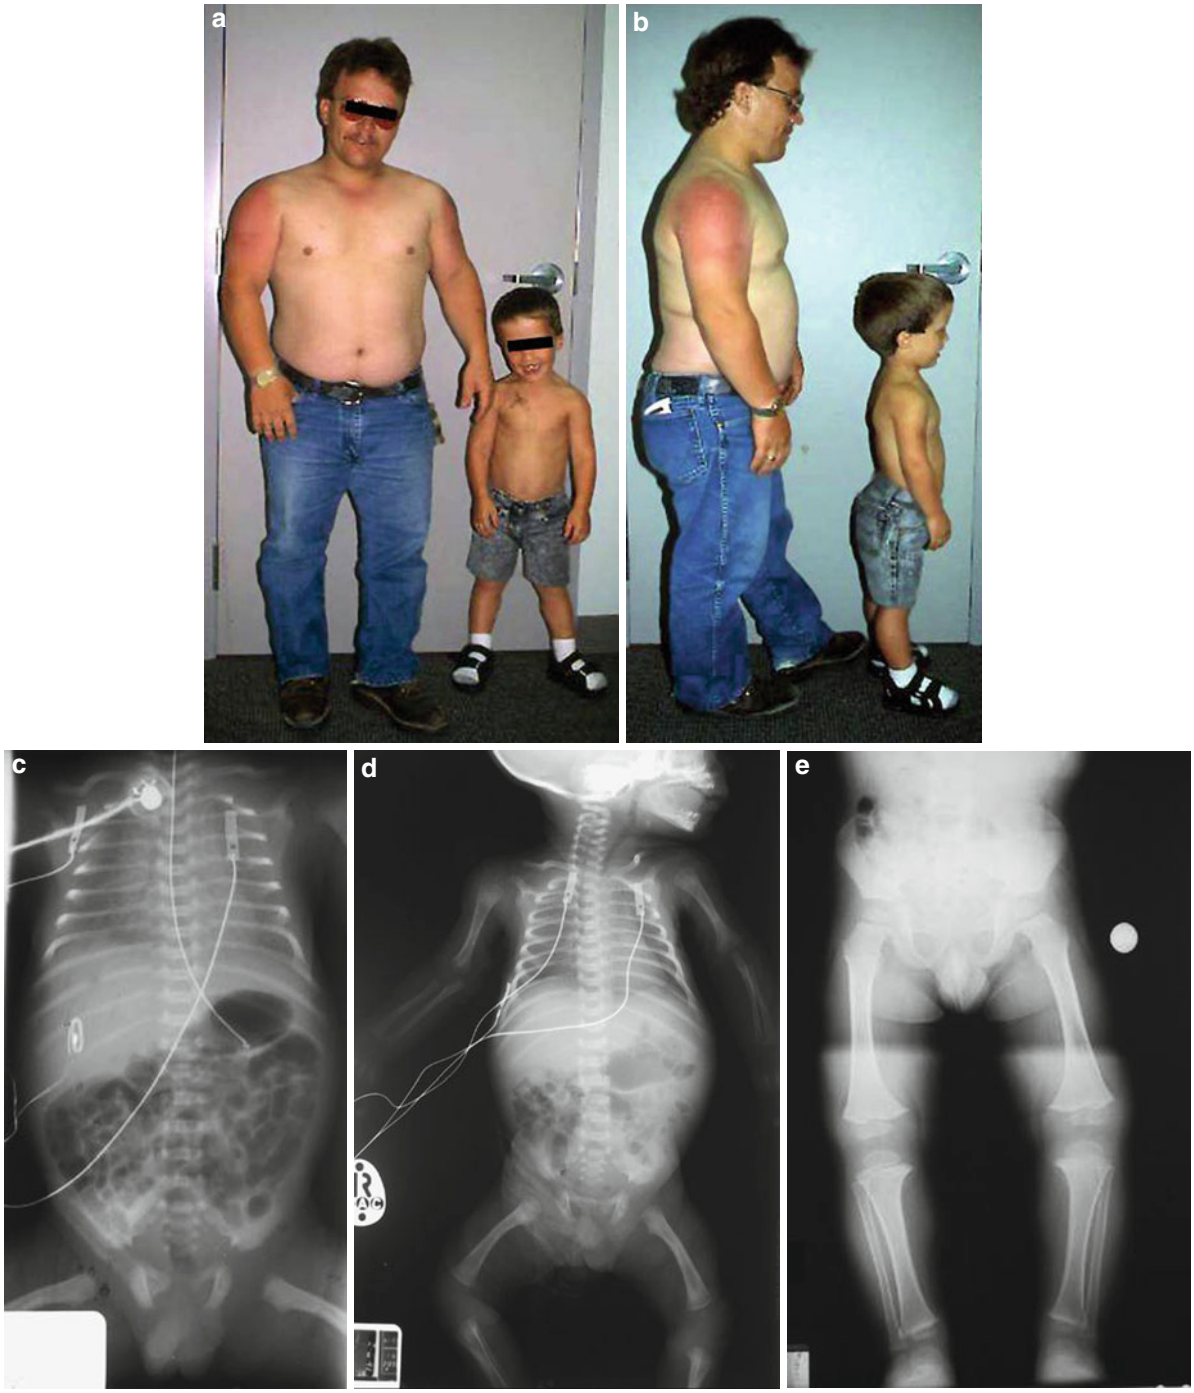

Fig. 2 (**a**–**e**) Father and son showing typical features of hypochondroplasia. The son's radiographs at birth, 17 days, and 2 years and 6 months showing unchanged lumbar interpedicular distance, mild shortening of long bones, and short, squared ilia

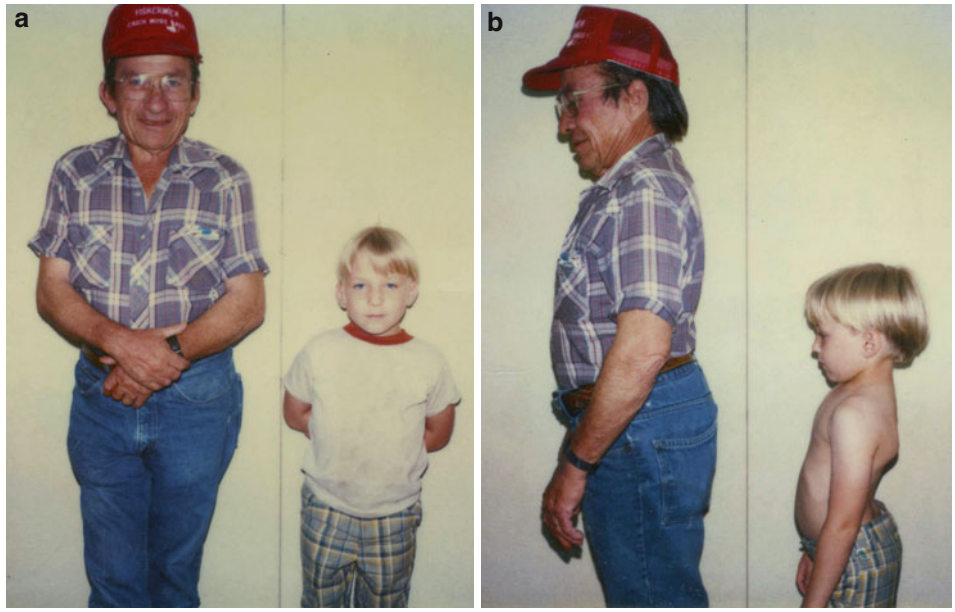

Fig. 3 (**a**, **b**) Father and son with clinical features of hypochondroplasia

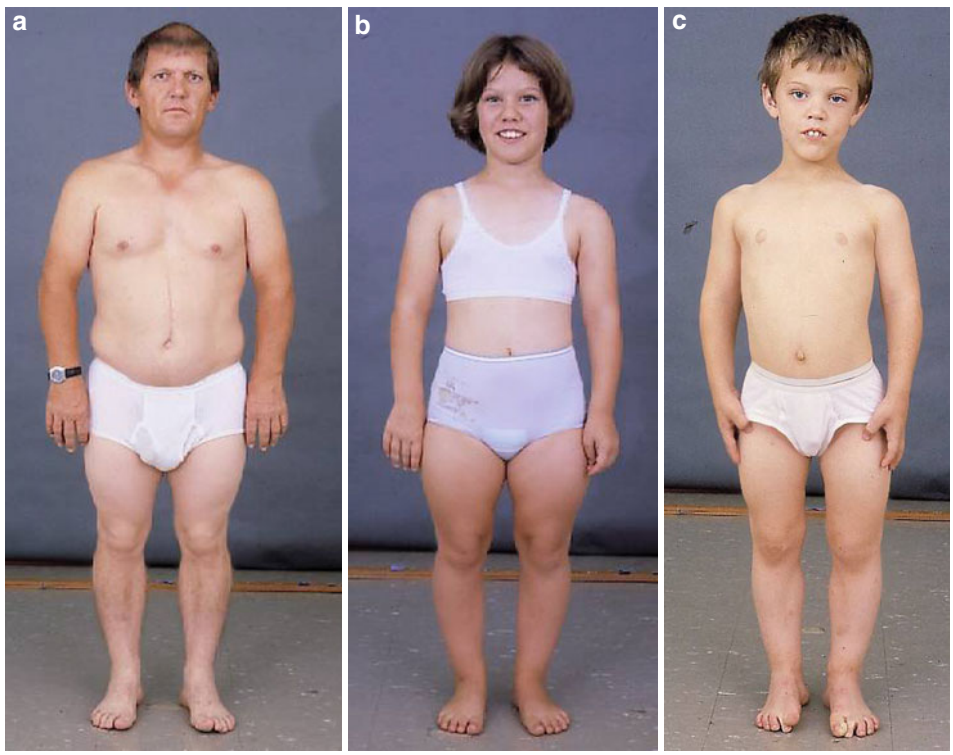

Fig. 4 (**a**–**c**) Father, daughter, and son affected with hypochondroplasia showing stocky build, mild short stature, normal facial appearance, rhizomelic shortening of the extremities, and absence of trident hands

Fig. 5 A 2-year-old boy with disproportional short stature with relatively short upper arms and thighs and mild lumbar gibbus. Molecular testing identified the presence of a C > A transversion at nucleotide 1620 (c.1620 C > A) of the fibroblast growth factor receptor 3 (*FGFR3*) gene. The presence of this mutation is consistent with a clinical diagnosis of hypochondroplasia

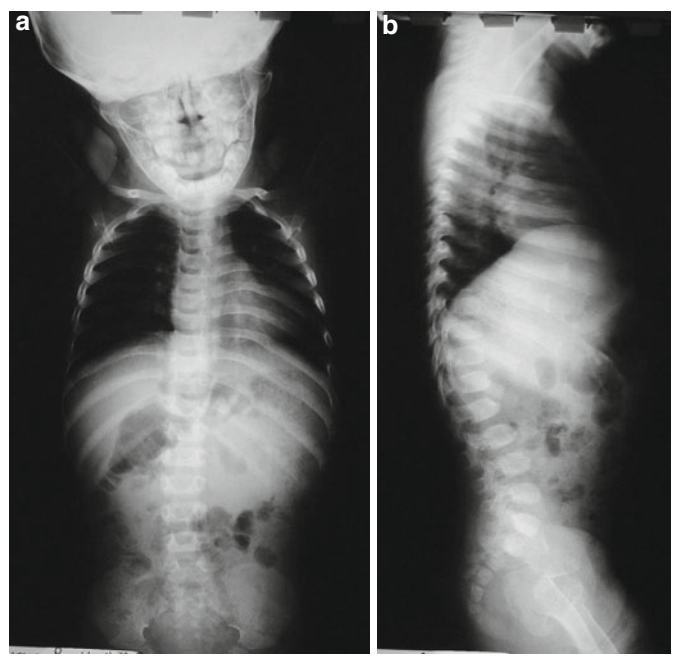

Fig. 6 (**a**, **b**) Radiographs of the spine (AP and lateral views) show caudal narrowing of lumbar interpedicular distance and the dorsal convexity of the lumbar vertebral bodies

Hypoglossia-Hypodactylia Syndrome

Hypoglossia-hypodactylia syndrome is an extremely rare condition characterized by a small tongue associated with distal limb deficiency. The syndrome is also called aglossia-adactylia syndrome, which is a misnomer since the tongue is never completely absent and the term "adactylia" does not convey the variation in limb defects of affected individuals. The syndrome is also known as oromandibular limb hypogenesis syndrome, a spectrum of congenital anomalies that affect the tongue, oromandibular region, and the limbs.

Synonyms and Related Disorders

Aglossia-adactylia syndrome; Oromandibular limb hypogenesis syndrome

Genetics/Basic Defects

1. Inheritance
   a. Sporadic in all reported cases.
   b. Autosomal dominant inheritance cannot be ruled out.
2. Pathogenesis (Yasuda et al. 2003)
   a. Impairments or insults to fetus during the early fetal life (fourth to seventh week) may be responsible for the findings of tongue and limb abnormalities seen in hypoglossia-hypodactylia syndrome because of the close chronological relationship between the development of the tongue and the limbs.
   b. A hypoplastic mandible with concurrent hypoglossia could be explained by the fact that the mandible originates from the same visceral arch as the tongue.
   c. Vascular mechanism (either hemorrhage or vasoocclusion) may be responsible for defects that are asymmetric and always distal.

Clinical Features

1. Mouth
   a. Mandible
      i. Micro-/retrognathia
         a) Minor feeding problems in infancy
         b) Minor speech impairment
      ii. Oligodontia
      iii. Absent mandibular incisors with concomitant hypoplasia of the associated alveolar ridge
      iv. Other features
         a) Mild lower lip defect
         b) Microstomia (markedly reduced mouth opening)
         c) Intraoral bands
         d) Oral frenula
         e) Oral syngnathia
   b. Tongue
      i. Varying degrees of hypoglossia
      ii. Ankyloglossia
      iii. Marked enlargement of the sublingual muscular ridges
      iv. Hypertrophy of the sublingual and submandibular glands
2. Variable limb anomalies
   a. May involve any limb

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_126,
© Springer Science+Business Media, LLC 2012

   b. Distal reduction anomalies
      i. Oligodactyly (absence of some fingers and toes)
      ii. Adactylia (congenital absence of the fingers and toes)
      iii. Peromelia (severe congenital malformation of the extremity, including absence of hand and foot)
   c. Syndactyly
3. Other associated anomalies
   a. Moebius syndrome
   b. Fused labia majora
   c. Unilateral renal agenesis
   d. Imperforate anus
4. Normal intelligence
5. Classification of syndromes of oromandibular and limb hypogenesis (Hall 1971)
   a. Type I
      i. Hypoglossia
      ii. Aglossia
   b. Type II
      i. Hypoglossia-hypodactylia
      ii. Hypoglossia-hypomelia (peromelia)
      iii. Hypoglossia-hypodactylomelia
   c. Type III
      i. Glossopalatine ankylosis
      ii. With hypoglossia
      iii. With hypoglossia-hypodactylia
      iv. With hypoglossia-hypomelia
      v. With hypoglossia-hypodactylomelia
   d. Type IV
      i. Intraoral bands and fusion
      ii. With hypoglossia
      iii. With hypoglossia-hypodactylia
      iv. With hypoglossia-hypomelia
      v. With hypoglossia-hypodactylomelia
   e. Type V
      i. The Hanhart syndrome
      ii. Charlie M syndrome
      iii. Pierre Robin syndrome
      iv. Moebius syndrome
      v. Amniotic band syndrome
6. Differential diagnosis with other oromandibular limb hypogenesis syndromes (Bonneau et al. 1999)
   a. Hanhart syndrome
      i. Micrognathia
         a) Microglossia
         b) Hypodontia
      ii. Limb anomalies
         a) Ranging from stunted digits, oligodactyly, to more severe peromelia
         b) May affect any limb
   b. Glossopalatine and ankylosis syndrome
      i. Tongue.
         a) Usually attached to the hard palate
         b) May adhere to the maxillary alveolar ridge
         c) Mildly cleft tongue tip
      ii. High-arched or cleft palate.
      iii. Hypoplastic mandible.
      iv. Hypodontia principally affects the incisor teeth.
      v. Ankylosis of the temporomandibular joint.
      vi. Facial paralysis.
      vii. Extremely variable limb anomalies.
         a) Oligodactyly
         b) Syndactyly
         c) Polydactyly
         d) Peromelia
   c. Limb deficiency-splenogonadal fusion syndrome (Bonneau et al. 1999)
      i. Splenogonadal fusion
         a) A rare malformation in which the spleen is abnormally connected to the gonad, or, more rarely, to a derivative of the mesonephros
         b) May occur as a rare malformation
      ii. Association with other malformations, especially with terminal limb defects
   d. Moebius syndrome (please refer to the chapter of Moebius Syndrome)

Diagnostic Investigations

1. Radiography
   a. Fusion of the temporomandibular joints
   b. Micro-/retrognathia
   c. Hypodontia
   d. Limb defects
      i. Variable distal limb deficiency
      ii. Asymmetric reduction deformities of the distal extremities
      iii. Severity ranging from hypoplastic digits to peromelia

   e. Other rare anomalies
      i. Dextrocardia
      ii. Transposition of abdominal organs
      iii. Jejunal atresia
      iv. Short bowel
      v. "Apple peel" bowel
2. Reconstructed 3D CT imaging of the craniofacial skeletal structures (Yasuda et al. 2003)
   a. Retruded and reduced mandible
   b. Steep inclination of the anterior surface of the mandible in relation to the lower mandibular plane
   c. Bone defect of the alveolar ridge at the midline area of the mandible
3. MRI of the tongue and the floor of the mouth (Yasuda et al. 2003)
   a. Degree of the hypoglossia
   b. Space between the tongue and the inferior surface of the palate
   c. Hypertrophy of the floor of the mouth

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased unless the condition represents an autosomal dominant inheritance, in which case there will be 50% risk to have an affected offspring
2. Prenatal diagnosis: not been reported
3. Management (Yasuda et al. 2003)
   a. Early surgical intervention for presence of severe anomalies that are life-threatening and interfere swallowing, breathing, and eating
   b. Extraction of the supernumerary tooth
   c. Orthodontic expansion appliance for widening the mandibular dental arch
   d. Distraction osteogenesis to improve the size and shape of the hypoplastic mandible
   e. Mandibular advancement

Fig. 1 (**a**–**c**) A 2-month-old female infant with hypoglossia-hypodactylia syndrome showing antimongoloid slant of the palpebral fissures, facial palsy, micro-/retrognathia, microstomia, hypoglossia, and limb anomalies with adactylia of the right hand and both feet and oligodactyly of the left hand

Fig. 2 (**a**, **b**) Another infant with hypoglossia-hypodactylia syndrome showing extreme micro-/retrognathia, hypoglossia, microstomia, and adactylia of both hands

Fig. 3 (**a**–**c**) A 3-month-old girl with hypoglossia-hypodactylia syndrome showing extreme micro-/retrognathia, hypoglossia, microstomia, and adactylia of both hands (*right upper* extremity showed a transverse growth arrest beyond the wrist and *left upper* extremity showed a transverse arrest beyond the proximal one third of the forearm)

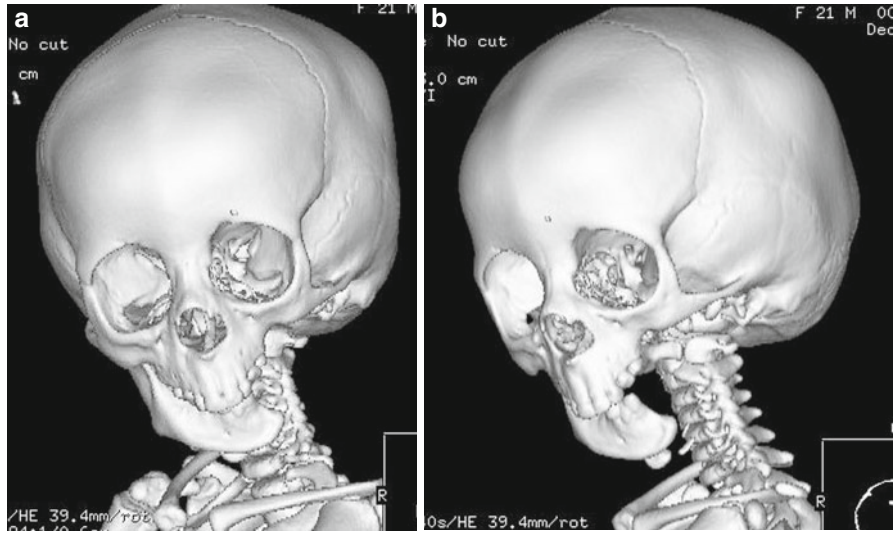

Fig. 4 (**a**, **b**) CT of the face (AP and lateral views) show left hemimandibular agenesis (complete absence of the body, angle, ramus, and condyle) and a significant aplasia of posterior maxilla on the left

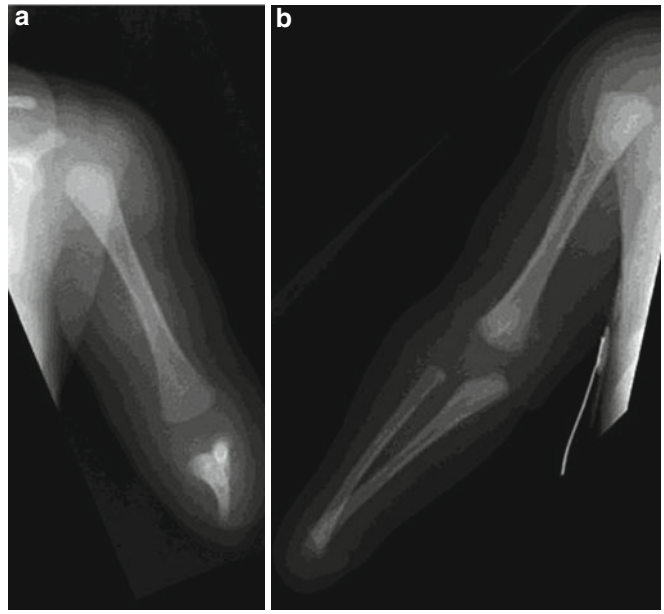

Fig. 5 (**a**, **b**) Plain radiographs show transverse growth arrest past the proximal one third of the left forearm and V-shaped formation of the radius and ulna with growth arrest past the right wrist

Fig. 6 The previous girl was seen at 3 years of age

Fig. 7 (**a**, **b**) Preoperative photos at 5 years of age

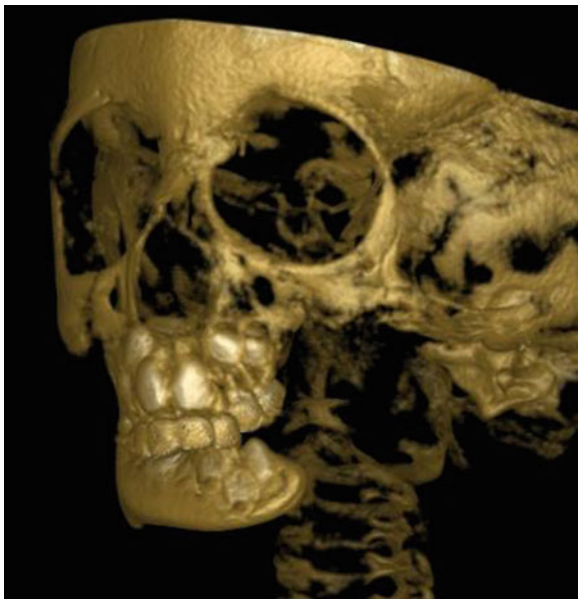

Fig. 8 Preoperative CT at the age of 5

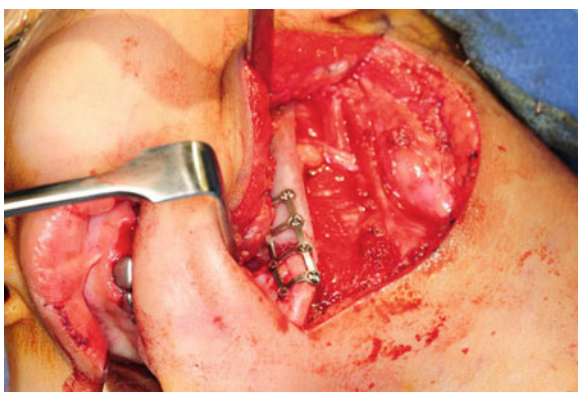

Fig. 9 Intraoperative photo. Costochondral graft fixated to the adjacent mandible. Cartilaginous cap seated in the glenoid fossa

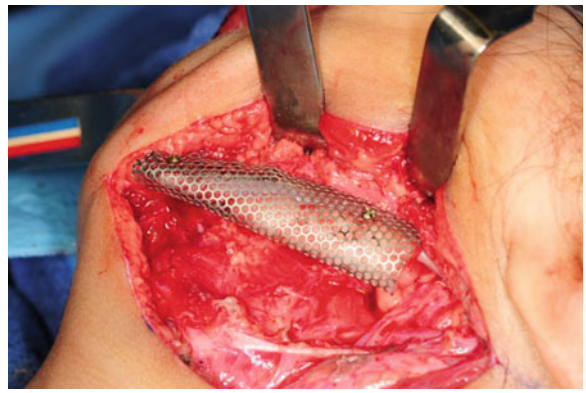

Fig. 10 Titanium mesh used as a crib for BMP at the inferior border of the rib graft

Fig. 11 (**a**, **b**) Postoperative photos at age 5. She was reconstructed with a right costochondral rib graft to replace the condyle and ramus region and established continuity of her mandible. This was combined with the use of a titanium mesh crib and some bone morphogenetic proteins (BMP) at the junction of the native mandible and the costochondral graft. Note the improved facial profile on the left. Despite improved result, the patient will require further surgery as she grows to correct her facial profile

Fig. 12 Three-month postoperative cone beam CT. Cartilaginous cap not apparent on this view

Fig. 13 Note the broad intraoral band extending from the left subglossal region to the soft palate. This band also attaches to the left lower lip causing retraction of the lip

Fig. 14 The patient protruding her tongue past the intraoral band. Maximum protrusion. Based on the hypoglossia, the oral band extending from the floor of mouth and left cheek to the soft palate, and the limb abnormalities (hypodactylomelia), the patient would fit best as Hall's type IVD (intraoral bands and fusion with hypoglossia-hypodactylomelia. Thus, the patient is classified as a type IVD with hemimandibular agenesis (Qaisi et al. 2010)

Hypohidrotic Ectodermal Dysplasia

Hypohidrotic ectodermal dysplasia (HED) is a common form of ectodermal dysplasia characterized by a defect in the hair, in the teeth, and in mucosal and sweat glands. It is also known as anhidrotic ectodermal dysplasia. The incidence is estimated to be 1 in 10,000 to 1 in 100,000 male live births (Crawford et al. 1991).

Synonyms and Related Disorders

Anhidrotic ectodermal dysplasia; Christ-Siemens-Touraine syndrome

Genetics/Basic Defects

1. Inheritance: genetically heterogeneous
   a. X-linked recessive type: the most common form of over 170 different ectodermal dysplasias
   b. Autosomal dominant type: less common
   c. Autosomal recessive type: less common
2. X-linked HED: the most common form
   a. Caused by mutations in the ectodysplasin-A gene (*EDA1*) which (Doffinger et al. 2001):
      i. Codes for the tumor necrosis factor (TNF) family member ectodysplasin-A (EDA)
      ii. Maps to chromosome Xq12-q13.1 by X autosome translocations of female EDA patients
      iii. Affects a transmembrane protein expressed by keratinocytes, hair follicles, and sweat glands
      iv. Possibly has a key role in epithelial-mesenchymal signaling
   b. Over 94% of patients with X-linked HED carry mutations in the *EDA1* gene.
   c. Tabby phenotype is caused by mutation in mouse homolog of the human *EDA* gene (Priolo et al. 2000).
   d. Hemizygous males show severe forms of the disease while heterozygous females often manifest mild to moderate symptoms because of X-chromosome inactivation.
3. Autosomal dominant form and some familial cases of autosomal recessive form of HED caused by at least two genes:
   a. *EDAR* (*EDA* receptor) gene (2q11-q13)
      i. Cause either dominant or recessive forms
      ii. Mutated in approximately 25% of non-EDA-related HED
   b. *EDARADD* (*EDAR*-associated death domain) gene (1q42-q43)
      i. Encodes a protein that interacts with the EDA receptor
      ii. Known to cause either autosomal recessive or dominant HED
      iii. Implicated in a very small number of HED patients (Chassaing et al. 2010)

Clinical Features

1. General features
   a. Characterized by a triad of symptoms
      i. Atrichosis or hypotrichosis (missing or sparse hair)
      ii. Anodontia, hypodontia, or misshapen teeth
      iii. Absent or reduced sweating
   b. Variable clinical features
   c. Short stature

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_127,
© Springer Science+Business Media, LLC 2012

d. Recurrent benign infectious disease seen in most patients with HED
e. Unusually severe infections observed in:
   i. Anhidrotic ectodermal dysplasia with immunodeficiency: a distinct syndrome
   ii. Ectodermal dysplasia with cleft lip/palate
   iii. Ectrodactyly-ectodermal dysplasia-cleft lip/palate
f. Otitis media
g. Infantile fever of unknown etiology
h. Hyperthermia
i. Hoarse voice

2. Clinical features in X-linked recessive hypohidrotic ectodermal dysplasia
   a. Affected individuals
      i. Hemizygous males: affected
      ii. Heterozygous female carriers: variable clinical symptoms (normal, or mild or partially affected)
         a) Dental abnormalities, such as hypodontia
         b) Mild hypohidrosis
         c) Mild hypotrichosis
   b. Clinical evidence of the distribution of normal and abnormal skin along Blaschko lines in heterozygous and postzygotic mutation carriers of X-linked hypohidrotic ectodermal dysplasia
      i. Presence of two different cell lines in a female heterozygous for the XHED due to random inactivation of one of the two X chromosomes during embryogenesis, reflected by the presence of different skin areas, some normal and some showing the result of the genetic abnormality.
      ii. These abnormal areas, disposed along Blaschko lines, reflect the lines of embryonal development of the epidermis and epidermal derivatives.
      iii. This clonal inactivation ("lyonization") of the X chromosome results in variable degree of clinical expression of the disorder.
   c. Clinically differentiating X-linked HED from autosomal forms of HED
      i. Finding heterozygous females with XHED
      ii. Finding parents with partial manifestations of the disorder due to a postzygotic mutation
   d. Clinical features
      i. Scalp hair
         a) Sparse
         b) Thin
         c) Light pigmented
         d) Slow growing
         e) Excessive fragility of the shafts, breaking easily with the usual wear and tear of childhood
      ii. Body hair
         a) Sparse
         b) Normal sexual hair (beard, pubic hair)
      iii. Sweating
         a) Greatly deficient sweating (hypohidrosis)
         b) Leading to hyperthermia
      iv. Teeth
         a) Congenital absence of teeth (hypodontia)
         b) Teeth that are present (smaller than average and have conical crowns)
      v. Facial features
         a) Frontal bossing
         b) A saddle nose (depressed nasal bridge)
         c) Thick lips
         d) Periorbital hyperpigmentation
      vi. Other features
         a) Normal growth and psychomotor development
         b) Atopic dermatitis
         c) Bronchial asthma
         d) Fever of unknown reason
         e) Sudden death during infancy and early childhood

3. Clinical features in autosomal recessive hypohidrotic ectodermal dysplasia
   a. Similar to (but indistinguishable from) the hemizygous form of X-linked hypohidrotic ectodermal dysplasia
      i. Decreased sweating
      ii. Hypodontia
      iii. Conical teeth
      iv. Hypotrichosis of the scalp
      v. Sparse or absent eyebrows and eyelashes
      vi. Sparse or absent body hair
      vii. Dry skin or eczema
      viii. Hypoplastic nails
      ix. Hypoplastic breasts
      x. Atrophic rhinitis
      xi. Depressed nasal bridge
      xii. Hyperpigmented and wrinkled periorbital skin
   b. Males and females equally affected

4. Clinical features in autosomal dominant hypohidrotic ectodermal dysplasia: milder in expression
   a. Hypodontia, anodontia, microdontia, or other dental anomalies (100%)
   b. Sparse eyelashes (100%)
   c. Sparse eyebrows (96%)
   d. Sparse, fine, slow-growing hair (89%)
   e. Decreased sweating (85%)
   f. Thin skin (78%)
   g. Sparse body hair (62%)
   h. Decrease heat tolerance (50%)
   i. Onychodysplasia (39%)

Diagnostic Investigations

1. Radiography
   a. Hypodontia and adontia
      i. Essential to determine the extent of hypodontia and adontia
      ii. Useful in the diagnosis of mildly affected individuals
   b. Recurrent respiratory infections
2. Normal hair morphology under electron microscopy
3. Starch-iodine test to confirm a mosaic distribution of functional sweat glands in a heterozygous female carrier of X-linked HED (Cambiaghi et al. 2000)
4. Molecular analysis: clinically available
   a. Sequence analysis
      i. Mutation in *EDA* gene for the X-linked form
      ii. Mutations in *EDAR* and *EDARADD* genes for the autosomal dominant or recessive forms
   b. Duplication/deletion testing: to detect exonic, multiexonic, or whole gene deletions in females which sequence analysis of *EDA* cannot detect

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. X-linked recessive: 50% of affected brothers if the mother is a carrier, otherwise the risk to sibs is low
      ii. Autosomal dominant: not increased unless a parent is affected, in which case the risk to the sibs is 50%
      iii. Autosomal recessive: 25% of the sibs affected
   b. Patient's offspring
      i. X-linked recessive
         a) Offspring of a male proband: none of the sons will be affected; 50% of the daughters will be carriers
         b) Offspring of a female proband: 50% of her son will be affected and 50% of her daughters will be carriers and may show minimal manifestations
      ii. Autosomal dominant: 50% risk to each child
      iii. Autosomal recessive: not increased unless the spouse is also a carrier, in which case the risk to offspring is 50%
2. Prenatal diagnosis
   a. Analysis of fetal skin obtained from fetoscopy-guided skin biopsy in the second trimester
   b. Three-dimensional ultrasonography to identify the distinct facial features during the third trimester
   c. Identification of the disease-causing mutation in the fetus
   d. Preimplantation genetic diagnosis for at-risk pregnancies is possible, provided disease-causing mutations have been identified
3. Management
   a. Environmental modification to control temperature
      i. Air condition for home, school, and work
      ii. Adequate supply of water during the hot weather
   b. Control body temperature
      i. Tepid sponging
      ii. Showers
      iii. Cold drink
      iv. Antipyretics
      v. Wet clothing
   c. Use moisturizers to prevent xerosis or eczema for dry skin
   d. Use artificial tears (eye drops) to prevent damage to the cornea in patients with defective tearing
   e. Remove nasal and aural concretions with suction devices or forceps and humidification of the ambient air to prevent their formation
   f. Treatment and prophylaxis for infections

g. Dental evaluation and intervention
   i. Early dental treatment
      a) Simple restoration
      b) Dentures
      c) Orthodontics
   ii. Dental implants
   iii. Orthodontic treatment
h. Wear wigs to improve appearance for patients with severe alopecia
i. Avoid vigorous physical activities for patients with hypohidrosis
j. Monitor growth

Hypomelanosis of Ito

In 1952, Ito reported a female patient with a widespread, symmetric pattern of depigmented whorls and streaks, naming it incontinentia pigmenti achromians because the distribution of the depigmented lesions is the negative image of the hyperpigmented streaks of incontinentia pigment. Hypomelanosis of Ito (HI) is a relatively common disorder with a frequency of 1 in 8,000–10,000 patients in a general pediatric hospital and 1 in 1,000 patients in a pediatric neurology service (Küster and Konig 1999).

Synonyms and Related Disorders

Incontinentia pigmenti achromians

Genetics/Basic Defects

1. Inheritance
   a. Sporadic occurrence in nearly all cases with no affected sibs or parents (Küster and Konig 1999)
      i. Result of a de novo postzygotic mutation
      ii. Mutation can only survive in a mosaic state
   b. Only a few cases with possible genetic inheritance reported
      i. X-linked dominant inheritance
      ii. Autosomal dominant
      iii. Autosomal recessive
2. Pathogenesis
   a. Chromosome abnormalities (52%)
      i. Mosaicism leading to generation of two cell lineages producing patterns of hypopigmented and hyperpigmented skin
      ii. Balanced X/autosome translocations
      iii. Supernumerary X chromosome/ring fragment
      iv. Ring chromosomes (10, 14, 22)
      v. Mosaic triploidy
      vi. Mosaic diploidy/tetraploidy
      vii. Mosaic trisomies (2, 8, 13, 14, 18, 20, 22)
      viii. Mosaic tetrasomy 13q
      ix. Mosaic translocations
      x. Mosaic deletions
      xi. Autosomal deletions and duplications involving chromosomes 7, 12, 13, 14, 15, and 18
      xii. Dup(Xp)
   b. X chromosome abnormalities
      i. Inactivation
      ii. Activation
      iii. Mosaicism
3. "Pigmentary mosaicism" (Taibjee et al. 2004)
   a. Hypomelanosis of Ito and related disorders such as linear and whorled nevoid hypermelanosis are due to mosaicism for a variety of chromosomal abnormalities.
   b. Classification of chromosome mosaicism
      i. Mosaicism with two or more different karyotypes, involving structural abnormalities of chromosomes
      ii. Mosaicism involving structural abnormalities of chromosomes, where the chromosome was undetermined
      iii. Chromosomal abnormality apparently affecting all cells, but where undetected mosaicism remains a possibility
      iv. Balanced X/autosome translocations affecting all cells, with functional mosaicism due to lionization

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_128,
© Springer Science+Business Media, LLC 2012

v. Polyploidy mosaicism (cells having different multiples of 23 chromosomes): can be associated with mosaic trisomy such as chromosome18
vi. Chimaerism

4. A descriptive term rather than a true syndrome
   a. Suggested by the pattern of chromosomal aberrations and the polymorphic nature of the disease
   b. A term used for a phenotype
      i. Presence of linear streaks lighter than the patient's background skin color, extending around the trunk and down the long axes of the extremities, roughly following the lines of Blaschko
      ii. Association with systemic findings

Clinical Features

1. Cutaneous symptoms (Küster and Konig 1999)
   a. Onset
      i. Recognizable at birth (54%)
      ii. Visible during childhood (70%)
   b. No signs of inflammation or verrucous changes characteristically seen in incontinentia pigmenti
   c. Hypopigmented lesions
      i. Typical phenotype
         a) Cutaneous pattern: essentially the reverse of the third stage of incontinentia pigmenti
         b) Bilateral or unilateral whirls, patches, and streaks corresponding to the lines of Blaschko, often showing a midline cutoff
         c) Eruption not preceded by any inflammatory lesions (unlike incontinentia pigmenti)
      ii. Unilateral skin lesions contralateral to the side of brain malformation in patients with HI and hemimegalencephaly
      iii. Wood lamp useful in demonstrating hypopigmented lesions in persons with fair skin
      iv. Atypical phenotype: checkerboard pattern zosteriform, dermatomal, or plaque-like arrangement
   d. Nonspecific skin lesions (20–40%)
      i. café-au-lait spots
      ii. Persistent Mongolian blue spots
      iii. Nevus of Ota
      iv. Nevus marmoratus and angiomatous nevi
      v. Soft fibroma
      vi. Pilomatrixoma
      vii. Aplasia cutis
      viii. Atopic dermatitis
2. Hair/nail/sweat gland anomalies
   a. Focal hypertrichosis
   b. Slow growth
   c. Diffuse alopecia
   d. Coarse, curly hair
   e. Trichorrhexis
   f. Widow's peak
   g. Generalized hirsutism
   h. Facial hypertrichosis
   i. Low hairline
   j. Ungual hypoplasia
   k. Hypohidrosis corresponding to hypopigmented areas
3. Associated extracutaneous anomalies (75%)
   a. CNS anomalies
      i. Mental retardation (50–75%)
      ii. Seizures (50%)
      iii. Autistic behavior (11%)
      iv. Microcephaly
      v. Hypotonia
      vi. Hyperkinesia
      vii. Ataxia
      viii. Deafness
      ix. Hemimegalencephaly
      x. Brain tumors (medulloblastoma, choroid plexus papilloma)
   b. Ophthalmological abnormalities (20%)
      i. Microphthalmia
      ii. Ptosis
      iii. Nonclosure of the upper lid
      iv. Symblepharon
      v. Dacryostenosis
      vi. Strabismus
      vii. Nystagmus
      viii. Myopia
      ix. Hyperopia
      x. Astigmatism
      xi. Amblyopia
      xii. Megalocornea
      xiii. Corneal opacification
      xiv. Cataracts
      xv. Iridal heterochromia
      xvi. Scleral melanosis

xvii. Heterochromia of the iris
xviii. Optic atrophy
xix. Striated patchy hypopigmented fundi
xx. Retinal detachment

c. Dental abnormalities
i. Defective dental implantation
ii. Conical teeth
iii. Partial anodontia
iv. Dental dysplasia/hypoplasia
v. Defective enamel
vi. Hamartomatous dental cusps

d. Skeletal defects
i. Short stature
ii. Facial and limb asymmetry (hemihypertrophy)
iii. Pectus carinatum or excavatum
iv. Scoliosis
v. Syndactyly
vi. Polydactyly
vii. Brachydactyly
viii. Clinodactyly

e. Congenital heart defect
i. Tetralogy of Fallot
ii. Pulmonary stenosis
iii. Ventricular septal defect
iv. Atrial septal defect
v. Incomplete right bundle branch block
vi. Cardiomegaly of unknown etiology

f. Abdomen/gastrointestinal anomalies
i. Diastasis recti
ii. Hepatomegaly
iii. Segmental dilation of the colon
iv. Diaphragmatic, umbilical, and inguinal hernias

g. Genitourinary anomalies
i. Hypospadias
ii. Micropenis
iii. Single kidney
iv. Urethral duplication
v. Cryptorchidism
vi. Precocious puberty
vii. Gynecomastia
viii. Asymmetrical breasts
ix. Nephritis

4. Diagnostic criteria (Ruiz-Maldonado et al. 1992)
a. Sine qua non criterion: congenital or early acquired nonhereditary cutaneous hypopigmentation in linear streaks or patches involving more than two body segments
b. Major criterion
i. One or more nervous system anomalies
ii. One or more musculoskeletal anomalies
c. Minor criterion
i. Two or more congenital malformations other than nervous system or musculoskeletal anomalies
ii. Chromosomal anomalies
d. Definitive diagnosis: sine qua non criterion plus one or more major criteria or two or more minor criteria
e. Presumptive diagnosis: sine qua non criterion alone or in association with one minor criterion

5. Classification of linear pigmentary disorders distributed along the Blaschko lines (Di Lernia 2007)
a. Linear and whorled hypermelanosis
i. Hyperpigmentation
ii. Diffuse distribution
iii. Presence of mosaicism
iv. Associated abnormalities ($\leq$30%)
b. Hypomelanosis of Ito
i. Hypopigmentation
ii. Diffuse distribution
iii. Presence of mosaicism
iv. Associated abnormalities ($\geq$30%)
c. Progressive cribriform and zosteriform hyperpigmentation
i. Hyperpigmentation
ii. Segmental distribution
iii. Associated abnormalities: very low incidence
d. Segmental nevus depigmentosus
i. Hyperpigmentation
ii. Segmental distribution
iii. Associated abnormalities: very low incidence

Diagnostic Investigations

1. Cytogenetic investigation
a. Peripheral blood karyotyping indicated especially when systemic manifestations are present
b. Fibroblast karyotyping by sampling the dark and light skin for demonstrating mosaicism or chromosomal abnormalities
c. Presence of a wide variety of karyotypic abnormalities

2. Histopathology
   a. Decreased numbers of melanocytes
   b. Decreased numbers and size of pigmented melanosomes
   c. Neuropathological features
      i. Polymicrogyria
      ii. Disarray of cortical lamination
      iii. Heterotopic neurons in the white matter
      iv. Giant cells
3. CT and MRI of the brain
   a. White matter abnormalities somewhat predictive of a poor neurological outcome
   b. Neuroblast migration
      i. Heterotopia
      ii. Pachygyria
      iii. Polymicrogyria
   c. Localized or generalized cerebral atrophy
   d. Cerebral hemiatrophy
   e. Hemimegalencephaly
   f. Other rare anomalies
      i. Noncommunicating hydrocephalus
      ii. Megacisterna magna
      iii. Arteriovenous malformation
      iv. Cerebellar hypoplasia (hemispheres and vermis)
      v. Brainstem hypoplasia
      vi. Brain tumors
4. Radiography for musculoskeletal anomalies
5. EEG for seizures

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent shows chromosomal abnormalities
   b. Patient's offspring
      i. Not increased unless the patient has chromosomal abnormalities
      ii. Guarded counseling in women with a phenotype similar to HI who have nonmosaic balanced X/autosome translocations
2. Prenatal diagnosis: undetermined for affected mother who has a specific type of chromosome abnormality
3. Management
   a. Early intervention programs including physical, occupational, and speech therapies
   b. Special education
   c. Seizure control
   d. Surgical treatment of cataracts and retinal detachment

Hypophosphatasia

Hypophosphatasia is a heritable metabolic disease, characterized by impaired ossification of the bones, reduction in tissue and plasma levels of alkaline phosphatase, and the presence of phosphoethanolamine in the urine. The incidence is estimated to be about 1 in 100,000 live births (Fraser 1957). The incidence of severe disease is especially high in Canadian Mennonites (1 in 2,500 newborns) (Gehring et al. 1999).

Synonyms and Related Disorders

Adult hypophosphatasia (mild hypophosphatasia, odontohypophosphatasia); Childhood hypophosphatasia; Perinatal lethal hypophosphatasia; Phosphoethanolaminuria

Genetics/Basic Defects

1. Genetic heterogeneity
   a. Perinatal lethal hypophosphatasia form: autosomal recessive
   b. Prenatal benign hypophosphatasia form: autosomal dominant
   c. Infantile hypophosphatasia form: autosomal recessive
   d. Childhood hypophosphatasia form: autosomal recessive (frequent) and dominant (rare)
   e. Adult hypophosphatasia form: autosomal recessive and dominant with variable penetrance
   f. Odontohypophosphatasia form: autosomal recessive and dominant
2. Cause
   a. Caused by mutations in the alkaline phosphatase gene (*ALPL*) which (Barcia et al. 1997):
      i. Codes for tissue nonspecific ("liver/bone/kidney") alkaline phosphatase (TNSALP)
      ii. Is mapped on chromosome 1p36.1–p34
   b. Typically, the other isoenzymes (placental and intestinal forms) are not affected (Gehring et al. 1999).
3. Pathophysiology
   a. Defects in mineralization.
      i. Caused by deficiency in TNSALP
      ii. Resulting in increased urinary excretion of phosphoethanolamine and inorganic pyrophosphate and an increase in serum pyridoxal 5'-phosphate
   b. Osteoclasts, although morphologically normal, lack membrane-associated alkaline phosphatase activity on histochemical analysis (Barcia et al. 1997).
      i. Impede the proper incorporation of calcium into newly formed bone matrix
      ii. Result in bone demineralization and hypercalcemia when the impaired matrix calcification process occurs with a rapid rate of bone resorption
4. Genotype-phenotype correlations
   a. A number of different mutations account for the clinical heterogeneity.
      i. Individuals with recessive hypophosphatasia with both defective TNSALP alleles.
         a) In general, manifest more severe symptoms, with many of those affected being stillborn or expiring shortly after birth.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_129,
© Springer Science+Business Media, LLC 2012

b) Exception when consanguineous marriage is a factor: the two defective alleles tend to have distinct point mutations resulting in different amino acid substitutions in the alkaline phosphatase protein.

ii. Individuals with dominant hypophosphatasia with only one defective TNSALP allele: usually manifest moderate symptoms, such as the premature exfoliation of fully rooted primary teeth.

iii. Division between dominant and recessive hypophosphatasia sometimes is not well defined because the heterozygous siblings with one defective TNSALP allele in kindreds with recessive hypophosphatasia may show mild or moderate symptoms of the disease.

b. Missense mutations in the TNSALP gene have been observed in some hypophosphatasia kindreds, particularly those families with the more severe perinatal and infantile forms of the disease.

c. Autosomal recessive inheritance has been observed in most cases of hypophosphatasia with affected individuals being compound heterozygotes for two different mutant hypophosphatasia alleles.

d. Autosomal dominant alleles cause a few relatively mild cases of hypophosphatasia.

e. Mild hypophosphatasia (Fauvert et al. 2009).

i. Can result from either compound heterozygosity for severe and moderate mutations but also in a large part from heterozygous mutations with a dominant negative effect.

ii. A sequence variation in linkage disequilibrium with haplotype E could in addition play the role of an aggravating factor resulting in loss of haplosufficiency.

Clinical Features

1. Presence of a wide phenotypic variability ranging from intrauterine death and extreme hypomineralization of the skeleton to lifelong absence of clinical symptoms (Gehring et al. 1999)
   a. The following four different forms of the hypophosphatasia have been defined:
      i. Perinatal lethal form
      ii. Infantile form
      iii. Childhood form
      iv. Adult form
   b. In general, the earlier the age of presentation, the more severe the presenting features.
2. Perinatal lethal form
   a. Often stillborn
   b. Skeletal deformities: presenting features
      i. A profound lack of skeletal mineralization in utero.
      ii. Skin-covered spurs extending from the forearms or legs (skin dimples) (Shohat et al. 1991): these spurs are often diagnostic for hypophosphatasia.
      iii. Markedly shortening and bowing of the long bones (short-limbed dwarfism).
      iv. Fractures (perinatal).
      v. Rickety rosary.
      vi. Metaphyseal swelling.
      vii. Soft, pliable cranial bones ("vault like a balloon").
      viii. Bulging anterior fontanelle.
   c. Respiratory distress due to hypoplastic lungs and rachitic deformities of the chest
   d. Other features
      i. Hypotonia
      ii. High-pitched cry
      iii. Vomiting
      iv. Constipation
      v. Unexplained fever
      vi. Apnea
      vii. Cyanosis
      viii. Irritability
      ix. Seizures
   e. Prognosis
      i. Lethal in utero or within a few days of birth.
      ii. In the rare prenatal benign form, despite prenatal symptoms, there is a spontaneous improvement of skeletal defects (Pauli et al. 1999; Moore et al. 1999; Wenkert et al. 2007).
3. Infantile form
   a. Appears normal at birth
   b. Onset of symptoms
      i. Before 6 months of age
      ii. Poor feeding
      iii. Failure to thrive (growth failure)
      iv. Hypotonia
      v. Convulsions

c. Associated with progressive bony demineralization
   i. Abnormal skull with apparent wide separation of the cranial sutures and a wide, bulging anterior fontanelle
   ii. Tendency toward developing craniosynostosis
      a) Formation of a sagittal ridge
      b) A bony prominence at the position of the anterior fontanelle
   iii. Rachitic skeletal deformities manifesting by age 6 months
   iv. Flail chest
   v. Pulmonary insufficiency
d. Late in walking
e. Development of genu valgum
f. Short stature
g. Complications
   i. Recurrent pneumonia
   ii. Increased intracranial pressure
   iii. Renal compromise secondary to:
      a) Hypercalcemia
      b) Hypercalcinuria
      c) Nephrocalcinosis
h. Prognosis:
   i. Fatal in approximately 50% of cases by the age of 1 year
   ii. Survivors
      a) Tend to improve symptomatically.
      b) Deformities persist and often become worse.

4. Childhood form
   a. Appears normal at birth.
   b. Often present after 6 months of age.
   c. History of delayed walking and waddling gait.
   d. Early loss of deciduous teeth (before age of 5 years): the most consistent clinical sign.
   e. Frequent bone pain.
   f. Defective bone mineralization presenting clinically as rickets in children.
   g. Respiratory complications due to rachitic deformities of the chest.
   h. Premature craniosynostosis despite open fontanelle resulting in increased intracranial pressure.
   i. Dolichocephalic skull.
   j. Enlarged joints.
   k. Short stature.
   l. Bone fractures.
   m. Presence of hypercalcemia causes increased excretion of calcium resulting in renal damage.
   n. Prognosis: improving both clinically and radiographically with age in some childhood hypophosphatasia patients.
5. Adult form
   a. Variable age of onset and severity.
   b. Onset usually during middle age.
   c. Defective bone mineralization presents clinically as osteomalacia in adults.
   d. Premature loss of deciduous teeth.
   e. Usually presents clinically with loss of adult teeth.
   f. Multiple fractures secondary to osteomalacia, often after minimal fractures.
   g. Foot pain due to stress fractures of the metatarsals.
   h. Thigh pain due to pseudofractures of the femur.
   i. Delay in healing after a fracture.
   j. Joint pain due to deposition of calcium pyrophosphate dihydrate (chondrocalcinosis).
6. Odontohypophosphatasic form: premature loss of adult teeth; the only physical finding in this form
7. Craniosynostosis
   a. Considered a known feature in the infantile and childhood types of hypophosphatasia (Whyte 1995; Mornet 2007; Collmann et al. 2009), while it is missed in the adult and odontohypophosphatasia forms
   b. Often progressively involves all cranial sutures and poses significant functional risks to the optic nerves, as well as the spinal cord

Diagnostic Investigations

1. Laboratory tests.
   a. Low serum alkaline phosphatase levels in all types of hypophosphatasia
   b. Increased levels of urinary phosphoethanolamine levels
   c. Elevated plasma levels of pyridoxal 5'-phosphate
   d. Normal serum calcium, except in infantile cases where hypercalcemia can be seen due to renal failure
   e. Normal serum phosphate: hyperphosphatemia in various forms of hypophosphatasia reported

2. Skeletal survey (Kozlowski et al. 1976).
   a. Lethal perinatal form
      i. Near absence of skeletal mineralization
      ii. Skull: tiny ossification of occipital and/or frontal bones or complete absence of ossification
      iii. Teeth: very poorly formed
      iv. Spine
         a) Some vertebrae frequently unossified
         b) Occasionally unossified vertebrae
         c) Abnormally shaped vertebrae: rectangular, round, flattened, sagittally cleft, or butterfly-shaped vertebrae
      v. Shortening and bowing of the long and tubular bones
      vi. Diaphyseal spurs
      vii. Skin-covered spurs extending from the medial and lateral aspects of the knee and elbow joints
      viii. Fractures
      ix. Rachitic changes
         a) Pathology most evident at metaphyses as in rickets where growth is most rapid, namely the wrists, knees, hips, and proximal humeri.
         b) Defective, irregular ossification of the metaphysis: the most diagnostic feature of the disease.
         c) Nearly absent provisional zone of calcification.
         d) Irregular widening of the epiphyseal plate.
         e) Grossly irregular ossification of metaphysis giving a "frayed" or "tufted" appearance: a distinguished feature in hypophosphatasia. In rickets, the decalcification is usually regular and may give a "ground glass" effect to the affected metaphysis (metaphyseal cupping).
   b. Infantile form
      i. Deficient skeletal mineralization.
      ii. Congenital bowing of the long bones.
      iii. Bands of decreased density in metaphyses.
      iv. Widened cranial sutures.
      v. Later craniosynostosis: premature craniosynostosis occurs despite an open fontanelle.
      vi. Asymmetrical, moderate to severe rickets-like metaphyseal changes.
      vii. Metaphyseal and epiphyseal ossification defects.
      viii. Distorted bone trabeculation with areas of decreased and increased transradiancy.
      ix. Thin cortical bone.
      x. Diaphyseal spurs.
   c. Childhood form
      i. Mild, asymmetrical, metaphyseal changes resembling rickets or metaphyseal dysplasia
      ii. Distorted bone trabeculation with areas of decreased and increased transradiancy
      iii. Thin cortical bone
      iv. Hypotubulation and bowing of long bones
      v. Stress fractures
      vi. Radiolucent projections from the epiphyseal plate into the metaphysis
   d. Adult form
      i. Pseudofractures often occur in the lateral aspect of the proximal femur: a hallmark of this form
      ii. Osteomalacia
      iii. An increased incidence of poorly healing stress fractures, especially of the metatarsals
   e. Odontohypophosphatasic form: normal radiographic findings
3. Radiography and ultrasound screening for nephrocalcinosis.
4. Histology.
   a. Growth plates
      i. Rachitic abnormalities
      ii. Poorly mineralized and ossified columns with broad osteoid seams in metaphysis
      iii. Osteoblasts lacking membrane-associated alkaline phosphatase activity on histochemical testing, disrupting incorporation of calcium into the matrix
   b. Teeth
      i. A decrease in cementum
      ii. Enlarged pulp chamber
      iii. Incisors tend to be affected
5. Molecular genetic diagnosis: ALPL, the gene-encoding alkaline phosphatase, tissue nonspecific isozyme (TNASALP), is the only gene known to be associated with hypophosphatasia.
   a. Targeted mutation analysis
   b. Sequence analysis

Genetic Counseling

1. Recurrence risk: genetic counseling is complicated by the inheritance that may be autosomal dominant or autosomal recessive, the existence of the uncommon prenatal benign form, and the variable expression of the disease (Simon-Bouy et al. 2008).
   a. Patient's sib
      i. Autosomal recessive: 25%
      ii. Autosomal dominant: not increased unless a parent is affected in which case the recurrence risk is 50%
   b. Patient's offspring
      i. Autosomal recessive: not increased unless a spouse is a carrier in which case the recurrence risk is 50%
      ii. Autosomal dominant: 50%
2. Prenatal diagnosis.
   a. Fetal radiography
   b. Prenatal ultrasonography
      i. 2D-ultrasonography
         a) Failure to visualize a well-defined skull
         b) Other fetal skeletal structures not readily discernable
      ii. 3D-ultrasonography: can demonstrate specific osseous spurs in a lethal form (Sinico et al. 2007)
   c. Assay of the alkaline phosphatase activity: a useful complementary and independent method, especially when a mutation is unidentified and DNA from the index case is unavailable
      i. Assay of the tissue nonspecific alkaline phosphatase activity in chorionic villus samples in the first trimester
      ii. Absent alkaline phosphatase activity in the amniotic fluid and cultured amniotic fluid cells in the second trimester
   d. Prenatal diagnosis and preimplantation genetic diagnosis: mutation analysis of fetal DNA from amniocentesis or CVS where the disease-causing mutation has been identified in the family
3. Management.
   a. No specific treatment available: efforts to effect improved mineralization in patients with hypophosphatasia have not been successful (Barcia et al. 1997).
      i. Nonsteroidal anti-inflammatory drugs for control of the bone pain.
      ii. Dietary phosphate restriction may be helpful (Wenkert et al. 2007).
      iii. Large dose of vitamin D: reversal of improvement in the bony architecture upon withdrawal of the drug (Anderton 1979).
      iv. Oral cortisone: reversal of improvement in serum alkaline phosphatase level and radiographic appearance of the bones upon withdrawal of the drug (Anderton 1979).
      v. Avoid saline solution, furosemide diuresis, steroid therapy, or a low-calcium diet because these approaches may actually worsen bone mineralization and nephrocalcinosis.
      vi. Inhibition of osteoclastic activity with calcitonin: continued demineralization despite returning of normal serum calcium concentration.
      vii. Plasma infusions designed to supplement alkaline phosphatase activity or induce alkaline phosphatase production: not consistently improve bone mineralization.
      viii. Pyridoxine and/or pyridoxal phosphate in neonates with intractable seizures (Balasubramaniam et al. 2010).
   b. A clinical trial of marrow cell transplantation for infantile hypophosphatasia.
      i. A significant, prolonged clinical and radiographic improvement followed soon after receiving a boost of donor marrow cells.
      ii. Biochemical features of hypophosphatasia, however, remain unchanged to date.
      iii. The most plausible hypothesis for the patient's survival and progress: transient and long-term engraftment of sufficient numbers of donor marrow mesenchymal cells forms functional osteoblasts and perhaps chondrocytes, to ameliorate the skeletal disease.
   c. Surgical care.
      i. Rachitic deformities
      ii. Gait abnormalities
      iii. Adult form
         a) Rod placement for pseudofractures of the adult type results in the union and relief of the pain.
         b) Primary bone grafting and plating for midshaft fractures.
         c) Anticipate delayed union of fractures.

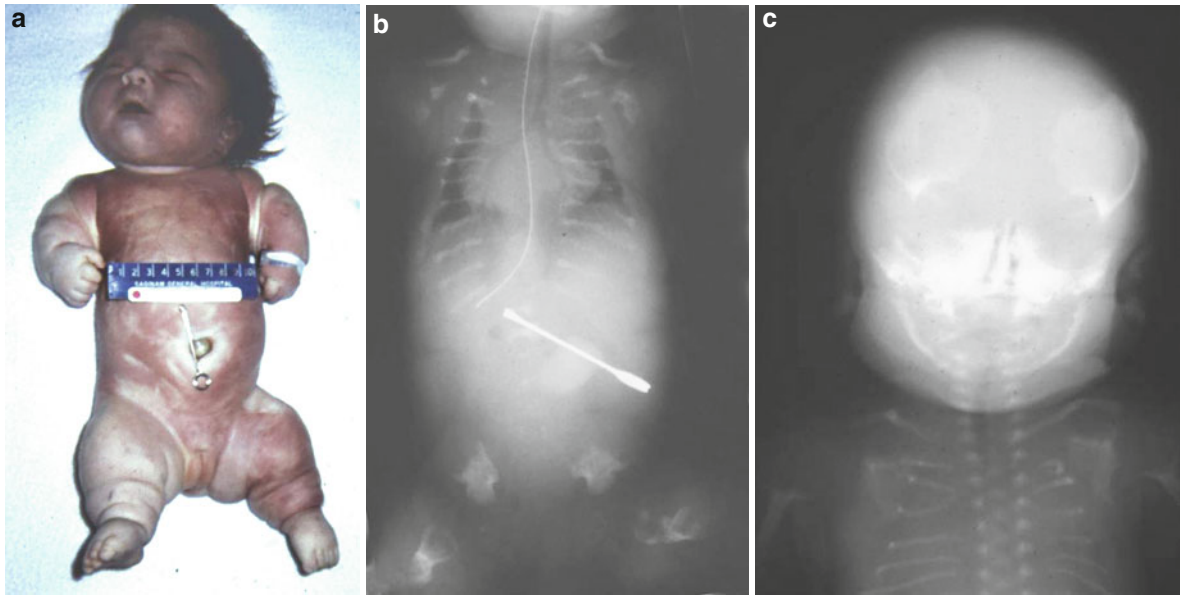

Fig. 1 (**a**–**c**) A neonate with perinatal lethal form of hypophosphatasia showing severe shortening of limbs. Radiograph shows markedly deficient ossification and abnormal bone development similar to achondrogenesis type I

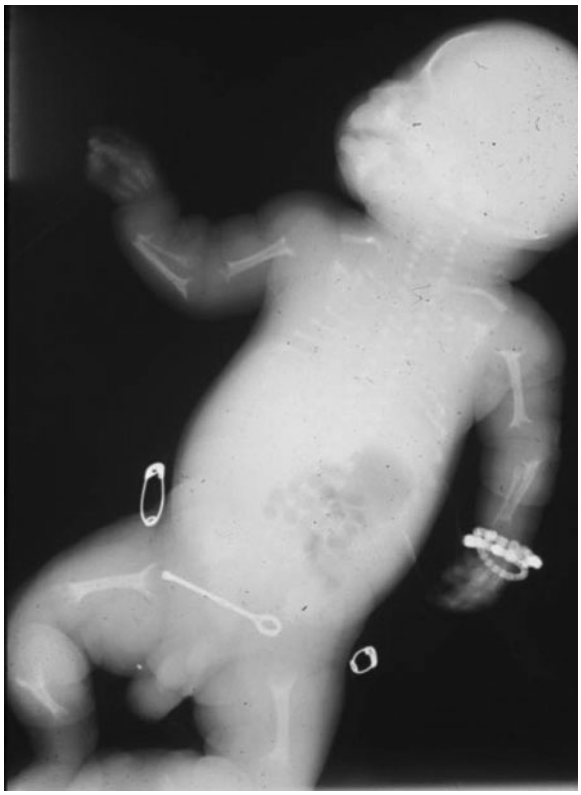

Fig. 2 Radiograph of another neonate with hypophosphatasia shows rickets-like metaphyseal cupping (spurs) and poor mineralization of cranial bones

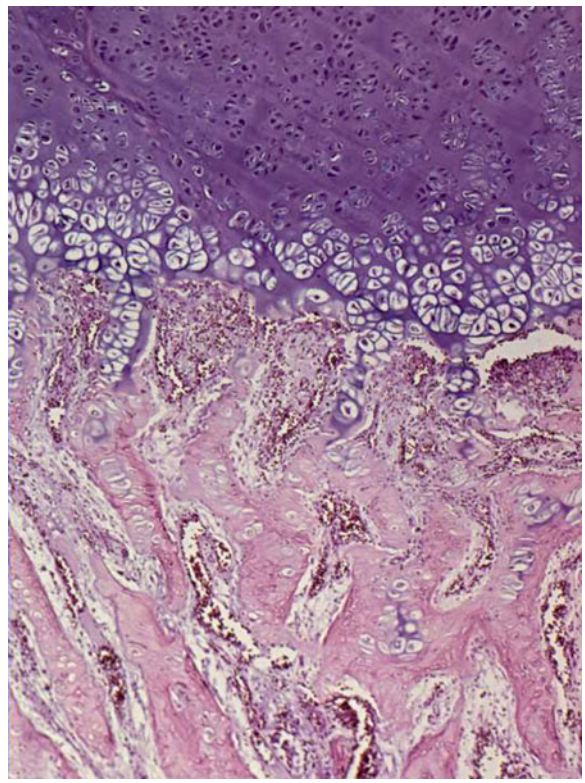

Fig. 3 Photomicrograph of a rib. Broad columns of hypertrophic chondrocytes with osteoid seams are present in the metaphysis. These columns are poorly mineralized and ossified

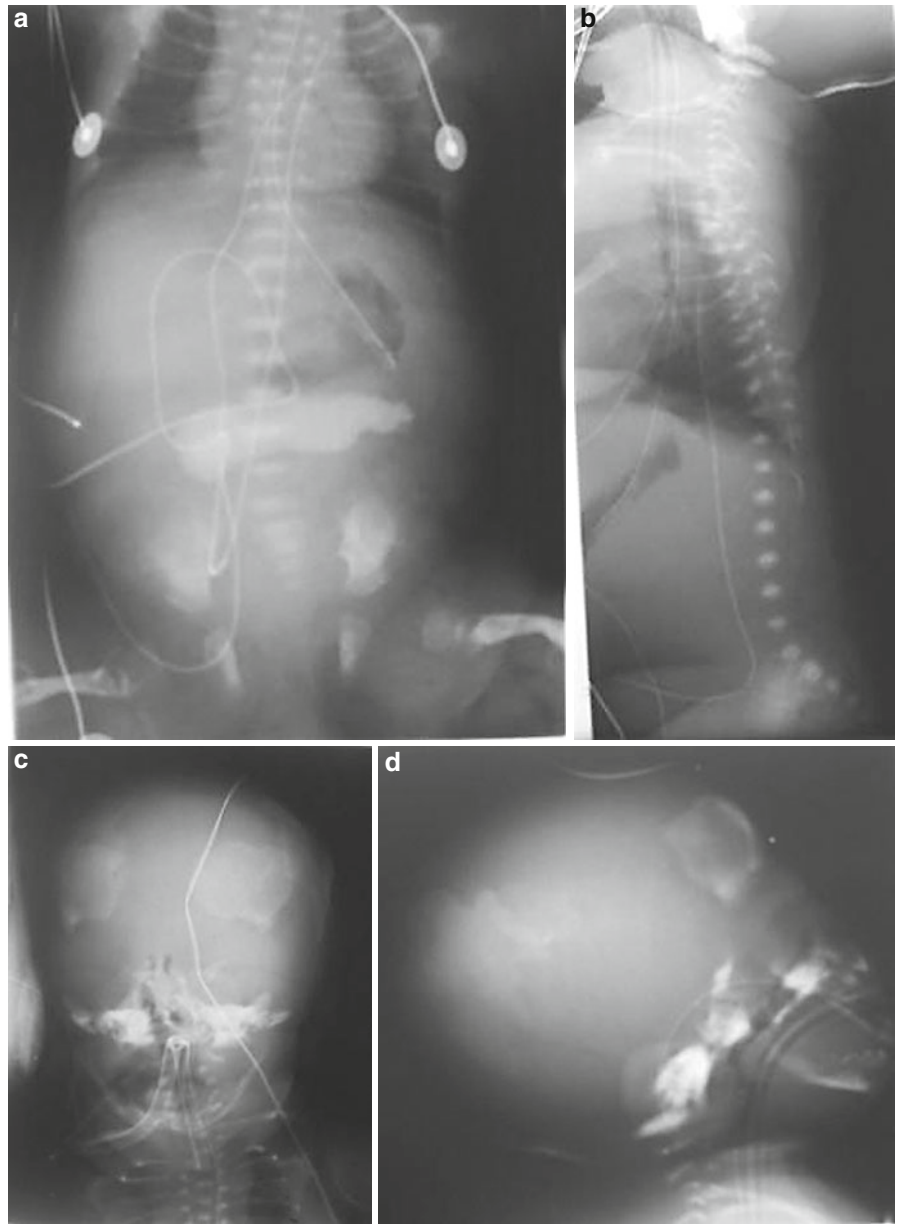

Fig. 4 (**a**–**d**) Radiographs of another neonate with perinatal lethal form of hypophosphatasia showing marked deficient skeletal mineralization, prenatal fracture of the left femur, and abnormal metaphyseal ossification of the proximal femurs

Fig. 5 Childhood hypophosphatasia in two brothers showing short stature and bowed legs

Hypopituitarism

Hypopituitarism is a term used to describe the deficiency of one or more of the hormones of the anterior or posterior pituitary gland. It can vary in severity and age at presentation. These hormonal deficits can also be present as part of a syndrome, with patients manifesting extrapituitary abnormalities such as in the eye and forebrain.

In clinical practice, panhypopituitarism is used to describe patients deficient in growth hormone (GH), gonadotropins, corticotropin, and thyrotropin in whom posterior pituitary function remains intact.

Hypopituitarism is rare, with an estimated annual incidence rate of 4.2 cases per 100,000 and with a prevalence rate of 45.5 per 100,000 (Regal et al. 2001).

Synonyms and Related Disorders

Adrenocorticotropin deficiency; Gonadotropin deficiency; Growth hormone deficiency; Pituitary hormone deficiency; Prolactin deficiency; Thyrotropin deficiency

Genetics/Basic Defects

1. Heterogeneous causes (Schneider et al. 2007; Kelberman and Dattani 2007; Toogood and Stewart 2008)
   a. Brain damage
      i. Traumatic brain injury (trauma to hypophysis)
      ii. Subarachnoid hemorrhage
      iii. Neurosurgery
      iv. Radiation
      v. Stroke
   b. Pituitary tumors
      i. Adenomas
      ii. Others
   c. Non-pituitary tumors
      i. Craniopharyngiomas
      ii. Meningiomas
      iii. Gliomas
      iv. Chordomas
      v. Ependymomas
      vi. Metastases
   d. Infections
      i. Abscess
      ii. Hypophysitis
      iii. Meningitis
      iv. Encephalitis
      v. Tuberculosis
      vi. Syphilis
   e. Infarction
      i. Anoplexia
      ii. Sheehan syndrome
   f. Autoimmune disorders: lymphocytic hypophysitis
   g. Infiltrative processes
      i. Hemochromatosis
      ii. Granulomatous diseases
      iii. Histiocytosis X
   h. Empty sella syndrome
   i. Perinatal insults
   j. Pituitary hypoplasia or aplasia
   k. Genetic causes
   l. Idiopathic causes
2. Genetic causes (mutations) of multiple pituitary hormone deficiencies
   a. *POU1F1* (*PIT-1*) (Andersen and Rosenfeld 2001): genetic combined pituitary hormone

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_130,

deficiency (CPHD) caused by mutations within the pituitary-specific transcription factor 1
   i. Hormone deficiencies
      a) GH
      b) Thyrotropin (TSH)
      c) Prolactin
   ii. Inheritance
      a) Autosomal dominant
      b) Autosomal recessive
   iii. Phenotypes
      a) Hormone deficiencies: severe
      b) Thyrotropin secretion: initially normal, but secondary hypothyroidism inevitable
      c) Pituitary size: variable
b. *PROP1* (Sornson et al. 1996): the most common cause of CPHD caused by mutations of *Prophet of PIT1*
   i. Hormone deficiencies
      a) GH
      b) TSH
      c) LH
      d) FSH
      e) Prolactin
      f) Occasionally adrenocorticotropic hormone (ACTH)
   ii. Inheritance: autosomal recessive (AR)
   iii. Phenotypes
      a) Deficiencies tend to be milder than in *POU1F1* mutations
      b) Evolving corticotropin deficiency with increasing age
      c) Enlarged pituitary size with later involution
      d) Can be associated with a mass lesion (Turton et al. 2005)
c. *HESX1* (Dattani et al. 1998)
   i. Hormone deficiencies: range from isolated GH deficiency to panhypopituitarism, including diabetes insipidus
   ii. Inheritance: autosomal dominant (AD), AR
   iii. Phenotypes
      a) May be associated with septo-optic dysplasia, combined pituitary hormone deficiency (CPHD), and isolated growth hormone deficiency.
      b) Mutations result in a variable phenotype: anterior pituitary hypoplasia, ectopic posterior pituitary, and midline forebrain abnormalities.
      c) Environmental factors, such as drugs and alcohol, are implicated.
d. *LHX3* (Netchine et al. 2000)
   i. Hormone deficiencies
      a) GH
      b) TSH
      c) LH
      d) FSH
      e) Prolactin
   ii. Inheritance: AR
   iii. Phenotypes
      a) Elevated and anteverted shoulders giving the appearance of a stubby neck with limited rotation of the head (short rigid cervical spine)
      b) Hypoplasia of anterior pituitary gland
      c) Preservation of corticotropin secretion
(e) *LHX4* (Machinis et al. 2001)
   i. Hormone deficiencies
      a) GH
      b) TSH
      c) Cortisol
   ii. Inheritance: AD
   iii. Phenotypes (MRI of the brain)
      a) Small sella
      b) Persistent craniopharyngeal canal
      c) Hypoplastic anterior pituitary and ectopic posterior pituitary
      d) Pointed cerebellar tonsils
3. Genetic causes (mutations) of isolated pituitary hormone deficiencies
   a. *TBX19* (*TPIT*) (Pulichino et al. 2003)
      i. Hormone deficiencies: corticotropin
      ii. Inheritance: AR
      iii. Phenotypes
         a) Presentation in neonatal period with severe hypoglycemia and prolonged cholestatic jaundice
         b) Undetectable corticotropin and cortisol levels
         c) Failure to respond to corticotropin-releasing hormone
         d) High incidence of neonatal death in affected families
   b. *SOX2* (Maheshwari et al. 1998)
      i. Hormone deficiencies: hypogonadotropic hypogonadism
      ii. Inheritance: de novo mutation reported
      iii. Phenotypes

a) Anophthalmia or microphthalmia
b) Learning difficulties
c) Developmental delay
d) Genital abnormalities
e) Esophageal atresia
f) Sensorineural hearing loss

c. *SOX3* (Hamel et al. 1996; Laumonnier et al. 2002)
i. Hormone deficiencies: isolated growth hormone deficiency
ii. Inheritance: XL recessive
iii. Phenotypes
a) Mental retardation
b) Anterior pituitary hypoplasia
c) Infandibular hypoplasia
d) Midline abnormalities

d. *GHRHR* (Maheshwari et al. 1998)
i. Hormone deficiencies: GH
ii. Inheritance: AR
iii. Phenotypes
a) Short stature
b) Proportionate growth
c) Anterior pituitary hypoplasia

e. *GH1* (Cogan et al. 1993)
i. Hormone deficiencies: GH
ii. Inheritance: AR
iii. Phenotypes
a) Short stature
b) Abnormal facies
c) Respond to exogenous GH treatment, but may develop antibodies

f. *KAL-1* (Legouis et al. 1991; Franco et al. 1991)
i. Hormone deficiencies
a) GnRH
b) FSH
c) LH
ii. Inheritance: X-linked
iii. Phenotypes
a) Failed or arrested puberty
b) Anosmia
c) Synkinesis
d) Unilateral renal agenesis

g. *FGFR-1* (*KAL-2*) (Dode et al. 2003)
i. Hormone deficiencies
a) GnRH
b) FSH
c) LH
ii. Inheritance: AD
iii. Phenotypes: failed or arrested puberty

h. *GNRHR1* (Beranova et al. 2001)
i. Hormone deficiencies
a) FSH
b) LH
ii. Inheritance: AR
iii. Phenotypes: variable, determined by the sensitivity of the mutant receptor to GnRH

i. *DAX1* (Lin et al. 2006)
i. Hormone deficiencies
a) FSH
b) LH
ii. Inheritance: AR, X-linked
iii. Phenotypes
a) Presents initially with severe neonatal hypoadrenalism
b) Subsequently fail to enter puberty or suffer delayed or arrested puberty

j. *GPR54* (de Roux et al. 2003)
i. Hormone deficiencies
a) FSH
b) LH
ii. Inheritance: AR
iii. Phenotypes: presents with absent or delayed puberty

k. *POMC* (Krude et al. 1998)
i. Hormone deficiencies: corticotropin
ii. Inheritance: AR
iii. Phenotypes (clinical triad)
a) Early-onset obesity
b) Adrenal hypoplasia
c) Cortisol deficiency

l. *Thyrotropin-β* (Vuissoz et al. 2001)
i. Hormone deficiencies: thyrotropin
ii. Inheritance: AR
iii. Phenotypes: severe congenital hypothyroidism if not detected and treated early on

Clinical Features

1. Nonspecific symptoms (Toogood and Stewart 2008)
a. Feeling of general ill health
b. Being abnormally tired
c. Increased lethargy
d. Feeling cold
e. Weight loss
f. Reduced appetite
g. Abdominal pain

2. Symptoms related to local effects of any underlying tumor
   a. Headaches
   b. Visual disturbance (typically a bitemporal hemianopia)
   c. Cerebrospinal fluid rhinorrhea
3. GH deficiency
   a. Neonates with congenital GH deficiency (or hypopituitarism)
      i. Severe neonatal hypoglycemia often associated with convulsions, presenting most frequently in the first 24 h of life (birth trauma)
      ii. Prolonged conjugated hyperbilirubinemia
      iii. Hypothermia
      iv. Possibly a micropenis (Ogilvy-Stuart 2003)
   b. Neonates with midline birth defects should be considered at risk for isolated or multiple pituitary hormone deficiencies
   c. Older babies who escape early diagnosis may present with failure to thrive and poor weight gain
   d. Older children
      i. Proportional short stature with height more than 2–3 standard deviations (SD) below the mean for the age
      ii. Reduced growth velocity for their age
      iii. Delayed bone maturation in the absence of an inherited skeletal dysplasia or chronic disease
      iv. Characteristic craniofacial appearance in patients with severe GH deficiency: a prominent forehead and depressed midface development caused by the lack of GH effect on endochondrial growth at the base of the skull, occiput, and sphenoid
      v. Delayed dentition
      vi. Presence of other features attributable to the underlying etiology of the GH deficiency
   e. Adults
      i. Multiple symptoms and pathophysiologic changes affecting a variety of biologic systems (none are pathognomonic) are attributed to GH deficiency in adult life (Molitch et al. 2006).
      ii. Impaired quality of life (Burman et al. 1995; Holmes and Shalet 1995)
         a) Complaining of tiredness
         b) Lack of energy
         c) Emotional lability
         d) Reduced sleep quality
         e) A degree of disability consistent with psychiatric illness requiring treatment (up to 30% of patients) (McGauley et al. 1990)
         f) Patients who have childhood-onset GH deficiency do not seem to suffer the same degree of impairment in quality of life as those who have adult-onset GH deficiency (Attanasio et al. 1997)
4. Gonadotropin (LH, FSH) deficiency
   a. Male infants with congenital hypogonadotropic hypogonadism: effect of relative androgen deficiency occurring during the third trimester
      i. Unilateral or bilateral cryptorchidism
      ii. Microphallus
   b. Adolescent boys
      i. Pubertal development
         a) Fail to initiate, or abnormal with failure to progress normally
         b) Testicular volumes vary between prepubertal boys (<4 cm^3) and normal adult size
         c) Pubic hair (mediated by testicular or adrenal androgens): present but unlikely to be normal
   c. Adolescent girls
      i. Gonadotropin deficiency becoming apparent in teenage years
      ii. Delayed breast development
      iii. Primary amenorrhea
   d. Isolated gonadotropin deficiency
      i. Normal growth during childhood
      ii. Slow growth during adolescence when the growth spurt fails to occur
      iii. Epiphyses, however, fail to fuse at the usual age, and the long bones continue to grow, ultimately resulting in tall stature and a eunuchoid habitus
   e. Men with acquired gonadotropin deficiency during adult life
      i. Usually achieve a normal height with proportionate growth.
      ii. Adult secondary sexual characteristics are present, although the testes may become soft and reduced in size because the FSH deficiency causes atrophy of the seminiferous tubules.

iii. Slowing of beard growth with less frequent shaving.
iv. Loss of body hair.
v. Skin becoming thin with development of thin wrinkles if the gonadotropin deficiency is severe and prolonged.
vi. Libido may be reduced, and the ability to achieve and maintain an erection may be compromised.
vii. Testosterone deficiency can lead to nonspecific symptoms, e.g.:
a) Tiredness
b) Reduced muscle bulk
c) Reduced exercise capacity
viii. Decreased bone mineral density with a risk for:
a) Osteopenia or osteoporosis
b) Increased fractures
ix. Azoospermia: usually present in prolonged gonadotropin deficiency, although there are exceptions.
x. Symptoms of hypogonadotropism: nonspecific and may not become evident for many years, particularly if fertility is not an issue.

f. Women with secondary gonadotropin deficiency
i. Diagnosed quickly when oligomenorrhea or amenorrhea develops.
ii. Symptoms of estrogen deficiency.
a) Vaginal dryness
b) Dyspareunia
c) Hot flashes
d) Breast atrophy
iii. Pubic and axillary hair remains unless there is coexistent corticotropin deficiency with adrenal androgen deficiency.

5. Adrenocorticotropin (ACTH) deficiency
a. Results in secondary hypoadrenalism.
b. The most serious of anterior pituitary hormone deficits.
c. During an intercurrent illness.
i. May develop an adrenal crisis with severe hyponatremia and hypovolemic shock
ii. Can result in death if not diagnosed and treated appropriately
d. Decompensation and shock occur during periods of illness or physical stress, such as surgery.
e. Other symptoms of cortisol deficiency.
i. Lethargy
ii. Fatigue
iii. Weight loss
iv. Nonspecific abdominal pain
v. Hypoglycemia
a) Feelings of hunger
b) Light-headedness
c) Sweating
d) Hypotension and complain of postural symptoms
vi. Absence of the pigmentation associated with primary adrenal failure in patients with corticotropin deficiency: the skin may be pale with an alabaster-like appearance (Arlt and Allolio 2003)
f. Patients who have hypopituitarism are protected somewhat from developing severe, acute hypoadrenalism compared with patients who have primary adrenal failure, as the angiotensin-aldosterone axis remains intact.

6. Thyrotropin (TSH) deficiency
a. Symptoms and signs
i. Similar to those of primary hypothyroidism but usually are less severe, as there often is some residual thyrotropin secretion
ii. Tiredness
iii. Cold intolerance
iv. Weight gain
v. Constipation
vi. Dry skin and hair are common features
b. With the exception of traumatic brain injury (TBI), thyrotropin deficiency usually occurs late in the evolution of hypopituitarism and often is seen with other anterior pituitary hormone deficits.
c. In children, secondary hypothyroidism contributes to poor growth, delayed bone age, and failure of secondary dentition.

7. Prolactin deficiency
a. Prolactin is inhibited predominately by dopamine; as a consequence, prolactin levels frequently are raised in the presence of hypothalamic-pituitary disease because of compression or transection of the pituitary stalk.
b. Hypoprolactinemia is found in patients who have mutations of the transcription factors, PIT1 and PROP1.
c. However, in patients with structural pituitary disease, prolactin deficiency is a marker of

severe pituitary damage (Mukherjee et al. 2003; Toledano et al. 2007).
   d. In women, prolactin deficiency can cause failure of lactation in the postpartum period.
   e. Although prolactin is an important hormone in the animal world with multiple identified roles in growth, water homeostasis, reproduction, behavior, and growth and immune modulation (Bole-Feysot et al. 1998), a phenotype attributable to prolactin deficiency in man has yet to be established.
8. *PROP1*-related combined pituitary hormone deficiency (Phillips et al. 2005)
   a. Most affected individuals are ascertained because of growth failure and failure to thrive starting in infancy or early childhood.
   b. Hypothyroidism
      i. Usually mild
      ii. Occurs in later infancy and childhood
   c. Absent or delayed and incomplete secondary sexual development with infertility
      i. Males: usually have a small penis and small testes
      ii. Females: some experience menarche, but subsequently require hormone replacement therapy
   d. GH deficiency
      i. Neonatal hypoglycemia
      ii. Proportionate short stature
      iii. Delayed bone age
   e. TSH deficiency
      i. Suspected in children with growth failure, poor weight gain, and delayed bone maturation
      ii. Large posterior fontanelle
      iii. Jaundice lasting more than 1 week after birth
      iv. Macroglossia
      v. Hoarse cry
      vi. Distended abdomen
      vii. Umbilical hernia
      viii. Hypotonia
   f. LH and FSH deficiency
      i. Newborn males
         a) Micropenis without hypospadias
         b) With or without cryptorchidism
      ii. Adolescent males
         a) Delayed onset of puberty (after age 14)
         b) Cessation of secondary sexual development
      iii. Adolescent females: lack of breast development or menses by age 14
   g. Prolactin deficiency: suspected in females with impaired lactation
   h. ACTH deficiency
      i. Less common
      ii. Usually occurs in adolescence or adulthood
      iii. Suspected in children with persistent weakness, abdominal pain, anorexia, and weight loss
      iv. Signs of acute ACTH deficiency
         a) Acute hypotension
         b) Dehydration
         c) Shock accompanied by hyponatremia, hyperkalemia, and hypoglycemia
9. *POU1F1* combined pituitary hormone deficiency (Phillips et al. 2005)
   a. Normal birth weight and birth length and uncomplicated perinatal course
   b. Growth failure in early infancy in most affected individuals
   c. Growth hormone deficiency: usually severe
   d. Proportional short stature
   e. Hypothyroidism
      i. Can be congenital
      ii. Can be mild and later onset
      iii. Progressive loss of TSH occurring over time
   f. Distinctive facies (Aarskog et al. 1997)
      i. Prominent forehead
      ii. Marked midface hypoplasia
      iii. Depressed nasal bridge
      iv. Deep-set eyes
      v. Short nose with anteverted nostrils
   g. MRI of the brain: pituitary usually appears hypoplastic

Diagnostic Investigations

1. Brain MRI (Toogood and Stewart 2008)
   a. To exclude tumors and other lesions of the sellar and parasellar region after confirmation of hypopituitarism.
   b. Normal MRI of the sellar and parasellar region cannot exclude hypopituitarism.
2. Growth hormone deficiency
   a. The definition of GH deficiency in adulthood differs from that in childhood.

i. In children, the diagnosis of GH deficiency is made in the presence of a reduced growth velocity.
ii. In adults, the clinical features attributed to GH deficiency are numerous and nonspecific; there is no single pathognomonic feature that alerts clinicians to the diagnosis.
iii. Diagnosis of GH deficiency should be considered only in adults who have a history of pituitary disease, secondary to neoplastic disease, surgery, or cranial radiation or in those who have had a history of treatment with GH during childhood and adolescence (Growth Hormone Research Society 1998).
iv. Results of dynamic tests of GH status are affected by obesity (all stimuli) (Shalet et al. 1998) and age (Toogood et al. 1998) and could lead to an inappropriate diagnosis.

b. The insulin tolerance test (ITT)
i. Considered the gold standard used to diagnose GH deficiency in adults, using a diagnostic threshold of 3 mg/L.
ii. Not suitable for use in all patients and is contraindicated in patients who have a history of seizures or ischemic heart disease.
iii. Consequently, the majority of endocrinologists do not use the ITT in patients over 65 in case undiagnosed heart disease is present.

c. Insulin-like growth factor (IGF-1)
i. A GH-dependent peptide, although the level of dependence seems to diminish with increasing age.
ii. In young adults who have childhood-onset GH deficiency, 95% (de Boer et al. 1994) have serum IGF-1 below the normal range, whereas 82% of GH-deficient patients over 60 years old have a normal IGF-1 (Toogood et al. 1998).

3. Gonadotropin deficiency
a. Women with gonadotropin deficiency
i. In women of postmenopausal age, low or undetectable levels of FSH and LH are sufficient to make a diagnosis.
ii. In younger women, amenorrhea with low estradiol levels and low or normal gonadotropins is consistent with the diagnosis of gonadotropin deficiency.
iii. Failure to induce a withdrawal bleed after a progesterone challenge confirms the presence of a hypoestrogenic state.

b. Men with gonadotropin deficiency
i. Diagnosed in the presence of low or normal serum gonadotropin levels and a low serum testosterone.
ii. Semen analysis is useful when considering fertility and may demonstrate oligospermia or azoospermia.

4. Adrenocorticotropin deficiency
a. The activity of the hypothalamic-pituitary-adrenal (HPA) axis exhibits a diurnal rhythm; serum cortisol levels often are undetectable at midnight during sleep, rising and reaching peak at approximately 5:00 AM, and declining gradually over the course of the day
b. The insulin tolerance test (ITT)
i. A peak response to hypoglycemia (blood glucose 2.2 mmol/L) of greater than 20 mg/dL: considered a normal response (Tuchelt et al. 2000; Nelson and Tindall 1978)
ii. Tests the integrity of the whole HPA axis and has the advantage of simultaneously assessing the GH status of patients
c. Short Synacthen test (SST): an alternative test to ITT
i. Measures the serum cortisol response after an intramuscular injection of cosyntropin (Synacthen) (250 mg) (Stewart et al. 1988; Clayton 1996; Kane et al. 1995)
ii. Based on the premise that corticotropin deficiency results in atrophy of the adrenal cortex and subsequently becomes unresponsive to a single pulse of corticotropin
iii. A serum cortisol value of 22 mg/dL (550 nmol/L) or higher 30 min after administration of Synacthen: consistent with normal corticotropin reserve
iv. Risk for a false negative result (a perception that patients have normal corticotropin reserve): the SST should not be performed until at least 6 weeks after surgery or an apoplectic event

5. Thyroid-stimulating hormone deficiency
a. Diagnosed based on the presence of a low or normal serum thyrotropin measurement with a low serum free thyroxine (fT4) level.

b. Measurement of serum fT3: not required but may be low or normal.
c. In patients treated with radiotherapy, sequential falls in the serum fT4 toward the lower end of the normal range associated with evolving symptoms of hypothyroidism may be sufficient to warrant instigation of levothyroxine.
d. The thyrotropin response to thyrotropin-releasing hormone: used less frequently since the introduction of sensitive thyrotropin assays.

6. *PROP1*-related combined pituitary hormone deficiency (CPHD) (Phillips et al. 2005)
   a. Testing for deficient secretion of GH, TSH, LH, FSH, prolactin, and ACTH: establishes the diagnosis
   b. *PROP1* is the only gene associated with *PROP1*-related CPHD
      i. Targeted mutation analysis for the common recurring deletion in which three AG repeats are reduced to two repeats: available clinically
      ii. This mutation accounts for 55% of familial cases and 12% of nonfamilial cases

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant inheritance
         a) Recurrence risk of 50% if a parent is affected
         b) Low recurrence risk if both parents are normal
      ii. Autosomal recessive inheritance: risk of recurrence 25%
      iii. X-linked recessive: 50% of male sibs affected if the mother is a carrier
   b. Patient's offspring
      i. Autosomal dominant inheritance: a 50% risk of offspring affected.
      ii. Autosomal recessive inheritance: low recurrence risk unless the spouse is affected or a carrier.
      iii. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.
2. Prenatal diagnosis
   a. Prenatal diagnosis is possible for pregnancies at increased risk for various conditions such as *PROP1* or *POU1F1* CPHD when the disease-causing mutation in the family is known.
   b. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member.
3. Management (Toogood and Stewart 2008)
   a. Pituitary hormone replacement therapy
      i. Growth hormone replacement
         a) GH replacement in children who have GH deficiency results in an increase in linear growth, and its use for that purpose is accepted universally.
         b) Recombinant human GH has allowed GH replacement to be used in adults.
         c) In the event of side effects (peripheral edema, arthralgia, and headaches) during the titration phase, the dose of GH should be reduced or, if severe, treatment should be withdrawn.
      ii. Sex steroid and gonadotropin replacement
         a) The aim of androgen replacement in men: to maintain secondary sexual characteristics, restore a sense of well-being, prevent loss of and optimize bone mass, and improve sexual function (Bhasin et al. 2006).
         b) Women who have gonadotropin deficiency require sex steroid replacement to alleviate the symptoms of estrogen deficiency and to optimize bone health.
         c) Induction of fertility can be achieved in men and women using exogenous gonadotropins. In men, human chorionic gonadotropin can be used initially to stimulate spermatogenesis (Vicari et al. 1992). In women, ovulation induction is initiated with FSH or human menopausal gonadotropin.
      iii. Adrenocorticosteroid replacement
         a) Cortisol: Hydrocortisone is the glucocorticoid of choice for patients who have secondary adrenal insufficiency

   b) Optimize and monitor glucocorticoid replacement therapy
  iv. Dehydroepiandrosterone
   a) In addition to cortisol, the adrenal cortex produces androgens regulated by corticotropin.
   b) Patients who have corticotropin deficiency also are deficient in dehydroepiandrosterone (DHEA) (Arlt et al. 1999).
  v. Thyroxine replacement
- b. Long-term consequences of hypopituitarism
  i. Patients who have hypothalamic-pituitary disease and are receiving a combination of sex steroids, glucocorticoids, and thyroxine, but not GH replacement, for a range of anterior pituitary hormone deficiencies have an approximately twofold increase in mortality compared with the general population (Rosen and Bengtsson 1990; Bates et al. 1996; Tomlinson et al. 2001).
  ii. In the largest study to date, there was an increase in deaths from cardiovascular, cerebrovascular, and respiratory disease (Tomlinson et al. 2001).
  iii. GH replacement therapy improves short-term individual cardiovascular risk profiles.
- c. Long-term follow-up of patients with hypopituitarism
  i. Continued follow-up under the care of a physician (endocrinologist) who has expertise in the field
  ii. Annual assessment to determine their cardiovascular risk once hormone replacement treatments are optimized
  iii. Attention to blood pressure and cholesterol levels and treatment with antihypertensives and cholesterol lowering agents instigated as appropriate

Fig. 1 A 16-year-old female was evaluated for pituitary hormone deficiency. She had short stature for which she received growth hormone therapy since 3 years of age. MRI scan of the brain showed a very small (hypoplastic) pituitary gland. Endocrine investigations revealed the following: low serum IGF-1 (somatomedin-C): <10 ng/mL (normal 11–206 ng/mL); low free T4: 0.67 ng/dL (normal 0.71–1.85 ng/dL); low TSH: 0.02 μU/mL (normal 0.47–5.01 μU/mL); normal cortisol: 7.5 μg/dL (normal 3.0–21 μg/dL); low ACTH-ICMA: 9.0 pg/mL (normal 10.0–60.0 pg/mL); low estradiol: < 0.5 ng/dL (normal 0.7–6.0 ng/dL); low FSH: 1.3 mIU/mL (normal 1.5–12.8 mIU/mL); normal LH: 0.38 mIU/mL (normal 0.10–12.0 mIU/mL). Molecular genetic testing for *POU1F1* gene mutation revealed no sequence variants. However, a different genetic basis for combined pituitary hormone deficiency cannot be ruled out

Fig. 2 A 6-year-old boy was evaluated for pituitary hormone deficiency. He had a history of hypoglycemia and a micropenis. He was noted to be very short, for which he received growth hormone shots daily. He was also treated for hypothyroidism. Past lab results: TSH: 3.16 μU/mL; low free T4: 0.56 ng/dL; normal IGF-1: 66 ng/mL; low IGFBP-3: 0.7 mg/L; normal cortisol: 5.5 μg/dL; normal ACTH-ICMA: 17 pg/mL. Molecular genetic testing for *POU1F1* gene mutation showed no sequence variation

I(1p), I(1q) Syndrome

In 1999, Chen et al. first described uniparental (paternal) isodisomy, resulting from 46,XX,i(1p),i(1q) in a woman with short stature, ptosis, micro/retrognathia, myopathy, deafness, and sterility.

Synonyms and Related Disorders

I(1p), I(1q) uniparental (paternal) isodisomy; Isochromosome 1p, isochromosome 1q syndrome

Genetics/Basic Defects

1. Uniparental disomy (UPD): inheritance of both homologues from one parent. Several types of errors in chromosome segregation during gamete formation may be responsible for uniparental disomy (Spence et al. 1988).
2. Uniparental isodisomy: caused by isochromosome formation from misdivision of the centromere (Bernasconi et al. 1996; Eggerding et al. 1994; Lindenbaum et al. 1991; Shaffer et al. 1997). Although maternal UPD (Pulkkinen et al. 1997; Turner et al. 2007) and paternal UPD (Gelb et al. 1998; Takizawa et al. 2000) of chromosome 1 have been reported previously, none of these involved an isochromosome.
3. Cytogenetic analysis from the peripheral blood of the patient demonstrated one i(1p) and one i(1q) without normal chromosome 1 homologues (Figs. 2–4, Table 1).
4. The most likely mechanism of formation of the rearranged chromosomes in our patient (Fig. 5) is as follows:
   a. The zygote contained a chromosome 1 from the father and none from the mother due to nondisjunction resulting in a monosomy 1 conceptus.
   b. Subsequently, misdivision at the centromere may have occurred, leading to two isochromosomes, one of each chromosome arm.
   c. At the next mitotic division, both went into the same daughter cell.
   d. In the following cell cycle, normal replication took place. This would produce two isochromosomes, made up of one i(1p) and one i(1q), with uniparental isodisomy.
5. Additionally, many mechanisms could account for the finding of isochromosomes, as put forward by Bernasconi et al. (1996) regarding two isochromosomes and UPD 2. Except for the possibility of homozygosity for recessive mutations, maternal uniparental disomy 2 appears to have no adverse impact on the phenotype.
6. Mechanisms of formation of the two isochromosome, maternal i(2q) and paternal i(2p) (Baumer et al. 2007):
   a. The initial maternal meiotic I error may have been a nondisjunction event of chromosome 2.
   b. Trisomy rescue may have occurred during the recombination event that led to the isochromosomes or, alternatively, the formation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_131,
© Springer Science+Business Media, LLC 2012

of the maternal i(2q) preceded that of the paternal i(2p). In this case, the formation of the paternal i(2p) would rescue the trisomy 2q and monosomy 2p.

c. A third possibility: the initial meiotic I rearrangement consisted in the formation of the maternal isochromosome; rescue of the trisomy 2q/monosomy 2p would have occurred postzygotically through formation of a paternal i(2p).

7. To the best of our knowledge, our patient is the first case of uniparental isodisomy resulting from i(1p) and i(1q).
   a. Our patient, therefore, has allelic homozygosity for all paternal chromosome 1 loci, demonstrated in part by our molecular studies.
   b. However, the possibility of areas of heterodisomy through meiotic recombination likely exists.
   c. The patient's abnormal phenotype is most likely due to unmasking of rare recessive mutations through isodisomy, but the possibility of genomic imprinting and the presence of mosaicism cannot be ruled out.
   d. The presence of myopathy in this patient suggests the possibility that the potential gene(s) involved may be localized on chromosome 1.

Clinical Features

1. Short stature
2. Bilateral conductive hearing loss
3. Facial features
   a. Downward slant of palpebral fissures
   b. Bilateral ptosis
   c. Malar hypoplasia
   d. Severe micro/retrognathia
4. High-arched palate
5. Cervical vertebral anomaly
6. Slightly short fingers
7. Scoliosis
8. Normal intelligence
9. Normal secondary sex characteristics
10. Menarche at 11 years with regular menstruation but never conceived in three marriages with different partners.

Diagnostic Investigations

1. Cytogenetic analyses: to demonstrate one i(1p) and one i(1q) without normal chromosome 1 homologues by:
   a. GBG banding
   b. CBG banding
   c. FISH analysis using whole chromosome 1 probe
2. Molecular investigations to demonstrate isochromosomes with complete homozygosity of either paternal or maternal markers

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: The presence of two isochromosome 1s would virtually exclude viable offspring since either duplication of the long arm with deletion of the short arm or duplication of short arm with deletion of long arm would be lethal to the fetus.
2. Prenatal diagnosis: demonstration of i(1p), i(1q) without two normal chromosome 1s by either CVS or amniocentesis
3. Management: supportive

D1S422	1q31.3	12	12	12	
D1S103	1q32	12	12	12	
D1S102	1q32-q44	12	12	12	
D1S459	1q42.12	13	22	22	*

The polymorphic markers used in the analysis are shown on the left, with fully informative ones indicated by *asterisks* (*) on the right, and their cytogenetic locations noted in the second column

Fig. 1 (**a**, **b**) A 43-year-old woman was referred for evaluation because of minor facial anomalies, myopathy, sterility, short stature, hearing loss, downward slant of palpebral fissures, bilateral ptosis, severe micro/retrognathia, high-arched palate, and scoliosis

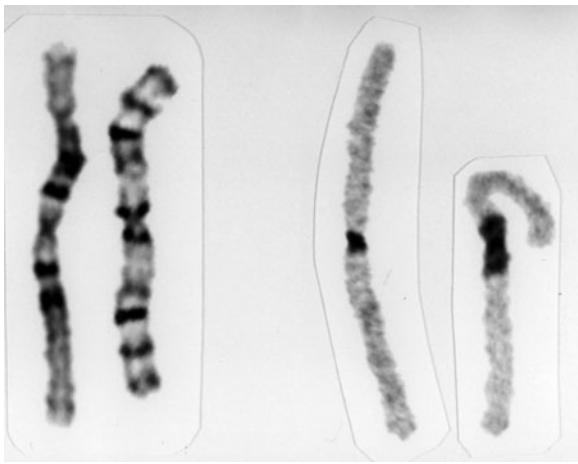

Fig. 2 Cytogenetic analyses utilizing GTG and CBG bandings showed presence of one i(1p) and one i(1q) without normal chromosome 1 homologues

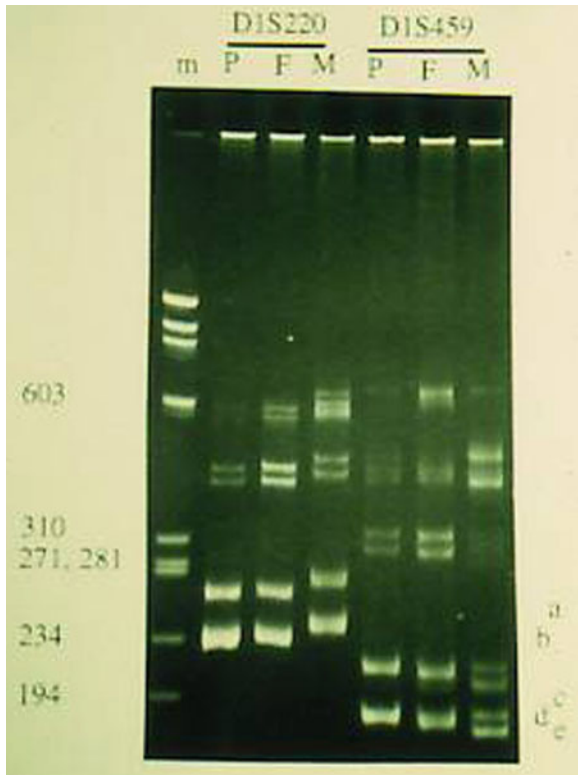

Fig. 4 PCR analyses of chromosome 1 markers (D1S220, D1S459) indicated that the patient (P) inherited b allele (using D1S220) and d allele (using D1S459) from the father (F) but none (a, c, or e alleles) from the mother (M) (D1S214, D1S550, D1S162, D1S188, D1S248, D1S514, and D1S2347 data not shown). The numbers on the left are standard marker size in bp

Fig. 3 Fluorescence in situ hybridization analysis showed hybridization to only two chromosomes, consistent with the G-banded interpretation of i(1p) and i(1q). To the best of our knowledge, this is the first case of isochromosomes 1p and 1q replacing the two normal chromosome 1s

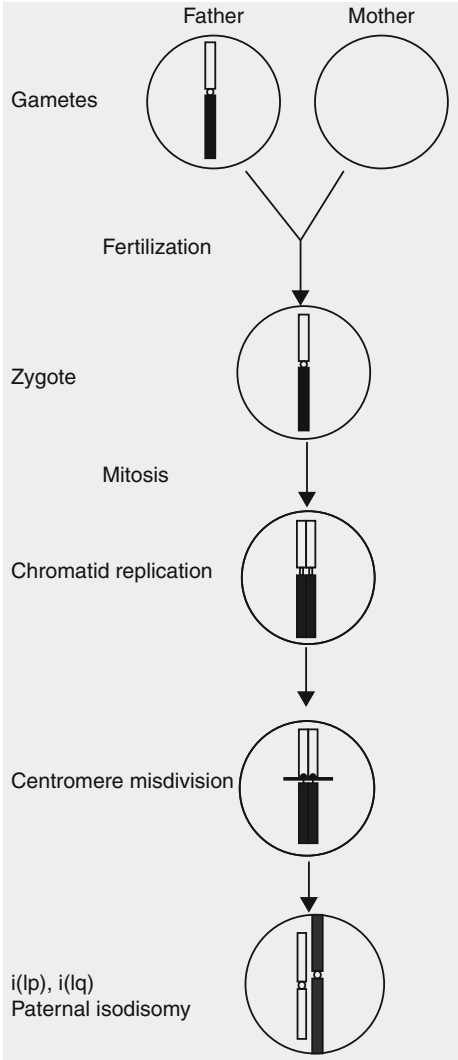

Fig. 5 Mechanism of i(1p) and i(1q) formation resulting in uniparental (paternal) isodisomy

Idic(Yq) Syndrome

Dicentric chromosomes are among the most common structural changes of the Y chromosome (deletions, rings, Y-autosomal or Y–X translocations, isochromosomes, and dicentrics). Among these structural abnormalities, dicentric Y chromosomes are the most commonly found (Hsu 1994; Yoshida et al. 1997).

The dicentric Y chromosomes have two different types: dic(Yq), resulting from the fusion between the short arms of two Y chromosomes in which some Yp material is maintained, and dic(Yp) in which only the Yq arms fuse (Codina-Pascual et al. 2004). If the dicentric has completely symmetric arms, it is considered an isodicentric chromosome. The sites of breakage and fusion at Yp and Yq are variable (Robinson et al. 1999).

Synonyms and Related Disorders

Isodicentric chromosome Yq syndrome

Genetics/Basic Defects

1. Isochromosome (DesGroseilliers et al. 2006)
   a. A chromosome with identical chromosome material in which two arms are mirror images and are of equal length.
   b. An isochromosome can be monocentric or dicentric.
2. Isodicentric chromosomes (dicentric isochromosomes)
   a. Likely resulting from a single break in the paracentric region followed by chromatid duplication and the joining of chromatids from one side of the break (Guevarra et al. 2009).
   b. Usually unstable during cell division and remain so until one of their centromeres is inactivated (Daniel et al. 1980; Therman et al. 1986), resulting in various types of cell lines (Kohn et al. 1997).
   c. Consequently, most reported patients have alternate cell lines, including 45,X (95% of cases) (Bouayed Abdelmoula and Amouri 2005a).
   d. The resulting phenotype depends on the proportion of each cell line and on the localization of the breakpoints (Alvarez-Nava et al. 2003; Bouayed Abdelmoula and Amouri 2005b).
   e. The most likely mechanism of formation of the isodicentric chromosome (Bouayed Abdelmoula and Amouri 2005a).
      i. An isochromatid break, followed by a U-type exchange.
      ii. Breakpoints in the short arm lead to a duplication of the entire long arm and a part of the short arm.
      iii. Breakpoints in the long arm lead to the duplication of the entire short arm and part of the long arm.
3. Isodicentric Y chromosome [idic(Y)]
   a. Isodicentric Y chromosome: formed by homologous crossing over between opposing arms of palindromes on sister chromatids (Lange et al. 2009).
      i. These ectopic recombination events occur at nearly all Y-linked palindromes.
      ii. Intrapalindrome sequence identity is maintained via noncrossover pathways of homologous recombination.
      iii. DNA double-strand breaks that initiate these pathways can be alternatively resolved

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_132,
© Springer Science+Business Media, LLC 2012

by crossing over between sister chromatids to form idic(Y) chromosomes, with clinical consequences ranging from spermatogenic failure to sex reversal and Turner syndrome.

b. Isodicentric Yq (Guevarra et al. 2009).
   i. Refers to a dicentric Y chromosome with two complete long arms and two symmetric incomplete portions of the short arms, arranged in a mirror image.
   ii. The breakpoints in the short arm of Y.
   iii. When two centromeres are not closely located, only one is active; the other is suppressed.

c. Most dicentric Y chromosomes (90%) are present in mosaic form due to the instability of isodicentric chromosomes during cell division (Kohn et al. 1997).
   i. The mosaicism may be more or less complex depending on its meiotic or postzygotic origin and on its mitotic stability, and it usually includes a 45,X, in addition to idic(Y), idic(Y)*x*2, del(Y), or 46,XY cell lines (Ying and Ives 1971; Daniel et al. 1980; Chandley et al. 1986; Stankiewicz et al. 2001; Codina-Pascual et al. 2004; Bouayed Abdelmoula and Amouri 2005a).
   ii. Errors occurring during gametogenesis, before the spermatid stage, or in the first mitotic division after fertilization would result in a mosaicism without a normal 46, XY cell line.
   iii. Errors occurring after the first zygotic division, a normal 46,XY cell line can be present (Fernandez et al. 2002).
   iv. Patients carrying a dicentric Y chromosome have a wide range of somatic, genital, and gonadal phenotypic manifestations, depending on the structure of the dicentric Y chromosome, the Yp and Yq breakpoints, and the types of mosaicism (Tuck-Muller et al. 1995).
   v. Of affected individuals, 40.9% were phenotypical females, 31.8% were phenotypical males, and 27.3% had different degrees of intersexuality (Hsu 1994).

d. The absence or mutation of SRY (sex-determining region on the Y chromosome) gene on the isodicentric Y chromosome: another factor adding to diversity of the phenotype, illustrated by case studies by DesGroseilliers et al. (2006).
   i. In one case of idic(Y), the female phenotype and Turner stigmata can be explained by the localization of the breakpoint, which is proximal to the SRY gene, in Yp11.2 or p11.31.
   ii. In three patients, who do not have a predominant 45,X cell line but possess two copies of SRY (as breakpoints are in the long arm), usually develop as males: They are often infertile due to the absenceof one of the azoospermia factor (AZF) regions or the incorrect pairing between the rearranged Y and the X chromosome during meiosis I (Chandley et al. 1986).

e. Nonmosaic 46,X,idic(Y) with breakpoints in the long arm has been reported in rare cases of females: dicentric chromosome Y associated with Leydig cell agenesis and sex reversal (female phenotype) (Genuardi et al. 1995).

4. The putative gonadoblastoma locus (GBY) hypothesized by Page in 1987
   a. Thought to correspond to the TSPY (testis-specific protein, Y-linked) gene (Lau et al. 2003), which has clusters in several loci on both the short and the long arms of the Y chromosome (Tsuchiya et al. 1995; Rottger et al. 2002).
   b. Presence of multiple GBY loci on the Y chromosome could explain why such tumors have been reported in both idic with breakpoints in the long and short arms (Hsu 1994; Tuck-Muller et al. 1995).

Clinical Features

1. Extremely variable physical and genital features (52 cases with dicentric Yq, studied by Guevarra et al. 2009) (Hsu 1994; Tuck-Muller et al. 1995; Bouayed Abdelmoula and Amouri 2005b; DesGroseilliers et al. 2006)
   a. Twelve phenotypic males (23%)
      i. Age/presenting symptoms
         a) Six adults: infertility (5), short stature (1)
         b) Six children: short stature (6)
      ii. Gonads
         a) Normal testes (10)

b) Not reported (2)
c) Gonadoblastoma (0)
iii. Stature
a) Short (6)
b) Normal (3)
c) Borderline (1)
d) Not reported (2)
iv. Turner syndrome stigmata (3)
b. 17 phenotypic ambiguities (33%)
i. Age/presenting symptoms
a) Two adults: inguinal mass/gynecomastia (1), ambiguous genitalia (1)
b) 15 children: short stature (4), ambiguous genitalia (12)
ii. Gonads
a) Normal testes (2)
b) Abdominal testes (2)
c) Mixed gonadal dysgenesis (10)
d) Not reported (3)
e) Gonadoblastoma (3)
iii. Stature
a) Short (9)
b) Normal (3)
c) Not reported (5)
iv. Turner syndrome stigmata (2)
c. Twenty-three phenotypic females (44%)
i. Age/presenting symptoms
a) Six adults: short stature (1), primary amenorrhea (5)
b) Thirteen children: short stature (9), primary amenorrhea (3), not reported (1)
ii. Gonads
a) Normal ovaries (0), mixed gonadal dysgenesis (15)
b) Gonadoblastoma (6)
iii. Stature
a) Short (16)
b) Normal (3)
c) Not reported (4)
iv. Turner stigmata (10)

2. Karyotype–phenotype correlations
a. Sexual differentiation of patients: depends on the distribution of the 45,X cell line in various tissues, including gonads.
i. Three cases reported by Alvarez-Nava et al. (2003):
a) 45,X/46,X,idic(Y) positive for the same Y chromosome molecular markers, with various degrees of abnormal sexual differentiation.
b) A predominant 45,X cell line was found in the streak gonads of the female with Turner stigmata, while the dysgenetic testes of the male had a predominant 46,X,idic(Y) cell line.
c) The individual with sexual ambiguity had a streak gonad with a predominant 45,X cell line on one side and a dysgenetic testis with a predominant 46,X,idic(Y) cell line on the other side.
ii. Nine female patients studied by DesGroseilliers et al. (2006)
a) An increase in the proportion of 45,X cells in the gonads compared to blood in four patients (93% vs 64%, 80–100% vs 39%, 82% vs 60%, and 79% vs 8%), thus could explain their female or ambiguous phenotypes.
b) A similar increase of the 45,X cell line was found in fibroblasts compared to blood in three patients (96% vs 39%, 92% vs 8%, and 95% vs 23%).
b. Great phenotypic variations observed in patients with an isodicentric Y chromosome greatly limit the genotype–phenotype correlation.
i. The variability is explained by the degree of mosaicism in different tissues and the various locations of the breakpoints.
ii. To improve the genotype–phenotype correlation.
a) Analyze more than one tissue, as significantly different proportions of various cell lines can be found.
b) Perform histological studies of the gonads.
c) Molecular definition of the breakpoints will provide more information, allowing for a better genetic counseling.

3. Differential diagnosis of idic(Yp) (Bruyere et al. 2006)
a. Adult males with idic Yp invariably present with a history of infertility
i. Likely, a result of loss or disruption of all or part of the Yq11.2 AZF gene cluster, which is crucial for spermatogenesis

(Siffroi et al. 2000; Stankiewicz et al. 2001; Marrocco et al. 2003; Yoshitsugu et al. 2003; Patsalis et al. 2005).

ii. Pairing dysfunction between the X and Y chromosomes during meiosis: proposed as an alternate mechanism for azoospermia in these men (Yoshida et al. 1997).

iii. All idic Yp cases in which paternal chromosome testing has been performed have been de novo (Schintzel 2001; Bruyere et al. 2006). This further supports the concept that males with an idic Yp are usually infertile. With the exception of cases, whose mosaicism included the presence of a structurally normal Y chromosome in a significant proportion of cells, normal fertility in these boys is unlikely.

b. Phenotype

i. Normal male phenotype with sterility with rare exception

ii. Rare ambiguous genitalia

Diagnostic Investigations

1. Cytogenetic analysis by high-resolution banding techniques (Q-, G-, and C-bandings).
   a. Blood
   b. Skin fibroblasts
   c. Gonadal tissues
2. Fluorescence in situ hybridization (FISH) and SKY (spectral karyotyping), using DNA probes specific for Y chromosome sequences present in Yp, in Yq, and in the centromeric Y region, allow the structural characterization of abnormal Y chromosomes (Robinson et al. 1999).
3. Molecular studies.
   a. Use of PCR to determine the presence or absence of specific Y chromosome sequences: may not provide enough information to determine the structure of the abnormal Y chromosome
      i. Amplify genes or chromosome regions (SRY, ZFY, DYZ1) which are needed for the male development
      ii. Y centromere sequence (DYZ3) (Tuck-Muller et al. 1995; Robinson et al. 1999)
   b. Comparative genomic hybridization (CGH)
4. Hormonal investigations.
   a. Estradiol level
   b. Follicle-stimulating hormone level
   c. Luteinizing hormone level
   d. Testosterone level
5. Abdominal ultrasonography and MRI (Mizuno et al. 2009): suspect the presence of a testicular component and the possibility of mixed gonadal dysgenesis or true hermaphroditism in a phenotypic girl without gonad (especially with a history of a high testosterone level, enlargement of the clitoris, response to human chorionic gonadotropin stimulation test, and the presence of SRY), followed by laparoscopic evaluation and biopsy of the specimen: laparoscopic bilateral gonadectomy when dysgenetic gonad is found.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Since reported cases so far have been de novo, recurrence risk to sib is not likely increased.
      ii. However, several sets of affected identical twins have been reported.
         a) Monozygotic twins with 47,X,idic(Y)(q11.2),idic(Y)(q11.2)/46,X,idic(Y)(q11.2)/45,X from peripheral blood: twin A (phenotypic female with 42% of Y-containing cells); twin B (phenotypic male with 94% of Y-containing cells) (Nonomura et al. 2002)
         b) Monozygotic twins with 45,X/46,X,idic(Y)(p11) from peripheral blood and skin fibroblasts: twin A (phenotypic female with 0–57% Y-containing cells); twin B (phenotypic male with 22–60% Y-containing cells) (Fujimoto et al. 1991)
   b. Patient's offspring: not likely increased since affected individuals are infertile
2. Prenatal diagnosis: possible via amniocentesis or CVS
   a. Cytogenetic analysis
   b. FISH
   c. SKY
   d. Molecular studies using specific Y chromosome sequence
3. Management
   a. Gender assignment after careful evaluation of the patient when there is a genital ambiguity.

b. Advise surgery to remove gonads in women with gonadal dysgenesis and Y material at young age since they are at higher risk (15–20%) of developing gonadoblastoma and seminoma (Verp et al. 1987; Fallat and Donahoe 2006).
c. A boy with 45,X/46,XidicY(p11) mosaicism and short stature who has shown an improved final adult height as a result of long-term growth hormone treatment (Guevarra et al. 2009).

Fig. 1 (**a**, **b**) An 18-year-old female was evaluated for primary amenorrhea and short stature (Tuck-Muller et al. 1995). She was noted to be obese. Laboratory findings included prepubertal female levels of estradiol (below 10 pg/mL) and high levels of luteinizing hormone (72 mU/mL with normal of 4–30 mU/mL), follicle-stimulating hormone (53 mU/mL with normal of 4–30 mU/mL) and testosterone (103 ng/dL with normal adult female value of 6.0–86 ng/dL). Laparoscopic exploration revealed an infantile uterus, a left streak gonad, and a right gonadal enlargement. Histological examination of the right gonad showed gonadoblastoma merged with a diffuse germ cell component diagnosed as dysgerminoma. The specimen leveled as left streak ovary consisted of vestigial Wolffian ducts. The analysis of genomic DNA from the patient indicated that sequences derived from the short arm (using SRY and ZFY mapped at Yp11.32), centromere (using Y97 mapped at Y centromere), and the middle and terminal portions of the long arm of the Y chromosome (using eD6 mapped at Yq11; 1 F5 mapped at Yq11.2; pY3.4 mapped at Yq12) were present

Fig. 2 Her external genitalia was characterized by clitoromegaly, rudimentary labia minora, hypoplastic labia major, and a narrow but patent vagina

Fig. 3 The predominant cell line in the patient's blood (29 of 40 cells), skin (33 of 35 cells), and right (31 of 33 cells) and left (25 of 25 cells) gonadal tissues had monosomy X. The second cell line had 46 chromosomes with one X and one abnormal Y chromosome, illustrated in this Q-banded spread showing isodicentric Y chromosome. Brightly fluorescent bands were present at the terminus of both arms of the abnormal chromosome, which stained darkly by C-banding (Fig. 4). The abnormal chromosome was interpreted to be a dicentric isochromosome composed of two copies of the long arm, centromere, and proximal portion of the short arm of the Y chromosome. Both parents were karyotypically normal

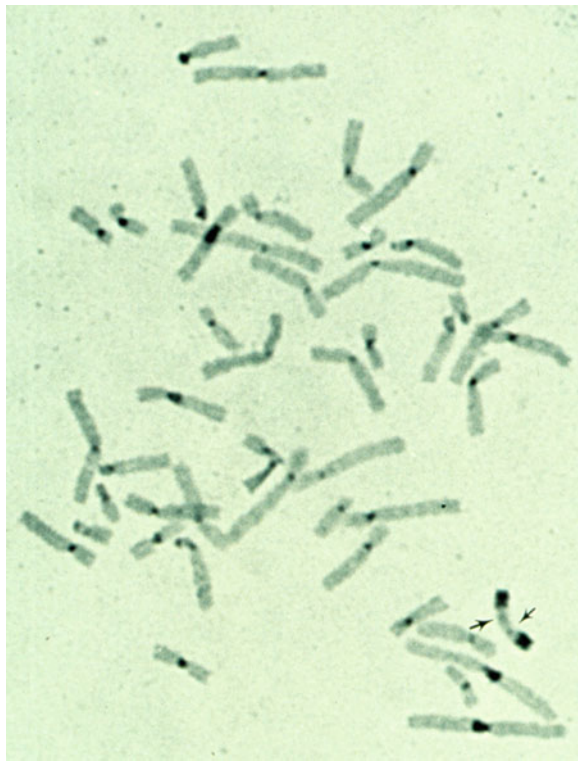

Fig. 4 The isodicentric Y chromosome (arrows) is illustrated in this C-banded spread

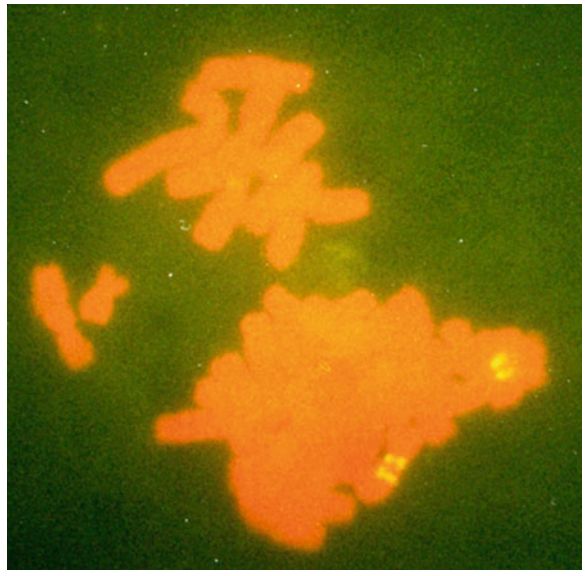

Fig. 5 The Y-specific α-satellite probe hybridized to the two centromeric regions of the abnormal Y chromosomes. The chromosome spread illustrates the presence of two idic(Y)

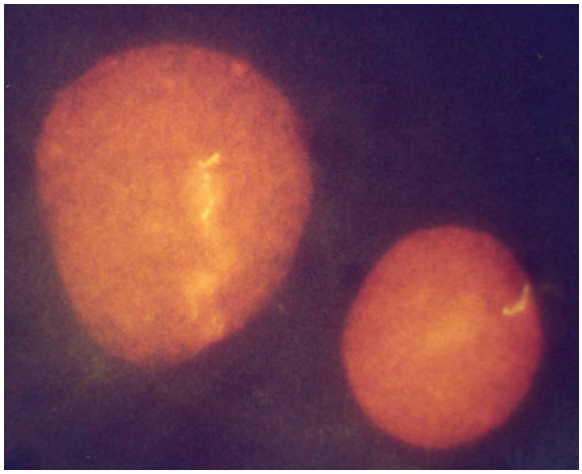

Fig. 6 FISH on interphase cells using Y probe shows idic(Yq) signals

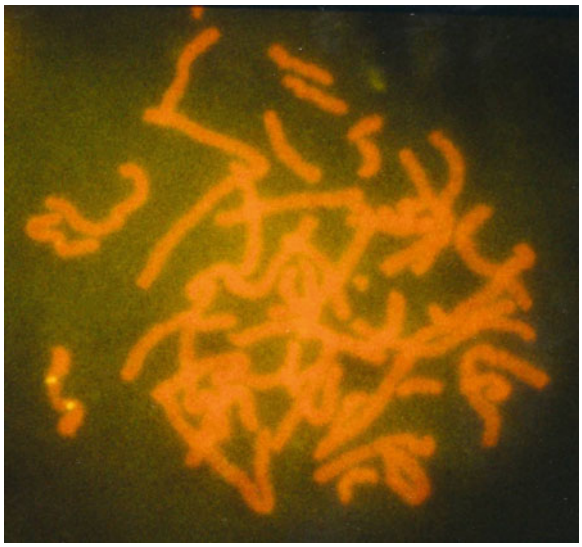

Fig. 7 FISH on a metaphase spread using Y centromeric probe shows idic(Yq) chromosome

Incontinentia Pigmenti

Bloch and Sulzberger, in 1926 and 1928, respectively (Bloch 1926; Sulzberger 1928), were credited for the first description of the clinical syndrome of incontinentia pigmenti (IP), known as Bloch–Sulzberger syndrome. It is a rare genodermatoses occurring in approximately 1 in 50,000 newborns (Aradhya et al. 2001).

Synonyms and Related Disorders

Bloch–Sulzberger Syndrome

Genetics/Basic Defects

1. Inheritance (Berlin et al. 2002).
   a. X-linked dominant transmission, usually prenatally lethal in males, suggested by pedigree analyses
   b. A high affected female/affected male ratio
   c. Instances of female-to-female transmission
   d. 1:1:1 affected female/normal female/normal male ratio in the offspring of an affected mother
   e. Increased incidence of miscarriages in patients with incontinentia pigmenti, presumably representing affected male conceptuses that typically fail to survive past the second trimester
2. Female patients with IP mutations.
   a. Dizygosity for the X chromosome
   b. Skewed X-inactivation
      i. Cells expressing the mutant X chromosome are eliminated selectively around the time of birth so that females with IP exhibit extremely skewed X-inactivation, based on the Lyon hypothesis (random inactivation of one X chromosome in each cell of the female at an early developmental stage, resulting in an X-chromosomal mosaic for each female with one X functioning in some of the cells and the other X functioning in the rest of the cells).
      ii. Female heterozygous for an X-linked incontinentia pigmenti gene: The pigmented areas on the skin represent cell populations in which the abnormal gene is active and the areas of normal skin tissue in which the normal gene is active.
      iii. Highly variable phenotype explainable by the chance variability in the number and position of the cells carrying the active incontinentia pigmenti gene.
3. The gene for IP: linked genetically to the *factor VIII* gene in Xq28.
4. Molecular pathophysiology (Fryssira et al. 2010).
   a. Attributed to mutations in the gene of nuclear factor kappa B (*NF-κB*) essential modulator (*NEMO*) currently known as *IKBKG* (inhibitor of kappa light polypeptide gene enhancer in B-cells, kinase gamma) (Smahi et al. 2000; Jentarra et al. 2006; Fusco et al. 2008).
   b. The *IKBKG* gene is located on chromosome X, band q28. It spans 23 kb and consists of 10 exons.
   c. An intrachromosomal rearrangement that deletes exons 4–10 of the gene accounts for approximately 80% of new mutations.
   d. The *IKBKG* gene encodes a protein which is essential for the activation of NF-jB transcription factor, which protects cells against tumor necrosis factor–induced apoptosis.

e. The *IKBKG* gene also regulates the expression of various cytokines, chemokines, and adhesion molecules (Smahi et al. 2000; Berlin et al. 2002).

5. Mechanisms for occasional survival of affected males (Berlin et al. 2002).
   a. Presence of an extra X chromosome (47,XXY Klinefelter syndrome)
   b. Skewed X inactivation
   c. Hypomorphic alleles
   d. Mosaics for common mutations (somatic mosaicism)
   e. A parent with gonadal mosaicism
6. Anhidrotic ectodermal dysplasia with immunodeficiency (EDA-ID):
   a. A disorder allelic to incontinentia pigmenti but with different phenotype due to various natures of genetic mutations underlying the two disorders
   b. A rare X-linked recessive disorder affecting only males
   c. Caused by mutations in the *NEMO* gene
   d. Possible family history of IP in boys with EDA-ID
   e. Presentation with severe recurrent infections caused by common encapsulated bacterial pathogens, suggesting functional defects in the immune response
   f. Rare opportunistic diseases
      i. Mycobacterial infections
      ii. Cytomegaloviral infections
      iii. *Pneumocystis carinii* pneumonitis
   g. Immunologic studies
      i. Normal or increased levels of B cells
      ii. Normal T-cell counts
      iii. Normal to low levels of IgG
      iv. Elevated levels of either IgM or IgA
7. Eosinophil recruitment through eotaxin release by activated keratinocytes.
8. Incontinentia nomenclature: The localization of the gene for IP to Xq28, coupled with reports of children with "incontinentia pigmenti" and X-autosome translocations with breakpoints at Xp11, resulting in a nomenclature differentiation of IP1 (sporadic) and IP2 (familial). However, IP1 and IP2 designation should be abandoned.
   a. IP1
      i. Disorder applied to cases associated with X-autosome translocations with Xp11 breakpoints and r(X) (Shastry 2000)
      ii. Skin changes different from patients to patients
      iii. Serves no useful purpose either causally or clinically
      iv. More appropriately using descriptive phrase "X-autosome translocation associated with pigmentary abnormalities"
   b. IP2: applied to cases of familial IP mapped to Xq28

Clinical Features

1. Highly variable clinical presentations among affected female family members (Berlin et al. 2002)
   a. Attributed to lyonization in females, resulting in functional mosaicism
   b. Clonal expansion of the progenitor cell along lines of embryonic development in that each cell determines which X chromosome to express during the first weeks of gestation
      i. Manifesting along the curvilinear lines of Blaschko in skin
      ii. Percentage of progenitor cells that express the mutated X chromosome reflecting the extent of expression
      iii. Mutation in a high percentage of ectodermal cells in severe cases
2. Clinical expression among small number of live-born male patients
   a. Generally not severer than that in affected females
   b. Many male patients with disease expression limited to cutaneous involvement of one or two limbs
3. Cutaneous manifestations: most often the first observed sign of IP and are present in nearly all patients. They are classically subdivided into the following four classic cutaneous stages:
   a. Vesicular, vesiculobullous, or inflammatory stage
      i. Frequency: about 90% of cases
      ii. Age of onset: within first 2 weeks of life (92%), by 6 weeks of age (4%), starting after the first year of life (several cases)
      iii. Age at resolution: blisters generally clearing by 4 months, recurrence usually short-

lived and less severe than the original eruption
   iv. Clinical features: erythema, superficial vesicles in linear distribution on torso and extremities (64%) and extremities alone (33%)
b. Verrucous (wart-like) stage
   i. Frequency: about 70% of cases
   ii. Age of onset: peak of onset between 2 and 6 weeks of age
   iii. Age at resolution: clearance by 6 months (80%)
   iv. Clinical features: verrucous hyperkeratotic papules and plaques almost exclusively involving extremities
c. Hyperpigmented stage
   i. Frequency: nearly all patients with IP (98%)
   ii. Age of onset: 12–26 weeks of age
   iii. Age at resolution: puberty
   iv. Clinical features: whorls and streaks of brown pigmentation following lines of Blaschko (multiple lines on the human body corresponding to the distribution of linear nevi and dermatoses) on torso and extremities (65%) and torso alone (27%)
d. Atrophic (dermal scarring) stage
   i. Frequency: 42%
   ii. Age of onset: early teens to adulthood
   iii. Age at resolution: permanent lesion
   iv. Clinical features: pale, hairless, atrophic patches, and/or hypopigmentation

4. Hair abnormalities (50%)
   a. Vertex alopecia
      i. The most common hair manifestation
      ii. Most commonly mild and unnoticed
      iii. Follows inflammation and vesiculation
      iv. May be associated with scarring
   b. Agenesis of eyebrows and eyelashes: infrequent
5. Nail abnormalities (7–40%)
   a. Ridging, pitting, or nail disruption
      i. Starting early childhood and involving all or most of the fingernails and toenails
      ii. Tend to regress and disappear with age
   b. Subungual and periungual keratotic tumors
      i. Appear at a later stage.
      ii. Affect fingers more than toes.
      iii. Continued growth results in pain, nail dystrophy, and destruction of the underlying bone of the terminal phalanx.
      iv. Bone lytic lesions caused by pressure from the overlying tumor.
6. Dental anomalies (>80%)
   a. Partial adontia or adontia (43%)
   b. Pegged and conical teeth (30%)
   c. Late eruption of teeth (18%)
   d. Enamel hypoplasia
7. Ophthalmologic anomalies (35%)
   a. Blindness (7.5%)
   b. Nonretinal manifestations
      i. Strabismus (18–33%)
      ii. Optic atrophy (4%)
      iii. Cataracts (4%)
      iv. Pseudoglioma (3.5%)
      v. Microphthalmia (3%)
      vi. Rare conjunctival pigmentation, iris hypoplasia, nystagmus, and uveitis
   c. Retinal manifestations
      i. Foveal hypoplasia
      ii. Mottled or hypopigmented retinal pigment epithelium
      iii. Avascular retina
      iv. Neovascularization
      v. Vitreous hemorrhages
      vi. Fibrovascular proliferation
      vii. Retinal detachment (3%)
8. Neurologic deficits (30%)
   a. Infantile spasms and seizure disorder (13%)
   b. Mental retardation (12%)
   c. Spastic paralysis (11%)
   d. Motor retardation (7.5%)
   e. Microcephalus (5%)
   f. Infrequent manifestations
      i. Cerebellar ataxia
      ii. Congenital hearing loss
      iii. Muscle paresis
      iv. Aseptic encephalomyelitis
9. Other associated anomalies
   a. Nipple anomalies
      i. Supernumerary nipple
      ii. Nipple hypoplasia
      iii. Breast hypoplasia/aplasia
   b. Oral anomalies
      i. High arched palate
      ii. Cleft lip/palate
   c. Skeletal anomalies
      i. Dwarfism
      ii. Chondrodysplasias
      iii. Short stature

iv. Spina bifida
v. Skull defects
vi. Club foot

d. Increased risk of serious and unusual infection in some patients
e. Occasional hypohidrosis with increased rates of bacterial skin infections: may be evidence of the continuum between IP and the allelic anhidrotic ectodermal dysplasia-immune deficiency
f. Cardiac abnormalities
i. Tricuspid insufficiency
ii. Pulmonary vein-to-superior vena cava shunt

10. Diagnostic criteria for incontinentia pigmenti (Landy and Donnai 1993)
a. Negative family history (no evidence of IP in a first-degree female relative): At least one major criterion is necessary to make a firm diagnosis of sporadic incontinentia pigmenti. The minor criteria, if present, will support the diagnosis. Because of their high incidence, complete absence of minor criteria should induce a degree of uncertainty.
i. Major criteria
a) Typical neonatal rash (erythema, vesicles, eosinophilia)
b) Typical hyperpigmentation (mainly trunk, Blaschko's lines, fading in adolescence)
c) Linear, strophic, hairless lesions
ii. Minor criteria
a) Dental involvement
b) Alopecia
c) Woolly hair/abnormal nails
d) Retinal disease
b. Positive family history (evidence of IP in a first-degree female relative of an affected female) plus demonstration of any of the following features, alone or in combination.
i. Suggestive history or evidence of typical rash
ii. Skin manifestation of IP
a) Hyperpigmentation
b) Scarring
c) Hairless streaks
d) Alopecia at vertex
iii. Anomalous dentition
iv. Woolly hair
v. Retinal disease
vi. Multiple male miscarriages

Diagnostic Investigations

1. Major histopathologic features from skin biopsy samples (Berlin et al. 2002)
a. Vesicular, vesiculobullous, or inflammatory stage
i. Spongiotic dermatitis
ii. Dermal and epidermal eosinophilia
iii. Eosinophil-filled vesicles
b. Verrucous stage
i. Papillomas
ii. Epidermal hyperplasia
iii. Hyperkeratosis
iv. Dyskeratotic cells
c. Hyperpigmented stage
i. Dermal melanophages
ii. Vascular changes in basal layer of epidermis
d. Atrophic stage
i. Loss of rete ridges
ii. Loss of dermal sweat coils
iii. Skin biopsy helpful for the diagnosis of IP at late stage (IV) (Fraitag et al. 2009)
a) Slight atrophy and some scattered apoptotic cells in the epidermis, epidermal hypopigmentation, and reduced melanocyte number.
b) The dermis appeared thickened and homogeneous and revealed a complete absence of hair follicles (23/26) and sweat glands (22/26).
c) There was no melanin incontinence or inflammatory cells, and the elastic network was normal.
2. CBC: marked peripheral blood leukocytosis and eosinophilia
3. Abnormal immune system: not a consistent finding
4. CT/MRI imagings of the brain
a. Optic atrophy
b. Retinal vasculopathy
c. Hypoplasia of the corpus callosum
d. Ventriculomegaly
e. Periventricular white matter lesions
f. Ischemic strokes
g. Hemorrhagic necrosis
h. Porencephalic cyst
5. Magnetic resonance angiography/spectroscopy for cerebral ischemia and a vaso-occlusive phenomenon

6. Fluorescein angiography for retinal vascular abnormalities
7. EEG for seizures
8. Chromosome analysis in male patients with IP
9. Molecular genetic testing: mutation detection for the majority of families, facilitated by the high frequency of specific deletion, using Southern blotting, PCR amplification, or DNA sequencing
   a. X-inactivation assay and Xq28 marker studies: X-inactivation analysis is indicated wherever a recombination event between Xq28 markers and the disease locus is suspected. Absence of recombination between the disease locus and Xq28 loci suggests that mosaicism is responsible for the discrepancy where Xq28 marker studies are at odds with the clinical assessment.
   b. Identification of the *IKBKG* (also known as *NEMO*) gene mutation as a biological marker for a molecular diagnosis of IP.
      i. Deletion/duplication analysis
      ii. Sequence analysis
      iii. Carrier testing for the mother who has an affected daughter with a known mutation
      iv. Determine whether the miscarried or stillborn male fetus has IP
      v. Prenatal testing of a fetus at risk

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk: $<1\%$, provided that the mother is not a carrier of the gene: a small increased risk due to either a new mutation in a second child or germ line mosaicism in a parent
      ii. Recurrence risk of 50% for sisters to be affected when the mother is a carrier of the gene
      iii. Recurrence risk of 50% for brothers to be affected (prenatally aborted fetuses or stillborns) when the mother is a carrier of the gene
   b. Offspring of an affected female
      i. Daughters: 50% affected; 50% normal
      ii. Sons: 50% affected (prenatally aborted fetuses or stillborns); 50% normal (all the live-born sons will be normal)
   c. Offspring of an affected male
      i. All daughters affected
      ii. All sons normal
2. Prenatal diagnosis possible if the disease-causing mutation has been detected in the families at risk
   a. Determination of the fetal sex by amniocentesis or CVS.
   b. An increased risk of miscarriage or stillborn for an affected male fetus (fetal karyotype 46,XY).
   c. If the fetal karyotype is 47,XXY: more severe IP phenotype in males and of Klinefelter syndrome.
   d. Molecular genetic testing of a female fetus: If the fetal karyotype is 46,XX, there is 50% of fetuses that are likely to be affected with IP.
   e. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified previously.
3. Management
   a. Reduce the risk of secondary infection of blisters
   b. Keep lesions dry
   c. Avoid trauma to blisters
   d. Dental care
   e. Early photocoagulation or cryotherapy in cases of retinal involvement
   f. Intervention programs for learning disabilities and developmental delay
   g. Antiseizure medications for seizures

Infantile Myofibromatosis

Infantile myofibromatosis, previously known as congenital generalized fibromatosis, is the most prevalent fibrous tumor of infancy. It is characterized by the formation of tumors, either in a solitary or in a multicentric fashion, in the skin, muscle, viscera, bone, and subcutaneous tissue.

Synonyms and Related Disorders

Congenital generalized fibromatosis; Juvenile myofibromatosi

Genetics/Basic Defects

1. Etiology: unknown but appears to originate in utero. Fetal estrogenic hormone stimulation or hamartomas of myofibroblasts have been considered.
   a. Sporadic in most cases
   b. Several reports of familial cases (Zand et al. 2004)
      i. Autosomal dominant
      ii. Autosomal recessive
2. Types
   a. Solitary myofibroma
      i. More common in males (69%)
      ii. Affects chiefly the soft tissues of the head-neck region and the trunk
   b. Multicentric myofibromatosis (more common in females, 63%)
      i. Without visceral involvement (bones)
      ii. With visceral involvement (bones and viscera)
3. Spontaneous regression of tumors: possibly due to apoptotic cell death

Clinical Features

1. Affects almost exclusively infants and young children
   a. Sixty percent noted at birth or shortly thereafter
   b. Eighty percent occurred before the age of 2 years
2. Characteristics of tumors
   a. Superficial
      i. Palpable, rubbery, firm, and freely moveable nodules
      ii. Fibrotic, plaquelike, indurated, and crusted lesions
   b. Deeper lesions: generally immovable
   c. Nontender and painless
3. Overlying skin
   a. Erythema or a purple discoloration resembling a hemangioma
   b. Ulceration and atrophic scar
4. Affected bones
   a. Radiolucent lytic lesions (cystic defects)
   b. Most commonly involved locations
      i. Cranium
      ii. Femurs
      iii. Tibias
      iv. Spine
      v. Ribs
   c. Circumscribed lytic tumors not present at birth but develop quickly over the first few days or weeks of life
5. Solitary form (myofibroma)
   a. About 80% of the cases
   b. Boys more commonly affected

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_134,
© Springer Science+Business Media, LLC 2012

c. Mostly involves the skin and bones, and rarely the CNS and viscera
d. A good outcome provided there is no visceral involvement
e. Natural history of myofibromas of the CNS without visceral involvement: frequently characterized by a period of initial rapid growth, subsequent stabilization, and spontaneous regression in many cases

6. Multicentric form (myofibromatosis)
   a. Without visceral involvement
      i. Girls more commonly affected
      ii. Typically undergoing spontaneous regression within the first 1 or 2 years of life when limited to the skin or bone
      iii. A good outcome
   b. With visceral involvement
      i. One fourth of cases of multicentric cases
      ii. Multiple nodules distributed throughout the body
         a) Soft tissues
         b) Bone
         c) Skeletal muscle
         d) Viscera (kidney, pancreas, retroperitoneum, lungs, gastrointestinal tract, peritoneum, diaphragm, heart, tongue, lymph nodes, peripheral nerves, liver)
      iii. Fatal outcome with visceral involvement usually within 4 months of life
         a) Localized mass effect on the lung, gastrointestinal tract, or within the conduction system of the heart
         b) Mortality rate approaches 75%.
      iv. Possible survival: spontaneous resolution of visceral lesions within the first year of life
      v. Disseminated pathologic process including proliferation of multiple nodules of collagen-forming fusiform cells
      vi. Likely origin of proliferating cells: myofibroblast (displaying both smooth muscle and fibroblast features)
7. Differential diagnosis
   a. Neurofibromatosis
   b. Leiomyomas
   c. Hyaline fibromatoses
   d. Hemangiomas
   e. Soft tissue sarcomas
   f. Metastatic neuroblastomas
8. Prognosis depending on the extent of involvement and location of the lesions (Orozco-Covarrubias et al. 2002)
   a. Solitary forms usually cause little morbidity and virtually no mortality. However, a solitary nodule involving the central nervous system (CNS) may be fatal.
   b. Lesions confined to soft tissue and bone: usually self-limited with good prognosis
   c. Good prognosis with frequent spontaneous regression when viscera are not involved
   d. Poor prognosis with infantile myofibromatosis with multiple visceral involvement
      i. May cause significant morbidity
      ii. Progression to death: usual outcome
      iii. Fatal in neonates (up to 75% of cases (Wiswell et al. 1998)
      iv. Death resulting from complications due to cardiopulmonary or gastrointestinal involvement

Diagnostic Investigations

1. Radiography, U/S, CT, and MRI
   a. Soft tissue lesions: round and well defined on U/S and MRI
   b. Invaluable in assessing the extent and progression or regression of the disease
      i. Soft tissue lesions (multiple subcutaneous and intramuscular tumors)
      ii. Bone lesions
      iii. Visceral lesions
   c. Radiography: lesions appearing as multiple areas of osteolysis with a sclerotic margin
   d. Ultrasonography: hyperechoic nodules with peripheral hyperperfusion on color Doppler
   e. CT scan
      i. Masses: isoattenuating with muscle or as low attenuating with slight enhancement in the periphery (Koujok et al. 2005)
      ii. Brain (Tamburrini et al. 2003)
         a) Partially calcific masses or isodense cystic lesions with intense peripheral contrast enhancement and smoothly marginated bone erosion

b) Typical absence of sclerosis of the margins

f. MRI: intramuscular, subcutaneous, and visceral (liver, lungs) lesions (Tamburrini et al. 2003; Koujok et al. 2005)
   i. Low signal on T1-weighted images
   ii. High or low signal of the center on T2-weighted images
   iii. All masses showed peripheral enhancement after gadolinium administration.

2. Histology (biopsy of tumors) (Chung and Enzinger 1981)
   a. Gross appearance of tumors: well demarcated
   b. Lesion consisting of bundles of elongated cells with features of both fibroblasts and smooth muscle cells
   c. Staining characteristics: intermediate between fibroblasts and smooth muscle
   d. Central part of the tumors often necrotic
3. Electron microscopy
   a. Characteristic intracytoplasmic myofilaments
   b. Dense bodies
   c. Focal basal lamina and macula adherens

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic form: not increased
      ii. Autosomal recessive form: 25% risk
      iii. Autosomal dominant form: not increased unless a parent is affected
   b. Patient's offspring
      i. Sporadic form: not increased
      ii. Autosomal recessive form: not increased unless the spouse is a carrier
      iii. Autosomal dominant form: 50% risk
2. Prenatal diagnosis by ultrasonography for detecting solitary or multicentric tumors in soft tissue, bones, or viscera
3. Management
   a. Observation
      i. Spontaneous regression
      ii. Possible sequelae (tissue loss or damage) resulting from spontaneous regression
   b. Surgical excision (Stanford and Rogers 2000)
      i. To prevent complications and improve prognosis
      ii. Reserved for symptomatic lesions or if vital organs are compromised, in view of the tendency to spontaneous regression
      iii. Radical resection reserved for those lesions posing an immediate threat due to their locations or massive size and those showing obvious progression
      iv. Seven to ten percent of lesions recurred after excision (Tamburrini et al. 2003).
   c. Chemotherapy with or without radiotherapy
      i. Necessary for recurrent or unresectable lesions
      ii. A combination of vincristine, adriamycin-D, and cyclophosphamide
      iii. Interferon
      iv. Successful use of combination of vinblastine and low-dose methotrexate in an infant with generalized infantile myofibromatosis (Azzam et al. 2009)

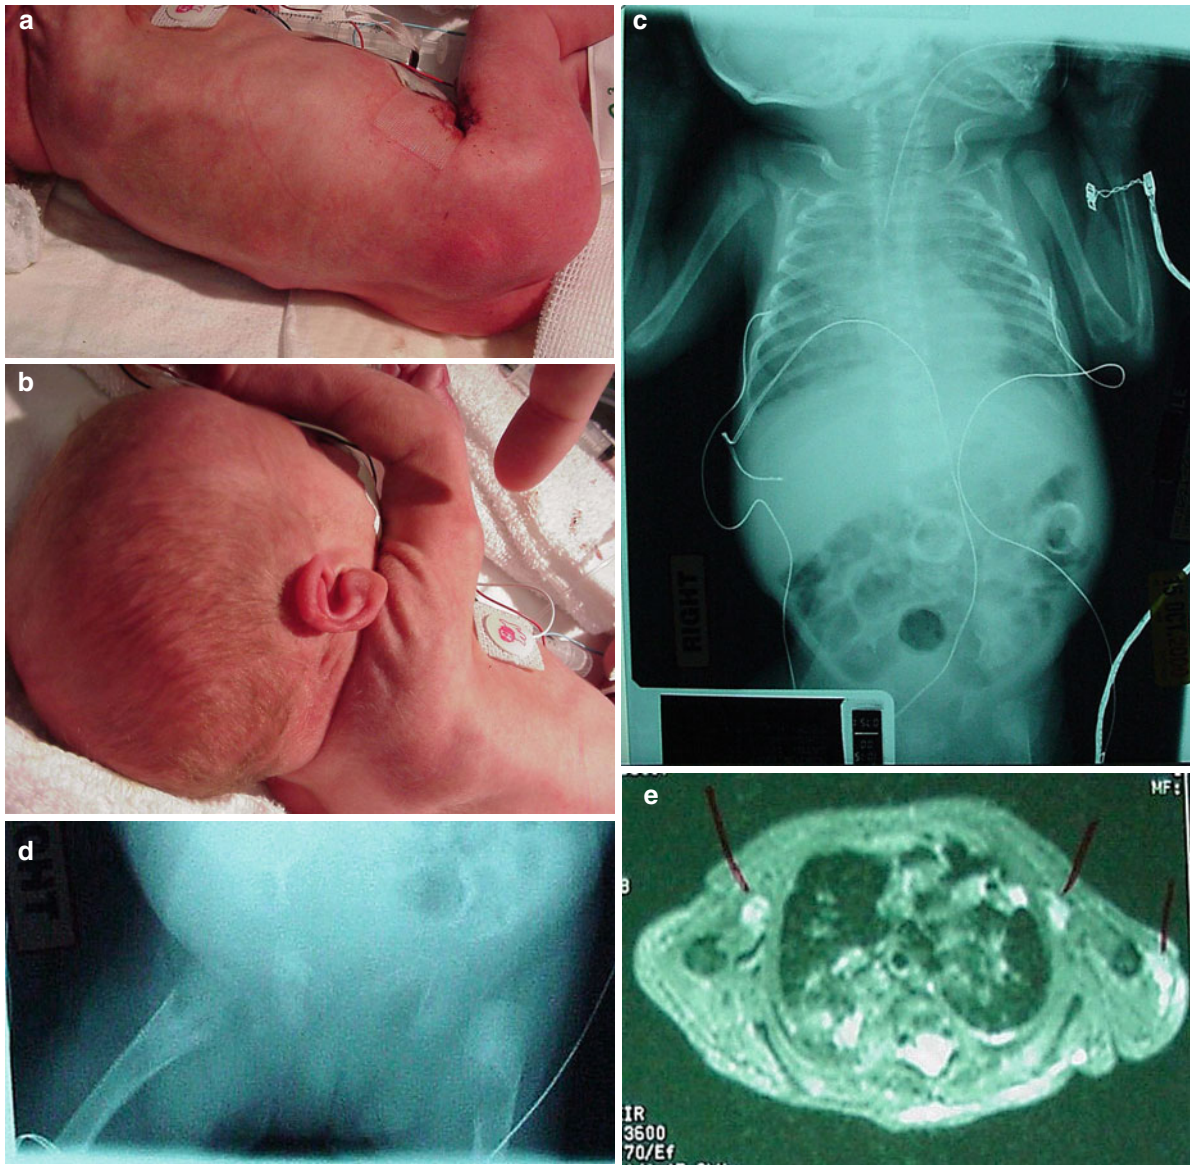

Fig. 1 (**a**–**e**) An infant with multicentric myofibromatosis showing subcutaneous nodules in the back, arm (pointed by a finger), cystic lytic lesions in the humeri and femora (radiographs), and multicentric nodules (identified by dark lines) in the chest wall by MRI

Ivemark Syndrome

Ivemark syndrome consists of visceroatrial heterotaxia associated with asplenia. It is also known as asplenia syndrome, heterotaxy syndrome, cardiosplenic syndrome, right atrial isomerism (two morphologically right atrial appendages), or bilateral right-sidedness. The incidence of the syndrome is estimated to be 1/10,000–1/40,000 live births (Rose et al. 1975; Noack et al. 2002). Ivemark syndrome accounts for 1–3% of all congenital heart defects (Cesko et al. 1997).

Synonyms and Related Disorders

Cardiosplenic syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive suggested by
   a. Reports of multiple affected siblings, both males and females, born to normal parents
   b. Reports of several instances of parental consanguinity
   c. Report of mutations in the gene encoding connexin 43 (Cx43)
2. Other possible cause: maternal diabetes
3. Heterotaxy syndrome: Heterotaxy results from failure of the embryo to establish normal left-right asymmetry (Bartram et al. 2005).
   a. A rare congenital disorder occurring in approximately 0.8% of patients with congenital heart disease
   b. Often associated with complex cyanotic heart disease and an abnormal cardiac conduction system
   c. Consisting of the following two groups of disease:
      i. Right isomerism (asplenia syndrome)
         a) Commonly has a combination of complete atrioventricular canal defect, total anomalous pulmonary venous return, double-outlet right ventricle, and pulmonary stenosis
         b) Often has paired atrioventricular nodes that may serve as the substrate for a special reentrant tachycardia ("nodal-to-atrioventricular nodal tachycardia")
      ii. Left isomerism (polysplenia syndrome)
         a) Tends to have few complex cardiac anomalies and therefore a better prognosis
         b) Likely to have defective sinus and atrioventricular nodes that may result in sinus node dysfunction, junctional escape rhythm, and atrioventricular block

Clinical Features

1. Congenital absence of the spleen (asplenia)
2. Congenital heart malformations
   a. Cardiac malpositions (44%)
      i. Dextrocardia
      ii. Right-sided aortic arch
   b. Venous system
      i. Systemic veins: bilateral superior vena cava (53%)
      ii. Pulmonary veins
         a) Total anomalous pulmonary venous drainage (72%)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_135,
© Springer Science+Business Media, LLC 2012

   b) Partial anomalous pulmonary venous drainage (6%)
  c. Great vessels
    i. Transposition of the great arteries (72%)
    ii. Pulmonary stenosis or atresia (78%)
  d. Coronary arteries: single coronary artery (19%)
  e. Intracardiac defects
    i. Single ventricle (44%)
    ii. Single AV valve (87%)
    iii. Absent coronary sinus (85%)
    iv. Endocardial cushion defect
    v. Double-inlet ventricle
    vi. Discordant ventriculoarterial connection
3. Maldevelopment of the abdominal organs (Mishalany et al. 1982)
  a. Abnormalities of the mesenteric attachment (intestinal malrotation), a major predisposing cause of midgut volvulus
  b. Situs inversus (heterotaxia)
  c. A midline (central) liver
  d. Tubular stomach
  e. Imperforate anus
  f. Annular pancreas and obstructing duodenal bands
  g. Esophageal varices
  h. Duplication of stomach
  i. Agenesis of gallbladder
  j. Rudimentary pancreas
  k. Meckel diverticulum
  l. Esophageal atresia and TE fistula
  m. Hiatus hernia
  n. Gastric hypoplasia
  o. Acute gastric volvulus: a rare complication
  p. Cleft palate
  q. Duplication of the hindgut
  r. Aganglionosis
4. Bronchopulmonary isomerism
  a. Abnormal lobation of the lungs
    i. Bilaterally trilobed
    ii. Bilaterally bilobed
  b. Bilateral eparterial bronchi
  c. Pulmonary hypoplasia
5. CNS malformations: uncommon
  a. Agenesis of the corpus callosum
  b. Porencephalic cyst
  c. Cerebellar cysts
  d. Focal cerebellar dysplasia
  e. Hydrocephalus
  f. Septum pellucidum abnormality
6. Genitourinary anomalies
  a. Horseshoe kidney
  b. Cystic kidney
  c. Bilobed urinary bladder
  d. Hydroureter
  e. Posterior urethral valves
  f. Ureteral valve with hydronephrosis
  g. Double collecting system
  h. Rectourethral fistula
  i. Bicornuate uterus
  j. Ovarian cysts
7. Endocrine abnormalities
  a. Fused or horseshoe adrenal
  b. Absent adrenal
8. Musculoskeletal abnormalities
  a. Equinovarus deformity
  b. Overlapping toes
  c. Clubbing of hands
  d. Absent radii
9. Miscellaneous
  a. Microphthalmia
  b. Single umbilical artery
10. Prognosis (Tkebuchava et al. 1997)
  a. Prognosis related to cardiac malformations
    i. Severe and incompatible with life (as a rule)
    ii. Anoxia
    iii. Cyanotic neonates die from cardiac insufficiency.
    iv. Most die from cardiac disease during the first year of life (usually the first month).
    v. Complications of surgery
    vi. Hemorrhage
  b. Prognosis related to asplenia
    i. Greater risk from infection for those who survive the first 12 months
    ii. Sudden death in infancy from sepsis and impaired resistance to infection

Diagnostic Investigations

1. Echocardiography for delineating congenital heart defects (Biggar et al. 1981)
2. Diagnosis of asplenia
  a. No splenic uptake on technetium sulfur colloid scan
  b. Presence of Howell-Jolly bodies in a peripheral blood smear after the first week of life

3. Immunologic assessment in congenital asplenia
   a. Quantitation of serum immunoglobulins
   b. Most common pathogens
      i. In children less than 6 months of age
         a) *Escherichia coli*
         b) *Klebsiella*
      ii. In children surviving past 6 months of age
         a) *Haemophilus influenzae*
         b) *Pneumococci*

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis by fetal echocardiography (Noack et al. 2002)
   a. No identifiable spleen (the fetal spleen can usually be detected at 20 weeks of gestation in the left gastrorenal angle) (Chitayat et al. 1988)
   b. Levocardia
   c. Complete atrioventricular septal defect
   d. Double-outlet right ventricle
   e. Dextro-malposition of the great arteries
   f. Pulmonary atresia/stenosis
   g. Other cardiac anomalies
3. Management
   a. Prophylactic antibiotics to prevent life-threatening sepsis
   b. Palliative cardiac surgery for congenital heart defects
   c. Surgical intervention for gastrointestinal malformations and other anomalies

Fig. 1 A 3-month-old with Ivemark syndrome who has asplenia with complex cardiovascular malformations (AV canal, single ventricle, transposition of the great vessels, pulmonary atresia, and total anomalous pulmonary venous return). She also has malrotation of intestine

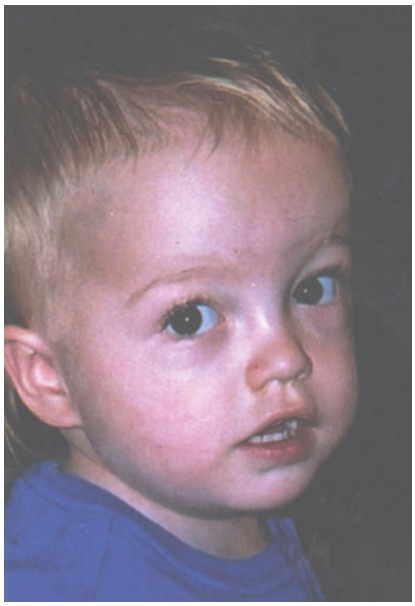

Fig. 2 A 19-month-old boy with Ivemark syndrome. He had heterotaxy syndrome with asplenia, situs inversus, and complex congenital heart defects consisting of a single ventricle, atrioventricular septal defect with small ostium primum ASD, pulmonary stenosis, interrupted IVC with azygous continuation to a left SVC, right aortic arch, and congenital complete heart block

Fig. 3 A 25-month-old girl with Ivemark syndrome. She had dextrocardia, situs inversus, complete AV canal, interrupted inferior vena cava, trachea compression by aorta, and status post pulmonary artery banding. Her complete AV canal was surgically repaired. Chromosome analysis was normal with normal FISH for DiGeorge syndrome

Jarcho–Levin Syndrome

In 1938, Jarcho and Levin first described a syndrome of malformations with abnormal fusion of thoracic vertebrae and ribs associated with a short trunk and respiratory insufficiency. At present, Jarcho–Levin syndrome is an eponym used to describe a variety of clinical phenotypes, consisting of short-trunk dwarfism associated with rib and vertebral anomalies. Two phenotypic subtypes of spondylothoracic dysostosis and spondylocostal dysostosis have recently been proposed.

Synonyms and Related Disorders

Costovertebral dysplasia; Costovertebral segmentation anomalies; Spondylocostal dysostosis/dysplasia; Spondylothoracic dysostosis/dysplasia

Genetics/Basic Defects

1. Inheritance and molecular defects (Cornier et al. 2003)
   a. Presence of considerable genetic heterogeneity with varied clinical presentations and associated abnormalities
   b. Spondylothoracic dysostosis
      i. Autosomal recessive inheritance
      ii. Linked to chromosome 2q32.1
      iii. No mutations found in the *DLL3* gene
   c. Spondylocostal dysostosis (Whittock et al. 2004; Turnpenny et al. 2009)
      i. Inheritance: either autosomal recessive or autosomal dominant
      ii. Mutations in the delta-like three gene (*DLL3*) on chromosome 19q13.1-q13 (Bulman et al. 2000; Turnpenny et al. 2003; Bonafe et al. 2003)
         a) As the major cause of autosomal recessive spondylocostal dysostosis
         b) *DLL3* encodes a ligand in the Notch gene signal pathway. When mutated, defective somitogenesis occurs resulting in a consistent and distinctive pattern of abnormal vertebral segmentation affecting the entire spine.
      iii. Mutated mesoderm posterior two homolog gene (*MESP2*) that codes for a basic helix-loop-helix transcription factor was found to cause spondylocostal dysostosis in one consanguineous family with two affected children (linkage to 15q21.3-15q26.1) (Whittock et al. 2004; Cornier et al. 2008).
      iv. Mutation in the *LFNG* O-fucosylpeptide 3-beta-N-acetylglucosaminyltransferase (on 7p22) (Sparrow et al. 2006)
      v. Mutations in the *HES7* (hairy and enhancer of split 7) gene (on 17p13.2)
2. Pathogenesis
   a. Vertebral anomalies: probably attributed to defective segmentation of the somite at about the fourth or fifth week of intrauterine life
   b. Costal anomalies: probably secondary to the vertebral anomalies
   c. *Pax1* and *Pax9* might be required for the phenotypic expression of Jarcho–Levin syndrome.

Clinical Features

1. Spondylothoracic dysostosis (Cornier et al. 2003)
   a. Vertebral segmentation and formation defects throughout cervical, thoracic, and lumbar spine
      i. Hemivertebrae
      ii. Block vertebrae
      iii. Unsegmented bars
   b. Fusion of all the ribs at the costovertebral joints bilaterally
   c. Absence of intrinsic rib anomalies
   d. Other clinical features
      i. Short-trunk dwarfism
      ii. Craniofacial features
         a) Brachycephaly
         b) Low posterior hairline
         c) Prominent nasal bridge
         d) High-arched palate
      iii. Short and rigid neck
      iv. Short thorax
      v. Protuberant abdomen
      vi. Inguinal and umbilical hernias
      vii. Urinary tract abnormalities
      viii. Talipes equinovarus
   e. Prognosis: poor but not an invariably lethal condition with 56% of survival among the prospectively evaluated patients
      i. Normal intelligence
      ii. Respiratory complications such as pneumonia
      iii. Congestive heart failure
      iv. Pulmonary hypertension
2. Spondylocostal dysostosis
   a. Constitutes a heterogeneous group of radiologic phenotypes with axial skeletal malformations
   b. Generally milder phenotype
   c. Multiple vertebral segmentation and formation defects
   d. Typical findings
      i. Intrinsic asymmetric rib anomalies
         a) Broadening
         b) Bifurcation
         c) Fusion
      ii. No symmetric fusion of the ribs
      iii. Do not display a fanlike configuration of the thorax
      iv. No cervical spine anomalies in some patients
      v. Short-trunk dwarfism
   e. Associate anomalies
      i. Congenital heart disease
      ii. Urogenital and anal anomalies
      iii. Limb abnormalities
      iv. Torticollis
      v. Diaphragmatic, umbilical, and inguinal hernias
   f. Prognosis
      i. A good prognosis, due in part to the asymmetry of the thoracic anomalies resulting in a less restrictive thorax
      ii. Normal intelligence

Diagnostic Investigations

1. Radiography (Cornier et al. 2003)
   a. Spondylothoracic dysostosis
      i. Bilateral fanning of the ribs with posterior fusion, giving the appearance of a common origin of ribs at the posterior thoracic spine
      ii. A decreased number of cervical, thoracic, and lumbar vertebrae
      iii. Multiple vertebral segmentation and formation defects
         a) Block and wedge vertebrae
         b) Unsegmented bars
         c) Hemivertebrae
         d) Anterior-posterior-lateral failure of closure
   b. Spondylocostal dysostosis
      i. Multiple vertebral formations and segmentation defects along the entire spine
         a) A decreased number of cervical, thoracic, and lumbar vertebrae
         b) Block and wedge vertebrae
         c) Agenesis of the coccygeal region
         d) Progressive scoliosis of the thoracic spine due to tethering effect secondary to the rib anomalies
      ii. Asymmetric intrinsic rib malformations
         a) Broading
         b) Bifurcation
         c) Fusion
         d) Do not display a fanlike configuration of the thorax as in spondylothoracic dysostosis

2. Reconstructed tridimensional CT scan of the chest
   a. Spondylothoracic dysostosis
      i. Bilateral rib fusion at the costovertebral junction
      ii. Segmentation and formation defects in all cervical, thoracic, and lumbar vertebrae. Sacrococcygeal regions are spared from any abnormality.
      iii. Increase in the coronal diameter of the thoracic and lumbar vertebrae which acquire a sicklelike appearance
   b. Spondylocostal dysostosis
      i. Varying extent of the thoracic fusion
      ii. Thoracic fusion always asymmetric with respect to each side of the thorax
      iii. Increase in the coronal diameter of the thoracic and lumbar vertebrae which acquire a sicklelike appearance
3. Pulmonary function tests for restrictive lung disease
4. Molecular genetic analysis (Turnpenny et al. 2009)
   a. *DLL3* mutations in spondylocostal dysostosis (homozygous or compound heterozygous mutations)
   b. Other subtypes are defined by identification of two mutant alleles in other three genes known to be associated with autosomal recessive spondylocostal dysostosis: *MESP2*, *LFNG*, and *HES7*.

Genetic Counseling

1. Recurrence risk
   a. Autosomal recessive inheritance (spondylothoracic dysostosis and spondylocostal dysostosis)
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is also a carrier, in which case, there is a 50% risk of having an affected offspring
   b. Autosomal dominant inheritance (spondylocostal dysostosis)
      i. Patient's sib: not increased unless a parent is affected, in which case, there is a 50% risk of having an affected sibling
      ii. Patient's offspring: 50%
2. Prenatal diagnosis by ultrasonography
   a. Ultrasonography
      i. Grossly distorted thoracic and lumbar spine
      ii. Marked kyphoscoliosis
      iii. Multiple vertebral segmentation anomalies
      iv. Fanned ribs
      v. A small chest with foreshortened spine
      vi. Increased fetal nuchal translucency thickness
      vii. Inguinoscrotal hernia in a fetus with vertebral anomalies: a clue for Jarcho–Levin syndrome and other pathologies that increase abdominal pressure (Basaran et al. 2010)
   b. Prenatal diagnosis by molecular genetic analysis of *DLL3*, *MESP2*, *LFNG*, or *HES7* gene mutations by sequencing entire coding region of fetal DNA obtained from amniocentesis or CVS, provided the disease-causing allele has been previously identified
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have identified previously.
3. Management (Cornier et al. 2003)
   a. Minimize positive end-expiratory pressure to avoid bronchopulmonary dysplasia.
   b. Continuous feeding instead of in boluses to avoid stomach distension that will lead to increase diaphragmatic pressure
   c. Aggressive treatment of infections
   d. Treat the spinal deformities.

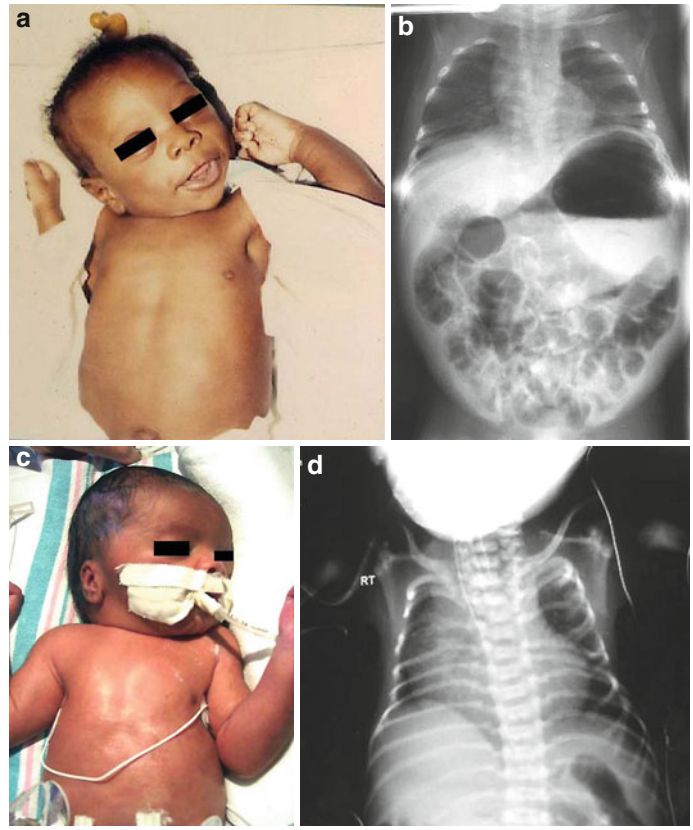

Fig. 1 (**a**–**d**) Two infants with spondylocostal dysostosis with typical crablike deformities of the chest with fused ribs (radiographs)

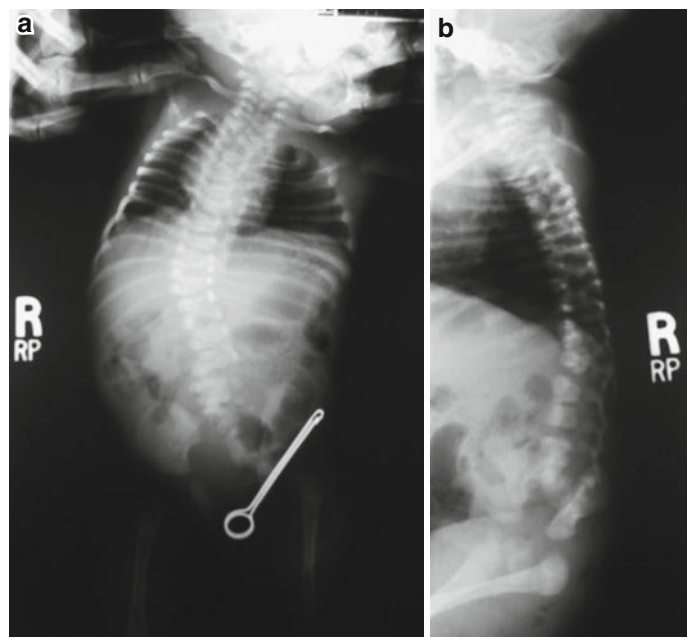

Fig. 2 (**a**, **b**) Radiographs of another infant with spondylocostal dysostosis showing fused ribs and fused vertebrae

Fig. 3 Radiographs of another infant with spondylothoracic dysostosis showing severe chest deformity

Fig. 4 (**a**–**d**) An Arabic female newborn was evaluated for multiple vertebral and rib anomalies. Her prenatal ultrasound showed vertebral anomalies, hydramnios, and possible TE fistula. Postnatally, she was noted to have short neck, short chest, and protuberant abdomen. The postnatal radiographs showed vertebral segmentation and formation defects throughout cervical, thoracic, and lumbar spine. Fusion of the ribs was present. Clinical diagnosis of Jarcho–Levin syndrome was made. The parents are first cousins. Molecular genetic diagnosis showed positive *DLL3* mutation. This patient is apparently homozygous in the *DLL3* gene for a frameshift mutation defined as c.329delT which is predicted to result in premature protein termination (p.Val110GlyfsStope22). This particular mutation has not been reported previously. However, it is the type expected to be pathogenic (e.g., Turnpenny et al. 2003). The homozygous c.329delT mutation is very likely the cause of recessive spondylocostal dysostosis

Fig. 5 (**a**–**c**) The previous infant at 3 months of age with follow-up X-rays

Joubert Syndrome

In 1969, Joubert et al. first documented three brothers and one sister who had episodic hyperpnea, abnormal eye movements, ataxia, mental retardation, and cerebellar vermian hypoplasia and aplasia. Later in 1977, Boltshauser and Isler reported three more cases with variable degrees of clinical symptoms and suggested the syndrome be called Joubert syndrome.

The prevalence in the United States has been estimated as approximately 1:100,000 (Parisi et al. 2006). This is likely to be an underestimate due to lack of recognition of the clinical signs or MRI findings and failure to diagnose the condition in more mildly affected individuals (Parisi et al. 2007).

Synonyms and Related Disorders

Cerebellooculorenal syndrome; Cerebelloparenchymal disorder; Jubert-Boltshauser syndrome

Genetics/Basic Defects

1. A rare autosomal recessive brain malformation disorder
2. Causative gene defects (genetic complexity) in Joubert syndrome and related disorders (JSRD) individuals (Parisi et al. 2006; Harris 2007)
   a. *NPHP1* (nephronophthisis 1, 2q13) gene homozygous deletion associated with juvenile nephronophthisis present in a subset of individuals with Joubert syndrome (Parisi et al. 2004) (1–2%)
   b. *AHI1* (Abelson helper integration site, 6q23.11) gene mutations (Parisi et al. 2006) (10–15%)
   c. *CEP290* (encoding centrosomal protein, 12q21.3) gene mutations causing pleiotropic forms of Joubert syndrome (Valenti et al. 2006) (approximately 10%)
   d. *NPHP6* (encoding centrosomal protein nephrocystin-6, 12q21.3) gene mutations in Joubert syndrome (Sayer et al. 2006)
   e. *ARL13B* cilia gene mutation leading to classical form of Joubert syndrome (Cantagre et al. 2008)
   f. Mutations in three genes (MKS3, CC2D2A, and RPGRIP1L) in COACH syndrome (Joubert syndrome with congenital hepatic fibrosis) (Doherty et al. 2010)

Clinical Features

1. Clinical features often cited as necessary for the diagnosis of classic Joubert syndrome (Joubert et al. 1969; Saraiva and Baraitser 1992; Steinlin et al. 1997; Maria et al. 1999a, b; Parisi et al. 2006; 2007)
   a. Cranial MRI findings of molar tooth sign (100%)
      i. Midline cerebellar vermis hypoplasia
      ii. Deepened interpeduncular fossa
      iii. Thick, elongated superior cerebellar peduncles
   b. Hypotonia in infancy (100%)
   c. Developmental delay/mental retardation, of variable severity (100%)
   d. One or both of the following (not absolutely required but supportive of the diagnosis):
      i. Irregular breathing pattern in infancy (episodic tachypnea and/or apnea)
      ii. Abnormal eye movements (including nystagmus, jerky eye movements, and oculomotor

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_137,
© Springer Science+Business Media, LLC 2012

apraxia or difficulty with smooth visual pursuits)

2. Typical facial features during childhood (Maria et al. 1999a)
   a. High rounded eyebrows
   b. Broad nasal bridge
   c. Mild epicanthus
   d. Anteverted nostrils
   e. Triangular-shaped open mouth with tongue frequently resting on the lower lip
   f. Low-set and coarse ears
3. Joubert syndrome may be considered an oculo-cerebello-renal syndrome because of the coincident involvement of all three organ systems (Valente et al. 2003).
4. JSRD: disorders sharing the MRI molar tooth sign (Gleeson et al. 2004). Clinical features in JSRD with the molar tooth sign (MTS) (Parisi et al. 2007) are:
   a. Other central nervous system anomalies
      i. Hypotonia
      ii. Mental retardation
      iii. Oculomotor apraxia
      iv. Breathing abnormalities
      v. Encephalocele
      vi. Polymicrogyria
   b. Ocular abnormalities
      i. Ocular coloboma
      ii. Retinal dystrophy
      iii. Leber congenital amaurosis
   c. Renal diseases
      i. Cystic dysplastic kidneys
      ii. Nephronophthisis
   d. Hepatic fibrosis
   e. Polydactyly
   f. Tongue hamartomas/oral frenulae
5. Proposed classification system for Joubert syndrome and related disorders (Zaki et al. 2008)
   a. Primary criteria include:
      i. Neurological signs
         a) Hypotonia/ataxia
         b) Developmental delay
         c) Oculomotor apraxia
      ii. Radiological hallmark of molar tooth sign
      iii. Occasional features (seen in all forms)
         a) Mental retardation
         b) Breathing abnormalities
         c) Postaxial polydactyly
         d) Mild retinopathy
         e) Polymicrogyria
         f) Corpus callosum abnormality
   b. Secondary criteria
      i. Joubert syndrome: may include
         a) Mild ocular sign (retinopathy)
         b) Mild renal sign
         c) Postaxial polydactyly
      ii. Cerebellar vermis hypo-/aplasia-oligophrenia-ataxia-ocular coloboma-hepatic fibrosis (COACH syndrome): at least one (typically both)
         a) Hepatic fibrosis
         b) Coloboma (choroidal or retinal)
      iii. Cerebello-oculo-renal syndrome (CORS): at least one ocular sign and at least one renal sign
         a) Ocular signs: retinopathy (typically congenital blindness), coloboma
         b) Renal signs: cysts, nephronophthisis, renal failure
      iv. Oro-facio-digital syndrome type VI (OFD-VI) syndrome: at least one orofacial sign and at least one digital sign
         a) Orofacial signs: cleft lip/palate, tongue tumors, notched upper lip
         b) Digital signs: mesaxial polydactyly (most specifically), preaxial polydactyly, bifid digits
   c. The presence of the primary criteria and the secondary criteria are used to support the diagnosis of a specific type of JSRD.

Diagnostic Investigations

1. Molar tooth sign, demonstrated by a high-quality MRI scan of the brain (Zaki et al. 2008) (Parisi et al. 2007)
   a. Result from images of cerebellar vermis hypoplasia, thick and maloriented superior cerebellar peduncles, and an abnormally deep interpeduncular fossa (Maria et al. 1999b)
   b. Extraordinarily useful in differentiating JSRD conditions from other hindbrain malformations
      i. Dandy-Walker malformation
      ii. Isolated cerebellar vermis hypoplasia
      iii. Pontocerebellar hypoplasia
      iv. Rhombencephalosynapsis

2. Medical genetics evaluation
   a. Family history
   b. Demonstration of congenital anomalies
      i. Micro-/macrocephaly
      ii. Facial dysmorphism
      iii. Clefts
      iv. Lingual nodules
      v. Polydactyly
      vi. Genital anomalies
      vii. Others
3. Developmental assessment
4. Neurologic evaluation for cerebellar function
5. EEG for seizures
6. Polysomnogram for abnormal sleep history (apnea/hyperpnea)
7. Ophthalmological evaluation
   a. Eye malformations such as coloboma
   b. Retinopathy or blindness
   c. Abnormal eye movement such as nystagmus or oculomotor apraxia
8. Abdominal ultrasonography
   a. Renal cystic disease
   b. Liver fibrosis
9. Clinical laboratory tests
   a. BUN
   b. Creatinine
   c. CBC for anemia
   d. First-morning void urinalysis with specific gravity
10. Liver function tests
    a. Transaminases
    b. Albumin
    c. Bilirubin
    d. Prothrombin time
11. Chromosome analysis: no consistent chromosomal aberrations identified
12. Molecular genetic testing
    a. FISH or microsatellite marker analysis for homozygous deletion of the *NPHP1* gene associated with juvenile nephronophthisis (Hildebrandt et al. 2001; Parisi et al. 2004) identified in only 1–2% of subjects with JS (Parisi et al. 2006)
    b. Molecular testing for mutations in the *AHI1* gene and the *CEP290* gene: clinically available. Each of these genes is estimated to account for about 10% of cases of JSRD. Mutations in both *AHI1* and *CEP290* are more likely to be associated with retinal disease, with *CEP290* implicated in some cases with congenital blindness or Leber amaurosis (den Hollander et al. 2006; Sayer et al. 2006).
    c. In rare families with a large number of affected children and/or known consanguinity, linkage analysis may be feasible on a research basis.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a 25% risk
   b. Patient's offspring: low recurrence risk unless the partner is a carrier or affected
2. Prenatal diagnosis
   a. Possible for pregnancy at risk, provided the disease-causing mutations have been identified in the affected individual
   b. Prenatal imaging for all other at-risk pregnancies
      i. Prenatal diagnosis of Joubert syndrome has been accomplished as early as the first trimester on the basis of extracranial anomalies, such as polydactyly or renal cysts, and major structural CNS malformations such as encephalocele (Wang et al. 1999).
      ii. Early diagnosis: more challenging when extracranial abnormalities are not present, because cerebellar vermis hypoplasia cannot be reliably diagnosed until 18–20 weeks gestation (Bromley et al. 1994) and the MTS has not been observed before 27 weeks gestation (Fluss et al. 2006)
   c. Prenatal diagnosis: suspected at 32 weeks gestation in the absence of a family history by observation of vermian agenesis, bilateral ventriculomegaly, postaxial polydactyly, and episodes of tachypnea (Aslan et al. 2002)
   d. Sensitivity and specificity of prenatal imaging findings for JSRD: not known (Doherty et al. 2005)
3. Management
   a. No specific treatments for Joubert syndrome exist.
   b. Supportive treatments with interventions for individuals with developmental disabilities
      i. Special education programs
      ii. Physical, occupational, and speech therapy

iii. Adaptive equipments as needed
iv. Seizure control

c. Dialysis and renal transplantation for nephronophthisis
d. Specific surgical interventions for esophageal varices or portal hypertension in liver fibrosis
e. Liver transplantation for COACH syndrome

Fig. 1 Patient 1 with Joubert syndrome. This 6-week-old boy presented with respiratory distress, tachypnea with episodes of apnea, and abnormal eye movement. Ultrasound revealed multiple bilateral renal cysts

Fig. 2 Lateral view of the patient

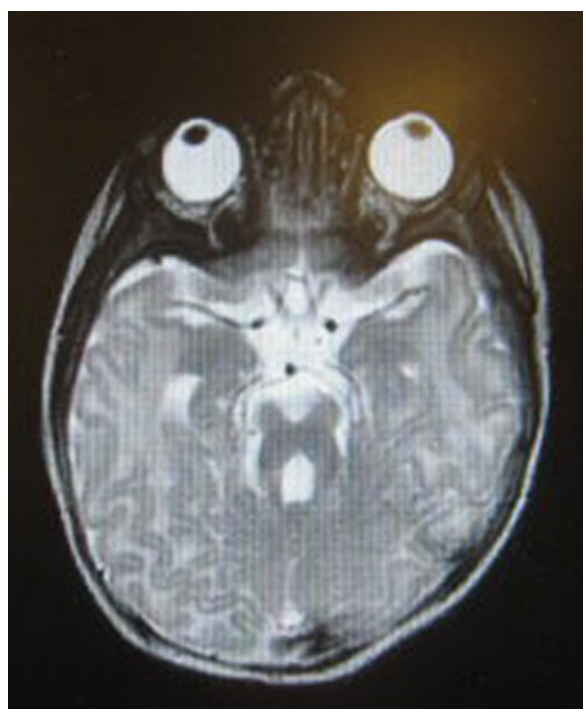

Fig. 3 MRI of the brain showed hypoplasia of cerebellum with "molar tooth sign" leading to diagnosis of Joubert syndrome

Fig. 4 This 22-month-old boy was evaluated for Joubert syndrome. He was delivered at 41 weeks of gestation via cesarean section with cord wrapping around the neck twice. Birth weight was 4,035 g and birth length 55 cm. Fetal ultrasound examination showed possible cerebellar hypoplasia. Follow-up MRI of the brain showed "molar tooth sign" consistent with Joubert syndrome. He had neonatal breathing dysregulation, delayed psychomotor development, hypotonia, and macrocephaly with prominent forehead, high-round eyebrows, low set and "tilted" ears, abnormal jerky eye movement with right chorioretinal coloboma, epicanthal folds, and ptosis. FISH using a probe to the NPHP1 locus showed no deletion of the *NPHP1* region. The result does not exclude the clinical diagnosis of Joubert syndrome and does not exclude a mutation in the *NPHP1* gene or other genes not detectable with this assay

Fig. 5 Note psychomotor retardation

Fig. 6 Note the genital hypoplasia

Kabuki Syndrome

In 1981, Niikawa and Kuroki independently described a previously unrecognized mental retardation-malformation syndrome, characterized by a unique combination of craniofacial anomalies, congenital heart defects, skeletal anomalies, persistent fetal fingertip pads, dermatoglyphic abnormalities, mental retardation, and short stature. Because the peculiar facial appearance resembles the makeup of Kabuki actors in a traditional Japanese theater, the Niikawa-Kuroki syndrome is also known as Kabuki or Kabuki makeup syndrome. The prevalence of the syndrome is estimated to be 1 in 32,000 live births in Japan (Niikawa et al. 1988). The syndrome is increasingly recognized in other parts of the world.

Synonyms and Related Disorders

Kabuki makeup syndrome; Niikawa–Kuroki syndrome

Genetics/Basic Defects

1. Sporadic in most cases
2. Autosomal dominant inheritance suggested in a few families
3. Other hypotheses
   a. Postzygotic mutation, suggested by discordance between the twins, although multifactorial causes cannot be ruled out
   b. Several instances of chromosomal abnormalities have been reported in the literature but without identical breakpoints in those autosomal abnormalities.
   c. Microdeletion involving several contiguous genes, suggested by sporadic cases in the majority of patients and a wide spectrum of clinical manifestations. So far, no chromosomal deletion was detected at the sites of the DiGeorge/velocardiofacial chromosomal region within 22q11.2 or flanking the van der Woude syndrome region at 1q32–q41.
   d. 8p23.1–p33 duplication, detected by CGH and FISH in six unrelated patients with Kabuki syndrome, was postulated to be a common etiology for the syndrome (Milunsky and Huang 2003). However, studies by Miyake et al. (2004) detected no aberrations of the 8p region by either CGH or FISH on other patients and suggested that the patients studied by Milunsky and Huang had either atypical Kabuki syndrome or possibly an "8p23.1–p33 duplication syndrome."
   e. It is possible that Kabuki syndrome is a heterogeneous disorder and abnormalities not only on chromosome 8 but also on other chromosomes, such as the X chromosome, could lead to similar Kabuki syndrome features (Adam and Hudgins 2004).
   f. Molecular karyotyping in 17 patients and mutation screening in 41 patients with Kabuki syndrome revealed no causative gene, but the locus of 9q21.11–q21.12, including *TRPM3*, *KLF9*, *SMC5*, and *MAMDC2*, may contribute to the cleft palate of Kabuki syndrome (Kuniba et al. 2009).

Clinical Features

1. Craniofacial abnormalities (Matsumoto and Nikawa 2003)
   a. Peculiar facial appearance (100%): The most striking feature of the syndrome
      i. Peculiar face that consists of eversion of the low lateral eyelid that is reminiscent of a Kabuki actor's makeup and arched eyebrows with sparseness of their lateral one third
      ii. Long palpebral fissures
      iii. Depressed nasal tip
      iv. Prominent, large ears
   b. Microcephaly (26%)
   c. Eye abnormalities
      i. Long palpebral fissure (99%)
      ii. Lower palpebral eversion (92%)
      iii. Arched eyebrow (85%)
      iv. Ptosis (50%)
      v. Epicanthus (46%)
      vi. Strabismus (36%)
      vii. Blue sclerae (31%)
   d. Nasal abnormalities
      i. Short nasal septum (92%)
      ii. Depressed nasal tip (83%)
   e. Ear abnormalities
      i. Prominent ears (84%)
      ii. Malformed ears (87%)
      iii. Preauricular dimple/fistula (22%)
   f. Oral abnormalities
      i. High-arched palate (72%)
      ii. Abnormal dentition (68%)
      iii. Microganthia (40%)
      iv. Cleft palate/lip (35%)
      v. Lower lip pit (27%)
   g. Low posterior hairline (57%)
2. Skeletal abnormalities (88%)
   a. Pilonidal sinus (83%)
   b. Short fifth phalanxes (80%)
   c. Short fifth fingers (79%)
   d. Joint laxity (74%)
   e. Clinodactyly of fifth fingers (50%)
   f. Sagittal cleft of vertebral body (36%)
   g. Scoliosis (35%)
   h. Short metacarpals (35%)
   i. Deformed vertebra/rib (32%)
   j. Foot deformity (24%)
   k. Spina bifida occulta (19%)
   l. Hip dislocation (18%)
   m. Rib anomaly (18%)
   n. Coarse carpal bone (17%)
   o. Cone-shaped epiphyses (13%)
   p. Patellar dislocation
   q. Craniosynostosis: rare (6%) (Armstrong et al. 2005)
3. Dermatoglyphic abnormalities
   a. Abnormal dermatoglyphics (96%)
      i. Frequent fingertip ulnar loop patterns
      ii. Absence of digital triradius "c" or "d"
      iii. An interdigital triradius "bc" or "cd"
      iv. Fourth interdigital area patterns
         a) Hypothenar loop patterns
         b) Ulnar loop patterns
   b. Presence of fingertip pads (89%): possible remnants of fetal pads
4. Neurologic abnormalities
   a. Mild to moderate mental retardation (IQ <80) (84%)
   b. Hypotonia (68%)
   c. Neonatal hypotonicity (28%)
   d. Seizures (17%)
   e. Brain atrophy (4%)
   f. Retinal pigmentation (3%)
5. Short stature (55%)
6. Visceral abnormalities
   a. Cutaneous abnormalities
      i. Hyperpigmented nevus (22%)
      ii. Generalized hirsutism (11%)
   b. Cardiovascular anomalies (42%)
      i. Ventricular septal defect
      ii. Atrial septal defect
      iii. Coarctation of the aorta
      iv. Transposition of great vessels
   c. Gastrointestinal abnormalities
      i. Umbilical hernia (9%)
      ii. Inguinal hernia (7%)
      iii. Malrotation of the colon (6%)
      iv. Anal atresia/rectovaginal fistula (5%)
   d. Genitourinary abnormalities
      i. Kidney/urinary tract malformations (28%)
      ii. Undescended testes (24%)
      iii. Small penis (10%)
7. Other features
   a. Susceptibility to infections
      i. Recurrent otitis media (63%)
      ii. Repeat upper respiratory tract infections and pneumonias

iii. Single case reports
a) Severe immunodeficiency
b) Autoimmune hemolytic anemia and polycythemia
c) Chronic idiopathic thrombocytopenia
d) Acquired hypogammaglobulinemia with anti-IgA antibody
b. Early breast development (28%)
c. Hearing loss (27%)
d. Neonatal hyperbilirubinemia (20%)
e. Obesity (19%)
f. Anemia (9%)
g. Polycythemia (4%)
h. Cystic fibrosis (2%)
i. Primary ovarian dysfunction (2%)

Diagnostic Investigations

1. Blood sugar during infancy for neonatal hypoglycemia (7%)
2. Thyroid profile for rare TBG deficiency (2%)
3. Growth hormone determination for rare growth hormone deficiency
4. Workup for autoimmune hemolytic anemia, if present
5. Audiologic screening for hearing loss
6. Radiography for skeletal abnormalities (Niikawa et al. 1981)
   a. Frequent features
      i. Abnormalities of the spinal column
         a) Thoracic or lumbar scoliosis
         b) Sagittal cleft vertebra
         c) Narrow disc space
         d) Cervical ribs
         e) Schmorl node
      ii. Dislocation of the hip joints
      iii. Abnormalities of the hands
         a) Brachymesophalangy of the fifth fingers
         b) Short fifth metacarpals
         c) Cone-shaped epiphysis of proximal phalanges II–V
   b. Less frequent features
      i. Defective dentition
      ii. Underpneumatized mastoids
      iii. Sacral spina bifida occulta
      iv. Osteoporotic changes of the carpal bone and metacarpals
      v. Underdeveloped ulnar styloids
      vi. Dysplastic acetabulum
      vii. Horseshoe kidney
      viii. Bifid renal pelvis
7. Renal ultrasonography for renal abnormalities
8. Echocardiography for congenital heart defects
9. EEG for seizures: characteristic features are focal seizures more frequently origin in fronto-central area (Lodi et al. 2010)
10. MRI/CT scan for rare CNS anomalies
11. Dermatoglyphic analysis

Genetic Counseling

1. Recurrence risk (Kawame et al. 1999)
   a. Patient's sib: low recurrence risk, unless a parent has an autosomal dominant form of the syndrome
   b. Patient's offspring: low recurrence risk, unless the patient has an autosomal dominant form of the syndrome
2. Prenatal diagnosis: none described to date
3. Management
   a. Multidisciplinary approach to developmental delay and mental retardation
   b. Hearing aids for hearing loss
   c. Treat infections
   d. Growth hormone replacement therapy for growth hormone deficiency
   e. Orthopedic intervention for scoliosis, dislocations, and foot deformities
   f. Cardiac surgery for severe congenital heart defects
   g. Surgical repair of cleft lip/palate, gastrointestinal, anorectal, and craniosynostosis anomalies

Fig. 1 (**a**–**c**) A 12-year-old girl with Kabuki syndrome showing arched eyebrows, long palpebral fissures, everted lateral half of the lower eyelid, short nasal septum, post–cleft lip repair, prominent ears, and prominent finger pads

Fig. 2 A 1-year-old girl with Kabuki syndrome showing arched eyebrows, long palpebral fissures, short nasal septum, and hypertrophic breasts. The infant also has cleft palate, large ears, and congenital hip dislocations

Fig. 3 A 1-year-old boy with Kabuki syndrome showing arched eyebrows, long palpebral fissures, everted lateral half of the lower eyelids, blue sclera, strabismus, short nasal septum, small chin, and large and prominent ears

Fig. 4 (**a**–**c**) A 12-year-old boy with Kabuki syndrome showing characteristic facial features consisting of long palpebral fissures, arched eyebrows, bilateral lower lateral palpebral eversion, short nasal septum, high-arched palate, low hairline, and prominent finger pads. Other anomalies include mild mental retardation, neonatal hypotonia, recurrent otitis media and upper respiratory infections, joint laxity, ventricular septal defect, hip dysplasia, and short and clinodactyly of the fifth fingers

Kasabach–Merritt Syndrome

Kasabach–Merritt syndrome (or phenomenon) is the association of a vascular tumor and thrombocytopenic coagulopathy (Enjolras et al. 2000). It is a life-threatening, localized consumptive coagulopathy, characterized by profound thrombocytopenia and microangiopathic anemia.

In 1940, Kasabach and Merritt described the first case of Kasabach–Merritt syndrome with a case report of consumptive coagulopathy associated with a hemangioma. However, it is now recognized that Kasabach–Merritt syndrome is usually associated with Kaposiform hemangioendothelioma and tufted angioma, rather than the classic involuting hemangioma of infancy (Enjolras et al. 1997).

Synonyms and Related Disorders

Hemangioma-thrombocytopenia syndrome

Genetics/Basic Defects

1. Genetics
   a. Sporadic in majority of cases
   b. Autosomal dominant inheritance in rare reports
   c. Can be a part of recognized syndromes
2. Pathophysiology (Hall 2001)
   a. Platelet trapping by abnormally proliferating endothelium within the hemangioma, resulting in the activation of platelets with a secondary consumption of clotting factors
   b. Continued consumption of both platelets and clotting factors along with the initiation of fibrinolysis eventually resulting in intralesional bleeding which manifests as rapid enlargement of the hemangioma

Clinical Features

1. Diverse clinical presentation (Enjolras et al. 2000; Hall 2001)
   a. Type of hemangiomas
      i. Kaposiform hemangioendothelioma: often found in noncutaneous sites such as the retroperitoneum, mediastinum, and pelvis, as well as the skin
      ii. Tufted angioma
      iii. Mixture of Kaposiform hemangioendothelioma and tufted angioma
      iv. Not "true" common hemangioma of infancy
   b. Reddish brown skin lesion progressing to a violaceous bulging mass
      i. Often painful
      ii. Aggressive infiltration with ulceration
      iii. Bruising in other areas
      iv. Possible infection
   c. Bleeding from thrombocytopenia and intravascular coagulopathy
   d. Increase in size and becoming tense, woody, and purplish of preexisting hemangiomas during pregnancy
2. Cutaneous involvement of Kaposiform hemangioendothelioma
   a. Smooth, shiny, dark purple, indurated, tender, and poorly delineated
   b. Nearly always single

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_139,
© Springer Science+Business Media, LLC 2012

3. Visceral involvement of hemangiomata
   a. Single
   b. Multiple
   c. Isolated within one organ as single or diffuse lesions
   d. Retroperitoneal hemangiomata
      i. Often giant in size
      ii. Easily missed clinically: diagnosis suspected in patients presenting with an unexplained thrombocytopenia and coagulopathy
      iii. Generally associated with high mortality
4. Diffuse and multiple nature
   a. Diffuse infantile (neonatal) hemangiomatosis
      i. Presence of multiple cutaneous and visceral hemangiomata
      ii. High morbidity and mortality
   b. Intraosseous and soft tissue hemangiomata
5. Lifelong hemangioma in adults
   a. Hormone alterations and increase in blood volume in pregnancy may affect preexisting lesions, triggering episodes of acute disseminated intravascular coagulation
   b. Development of acute consumptive coagulopathy after surgery of other unrelated tumor
6. Thrombocytopenic coagulopathy in patients with hemangiomata as a part of a recognized syndrome
   a. Klippel–Trenaunay syndrome
      i. A rare congenital generalized mesodermal abnormality
      ii. Macular vascular nevus, skeletal/soft tissue hypertrophy
      iii. Venous and lymphatic anomalies including viscera and facial hemangiomata
   b. Blue rubber bleb nevus syndrome
      i. Multiple cutaneous cavernous hemangiomata
      ii. Cutaneous and occasional visceral hemangiomata
   c. Gorham–Stout disease ("vanishing bone disease")
      i. Massive osteolysis (Gorham sign)
      ii. Followed by replacement of the bony matrix by proliferating thin-walled vascular and lymphatic channels
      iii. Extension of these angiomatous masses into soft tissues
7. Prognosis
   a. Incomplete regression of the lesion after months or years
   b. Visceral involvement
      i. Mediastinum
      ii. Neck
      iii. Retroperitoneum
      iv. Pelvis
   c. Hemorrhage by aggressive invasion
   d. Petechiae, ecchymoses, or purpura
   e. Profound thrombocytopenia
   f. Anemia
   g. Congestive heart failure
   h. Severe infections
   i. Residual lesions after "cure" of Kasabach–Merritt phenomenon (Enjolras et al. 2000)
      i. Common after the resolution of thrombocytopenia and coagulopathy
      ii. Clinical patterns
         a) Cutaneous red stain with or without associated red papules
         b) Telangiectatic streaks and swelling
         c) A minor, firm, irregular subcutaneous mass assessed by palpation or deep infiltration evidenced by CT scan or MRI
         d) Sequelae in muscles and/or joints
   j. Overall mortality (estimated to be 20–30%) (El-Dessouky et al. 1988) due to complications such as (Enjoiras et al. 1990):
      i. Disseminated intravascular coagulation
      ii. Respiratory failure due to a pressured airway
      iii. High-output heart failure due to presence of a huge tumor

Diagnostic Investigations

1. Laboratory studies (Hall 2001)
   a. Generally severe thrombocytopenia: occurs in 1–2 per 300–700 cases of hemangioma
   b. Consumptive coagulopathy
      i. Prominent fibrinogenopenia
      ii. Usually elevated fibrin split (degradation) products
      iii. Usually elevated D-dimers (a measure of fibrin split products)
      iv. Depressed clotting factors V and VII
2. Ultrasound, MRI, or CT
   a. To assess extent of the lesions
   b. To identify the occult lesions

3. Histology to determine subtypes of hemangioma
   a. Kaposiform hemangioendothelioma of infancy and childhood
      i. The most frequently reported histological type
      ii. A locally aggressive, low-grade malignant tumor
      iii. Lobules or sheets of tightly packed spindle cells or more rounded endothelial cells and pericytes
      iv. Infiltrative pattern of the cellular areas in the dermis and subcutaneous fat and muscles, generally containing few obvious vascular lumina
      v. Aggregates of rounded dilated capillaries, lined by attenuated endothelial cells with small dark nuclei and filled with red blood cells
      vi. Containing lymphatic-like vessels
   b. Tufted angioma
      i. A benign lesion
      ii. Small tufts or lobules of rounded capillaries with small lumina
      iii. Tufts: discrete and evenly distributed in a cannon ball pattern, characterized by peripheral crescentic slit-like vessels and fibrosis
      iv. Aggregates of rounded dilated capillaries, lined by attenuated endothelial cells with small dark nuclei and filled with red blood cells

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected
   b. Patient's offspring: 50% in case of autosomal dominant inheritance
2. Prenatal diagnosis: Prenatal diagnosis of fetal facial hemangioma in a case of Kasabach–Merritt syndrome
3. Management (Ryan et al. 2010)
   a. General premise regarding treatment: Resolution of the lesion will lead to a correction of the consumptive coagulopathy, which is heralded by a recovery in the platelet count.
   b. Principle of management of thrombocytopenia in Kasabach–Merritt syndrome should be to "treat the patient and not the numbers."
   c. Prompt and vigorous management
      i. Help to optimize the outcome
      ii. No one treatment modality established as consistently efficacious
   d. Blood product support in the presence of sudden decompensation or enlargement of the lesion
      i. Fresh frozen plasma
      ii. Cryoprecipitate if fibrinogen still less than 1.0 g/L
      iii. Platelets transfusion should be reserved for thrombocytopenic patient who is actively bleeding or in preparation for a surgical procedure.
      iv. Tranexamic acid for profound fibrinolysis
   e. Simple or single lesion
      i. Vascular ligation
      ii. Embolization
      iii. Surgical excision
         a) Surgical removal of a giant hemangioma: usually hazardous in the presence of an uncontrolled consumptive coagulopathy
         b) Supporting and stabilizing hemostasis while trying to remove or ablate the lesion
         c) Partial resection of tumor, reduction of tumor blood, and vincristine chemotherapy (Shen et al. 2010): Since the huge tumor is the major cause of rapid platelet destruction, the partial removal of the tumor and U-shaped suture to reduce tumor blood supply would reduce the platelet destruction and, therefore, improve the clinical condition, followed by skin graft or flaps of the wound, and vincristine chemotherapy necessary to prevent the enlargement of the remaining tumor.
   f. Diffuse or extensive lesions
      i. Prednisone
      ii. Alpha interferon
   g. Adjuvant therapies
      i. Vincristine
      ii. Localized radiotherapy
      iii. Combination chemotherapy (vincristine, cyclophosphamide)
      iv. Antifibrinolytic or antiplatelet agents (tranexamic acid, ε-amino caproic acid, pentoxifylline, ticlopidine)

h. Potential future therapies
   i. Laser therapy
   ii. Antiangiogenic agents
   iii. Pegylated recombinant human megakaryocyte growth and development factor (peg-rHuMGDF)

KID Syndrome

KID syndrome is an acronym for the syndrome characterized by *k*eratitis, *i*chthyosis, and *d*eafness, a term proposed by Skinner et al. in 1981 (Skinner et al. 1981).

Synonyms and Related Disorders

Keratitis-ichthyosis-deafness syndrome

Genetics/Basic Defects

1. Genetic heterogeneity
   a. Sporadic in most cases
   b. Existence of familial cases suggesting a genetic etiology
      i. A vertical transmission suggesting an autosomal dominant disease
      ii. The occurrence in two sisters born to consanguineous, unaffected parents suggesting an autosomal recessive inheritance
2. Caused by heterozygous missense mutations in the connexin-26 gene, *GJB2*, which is implied in the normal corneal function, hair growth, and carcinogenesis
   a. Mutations in *GJB2* were identified de novo in 13 unrelated patients with KID and in a case of transmission of the disease from father to son (Richard et al. 2002a; Van Steensel et al. 2002; Alvarez et al. 2003; Yotsumoto et al. 2003).
   b. Mutations in several other genes [*GJB3* (connexin-31), *GJB6* (connexin-30)], which encode members of the connexin family of gap junction proteins, are shown to be responsible for hearing impairment and skin disorders.
3. Occurrence of parental germ line mosaicism in the lethal form of KID syndrome: suggested by three affected children (carry the same G45E mutation) born to healthy parents (mutation not detected) (Sbidian et al. 2010)
4. Fatal form of KID syndrome (Janecke et al. 2005)
   a. A fatal course of KID in the first year of life, due to severe infections of the skin lesions and septicemia, has been reported in at least nine patients (Gilliam and Williams 2002; Janecke et al. 2005).
   b. Caused by G45E mutation of *GJB2* gene.
   c. The phenotype bears similarities to cutaneous disorders associated with sensorineural hearing loss (HL) known to be caused by mutations in genes encoding gap junction proteins (connexins).
      i. Vohwinkel syndrome (Maestrini et al. 1999)
      ii. Dominant HL associated with palmoplantar keratoderma (Heathcote et al. 2000)
      iii. Keratoderma without HL
         a) Clouston syndrome (Lamartine et al. 2000)
         b) Erythrokeratodermia variabilis (Richard et al. 1998b)
5. Pathogenesis: failure in development and differentiation of multiple stratifying epithelia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_140,

Clinical Features

1. Cutaneous features (McGrae 1990)
   a. Abnormal skin at birth: red, dry, thickened, and leathery
   b. Subsequent development of keratodermatous, nonscaly plaques
      i. Generally develop during the first year of life
      ii. Described as verrucous, ichthyotic, doughy, rugal, or elephant-skin-like
      iii. Develop primarily on the face and extremities
      iv. Plaques sharply demarcated and map-like in contour
      v. Plaques symmetrically located on the face
         a) Especially the cheeks
         b) With variable involvement of the forehead, ears, chin, and nose
         c) Furrows in the thickened skin of the chin and around the mouth
      vi. Transverse ripples marking the surface of plaques over the knees
      vii. Follicular keratoses, occasionally with spine like projections, on the extremities, eyebrows, scalp, earlobes, neck, and nose
   c. Distinct keratoderma of the palms and soles
      i. Pebbly excrescences and an intervening coarsely stippled pattern analogous to heavily grained leather
      ii. Patulous stippling rendering a moth-eaten appearance
   d. Abnormal hair
      i. Sparse, fine, and sometimes absent scalp, eyebrow, and eyelash hair
      ii. Pattern of patch scalp alopecia resembling pseudopelade
      iii. Body hair may be absent
      iv. Nails
         a) Thickened
         b) Hypoplastic
         c) Absent
         d) White
         e) Infrequently normal
2. Ophthalmologic features (Ghadially and Chong 1992)
   a. Invariably involving epibulbar structures with inflammation of the cornea
      i. Vascularized keratitis in majority of cases
      ii. Secondary pannus formation
   b. Photophobia
   c. Varying degree of visual impairment
   d. Onset: usually before adolescence
3. Auditory features
   a. Sensorineural deafness
   b. Repeat otitis media and externa
4. Other ectodermal abnormalities
   a. Dental abnormalities
      i. Carious
      ii. Brittle
      iii. Malformed
      iv. Delayed adult dentition
   b. Hypohidrosis
5. Neuroectodermal abnormalities
   a. Short heel cord
   b. Cerebellar hypoplasia
6. Other associated features
   a. Normal intelligence
   b. Growth delay
   c. Increased risk of developing squamous cell carcinoma
   d. Increased susceptibility to viral, bacterial, and mycotic infections
      i. Most commonly reported pathogens.
         a) Staphylococcus aureus
         b) E. coli
         c) Pseudomonas aeruginosa
         d) Trichophyton rubrum
         e) Candida albicans
      ii. Invasive and overwhelming infection may be present in infancy and early childhood. Death secondary to overwhelming sepsis has been reported in infancy.
      iii. Infections typically persistent and recurrent but usually limited to the skin in older children and adults.
      iv. No consistent pattern of immunologic dysfunction demonstrated in patients with KID syndrome.
7. Fatal form of KID syndrome
   a. A fatal course of KID has been reported in the first year of life due to severe infections of the skin lesions and septicemia.
   b. Characteristic severe neonatal phenotype (Sbidian et al. 2010).
      i. Facial dysmorphism
      ii. Severe cornification with massive focal hyperkeratosis of the skin with erythroderma
      iii. Dystrophic nails

iv. Complete atrichia (absence of hair)
v. Absence of foreskin

Diagnostic Investigations

1. Dental examinations for teeth abnormalities
2. Ophthalmological examination for corneal pathology and visual acuity
3. Audiologic examination to demonstrate sensorineural hearing loss
4. Histopathology of the skin (McGrae 1990)
   a. Findings not specific.
   b. Stratum corneum.
      i. Always hyperkeratotic, usually with a basket weave pattern
      ii. Orthokeratotic and occasionally parakeratotic
   c. Stratum granulosum: generally intact.
   d. Eccrine sweat glands appearing normal, although a diminished number and aberrant morphology have been noted.
   e. Absent or atrophic hair follicles indicating the customary state of alopecia.
   f. Follicular plugging is the rule.
5. Molecular genetic study to detect connexin-26 gene (*GJB2*) mutation: clinically available

Genetic Counseling

1. Recurrence risk.
   a. Patient's sib
      i. Autosomal dominant inheritance: not increased unless a parent is affected or parental germ line mosaicism exists
      ii. Autosomal recessive inheritance: 25%
   b. Patient's offspring
      i. Autosomal dominant inheritance: 50%
      ii. Autosomal recessive inheritance: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis: Prenatal molecular genetic diagnosis of the lethal form of KID syndrome relating to a G45E mutation has been reported (Sbidian et al. 2010).
3. Management.
   a. No specific treatment for the skin lesions.
   b. Isotretinoin with inconsistent results.
      i. May cause exacerbation of eye lesion
         a) Marked increase in pannus formation
         b) Marked increase in vascularization
      ii. Side effects of higher doses of isotretinoin
         a) Corneal opacities
         b) Punctate erosions
         c) Blepharoconjunctivitis
   c. Ophthalmologic evaluations and follow-up. Corneal grafts revascularize rapidly with subsequent loss of vision.
   d. Treat infections vigorously.
   e. Surveillance for skin and mucosal malignancy.
   f. Hearing aids.
   g. Appropriate school placement.

Fig. 1 (**a**–**b**) A 26-year-old woman with keratitis, ichthyosis, and deafness. Cutaneous manifestations show sharply demarcated red–brown hyperkeratotic plaques on the central face, around both eyes, and upper and lower extremities

Fig. 2 Marked hyperkeratosis is visible around the eye and the outer rim of the ear

Fig. 3 Chronic *Candida albicans* onychia and paronychia with hypertrophy of the distal digits and hyperkeratosis of the skin are apparent on both hands

Klinefelter Syndrome

In 1942, Klinefelter et al. published a report on nine men who had enlarged breasts, sparse facial and body hair, small testes, and an inability to produce sperm. In 1959, these men with Klinefelter syndrome were discovered to have an extra sex chromosome (genotype XXY) instead of the usual male sex complement (genotype XY).

Klinefelter syndrome is the most common sex chromosomal disorder associated with male hypogonadism and infertility. Approximately 1 in 500–1,000 males is born with an extra X chromosome. Over 3,000 affected males are born yearly in the USA.

Synonyms and Related Disorders

47,XXY syndrome; Klinefelter syndrome mosaicism (46,XY/47,XXY, 46,XY/48,XXXY, 47,XXY/48,XXXY); Klinefelter syndrome variants (48,XXYY, 48,XXXY, 49,XXXYY, 49,XXXXY); Klinefelter syndrome with structurally abnormal X chromosome [47,X,i(Xq)Y, 47,X,del(X)Y]

Genetics/Basic Defects

1. Caused by at least an additional X chromosome in a male
2. The XXY form of Klinefelter syndrome
   a. Due to meiotic nondisjunction of the sex chromosomes during gametogenesis in either parent
   b. Responsible meiotic nondisjunction
      i. About 40% occur in the father
      ii. About 60% occur in the mother
         a) Meiosis I errors (75%) when origin is maternal
         b) Presence of maternal age effect in the maternally derived cases
3. The mosaic forms of Klinefelter syndrome
   a. Due to mitotic nondisjunction after fertilization of the zygote
   b. Can arise from a 46,XY zygote or a 47,XXY zygote
4. The variant forms
   a. 48,XXXY: nondisjunction occurring either at the first or second meiotic divisions of oogenesis, resulting an XXX ovum which is then fertilized by a Y bearing sperm
   b. 49,XXXXY: please refer to 49,XXXXY chapter
   c. 48,XXYY and 49,XXXYY: occurrence of nondisjunction in paternal meiosis to have two Y chromosomes
      i. An X ovum fertilized by an XYY sperm arising from successive nondisjunction in the first and second meiotic divisions, or
      ii. An XX ovum from 47,XXX mother fertilized by a YY sperm
5. Pathophysiology (Chen 2011)
   a. The X chromosome carries genes that play roles in many body systems, including testis function, brain development, and growth (Giedd et al. 2007).
   b. The addition of more than one extra X or Y chromosome to a male karyotype results in variable physical and cognitive abnormalities.
   c. In general, the extent of phenotypic abnormalities, including mental retardation, is directly related to the number of supernumerary X chromosomes.
   d. As the number of X chromosomes increases, somatic and cognitive development are more likely to be affected.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_141,
© Springer Science+Business Media, LLC 2012

Clinical Features

1. Growth
   a. Infants and children: normal heights, weights, and head circumferences
   b. Adolescents and adults
      i. Eunuchoid body habitus
      ii. Usually taller than average
      iii. Disproportionately long arms and legs
2. Mild developmental, learning, and behavioral difficulties (70% of patients)
   a. Delayed speech and language acquisition
   b. Academic and reading difficulties
   c. Attention deficit disorder
   d. Poor self-esteem
   e. Insecurity
   f. Shyness
   g. Poor judgment
   h. Inappropriate assertive activity
   i. Decreased ability to deal with stress
   j. Fatigue
   k. Weakness
3. CNS
   a. Normal intelligence in most cases
   b. Subnormal intelligence or mental retardation associated with a higher number of X chromosomes
   c. Diminished short-term memory
   d. Prone to epilepsy and essential tremor
   e. Psychiatric disorders involving anxiety, depression, neurosis, and psychosis: more common than general population
4. Taurodontism (enlargement of the molar teeth by an extension of the pulp): present in about 40% of patients (versus 1% in normal XY individuals)
5. Cardiac and circulatory problems
   a. Mitral valve prolapse (55% of patients)
   b. Varicose veins (20–40% of patients)
      i. Venous ulcers
      ii. Deep vein thrombosis
      iii. Pulmonary embolism
6. A slightly increased risk of autoimmune disorder
   a. Rheumatic diseases (Rovensky et al. 2010)
      i. Inflammatory rheumatic diseases
      ii. Rheumatoid arthritis
      iii. Juvenile idiopathic arthritis
      iv. Psoriatic arthritis
      v. Polymyositis/dermatomyositis
      vi. Systemic lupus erythematosus
      vii. Systemic sclerosis
      viii. Mixed connective tissue disease
      ix. Antiphospholipid syndrome
      x. Ankylosing spondylitis
   b. Thyroid disease
   c. Sjogren syndrome
   d. Diabetes mellitus
7. Sexual characteristics
   a. Gynecomastia secondary to elevated estradiol levels and increased estradiol/testosterone ratio
      i. Develop by late puberty in 30–50% of boys with Klinefelter syndrome
      ii. Risk of developing breast cancer: at least 20 times higher than normal
   b. Lack of secondary sexual characteristics secondary to decrease in androgen production
      i. Sparse facial, body, and sexual hair
      ii. High-pitched voice
      iii. Female type of fat distribution
   c. Male psychosexual orientation in most patients
   d. Subnormal libido
   e. Erectile dysfunction
   f. Oligospermia or azoospermia
   g. Testicular dysgenesis in postpubertal patients
      i. Small, firm testes
      ii. Testis size <10 mL
   h. Infertility and azoospermia resulting from atrophy of the seminiferous tubules
      i. Seen practically in all patients with a 47, XXY karyotype
      ii. Klinefelter syndrome mosaics (46,XY/47, XXY): can be fertile
8. Other characteristics
   a. An increased prevalence of extragonadal germ cell tumors in the mediastinum (Völki et al. 2006) and brain.
   b. More common varicose veins, venous stasis ulcers, and thromboembolic disease.
   c. The syndrome may go undiagnosed in the majority of affected men.
9. Klinefelter mosaics and variants
   a. Klinefelter mosaic (46,XY/47,XXY)
      i. Less severe manifestations
      ii. May have normal-sized testes
      iii. Less severe endocrine abnormalities
      iv. Less common gynecomastia and azoospermia
      v. Occasional fertile men

b. Klinefelter variants (Visootsak and Graham 2006)
   i. 48,XXYY variant (Tartaglia et al. 2008)
      a) Tall stature.
      b) Disproportionately long lower extremities.
      c) Clinodactyly.
      d) Pes planus.
      e) Hypertelorism.
      f) Dental problems.
      g) Gynecomastia.
      h) Intention tremor.
      i) Neurodevelopmental disorders, including developmental delays, ADHD, autism spectrum disorders, mood disorders, and tic disorders.
      j) Unusual dermatoglyphic patterns.
      k) Peripheral vascular disease, especially varicose veins and stasis dermatitis.
      l) Poorly developed secondary sexual characteristics.
      m) Hypogonadism.
      n) Testicular histology similar to that of 47, XXY patients.
      o) The sex chromatin pattern indistinguishable from that of the 47,XXY patients except two fluorescent Y bodies are present in a high proportion of somatic nuclei.
   ii. 48,XXXY variant
      a) Moderate to severe mental retardation
      b) Behavior: often immature and consistent with IQ level, typically described as passive, cooperative, and not particularly aggressive
      c) Normal to tall stature
      d) Dysmorphic facies
      e) Radioulnar synostosis
      f) Fifth finger clinodactyly
      g) Hypergonadotropic hypogonadism
      h) Small testes
      i) Signs of androgen deficiency
   iii. 49,XXXYY variant
      a) Mental retardation
      b) Somatic anomalies
      c) Small testes
   iv. 49,XXXXY variant: severity and frequency of somatic anomalies increase as the number of X chromosomes increases
      a) Mental retardation
      b) Microcephaly
      c) Short stature
      d) Hypotonia with lax joints
      e) Facial dysmorphic features: ocular hypertelorism, flat nasal bridge, epicanthal folds, bifid uvula, or cleft palate
      f) Short neck
      g) Congenital heart defects
      h) Radioulnar synostosis
      i) Genu valgum
      j) Pes cavus
      k) Fifth finger clinodactyly
      l) Hypergonadotropic hypogonadism with small genitalia
      m) Behavioral disorders: shy, friendly, occasional irritability, temper tantrums, low frustration tolerance, and difficulty changing routines

Diagnostic Investigations

1. Cytogenetic studies
   a. 47,XXY (80–90%)
   b. Mosaicism (10%)
      i. 46,XY/47,XXY
      ii. 46,XY/48,XXXY
      iii. 47,XXY/48,XXXY
   c. Variants
      i. 48,XXYY
      ii. 48,XXXY
      iii. 49,XXXYY
      iv. 49,XXXXY
   d. Structural abnormal X in addition to a normal X and Y
      i. 47,X,i(Xq)Y
      ii. 47,X,del(X)Y
2. Endocrinologic studies
   a. A variable degree of feminization and insufficient androgenization
      i. Elevated plasma FSH, luteinizing hormone, and estradiol levels
      ii. Low plasma testosterone levels in patients age 12–14 years
   b. Subnormal increased testosterone in response to human chorionic gonadotropin administration
3. Imaging studies
   a. Echocardiography to demonstrate mitral valve prolapse

   b. Radiography
      i. Lower bone mineral density
      ii. Radioulnar synostosis
      iii. Taurodontism
4. Histology
   a. Small, firm testes
   b. Seminiferous tubular hyalinization, sclerosis, and atrophy with focal hyperplasia of mostly degenerated Leydig cells
   c. Deficient or absent germ cells
   d. Rare spermatogenesis (azoospermia)
   e. Progressive degeneration and hyalinization of seminiferous tubules after puberty in mosaic patients

Genetic Counseling

1. Recurrence risk
   a. Patient's sibs: recurrence risk not increased for nonmosaic patients
   b. Patient's offspring
      i. Recurrence risk not increased since all 47, XXY individuals are infertile
      ii. Report of paternity in nonmosaic 47,XXY males (no other tissues were examined for possible mosaicism with a 46,XY cell line)
   c. A risk of having a 47,XXY offspring in a few 46, XY/47,XXY mosaic patients who fathered a child
2. Prenatal diagnosis
   a. Cytogenetic analysis of fetal cells obtained from amniocentesis and CVS.
   b. Dilemma for parents since prognosis for the fetus with XXY is good but the possibility of phenotypic abnormalities does exist.
   c. Explanation to each couple the genetic risks resulting from intracytoplasmic sperm injection (ICSI) (increased risk of sex chromosome and autosome abnormalities).
   d. Preimplantation genetic diagnosis by embryo biopsy offers an efficient tool for embryo selection (Friedler et al. 2001).
3. Management
   a. Speech therapy.
   b. Physical therapy.
   c. Occupational therapy.
   d. Educational services.
   e. Reassurance of patients that most of the clinical features can be explained by the diminished ability of the testes to produce testosterone.
   f. Testosterone replacement: Optimal time to initiate therapy is at age 11–12 years of age to allow for the maximum effect and permit boys to experience pubertal changes with their peers.
      i. Corrects hormone imbalance (symptoms of androgen deficiency)
      ii. Improves self-image
      iii. Positive effect on mood and behavior
      iv. Increase in masculinity
      v. Increase in strength
      vi. Increase in libido
      vii. Increase in facial and pubic hair
      viii. Diminish fatigue and irritability
      ix. No positive effect on infertility
   g. Management of gynecomastia
      i. Androgen replacement therapy effective in achieving regression of less severe gynecomastia in some patients
      ii. Reduction mammoplasty or liposuction for severe or psychologically disturbing gynecomastia
   h. Management of infertility (Lanfranco et al. 2004)
      i. Nowadays patients with Klinefelter syndrome, including the nonmosaic type, need no longer be considered irrevocably infertile because intracytoplasmic sperm injection offers an opportunity for procreation even when there are no spermatozoa in the ejaculate.
      ii. In a substantial number of azoospermic patients, spermatozoa can be extracted from testicular biopsy samples, and pregnancies and live births have been achieved.
      iii. The frequency of sex chromosomal hyperploidy and autosomal aneuploidies is higher in spermatozoa from patients with Klinefelter syndrome than in those from normal men. Thus, chromosomal errors might in some cases be transmitted to the offspring of men with this syndrome.
      iv. The genetic implications of the fertilization procedures, including pretransfer or prenatal genetic assessment, must be explained to patients and their partners.

Klippel–Feil Syndrome

In 1912, Klippel and Feil described a patient with a short neck, a low posterior hairline, and a severe restriction of motion of the neck due to complete fusion of the cervical vertebrae. These features now constitute a clinical triad of the Klippel–Feil syndrome (KFS) (Hensinger et al. 1974).

Synonyms and Related Disorders

Cervical vertebral fusion

Genetics/Basic Defects

1. Genetic etiology unknown.
   a. Sporadic in majority of cases
   b. Rare autosomal dominant transmission: identification of a familial KFS gene locus on 8q [inv(8)(q22.2q23.3)] segregated with congenital vertebral fusion
2. Mechanism: failure in the process of segmentation of the vertebra.
3. Possible causes of phenotypic variation (Pourguie and Kusumi 2001).
   a. Variable expression of single genes
   b. Associated phenotypes due to deletions or large-scale rearrangements that disrupt several genes
   c. Secondary phenotypes resulting from disruption of normal cervical vertebral patterning
4. Familial Klippel–Feil syndrome.
   a. Characterized by congenital fusion of spinal vertebrae in addition to other congenital anomalies
      i. Otolaryngological abnormalities
      ii. Craniofacial abnormalities
   b. The first KFS gene (*SGM1*) locus identified on chromosome 8q [inv(8)(q22.2q23.3)] segregating with vertebral fusions and associated vocal impairment within the family
5. Suggestion of a possible role of *PAX1* haploinsufficiency in Klippel–Feil syndrome (McGaughran et al. 2003).
   a. Observation that the mouse *PAX1* mutant phenotype *undulated* is characterized by vertebral segmentation defects reminiscent of the human disorder Klippel–Feil syndrome.
   b. Observation of differences in the *PAX1* sequence (missense, silent, or intronic changes not represented in the control panel tested) in 6 out of 63 patients.
6. Mutations in growth/differentiation factor 6 (*GDF6*, on chromosome 8q22.1) are associated with vertebral segmentation defects in Klippel–Feil syndrome (Tassabehji et al. 2008).
   a. Mutations at the *GDF6* gene locus in familial and sporadic cases of KFS including the recurrent missense mutation of an extremely conserved residue c.866T>C (p.Leu289Pro) in association with mirror movements and an inversion breakpoint downstream of the gene in association with carpal, tarsal, and vertebral fusions.
   b. *GDF6* is expressed at the boundaries of the developing carpals, tarsals, and vertebrae and within the adult vertebral disc.
   c. *GDF6* knockout mice are best distinguished by fusion of carpals and tarsals, and *GDF6* knockdown in *Xenopus* results in a high incidence of anterior axial defects consistent with a role for *GDF6* in the etiology.

Clinical Features

1. Triad seen in <50% of patients indicating almost complete cervical involvement and may be clinically evident at birth (Herman and Pizzutillo 1999)
   a. Short, webbed neck
   b. Low posterior hairline
   c. Limitations of cervical motion (lateral bend and rotation) with associated congenital cervical fusions
2. Facial asymmetry
3. Torticollis
4. Associated anomalies
   a. Congenital scoliosis (60%)
   b. Sprengel deformity (30%)
      i. Congenital elevation of the scapula resulting from interruption of the normal caudal migration of the scapula
      ii. Hypoplastic scapula
      iii. Scapula fixation
      iv. Associated anomalies including absent or fused ribs, chest wall asymmetry, Klippel–Feil syndrome, cervical ribs, congenital scoliosis, cervical spina bifida, and presence of omovertebral bone
   c. Hearing impairment (audiologic testing) (30%)
   d. Synkinesia (mirror movements) (20%)
   e. Renal anomalies (35%) (renal ultrasound)
      i. Unilateral renal agenesis (most common renal anomaly)
      ii. Renal malrotation
      iii. Horseshoe kidney
      iv. Ectopic kidney
      v. Renal pelvic and ureteral duplication
      vi. Renal dysgenesis
   f. Congenital heart disease (14%): most common being ventricular septal defect
   g. Hemifacial microsomia
   h. Neural tube defects
   i. Ptosis
   j. Cervico-oculo-acoustic (Wildervanck) syndrome
      i. Mixed hearing loss
      ii. Fused cervical vertebra
      iii. Bilateral abducens palsy with retracted bulb (Duane syndrome)
   k. Lateral rectus palsy
   l. Facial nerve palsy
   m. Upper extremity anomalies
5. Complaints
   a. Issues of appearance
   b. Torticollis (head tilt)
   c. Neck pain
   d. Changes in exercise tolerance
   e. Excessive instability of the upper cervical spine
   f. Problems related to associated anomalies
   g. Neurological problems from direct irritation of or impingement on a nerve root or from compression of the spinal cord
      i. Cranial nerve abnormalities
      ii. Cervical radiculopathy from involvement of the nerve root
      iii. Symptoms from spinal cord compression
         a) Spasticity
         b) Hyperreflexia
         c) Muscle weakness
         d) Complete paralysis
      iv. At risk of sustaining a neurologic deficit including quadriplegia after minor trauma
6. Three clinical subtypes (Gunderson et al. 1967)
   a. Type I characterized by massive cervical and thoracic vertebral fusions into bony blocks
   b. Type II with fusion at one or two vertebral junctures, occipitoatlantal fusion, lower thoracic abnormalities, and more severe cervicothoracic fusions
   c. Type III with both cervical and lower thoracic or lumbar fusions
7. Risk factors
   a. Type I and III fusions
      i. Various neurologic, cutaneous, cardiac, skeletal, and oral anomalies
      ii. Difficulty in the birth process
      iii. Marked abnormal facial appearance with Sprengel deformity, accessory ear lobes, and pterygium colli
      iv. Serious neurologic anomalies with early death or long-term neurologic deficits
   b. Type II fusion
      i. Normal appearance
      ii. Normal lives
      iii. Incidental symptoms from osteoarthritis, basilar impression, or occiptio-atlas fusion
   c. Hypermobility of the upper cervical spine at increased risk of neurologic injury

with presentation of neurologic sequelae in the teens or 20s
   d. Lower cervical involvement at risk of developing cervical spondylosis at more advanced ages

Diagnostic Investigations

1. Audiologic evaluation for hearing loss
2. Renal ultrasonography
3. Radiography (Hensinger et al. 1974)
   a. Cervical spine fusion on flexion and extension views: roentgenographic hallmark of the Klippel–Feil syndrome
      i. Type I cervical fusion (C2–C3 fusion with occipitalization of the atlas)
      ii. Type II cervical fusion (long cervical fusion with an abnormal occipitocervical junction)
      iii. Type III cervical fusion (two blocked vertebral segments with a single open interspace)
   b. Other associated skeletal anomalies
      i. Flattening and widening of involved vertebral bodies
      ii. Absent disc spaces
4. CT scan helpful in diagnosing nerve root and spinal cord impingement by osteophyte
5. MRI to evaluate instability and the risk of neurological compromise
   a. Spinal stenosis
   b. Cord compression
   c. Syringomyelia
6. Molecular genetic diagnosis: clinically available
   a. Analysis of the entire coding region
   b. Sequence analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent has an autosomal dominant disorder
   b. Patient's offspring: not increased unless the patient has an autosomal dominant type of the disorder
2. Prenatal diagnosis
   a. Ultrasonography: difficult to diagnose cervical vertebral anomalies and torticollis by ultrasonography
   b. Molecular genetic analysis on fetal DNA obtained from amniocentesis or CVS for *GDF6* mutation, provided the disease-causing allele of an affected family member has been identified prior to prenatal diagnosis
3. Management
   a. Treat renal, cardiovascular, and auditory anomalies accordingly
   b. Mechanical symptoms caused by degenerative joint disease
      i. Traction
      ii. Wearing a cervical collar
      iii. Analgesics
   c. Neurological symptoms
      i. Surgical stabilization with or without decompression
      ii. Surgical correction of Sprengel deformity to improve appearance

Klippel–Trenaunay Syndrome

Klippel–Trenaunay syndrome (KTS) is primarily a rare congenital capillary-venous vascular malformation associated with altered limb bulk and/or length. In 1900, Klippel and Trenaunay first reviewed systematically a condition consisting of capillary nevus, early onset of varicosities, and hypertrophy of tissues and bones of the affected limb. These three features constitute the primary diagnostic criteria of the syndrome today. The additional name Weber is sometimes added to describe those individuals who also have clinically significant arteriovenous malformations as a component of the syndrome, an association noted by Weber in 1918. More than 1,000 cases of Klippel–Trenaunay syndrome have now been reported in the literature (Berry et al. 1998).

Synonyms and Related Disorders

Klippel–Trenaunay–Weber syndrome

Genetics/Basic Defects

1. Etiology
   a. Sporadic occurrence
   b. Somatic mutation of an as-yet-unknown gene
   c. Multifactorial inheritance
   d. Autosomal dominant inheritance with variable expression
2. Genetics of KTS (Wang 2005): three chromosomal abnormalities reported in three different KTS patients
   a. Two balanced translocations t(5;11)(q13.3;p15.1) (Tian et al. 2004).
      i. Chromosomal breakpoints involved in translocation t(5;11)(q13.3;p15.1) have been fully characterized, which has led to the identification of a susceptibility gene, *AGGF1* (previously known as *VG5Q*), for KTS.
      ii. *AGGF1* is located on chromosome 5q13.3 and encodes an angiogenic factor.
      iii. *AGGF1* as the first susceptibility gene that confers a risk to the development of KTS, and suggests that that the molecular mechanism for the pathogenesis of KTS is the "increased" angiogenesis. These results are consistent with histological studies that showed an increase in both the number and diameter of the venules in the dermis and subdermal fat of KTS tissues (Baskerville et al. 1985).
   b. Translocation t(8;14)(q22.3;q13) (Wang et al. 2001) and an extra supernumerary ring chromosome 18 (Timur et al. 2004) were reported in patients with KTS.
      i. Shown to arise de novo, which strongly suggests that genetic factors contribute to the pathogenesis of KTS.
      ii. The specific vascular gene disrupted by either 8q22.3 or 14q13 breakpoints remains to be identified.
      iii. The ring chromosome 18, r(18), was mostly derived from the short arm of chromosome 18, and further analyses of the genes on the r (18) may lead to the identification of a vascular gene.
   c. Sporadic occurrence of KTS and a mosaic pattern of KTS features may be explained by the two-hit hypothesis and the concept of

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_143,
© Springer Science+Business Media, LLC 2012

paradominant inheritance proposed by Happle (Happle 1986, 1987, 1993).
   i. Germline mutations in a KTS gene (e.g., *AGGF1*) are important for development of KTS, but not sufficient
   ii. A "second hit," somatic mutation in the same KTS gene or in a different gene is required for the development of KTS features
3. Possible mechanisms/pathogenesis leading to overgrowth of the affected limb: poorly defined
   a. Two phases of manifestations
      i. Increased bulk or girth
      ii. Increased length accompanied by bone enlargement
   b. Increased girth and size of bone due to venous hypertension, based on observations following hind leg deep vein ligation in dogs
   c. Atresia of the venous system leading to stasis, edema, varicosities, and ultimately to limb elongation and hypertrophy
   d. Limb enlargement seen in children following thrombosis or ligation of a deep vein postnatally
   e. Overgrowth in fetal life promoted by increased blood flow through the abnormal capillary network and cutaneous venous channels
   f. A mesodermal defect acting on angiogenesis leading to the formation of hemangiomas and varicose veins (Martin et al. 2001)
   g. A defect in the process of vessel remodeling during embryogenesis

Clinical Features

1. Triad (Berry et al. 1998; Cohen 2000)
   a. Combined vascular malformations of the capillary, venous, and lymphatic types
   b. Varicosities of unusual distribution, in particular the lateral venous anomaly observed during infancy or childhood
   c. Limb enlargement
2. Cutaneous manifestations
   a. Primarily a diffuse capillary malformation
   b. Typically present on an affected limb
   c. May be present on any body part
   d. Often presenting as an irregular but relatively linear border
   e. Rarely crossing the midline when present on the trunk, sometimes exhibiting a sharp demarcation
3. Vascular malformations
   a. Typically combined with cutaneous capillary malformation
   b. Persistence of abnormal superficial veins associated with deep venous hypoplasia/duplications and abnormal venous valve formation
   c. Presence of mixed vascular malformations including capillary, venous, arterial, and lymphatic systems
   d. Classification of vascular malformations by Mulliken and Glowacki (1982)
      i. Capillary-venous malformation (CVM): typical finding
      ii. CVLM (CVM+lymphatic malformation): common finding
      iii. CLAVM (including arterial malformation): uncommon
   e. Congenital in nature
   f. Not responding to agents used in the treatment of hemangiomas such as prednisone or interferon-α
4. Limb hypertrophy
   a. Due to an increase in bulk of the subcutaneous tissues
   b. Bony hypertrophy
5. Sites of involvement (Mueller-Lessmann et al. 2001)
   a. Lower limb most common (about 95%)
   b. Upper limb (about 5%)
   c. Trunk only: uncommon
   d. Orofacial involvement
      i. Jaw enlargement
      ii. Facial asymmetry
      iii. Malocclusions
      iv. Premature tooth eruption
      v. Hemangioma of the lips, tongue, and oral mucosa
6. Sex ratio: males and females affected equally
7. Complications
   a. Abnormal vasculature
      i. Thrombosis
      ii. Coagulopathy
      iii. Pulmonary embolism
      iv. Heart failure (in the presence of significant AVM)
      v. Bleeding from abnormal vessels in gut, kidney, or genitalia

b. Gastrointestinal varicoses
   i. Bleeding
   ii. Pain
   iii. Diarrhea
c. Protein-losing enteropathy secondary to intestinal lymphangiectasia
d. Infection is a particular risk for patients with abnormal lymphatic drainage. Antibiotics indicated in:
   i. Cellulitis
   ii. Surgery
   iii. Injury in an affected limb
e. Pain due to venous insufficiency or lymphedema in some older children and adults
f. Venous thromboembolism
   i. Chronic thromboembolic pulmonary hypertension
   ii. Subsequent right ventricular failure
g. Occurrence of ulceration on affected leg
h. Rare occurrence of skin tumors on the affected limb
   i. Squamous cell carcinoma possibly secondary to a long-standing venous ulcer
   ii. Basal cell carcinoma
i. Pregnancy and KTS: known perinatal risks to both the mother and fetus (Fait et al. 1996; Stein et al. 2006)
   i. Hemorrhage secondary to increased hemangiomas and varices
   ii. Deep and superficial thrombosis
   iii. Acute and chronic disseminated intravascular coagulation
   iv. Kasabach–Merritt syndrome (Neubert et al. 1995)
   v. Placental abnormalities

8. Four levels of severity of Klippel–Trenaunay syndrome (You et al. 1983)
   a. Venous dysplasias: phlebectasic dysplasias (Klippel–Trenaunay syndrome)
   b. Arterial dysplasias
   c. Arterial and associated venous dysplasias:
      i. Phlebarterectasia (no arteriovenous shunt)
      ii. Angiodysplasias with shunt (Klippel–Trenaunay–Weber syndrome)
   d. Mixed angiodysplasias: a typical Klippel–Trenaunay syndrome
9. Diagnostic criteria: Presence of two of the three following cardinal features is sufficient to make a diagnosis (Jacob et al. 1998)
   a. Capillary malformations (98%)
   b. Venous malformations or varicose veins (72%)
   c. Hypertrophy of the affected tissues (67%)
10. Diagnostic criteria and proposed definition: two major features at least one from congenital vascular malformations, which should always include either capillary malformations or venous malformations and at least one from disturbed growth (bi or bii) (Oduber et al. 2008)
   a. Congenital vascular malformations
      i. Capillary malformations (CMs). This includes port-wine stains
      ii. Venous malformations (VMs): This includes hypoplasia or aplasia of veins, persistence of fetal veins, varicosities, hypertrophy, tortuosity, and valvular malformations
      iii. Arteriovenous malformations (AVMs): This includes only very small AVMs or arteriovenous fistulas (AVF)
      iv. Lymphatic malformations (LM): This includes any LM
      v. Localization
         a) CM can be located anywhere on the body, although location in the face is exceedingly rare
         b) AVM, VM, and LM are mainly located on the extremities and adjacent parts of the trunk (pelvis, shoulder) but in expressed forms of KTS also elsewhere (bladder, rectum, lower GI tract, penis, uterine, vulva, vagina, liver, kidneys, lung, spine)
         c) AVM, VM, and LM are not located in the face or brain
   b. Disturbed growth
      i. Disturbed growth of bone in the length or girth
      ii. Disturbed growth of soft tissue in the length or girth
      iii. The disturbed growth includes:
         a) Hypertrophy (frequent) of a small body part (isolated finger, macrodactyly) or larger body part (total limb, half of the total body)

b) Hypotrophy (infrequent) of a small or larger body part
iv. Can be present both on the same site as the vascular malformation(s) (frequent) and at another site (infrequent)

11. Four commonly held conceptions about Klippel–Trenaunay syndrome challenged
    a. Renaming Klippel–Trenaunay–Weber syndrome by addition of arteriovenous fistulas
        i. Significant arteriovenous communications not observed in Klippel–Trenaunay syndrome in large surgical series
        ii. Parkes Weber syndrome characterized by enlarged arteries and veins, capillary or venous malformations and enlargement of a limb
        iii. Lymphatic malformations found in Klippel–Trenaunay syndrome not observed in Parkes Weber syndrome
    b. Overlap with Sturge–Weber syndrome
        i. Characteristics of Sturge–Weber syndrome: craniofacial angiomatosis, port-wine nevus, and cerebral calcification.
        ii. Overgrowth in Sturge–Weber syndrome tends to be minor and is always secondary to the vascular anomaly. In contrast, overgrowth in Klippel–Trenaunay syndrome is striking.
    c. Presence of a bleeding diathesis of the Kasabach–Merritt type
        i. Kasabach–Merritt syndrome erroneously applied to patients with extensive venous or lymphaticovenous malformations who develop a localized intravascular coagulopathy in which the platelet count is minimally depressed (varying from 50,000 to 150,000/mm^3)
        ii. Profound thrombocytopenia in true Kasabach–Merritt phenomenon (varying from 3,000 to 60,000/mm^3)
    d. Familial aggregation with various genetic interpretations
        i. Inadequate documentation of cases
        ii. Over interpretation of minor manifestations in relatives, including "nevus flammeus," hemangiomas, and varicosities (common manifestations in general populations)
        iii. Klippel–Trenaunay syndrome defined as a capillary malformation with or without "hemihypertrophy" without mentioning of lymphatic malformations, lateral venous anomaly, lymphatic vesicles, or venous flares within the capillary malformation, or macrodactyly
    e. Klippel–Trenaunay syndrome, Parkes Weber syndrome, and Sturge–Weber syndrome
        i. Each occurring sporadically
        ii. Each considered separate entity because clinical manifestations and types of complications are different

Diagnostic Investigations

1. Color duplex ultrasonography (Berry et al. 1998)
    a. AV malformation
    b. Deep venous hypoplasia (a decrease in caliber of at least 50% of a vein along its length)
    c. Venous duplication
    d. Variable varicosities
2. Radiography
    a. Enlargement of the limb bones
    b. Yearly to monitor evidence of leg length discrepancy
3. Noninvasive imaging and endoscopy for severe gastrointestinal bleeding
4. Lymphoscintigraphy using radionuclide tracers
    a. Indication: edema or a girth discrepancy more than 4 cm
    b. No uptake of tracer along major lymphatics of the affected limb during repeated scans over at least a 1-h period
5. MRI
    a. Pelvis: to look for vascular malformations involving the kidneys, bladder, or intestines
    b. MRI with gadolinium to distinguish lymphatic from venous malformations
    c. Magnetic resonance venogram or phlebography/venography to document the lateral venous anomaly and any abnormalities that may be present in the deep veins of the leg
    d. Able to demonstrate arteriovenous fistulas in Parkes Weber syndrome

Genetic Counseling

1. Recurrence risk
    a. Patient's sib: not increased
    b. Patient's offspring: not increased (doubtful that autosomal dominant inheritance exists)

2. Prenatal diagnosis
   a. Ultrasonography
      i. Asymmetric limb hypertrophy associated with cutaneous or subcutaneous cystic or multicystic lesions
      ii. Limb edema
      iii. Cardiac failure ranging from isolated cardiomegaly to severe hydrops
   b. MRI
      i. Limb hypertrophy
      ii. Multiple subcutaneous and internal hemangiomas
      iii. Good definition of soft tissue lesions
      iv. Identify vascular malformations and their extent
      v. Presence of low signal indicating flow voids, hemosiderin deposits or calcification indicative of vascular malformations
3. Management (James et al. 1999; Gloviczki and Driscoll 2007)
   a. Elastic garment or compression bandage: beneficial in managing both lymphedema and chronic venous insufficiency
   b. Physical therapy using massage treatment and intermittent pneumatic compression therapy
   c. Local wound care, compression dressings, special orthopedic footwear, and lifestyle modification
   d. Psychological support: participate in the activities of a support group
   e. Stripping of superficial varicose veins
   f. Pulsed dye laser treatment for superficial hemangioma component (Jih 2003)
   g. Sclerotherapy and embolotherapy
   h. Reduction of significant arteriovenous malformations
   i. Rare reconstructive surgery at sites of deep venous obstruction
   j. Orthopedic procedures for overgrowth
      i. Significant leg length discrepancy (epiphysiodesis)
      ii. Excision of soft tissue hypertrophy

Fig. 1 A newborn with Klippel–Trenaunay syndrome showing overgrowth of left leg with vascular malformation

Fig. 2 A neonate with Klippel–Trenaunay syndrome showing left leg overgrowth with vascular malformation

Fig. 3 (**a**, **b**) A boy with Klippel–Trenaunay syndrome showing overgrowth of the right arm and leg with vascular malformation

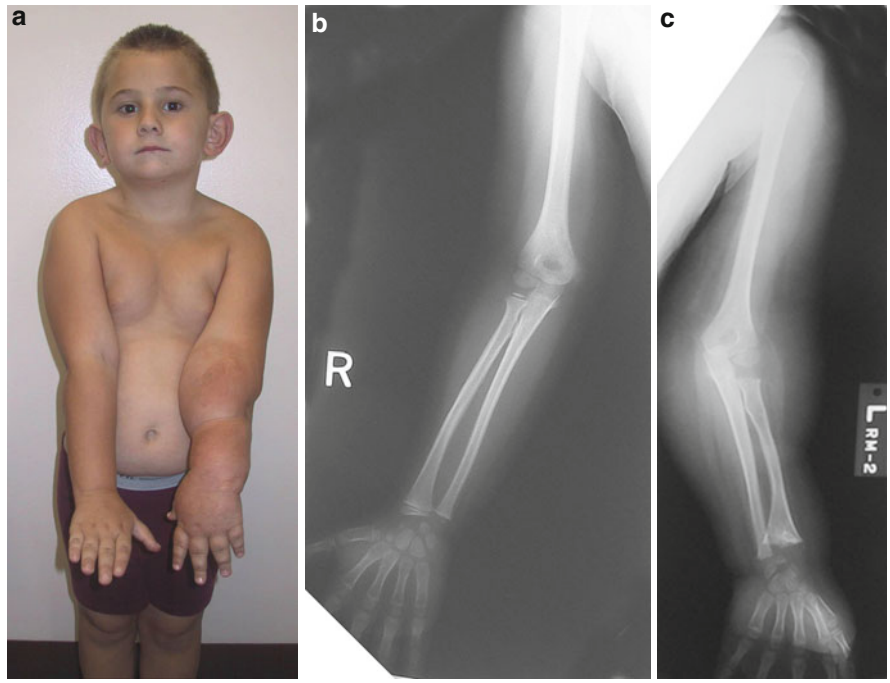

Fig. 4 (**a**–**c**) A 6-year-old boy with Klippel–Trenaunay syndrome showing overgrowth of left arm (illustrated by radiographs) associated with vascular malformation

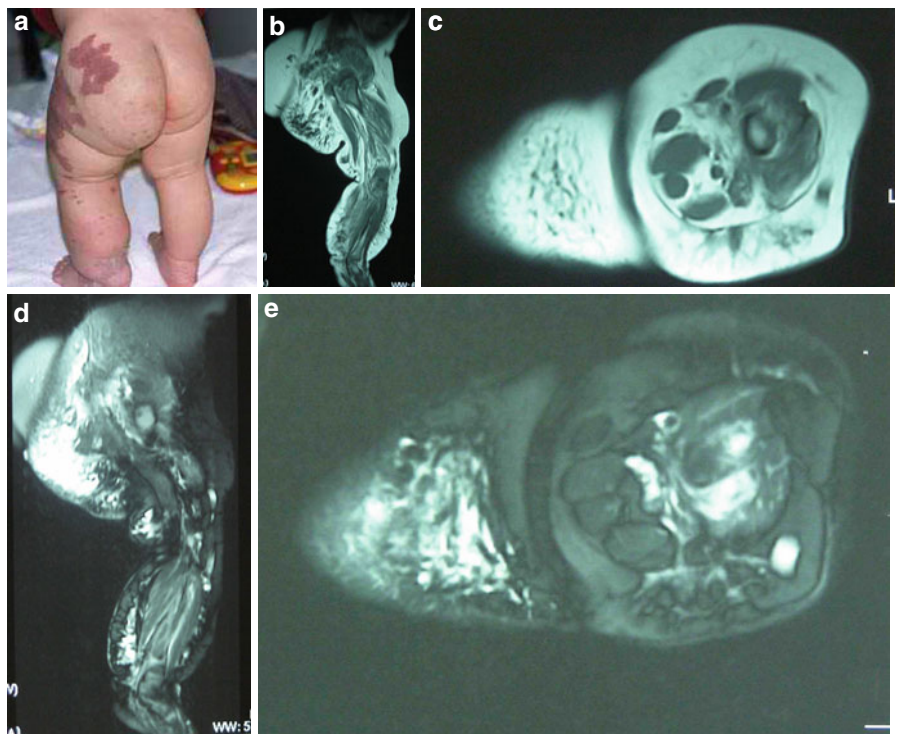

Fig. 5 A 1-year-old infant with Klippel–Trenaunay syndrome showing asymmetric lower extremities with hypertrophic left lower extremity associated with vascular malformation (**a**). T1-enhanced MRI (**b**, **c**) and T2-enhanced MRI (**d**, **e**) images at thigh level show cystic and vascular lesions, indicated by high signals suggesting lymphangiomas and hemangiomas

Kniest Dysplasia

Kniest dysplasia is a type II collagenopathy with characteristic clinical, radiographic, and histological findings. Kniest dysplasia is distinguished by platyspondyly and delay in ossification of the proximal epiphyses. After ossification, the epiphyses are enlarged resulting in dumbbell-shaped long bones.

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant (Wilkin et al. 1999)
   b. New dominant mutations in most cases
2. Molecular basis
   a. Caused by mutations in the gene (*COL2A1*) that encodes type II collagen, the predominant protein of cartilage
   b. A specific type of mutation and/or position of mutation within the collagen chain may explain the unique features of Kniest dysplasia among the type II collagenopathies
3. Kniest dysplasia in the middle of the following phenotypic spectrum of disease
   a. Achondrogenesis type II/hypochondrogenesis at the severe end
   b. Spondyloepiphyseal dysplasias/spondyloepimetaphyseal dysplasias in the middle
   c. Genetically heterogeneous Stickler syndrome and familial osteoarthritis at the milder end

Clinical Features

1. Sk eletal anomalies (Wilkin et al. 1999)
   a. Disproportionate dwarfism
   b. A short trunk
   c. Short, slightly bowed limbs
   d. More severe rhizomelic shortness in the lower limbs
   e. Prominent joints
   f. Delayed motor milestones secondary to joint deformities
   g. Progressive and painful joint enlargement accompanied by joint contractures
   h. Muscle atrophy resulting from disuse
   i. Short and broad thorax with sternal protrusion
   j. Kyphoscoliosis
      i. Dorsal kyphosis
      ii. Accentuated lumbar lordosis
      iii. Thoracic scoliosis
   k. Odontoid hypoplasia resulting in atlantoaxial instability
   l. Clubfoot
   m. Small pelvis
   n. Premature osteoarthritis that restrict movement
   o. Waddling gait
2. Craniofacial characteristics
   a. Relatively large head
   b. Flat face
   c. Shallow supraorbital ridges

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_144,
© Springer Science+Business Media, LLC 2012

   d. Prominent eyes
   e. Flat nasal bridge
   f. Short nose
   g. Micrognathia
   h. Cleft palate
3. Ocular manifestations
   a. Abnormal long axial length causing high early-onset myopia
   b. Vitreoretinal degeneration
   c. Retinal detachment
   d. Cortical and posterior subcapsular opacity of the lens
   e. Veil-like vitreous opacity in the periphery
   f. Congenital glaucoma
   g. Blindness
4. Hearing loss
5. Prognosis: phenotype varying significantly
   a. Frequently potentially life-threatening complications
      i. Early postnatal tracheomalacia resulting in respiratory insufficiency and feeding difficulties
      ii. Secondary failure to thrive
   b. Can lead a relatively normal life with mild disproportionate short stature, kyphoscoliosis, and/or craniofacial manifestations

Diagnostic Investigations

1. Radiography (Gilbert-Barnes et al. 1996; Wilkin et al. 1999)
   a. Distinguishing radiographic features from other type II collagenopathies identifiable at birth
      i. Coronal clefts of the vertebrae
      ii. Dumbbell-shaped femora
   b. Other radiographic features
      i. Narrowed joint spaces
      ii. Platyspondyly
      iii. Kyphoscoliosis
      iv. Short tubular bones
      v. Dysplastic epiphyses and metaphyses
         a) Broad metaphyses
         b) Enlarged and deformed epiphyses
2. MR imaging of both unossified and ossified epiphyses reveals a similar pattern of lakes of bright T2 signal against a relatively normal background, representing an interesting analogue to the histologic and radiographic features (Dwek 2005)
3. Histopathology (Gilbert-Barnes et al. 1996)
   a. Pathologic changes of cartilage
      i. "Swiss cheese" appearance of the cartilage matrix (a bizarre pattern of chondrocytes lying amid a highly vacuolated matrix) (Dwek 2005)
      ii. Ossified epiphyses: unusual in showing clouds of dense punctuate calcifications randomly distributed throughout
      iii. Soft crumbly cartilage
   b. Microscopic changes
      i. Disorganization of the growth plate.
      ii. Deficiency of collagen matrix.
      iii. Poorly staining cartilage with myxoid degeneration.
      iv. PAS positive cytoplasmic inclusions in many chondrocytes. Ultrastructurally, the inclusions correspond to pools of proteinaceous material within dilated rough endoplasmic reticulum.
4. Hearing test
5. Visual evaluation
6. Molecular genetic analysis of *COL2A1* gene mutation
   a. Targeted mutation analysis
   b. Mutation scanning
   c. Sequencing of entire coding region

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low recurrence risk unless a parent is affected or has gonadal mosaicism
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Difficult to diagnose Kniest dysplasia by early sonography since the biometry does not become notably abnormal until the third trimester (Bromley et al. 1991).
   b. Fetal MRI findings: By delineating the cartilaginous abnormalities, fetal MRI can contribute to the prenatal diagnosis of chondrodysplasias (Yazici et al. 2010).
      i. Enlarged hyaline cartilaginous structures with abnormally high T2 signal intensity
      ii. Delayed ossification of the pubic and ischial bones
      iii. Platyspondyly

c. Molecular genetic analysis of *COL2A1* mutation on fetal DNA obtained from amniocentesis or CVS for previously characterized disease-causing gene mutation in the proband.

3. Management
   a. Cleft palate repair
   b. Hearing aid for hearing loss
   c. Vitrectomy and silicon oil injection for reattaching the retina from retinal detachment
   d. Orthopedic care for clubfoot and kyphoscoliosis

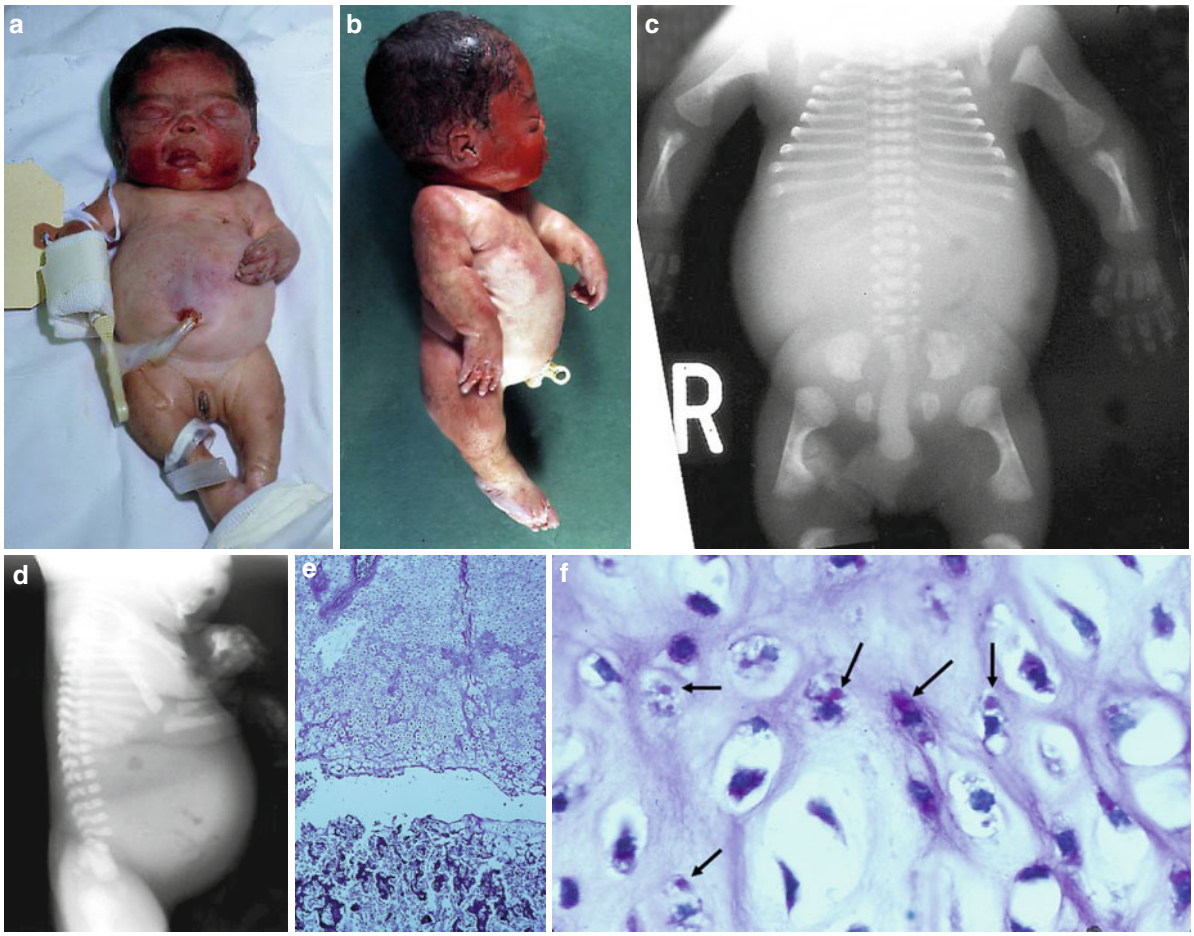

Fig. 1 (**a**–**f**) A neonate with Kniest dysplasia showing short trunk and large head, similar to SED congenita. However, the moderately shortened limbs show prominent joints. Radiographs show enlarged metaphyses of limb bones (dumbbell-shaped femora) and coronal clefts of the vertebrae. The remaining findings are similar to those of SED congenita. The physeal growth zone of femur is hypercellular and disorganized. The transverse cleft beneath the physis is an artifact. Many chondrocytes contain cytoplasmic inclusions (*arrows*); they are seen in the resting cartilage and the zone of proliferation, similar to those of SED congenita

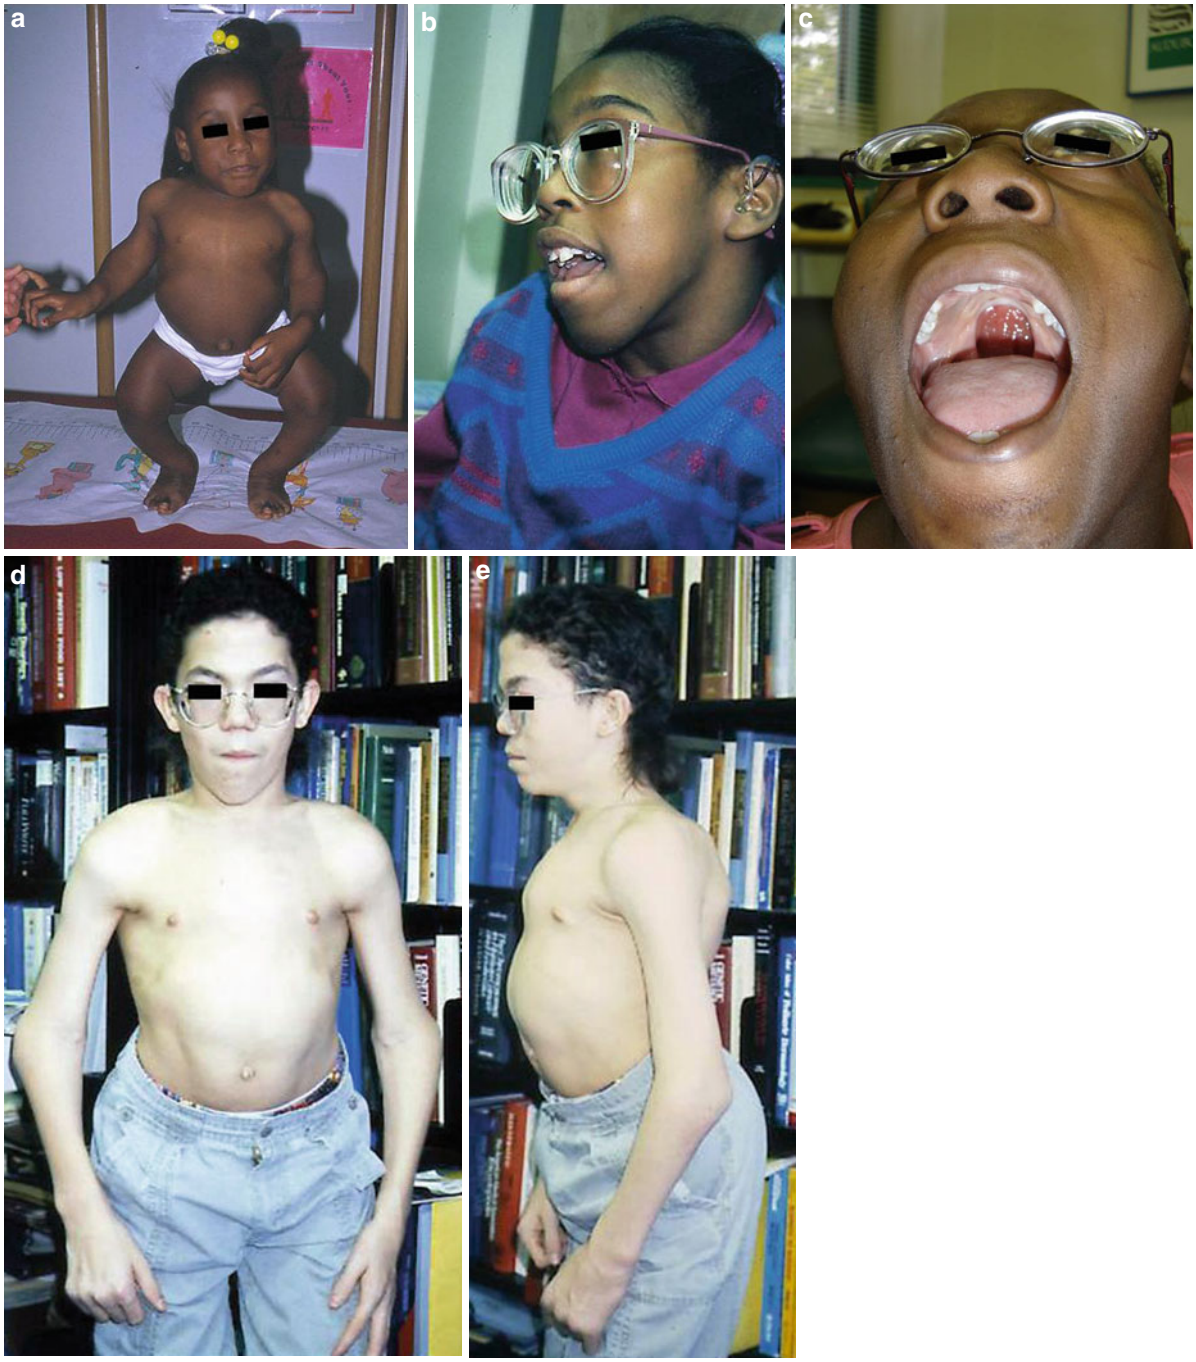

Fig. 2 (**a**–**e**) Three children with Kniest dysplasia showing varying features of the dysplasia: short trunk dwarfism, flat facies, myopia, cleft palate, deafness requiring hearing aids, dorsal kyphosis, accentuated lumbar lordosis, short and broad thorax with sternal protrusion, and prominent joints with restricted joint mobility

Larsen Syndrome

In 1950, Larsen et al. described a condition characterized by multiple large joint dislocations and flat face (Larsen et al. 1950). The condition occurs in approximately 1 in 100,000 births.

Synonyms and Related Disorders

Lethal Larsen-like syndrome; Multiple joint dislocations, short stature, craniofacial dysmorphism, and congenital heart defects

Genetics/Basic Defects

1. Subtypes
   a. Sporadic form
   b. Autosomal dominant form
   c. Autosomal recessive form: clinical phenotype more debilitating with higher mortality than the autosomal dominant form
   d. Possible lethal form
2. The first known gene mutated in Larsen syndrome, *LAR1*, for autosomal dominant form: mapped to 3p21.1-14.1 in the proximity of, but distinct from, the *COL7A1* locus.
3. Clinical similarities between Larsen syndrome and a group of lethal osteochondrodysplasias including atelosteogenesis types I (AOI) and III (AOIII) and boomerang dysplasia suggested that they represent an allelic series of conditions (Hunter and Carpenter 1991; Sillence et al. 1997).
   a. These more severe dysplasias are characterized by underossification of skeletal elements, hypoplastic or absent limb bones, joint dislocations, and craniofacial abnormalities.
   b. These observations, with the phenotypic similarities between Larsen syndrome and otopalatodigital syndrome type 1 (OPD1), an X-linked skeletal disorder caused by mutations in *FLNA* (Robertson et al. 2003), the gene encoding filamin A, led to the description of mutations in the paralogous gene filamin B gene (*FLNB*) underlying Larsen syndrome, AOI, AOIII, and boomerang dysplasia. (Bicknell et al. 2005; Krakow et al. 2004).
   c. Mutations leading to AOI and AOIII were clustered in calponin homology domain 2 (CH2) and repeats 13–17 (Farrington-Rock et al. 2006).
4. Molecular and clinical study of Larsen syndrome caused by mutations in *FLNB* (Bicknell et al. 2007)
   a. The clinical signs most frequently associated with an *FLNB* mutation are the presence of supernumerary carpal and tarsal bones and short, broad, spatulate distal phalanges, particularly of the thumb.
   b. All individuals with Larsen syndrome–associated *FLNB* mutations are heterozygous for either missense or small inframe deletions.
      i. Three mutations are recurrent, with one mutation, 5071GRA, observed in 6 of 20 subjects.
      ii. The distribution of mutations within the *FLNB* gene is nonrandom, with clusters of mutations leading to substitutions in the actin-binding domain and filamin repeats 13–17 being the most common cause of Larsen syndrome.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_145,
© Springer Science+Business Media, LLC 2012

   c. These findings collectively define autosomal dominant Larsen syndrome and demonstrate clustering of causative mutations in *FLNB*.
5. Molecular basis of recessive Larsen syndrome (Hermanns et al. 2008)
   a. Eight *CHST3* (carbohydrate sulfotransferase 3, also known as chondroitin 6-sulfotransferase) mutations, causing CHST3 deficiency, were identified in six unrelated individuals who presented at birth with congenital joint dislocations.
      i. These patients had been given a diagnosis of either Larsen syndrome (three individuals) or humero-spinal dysostosis (three individuals), and their clinical features included congenital dislocation of the knees, elbow joint dysplasia with subluxation and limited extension, hip dysplasia or dislocation, clubfoot, short stature, and kyphoscoliosis developing in late childhood.
      ii. Analysis of chondroitin sulfate proteoglycans in dermal fibroblasts showed markedly decreased 6-O-sulfation but enhanced 4-O-sulfation, confirming functional impairment of CHST3 and distinguishing them from diastrophic dysplasia sulfate transporter (DTDST)–deficient cells.
   b. These observations provide a molecular basis for recessive Larsen syndrome and indicate that recessive Larsen syndrome, humero-spinal dysostosis, and spondyloepiphyseal dysplasia Omani type form a phenotypic spectrum.
6. Unilateral manifestation of typical skeletal defects in some patients indicates that this condition might represent unilateral somatic cell-line mosaicism.

Clinical Features

1. Broad inter- and intrafamilial clinical variability
2. Characteristic flat facial appearance ("dish face")
   a. Prominent forehead (frontal bossing)
   b. Hypertelorism
   c. Hypoplastic midface
   d. Depressed nasal bridge
   e. Micrognathia
   f. Occasional cleft palate, lip, or uvula
3. Bilateral multiple joint dislocations
   a. Shoulders
   b. Elbows
   c. Wrists
   d. Hips
   e. Patella
   f. Ankles
   g. Knees
4. Variable handicap due to joint luxations
5. Hand abnormalities
   a. Long, cylindrical, and tapering fingers (pseudoclubbing)
   b. Spatulate/bifid thumbs
   c. Dislocation of distal radioulnar joint
   d. Delayed carpal ossification
   e. Supernumerary ossification centers
   f. Brachymetacarpia
   g. Brachytelephalangia
   h. Hyperextension of distal interphalangeal joints
6. Feet abnormalities
   a. Spatulate hallux
   b. Equinovarus or valgus deformities of the feet
7. Respiratory distress due to tracheolaryngomalacia
   a. Stridor
      i. Inspiratory reflecting laryngomalacia or extrathoracic cervical tracheomalacia
      ii. Expiratory reflecting intrathoracic tracheomalacia
   b. Cyanosis
   c. Obstructive apnea
   d. Possibly life-threatening
8. Bronchomalacia
   a. Lobar atelectasis
   b. Hyperinflation
   c. Pneumonias
9. Respiratory embarrassment in infancy due to soft tracheolaryngeal cartilage
10. Soft/collapsing thorax
11. Cardiovascular abnormalities
   a. Congenital defects
      i. Bicuspid aortic valve
      ii. Subaortic stenosis
      iii. Atrial septal defect
      iv. Ventricular septal defect
      v. Patent ductus arteriosus
      vi. Pulmonary stenosis
      vii. Endocardial fibroelastosis

b. Acquired lesions
   i. Dilated aortic root
   ii. Elongated aorta
   iii. Mitral valve prolapse
   iv. Aneurysm of ductus arteriosus
   v. Arterial tortuosity and dilatation
12. Associated spinal anomalies (Banks et al. 2003)
   a. Cervical spine involvement
      i. More often affected than thoracic or lumbar spine
      ii. Results in:
         a) Midcervical kyphosis, usually at the C4-5 region
         b) Cervicothoracic lordosis
         c) Spinal instability
      iii. Flattened, hypoplastic, and often bifid cervical vertebrae
   b. Atlantoaxial instability
      i. A rare finding
      ii. May be associated with other abnormalities of the upper cervical spine
         a) Occipitalization of the atlas
         b) Basilar impression
   c. Lumbosacral dysraphism: may lead to neurological impairment
   d. Thoracic scoliosis
   e. Hypoplasia of the vertebral bodies or posterior elements
   f. Quadriplegia secondary to segmentation abnormalities of the vertebrae
13. Mixed hearing loss due to ossicular abnormality
14. CNS anomalies
   a. Hydrocephalus (rare)
   b. Glial proliferation in the brain
15. Short stature
16. Normal intelligence
17. Possible lethal form
   a. Tracheomalacia
   b. Pulmonary hypoplasia
   c. Collagen fiber dysmaturity
18. Prognosis
   a. Generally good after aggressive orthopedic management, except some lethal cases due to tracheolaryngomalacia and/or lung hypoplasia
   b. Compatible with successful pregnancy if the maternal and fetal safety issues are properly considered

Diagnostic Investigations

1. Radiography
   a. Bilateral dislocations of shoulders, elbows, wrists, hips, patella, ankles, and knees (anterior dislocation of the tibia on the femur, most characteristic)
   b. Genu recurvatum
   c. Talipes deformities (clubfeet)
   d. Spatulate thumbs
   e. Shortened metacarpals
   f. Multiple supernumerary carpal ossification centers (short, small, and increased in number)
   g. Poor ossification of phalanges
   h. Delayed coalescence (duplication) of calcaneal ossification centers
   i. Occasional abnormal segmentation of vertebrae (+/− fusion defects of cervical spine)
   j. Cervical kyphosis
   k. Spina bifida occulta
   l. Scoliosis
   m. Craniofacial disproportion
2. Polysomnography for assessing the severity of airway obstruction
3. Echocardiography for cardiovascular lesions
4. MRI of the brain for cerebral malformations
5. Diagnosis: based on clinical and radiographic findings and confirmed by *FLNB* molecular genetic testing

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic form (consider germ-line mosaicism when neither parent appears to be affected)
      ii. Autosomal dominant inheritance: risk not increased unless a parent is affected
      iii. Autosomal recessive inheritance: 25% risk of having sibs affected
   b. Patient's offspring
      i. Sporadic form: risk not increased unless the patient has germ-line mosaicism
      ii. Autosomal dominant inheritance: 50% risk of having offspring affected

iii. Autosomal recessive inheritance: risk not increased unless the spouse is also a carrier

2. Prenatal diagnosis
   a. Ultrasonography: prenatal diagnosis accomplished in rare cases by ultrasonography in pregnancies at risk
      i. Multiple joint dislocations
         a) Elbow
         b) Knees
         c) Hips
      ii. Flat facial profile
         a) Prominent forehead
         b) Hypertelorism
         c) A depressed nasal bridge
         d) Micrognathia
         e) Cleft palate
      iii. Genu recurvatum
      iv. Clubfeet
   b. Molecular genetic testing: possible for at-risk pregnancies provided that prior identification of the disease-causing mutation(s) in the family is done
3. Management
   a. Supporting therapy for airway difficulty
      i. Antibiotics as needed
      ii. Supplemental oxygen
      iii. Chest physiotherapy to augment mucus clearance
      iv. Require intubation for severe respiratory distress with positive end-expiratory pressure (PEEP) to maintain a patent airway (Rock et al. 1988)
   b. Cleft palate repair
   c. Closed or open reduction and stabilization of dislocated joints (Lutter 1990)
      i. Securing stability of the knee joints for weight-bearing: primary importance
      ii. Correction of foot deformities through operative and nonoperative measures
   d. Stabilization of the cervical spine (Banks et al. 2003)
      i. Early bracing and stabilization
      ii. Stabilization of the neck may be required before surgical correction of joint abnormalities to prevent possible complications associated with the induction of anesthesia.
   e. Care for possible poor wound healing
   f. Obstetrical care of an affected mother and fetus (Rochelson et al. 1993)
      i. Regional anesthesia for possible difficulty in intubation and the cervical spine may be subluxated during extension of the neck for intubation
      ii. Cesarean section if the patient is unable to abduct the hips, making vaginal delivery potentially traumatic for both mother and infant
      iii. Risk of fetal injury includes cervical spine instability.

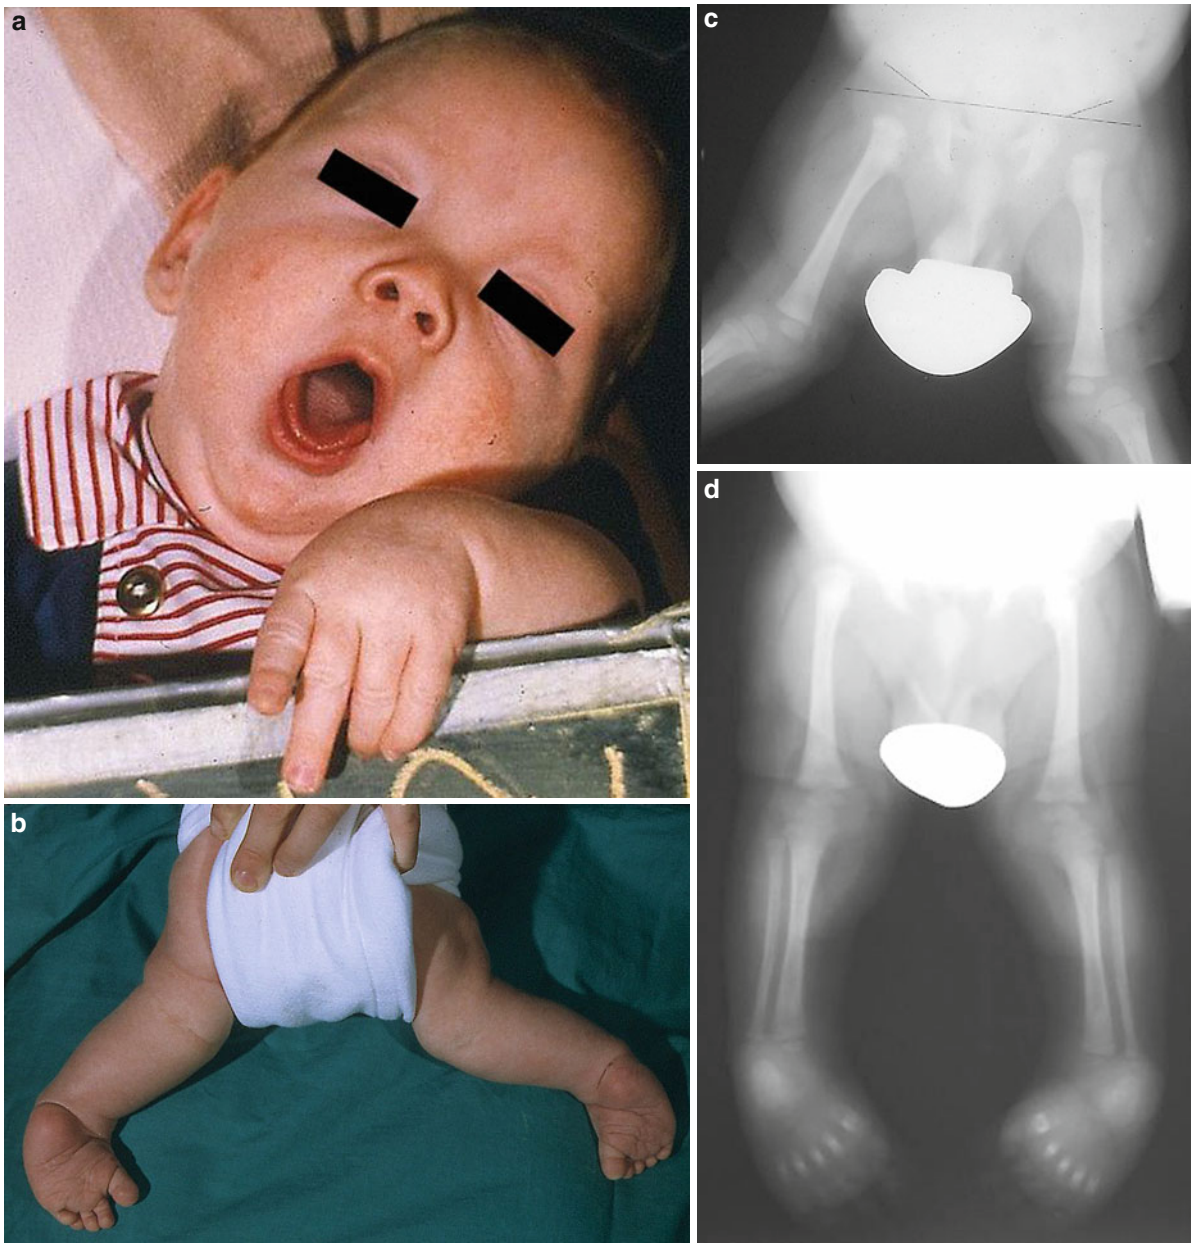

Fig. 1 (**a**–**d**) An infant with Larsen syndrome showing characteristic flat facies with hypertelorism, depressed nasal bridge, cleft palate, dislocations of hips, knees, and talipes equinovarus, demonstrated by radiographs

Fig. 2 (**a**, **b**) Another infant with Larsen syndrome showing flat facies with prominent forehead, hypertelorism, depressed nasal bridge, micrognathia, tracheostomy for tracheomalacia, scoliosis, dislocation of knees, and club feet

Fig. 3 (**a**–**e**) A girl with Larsen syndrome showing characteristic flat facies with prominent forehead, depressed nasal bridge, bilateral knee dislocations, and long, cylindrical fingers with spatulate thumbs and great toes. Radiograph shows lateral and anterior dislocation of both knees

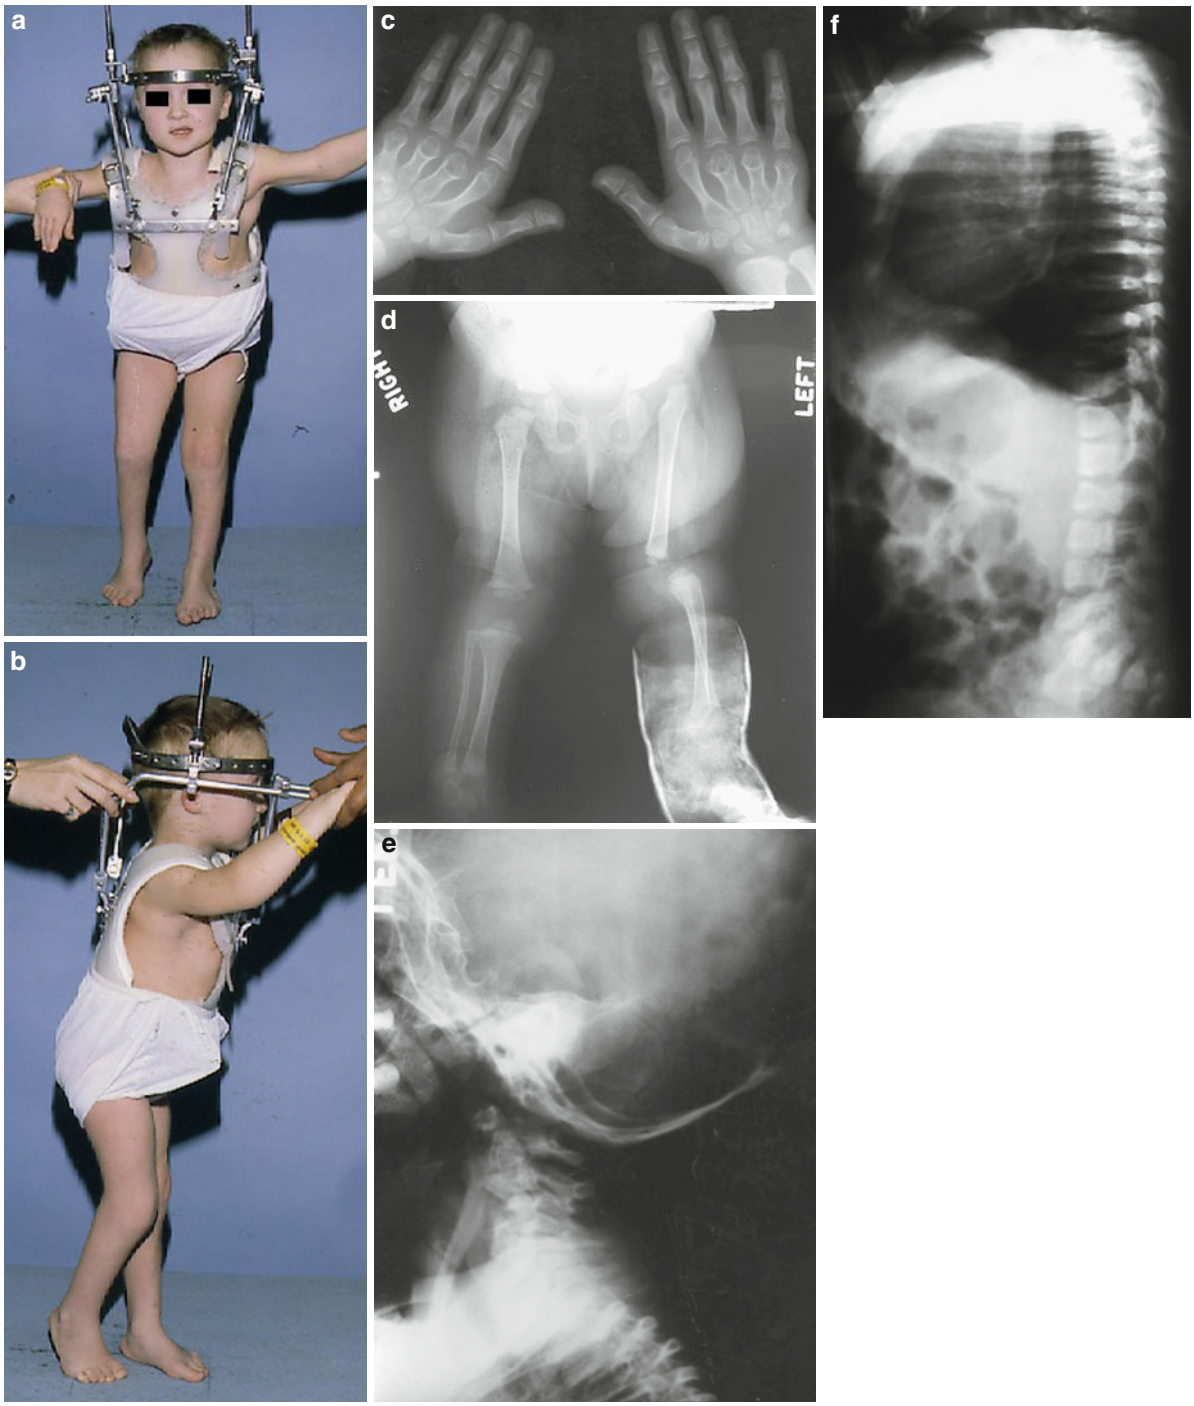

Fig. 4 (**a**–**f**) A girl with Larsen syndrome wearing orthosis, showing flat facies. Radiographs show increased number of carpal bones, anterior and lateral dislocation of tibiae, hyperextended cervical vertebrae, and coronal clefting of the lumbar vertebrae

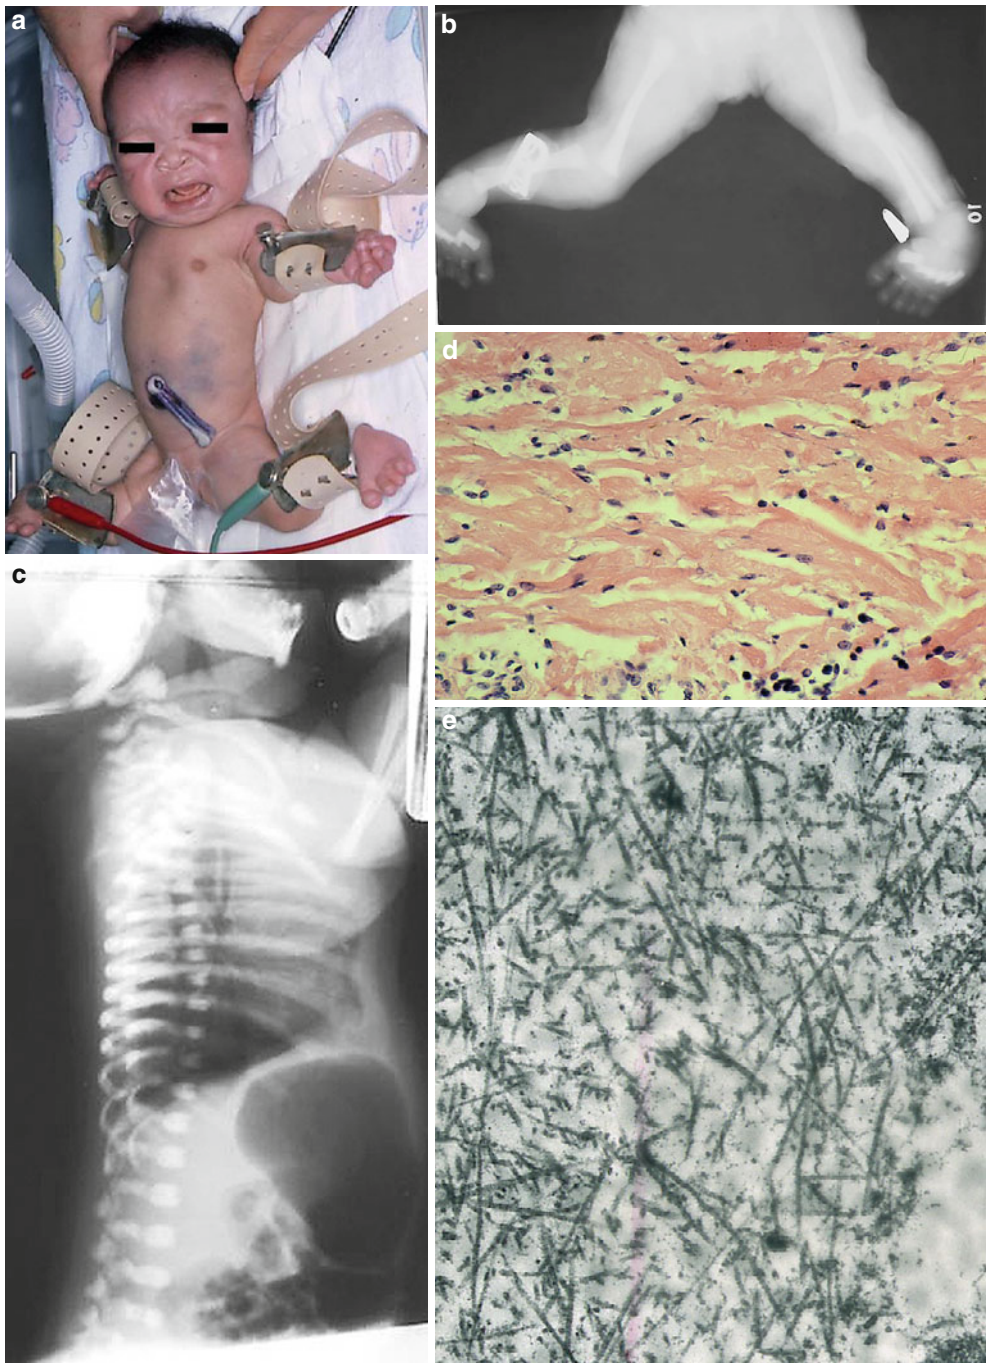

Fig. 5 (**a**–**e**) An infant with lethal, Larsen-like syndrome showing characteristic flat facies (prominent forehead, hypertelorism, depressed nasal bridge, micrognathia, and cleft palate); multiple dislocations involving shoulders, elbows, wrists, knees, ankles, and hips, and talipes equinovarus. The radiographs showed anterior dislocation of the tibia, lateral dislocation of the hips, hypoplasia of fibulae and of distal ends of the fibulae, cervical kyphosis with the apex at C-4, and coronal clefts of the lower lumbar vertebrae. Necropsy showed tracheomalasia. The dermal histology showed relatively broad and smudgy collagen bundles. The electron microscopic study showed a relative increase in small short fibers with a reduction of mature collagen fibers in the hyaline cartilage of the trachea

LEOPARD Syndrome

The acronym "LEOPARD syndrome," coined by Gorlin et al. (1969), is derived from clinical features which include *l*entigines, *e*lectrocardiographic conduction abnormalities, *o*cular hypertelorism, *p*ulmonary stenosis, *a*bnormal genitalia, growth *r*etardation, and sensorineural *d*eafness. It is also known as multiple lentigines syndrome and Moynahan syndrome and classified as a cardiocutaneous syndrome of neural crest origin (Moynahan 1970).

Synonyms and Related Disorders

Cardiomyopathic lentiginosis; Multiple lentigines syndorme

Genetics/Basic Defects

1. Inheritance
   a. An autosomal dominant disorder with high penetrance and variable expressivity
   b. Allelic to Noonan syndrome
2. Caused by mutations in the protein tyrosine phosphatase nonreceptor type 11 (*PTPN11*) gene, mapped on chromosome 12q22-qter, which is known to be mutated in the Noonan syndrome (Digilio et al. 2002)
   a. Missense mutation (836A → G; Tyr279Cys) in exon 7
   b. Missense mutation (1403C → T; Thr468Met) in exon 12
   c. Both mutations affect the PTPN11 phosphotyrosine phosphatase domain, which is involved in <30% of the Noonan syndrome *PTPN11* mutations.
3. Also can be caused by mutations in the V-RAF-1 murine leukemia viral oncogene homolog 1 (*RAF1*) gene (mapped on chromosome 3p25)

Clinical Features

1. Cutaneous features (Abdelmalek et al. 2002)
   a. Lentigines
      i. Dark brown irregularly shaped macules ranging from pinpoint size to 5 cm in diameter
      ii. Noted in infancy or childhood
      iii. Continue to increase in number until puberty
      iv. Primarily on the face, neck, and upper trunk with some involvement of the extremities
      v. Less commonly on the palms, soles, genitalia, iris, and sclera, but sparing oral mucosa
      vi. Generalized symmetric distribution of lentigines
   b. Other cutaneous abnormalities
      i. Café au lait spots (38% of patients)
      ii. Café noir spots (a term proposed in 1971 by Gorlin et al.): by analogy to café au lait spots to describe larger and more pigmented lentigines in patients with LEOPARD syndrome (Bujaldón 2008)
      iii. Melanoma
      iv. Localized hypopigmentation
      v. Interdigital webs

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_146,
© Springer Science+Business Media, LLC 2012

vi. Dermatoglyphic abnormalities
vii. Onychodystrophy
viii. Multiple granular cell myoblastomas
ix. Steatocystoma multiplex
x. Hyperelastic skin

2. Noncutaneous features
   a. Cardiac anomalies
      i. Valvular pulmonary stenosis: the most common cardiac anomaly (40% of cases)
      ii. Subaortic stenosis
      iii. Subpulmonic stenosis
      iv. Mitral valve involvement
      v. Hypertrophic obstructive cardiomyopathy
      vi. Left and right ventricular outflow tract obstructions
      vii. Atrial septal defect
      viii. Atrial myxomas
      ix. Variable conduction abnormalities
         a) Benign asymptomatic arrhythmia
         b) Malignant arrhythmias resulting in sudden cardiac death
      x. Cardiac symptoms
         a) Dyspnea on exertion
         b) Congestive heart failure
         c) Paroxysmal atrial tachycardia
         d) Sudden death
         e) Death at cardiac surgery
   b. Noncardiac anomalies
      i. Craniofacial features
         a) Ocular hypertelorism (25%)
         b) Epicanthic folds
         c) Ptosis
         d) Mandibular prognathism
         e) High-arched palate
         f) Dental abnormalities
         g) Low-set posteriorly rotated ears
      ii. Skeletal abnormalities
         a) Joint hypermobility
         b) Short webbed neck
         c) Winging of the scapula
         d) Pectus excavatum and carinatum
         e) Rib anomalies
         f) Cervical spine fusion
         g) Syndactyly
         h) Scoliosis
      iii. Genitourinary abnormalities (26% of cases)
         a) A small penis
         b) Cryptorchidism
         c) Hypospadias
         d) Ovarian disorders
      iv. Neurologic abnormalities
         a) Learning disability
         b) Mild mental retardation
         c) Sensorineural deafness
         d) Nystagmus
         e) Seizures
         f) Hyposmia
         g) Mild atrophy of the brain
      v. Retardation of growth (short stature)
      vi. Delayed puberty

3. Diagnostic criteria (Voron et al. 1976)
   a. Multiple lentigines plus two other features
   b. Immediate family member with LEOPARD syndrome plus at least three other features in the absence of lentigines

4. Differential diagnosis with other neuro-cardio-facial-cutaneous syndromes (Kalev et al. 2010)
   a. Noonan syndrome: please see chapter on Noonan syndrome
   b. Costello syndrome
      i. Causative genes: *HRAS*, *KRAS*, *BRAF*, and *MEK1*
      ii. Autosomal dominant
      iii. Phenotype
         a) Short stature
         b) Congenital heart defect
         c) Characteristic facies with more coarse features
         d) Mental retardation: more severe
         e) Distinctive skin involvement – curly, sparse hair; loose soft skin; and papillomata
   c. Cardio-facio-cutaneous syndrome
      i. Causative genes: *KRAS*, *BRAF*, *MEK1*, and *MEK2*
      ii. Autosomal dominant, de novo
      iii. Phenotype
         a) Short stature
         b) Congenital heart defect
         c) Cardiomyopathy
         d) Characteristic facies
         e) Mental retardation: more severe
         f) Distinctive features: hyperkeratotic dry skin; sparse, curly hair.
         g) Phenotype overlaps most with Noonan syndrome, but facial appearance tends to be coarse.
         h) Cardiac problems overlap mostly with LEOPARD syndrome.

d. Neurofibromatosis type 1: please see chapter on neurofibromatosis type 1

Diagnostic Investigations

1. ECG abnormalities (Torres et al. 2004)
   a. Left axis deviation
   b. Bundle branch block
   c. Abnormal P wave
   d. Prolongation of the P-R interval
   e. Right or left ventricular hypertrophy
   f. Infarction patterns
   g. Ischemic patterns with nonspecific ST and T wave changes
   h. Isolated ventricular ectopic beats
   i. Ventricular fibrillation
   j. Bradycardia
   k. Paroxysmal atrial fibrillation
2. Careful cardiac assessment including echocardiography
3. Hearing tests
4. Histology of lentigines
   a. Large membrane-bound accumulations of melanin granules within the Langerhans cells
   b. Giant melanosomes rarely seen within keratinocytes and melanocytes
5. Mutation screening of *PTP11* or *RAF1*: by direct sequencing of select exons or entire coding region

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low unless a parent has the syndrome (possibility of germline mosaicism exists)
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Available clinically by mutation analysis of *PTPN11* or *RAF1* genes on fetal DNA obtained by amniocentesis or CVS, provided the disease-causing allele has been identified in an affected family member
   b. Preimplantation genetic diagnosis (PGD) may be available for families in which the disease-causing mutation has been identified.
3. Management
   a. Avoid strenuous physical exercise when outflow tract obstruction or significant cardiac dysrhythmias are present.
   b. β-adrenergic receptor or calcium channel blocking agents to reduce cardiac outflow tract obstruction and adrenergic responsiveness
   c. Amiodarone treatment in cases of life-threatening ventricular ectopy
   d. Surgery may be needed to relieve severe cardiac outflow tract obstruction.
   e. Surgery for cryptorchidism or severe skeletal deformity
   f. Hearing aids for sensorineural deafness
   g. Dermabrasion for cosmetic correction on the face

Fig. 1 A lady (**a**, **b**) with LEOPARD syndrome showing ocular hypertelorism and generalized symmetric distribution of lentigines. Close views of lentigines (**c**–**e**) show variation in size and color. There is striking mottling of pigment within any one lentigo

Lesch–Nyhan Syndrome

In 1964, Lesch and Nyhan provided the first detailed clinical description of Lesch–Nyhan syndrome with a report of two brothers with hyperuricemia and a characteristic neurobehavioral syndrome that included motor dysfunction and self-injurious behavior. The prevalence of the syndrome is estimated to be approximately 1:380,000.

Synonyms and Related Disorders

Hypoxanthine guanine phosphoribosyltransferase 1 deficiency

Genetics/Basic Defects

1. Inheritance: X-linked recessive
2. Enzymatic defect: caused by deficiency of the enzyme hypoxanthine-guanine phosphoribosyltransferase (HPRT), which catalyzes the conversion of hypoxanthine to inosine monophosphate and guanine to guanine monophosphate in the presence of phosphoribosylpyrophosphate
3. Hypoxanthine-guanine phosphoribosyltransferase gene (*HPRT1*)
   a. Mapped to chromosome Xq26-q27.2
   b. The only gene known to be associated with Lesch–Nyhan syndrome
   c. Heterogeneous mutations
      i. Single base substitutions
      ii. Deletions
      iii. Insertions
      iv. Substitutions
4. Heterogeneity of clinical phenotype (Sarafoglou et al. 2010)
   a. An approximately inverse relationship exists between HPRT enzyme activity measured in intact cells and clinical severity (Page et al. 1981; Puig et al. 2001).
   b. Affected patients with classic Lesch–Nyhan disease, the most severe and frequent form, have the lowest HPRT enzyme activity (<1.5% of normal) in intact cultured fibroblasts, and the patients display the full spectrum of clinical abnormalities.
   c. Patients with partial HPRT deficiency, designated as Lesch–Nyhan variants (LNVs), have HPRT enzyme activity ranging from 1.5% to 8.0% (Nyhan 2008).
   d. Individuals with the intermediate form of LNV (also known as neurologic variants) have a variable clinical phenotype and, in most cases, are neurologically indistinguishable from patients with Lesch–Nyhan disease (Puig et al. 2001; Nyhan 2009).
   e. However, they do not have self-injurious behaviors, and their intelligence is normal or near normal. The least-affected patients with LNV have residual HPRT enzyme activity exceeding 8%, and their only manifestations have been attributed to hyperuricemia and include gout, hematuria, and nephrolithiasis.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_147,
© Springer Science+Business Media, LLC 2012

f. There is another LNV, HPRT Salamanca, that is characterized by spastic gait, mental retardation, and skeletal abnormalities (Nyhan 2008; Page et al. 1987).

5. Pathogenesis
   a. Metabolic basis of overproduction of uric acid: results from changes in the regulation of purine synthesis and degradation.
   b. Pathogenesis of neurologic and behavioral features remains incompletely understood. Growing evidence suggests that these features result from dysfunction of the dopamine transmitter systems of the basal ganglia (Baumeistger and Frye 1985).

Clinical Features

1. Normal prenatal and perinatal course.
2. Early developmental milestones.
   a. Hypotonia and developmental delay: most common presenting features evident by 3–6 months of age
   b. Failure to reach normal motor milestones, such as delayed in crawling, sitting, and walking
3. Within the first few years.
   a. Extrapyramidal involvement
      i. Dystonia
      ii. Choreoathetosis
      iii. Opisthotonus
      iv. Ballismus
   b. Pyramidal involvement
      i. Spasticity
      ii. Hyperreflexia
      iii. Extensor plantar reflexes
      iv. Ankle clonus
      v. Scissoring of the legs
4. Between 2 and 3 years.
   a. Impaired cognition
      i. Moderate to severe mental retardation in most patients
      ii. Varying degree of impairment
      iii. Difficult to obtain adequate assessments of cognitive abilities
   b. Compulsive behavioral disturbances
      i. Aggressiveness
      ii. Vomiting
      iii. Spitting
      iv. Coprolalia
      v. Copropraxis
      vi. Manipulative behavior
   c. Persistent self-injurious behavior: a hallmark of the disease
      i. Biting the fingers, hands, lips, and buccal mucosa
      ii. Banging the head or limbs
5. Overproduction of uric acid: hyperuricemia-related renal and articular symptoms. These symptoms are present in all HPRT-deficient patients and are not related to the severity of the enzyme defect (Torres and Puig 2005).
   a. Uric acid crystalluria noted as orange crystals in the diaper during the first weeks of life.
   b. Deposition of uric acid crystals or calculi in the kidneys, ureters, or bladder.
   c. Leading to nephrolithiasis, obstructive uropathy, and azotemia if untreated.
   d. Gouty arthritis develops later in the course of the disease.
   e. All characteristic findings associated with gout may be present (acute arthritis, tophi, nephrolithiasis or urolithiasis, and renal disease). However, nowadays, allopurinol treatment prevents the development of gouty manifestations.
6. Other features.
   a. Delayed growth and puberty
   b. Testicular atrophy in most affected males
   c. Associated orthopedic problems
      i. Hip subluxation or dislocation
      ii. Fractures
      iii. Autoamputation
      iv. Infections
      v. Minor scoliosis
      vi. Contractures
7. Life expectancy.
   a. Most surviving into the second or third decade of life if properly managed
   b. No evidence suggesting disease progression over time
   c. Complications
      i. Aspiration pneumonia
      ii. Chronic nephrolithiasis
      iii. Renal failure
      iv. Sudden unexpected death
8. Lesch–Nyhan syndrome in females.
   a. Extremely rare
   b. Female carriers
      i. Generally considered to be asymptomatic

ii. Have increased uric acid excretion
iii. Develop symptoms of hyperuricemia in later years

c. Affected females
i. Affected carrier females: considered to have nonrandom X chromosome inactivation or skewed inactivation of the normal *HPRT1* allele.
ii. The first female case reported was caused by a microdeletion of the maternally derived *HPRT* gene and nonrandom inactivation of the paternally derived X chromosome.
iii. Two additional cases were caused by a point mutation in one allele and markedly reduced mRNA expression from the other allele.

Diagnostic Investigations

1. EEG: nonspecific changes of slowing or disorganization (Nicklas et al. 2010).
2. CT and MRI of the brain: nonspecific changes of atrophy of the basal ganglia or cerebrum.
3. Positron emission tomography to demonstrate a selective decrease of 50–70% in dopamine transporters in the caudate and putamen.
4. Hyperuricuria or hyperuricemia (serum uric aids concentration >8 mg/dL): often present but not sensitive or specific enough for diagnosis.
5. 24-h uric acid excretion (>20 mg/kg): characteristic but not diagnostic.
6. Uric acid to creatinine ratio >2.0: characteristic for patients under 10 years of age.
7. In males: hypoxanthine-guanine phosphoribosyltransferase enzyme activity <1.5% of normal enzyme activity in cells from any tissue (blood, cultured fibroblasts, or lymphoblasts): establishes the diagnosis.
8. In females: measurement of HPRT enzyme activity for carrier detection is technically demanding and not widely used. Measurement of HPRT enzyme activity on hair bulbs from women at risk has had both false-positive and false-negative results.
9. Molecular genetic testing of the *HPRT1* gene (Nyhan et al. 2010).
   a. Purposes
      i. To define the mutation in the affected males
      ii. To determine carrier status in at-risk females: requires prior identification of the disease-causing mutation in the family
   b. Sequence analysis or mutation scanning to detect *HPRT1* mutations in males affected with Lesch–Nyhan syndrome: available on clinical basis
   c. Deletion/duplication analysis
      i. To detect exonic or whole-gene deletions
      ii. Between 21% and 24% of mutations in *HPRT1* are large deletions that cannot be detected in females by sequence analysis

Genetic Counseling

1. Recurrence risk.
   a. Patient's sib
      i. When the mother is not a carrier: not increased unless the mother has germ line mosaicism in which case there is an undetermined, but real, risk of having future affected sons or carrier daughters
      ii. When the mother is a carrier
         a) A 25% risk of having an affected male
         b) A 25% risk of having a carrier female
         c) A 50% risk of having an unaffected male or female
   b. Patient's offspring
      i. Severely affected males: not surviving to reproductive age
      ii. Less severely affected males: all of his daughters are obligatory carriers and none of his sons affected
2. Prenatal diagnosis available to at-risk pregnancies.
   a. Fetal sex determination by amniocentesis or CVS
   b. Confirmation of a previously known *HPRT1* disease-causing mutation in a male fetus
      i. Perform HPRT enzyme activity
      ii. Perform molecular genetic testing
   c. Assay of HPRT enzyme activity in cultured amniocytes or chorionic villus cells: the method of choice if the *HPRT1* mutation has not been identified in the family
   d. Preimplantation genetic diagnosis possible for a previously characterized disease-causing mutation (Ray et al. 1999)
3. Management (Nicklas et al. 2010).
   a. Hyperuricemia.
      i. Control hyperuricemia to reduce the risk of nephropathy, nephrolithiasis, and gouty arthritis

ii. Allopurinol
   a) To block the conversion of oxypurines into uric acid
   b) To prevent uric acid accumulation and subsequent arthritic tophi, renal stones, and nephropathy
   c) Has no effect on behavioral and neurologic symptoms

b. Renal stones.
   i. Lithotripsy
   ii. Surgery

c. Neurologic dysfunction.
   i. No medication known to be consistently effective in controlling the extrapyramidal motor features
   ii. Baclofen or benzodiazepine for spasticity

d. Neurobehavioral symptoms.
   i. No effective intervention available
   ii. Use behavioral modification techniques
   iii. Control self-injurious behavior
      a) Requires physical restraints
      b) Removal of teeth
      c) A noninvasive approach with a special appliance fabricated for the prevention of damage to oral and perioral soft tissues (Fardi et al. 2003)
      d) Carbamazepine to attenuate the behavioral manifestations

e. Surgery for orthopedic problems.

f. Bone marrow transplantation or red blood cell transfusions do not significantly ameliorate the neurologic disorder.

Lethal Multiple Pterygium Syndrome

Lethal multiple pterygium syndrome (LMPS) is a lethal hereditary disorder characterized by a distinct constellation of multiple anomalies, consisting of multiple pterygia, flexion contractures of multiple joints, characteristic facial appearance, cystic hygroma, hydrops, and pulmonary and cardiac hypoplasia.

Synonyms and Related Disorders

Chen syndrome; Gillin–Pryse–Davis syndrome; Herva syndrome; van Regemorter syndrome

Genetics/Basic Defects

1. Inheritance: possible heterogeneity
   a. Autosomal recessive inheritance
   b. Possible X-linked recessive inheritance (Tolmie et al. 1987; Meyer-Cohen et al. 1999)
2. Classification by Hall (1982; 1984) and Entezami et al. (1998)
   a. Based on the following concomitant abnormalities
      i. Age of onset of intrauterine growth retardation
      ii. Timing and extent of neck swelling
      iii. Presence or absence of bony fusions and bone modeling errors
   b. Type I (Gillin–Pryse–Davis syndrome)
      i. Multiple pterygia
      ii. Pulmonary hypoplasia
      iii. Genital anomalies
      iv. Facial anomalies
      v. Strongly flexed extremities with a reduced muscle mass
   c. Type II (Chen syndrome)
      i. Multiple pterygia
      ii. Hygroma colli
      iii. Facial anomalies
      iv. Shortened extremities
      v. Undermodeled long bones
      vi. Cartilaginous fusion of joints and bony fusion of the spinous processes of the vertebrae
      vii. Polyhydramnios
      viii. Hypoplastic lungs and heart
      ix. Diaphragmatic hernia
   d. Type III (van Regemorter syndrome)
      i. Multiple pterygia
      ii. Pulmonary hypoplasia
      iii. Facial anomalies
      iv. Thin extremities with reduced muscle mass
      v. Fusions of the long tubular bones
   e. Type IV (Herva syndrome)
      i. Multiple pterygia
      ii. Degeneration of the anterior horn cells of the spinal cord
      iii. Found particularly in Finland
3. Classification by de Die-Smulders et al. (1990a)
   a. Early LMPS
      i. A group with presumed genetic heterogeneity
      ii. Lethality in the second trimester
      iii. Hydrops fetalis
      iv. Cystic hygroma
   b. Late LMPS
      i. Survival into the third trimester
      ii. Absence of fetal hydrops
   c. Finnish-type LMPS
      i. Fetal hydrops from the 15th gestational week
      ii. Lethality at average gestation of 29 weeks

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_148,
© Springer Science+Business Media, LLC 2012

   iii. Occasional pterygia of the neck and elbows
   iv. Distinct neuropathologic findings
4. Pathogenesis (Moerman et al. 1990)
   a. Combination of the following two sequences:
      i. Fetal akinesia deformation sequence
         a) Resulting from myoneural dysfunction (generalized amyoplasia) and/or intrauterine growth constraint leading to fetal akinesia
         b) Fetal akinesia, in turn, leading to growth retardation, pulmonary hypoplasia, short umbilical cord, limb positional defects, and facial anomalies
      ii. Jugular lymphatic obstruction sequence: delay in development of the connection between jugular lymph sacs and the internal jugular vein resulting in dilatation of tributary lymphatics and peripheral lymphedema
   b. Fragile collagen proposed as a possible pathogenesis (Hartwig et al. 1989)
5. A gene responsible for some cases of lethal MPS (LMPS) and Escobar variant of MPS has now been identified.
   a. Caused by mutation in the *CHRNG* gene (Hoffmann et al. 2006; Morgan et al. 2006)
   b. Caused by mutations in the *CHRNA1* and *CHRND* genes (Michalk et al. 2008)

Clinical Features

1. Prenatal history
   a. Nonimmune fetal hydrops
   b. Diminished fetal activity
   c. Maternal hydramnios
   d. Often presented with fetal demise
2. Characteristic facial features
   a. Ocular hypertelorism
   b. Antimongoloid slant of the palpebral fissures
   c. Epicanthal folds
   d. Markedly flattened nasal bridge with hypoplastic nasal alae
   e. Micrognathia
   f. Cleft palate
   g. Apparently low-set malformed ears
3. Neck
   a. Short
   b. Cystic hygroma
4. Chest
   a. Small chest
   b. Hypoplastic lungs
   c. Hypoplastic heart
5. Multiple pterygia
   a. Symmetrical
   b. Sites
      i. Chin-to-sternum
      ii. Cervical
      iii. Axillary
      iv. Antecubital
      v. Crural
      vi. Popliteal
6. Other limb anomalies
   a. Multiple contractures: always present
   b. Camptodactyly
   c. Calcaneovalgus foot deformities
7. Gastrointestinal anomalies
   a. Intestinal malrotation
   b. Short bowel
   c. Thin colon
   d. Colonic atresia
   e. Absent vermiform appendix
8. Genitourinary anomalies
   a. Hydronephrosis
   b. Unilateral renal dysplasia
   c. Cryptorchidism
9. Other associated anomalies
   a. Kyphoscoliosis
   b. Near-complete absence of diaphragmatic muscle
   c. Aortic coarctation
   d. Absent abdominal wall muscle
   e. Adrenal hypoplasia
   f. Short umbilical cord
   g. Rare cerebral anomalies
      i. Hydranencephaly
      ii. Holoprosencephaly
      iii. Dilated ventricles with intracerebral cyst

Diagnostic Investigations

1. Radiography
   a. Craniofacial abnormalities
      i. Scalp edema
      ii. Microbrachycephaly
      iii. Flattened mandibular angle

   b. Hypoplasia and undermodeling of the bones
      i. Thin crowded ribs
      ii. Markedly hypoplastic scapulae
      iii. Hypoplastic iliac wings, ischia and pubic bones
      iv. Lack of normal curvature at the cervico-thoracic junction
   c. Bony fusion
      i. Marked bony fusion of posterior spinous processes
      ii. Radioulnar synostosis
2. Histologic studies of the skeletal system
   a. Cartilaginous and bony fusion of the spinous processes
   b. Fusion of epiphyseal cartilages of distal humerus and proximal ulna
   c. Poorly developed joint space
   d. An abnormal growth plate
   e. Weak safranin staining of the resting cartilages
   f. Placenta
      i. Scalloped chorionic villi
      ii. Intravillous trophoblast invaginations
   g. Muscular and neural abnormalities
3. Chromosome analysis: normal

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive inheritance: 25%
      ii. X-linked recessive inheritance: 50% risk of having an affected brother if the mother is a carrier
   b. Patient's offspring: a lethal entity not surviving to reproductive age
2. Prenatal diagnosis by ultrasonography: possible (Entezami et al. 1998)
   a. Nonimmune fetal hydrops
   b. Cystic hygroma
   c. Diminished fetal activity
   d. Short and fixed limbs
   e. Maternal hydramnios
   f. Other ultrasonographically detectable anomalies
      i. Diaphragmatic hernia
      ii. Scoliosis
      iii. Pterygia
   g. Ultrasonographic features at first trimester of pregnancy (Chen et al. 2005; Gundogan et al. 2006)
      i. Cystic hygroma
      ii. Generalized edema
      iii. Ascites
      iv. Markedly increased nuchal translucency
      v. No fetal movement
      vi. Flexed upper and lower limbs
      vii. Cutaneous webs across both elbow joints
      viii. Hypoplastic left heart
3. Management: a lethal entity

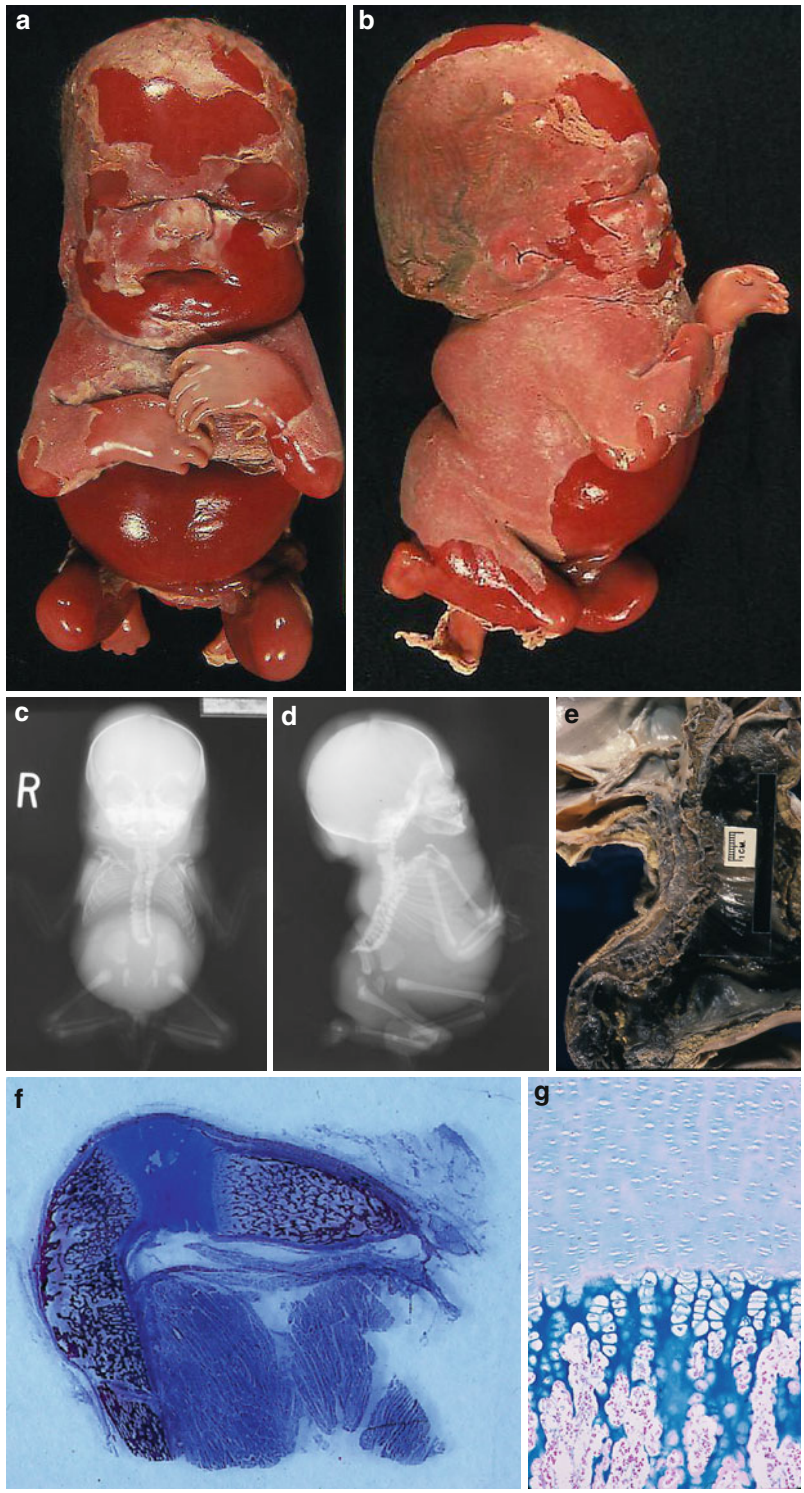

Fig. 1 The macerated 32-week stillborn (**a**, **b**) with Chen syndrome showing multiple pterygia involving the neck, axillae, antecubital, crural, popliteal, and interphalangeal areas, hygroma coli, and facial anomalies (hypertelorism, antimongoloid slant of the palpebral fissures, a shortened nose, depressed nasal bridge and tip of the nose, a long philtrum, a receding chin, apparently low-set and malformed ears). Contractures of the fingers were present with ulnar deviation of the hands. Polyhydramnios and fetal hydrops were noted by ultrasonography at 30 weeks of gestation. Autopsy showed hypoplastic lungs and heart and a large left diaphragmatic hernia (containing intestine, pancreas, and part of the stomach and ascites). Radiographs (**c**, **d**) and postmortem section (**e**) revealed a large cystic hygroma, hypoplastic vertebral bodies, fusion of the posterior elements extended from the cervical into the midthoracic spine, angulated cervicothoracic junction, and undermodeled long bones. Representative section of the elbow (**f**) showed fusion of epiphyseal cartilages of the distal humerus and proximal ulna resulting in bending of the proximal portion of the ulna and a deficient joint space. The resting cartilage (**g**) was distinctly demarcated from the physeal growth plate, which showed slightly retarded but normally arranged chondrocytic column

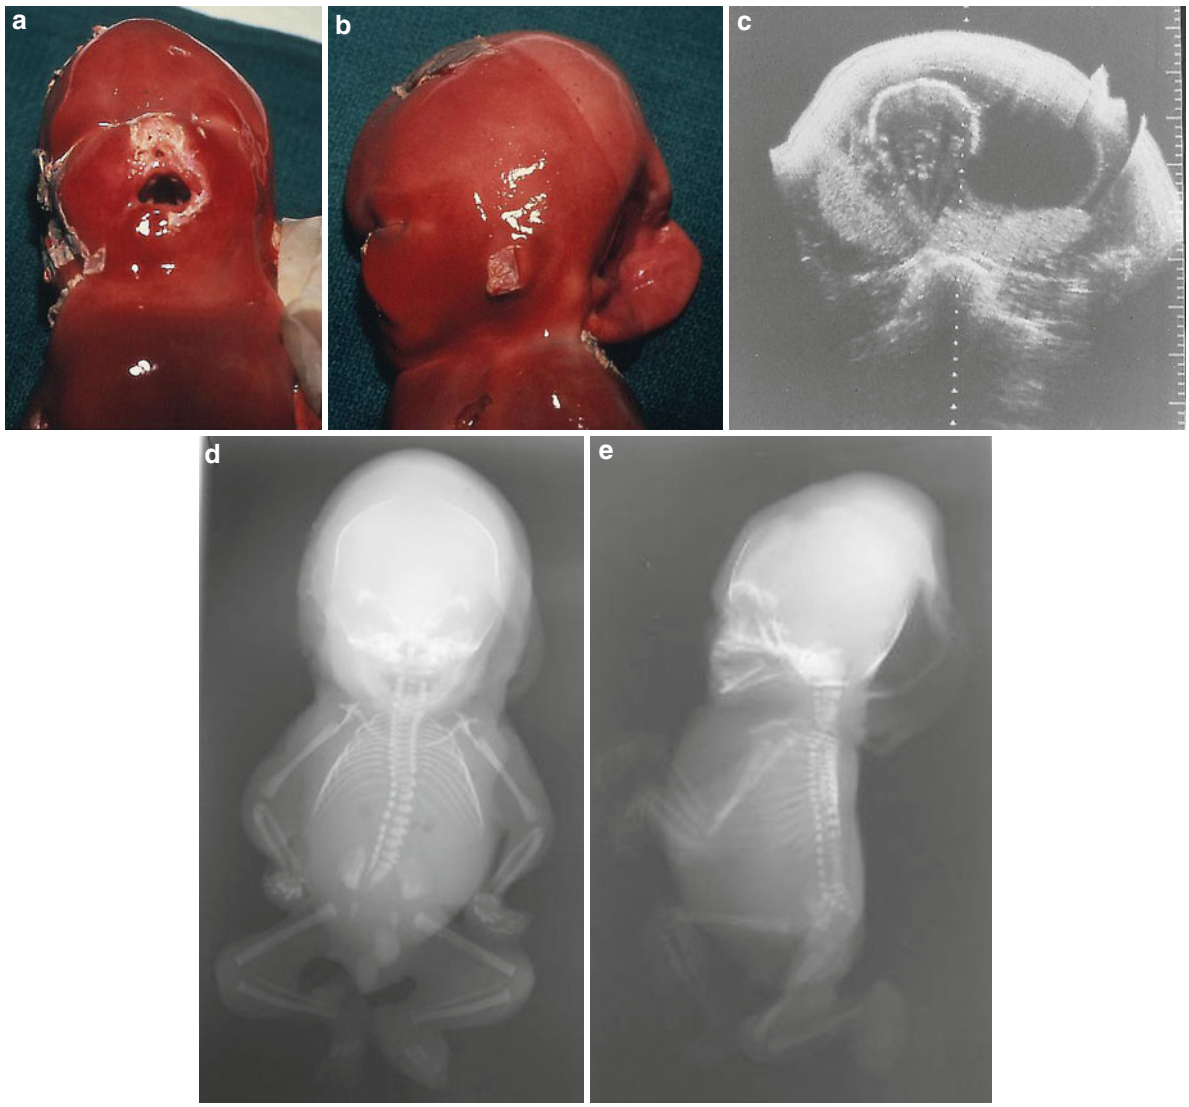

Fig. 2 A malformed macerated 28-week fetus (**a**, **b**) with Chen syndrome showing impressive skin webbing at the neck, axillae, antecubital, crural, and popliteal areas, and abnormal facies (markedly flattened nasal bridge with anteverted and hypoplastic nasal alae, low-set ears, and a small mouth with cleft soft palate). In addition, there were contractures of the hands and fingers and rocker bottom feet. The prenatal ultrasound at 25 weeks of gestation (**c**) showed a large cystic hygroma at the back of the head. Radiographs (**d**, **e**) revealed massive edema of the scalp contiguous with the neck pterygia, hypoplastic vertebral bodies, multiple fusions of the posterior elements of the cervical and lumbosacral spine bodies, and incipient fusion of the radius and ulna bilaterally. Post mortem study revealed markedly hypoplastic lungs and heart

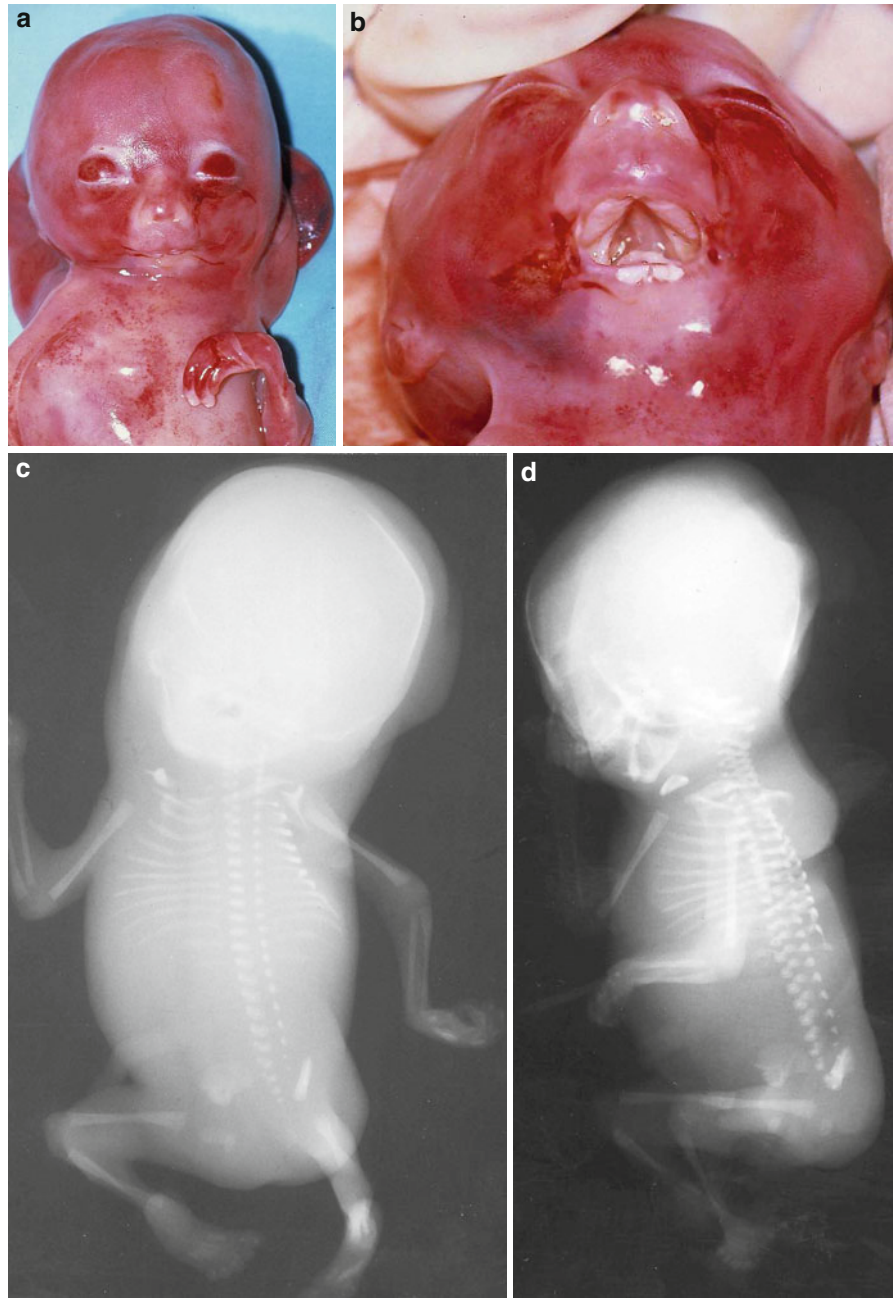

Fig. 3 A 19-week fetus with Chen syndrome (**a**, **b**) showing a large cystic hygroma, detected by prenatal ultrasonography, multiple pterygia involving neck, axillae, elbows, fingers, and knees with contractures, illustrated by radiographs (**c**, **d**). Distinctive facial features include hypertelorism, flat nasal bridge, cleft palate, and micrognathia. Postmortem study revealed hypoplastic lungs and heart, fusion of cartilage of the elbow joints, and hypoplastic cervical vertebral bodies with posterior elements beginning to come together but were not yet fused

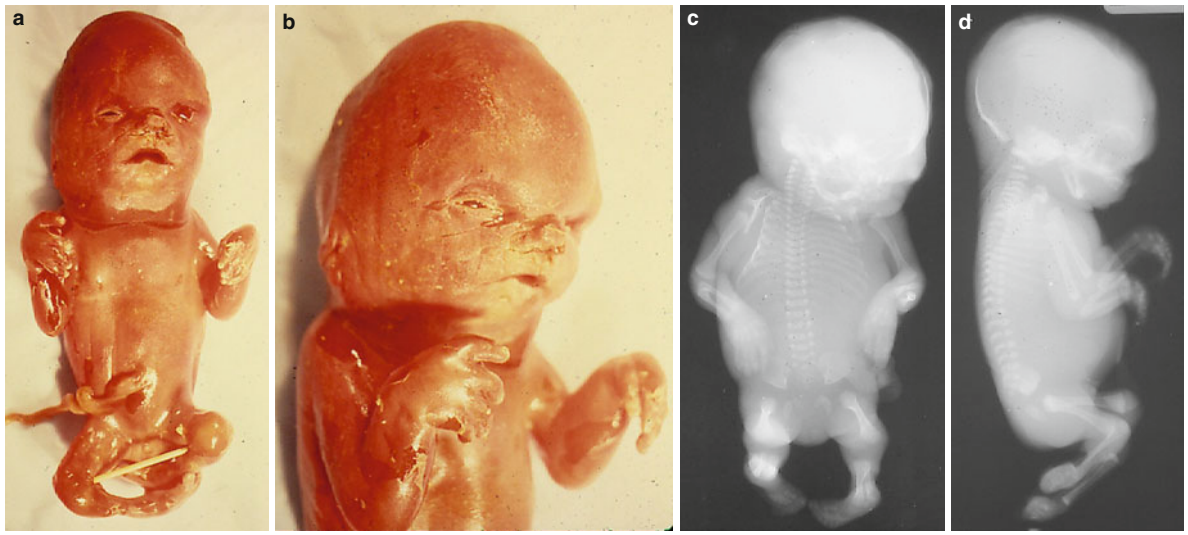

Fig. 4 A fetus with lethal multiple pterygium (**a**, **b**) syndrome showing multiple pterygia involving neck, axilla, elbows, and knees associated with multiple contractures, illustrated by radiographs (**c**, **d**). There were hypertelorism, small nose, micrognathia and micrognathia

Fig. 5 (**a**, **b**) A stillbirth with lethal multiple pterygium syndrome showing flexion of all four limbs with multiple pterygia involving neck, axillae, elbows, and knees; short neck; and cystic hygroma colli. There were antimongoloid slant of the palpebral fissures, hypertelorism, flat nasal bridge, micrognathia, and high-arched palate. The upper extremities were held in extreme flexion with ulnar deviation of both hands and camptodactyly. The lower limbs were rotated externally and flexed in a crossed position with bilateral calcaneus deformities of the feet. Postmortem findings include multiloculated cystic hygroma, hypoplastic lungs, and kyphoscoliosis

Loeys–Dietz Syndrome

Loeys–Dietz syndrome (LDS), a newly recognized connective tissue disorder, shares overlapping features with Marfan syndrome (MFS) and the vascular type of Ehlers–Danlos syndrome (EDS), including aortic root dilatation and skin abnormalities.

Synonyms and Related Disorders

Loeys-Dietz aortic aneurysm syndrome; TGFBR1-related Loeys-Dietz syndrome; TGFBR2-related Loeys-Dietz syndrome

Genetics/Basic Defects

1. An autosomal dominantly inherited disorder of connective tissue
2. Caused by heterozygous mutations in the gene encoding type I or II transforming growth factor beta (TGF-β) receptor
3. An altered signaling of the TGF-β cytokine family
   a. Plays an important role in cell proliferation and differentiation, apoptosis and extracellular matrix formation, underling both LDS and MFS
   b. Causes disarrayed elastic fibers and loss of elastin content in the aortic media, predisposing to dilatation and dissection of the aortic wall
   c. Disruption of the normal TGF-β signaling takes place at the level of the TGF-β receptors. Mutations in either the TGF-β receptor 1 or 2 genes have been identified in one third and two thirds of LDS patients, respectively. However, in MFS an abnormal fibrillin protein causes an increased activity of TGF-β, leading to the typical phenotypic characteristics of the MFS.
4. No differences in phenotype are observed between individuals with mutations in *TGFBR1* and *TGFBR2*
5. Marfan syndrome–related disorders and mutated genes
   a. Marfan syndrome: *FBN1*, *TGFBR*1, *TGFBR2*
   b. Neonatal Marfan syndrome: *FBN1*
   c. Familial thoracic aortic: aneurysms and dissections: *FBN1*, *TGFBR1*, *TGFBR2*
   d. Isolated ectopia lentis: *FBN*1
   e. Shprintzen–Goldberg craniosynostosis syndrome: *FBN1*, *TGFBR2*
   f. Autosomal dominant Weill–Marchesani syndrome: *FBN1*
   g. Loeys–Dietz syndrome: *TGFBR1*, *TGFBR2*

Clinical Features

1. Clinical types
   a. Type I (about 75% of cases): recognized by recognizable craniofacial characteristics (hypertelorism, bifid uvula, or cleft palate)
   b. Type II (about 25% of cases): absence of facial characteristics (However, certain common facial features have been recently observed in type II patients.)
   c. Generalized arteriopathy: the most salient feature in LDS whether in type I or type II
   d. Aortic root aneurysms are present in 98% of LDS patients.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_149,
© Springer Science+Business Media, LLC 2012

e. Dural ectasia has recently been observed in LDS patients.
f. Both types with interfamilial and intrafamilial phenotypic variability

2. LDS type I
   a. Overlapping features with MFS
      i. Aortic root dilatation/aneurysm
      ii. Arachnodactyly (long slender fingers)
      iii. Dolichostenomelia (thin body habitus and long extremities)
      iv. Pectus deformity
      v. Joint laxity
   b. Typical characteristics
      i. Aortic root aneurysm (98%)
      ii. Aneurysms of other vessels (52%)
      iii. Generalized arterial tortuosity (84%)
   c. Typical and easily recognizable facial characteristics
      i. Ocular hypertelorism (increased distance between the pupils) (90%)
      ii. Cleft palate or bifid uvula (90%)
      iii. Other facial features
         a) Blue sclera (40%)
         b) Malar hypoplasia (60%)
         c) Exotropia
         d) Proptosis
         e) Retrognathia (50%)
   d. Musculoskeletal manifestations
      i. Craniosynostosis (premature closure of cranial sutures) (48%)
         a) Premature fusion of the sagittal suture (resulting in dolichocephaly) most commonly involved
         b) Coronal suture synostosis (resulting in brachycephaly)
         c) Metopic suture synostosis (resulting in trigonocephaly)
      ii. Dolichostenomelia (18%)
      iii. Cervical spine instability
      iv. Pectus deformity (68%)
      v. Arachnodactyly (70%)
      vi. Scoliosis (50%)
      vii. Joint laxity (68%)
      viii. Talipes equinovarus (45%)
      ix. Camptodactyly (38%)
   e. Cutaneous manifestations
      i. Velvety skin (28%)
      ii. Translucent skin (32%)
   f. Congenital heart defects
      i. Patent ductus arteriosus (35%)
      ii. Atrial septal defect (22%)
      iii. Bicuspid aortic valve
      iv. Bicuspid pulmonary valve
      v. Mitral valve prolapse
   g. Developmental delay (15%)
   h. Absence of ectopia lentis (lens subluxation) (0%) and other ocular manifestations seen in MFS

3. LDS type II
   a. Aortic root aneurysm with dissection (100%)
   b. Other aortic aneurysm (73%)
   c. Arterial tortuosity (67%)
   d. Overlapping features with the vascular type of EDS
      i. Skin abnormalities
         a) Easy bruising (67%)
         b) Translucent skin (64%)
         c) Velvety skin (83%)
         d) Skin hyperextensibility (20%)
         e) Atrophic scars (50%)
      ii. Joint laxity (100%)
      iii. Rupture of visceral organs
         a) Vascular rupture during pregnancy (50%)
         b) Uterine rupture (33%)
         c) Splenic or bowel rupture (25%)
      iv. Uterine hemorrhage (17%)
      v. Inguinal hernia (36%)
   e. Facial features observed in most patients, although not exclusive to LDS II (Adès 2008)
      i. Dolichocephaly
      ii. A tall broad forehead
      iii. Frontal bossing
      iv. A high anterior hairline
      v. Hypoplastic supraorbital margins
      vi. A "jowly" appearance (particularly in the first 3 years of life)
      vii. Translucent and redundant facial skin (often most pronounced in the periorbital region)
      viii. Prominent upper central incisors in late childhood/adulthood
      ix. An open-mouthed myopathic face
      x. The adult faces appeared prematurely aged

4. Cardiovascular involvement
   i. Type I
      a) Mean craniofacial-severity-index score (scores range from 0 to 11 with higher scores indicating more severe abnormalities): 4.8 years

b) Mean age at first major event: 24.5 years
c) Age at death: 22.6 years (0.5–45.0)
d) Cause of death: thoracic aortic dissection (19%), abdominal aortic dissection (5%), subclavian artery dissection (0%), and cerebral bleeding (3%)
e) Age at first cardiovascular surgery 16.9 years (1.2–46.0)
f) Distribution of aneurysms: ascending aorta (84%), transverse aorta (5%), descending thoracic aorta (6%), abdominal aorta (8%), thoracic arterial branches (27%), head or neck arterial branches (11%), and abdominal arterial branches (3%)

ii. Type II
a) Mean craniofacial-severity-index score: 0.8 year
b) Mean age at first major event: 29.8 years
c) Age at death: 31.8 years (18.0–47.0)
d) Cause of death: thoracic aortic dissection (23%), abdominal aortic dissection (12%), subclavian artery dissection (4%), and cerebral bleeding (0%)
e) Age at first cardiovascular surgery: 26.9 years (14.0–38.0)
f) Distribution of aneurysms: ascending aorta (85%), transverse aorta (23%), descending thoracic aorta (19%), abdominal aorta (15%), thoracic arterial branches (8%), head or neck arterial branches (8%), and abdominal arterial branches (15%)

5. Differential diagnosis
a. Vascular type of Ehlers–Danlos syndrome (please see Atlas)
b. Marfan syndrome (please see Atlas)
c. Shprintzen–Goldberg syndrome (Marfanoid craniosynostosis syndrome)
i. Phenotypes overlapping with some LDS patients with mutations in TGFBR1 or TGFBR2
ii. Not associated with cleft palate, arterial tortuosity or risk of aneurysm, or dissection other than at the aortic root
iii. Most affected individuals have no vascular pathology.
iv. Sequencing of TGFBR1 and TGFBR2 in five individuals with classic SGS identified no mutations (data not shown). Nevertheless, given the extent of phenotypic overlap between SGS, MFS and selected individuals with mutations in either TGFBR1 or TGFBR2, the pathogenesis of SGS probably also relates to alteration in TGF-β signaling.
d. Children who present with diffuse hypotonia, joint laxity, and/or joint contractures and in whom a diagnosis of arthrogryposis, Larsen syndrome, or Beal syndrome is being entertained should undergo thorough genetic evaluation to rule out a *TGFBR1* or *TGFBR2* mutation.

Diagnostic Investigations

1. Diagnosis of LDS
a. Based on characteristic clinical findings in the proband and family members
b. Craniofacial examination for evidence of bifid uvula, cleft palate, and craniosynostosis
c. Ophthalmologic examination by an ophthalmologist with expertise in connective tissue disorders
i. Slit-lamp examination through a maximally dilated pupil for exclusion of lens subluxation or luxation
ii. Careful refraction and visual correction, especially in young children at risk for amblyopia
iii. Specific assessment for retinal detachment and blue sclerae
d. Magnetic resonance angiography (MRA) or CT scan with 3D reconstruction from head to pelvis: to identify arterial aneurysms and arterial tortuosity throughout the arterial tree
e. Radiographs to detect skeletal manifestations (e.g., severe scoliosis, cervical spine instability) that may require attention by an orthopedist
f. Molecular genetic testing of *TGFBR1* and *TGFBR2*, the only two genes known to be associated with LDS, available on a clinical basis
2. Genetic testing of relatives at risk
a. To clarify genetic status of family members at risk if the causal *TGFBR1* or *TGFBR2* mutation is known in the proband
b. To evaluate relatives at risk for signs of LDS, including echocardiography and extensive vascular imaging if the mutation is not known in the proband

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. If a parent of the proband is affected: the risk to the sibs is 50%
      ii. If parents are clinically unaffected: the risk to the sibs of a proband appears to be low but greater than that of the general population because of reported rare cases of somatic and germline mosaicism
   b. Patient's offspring
      i. A 50% chance of inheriting the mutation and the disorder
      ii. Since the penetrance of disease-causing *TGFBR1* and *TGFBR2* mutations is reported to be near 100%, offspring who inherit a mutant allele from a parent will have LDS, although the severity cannot be predicted.
2. Prenatal diagnosis
   a. Ultrasound examination in the first two trimesters: not sensitive in detecting manifestations of LDS although prenatal occurrence of aortic dilatation has been described
   b. Molecular genetic testing
      i. Prenatal diagnosis for pregnancies at increased risk for LDS is possible by analysis of DNA extracted from fetal cells obtained by amniocentesis usually performed at approximately 15–18 weeks' gestation or chorionic villus sampling (CVS) at approximately 10–12 weeks' gestation
      ii. The disease-causing allele of an affected family member must be identified or linkage established in the family before prenatal testing can be performed.
      iii. Linkage analysis should be used with caution unless *TGFBR1* or *TGFBR2* marker alleles can be shown to cosegregate with disease in a large family.
      iv. Preimplantation genetic diagnosis: available for families in which the disease-causing mutations have been identified
3. Management
   a. Careful follow-up and aggressive surgical treatment mandatory because of the following reasons:
      i. Aortic dissection and rupture in LDS tend to occur at a young age vs. MFS.
      ii. Vascular pathology can be seen throughout the entire arterial tree.
   b. Echocardiographic assessment of the aortic root diameter and its growth
   c. MR angiography from head to pelvis to discover other possible aneurysms
   d. Surgical fixation of cervical spine instability to prevent spinal cord damage
   e. Standard treatment of clubfeet and severe pes planus
   f. Standard management of cleft palate and craniosynostosis, preferably by a craniofacial team
   g. Prevention of secondary complications: consider subacute bacterial endocarditis prophylaxis in those undergoing dental work or other procedures expected to contaminate the bloodstream with bacteria
   h. Initiate β-blockade therapy to reduce further aortic root dilatation or alternatively treat with angiotensin II receptor antagonist
   i. Indications for surgical intervention in Loeys–Dietz syndrome (Williams et al. 2007)
      i. Adults
         a) Aortic root >4.0 cm or expanding rapidly (>0.5 cm/year)
         b) Descending thoracic aorta >5.0 cm or expanding rapidly (>0.5 cm/year)
         c) Abdominal aorta >4.0 cm or expanding rapidly (>0.5 cm/year)
         d) Rapid expansion of peripheral aneurysms
      ii. Children
         a) Severe craniofacial features: aortic root z-score >3.0 or expanding rapidly (>0.5 cm/year), or mild craniofacial features: aortic root z-score >4.0 or expanding rapidly (>0.5 cm/year)
         b) Effort should be made to delay surgery until the annulus reaches 1.8 cm, allowing placement of a valve-sparing graft of sufficient size to accommodate growth.
         c) Large size or rapid expansion of the descending aorta or other vessels
   j. Situations and agents to avoid
      i. Contact sports
      ii. Competitive sports
      iii. Isometric exercise
      iv. Agents that stimulate the cardiovascular system including routine use of decongestants
      v. Activities that cause joint injury or pain

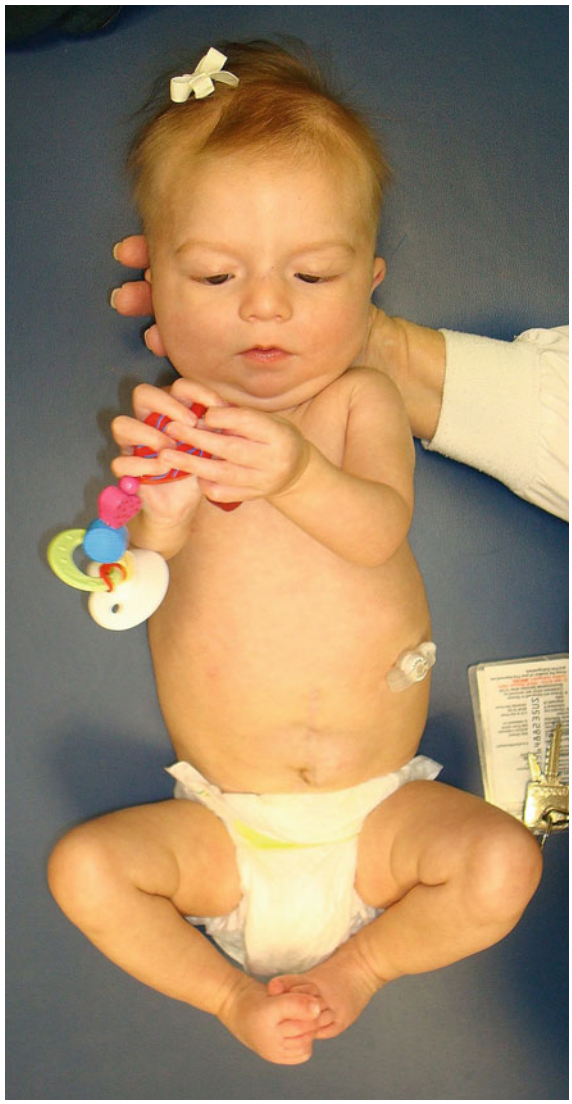

Fig. 1 A 5-month-old infant girl with molecularly confirmed Loeys–Dietz syndrome with *TGFBR1* exon 4 mutation c.722C>T (Ser241Leu). She was evaluated initially for possible neonatal Marfan syndrome because of very long fingers and toes. At 3 weeks of age, she was diagnosed to have intestinal malrotation which was surgically repaired and a Nissen fundoplication was performed. She had seizures since birth (eyes rolling up, occasional twitching and head pulling back for a very short period). MRI of the brain showed bilateral caudal thalamic groove cyst. At 3 months of age, she was noted to be abnormally pale and was found to have bleeding due to a ruptured wandering spleen in the pelvis which was surgically removed. She had a surgical incision hernia at the site of the first surgery in addition to her original inguinal hernia. Multiple echocardiograms showed no aortic root dilatation but the patient was put on β-blocker for aortic root dilatation prevention. Family history was noncontributory. Note the ocular hypertelorism, dolichostenomelia, and arachnodactyly

Fig. 2 Note the large incisional umbilical hernia

Fig. 3 Note the marked hypotonia and long and slender extremities

Fig. 4 Note the long toes

Lowe Syndrome

Lowe syndrome, also known as oculocerebrorenal syndrome, is a rare X-linked recessive disorder. It was initially recognized in 1952 by Lowe and colleagues who described the triad of congenital cataracts, mental retardation, and generalized aminoaciduria. In 1954, a renal Fanconi syndrome was recognized as being associated with the syndrome (Bickel & Thurshby-Pelnam 1954) and in 1965, an X-linked recessive pattern of inheritance was determined (Richards et al. 1965). Its prevalence is estimated to be several cases per 100,000 males.

Synonyms and Related Disorders

Dent-2 disease; Oculocerebrorenal syndrome

Genetics/Basic Defects

1. Inheritance
   a. X-linked recessive disorder predominantly affecting males, although several affected females have been reported
   b. New mutations in 31.6% of affected males
   c. Germline mosaicism in 4.5%
2. The gene involved (*OCRL1*)
   a. Map locus: Xq26.1, based on
      i. Balanced X-autosome translocations with a break-point in band Xq25-q26 in two unrelated female patients
      ii. Linkage analysis with RLFP in families with multiple affected individuals
   b. Mapped in 1977
   c. Cloned in 1992
   d. Encoding *OCRL1*, a 105-kD enzyme with phosphatidylinositol 4,5-bisphosphate 5-phosphatase (PtdIns-4,5-P_2) activity localized to the Golgi complex
      i. Loss or reduction of the enzyme demonstrated in affected males
      ii. Carrier status of OCRL in females not readily determined by assays of the enzyme due to the X-linked nature of *OCRL1* and random X inactivation
3. Mutations of *OCRL1* gene responsible for Lowe syndrome
   a. Nonsense mutations and deletions causing frameshifts and premature termination
   b. Deletions
   c. Missense mutations in domains conserved among all the known PtdIns(4,5)P_2 5-phosphatases
4. Carrier females with typical lens opacities
5. Affected females as a result of
   a. Unfavorable lyonization
   b. Turner syndrome
   c. X-autosome translocation through the relevant gene
6. Dent-2 disease (a mild variant of Lowe syndrome (Bökenkamp et al. 2009)
   a. Dent disease
      i. An X-linked tubulopathy characterized by low-molecular-weight proteinuria, hypercalciuria, and nephrolithiasis/nephrocalcinosis (1)
      ii. In more than half the patients, Dent disease is caused by mutations affecting the voltage-gated chloride channel and chloride/proton antiporter (ClC-5).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_150,
© Springer Science+Business Media, LLC 2012

b. Dent-2 disease
   i. In approximately 15% of patients with a Dent phenotype, mutations in the oculocerebrorenal syndrome of Lowe gene (*OCRL*) encoding a phosphatidylinositol 4,5-bisphosphate 5-phosphatase, have been found (Hoopes et al. 2005; Utsch et al. 2006; Sekine et al. 2007; Cho et al. 2008).
   ii. These patients are classified as having "Dent disease-2" to distinguish them from most patients with an *OCRL* mutation who have the more severe oculocerebrorenal syndrome of Lowe phenotype (Charnas et al. 1991) which is characterized by a proximal tubulopathy (Böckenhauer et al. 2008; Kleta 2008), congenital cataract, severe mental retardation, and behavioral disturbances.

Clinical Features

1. Variable age of onset and severity of clinical manifestations
2. Eye abnormalities
   a. Congenital cataracts (the hallmark of the disease)
      i. Developed prenatally
      ii. Always present prior to birth
   b. Congenital glaucoma with or without buphthalmos (50–60%)
   c. Microphthalmos
   d. Nystagmus
   e. Decreased visual acuity (blindness)
   f. Corneal scarring and keloid formation
      i. Develops spontaneously without trauma
      ii. Onset usually after age 5
      iii. Causes significant visual impairment
3. Renal abnormalities
   a. Fanconi syndrome of renal tubules (the cardinal features)
      i. Bicarbonaturia
      ii. Proximal tubular acidosis
      iii. Generalized aminoaciduria
      iv. Hyperphosphaturia leading to osteomalacia, renal rickets, and pathologic fractures
      v. Hypercalciuria
      vi. Proteinuria
      vii. Glycosuria (not a feature of the renal tubular dysfunction)
      viii. Impairment in urine-concentration (polyuria)
      ix. Carnitine wasting
   b. Variable age of onset and severity of the tubular dysfunction
      i. Failure to thrive
      ii. Recurrent infections
      iii. Metabolic collapse
      iv. Severe hypokalemia or hypocalcemia requiring replacement therapy in a minority of patients. This is probably a part of preterminal exacerbation of tubular dysfunction.
      v. Slowly progressive renal failure may occur in the second to fourth decade of life.
4. CNS (prominently involved organ) and behavioral abnormalities
   a. Cardinal features
      i. Neonatal/infantile hypotonia
      ii. Delay in motor milestones
      iii. Cognitive impairment
      iv. Areflexia by 1 year of age
   b. Mental retardation (common but not cardinal feature)
   c. Seizures
   d. Neuropathologic and neuroimaging abnormalities
   e. Stereotypic behaviors
      i. Temper tantrum (Lowe tantrum)
      ii. Aggression
      iii. Irritability
      iv. Stubbornness
      v. Rigidity of thought
      vi. Self injury
      vii. Repetitive nonpurposeful movements
5. Musculoskeletal abnormalities
   a. Secondary consequences of hypotonia, renal tubular acidosis, and/or hypophosphatemia
      i. Short stature
      ii. Joint hypermobility
      iii. Dislocated hips
      iv. Genu valgum
      v. Scoliosis
      vi. Kyphosis
      vii. Platyspondylia
      viii. Fractures
   b. Primary abnormality of excessive connective tissue growth
      i. Nontender joint swelling
      ii. Subcutaneous nodules

6. Typical facies
   a. Frontal bossing
   b. Characteristic deep-set eyes
   c. Inattentiveness
7. Other features
   a. Increased hemorrhagic risk (Lane et al. 2010)
   b. Cryptorchidism
8. Natural history
   a. Succumb to either severe renal insufficiency and dehydration or infection
   b. Survival to adulthood if metabolic abnormalities are adequately treated
9. Manifestation in the carriers
   a. Lens involvement
      i. Micropunctate cataracts clustered in a radial wedge pattern
      ii. Occasional dense posterior cortical cataract
   b. Sensitivity of carrier detection by slit-lamp examination (>90%), due to random inactivation of Lowe syndrome allele in the proportion of cells in the lens of female carriers
   c. Germ line or somatic mosaicism documented
   d. Positive family history of early cataracts in mother, maternal female relatives, and institutionalized maternal uncles

Diagnostic Investigations

1. Blood chemistry
   a. Blood gas for metabolic acidosis
   b. Electrolyte disturbances (likely absent in neonates and young infants)
2. Urine
   a. Aminoaciduria
   b. Hyperphosphaturia
   c. Low-molecular-weight (LMV) proteinuria: characterized by the excretion of proteins such as retinal binding protein and N-acetyl glucosaminidase, is seen in
      i. Lowe syndrome: LMW proteinuria can be seen early in life even in the absence of clinically significant aminoaciduria or other renal tubular abnormalities (Laube et al. 2004)
      ii. The allelic disorder Dent disease
      iii. Many other diseases associated with the Fanconi syndrome
   d. Glycosuria
   e. Low urine osmolality
   f. Elevated 24-h volume
3. Serum enzyme values
   a. Elevated CK
   b. Elevated SGOT
   c. Elevated LDH
   d. Elevated α2-globulin
4. Measurement of inositol polyphosphate 5-phosphatase OCRL1 activity in cultured skin fibroblasts (Lewis et al. 2008)
   a. Males: to confirm the diagnosis in affected males (Suchy et al. 1995; Zhang et al. 1995)
      i. Affected males have less than 10% normal activity of the enzyme.
      ii. Such testing is abnormal in more than 99% of affected males.
   b. Carrier females. The activity is not accurate for carrier detection because of lyonization (random X-chromosome inactivation), which results in a wide range of "normal" activity in females (Lin et al. 1999).
5. Karyotype. Translocations between an autosome and an X chromosome with a breakpoint through the OCRL locus (Xq26.1) have been observed (Hodgson et al. 1986; Mueller et al. 1991)
6. Radiography
   a. Rickets/osteoporosis
   b. Pathological fractures
   c. Frontal bossing
   d. Kyphoscoliosis
   e. Cervical spine anomalies
   f. Platyspondyly
   g. Hip subluxations/dislocation
7. Neuroimaging
   a. Cranial MRI
      i. Mild ventriculomegaly (33%)
      ii. Multiple tiny periventricular cysts (no clinical significance)
      iii. Two patterns of brain lesions (de Carvalho-Neto et al. 2009)
         a) Hyperintensities on T2-weighted images
         b) Periventricular cystic lesions
   b. Neuropathologic examination of the brain
      i. Normal in some cases
      ii. Diffuse or focal myelin pallor without myelin breakdown
      iii. Ventriculomegaly
      iv. Mild cerebral abnormalities

v. Isolated cases of subependymal cysts
vi. Mesencephalic porencephaly
vii. Postencephalitic changes
viii. Blunted and foreshortened frontal lobes
ix. Acute pontine necrosis
x. Cerebellar hypoplasia
xi. Aberrant neuronal migration
xii. Multiple tiny cysts without inflammatory changes

8. Affected male patients
   a. Biochemical assay of reduced activity (<10%) of PtdIns (4,5)P_2 5-phosphatase in cultured fibroblasts to confirm diagnosis of patients with OCRL. Peripheral blood cannot be tested since the enzyme is not present in lymphocytes.
   b. Molecular analysis to detect mutations in the *OCRL* gene in about 95% of affected males
      i. Sequence analysis
      ii. Fluorescence in situ hybridization analysis (FISH), with cosmid probes that span the entire *OCRL1* gene
9. Carrier females
   a. Karyotyping to rule out X-autosome translocation with a breakpoint through the *OCRL* locus
   b. Carrier detection
      i. Biochemical assay of reduced activity of PtdIns (4,5)P_2 5-phosphatase in cultured fibroblasts is not suitable for determining OCRL carrier status, since random X inactivation could result in a wide range of enzyme activity that may overlap with the normal range.
      ii. An obligatory carrier based on evaluation of the family pedigree
      iii. Slit-lamp examination for numerous punctate opacities, especially in prepubertal females, is a better method and it has a low false-negative rate.
      iv. By direct detection of mutations when the mutation is previously identified (in about 95% of carrier females)
      v. By mutation scanning of high-risk females by denaturing high performance liquid chromatography (DHPLC) when:
         a) The affected male is not available
         b) The diagnosis has been confirmed by enzyme analysis
      vi. By linked markers when the mutation is unknown

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. A 25% risk of having an affected boy and a 25% risk of having a carrier daughter if the mother is a carrier
      ii. A low but finite recurrence risk (estimated to be about 1.5%) in case of a new mutation due to possibility of nonpenetrance or gonadal mosaicism in the mother
   b. Patient's offspring: affected males not known to reproduce
2. Prenatal diagnosis available for pregnancies at risk
   a. Determine fetal gender by amniocentesis or CVS
   b. Biochemical assay for deficiency of PtdIns(4,5)P_2 5-phosphatase from cultured amniotic fluid cells or cultured CVS if the fetal karyotype shows 46,XY (not suitable for determining OCRL carrier status for females)
   c. Molecular analysis
      i. By direct detection of mutations when the *OCRL* disease-causing mutation in the family is known
      ii. By linked markers in informative families when the mutation is unknown
   d. Offer prenatal diagnosis by enzymatic analysis to every mother of a son with Lowe syndrome because of the relatively high rate (4.5%) of germline mosaicism, even with the following situations:
      i. Negative family history
      ii. Negative dilated slit-lamp examination
      iii. DNA testing showing that the mother is not a carrier
3. Management
   a. Ocular management
      i. Cataract extraction to avoid amblyopia
      ii. Refraction for aphakia
      iii. Control of glaucoma
      iv. Removal of corneal keloids: often with recurrence and enlargement of the lesions
   b. Speech and physical therapy for developmental delay
   c. Medications
      i. Anticonvulsants
      ii. Behavior-modifying medications if needed

d. Replacement/supplementation
   i. Phosphate and sodium-potassium citrate for renal tubular acidosis (urinary bicarbonate, water, and phosphate losses) and bone disease (rickets)
   ii. L-carnitine
   iii. Vitamin D supplements as indicated
e. Anesthetic risks
   i. Chronic metabolic acidosis
   ii. Existing hypokalemia, a risk for serious cardiac arrhythmia
   iii. A risk of glaucoma
   iv. Hypophosphatemic rickets causing fragility of bone structures
      1. Requires attention while positioning
      2. Difficulty in maintaining the airway due to craniofacial abnormalities and abnormal teeth structure

Fig. 1 (**a**–**d**) One and half year-old boy with Lowe syndrome showing frontal bossing and deep-set eyes. He had a history of profound hypotonia, failure to thrive, cataracts, glaucoma, seizures, and generalized aminoaciduria. The diagnosis was confirmed by assay of markedly deficient phosphatidylinositol bisphosphate phosphatase activity in the cultured fibroblasts (0.05, control: 2–5 mmol/min/mg protein). The recent photos were taken at 6 and 9 years of age

Fig. 2 (**a**, **b**) A 10-year-old boy with Lowe syndrome showing short stature and visual impairment. The diagnosis was confirmed by assay of markedly deficient phosphatidylinositol bisphosphate phosphatase activity (0.05 with normal control of 2–5 nmol/min/mg protein) in the cultured fibroblasts

Marfan Syndrome

Marfan syndrome (MFS) is an inherited connective tissue disorder, noteworthy for its worldwide distribution, relatively high prevalence, clinical variability, and pleiotropic manifestations involving primarily the ocular, skeletal, and cardiovascular systems, some of which are life threatening. Its estimated frequency is 2–3 per 10,000 individuals.

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. New mutation in about 25–30% of the cases
   c. About 70–75% of individuals diagnosed with Marfan syndrome have an affected parent.
2. Caused by a wide variety of mutations in the fibrillin-1 (*FBN1*) gene located on chromosome 15q21.1
3. Molecular defects in the fibrillin gene are responsible for the impaired structural integrity of the skeletal, ocular, and cardiovascular systems.
4. Almost all mutations are specific (unique) to a particular individual or family.
5. *FBN1* mutation is helpful diagnostically only if it has been previously found in the person who independently meets the criteria for Marfan syndrome.
6. Criteria for causal *FBN1* mutation (Loeys et al. 2010)
   a. Mutation previously shown to segregate in Marfan family
   b. De novo (with proven paternity and absence of disease in parents) mutation (one of the five following categories)
   c. Nonsense mutation
   d. Inframe and out of frame deletion/insertion
   e. Splice site mutations affecting canonical splice sequence or shown to alter splicing on mRNA/cDNA level
   f. Missense affecting/creating cysteine residues
   g. Missense affecting conserved residues of the EGF consensus sequence ((D/N)X(D/N)(E/Q)Xm(D/N)Xn(Y/F) with m and n representing variable number of residues; D aspartic acid, N asparagine, E glutamic acid, Q glutamine, Y tyrosine, F phenylalanine)
   h. Other missense mutations: segregation in family if possible plus absence in 400 ethnically matched control chromosomes, if no family history absence in 400 ethnically matched control chromosomes
   i. Linkage of haplotype for $n \geq 6$ meioses to the FBN1 locus
7. No obvious correlation between location of mutation and phenotypic severity (except an apparent clustering of mutations associated with the most severe form of Marfan syndrome, i.e., neonatal Marfan syndrome)
8. Pathophysiological consequence of the elastic fiber degeneration: reduced distensibility in response to the pulse pressure wave or increased stiffness (Dean 2002)
9. Intrafamilial and interfamilial variability of clinical expression
10. Fibrillin-1 mutations also observed in related disorders of connective tissue (type I fibrillinopathies) (Dietz 2009; Loeys et al. 2010)
    a. Autosomal dominant ectopia lentis (bilateral ectopia lentis without the typical skeletal and

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_151,
© Springer Science+Business Media, LLC 2012

cardiovascular manifestations of the Marfan syndrome)

b. Shprintzen-Goldberg syndrome
   i. Unclear inheritance pattern
   ii. Marfanoid habitus
   iii. Craniosynostosis
   iv. Mental retardation
   v. Rarely aortic root dilatation
   vi. Mitral valve prolapse
   vii. Majority of cases are not caused by *FBN1* mutations

c. Autosomal dominant Weill-Marchesani syndrome
   i. Ectopia lentis
   ii. Short stature

d. Familial ectopic lentis
   i. An autosomal dominant condition
   ii. Bilateral ectopia lentis
   iii. Scoliosis in some cases
   iv. No cardiovascular manifestations

e. Familial aortic aneurysm
   i. Ascending aortic aneurysm and dissection
   ii. No ectopia lentis
   iii. No specific skeletal findings

f. MASS phenotype
   i. An autosomal dominant condition
   ii. Acronym MASS stands for:
      a) *M*itral valve prolapse
      b) *A*ortic root dilation without dissection
      c) *S*keletal abnormalities
      d) *S*kin abnormalities

g. Mitral valve prolapse syndrome
   i. An autosomal dominant condition
   ii. Mitral valve prolapse
   iii. Associated with subtle skeletal features that are reminiscent of the Marfan syndrome

h. New variant of Marfan syndrome
   i. Skeletal features of Marfan syndrome
   ii. Joint contractures
   iii. Knee joint effusions
   iv. Ectopia lentis
   v. No cardiovascular manifestations

i. Marfan-like (Marfanoid) skeletal abnormalities
   i. Tall stature
   ii. Scoliosis
   iii. Pectus excavatum
   iv. Arachnodactyly

11. Other disorders overlap with Marfan syndrome (Dietz 2009; Loeys et al. 2010).
   a. Loeys-Dietz syndrome: please see the chapter on Loeys-Dietz syndrome
      i. An autosomal dominant condition
      ii. Shares many features of Marfan syndrome but ectopia lentis is absent
      iii. Unique features
         a) Craniofacial involvement (bifid uvula/cleft palate, hypertelorism, craniosynostosis)
         b) Skin: soft, velvety, and translucent
         c) Easy bruising
         d) Generalized arterial tortuosity and aneurysms
         e) Dissection throughout the arterial trees
      iv. Other features
         a) Clubfoot
         b) Cervical spine instability
      v. Caused by mutations in either the *TGFBR1* or *TGFBR2* gene (Loeys et al. 2005, 2006)
      vi. Loeys-Dietz syndrome types 1 and 2: designate those with and without severe craniofacial involvement respectively (Loeys et al. 2006)
   b. Congenital contractural arachnodactyly
      i. Caused by fibrillin-2 (*FBN2*) mutations (highly homologous to BBN1, mapped to chromosome 5q23-31)
      ii. Characteristic features
         a) Marfanoid habitus
         b) Arachnodactyly
         c) Camptodactyly
         d) Crumpled ears
         e) Mild contractures of the elbows, knees, and hips
         f) Mild muscle hypoplasia especially of the calf muscles
   c. Ehlers-Danlos syndrome: please see the chapter on Ehlers-Danlos syndrome
   d. Homocystinuria
      i. An autosomal recessive condition
      ii. Caused by cystathionine β-synthase deficiency resulting from mutations in the *CBS* gene
      iii. Characteristic clinical features

a) Variable mental retardation
b) Ectopia lentis and/or severe myopia
c) Skeletal abnormalities (including excessive height and limb length)
d) Excessive overlap with Marfan syndrome (a long and lean body habitus, pectus deformity, scoliosis, mitral valve prolapse, highly arched palate, hernia, and ectopia lentis)
e) A tendency for intravascular thrombosis and thromboembolic events: Thromboembolic events can be life threatening. Approximately half of affected individuals are responsive to pharmacologic doses of vitamin B6, highlighting the need to consider this diagnosis.

e. Stickler syndrome: please see the chapter on Stickler syndrome
f. Fragile X syndrome: please see the chapter on Fragile X syndrome

Clinical Features

Ghent criteria: For the diagnosis of Marfan syndrome in the first (index) case in a family, major criteria must be found in at least two different organ systems and minor criteria in a third body system. If a fibrillin-1 mutation is identified, a major criterion in one system and involvement of another system are required. In a relative of an individual with confirmed Marfan syndrome, a major criterion in one body system and involvement of another system are all that are needed for the diagnosis (Pyeritz 2000).

1. Skeletal system (requires at least two majors or one major plus two minors): Affected patients are usually tall and thin with respect to the family profile. Limbs are disproportionately long compared with the trunk (dolichostenomelia). Arachnodactyly is a very common feature.
   a. Major criteria (requires at least four manifestations)
      i. Pectus carinatum
      ii. Pectus excavatum requiring surgery
      iii. Reduced upper-to-lower body segment ratio (<0.85 in Caucasians and <0.78 in African descents) or arm span-to-height ratio greater than 1.05. Arms and legs may be unusually long in proportion to the torso.
      iv. Positive wrist (Walker-Murdoch) and thumb (Steinberg) signs for arachnodactyly. Two simple maneuvers may help demonstrate arachnodactyly. First, the thumb sign is positive if the thumb, when completely opposed within the clenched hand, projects beyond the ulnar border. Secondly, the wrist sign is positive if the distal phalanges of the first and fifth digits of one hand overlap when wrapped around the opposite wrist.
      v. Scoliosis ≥20 or spondylolisthesis. More than 60% of patients have scoliosis. Progression is more likely with curvature greater than 20° in growing patients.
      vi. Reduced extension of the elbows (<170°).
      vii. Medial displacement of the medial malleolus, resulting in pes planus
      viii. Protrusio acetabuli (intrapelvic protrusion of the acetabulum; abnormally deep acetabulum with accelerated erosion) of any degree (ascertained by pelvic radiograph). Prevalence is about 50%.
   b. Minor criteria
      i. Pectus excavatum of moderate severity
      ii. Joint hypermobility
      iii. High arched palate with dental crowding
      iv. Typical face
         a) Dolichocephaly
         b) Malar hypoplasia
         c) Enophthamos
         d) Retrognathia
         e) Down-slanting palpebral fissures
2. Ocular system (requires one major or at least two minors).
   a. Major criterion: ectopia lentis (usually superior temporal dislocation, almost always bilateral, occurs in up to 80% of affected individuals). This may present at birth or develop during childhood or adolescence.
   b. Minor criteria
      i. Abnormally flat cornea (measured by keratometry)

ii. Increased axial length of the globe (measured by ultrasound)
iii. Hypoplastic iris or hypoplastic ciliary muscle causing decreased miosis

3. Cardiovascular system (requires one major or one minor): the most serious problems associated with Marfan syndrome
   a. Major criteria
      i. Dilatation of the ascending aorta with or without aortic regurgitation and involving at least the sinuses of Valsalva. The prevalence of aortic dilatation in Marfan syndrome is 70–80%. It presents at an early age and tends to be more common in men than women.
      ii. Dissection involving the ascending aorta
   b. Minor criteria
      i. Mitral valve prolapse with or without mitral valve regurgitation. The prevalence of mitral valve prolapse is 55–69%.
      ii. Dilatation of main proximal pulmonary artery in the absence of valvular or peripheral pulmonic stenosis or any other obvious cause, below the age of 40 years
      iii. Calcification of mitral annulus in patients less than 40 years of age
      iv. Dilatation or dissection of abdominal or descending thoracic aorta in patients less than 50 years of age
4. Pulmonary system (requires one minor)
   a. Major criterion: none
   b. Minor criteria
      i. Spontaneous pneumothorax: occurs in about 5% of patients
      ii. Apical blebs (on chest radiography)
5. Skin and integument (requires one minor)
   a. Major criterion: none
   b. Minor criteria
      i. Striae atrophicae (stretch marks) not associated with marked weight changes, pregnancy, or repetitive stress. Stretch marks are usually found on the shoulder, midback, and thighs.
      ii. Recurrent or incisional hernia
6. Dura (requires the major criterion)
   a. Major criterion: lumbosacral ectasia (ballooning or widening of the dural sac) by CT or MRI. Fewer than 20% of patients experience serious dural ectasia. Dural ectasia is thought to be caused by CSF pulsations against weakened dura.
   b. Minor criteria: none
7. Family history (requires one major)
   a. Major criteria
      i. Having a parent, child, or sibling who meets the diagnostic criteria independently
      ii. Presence of a mutation in *FBN1* known to cause the MFS
      iii. Presence of a haplotype around *FBN1*, inherited by descent, known to be associated with unequivocally diagnosed MFS in the family
   b. Minor criterion: none
8. Other features not in the Ghent criteria
   a. Ocular features
      i. Myopia (most common ocular feature)
      ii. At increased risk for retinal detachment, glaucoma, and early cataract formation
   b. Skeletal system
      i. Bone overgrowth
      ii. Disproportionately long extremities for the size of the trunk (dolichostenomelia)
      iii. Overgrowth of the ribs pushing the sternum in (pectus excavatum) or out (pectus carinatum)
      iv. Mild, severe, or progressive scoliosis
9. Natural history: age-related nature of some clinical manifestations and variable phenotypic expression
   a. At birth, early in life, and childhood
      i. Dolichostenomelia
      ii. Arachnodactyly
      iii. Manifestations of other organ systems usually not present at birth, making the diagnosis during neonatal period difficult in the absence of family history
      iv. Asthenic habitus
      v. Lens dislocation or lens subluxations (a hallmark feature) commonly diagnosed during the first year of life (not present at birth)
   b. Childhood and puberty
      i. Skeletal manifestations apparent during childhood
      ii. Pectus deformities and scoliosis worsen during puberty

iii. Upper normal or larger than normal aortic root size in early childhood
iv. Rapidly increasing magnitude of dilatation during puberty

c. Adulthood
i. Lumbosacral dural ectasia manifesting as progressive dilatation of the dura with consequent erosion of vertebral bone during adulthood
ii. Aortic disease as the major cause of cardiovascular morbidity and reduced life expectancy (initial life expectancy: 32 +/− 16 years)
iii. Increased life expectancy attributes to successive elective and emergent aortic surgery and to the use of β-adrenergic receptor antagonists for the prevention of the progression of aortic root dilatation (current life expectancy: 41 ± 18 years)

10. Revised Ghent nosology for the Marfan syndrome (Loeys et al. 2010)
a. Established by an international expert panel
b. Puts more weight on the cardiovascular manifestations in which aortic root aneurysm and ectopia lentis are the cardinal clinical features
i. In the absence of any family history, the presence of aortic root aneurysm and ectopic lentis is sufficient for the unequivocal diagnosis of MFS.
ii. In absence of either of aortic aneurysm or ectopic lentis, the presence of a bonafide *FBN1* mutation or a combination of systemic manifestations is required. The following new scoring system has been designed for systemic features: The score of ≥7 indicates systemic involvement (maximum total of 20 points).
a) Wrist and thumb sign: 3 (wrist or thumb sign: 1)
b) Pectus carinatum deformity: 2 (pectus excavatum or chest asymmetry: 1)
c) Hindfoot deformity: 2 (plain pes planus: 1)
d) Pneumothorax: 2
e) Dural ectasia: 2
f) Protrusio acetabuli: 2
g) Reduced US/LS and increased arm/height and no severe scoliosis: 1
h) Scoliosis or thoracolumbar kyphosis: 1
i) Reduced elbow extension: 1
j) Facial features (3/5): 1 (dolichocephaly, enophthalmos, down-slanting palpebral fissures, malar hypoplasia, retrognathia)
k) Skin striae: 1
l) Myopia >3 diopters: 1
m) Mitral valve prolapse (all types): 1
c. In this revised nosology, *FBN1* testing, although not mandatory, has greater weight in the diagnostic assessment.
d. Special considerations are given to the diagnosis of MFS in children and alternative diagnoses in adults.
e. These new guidelines may delay a definitive diagnosis of MFS but will decrease the risk of premature or misdiagnosis and facilitate worldwide discussion of risk and follow-up/management guidelines.

11. Neonatal Marfan syndrome
a. Diagnosed early in life because of striking and severe clinical manifestations
i. Two symptoms that are uncommon in severe Marfan syndrome presenting at birth but very common in neonatal Marfan syndrome (Hannekam 2005)
a) Congenital pulmonary emphysema
b) Mitral or tricuspid insufficiency (multivalvular involvement)
ii. Congestive heart failure
iii. Joint contractures
iv. Death usually within the first year of life
b. Characteristic aged facial appearance
i. Deep-set eyes
ii. Down-slanted palpebral fissures
iii. Crumpled ears
iv. High arched palate
c. Striking arachnodactyly of the fingers and toes
d. Pectus deformities
e. Scoliosis
f. Flexion contractures
g. Pes planus
h. Aortic root dilatation
i. Ectopia lentis
j. A cluster of mutations in exons 24–27 as well as in exons 31–32

Diagnostic Investigations

1. Annual physical examination including blood pressure measurement
2. Slit lamp examination for lens dislocation
3. Electrocardiogram for symptomatic palpitations, syncope or near-syncope, and conduction disturbance
4. Echocardiography and targeted imaging studies to carefully monitor the cardiovascular status
   a. Cross-sectional echocardiography for detecting aortic root dilatation
   b. Standard echocardiography for assessing mitral valve prolapse, left ventricular size and function, left atrial size, and tricuspid valve function
   c. Transesophageal echocardiography for visualizing the distal ascending and descending aorta and assessing prosthetic valves
   d. Doppler echocardiography for detecting and assessing the severity of aortic and mitral regurgitation
5. Radiography
   a. Chest X-ray for apical blebs, enlargement of cardiac silhouette, and detecting dissecting aneurysm of aorta
   b. Pelvic X-ray for additional diagnostic criteria of protrusio acetabuli
   c. Feet X-ray for medial displacement of the medial malleolus, responsible for pes planus
6. Computed tomography (CT) and magnetic resonance imaging (MRI)
   a. MRI: best choice for assessing chronic dissection of any region of the aorta
   b. CT or MRI of the lumbosacral spine for detecting dural ectasia
7. Aortograph: still considered by many to be the gold standard for diagnosing acute aortic dissection although sensitivity is not 100% and there are associated risks
8. Molecular analysis of *FBN1* mutations by sequence analysis, mutation scanning, deletion analysis, or linkage analysis (may be used to determine if an individual has inherited an FBN1 allele that is associated with Marfan syndrome in family members)
   a. Routine mutation detection not available clinically due to the large size and complexity of *FBN1* gene
   b. Mutations detected nearly always specific to each family
   c. *FBN1* mutations observed in 20–80% of patients depending upon the clinical selection of patients and the mutation detection method used
      i. Mutation scanning
      ii. Targeted mutation analysis
      iii. Sequencing of entire coding region
   d. Genotype-phenotype correlations (Pyeritz 2000)
      i. Little correlation observed in several hundred mutations reported to date
      ii. Severe MFS detected in infancy (inappropriately termed neonatal MFS) usually caused by point mutations or small deletions inframe in the epidermal growth factor (ECF)–like motifs in the middle third of the fibrillin-1 protein
      iii. Less severe phenotype, verging on the MASS phenotype, usually caused by chain-terminating mutations resulting in essence in null mutants
      iv. Marked variability among individuals with the same mutation
   e. *FBN1* mutations of various types reported
      i. Classic Marfan syndrome
      ii. Nonclassical Marfan related phenotypes
   f. Molecular diagnosis practical in the following two situations (Pyeritz 2000)
      i. Information about a known *FBN1* mutation in a person with MFS applied to relatives
      ii. Linkage analysis using sufficient intragenic and tightly linked polymorphisms to MFS families with several available and willing relatives
9. Histology of the aorta
   a. Elastic fiber fragmentation and disarray
   b. Paucity of smooth muscle cells
   c. Deposition of collagen and the mucopolysaccharide between the cells of the media

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk: small if neither parent is affected

ii. Gonadal mosaicism reported as the cause of multiple affected offspring being born to unaffected parents
iii. Fifty percent if one parent is affected

b. Patient's offspring
i. Fifty percent if the spouse is normal
ii. "Homozygous" MFS reported in case of an affected spouse
iii. "Compound heterozygosity" at the *FBN1* locus confirmed at the molecular level; the affected child had a severe phenotype leading to early death

2. Prenatal diagnosis
a. Ultrasonography insensitive in the first two trimesters for detecting a fetus with MFS
b. Fetal echocardiography with careful limb length measurements by level II ultrasonography for at-risk pregnancy during 20th–24th weeks of gestation
c. Main clinical cardiovascular features for the prenatal diagnosis of Marfan syndrome (Lopes et al. 2006)
i. Cardiomegaly
ii. Dilated great vessels
iii. Dysplastic atrioventricular valves with tricuspid regurgitation and aneurysms of the pulmonary artery and/or sinus of Valsalva
d. Prenatal diagnosis of Marfan syndrome can be confirmed in affected families by gene identification using chorionic villus sampling (Godfrey et al. 1993; Rantamaki et al. 1995).
i. Only if the family's mutation is known in an affected parent
ii. Neonatal Marfan syndrome, mostly sporadic, appears to be more severe than those in familiar forms (Gross et al. 1989). Inability to predict exons 24–32 mutation to be associated with "classic, atypically severe or neonatal" Marfan syndrome (Tieck et al. 2001)
iii. Presence of sufficient affected family members available for genetic linkage analysis if linkage with markers in and around the *FBN1* locus can be established
e. Preimplantation diagnosis accomplished but complicated by the potential for selective PCR amplification of the normal allele as with all autosomal dominant conditions

3. Management
a. Address patients' perceptions of Marfan syndrome and its associated pain, fatigue, and depressive symptoms to enhance patient adaptation.
b. Stress benefits of medication use (β-blockers or calcium-channel blockers to retard aortic root dilatation and dissection) and restriction of physical activities (to delay the onset of a severe cardiovascular event and prevent other syndrome-related problems such as lens dislocation).
i. β-Blockers
a) Should be considered in all Marfan patients, particularly in the younger age group
b) Not suitable for patients with asthma, cardiac failure, or bradyarrhythmias
ii. Other treatments aimed at reducing the ejection impulse
a) Calcium antagonists
b) Angiotensin converting enzyme (ACE) inhibitors
c. Lifestyle changes
i. Avoid competitive and collision/contact sports which are potentially dangerous due to underlying aortic weakness and dilatation, valvular insufficiency, ocular abnormalities, and skeletal problems.
ii. Avoid blows to the head such as boxing and high diving.
iii. Protect against blows to the globe (racquet sports) with cushioned spectacles.
iv. Avoid activities involving isometric work to prevent excessive elevations of systolic blood pressure and sudden death.
a) Weight lifting
b) Climbing steep inclines
c) Gymnastics
d) Water skiing
e) Pull-ups
v. Avoid rapid decompression associated with quick ascents in elevators, scuba diving, and flying in unpressurized aircraft to protect against pneumothorax.
vi. Favor noncompetitive, isokinetic activity performed at a nonstrenous aerobic pace.
a) Golfing
b) Walking
c) Fishing

d. Surgical intervention recommended for affected individuals with significantly dilated or dissected aortic roots
e. Management of scoliosis
   i. Bracing
   ii. Physical therapy
   iii. Surgery for severe scoliosis
f. Pectus repair
   i. Repair of pectus excavatum to improve respiratory mechanics: should be delayed until midadolescence to lessen the chance of recurrence
   ii. Repair of pectus carinatum performed mainly for cosmetic purpose
g. Pneumothorax
   i. Chest tube: an appropriate initial therapy
   ii. Bleb resection and pleurodesis recommended after one recurrence
h. Ocular management
   i. Removal of dislocated lens (pars plana lensectomy and vitrectomy), only in the following few instances, due to an increased risk of retinal detachment related to lens extraction
      a) Dislocation of a lens in the anterior chamber, especially when it touches the corneal endothelium
      b) Significant lens opacity
      c) Evidence of lens-induced uveitis and glaucoma
      d) Inadequate visual acuity that is not correctable by refraction and iris manipulation
      e) Imminent complete luxation of the lens
   ii. Lasers to restore a detached retina
i. Pregnancy in women with MFS
   i. Preconceptional counseling of maternal risks during pregnancy and risk of transmitting the condition to offspring
   ii. A significantly increased risk of cardiovascular complications during pregnancy, particularly risk of dissecting aortic aneurysm
   iii. A high risk of spontaneous abortion but no other adverse maternal or fetal effects
   iv. Need for close surveillance during pregnancy
   v. Avoid pregnancy if echocardiography suggests a high risk of life-threatening cardiovascular compromise. Pregnancy bears a 1% risk of fatal complication; the risk rises with increasing aortic root diameter.
   vi. β-Blockers recommended in pregnant women to prevent aortic dilatation
   vii. Caesarean section should be offered at 38 weeks gestation if aortic root diameter is greater than 4.5 cm (Child 1997).

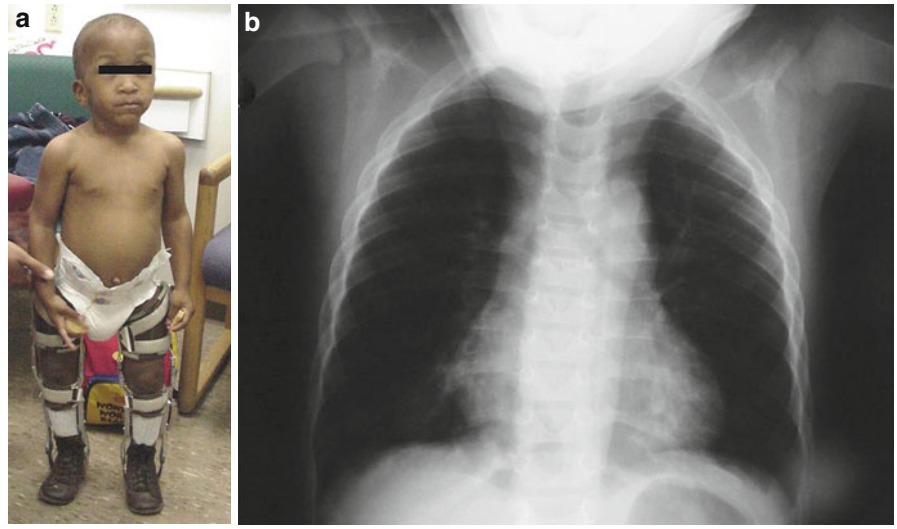

Fig. 1 (**a**, **b**) A boy with severe Marfan syndrome showing arachnodactyly, joint contractures, and aortic root dilatation, illustrated by the chest radiography

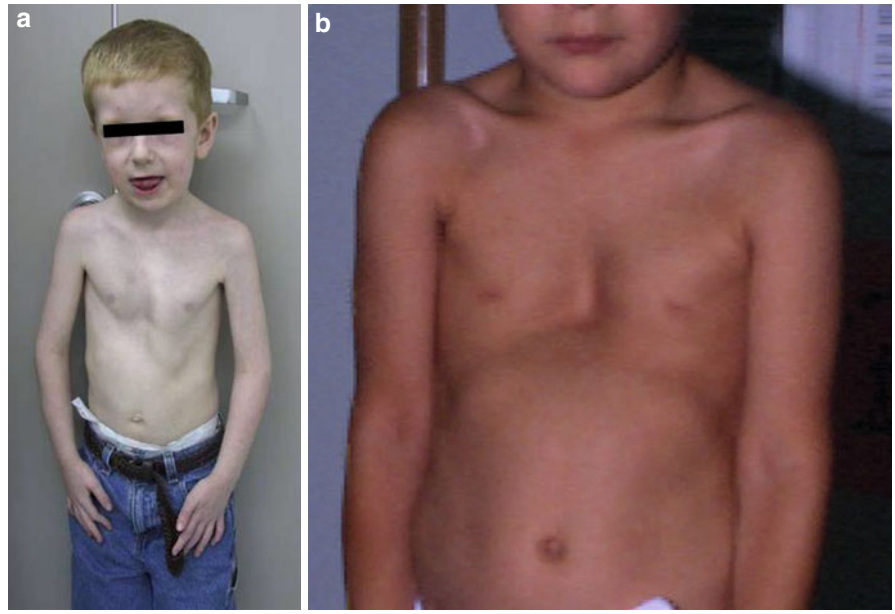

Fig. 2 (**a**, **b**) Two children with Marfan syndrome showing pectus and arachnodactyly. The first patient had dural ectasia detected by MRI. The second patient had aortic root dilatation and mitral valve prolapse

Fig. 3 A 4-year-old girl with Marfan syndrome showing pectus excavatum and the operation scar from surgical correction of marked aortic dilatation. She also has hyperextensible joints and scoliosis

Fig. 4 A 5-year-old boy with Marfan syndrome showing tall and slender body habitus. He was noted to have mitral valve prolapse and aortic root dilatation at age 2. In addition, he has bilateral lens dislocations and scoliosis

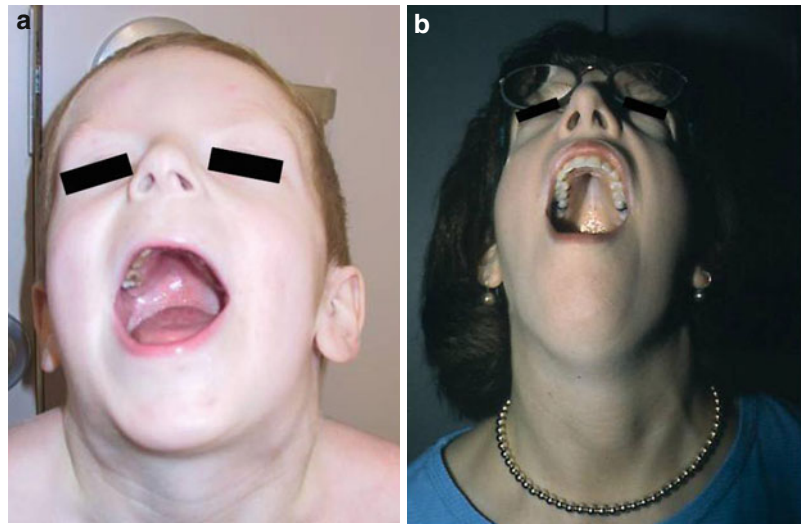

Fig. 5 (**a**, **b**) A child and an adult with Marfan syndrome showing high arched palate

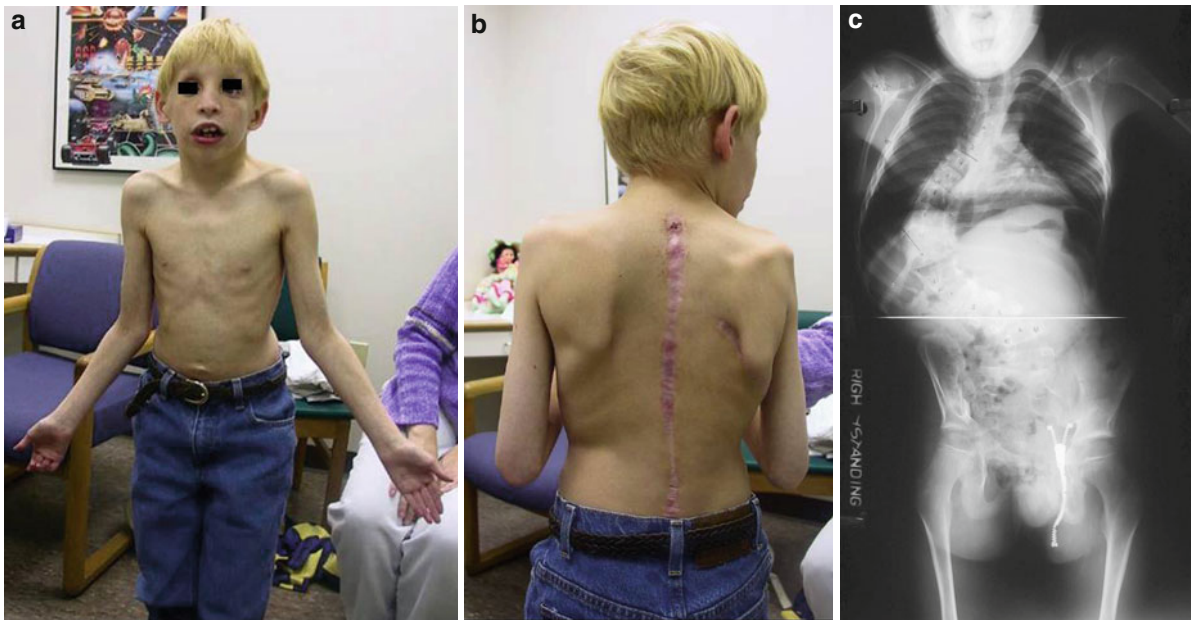

Fig. 6 (**a**–**c**) A child with Marfan syndrome showing cubitus valgus, arachnodactyly, and postsurgical spinal fusion for severe scoliosis (illustrated by radiograph)

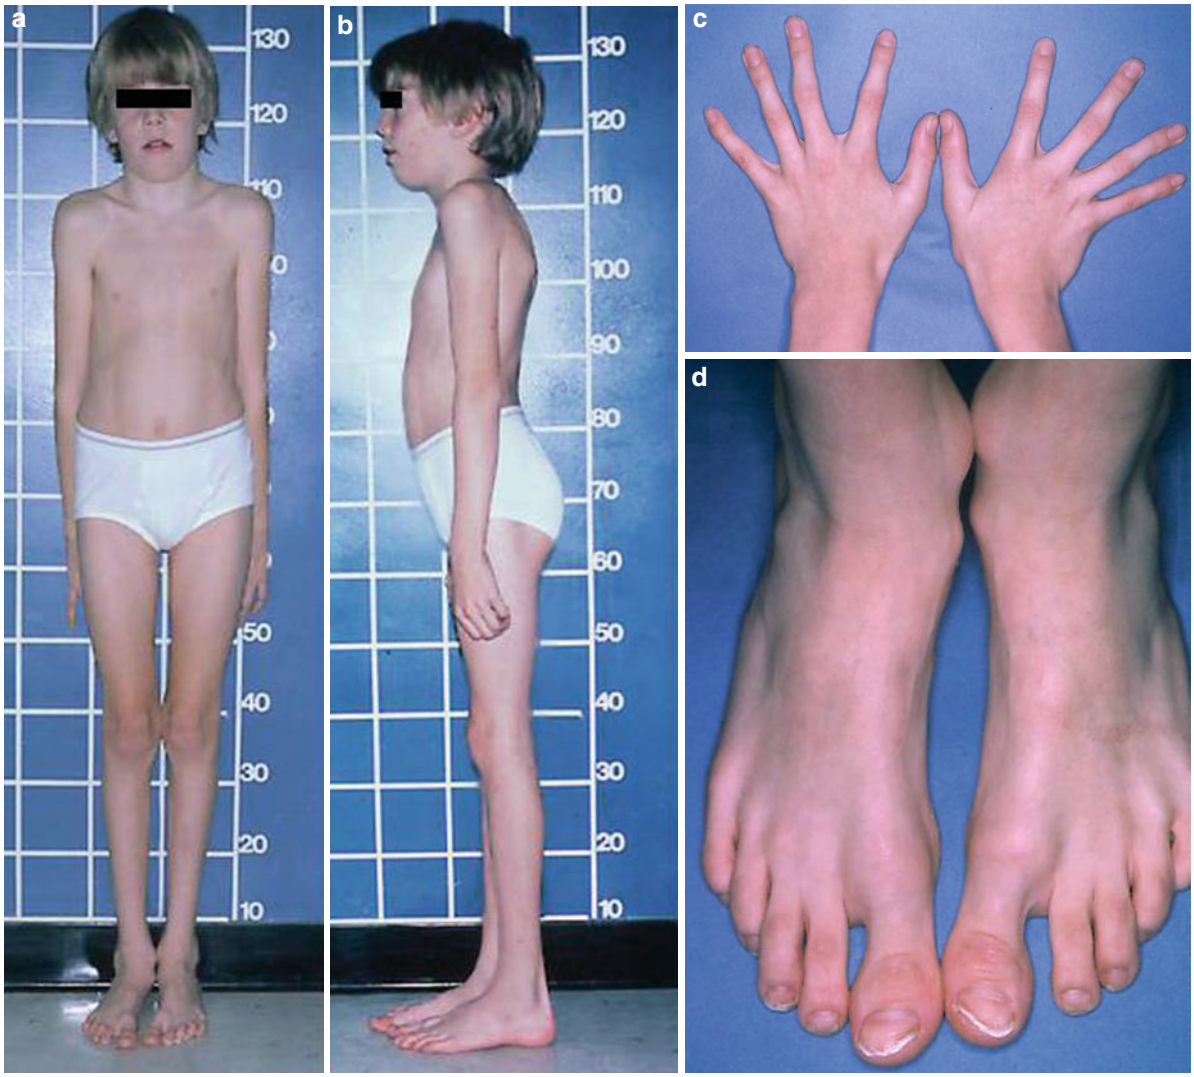

Fig. 7 (**a**–**d**) A boy with Marfan syndrome showing a slender/tall habitus and arachnodactyly

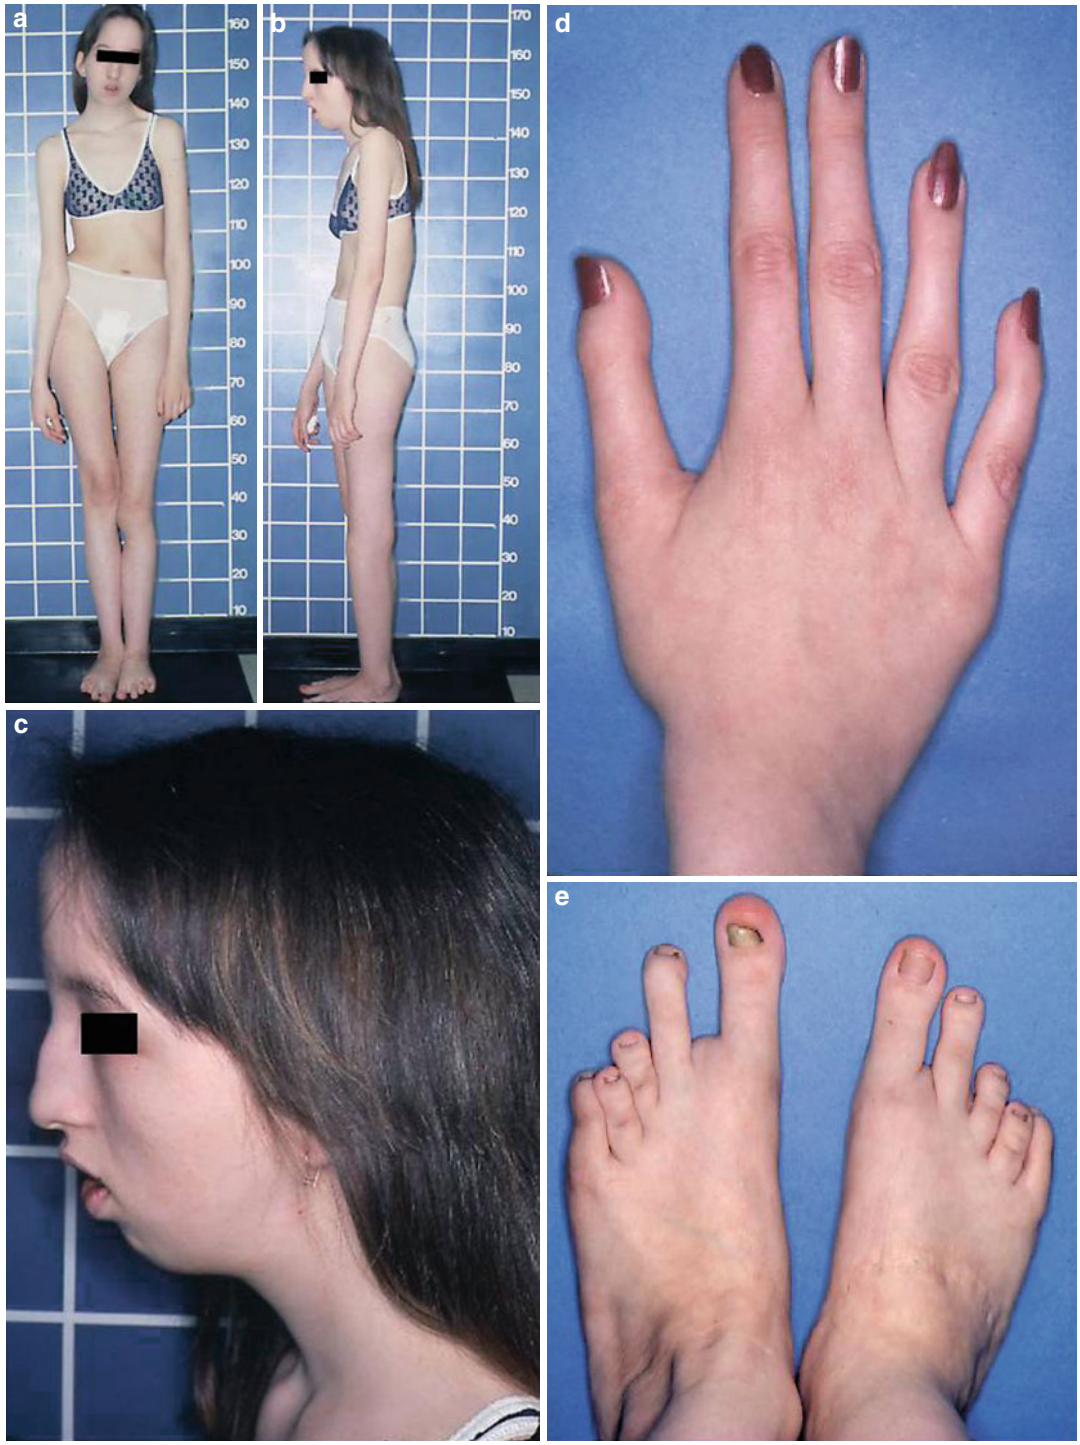

Fig. 8 (**a**–**e**) A girl with Marfan syndrome showing a slender/tall habitus, typical facies, arachnodactyly, and toe anomalies

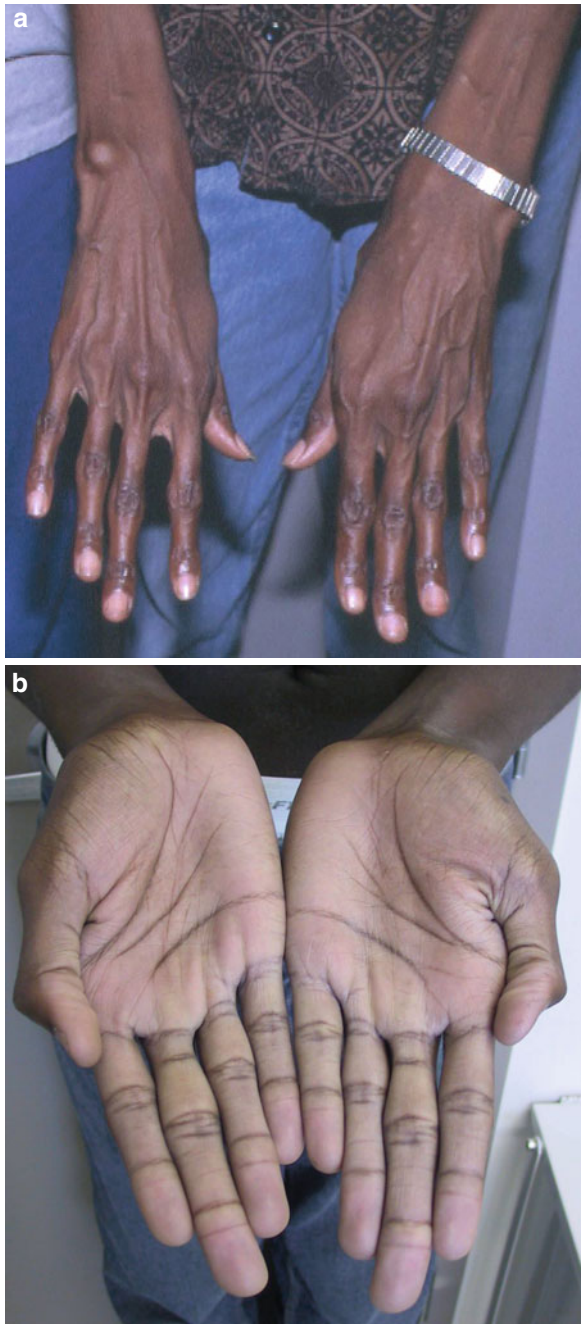

Fig. 9 (**a**, **b**) Arachnodactyly in two adult patients with Marfan syndrome

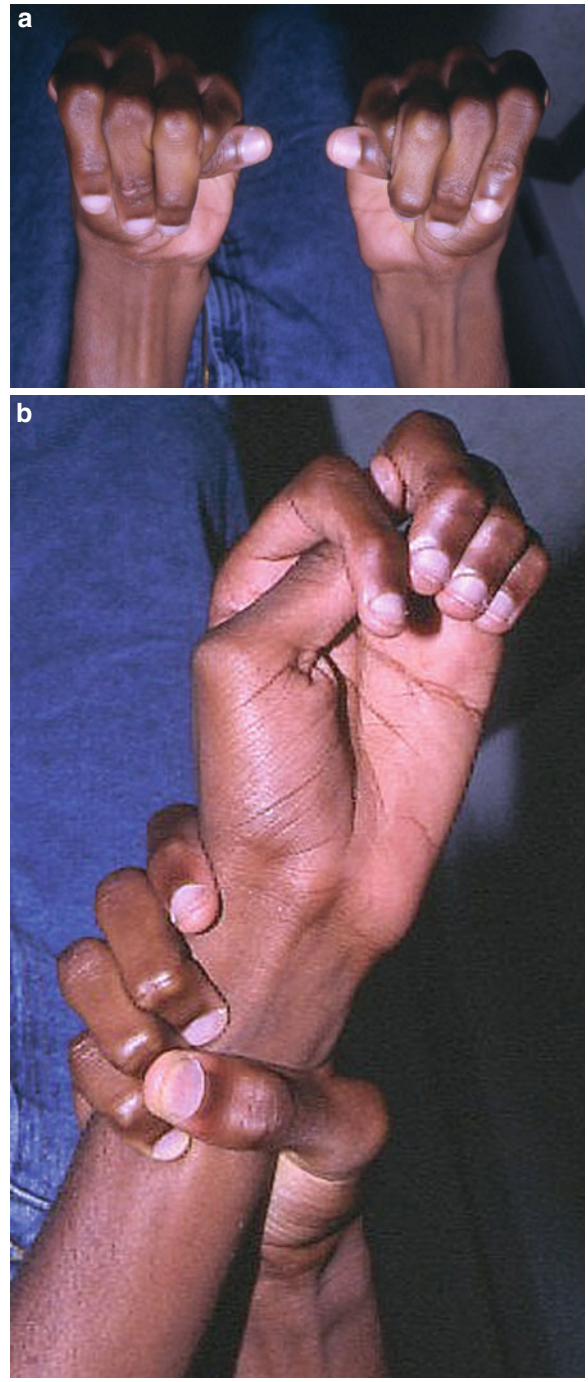

Fig. 10 (**a**, **b**) Thumb and wrist signs

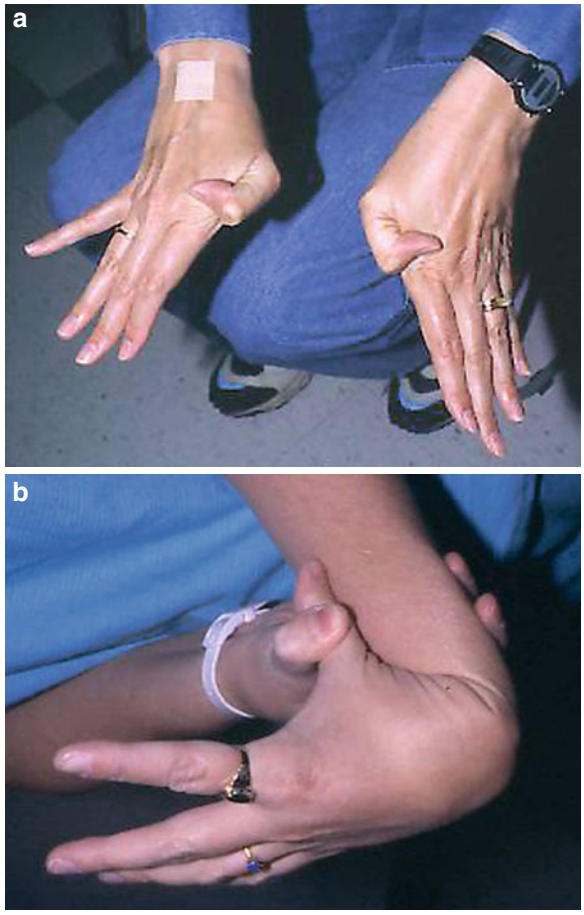

Fig. 11 (**a**, **b**) Hypermobile joints in two patients with Marfan syndrome

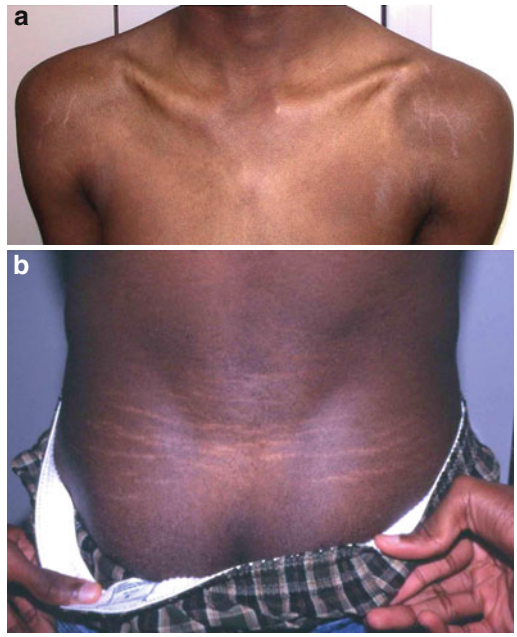

Fig. 12 (**a**, **b**) Stretch marks in the shoulders in one patient and in the buttock region in other patient with Marfan syndrome

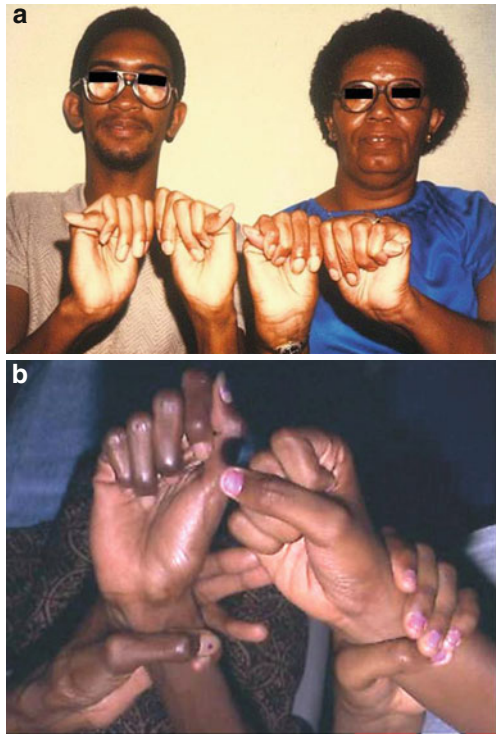

Fig. 13 (**a**, **b**) Familial Marfan syndrome in a mother and a son showing extreme myopia (lens dislocation) and thumb and wrist signs

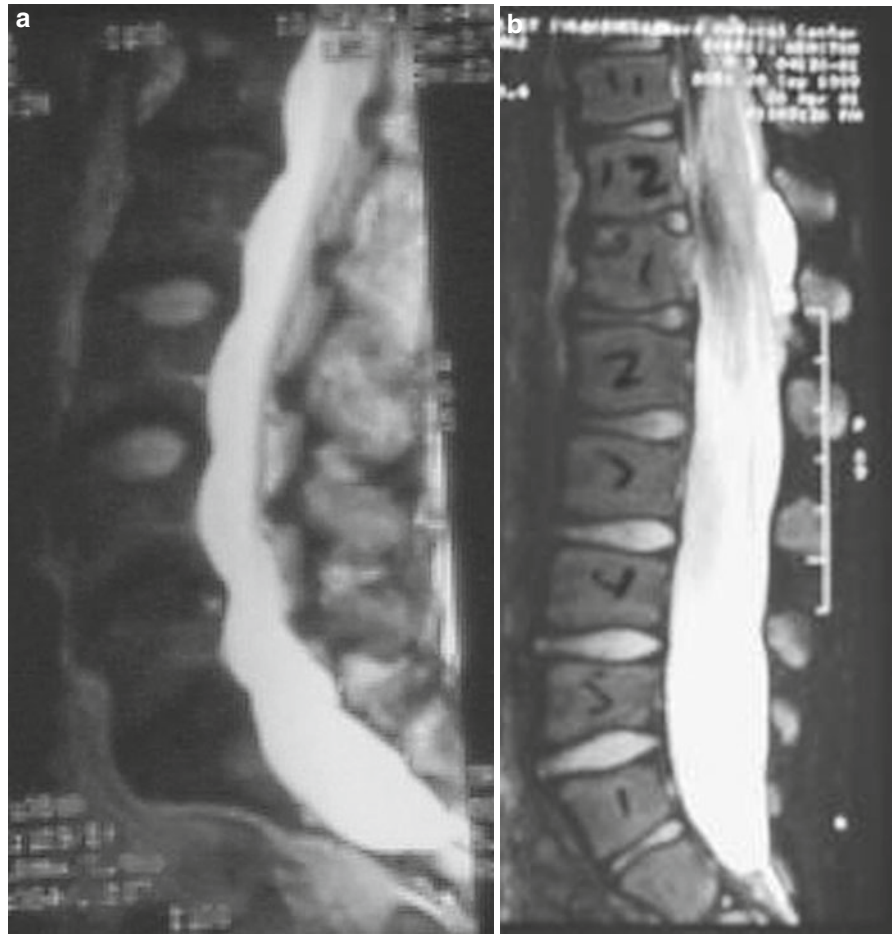

Fig. 14 (**a**, **b**) MRI of the lumbosacral spine in two patients showing dural ectasia

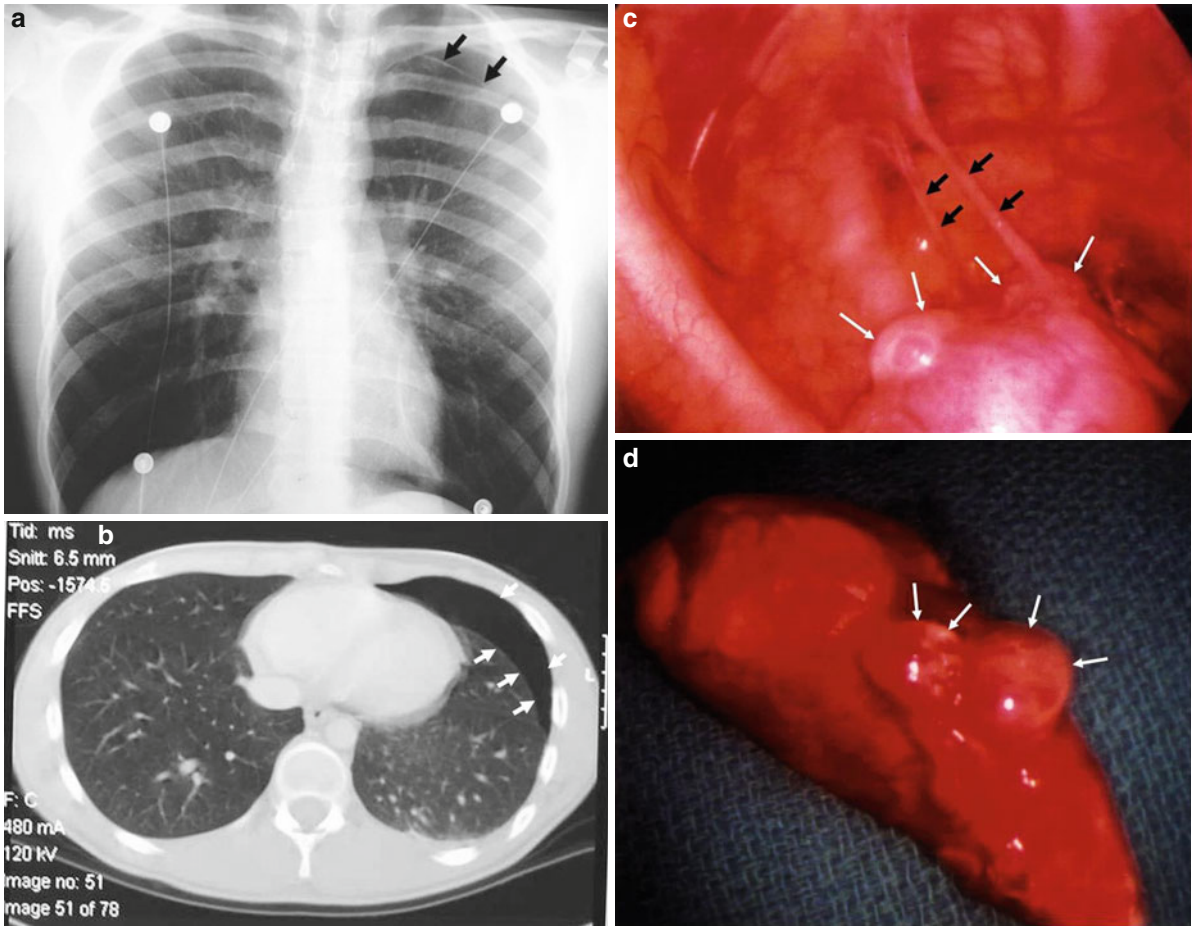

Fig. 15 (**a–d**) A 20-year-old male with Marfan syndrome with repeat spontaneous pneumothorax from ruptures of apical blebs. The chest X-ray shows collapsed left lung with pleural line (arrows). The CT of the chest shows pneumothorax on the right lung (*arrows*). Thoracoscope image from the right lung shows two bands representing the old adhesions due to previously ruptured apical blebs (*black arrows*) and two intact blebs (*white arrows*). The wedge biopsy specimen of the right apex shows two emphysematous blebs (*white arrows*) which were demonstrated in the previous figure

McCune-Albright Syndrome

McCune-Albright syndrome (MAS) consists of polyostotic fibrous dysplasia, precocious puberty, café-au-lait spots, and other endocrinopathies secondary to hyperactivity of various endocrine glands. It is a rare disease with an estimated prevalence between 1/100,000 and 1/1,000,000.

Synonyms and Related Disorders

Albright syndrome; Polyostotic fibrous dysplasia

Genetics/Basic Defects

1. Inheritance
   a. A sporadic condition
   b. Lack of genetic transmission in this syndrome
2. Molecular basis (Akintoye et al. 2002)
   a. Caused by a noninherited postzygotic somatic mutations in the guanine nucleotide-binding protein alpha subunit (*GNAS1*) gene coding for the alpha subunit of the stimulatory G protein ($G_s\alpha$).
   b. Mutations in *GNAS1* result in the constitutive activation of adenyl cyclase, which stimulates the synthesis of cAMP from ATP within cells.
   c. G proteins.
      i. Involved in transmitting hormone signals intracellularly by coupling cell surface receptors to intracellular signaling cascades.
      ii. Constitutively activated Gs protein stimulates autonomous cell proliferation in skin and bones and hormonal hypersecretion of gonads, hypophisis, thyroid, and adrenal glands.
      iii. Constitutive activation of these intracellular signaling cascades is caused by the specific mutations in the absence of hormone stimulation.
   d. Vast majority of $G_s\alpha$ mutations.
      i. Point mutations at the Arg201 position
      ii. Most being Arg201His or Cys
   e. The term *gsp* oncogene assigned to these mutations due to their association with certain neoplasms.
   f. Presence of somatic mosaicism is reflected by the identification of normal and mutated cells throughout the body.
   g. Timing of mutations.
      i. Early in embryogenesis: widespread involvement of the tissue and is likely lethal (accounts for the lack of autosomal dominant transmission of this disorder)
      ii. Late in embryogenesis: milder phenotype
      iii. Very late in tissue development after differentiation into a specific cell line
         a) Development of a single adenoma
         b) $G_s\alpha$-activating mutations reported in isolated hyperfunctioning thyroid nodules and in somatotroph adenomas

Clinical Features

1. Clinical features (Boston 2010)
   a. Extremely variable among affected individuals
   b. Consistent with a postzygotic somatic mutational event resulting in a mosaic distribution of the mutation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_152,
© Springer Science+Business Media, LLC 2012

c. Clinical triad
   i. Polyostotic fibrous dysplasia
   ii. Patchy cutaneous pigmentation (café-au-lait)
   iii. Gonadotropin-independent sexual precocity

2. Endocrine abnormalities
   a. Precocious puberty
      i. The most common endocrine feature and a central hallmark of MAS
      ii. Resulting from gonadotropin-independent autonomous ovarian or testicular function
      iii. Far more commonly observed in girls than boys (>50% of affected girls; only 15% of affected boys)
      iv. The signs of puberty (development of breasts, testes, pubic and axillary hair, body odor, menstrual bleeding, and increased growth rate) may appear before the age of 8 years in girls and 9 1/2 years in boys.
      v. Affected girls
         a) Breast development or vaginal bleeding as early as 4 months of age
         b) Premature development of secondary sex characteristics
         c) Excessive estrogen production, independent of gonadotropin activities, with development of ovarian cysts, sexual precocity, increased growth velocity, and markedly advanced skeletal maturity
      vi. Affected boys
         a) Premature testicular enlargement
         b) Premature spermatogenesis
         c) Premature development of secondary sex characteristics
   b. Hyperthyroidism (30%)
      i. The second most commonly associated endocrinopathy
      ii. Typically occurring in later childhood but occasionally within the first year of life
      iii. Primarily due to multinodular toxic goiter
      iv. Clinical effects
         a) Severe failure to thrive in infants and young children
         b) Decreased attention span
         c) Osteoporosis
         d) Tachycardia
   c. Acromegaly/gigantism
      i. Resulting from excess growth hormone secreted by somatotroph adenomas in the pituitary
      ii. Characteristic stigmata
         a) Coarsening of facial features, such as frontal bossing and prognathism
         b) Enlargement of hands and feet
         c) Arthritis
      iii. Complications
         a) Glucose intolerance
         b) Hypertriglyceridemia
         c) Hypertension
         d) Mild myopathy
   d. Cushing syndrome
      i. Adrenocorticotropic hormone (ACTH) independent
      ii. Caused by adrenal enlargement and excessive secretion of the adrenal hormone cortisol
      iii. Described mostly in infants and children
      iv. Clinical signs
         a) Cessation of growth
         b) Poor muscle tone
         c) Obesity of the face and trunk
         d) Weight gain
         e) Skin fragility
         f) Hypertension in infancy
         g) Death possible in long-term untreated hypercortisolism
   e. Gonadotropinomas
   f. Hyperprolactinemia
   g. Hyperparathyroidism
   h. Gynecomastia

3. Nonendocrine abnormalities
   a. Skin pigmentation (café-au-lait spots)
      i. Flat brown patches of pigmentation with irregular contour (coast of Maine) of varying size.
      ii. Frequently evident at birth.
      iii. Involved area may be extensive.
   b. Fibrous dysplasia
      i. The invariable component of the syndrome
      ii. Bone lesions usually evident by age of 10 years, often presenting with a limp, leg pain, or fractures
      iii. Polyostotic in nature
         a) Affecting any bones

b) Most commonly involving the femur, tibia, pelvis, phalanges, ribs, and the base of the skull

iv. Size and extent of involvement: ranging from small asymptomatic areas to markedly disfiguring lesions resulting in limping deformities
a) Leg length discrepancy
b) Coxa vara
c) Shepherd's crook deformity of the femur (a characteristic sign of the disease)
d) Bowing of the tibia
e) Harrison's groove
f) Protrusio acetabuli
g) Frequent pathologic fractures
h) Impingement on vital nerves

v. Craniofacial form (50% of the polyostotic form)
a) Involvement of orbital and periorbital bones resulting in hypertelorism, cranial asymmetry, facial deformity such as leontiasis ossea, visual impairment, exophthalmos, and blindness
b) Involvement of the sphenoid wing and temporal bones resulting in vestibular dysfunction, tinnitus, and hearing loss
c) Involvement of cribriform plate resulting in hyposmia or anosmia

vi. Low risk of malignant degeneration (0.4%)

vii. Fibrous dysplasia associated with single or multiple intramuscular or juxtamuscular myxomas (Mazabraud syndrome)

c. Hypophosphatemia
i. Resulting from decreased reabsorption of phosphate in the renal tubule
ii. Causing rickets and short stature
iii. Normal parathyroid hormone levels

d. Chronic liver disease
i. Mild cases: mild elevation of hepatic transaminases
ii. Severe cases: neonatal jaundice and chronic cholestasis

e. Persistent tachycardia: rare sudden death presumably due to cardiac arrhythmias

f. Associated malignancies (rare)
i. Osteosarcomas (most common)
ii. Chondrosarcomas
iii. Fibrosarcomas
iv. Liposarcomas
v. Breast cancer
vi. Thyroid cancer

Diagnostic Investigations

1. Elevated estradiol levels and suppressed or undetectable gonadotropins: diagnostic of gonadotropin-independent precocious puberty (Boston 2010).
2. Suppressed or undetectable levels of LH and FSH after administration of luteinizing hormone-releasing hormone: consistent with the diagnosis.
3. Elevated liver enzymes or hyperbilirubinemia even after normalization of cortisol or thyroxine levels suggests presence of G_s α activating mutations in the liver.
4. Hypophosphatemia (rickets and osteomalacia) results from increased urinary phosphate excretion.
5. Elevated thyroxine levels and suppressed TSH levels: consistent with hyperthyroidism.
6. Generally suppressed ACTH levels despite elevated cortisol levels since the glucocorticoid secretion is ACTH independent.
7. Elevated cortisol levels after dexamethasone suppression test: suggestive of Cushing syndrome.
8. Elevated 24-h urine-free cortisol levels: suggestive of Cushing syndrome.
9. Elevated serum growth hormone and insulin-like growth factor 1 levels in individuals with somatotroph adenomas due to G_s α activating mutations.
10. Biopsy of fibrous dysplasia lesions: can confirm the diagnosis if doubt remains after review of the radiographs.
11. Histology.
a. Fibrous dysplasia:
i. Caused by hyperproliferation of preosteoblastic cells
ii. Replacement of normal bones by irregular masses of fibroblasts
b. Ovarian cyst: generally large, unilateral, and follicular in nature
c. Thyroid nodules: ranging from multinodular hyperplasia to colloid goiter

d. Adrenal hyperplasia
e. Somatotroph adenoma
f. Liver: ranging from normal hepatocytes with some fatty infiltration to focal nodular hyperplasia with fibrosis and chronic cholestasis

12. Pelvic ultrasound to detect ovarian cysts.
13. Isotopic bone scan.
    a. The most sensitive tool for detecting the presence of fibrous dysplasia lesions
    b. To detect asymptomatic fibrous dysplasia sites
    c. Often useful, especially at the initial evaluation, for determining the extent of the disease and predicting functional outcome
14. Skeletal survey (Anand 2011).
    a. Plain radiographs (Dumitrescu and Collins 2008)
        i. Often sufficient to make the diagnosis of fibrous dysplasia.
        ii. Plain radiographs, demonstrating the classic ground-glass appearance, are usually sufficient for the diagnosis of fibrous dysplasia in the axial and appendicular skeleton. (The axial skeleton is comprised of bones of the skull, hyoid bone, vertebra, sternum, and ribs; the appendicular skeleton includes the hip, pelvic bone, and the shoulder girdle (clavicle and scapula).
    b. Advanced skeletal maturation
    c. Premature closure of growth plates resulting in short stature
    d. Polyostotic fibrous dysplasia
        i. Often unilateral
        ii. More frequently involved sites
            a) Lower extremities: femur (91%), tibia (81%)
            b) Pelvis (78%)
            c) Skull and facial bones (50%)
            d) Ribs
            e) Upper extremities
            f) Spine
            g) Shoulder girdle
    e. Pathological fractures (up to 85%)
        i. X-rays are often unable to detect new, small microfractures.
        ii. When new focal pain develops in a fibrous dysplasia lesion and no fracture is evident on plain radiograph, CT and/or MRI can be useful for detecting subtle fractures.
        iii. The classic lesion of the proximal femur in FD, the shepherd's crook deformity is common.
    f. Long and short tubular bones
        i. Lucent lesions in the diaphysis or metaphysis
            a) With endosteal scalloping
            b) With or without bone expansion
            c) Absence of periosteal reaction
            d) Usually smooth and relatively homogeneous matrix of the lucency, described as a ground-glass appearance
            e) Presence of irregular areas of sclerosis with or without calcification
            f) The ring sign (a lucent lesion with a thick sclerotic border)
        ii. Extension of lesions into the epiphysis observed only after fusion
            a) Premature fusion of the ossification centers resulting in adult dwarfism
            b) Dysplastic bone undergoing calcification and endochondral bone formation
    g. Skull and facial bones
        i. Sclerotic skull base. Diffuse sclerosis of the base of the skull often involves the sphenoid, sella turcica, roof of the orbit, thickening of the occiput, and obliteration of the paranasal sinuses
        ii. Mixed radiolucent and radiopaque pattern of maxillary and mandibular bones
            a) Displacement of the teeth
            b) Distortion of the nasal cavities
    h. Pelvis and ribs
        i. Common cystic lesions characterized by a diffuse ground-glass appearance and ring lesions
        ii. Protrusio acetabuli
    i. Spine
        i. Well-defined, expansile, and radiolucent lesions with multiple internal septa or striations involving the vertebral body and, occasionally, the pedicles and arches
        ii. Kyphotic deformity
        iii. Spinal cord compression
        iv. Rare paraspinal soft tissue extension and vertebral collapse
    j. Radiographic features suggestive of malignant degeneration
        i. A rapid increase in the size of the lesion

ii. A change from a previously mineralized bony lesion to a lytic lesion

15. Bone scintigraphy: valuable in early detection of the bone lesions.
16. CT scan.
    a. CT scan of the skull: the most useful test for diagnosis of craniofacial fibrous dysplasia
    b. CT scan of the abdomen to demonstrate bilateral enlargement of the adrenal glands in infantile Cushing syndrome
17. Whole-body MRI can be used for evaluation and follow-up of polyostotic fibrous dysplasia (Ferreira et al. 2010).
18. Mutation detection (Akintoye et al. 2002).
    a. Standard PCR-based amplification
    b. Followed by sequencing of the appropriate region of the *GNAS1* gene

Genetic Counseling

1. Recurrent risk
    a. Patient's sib: not increased since MAS is due to a somatic mutation
    b. Patient's offspring: not increased since a germ line–activating mutation in the G_s α gene might be lethal
2. Prenatal diagnosis: not been reported
3. Management (Boston 2010)
    a. Precocious puberty
        i. Medical care
            a) Difficulty to treat precocious puberty.
            b) The biosynthetic forms of gonadotropin-releasing hormone such as deslorelin, histrelin, and Lupron which suppress LH and FSH are not effective in most girls with MAS.
            c) Provera, a progesterone-like hormone, for cessation of vaginal bleeding but not effective in slowing the rapid rates of growth and bone development and may have unwanted effects on adrenal functioning.
            d) Ketoconazole, aimed at interrupting adrenal steroid biosynthesis, for cessation of vaginal bleeding.
            e) Testolactone and fadrozole (aromatase inhibitors, to block the conversion of testosterone to estradiol, thus lowering circulating estrogen levels) for halting pubertal progression.
            f) A multicenter trial of tamoxifen (an estrogen agonist/antagonist) treatment of precocious puberty in girls resulting in a reduction of vaginal bleeding and significant improvements in growth velocity and rate of skeletal maturation.
        ii. Surgical care: ovarian cystectomy or oophorectomy not typically warranted because of the likelihood of cyst recurrence in residual ovarian tissue
    b. Hyperthyroidism
        i. Medical care: propylthiouracil or methimazole, drugs which block thyroid hormone synthesis, for patients with excessively high thyroid hormone levels
        ii. Surgical care: thyroidectomy or hemithyroidectomy for hyperthyroidism associated with a goiter
    c. Infantile Cushing syndrome
        i. Medical care
            a) Treat with drugs that block cortisol synthesis
            b) Adequate adrenal steroid (hydrocortisone, Florinef) replacement after bilateral adrenalectomy
        ii. Surgical care: surgical removal of the affected adrenal glands
    d. Acromegaly/gigantism
        i. Medical care: treat with synthetic analogs of the hormone somatostatin to suppress growth hormone secretion (Bhansali et al. 2003)
        ii. Surgical care: surgical removal of the area of the pituitary which is secreting the pituitary growth hormone
    e. Early detection and treatment of patients with excess growth hormone to prevent morbidity related to the craniofacial form of the fibrous dysplasia (50% of polyostotic form)
        i. Morbidity
            a) Hearing loss
            b) Blindness
        ii. Therapy
            a) Cabergoline
            b) Long-acting octreotide therapy
    f. Hypophosphatemic rickets: treat with oral phosphates, supplement with vitamin D

g. Fibrous dysplasia
   i. Medical care (Isaia et al. 2002)
      a) Monitor vision and hearing closely if lesions are located near or around the orbits.
      b) Avoid contact sports to minimize the risk of pathologic fractures.
      c) Bisphosphonates used to inhibit bone absorption by osteoclast activity through apoptosis induction and protein prenylation inhibition.
      d) Pamidronate, a second generation aminobisphosphonate for reduction in bone pain and markers of bone turnover.
   ii. Surgical care: grafting, pinning, and casting to surgically correct fractures and deformities

Meckel–Gruber Syndrome

Meckel–Gruber syndrome (MKS) is a rare, lethal, and autosomal recessive disorder, characterized by occipital encephalocele, cystic dysplastic kidneys, and postaxial polydactyly. The incidence is estimated to be 1/13,250 (in USA) and 1/149,000 (in Great Britain) live births. The incidence in North African and Finnish populations is much higher at 1/3,500 and 1/9,000 respectively. Meckel–Gruber syndrome is considered the most frequent syndromic cause of neural tube defects (Paetau et al. 1985; Morgan et al. 2002).

Synonyms and Related Disorders

Dysencephalia splanchnocystica; Guber syndrome; Meckel syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Genetic (locus) heterogeneity (Morgan et al. 2002; Jayakar et al. 2011)
   a. *MKS1* locus to 17q21-24 in Finnish kindreds
   b. *MKS2* locus to 11q13 in North African-Middle Eastern cohorts
   c. *MKS3* to 8q21.3-q22.1 in Indian sub-continent cohorts: *MKS3* mutation also cause Jubert syndrome (Baala et al. 2007)
   d. *MKS4* to 12q21.31-q21.33 in a Kosovar Albanian family with two affected male fetuses
   e. *MKS5* to 16q12.2
   f. *MKS6* to 4p15.3 in 11 Finnish families

Clinical Features

1. Major clinical features
   a. Clinical triad (Nyberg et al. 1990)
      i. Occipital encephalocele (85%)
         a) Extrusion of rhombic roof elements (cerebellar vermis, caudal third ventricle, distended fourth ventricle) through a widened posterior fontanelle
         b) Protruding CNS structures covered by a dural sac
         c) Medial occipital cortex occasionally included in the sac formed by the dilated caudal third ventricle
      ii. Dysplastic kidneys (100%)
         a) Result in oligohydramnios
         b) Lead to fetal pulmonary hypoplasia
      iii. Postaxial polydactyly (55%)
   b. Microcephaly
   c. Oral clefts
      i. Cleft lip
      ii. Cleft palate
   d. Ambiguous genitalia
2. Other clinical features
   a. CNS abnormalities
      i. Absent olfactory lobe
      ii. Absent pituitary gland (hypopituitarism)
      iii. Hydrocephalus
      iv. Dandy–Walker malformation
   b. Craniofacial features
      i. Sloping forehead
      ii. Microphthalmia/anophthalmia
      iii. Micrognathia
      iv. Malformed tongue
      v. Abnormal ears

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_153,
© Springer Science+Business Media, LLC 2012

c. Short neck
d. Hypoplastic thyroid
e. Congenital heart defect
f. Gastrointestinal abnormalities
   i. Omphalocele
   ii. Malrotated bowel
   iii. Fibrotic or cystic liver
g. Absent or small adrenals
h. Accessory spleen
i. Urinary tract anomalies
j. Short limbs
k. Abnormal palmar creases
l. Club feet
m. Syndactyly

3. Lethal outcome
   a. Abortions
   b. Stillborns
   c. Neonatal deaths
   d. Rare survivals till 2 years of age

Diagnostic Investigations

1. Ultrasonography
   a. CNS anomalies
   b. Cystic dysplastic kidneys
2. MRI of the brain for CNS anomalies
3. Echocardiography for congenital heart defect
4. Radiography (Seppänen and Herva 1983)
   a. Microcephaly with an occipital bone defect and encephalocele or hydrocephaly
   b. Short upper extremities
   c. Bell-shaped thorax with abdominal distension
   d. Postaxial polydactyly in the hands and feet
5. Necropsy
   a. Renal anomalies
      i. Cystic dysplastic kidneys
      ii. Hypoplastic kidneys/ureters/bladder
      iii. Rectovesical fistula
   b. Triad of CNS malformations (Herman and Siegel 1996)
      i. Prosencephalic dysgenesis (Ahdab-Barmada and Claassen 1990)
         a) Agenesis of olfactory bulbs and tracts (arhinencephaly)
         b) Complete holoprosencephaly
         c) Hypoplasia of optic nerves and chiasm
         d) Microphthalmia
         e) Agenesis of the corpus callosum
         f) Fused thalami
         g) Hypoplasia of the third ventricle
         h) Small or absent pituitary gland
         i) Microcephaly
         j) Cleft/high arched palate
         k) Micrognathia
      ii. Occipital encephalocele
         a) Displacement of rhombic roof elements including caudal third ventricle, cerebellar vermis and fourth ventricle
         b) Extruded through an enlarged posterior fontanelle rather than through an occipital cranium bifidum
         c) Often associated with a variant of Dandy–Walker cyst with Chiari malformation
      iii. Rhombic roof dysgenesis
         a) Absent brain stem tectum
         b) Agenesis/dysgenesis cerebellar vermis
         c) Elongated brain stem
         d) Aqueduct stenosis
   c. Histologic features of the CNS (Paetau et al. 1985)
      i. Polymicrogyria
      ii. Heterotopias
      iii. Characteristic neuroepithelial rosettes
   d. Hepatic dysgenesis
      i. Consistent features
      ii. Arrested development of the intrahepatic biliary system
         a) Reactive biliary bile duct proliferation
         b) Bile duct dilatation
         c) Portal fibrovascular proliferation
   e. Lung hypoplasia
   f. Gastrointestinal anomalies
      i. Pancreatic cyst
      ii. Malrotated bowel
      iii. Anal atresia
   g. Genital anomalies
      i. Hypoplastic genitalia
      ii. Bicornuate uterus
      iii. Persistent urogenital sinus

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not surviving to reproductive age

2. Prenatal diagnosis
   a. Ultrasonography: diagnosis more difficult in the second trimester because of oligohydramnios secondary to poor renal output impairing visualization
      i. Occipital encephalocele
      ii. Renal anomalies (large cystic kidneys, renal agenesis, renal hypoplasia, and ureteral duplication)
      iii. Polydactyly
      iv. Oligohydramnios
      v. Dandy–Walker malformation
      vi. Cerebellar hypoplasia
   b. MRI, a valuable complement to ultrasonography in assessing fetal anomalies in the presence of severe oligohydramnios
   c. Elevated serum α-fetoprotein
   d. Amniocentesis
      i. Elevated amniotic fluid α-fetoprotein
      ii. Normal karyotype
3. Management
   a. No specific treatment
   b. Supportive care for lethal cases
   c. Operative excision of a small encephalocele
   d. Ventriculoperitoneal shunt for hydrocephalus

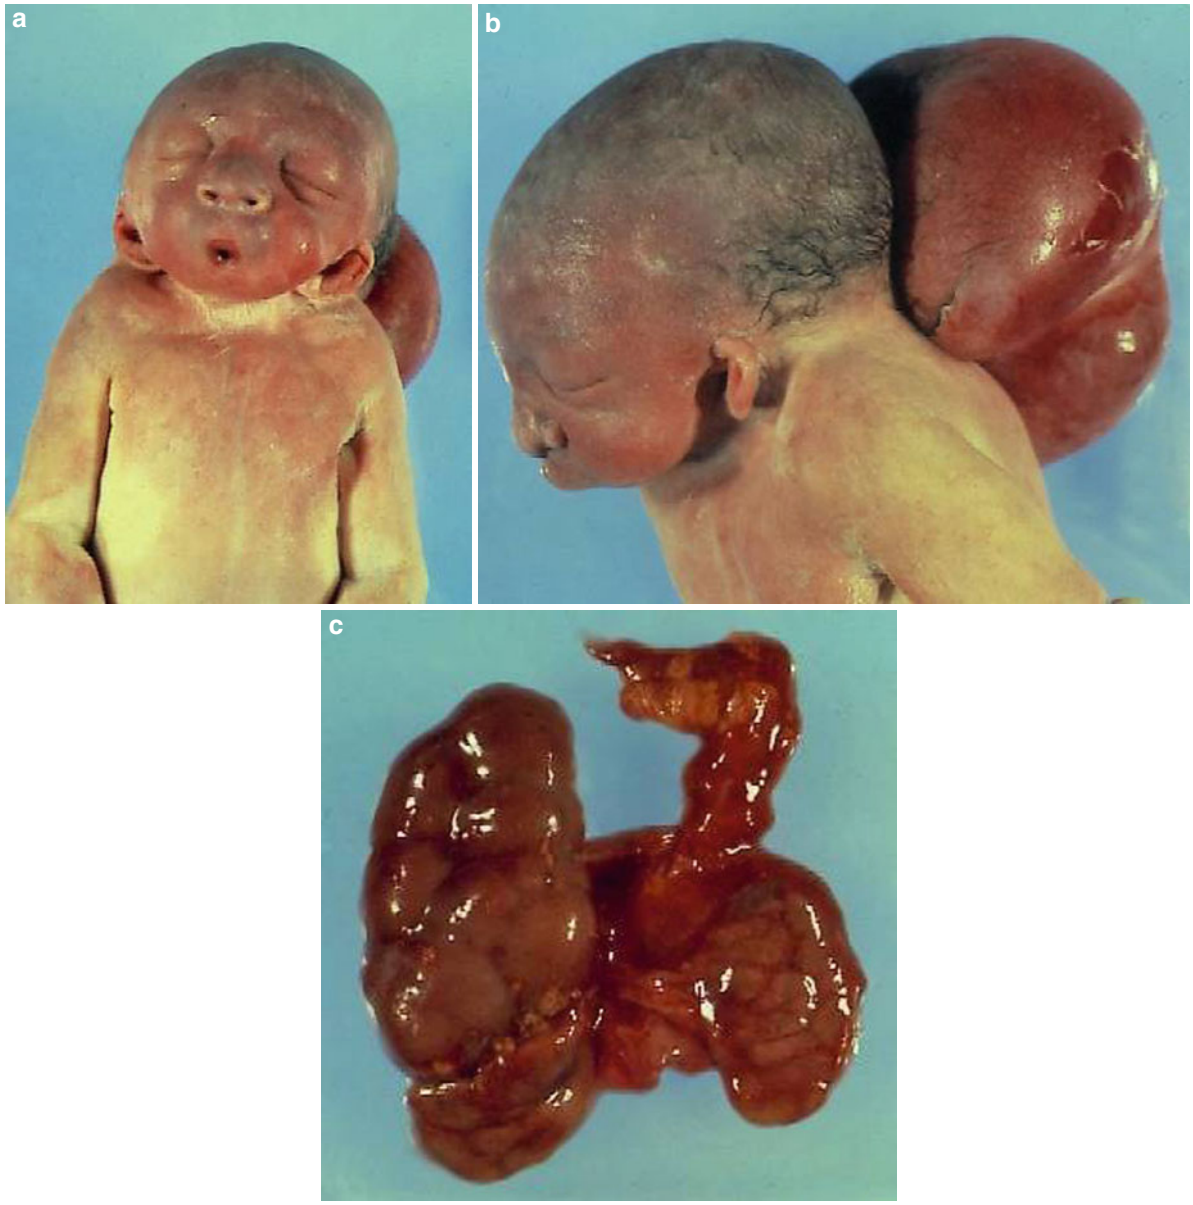

Fig. 1 (**a**–**c**) A neonate with Meckel–Gruber syndrome showing a large occipital encephalocele, microcephaly, sloping forehead, micrognathia/retrognathia, low-set malformed ears, and short neck. The infant also had post-axial polydactylies. Necropsy showed unilateral renal dysgenesis. Contralateral renal cystic dysplasia was present

Fig.2 (**a**–**e**) Another neonate with Meckel–Gruber syndrome showing a large occipital encephalocele, microcephaly, sloping forehead, micrognathia/retrognathia, low-set malformed ears, short neck and post-axial polydactylies

Megalencephalic Leukoencephalopathy with Subcortical Cysts

In 1995, van der Knaap et al. described a syndrome of cerebral leukoencephalopathy and megalencephaly with infantile onset in eight children, including two siblings. These children had normal or near-normal neurologic status despite evidence of severe white matter disease. The syndrome is currently termed megalencephalic leukoencephalopathy with subcortical cysts.

Synonyms and Related Disorders

van der Knaap Disease

Genetics/Basic Defects

1. An autosomal recessive disorder suggested by parental consanguinity and affected siblings
2. Caused by mutation in the *MLC1* gene which is expressed predominantly in astrocytes, located on 22qt13.33, encoding a putative membrane protein with eight predicted transmembrane domains
3. Genetically determined homozygous or compound heterozygous cases have been documented in almost all racial groups throughout the world and in both sexes equally.
4. Although the disease is considered rare, a higher frequency is observed in populations where consanguinity remains a common cultural practice.
   a. Among the Agarwals of India, almost all documented cases test positive for a homozygous insertional mutation (135insC) owing to founder effect.
   b. G59E mutation appears to be common among Libyan Jews.
   c. S93L mutation appears to be somewhat among in the Japanese.
5. Marked clinical intrafamilial and interfamilial variability in mutation-proven cases
6. A broad spectrum of pathogenetic mutations (missense, splice site, insertion, and deletions) identified in the *MLC1* gene, enlarging the spectrum of allelic variants without a straightforward genotype–phenotype correlation

Clinical Features

1. Clinical findings of 122 patients reviewed by Riel-Romero et al. (2005)
   a. Clinical presentation
      i. Accelerated head growth beginning in the first year of life, resulting in extreme macrocephaly (48%)
      ii. Mild developmental delay (25%)
   b. Gradually increasing spasticity (pyramidal findings) (86%) and ataxia (78%)
   c. Seizures (66%)
   d. Loss of ambulation (38%)
   e. Dysarthria (15%)
   f. Hypotonia (11%)
   g. Dysmetria (9%)
   h. Tremor (7%)
   i. Dysonia (5%)
   j. Dysphagia (5%)
   k. Choreoathetosis (3%)
2. Clinical course: Although progressive in its nature, MLC is characterized by a relatively mild clinical

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_154,
© Springer Science+Business Media, LLC 2012

course (discrepantly mild cognitive impairment) compared with the severity of the neuroradiological findings

3. Differential diagnosis: infantile megalencephalic leukoencephalopathies (neurologic disorders characterized by progressive deterioration and severe impairment of neurological function resulting in marked disability and a shortened life span, leukodystrophic changes on neuroimaging, and megalencephaly)
   a. Alexander disease
      i. A rare neurological disorder that follows a progressive and usually fatal course
      ii. Does not share the relatively benign course of MLC
      iii. The most common infantile form: characterized by loss of developmental milestones, inexorable psychomotor retardation, megalencephaly, spasticity, seizures, ataxia, hyperreflexia, and pyramidal signs, with a lifespan of a few months to early childhood
      iv. Considered a leukodystrophy because myelin changes are invariably observed while sparing the axons
      v. *GFAP* as the causative gene for Alexander disease
      vi. MRI findings
         a) Abnormal enhancement of caudate nuclei, anterior columns of the fornices and periventricular areas
         b) Frequent hydrocephalus
         c) Cavitations in the frontal deep white matter
   b. Canavan disease
      i. Does not share the relatively benign course of MLC
      ii. MRI findings: Frequent involvement of the globus pallidus and thalami which are not involved in MLC
      iii. The white matter may be cystic in Canavan disease, but the typical subcortical cysts seen in MLC are lacking.
      iv. N-acetyl aspartate is elevated in urine and blood.
      v. Deficiency of the enzyme aspartoacylase can be demonstrated in cultured fibroblasts
   c. Glutaric aciduria I: presence of biochemical abnormalities (glutaric acid, 3-OH-glutaric acid in the urine, glutarylcarnitine in the blood)
4. Other differential diagnosis
   a. Merosin-deficient congenital muscular dystrophy
      i. Typical subcortical cysts are generally lacking, although the white matter disease most clearly resembles that observed in MLC.
      ii. Prominent weakness and hypotonia in affected individuals, not shared by individuals with MLC
      iii. Diagnosis: confirmed using muscle biopsy and staining for merosin
   b. Infantile GM gangliosidosis
      i. GM1 gangliosidosis
         a) Demonstration of deficiency of beta-galactosidase activity in leukocytes or cultured fibroblasts confirms the diagnosis.
         b) MRI features in infantile GM1 gangliosidosis very similar to those of GM2 gangliosidosis
      ii. Infantile GM2 gangliosidosis
         a) MRI: characterized by prominent involvement of the basal ganglia and thalami in addition to the white matter abnormalities
         b) Definitive diagnosis: established by assaying hexosaminidase A and B in serum, leukocytes, or cultured skin fibroblasts

Diagnostic Investigations

1. Brain imaging (CT, MRI)
   a. Diffusely abnormal and swollen white matter of the cerebral hemispheres
   b. Presence of subcortical cysts in the anterior temporal and frontoparietal region with preservation of gray matter structures
2. Quantitative proton MRS
   a. Underlines the MRI evidence of a white-matter disorder without cortical involvement
   b. Most striking MRS features: marked decrease in tNAA, tCr, and Cho, with normal Ins in abnormal-appearing hemispheric white matter
3. Technetium-99m-ethyl cysteinate dimer SPECT
   a. Hypoperfusion in the cerebral whitematter (shown high signal intensity on magnetic resonance imaging (MRI) T2 images)

   b. Hypoperfusion found unexpectedly in the frontal cortices (corresponded clinically to a low score on the frontal assessment battery), which showed no abnormalities on MRI.
   c. Decreased GABA receptor density as suggested by ^{123}I-Iomazenil SPECT provided further evidence of cortical neuron dysfunction.
   d. Findings suggest that SPECT can be used to non-invasively monitor in vivo cortical function in this disease.
4. Histopathology
   a. Splitting of the outer most lamellae of the myelin sheaths consistent with an edematous process, with sparing of the axons
   b. Cavitating spongiform leukoencephalopathy with vacuoles in the outermost lamellae of myelin sheaths
   c. Intense fibrillary astrogliosis of subcortical white matter with well preserved myelinated axons
   d. Normal cortical neuronal structure
5. Molecular genetic testing
   a. *MLC1* gene mutations determination clinically available
   b. Sequence analysis of *MLC1* gene mutations detects approximately 70% of cases whose MRI and clinical picture are consistent with the diagnosis of MLC, implying that at least one other gene may be responsible for the remaining 30% of cases.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Twenty five percent chance of inheriting both mutation alleles and being affected
      ii. Two thirds chance of being carriers in unaffected sibs
   b. Patient's offspring: recurrence risk not increased unless the spouse is a carrier, in which case 50% of offspring will be affected; otherwise, all offspring of the affected parent will be carriers who will be asymptomatic
2. Prenatal diagnosis for pregnancies at increased risk and carrier testing for relatives at risk: possible if both *MLC1* disease-causing alleles have been identified in the family
3. Management: largely supportive
   a. Antiepileptic drugs for seizure control
   b. Physical therapy to improve motor function
   c. Occupational therapy
   d. Speech therapy as needed
   e. Special education
   f. Antibiotic treatment for infections
   g. Attention to general care and nutritional requirements
   h. Prevention of head trauma: protective helmet suggested

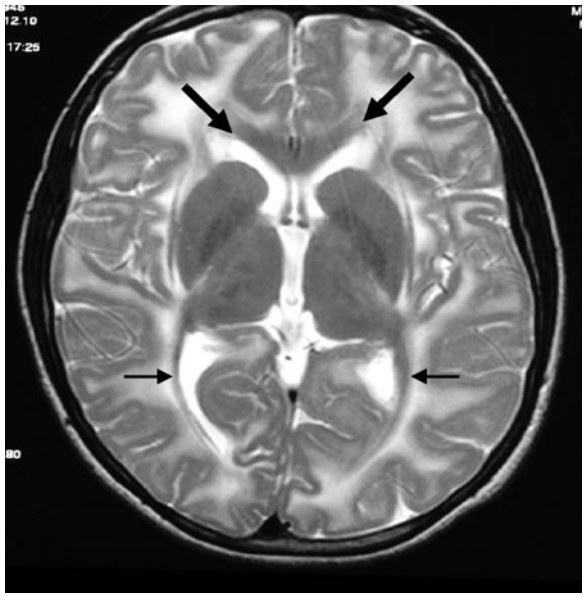

Fig. 1 A 15-year-old Caucasian female was evaluated for megalencephaly and possible leukodystrophy. Early developmental status was normal except for the presence of macrocephaly. She had a bicycle accident with trauma to her head, followed by a generalized tonic-clonic seizure 7 months later. At 15 years of age, she had striking macrocephaly (head circumference of 65 cm), receiving special education, and was found to have mild bilateral clonus Axial Tj-weighted scan demonstrates hyperintensity throughout cerebral white matter with sparing of the genu of the corpus callosum (*large arrowheads*), middle portion of the internal capsule, and the geniculocalcarine tracts (*small arrows*). Sequence analysis of the *MLC1* gene revealed two novel mutations, One mutation was inherited from the mother and was characterized by the substitution of adenine for guanine at nucleotide position 366 in exon 3. This mutation resulted in a change in the corresponding amino acid from arginine to histidine at amino acid position 84 (R84H). The other mutation was inherited from her father; it is in the canonical splicing site following exon 5 (538+1g → a) and is expected to cause the transcription of a variant messenger ribonucleic acid (RNA) that can be translated into an altered protein. A 12-year-old brother was noted to have macrocephaly, seizures, significant learning difficulty, behavioral problems, increasing difficulty in ambulation, hyperreflexia, spasticity with positive Babinski reflexes, sustained clonus and difficulty with tandem gait. His MRI showed a markedly increased T2-weighted signal throughout the supratentorial white matter with cysts in both temporal lobes in a pattern virtually identical to his sister's. Sequencing of the MLC1 gene revealed the same mutations identical to his older sister

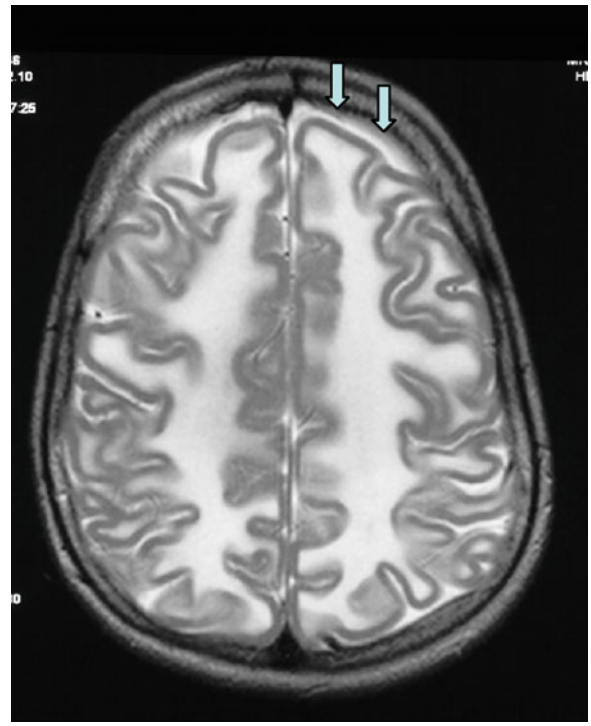

Fig. 2 Axial T-weighted scan at a more rostral level shows that the cortical U fibers are also hyperintense and therefore not spared (*arrows*)

Fig. 3 Anterior temporal regions show homogeneous white matter hyperintensity within the cysts, which expand and smooth the convolutions of the temporal poles – typical findings in megalencephalic leukoencephalopathy with subcortical cysts

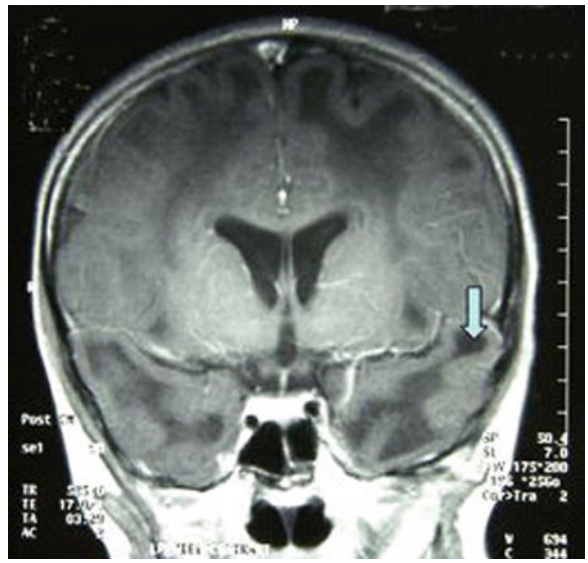

Fig. 4 Gadolinium-enhanced T-weighted coronal slice through the anterior temporal lobes demonstrates absence of abnormal enhancement in the white matter or elsewhere and hypointensity within a subcortical cyst (*arrowhead*)

Menkes Disease

Menkes and colleagues described Menkes disease in 1962 that reported five male infants in a family affected with a distinctive syndrome of neurologic degeneration, peculiar hair, and failure to thrive. Menkes disease is also called "kinky or steely hair disease." The incidence of Menkes disease is estimated to be 1/100,000–1/250,000 live births.

Synonyms and Related Disorders

ATP7A-related copper transport disorders; ATP-related distal motor neuropathy; Kinky hair syndrome; Occipital horn syndrome

Genetics/Basic Defects

1. Inheritance
   a. An X-linked recessive disorder of copper metabolism (Tümor 1998)
      i. Recognized to segregate as an X-linked recessive trait when it was described by Menkes et al. in 1962
      ii. Observation of two different cell populations (normal fibroblasts and mutant cells with increased copper accumulation) in cultured fibroblasts of female Menkes carriers, suggesting that the Menkes disease gene was subject to random X-inactivation and also confirming the X-linked recessive inheritance of the disease
   b. New mutations in one third of cases
2. Menkes gene mapped to chromosome Xq13.3
   a. Physical evidence of the location of the Menkes disease gene (*ATP7A*; *MNK*) suggested by observation of a female patient with a de novo balanced X:2 translocation (X break point at Xq13) and a male patient with X chromosome rearrangements with a breakpoint at Xq13.3 (Kodama and Murata 1999)
   b. The Xq13.3 breakpoint subsequently shown to be at the *MNK* locus by fluorescence in situ hybridization (FISH) analyses
   c. MNK belongs to a large family of cation-transporting P-type ATPases.
3. Cause: Mutations in *ATP7A* gene, which encodes a transmembrane copper-transporting P-type adenosine triphosphatase (ATPase) protein, leading to deficiencies of copper absorption in intestinal absorption and in intracellular processing of copper in the central nervous system and connective tissues, whereby enzymes requiring copper as a cofactor no longer function properly
4. Mutation spectrum
   a. Cytogenetic abnormalities (Tümor 1998)
      i. Visible cytogenetic abnormalities comprising about 1% of the underlying genetic defect in Menkes disease
      ii. Four female patients reported to have balanced X-autosomal translocations
      iii. A male patient reported to have a unique rearrangement of the X chromosome where the long arm segment Xq13.3-q21.2 was inserted into the short arm

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_155,
© Springer Science+Business Media, LLC 2012

b. Gross deletion mutations (20%)
c. Point mutations (remaining genetic defects)
   i. Splice site (23%)
   ii. Nonsense (20.7%)
   iii. Missense (17.2%)
   iv. Small insertions/deletions (39.1%)

5. Genetic defect/pathogenesis
   a. Failure of copper transport to the affected fetus resulting in copper deficiency in utero; compounded by impairment of copper absorption and ineffective copper transport into the central nervous system after birth
   b. Decreased copper transport across cellular compartments, particularly the gut
   c. Decreased availability of copper for cuproenzymes
   d. Dysfunction of numerous copper-dependent enzyme systems (decreased enzyme activities)
      i. Dopamine β-hydroxylase
         a) Severe neurodegeneration
         b) Hypothermia
         c) Abnormalities in serum catecholamines
      ii. Ascorbate oxidase: skeletal deformities
      iii. Cytochrome c oxidase
         a) Hypothermia
         b) Severe neurodegeneration
         c) Impaired myelination
         d) Muscle weakness
         e) Mitochondrial abnormalities
      iv. Lysyl oxidase: decreased strength of collagen and elastin
         a) Frayed/split internal elastic layer of arteries
         b) Bladder diverticula
         c) Loose skin and joints
      v. Monamide oxidase
         a) Kinky hair
         b) Reduced pigmentation of hair and skin
         c) Severe neurodegeneration
      vi. Tyrosinase
         a) Depigmentation of hair
         b) Skin pallor
      vii. Sulfhydryl oxidase: pili torti (Kodama and Murata 1999)
      viii. Ceruloplasmin: decreased levels of circulating copper
      ix. Copper-zinc superoxide dismutase
         a) Failure of free radical detoxification, contributing to profound Purkinje cell loss
         b) Cytotoxic effects
6. Loss of function of specific cuproenzymes resulting in the clinical features of Menkes disease
   a. Abnormal hair and pigmentation
   b. Laxity of the skin
   c. Metaphyseal dysplasia
   d. Cerebellar degeneration
   e. Failure to thrive
7. Favorably skewed X-inactivation accounts for neurological sparing in female carriers of Menkes disease (Desai et al. 2011)
8. Allelic heterogeneity resulting in milder forms of the disease, occipital horn syndrome, also known as X-linked cutis laxa or Ehlers-Danlos syndrome type IX (Tümor 1998)
   a. Clinical resemblances to Menkes disease with milder manifestations
   b. Biochemical resemblances to Menkes disease
      i. Patients typically have between 20% and 35% residual copper transport function and far less severe neurodevelopmental abnormalities, even in the absence of early diagnosis and treatment (Kaler et al. 1994)
      ii. Low serum copper and ceruloplasmin
      iii. Increased copper accumulation and markedly low lysyl oxidase activity
      iv. Impairment of *MNK* in patients with occipital horn syndrome (base-pair substitution mutations affecting the normal mRNA splicing) giving a direct molecular evidence for the allelic relationship between the two diseases
9. *ATP7A*-related distal motor neuropathy
   a. Another allelic variant of Menkes disease
   b. Caused by mutations in the copper-transporting P-type ATPase gene, *ATP7A*
   c. Males with *ATP7A* mutations have even greater quantity of residual copper transport activity and manifest a late-onset syndrome restricted to progressive distal motor neuropathy, without overt signs of systemic copper deficiency (Kennerson et al. 2010).

Clinical Features

1. Phenotype: considerable variability in the severity of clinical expression encompassing the severe classical form (90–95% of patients) to the mild occipital horn syndrome
2. Distinctive clinical features present by 3 months of age, often manifested by:
   a. Loss of early developmental milestones
   b. Poor weight gain (failure to thrive)
3. Neonatal hypothermia
4. Neonatal hypoglycemia
5. Hyperbilirubinemia
6. Poor feeding
7. Impaired weight gain (failure to thrive)
8. CNS abnormalities
   a. Profound (truncal) hypotonia
   b. Abnormal head control
   c. Hyperactive reflexes
   d. Generalized seizures
      i. Myoclonic
      ii. Occasional tonic-clonic
   e. Developmental delay
   f. Severe mental retardation
9. Abnormal and characteristic hair, responsible for the synonyms of "kinky hair disease" or "steely hair disease" in the past
   a. Depigmented, short, sparse, coarse, and twisted scalp hair: a striking and pathognomonic feature
   b. Fragile, frequently broken hair
   c. Twisted strands reminiscent of steel wool cleaning pads
   d. Eyebrows
      i. Unusual appearance
      ii. Scant
   e. White or gray hair lacking pigment secondary to absence of tyrosinase activity
10. Characteristic face
    a. "Jowly," "pudgy," or "cherubic" face
    b. Sagging cheeks
    c. Large-appearing ears
    d. High-arched palate
    e. Delayed tooth eruption
11. Ocular abnormalities
    a. Retinal hypopigmentation
    b. Retinal vessel tortuosity
    c. Macular dystrophy
    d. Congenital cataracts
    e. Partial optic nerve atrophy
    f. Decreased retinal ganglion cells
    g. Microcysts in the pigment epithelium of the iris
12. Connective tissue abnormalities secondary to loss of lysyl oxidase activity
    a. Loose skin (cutis laxa)
    b. Pectus excurvatum
    c. Umbilical and/or inguinal hernias
    d. Diverticula of the bladder, uterus, and other organs
    e. Vascular complications including aortic aneurysms commonly present
    f. Tortuosity of the intracranial blood vessels by neuroimaging techniques
    g. Radiographic evidence
       i. Wormian skull bones
       ii. Osteoporosis
       iii. Metaphyseal dysplasia including anterior flaring and fracture of the ribs
13. Progressive neurologic deterioration
    a. Usually death by 3 years of age
    b. Rare survival beyond childhood in some children with profound neurologic deficits
    c. Long survival, especially with copper therapy, to teens and people in their twenties
14. Patients with milder or atypical manifestations than "classical" Menkes disease
    a. Milder phenotype
       i. Mild intellectual delay
       ii. Ataxia
    b. Later onset of symptoms
    c. Less severe clinical course
    d. A longer life span
15. Occipital horn disease: a very mild allelic form of Menkes disease
    a. A connective tissue disorder caused by a secondary deficiency of the cuproenzymes, lysyl oxidase
    b. Milder phenotypic manifestations
    c. Connective tissue abnormalities
       i. Hyperelastic and easily bruisable skin
       ii. Bladder diverticula
       iii. Varicosities
       iv. Hypermobile joints

d. Skeletal abnormalities
   i. Short broad clavicles
   ii. Fused carpal bones
   iii. Thoracic malformations
   iv. Bony exostosis of the occiput (occipital horn) secondary to calcifications of the muscle at the insertion sites
e. Occasional mild neurologic impairment
f. Any male infant with connective tissue abnormalities and mental retardation should be evaluated for the possibility of Menkes disease because of somewhat atypical presentation of these milder phenotypes.

Diagnostic Investigations

1. Biochemical phenotype
   a. Low levels of copper in serum, liver, and brain resulting from impaired intestinal absorption (Kaler 2010)
   b. Low serum ceruloplasmin levels
   c. Diagnosis of Menkes disease is confirmed by decreased serum copper and ceruloplasmin. Interpretation of these values is difficult in the first months of life. In such cases, the following analysis may be helpful in confirming the diagnosis.
      i. Copper accumulation in the placenta or chorionic villi
      ii. Copper accumulation in the cultured skin fibroblasts
   d. Low activities of numerous copper-dependent enzymes (Kaler 2010)
      i. Dopamine β-hydroxylase
         a) Temperature instability
         b) Hypoglycemia
         c) Eyelid ptosis
         d) Pupillary constriction
      ii. Peptidylglycine α-amidating monooxygenase (reduced bioactivity of many neuroendocrine peptides)
      iii. Cytochrome c oxidase (impaired myelination, muscle weakness)
      iv. Copper-zinc superoxide dismutase (diminished protection against O_2 free radicals, possible motor neuron damage)
      v. Tyrosinase (reduced pigmentation of hair and skin)
      vi. Diamine oxidase (reduced histamine degradation)
      vii. Lysyl oxidase (decreased strength of collagen and elastin)
      viii. Ceruloplasmin (decreased circulating copper levels)
   e. Paradoxical accumulation of copper in certain tissues, such as duodenum, kidney, spleen, pancreas, skeletal muscle, and placenta
2. Light microscopy of hair (Chang 2009)
   a. Pathognomonic pili torti (180° twisting of the hair shaft)
   b. Trichoclasis (transverse fracture of the hair shaft)
   c. Trichoptilosis (longitudinal splitting of the shaft)
   d. Trichorrhexis nodosa (small, beaded swelling with fractures at regular intervals)
   e. Monilethrix elliptica (swelling with intervening tapered constrictions)
3. MRI/MRA of the brain
   a. White matter abnormalities reflecting impaired myelination
   b. Progressive degeneration of gray matter
   c. Cortical encephalomalacia
   d. Diffuse cerebral atrophy
   e. Cerebellar atrophy
   f. Ventriculomegaly
   g. Tortuosity (corkscrew appearance) of cerebral blood vessels
   h. Subdural hematoma (common in infants)
   i. Cerebrovascular accidents in older patients
4. Cerebral angiogram for tortuous winding vessels
5. Variable electroencephalogram (normal, moderately to severely abnormal)
   a. Hypsarrhythmia after 5 months of age
   b. Low amplitude or absent evoked potentials
6. Echocardiography
   a. Dysplastic coronary vessels
   b. Vascular complications including aortic aneurysms
7. Pelvic ultrasound to detect diverticula of the urinary bladder
8. Renal ultrasound
   a. Hydronephrosis
   b. Hydroureter
   c. Bladder diverticula

9. Radiography
   a. Skull radiograph
      i. Wormian bones in the lambdoidal and posterior sagittal sutures
      ii. "Occipital horn"
   b. Metaphyseal spurring of long bones
   c. Diaphyseal periosteal reaction
   d. Anterior flaring or multiple fractures of ribs
   e. Scalloping of the posterior aspects of the vertebral bodies
   f. Osteoporosis seen after 6 months of age
10. Histologic examination of torturous cerebral blood vessels
   a. Thinning of the connective tissue
   b. Disruption of the elastic lamina
11. Cytogenetic studies using traditional chromosome banding techniques verified by FISH using yeast artificial chromosomes spanning the gene
   a. Mainly carried out in affected females for identification of possible X:autosome translocation at Xq13.3
   b. Rare chromosome abnormality in male patients
12. Molecular diagnosis
   a. Molecular diagnosis of Menkes disease: complicated by the heterogeneity at this locus
   b. Almost all mutations detected in the Menkes disease gene are unique to an affected family.
   c. About 20% of these mutations involve rearrangements or partial gene deletions that can be identified by Southern blot analysis.
   d. Molecular diagnosis (superior to biochemical information) when the mutation in a given family is known, especially in cases of prenatal diagnosis
   e. Carrier diagnosis is best done with mutation analysis and is readily accomplished when the specific mutation is known. In families where the mutation has not been identified, polymorphic markers and intragenic repeats have been used to facilitate carrier diagnosis.
13. Female carrier determination
   a. Measurement of copper (^{64}Cu) accumulation in fibroblasts: difficult to interpret negative results because of random X inactivation of one of the X chromosomes. Normal results do not completely exclude carrier status (Tümor 1998).
   b. Presence of pili torti in the hair: a positive clinical indicator, but its absence does not eliminate the possibility
   c. Heterozygote detection by mutation detection in a given family with a known mutation (Kaler 2010)
      i. Allele-specific PCR
      ii. Restriction enzyme analysis
      iii. Heteroduplex analysis
      iv. SSCP followed by DNA sequencing
      v. Southern blot analysis
   d. Linkage studies using intragenic polymorphic markers helpful in carrier detection, prenatal diagnosis, and genetic counseling where the mutation has not been identified (Tümor 1998)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Carrier mother: 50% of brothers affected, 50% of brothers normal; 50% of sisters carriers, 50% of sisters normal
      ii. Noncarrier mother: instances of recurrence reported due to gonadal mosaicism
   b. Patient's offspring: not surviving to reproduction
2. Prenatal diagnosis of a male fetus at risk
   a. 1st trimester: measurement of total copper content in chorionic villus samples
   b. Second trimester: copper (^{64}Cu) accumulation and kinetic studies in cultured amniotic fluid cells
   c. Mutation detection in a given family with a known mutation
3. Management
   a. No definitive therapeutic options currently available
   b. Oral copper treatment not effective
   c. Early parenteral administrations of cupric acetate
      i. Normalizes serum copper and ceruloplasmin levels but not CNS copper levels
      ii. Improves seizure control
      iii. Will not interrupt the progression of neurologic manifestations

d. Early subcutaneous injections of copper-histidine with encouraging results (Christodoulou et al. 1998)
   i. Normalizes serum copper, ceruloplasmin, dopamine, and norepinephrine levels after 3 months of treatment
   ii. May be able to cross the blood-brain barrier and thus disrupt the progression of neurological symptoms including decreased seizures
   iii. Prolong survival, especially if treatment started within 1 month of life
   iv. Does not prevent the connective tissue complications because lysyl oxidase may not incorporate copper-histidine well

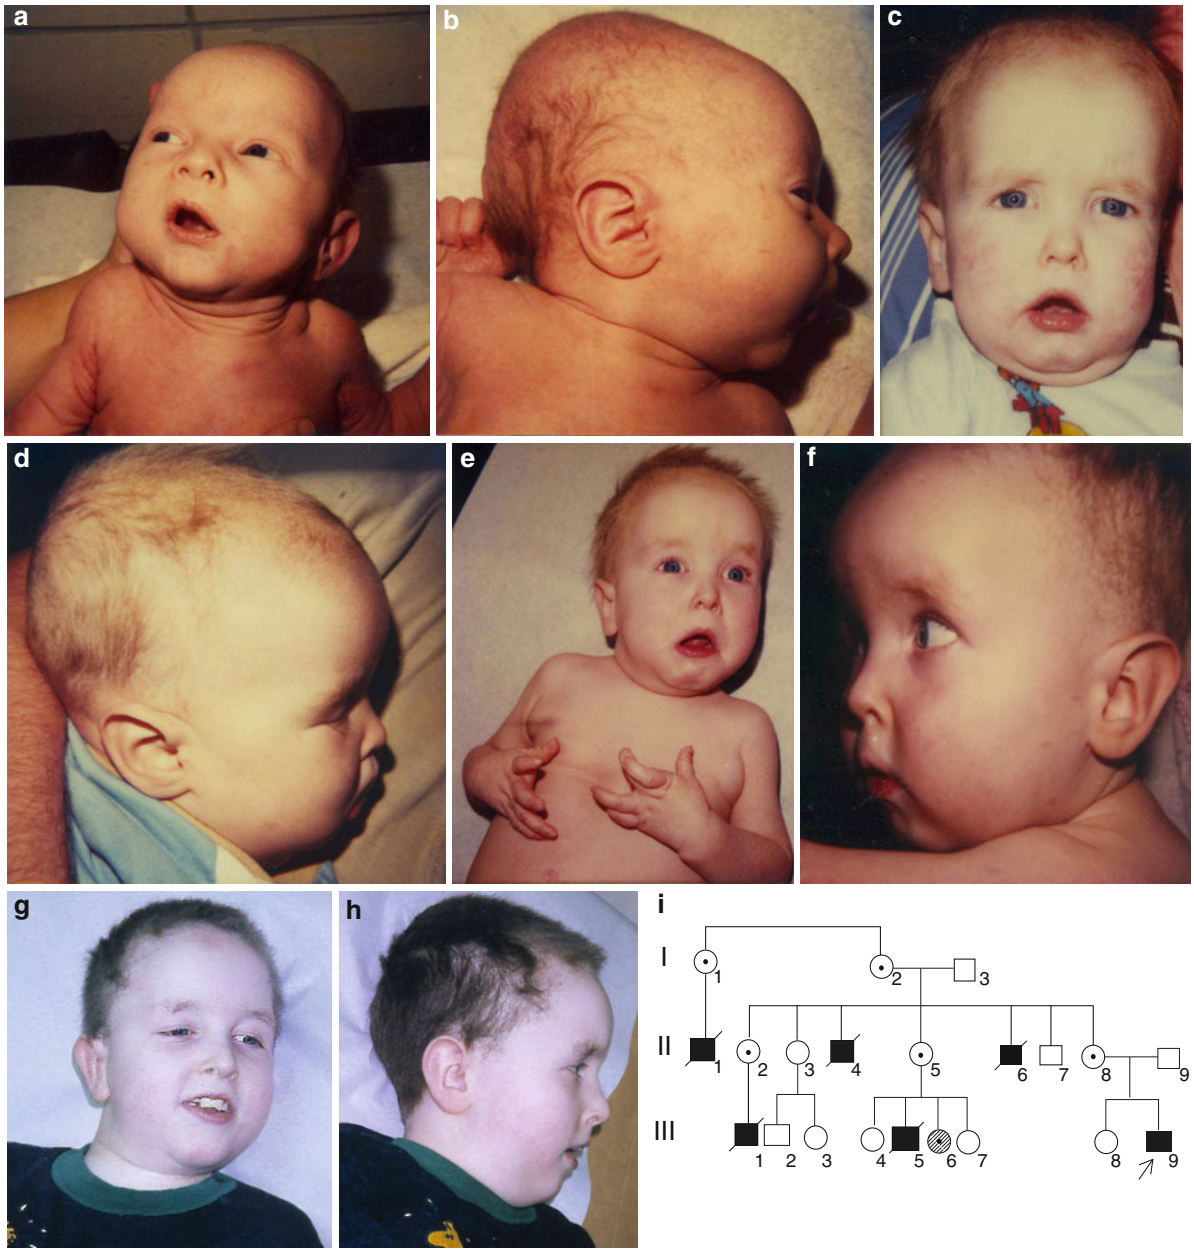

Fig. 1 (**a**–**i**) A boy with Menkes disease at 1 month, 9 months, 1 year, 27 months, and 9 years showing sparse, coarse, twisted hair; sagging cheeks; large-appearing ears; and pectus excurvatum. The boy was treated with cuprous sulfate and survived to his twenties. The pedigree is shown here illustrating X-linked recessive mode of inheritance

Fig. 2 (**a**–**b**) A cousin of the previous child with Menkes disease at 3 years of age showing coarse/twisting hair, sagging cheeks, and large-appearing ears

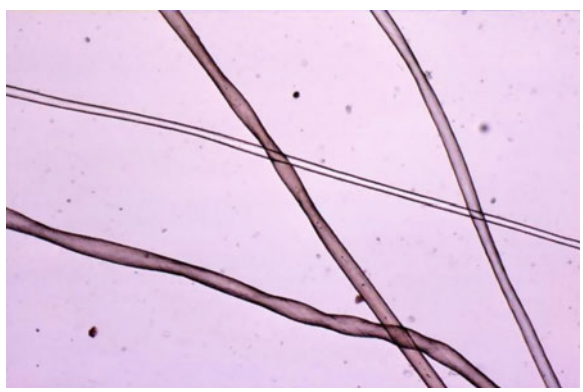

Fig. 3 Hairs showing pili torti (moderate variation in diameters; two hair shafts are twisted) in an 8-month-old male infant affected with Menkes disease

Metachromatic Leukodystrophy

Metachromatic leukodystrophy (MLD) is a lysosomal storage disease resulting from the deficient arylsulfatase A activity and the accumulation of sulfatides. The incidence among Caucasian is estimated to be about 1 in 40,000 births. The name of MLD originated from the metachromatic staining of the stored substance in histological sections.

Synonyms and Related Disorders

Arylsulfatase A deficiency; Cerebroside sulfatase deficiency; Metachromatic leukoencephalopathy

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Caused by deficiency of arylsulfatase A (ASA) activity
   a. Resulting in accumulation of the enzyme substrate sulfatide (cerebroside sulfuric ester) in
      i. Oligodendrocytes and Schwann cells
      ii. Visceral organs such as kidneys (sulfatide excreted in high amounts in the urine)
   b. Leading to severe myelin breakdown
      i. Resulting in demyelination of the white matter of the brain, spinal cord, and peripheral nerves
      ii. Providing the pathophysiologic basis for the deterioration and eventual premature demise
3. Arylsulfatase (*ARSA*) gene
   a. Mapped to 22q13.31
   b. MLD caused by *ARSA* mutations (Gieselmann 2008): more than 11 different mutations have been identified in the *ASA* gene (Missense mutations are by far the most frequent type of defect found.)
      i. Two most common mutations observed in Europe are (Berger et al. 1997)
         a) 459+1G>A
         b) A missense mutation causing a Pro426Leu substitution (accounts for about 25% of all alleles among European patients) (Polten et al. 1991)
      ii. A missense mutation causing an Ile179Ser substitution (accounts for about 12% of all defective alleles) (Berger et al. 1997)
      iii. All other mutant alleles have only been found in a few or single patients (Schestag et al. 2002).
   c. ASA pseudodeficiency (ASA-PD) caused by *ARSA* mutation
      i. Originally described in healthy individuals
      ii. Low ASA activity
      iii. Normal urinary sulfatide levels
      iv. The pseudodeficiency, in most cases, is caused by homozygosity for the arylsulfatase A pseudodeficiency (ASA-PD) allele (Polten et al. 1991).
      v. MLD mutations also known to occur within this allele: 1–2% of PD alleles are estimated to have a disease-causing mutation (Rafi et al. 2003).
   d. Chromosomal deletion unmasking a recessive disease: 22q13 deletion syndrome and metachromatic leukodystrophy (Bisgaard et al. 2009)
      i. One patient had a pathogenic mutation in the *ARSA* gene and succumbed to MLD.
      ii. Another patient had a pseudoallele which did not lead to MLD.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_156,
© Springer Science+Business Media, LLC 2012

e. Pathophysiology (Ikeda et al. 2010)
   i. Inability to degrade sulfated glycolipids, especially the galactosyl-3-sulfate ceramides, characterizes metachromatic leukodystrophy.
   ii. A deficiency in the lysosomal enzyme sulfatide sulfatase (arylsulfatase A) is present in metachromatic leukodystrophy.
   iii. Some patients with clinical metachromatic leukodystrophy have normal arylsulfatase A activity but lack an activator protein that is involved in sulfatide degradation.
   iv. Both defects result in the accumulation of sulfatide compounds in neural and in nonneural tissue, such as the kidneys and gallbladder.
   v. These defects may result from a number of different mutations, and many new causative mutations have been identified (Anlar et al. 2006; von Figura et al. 2001).

Clinical Features

1. Three main clinical forms based on the age of onset of the disease
   a. Late-infantile form (50–60% of cases)
   b. Juvenile form (20–30% of cases)
   c. Adult form (15–20% of cases)
2. Late-infantile form (Clark et al. 1979)
   a. The most common form
   b. Onset of the disease: between the ages of 15 months and 2 years
   c. Clinical symptoms
      i. Loss of acquired motor skills
      ii. Flaccid weakness and hypotonia
      iii. Ataxic gait with absent tendon reflexes
   d. Progression of the disease
      i. Quadriplegia
      ii. Speech disturbances
         a) Dysarthria
         b) Aphasia
         c) Speech deterioration leading to loss of speech
      iii. Difficulty in feeding (dysphagia) with bulbar and pseudobulbar palsies
      iv. Irritability
      v. Muscle wasting
      vi. Peripheral neuropathy
      vii. Ataxia
      viii. Ophthalmic features
         a) Nystagmus
         b) A cherry-red spot in the macula in some patients (Crumrine 2001)
         c) Optic atrophy leading to blindness
      ix. Epileptic seizures usually occur at advanced stages of the disease.
      x. Mental deterioration progresses with the disease until the patients are no longer able to establish any contact with their surroundings.
      xi. Death generally occurs 1–7 years after onset.
3. Juvenile form
   a. Clinical symptoms usually develop between the ages of 4 and 12 years.
   b. Progression of the illness similar to that of the infantile form
   c. Clinical characteristics
      i. Loss of developmental milestones by the end of the first decade
      ii. Gross motor
         a) Incoordination
         b) Clumsiness
         c) Ataxia with progressive gait disturbance leading to loss of ambulation
         d) Progressive hypertonia with tremor, postural abnormalities, and/or leg scissoring
         e) Diminished deep tendon reflexes
      iii. Speech and language
         a) Slurred speech
         b) Speech deterioration
      iv. Cognitive and behavioral changes
         a) Abnormal and bizarre behavior
         b) Daydreaming
         c) Difficulty in following directions
         d) Emotional difficulties
         e) Intellectual decline
         f) Mental deterioration
      v. Ophthalmologic features: optic atrophy leading to blindness
      vi. Other CNS manifestations
         a) Pseudobulbar palsy
         b) Epileptic seizures usually occur at advanced stages of the disease.
         c) Mental illness with features of psychosis, dementia, and emotional disorders in older children
         d) Progressive neurological problems but less severe than in the late-infantile form

d. Prognosis
   i. Fatal in majority of cases
   ii. Course of disease may last more than 20 years in a few cases.
4. Adult form
   a. Wide range of onset: from 19 to 46 years
   b. Very rare occurrence
   c. Slow progression of the disease
   d. Survival of 5–10 years common
   e. Cognitive and behavioral changes: the first symptoms in many cases
      i. Personality changes
         a) Anxiety
         b) Apathy
         c) Bewilderment
         d) Emotional instability
         e) Psychosis
      ii. Poor school or job performance
         a) Decreased mental alertness
         b) Defective visual-spatial discrimination
         c) Disorganized thinking
         d) Poor memory
   f. Mental deterioration
      i. Often the first symptom
      ii. Loss of professional abilities leading to total incapacity
      iii. Progressive deterioration eventually leading to dementia
   g. Rare epileptic seizures
   h. Ophthalmologic features
      i. Horizontal nystagmus
      ii. Optic atrophy leading to blindness
   i. Final stages
      i. Lose of speech
      ii. Immobility
      iii. Incontinence
5. Arylsulfatase pseudodeficiency
   a. Low arylsulfatase activity in healthy individuals
   b. Allelic variant metachromatic leukodystrophy
6. Nonallelic variants of MLD (Fluharty 2008)
   a. Multiple sulfatase deficiency (Austin variant of MLD)
      i. Caused by a defect in processing of an active site cysteine to formylglycine (alanine-semialdehyde), a proenzyme activation step common to most sulfatases (Dierks et al. 2005; Zafeiriou et al. 2008)
      ii. Findings suggesting a diagnosis of multiple sulfatase deficiency include
         a) Reduced activity of other sulfatases including arylsulfatase B, arylsulfatase C, iduronate sulfatase (the enzyme that is deficient in Hunter syndrome, and heparan-N-sulfamidase in leukocytes or cultured cells)
         b) Presence of mucopolysaccharides (glycosaminoglycans) as well as sulfatides in the urine
      iii. Although clinical variability of multiple sulfatase deficiency is great, features of both MLD and a mucopolysaccharidosis (MPS) may be present (Macaulay et al. 1998).
      iv. More severe forms of multiple sulfatase deficiency resemble late-infantile MLD. In other cases, MPS-like features such as coarse facial features and skeletal abnormalities may be evident in infancy and early childhood, with MLD-like symptoms becoming evident in later childhood.
      v. Eventually, the disease course resembles MLD with demyelination dominating the clinical picture (von Figura et al. 2001). Ichthyosis, common to arylsulfatase C deficiency, is also often present.
      vi. A defect in the formylglycine-generating enzyme (FGE) is causative (Dierks et al. 2005) and is responsible for the activation of most sulfatases, and a variable degree of arylsulfatase A deficiency occurs in many tissues in its absence.
   b. Sphingolipid activator protein B deficient MLD (saposin B deficiency)
      i. A defect in the glycolipid-binding protein saposin B, which is needed to solubilize sulfatides before they can be hydrolyzed by arylsulfatase A, causes an MLD-like disorder.
      ii. While a number of other glycolipid degradative processes are disrupted in saposin B deficiency, it is the failure in sulfatide catabolism that dominates the clinical picture.
      iii. Age of onset is variable, with too few cases having been reported to delineate a typical clinical picture.

iv. An MLD-like clinical presentation, leukodystrophy on MRI, normal arylsulfatase A enzyme activity, and evidence of excess urinary sulfatide excretion and/or sulfatide storage suggest activator deficiency.
v. Diagnosis depends on depressed sulfatide degradation by cultured cells, immunochemical assessment of saposin B levels, or sequence analysis of the gene encoding prosaposin (Sandhoff et al. 2001).

Diagnostic Investigations

1. Diagnosis suspected in individuals with progressive neurologic dysfunction and MRI evidence of a leukodystrophy.
2. Demonstration of decreased (<10% of normal controls) or absence ASA enzyme in the urine, leukocytes, or cultured skin fibroblasts (Gieselmann 1991)
   a. Low ASA activity also observed in
      i. Individuals with multiple sulfatase deficiency
      ii. Individuals with copies of pseudodeficiency (PD) allele
   b. Low ASA activity is seen in individuals without MLD due to the high frequency of the common PD allele in the general population.
   c. Differentiation of ASA pseudodeficiency from MLD
      i. Inability to reliably distinguish MLD and ASA pseudodeficiency, based solely on enzyme activity determinations
      ii. Cerebroside sulfate loading test
         a) Exposure of the cells to radioactively labeled cerebroside sulfate, the natural substrate of arylsulfatase A
         b) Cultured cells from pseudodeficient individuals will degrade this substrate at normal rates, whereas those from MLD patients do not.
         c) Disadvantages: require experienced investigator, noncommercially available substrate, and tissue culture facilities
      iii. PD allele mutations studies using allele specific amplification
3. Urinalysis showing metachromatic granules in the urine sediment
4. Urine chemistry showing markedly increased sulfatide levels
5. Sulfatide loading of fibroblast cultures and subsequent measurement of hydrolysis of added substrate: The differences in hydrolysis of added sulfatide provide a functional test that separates late-infantile, juvenile, and adult forms (Krivit et al. 1995).
6. Absence of gallbladder function on a cholecystography (Crumrine 2001)
7. Abnormal brain stem auditory, visual, and somatosensory evoked potentials
8. Elevated CSF protein levels
9. Brain imaging shows progressive loss of white matter due to demyelination (Faerber et al. 1999).
   a. Symmetric diffuse high-intensity signal on proton density and T2-weighted images throughout the white matter consistent with demyelination
   b. Hypointense signal abnormalities in the white matter of the centrum semiovale with following two distinct appearances
      i. A radiating pattern ("tigroid" appearance) of linear tubular structures or horizontal linear hypodensity indicative of spared perivascular white matter
      ii. Areas of relatively normal-appearing white matter: a punctate appearance to the linear structures ("leopard-skin" appearance) within the demyelinated centrum semiovale
   c. Cerebral atrophy with ventricular enlargement
10. Nerve conduction studies show decreased nerve conduction velocities.
11. Nerve biopsies show metachromasia of Schwann cells.
12. Molecular studies of ASA mutations (Fluharty 2008)
   a. Targeted mutation
      i. *ARSA*-mild alleles
      ii. *ARSA*-PD alleles
   b. Sequence analysis/mutation scanning
   c. Deletion/duplication analyses

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk: 25%
      ii. Younger siblings in the same family with an older sibling who is clinically affected by MLD (Krivit et al. 1995)
         a) Require appropriate and rapid evaluation
         b) May be affected but clinically presymptomatic
         c) Therapy with bone marrow transplantation in affected but asymptomatic sibling may be curative.
         d) Sibling with very low levels of white blood cell arylsulfatase A may not indicate the presence of disease because of the combination of the pseudodeficient gene with a metachromatic leukodystrophy gene.
   b. Patient's offspring
      i. Do not survive into reproductive age in late-infantile and juvenile forms
      ii. Not increased in adult form unless the spouse is a carrier
2. Carrier detection (Gieselmann 1991)
   a. Individuals with about 50% of arylsulfatase A
      i. Suspected to be carriers of a MLD allele and have genetic risk for MLD
      ii. Likely to be carriers of a pseudodeficiency allele and have no genetic risk for MLD
   b. Enzyme activity determination: impossible to distinguish heterozygotes of a pseudodeficiency allele from heterozygous of an MLD allele
   c. Mutation detection of the pseudodeficiency allele in the DNA to facilitate the differential diagnosis of MLD and pseudodeficiency
3. Prenatal diagnosis for couples at risk
   a. Demonstration of the absence of arylsulfatase A in cultured chorionic villi or amniocytes
   b. A combination of biochemical and molecular tests performed on chorionic villus samples or cultured amniotic fluid cells
   c. Demonstration of the disease-causing mutation previously identified in the proband on fetal DNA obtained from amniocentesis or CVS
   d. Preimplantation genetic diagnosis for at-risk pregnancies requires prior identification of the disease-causing mutations in the family.
4. Management
   a. Primarily supportive
      i. Currently, no available treatment can reverse the fatal outcome of the devastating MLD.
      ii. Nasogastric or G-tube feeding for dysphagia of bulbar and pseudobulbar palsies
      iii. Multidisciplinary approach
   b. Bone marrow transplantation
      i. For individuals who are presymptomatic or have only mild neurologic manifestations
      ii. Significant risks associated with this procedure
      iii. Highly dependent on the availability of adequately matched donors
      iv. Appears to slow the progression of the disease and improve the quality of life
      v. Successful treatment of metachromatic leukodystrophy using bone marrow transplantation of HoxB4 overexpressing cells in the mouse model (Miyake et al. 2010)

Fig. 1 A 28-month-old boy with late-infantile form metachromatic leukodystrophy showing extreme hypotonia. At about 15 month of age, he stopped talking and showed muscle weakness. MRI of the brain demonstrated demyelination. Arylsulfatase A activity was absent in the cultured fibroblasts. Urinary excretion of excess sulfatides confirmed the diagnosis of metachromatic leukodystrophy. DNA analysis shows no copies of the pseudodeficiency allele or the common late-infantile mutation. Mutation screening of the entire coding sequence of the arylsulfatase A gene revealed the mutation E253K which was inherited from the mother and the second mutation P192R which was inherited from the father. The E253K mutation has been described as a disease-causing mutation in the literature. The second mutation P192R most likely is a disease causing mutation

Fig. 2 A 3-year-old girl presented with progressive muscle weakness in the lower limbs for 2–4 months. The low leukocyte arylsulfatase A at 0.4 (control: $\geq$2.5) was consistent with diagnosis of metachromatic leukodystrophy

Miller–Dieker Syndrome

In 1963, Miller reported two siblings with a specific pattern of malformations in which lissencephaly was a key feature. Later in 1969, Dieker et al. described a similar condition. Jones et al. in 1980 further characterized the phenotype and suggested the designation Miller–Dieker syndrome to distinguish it from other lissencephaly syndromes. At present, Miller–Dieker syndrome is known to be a contiguous gene disorder caused by haploinsufficiency of a gene or genes having a major role in the development of the brain and the face (Alvarado et al. 1993).

Synonyms and Related Disorders

Chromosome 17p13.3 deletion syndrome; Miller-Dieker lissencephaly syndrome

Genetics/Basic Defects

1. Genetics: a contiguous gene deletion syndrome involving chromosome 17p13.3 (Chitayat et al. 1997)
   a. Association of Miller–Dieker syndrome and del (17)(p13)
      i. First reported by Dobyns et al. in 1983
      ii. Familial cases reported by Miller (1963) with affected members being carriers of an unbalanced rearrangement from t(15;17)(q26.1;p13.3)
      iii. Family reported by Dieker et al. (1969) with affected members being carriers of an unbalanced rearrangement from t(12;17)(q24.31;p13.3)
   b. A microdeletion in a critical 350-kb region of chromosome 17p13.3 observed in familial and sporadic cases, detected by high-resolution banding
   c. Southern blot analysis of restriction fragment length polymorphism with several different DNA markers in 17p13.3, and later FISH analysis using different DNA probes of this segment
      i. Observed in >90% of patients with Miller–Dieker syndrome
      ii. Observed in 38% of patients with isolated lissencephaly
2. Mutations and large deletions of the lissencephaly gene (*LIS1*)
   a. Deletions involving *LIS1*: more common than mutations
   b. *LIS1* deleted in Miller–Dieker syndrome
   c. *LIS1* mutations observed in patients with isolated lissencephaly sequence
      i. Missense mutations
      ii. Nonsense mutations
      iii. Small deletions or insertions
      iv. Splice site mutations
      v. Partial deletions
   d. Phenotype-genotype correlations (Cardoso et al. 2002)
      i. Most severe LIS phenotypes observed in patients with large deletions of 17p13.3
      ii. Milder phenotypes observed in patients with intragenic mutations
      iii. Mildest phenotypes observed in patients with missense mutations
3. Classification of lissencephaly (Dobyns et al. 1984; Spalice et al. 2009)
   a. Lissencephaly type I (classical)
      i. Isolated lissencephaly sequence

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_157,
© Springer Science+Business Media, LLC 2012

   ii. Miller–Dieker syndrome
   iii. Subcortical band heterotopia
   iv. Nonclassified forms
  b. Lissencephaly type II (cobblestone)
   i. Walker–Warburg syndrome
   ii. Fukuyama congenital muscular dystrophy
   iii. Muscle-eye-brain disease
   iv. Non-unclassified forms
  c. Rare forms
   i. Neu–Laxova syndrome
   ii. Cerebro-cerebellar syndrome
4. Cytogenetic mechanisms in Miller–Dieker syndrome (Dobyns et al. 1991)
  a. De novo abnormalities (44%)
   i. Deletion (terminal or interstitial) (36%)
   ii. Dicentric translocation (4%)
   iii. Ring chromosome (4%)
  b. Familial rearrangement (12%)
   i. Reciprocal translocation (8%)
   ii. Pericentric inversions (4%)
  c. Normal karyotype (44%)
   i. Submicroscopic deletion (36%)
   ii. No deletion detected (8%)
5. Molecular explanation for Miller–Dieker syndrome (Toyo-oka et al. 2003)
  a. Heterozygous deletions of 17p13.3 result in the human neuronal migration disorders.
   i. Isolated lissencephaly sequence
   ii. More severe Miller–Dieker syndrome
  b. Mutations in *PAFAH1B1* (the gene encoding LIS1): responsible for isolated lissencephaly sequence and contributing to Miller–Dieker syndrome
  c. The gene encoding 14-3-3ϵ (YWHAE), one of a family of ubiquitous phosphoserine/threonine-binding proteins: always deleted in individuals with Miller–Dieker syndrome, providing a molecular explanation for the differences in severity of human neuronal migration defects with 17p13.3 deletions

Clinical Features

1. Prenatal and neonatal history
  a. Polyhydramnios
  b. Prenatal growth deficiency
  c. Neonatal resuscitation
  d. Neonatal jaundice
  e. Postnatal growth deficiency
2. CNS anomalies
  a. Type I (classical) lissencephaly: can occur either in association with the Miller–Dieker syndrome or as an isolated finding, termed "isolated lissencephaly sequence."
   i. Agyria (absent gyration of the cerebral cortex)
   ii. Pachygyria (unusually thick convolutions of the cerebral cortex)
  b. Absent or hypoplastic corpus callosum
  c. Cavum septi pellucidi
  d. Midline calcification
  e. Ventricular dilatation
  f. Abnormal positioning of the olivary nuclei in the midbrain
  g. Occasional mild cerebellar vermis hypoplasia
  h. Microcephaly
  i. Seizures usually by age 9 weeks
  j. Cerebral palsy
  k. Profound mental retardation
3. Craniofacial features
  a. High, prominent, and wrinkled forehead
  b. Bitemporal narrowing
  c. Furrowed brow
  d. Epicanthal folds
  e. Broad nasal bridge
  f. Short and pointed nose with anteverted nostrils
  g. Long prominent upper lip with thin upper vermilion border
  h. Micrognathia
  i. High-arched palate
  j. Low-set and malformed ears
4. Congenital heart defects
5. Omphalocele (Chitayat et al. 1997)
6. Hands and fingers
  a. Clinodactyly
  b. Camptodactyly
  c. Transverse palm crease
7. Sacral dimple
8. Cryptorchidism
9. Prognosis: often die within the first few months of life
10. Differential diagnosis
  a. Isolated lissencephaly sequence (Dobyns et al. 1984)
   i. Brain abnormalities
    a) Lissencephaly (type I)
    b) Numerous heterotopias
    c) Failure of opercularization

d) Enlarged ventricles (usually colpocephaly)
e) Probable hypoplasia of the corpus callosum

ii. Neurologic abnormalities
a) Profound mental retardation
b) Decreased spontaneous activity
c) Early hypotonia
d) Subsequent hypertonia
e) Poor feeding
f) Seizures

iii. Craniofacial features
a) Microcephaly
b) Bitemporal hollowing
c) Prominent occiput
d) Micrognathia

iv. Occasional abnormalities
a) Prenatal polyhydramnios, decreased fetal movement
b) Postnatal: may require resuscitation at birth
c) Neurological: infantile spasms

v. Chromosome studies
a) Normal chromosomes by conventional studies
b) Submicroscopic deletions by FISH observed in increasing numbers

b. Norman–Roberts syndrome (Dobyns et al. 1984)
i. Probably an autosomal recessive disorder
ii. Brain abnormalities
a) Lissencephaly (type I)
b) Numerous heterotopias
c) Failure of opercularization
d) Slightly enlarged ventricles (probable colpocephaly)
e) Probable hypoplasia of the corpus callosum

iii. Neurologic abnormalities
a) Profound mental retardation
b) Decreased spontaneous activity
c) Poor feeding
d) Seizures

iv. Cranial abnormalities
a) Microcephaly
b) Bitemporal hollowing
c) Slightly prominent occiput
d) Low, sloping forehead

v. Facial features
a) Widely set eyes
b) Broad, prominent nasal bridge
c) Micrognathia
d) Absence of upturned nares
e) Normal eyes

vi. Other features
a) Clinodactyly
b) Chordee
c) Low birth weight

vii. Normal chromosomes

c. Walker–Warburg syndrome
i. Most commonly seen in the United Kingdom
ii. An autosomal recessive disorder
iii. Type II lissencephaly
iv. Hydrocephalus
v. Cerebellar malformation (vermian hypoplasia)
vi. Eye abnormalities
a) Retinal dysplasia
b) Microphthalmia
c) Colobomata
d) Cataracts
e) Glaucoma
f) Corneal clouding commonly due to a Peter anomaly
g) Congenital muscular dystrophy in all patients
h) Elevated CK
i) Abnormal EMG
j) Pathological changes on muscular histology

vii. Other abnormalities
a) Cleft lip/palate
b) Genital anomalies in males: cryptorchidism, small penis
c) Occasional contractures

d. Muscle-eye-brain disease
i. Mainly reported in Finnish population
ii. An autosomal recessive disorder
iii. Type II lissencephaly
iv. Hydrocephalus
v. Eye abnormalities
a) Primarily myopia
b) Occasional glaucoma, retinal dystrophy, and cataracts

vi. Congenital muscular dystrophy: a constant feature
vii. Elevated CK levels
viii. Hypotonia
ix. Feeding difficulties

x. Severe mental retardation
xi. Seizures common

e. Fukuyama congenital muscular dystrophy
i. Mainly reported in the Japanese population
ii. An autosomal recessive disorder
iii. Cobblestone lissencephaly (type II)
iv. Eye abnormalities
a) Myopia
b) Optic atrophy in some patients
v. Muscular dystrophy in all patients
vi. CK levels ranging from 10 to 50 times of normal
vii. Hypotonia
viii. Marked mental retardation

Diagnostic Investigations

1. Chromosome analysis to detect microdeletion at 17p13.3
   a. High-resolution analysis indicated for all patients with type I or atypical lissencephaly
   b. Molecular cytogenetic technology using FISH to detect a submicroscopic deletion when chromosome analysis is normal and Miller–Dieker syndrome is suspected based on clinical evaluation
   c. Parental studies in case of positive findings
2. MRI of the newborn brain
   a. Smooth brain
   b. Bilateral primitive Sylvian fissure giving rise to a "figure 8" appearance of the brain
   c. Persistent fetal configuration of the posterior horns of the ventricular system (colpocephaly)
3. DNA mutation analysis of *LIS1* available clinically (Dobyns and Das 2009)
   a. Direct sequencing
   b. Deletion/duplication analysis to identify deletions/duplications not detectable by sequence analysis
   c. Array comparative genomic hybridization (aCGH)
   d. Multiplex ligation-dependent probe amplification (MLPA) analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: based on the specific cytogenetic mechanism involved
      i. Very low recurrence risk in most patients (80% of individuals with MDS) whose abnormalities occur de novo
      ii. Very high recurrence risk in families (20% of individuals with MDS) where one parent is the carrier of a balanced chromosome rearrangement involving 17p13
      iii. Proband with an intragenic mutation in *LIS1*: The risk to sibs is negligible if neither parent has mosaicism for the mutation present in the proband.
   b. Patient's offspring: patients not surviving to reproductive age
   c. A high risk for abnormal phenotypes for an individual carrying a balanced translocation with a breakpoint in 17p13 ascertained because of a relative with Miller–Dieker syndrome or dup(17p)
      i. Approximately 26% risk in all recognized pregnancies
      ii. Thirty-three percent risk in pregnancies which remain viable in the second trimester or after
      iii. Frequency of spontaneous miscarriages and stillbirths not appearing to be unduly elevated in these families
2. Prenatal diagnosis
   a. Ultrasonography for pregnancy at risk (Sultzman 1991)
      i. Polyhydramnios
      ii. IUGR
      iii. Lissencephaly
      iv. Microcephaly
      v. Mild ventriculomegaly
      vi. Absence of corpus callosum
      vii. Cardiac and other malformations
   b. Prenatal diagnosis by amniocentesis or CVS
      i. Indications
         a) Carrier parents with balanced chromosome rearrangements involving 17p13
         b) Probably parents of all Miller–Dieker syndrome patients because of the small possibility of gonadal mosaicism in apparently de novo cases
         c) Normal relatives of unknown karyotype
      ii. Cytogenetic analysis
         a) High-resolution analysis of chromosome 17
         b) Molecular cytogenetic studies (FISH)
      iii. Analysis of fetal DNA if a *LIS1* variant is identified in the proband.

iv. Preimplantation genetic diagnosis: available for families in which the disease-causing mutation has been identified.

3. Management
   a. Supportive care
   b. Early infant intervention
   c. Anticonvulsants for seizures

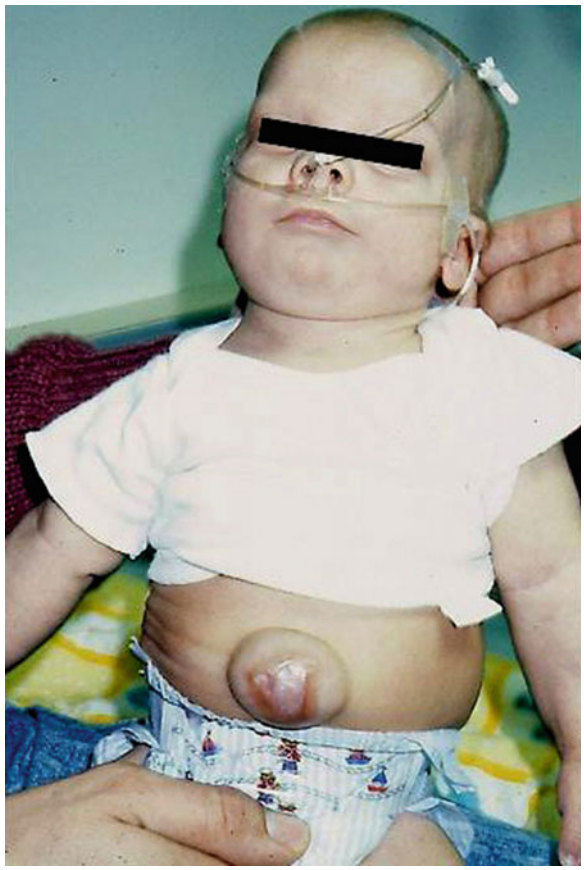

Fig. 1 A child with Miller–Dieker syndrome showing high forehead, frontal bossing, bilateral temporal narrowing, small nose with anteverted nares, prominent upper lip, micrognathia, and a surgically repaired omphalocele

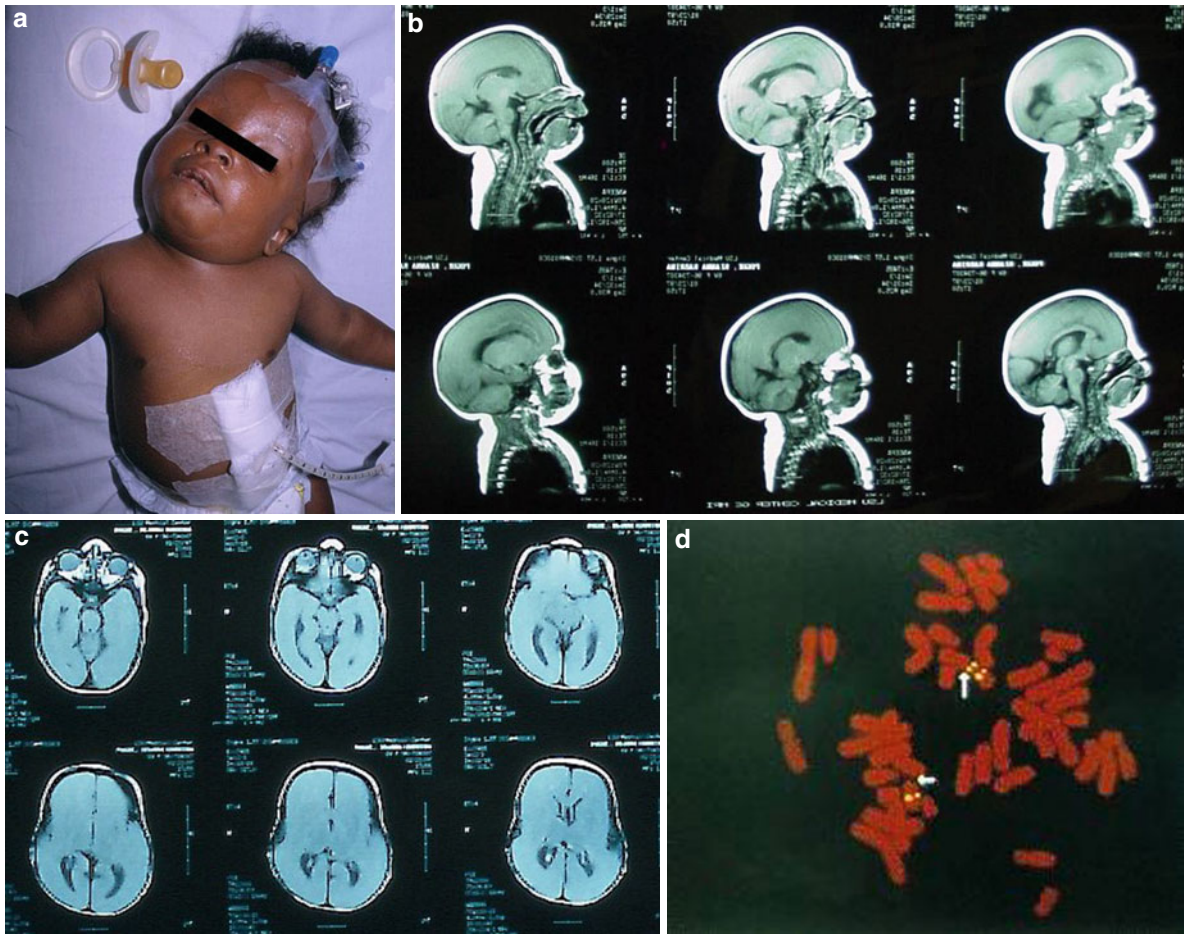

Fig. 2 (**a**–**d**) A child with Miller–Dieker syndrome showing characteristic facial traits like the previous child. The MRI of the brain showed diffuse and complete type I lissencephaly. FISH revealed one chromosome 17 lacked a signal at 17p13 indicating the presence of a deletion

Mitochondrial Leber Hereditary Optic Neuropathy

Mitochondrial disorders are a major cause of chronic human disease with an estimated prevalence of 1 in 10,000 in the United Kingdom, and 1 in 200 individuals are at-risk mutational carriers (Elliott et al. 2008; Schaefer et al. 2008). Ocular involvement, especially optic nerve dysfunction, is a prominent feature in this group of disorders, suggesting the underlying mitochondrial etiology. Leber hereditary optic neuropathy (LHON) and autosomal dominant optic atrophy (DOA) (Kjer type optic atrophy) are the two most common inherited optic neuropathies, resulting from mitochondrial dysfunction.

In 1871, the German ophthalmologist Theodore Leber first described the distinctive clinical entity of LHON with a characteristic pattern of visual loss among members of four families, subsequently confirmed in pedigrees from different populations (Bell 1931; Imai and Moriwaki 1936; Lundsgaard 1944). These early studies highlighted the salient features of LHON, including the maternal transmission of the disease, the predilection of males to lose vision, and the almost exclusive involvement of the optic nerve.

Autosomal dominant optic atrophy is the most common primary hereditary optic neuropathy (Yoshida et al. 2006). It is characterized by optic nerve pallor and reduced visual acuity (Eliott et al. 1993; Votruba et al. 1998a, b). It was first described clinically by Batten (1896) and later by Kjer (1959) and typically presents in childhood with bilateral visual loss that is usually symmetrical, temporal optic nerve pallor, centrocaecal visual field scotoma, and color vision deficit (Caldwell et al. 1971; Smith 1972; Hoyt 1980; Jaeger 1988).

Synonyms and Related Disorders

Hereditary optic neuropathy; Leber optic atrophy; Leber optic neuropathy; LHON

Genetics/Basic Defects

1. LHON (Yu-Wai-Man et al. 2009)
   a. Caused by primary mitochondrial DNA (mtDNA) mutations affecting the respiratory chain complexes
      i. Over 95% of LHON pedigrees are now known to harbor one of three mitochondrial DNA (mtDNA) point mutations: m.3460G > A, m.11778G > A (a point mutation within the mitochondrial genome known to cause the first human disease, LHON) (Wallace et al. 1988), and m.14484T > C, which all involve genes encoding complex I subunits of the mitochondrial respiratory chain (Mackey et al. 1996).
   b. Mitochondrial genetic factors
      i. Homoplasmy: In most LHON pedigrees, the primary mutation is homoplasmic (every mtDNA molecule harbors the mutant allele, i.e., only one type of mtDNA exists within an individual).
      ii. Heteroplasmy (both mutant and wild-type mtDNA coexist within an individual)
         a) Cells can contain anywhere between 100 and 10,000 mitochondria depending on their metabolic demands. With 2–10 mtDNA molecules in each

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_158,
© Springer Science+Business Media, LLC 2012

mitochondrion, this results in a very high copy number per cell.
b) Ten to fifteen percentage of LHON carriers are thought to be heteroplasmic (one mtDNA subpopulation carrying the wild-type allele) (Smith et al. 1993; Harding et al. 1995; Man et al. 2003).
c) Available data suggest that heteroplasmy contributes to incomplete penetrance, with the risk of blindness being minimal if the mutational load is <60% (Chinnery et al. 2001).

iii. MtDNA haplogroups
a) MtDNA accumulates mutations ~10 times faster than nuclear genome, resulting in a high degree of polymorphism (Brown et al. 1979).
b) Because human mtDNA is strictly maternally inherited and does not recombine, polymorphisms have accumulated sequentially along radiating female lineages as women migrated out of Africa into the different continents ~150,000 years ago (Wallace et al. 1999).
c) Reflecting its evolution, a number of stable polymorphic variants cluster together in specific combinations referred to as haplogroups, with individuals of European ancestry belonging to one of nine haplogroups: H, I, J, K, T, U, V, W, and X (Torroni et al. 1996; Hofmann et al. 1997).
d) A recent meta-analysis of 159 European LHON pedigrees indicated that the risk of visual loss for the three primary LHON mutations is influenced by the mtDNA background (Hudson et al. 2007).

c. Nuclear genetic factors
i. The predominance of affected males in LHON cannot be explained by mitochondrial inheritance, and segregation analysis suggests the existence of a recessive X-linked susceptibility gene acting in synergy with the mtDNA mutation to precipitate the optic neuropathy (Bu and Rotter 1991, 1992; Nakamura et al. 1993).
ii. Although the actual causative gene in this region of interest has not yet been identified, a high-risk haplotype (DXS8090-DXS1068) at Xp21 was defined which increased the risk of visual failure ~35-fold for the m.11778G > A and m.14484T > C mutations but not for m.3460G > A (Hudson et al. 2005).
iii. The possibility of other autosomal nuclear modifier genes in LHON has not been excluded, and the genetic etiology of LHON might prove even more complex, with epistatic interaction of these multiple nuclear susceptibility loci and genetic heterogeneity.

d. Environmental factors
i. Existence of discordant monozygotic twins strongly suggests that environmental factors also contribute to penetrance.
ii. Anecdotal reports of nutritional deprivation, exposure to industrial toxins, antiretroviral drugs, psychological stress, or acute illness precipitating the onset of blindness in LHON (Mackey et al. 2003; Sanchez et al. 2006; Carelli et al. 2007)
iii. The role of environmental triggers in LHON remains largely unanswered, and more robust epidemiological data are needed, which will necessitate a multicenter collaborative effort in order to collect sufficient number of subjects for analysis.

2. DOA: caused by mutations in the *OPA1* gene, a gene encoding for a dynamin-like mitochondrial GTPase, an inner mitochondrial membrane protein critical for mtDNA maintenance and oxidative phosphorylation, in the majority of DOA families
3. Pathology for both LHON and DOA: limited in the majority of cases to the retinal ganglion cells (RGCs), a highly specialized group of cells within the eye
4. Expanding phenotype associated with LHON and DOA: providing important insights into possible disease pathways leading to optic nerve degeneration and visual failure

Clinical Features

1. LHON (Yu-Wai-Man et al. 2009; Milea et al. 2010)
a. Presymptomatic phase
i. Fundal abnormalities such as telangiectatic vessels around the optic discs and variable degrees of retinal nerve fiber layer edema
a) Documented in some asymptomatic carriers
b) Can fluctuate with time

ii. Thickening of the temporal retinal nerve fiber layer found in a proportion of unaffected carriers by using optical coherence tomography imaging: provides further evidence that the papillomacular bundle is particularly vulnerable in this disorder (Savini et al. 2005; Quiros et al. 2006)
iii. Subtle impairment of optic nerve function in some individuals on detailed psychophysical testing (Sadun et al. 2006)
a) Loss of color vision affecting mostly the red–green system
b) Reduced contrast sensitivity
c) Subnormal visual electrophysiological parameters

b. Acute phase
i. Experiencing blurring or clouding of vision in one eye
ii. Subacute presentation in the vast majority of an early age of onset (<20 years) with slow progression of the visual deficits and large optic nerve head surface area (Nikoskelainen et al. 1996; Barboni et al. 2006)
iii. Devastating, with the majority of patients showing no functional improvement and remaining as legally blind

c. Associated features
i. Cardiac arrhythmias
ii. Neurological abnormalities: rarely clinically significant, but a small number of LHON pedigrees have severe neurological deficits such as spastic dystonia, ataxia, and juvenile onset encephalopathy in addition to the optic neuropathy ("LHON plus" syndromes) (Bower et al. 1992; Nikoskelainen et al. 1994; 1995; Meire et al. 1995; Mashima et al. 1996)
a) Postural tremor
b) Peripheral neuropathy
c) Nonspecific myopathy and movement disorders

2. DOA
a. Prevalence
i. A historical figure of 1 in 50,000 among Caucasians often quoted in the literature (Lyle 1990)
ii. Thought to be the most common inherited optic neuropathy in the Netherlands, with a population frequency of 1 in 12,000, a higher prevalence linked to a mutational founder event (Thiselton et al. 2001)

b. Insiduous onset of symptoms: 13–25% of patients with optic atrophy in premolecular case series were visually asymptomatic and were only identified through contact tracing via other affected family members (Kline and Glaser 1979; Hoyt 1980).

c. Pronounced inter-/intrafamilial variability in the severity of visual symptoms
i. Makes genetic counseling difficult
ii. Visual decline: classically starts in the first two decades of life
iii. Visual acuity: ranges from 6/6 to the detection of hand movement only
iv. Rate of progression of visual loss: not easy to predict, with 19–50% of patients experiencing further, albeit slow, deterioration on long-term follow-up. (Kjer 1959; Eliott et al. 1993; Votruba et al. 1998a, b; Puomila et al. 2005; Cohn et al. 2008)

d. Better overall visual prognosis compared to LHON (Kjer et al. 1996; Votruba et al. 1998a, b; Cohn et al. 2007)
i. A mean visual acuity of 6/24–6/36
ii. Results in significant visual impairment with about half of all affected individuals failing the driving standards and 13–46% registered as legally blind

e. Generalized dyschromatopsia: predominant color defect involving both the blue–yellow and red–green axes, with a minority of patients having pure tritanopia (<10%), which was once considered to be a pathognomonic feature of dominant optic atrophy (Berninger et al. 1991)

f. Central, centrocaecal, and paracentral scotomas are the most common field abnormalities with sparing of the periphery, findings consistent with the primary involvement of the papillomacular bundle in this condition

g. The optic disc pallor in DOA falls into two main categories (Kline and Glaser 1979; Hoyt 1980; Kjer 1959)
i. Diffuse pallor involving the entire neuroretinal rim in about half of all cases
ii. A temporal wedge in the remainder of cases

h. Other common optic disc findings (Votruba et al. 1998a, b, 2003; Fournier et al. 2001)
i. Saucerization (79%)

ii. Peripapillary atrophy (69%)
iii. A cup to disc ratio 0.5 (48%)
iv. A typical profile with bilateral symmetrical thinning around the optic disc, most pronounced in the temporal quadrant (circumpapillary retinal nerve fiber layer thickness using optical coherence tomography) (Ito et al. 2007; Kim and Hwang 2007)

i. Normal tension glaucoma: single nucleotide polymorphisms in intron 8 and exon 4 of the *OPA1* gene could increase the risk of normal (but not high) tension glaucoma in whites (Yu-Kai-Man et al. 2010).
j. Extraocular findings: *OPA1* gene may be responsible for a continuum of phenotypes, ranging from mild visual loss to very variable, sometimes severe, multisystemic involvement of the disease (Amati-Bonneau et al. 2008; Hudson et al. 2008).
k. Optic atrophy associated with multiple sclerosis–like disease in a patient carrying a new missense *OPA1* mutation (p.S646L) in the highly conserved dynamin domain (Vemy et al. 2008), suggesting a relationship between mitochondrial dysfunction and the central nervous system defect
l. Optic atrophy and deafness occurring in patients with a specific R445H mutation (Zeviani 2008) and other mutations
m. Multisystemic disorders associated with optic atrophy 1 mutations (autosomal dominant optic atrophy "plus") (ADOA "plus syndrome"): an optic atrophy associated with early onset in childhood, followed by chronic progressive external ophthalmoplegia, ataxia, sensorineural deafness, sensorimotor neuropathy, and myopathy in adult life

Diagnostic Investigations

1. LHON (Yu-Wai-Man et al. 2009)
   a. Tentative diagnosis of LHON usually be made on the following:
      i. Clinical grounds (especially if classical ophthalmological features are present)
      ii. A clear maternal history is elicited.
   b. Ophthalmoscopic findings (Huoponen 2001)
      i. Presymptomatic stage
         a) Peripapillary telangiectatica microangiopathy visible in the presymptomatic stage: the first sign of the disease (Nikoskelainen et al. 1982, 1983)
         b) Increased hyperemia, swelling of the optic disc, and arteriolar dilation at the end of the presymptomatic stage
      ii. Acute stage
         a) Visual loss
         b) Severe hyperemia, arteriolar dilation, disc swelling, telangiectatica angiopathy, and a glistening, whitish, opaque nerve fiber layer: hallmarks of this stage of the disease
         c) Decreased visual acuity and development of a relative centrocaecal scotomas can be minimal or even absent.
      iii. End stage
         a) Disappearance of microangiopathy
         b) Fading of retinal nerve fiber layer
         c) Large and absolute centrocaecal scotoma
   c. Molecular genetic testing on a blood DNA sample: remains the gold standard and will confirm that the patient harbors one of the three primary mtDNA LHON mutations, with implications for future genetic counseling
      i. Targeted mutation analysis
         a) Primary pathogenic LHON-causing mtDNA mutations
         b) Secondary LHON-causing mtDNA mutations
      ii. Sequence analysis and mutation scanning
   d. Biochemical findings associated with the primary mutations
      i. Variable Complex I defects: associated with all the primary mutations
      ii. A defect in respiratory chain function in LHON: first demonstrated in platelet mitochondria from a family that was subsequently shown to harbor the ND1/3460 mutations (Parker et al. 1989)
      iii. A marked reduction in the specific activity of Complex I associated with the ND1/3460 mutation: further detected in lymphoblasts (Majander et al. 1991; Brown et al. 2000),

leukocytes (Carelli et al. 1997), and fibroblasts (Cock et al. 1999)
   iv. ND4/11778 mutation: less severe reduction in Complex I function
   v. A reduction in respiration of NADH-linked substrates (Majander et al. 1991; Lodi et al. 2000)
   vi. Alteration in the affinity of Complex I for ubiquinone (Degli Esposti et al. 1994)
e. Electrophysiological studies, including pattern electroretinograms (PERGs) and visual evoked potentials (VEPs), if indicated, can be carried out to exclude retinal pathology and confirm optic nerve dysfunction (Sherman and Kleiner 1994).
f. An electrocardiogram is also recommended to exclude a preexcitation syndrome which has been documented in LHON, although such a finding is rare and does not require any intervention in the absence of cardiac symptoms (Nikoskelainen 1994; Riordan-Eva and Harding 1995).
g. Computed tomography (CT) and magnetic resonance imaging (MRI) scans are usually normal in LHON.

2. DOA (Votruba et al. 1998a, b; Delettre-Cribaillet et al. 2009)
   a. Clinical diagnosis: the majority of patients present in early to mid-childhood and the clinical diagnosis is generally reliable from 6 years of age and above, except in rare cases.
   b. Visual acuity
   c. Color vision
   d. Visual fields
   e. Assessment of extraocular muscles
   f. Hearing evaluation
   g. Electrophysiology
      i. Visual evoked potentials (VEPs): typically absent or delayed, indicating a conduction defect in the optic nerve
      ii. Pattern electoretinogram (PERG): an abnormal N95:P50 ratio with reduction in the amplitude of the N95 waveform (Holder et al. 1998), supporting a ganglion cell origin for the optic atrophy since the N95 component of the PERG, is thought to be specific for the retinal ganglion cell.
   h. Molecular genetic testing available clinically
      i. Sequence analysis of all exons of *OPA1*
      ii. Target mutation analysis for the Danish founder mutation
      iii. Sequence analysis of RNA RT-PCR amplification on *OPA1*
      iv. Deletion/duplication analysis

Genetic Counseling

1. Recurrence risk (Yu-Wai-Man and Chinnery 2008; Yu-Wai-Man et al. 2009)
   a. LHON
      i. Not possible to predict accurately whether or when LHON carriers will become affected
      ii. Two main predictive factors for visual failure:
         a) Gender: males: a 50% lifetime risk of blindness; females: only 10% lifetime risk of blindness
         b) Age: Most patients experience visual loss in their late teens and 20s. Probability of becoming affected decreases with age, being minimal once past the age of 50 years.
      iii. Once a primary LHON mutation has been identified in a proband, other maternally related family members can be offered molecular genetic testing to exclude the possibility of a de novo mutation, which is rare.
      iv. Since LHON shows strict maternal inheritance, male carriers can be reassured that none of their children will inherit the mtDNA mutation whereas female carriers will transmit the pathogenic mutation to all of their offspring.
      v. Since most mothers are homoplasmic, their children will only harbor the mutant species, but the situation is more complex for a heteroplasmic mother as she could transmit a higher or a lower level of the mutation to a particular offspring, which will impact on the latter's risk of visual failure.
      vi. Although the mutant level can be determined and there is evidence that a mutational threshold of ~60% in blood is necessary for disease expression, genetic counseling for these unaffected heteroplasmic carriers remains difficult.
      vii. For similar reasons, the prenatal genetic testing of heteroplasmic women with

amniocentesis or chorionic villus sampling (CVS) would be difficult to interpret.

viii. Patient's sib
  a) The recurrent risk depends on the genetic status of the mother.
  b) All sibs at risk of inheriting the mutation if the mother has the mtDNA mutation.

ix. Patient's offspring
  a) An affected or unaffected male with a primary LHON-causing mtDNA mutation cannot transmit the mutation to any of his offspring.
  b) An affected or unaffected female with a primary LHON-causing mtDNA mutation transmits the mutation to all of her offspring.
  c) An affected female with heteroplasmy may transmit a low level of mutant mtDNA to her offspring, confirming a low disease risk (Chinnery et al. 2001).

x. Other family members
  a) The recurrence risk depends on the genetic status of the proband's mother.
  b) If the proband's mother has an mtDNA mutation, her sibs and mother are also at risk.

b. DOA (Votruba et al. 1998a, b; Yoshida et al. 2006; Delettre-Cribaillet et al. 2009)

i. Despite DOA being an autosomal dominant Mendelian disorder with high penetrance (0.98) (Eiberg et al. 1994), genetic counseling for mutational carriers is difficult because of the pronounced inter- and intrafamilial heterogeneity and variability in the visual phenotype.

ii. A multidisciplinary approach to the diagnosis and management of these patients is helpful, involving both clinical ophthalmologists and geneticists, electrodiagnostic services, low vision specialists, and educational advisors.

iii. An apparently sporadic person who presents with nonprogressive optic atrophy and normal neuroimaging
  a) Important to examine all family members fully, as relatives may be only mildly affected
  b) Establish a disease pedigree and the mode of transmission.

iv. A person uncertain of his clinical status from a family known to be affected by dominant optic atrophy: needs to include color vision and electrophysiology in the full clinical assessment of the patient in order to be able to make a diagnosis

v. Patient with absence of a mutation: genetic counseling relies on conventional risk assessment.

vi. With the availability of molecular testing for *OPA1* becoming more accessible, an increasing number of individuals with pathogenic mutations are being identified who are otherwise visually unaffected.

vii. Patient with *OPA1* mutation
  a) Genetic counseling is difficult since clinical manifestation of the same mutation within a family can be remarkably variable.
  b) Dramatic psychological impact on the person involved with awareness of one's susceptibility to the disease without an actual possibility of intervention

viii. Patient's sib
  a) Risk depends on the genetic status of the parents.
  b) A 50% risk if a parent is affected
  c) Apparently low risk when the parents are found to be clinically unaffected on the basis of visual acuity study, color vision evaluation, fundus examination, VET, and PERG
  d) Possibilities of germline mosaicism in a parent or a de novo mutation in the proband exist if a disease-causing mutation cannot be detected in the DNA of either parent.

ix. Patient's offspring: a 50% risk of inheriting the mutation

2. Prenatal diagnosis

a. LHON

i. Prenatal diagnosis for pregnancies at increased risk: possible by amniocentesis or CVS

ii. MtDNA mutation in the mother must be identified before prenatal testing can be performed.

iii. Reasons for difficult accurate interpretation of a positive prenatal test:
   a) The mtDNA mutational load in amniocytes and chorionic villi is unlikely to correspond to that of other fetal or adult tissues because of mitotic segregation.
   b) The presence of the mtDNA mutation does not predict the occurrence, age of onset, severity, or rate of progression of this typically adult-onset disease.

b. DOA
   i. Prenatal diagnosis for pregnancies at an increased risk is possible by amniocentesis or CVS.
   ii. The disease-causing allele of an affected family member must be identified before prenatal testing can be performed.

3. Management
   a. LHON
      i. Mainly supportive
         a) Provision of visual aids
         b) Registration with the relevant social services
      ii. ECG may reveal a preexcitation syndrome in both affected and unaffected LHON carriers.
   b. DOA
      i. Supportive
      ii. Treatment of decreased visual acuity

Fig. 1 A 10-year-old boy was relatively healthy until last year when he suddenly started having trouble seeing and complained constant headache. He was noted to have painless visual failure, optic nerve atrophy in his left eye, and exophthalmos. He has also experienced minor tremors, muscle weakness, nausea, and movement disorder. Family history revealed similarly affected males in two generations on the maternal side of the family. Molecular genetic analysis detected an apparently homoplasmic m.11778G > A mutation. This mutation in *ND4* gene is commonly associated with Leber hereditary optic neuropathy (LHON). The result confirms the carrier/affected status of this boy for a mitochondrial DNA disorder

Möbius Syndrome

Möbius syndrome (MBS) is a rare congenital disorder characterized by complete or partial facial diplegia accompanied by other cranial nerve palsies and musculoskeletal anomalies.

Synonyms and Related Disorders

Mobius sequence

Genetics/Basic Defects

1. Multifactorial etiology
   a. The term "Möbius sequence" represents a pattern of multiple anomalies due to multiple etiologies, compared with the designation "syndrome" which implies a single cause.
   b. Usually a sporadic occurrence but familial descriptions have been rarely reported (Briegel 2006; Graziadio et al. 2010)
   c. Genetic heterogeneity
      i. Familial cases usually without associated anomalies
      ii. Low incidence of familial cases with associated anomalies such as limb defects and mental retardation
      iii. Autosomal dominant inheritance (Verzijl et al. 1999)
         a) Autosomal dominant Möbius syndrome has been linked to markers on 3q21-q22 in a large Dutch family (Kremer et al. 1996).
         b) A second gene for autosomal dominant Möbius syndrome is localized to chromosome 10q in a second large Dutch family.
      iv. Autosomal recessive inheritance
      v. X-linked recessive inheritance
   d. Four genetic loci for MBS have been described to date (Van Der Zwaag et al. 2002).
      i. MBS1 on chromosome 13q12.2-q13 (Ziter et al. 1977; Slee et al. 1991), based on the following observations:
         a) A reciprocal translocation of 13q12.2-q13 cosegregating with the disease in a three-generation MBS family
         b) An MBS patient with a deletion of chromosome 13q12.2
      ii. MBS2 on chromosome 3q21-q22 (Kremer et al. 1996)
      iii. MBS3 on chromosome 10q21.3-22.1 (Verzijl et al. 1999)
      iv. MBS4 on chromosome 1p22 (Donahue et al. 1993; Nishikawa et al. 1997), based on
         a) A t(1;11)(p22;p13) in a patient with Möbius syndrome
         b) A t(1;2)(p22.3;q21.1) in a patient with Möbius-like syndrome
   e. *HOXA1* mutations: not a common cause of sporadic Möbius syndrome in the general population (Rankin et al. 2010)
      i. The *HOXA1*-related syndromes result from autosomal recessive truncating mutations in the homeobox transcription factor, *HOXA1*.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_159,
© Springer Science+Business Media, LLC 2012

ii. Limited horizontal gaze and sensorineural deafness are the most common features.
iii. Affected individuals can also have facial weakness, mental retardation, autism, motor disabilities, central hypoventilation, and carotid artery and/or conotruncal heart defects.
iv. Möbius syndrome is also phenotypically heterogeneous, with minimal diagnostic criteria of nonprogressive facial weakness and impaired ocular abduction; mental retardation, autism, motor disabilities, additional eye movements restrictions, hearing loss, hypoventilation, and craniofacial, lingual, and limb abnormalities also occur.

f. Chromosome abnormalities (Verzijl et al. 1999)
g. Ischemia: vascular disruption in the subclavian artery territory
h. Teratogens
i. Thalidomide
ii. Alcohol
iii. Benzodiazepines
iv. Cocaine
v. Ergotamine
vi. Infections
vii. Hyperthermia
viii. Trauma
ix. Misoprostol (a synthetic prostaglandin analogue used in the therapy of upper gastrointestinal ulceration or self-administered by the mothers in Brazil as an abortifacient) (Strömland et al. 2002)

2. Pathogenesis (Van Der Zwaag et al. 2002; Graziadio et al. 2010)
a. A primary metameric defect in the brain stem nuclei in the region of the tegmentum
b. An ischemic process resulting from an interruption of the vascular supply of the brain stem and other structures during early fetal development
3. An etiopathologic classification (Pedraza et al. 2000)
a. Type I (central lesion in the brain stem nuclei due to congenital origin)
b. Type II (primary peripheral nerve involvement)
c. Type III (central lesion in the brain stem nuclei due to an anoxic-infectious cause)
d. Type IV (wasting of skeletal muscle tissue due to myopathic cause)

Clinical Features

1. Congenital onset
2. Complete or partial facial diplegia (essential for the diagnosis of Möbius syndrome), often accompanied by other cranial nerve palsies
a. Signs and symptoms
i. Incomplete eyelid closure during sleep
ii. Drooling
iii. Difficulty in sucking
iv. Inability to smile
v. Lack of facial movement when crying (masklike facies)
vi. Asymmetry of the angles of the mouth
vii. Indistinct speech secondary to the inability to close the lips leading to labial sounds
b. Involved cranial nerves (Kumar 1990)
i. Facial nerve (VII) palsy (all cases), resulting in masklike facies and flattened facial expression
ii. Abducens nerve (VI) palsy (75%), less commonly oculomotor (III) and trochlear (IV) nerve palsies, resulting in marked internal strabismus, lateral gaze paralysis, and ophthalmoplegia
iii. Hypoglossal nerve (XII) palsy (25%), leading to paralysis, hypoplasia, and atrophy of the tongue
iv. Paresis of cranial nerves V (trigeminal), IX (glossopharyngeal), and X (vagus), leading to bulbar weakness (swallowing and speech difficulties due to velopharyngeal insufficiency)
3. Involvement of cerebellum, hypothalamus, and pituitary gland
4. Oculofacial abnormalities (Strömland et al. 2002)
a. Masklike facial appearance: may create profound difficulties in social interactions with other people, especially strangers who are unfamiliar with the syndrome
b. Epicanthal folds
c. Ptosis
d. Strabismus
e. Nystagmus
f. Micrognathia
g. Tongue abnormalities
i. A common anomaly

   ii. A small asymmetric tongue with irregular atrophic areas: characteristic of Möbius syndrome
   iii. Impaired motility and fasciculations
  h. At risk for caries and periodontal disease
  i. Impaired speech
   i. A severe and disabling condition
   ii. Factors affecting speech development
    a) Cognitive and language skills
    b) Hearing
    c) Communication ability
    d) Orofacial anatomy
    e) Oral motor function
   iii. Dysarthria caused by cranial nerve dysfunction, worsened by orofacial anomalies, mental retardation, and autism
5. Frequent occurrence of limb malformations
  a. Reduction malformation of limbs
  b. Hypoplasia to aplasia of digits
  c. Brachydactyly
  d. Syndactyly
  e. Ectrodactyly
  f. Talipes deformities (club foot)
  g. Clinodactyly
  h. Polydactyly
  i. Joint contractures
6. Other musculoskeletal features
  a. Rib defects
  b. Klippel–Feil anomaly
  c. Aplasia of muscles
7. Mental retardation (10%)
8. Autistic behavior (30–40%)
9. Association with other anomalies or syndromes
  a. Poland syndrome
   i. Hypoplasia/aplasia of pectoralis major muscle
   ii. Generally unilateral
   iii. Associated with mammary hypoplasia of the same side
   iv. Poland syndrome, Möbius syndrome, and Möbius–Poland syndrome may be a spectrum of the same condition.
  b. Hyoglossia-hypodactyly
  c. Arthrogryposis multiplex congenita
  d. Dextrocardia
  e. Robin syndrome
  f. Corey–Fineman–Ziter syndrome (congenital nonprogressive myopathy with Möbius and Robin sequence)
  g. Kallmann syndrome (association with anosmia and hypogonadotropic hypogonadism)
10. Several similar syndromes (Strömland et al. 2002)
  a. Oromandibular-limb hypogenesis syndrome
   i. Characteristic features
    a) Micrognathia
    b) Cranial nerve palsies
    c) Limb anomalies
    d) Sometimes combined with aplasia of the pectoral muscle (Poland anomaly)
   ii. Entities included:
    a) Möbius syndrome
    b) Hanhart syndrome
    c) Hypoglossia-hypodactyly (aglossia/adactyly)
    d) Glossopalatinus ankylosis
  b. Terminal transverse defects with orofacial malformations
   i. Orofacial features
    a) Micrognathia
    b) Cleft palate
    c) Tongue anomalies
    d) Ear anomalies
    e) Dental anomalies
   ii. Limb malformations
    a) Syndactyly
    b) Clubfeet
    c) Toe deformities
    d) Symbrachydactyly
    e) Absent digits (ectrodactyly)
    f) Amputation-type defects of the limbs

Diagnostic Investigations

1. CT of the head: normal in most patients (Pedraza et al. 2000)
  a. Medial deviation of the eyes
  b. Hypoplastic or dysplastic brain stem
  c. Hypoplastic cerebellum consistent with Dandy–Walker variant malformation
  d. Bilateral calcifications adjacent to the fourth ventricle floor at the level of the VIth cranial nerve nuclei
2. Autopsies in patients with normal CT studies
  a. Focal necrosis and calcifications
  b. Hypoplasia to agenesis of the respective cranial nerve nuclei

3. MRI of the brain
   a. Calcification in the pons within the abducens nuclei
   b. Hypoplasia of the brain stem
   c. Hypoplasia of the cerebellum
4. Neurophysiological studies: may be helpful in locating the site of the lesion
   a. Abnormal nerve conduction studies
   b. Electromyography (EMG) of facial muscles (Jaradeh et al. 1996):
      i. Reveals multifocal chronic neurogenic changes
      ii. Indicates a brain stem process predominantly affecting the facial nuclei and their internuclear connections rather than a supranuclear or muscular site of involvement
   c. Abnormal brain stem evoked potential

Genetic Counseling

1. Recurrence risk
   a. Lower recurrence risk (2%) for Möbius syndrome with congenital sixth and seventh nerve paralysis with skeletal defects (MacDermot et al. 1991)
   b. Higher recurrence risk (25–30%) for Möbius syndrome with isolated facial palsy, deafness, ophthalmoplegia, and digital contractures without skeletal defects (MacDermot et al. 1991)
   c. Autosomal recessive inheritance
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier
   d. Autosomal dominant inheritance
      i. Patient's sib: 50% if a parent is affected; otherwise not increased
      ii. Patient's offspring: 50%
   e. X-linked recessive inheritance
      i. Patient's sib: 50% affected in the brothers if the mother is a carrier; otherwise not increased
      ii. Patient's offspring: 50% carrier risk in the daughters
2. Prenatal diagnosis possible in the Möbius–Poland spectrum
3. Management
   a. Supportive care
   b. Intervention programs
      i. Physical therapy useful for congenital orthopedic problems or postoperative orthopedic intervention
      ii. Occupational therapy to help activities of daily living, especially in patients with absent hands or digits
      iii. Speech therapy for patients affected by severe facial nerve paralysis or lower cranial nerve deficit
   c. Dental hygiene
   d. Treat corneal ulcerations or abrasions secondary to exposure keratitis and conjunctivitis secondary to incomplete eyelid closure
   e. Splints and prostheses for congenital limb anomalies
   f. Surgical care
      i. Clubfoot
      ii. Tracheotomy to support the airway and permit tracheobronchial clearing when airway functions are compromised
      iii. Feeding gastrostomy tube required in some cases
      iv. Ocular surgical procedures in some cases

Mowat–Wilson Syndrome

In 1998, Mowat et al. described a new syndrome, now known as Mowat–Wilson syndrome (MWS), consisting of Hirschsprung disease or severe constipation, microcephaly, mental retardation, and characteristic facial features, including hypertelorism, medially flared and broad eyebrows, prominent columella, pointed chin, and uplifted earlobes.

The prevalence of MWS is currently unknown. However, it seems probable that the syndrome is underdiagnosed, particularly in patients without Hirschsprung disease. Approximately 171 patients with *ZEB2* mutations, deletions or cytogenetic abnormalities have been reported and over 100 mutations have been described.

Synonyms and Related Disorders

Hirschsprung disease-mental retardation syndrome; Microcephaly, mental retardation, and distinct facial features with or without Hirschsprung disease

Genetics/Basic Defects

1. Caused by heterozygous mutations and deletions in the gene ZEB2 on chromosome 2 (also known as ZFHX1B or SIP-1) in approximately 81% of cases
2. Typically resulting from a de novo dominant mutation
3. Cytogenetic deletions or translocations of the chromosome 2q21-q23 region were found in several patients

Clinical Features

1. Typical facial features
   a. Seen in all individuals with this combination of characteristics were found to have mutations or deletions in the *ZEB2* gene (Zweier et al. 2005)
      i. Ocular hypertelorism
      ii. Medially flared and broad eyebrows
      iii. Prominent columella
      iv. Prominent or pointed chin
      v. Open-mouthed expression
      vi. Uplifted earlobes with a central depression
         a) Earlobes described as resembling "orechietta pasta" or "red blood corpuscles."
         b) Ear configuration not changing significantly with age with the exception of the central depression, which is less obvious in adults.
   b. Additional suggestive facial features (Mowat et al. 2003; Adam et al. 2006)
      i. Telecanthus
      ii. Deep-set eyes
      iii. Broad nasal bridge with prominent and rounded nasal tip
      iv. Full or everted lower lip
      v. Posteriorly rotated ears
   c. Natural history of facial phenotype (Wilson et al. 2003; Horn et al. 2004)
      i. More pronounced facial phenotype with age, making diagnosis easier in older individuals
      ii. Lengthening of the nasal tip and becoming more depressed

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_160,
© Springer Science+Business Media, LLC 2012

iii. More pronounced columella, leading to appearance of a short philtrum
iv. Elongation of the face
v. More prominent jaw
vi. Eyebrows becoming heavier with an increased medial flare

2. Spectrum of structural anomalies
   a. Gastrointestinal anomalies
      i. Hirschsprung disease
         a) A strong cross-reference marker when present
         b) Not a constant finding
         c) Present in approximately 57–63% of cases
      ii. Pyloric stenosis
   b. Genitourinary anomalies, particularly hypospadias in males
   c. Congenital heart defects, including abnormalities of the pulmonary arteries and/or valves
   d. Agenesis or hypogenesis of the corpus callosum
   e. Ophthalmologic anomalies, including microphthalmia and Axenfeld anomaly
   f. Teeth anomalies
      i. Widely spaced teeth
      ii. Dental crowding
      iii. "Malpositioned" teeth
      iv. Delayed tooth eruption
3. Other features
   a. Mental retardation, typically in the moderate to severe range, with severe speech impairment but relative preservation of receptive language
   b. Seizures
   c. Growth retardation (short stature) with microcephaly
   d. Chronic constipation in those without Hirschsprung disease

Diagnostic Investigations

1. Cytogenetic testing
   a. Chromosomal rearrangements that disrupt the *ZEB2* gene cause MWS in approximately 2% of cases
   b. FISH analysis. Large deletions encompassing all or part of the *ZEB2* gene detectable by FISH in approximately 15% of cases
2. Molecular genetic testing
   a. *ZEB2* mutation detection rate by sequencing/FISH/QPCR for individuals with the "typical MWS" facial phenotype approaches 100%
   b. No evidence of locus heterogeneity for MWS
3. Hirschsprung disease evaluation
4. MRI imaging of the brain for CNS anomalies
5. Echocardiograph for congenital heart disease
6. Ophthalmologic evaluation for eye anomalies
7. Renal ultrasound for renal anomalies
8. EEG for seizures

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. De novo mutation: low recurrence risk
      ii. Possibility of constitutional and/or germline mosaicism: low recurrence risk but greater than that of the general population (1–2%)
         a) Possibility of germline mosaicism suggested in two families with two and three affected sibs, respectively
         b) Low-level paternal mosaicism observed in a family with two affected sibs has been reported
   b. Patient's offspring: individuals with MWS and an unbalanced chromosome rearrangement unlikely to reproduce
2. Prenatal diagnosis
   a. Prenatal diagnosis of a pregnancy at theoretically increased risk because of constitutional and/or germline mosaicism in a clinically unaffected parent.
      i. Disease-causing allele of an affected family member being identified prior to prenatal diagnosis
      ii. Molecular genetic analysis on DNA extracted from fetal cells obtained by amniocentesis or chorionic villus sampling
   b. Prenatal diagnosis of a pregnancy at increased risk because of parental balanced structural rearrangement: possible by chromosome analysis of fetal cells obtained by amniocentesis or chorionic villus sampling.
   c. Preimplantation genetic diagnosis: available for families at increased risk because of parental

mosaicism in which the disease-causing mutations have been identified.

3. Management
   a. Mostly supportive including seizure control and developmental intervention
   b. Specific management for structural anomalies, including Hirschsprung disease

Fig. 1 (**a**–**d**) A three-and-a-half-year-old boy was noted to have Mowat–Wilson syndrome. Note the unusual facies (hypertelorism, telecanthus, strabismus, wide prominent nasal bridge, an unusual nose with a rounded tip and prominent columella, a prominent chin, and unusual ears with fleshy uplifted ear lobes), long tapering fingers, and an unusual stereotypic use of his hands in which he moves his fingers in front of his face and regards them. He is severely developmentally delayed and has hypotonia. Chromosome microarray analysis revealed a loss in copy number in the long arm of chromosome 2, detected with two clones, spanning at least 100 kb (including the ZFHX1B gene), and confirmed by FISH analysis. Deletions in this region have been associated with Mowat–Wilson syndrome

Mucopolysaccharidosis I (MPS I)

Mucopolysaccharidosis I consists of three clinical entities with varying degrees of clinical manifestations, all due to the same lysosomal enzyme deficiency, α-L-iduronidase. Hurler (MPS I-H) and Scheie (MPS I-S) syndromes represent phenotypes at the two ends of the clinical spectrum; the Hurler–Scheie syndrome (MPS I-H/S) represents a phenotype of intermediate clinical severity. In most instances, the subtype of MPS I can only be assigned on the basis of clinical criteria, including the rate of progression of symptoms. The incidences for MPS I-H, MPS I-H/S, and MPS I-S are estimated to be 1/76,000–1/144,000, 1/280,000, and 1/840,000–1/1,300,000 live births, respectively.

Synonyms and Related Disorders

α-L-Iduronidase deficiency; Hurler (MPS I-H); Hurler–Scheie (MPS I-H/S); Scheie (MPS I-S) Syndromes

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. The *IDUA* gene
   a. Localized to chromosome 4p16.3, close to the Huntington disease gene
   b. Spans 19 kb including 14 exons
3. Caused by mutations in the α-L-iduronidase (*IDUA*) gene
   a. Two major alleles (W402X and Q70X) and a minor allele (P533R) accounting for over half the MPS I alleles in the Caucasian population.
   b. No functional enzymes produced by above-mentioned alleles, giving rise to the severe form of α-L-iduronidase deficiency (MPS I-H).
   c. Limited mutations expected to cause the attenuated clinical phenotypes of MPS I-S or MPS I-H/S.
   d. One of a mutation resulting in Scheie syndrome is a base substitution in intron 7 that creates a new splice site and produces a frameshift. Since the old splice site is not obliterated, some normal enzymes still can be made to overcome the worst features of MPS I.
   e. Most other alleles that lead to MPS I-S or MPS I-H/S carry missense mutations.
   f. In the Japanese population studied, MPS I-H/S results from compound heterozygosity of two mutations (704ins5 and R89Q), which, in homozygous form, would give rise to MPS I-H and MPS I-S, respectively.
4. Genotype-phenotype correlations
   a. General principle
      i. Any combination of two severe alleles leads to severe MPS I. A severe allele is one that produces the severe phenotype in either the homozygous state or compound heterozygous state.
      ii. Intermediate and mild MPS I: usually associated with one severe allele and another allele that permits production of some residual enzyme activity.
   b. Alleles associated with severe phenotype
      i. Two common severe mutations (W402X and Q70X) always confer a severe phenotype whether present in a homozygous state or in a compound heterozygous state.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_161,
© Springer Science+Business Media, LLC 2012

ii. Additional mutations (474-2a-g, A327P, P533R, A75T, L218P).
c. Alleles associated with mild phenotype
i. 678-7a-g
ii. R89Q
5. Pathophysiology
a. Underlying molecular defect leads to a loss or marked reduction in α-L-iduronidase (*IDUA*), a lysosomal enzyme involved in the degradation of glycosaminoglycans heparan sulfate and dermatan sulfate.
b. Because of the enzyme deficiency, excessive accumulation of acid mucopolysaccharides (glycosaminoglycans) in the tissue occurs, leading to wide effect on various systems and remarkable changes in the morphogenesis.

Clinical Features

1. Hurler syndrome (MPS I-H)
a. General clinical characteristics
i. The prototype of MPS representing the severe end of clinical spectrum
ii. A progressive disorder with multiple organ and tissue involvement, leading to death in childhood
iii. Normal phenotype at birth and in early infancy but deteriorates progressively afterward
iv. Diagnosis usually made between 4 and 18 months of age
v. Short stature (linear growth stops at 2–3 years of age)
vi. Developmental delay by age 12–24 months, with a maximum functional age at the level of 2–4 years, followed by progressive mental deterioration
b. Coarse facial features (one of the earliest signs)
i. Ocular hypertelorism
ii. Prominent eyes
iii. Bushy eyebrows
iv. Depressed nasal bridge
v. Wide nostrils
vi. Large and thickened lips
vii. Large tongue
viii. Hypertrophy of the gum and the bony alveolar ridge
c. Other craniofacial features
i. A large scaphocephalic head with frontal bossing.
ii. Communicating hydrocephalus common after age 2–3 years. Shunting procedures may be beneficial for relieving increased intracranial pressure for some children.
iii. Noisy breathing with persistent nasal discharge (chronic rhinorrhea).
iv. Upper respiratory and ear infections.
d. Ophthalmologic features
i. Progressive clouding of the cornea (the hallmark of the syndrome) beginning at the first year of life, leading to impaired vision
ii. Open-angle glaucoma
iii. Retinal degeneration resulting in decreased peripheral vision
iv. Night blindness
e. Auditory features
i. Frequent sensorineural or mixed deafness
ii. Contributing factors:
a) Frequent middle ear infection from Eustachian tube dysfunction, caused by storage of glycosaminoglycans within the oropharynx
b) Dysostosis of the ossicles of the middle ear
c) Scarring of the tympanic membrane
d) Damage to the eighth nerve
f. Cardiovascular features
i. Cardiac valvular disease resulting from storage of mucopolysaccharide in the mitral, aortic, tricuspid, or pulmonary valves, leading to congestive heart failure.
ii. Thickened coronary artery valves, leading to angina pectoris and myocardial infarction.
iii. Possible fatal cardiomyopathy as a presenting feature for some MPS I infants less than 1 year old. Endocardial fibroelastosis has been noted postmortem in these patients.
iv. Aortic stenosis and uncontrolled hypertension (Taylor et al. 1991; Eakins and Kan 2010): Although uncommon, aortic stenosis should be included in the differential diagnoses in children with Hurler syndrome and poorly controlled hypertension.
g. Gastrointestinal features
i. Protuberant abdomen
ii. Progressive hepatosplenomegaly
h. Skeletal abnormalities: dysostosis multiplex
i. Short neck

ii. Characteristic kyphoscoliosis when on attempt to sit
iii. Ultimate frank gibbus deformity
iv. Stiff joints with limited mobility
v. Claw hands (flexed stubby fingers and broad hands)

i. Connective tissue abnormalities
i. Inguinal and umbilical hernias: common findings and usually present at birth
ii. Thick skin

j. Prognosis
i. Bedridden before the end of the juvenile period
ii. Early demise prior to 10 years of age
iii. Usual causes of death
a) Obstructive airway disease
b) Respiratory infection
c) Cardiac complications

2. Scheie syndrome (MPS I-S)
a. The mildest form of MPS I
b. Normal stature
c. Normal intelligence
d. Onset of significant signs usually after 5 years
e. Diagnosis commonly made between 10 and 20 years of age
f. Coarse facial features
g. Deafness in some patients
h. Joint stiffness
i. Claw hands
ii. Stiff painful foot
i. Carpal tunnel syndrome
j. Pes cavus
k. Genu valgum
l. Ocular manifestations
i. Corneal clouding
ii. Glaucoma
iii. Retinal degeneration
m. Aortic valvular disease (stenosis and regurgitation due to mucopolysaccharide deposits in the valves and chordae tendineae)
n. Obstructive airway disease with sleep apnea in some patients
o. Mild hepatosplenomegaly
p. Mild dysostosis multiplex
q. Less common pachymeningitis cervicalis (compression of the cervical cord by thickened dura) than MPS I-H/S
r. Potential normal life span

3. Hurler–Scheie compound (MPS I-H/S)
a. Clinical phenotype intermediate between Hurler and Scheie syndromes
b. Progressive somatic involvement, including dysostosis multiplex, with little or no intellectual dysfunction
c. Age of onset: usually between 3 and 8 years
d. Survival to adulthood: common
e. Deafness
f. Craniofacial features
i. Coarse facial features: less obvious
ii. Micrognathia in some patients
iii. Broad mouth
iv. Square jaw
v. Short neck
g. Ophthalmologic features
i. Corneal clouding in all patients
ii. Glaucoma
iii. Retinal degeneration
iv. Optic atrophy
h. Valvular heart disease (mitral valve insufficiency) developing by the early to mid-teens
i. Skeletal features
i. Short stature
ii. Small thorax
iii. Severe joint involvement (stiffness)
iv. Kyphoscoliosis
v. Back pain
vi. Characteristic claw hand deformity
vii. Carpal tunnel syndrome
j. Gastrointestinal features
i. Varying degrees of hepatomegaly
ii. Hernias
k. Pachymeningitis cervicalis (compression of the cervical cord due to mucopolysaccharide accumulation in the dura)
l. Communicating hydrocephalus uncommon in patients who have normal intelligence
m. Spondylolisthesis of the lower spine, leading to spinal cord compression
n. Causes of death (around teens and 20s)
i. Upper airway obstruction
ii. Cardiac involvement

Diagnostic Investigations

1. Developmental assessment
2. Ophthalmologic examination

3. ECG and echocardiography for cardiac status
4. Cranial ultrasound for hydrocephalus
5. Skeletal survey
   a. Dysostosis multiplex
   b. Skull
      i. Large, thickened calvarium
      ii. Premature closure of lambdoidal and sagittal sutures
      iii. Shallow orbits
      iv. Enlarged J-shaped sella
      v. Abnormally spaced teeth with dentigerous cysts
   c. Ribs
      i. Oar-shaped, narrowed at the vertebral ends
      ii. Flat/broad at the sternal ends
   d. Vertebra
      i. Beaked anteriorly (anterior hypoplasia) of lumbar vertebrae with kyphosis (an early sign)
      ii. Scalloped posteriorly
      iii. Thoracolumbar gibbus, resulting from anterior wedging of the vertebrae
      iv. Hypoplasia of the odontoid, leading to atlantoaxial subluxation
   e. Pelvis
      i. Poorly formed pelvis
      ii. Small femoral heads
      iii. Coxa valga
   f. Long bones
      i. Widened diaphysis of the long bones
      ii. Lack of normal modeling and tabulation
      iii. Irregular metaphysis
      iv. Poorly developed epiphyseal centers
      v. Distal ends of the radius and ulna angulate toward each other
      vi. Claw hands
      vii. Thickened and bullet-shaped phalanges
      viii. Coarsening of the trabeculae of the phalanges and metacarpals
      ix. Proximal narrowing of the metacarpals
      x. Marked irregularity and retarded ossification of the carpal bones
   g. Other bones
      i. Short, thickened, and irregular clavicles
      ii. Shortened and trapezoid-shaped phalanges with widened diaphyses
6. Biochemical/molecular studies for MPS I-H, MPS I-HS, and MPS I-S
   a. Excessive urinary excretion of glycosaminoglycans (dermatan and heparan sulfates): a useful preliminary test
   b. Metachromatic staining of fibroblasts and leukocyte inclusions (nonspecific lab findings)
   c. Enzyme assay: deficient α-L-iduronidase in WBC, serum, cultured fibroblast, and CSF
   d. Accumulation of glycosaminoglycans in cultured fibroblasts correctable by uptake of α-L-iduronidase
   e. Mutation analysis or sequence analysis of *IUDA* gene: possible to identify both *IDUA* mutations in 95% of patients with MPS I
   f. Characterization of gene mutation: worthwhile for phenotype prediction and genetic counseling
7. Carrier testing
   a. Measurement of α-L-iduronidase enzyme activity: not a reliable method, requiring testing of obligatory carriers within the family first to determine if their levels of IDUA enzyme activity can be distinguishable from the normal
   b. Molecular genetic testing of *IUDA* to identify carriers among at-risk family members when both mutation alleles have been identified in an affected family member

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25% chance of being affected
   b. Patient's offspring:
      i. MPS I-S: not increased unless the spouse is a carrier
      ii. MPS I-H and MPS I-H/S: not surviving to reproductive age
2. Prenatal diagnosis from samples of CVS, amniocentesis, and fetal blood
   a. Enzyme assays (deficient α-L-iduronidase) and increased level of ^{35}S-sulfate incorporation measured in cultured cells obtained from amniocentesis or CVS for pregnancy at risk
   b. Mutation analysis of the *IDUA* gene in fetal DNA extracted from cells obtained by CVS or amniocentesis if both mutant *IDUA* alleles have been identified in a previously affected sib or in the parents of the at-risk fetus
3. Preimplantation genetic diagnosis (PGD) for at-risk pregnancies: requires prior identification of both *IDUA* disease-causing mutations in the family

4. Management (Clarke and Heppner 2011)
   a. Supportive care
      i. Early infant stimulation programs
      ii. Eye care: corneal transplantation successful but donor grafts eventually becoming cloudy
      iii. Range of motion exercises to preserve joint function
      iv. Physical therapy
   b. Orthopedic surgery (Peters et al. 1998)
      i. Surgical decompression of the median nerve for carpal tunnel syndrome resulting in various restoration of motor hand activity
      ii. Trigger digits
      iii. Genu valgum
      iv. Kyphoscoliosis
      v. Acetabular dysplasia
      vi. Atlantooccipital stabilization
   c. Ventriculoperitoneal shunting for hydrocephalus
      i. Generally palliative
      ii. May improve quality of life
   d. Tracheotomy or high-pressure continuous positive airway pressure with supplemental oxygen
   e. Tonsillectomy and adenoidectomy to correct Eustachian tube dysfunction and to decrease upper airway obstruction
   f. Cardiovascular care
      i. Bacterial endocarditis prophylaxis
      ii. Valve replacement surgery
   g. Surgical repair of inguinal hernias
   h. Early surgical intervention to prevent severe complications from progressive compression of the spinal cord
   i. Major anesthetic risks exhibited by patients with MPS I
      i. Avoid hyperextension of the neck since dysostosis multiplex can lead to instability of the spine including the atlantoaxial joint
      ii. Difficulty in induction of anesthesia due to inability to maintain an adequate airway
      iii. Require fiberoptic laryngoscopy for intubation
      iv. Slow recovery from anesthesia
      v. Common postoperative airway obstruction
   j. Allogenic bone marrow transplantation from an unaffected, HLA-compatible donor
      i. Beneficial effect: replacement of deficient macrophages by marrow-derived donor macrophages to provide ongoing source of normal enzyme capable of gaining access to the various sites of storage.
      ii. Slows the course of cognitive decline if the therapy starts before the developmental delay is evident.
      iii. Improves survival, reducing facial coarseness, hepatosplenomegaly, hearing, and normal cardiac function.
      iv. Skeletal manifestations and corneal clouding continue to progress despite successful transplantation. Surgeries will be required for the persistent orthopedic problems.
      v. Significantly limited by the availability of donors. The immunosuppressive therapy for the prevention of rejection carries significant toxicity.
      vi. The procedure of the transplantation carries a high risk of morbidity and mortality. Failure to achieve stable engraftment and development of graft-versus-host disease are significant barriers to successful bone marrow transplantation for many children.
      vii. Hematopoietic stem cell transplantation: the treatment of choice for a child with Hurler syndrome who is younger than 2 years of age and has minimal or no central nervous system disease (Muenzer 2004).
   k. Cord blood transplantation (Staba et al. 2004)
      i. Use cord blood transplants from partially HLA-matched, unrelated donors
      ii. Donors readily available
      iii. An excellent source of stem cells for transplantation
      iv. Sustained engraftment can be achieved without total-body irradiation in young children.
      v. Low incidence for acute graft-versus-host disease (GVHD)
      vi. Absence of extensive chronic GVHD
      vii. As effective as bone marrow transplantation
   l. Enzyme replacement therapy (ERT)
      i. An etiology-specific treatment that seeks to address the underlying pathophysiology of MPS I by delivering sufficient IDUA activity to reverse and prevent glycosaminoglycans accumulation (Wraith et al. 2004)
      ii. Effectiveness depending on the ability of recombinant enzymes injected intravenously to enter cells and localize to the lysosome, the appropriate intracellular site

iii. Use of recombinant human α-L-iduronidase (laronidase: Aldurazyme)
   a) Aldurazyme®: currently licensed in the USA, Europe, and Canada for use in treating non-CNS manifestations of MPS I. The current dose regime involves premedication with an anti-inflammatory and antihistamine drugs and intravenous weekly infusion of 100 U/kg of Aldurazyme® over 4 h (Clarke and Heppner 2011).
   b) Significant reduction in liver size.
   c) Increase in height and weight.
   d) Decrease in joint restriction.
   e) Improvement in breathing (respiratory function) and sleep apnea.
   f) Decreased glycosaminoglycan storage.
   g) Improvements in cardiopulmonary function, airway obstruction and joint mobility in Hurler–Scheie syndrome (nonneuronopathic MPS I) (Bijarnia et al. 2009).
   h) Recommended for patients with milder or attenuated forms of MPS I. Infusions of recombinant enzyme are a safer alternative for treating the somatic disease and improving the quality of life of such patients. Intravenously administered enzyme is not expected to cross the blood–brain barrier and affect central nervous system disease (Muenzer 2004).

m. Hematopoietic stem cell transplantation (HSCT) (Bijarnia et al. 2009): Treatment of choice for children <2 years of age with MPS IH who have minimal or no central nervous disease

n. Combination of ERT followed by HSCT in neuronopathic Hurler syndrome
   i. Corrects the enzyme deficiency until endogenous enzyme production is established
   ii. Reverses airway obstruction and cardiovascular complications thus reducing mortality and morbidity at the time of transplant

Fig. 1 (**a**, **b**) A child with Hurler syndrome showing a large head with frontal bossing, coarse facial features, ocular hypertelorism, cloudy (steamy) cornea, depressed nasal bridge, large tongue, short neck, protuberant abdomen, umbilical hernia, stiff joints, and claw hands

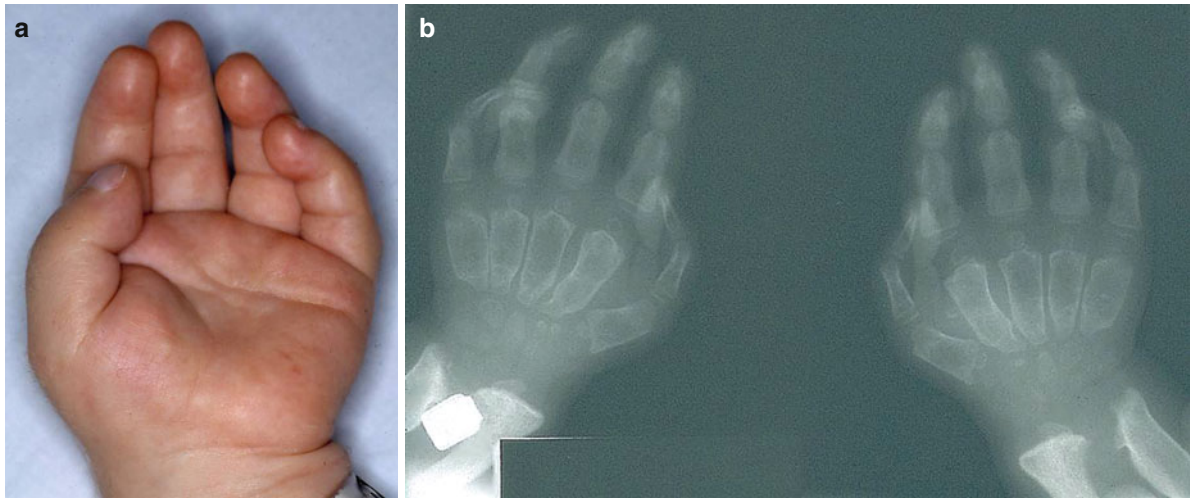

Fig. 2 (**a**, **b**) Claw hand. The radiographs show thick bullet-shaped phalanges, proximal narrowing of the metacarpals, poorly ossified carpal bones, and angulating toward each other of the distal ends of the radius and the ulnar

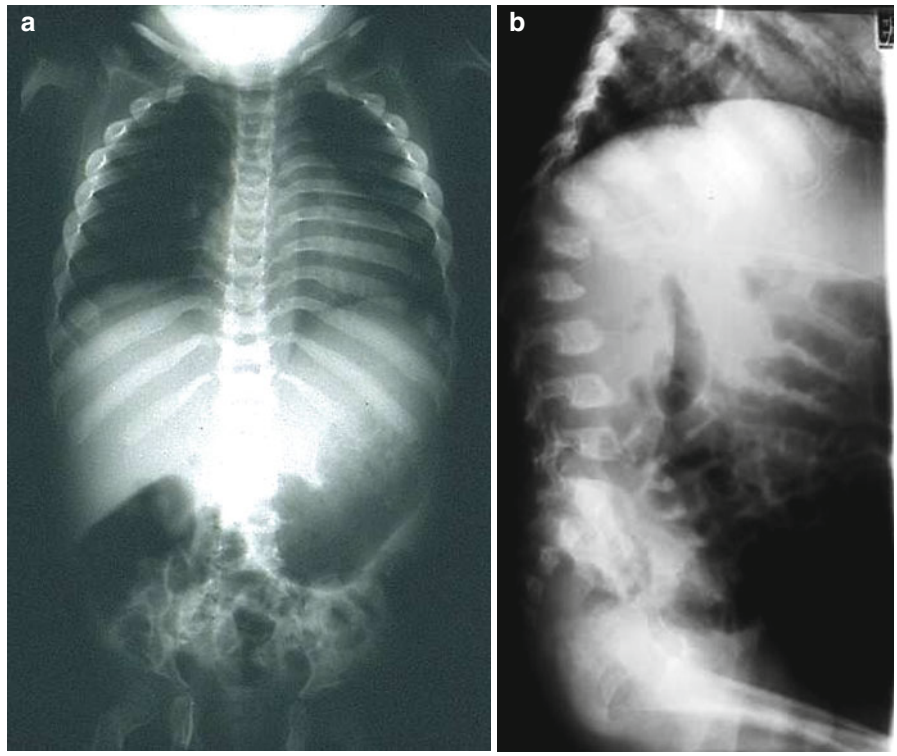

Fig. 3 (**a**, **b**) Radiographs showing oar-shaped ribs with relatively narrow proximal portion, narrow iliac bodies and flaring wings, shallow acetabula, coxa valga, anterior wedging of the lumbar vertebrae, decreased AP diameter of the vertebral bodies with posterior scalloping, and marked thoracolumbar gibbus

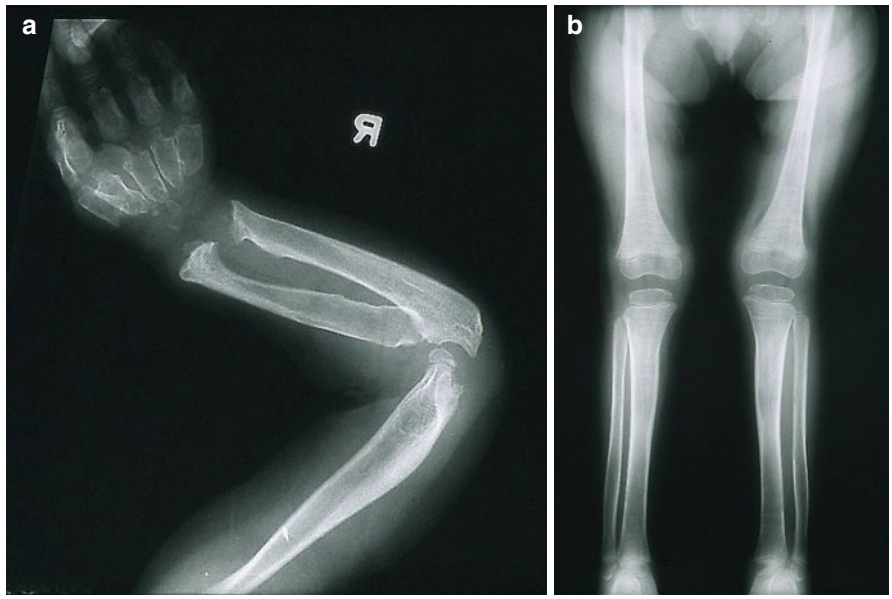

Fig. 4 (**a**, **b**) Radiograph of the upper extremities show the lack of normal modeling and tabulation of the diaphyses, leading to short tubular bones. The radial and ulnar articular surfaces are angulated toward each other. Marked irregularity and retarded ossification of the carpal bones are noted. The findings in the lower extremities are less marked

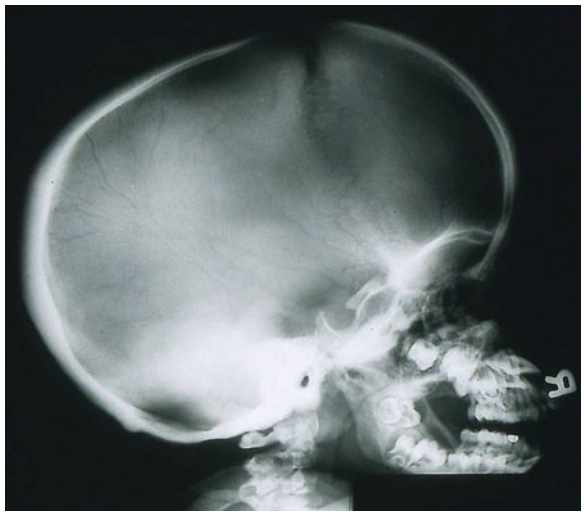

Fig. 5 Skull radiograph showing a large scaphocephalic calvarium with early appearance of the J-shaped sella turcica

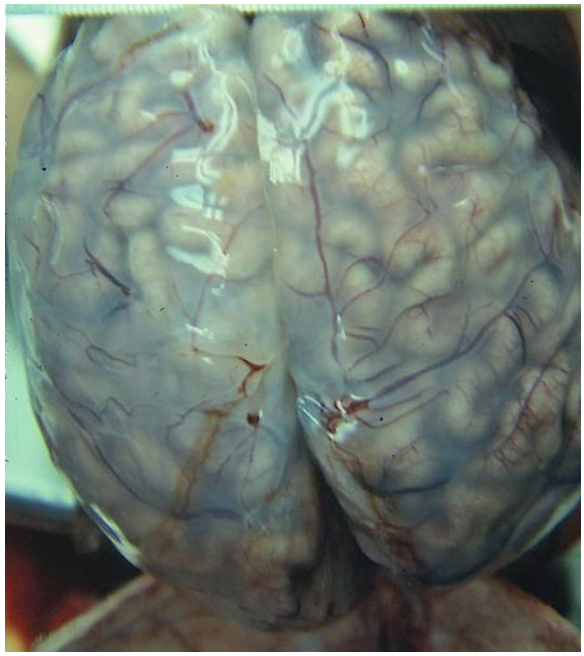

Fig. 6 Postmortem findings of the brain showing cloudy leptomeninges secondary to cloudy CSF

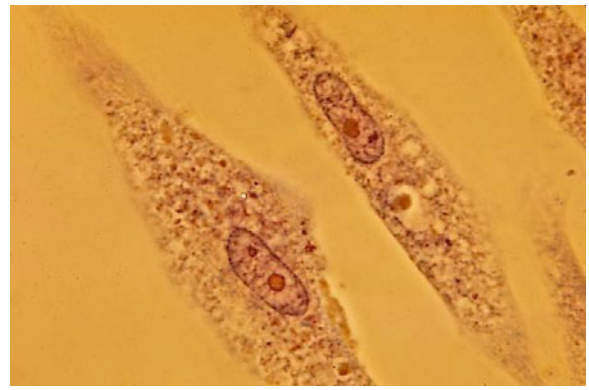

Fig. 7 Metachromasia of the cultured fibroblasts

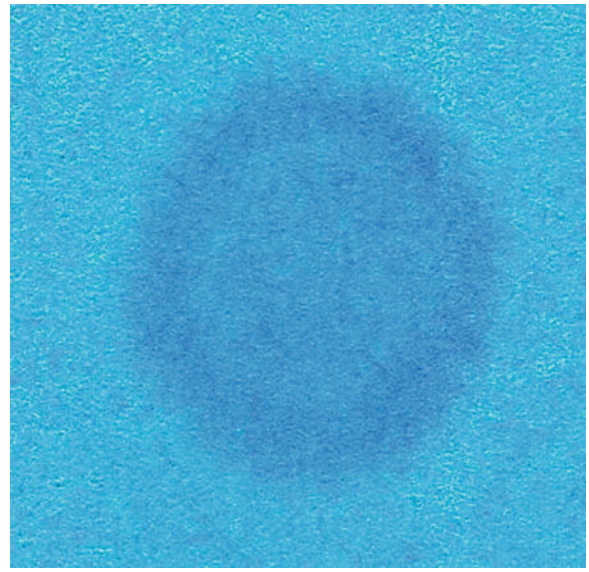

Fig. 8 Positive MPS spot test

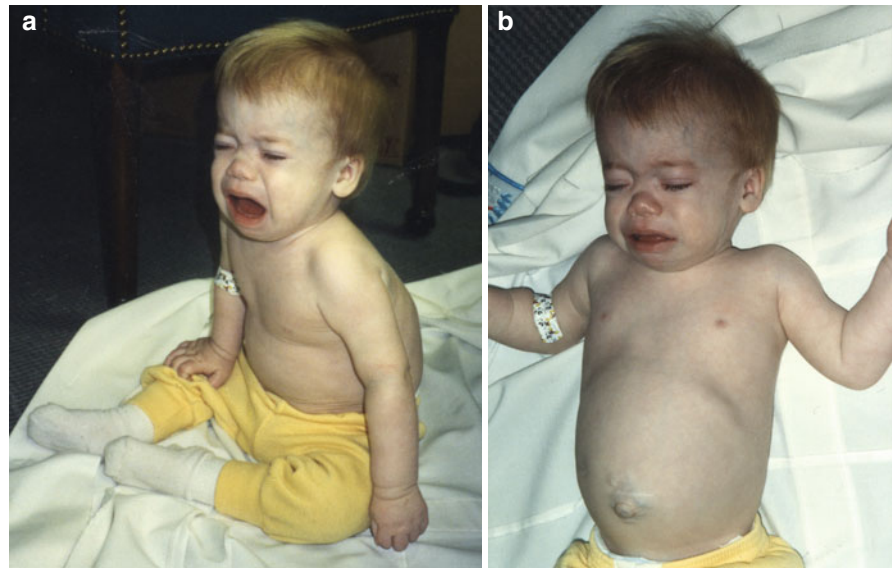

Fig. 9 (**a**, **b**) A 14-month-old boy with Hurler syndrome showing a large head, coarse facies, protuberant abdomen, umbilical hernia, a lumbar gibbus, and claw hands. The radiographs showed cardiomegaly, thickened ribs, and beaked vertebral body (L2). The α-L-iduronidase enzyme level was 0.0 (87.10–190.50 nmol/mg/h)

Fig. 10 A 14-year-old boy with Hurler–Scheie compound showing short stature, semi-crouching stance, joint stiffness (**a, b**), coarse facies (**c, d**), and claw hands (**e**). When he was 3½ year old, he started to complain difficulty in raising his arms above his head and difficulty in moving his hands and fingers because of bent fingers and joint contractures. He was noted to have dwarfism; coarse thickened skin; hirsutism; a big head with frontal bossing; coarse facies with hypertelorism; cloudy cornea; large lips and large tongue; short neck; short trunk with a mild kyphosis; hepatomegaly; claw hands; anteriorly converted shoulders; protuberant abdomen; flexion contractures of elbows, wrists, and knees; and crouching stance. The urine for mucopolysaccharide was positive, and the blood for metachromasia was positive. Skin fibroblasts was deficient in α-L-iduronidase

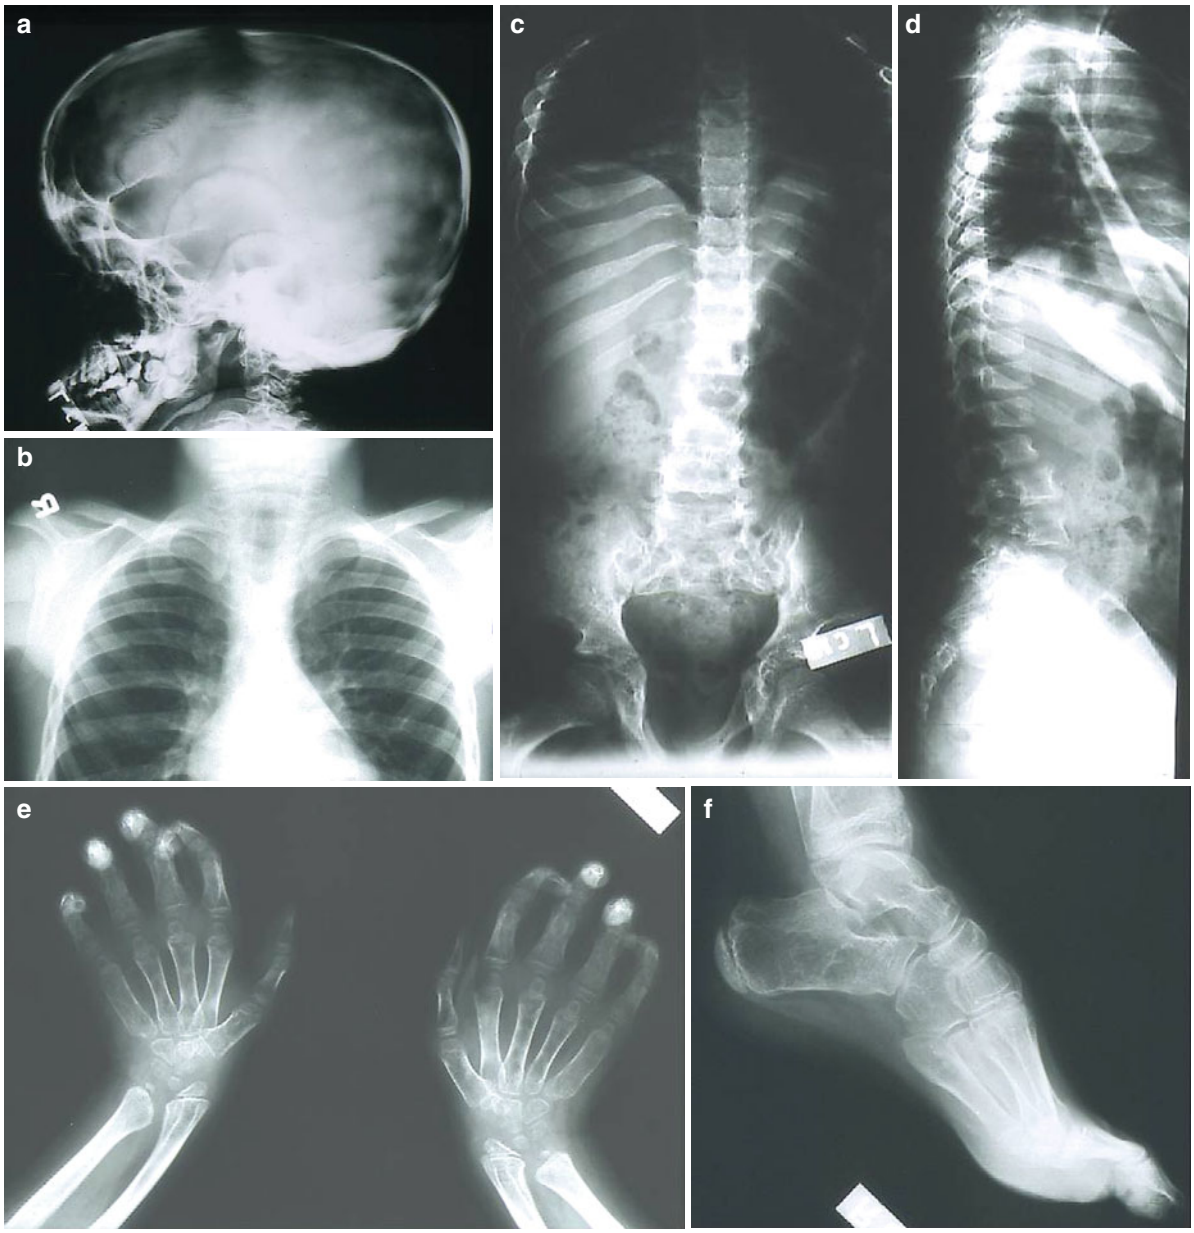

Fig. 11 Radiographs. Skull (**a**) shows macrocephaly, frontal bossing, small and airless mastoids, and anterior pocketing of the sella turcica ("shoe-shaped" or "J-shaped" sella). Clavicles (**b**) are short with widened medial aspects of both clavicles. Ribs are oar-shaped and wide in their lateral and anterior portions with moderate narrowing of the paravertebral portions of the lower ribs (**c, d**). Vertebral bodies have concaved anterior and posterior margins and decreased in sagittal diameters. The second lumbar vertebra was hypoplastic with anterior inferior beaking forming almost a hook-shaped deformity. Claw hands were present with tapering of both distal ends of radius and ulna to form "V-shaped" (**e**). Carpal bones were small, irregular, and crowded together. Metacarpals and phalanges were wide and short with proximal pointing of metacarpals. Bone age was retarded. Pes cavus was present (**f**)

Fig. 12 (**a**–**e**) A 7-year-old girl was diagnosed to have Hurler syndrome at the age of 2. She received a male, 4/6 HLA-matched unrelated umbilical cord blood transplant. She engrafted quickly with an absolute neutrophil count greater than 500 on day +28. Her transplant complications included a Klebsiella UTI prior to admission, mucositis, medicine-induced hypertension controlled with nifedipine, diarrhea treated with Flagyl empirically, and graft-versus-host disease. Presently, she has less coarse facial features, resolving cloudy cornea, improved cognitive capacity, but still has some claw hands and lumbar gibbus which is illustrated radiographically

Mucopolysaccharidosis II

In 1917, Hunter described the syndrome in two brothers. Hunter syndrome is an X-linked recessive form of the mucopolysaccharidosis. Severe and mild (attenuated) forms of the syndrome are caused by the same enzyme deficiency, iduronate-2-sulfatase with consequent increase of the urinary concentration of the glycosaminoglycan (CAG) dermatan sulfate and heparin sulfate. The estimated incidence is approximately 1 in 100,000 births.

Synonyms and Related Disorders

Hunter syndrome; Iduronate 2-sulfatase deficiency

Genetics/Basic Defects

1. Inheritance (Beighton 1993)
   a. X-linked recessive inheritance from pedigree data
   b. The gene for iduronate sulfatase mapped to Xq28
2. Primary biochemical defect and pathophysiology
   a. Deficient iduronate-2-sulfatase (*IDS*), the enzyme required for cleavage of sulfate from iduronic acid moieties of dermatan and heparan sulfates
   b. Excessive intracellular accumulation of acid mucopolysaccharides (dermatan sulfate and heparan sulfate) due to deficient iduronate sulfatase activity, leading to multiple organ system involvement, including the musculoskeletal, integumentary, cardiovascular, pulmonary, and ocular systems
3. Molecular defect
   a. Mutations of *IDS* gene.
      i. Missense and nonsense mutations
      ii. Mutations affecting splicing
      iii. Small insertions and deletions
      iv. Partial gene deletions
      v. Deletions or rearrangements of the whole *IDS* gene
   b. Major structural alterations and gross deletions of the *IDS* gene result in the most severe forms of Hunter syndrome.
   c. Single-base substitutions causing diminished but not obliterated enzyme activity is observed in mild disease.
4. Hunter syndrome in females: an exceedingly rare event possibly due to the following mechanisms:
   a. As the offspring of a carrier female and affected male or an unaffected male whose sperm carries a new mutation
   b. Uniparental disomy of the mutant X chromosome from a heterozygous female or an affected male
   c. Genetic rearrangement: e.g., translocation or deletion resulting in nonrandom lyonization toward expression of a mutant allele

Clinical Features

1. Clinical presentation showing a spectrum of mild to severe forms as a result of different mutations in the functional gene (Beighton 1993)
2. Severe Hunter syndrome (MPS IIA)
   a. Onset: usually between 2 and 4 years of age with progressive neurologic and somatic involvement

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_162,
© Springer Science+Business Media, LLC 2012

b. More common than the mild form
c. Short stature not pronounced
d. Coarse facial features
    i. Frontal bossing
    ii. Depressed nasal bridge
    iii. Wide nostrils
    iv. Depressed nasal bridge
    v. Thick lips
    vi. Hypertrophic gums
    vii. A large tongue
e. Skeletal deformities
    i. Kyphosis
    ii. Digital contractures
    iii. Claw hands
    iv. Joint stiffness
    v. Absence of gibbus
f. CNS manifestations (Al Sawal et al. 2008)
    i. Mental retardation
    ii. Hydrocephalus
    iii. Seizures
    iv. Sleep apnea
    v. Cerebral infarction
    vi. Spinal cord compression/cervical myelopathy
    vii. Other CNS lesions
        a) Enlarged perivascular spaces
        b) Widening of subarachnoid spaces
        c) White-matter lesions
        d) Delayed myelination
g. Ocular manifestations
    i. Absence of corneal clouding
    ii. Thickened sclera
    iii. Optic atrophy
    iv. Papilledema
    v. Retinitis pigmentosa–like retinal fundus
    vi. Night blindness
    vii. Scotomas
h. Hearing loss
i. Respiratory difficulties
    i. Upper airway obstruction due to adenoid hypertrophy, nasal congestion, and thick rhinorrhea
    ii. Mouth breathing secondary to choanal stenosis
    iii. Sonorous breathing, frank obstructive sleep apnea, and even death secondary to adenoid hypertrophy, tongue enlargement, and supraglottic swelling
j. Cardiovascular disorders
    i. Cardiac valvular involvement leading to congestive heart failure, the leading cause of death in affected individuals
    ii. Mild thickening and shortening of the chordae tendineae contributing to the regurgitant valve dysfunction
k. Gastrointestinal problems
    i. Chronic diarrhea secondary to autonomic nervous system involvement and mucosal dysfunction
    ii. Hepatosplenomegaly
    iii. Umbilical and inguinal hernias
l. Thick skin often with nodular skin lesions over the scapular area or arms
m. Peripheral nervous system manifestations
    i. Carpal tunnel syndrome secondary to median nerve compression
    ii. Cubital tunnel syndrome
n. Additional features of most severely affected patients, caused by large deletions that include iduronate sulfate sulfatase and contiguous genes
    i. Hurler-like symptoms
    ii. Early onset of seizures
    iii. Ptosis
o. Prognosis: typically advancing to cachexia and death before 15 years

3. Mild Hunter syndrome (MPS IIB)
    a. Diagnosed slightly later than the severe form
    b. Much less frequent than the severe form
    c. Preservation of normal intelligence
    d. No central nervous system involvement
    e. Somatic involvement less progressive
    f. Hearing impairment
    g. Cardiovascular disorders
    h. Joint stiffness
    i. Cervical myopathy due to a narrowed spinal canal and cord compression
    j. Carpal tunnel syndrome more frequent and severe compared to the severe form
    k. Loss of hand function resulting from joint stiffness and carpal tunnel syndrome
    l. Prognosis
        i. Longer survival
        ii. Typically surviving to adulthood
        iii. Possible death in early adulthood or even in the late teens due to airway obstruction and cardiac failure

Diagnostic Investigations

1. Echocardiography
2. Electrocardiography
3. Radiographic features
   a. Kyphosis
   b. Claw hands
   c. Thick cortex of the bones progressively becoming thinner as the marrow cavities expand
   d. Large calvarium with shoe-shaped sella
   e. Broad and spatulate lower ribs
   f. Hypoplasia and beaking of the lumbar vertebrae
4. MRI of the brain (Al Sawaf et al. 2008)
   a. Most common findings: widely distributed white-matter lesions, predominantly found peri- and supraventricularly as well as in the basal ganglia and the corpus callosum. These changes were regarded as filling defects rather than immaturity of white matter and are suspected to progress with age.
   b. Even before the development of white-matter lesions, clearance of MPS deposits in white matter may result in demyelination. In addition, delay of myelination may also occur in Hunter disease.
   c. Common findings with questionable clinical relevance
      i. Enlargement of the perivascular spaces
      ii. Ventriculomegaly
      iii. Mega cisterna magna
      iv. Widening of the subarachnoid spaces
5. Biochemical/molecular studies
   a. Measurement of mucopolysaccharides in the urine: abnormal excretion of a large amount of dermatan sulfate and heparin sulfate in the urine
   b. Deficient iduronate sulfatase in leukocytes and fibroblasts
   c. Excessive intracellular accumulation of dermatan sulfate and heparin sulfate
   d. Peripheral lymphocytes, when stained with toluidine blue, exhibit metachromatic granules within vacuoles.
   e. The gold standard for diagnosis of MPS II in a male proband is assay of I2S enzyme activity in white cells or serum (Martin 2007).
   f. Molecular genetic testing of *IDS*, the only gene known to be associated with MPS II, is used to confirm the diagnosis in a male proband with an unusual phenotype or a phenotype that does not match the results of GAG testing (Martin 2007).
      i. Sequence analysis
      ii. Deletion testing for exonic and whole gene deletions
      iii. Southern blot analysis: used to detect complex rearrangements resulting from recombination with the pseudogene and accounting for 9% of all mutations (Froissart et al. 2007)
6. Heterozygote detection
   a. Carrier detection by enzyme analysis for MPS II is unreliable.
   b. Identification of *IDS* gene mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Carrier mother: 50% of brothers affected, 50% of brothers normal, 50% of sisters carriers, 50% of sisters normal
      ii. Noncarrier mother (mother of a sporadic case): recurrence possible due to presence of gonadal mosaicism
   b. Patient's offspring
      i. Severe form: not surviving to reproduction
      ii. Mild form: none of the sons affected, all daughters carriers
2. Prenatal diagnosis
   a. Maternal serum analysis
      i. Consistent increase of iduronate sulfatase in the serum of pregnant women from prepregnancy levels toward the end of pregnancy
      ii. No change in the serum enzyme levels of heterozygous mothers until the affected fetuses are aborted
   b. Amniocentesis
      i. Reduced enzyme activity in the amniotic fluid
      ii. Low enzyme levels in cultured amniotic cells
      iii. Abnormal $^{35}SO_4$ incorporation into cultured amniotic fluid cells
      iv. Karyotyping for fetal sex

v. Direct detection of *IDS* gene mutation, provided the disease-causing mutation in the family has been identified previously

c. CVS
   i. Diminished enzyme activity in uncultured chorionic villi of affected male fetuses. This may be seen in female carrier fetuses.
   ii. Karyotyping for fetal sexing
   iii. Direct detection of *IDS* gene mutation, provided the disease-causing mutation in the family has been identified previously

d. Umbilical fetal blood sampling: severe deficiency of iduronate sulfate sulfatase in the plasma of affected male fetuses

e. Preimplantation diagnosis for at-risk pregnancies requires prior identification of the disease-causing mutation in the family.

3. Management (Beighton 1993)
   a. Tympanostomy, adenoidectomy, and provision of hearing aids for management of otologic complications
   b. Symptomatic management of airway obstruction (sleep apnea)
   c. Ventriculoperitoneal shunting for hydrocephalus, a relatively rare complication of Hunter syndrome
   d. Difficulties during anesthesia secondary to the following factors:
      i. Rigid thoracic cage
      ii. Abdominal distention
      iii. Macroglossia
      iv. Temporomandibular ankylosis
      v. Atlantoaxial instability
      vi. Short and wide neck
   e. Prophylactic antibiotics for at-risk procedures in patient with mucopolysaccharidosis
   f. Surgical repair of inguinal and umbilical hernias
   g. Surgical release to preserve apposition of the thumbs at the earliest sign of an electrophysical evidence of progressive median nerve compression
   h. Musculoskeletal complications
      i. Shoe orthotics and ankle braces well tolerated and useful in maintaining mobility
      ii. Achilles tendon release in some patients with advanced disease
      iii. Surgical stabilization of the spine rarely indicated for kyphoscoliosis which is only mildly progressive and not usually resulting in spinal cord compression
   i. Bone marrow transplantation
      i. Possible reduction in hepatosplenomegaly, improvement in airway disease, and reduction in urinary glycosaminoglycan excretion
      ii. Long-term prognosis for longevity, cardiac complications, and neurologic outcome after marrow transplantation still remained to be determined.
   j. Hematopoietic stem cell transplantation (HSCT) has been performed in numerous individuals with varying degrees of severity of MPS II, but limited success and significant risk; therefore, HSCT is not currently recommended for individuals with MPS II (Martin et al. 2008).
   k. Enzyme replacement therapy (ERT) (Burrow and Leslie 2008; da Silva et al. 2010)
      i. Recently, recombinant iduronate-2-sulfatase (idursulfase, Elaprase®; Shire Human Genetic Therapies, Inc., Cambridge, MA), a recombinant human I2S produced in a human cell line, was approved in the United States and the European Union as a safe and effective treatment for individuals with MPS II.
      ii. The rationale for therapy is that exogenous I2S would replace the iduronate-2-sulfatase that is deficient in patients and either stop or reverse disease progression.
      iii. Recent clinical trials have shown promise in the treatment of MPS II, with potential to help many patients, providing that it is started early in the course of the disease (Wraith et al. 2008).
      iv. ERT involves the intravenous administration of a recombinant human enzyme into individuals in whom the enzyme is missing or defective.
      v. The recombinant enzyme undergoes receptor-mediated cell uptake and subsequent intracellular trafficking into the lysosomes, where it carries out its specific function.
      vi. Elaprase® does not cross the blood–brain barrier; thus, no effect on CNS disease is anticipated. Thus, CNS disease remains a major challenge, and an innovative approach to treatment will be needed if this is to be addressed fully (Wraith et al. 2008).

Fig. 1 (**a**, **b**) A boy with MPS II showing mild short stature, coarse facial features, large abdomen, and claw hands

Mucopolysaccharidosis III

In 1962 and 1963, Sanfilippo et al. described eight children with mental retardation and heparan sulfate mucopolysaccharidosis and delineated the syndrome which now bears his name. Earlier in 1961, Harris reported a 6-year-old girl with hepatosplenomegaly, a normal skeletal survey, and excretion of large amounts of heparan sulfate in the urine. Sanfilippo syndrome is one of the most common mucopolysaccharidoses (MPS) (1/24,000–1/200,000).

Sanfilippo syndrome is comprised of four biochemically heterogeneous types (MPS IIIA, IIIB, IIIC, and IIID), which are clinically indistinguishable. Because the deficiency of these four various lysosomal enzymes involved the same breakdown of heparan sulfate, their clinical phenotype is similar. Type A is the most common type of MPS III in Northwest Europe, while type B is thec most frequent type in Southeast Europe (Meikle et al. 1999; Poorthuis et al. 1999; Baehner et al. 2005). Types C and D appear to be much rarer (Valstar et al. 2008).

Synonyms and Related Disorders

Sanfilippo Syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Failure to degrade heparan sulfate may result from deficiency of one of the following four lysosomal enzymes:
   a. MPS IIIA caused by deficient heparan N-sulfatase (sulfamidase)
   b. MPS IIIB caused by deficient α-N-acetylglucosaminidase
   c. MPS IIIC caused by deficient acetyl-CoA:α-glucosaminide-N-acetyltransferase
   d. MPS IIID caused by deficient N-acetyl-α-glucosamine-6-sulfatase
3. Four subtypes of MPS III
   a. Clinically indistinguishable
   b. Each characterized by deficiency of a different enzyme
   c. MPS IIIA mapped to 17q25.3
   d. MPS IIIB mapped to 17q21
   e. MPS IIIC mapped to 8p11.1
   f. MPS IIID mapped to 12q14

Clinical Features

1. Severe CNS involvement
   a. Developmental milestones near normal prior to age 3–4 years
   b. Developmental delay, especially in speech (first stage usually starts between 1 and 4 years of age)
   c. Behavioral problems (second stage usually starts around 3–4 years)
      i. Aggressiveness
      ii. Hyperactivity
      iii. Attention deficit
      iv. Temper tantrums
      v. Destructive behavior
      vi. Physical aggression
      vii. Sleep disturbance
         a) Setting difficulties
         b) Night walking

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_163,
© Springer Science+Business Media, LLC 2012

c) Sometimes awake all night
d) Crying out
e) Wandering around house
f) Entering parents' bed
g) Talking in sleep
h) Body rocking
i) Chewing bedclothes

viii. Poor attention span
ix. Marked mood swings
x. Self-injury

d. Progressive motor difficulties due to spasticity and joint stiffness and slowly disappearing behavioral problems, starting about 10 years of age (marking the third and final stage)
e. Severe hearing loss common in the moderate to severely affected patient
f. Severe neurologic degeneration occurring in most patients by 6–10 years of age, accompanied by rapid deterioration of social and adaptive skills (mental deterioration)
g. Progressive dementia resulting in withdrawal and losing contact with the environment
h. Seizures: uncommon
i. Patients usually die at the end of the second or beginning of the third decade of life, although survival into the fourth decade has been reported.

2. Mild somatic disease
   a. Coarse hair (hirsutism): hypertrichosis often present, especially on the back
   b. Macrocephaly
   c. Copious nasal discharge
   d. Repeated upper respiratory tract infections
   e. Cardiac signs and symptoms much lesser degree compared to other types of mucopolysaccharidosis
   f. Mild hepatosplenomegaly
   g. Joint stiffness
   h. Recurrent and sometimes severe diarrhea, usually improves in later childhood
   i. Early onset of puberty
3. Prognosis
   a. Type A
      i. The most severe type
      ii. Earlier onset
      iii. More rapid progression of symptoms
      iv. Shorter survival: death usually by late teens
   b. Type B: known to remain functional into the third or even fourth decades
   c. Type C: clinically heterogeneous
   d. Type D
      i. Least common type
      ii. Clinically heterogeneous

Diagnostic Investigations

1. Increased urinary excretion of heparan sulfate
2. Imaging features
   a. Radiography: mild degree of dysostosis multiplex
   b. Echocardiography for rare cardiac abnormalities
   c. CT
      i. Mild to moderate cortical atrophy at onset
      ii. Severe cortical atrophy at late stage
   d. MRI (Barone et al. 1999)
      i. Cortical atrophy
      ii. Corpus callosum atrophy
      iii. Abnormal or delayed myelination
      iv. MRI findings may precede the onset of overt neurological symptoms.
3. Biochemical analysis (Defendi and Varma 2009)
   a. Biochemical differentiation of the different forms within MPS II is possible, and diagnosis is confirmed by specific enzymatic assay.
      i. Deficient heparan N-sulfatase (type A)
      ii. Deficient N-acetylglucosaminidase (type B)
      iii. Deficient α-glucosamine-N-acetyltransferase (type C)
      iv. Deficient N-acetyl-α-glucosamine-6-sulfatase (type D)
   b. Enzymatic activity for all types of MPS III may be assayed in cultured skin fibroblasts and in peripheral blood leukocytes.
4. Mutation studies are available clinically by sequence analysis and deletion/duplication analysis.
   a. MPS IIIA
      i. Missense mutations (most common)
      ii. Premature termination mutations
      iii. Small deletion mutations
   b. MPS IIIB
      i. Great molecular heterogeneity
      ii. Most mutations: private mutations
   c. MPS IIIC: no mutation analysis available currently
   d. MPS IIID: frameshift and premature termination mutation

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not reproducing due to mental retardation
2. Prenatal diagnosis (Di Natale et al. 1999)
   a. Fetuses at risk for MPS IIIA
      i. Measuring sulfamidase activity using radioactive assay in CVS and amniocytes
      ii. Using fluorimetric sulfamidase assay in CVS and amniocytes
      iii. Molecular diagnosis in characterized families
   b. Fetuses at risk for MPS IIIB
      i. Assay of α-N-acetylglucosaminidase activity in cultured amniocytes and CVS
      ii. Increased level of heparan sulfate in amniotic fluid by two-dimensional electrophoresis of glycosaminoglycans: used as an adjunctive method in prenatal diagnosis
      iii. Molecular diagnosis in characterized families
   c. Fetuses at risk for MPS IIIC
      i. Assay of Acetyl-CoA:α-glucosamine-N-acetyltransferase in amniocytes and CVS
      ii. Molecular diagnosis in characterized families
   d. Fetuses at risk for MPS IIID
      i. Spectrophotometric assay for the N-acetyl-α-glucosamine-6-sulfatase activity
      ii. Molecular diagnosis in characterized families
3. Management (Cleary and Wraith 1993)
   a. Supportive treatments
      i. Antibiotics for otitis media and respiratory tract infections
      ii. Anticonvulsants for seizure activities
   b. Muscle relaxants for painful spasms
   c. Gastrostomy to maintain adequate nutrition
   d. Special education program
   e. Behavioral management to allow the family to function as near normal as possible
      i. Alteration to the physical environment within home
      ii. Drug treatment to control hyperactivity and aggression
   f. Physical therapy to maintain joint mobility
   g. Wheelchair for transportation
   h. Respite care: availability of suitable respite accommodation
   i. Identify professional and community resources.
   j. Risperidone treatment of behavioral disorder in children with MPS IIIA: appeared to be safe and effective (Ucar et al. 2010)
   k. Bone marrow transplantation
      i. Biochemical correction readily achievable
      ii. Disappointing intellectual outcome

Fig. 1 (**a**–**c**) A child with MPS IIIA at 8 months and 3 years

Fig. 2 A 32-year-old male with Sanfilippo syndrome type A showing mental retardation and severe behavioral problems. Molecular genetic analysis revealed heparan sulfamidase (SGSH) gene mutations. A C > T substitution was detected at nucleotide 892 resulting in a serine being replaced by a proline at amino acid 298 (S298P). The second nucleotide change resulted in insertion of a cystine at nucleotide 1,028 which creates a frameshift and premature truncation of protein (1028insC). The detection of two mutations in the heparan sulfamidase gene is associated with Sanfilippo A syndrome

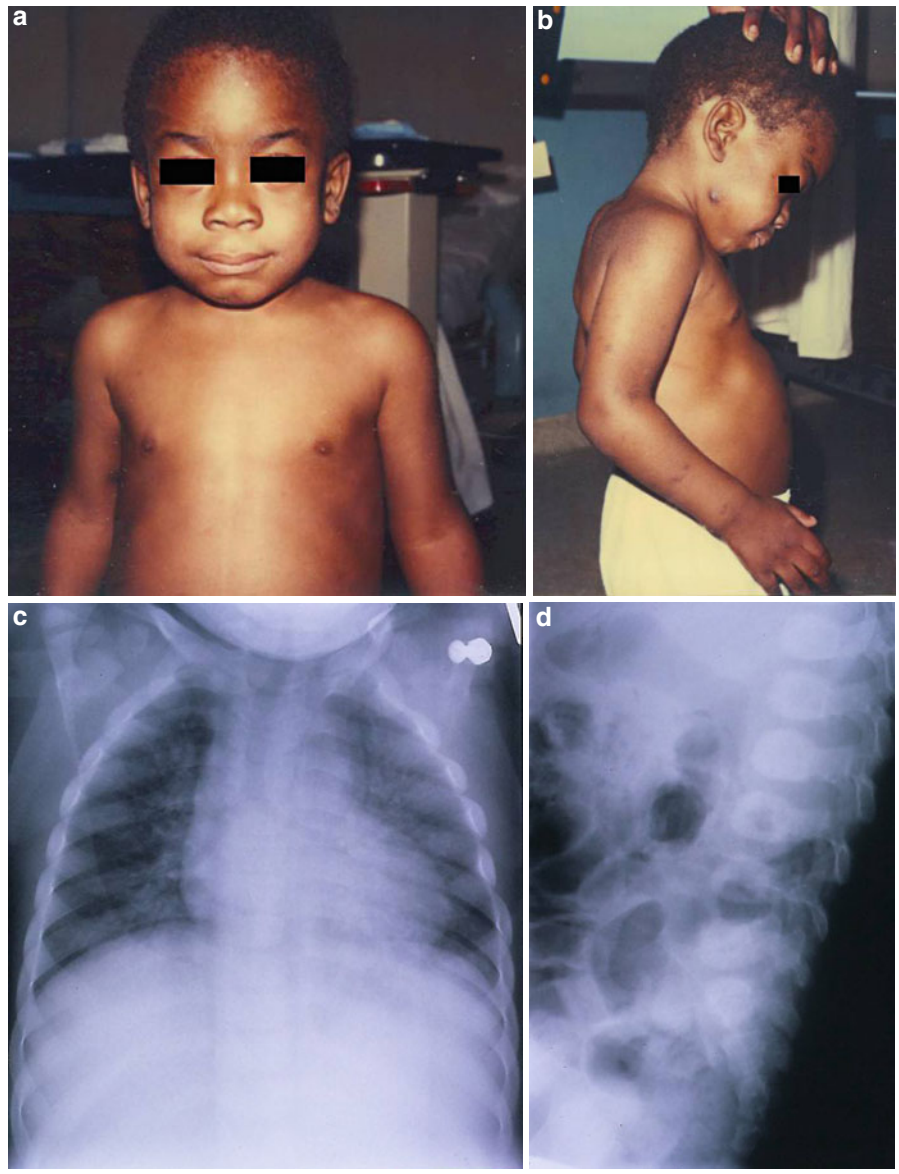

Fig. 3 (**a**–**d**) A child with MPS IIIB at 3 years of age. The radiographs show mild degree of dysostosis multiplex

Mucopolysaccharidosis IV

In 1929, Morquio and Brailsford independently described cases of what is now believed to be Morquio syndrome. The exact incidence is unknown but is estimated to be 1 in 75,000–1 in 200,000.

Synonyms and Related Disorders

Galactosamine-6-sulfatase deficiency; Morquio disease; Morquio syndrome

Genetics/Basic Defects

1. Genetic inheritance: autosomal recessive
2. Two forms of MPS IV
   a. MPS IVA
      i. Deficient *N*-acetyl-galactosamine-6-sulfate sulfatase (*GALNS*) gene, which is mapped to 16q24.3
      ii. Wide spectrum of clinical manifestations
   b. MPS IVB
      i. Deficient β-galactosidase (*GLB1*) gene
      ii. Wide spectrum of clinical manifestations
3. Pathogenesis (Braverman and Hoover-Fong 2003)
   a. Defective degradation of keratan sulfate secondary to deficiency of either *N*-acetyl-galactosamine-6-sulfate sulfatase (*GALNS* gene) in MPS IVA or β-galactosidase (*GLB1* gene) in MPS IVB
   b. Cartilage and cornea: The major organs affected in Morquio syndrome since keratan sulfate is predominantly found in these tissues.

Clinical Features

1. MPS IVA
   a. Classic form
      i. The most common form
      ii. Appears normal at birth
      iii. Skeletal symptoms occurring between 1 and 3 years of age
      iv. Clinical diagnosis usually not made until 3–15 years of age
      v. Skeletal manifestations
         a) Marked dwarfism
         b) Waddling gait with tendency to fall
         c) Short neck
         d) Hypoplasia or absence of the odontoid process of the axis with risk of resulting in life-threatening atlantoaxial subluxation
         e) Cervical myelopathy
         f) Gibbus
         g) Restrictive chest wall movement
         h) Pectus carinatum
         i) Kyphoscoliosis
         j) Genu valgum
         k) Semicrouching stance
         l) Progressive skeletal deformities frequently resulting in neurologic compromise
      vi. Joint manifestations
         a) Hypermobile due to ligamentous laxity
         b) Decreased mobility in large joints (e.g., hips, knees, elbows)
      vii. Unusual facial appearance
         a) Coarse facies
         b) Prognathism
         c) Broad mouth

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_164,
© Springer Science+Business Media, LLC 2012

viii. Eye manifestations
  a) Mild corneal clouding
  b) Glaucoma
  c) Cataract
ix. Dental features (Rølling et al. 1999)
  a) Abnormally thin enamel
  b) Spade-shaped incisors
  c) Pointed cusps
  d) Pitted buccal surfaces
  e) Frequent caries formation
x. Cardiac manifestations
  a) Aortic valve insufficiency or stenosis
  b) Mitral valve thickening and stenosis
  c) Cardiac failure
xi. Progressive deafness
xii. Hepatomegaly
xiii. Upper airway obstruction
  a) Obstructive sleep apnea
  b) Nocturnal dyspnea
xiv. Intelligence usually normal, rarely with progressive mental regression

b. Mild form
  i. Almost normal stature
  ii. Mild skeletal abnormalities
    a) Odontoid dysplasia but without atlantoaxial instability
    b) Pectus carinatum deformity
    c) Dysplastic hips
    d) Waddling gait
    e) Kyphoscoliosis
    f) Deformity of femoral heads
    g) Platyspondyly
    h) Limitation of joint movement
    i) Deformities of metacarpals
  iii. Enamel hypoplasia
  iv. Mild corneal clouding
  v. Absent keratosulfaturia

2. MPS IVB
  a. Severe form: clinical manifestations as severe as MPS IVA
  b. Mild form
    i. Less severe progression of skeletal dysplasia
    ii. Less severe short stature
3. Prognosis
  a. Atlantoaxial instability and subsequent cervical myelopathy
    i. Cord transection and subsequent quadriparesis or death secondary to a minor fall or extension of the neck
    ii. Bowel and bladder dysfunction and apnea secondary to cervical myelopathy
    iii. Prolonged periods of hypoxia, pulmonary hypertension, and even death from obstructive sleep apnea
    iv. Airway obstruction secondary to thickening of tissue in the upper airway from mucopolysaccharide deposition
  b. Predisposition to pulmonary infection because of progressive truncal deformity and immobility
  c. Early-onset coronary heart disease and valve thickening (aortic and mitral) with resultant cardiac dysfunction
  d. Visual disturbance and photophobia secondary to corneal clouding
  e. Predisposition to dental caries secondary to enamel abnormalities

Diagnostic Investigations

1. Urine MPS spot tests: associated with false-positive and false-negative results
2. Excessive urinary excretion of keratin sulfate: determination by spectrophotometric assays with dimethylmethylene blue
3. Metachromatic granules in cultured fibroblasts
4. Diagnosis confirmed by direct enzymatic assay in leukocytes or fibroblasts
  a. N-acetylgalactosamine-6-sulfatase deficiency (classic form)
  b. β-galactosidase deficiency (mild form)
5. Radiographic features
  a. Short trunk dwarfism
  b. Dysostosis multiplex
  c. Spondyloepiphyseal dysplasia (the hallmark of the syndrome)
  d. Odontoid hypoplasia
  e. Sternal protrusion
  f. Platyspondylia
  g. Kyphosis
  h. Hyperlordosis
  i. Scoliosis
  j. Ovoid deformities of the thoracic vertebrae
  k. Hook-shaped lumbar bodies
  l. Long pelvic configuration
  m. Coxa valga
  n. Genu valgum
  o. Ulnar deviation of the wrist

p. Valgus deformity of the elbow
q. Inclinations of distal ends of radius and ulna toward each other
r. Metacarpal deformities
s. Short phalanges
t. Epiphyseal deformities of the tubular bones
u. Wide metaphysis
v. Osteoporosis

6. CT and MRI of the brain and cervical spine for evaluation of odontoid hypoplasia and cord compression
7. Echocardiography for cardiac involvement
   a. Aortic valve insufficiency or stenosis
   b. Mitral valve thickening and stenosis
   c. Ventricular hypertrophy
8. Slit-lamp examination for corneal clouding
9. Molecular genetic diagnosis
   a. Sequence analysis
   b. Deletion/duplication analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier in which case there will be 50% of offspring affected
2. Prenatal diagnosis (von Figura et al. 1982; Mossman and Patrick 1982; Zhao et al. 1990; Beck et al. 1992; Kleijer et al. 2000)
   a. Demonstration of GalNac-6S or Gal-6S sulphatase deficiency in cultured amniotic fluid cells or chorionic villi
   b. Abnormal glycosaminoglycans electrophoretic pattern in amniotic fluid
   c. Mutation analysis in amniocytes or chorionic villi, provided the disease-causing mutation has been identified in the family member
3. Preimplantation genetic diagnosis of Morquio syndrome: accomplished by mutation analysis from the embryos following whole genome amplification of single blastomeres using multiple displacement amplification (Qubbaj et al. 2008)
4. Management (Mikles and Stanton 1997)
   a. Orthopedic management
      i. Surgery to stabilize the upper cervical spine, usually by spinal fusion, can be lifesaving for spinal cord compression
      ii. Bilateral osteotomies to correct the knock-knee deformity (severe coxa valgum)
   b. Anesthetic difficulties
      i. Difficult endotracheal intubation due to odontoid hypoplasia and atlanto-axial instability
      ii. Compression of the cord during hyperextension of the neck
      iii. Reduction in vital capacity, functional residual capacity, and total lung capacity due to chest cage dysfunction (kyphoscoliosis and pectus carinatum)
   c. Infection control
   d. Medications for glaucoma
   e. Cornea transplant not very helpful
   f. Hearing aids helpful
   g. Hernia repairs
   h. Cardiac management
      i. Aortic regurgitation
      ii. Endocarditis prophylaxis
      iii. Cardiac valve replacement historically not considered for these patients
   i. Potential strategies for treatment including enzyme replacement, gene therapy, and allogenic bone marrow transplantation in which engrafted cells provide the normal enzyme

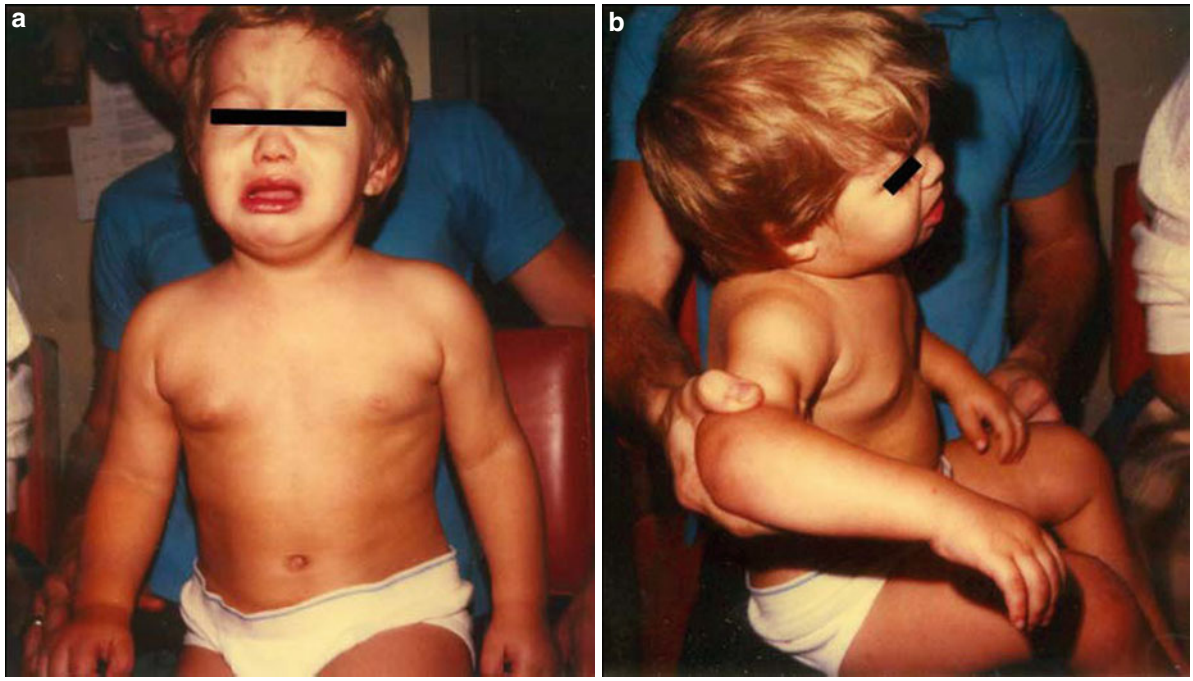

Fig. 1 (**a**, **b**) A boy with MPS IVB showing coarse facial appearance and short trunk

Fig. 2 Lateral view of the spine showing platyspondyly, anterior beaking of vertebral bodies, and lumbar gibbus similar to those seen in Hurler syndrome

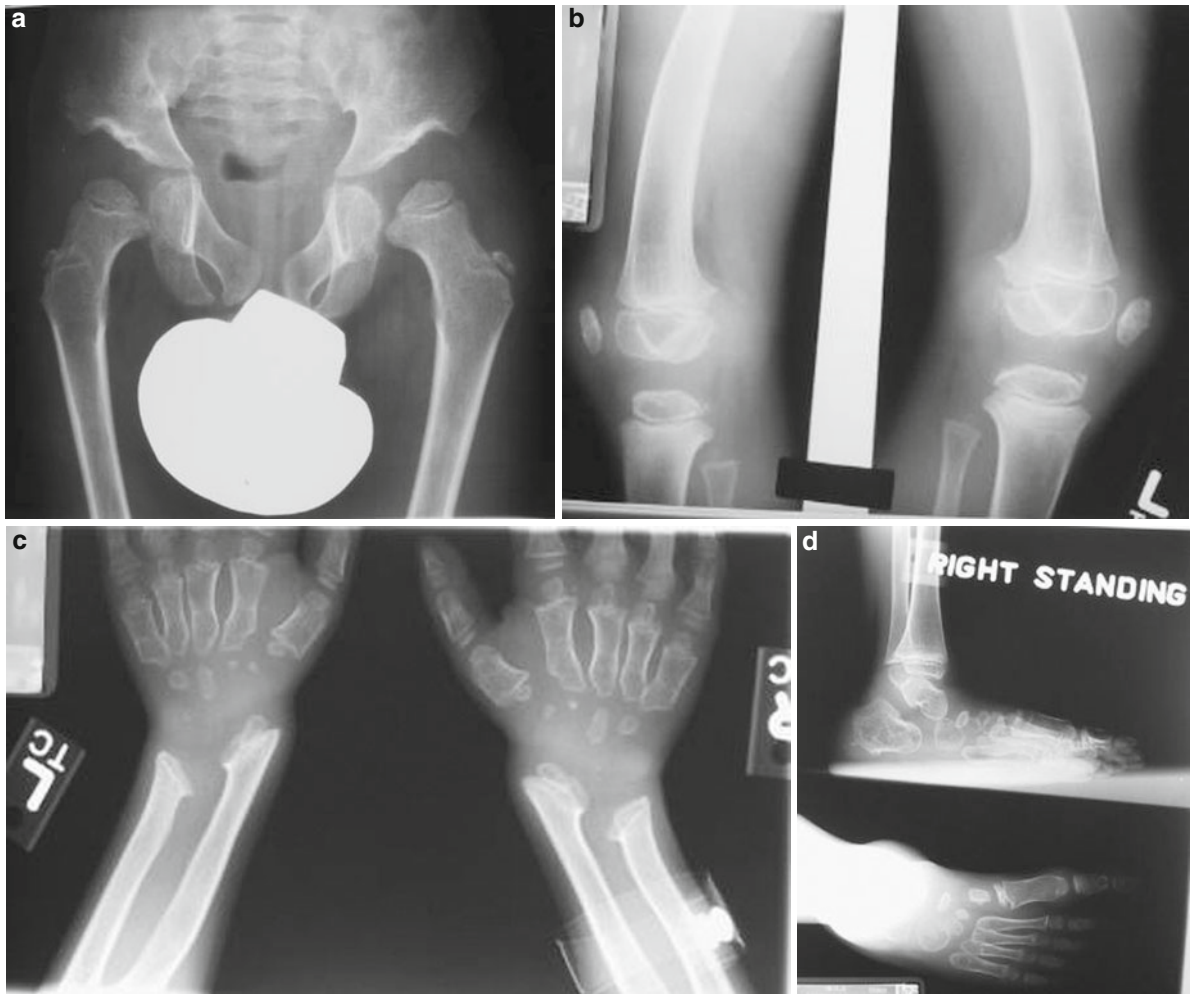

Fig. 3 (**a**–**d**) Radiographic studies showing dysostosis multiplex with proximal conical metacarpals and angling of the ulna toward the radius with dysplastic ulnar and radial growth plates

Mucopolysaccharidosis VI

Mucopolysaccharidosis VI was first recognized by Maroteaux and coworkers in 1963 as a Hurler-like syndrome but with preservation of intelligence and excretion of dermatan sulfate unaccompanied by heparan sulfate. Milder forms of MPS VI have been recognized since the initial description of the disorder. The estimated birth incidence of MPS VI ranges from 1 in 100,000 to 1 in 1,300,000 in various populations (Harmatz et al. 2004).

Synonyms and Related Disorders

Arylsulfatase B deficiency; Maroteaux–Lamy syndrome

Genetics/Basic Defects

1. Genetic inheritance: autosomal recessive
2. Cause
   a. Deficiency of *N*-acetylgalactosamine-4-sulfatase (arylsulfatase B) which:
      i. Is deficient in both mild and severe forms
      ii. Is Involved in the degradation of dermatan sulfate and chondroitin 4-sulfate
      iii. Causes intralysosomal storage and urinary excretion of the glycosaminoglycan, dermatan sulfate
   b. The gene encoding *N*-acetylgalactosamine-4-sulfatase (*ARSB*) mapped to chromosome 5q13-q14
   c. Mutations: The vast majority of MPS VI mutant alleles are either unique to a patient or are present in a small number of patients.
      i. Null mutations
         a) Frameshift mutations
         b) Nonsense mutations
      ii. Missense mutation giving rise to:
         a) Severe disease
         b) Intermediate disease
         c) Mild disease
   d. Genotype/phenotype correlation for missense mutations in MPS VI: not reliable enough for prognosis or counseling

Clinical Features

1. Variable clinical phenotype (mild to severe) causing considerable difficulty in recognition and diagnosis of the syndrome
2. The severe form (MPS IVA)
   a. Somatic involvement similar to that in Hurler syndrome
   b. Growth
      i. Normal growth for the first few years of life
      ii. Growth retardation (short stature) first noted at the age of 2–3 years
      iii. Ultimate height of 110–140 cm in severely affected patients
   c. Other skeletal involvement
      i. An enlarged head at birth
      ii. Deformed chest at birth
      iii. Joint stiffness (knee, hip, and elbow) developing in the first years of life
      iv. Progressively restricted articular movements
      v. Crouching stance

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_165,
© Springer Science+Business Media, LLC 2012

vi. Shortened limbs
vii. Claw hand deformities secondary to flexion contractures of the fingers
viii. Carpal tunnel syndrome contributing to the hand abnormality
ix. Shortened trunk
x. Anterior sternal protrusion
xi. Lumbar gibbus
xii. Prominent lumbar lordosis/kyphosis
xiii. Genu valgum

d. Mental development usually normal
e. The facies
   i. Mild coarseness of facies in some patients
   ii. Coarse facies characteristic of Hurler syndrome in other patients
f. Ocular findings
   i. Corneal opacities (clouding) developing early, resulting in significant visual impairment
   ii. Glaucoma
   iii. Pigmented retinopathy
g. Dentigerous cysts
h. Upper airway obstruction
i. Cardiovascular involvement
   i. Thickened atrioventricular valves of the heart
   ii. Endomyocardial fibroelastosis
   iii. Dilated cardiomyopathy
j. Associated neurologic complications
   i. Not typically associated with progressive impairment of mental status, although physical limitations may impact learning and development
   ii. Hydrocephalus
   iii. Spinal cord compression secondary to:
      a) Atlantoaxial subluxation associated with craniovertebral canal stenosis
      b) Hypertrophy of the posterior longitudinal ligament
      c) Dural thickening secondary to the deposition of glycosaminoglycans
   iv. Spastic paraplegia resulting from compressive myelopathy
   v. Arachnoid cysts
   vi. Pachymeningitis
   vii. Nerve entrapment syndromes, particularly of the carpal tunnel
   viii. Occasional hearing loss due to recurrent otitis media
k. Abdomen and visceral involvement
   i. Hepatomegaly always present after the age of 6 years
   ii. Splenomegaly in 50% of patients
   iii. Prominent abdomen
   iv. Inguinal/umbilical hernias common
l. Skin
   i. Tightness
   ii. Hirsutism
m. Most reported patients with the severe form died from heart failure in the second to third decades

3. The mild to intermediate form (MPS IVB)
   a. Clinical recognition often delayed till 5 years of age
   b. Mildly affected
   c. Minimal dysostosis multiplex
   d. Aortic and mitral valvular dysfunction
      i. Primarily due to calcified thickened and stenotic valves
      ii. The most prominent cardiac involvement in the milder phenotypes
   e. Spinal cord compression from thickening of the dura in the upper cervical spinal canal with resultant myelopathy: a frequent occurrence in patients with the milder forms
   f. Compression myelopathy associated with a kyphoscoliotic deformity of thoracolumbar spine

Diagnostic Investigations

1. Increased urinary excretion of glycosaminoglycans (Valayannopoulos et al. 2010)
   a. Dermatan sulfate accumulation
   b. Absence of chondroitin 4-sulfate, heparan sulfate, keratan sulfate, or hyaluronate using thin layer chromatography (TLC) or high-resolution electrophoresis fractionation
2. Biochemical diagnosis (Valayannopoulos et al. 2010)
   a. Demonstration of deficient N-acetylgalactosamine-4-sulfatase (arylsulfatase B) in cultured skin fibroblasts or leukocytes (generally less than 10% of the lower limit of normal ASB activity)
   b. Identification of normal enzyme activity of a different sulfatase to exclude the diagnosis of multiple sulfatase deficiency

3. Demonstration by an accredited laboratory of intermediate levels of leukocyte ASB enzyme activity in both parents to support diagnosis of carriers
4. Slit-lamp examination for corneal opacities
5. Radiographic features
   a. Skeletal changes similar to radiographic findings of Hurler syndrome in the severe form
   b. Striking examples of dysostosis multiplex, particularly severe pelvic changes
      i. Acetabulum hypoplasia
      ii. Small flared iliac wings
   c. Macrocephaly with a large sella
   d. Vertebrae
      i. Ovoid deformity of vertebral bodies
      ii. A hood-shaped deformity or blunt anterior hypoplasia of vertebral bodies of L1 or L2
      iii. Epiphyseal dysplasia of the proximal femur
      iv. An elongated femoral neck in a valgus position
      v. Irregular diaphyseal distension of tubular bones
      vi. Vertebral subluxation, especially atlantoaxial joint
6. Confirmation by mutational analysis of the *ARSB* gene (Karageorgos et al. 2007) should be considered if the diagnosis is in question, and is important in carrier testing or prenatal diagnosis.
   a. Sequence analysis
   b. Duplication/deletion analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis
   a. Demonstration of deficient N-acetylgalactosamine-4-sulfatase (arylsulfatase B) in amniotic-fluid cells from the pregnancy at risk (Kleijer et al. 1976)
   b. Mutation analysis of amniocytes and CVS in characterized families
3. Management
   a. Supportive care
      i. Optimizing general health with nutrition counseling
      ii. Occupational and physical therapy
      iii. Management of individual symptom complications
         a) Respiratory insufficiency requiring oxygen and/or positive airway pressure during sleep, tonsillectomy, adenoidectomy, or tracheostomy
         b) Cardiac failure requiring medications
   b. Keratoplasty for progressive opacification of the cornea
   c. Surgery to improve common nerve entrapment syndromes, particularly of the carpal tunnel
   d. Successful single and double (aortic and mitral) valve replacements have been reported in MPS.
   e. Substantial improvement following laminectomy and excision of the markedly thickened dura in myelopathy due to spinal canal stenosis
   f. Bone marrow transplantation or hematopoietic stem cell transplantation in patients with the severe form of MPS VI
      i. Efficacy
         a) Arylsulfatase B activity increased to normal levels in peripheral lymphocytes and granulocytes
         b) Decreased urinary excretion of acid mucopolysaccharide
         c) Decreased inclusions in the liver
         d) Improved cardiopulmonary function
         e) Improved visual acuity and joint mobility
         f) May provide better life quality (improved motor function, exertional dyspnea, severe snoring, and vertigo) (Wang et al. 2008)
      ii. Not universally performed due to lack of a suitable donor and is associated with significant morbidity and mortality
   g. Allogeneic CD34 selected peripheral stem cell transplant with rapid hemopoietic and biochemical reconstitution
   h. Enzyme replacement therapy
      i. Clinical trials of enzyme replacement therapy with human recombinant N-acetylgalactosamine-4-sulfatase (rhASB) (Harmatz et al. 2006, 2004)
         a) Well tolerated
         b) Reduces lysosomal storage as evidenced by a dose-dependent reduction in urinary glycosaminoglycan
         c) An increase in distance walked

d) Stair-climbing ability
e) Shoulder range of motion
f) Decrease in pain and arthritis

ii. The largest gains occurred in patients with advanced disease receiving high-dose rhASB

iii. Currently, a recombinant formulation (galsulfase) (Naglazyme®) is available as an enzyme replacement therapy: Therapeutic response may be influenced by disease stage, and early intervention may lead to better outcomes (El Dib and Pastores 2009).

Mucolipidosis II

Mucolipidosis II (ML II), or I-cell disease, is a rare autosomal recessively inherited storage disorder of lysosomal enzyme hydrolase trafficking due to deficient activity of the multimeric enzyme UDP-*N*-acetylglucosamine-1-phosphotransferase. The term "I-cell disease" is derived from the observation that fibroblasts from affected individuals show dense inclusions filled with storage material.

Synonyms and Related Disorders

I-cell disease

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Uridine diphosphate (UDP)-*N*-acetylglucosamine-1-phosphotransferase (GlcNAc-PT) (Beck et al. 1995)
   a. An enzyme that transfers phosphate groups onto oligosaccharide units of lysosomal enzyme precursors
   b. Deficient in mucolipidosis II (also in mucolipidosis III) (Bargal et al. 2006)
   c. Consequences of the enzyme deficiency
      i. Not generating common phosphomannosyl recognition marker of acid hydrolases
      ii. The enzymes not targeting to the lysosomes
      iii. Secretion of the enzymes into the extracellular space (high activities found in the serum of the patients)
      iv. Considerable reduction of the enzyme levels inside the cells (fibroblasts)
   d. GlcNAc-PT is made up of three subunits, α, β, and γ.
      i. The α/β subunits are encoded by the *GNPTA* gene (Tiede et al. 2005) and have a catalytic function (Reitman and Kornfeld 1981, Reitmman et al. 1981).
      ii. The γ subunit which is encoded by the *GNPTAG* gene (Raas-Rothschild et al. 2000) has a recognition and regulation function (Reitman et al. 1981a, 1981b).
   e. Mutations in *GNPTAB*, which encodes the α/β subunit, cause ML II and ML III α/β (Tiede et al. 2005). The γ subunit is encoded by *GNPTG*, and mutations in this gene lead to the clinically milder condition known as ML III γ (Raas-Rothschild et al. 2000).
3. Genotype-phenotype correlations (Leroy et al. 2009)
   a. *GNPTAB* gene sequencings have confirmed that homozygous and compound heterozygous genotypes that predict enzyme inactivation (caused by premature translation termination and/or frameshift effects) result in the ML II phenotype.
   b. The combination of less "morbid" mutations, such as missense and most of the splice-site mutations that may decrease but not abolish enzyme activity, often yields the more slowly evolving ML III phenotype alpha/beta with later clinical onset (Paik et al. 2005; Tiede et al. 2005; Bargal et al. 2006; Kudo et al. 2006).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_166,
© Springer Science+Business Media, LLC 2012

c. Some children have clinically intermediate phenotypes between the delineated ML II and ML III alpha/beta.
d. Correlating these phenotypes with the specific mutant genotypes requires more detailed and extensive clinical research efforts that are ongoing (Cathey et al. 2008).

Clinical Features

1. Symptoms and signs of ML II are similar to those encountered in patients with mucopolysaccharidoses and to a lesser extent gangliosidoses: characterized by coarse facial features, short stature, hyperplastic gums, organomegaly, and retarded psychomotor development (Maroteaux and Lamy 1966; Okada et al. 1985; Leroy and Opitz 1969).
2. A wide range of inter- and intrafamilial variability
   a. Age of onset: present at birth or appear in the first few months of life
   b. Organ manifestation
   c. Radiological findings
   d. Unusual findings in some patients
      i. Pericardial effusion
      ii. Profound brain atrophy
3. Features evident in affected newborn
   a. Coarse facial (gargoyle-like) features (Lee and O'Donnell 2003)
      i. Puffy eyelids with slight exophthalmia
      ii. Excessive prominence of the epicanthal folds
      iii. Depressed nasal bridge
      iv. Full cheeks exhibiting multiple fine telangiectasia
      v. Gingival hyperplasia and alveolar enlargement with buried teeth
      vi. Thick tongue
   b. Restricted joint mobility
   c. A tight, thickened skin
4. Early clinical features
   a. Low birth weight
   b. Congenital hip dislocation
   c. Pes equinovarus
   d. Joint contractures
   e. Inguinal hernias
   f. Generalized hypotonia
   g. Ocular abnormalities (Libert et al. 1977)
      i. Corneal clouding
      ii. Glaucoma
      iii. Megalocornea
5. Older patients
   a. Predominant features
      i. Skeletal deformities (dysostosis multiplex)
      ii. Progressive failure to thrive
      iii. Developmental delay with variable mental retardation
   b. Other features
      i. Short stature
      ii. Craniosynostosis
      iii. Progressive stiffness of all joints, first apparent in the shoulders
      iv. Variable hepatosplenomegaly
      v. Congestive heart failure
      vi. Recurrent pulmonary infections
6. Natural history (Leroy and Martin 1975)
   a. Slowly progressive course
   b. Fatal outcome usually before 4 years of age
7. ML III (see next Chapter Mucolipidosis III)
   a. Genetically heterogeneous
   b. A milder disorder with attenuated characteristics and survival to adult life (Kelly et al. 1975)
8. Differential diagnosis with other lysosomal storage disease (Leroy et al. 2009)
   a. Mucopolysaccharidosis type 1 H (see the Chapter Mucopolysaccharidosis I)
   b. GM1 gangliosidosis type 1
      i. More severe hepatomegaly
      ii. Dysostosis multiplex indistinguishable
      iii. Beta-D-galactosidase deficiency in leukocytes and plasma
   c. Infantile galactosialidosis
      i. Storage phenomena less pronounce than in GM1 gangliosidosis but more than in ML II
      ii. Absence of acid sialidase and of beta-D-galactosidase activity in leukocytes in addition to cathepsin A deficient in leukocytes and cultured fibrocytes
      iii. May present as congenital nonimmune hydrops fetalis
   d. Infantile sialidosis (formerly sialidosis type 2)
      i. May present as congenital nonimmune hydrops fetalis
      ii. More chronic disorder with moderate organomegaly, dysostosis multiplex that is milder than that of ML II
      iii. Mild limitation of joint mobility

iv. Growth and cognitive development considerably better than in children with ML II

e. Infantile free sialic acid storage disease
   i. Excessive amounts of free sialic acid in the urine
   ii. Deficient acid sialidase only
   iii. Less facial dysmorphism and much less dysostosis multiplex than ML II

Diagnostic Investigations

1. Elevated activities of multiple lysosomal enzymes in serum or plasma, including the following enzymes: Activity of nearly all lysosomal hydrolases is 5- to 20-fold higher in plasma and other body fluids than in normal controls because of improper targeting of lysosomal acid hydrolases to lysosomes in ML II.
   a. Arylsulfatase A
   b. α-Mannosidase
   c. β-Glucuronidase
   d. β-Hexosaminidase
2. Deficient enzyme activities in cultured fibroblasts, including the following enzymes:
   a. β-Galactosidase
   b. Arylsulfatase A
   c. β-Hexosaminidase
   d. β-Glucuronidase
   e. α-L-iduronidase
3. Primary biochemical defect: decreased or absent N-acetylglucosamine-1-phosphotransferase in cultured fibroblasts and leukocytes
4. Excessive urinary excretion of oligosaccharides
5. Normal excretion of urinary mucopolysaccharide
6. Radiography
   a. Fetal radiography
      i. Diffuse decrease in bone mineralization
      ii. A coarse, lacy, trabecular pattern
      iii. Overall shortening and undermodelling of the long bones
      iv. Subperiosteal bone deficiency in the diaphysis giving the appearance of periosteal new bone (cloaking)
      v. Retarded ossification of the vertebral bodies
      vi. Hypoplasia of the anterior superior aspect of the upper lumbar vertebral bodies
      vii. Broad ribs
      viii. Abnormal pelvis with squared iliac wings and flattened acetabular roofs
      ix. Brachyphalangy
      x. Mild tapering of the proximal ends of the metacarpals
      xi. A small irregular calcaneal "ossification center"
   b. Radiographic findings in early infancy
      i. Diffuse demineralization
      ii. Metaphyseal cupping and fraying
      iii. Excessive periosteal new bone formation
      iv. Diaphyseal expansion of the long tubular bones
      v. Irregular trabeculation without differentiation between the cortical and medullary zones
      vi. Mild anteriosuperior hypoplasia of the upper lumbar bodies
      vii. Pelvic dysplasia
      viii. Occasional punctate calcifications and bone defects following intrauterine calcific deposits
      ix. Skeletal changes in the neonatal I-cell disease resembling those of rickets, osteomyelitis, and hyperparathyroidism (David-Vizcarra et al. 2010)
   c. Dysostosis multiplex
      i. Neurocranium
         a) Long and thick
         b) Thickened and sclerotic cranial base
      ii. Widened ribs
      iii. Kyphoscoliosis
      iv. Anterior beaking and wedging of the vertebral bodies
      v. Lumbar gibbus deformity
      vi. Cloaking appearance of the long tubular bones
      vii. Proximal pointing of the metacarpals
      viii. Bullet-shaped phalanges
      ix. Claw hand deformities
7. Slit lamp examination to demonstrate corneal clouding
8. Echocardiography for valve thickening and valve insufficiency
9. MRI or CT scan: mild brain atrophy in most cases
10. Light microscopy and electron microscopy
    a. Inclusion bodies in peripheral lymphocytes in blood smear

b. An increased number of empty, large vacuoles that may fill the cytoplasm of cultured skin fibroblast cells
c. Presence of numerous intracytoplasmic inclusions in cells of mesenchymal origin
   i. Membrane-bound vacuoles filled with fibrillogranular material
   ii. Appear to contain a variety of lipids, mucopolysaccharides, and oligosaccharides
d. Cytoplasmic inclusions also observed in various types of cells in fetal I-cell disease
e. Molecular genetic diagnosis (Leroy et al. 2009)
   i. Sequence analysis: Bidirectional sequencing of the entire *GNPTAB* coding region detects two disease-causing mutations in more than 95% of persons with ML II.
   ii. Deletion/duplication analysis is also clinically available.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not surviving to reproductive age
2. Prenatal diagnosis (Carey et al. 1999)
   a. Ultrasonography
      i. Intrauterine growth retardation
      ii. Short tubular bones
   b. Measuring the levels of lysosomal enzymes (elevated activity of several lysosomal hydrolases) in cell-free amniotic fluid or cultured amniocytes
   c. Assay of the transferase activity (deficient) in cultured CVS cells and amniocytes
   d. Electron microscopy of chorionic villus biopsy tissue for detection of inclusion bodies
   e. Prenatal diagnosis and preimplantation genetic diagnosis for at-risk pregnancies require prior identification of the disease-causing mutations in the family (Leroy et al. 2009).
3. Management
   a. Supportive care
      i. Low-impact therapies to avoid joint and tendon strain, including aqua therapy
      ii. Cognitive stimulation through interactive programs
      iii. Gingivectomy as needed for oral health
      iv. Myringotomy tube placement as needed for recurrent ear infections
   b. Prevention of secondary complications
   c. Bone marrow transplant from an HLA-identical carrier sibling (Grewal et al. 2003)
      i. Neurodevelopmental gains
      ii. Prevention of cardiopulmonary complications
      iii. No alteration to the course of musculoskeletal disease

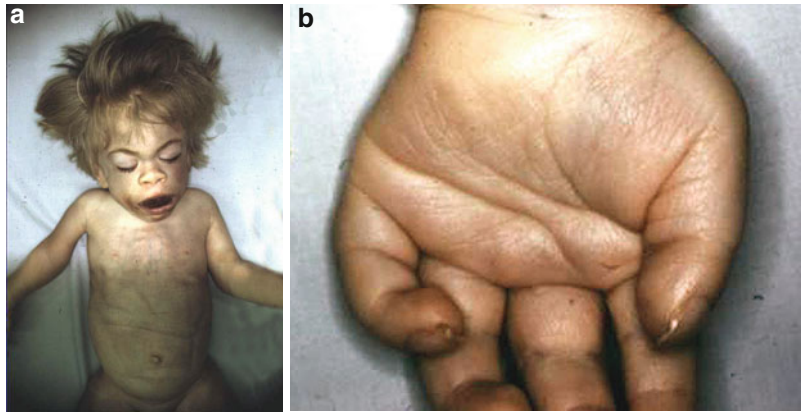

Fig. 1 (**a**, **b**) An 8-year-old girl with I-cell disease. She had severe growth retardation (67 cm), coarse facial features, claw hands, severe skeletal dysplasia, marked gingival hypertrophy, cardiomegaly with marked thickening and deformity of mitral and tricuspid valves, and bilateral duplication of ureters. Histological investigations showed foam cell infiltration in renal glomeruli, splenic corpuscles, atrioventricular valves, and thymus

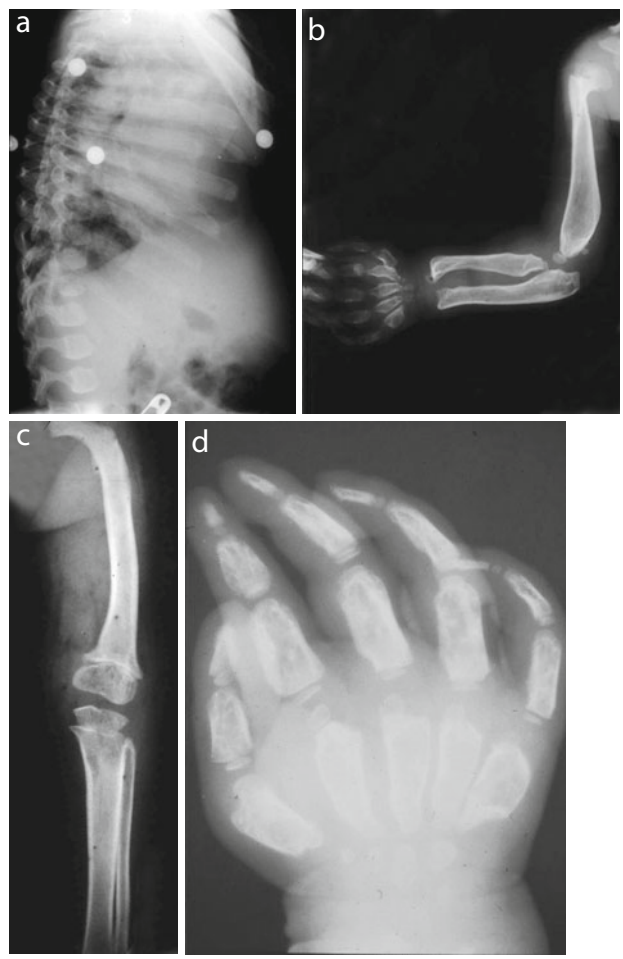

Fig. 2 Radiographs showed generalized dysplastic changes in the chest and upper and lower extremities. The ribs were extremely wide (**a**). Some vertebral bodies were slightly hook-shaped. The pedicles were long and there was slight gibbus. Midshafts of the humerus, radius, and ulna were wide and the neck of the humerus in varus position (**b**). Widening of the midshafts of the lower extremities was less marked than in the upper extremities (**c**). Metacarpals and phalanges were wide, but distal phalanges were short and thin (**d**). Metacarpal bones pointed proximally. Carpal bones were hypoplastic

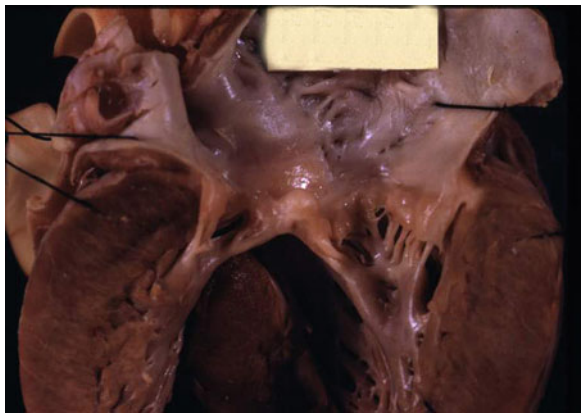

Fig. 3 Mitral valve was thickened and deformed

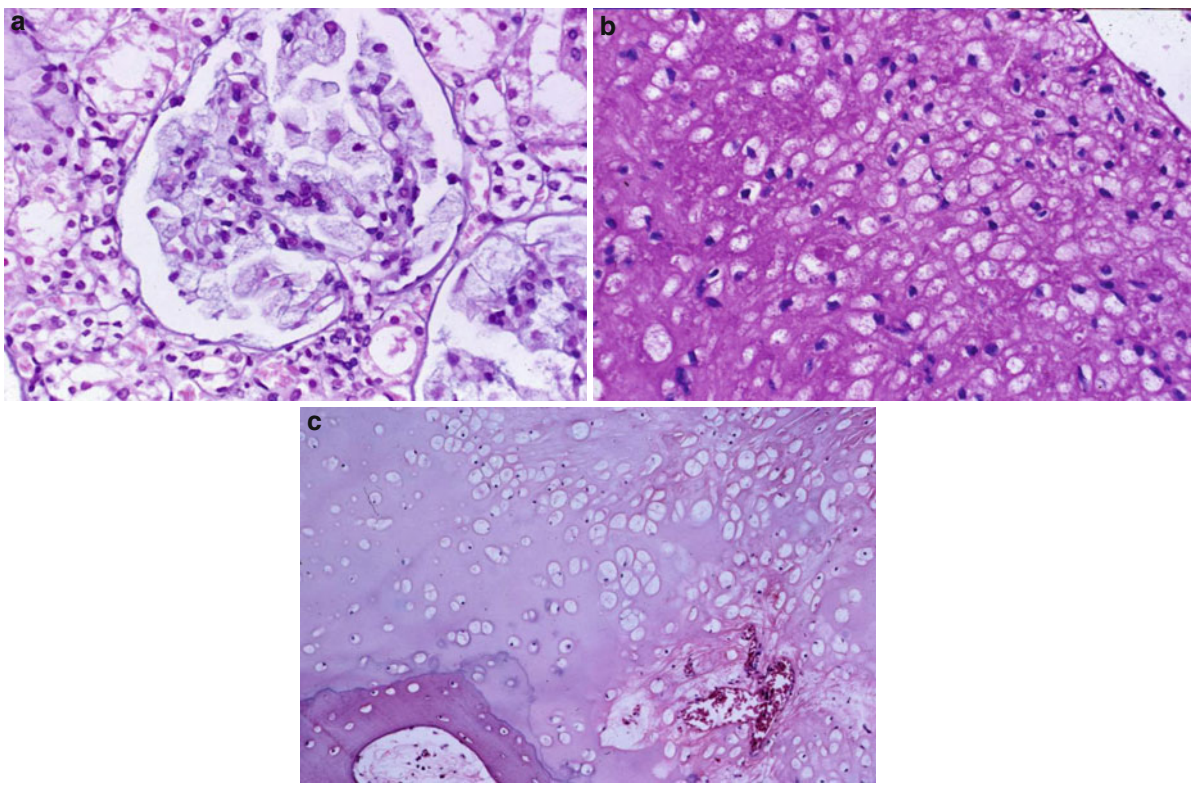

Fig. 4 (**a**–**c**) Foam cells were present in the renal glomeruli, mitral valve, and chondrocytes of cartilage

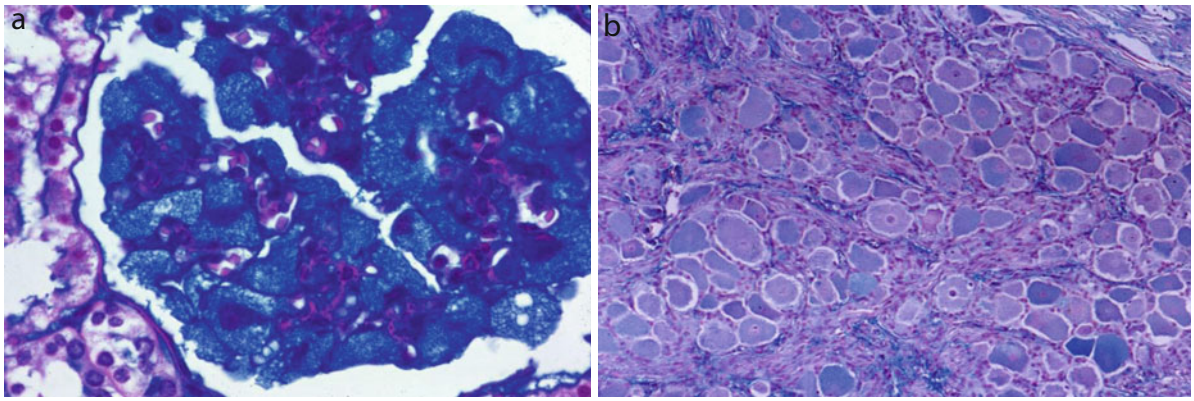

Fig. 5 (**a**, **b**) The foamy material was reactive with colloidal iron stain (renal glomeruli) and sympathetic ganglion (Alcian blue stain), indicating the presence of mucopolysaccharide

Mucolipidosis III

In 1966, Maroteaux and Lamy first described four girls with pseudo-Hurler polydystrophy, a condition milder in severity than the Hurler syndrome and similar to the Scheie syndrome but without hepatosplenomegaly, cloudy cornea or mucopolysaccharidiuria. In 1970, Spranger and Wiedemann designated pseudo-Hurler polydystrophy as mucolipidosis III because of Hurler-like features and vacuolated bone marrow cells (Kelly et al. 1975b).

Synonyms and Related Disorders

Pseudo-Hurler Polydystrophy

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Basic defect
   a. Resulting from deficiency of the enzyme UDP-*N*-acetylglucosamine: lysosomal protein precursor *N*-acetyl glucosamine 1-phosphate transferase (G1cNAcPT) (Mucolipidosis II also caused by deficiency of the same enzyme)
   b. Genetic complementation analysis of cultured fibroblasts derived from patients with mucolipidosis III identified complementation groups A, B, and C.
   c. Inability to form the correct recognition marker on lysosomal enzymes resulting in a marked intracellular deficiency of most lysosomal enzymes in various tissues, impairment of many lysosomal catabolic processes, and concomitant increase in lysosomal enzymes in plasma
3. Recent finding of molecular basis for mucolipidosis IIIC (variant pseudo-Hurler polydystrophy): a mutation, in C at codon 167, in the γ subunit of the G1cNAcPT in mucolipidosis IIIC (Raas-Rothschild et al. 2000). Mutations in *GNPTAB*, which encodes the α/β subunit, cause ML II and ML III α/β (Tiede et al. 2005).

Clinical Features

1. Onset of disease
   a. Usually appear at 2–4 years of age
   b. Progress slowly
   c. First sign: stiffness in the hands and shoulders
2. Short stature
3. Mild Hurler-like facial dysmorphism, usually apparent after age 6 years
4. Ophthalmologic abnormalities
   a. Constant ocular features
      i. Corneal opacities consisting of fine, peripheral infiltrates
      ii. Hyperopic astigmatism
   b. Optic nerve head swelling
   c. Surface wrinkling maculopathy
   d. Retinal vascular tortuosity
5. Mild mental retardation
6. Valvular heart disease
7. Orthopedic problems
   a. Stiffness of the hands progressing to claw hand deformities by 6 years of age in all patients
   b. Slow progression of the skeletal dysplasia during school years, the resulting physical disability most apparent in the hands, hips, elbows, and shoulders

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_167,
© Springer Science+Business Media, LLC 2012

c. Generalized joint stiffness (limited joint mobility)
d. Spine abnormalities
   i. Kyphosis
   ii. Lordosis
   iii. Gibbus
e. Hip pain
f. Hip dysplasia
g. Less common clinical features (Smuts et al. 2009)
   i. Claw hand deformities
   ii. Carpal tunnel syndrome further complicates the claw hand deformities.
   iii. Recurrent, intermittent trigger fingers
   iv. Claw toes

8. Mucolipidosis III gamma (also known as variant ML III)
   a. Clinical features similar to but milder than those observed in individuals with mucolipidosis III alpha/beta (ML III alpha/beta)
   b. Affected individuals are mostly of Middle Eastern descent (Raas-Rothschild et al. 2000, 2004; Cathey et al. 2007).
9. Natural course of the illness: survive into beyond the fifth to sixth decade
10. Differential diagnosis (Leroy et al. 2009)
    a. Lysosomal storage diseases
       i. Attenuated MPS I (formerly called Hurler-Scheie syndrome or Scheie syndrome)
       ii. Attenuated MPS II (Hunter syndrome)
       iii. Morquio disease type B (MPS IV B)
       iv. Maroteaux-Lamy disease type B (MPS VI B)
       v. Sly disease type B (MPS VII B)
    b. Disorders clinically allied to the oligosaccharidoses
       i. Late infantile sialic acid storage disorder or Salla disease (free sialic acid storage disorders) and mucosulfatidosis: In both disorders, the neurodegenerative aspects are much more prominent.
       ii. In free sialic acid storage disorders, dysostosis multiplex is absent or minimal, and urinary excretion of free sialic acid is excessive.
       iii. In mucosulfatidosis, urinary acid mucopolysaccharides and sulfatides are excessive.
    c. Osteochondrodysplasias

Diagnostic Investigations

1. Radiography showing dysostosis multiplex (Melhem et al. 1973; Freisinger et al. 1992)
   a. Pelvis
      i. Flaring of the iliac wings
      ii. Constriction of the iliac bodies
      iii. Oblique acetabular roofs
   b. Vertebral bodies
      i. Moderately flattened
      ii. Presenting as a roughly ovoid contour
      iii. Underdevelopment of posterior parts in the dorsal spine
      iv. Hypoplasia of anterior third in the lumbar spine
      v. Irregular endplates
      vi. Scoliosis secondary to vertebral abnormalities
   c. Tubular bones
      i. Shortened and wide
      ii. The most striking changes observed in the proximal femur
         a) A small, flattened and irregular epiphysis
         b) Coxa valga deformity of the neck
         c) Subluxation
      iii. Hands
         a) Short first metacarpals
         b) Mild proximal pointing of the metacarpals
         c) Mild to moderate claw-hand deformities
         d) Relatively wide diaphysis of some phalanges
      iv. Retarded bone age
   d. Skull: normal despite the presence of craniostenosis in some patients
2. Nerve conduction test and electromyography to confirm the carpal tunnel syndrome
3. Slit-lamp examination for cornea opacification
4. Normal urinary excretion of acid mucopolysaccharides
5. Presence of cytoplasmic inclusions within cultured fibroblasts as demonstrated by phase-contrast or dark-field microscopy
6. Bone marrow: large, vacuolated plasmocytes
7. ML III alpha/beta (Leroy et al. 2009)
   a. Activity of nearly all lysosomal hydrolases: up to tenfold higher in plasma and other body fluids than in normal controls because of inadequate targeting to lysosomes (also in ML III gamma)

   b. Urinary excretion of oligosaccharides, a nonspecific finding, can be excessive but is not always present
   c. Significant deficiency (1–10% of normal) of the activity of the enzyme UDP-*N*-acetylglucosamine: Lysosomal hydrolase *N*-acetylglucosamine-1-phosphotransferase (GNPTA), encoded by *GNPTAB*, confirms the diagnosis.
8. Molecular genetic testing
   a. ML III alpha/beta (Leroy et al. 2009).
      i. Bidirectional sequencing of the entire *GNPTAB* coding region detects two disease-causing mutations in more than 95% of individuals with ML III alpha/beta. Such testing is clinically available.
      ii. Duplication/deletion analysis is also available.
   b. In ML III gamma: Molecular testing of *GNPTG* detects two disease-causing mutations in more than 95% of individuals with ML III gamma (Raas-Rothschild and Spiegel 2010).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis (Falik-Zaccai et al. 2003)
   a. Diagnosis confirmed by markedly reduced lysosomal enzyme activities in cultured chorionic villi
   b. Identification of the disease-causing mutation in fetal DNA in a newly recognized large Bedouin-Moslem kindred, allowing prenatal diagnosis, carrier detection, and identification of couples at risk
   c. Prenatal diagnosis and preimplantation genetic diagnosis for at-risk pregnancies require prior identification of the disease-causing mutations in the family.
3. Management (Hetherington et al. 1999)
   a. Physiotherapy for joint stiffness and contractures
   b. Padded insoles for clawing of toes
   c. Carpal tunnel decompression for the median nerve entrapment
   d. Pelvic osteotomy for severe hip dysplasia

Fig. 1 (**a**, **b**) Patient 1 (9-year-old boy) with mucolipidosis III showing short stature, mild coarse facial features, flexion contractures of knees, hips, elbows, wrists, and fingers. Fibroblast lysosomal acid hydrolase study revealed β-galactosidase 0.06 (control: 0.36 μmoles/h/mg protein), β-glucuronidase 0.05 (0.21), β-glucosaminidase 0.03 (3.9), α-L-iduronidase 0.12 (0.87), and aryl-sulfatase A 0.10 (0.67)

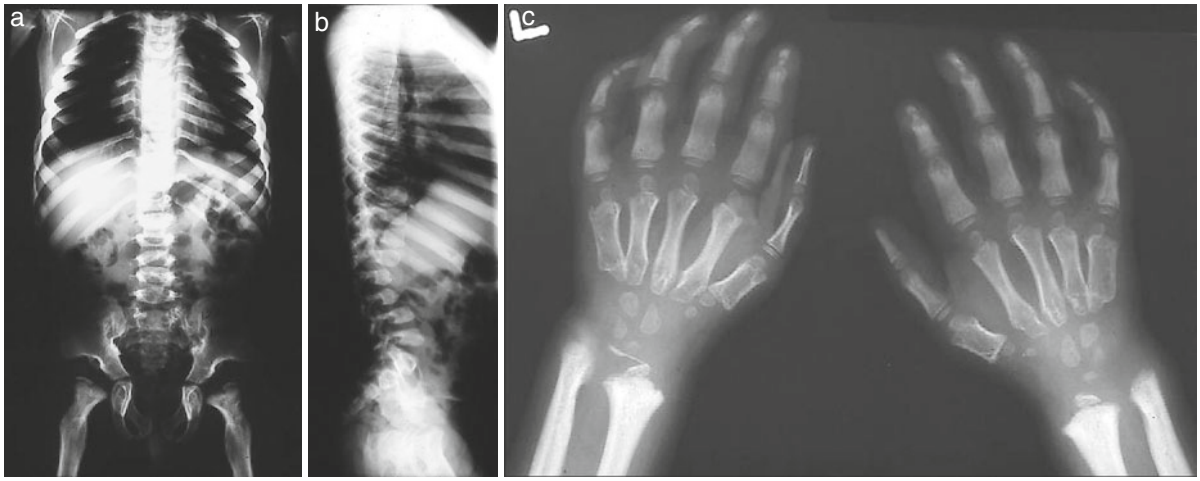

Fig. 2 (**a**–**c**) Radiographs of patient 1. Lateral lumbar spines showed severe hypoplasia with characteristic "beaked" configuration along their inferior aspects. Iliac bones were narrow and the basilar portions were hypoplastic with slanting acetabular roofs. Coxa valga deformity was present. Mild claw hand deformities with retarded bone age were evident

Fig. 3 (**a**, **b**) Patient 2 (sister of the patient 1) at age 7 years and 6 months showing similar clinical findings

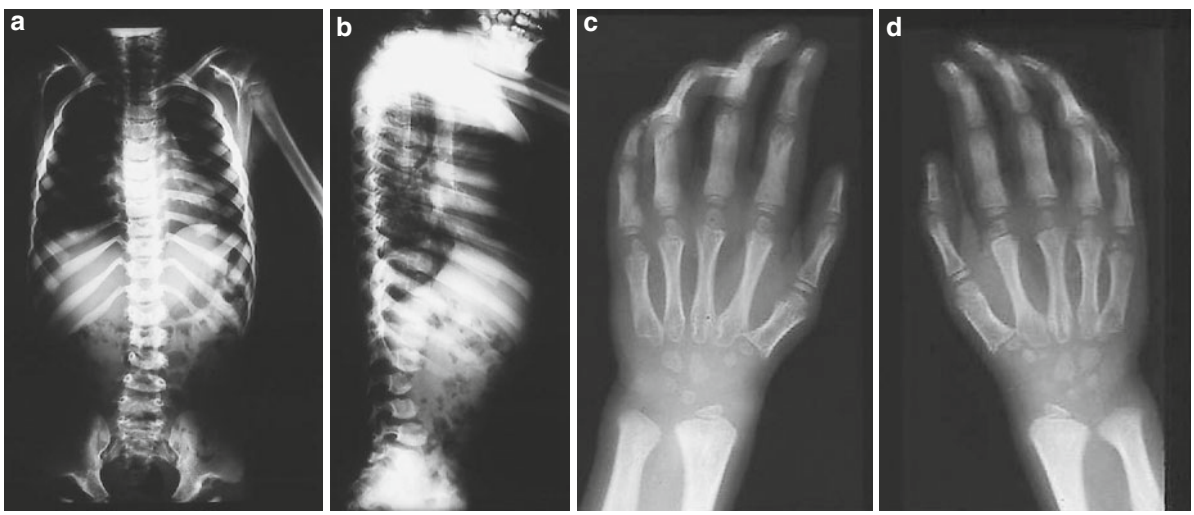

Fig. 4 (**a**–**d**) Radiographs of patient 2 showing similar radiographic findings

Fig. 5 (**a**, **b**) Two sisters (ages 10 years and 9 years) with mucolipidosis III showing developing delay, coarse facial features, claw hands, and more severe joint contractures. Radiographs (not shown) revealed bullet-shaped proximal phalanges, small carpal bones, and misshapen femoral heads

Multiple Endocrine Neoplasia Syndromes

The multiple endocrine neoplasia (MEN) syndromes are rare autosomal dominant conditions predisposing affected individuals to benign and malignant tumors of the pituitary, thyroid, parathyroids, and adrenals, endocrine pancreas, paraganglia, or nonendocrine organs. The classic MEN syndromes include MEN type 1 (MEN1) and MEN type 2 (MEN2). The prevalence of MEN1 is estimated to be 1 in 20,000–40,000 individuals and that of MEN2 is estimated to be 1 in 35,000 individuals (DeLellis et al. 2004).

MEN1 is a rare endocrine disorder presenting with various combinations of parathyroid, gastroenteropancreatic, and anterior pituitary tumors, but it can also include various combinations of more than 20 endocrine and nonendocrine tumors such as foregut, bronchial, and thymic carcinoids, lipomas and skin tumors (Gagel and Marx 2007). Generally, tumors in MEN1 are benign, although gastrinomas and foregut carcinoids may exhibit a malignant course (Falchetti et al. 2008).

MEN2 is a rare hereditary syndrome characterized by medullary thyroid carcinoma (MTC), unilateral or bilateral pheochromocytoma, and other hyperplasia and/or neoplasia of different endocrine tissues (Falchetti et al. 2008). If not diagnosed precociously, MTC can be fatal. MEN2 includes three clinical subtypes: MEN2A, MEN2B, and familial medullary thyroid carcinoma (FMTC).

Synonyms and Related Disorders

Familial medullary thyroid carcinoma; MENI (multiple endocrine adenomatosis, Wermer syndrome); MENIIA (pheochromocytoma and amyloid-producing medullary thyroid carcinoma, Sipple syndrome); MENIIB (mucosal neuroma syndrome)

Genetics/Basic Defects

1. MEN1
   a. Caused by a germ-line mutation in the *MEN1* gene, which encodes the tumor suppressor protein menin
   b. Mutated gene: *MEN1* (inactivating mutations of the MEN1 gene)
      i. Mapped on chromosome 11q13
      ii. Menin: consists of ten exons with noncoding first exon and produces a 610-amino acid protein.
      iii. Two independent somatic mutations must occur within a single cell for tumor formation.
      iv. A single mutation is required in an individual with *MEN1*, since the first mutation is already present in all of the patient's cells (Pack et al. 1998; Vortmeyer et al. 1999).
      v. This accounts for the multiple tumors and the tumors occurring at an earlier age.
      vi. Approximately 700 different somatic and germline mutations have been identified (Thakker 2001).
   c. No genotype-phenotype correlations observed
2. MEN2
   a. Caused by germ line–activating missense mutations of the *RET* (*RE*arranged during *T*ransfection) proto-oncogene which:
      i. Mapped on chromosome 10q11.2

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_168,
© Springer Science+Business Media, LLC 2012

ii. Encodes a receptor tyrosine kinase that functions as a signal transducer upon interaction with the glial-derived neurotrophic factor family of ligands (Santoro et al. 2004)
iii. MEN2-associated mutations: almost always located in exons 10, 11, or 13 through 16, although mutations in exons 5 and 8 have been reported on rare occasions (Dvorakova et al. 2005; Da Silva et al. 2003)

b. Strong genotype-phenotype correlations exist with respect to:
i. Clinical subtype
ii. Age at onset
iii. Aggressiveness of MTC in MEN2

c. MEN2A: at least 95% of individuals with MEN2A have an identifiable *RET* mutation (Schuffenecker et al. 1994; Mulligan et al. 1994)

d. MEN2B
i. An identifiable *RET* mutation in at least 98% of patients.
ii. The mutation is almost invariably M918T.
iii. Some individuals with mutation A883F (Mulligan et al. 1995; Gimm et al. 1997).

e. FMTC: mutated gene (*RET proto-oncogene*)

Clinical Features

1. MEN1 (Marini et al. 2006a, b; Callender et al. 2008; Falchetti et al. 2008)
   a. Presence of intrafamilial and interfamilial variation: highly variable in terms of the number of organ systems involved and the age of onset of tumors and symptoms
   b. MEN1 should be considered in patients with the following diagnoses:
      i. Primary hyperparathyroidism under age of 30 years
      ii. Primary hyperparathyroidism resulting from multigland involvement
      iii. Familial primary hyperparathyroidism
      iv. Zollinger–Ellison syndrome
      v. Multifocal pancreatic endocrine tumors or two or more MEN1-related tumors.
   c. Clinical diagnosis of MEN1 should be considered in:
      i. Patients with tumors in two of the three most commonly affected endocrine organs (parathyroid, pituitary, and pancreatic/duodenal endocrine tumors)
      ii. Patients with one such tumor and a family history of MEN1
   d. Clinical signs and symptoms: in order of decreasing frequency (Doherty 2005)
      i. Hypercalcemia
      ii. Nephrolithiasis
      iii. Peptic ulcer disease
      iv. Hypoglycemia
      v. Visual field loss
      vi. Hypopituitarism
      vii. Acromegaly
      viii. Galactorrhea–amenorrhea syndrome
      ix. Rarely Cushing's syndrome
   e. Characteristic endocrine tumors (Schussheim et al. 2001)
      i. Pituitary
         a) Prolactinoma (20%)
         b) GH and GH plus prolactin (10%)
         c) NF1 (5%)
         d) ACTH (2%)
         e) TSH and others (rare)
      ii. Parathyroid: adenoma (90%)
      iii. Foregut carcinoid
         a) Nonfunctioning gastric enterochromaffin-like cell tumor (10%)
         b) Bronchial carcinoid (2%)
         c) Thymic carcinoid (2%)
      iv. Entero-pancreatic
         a) Gastrinoma (40%)
         b) Insulinoma (10%)
         c) Nonfunctioning including pancreatic polypeptide (20%)
         d) Other (glucagonoma, VIPoma and somatostatinoma) (2%)
   f. Prognosis
      i. Decreased life expectancy, with a 50% probability of death by age of 50, and one half of MEN-1 patients die as a result of a malignant tumoral process or sequela of the disease (Wilkinson et al. 1993; Doherty et al. 1998; Dean et al. 2000)

ii. Pancreatic neuroendocrine tumors are responsible for significant morbidity and mortality in MEN1 kindreds

2. MEN2
   a. Following characteristics in a single patient
      i. Hallmark of MEN2: an extremely high lifetime risk of developing medullary thyroid carcinoma (MTC) (>95% in untreated patients)
      ii. Unilateral or bilateral pheochromocytoma
      iii. Other hyperplasia and/or neoplasia of different endocrine tissues
   b. Signs and symptoms (Richards 2010)
      i. Hypertension if a pheochromocytoma presents
      ii. Chronic constipation: constant finding in MEN2B patients resulting from hyperplasia of the intrinsic autonomic ganglia in the intestinal wall
      iii. A neck mass or dominant thyroid nodule with nontender anterior neck lymph nodes arising insidiously with progressive enlargement: may signify regional metastasis
      iv. MEN2B patients
         a) Marfanoid habitus (high-arched palate, pectus excavatum, bilateral pes cavus, and scoliosis)
         b) Neuromas on the eyelids, conjunctiva, nasal and laryngeal mucosa, tongue, and lips
         c) Prominent hypertrophied lips leading to a characteristic facies.
   c. Presence of three clinical subtypes
      i. MEN2A
      ii. MEN2B
      iii. Familial MTC (FMTC)
3. MEN2A
   a. The most common subtype.
   b. Associated with MTC.
   c. Risk of developing pheochromocytoma (approximately 50%).
   d. Risk of developing primary hyperparathyroidism (30–40%).
   e. Typical age at onset of biochemical evidence of MTC in untreated patients with MEN2A: 15–20 years. However, MTC is frequent in children ages 10 years and younger (Lips et al. 1994; Machens et al. 2003; O'Riordain et al. 1994).
   f. Rare variants of MEN2A can be associated with paraneoplastic syndromes.
      i. Cutaneous lichen amyloidosis
      ii. Excessive production of corticotrophin
      iii. Hirschsprung disease
4. MEN2B
   a. The rarest and most aggressive subtype
      i. Associated with the earliest onset (usually 10 years earlier than that for MEN2A) and most aggressive type of MTC
      ii. Pheochromocytomas (40–50% of patients)
      iii. Multiple neuromas and/or diffuse ganglioneuromatosis of the gastro-enteric mucosa (approximately 40% of patients)
   b. Characteristic facial appearance: resulting from mucosal neuromas in the tongue, lips, and eyelids (Schimke et al. 1968)
      i. Enlarged lips
      ii. A "bumpy" tongue
      iii. Eversion of the eyelids
   c. Often with a thin and lanky (Marfanoid) habitus with increased joint mobility, and with decreased subcutaneous fat
   d. Frequently with thickening of the corneal nerves or ganglioneuromatosis of the gastrointestinal tract, which can result in abdominal distention, megacolon, constipation, or diarrhea
   e. The physical traits: usually evident in early childhood
   f. Without prophylactic thyroidectomy at a young age (before 1 year of age), most patients with MEN2B develop metastatic MTC in childhood or adolescence (O'Riordain et al. 1994)
   g. Patients with MEN2B do not develop primary hyperparathyroidism
5. Familial medullary thyroid carcinoma (FMTC)
   a. MTC is the only clinical feature
   b. Refers to occurrence of medullary thyroid cancer in at least four affected members within the same family with documented absence of other endocrinopathies
   c. Clinical course of MTC
      i. More benign than that of MEN2A and MEN2B
      ii. Prognosis: relatively good in most cases

6. Differential diagnosis of other category of MEN (Callender et al. 2008)
   a. Von Hippel–Lindau syndrome (VHL)
      i. Mutated gene: *VHL*
      ii. Manifestations
         a) Pheochromocytoma
         b) Retinal and central nervous system hemangioblastoma
         c) Renal cysts and clear cell carcinoma
         d) Pancreatic cysts and islet cell tumors
         e) Endolymphatic sac tumors
         f) Papillary cystadenomas of the epididymis and broad ligament
   b. Familial pheochromocytoma/paraganglioma syndrome
      i. Mutated gene: *SDHB, SDHC, SDHD*
      ii. Manifestations: multiple paragangliomas and pheochromocytoma
   c. Cowden syndrome
      i. Mutated gene: *PTEN*
      ii. Manifestations
         a) Nonmedullary thyroid cancer (usually follicular rather than papillary)
         b) Benign and malignant tumors of skin, oral mucosa, breast, and uterus
   d. Carney complex
      i. Mutated gene: *PRKAR1A*
      ii. Manifestations
         a) Endocrine tumors (including thyroid, pituitary, and primary pigmented nodular adrenocortical diseases)
         b) Characteristic skin pigmentation
         c) Myxomas
         d) Melanotic schwannomas
   e. Familial isolated hyperparathyroidism
      i. Mutated gene: *MEN1, HRPT2, CASR*, others
      ii. Manifestations: nonsyndromic primary hyperparathyroidism
   f. Hyperparathyroidism-jaw tumor syndrome
      i. Mutated gene: *HRPT2*
      ii. Manifestations
         a) Primary hyperparathyroidism (usually single adenoma)
         b) Ossifying fibromas of maxilla or mandible
         c) Renal cysts and hamartomas
         d) Fifteen percent risk of parathyroid carcinoma
   g. Familial hypocalciuric hypercalcemia
      i. Mutated gene: *CASR*
      ii. Manifestations
         a) Benign hypercalcemia.
         b) Hypocalciuria.
         c) Low to normal parathyroid hormone levels.
         d) Renal calcium-to-creatinine clearance ratio <0.01.
         e) Parathyroidectomy does not cure hypercalcemia.
   h. Neurofibromatosis type I
      i. Mutated gene: *NF1*
      ii. Manifestations
         a) Pheochromocytoma
         b) Characteristic physical features (e.g., café-au-lait spots, neurofibromas, axillary and inguinal freckling)
   i. Familial adenomatous polyposis
      i. Mutated gene: *APC*
      ii. Manifestations
         a) Hundreds of adenomatous colon polyps
         b) Colon cancer
         c) Cribriform morular variant of papillary thyroid cancer
   j. Familial nonmedullary thyroid cancer
      i. Mutated gene: unknown
      ii. Manifestations: nonsyndromic nonmedullary thyroid cancer

Diagnostic Investigations

1. Diagnosis of component tumors in MEN1 (Callender et al. 2008)
   a. Hyperparathyroidism
      i. An elevated or high-normal serum calcium level in concordance with an inappropriately elevated serum parathyroid hormone level
      ii. A 24-h urine collection documenting no evidence of hypocalciuria (urinary calcium excretion <100 mg/24 h) should be performed to exclude the possibility of familial hypocalciuric hypercalcemia
   b. MEN1-related pituitary adenomas
      i. Most common functioning tumors produce prolactin (prolactinomas), growth hormone (somatotropinomas), or corticotropin
      ii. Approximately 15% of tumors are nonfunctioning with no hormone production (DeLellis et al. 2004)

c. Pancreatic and duodenal tumors
   i. Gastrinomas
      a) Gastrin level usually >1,000 pg/mL
      b) A rise in the gastrin level of >200 pg/mL by a secretin stimulation test confirms the diagnosis
      c) Tumors localized by a combination of octreotide scan, CT, and endoscopic ultrasonography
   ii. Insulinomas presents as "Whipple's triad":
      a) Fasting or exercise-induced hypoglycemia
      b) Plasma glucose level <50 mg/dL
      c) Reversal of symptoms with administration of glucose
      d) Localized by CT and endoscopic ultrasonography
   iii. Glucagonomas
      a) A serum glucagons level >1,000 pg/mL
      b) A secretin stimulation test may be useful
      c) Localized with an octreotide scan, CT, and endoscopic ultrasonography
   iv. Vasoactive intestinal peptide tumors (VIPomas)
      a) Fasting plasma vasoactive intestinal peptide (VIP) levels >200 pg/mL
      b) VIPomas: usually located in the body and tail of the pancreas and are localized by an octreotide scan, CT, and endoscopic ultrasonography
   v. Somatostatinoma
      a) A fasting somatostatin level of >100 pg/mL
      b) Localized with an octreotide scan, CT, and endoscopic ultrasonography
   vi. Nonfunctioning MEN1-associated pancreatic endocrine tumors: localized by an octreotide scan, CT, and endoscopic ultrasonography
d. Other tumor types: not part of the diagnostic criteria for MEN1, but their presence helps to support a diagnosis of MEN1
   i. Foregut (thymic, bronchial, or gastric) carcinoid tumors
   ii. Adrenal cortex tumors (adenomas, pheochromocytoma, adrenocortical carcinomas)
   iii. Thyroid tumors (follicular adenomas, goiters, nonmedullary thyroid carcinoma)
   iv. Benign facial angiomas
   v. Collagenomas of the neck, upper limbs and chest
   vi. Subcutaneous or visceral lipomas
   vii. Uterine or esophageal leiomyomas
   viii. Meningiomas
   ix. Spinal ependymomas

2. Diagnosis of component tumors in MEN2 (Falchetti et al. 2008).
   a. Medullary thyroid carcinoma
      i. Pentagastrin or calcium stimulation to evaluate calcitonin secretion: earlier detection of MTC
      ii. Ultrasonography, CT, or MRI: localize tumor extension and possible distant metastases
   b. Pheochromocytoma
      i. 24-h measurement of urinary excretion of catecholamines and their metabolites to assess adrenal gland function: recommended on an annual basis
      ii. CT and MRI to localize the tumor
   c. Primary hyperparathyroidism: diagnosis made by elevated serum PTH and calcium concentrations
3. Routine surveillance of presymptomatic patients and treated patients who are currently without evidence of disease (Brandi et al. 2001).
   a. Annual biochemical testing for all tumor types
      i. Parathyroid: serum calcium, parathyroid hormone (starts to screen at age of 8 years)
      ii. Gastrinoma: serum gastrin (starting at age of 20 years)
      iii. Insulinoma: fasting serum glucose, insulin (starting at age of 5 years)
      iv. Other enteropancreatic: chromogranin A, glucagons, proinsulin (starting at age of 20 years)
      v. Anterior pituitary: prolactin, insulin-like growth factor 1 (starting at age of 5 years)
   b. Imaging studies (CT or MRI) every 3 years
      i. Other enteropancreatic: octreotide scan, CT, or MRI (starting at age of 20 years)
      ii. Anterior pituitary: MRI of the brain (starting at age of 5 years)
      iii. Foregut carcinoid: CT (starting at age 30 years)
4. Molecular genetic testing for MEN1
   a. Should be offered to patients in whom a diagnosis of MEN1 is being considered.
   b. The benefit of offering genetic testing: a diagnosis of MEN1 at an early age allows

patients to be monitored for the development of subsequent MEN1-related tumors
   c. Sensitivity of genetic testing: varies, depending on the combination of affected organs and whether the patient is an index or familial case
   d. Mutations can be identified in only 75–90% of patients with a clinical diagnosis of MEN1.
      i. A negative test result cannot definitively rule out the risk for further MEN1-related tumors
      ii. Follow-up screening recommendations in such cases are controversial and require careful consideration of the index of suspicion of MEN1 based on the patient's personal and family history.
5. Molecular genetic testing for MEN2 (Moline and Eng 2010)
   a. MEN2A
      i. Approximately 95% of families with MEN 2A have a *RET* mutation in exon 10 or 11.
      ii. Other rare mutations, including codon 804 alterations, have been reported in a few cases
   b. MEN2B
      i. Approximately 95% of individuals with the MEN2B phenotype have a single point mutation in the tyrosine kinase domain of the *RET* gene at codon 918 in exon 16 (M918T).
      ii. Other rare mutations include second mutation at codon 883 in exon 15 (A883F) and two mutations (V804M and Y806C) in cis configuration
6. Molecular genetic testing for FMTC (Moline and Eng 2010): approximately 88% of families with FMTC have an identifiable *RET* mutation.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a 50% risk if a parent is affected or has a disease-causing mutation
   b. Patient's offspring: a 50% risk of inheriting the mutation
2. Prenatal diagnosis: possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells by amniocentesis or CVS, provided the disease-causing allele of an affected family member must be identified or linkage established in the family
3. Management
   a. MEN1 (Callender et al. 2008)
      i. Parathyroidectomy for parathyroid tumors
      ii. Transcervical thymectomy because there is an increased risk of supernumerary parathyroid glands and developing carcinoid tumors in the thymus
      iii. Pituitary tumors
         a) Surgery (usually from a minimally invasive transsphenoidal approach)
         b) Medication for patients with prolactin- or growth hormone–producing tumors with dopamine agonists, such as bromocriptine or cabergoline, and a GH receptor antagonist, respectively
         c) Radiation
      iv. Gastrinomas
         a) Proton pump inhibitors for medical control of acid hypersecretion
         b) Surgical approaches: no consensus
      v. Insulinomas
         a) Manage surgically
         b) Treat unresectable tumors with diazoxide (Proglycem)
      vi. VIPoma
         a) Manage surgically
         b) Octreotide (Sandostatin) for diarrhea control
   b. MEN2 (Falchetti et al. 2008)
      i. Medullary thyroid carcinoma
         a) Total thyroidectomy with lymph node dissection of at least the central compartment.
         b) An elevated serum calcitonin level after surgery can be a sign of persistent, recurrent or generalized MTC.
         c) Total thyroidectomy within the first month of life should be performed in patients with the highest risk mutations (MEN2B, codons 883 and 918) (Lewis and Yeh 2008).
      ii. Pheochromocytoma
         a) Surgical laparoscopy excision.
         b) Recommend lifelong follow-up after surgery.
         c) Long-term drug treatment with α and β adrenergic blockers should only be considered in those patients in whom the tumor is unresectable.

iii. Primary hyperparathyroidism
   a) Subtotal parathyroidectomy or total parathyroidectomy with autotransplantation of normal fresh or cryopreserved tissue in the forearm.
   b) All individuals who have undergone partial or total parathyroidectomy with autotransplantation need to be monitored for possible recurrences.

Fig. 1 (**a**–**c**) The patient, a 13-year-old Caucasian female, was seen initially because of a history of weight loss of approximately 17 lb over a period of 4–6 weeks and a mass in her neck. The biopsy of the neck mass revealed a medullary thyroid carcinoma. She has a long history of developmental delay and an unusual appearance with a thin body habitus, long face, and full kips. *MEN2* mutation screening revealed a sequence change in exon 16 of 2,753T > C (ATG > ACG) with an amino acid change of M918T (Met918Thr). The presence of this mutation in codon 918 of the RET proto-oncogene is consistent with a clinical diagnosis of MEN2B

Multiple Epiphyseal Dysplasia

In 1945, Fairbank first described multiple epiphyseal dysplasia (MED). MED is a type of short-limbed dwarfism characterized by impaired endochondral ossification affecting multiple epiphyses and premature degenerative joint disease.

Synonyms and Related Disorders

Autosomal dominant multiple epiphyseal dysplasia (Fairbank type, Ribbling type); Autosomal recessive multiple epiphyseal dysplasia (with bilayered patellae, with clubfoot)

Genetics/Basic Defects

1. Inheritance: genetically heterogeneous
   a. Autosomal dominant (Briggs et al. 2011)
      i. Multiple epiphyseal dysplasia type I (EDM1)
      ii. Multiple epiphyseal dysplasia type II (EDM2)
      iii. Multiple epiphyseal dysplasia type III (EDM3)
      iv. Multiple epiphyseal dysplasia type V (EDM5)
      v. Multiple epiphyseal dysplasia type VI (EDM6)
   b. Autosomal recessive: multiple epiphyseal dysplasia type IV (EDM4)
2. Causes
   a. EDM1: mutations in the gene (*COMP*) encoding cartilage oligomeric matrix protein (COMP) on the centromeric region of 19p (19p13.1-p12), same locus as (allelic to) pseudoachondroplasia (the disease that shares some clinical features with multiple epiphyseal dysplasia)
   b. EDM2: mutations in the type IX collagen, alpha-1 polypeptide gene (*COL9A1*) on 6q13
   c. EDM3: mutations in the type IX collagen, alpha-2 polypeptide gene (*COL9A2*) on 1p33-p32.2
   d. EDM4
      i. Mutations in the diastrophic dysplasia sulfate transporter gene (*DTDST*) on 5q32-q33.1
      ii. Recessive mutations in the *DTDST* gene also cause a spectrum of osteochondrodysplasias, including achondrogenesis type IB, atelosteogenesis type II, and diastrophic dysplasia
   e. EDM5: mutations in the gene (*MATN3*) encoding matrilin-3 on 2p24-p23
   f. EDM6: mutations in the type IX collagen, alpha-3 polypeptide gene (*COL9A3*) on 20q13.3
3. Mutations in extracellular matrix proteins, COMP, types II and IX collagens, and matrilin-3
   a. Produce a spectrum of mild to severe chondrodysplasias characterized by epiphyseal and vertebral abnormalities
   b. Disrupt protein processing and excessive accumulation of some of these proteins in the rER that appears to compromise cellular function
4. Genotype-phenotype correlations (Briggs et al. 2011)
   a. Patients with *COMP* mutations
      i. Significant involvement at the capital femoral epiphyses
      ii. Irregular acetabuli
   b. Patients with type IX collagen defects
      i. More severe involvement of the knees
      ii. Relative sparing of the hips
   c. Patients with *MATN3* mutations
      i. Abnormalities similar to those in patients with *COL9A2* mutations: more severe hip abnormalities
      ii. More intrafamilial/interfamilial variability

Clinical Features

1. Broad historical classification: has not proved useful
   a. Ribbing: milder form with flat epiphyses and minimal involvement of the hands and feet
   b. Fairbank: more severe form with late appearing epiphyses and greater involvement of the hands and feet
2. Onset usually in childhood: as a rule, not recognizable at birth or during the first 1–2 years of life
   a. Joint pain after exercise initially: a common presenting sign
   b. Limp, pain, and stiffness in hip, knee, and ankle joints
   c. Waddling gait
   d. Easy fatigue
3. Mild to moderate short stature with normal body proportion
4. Mild short-limbed dwarfism
5. Stubby hands and feet
6. Osteoarthritis: severe osteoarthritis of the hip develops in early childhood.
7. Limited joint motions
8. Proximal muscle weakness with mild variability in muscle fiber size in EDM3
9. Association with diabetes mellitus in early infancy (Wolcott-Rallison syndrome)
10. Consider MED (Unger et al. 2008) in:
    a. Any child with bilateral Perthes disease
    b. Any child with noninflammatory joint pain, especially involving the knees
    c. Family history of early joint replacement
11. Prognosis
    a. Normal life expectancy
    b. Joint deformities resulting from abnormal epiphyseal ossification frequently leading to early degenerative arthroses
12. Distinctive features of the different forms of MED (Unger et al. 2008)
    a. EDM1 (COMP-MED)
       i. Distinctive clinical features
          a) Muscular hypotonia
          b) Pseudomyopathy
          c) Joint laxity
          d) Mild genu vara
       ii. Distinctive radiographic features
          a) Hand: carpal bones more delayed than phalangeal epiphyses; ragged carpal bones, small, rounded phalangeal epiphyses
          b) Proximal femoral epiphyses: round and small
          c) Knee: small epiphyses with lateral thinning, additional ossification centers with "glacier crevice" sign before puberty
    b. EDM4 (rMED)
       i. Homozygous and compound heterozygous mutations in the *DTDST* gene lead to a relatively mild phenotype that seems to be clinically dominated by a tendency to recurrent dislocation of a bilateral multilayered patella and by early-onset osteoarthritis of the hip joints (Miyake et al. 2008; Cho et al. 2010; Hinrichs et al. 2010).
       ii. Distinctive clinical features
          a) Club feet at birth
          b) Genu valga rather than genu vara
          c) Joint contractures
          d) Mild to moderate brachydactyly
       iii. Distinctive radiographic features
          a) Hand: phalangeal epiphyses delayed, but maturation of carpal bones normal or advanced; flat epiphyses or phalanges and radius; "snow cap" sign of metacarpals
          b) Proximal femoral epiphyses: small and flat
          c) Knee: double-layered patella
    c. EDM5 (MATN3-MED)
       i. Distinctive clinical features: not specific
       ii. Distinctive radiographic features
          a) Hand: unspecific changes at the hands
          b) Proximal femoral epiphyses: small but not as rounded as in COMP-MED
          c) Knee: small epiphyses with "harlequin hat" appearance; metaphyseal striations
    d. EDM2 (*COL9A2*)
       i. Rare but may be under reported
       ii. Knee epiphyses: more affected than proximal femoral epiphyses
    e. EDM3 (*COL9A3*)
       i. Rare but may be under reported
       ii. Knee epiphyses: more affected than proximal femoral epiphyses
    f. EDM6 (*COL9A1*): Very rare (only single family reported)

Diagnostic Investigations

1. Radiography
   a. Radiographic abnormalities may be present before the onset of physical symptoms.
   b. Predominantly epiphyseal involvement
      i. Initial stage: delayed appearance of epiphyseal ossification
      ii. Later stage in the appearance of epiphysis
         a) Usually small ossification centers
         b) Sometimes fragmented ossification centers with irregular contours
         c) Adjacent metaphyseal borders may be slightly abnormal.
      iii. Adulthood
         a) Flattened and dysplastic articular surfaces
         b) Presence of early features of osteoarthrosis
      iv. Characteristic epiphyseal involvement
         a) Epiphyses of the hips and knees: most affected
         b) Ivory epiphyses in the hands
         c) Schmorl nodes in the spine
         d) Double-layered patella
   c. Vertebrae
      i. Ovoid vertebral bodies
      ii. Mildly irregular vertebral endplates
   d. Limbs
      i. Late ossifying epiphyses
      ii. Small, irregular, fragmented, and in some cases flattened epiphyses
      iii. Osteoarthritis
      iv. Short femoral neck
      v. Markedly dysplastic capital femoral epiphyses
      vi. Often initially diagnosed as Legg-Perthes disease (avascular necrosis of femoral head)
      vii. Genu varum or valgum
      viii. Short metacarpals and phalanges with irregular epiphyses
      ix. Small, irregular carpal and tarsal bones
      x. Normal metaphyses
   e. Irregular acetabuli
   f. Patella
      i. Doubled-layered
      ii. Dislocation or subluxation
   g. Absence of severe spinal involvement and minimal metaphyseal defects allows differentiating multiple epiphyseal dysplasia from other disorders with similar clinical features such as spondyloepimetaphyseal dysplasia and spondyloepiphyseal dysplasia.
2. Histology: chondrocytic inclusion (ultrastructurally, a dilated rER containing accumulated material)
3. Molecular genetic diagnosis is important for accurate prognosis and genetic counseling: mutation analyses are available on clinical basis
   a. Mutations in the *COMP* gene
   b. Mutations in the *COL9A1* gene
   c. Mutations in the *COL9A2* gene
   d. Mutations in the *COL9A3* gene
   e. Mutations in the *MATN3* gene
   f. Mutations in the *DTDST* gene

Genetic Counseling

1. Recurrence risk
   a. Autosomal dominant inheritance
      i. Patient's sib
         a) 50% if one of the parent is affected
         b) Not increased if parents are normal
      ii. Patient's offspring: 50%
   b. Autosomal recessive inheritance
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is also carrying the gene
2. Prenatal diagnosis for pregnancies at risk for *COMP* and other mutations is possible if the disease-causing allele of an affected family member has been identified.
   a. Amniocentesis
   b. CVS
3. Management (Briggs et al. 2011)
   a. Initial aims of management
      i. Control pain
         a) Can be difficult
         b) Combination of analgesics and physiotherapy including hydrotherapy
      ii. Limit joint destruction and the development of osteoarthritis
   b. Weight control
   c. Avoid exercise that causes repetitive strain on affected joints

d. Realignment osteotomy and/or acetabular osteotomy to slow the progression of symptoms
e. Total joint arthroplasty in some cases
f. Psychosocial support to address issues of short stature, disability, and employment

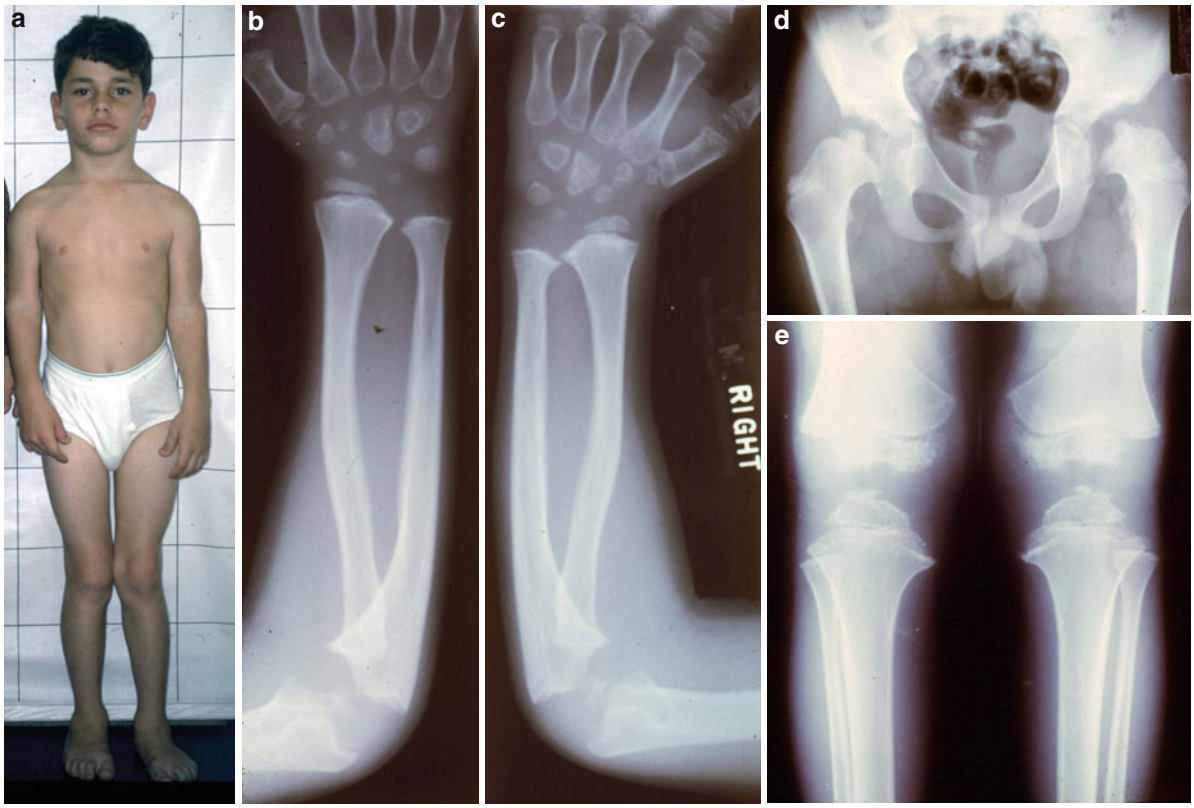

Fig. 1 (**a**–**e**) A boy with multiple epiphyseal dysplasia showing short stature and epiphyseal dysplasia in the wrists, hips, and knee joints

Fig. 2 (**a**, **b**) A girl and an adult female with multiple epiphyseal dysplasia showing mild short stature with normal body proportion

Fig. 3 Radiograph of the pelvis of a 12-year-old boy with multiple epiphyseal dysplasia showing poorly developed acetabular fossae and flat, fragmented femoral heads

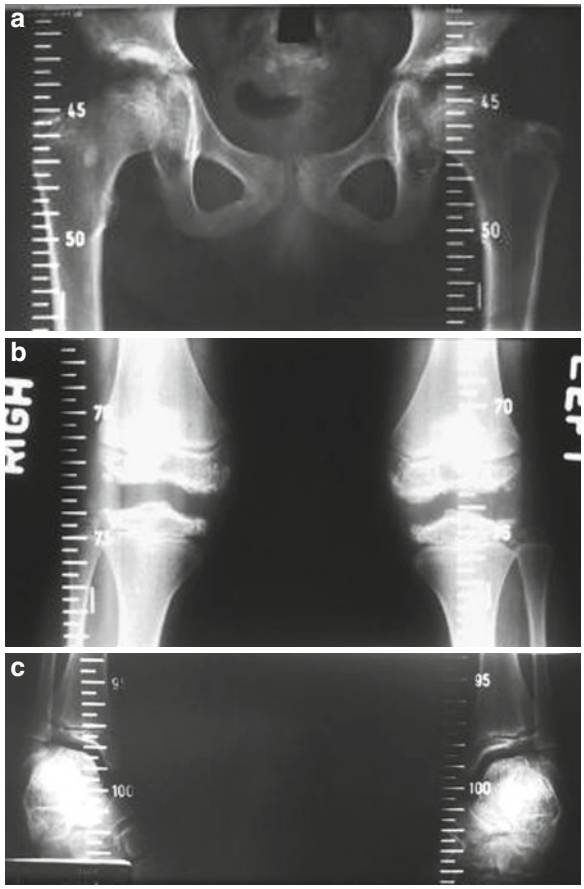

Fig. 4 (**a**–**c**) Radiographs of another patient with multiple epiphyseal dysplasia showing poorly formed acetabular fossae, poorly ossified femoral heads, and flattened epiphyses of the knees and ankles

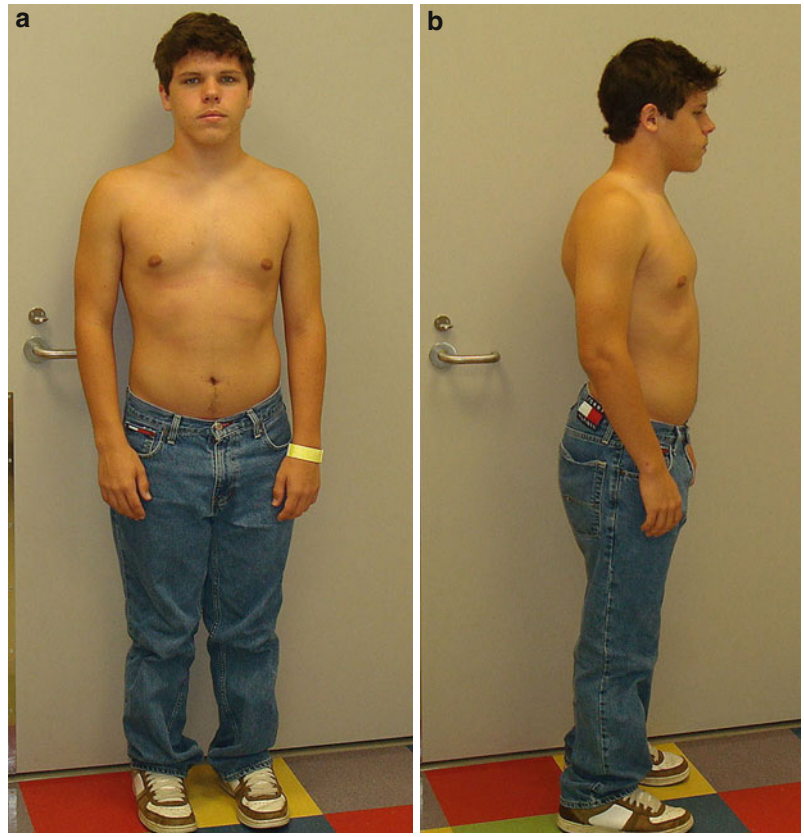

Fig. 5 (**a**, **b**) A 13 year old boy with multiple epiphyseal dysplasia has been complaining pain in knees, legs, and feet since 4 years of age. He was also noted to have limp, joint stiffness, and worsening waddling gait. Mutation analysis showed a heterozygous G > A nucleotide substitution in exon 16, resulting in the replacement of an aspartic acid codon (GAC) with an asparagine codon (AAC) at amino acid position 605 (c.1813G > A or p.Asp605Asn (D605N)). The D605N missense mutation in the COMP gene has been reported previously in association with multiple epiphyseal dysplasia and is consistent with the diagnosis of this patient

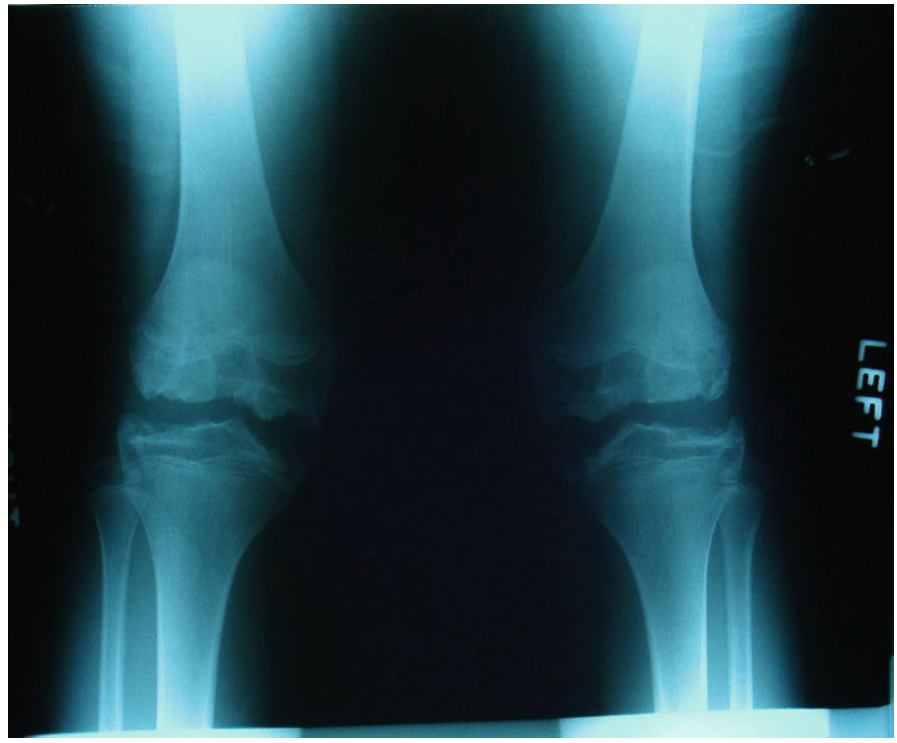

Fig. 6 Radiographs of the same patient showing epiphyseal dysplasias at the distal femoral epiphyses and the proximal tibial epiphyses causing weakness and pains at the knees

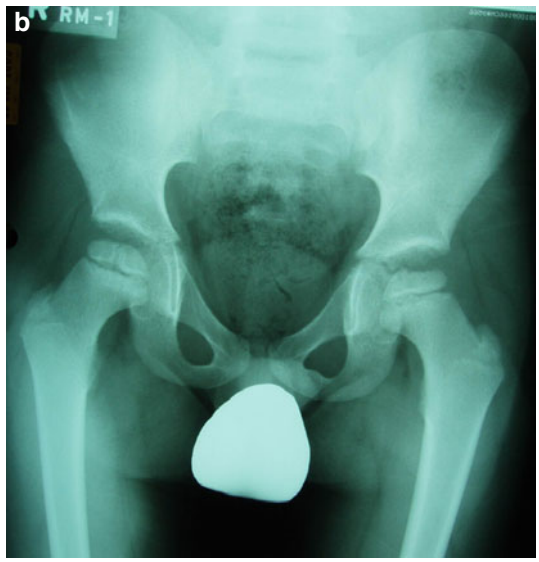

Fig. 7 (**a**, **b**) A 12-year-old boy with multiple epiphyseal dysplasia. Radiograph of the pelvis at 8 years of age showed poorly developed acetabular fossae and flat femoral heads

Fig. 8 A 10-year old girl was seen because of short stature. The radiographs were consistent with multiple epiphyseal dysplasia. DNA sequencing revealed a c.1445A > G transition in exon 13 of the *COMP* gene. This change converts a codon for aspartic acid (GAC) to a codon for glycine (GGC). The patient is heterozygous for the mutation. The mutation confirms the diagnosis of multiple epiphyseal dysplasia. She was also diagnosed to have growth hormone deficiency and was receiving daily Humatrope injection

Fig. 9 Note the short upper arms with short fingers

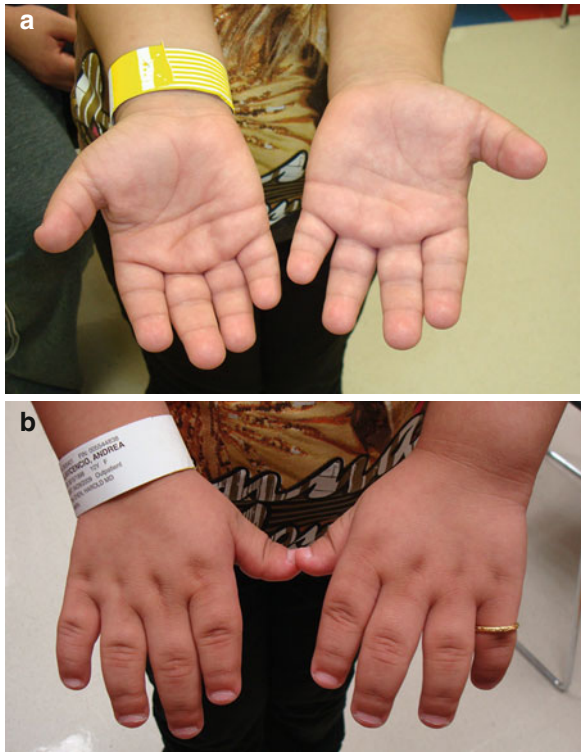

Fig. 10 (**a**, **b**) Note the short and stubby fingers

Fig. 11 Note short and stubby toes

Fig. 12 Hip radiograph 6 months earlier shows poorly developed acetabular fossae and flat fragmented femoral heads

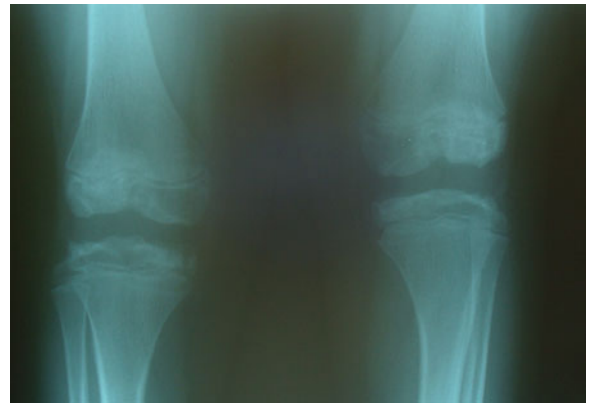

Fig. 13 Knee radiograph shows flattened epiphyses of the knees

Fig. 14 Hand radiograph shows short and broad phalanges

Fig. 16 Radiograph of feet shows short and stubby phalanges

Fig. 15 Radiograph of left upper extremity shows relatively short tubular bones with small proximal epiphysis of the left humerus

Multiple Pterygium Syndrome

Multiple pterygium syndrome is a distinct syndrome consisting of a constellation of congenital anomalies characterized by pterygia of the neck, antecubital, popliteal and intercrural areas, numerous flexion contractures of the joints, growth retardation, ptosis, antimongoloid slant with or without epicanthal folds, cleft palate, scoliosis, vertebral anomalies, rocker-bottom deformity of the feet, and genital anomalies.

Synonyms and Related Disorders

Escobar syndrome

Genetics/Basic Defects

1. Inheritance: genetic heterogeneity (Chen 2009)
   a. Autosomal recessive inheritance in most cases
      i. Recessive forms of MPS: clinically and genetically heterogeneous.
         a) May result from early-onset fetal akinesia
         b) Traditionally classified into prenatally lethal MPS and nonlethal Escobar variant-MPS
      ii. Escobar syndrome: Mutations in *CHRNG* gene, which encodes the acetylcholine receptor γ-subunit cause the autosomal recessive Escobar syndrome, one of the most common types of MPS, although other genes may be involved (Hoffmann et al. 2006; Morgan et al. 2006; Prontera et al. 2007).
      iii. Escobar syndrome has been recently described as a prenatal form of myasthenia associated with recessive mutations in genes of the neuromuscular junction (*CHRNG*, *CHRNA1*, *CHRNB1*, *CHRND*, and *RAPSN*) (Hoffmann et al. 2006; Morgan et al. 2006; Michalk et al. 2008; Vogt et al. 2008). This observation expands the cause of Escobar variant-MPS to a component of the contractile apparatus.
      iv. The first report of the clinical expression of the complete absence of TPM2 in human indicated that TPM2 expression at the early period of prenatal life plays a major role for normal fetal movements (Monnier et al. 2009).
      v. Clinical features.
         a) Multiple joint contractures with marked pterygia
         b) Dysmorphic facies (flat, sad, motionless facial appearance)
         c) Cervical vertebral anomalies
   b. Autosomal dominant inheritance in some cases (Mckeown and Harris 1988)
      i. Great variation in severity between affected individuals
      ii. Characterized by multiple pterygia with or without mental retardation
   c. X-linked inheritance (MacArthur and Pereira 1996)
   d. Sporadic occurrence (Ramer et al. 1988; Spranger et al. 1995; Aslani et al. 2002)
2. Phenotypic analysis
   a. Multiple congenital pterygia, joint contractures, and severe foot defects: deformation sequence secondary to reduced frequency of fetal movement
   b. Micrognathia: resulting from reduced use and represents "disuse hypotrophy"

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_170,
© Springer Science+Business Media, LLC 2012

   c. Cleft palate: a mechanical disruption due to presumed interposition of tongue between palatine shelves
   d. Neck pterygia
      i. Able to exert a downward pull on facial structures
      ii. Responsible for the following effects:
         a) Down-turned angles of the mouth
         b) Long philtrum
         c) Antimongoloid slant of palpebral fissures
         d) Low posterior hairline
         e) Anteversion and apparently low-set position of auricles
         f) Often with strikingly abnormal directional hair patterning in posterior and posterior-lateral areas of scalp
      iii. Short neck due to:
         a) Lateral cervical pterygia
         b) Secondary fusion of upper vertebrae
   e. Congenital scoliosis: secondary to abnormal prenatal position, movement, and/or muscle pull
   f. Genital anomalies
      i. Small scrotum and apparently absent or hypoplastic labia majora: resulting from the pull of the intercrural pterygia which affects a flattening of these structures
      ii. Cryptorchidism: representing mechanical obstruction of the processus vaginalis from pull of intercrural web or some intrinsic defect of the gubernaculums testis which is unable to effect descent of the gonads
3. Pathogenesis
   a. The underlying pathogenesis of the secondary deformities and distortions, hypotrophies, disruptions, bony fusions, and incomplete or impeded morphogenetic movements is unknown
   b. A neuromuscular disease causing fetal akinesia (Chen et al. 1980; Bhargava et al. 2002) is suspected.
   c. Intrauterine crowding and oligohydramnios are contributory factors to joint contractures associated with MPS (Chen 2009).

Clinical Features

1. Short stature
2. Cutaneous and musculoskeletal
   a. Pterygia involving the following areas:
      i. Neck
      ii. Axillary
      iii. Antecubital
      iv. Popliteal
      v. Digital
      vi. Intercrural
   b. Multiple joint contractures
   c. Rib or vertebral anomalies
   d. Scoliosis/lordosis
   e. Rocker-bottom feet with vertical talus
3. Standing with a crouching or semi-crouching stance
4. Orofacial features
   a. A flat, sad, motionless facial appearance
   b. Epicanthal folds
   c. Ptosis
   d. Antimongoloid palpebral fissure
   e. Long philtrum
   f. Pointed, receding chin
   g. Down-turned angles of the mouth
   h. Cleft lip+/− palate
   i. Apparent low-set ears
5. Genitalia
   a. Males
      i. Small penis and scrotum
      ii. Cryptorchidism
   b. Females
      i. Apparent aplasia of the labia majora
      ii. A small clitoris

Diagnostic Investigations

1. Radiography
   a. Multiple joint contractures
   b. Fusion of cervical vertebrae
   c. Scoliosis/lordosis
   d. Flexion contractures of fingers
   e. Rocker-bottom feet with vertical talus
2. Pathological evaluations of muscle and nerve tissue: no consistent abnormality

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive inheritance: 25%
      ii. Autosomal dominant inheritance: not increased unless a parent is also affected

   b. Patient's offspring
      i. Autosomal recessive inheritance: not increased unless the spouse is a carrier
      ii. Autosomal dominant inheritance: 50%
2. Prenatal diagnosis possible by ultrasonography for the family at risk
   a. Micrognathia
   b. Low-set ears
   c. Hypertelorism
   d. Cystic hygroma colli
   e. Rocker-bottom feet
3. Management (McCall and Budden 1992)
   a. Correction of the hand deformities
      i. Attention given to any deformities in the shoulder and elbow to maximize function of the limb before initiating correction of hand deformities
      ii. Intensive physiotherapy and occupational therapy preferable to surgery for management of the upper extremity and hand anomalies
   b. Correction of mild hip flexion contractures of $<30^\circ$ due to inguinal webbing and crouched stance: responding well to active and passive stretching programs
   c. Correction of popliteal webbing
      i. Physiotherapy.
      ii. Traction.
      iii. Popliteal skin web Z-plasty with serial casting or with cable grafting the sciatic nerve (to achieve further knee extension and independent ambulation).
      iv. Arthrodesis.
      v. Amputation.
      vi. Excision of a significant fibrous band extending from the ischium to the calcaneus allows significant improvement in extension.
   d. Correction of knee flexion contracture $<25^\circ$ without severe ambulatory limitations: conservative, consisting of a stretching program and night splints
   e. Correction of knee flexion contracture of 25–90°
      i. Physiotherapy followed by popliteal Z-plasty, fibrous band excision, and lengthening of all tense structures that are not neurovascular
      ii. Post-operative serial casting
      iii. Cable grafting or femoral shortening for neurovascular compromised cases
   f. Correction of knee flexion contracture of $>90^\circ$ which poses significant ambulatory difficulty
      i. Arthroses in extension
      ii. Disarticulation
   g. Correction of vertical talus
      i. Children 6 years or younger: treated with soft tissue procedures and/or Grice subtalar arthrodeses
      ii. Children over 6 years: undergo triple arthrodesis at age 12

Fig. 1 (**a**–**f**) Two Honduran siblings (a 5-year-old girl and a 9-year-old boy) with multiple pterygium syndrome showing multiple pterygia involving neck, axillary, antecubital, popliteal, and intercrural areas. In addition, they had multiple joint contractures affecting hips, elbows, and interphalangeal, and popliteal joints; semi-crouching stance; and rocker-bottom feet due to vertical tali. Vigorous physiotherapy was performed initially for both upper and lower extremity contractures. Popliteal Z-plasty with release of the posterior capsule and excision of a fibrous band extending from the ischial tuberosity to the calcaneus resulted in better knee extension, but further correction was limited by tight neurovascular structures. Vertical tali were addressed surgically with triple arthrodeses on the boy at age 12, and soft tissue release combined with a Grice subtalar arthrodesis on the girl at age 6. Both children attained painless plantigrade feet at discharge

Fig. 2 (**a**–**i**) Three Nicaraguan siblings (parents are third cousins) with multiple pterygium syndrome showing similar features. Radiographs showed rocker-bottom feet with vertical talus and the fusion of cervical vertebrae. Patient 1 (a 7-year-old boy) had motionless facial appearance, cleft palate, multiple flexion contractures, and severe webbing at the antecubital and popliteal fossae, and interphalangeal regions. He also had severe foot deformities with calcaneus heels and vertical talus. Patient 2 (a 9-year-old girl) crawled at 4 years of age but had never walked. She was much more severely affected. Patient 3 (an 11-year-old boy) walked with difficulty but much less severely affected than younger brother and sister. Digital deformities were addressed surgically with some recurrence of original deformities. Hip flexion contractures were addressed with an active stretching program and prone positioning, resulting in satisfactory resolution. Popliteal webbing was treated by either physiotherapy alone and/or operative procedures. Bilateral congenital tali were treated by either bilateral talectomy or arthrodesis with partial talectomies

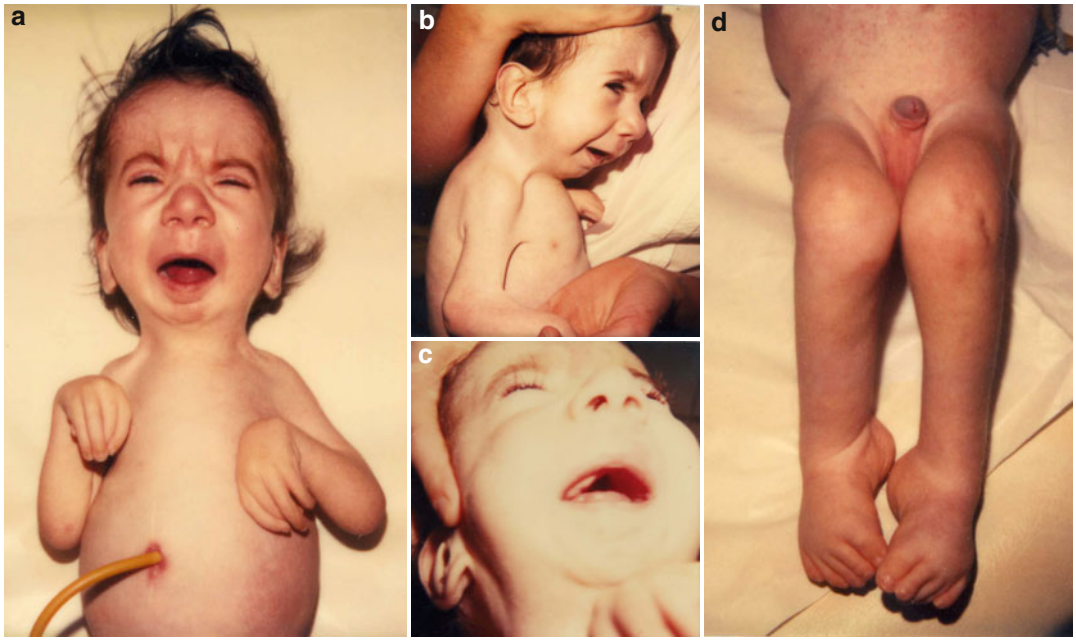

Fig. 3 (**a**–**d**) A boy with a sporadic case of multiple pterygium syndrome showing multiple pterygia, long philtrum, receding chin, cleft palate, low-set ears, and multiple contractures

Fig. 4 (**a**–**c**) An 11-year-old girl with typical Escobar syndrome with severe kyphoscoliosis

Myotonic Dystrophy Type I

Myotonic dystrophy type 1 (DM1) is the most common form of muscular dystrophy affecting adults with an estimated incidence of 1 in 8,000 among Caucasians (Brook et al. 1992).

Synonyms and Related Disorders

Myotonic dystrophy type 1 (dystrophia myotonica 1; Steinert disease); Myotonic dystrophy type 2 (dystrophia myotonica 2, proximal myotonic myopathy, proximal Ricker syndrome)

Genetics/Basic Defects

1. Inheritance: autosomal dominant with an anticipation phenomenon (Harley et al. 1993)
2. Molecular genetic perspective (Brook et al. 1992)
   a. Considerable variability of phenotype between affected individuals even within the same family
   b. An association of myotonic dystrophy with specific haplotypes in the population, indicating that most cases have resulted from a small number of genetic events
   c. Multisystemic nature of the phenotype
   d. An apparent increase in severity of symptoms and reduction in age at onset that is observed during transmission of the gene within families
3. Genetic defect: caused by an expanded CTG (cytosine-thymine-guanine) repeat in the dystrophia myotonica phosphokinase (*DMPK*) gene
   a. Encodes for a serine-threonine protein kinase
   b. Mapped on chromosome 19q13.3
4. CTG triplet repeat
   a. Transcribed and located in the 3′ untranslated region of an mRNA that is expressed in tissues affected by myotonic dystrophy
   b. Repeat size
      i. Highly variable in the normal population (5–36 triplets)
      ii. Undergoing expansion in myotonic dystrophy patients (50 to several thousand copies)
         a) Expansion of at least 50 repeats in patients who are minimally affected
         b) Expansion of up to several kilobase pairs in more severely affected patients
   c. Intergenerational instability (unstable CTG expansion at mitotic and meiotic levels with a bias toward length increase in the successive generations)
      i. Accounting for anticipation (the CTG repeat size increases in successive generations in parallel with increasing severity of the disease)
      ii. Accounting for somatic instability and mosaicism (the CTG repeat size varies considerably among different tissues and organs with coexistence in the same subject of cell lines with different CTG repeats)
   d. Genotype-phenotype correlations (Finsterer et al. 2001)
      i. Size of the CTG trinucleotide repeats generally correlated with the age of onset and clinical severity of the disease
      ii. Longer CTG repeat expansions correlate, in general, with an earlier age of onset and more severe disease.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_171,
© Springer Science+Business Media, LLC 2012

iii. Relation of cardiac abnormalities and CTG repeat size in myotonic dystrophy
  a) Increased cardiac involvement with increasing CTG repeat size in patients age 21–50
  b) The number of CTG repeats needed to develop a reasonable cardiac involvement is higher in young patients than in older patients.

Clinical Features

1. Highly variable phenotypic expression and age of onset
   a. The mildest form
      i. Seen in middle or old age (>50)
      ii. Characterized by cataracts and baldness with little or no muscle involvement
      iii. CTG repeats: 50–100
      iv. Occasionally difficult to diagnose: The pleomorphic manifestations, due to a dynamic mutation in the length of CTG repeat, lead to difficulty in clinical identification of asymptomatic or mildly affected patients.
   b. The classic (juvenile or adult) form
      i. The more common form
      ii. Usually becoming evident between the ages of 15 and 35 years
      iii. CTG repeats: 100–1,000
      iv. Phenotypically variable
      v. Characteristic clinical features
         a) Myotonia
         b) Muscle weakness
         c) Cardiac arrhythmias
         d) Male balding
         e) Hypogonadism
         f) Psychocognitive dysfunction
         g) Glucose intolerance
   c. The childhood form
      i. Age at onset: 1–10
      ii. CTG repeats: 500–>2,000
      iii. Clinical manifestations
         a) Hypotonia
         b) Learning difficulties
         c) Limited motor skills
   d. The most severe (congenital) form
      i. Recognized at birth or in the neonatal period
      ii. Pregnancy
         a) Maternal polyhydramnios
         b) Reduced fetal movement
         c) Breech presentation
         d) Prematurity
      iii. Associated with generalized muscular hypotonia
      iv. Respiratory distress
         a) Aspiration pneumonia
         b) Recurrent bronchitis
         c) Hypoventilation
         d) Sleep apnea
         e) Bronchiectasis
      v. Feeding difficulties
      vi. Dysphagia
      vii. Nasal regurgitation
      viii. Facial diplegia with a "tented-shaped" mouth
      ix. Delayed motor development
      x. Joint deformities
      xi. Mental retardation
      xii. High neonatal mortality
      xiii. Those survived invariably exhibiting the classical form of the disease in late childhood or adolescence
      xiv. Almost all congenital cases are exclusively maternally transmitted
      xv. CTG repeats: 1,000–5,000
      xvi. The phenomenon of anticipation often most strikingly manifested in a family producing a congenitally affected child
2. Neurologic manifestations
   a. Myotonia (100%) (Miller 2008)
      i. Delayed relaxation of muscles after an initial voluntary contraction or percussion.
      ii. Muscle stiffness that improves with repeated use of the muscle, the so-called warm-up phenomenon.
      iii. On examination, myotonia may be apparent from the first handshake, presenting with a delayed release of the hand. This can also be appreciated by asking the patient to repeatedly grip and release the examiner's fingers. Another helpful maneuver is to ask the patient to repeatedly close the eyes tightly. After the first closure, there may be lag in opening the eyes, but this will improve with repeated efforts.

iv. Myotonia may be provoked by percussion of muscle, e.g., by percussion of the thenar eminence. The muscle stiffens, often adducting the thumb.

b. Muscle weakness and atrophy
   i. Muscles most prominently affected
      a) Superficial facial muscles
      b) Levator palpebrae superioris
      c) Temporalis
      d) Sternocleidomastoids
      e) Distal muscles of forearm
      f) Dorsiflexors of foot
   ii. Other muscles commonly affected
      a) Quadriceps
      b) Diaphragm and intercostals
      c) Intrinsic muscles of hand and feet
      d) Palate and pharyngeal muscles
      e) Tongue
      f) External ocular muscles

c. Percussion myotonia and voluntary myotonia aggravated by cold
d. Dysarthria
e. Slow nasal indistinct speech
f. Foot drop
g. Step page gait
h. Contractures of the Achilles tendon
i. Diminished deep tendon reflexes
j. Cognitive and behavioral abnormalities

3. Craniofacial appearance
   a. Long thin face
   b. Flat, sagging, sad, and expressionless face
   c. Frontal bossing
   d. Hollow temple secondary to atrophy of temporalis
   e. Bilateral facial weakness (facial diplegia)
   f. Tented mouth
   g. Micrognathia
   h. Swan neck appearance (sternocleidomastoid muscle wasting)
4. Ocular findings
   a. Cataracts (>85%)
   b. Ptosis
   c. Extraocular weakness
   d. Peripheral retinal changes
   e. Coloboma of retina/choroid
   f. Optic atrophy
   g. Blepharospasms
   h. Decreased ocular pressure
5. Cardiac involvement (76%)
   a. An integral part of myotonic dystrophy targeting
      i. Almost selectively the conduction system
      ii. Less specifically the myocardium
   b. Electrocardiographic conduction abnormalities
      i. Manifesting with or without ventricular tachyarrhythmias or bradyarrhythmias
      ii. The first-degree atrioventricular (AV) block (most common)
      iii. Intraventricular conduction abnormalities (premature ventricular complexes like couplets and triplets)
      iv. Atrial arrhythmias (atrial fibrillation and flutter)
   c. A high incidence of sudden death
   d. Possible cardiomyopathy
   e. Congestive heart failure (6%)
6. Gastrointestinal findings
   a. Achalasia
   b. Gastroparesis
   c. Constipation
   d. Megacolon
   e. Gallstones
7. Genitourinary findings
   a. Dysuria
   b. Urinary retention
   c. Polycystic kidneys
   d. Testicular atrophy
8. Endocrine findings
   a. Hypogonadism
   b. Male infertility secondary to testicular atrophy
   c. Hypothyroidism
   d. Goiter/hyperparathyroidism
   e. Multiple endocrine neoplasia type 2A (pheochromocytoma and amyloid-producing medullary thyroid carcinoma)
   f. Dysmenorrhea
   g. Postprandial hyperinsulinemia
9. Orthopedic problems
   a. Arthrogryposis
   b. Talipes
   c. Kyphoscoliosis
10. Female patients
   a. Decreased total reproductive rate
   b. Obstetrical complications (Rudnik-Schöneborn and Zerres 2004)
      i. Higher rate of spontaneous abortions

ii. Ectopic pregnancies
iii. Abnormal placentation
iv. Urinary tract infections

11. Occasional accompanying benign or malignant neoplasms
    a. Pilomatrixoma
    b. Parathyroid adenoma
    c. Small bowel carcinoma
    d. Neurofibromatosis
    e. Thymoma
    f. Pleomorphic adenoma of the parotid gland
    g. Pituitary adenoma
    h. Ovarian cancer
    i. Ovarian cyst
    j. Laryngeal cancer not previously reported
12. Natural history
    a. Usually progressive
    b. Usually leading to severe disability within 15–20 years
    c. Greatly reduced life expectancy, particularly in the case of an early disease onset and proximal muscle involvement
    d. The high mortality rate reflecting an increase in deaths due to
        i. Respiratory diseases
        ii. Cardiovascular diseases
        iii. Neoplasms
        iv. Sudden deaths induced by cardiac arrhythmias
13. Differential diagnosis of myotonic disorders (Meola 2000; Miller 2008)
    a. Myotonic dystrophy type 2 (DM2)
        i. Clinical characteristics similar to those of DM1: an adult-onset muscular dystrophy associated with
            a) Myotonia (clinically and on EMG)
            b) Proximal weakness
            c) Frontal balding
            d) Polychromatic cataracts
            e) Cardiac arrhythmias
            f) Facial and respiratory muscles: relatively spared
            g) Insulin resistance
            h) Infertility
            i) Absence of congenital form of DM2 comparable with DM1
        ii. Molecular basis: DM2: caused by an expansion of a cytosine-cytosine-thymine-guanine (CCTG) repeat in the zinc finger protein 9 (ZNF9) gene on chromosome 3 (Liquori et al. 2001)
    b. Myotonia congenita
        i. Myotonia: prominent clinical symptom.
            a) Stiffness especially when first starting an activity in severe classic myotonia
            b) Perform activities at a normal or advanced level, including competitive sports, once warmed up
            c) Presents in early childhood, described by the parents as weakness and clumsiness in addition to or instead of stiffness
            d) Despite the reported difficulties, affected children appear "athletic," with increased muscle bulk, presumably because of the sustained muscle activity.
            e) The myotonic symptoms often improve with age but do not completely disappear.
        ii. Caused by a mutation in the gene encoding skeletal muscle chloride channel-1 (*CLCN1*) (Renner and Ptacek 2002). The chloride channel defect leads to an elevation of the resting membrane potential and thus a tendency toward repeated muscle contractions.
        iii. Inheritance: either autosomal dominant (Thomsen myotonia congenita) or autosomal recessive (Becker myotonia congenita).
    c. Schwartz-Jampel syndrome (chondrodystrophic myotonia)
        i. Caused by loss-of-function mutation in the *HSPG2* gene, which encodes perlecan, a heparan sulfate proteoglycans secreted into basement membranes (Nicole et al. 2000)
        ii. Clinical manifestations
            a) Severe myotonia: one of the first symptoms present in childhood. No warm-up phenomenon for the myotonia
            b) Short stature
            c) Muscular hypertrophy
            d) Diffuse bone disease
            e) Ocular and facial abnormalities
            f) Joint contractures

Diagnostic Investigations

1. Clinical examination to search muscle and nonmuscle manifestations (Meola 2000)
2. Lab: mildly elevated serum creatine kinase
3. Electromyography to identify subclinical myotonia
4. Slit-lamp examination to detect characteristic cataracts
5. Muscle biopsy
   a. Diagnostic but not indicated or useful for routine clinical evaluation
   b. Atrophic small type I fibers
   c. An increase in central nuclei
   d. Ringed fibers
6. Radiography
   a. Kyphosis of cervical spine
   b. Thin ribs observed in neonates suffering from myotonic dystrophy
7. Electrocardiogram abnormalities (60–70%) (Finsterer et al. 2001)
   a. ST abnormalities
   b. AV block I
   c. Increased QTc interval
   d. Tall R and/or S waves
   e. Left anterior hemiblock
   f. Supraventricular ectopic beats
   g. T wave abnormalities
   h. Pacemaker
   i. Missing R progression
   j. Abnormal U wave
   k. Left bundle branch block
8. Echocardiography (Finsterer et al. 2001)
   a. Septal thickness >11 mm
   b. Posterior wall thickness >11 mm
   c. Fractional shortening <30%
   d. E/A ratio >1
   e. Left ventricular end-diastolic diameter >57 mm
   f. Valve abnormalities
9. DNA testing for CTG repeat size: detects mutations in nearly 100% of affected individuals and is clinically available (Bird 2007)
   a. Gold standard for the diagnosis of DM1
   b. CTG repeat size
      i. Normal alleles: 5–34 CTG repeats
      ii. Premutation (mutable normal alleles): 35–49 CTG repeats
      iii. Full penetrance alleles (associated with disease manifestations): >50 CTG repeats
   c. Clinical testing by targeted mutation analysis
10. Presymptomatic carrier testing
    a. Leukocyte DNA analysis: provides an earlier opportunity to diagnose DM1 in family members at risk who are clinically asymptomatic
    b. Providing more aggressive monitoring program to detect
       i. Early cardiac conduction disturbance
       ii. Cataract formation
       iii. Respiratory difficulties
       iv. At risk of developing anesthetic complications, especially delayed-onset apnea

Genetic Counseling

1. Recurrence risk (Bird 2007)
   a. General principle for genetic counseling
      i. A normal molecular analysis excludes the risk of developing or transmitting myotonic dystrophy in essentially all situations.
      ii. For women who have had a child with congenital myotonic dystrophy, almost all subsequently affected pregnancies are likely to be severely affected.
      iii. Clinically affected women, in general, have around a 30% chance that an affected child would have congenital or severe childhood myotonic dystrophy. The risk of a congenitally affected child is related to maternal repeat size.
      iv. The risk for the healthy sib of a congenitally affected patient developing the disorder after childhood is low.
      v. For the adult healthy sib of an adult-onset case, the risk of carrying the mutation is also low (around 10%), with about half of this developing clinically significant disease.
   b. Patient's sib: recurrence risk depending on the genetic status of the parents
      i. Not increased if both parents are normal
      ii. Fifty percent risk if one parent has an expanded DMPK allele

c. Patient's offspring
   i. Offspring of an individual with an expanded allele (>34 CTG repeats) have a 50% chance of inheriting the mutant allele.
   ii. Disease-causing alleles may expand in length during gametogenesis, resulting in the transmission of longer CTG trinucleotide repeat alleles that may be associated with earlier onset and more severe disease than that observed in the parent.

2. Prenatal diagnosis
   a. Prenatal ultrasonography in congenital myotonic dystrophy
      i. Polyhydramnios
      ii. Talipes
      iii. Decreased fetal movements reflecting the neuromuscular failure of swallowing and movement
   b. Prenatal diagnosis possible by using mutation analysis (requires prior confirmation of the diagnosis of DM1 by molecular genetic testing of DMPK in an affected family member) and detection of the CTG repeat expansion with the *DMPK* gene in amniocytes or chorionic villi
   c. More challenging by using the CTG repeat test to determine whether the fetus is at risk for the severe form of myotonic dystrophy
      i. Generally, in amniocytes, congenital myotonic dystrophy is associated with CTG repeat expansion larger than that of the affected mother.
      ii. CTG repeat size may change over time in CVS or amniocentesis, providing different CTG repeat size at different gestational ages.
   d. Counseling of pregnant patients affected with myotonic dystrophy
      i. An explanation of the risk associated with anticipation, which is the tendency toward large intergenerational expansion of the CTG repeat during maternal transmission, resulting in offspring with congenital myotonic dystrophy
      ii. CTG repeat number provides only an approximate guide to prognosis or to pregnancy outcome. Most cases with over 2,000 repeats will have congenital or severe childhood-onset disease; most individuals with 50–100 repeats will not have significant neuromuscular disease.
      iii. An intergenerational contraction of the CTG fragment observed in approximately 7% of cases. Clinical anticipation was seen despite the reduced CTG repeat size, resulting in congenital myotonic dystrophy in the offspring.
      iv. Prenatal diagnosis (PND) is available; however, the decision to terminate affected pregnancies is difficult as the extent of disability is hard to predict from the size of the expansion.
   e. Preimplantation genetic diagnosis (PGD) genetic analysis: available and is carried out before the establishment of pregnancy (Kakourou et al. 2008)

3. Management
   a. No specific treatment available for the progressive weakness that is responsible for most of the disability in patients with myotonic dystrophy
   b. Patients with myotonic dystrophy usually do not seek treatment for the myotonia per se, or they are not compliant with medication regimens to treat it, either because myotonia is much milder than their other symptoms or because they avoid medical treatment as part of their personality (Conravey and Santana-Gould 2010).
   c. To alleviate myotonia by drugs
      i. Quinine, quinidine, dilantin, carbamazepine, procainamide, diamox to alleviate myopia not universally successful
      ii. Encouraging results with mexiletine (Logigian et al. 2010) and tocainide
   d. Avoid cold which may induce myotonia
   e. Prescription for orthoses, wheelchairs, or other assisted devices
   f. Treat cataracts, diabetes mellitus, hypothyroidism, and sleep apnea
   g. Avoid surgery and anesthesia (sensitive to narcotics and sedatives)

Fig. 1 An adult (**a**) with myotonic dystrophy showing hard to release after shaking hand (**b**) and thenar myotonia after tapping (**c**)

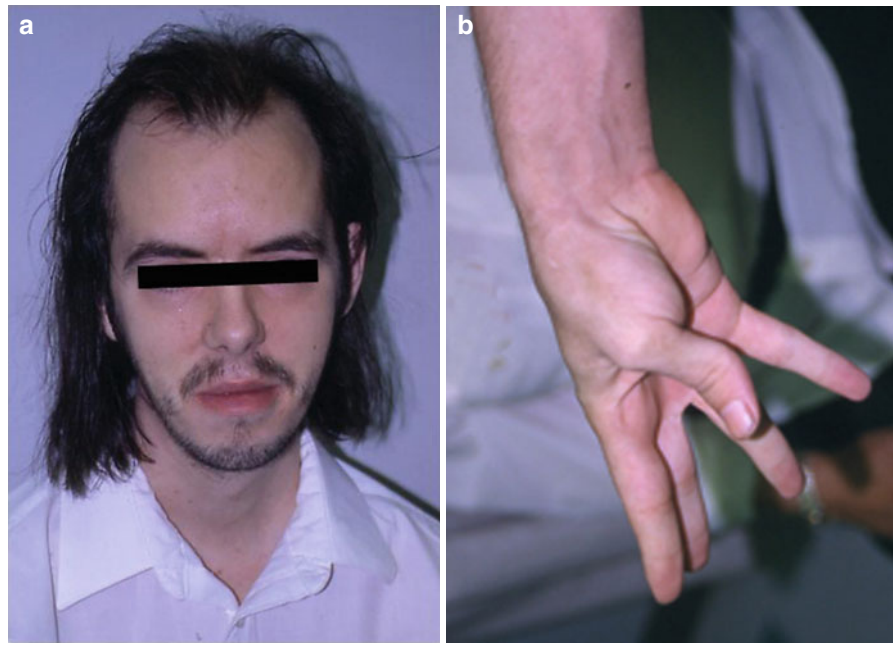

Fig. 2 (**a**, **b**) An adult with myotonia dystrophy showing long thin face with frontal bossing and thenar myotonia after tapping

Fig. 3 (**a**–**c**) A 23-year-old mother and her 21-month-old daughter with myotonia congenita type 1. The mother has myotonia (hard to relax after shaking hand), thenar myotonia after tapping, and absent tendon reflexes. The pregnancy was complicated by polyhydramnios, feeble fetal movement, and breech presentation. After scheduled cesarean section, the baby breathed only once and needed intubation for 5 days. She was very floppy and just started to walk about 2 months prior to the clinic visit. She chokes easily and does not chew and talk. On physical examination, in addition to hypotonia, there is a long and sagging face with marked tented-mouth. Molecular genetic testing of the daughter showed CTG repeats of 1,050

Nail-Patella Syndrome

In 1820, Chatelain first observed the nail-patella syndrome in a patient with a triad of abnormal nails, elbows, and knees. The hereditary nature of the syndrome was first described by Pye-Smith in 1883 in the English literature. The presence of iliac horns was first noted by Kieser in 1939 and later by Fong in 1946. In 1948, Mino et al. described the tetrad of abnormal nails, elbows, knees, and iliac horns for which the name hereditary onycho-osteodysplasia was coined by Duncan and Souter in 1963.

Synonyms and Related Disorders

Hereditary onycho-osteodysplasia

Genetics/Basic Defects

1. An autosomal dominant disorder with complete penetrance
2. *LMX1B*
   a. The only gene known to be associated with nail-patella syndrome
   b. A LIM-homeodomain transcription factor involved in normal patterning of the dorsoventral axis of the limb during development and early morphogenesis of the glomerular basement membrane

Clinical Features

1. Classic clinical tetrad
   a. Onychodysplasia: the most constant feature of the syndrome (approximately 98% of cases)
      i. Absent, hypoplastic, or dystrophic nails usually noted at birth
      ii. Bilateral or symmetrically involved
      iii. Longitudinally or horizontally ridged (grooved) nails
      iv. Thin or less often thickened nails
      v. Triangular lunules (lunulae): a characteristic feature of the syndrome
      vi. Most pronounced involvement in thumbnails, decreases in severity ulnarward
      vii. Dysplasia of toenails usually less marked, often affecting little toenails, and less frequent than that of the fingernails
   b. Knee dysplasia (approximately 74% of cases)
      i. Small, irregularly shaped, or absent patella that is prone to dislocate
      ii. May be asymmetrically involved
      iii. Hypoplastic patella often located laterally and superiorly, even though not actually dislocated
      iv. May be associated with prominent medial femoral condyles, hypoplastic lateral femoral condyles, and prominent tibial tuberosities
      v. Appearance of flattened profile of knee joints

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_172,
© Springer Science+Business Media, LLC 2012

   c. Elbow dysplasia (approximately 70% of cases)
      i. May be asymmetrical
      ii. The deformity is characterized by hypoplasia of the capitellum, commonly by secondary dysplasia and dislocation, usually posteriorly, of the radial head, associated with limitation of rotation (pronation and supination) of variable degree.
      iii. Triceps hypoplasia with antecubital pterygia, a frequent accompaniment of the syndrome, further limiting extension resulting in cubitus valgus
   d. "Iliac horns"
      i. Clinically palpable
      ii. Generally symmetrical
      iii. Known to develop a secondary center of ossification
      iv. The iliac horns can be present at birth by X-ray examination
2. Other skeletal abnormalities
   a. Talipes equinovarus, talipes calcaneovalgus deformities, and flat feet
   b. Mild short stature
3. Associated nephropathy (30–50% of cases) (renal failure in approximately 5% of cases)
   a. Proteinuria
      i. Usually the first sign of renal involvement
      ii. With or without hematuria
      iii. May present at any age from birth onward
      iv. May be intermittent
      v. May remit spontaneously, remain asymmetric, progress to nephritic syndrome, and occasionally to renal failure
      vi. May be exacerbated during pregnancy
   b. Progression to chronic glomerulonephritis leading rarely to renal failure
      i. May occur rapidly
      ii. May occur after many years of asymptomatic proteinuria
4. Eye involvement
   a. Primary open-angle glaucoma
   b. Ocular hypertension
   c. Iris pigmentary changes: frequent observation of a zone of darker pigmentation shaped like a cloverleaf or flower around the central part of the iris (Lester's sign)
5. Gastrointestinal involvement (about one-third of cases)
   a. Constipation
   b. Irritable bowel syndrome
6. Neurological involvement
   a. Intermittent numbness, tingling, and burning sensations in the hands and feet in some cases
   b. Epilepsy (6% of cases)
7. Vasomotor problems in some cases
   a. Poor peripheral circulation, presenting as very cold hands and feet even in warm weather
   b. Raynaud's phenomenon
8. Dental problems
   a. Weak, crumbling teeth
   b. Thin dental enamel

Diagnostic Investigations

1. Diagnosis based on clinical and radiographic findings
2. Laboratory studies
   a. Urinalysis: proteinuria, hematuria
   b. Plasma urea, BUN, creatinine concentrations
3. Radiologic features
   a. Elbow involvement
      i. Dysplasia of the radial head
      ii. Hypoplasia of the lateral epicondyle and capitellum
      iii. Prominence of the medial epicondyle
      iv. Dislocation of the radial head, usually posteriorly
   b. Iliac horns
      i. Bilateral, conical, bony processes that project posteriorly and laterally from the central part of the iliac bones of the pelvis
      ii. Present in about 70% of cases
      iii. Considered pathognomonic of the syndrome
      iv. Pelvic X-ray
         a) Usually necessary for detection of iliac horns, but large horns may be palpable clinically
         b) Iliac horns: may be observed at birth
         c) An epiphysis at the apex of iliac horns: may be present in children
4. MRI for possible bone/soft tissue abnormalities
5. Ultrastructural (electron microscopic) abnormalities: the most specific histologic changes seen in nail-patella syndrome
   a. Collagen fibril deposition within the basement membrane and the mesangial matrix

   b. Irregular thickening of the glomerular basement membrane with electron-lucent areas giving a mottled "moth-eaten" appearance
6. Molecular genetic testing: *LMX1B* gene mutation analysis available clinically

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. An affected parent: a 50% risk
      ii. Clinically unaffected parents
         a) A low risk in a case of de novo mutation in the proband
         b) An increased risk if germline mosaicism exists in a parent (not been reported)
   b. Patient's offspring: a 50% risk
2. Prenatal diagnosis: demonstration of the disease-causing mutation previously identified in the proband on fetal DNA obtained from amniocentesis or CVS
3. Management
   a. Patella dysplasia: most patients asymptomatic, rarely require surgical treatment
   b. Physiotherapy for orthopedic complaints
   c. Surgical treatment
      i. Bilateral elbow soft tissue release
      ii. Bilateral radial head excisions
      iii. Foot and ankle reconstructive procedures for equinus, pes cavus, calcaneovalgus, congenital vertical talus, and clubfoot deformities
      iv. Congenital permanent dislocation of the patella
   d. Screening for proteinuria
   e. Screening for glaucoma

Fig. 1 (**a**–**i**) A 10-year-old boy has classic nail-patellar syndrome. Note webbings of the neck and the elbows causing marked elbow contractures, abnormal muscle distribution of the upper extremities, nail hypoplasia, and absent patella. The radiographs show "iliac horn" sign of the pelvis and patella agenesis

Neonatal Herpes Simplex Infection

Hass in 1935 described a fatal case of neonatal herpes simplex virus (HSV) infection with hepatoadrenal necrosis and intranuclear inclusion bodies. Neonatal herpes is defined as the diagnosis of HSV infection in an infant within the first 28 days of life.

Synonyms and Related Disorders

Fetal/intrauterine herpes simplex infection

Genetics/Basic Defects

1. HSV-1 and HSV-2
   a. Belong to Herpesvirus family
      i. Herpes simplex viruses
         a) Enveloped, double-stranded DNA viruses
         b) Exist as two serotypes, 1 and 2 (HSV-1 and HSV-2)
      ii. Infections with HSV-1 generally involve the face and skin "above the waist" and are associated with orolabial disease. Most infections occur during childhood. HSV-1 also can cause genital infection, resulting more frequently from oral-genital contact.
      iii. Infections with HSV-2 usually involve the genitalia and skin "below the waist" in sexually active adolescents and adults, usually resulting from sexual intercourse. Most HSV disease in neonates is due to HSV-2. HSV-2 also causes oral lesions in approximately 25% of the infected population.
   b. Viruses are transmitted from infected to susceptible individuals during close personal contact.
   c. Recurrent HSV infections occur in over one-third of the world's population due to the rare fatal nature of the infection and a latency period.
   d. Infections in children and nonpregnant adults
      i. Recurrent herpes labialis: the largest reservoir of HSV infections in the community
      ii. Genital herpes
         a) A first-episode primary infection occurs in a person with no prior HSV-1 or HSV-2 antibody.
         b) A first-episode nonprimary infection occurs in a person with preexisting HSV-1 antibody acquiring HSV-2 genital infection.
         c) Recurrent infections can result from viral reactivation from latency and subsequent antegrade translocation of virus back to the skin and mucosal surfaces.
   e. Maternal genital infections
      i. Twenty-two percent of pregnant women are seropositive for herpes simplex virus (HSV)-2, and more than 2% of women acquire genital herpes during pregnancy.
      ii. Recurrent genital herpes infections: the most common form of genital HSV infections during gestation
      iii. The most devastating complication of genital HSV is infection of the neonate caused by contact with infected genital secretions at the time of delivery.
      iv. Woman with primary genital HSV disease: at highest risk of transmitting the virus to her baby
      v. Neonatal transmission occurs in the peripartum period, provided the gravid woman is shedding

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_173,
© Springer Science+Business Media, LLC 2012

virus, either symptomatically or asymptomatically, at the time of delivery.

vi. Factors influencing transmission from mother to neonate
  a) Type of maternal infection (primary versus recurrent): Mothers with a first episode of genital HSV infection near term are at much greater risk of developing neonatal herpes than those whose mothers have recurrent genital herpes.
  b) Maternal antibody status
  c) Duration of rupture of membranes: Cesarean delivery within 4 h of membrane rupture in a woman with active genital lesions can reduce the infant's risk of acquiring HSV.
  d) Integrity of mucocutaneous barriers (e.g., use of fetal scalp electrodes)
  e) Mode of delivery (cesarean section versus vaginal): effective in the prevention of HSV transmission to the neonate from a mother actively shedding virus from the genital tract. Neonatal infection has occurred in spite of cesarean delivery performed prior to the rupture of membranes.

f. Incidence of neonatal disease: estimated at approximately 1 in 3,200 deliveries (an estimated 1,500 cases of neonatal HSV infection annually in the United States)

g. Transmission of HSV disease to neonates occurs in the following three distinct time intervals:
  i. Intrauterine (in utero): 5% infected with HSV in utero
  ii. Peripartum (perinatal): overwhelming majority (~85%) of infected neonates
  iii. Postpartum (postnatal): an additional 10% of infected neonates

h. Disease classification of HSV infections acquired either peripartum or postpartum: predictive of both morbidity and mortality
  i. Disease localized to the skin, eyes, and/or mouth (SEM disease, accounting for ~45% of cases of neonatal HSV)
  ii. Encephalitis, with or without SEM involvement (CNS disease, accounting for ~30% of cases of neonatal HSV)
  iii. Disseminated infection involving multiple organs, including the CNS, lungs, liver, adrenal glands, skin, eyes, and/or mouth (disseminated disease, accounting for ~25% of cases of neonatal HSV)

2. Two biologic properties of HSV that directly influence human diseases
  a. Latency: a period of reactivation of virus multiplication, resulting in clinically apparent disease (lesions) or clinically inapparent (asymptomatic, or subclinical) infection
  b. Neurovirulence: an affinity with which HSV is drawn to and propagated in neuronal tissue, resulting in profound disease with severe neurologic sequelae:
    i. Neonatal HSV central nervous system (CNS) disease
    ii. Herpes simplex encephalitis in older children and adults

Clinical Features

1. Intrauterine infection
  a. Incidence: approximately 1 in 300,000 deliveries
  b. In utero disease unlikely to be missed due to the extent of involvement of affected babies
  c. A triad of clinical findings
    i. Cutaneous manifestations
      a) Scarring
      b) Active lesions
      c) Hypo-/hyperpigmentation
      d) Aplasia cutis
      e) Erythematous macular exanthem
    ii. Ophthalmologic findings
      a) Microphthalmia
      b) Retinal dysplasia
      c) Optic atrophy
      d) Chorioretinitis
    iii. Neurologic involvement
      a) Microcephaly
      b) Encephalomalacia
      c) Hydranencephaly
      d) Intracranial calcification

2. Disseminated disease involving multiple organs, most prominently the liver and lungs and possibly with a central nervous system (CNS) component
  a. Incidence: approximately 25% of all children with neonatal HSV disease

   b. Has the earliest age of onset, often during the first postnatal week
   c. Encephalitis: about 60–75% of infants with disseminated disease
   d. Vesicular rash: over 20% of neonates with disseminated HSV disease do not develop cutaneous vesicles during the course of their illness
   e. Death relates primarily to the severe coagulopathy, liver dysfunction, and pulmonary involvement of the disease.
3. Localized CNS disease with or without SEM involvement: observed in almost one-third of all neonates with HSV infection and has the latest age of onset, usually between the second and third weeks after birth
   a. Seizures (both focal and generalized)
   b. Lethargy
   c. Irritability
   d. Tremors
   e. Poor feeding
   f. Temperature instability
   g. Bulging fontanelle
   h. Associated skin vesicles in 60% and 70% of babies classified as having CNS disease
   i. Death usually caused by devastating brain destruction, with resulting acute neurologic and autonomic dysfunction
4. SEM disease
   a. Incidence: approximately 45% of all cases of neonatal HSV disease
   b. Represents a spectrum of disease manifestations having more limited viral dissemination but without visceral involvement (e.g., liver, lung) as detected biochemically (e.g., elevated transaminase levels) or clinically (e.g., pneumonitis)
5. Factors affecting the severity of neonatal disease
   a. Prompt diagnosis: PCR assay to detect HSV DNA in neonates has improved early diagnosis of disease.
   b. Initiation of antiviral (intravenous acyclovir) therapy
      i. Reduces mortality and morbidity among neonates with skin, eye, and mouth disease
      ii. Unable to reduce morbidity associated with disseminated or CNS disease
6. Despite early intervention with high-dose antiviral therapy, 30% of infants with disseminated disease die, and 40% of survivors of CNS disease have severe neurologic damage. Therefore, prevention of neonatal infection is critical.

Diagnostic Investigations

1. Clinical diagnosis based on:
   a. Typical findings (HSV culture not necessary):
      i. Herpes labialis
      ii. Gingivostomatitis
      iii. Genital herpes
   b. Atypical HSV infections (culture and antiviral susceptibility testing needed to guide antiviral therapy)
      i. Immunocompromised patients
      ii. HSV conjunctivitis and keratitis: need an ophthalmologist consultation
2. Diagnostic evaluations obtained prior to initiation of acyclovir therapy
   a. HSV cultures: remains the definitive diagnostic method of establishing HSV disease
      i. Skin vesicles, if present
      ii. Oropharynx
      iii. Conjunctivae
      iv. Urine
      v. Blood
      vi. Stool
      vii. Rectum
      viii. Cerebrospinal fluid (CSF)
   b. Liver transaminase: Elevated levels suggest disseminated HSV infection.
3. Serologic testings
   a. Type-specific antibody assays to distinguish between HSV-1 and HSV-2 antibodies
   b. Identifies only past infection but cannot identify the site of HSV infection
   c. Patients with cold sores due to HSV-1 will test HSV-1 seropositive regardless of presence or absence of genital HSV-1 infection.
   d. Possible to identify serodiscordant couples in which the woman is HSV-2 seronegative and the partner is seropositive. Women in such couples are at risk for acquiring primary genital HSV infection during pregnancy and are thus at higher risk of transmitting the virus to their babies during birth.

e. Serologic studies, in general, play no role in the diagnosis of neonatal HSV disease.

4. Classification of genital HSV based on serologic and viral detection test results: important in pregnancy because the risk of perinatal HSV transmission varies accordingly
   a. Primary first episode: characterized by isolation of HSV-1 or HSV-2 from genital secretions in the absence of HSV antibodies in serum
   b. Nonprimary first episode: characterized by isolation of HSV-2 from genital secretions in the presence of HSV-1 antibodies in serum
   c. Reactivation disease: characterized by isolation of HSV-1 or HSV-2 from the genital tract in the presence of HSV antibodies of the same serotype as the isolate
5. PCR amplification
   a. Able to correctly diagnose neonatal HSV disease, especially in patients without overt manifestations such as skin vesicles
   b. Able to assess the response to therapy
      i. Having HSV DNA detected in CSF at or after the completion of intravenous therapy is associated with poor outcomes.
      ii. Repeat lumbar puncture of all patients with CNS HSV involvement is indicated at the end of intravenous acyclovir therapy to determine that the specimen is PCR negative in a reliable laboratory and to document the end-of-therapy CSF indices. Persons who remain PCR positive should continue to receive intravenous antiviral therapy until PCR negativity is achieved.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Unknown
      ii. No cases in siblings reported
   b. Patient's offspring
      i. Unknown
2. Prenatal diagnosis
   a. Genetic counseling complicated due to:
      i. Fetal infection may follow primary or recurrent disease.
      ii. Fetal infection can occur at any time in gestation.
      iii. Only approximately one third of cases have a history suggestive of maternal herpes infection during pregnancy.
   b. Isolation of the virus from amniotic fluid obtained at amniocentesis does not necessarily imply fetal infection.
   c. Currently no accurate risk estimate available for congenital malformations following maternal herpes infection during pregnancy
      i. Appears to be small
      ii. Highest risk for women with primary infection during the first trimester
3. Management
   a. Antiviral drugs
      i. Vidarabine (1-β-D-arabinofuranosyl-adenine): the first systemically administered antiviral medication with activity against HSV for which the therapeutic efficacy outweighed its toxicity
         a) Administered over prolonged infusion times and in large volumes of fluid
         b) Management of life-threatening HSV and varicella zoster virus infections, HSV encephalitis, and herpesvirus infections in immunocompromised patients
      ii. Acyclovir
         a) Lower dose: lower toxicity and improved ease of administration
         b) Higher dose: improved outcome in mortality and morbidity achieved with use of higher-dose acyclovir
   b. Antibody therapy
      i. Use of passive immunotherapy as an adjuvant to active antiviral interventions.
      ii. Neonates with higher neutralizing antibody titers: less likely to become infected with HSV following perinatal exposure and being more likely to have localized disease (and less likely to have disseminated disease) once they are infected
      iii. Intravenous gamma globulin currently not recommended for the management of neonates with HSV disease due to variable amount of anti-HSV antibodies present in conventional intravenous gamma globulin preparations
      iv. A monoclonal antibody directed against γD may be available for clinical investigation as an adjuvant therapeutic agent by

the NIAID Collaborative Antiviral Study Group in the future.

c. Prevention of neonatal HSV infections
   i. Prevention strategies
      a) Identification of women at risk for HSV acquisition during pregnancy by testing women and possibly their partners for HSV antibodies
      b) Provide counseling to prevent transmission to women in late pregnancy
   ii. Cesarean section
      a) Reduces the infant's risk of acquiring HSV in women with active genital lesions present at the time of delivery
      b) Limitations: 60–80% of babies who develop neonatal HSV disease are born to women without a history of genital herpes, and thus, infection in these babies may not be prevented by this approach, and women with recurrent infections who are shedding virus at the time of delivery are at low risk of their babies developing neonatal HSV disease.
   iii. Antiviral therapy during pregnancy
      a) Oral acyclovir near the end of pregnancy to suppress genital HSV recurrences becoming increasingly common in clinical practice
      b) Additional studies are needed to more definitively establish the effectiveness and safety of late-pregnancy maternal HSV suppression.
   iv. Vaccine development for genital herpes: A candidate HSV-2 gD subunit vaccine adjuvanted with alum combined with 3-deacylated monophosphoryl lipid A has recently demonstrated promising results in preventing HSV-1 or HSV-2 genital herpes disease and HSV-2 infection, efficacy limited only to women who were HSV-1 and HSV-2 seronegative prior to vaccination.

d. Avoid unnecessary invasive procedures in labor.
   i. Vaginal delivery in women with genital herpes but without lesions or symptoms at the time of labor
   ii. Avoid the following procedures to lessen the risk of HSV transmission, except when critical to obstetric care:
      a) Artificial rupture of membranes
      b) Fetal scalp electrodes
      c) Vacuum or forceps delivery

Nephrogenic Diabetes Insipidus

Hereditary nephrogenic diabetes insipidus (NDI) is a rare disorder of defective vasopressin-stimulated water reabsorption via the luminal water channels in the cortical and medullary collecting ducts (Knoers and Deen 2001).

Genetics/Basic Defects

1. Causes of diabetes insipidus (Linshaw 2007)
   a. Central: hypothalamic/pituitary lesions leading to insufficient production or release of antidiuretic hormone (ADH)
      i. Postoperative brain surgery
      ii. Intracranial lesions (cysts, aneurysms, tumors of pituitary, brainstem)
      iii. Infiltrative malignancies (lymphoma, leukemia)
      iv. Infections, including encephalitis, meningitis, abscess
      v. Head trauma
      vi. Hypoxic injury
      vii. Congenital, inherited as an autosomal dominant disorder
   b. Nephrogenic: renal resistance (lack of response of the distal nephron) to ADH from lesions interfering with the renal concentrating mechanism
      i. Acquired metabolic aberrations
         a) Hypokalemia (chronic, Bartter syndrome)
         b) Hypercalcemia
         c) Hypercalciuria (rare)
         d) Diabetes mellitus
      ii. Medullary damage
         a) Chronic pyelonephritis
         b) Infiltrative disease (leukemia, lymphoma, amyloidosis)
         c) Sickle cell disease
         d) Cystinosis
         e) Other forms of chronic renal failure
         f) Obstructive uropathy
      iii. Drugs
         a) Lithium
         b) Demeclocycline
         c) Amphotericin B
         d) Diphenylhydantoin
      iv. Inherited
         a) X-linked recessive: approximately 90% of cases of hereditary nephrogenic diabetes insipidus
         b) Autosomal recessive: approximately about 9% of cases
         c) Autosomal dominant: about 1% of cases
2. X-linked inheritance
   a. Caused by mutations in the arginine vasopressin V2 receptor (*AVPR2*) gene on the X chromosome (mapped on Xq28), encoding the arginine vasopressin receptor type 2 (VR2): molecular basis for lack of concentration of urine
   b. Males who carry the defective gene
      i. Do not concentrate urine after administration of arginine vasopressin (AVP): defined as the excretion of increased (>30 ml/kg/day) volumes of diluted urine (<250 mmol/kg) (Fujiwara and Bichet 2005)
      ii. Tend to have more serious symptoms
         a) Polydipsia (excessive thirst)
         b) Polyuria (excessive urine production)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_174,
© Springer Science+Business Media, LLC 2012

   c. Females who carry the defective gene: can have variable (rarely severe) degrees of polydipsia and polyuria because of skewed X chromosome inactivation
3. Autosomal recessive inheritance
   a. Caused by aquaporin 2 (*AQP2*, mapped on 12q13) mutations
   b. Polyuria and polydipsia are usually present at, or shortly after, birth
   c. Disease tends to be more severe, with urine osmolality generally not exceeding approximately 200 mOsm/kg water.
4. Autosomal dominant inheritance
   a. Caused by *AQP2* mutations
   b. Clinical expression
      i. Tends to become noticeable after 6–12 months or even later
      ii. May not be as severe (urine osmolality may be higher)
      iii. Transient response to ADH may be present.

Clinical Features

1. Medical history (Linshaw 2007)
   a. Failure to thrive
   b. Extreme thirst
   c. Unexplained fever
   d. Irritability
   e. Constipation
   f. Impressive polyuria
   g. Vomiting
   h. Seizures
2. Physical features
   a. Dry mouth and eyes
   b. Poor skin turgor
   c. Sunken eyes and anterior fontanelle
   d. Mottled skin
   e. Decreased peripheral pulses
   f. Low blood pressure
   g. Multiple abdominal masses/fecaliths

Diagnostic Investigations

1. Laboratory features (Knoers 2007; Linshaw 2007)
   a. Hypernatremia: serum sodium concentration >143 mEq/L in the presence of a low urine specific gravity and in the absence of excessive sodium intake: highly suggestive of diabetes insipidus.
   b. Failure to concentrate the urine in the presence of high plasma vasopressin concentration and in the presence of parenteral administration of vasopressin or desmopressin: diagnostic of NDI.
   c. Hyperchloremia
   d. Metabolic acidosis
   e. Normal potassium concentration
   f. Hyperuricemia
   g. High serum and low urine osmolality
2. Molecular identification underlying X-linked NDI (*AVPR2*): immediate clinical significance because early diagnosis and treatment of affected infants can avert the physical and mental retardation that results from repeated episodes of dehydration (Fujiwara and Bichet 2005)
3. Molecular identification underlying autosomal recessive and autosomal dominant NDI (*AQP2*)

Genetic Counseling

1. Recurrence risk (Knoers 2007)
   a. Patient's sib
      i. X-linked recessive: risks of sibs depending on the genetic status of the proband's mother
         a) If the mother is a carrier: 50% of male sibs will be affected (inheriting the maternal *AVPR2* mutation); 50% of female sibs will be carriers
         b) A low recurrence risk but not zero due to possible germline mosaicism if the proband is the only one affected in the family and the disease-causing mutation cannot be detected in the DNA of the mother
      ii. Autosomal recessive inheritance: risk of recurrence 25%
      iii. Autosomal dominant inheritance
         a) Recurrence risk of 50% if a parent is affected
         b) A low recurrence risk if both parents are normal
   b. Patient's offspring
      i. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.

   ii. Autosomal recessive inheritance
      a) Obligatory carriers for a disease-causing mutation in the *AQP2* gene
      b) A low recurrence risk unless the spouse is affected or a carrier
   iii. Autosomal dominant inheritance: a 50% risk of offspring affected (inheriting the *AQP2* mutation)
2. Prenatal diagnosis
   a. X-linked recessive: available for pregnancies at increased risk if the *AVPR2* mutation has been identified in an affected family member by amniocentesis of CVS if the fetal karyotype is 46,XY
   b. Autosomal recessive and autosomal dominant: available for pregnancies at increased risk for the *AQP2* mutation
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation(s) has/have been identified.
3. Management (Linshaw 2007)
   a. Sufficient water to maintain normal electrolytes
   b. Low renal solute load to minimize water loss
   c. Adequate calories to support growth
   d. Pharmacotherapy: usually needed
      i. Thiazide
         a) Hydrochlorothiazide: 1–3 mg/kg/day bid
         b) Hypokalemia
         c) Hyponatremia
         d) Alkalosis
         e) Hypercalcemia
         f) Hyperglycemia
         g) Hyperuricemia
         h) Hepatitis
         i) Intestinal symptoms
         j) Bone marrow suppression
   e. Amiloride
      i. 20 mg/1.73 m^2/day bid–tid
      ii. Hyperkalemia
      iii. Headaches
      iv. Gastrointestinal discomfort
   f. Indomethacin
      i. 1.5–2.5 mg/kg/day tid
      ii. Gastrointestinal discomfort
      iii. Gastrointestinal bleeding
      iv. Headaches
      v. Renal toxicity
      vi. Hematopoietic adverse effects

Fig. 1 A 3-year-old girl was evaluated because her father has nephrogenic diabetes insipidus. He has problems with dehydration, polyuria, and polydipsia. His mother is a carrier and his maternal grandfather died of nephrogenic diabetes insipidus. The girl was found to have a mutation in the *AVPR2* gene. The mutation detected is g692–693delCT where two bases (CT) in codon 111 are deleted. The deletion causes a frameshift mutation that begins with a change of the amino acid at position 111 and results in a premature termination of protein synthesis at codon 190.This mutation has been reported to cause nephrogenic diabetes insipidus (NDI). The genetic data along with the family history are consistent with this female being a carrier of X-linked NDI

Netherton Syndrome

Netherton syndrome is a rare hereditary disorder of keratinization. It was described by Comèl in 1949 and Netherton in 1958. The syndrome is sometimes called Comèl–Netherton syndrome. The incidence is about 1 in 200,000 (Bitoun et al. 2002b).

Synonyms and Related Disorders

Netherton disease

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Bitoun et al. 2002b)
2. Defective gene in Netherton syndrome
   a. Serine protease inhibitor, Kazal-type 5 (*SPINK5*) mapped on chromosome 5q31-32
   b. The protein encoded by *SPINK5* is highly expressed in thymus and mucous epithelia, thereby termed LEKTI for lymphoepithelial Kazal type–related inhibitor.
      i. LEKTI possibly plays a role in anti-inflammatory and/or antimicrobial protection of mucous epithelia.
      ii. LEKTI possibly have similar function in the epidermis.

Clinical Features

1. Clinical triad
   a. Congenital ichthyosis
      i. Extent of involvement: highly variable
      ii. Natural course
         a) At birth: usually normal appearing skin
         b) Within a few weeks of age: skin becomes erythematous and develops serpiginous double-edged scales typical of ichthyosis linearis circumflexa or ichthyosiform erythroderma.
   b. Hair abnormality
      i. Trichorrhexis invaginata/nodosa
         a) Sparse and brittle scalp hair with a characteristic "bamboo" shape under light microscope due to invagination of the distal part of the hair shaft to its proximal part
         b) The major diagnostic sign (considered pathognomonic) but may be difficult to detect in infancy and early childhood
         c) May not affect all hair and can be limited to the lateral part of the eyebrows
      ii. Pili torti
      iii. Eyelashes and eyebrows may be affected.
   c. Atopic manifestations (Bitoun et al. 2002b)
      i. Eczema-like rashes
      ii. Atopic dermatitis
      iii. Pruritus
      iv. Allergic rhinitis
      v. Asthma
      vi. Urticaria/angioedema
2. Prognosis: poor (Bitoun et al. 2002b)
   a. Frequent life-threatening complications during the neonatal period
      i. Hypernatremic dehydration
      ii. Hypothermia
      iii. Extreme weight loss

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_175,
© Springer Science+Business Media, LLC 2012

iv. Recurrent infections
v. Bronchopneumonia
vi. Sepsis

b. Failure to thrive common during childhood resulting from
i. Malnutrition
ii. Metabolic disorders
iii. Chronic erythroderma
iv. Persistent cutaneous infections
v. Severe enteropathy with villous atrophy
vi. Growth retardation

c. Other abnormalities
i. Renal failure
ii. Aminoaciduria
iii. Congenital heart defects
iv. Hydroureter
v. Infantile pyloric stenosis
vi. Increased susceptibility to skin cancer
a) Squamous cell carcinoma
b) Vulvar cancer

Diagnostic Investigations

1. Clinical laboratory
   a. Increased serum immunoglobulin E levels
   b. Hypereosinophilia
   c. No consistent or significant abnormalities of immune function
   d. IgG abnormalities (both hypo- and hyper-IgG)
   e. T-cell and neutrophil defects may also occur.
   f. Selective humoral deficiency to bacterial polysaccharide antigens has been described.
   g. Specific IgE antibodies against airborne and food allergens frequently present
2. Dermatoscopy (trichoscopy) (Sun and Linden 2005; Burk et al. 2008; Rakowska et al. 2009)
   a. Trichorrhexis invaginata (bamboo hairs)
      i. A focal defect of the hair shaft that produces development of torsion nodules and invaginated nodules
      ii. The proximal element of the node overlaps the distal portion, causing an intussusception.
   b. Golf tee–like endings of hair shafts: If hair is pulled distally from this focal defect, a golf tee–like deformity is left. Hence, any hairs examined should be cut, rather than plucked.
   c. The hair shaft nodules caused by this defect are sometimes able to be seen by the naked eye. These hair defects can be found in scalp, eyebrow, or eyelash hairs. Grossly, scalp hair is described to be sparse and brittle.
   d. The hair shaft abnormality was reported to be secondary to intermittent incomplete formation of disulfide bonds in the keratogenous zone (Ito et al. 1984).
   e. Other hair shaft abnormalities
      i. Pili torti
      ii. Trichorrhexis nodosa
      iii. Helical hairs (Lurie and Garty 1995)
3. Immunohistochemistry using anti-LEKTI antibodies: shows a complete absence of LEKTI in the skin samples (Shimomura et al. 2005)
4. Histology and ultrastructural studies of skin sections
   a. Incomplete keratinization or defective cornification of the epidermis
   b. Dermal lymphocytic infiltrate
   c. Ultrastructure of the stratum corneum: characterized by premature degradation of corneodesmosomes with separation of corneocytes (Chao et al. 2005).
5. Molecular genetic testing of *SPINK5*: clinically available
   a. Mutation analysis of patients
   b. Carrier testing

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier of the gene
2. Prenatal diagnosis (Bitoun et al. 2002a)
   a. Ultrastructural examination of fetal skin biopsies for defective cornification of the epidermis is not reliable, since fetal skin keratinization does not begin until the 24th week of gestation, whereas in utero, fetal skin biopsy is usually performed between 19 and 22 weeks.
   b. DNA-based prenatal diagnosis on fetal DNA obtained from amniocentesis or CVS.
      i. *SPINK5* mutation detection
      ii. Indirect genotype analysis at the *SPINK5* locus using linkage analysis
         a) This approach is reliable since there is no evidence of locus heterogeneity.

   b) Presence of a large number of SPINK5 intragenic restriction fragment length polymorphisms (RFLPs) showing a high percentage of heterozygosity

3. Management
   a. No specific treatment available
   b. Emollients
   c. Keratolytics
   d. Antibiotics for recurrent infections
   e. Topical corticosteroids
   f. Topical tacrolimus and pimecrolimus with good control of skin disease without toxic effect (Saif and Al-Khenizan 2007)
   g. Medium dose of psoralen-UVA1 phototherapy may be effective and tolerated in adult.

Fig. 1 A neonate (**a**) with Netherton syndrome showing erythroderma. The patient had markedly elevated serum total IgE levels of 409 IU/mL at age 8 months and 285 IU/mL at 14 months of age. Molecular genetic analysis of *SPINK5* showed a compound heterozygote with a mutation 316DelGA in exon 5 inherited from the mother, and a mutation 2441+1delGTGA in exon 25 inherited from the father. The same patient at age 3 years (**b**) showed generalized erythroderma and marked growth retardation (height age of 7 months and weight age of 4 months). Microscopic analysis of the hair (**c** and **d**, lower and higher magnification) showed trichorrhexis invaginata/nodosa (*bamboo hair*) (*pink arrows*), pili torti (*yellow arrow*), and fractured hair shaft at the site of invagination (*blue arrow*)

Neu–Laxova Syndrome

The Neu–Laxova syndrome is a lethal disorder characterized by multiple congenital malformations. Microcephaly, lissencephaly, absence of corpus callosum, facial anomalies (notably absent eyelids), short broad neck, peripheral edema, ichthyosis, limb anomalies, and other malformations are common findings. The syndrome was described first by Neu et al. in 1971 and Laxova et al. in 1972 (Neu et al. 1971; Laxova et al. 1972).

Genetics/Basic Defects

1. Inheritance: autosomal recessive inheritance (King et al. 1995)
2. Pathogenesis (Coto-Puckett et al. 2010): remains unknown and differing etiologies have been postulated:
   a. A form of neuroectodermal dysplasia given the CNS and skin findings (Lazjuk et al. 1979; Ejeckam et al. 1986; Muller et al. 1987; Naveed and Sreenivas 1990)
   b. CNS pathology described as a neuronal migration defect with arrest of development early at 12–14 weeks of embryogenesis (Muller et al. 1987; Ostrovskaya and Lazjuk 1988)
   c. A neurodegenerative disorder with abnormal cell death causing neuronal atrophy and depletion (Allias et al. 2004)
   d. Limb deformities: caused by failure of muscle, bone, nerve, and arterial development in early embryogenesis (Shved et al. 1985)
   e. Contractures: secondary to reduced fetal movements or fetal akinesia/hypokinesis (Fitch et al. 1982; Russo et al. 1989)
   f. Ichthyotic skin changes: the cause of the deformed limbs, reduced movement, massive edema, and IUGR (Karimi-Nejad et al. 1987; Russo et al. 1989)
   g. Mechanism of ichthyosis proposed as hypoproteinemia caused by protein leakage through skin fissures as the primary pathogenesis of Neu–Laxova syndrome (Karimi-Nejad et al. 1987)
   h. It is the restrictive dermopathy that leads the various authors to characterize Neu–Laxova syndrome as a malformation sequence

Clinical Features

1. Considerable intrafamilial and interfamilial variation in clinical features
2. Prenatal history
   a. Severe intrauterine growth retardation
   b. Polyhydramnios
3. Spectrum of skin lesions
   a. Edema over the dorsum of foot and hand, often associated with hypoplastic phalanges
   b. Thick, waxy, and stretched in appearance
   c. Peeling of skin, scaling, and extensive plaque formation over scalp, face, neck, back, and arm
   d. Translucent flexible membrane covering most of the skin
   e. Varying degrees of lamellar ichthyosis
4. Craniofacial features
   a. Receding forehead
   b. Ocular hypertelorism
   c. Exophthalmos (protruding eyes)
   d. Absence of the eyelids
   e. Flat, abnormal nose

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_176,
© Springer Science+Business Media, LLC 2012

f. Eclabium
g. Cataract
h. Micrognathia
i. Cleft palate/lip
j. Hypodontia
k. Low-set, malformed ears

5. CNS abnormalities
   a. Microcephaly
   b. Lissencephaly
   c. Hypoplastic or abnormal cerebellum
   d. Agenesis or dysgenesis of the corpus callosum
   e. Decreased or absent gyri
   f. Dilatation or abnormal ventricles
   g. Dandy–Walker malformation
   h. Choroid plexus cysts
6. Limb anomalies
   a. Deformed digits
   b. Deformed limbs
   c. Flexion deformity
   d. Severe edema of the hands and feet
   e. Syndactyly
   f. Rocker-bottom feet
7. Other features
   a. Short broad neck
   b. Cystic hygroma
   c. Subcutaneous edema
   d. Small thorax
   e. Hypoplastic or atelectatic lungs
   f. Small abdomen
   g. Hypoplastic genitalia
   h. Short umbilical cord
   i. Absence of hair
   j. Muscle atrophy
8. Classification proposed by Curry (1982): may represent heterogeneity of the condition or different grades of severity, representing the wide spectrum of varying expressivity of the heterogeneous condition (Coto-Puckett et al. 2010).
   a. Group I
      i. Joint contractures
      ii. Partial syndactyly
      iii. Thin scaly skin
      iv. Mild ichthyosis
      v. Poor mineralization of bones
   b. Group II
      i. Massive swelling of hands and feet
      ii. More severe ichthyosis
      iii. Undermineralized bones leading to intrauterine fractures
   c. Group III
      i. Hypoplastic digits
      ii. Most severe ichthyosis (harlequin-like fetus)
      iii. Short limbs
      iv. Stick-like long bones
9. Prognosis
   a. Stillborn
   b. Die shortly after birth
10. Differential diagnosis
   a. Harlequin ichthyosis: see the chapter
   b. Restrictive dermatopathy (dermopathy) (Kulkarni et al. 2006; Khanna et al. 2008)
      i. A rare autosomal recessive disorder characterized by extreme tautness of the skin causing restricted intrauterine movement and a fetal akinesia deformation sequence
      ii. Uniformly mostly neonatally fatal
      iii. Diagnostic findings
         a) Skin tautness with near absence of the dermal elastic fibers, usually with no or only minor anomalies of the internal organs
         b) Abnormal face
         c) Absence of skin cracking (tight skin)
         d) Absence of skin edema
         e) Arthrogryposis multiplex
      iv. Secondary skeletal changes with variable radiographic findings which when present is pathognomonic of restrictive dermatopathy
         a) Poorly mineralized skull with large fontanelle
         b) Micrognathia
         c) Thin dysplastic clavicles
         d) Ribbon-like ribs
         e) Overtubulated humerus and forearm bones
   c. Lethal arthrogryposis with ichthyosis (Thakur et al. 2004)
      i. A lethal condition with joint contractures
      ii. Subcutaneous edema, ectropion
      iii. A severely flattened nose
      iv. “O”-shaped open mouth
      v. Extensive peeling of the skin (skin changes of ichthyosis)

Diagnostic Investigations

1. Radiography
   a. Multiple contractures
   b. Hemivertebrae
   c. Kyphoscoliosis
2. Histopathology of the skin
   a. Hyperkeratosis
      i. With or without parakeratosis
      ii. Associated with abundant subcutaneous tissue and excess of fat
   b. Myxomatous connective tissue associated with excess subcutaneous adipose tissue
   c. Epidermal and dermal atrophy
3. Ultrasound of the brain for CNS anomalies
4. Normal chromosomes

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: a lethal entity not surviving to reproductive age
2. Prenatal ultrasonography (Durr-e-Sabih et al. 2001; Rode et al. 2001)
   a. Severe growth retardation: a major feature
   b. Polyhydramnios
   c. Microcephaly/deficient calvarial ossification
   d. CNS abnormalities
   e. Abnormal facies including receding forehead
   f. Exophthalmos
   g. Cataract
   h. Cystic hygromas
   i. Pulmonary hypoplasia
   j. Contractures
   k. Excessive edema of the hands and feet
   l. Syndactyly
   m. Clubbing of the feet
   n. Absence of breathing movements, sucking, swallowing, or normal isolated arm and leg movements
   o. Restricted fetal movement
3. Management
   a. No specific treatment for the uniformly lethal disorder
   b. Mainly supportive with initial management of ventilatory, thermal, and nutritional support

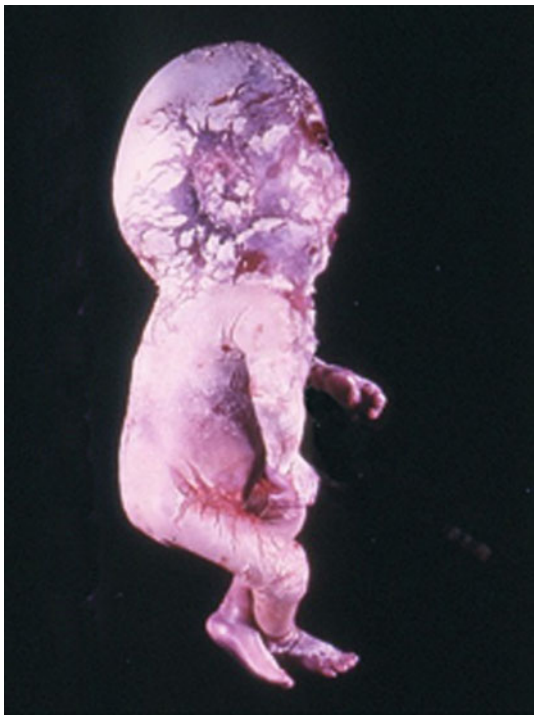

Fig. 1 An infant with Neu–Laxova syndrome showing severe ichthyosis (thick, cracked skin lesions forming deep fissures), characteristic facial features (absent eyelids, flattened nose, round gaping mouth, low-set ears with poorly developed pinnae), short broad neck, flexion contractures of the limbs, and short, small-caliber umbilical cord. Photomicrographs of skin (not shown) demonstrated a prominent hyperkeratosis of the epidermis and a thick layer of subcutaneous adipose tissue due to edema

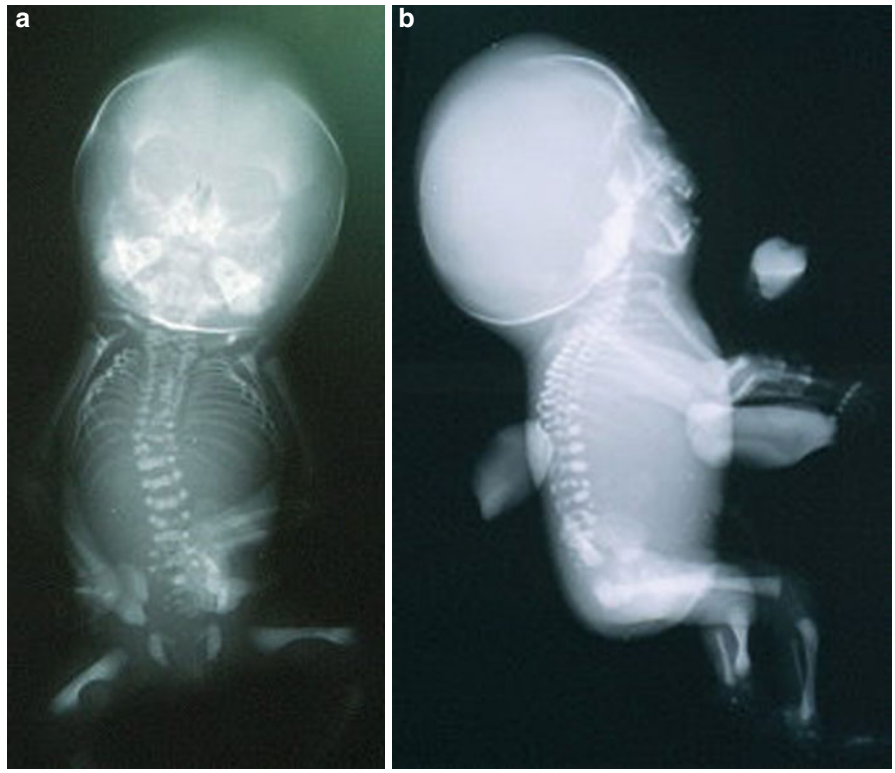

Fig. 2 (**a**, **b**) Radiographs showing hemivertebrae, kyphoscoliosis, and 11 pairs of ribs

Neural Tube Defects

Neural tube defects (NTDs) are among the most common severe congenital malformations of the central nervous system. Approximately 1 in 500 to 1 in 1,000 pregnancies result in NTDs. About 4,000 fetuses are affected each year in the USA. The incidence varies with geographic areas and ethnic groups. The incidence, however, appears to be decreasing recently.

Synonyms and Related Disorders

Anencephaly; Cranial meningocele; Cranio/spinal rachischisis; Cranium bifidum occultum; Encephalocele; Iniencephaly; Spina bifida

Genetics/Basic Defects

1. Caused by a defect in closure of the neural tube, which is normally closed by 28 days
2. Etiology: complex, involving environmental and genetic factors that interact to modulate the incidence and severity of the developing phenotype.
3. Specific causes are identified in less than 10% of affected infants.
   a. Chromosomal abnormalities
   b. Single gene mutations
   c. Teratogens
4. Defects in the neural tube closure linked to 5,10-methylenetetrahydrofolate reductase deficiency and defects in the metabolism of folic acid
5. Low erythrocyte folate in the first trimester of pregnancy: associated with an increased risk of neural tube defects
6. Mildly elevated homocysteine in some pregnant women who subsequently give birth to infants with NTDs (Akar 2000)
7. Genetic factor: *MTHFR C677T* polymorphism: a specific mutation known as *C677T* polymorphism
   a. More common in parents of children affected with NTDs
   b. This polymorphism affects the enzyme methylenetetrahydrofolate reductase (MTHFR), causing it to require more folic acid to work properly
8. Major epidemiologic finding in NTDs: the protective effect of perinatal folic acid supplementation that reduces risk by 60–70%
9. Genetic studies in NTDs
   a. Have focused mainly on folate-related genes and identified a few significant associations between variants in these genes and an increased risk for NTDs
   b. However, we are witnessing a rapid and impressive progress in understanding the genetic basis of NTDs, based mainly on the development of whole genome innovative technologies and the powerful tool of animal models (Bassuk and Kibar 2009).

Clinical Features

There are several morphologic types of NTDs: open NTDs (anencephaly, cranial or spinal rachischisis, iniencephaly, meningomyelocele, cranioectomesodermal hypoplasia), closed NTDs (cranial meningocele, cranial encephalocele, spinal meningocele alone or with spinal cord abnormality), and myelocystocele.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_177,
© Springer Science+Business Media, LLC 2012

1. Anencephaly
   a. Refers to an absence of the brain and the calvarium covering the brain
   b. The most severe form of NTDs
   c. Incidence: about 1/1,000 live births
   d. Responsible for about 50% of all NTDs
   e. Infants with anencephaly
      i. Stillborn
      ii. Die shortly after birth
   f. Anterior pituitary, eyes, and brainstem usually spared
   g. Remaining tissue covering the basal cranium: a highly vascular and friable membrane referred to as area cerebrovasculosa
   h. Striking craniofacial appearance
      i. Absent cranial vault
      ii. An angiomatous membranous mass lying on the floor of the cranium
      iii. An absent or backward sloping of the forehead
      iv. Frog-like eyes (ocular proptosis)
      v. Puffy eyelids
      vi. A flattened nose
      vii. Large folded-down ears
      viii. Often an open mouth
      ix. A short neck
   i. Syndromes associated with anencephaly
      i. Chromosomal disorders [e.g., r(13), trisomy 18, del(13q)]
      ii. Monogenic disorder (e.g., Meckel syndrome)
      iii. Disruptive sequences (e.g., amniotic bands, maternal hyperthermia)
      iv. Associations (e.g., spina bifida, holoprosencephalic face syndrome, craniofacial duplication)
2. Craniorachischisis or spinal rachischisis
   a. Rachischisis: refers to anencephaly with a contiguous spinal defect involving at least the cervical spine region and extending for varying degrees down the spinal column
   b. The area cerebrovasculosa and the area medullovasculosa fill the skeletal defects of the cranium and of the spinal column.
   c. Short neck
   d. Upward-turned face
   e. Ears touching the shoulders
   f. Frequent polyhydramnios
   g. Frequently stillborn
   h. Neurologic involvement
      i. Primarily limited to brainstem and spinal reflexes
      ii. Occasional seizures resembling infantile spasms
3. Iniencephaly (Balci et al. 2001)
   a. The name iniencephaly derived from an abnormality of the neck (inion) and the brain (cephaly)
   b. Triad
      i. Deficient cranial bone
      ii. Cervical dysraphism (rachischisis)
      iii. Fixed retroflexion of the fetal head and severe lordosis of the cervicothoracic spine
   c. Closed or open lesions
      i. A closed lesion when the occipital bone is not malformed
      ii. An open lesion when the occipital bone is hypoplastic
   d. Site of the neural tube lesion: at the level of the cervical spine
   e. Severity of lesion
      i. Spina bifida with intact skin
      ii. Meningomyeloencephalocele
      iii. Open rachischisis
   f. Associated CNS malformations
      i. Anencephaly
      ii. Encephalocele
      iii. Microcephaly
      iv. Hydrocephaly
      v. Holoprosencephaly
      vi. Posterior fossa defects
      vii. Spinal defects such as cervical dysraphism
      viii. Fixed cervical hyperlordosis
   g. Other associated malformations
      i. Diaphragmatic hernia
      ii. Omphalocele
      iii. Thoracic cage deformities
      iv. Hypoplastic lungs
      v. Genitourinary malformations
      vi. Cyclopia
      vii. Cleft lip and palate
      viii. Imperforate anus
      ix. Clubfoot
      x. Single umbilical artery
   h. Die within a few hours in most newborns
4. Cranium bifidum occultum
   a. The most benign type
   b. Generally asymptomatic
   c. Skull defects often close over time

d. Persistent parietal foramina (sometimes called "Caitlin marks" after the family for which it was described; transmitted as an autosomal dominant trait via a gene located on 11p)
e. Persistent wide fontanelle

5. Cranial meningocele
   a. Associated with a defect in the skull
   b. Associated with protrusion of the leptomeninges
6. Encephalocele
   a. A type of cephalocele (a herniation of cranial contents though a skull defect) that contains brain
   b. Incidence: 1/10,000 live births
   c. Occurring most frequently in the occipital region (80–90%) and commonly associated with a variety of syndromes, notably Meckel–Gruber syndrome and Walker–Warburg syndrome
   d. Anterior encephaloceles: found more commonly in Roberts syndrome
   e. An isolated malformation of frontal encephalocele: more commonly seen in southeast Asia
   f. Outcome depending on the position of the defect and on the associated anomalies
   g. Chromosome syndromes associated with encephalocele
      i. Trisomy 13
      ii. Trisomy 18
      iii. Del(13q)
      iv. Del(2)(q21 → q24)
      v. Dup(1q)
      vi. Dup(6) (q21 → qter)
      vii. Dup(7)(qter → p11)
      viii. Dup(8)(q23 → qter)
      ix. Turner syndrome
   h. Monogenic disorders associated with encephalocele
      i. Meckel syndrome
      ii. Cryptophthalmos syndrome
      iii. Silverman–Handmaker type and Rolland–Desbuquois type of dyssegmental dysplasias
      iv. Knobloch syndrome
      v. Chemke syndrome
      vi. Roberts syndrome
      vii. Walker–Warburg syndrome
      viii. van Voss–Cherstovy syndrome
   i. Disruptive sequences associated with encephalocele
      i. Maternal hyperthermia
      ii. Warfarin embryopathy
      iii. Amniotic bands
   j. "Associations" associated with encephalocele
      i. Absent corpus callosum
      ii. Dandy–Walker malformations
      iii. Arnold–Chiari malformation
      iv. Holoprosencephaly
      v. Craniosynostosis
      vi. Ectrodactyly
      vii. Frontonasal dysplasia
      viii. Hypothalamic-pituitary dysfunction
      ix. Klippel–Feil anomaly
      x. Iniencephaly
      xi. Myelomeningocele
      xii. Oculoauriculovertebral spectrum
7. Spina bifida cystica (the most common lesion)
   a. Myelomeningoceles (meningomyeloceles)
      i. A herniation of the spinal cord and/or nerves through a bony defect of the spine
      ii. Usually open defects in which meninges and/or neural tissue is exposed to the environment associated with leaking CSF
      iii. The most common type of spina bifida cystica (about 90%)
      iv. Approximately 20% of affected infants have additional congenital anomalies, such as gastrointestinal, cardiac, and urogenital malformations.
      v. Surviving infants with spina bifida likely have severe, lifelong disabilities, and psychosocial maladjustment.
      vi. Medical problems
         a) Paralysis
         b) Hydrocephalus
         c) Arnold–Chiari type II malformation (herniation of the cerebellar vermis and brainstem below the foramen magnum)
         d) Endocrine abnormalities
         e) Tethered cord
         f) Syringomyelia (cavitation of the spinal cord whose walls are composed of glial tissue)
         g) Syringobulbia
         h) Deformed limbs and spine
         i) Bladder/bowel/sexual dysfunction
         j) Learning disabilities
      vii. Neonates with Arnold–Chiari malformation presenting with:
         a) Stridor secondary to vocal cord paralysis
         b) Central apnea
         c) Aspiration

d) Dysphagia
e) Hypotonia
f) Progressive brainstem dysfunction
g) Myelopathy
h) Quadriparesis
i) Nystagmus
j) Strabismus
k) Poor sucking
l) Swallowing difficulties

b. Meningoceles
i. A saccular herniation of meninges and CSF through a bony defect of spine and usually covered by normal skin
ii. No herniation of the spinal cord or nerve roots into the dorsal dural sac
iii. A cystic mass full of cerebrospinal fluid
iv. Without associated neurologic problems such as hydrocephalus and Chiari II malformation

c. Lipomeningocele or lipomyelomeningocele
i. A lipomatous mass herniating through the bony defect and attaching to the spinal cord, tethering the cord and often its nerve roots
ii. Presentation with a skin-covered mass above the buttocks and eventual neurologic deficits
iii. Absent associated hydrocephalus

d. Myelocystocele
i. A large terminal cystic dilatation of the spinal cord secondary to hydromyelia giving rise to a large terminal skin-covered sac
ii. Constituting 4–6.5% of the skin-covered masses overlying the lower spine
iii. The majority of cases are dorsally located; only rarely (about 0.5%) are ventral in location
iv. The ventral type is an anterior sacral meningocele, most often presenting as a pelvic mass in females
v. Cervical myelocystocele
vi. Lumbar myelocystocele
vii. Terminal myelocystoceles accompanying midline abdominal and pelvic defects such as part of the OEIS (*o*mphalocele-*e*xstrophy of the bladder-*i*mperforate anus-*s*pinal defects) complex
viii. Chiari malformation less frequent since the lesion is covered by dura with regular hydrodynamics of the cerebrospinal fluid
ix. Other associated malformations
a) Genitourinary tract anomalies
b) Intestinal malrotation
c) Club feet
x. Differential diagnoses
a) Meningomyelocele
b) Lumbosacral and sacrococcygeal teratomas
c) Lipomas
d) Lipomyelomeningoceles
e) Hamartomas

e. Lifelong disability risks in infants with spina bifida
i. At risk for psychosocial maladjustment
ii. Medical problems resulting from the neurologic defects or from its repair
a) Paralysis
b) Hydrocephalus
c) Arnold–Chiari malformation
d) Endocrine abnormalities
e) Tethered cord
f) Syringomyelia
g) Syringobulbia
iii. Medical problems as sequelae of the neurologic deficits
a) Deformations of the limbs and spine
b) Bowel, bladder, and sexual dysfunction
c) Learning disabilities

8. Spina bifida occulta
a. A bony defect of the spine occurs most often at S1 and/or S2 and is covered by normal skin (a closed lesion)
b. No herniation of the meninges through the bony defect
c. Without associated hydrocephalus or Chiari II malformations
d. Paraspinal cutaneous lesions with high index of suspicion pointing towards the underlying spina bifida (Drolet 2000)
i. Hypertrichosis or hairy patches
ii. Lumbosacrococcygeal dimples and sinuses
iii. Acrochordons (skin tags): a small, flesh-colored to dark brown, sessile or pedunculated lesion consisting of a hyperplastic epidermis enclosing a dermal stalk of connective tissue
iv. True tails: a caudal midline appendage capable of spontaneous or reflex motion consisting of skin covering muscle, adipose, connective tissue, blood vessels, and nerves but lack vertebrae and abnormal tissue

v. Pseudotails: a caudal protrusion composed of adipose (lipoma), teratomatous elements, or cartilage
vi. Lipomas
vii. Hemangiomas: indicator for tethered cord syndrome
viii. Aplasia cutis congenita (congenital absence of skin) or scar
ix. Dermoid cyst or sinus: 12–35% of children with spina bifida occulta have sacrococcygeal dermoid cysts or sinuses, which rarely connect with the intraspinal canal. Lesions above these levels along the spine are more likely to connect with the intraspinal canal and increasingly associated with spina bifida occulta.

e. Paraspinal cutaneous lesions with low index of suspicion (Drolet 2000)
i. Telangiectasia
ii. Capillary malformation (port-wine stain)
iii. Hyperpigmentation (lentigines or café-au-lait-like lesions)
iv. Melanocytic nevi
v. Teratomas: most common in the sacrococcygeal region in infancy

f. Neurologic deficits (Ellenbogen 2001)
i. Weakness of leg or legs
ii. Leg atrophy or asymmetry
iii. Loss of sensation
iv. Painless sores
v. Hyperreflexia
vi. Unusual back pain
vii. Abnormal gait
viii. Radiculopathy
ix. Neurogenic bladder
x. Incontinence

9. Multiple NTDs at different sites (Ahmad et al. 2008): The presence of meningomyelocele and/or encephaloceles at multiple (two or more) sites along the vertebral axis is a very rare event occurring in 1% of cases
a. Double NTDs
b. Triple NTDs

Diagnostic Investigations

1. Neurological examination of neonates
a. Size, site, and level of the lesion
b. Motor and sensory level
c. Presence of associated hydrocephalus
d. Presence of associated symptomatic hindbrain herniation such as Chiari II malformation
e. Presence of associated orthopedic deformity
2. Neonatal cranial ultrasonography to demonstrate hydrocephalus
3. Radiography
a. Occult spinal disorders in children (Ellenbogen 2001)
i. Lamina defects
ii. Hemivertebrae
iii. Scoliosis
iv. Widening of interpedicular distance
v. Butterfly vertebrae
b. Generally to detect bony defects
4. CT
a. Cranial defects
b. Spinal defects
5. MRI: provide exquisite detail of both the cranial defect and the herniated contents
a. Cranial defects
b. Cerebral defects
i. Hydrocephalus
ii. Gray matter heterotopia
iii. Schizencephaly
iv. Gyral abnormalities
v. Agenesis and thinning of the corpus callosum
vi. Abnormal thalami
vii. Abnormal white matter
c. Herniated contents in Chiari malformations
d. Associated lesions
i. Diastematomyelia
ii. Syringomyelia
iii. Hydromyelia
iv. Tethered cord

Genetic Counseling

1. Recurrence risk
a. Affected first-degree relatives
i. 1 sib affected (5%)
ii. 2 sibs affected (10%)
iii. 3 sibs affected (21%)
iv. 1 parent affected (3–4.5%)
v. 1 parent and 1 sib affected (13%)

b. Affected second-degree relative: uncle/aunt, half sib (2%)
c. Third-degree relative: first cousin (1% or less)

2. Prenatal diagnosis (Cameron and Moran 2009)
   a. Risk assessment prior to biochemical and/or ultrasonic screening
      i. The most significant risk factor: a history of having a previous child affected with neural tube defect
      ii. Other independent (nongenetic) risk factors (Cameron and Moran 2009; Copp and Greene 2010)
         a) Valproic acid
         b) Folic acid antagonists (methotrexate, aminopterin, carbamazepine, fumonisin, trimethoprim)
         c) Vitamin A
         d) Maternal diabetes
         e) Maternal obesity
         f) Hyperthermia
         g) Micronutrient deficiencies (folate, inositol, vitamin B12, zinc)
   b. Two approaches used for NTD screening in low-risk population
      i. Biochemical testing of maternal blood for alpha-fetoprotein (AFP)
         a) Measurement of maternal serum alpha-fetoprotein (MSAFP): a useful tool for mass screening of pregnant women for NTDs
         b) All cases of anencephaly and about 65% of cases of spina bifida are identified by measurement of MSAFP and ultrasonography.
         c) Not effective in closed NTDs (10% of lesions) which do not increase AFP
         d) AFP needs to be expressed as multiples of the median (MoM), since the maternal serum level of AFP varies with gestation.
         e) Using 2.5 MoM as screen positive in singleton pregnancies, the detection rate for anencephaly is expected to be >95% and for open NTD between 65% and 80%.
         f) False-positive rates should lie between 1% and 3% (Bradley et al. 2005). A raised serum AFP is not diagnostic for open NTD as it can be associated with other abnormalities including gastroschisis, omphalocele, congenital nephrosis, and fetal demise.
      ii. Use of 2D/3D ultrasonography
         a) Used both as a screening test and as a follow-up test after positive results on MSAFP screening
         b) First trimester detection rates for anencephaly and encephalocele: typically quoted as >90% for anencephaly and encephalocele and lower rates for spina bifida (44%)
         c) Second trimester scanning improves the detection of spina bifida, typically to 92–95%
         d) Direct demonstration of the spinal defect
         e) Indirect signs: lemon sign (referring to a symmetrical bifrontal narrowing of the skull) and banana sign (cerebellar abnormality)
         f) Carefully evaluate the whole fetus because of associated malformations in around 20% (Stoll et al. 2007)
      iii. Fetal MRI (Saleem et al. 2009)
         a) An important adjunct to US in assessing NTD
         b) Can identify topography and contents of sacs, add CNS and non-CNS findings
         c) Influence management decision
   c. Prenatal diagnosis of iniencephaly by careful sonography
      i. Marked fixed retroflexion of the head and neck
      ii. Rachischisis
      iii. Extreme lordosis of the fetus
   d. Amniotic fluid alpha-fetoprotein (AFAFP) and amniotic fluid acetylcholinesterase (AFAChE): confirmatory tests for spina bifida

3. Management: complex and challenging
   a. Prevention
      i. Folic acid supplementation of 0.4 mg/day to all women capable of becoming pregnant: decrease the first occurrence of NTDs by at least 40%
      ii. Folic acid supplementation of 4 mg/day in families with previous children born with NTDs: decrease risk of recurrence by 70%
      iii. Periconceptional use of folic acid supplementation will prevent 50–70% of NTDs.
   b. Medical management
      i. Antibiotic prophylaxis to prevent meningitis and ventriculitis

ii. Urological management
iii. Management of rectal incontinence
iv. Preventable conditions
a) Urinary tract infections
b) Calculi
c) Skin ulcerations
d) Latex allergy and sensitization

c. Surgical treatment
i. Closing all but the prognostically worst cases
ii. Concurrent shunting of coexisting hydrocephalus often necessary
iii. Decompression of the posterior fossa and/or cervical cord in Chiari II malformations
iv. Spina bifida occulta: prophylactic surgical repair more effective than waiting for patients to experience a significant neurologic deficit such as a neurogenic bladder or leg weakness from these occult spinal lesions
v. Orthopedic management of scoliosis

d. Fetal spina bifida repair (Fichter et al. 2008)
i. Several reports of intrauterine repair of meningomyelocele with benefits to motor function and a decreased incidence of shunt-dependent hydrocephalus and a reversal of hindbrain herniations
ii. Especially fetuses treated before 26 weeks of gestational age, with small ventricles (<14 mm) at the time of surgery, and lesion levels below L2 seem to profit from fetal surgery
iii. However, the clinical relevance of the observed regression of Chiari II malformation is still in dispute and a positive effect on sensorimotor function could only be observed for patients with higher lumbar and thoracic spinal defects in the early postnatal period.

e. Rehabilitation programs
i. Physical therapy
ii. Occupational therapy
iii. Speech therapy
iv. Recreational therapy

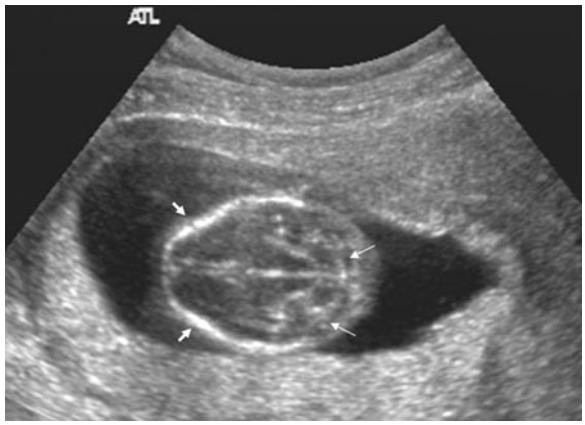

Fig. 1 Inward scalloping of the frontal bones, known as "lemon sign" (*short arrows*) and "banana sign" configuration of the cerebellum (*long arrows*), in a fetus with open spina bifida

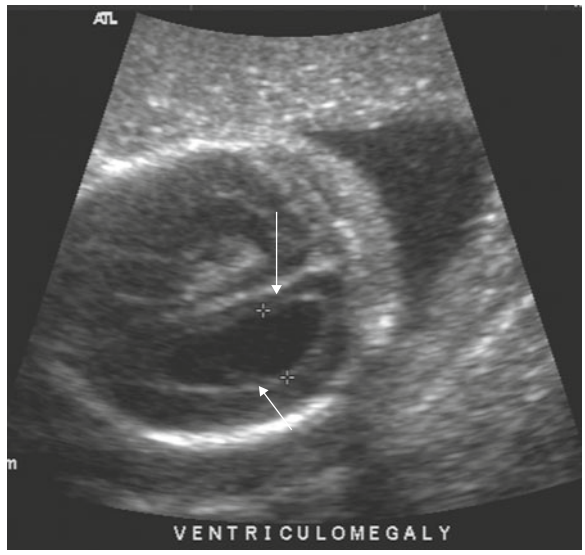

Fig. 3 Ventriculomegaly (*arrows*) observed in a fetus with lumbar meningomyelocele

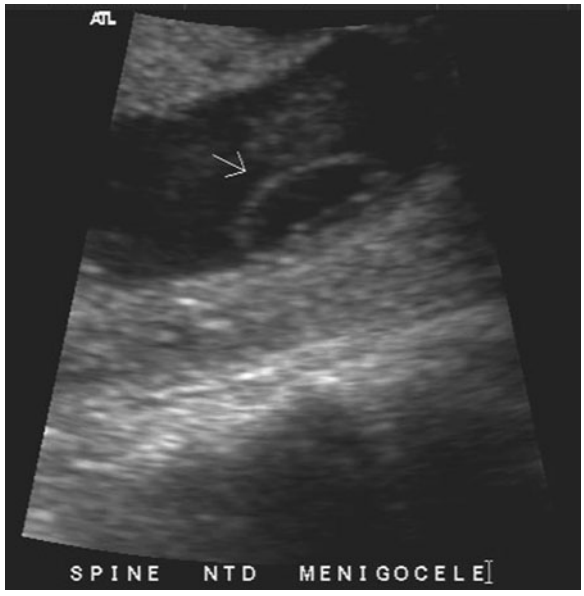

Fig. 2 A paraspinal unilocular cyst (*arrow*) in a fetus with lumbosacral meningocele

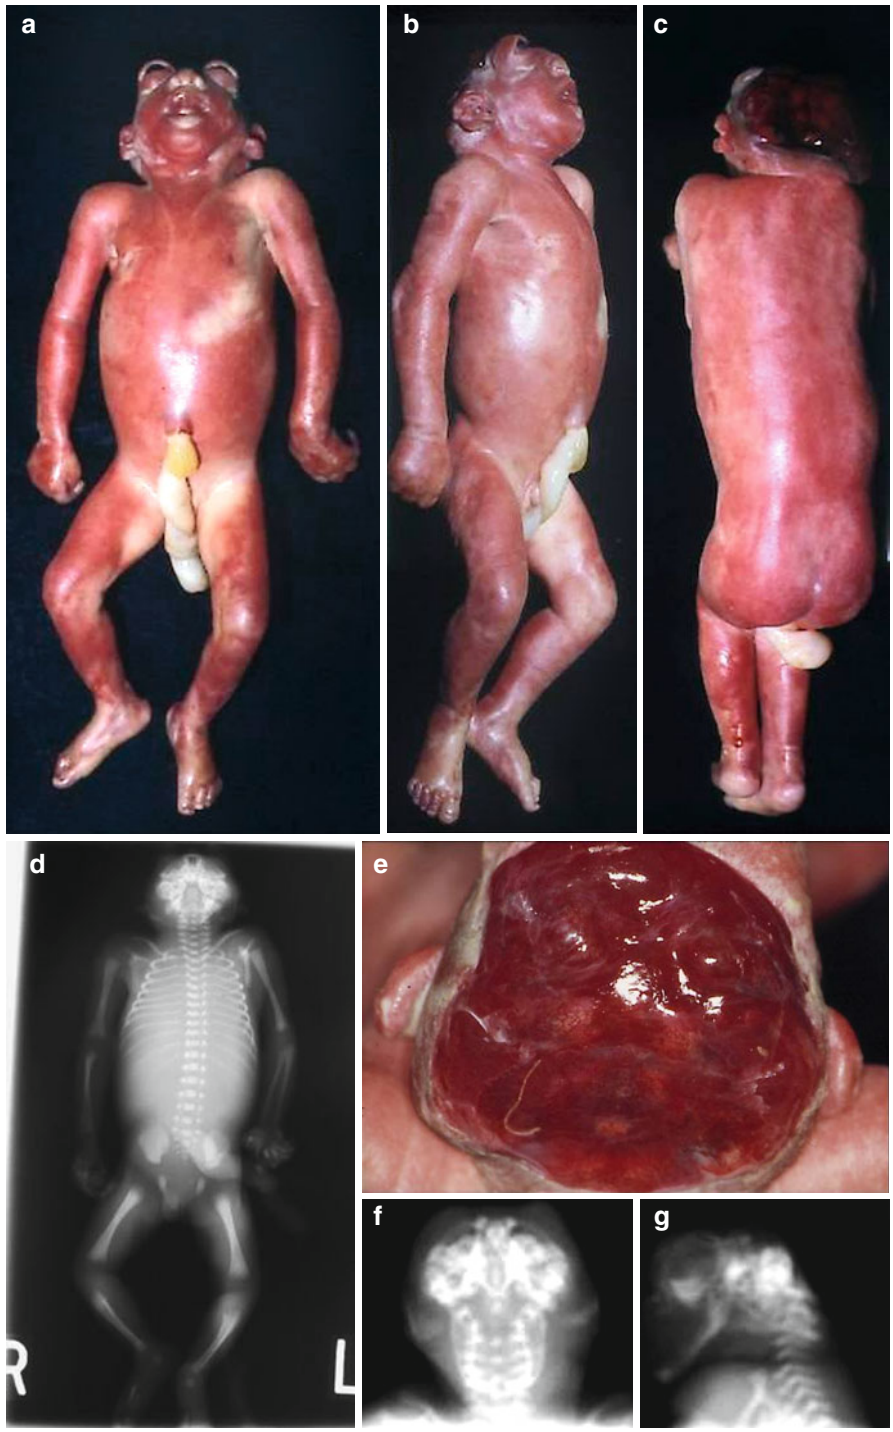

Fig. 4 (**a**–**g**) A stillbirth with classic anencephaly showing absent cranial vault, an angiomatous mass on the skull base, an absent forehead, protuberant, puffy "frog-like" eyes, an open mouth, large folded-down ears, and a short neck. Radiographs show the absent calvarium

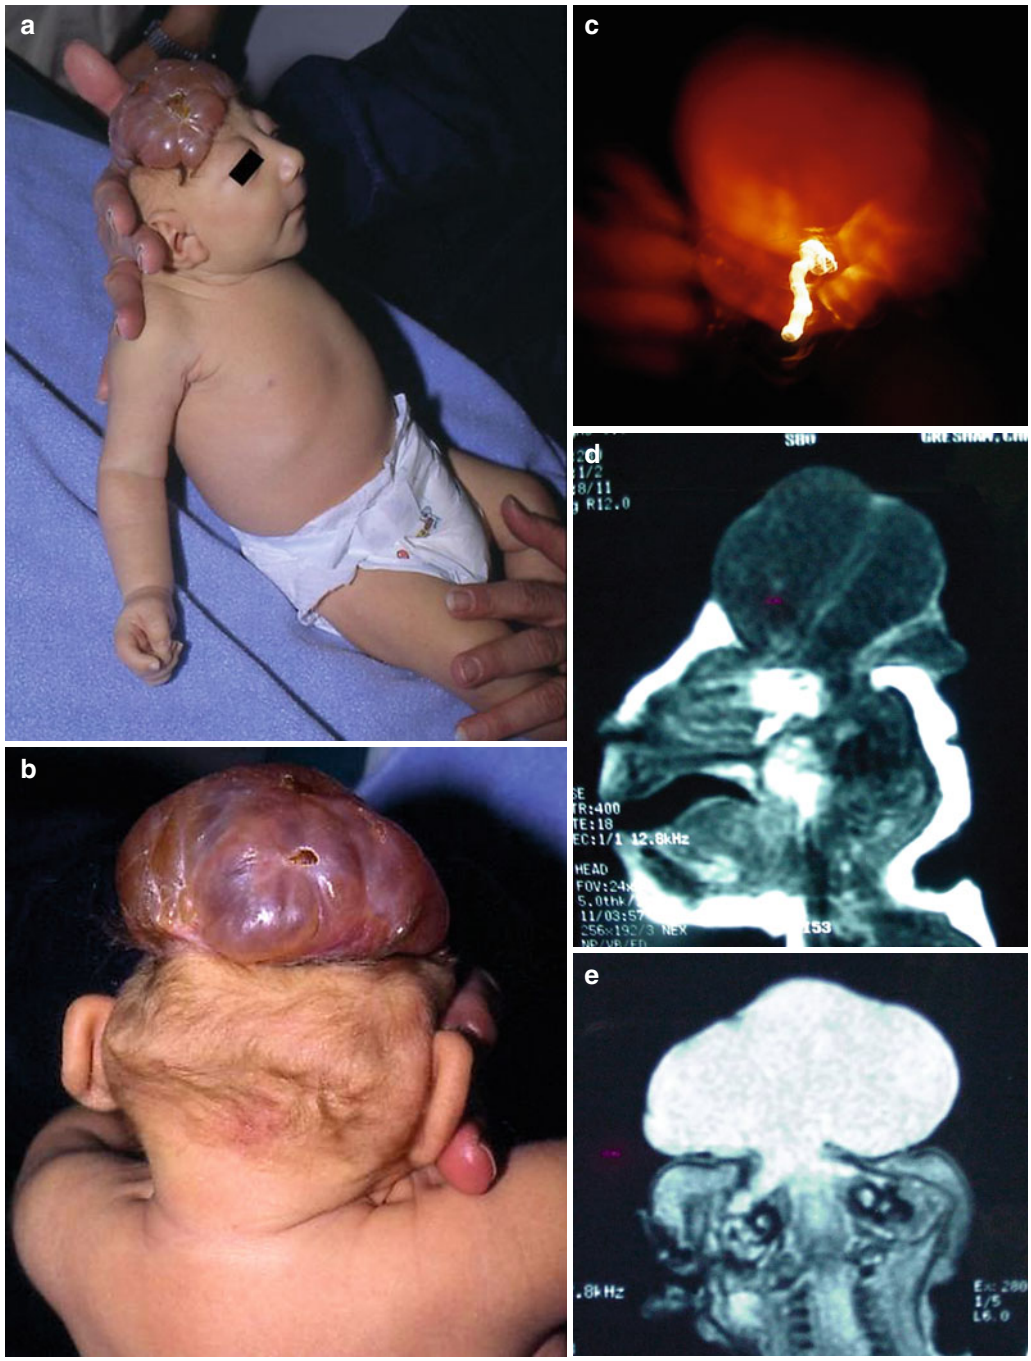

Fig. 5 (**a**–**e**) A newborn with anencephaly/meningocele showing the presence of a meningeal sac above the base of the skull without containing the brain tissue, illustrated by transillumination and MRI of the brain with or without contrast

Fig. 6 Another neonate with anencephaly/meningocele showing similar craniofacial anomalies

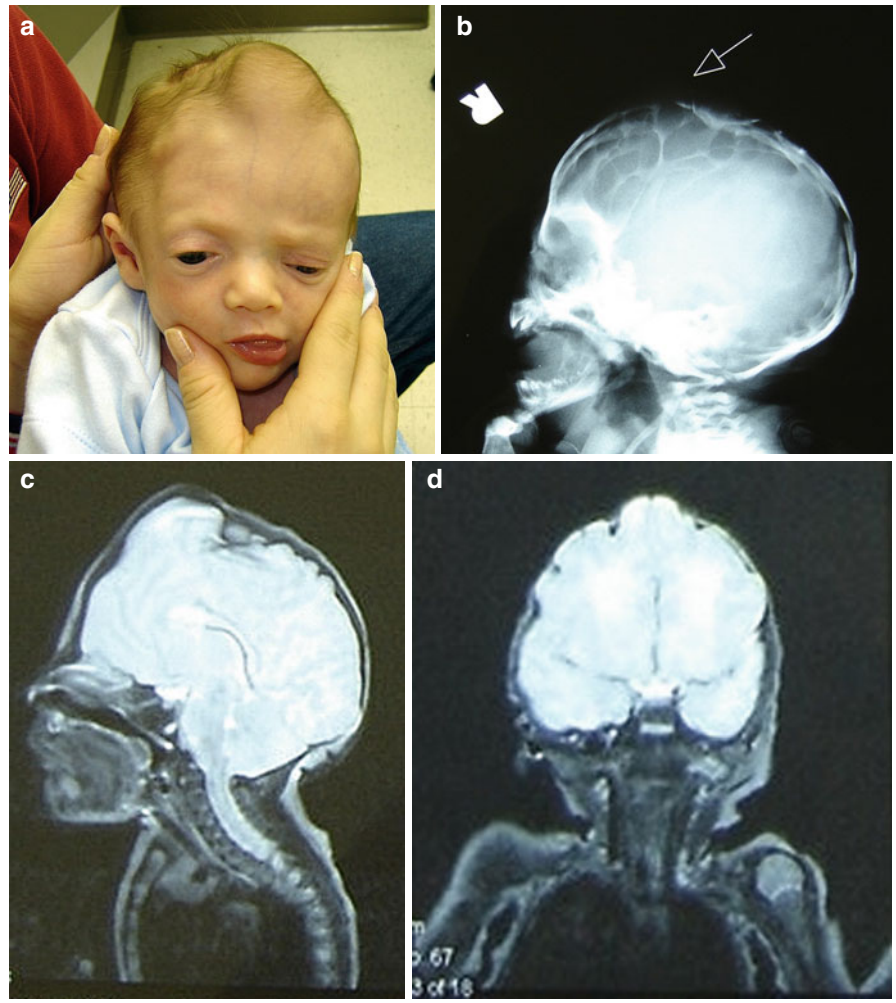

Fig. 7 (**a**–**d**) A 2-week-old infant with frontal encephalocele, illustrated by lateral skull radiograph and MRI of the brain

Fig. 8 (**a**, **b**) Newborns with an occipital encephalocele

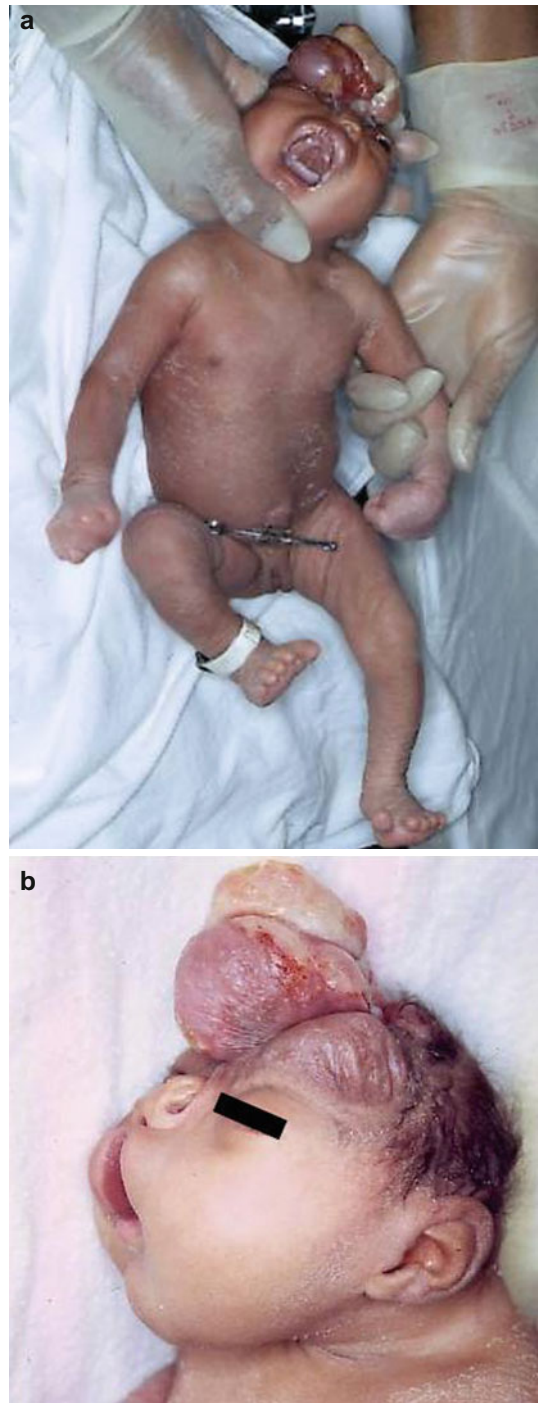

Fig. 9 (**a**, **b**) Encephalocele associated with amniotic band syndrome

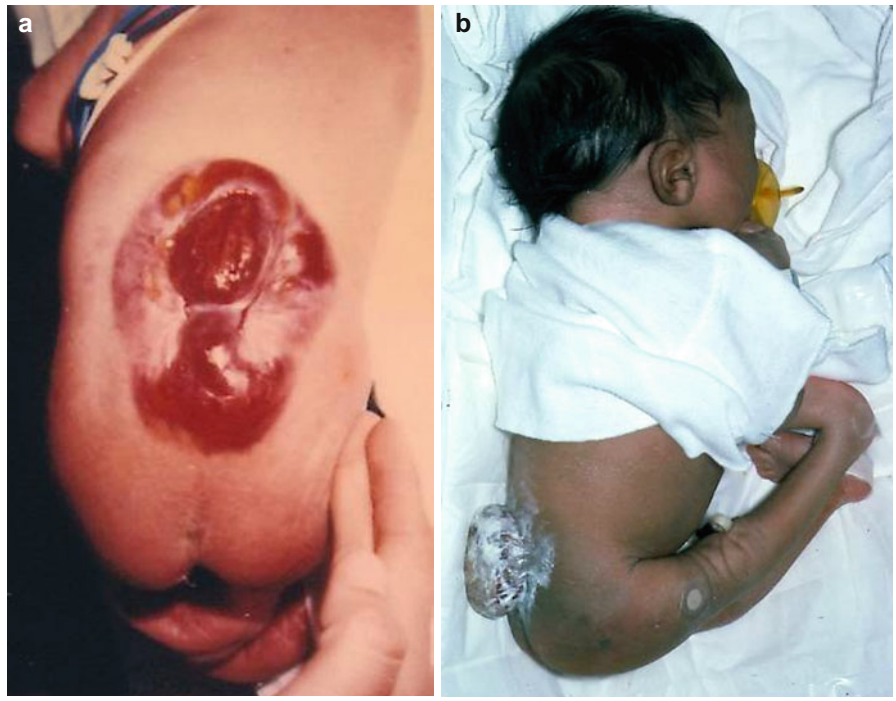

Fig. 10 (**a**, **b**) Newborns with a lumbosacral myelomeningocele

Fig. 11 (**a**, **b**) A fetus with trisomy 18 and open lumbosacral spina bifida

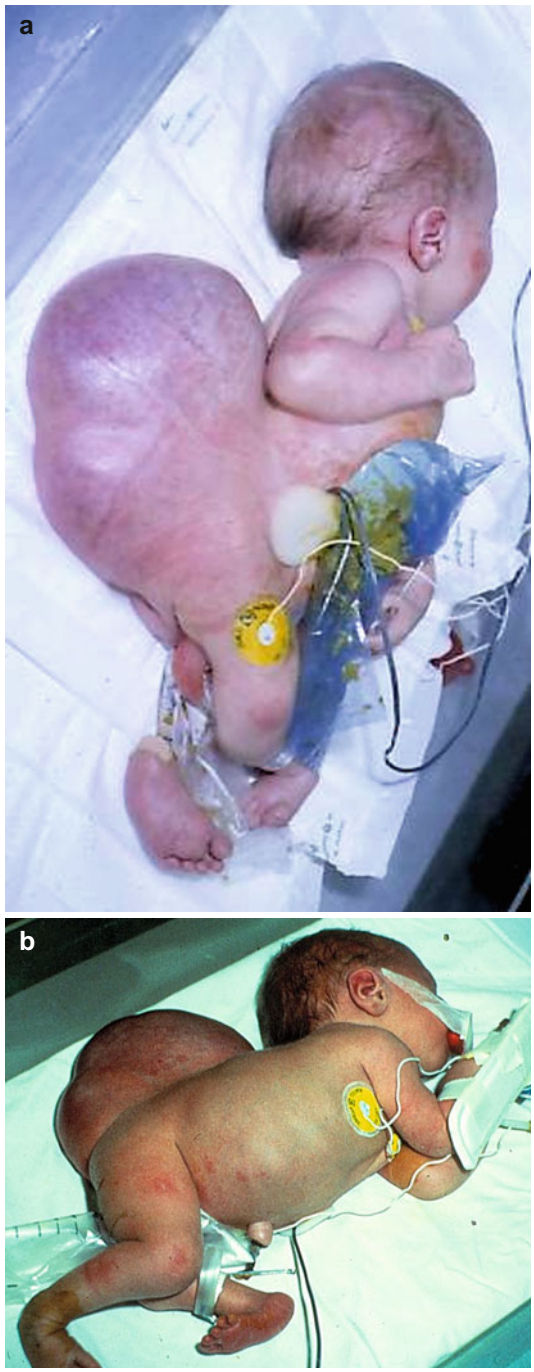

Fig. 12 (**a**, **b**) Two infants with a large lumbosacral myelocystocele covered with skin

Fig. 13 (**a**–**c**) A stillborn with iniencephaly showing deficient cranium, short neck, cervical rachischisis, fixed retroflexion of the head, and severe lordosis of the cervicothoracic spine

Fig. 14 (**a**, **b**) A stillborn with craniorachischisis showing anencephaly with a contiguous spinal defect involving cervical spine region and extending down the spinal column, short neck, upward-turned face, and ears touching the shoulders

Neurofibromatosis I

Neurofibromatosis I (NF1) was described in 1882 by von Recklinghausen (von Recklinghausen 1882) who gave the disease its first full description, including recognition that the tumors arose from the fibrous tissue surrounding small nerves, leading to his designation of these tumors as "neurofibromas." Thus, it is also called von Recklinghausen disease. It is one of the most common dominantly inherited genetic disorders affecting about 1 in 3,000 newborns and 1,000,000 people worldwide.

Synonyms and Related Disorders

Peripheral type neurofibromatosis; von Recklinghausen disease

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. High spontaneous mutation rate
      i. One of the highest in humans (1×10^{-4} per gamete per generation)
      ii. 50% of the cases are due to new mutations.
      iii. Most patients are expected to have different mutations due to the high mutation rate at the *NF1* locus.
   c. Full penetrance: essentially 100% in adults after careful examination by a slit-lamp examination
   d. Widely variable expressivity even among family members with the same mutation (Riccardi and Lewis 1998; Korf and Rubenstein 2005)
   e. Highly pleiotropic
2. The *NF1* gene
   a. Mapped to pericentromeric region of 17q11.2
   b. Entire sequence of the expressed *NF1* gene has been identified by a positional cloning strategy.
   c. A large size of the gene spanning over 350 kb of genomic DNA
   d. Consisting of at least 60 exons
   e. Translated into a 240-kDa protein, neurofibromin
3. Mutations of the *NF1* gene
   a. Most described mutations are unique to a particular family.
   b. Type of mutations (over 250 different mutations described)
      i. Stop codon
      ii. Substitutions
      iii. Deletions of only one or a few base pairs, multiple exons, or the entire gene
      iv. Insertions
      v. Intronic changes affecting splicing
      vi. Alterations of the 3′ untranslated region of the gene
      vii. Gross chromosomal rearrangements
   c. Severe truncation of the gene product in about 70% of the germ-line mutations
   d. *NF1* gene usually classified as a tumor suppressor gene since mutations in both *NF1* alleles are detectable in malignant tumors associated with NF1 and in benign tumors, such as neurofibromas.
4. Knudson two-hit hypothesis is also applicable to explain the mechanism by which the manifestations of *NF1* occur (Dupuis and Nezarati 2001).
   a. A mutated tumor suppressor gene (the first hit)
      i. Inherited from a parent
      ii. Presents in every cell of the body

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_178,
© Springer Science+Business Media, LLC 2012

b. A second mutation (hit) in some somatic cells of the individual
   i. Knocks out the other copy of the gene
   ii. Resulting in complete loss of the gene product and unregulated cell growth/division
   iii. Resulting in a predisposition to cancer in the cells

5. Pathogenesis of NF1 (Boyd et al. 2009)
   a. Neurofibromin
      i. The *NF1* gene protein product
      ii. A tumor suppressor expressed in many cells, primarily in neurons, glial, Schwann cells and early in melanocyte development (Stocker et al. 1995)
      iii. A regulator of ras guanosine triphosphatase activity (GTPase-activating protein, GAP), and as such, serves as a regulator of signals for cell proliferation and differentiation (Korf and Rubenstein 2005)
      iv. Loss of function of neurofibromin may, therefore, remove this regulation and lead to uncontrolled cell proliferation
   b. Schwann cells in neurofibromas and melanocytes in café-au-lait macules
      i. Have a mutation in both *NF1* alleles, including a germ line and an acquired somatic mutation
      ii. Considered the primary tumor cell in their respective cutaneous manifestation
      iii. Based on these findings, it is likely that NF1 functions as a tumor suppressor gene (Maertens et al. 2007; de Schepper et al. 2008).
      iv. Both of these cell types are descendants of neural crest.
      v. The exact timing of the acquired mutation is unknown but is crucial in the development of the various manifestations.
         a) Experiments have shown that *NF1* gene inactivation at the neural crest stage and mature Schwann cell stage do not lead to tumor formation.
         b) However, in a progenitor intermediate step between these two stages, tumor formation occurs with *NF1* gene inactivation (Wu et al. 2008).

6. Marked heterogeneity in NF1
   a. Whole gene deletion with distinctive phenotype
      i. Early onset of cutaneous neurofibromas
      ii. Facial anomalies
         a) Macrocephaly
         b) Hypertelorism
         c) Ptosis
         d) Down-slanting palpebral fissures
         e) Short nose
         f) Low-set ears
         g) Micrognathia
      iii. Developmental delay
      iv. Other standard features of NF1
   b. Alternate forms of NF1 (conditions with incomplete/atypical features)
      i. Mixed neurofibromatosis
      ii. Localized neurofibromatosis
         a) Segmental neurofibromatosis (occasional localized café-au-lait spots, segmental distribution of dermal neurofibromas, no systemic manifestations, uncommon internal manifestations of neurofibromas)
         b) Gastrointestinal neurofibromatosis
         c) Familial spinal neurofibromatosis (multiple café-au-lait spots and neurofibromas involving spinal cord, lack dermal neurofibromas, and Lisch nodules)
         d) Familial café-au-lait spots (autosomal dominant café-au-lait spots in rare multigeneration families, lack of neurofibromas, axillary freckling, and Lisch nodules)
   c. Related forms of NF1 (conditions with additional features)
      i. Neurofibromatosis/Noonan syndrome (may or may not fit the criteria of NF1 but with features of Noonan syndrome)
      ii. Watson syndrome
         a) Multiple café-au-lait spots
         b) Pulmonary stenosis
         c) Intertriginous freckling
         d) Short stature
         e) Low intelligence

7. Several pathways are thought to be involved in the development of tumors associated with NF1 (Brems et al. 2009).
   a. Rat sarcoma viral oncogene homologue (RAS)–mitogen-activated protein kinase (MAPK): Neurofibromin is involved in the downregulation of RAS–MAPK pathway, and NF1 belongs to the group of RAS–MAPK disorders that include Noonan, cardiofaciocutaneous, Costello, LEOPARD, and NF1-like syndrome.

b. Mammalian target of rapamycin (mTOR)
c. P21 protein (Cdc42/Rac)–activated kinase 1 (PAK1)

8. Variable expressivity (one of the hallmarks of NF1)
   a. Intrafamilial variability (marked phenotypic differences may be observed within the same family).
   b. Interfamilial variability (full spectrum of the disease, mild to severe form, may be present in different families in which affected individuals have the same NF1 mutation).
9. Prototype of a pleiotropic congenital multiple dysplasia syndrome involving CNS, vascular and skeletal systems, and a predilection for hamartomas, dysplasia, and malignancies
10. Mosaicism resulting from somatic mutations
    a. Early somatic mutation gives rise to generalized disease, clinically indistinguishable from nonmosaic form.
    b. Late somatic mutation gives rise to localized disease often described as segmental form.
    c. Individuals with the mosaic form
       i. Less likely to have severe disease even with a generalized phenotype
       ii. Lower offspring recurrence risk than individuals with the nonmosaic form

Clinical Features

1. Extreme interfamilial and intrafamilial clinical variability
2. Often not diagnosed at birth, especially a new mutation case
3. Cutaneous manifestations
   a. Café-au-lait spots (analogy of the color to coffee with milk)
      i. Present in nearly all patients
      ii. Round or oval, discrete, well circumscribed, uniformly light brown–pigmented, macular lesions
      iii. Usually present at birth but continue to increase in number and size during the first decade
      iv. Six or more café-au-lait spots exceeding 0.5 cm in diameter in prepubertal children or exceeding 1.5 cm in broadest diameter in postpubertal individuals: the pathognomonic sign for NF1
   b. Hyperpigmentation patches may be associated with underlying plexiform neurofibromas, which are congenital in origin and which may lead to extensive localized hypertrophy.
   c. Freckles in the axillary, groin, and intertriginous areas (almost 90%): a helpful diagnostic feature
   d. Dermal neurofibromas, usually present in adults with NF1
   e. Xanthogranulomas (2–5%)
   f. Hemangiomas (5–10%)
4. Lisch nodules (asymptomatic pigmented iris hamartomas)
   a. An extremely important diagnostic feature
      i. A characteristic sign of NF1 present in 97% of postpubertal patient
      ii. Lesions typically not detected before 5 years of age
      iii. Often appear before development of neurofibromas
   b. Best observed with slit-lamp examination
   c. Raised, often pigmented nodules of the iris, pathologically representing hamartomas
   d. Never resulting in significant disease
5. Peripheral neurofibromas
   a. Benign histologically
   b. May involve viscera, such as bowel, bladder, and liver, causing bleeding and obstruction
   c. May result in functional compromise and cosmetic disfigurement
   d. Increase in size and number during puberty and pregnancy
6. Gross forms of neurofibromas (Woodruff 1999)
   a. Localized cutaneous neurofibromas (nodular or polypoid): the most common form of neurofibromas. Numerous localized cutaneous neurofibromas are the hallmark of NF1.
   b. Localized intraneural neurofibromas (causing fusiform enlargement of the affected nerve)
   c. Plexiform neurofibromas (25%)
      i. Diffuse lesion involving nerve, muscle, connective tissue, vascular elements, and overlying skin
      ii. Commonly leading to overgrowth of surrounding tissues during childhood
      iii. Usually congenital
      iv. Almost invariably apparent by 4 or 5 years of age
      v. One of the most common and debilitating complications of NF1

vi. Account for substantial morbidity, including disfigurement, functional impairment, and life-threatening complications
vii. Subject to transformation into malignant peripheral nerve sheath tumor (2–5%)

d. Diffuse neurofibromas involving skin and subcutaneous tissue
e. Massive soft-tissue neurofibromas (extreme neurofibromatous growth producing massive, diffuse infiltration of soft tissue of a body part, often a distal extremity, leading to localized gigantism, cape formation, or, at the extreme end of the spectrum, formation of disfiguring redundant soft-tissue masses)

7. Certain selected clinical features of NF1 in different age groups
   a. Infancy
      i. Pseudarthrosis
      ii. Seizures
      iii. Constipation
      iv. Congenital glaucoma
      v. Deafness
      vi. Optic gliomas
   b. Childhood
      i. Optic gliomas
      ii. Other brain tumors
      iii. Kyphoscoliosis
      iv. Genu valgum
      v. Seizures
      vi. Cognitive disorders
         a) Developmental delay
         b) Learning disabilities
         c) Mental retardation
      vii. Speech impediments
      viii. Short stature
      ix. Macrocephaly
      x. Early puberty
      xi. Hypertension
      xii. Embryonal tumors
      xiii. Leukemia
   c. Preadolescence and adolescence: worsening of previous problems such as
      i. Scoliosis
      ii. Cosmetic disfigurement
      iii. Major psychologic burden
      iv. Malignancy (neurofibrosarcoma)
   d. Early adulthood
      i. Increase in the number and size of cutaneous, subcutaneous, and plexiform neurofibromas
      ii. Cosmetic disfigurement
      iii. Functional compromise
         a) Pain
         b) Paralysis
         c) Gastrointestinal hemorrhage
         d) Renovascular hypertension
   e. Adulthood
      i. An increased risk of developing a specific cancer (2–5% of patients with NF1)
      ii. Neurofibrosarcoma and malignant peripheral nerve sheath tumor commonly arise in a plexiform neurofibroma in a young adult with symptoms of pain or rapid growth.
8. Skeletal involvement (50% of cases)
   a. Short stature (30%)
   b. Scoliosis
      i. Observed in approximately 20% of children with NF1
      ii. The most common skeletal defect
      iii. With or without classic dystrophic features such as vertebral scalloping and rib penciling
   c. Kyphosis
   d. Cervical spine abnormalities
   e. Spondylolisthesis
   f. Congenital pseudarthroses (3%), frequently with bowing of the tibia and fibula (2–5%)
      i. A peculiar and uncommon complication
      ii. First noted as bowing, particularly of the tibia and fibula, in young children
      iii. May progress to thinning of the cortex, pathologic fracture, and severe difficulties with nonunion of the fragments
      iv. May go on to form a pseudarthrosis, or false joint, leaving the limb severely compromised
   g. Macrocephaly (40%)
   h. Skull bony defects
      i. Posterosuperior orbital wall bony defect
      ii. Overgrowth of cranial bones
      iii. Craniofacial asymmetry
      iv. Sphenoid wing dysplasia (5–10%)
   i. Ocular hypertelorism
   j. Hemihyperplasia of a limb or digit
   k. Spina bifida
   l. Absent patella
   m. Elevated scapulas
   n. Congenital dislocation (hip, radius, ulna)

o. Clubfoot
p. Syndactyly
q. Complete or partial absence of the limb bones

9. Endocrine abnormalities
   a. Sexual precocity (2–5%, the most common endocrine abnormality)
   b. Hypopituitarism
   c. Hypogonadism
   d. Gigantism
   e. Acromegaly
   f. Delayed sexual development
   g. Obesity
   h. Hypoglycemia
   i. Diabetes insipidus
   j. Goiter
   k. Myxedema
   l. Hyperparathyroidism
10. Cardiovascular diseases
   a. Vasculopathy
      i. Asymptomatic throughout life in many patients
      ii. Symptomatic vasculopathy: uncommon
      iii. Affects vessels, from aorta to small arterioles, result in vascular stenosis, occlusion, aneurysm, pseudoaneurysm, rupture, or fistula formation
      iv. Renal arteries: the most frequently involved site
      v. NF1-associated cerebrovascular disease in children: presents with weakness, involuntary movements, headaches, or seizures as a result of cerebral ischemia
      vi. NF1-related cerebrovascular disease in adults: similar symptoms and signs as a result of intracranial hemorrhage
   b. Hypertension
      i. Extremely common in adult patients with NF1 (33%)
      ii. Causes
         a) Essential hypertension
         b) Renal artery stenosis
         c) Pheochromocytomas
   c. Congenital heart disease (0.4–6.4%)
      i. Pulmonary stenosis (recognized feature of Watson syndrome, NF1–Noonan syndrome, and individuals with large deletions of the NF1 gene)
      ii. Left heart obstruction (aortic stenosis or coarctation)
      iii. Other CHD
11. Neuropsychological impairment
   a. Cognitive impairments (30–65%)
   b. Learning disabilities (30–60%)
      i. Easy distractibility
      ii. Impulsiveness
      iii. Deficient visual–motor coordination
      iv. Language and vocabulary deficits
   c. Mental retardation (4–8%)
   d. Behavioral difficulties
   e. Hydrocephalus (5%)
   f. Neurosensory hearing loss (5%)
12. Tumor types associated with NF1 (Brems et al. 2009)
   a. Non–nervous system tumors
      i. Adulthood
         a) Gastrointestinal stromal tumor
         b) Somatostatinoma
         c) Pheochromocytoma
         d) Breast cancer
      ii. Childhood: rhabdomyosarcom
   b. Nervous system tumors
      i. Adulthood and childhood
         a) Astrocytoma
         b) Malignant peripheral nerve sheath tumor
      ii. Childhood: neuroblastoma
13. Miscellaneous complications
   a. Headache (10–20%)
      i. Bothersome but usually not a disabling complaint
      ii. Headache possibly indicates the presence of an intracranial tumor but no identifiable etiology in many patients.
   b. Generalized itching or itching localized to newly developing neurofibromas experienced by many individuals
   c. Constipation observed especially in patients with plexiform neurofibromas in the pelvic area which interfere with autonomic innervation of the colon and produce both bowel and bladder problems
14. Pathological manifestations of NF1 (Woodruff 1999)
   a. Epidermis (pigmented macule or café-au-lait spot)
   b. Iris (Lisch nodule, optic glioma)
   c. Skeleton (malformations)
   d. Blood vessels (mesodermal vascular dysplasias): Intrinsic lesions of arterial walls

(vasculopathy) are important manifestations of NF1. It appears to contribute to excessmortality of young patients with NF1.
   i. Asymmetric
   ii. Renal artery stenosis with consequent hypertension
   iii. Occlusion resulting in cerebral or visceral infarcts
   iv. Aneurysms resulting in hemorrhage
   v. Arteriovenous fistulae
e. Brain
   i. Glial hamartomas
   ii. Astrocytomas
f. Adrenal (pheochromocytoma)
g. Intestine
   i. Somatostatinoma
   ii. Gastrointestinal autonomic nerve tumor
h. Peripheral nerve sheath
   i. Neurofibromas
   ii. Malignant peripheral nerve sheath tumors

15. NIH diagnostic criteria
   a. National Institutes of Health consensus development conference identified seven important components of neurofibromatosis. Two or more of these components must be present for a diagnosis of neurofibromatosis.
      i. Six or more café-au-lait spots, which are more than 5 mm in diameter in prepubertal patients and more than 15 mm in diameter in postpubertal individuals
      ii. Two or more neurofibromas of peripheral nerves of any type or one plexiform neurofibroma
      iii. Freckling in the axillary or inguinal region
      iv. Optic glioma (age of presentation at preschool years)
      v. Two or more Lisch nodules (hamartomas of the iris)
      vi. A distinctive bony lesion such as dysplasia of the sphenoid at the base of the skull or pseudarthrosis or thinning of long bone cortex, with or without complete interruption of the bone
      vii. A first-degree relative (parent, sib, or offspring) affected with neurofibromatosis type 1 which was diagnosed according to the preceding criteria
   b. These diagnostic criteria have been shown to be both highly specific and sensitive for adults with NF1 (Gutmann et al. 1997).
   c. Because some of the criteria may not manifest until later in life, they are not as sensitive in children, especially those under the age of 8.
   d. A 2,000 retrospective review of nearly 1,900 cases of NF1 found that 46% of sporadic cases did not meet criteria by age 1; however, 97% met criteria by age 8, and all fulfilled them by age 20 (DeBella et al. 2000).
16. Syndromes related to NF1
   a. Neurofibromatosis type 2 (bilateral vestibular neurofibromatosis)
      i. Clinically and genetically distinct from NF1
      ii. *NF2* gene is mapped to chromosome 22.
      iii. Inheritance: autosomal dominant
      iv. Often with a small number of café-au-lait spots (rarely more than six)
      v. Often with one or two peripheral neurofibromas (usually not more)
      vi. Occasionally with Lisch nodules
      vii. Posterior subcapsular cataracts detected by ophthalmologic examination in a sizable proportion of patients
      viii. The hallmark of NF2: development of bilateral eighth cranial nerve tumors, properly called vestibular schwannomas rather than acoustic neuromas (by age 30 years in 95% of patients)
      ix. Other tumors of cranial and cervical nerve roots common
      x. NF2 much less common than NF1, affecting approximately 1 in 40,000 individuals
   b. Segmental or mosaic NF1
      i. Presence of NF1 features (café-au-lait spots, freckling and peripheral or plexiform neurofibromas, and Lisch nodules) in an individual with a segment of the body affected
      ii. Family history with invariably normal parents who, on rare occasions, can have a child with classic NF1
      iii. Presence of strong circumstantial evidence suggests somatic mutation of the *NF1* gene early in embryogenesis so that derivatives of that mutant line display the features of NF1.

iv. May transmit the disease if the mosaicism involves the germ line
v. Germ-line mosaicism for an *NF1* gene mutation has been observed in a clinically unaffected father of a child with new onset NF1.
vi. Somatic mosaicism for an *NF1* gene deletion has been detected in an individual with NF1.
vii. Possibility of demonstrating similar somatic mosaicism if cases of segmental NF1 are analyzed.

c. Watson syndrome
i. Pulmonary stenosis with café-au-lait spots
ii. Dull intelligence
iii. Short stature
iv. A small number of neurofibromas
v. Lisch nodules
vi. Deletions present in the NF1 gene in at least two families: no distinguishing aspect between the deletions causing Watson syndrome and those associated with more classic NF1

d. Neurofibromatosis 1–Noonan syndrome
i. A Noonan syndrome phenotype in patients with NF1 (about 12%)
ii. Clinical features in addition to NF1
a) Ocular hypertelorism
b) Down-slanting palpebral fissures
c) Low-set ears
d) Webbed neck
e) Pulmonic stenosis
f) Pectus excavatum
g) Mild hypertelorism
h) Short stature
iii. Relatives affected with NF1 present with or without concomitant features of Noonan syndrome.
iv. Current understanding: The phenotype of NF1 can include features overlapping with those described in Noonan syndrome, but these disorders are probably genetically distinct.

e. Predominance of spinal tumors and relatively few peripheral neurofibromas identified in rare families
i. Locus heterogeneity
ii. Not representing a distinct subtype of NF

17. Prognosis of NF1
a. Progression of the disease with time
b. Pregnancies in women with NF1
i. Normal pregnancies in most patients but serious complications have been noted in some patients.
ii. Rapid increase in the number and size of neurofibromas during pregnancy
iii. First onset of hypertension or marked exacerbation of pre-existing hypertension during pregnancy
iv. Delivery complicated by large pelvic or genital neurofibromas often necessitates cesarean section in pregnant women with NF1.

c. Anesthetic risk
i. Intraoral lesions compromising the airway (5%)
ii. Coexisting kyphoscoliosis (2%) and fibrosing alveolitis (20%) complicating the perioperative period
iii. Careful regional anesthesia to monitor the existence of neurofibromas affecting peripheral nerves and nerve roots
iv. Possible long-term muscular blockade following the use of suxamethonium and non-depolarizing muscle relaxants

d. Average life expectancy overall reduced by at least 15 years
i. Malignancy and hypertension contributing to increased morbidity in adults with NF1
ii. Risk for neurofibromatosis-related malignancy (8%)
iii. Most common malignancy: malignant peripheral nerve sheath tumors
iv. Better prognosis in patients with only mild and cosmetic symptoms of the disease

Diagnostic Investigations

1. Diagnosis of neurofibromatosis 1 based largely on clinical criteria despite progress in defining the molecular genetics of the disorder
2. Slit-lamp examination of the eyes to detect Lisch iris nodules

3. Radiography to detect bony abnormalities
   a. Skull
      i. Macrocephaly
      ii. Absence of the greater and lesser wings of the sphenoid
      iii. Absence of the orbital floor
      iv. Hypoplasia of the lesser wings of the sphenoid
      v. Enlarged orbits
      vi. Enlargement of cranial foramina
      vii. Enlargement of orbital margins
      viii. Sclerosis in the vicinity of the optic foramen (optic nerve sheath meningioma)
      ix. Facial asymmetry
      x. Hypoplasia of the paranasal sinuses
      xi. Mandibular abnormalities
      xii. Mandibular hypoplasia with flattening of the external contour
      xiii. Thinning of the ramus
      xiv. Coronoid hyperplasia
      xv. Widening of the lateral and medial coronoid spaces
      xvi. Calvarial defects adjacent the left lambdoid suture
      xvii. Osseous defects associated with multiple frontonasal osseomeningeal defects causing cerebrospinal fluid (CSF) rhinorrhea
   b. Chest
      i. Inferior rib notching
      ii. Twisted ribbonlike ribs in the upper thoracic cage
      iii. Posterior mediastinal masses secondary to intrathoracic meningoceles
      iv. Mediastinal and lung masses secondary to neurofibromas
      v. Dumbbell neurofibromas
      vi. Progressive pulmonary interstitial fibrosis leads to formation of bullae and honeycomb lung.
      vii. Increased incidence of spontaneous pneumothorax and hemothorax
      viii. Dilatation/enlargement of the central pulmonary arteries and peripheral pruning of vessels secondary to changes of interstitial lung disease and pulmonary hypertension
   c. Spine
      i. A sharply angled kyphoscoliosis centered at the thoracolumbar junction in 50% of patients
      ii. Enlargement of the intervertebral foramina
      iii. Scalloping of the vertebral bodies (anterior, posterior, lateral)
      iv. Hypoplasia of the vertebral pedicles
      v. Wedged-shaped vertebrae
      vi. Spondylolisthesis
      vii. Spinal clefts
      viii. Osteolysis
      ix. Spindling of the transverse processes
   d. Appendicular skeleton
      i. Bowing of long bones
      ii. Hyperplasia or hypoplasia of long and short bones
      iii. Pseudarthrosis
      iv. Erosions
      v. Periosteal dysplasia
      vi. Intramedullary longitudinal osteosclerotic streaks
      vii. Single or multiple cystic bone lesions
      viii. Focal gigantism
      ix. Protrusio acetabuli
      x. Dislocation of the hip
      xi. Dislocation of the radius and ulna
      xii. Absence of a patella
      xiii. Neuropathic arthropathy of the knee
   e. Gastrointestinal
      i. Neurofibromas within the stomach, small and large bowels, and rectum
      ii. Intussusception of the bowel presenting with intestinal obstruction
      iii. Bowel obstruction simulating Hirschsprung disease secondary to plexiform neurofibroma of the colon
      iv. Pseudoobstruction
      v. Biliary strictures and bile duct intraluminal neurofibromas rarely reported
   f. Urinary tract
      i. Renal collecting system and bladder intrinsically involved or extrinsically compressed or displaced by neurofibromas
      ii. Intravenous urogram providing useful information regarding the nature and site of obstruction and function
4. Echocardiography for pulmonic stenosis, aortic coarctation, or other CHD
5. CT imaging
   a. Solid fusiform masses
      i. Present in the distribution of nerves, with central areas of low attenuation and calcification

ii. May present in the paravertebral, laryngeal, mediastinal, abdominal, and pelvic/ischiorectal fossae
b. Plexiform neurofibromas seen as widespread sheets of nodular tissue
c. Paraspinal neurofibromas seen at every level, vary in size, may be dumbbell-shaped, or may comprise fusiform/spherical soft-tissue masses.
d. Mesenteric plexiform neurofibromas trap mesenteric fat within an entangled network.
e. Nonneoplastic cerebral and cerebellar calcification and choroid plexus calcification on cranial CT scans
f. Hydrocephalus in NF1 results from benign aqueduct stenosis or a glioma of the tectum/tegmentum of the mesencephalon.
g. Intracranial nerve sheath tumors with associated bone erosions
h. Meningiomas with associated changes in the calvarium/skull
i. Extrinsic bladder involvement, intrinsic infiltrative processes, or extrinsic compression of the renal collecting system by a neurofibroma
j. A role in the investigation of thoracic, abdominal, and pelvic complications of NF1

6. MRI imaging
   a. Brain
      i. T2 hyperintensities (60–70%)
      ii. Hamartomas in the brain
      iii. Optic nerve pathology
   b. Internal lesions
      i. Mediastinal masses
      ii. Spinal cord tumors
      iii. Deep plexiform neurofibromas
      iv. Neurofibromas of the brachial or sacral plexus
7. Histopathology
   a. Confirmation of neurofibromas
      i. Arisen from cells in the peripheral nerve sheath
      ii. Consist of a mixture of cell types, including Schwann cells, fibroblasts, mast cells, and vascular elements
   b. Verification of malignant transformation to neurofibrosarcoma
8. Linkage analyses using polymorphic markers that segregate with the disease in familial cases
9. Either FISH, loss of heterozygosity or southern blotting analyses reveal 5% of patients with large deletions of *NF1* gene encompassing part or the whole *NF1* gene.
10. Mutation analysis in sporadic and familial cases (Friedman 2009)
    a. Protein truncation test based on the detection of truncated proteins via in vitro transcription and translation from RT-PCR fragments spanning the entire *NF1* cDNA
       i. *NF1* mutations detected
          a) Nonsense mutations
          b) Frameshift mutations
          c) Splicing mutations
       ii. Method of exploring the RNA for changes that are compatible with mutations in the gene
       iii. Positive in 80% of the cases
    b. Gene sequencing: specific search of exon by exon for the mutation
11. Multi-step detection protocol: preferred because of the large size of the NF1 gene and the lack of mutation hotspots
    a. Testing methods
       i. Optimized protein truncation testing
       ii. Sequence analysis
       iii. FISH
       iv. Long-range RT-PCR
       v. Southern blot analysis
       vi. Cytogenetic analysis
    b. NF1 mutations detected
       i. Nonsense mutations
       ii. Frameshift mutations
       iii. Splicing mutations
       iv. Missense mutations
       v. Deletions
       vi. Other rearrangements
    c. Mutation detection rate in patients with a clinical diagnosis of NF1: >95%
12. Presymptomatic/preconceptional genetic testing: molecular characterization in familial and in sporadic cases
13. Limitation of genetic testing
    a. Lack of genotype–phenotype correlations: A positive test will not predict disease severity or outcome
    b. Two exceptions
       i. Complete loss of the *NF1* gene along with multiple contiguous genes

a) Occurs in 4–5% of patients with NF1 (Kluwe et al. 2004)
b) Patients with whole gene deletion present with a very large neurofibroma burden, more severe cognitive impairment, large hands and feet, dysmorphic facial features, and have a higher lifetime risk of developing malignant peripheral nerve sheath tumors (MPNST) (Leppig et al. 1997; De Raedt et al. 2003).

ii. A 3-base pair in-frame deletion in exon 17 of the *NF1* gene: Patients with this genetic mutation have an absence of cutaneous neurofibromas and appear to have a lower incidence of serious complications.

Genetic Counseling

1. Recurrence risk
   a. Patient's sibling
      i. Risk not increased unless a parent is affected or has gonadal mosaicism.
      ii. If a parent is affected, the risk to the sibs is 50%.
      iii. Possibility of germ-line mosaicism in a clinically normal parent: recurrence risk based on the percentage of the germ-line mosaicism
   b. Patient's offspring
      i. Risk: 50% of inheriting the disease with extremely variable disease manifestations
      ii. Risk of having a child with NF1 in a patient affected with segmental NF1
         a) A small but greater than the general population risk
         b) Some cases of segmental NF1 apparently being "transmitted" to offspring; the mechanism (if one exists) behind this is unclear (Boyd et al. 2009).
         c) Segmental neurofibromatosis is believed to be due to somatic mosaicism for a mutation in the NF gene. The mutation occurred postconceptionally and present in the limited population of cells. Gonadal cells may or may not have a mutation (Dupuis and Nezarati 2001).
2. Prenatal diagnosis
   a. Influence of knowledge of the disease in the reproductive decisions of affected individuals (Ars et al. 1999)
      i. Interest in prenatal test by 41% of the subjects considering becoming pregnant
      ii. Only 10% considering terminating an affected pregnancy
   b. Prenatal diagnosis of NF1 difficult to be made in the past due to the following reasons (Vitale et al. 2002):
      i. Large size of the NF1 gene
      ii. Lack of any hotspots where the mutations arise
      iii. Variable expression even within members of a family with NF1
      iv. Lack of a tight genotype–phenotype correlation
      v. High spontaneous mutation rate
   c. Currently available prenatal diagnosis
      i. Direct characterization of the mutation from a parent affected by NF1
      ii. Analysis of the genomic DNA mutation from the fetus either by amniocentesis or CVS
      iii. Indirect linkage analysis to familial cases using informative polymorphic markers
      iv. Protein truncation test
      v. Fluorescence in situ hybridization
   d. Molecular diagnosis, unfortunately, cannot predict clinical expression of the disease in the fetus.
3. Management
   a. Developmental assessment in children
   b. Medical management for itching, pain, depression, and other psychological and social problems
   c. Treatment of hypertension depending on the etiology
      i. Pheochromocytomas
      ii. Renal artery stenosis
   d. Laser or electrocautery for small discrete cutaneous or subcutaneous neurofibromas
   e. Surgical resection of tumors
      i. Resection of neurofibromas pressing on vital structures, obstructing vision, or rapidly growing lesions causing irritation, discomfort, and pain
      ii. Plexiform neurofibromas: extremely difficult to approach surgically and often recur after resection because of residual cells resting deeply in the soft tissues
      iii. Resection of spinal cord tumors: quite difficult but often is necessary to prevent progressive paraplegia or quadriplegia

f. Surgical treatment of disfigurement
   i. Excision of multiple neurofibromas
   ii. Reconstructive surgery for plexiform neurofibromas
g. Orthopedic care indicated for rapidly progressive scoliosis and for some severe bony defects
h. Optic pathway gliomas in most children with NF1 (Jett and Friedman 2010)
   i. Usually do not require treatment
   ii. Chemotherapy is the treatment of choice for progressive tumors.
   iii. Surgical treatment: reserved for cosmetic palliation in a blind eye
   iv. Radiotherapy usually avoided because of the risk of inducing malignancy or moyamoya in the exposed field
i. Treatment of congenital pseudarthrosis of the tibia: challenging (Vitale et al. 2002)
   i. Bracing mainly of early treatment before fracture develops
   ii. A knee-ankle-foot-orthosis when weight bearing
   iii. Intramedullary rod fixation, often in combination with autogenous bone grafting of the pseudarthrosis site
j. Advise high-risk pregnancy care to pregnant patient with neurofibromatosis
   i. Maternal hypertension
   ii. Aggravating features of neurofibromatosis

Fig. 1 (**a**–**d**) Typical café-au-lait spots in different patients

Fig. 2 (**a**, **b**) Axillary freckles in a child and an adult

Fig. 3 (**a**–**c**) Café-au-lait spots and numerous localized cutaneous neurofibromas in three different patients

Fig. 4 (**a**–**e**) Diffuse cutaneous neurofibromas (nodular and polypoid shapes) in four patients affecting skin and subcutaneous tissue resulting in marked cosmetic disfigurements and functional disturbances

Fig. 5 (**a**–**c**) Neurofibromas involving vessels of the face and subcutaneous tissue of the fingers

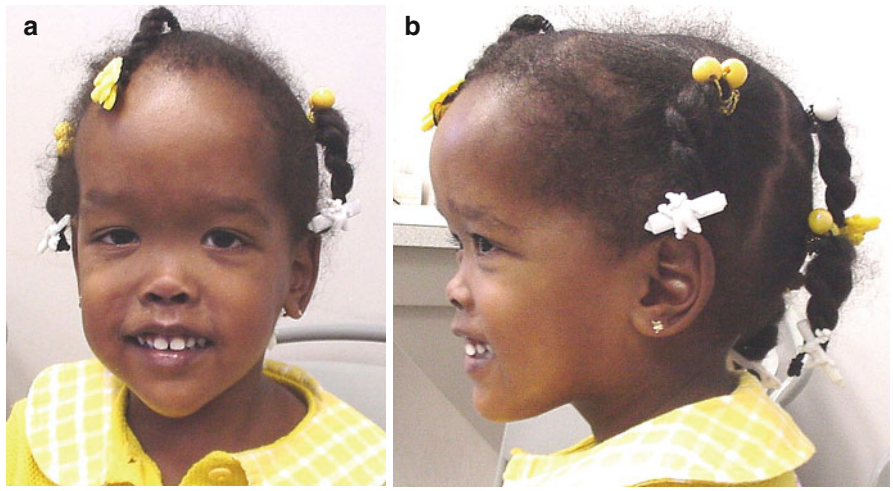

Fig. 6 (**a**, **b**) Macrocephaly with prominent forehead and depressed nasal bridge

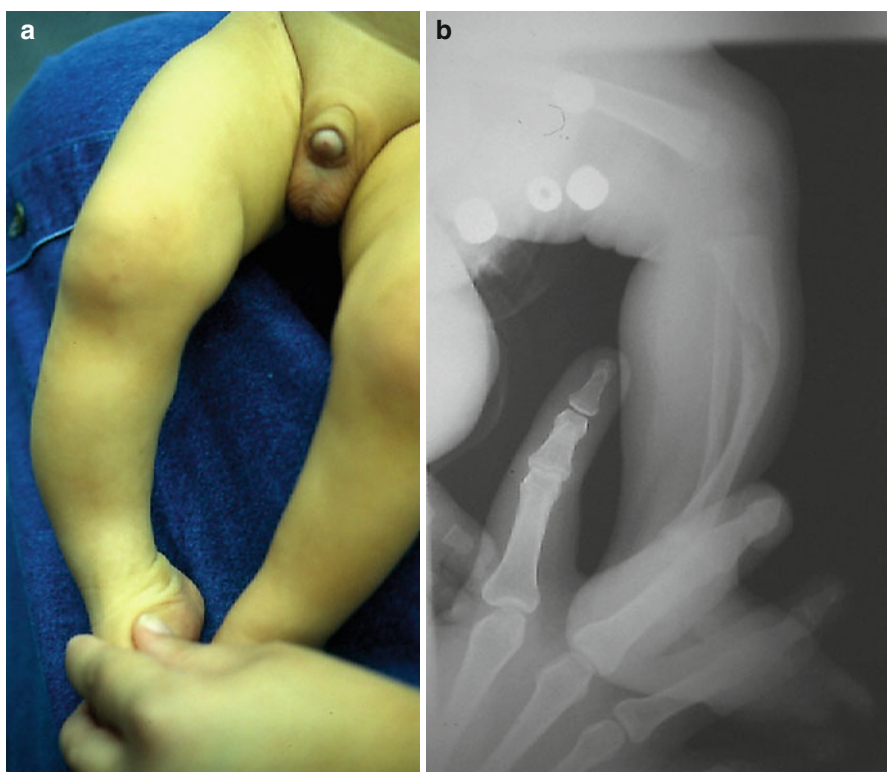

Fig. 7 (**a**, **b**) Pseudoarthrosis of right tibia manifesting as bowed leg

Fig. 8 (**a**, **b**) A child with NF1 having pseudoarthrosis of the left tibia and fibula resulting in fractures

Fig. 9 Localized intraneural neurofibromas of a median nerve, causing fusiform enlargement of the affected nerve

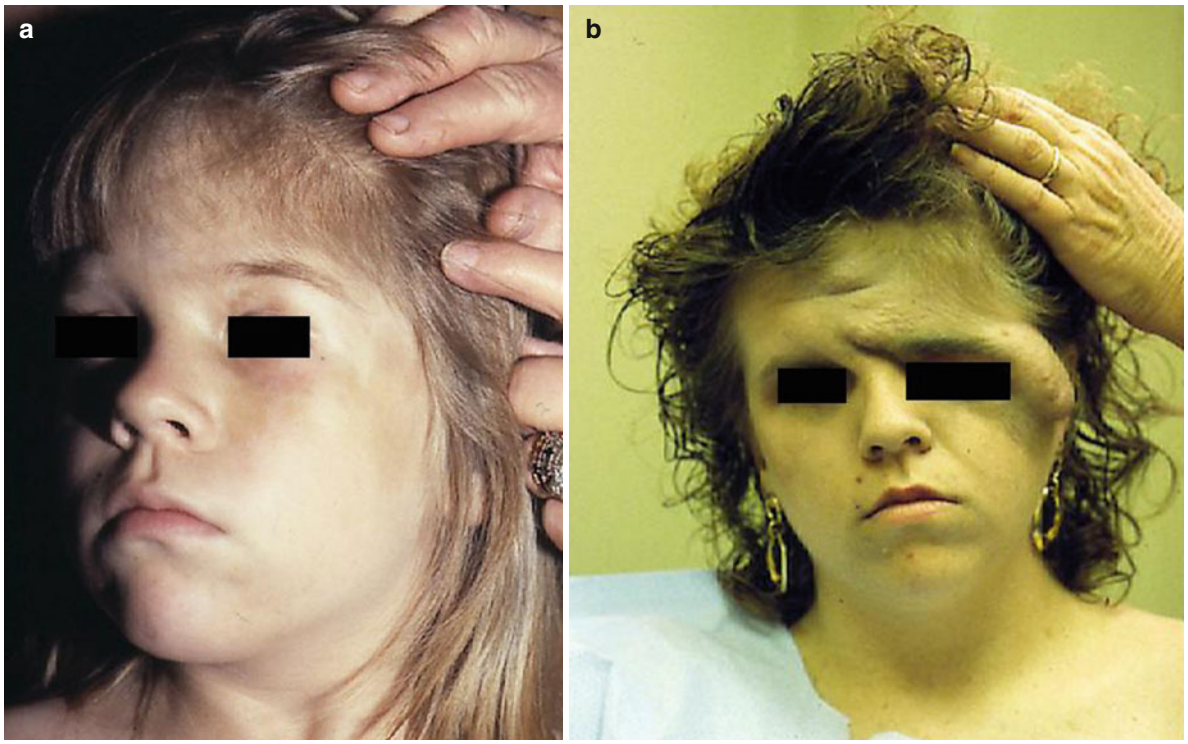

Fig. 10 (**a**, **b**) Plexiform neurofibromas affecting left orbital region in different ages

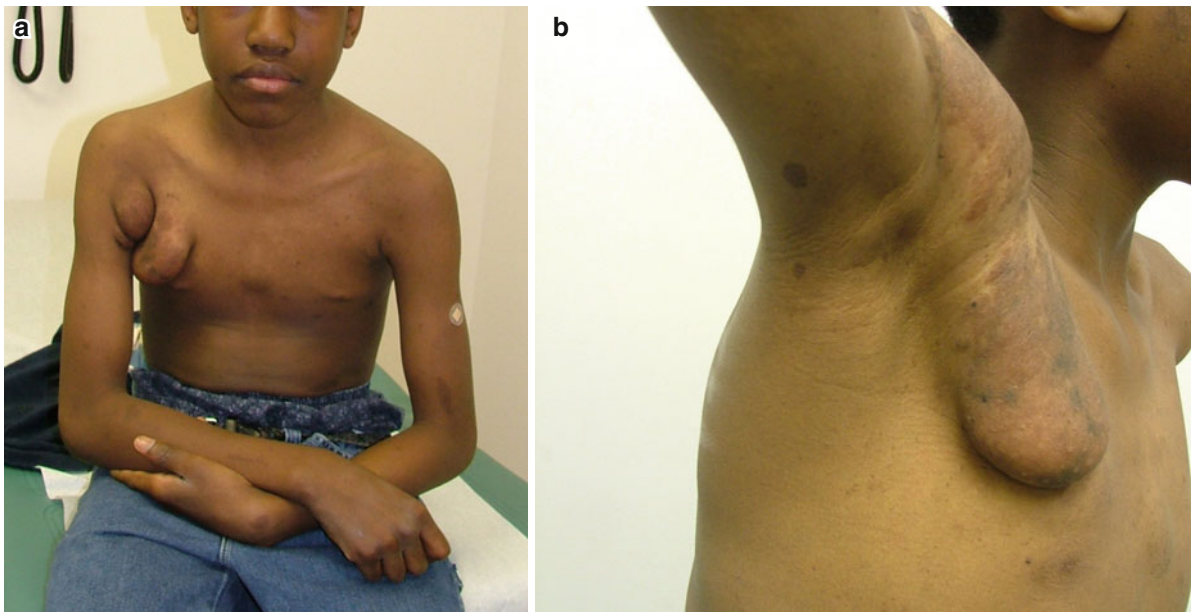

Fig. 11 (**a**, **b**) A 12-year-old boy with NF1 showing a large plexiform neurofibroma on the right upper chest

Fig. 12 (**a–d**) A man with NF1 showing plexiform neurofibromas on the left cheek, right upper back, and sole of the foot

Fig. 13 (**a–c**) Massive soft-tissue neurofibromas affecting two patients. Extreme neurofibromatous growth producing massive, diffuse infiltration of soft tissue of the thigh producing disfiguring redundant soft-tissue masses

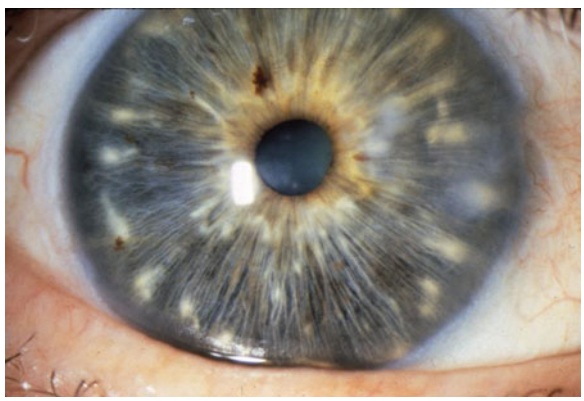

Fig. 14 Tannish white iris Lesch nodules in a patient with NF1

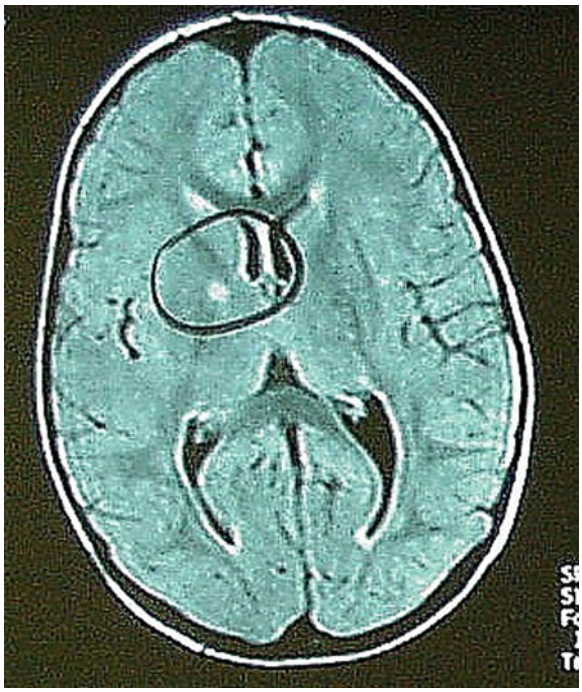

Fig. 15 MRI of the brain showing a hamartomatous lesion of the right globus pallidus. This patient has numerous cutaneous café-au-lait spots of varying size and typical axillary freckles. He was shown to have a truncating mutation in the segment 3 of the neurofibromin (NF1) gene

Fig. 16 (**a–d**) A 26-year-old female with segmental neurofibromatosis showing axillary freckles, multiple small neurofibromas, and hyperpigmentation, all involving the right side of the body. Left side of the body is spared, including left axilla which showed no freckles

Fig. 17 (**a–d**) A 36-year-old present with >8 large café-au-lait spots, bilateral axillary freckling, several cutaneous, intradermal, and subcutaneous neurofibromas. A heterozygous missense alteration in exon 13 of the NF1 gene was identified (c.2072 T>C) (p.Leu691Pro). The 2-year and 3-month-old daughter was found to have multiple café-au-lait spots with a single neurofibroma on the right scalp

Fig. 18 A 14-month-old infant was seen because of multiple café-au-lait spots without neurofibroma. A splice mutation was identified in the *NF1* gene, 6641 + 1 G > T, leading to skipping of exon 35. This finding confirms the diagnosis of NF1 in this patient

Fig. 19 A 13-year-old boy with multiple café-au-lait spots, axillary freckles, and small neurofibromas throughout the body. The molecular study revealed a recurrent deep intronic splicing mutation in the *NF1* gene (c.5749 + 322 A > G). This mutation leads to missplicing of intron 30. This finding confirms the diagnosis of neurofibromatosis I

Neurofibromatosis 2

Historically, neurofibromatosis 2 (NF2) has been previously known as bilateral acoustic neurofibromatosis or central neurofibromatosis. It has frequently been confused with the more common neurofibromatosis 1 (NF1), also known as von Recklinghausen disease or peripheral neurofibromatosis (MacCollin and Mautner 1998). Gardner and Frazier in 1930 were the first to persuasively argue that bilateral vestibular tumors can be clinically and pathologically distinguished from both von Recklinghausen neurofibromatosis and from sporadic tumors from studying a large family with 38 affected members over five generations.

The first clear description of NF2 was made by Wishart in 1822 (Wishart 1822). NF2 occurs in about 1 in 25,000 live births.

Synonyms and Related Disorders

Bilateral acoustic neurinoma; Bilateral acoustic neurofibromatosis; Bilateral acoustic Schwannomas; Central neurofibromatosis

Genetics/Basic Defects

1. An autosomal dominant disorder: resulting from a mutation in the *NF2* tumor suppressor gene on chromosome 22q12 (Asthagiri et al. 2009)
   a. Truncating mutations (nonsense and frameshifts): most frequent germ line event causing the most severe disease
   b. Single and multiple exon deletions are also common.
2. *NF2* tumor suppressor gene: consists of 17 exons that encode for a 69-kDa protein product called merlin (moesin-ezrin-radixin-like protein) or schwannomin (Rouleau et al. 1993; Trofatter et al. 1993)
3. Consistent with Knudson's two-hit hypothesis for tumorigenesis (tumor formation initiates when both alleles of this gene are inactivated) (Knudson 1971)
   a. Patients inherit a germ line mutation of one affected allele from a parent or acquire a de novo mutation of an allele at the postzygotic stage of embryogenesis.
   b. Subsequent development of tumors in susceptible target organs, such as nervous system, eyes, and skin, from cells that lose function of the wild-type (normal) *NF2* allele.
4. Abnormal or absent merlin function can disrupt tumor suppression in NF2.
5. High frequency of somatic mosaicism in patients with de novo mutations (Kluwe and Mautner 1998; Moyhuddin et al. 2003; Evans et al. 2007)
   a. Mutation takes place after conception in patients with mosaicism, resulting in two separate cell lineages.
   b. Patients with mosaicism tend to have mild generalized or even localized disease (e.g., unilateral vestibular schwannoma with ipsilateral tumors).
   c. Only a portion of the germ cells in a person with *NF2* mosaicism are likely to carry the mutation.
      i. Risk of transmission to offspring will be less than the expected one in two (50%) for an inherited mutation.
      ii. Children who inherit the mutation from a mosaic parent will probably have more severe disease than will the parent because the mutation will be present in all their somatic cells.

Clinical Features

1. Young adulthood (age 20–30 years) (Asthagiri et al. 2009)
   a. Hearing loss from a vestibular schwannoma, often unilateral initially
   b. Accompanied symptoms
      i. Tinnitus
      ii. Dizziness
      iii. Imbalance
   c. A significant proportion of cases (20–30%) present with
      i. Headaches and/or seizures from an intracranial meningioma
      ii. Pain, muscle weakness, and/or paresthesia from spinal tumor
      iii. Cutaneous tumor induced symptoms
2. Children (up to 30%)
   a. May present with the same symptoms as adults
   b. More frequently present with the following:
      i. Visual disturbance
         a) Cataract
         b) Hamartomas
         c) Intracranial tumors
      ii. Skin tumors
      iii. Mononeuropathy
         a) Facial paresis
         b) Foot drop
      iv. Symptomatic spinal cord tumors
      v. Non-vestibular intracranial tumors
3. Lesions associated with NF2
   a. Neurological lesions
      i. Bilateral vestibular schwannomas (90–95%)
      ii. Other cranial nerve schwannomas (24–51%)
      iii. Intracranial meningiomas (45–58%)
      iv. Spinal tumors (63–90%)
         a) Extramedullary tumors (55–90%)
         b) Intramedullary tumors (18–53%)
      v. Peripheral neuropathy ($\leq$66%)
   b. Ophthalmological lesions
      i. Cataracts (60–81%)
      ii. Epiretinal membranes (12–40%)
      iii. Retinal hamartomas (6–22%)
   c. Cutaneous lesions
      i. Skin tumors (59–68%)
      ii. Skin plaques (41–48%)
      iii. Subcutaneous tumors (43–48%)
      iv. Intradermal tumors (rare)
4. Diagnostic criteria for NF2 including the NIH criteria with additional criteria (Manchester criteria which expanded the previous NIH diagnostic criteria and were designed to include patients with neither a family history of NF2 nor bilateral vestibular schwannomas, but who had multiple schwannomas or meningiomas). (Evans et al. 2005; Evans 2009a, b; Asthagiri et al. 2009)
   a. Major criteria
      i. Bilateral vestibular schwannomas or
      ii. First degree family relative with NF2 plus unilateral vestibular schwannoma or two NF2-associated lesions (meningioma, glioma, neurofibroma, schwannoma, or cataract)
   b. Additional criteria
      i. Unilateral vestibular schwannoma plus any two NF2-associated lesions (meningioma, glioma, neurofibroma, schwannoma, or cataract), or
      ii. Multiple meningiomas plus unilateral vestibular schwannoma or two other NF2-associated lesions (glioma, neurofibromas, schwannoma, or cataract)
5. Patient populations at risk for NF2 (Evans et al. 2005)
   a. First-degree relative with NF2 (affected parent, sibling, or children)
   b. People younger than age 30 years with a unilateral vestibular schwannoma or meningiomas
   c. People with multiple spinal tumors (schwannomas, meningiomas)
6. Recommended intervals for screening children of an affected parent (Evans et al. 2005)
   a. Ophthalmological examination yearly from infancy
   b. Neurological examination yearly from infancy
   c. Audiology with auditory brain stem evoked potentials yearly from infancy
   d. Presymptomatic genetic testing: one test from 10 years of age
   e. Cranial MRI at 10–12 years of age
   f. Spinal MRI at 10–12 years of age (every 2–3 years)
   g. For presymptomatic genetic testing, cranial MRI, and spinal MRI, screening may start

earlier than age 10 years in severely affected families and families in which early detection of disease would aid family preparation for future events related to NF2.

7. Variable expressivity of NF2 among individuals
   a. Varying size, location, and number of tumors.
   b. Although these tumors are not malignant, their anatomical location and multiplicity lead to great morbidity and early mortality.
   c. The average age of death is 36 years.
   d. Actuarial survival from the time of establishing the correct diagnosis is 15 years.
   e. Survival is improving with earlier diagnosis and better treatment in specialty centers (Baser et al. 2002; Evans et al. 2005).
   f. Underrecognized in children in whom skin tumors and ocular findings may be the first manifestations (NF2 is usually considered an adult-onset disease).
8. Penetrance: 100%
9. Differential diagnosis
   a. Main differential diagnosis of NF2: schwannomatosis (multiple schwannomas without the vestibular schwannomas that are diagnostic of NF2)
   b. Multiple non-cranial schwannomas: Some patients turn out to have mosaic NF2 (Moyhuddin et al. 2003; Evans et al. 2007).
   c. Neurofibromatosis 1
10. Prognosis is adversely affected by
    a. Early age at onset
    b. A higher number of meningiomas
    c. Having a truncating mutation

Diagnostic Investigations

1. Clinical and family history (Evans 2009a)
2. Physical examination including cutaneous and ophthalmic (slip lamp)
3. Craniospinal MRI
4. Hearing evaluation, including BAER
5. Chromosome analysis: Gross chromosomal changes are rare but may reveal a variety of chromosome abnormalities.
   a. Cytogenetically visible deletions encompassing the NF2 gene: may cause mental retardation and multiple congenital abnormalities (Barbi et al. 2002)
      i. Ring chromosome 22 (Tsilchorozidou et al. 2004)
      ii. Can cause multiple meningiomas and vestibular schwannomas fulfilling NF2 diagnostic criteria, NF2 locus itself is usually present within the ring, but the ring itself is frequently loss as a result of instability.
      iii. Apparently balanced chromosomal translocations disrupting the *NF2* gene causing NF2
      iv. Fluorescence in situ hybridization (FISH) to identify smaller deletions that remove multiple exons of the NF2 gene or the whole gene
6. Molecular genetic analysis
   a. Sequence analysis/mutation scanning of *NF2* gene (Evans et al. 2007)
      i. In 73% of families with NF2, sequence analysis identified a mutation in a member of the second generation.
      ii. In simplex cases (a single occurrence in a family), the mutation detection rate is approximately 60%.
      iii. Approximately 25–33% of mutations are not detected as a result of somatic mosaicism.
      iv. Mutations with mosaicism levels >10% can be detected in lymphocyte DNA.
      v. Identification of the remainder of mosaic mutations usually requires testing of tumor material.
   b. Deletion/duplication analysis
      i. Systematically detects whole exon deletions and duplications
      ii. Most large deletions and, less commonly, duplications of single exons or multiple exons can be detected by multiple ligation-dependent probe amplification (MLPA).
   c. Linkage analysis
      i. In families in whom no disease-causing mutation is identified, and at least two family members of different generations are affected.
      ii. Modified linkage analysis using both constitutional and tumor DNA can exclude NF2 in those children of a simplex case who have not inherited the allele lost in the tumor.

7. Presymptomatic genetic testing is an integral part of the management of NF2 families.
   a. At-risk relatives whose genetic status is unknown can be tested for presence of the *NF2* mutation (either constitutional or somatic mosaic) identified in an affected relative.
   b. In the rare instance in which an *NF2* mutation cannot be identified, linkage analysis can be used in families with at least two affected family members of different generations, or tumor DNA can be used to clarify the genetic status of children of a simplex case.

Genetic Counseling

1. Recurrence risk: presence of an affected parent in approximately 50% of individuals with NF2 (other 50% have NF2 as the result of a de novo mutation; 20–33% of simplex cases without family history are mosaic for an *NF2* mutation) (Evans 2009a)
   a. Patient's sib
      i. Affected parent: a 50% risk
      ii. Asymptomatic parents: a low risk since the age of onset of symptoms is relatively uniform within families
         a) A single case of germ line mosaicism in a clinically normal parent has been reported.
         b) Somatic mosaicism which may include germ line mosaicism is found in 25–33% of individuals with NF2 who are simplex cases.
   b. Patient's offspring
      i. The risk of disease transmission is 50% in the second generation and beyond.
      ii. The risk of transmission in people with new NF2 mutations is less than 50% due to mosaicism, in which only a proportion of cells have the mutated *NF2* gene (Evans et al. 1998; Kluwe and Mautner 1998).
2. Prenatal diagnosis and preimplantation genetic diagnosis: possible for at risk pregnancies, provided prior identification of the disease-causing mutation in the family
3. Management
   a. Surgery remains the focus of current management.
      i. Surgical removal of symptomatic cranial and spinal tumors
      ii. More difficult to determine the timing of removal of vestibular schwannomas
   b. Stereotactic radiosurgery, most commonly with the gamma knife, may be an alternative to surgery.
   c. Important to balance the use of microsurgery and radiation treatment, which can have a role in patients who have particularly aggressive tumors, or who are poor surgical risks, or who refuse surgery.
   d. Hearing preservation and augmentation with hearing aids or auditory rehabilitation with a cochlear or brain stem implant.
   e. Watchful waiting with careful surveillance and occasionally radiation treatment have a role.

Fig. 1 (**a**, **b**) A 23-year-old female had resection of anterior fossa meningioma 2 years previously. She complained worsening headaches with intermittent vomiting and blurry vision recently. She underwent a posterior fossa craniectomy and resection of a large cervical medullary tumor, consistent with a spindle cell tumor (schwannoma). She also has history of bilateral hearing loss and balance dysfunction. Molecular genetic testing revealed a truncating mutation in the *NF2* gene (c.553delG) confirming the diagnosis of NF2 in this patient

Noonan Syndrome

Noonan syndrome (NS) is a relatively common but genetically heterogeneous autosomal dominant malformation syndrome. The incidence of Noonan syndrome is estimated to be 1 in 1,000–1 in 2,500 live births.

Synonyms and Related Disorders

Female pseudo-Turner syndrome; Male Turner syndrome; Turner phenotype with normal karyotype

Genetics/Basic Defects

1. Inheritance (Allanson 1987; Tartaglia et al. 2010)
   a. Autosomal dominant inheritance
   b. Many affected individuals with de novo mutations
   c. Affected parent recognized in 30–70% of families
2. Caused by mutations in the *PTPN11*, *SOSI*, *KRAS*, *RAF1*, *BRAF*, and *MEK1* (*MAP2K1*) genes: accounting for approximately 70% of affected individuals
   a. The gene *PTPN11* (protein tyrosine phosphatase, nonreceptor type 11), mapped on 12q24.1, encoding the protein tyrosine phosphatase SHP-2.
      i. Heterozygous point mutations in the gene *PTPN11* identified in the following:
         a) Families showing linkage to the *NS1* locus in 12q24
         b) Some sporadic cases with NS
      ii. All mutations detected to date: missense mutations
      iii. The majority of mutations found in exons 3 and 8, which correspond to the interacting regions of the N-SH2 and protein tyrosine phosphatase domains of the gene
      iv. Genotype-phenotype correlation of *PTPN11* mutations
         a) Increased frequency of *PTPN11* mutations observed in individuals with Noonan syndrome with pulmonary stenosis (70%)
         b) Infrequent frequency of *PTPN11* mutations observed in individuals with hypertrophic cardiomyopathy (6%)
   b. SHP-2 (encoded by *PTPN11*), SOS1, BRAF, RAF1, and MEK1 positively contribute to RAS-MAPK signaling and possess complex autoinhibitory mechanisms that are impaired by mutations.
   c. Similarly, reduced GTPase activity or increased guanine nucleotide release underlies the aberrant signal flow through the MAPK cascade promoted by most *KRAS* mutations.
3. Mutation in *SHOC2*
   a. Encodes a cytoplasmic scaffold positively controlling RAF1 activation.
   b. Has been discovered to cause a closely related phenotype previously termed Noonan-like syndrome with loose anagen hair.
   c. This mutation promotes aberrantly acquired N-myristoylation of the protein, resulting in its constitutive targeting to the plasma membrane and dysregulated function.
4. *PTPN11*, *BRAF*, and *RAF1* mutations
   a. Also account for approximately 95% of LEOPARD syndrome.
      i. A condition which resembles NS phenotypically

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_180,

© Springer Science+Business Media, LLC 2012

ii. Characterized by multiple lentigines dispersed throughout the body, café-au-lait spots, and a higher prevalence of electrocardiographic conduction abnormalities, obstructive cardiomyopathy, and sensorineural hearing deficits

b. These recent discoveries demonstrate that the substantial phenotypic variation characterizing NS and related conditions can be ascribed, in part, to the gene mutated and even the specific molecular lesion involved.

Clinical Features

1. Clinical features (Allanson 1987)
   a. Growth
      i. Average length at birth: 47 cm
      ii. Generally normal birth weight but can be high due to subcutaneous edema
      iii. Prepubertal growth parallel to the third centile (40%) with a relatively normal growth velocity
      iv. Pubertal growth spurt often reduced or absent
   b. Craniofacial features: change with age (see below)
   c. Ocular abnormalities (observed up to 95% of cases)
      i. Strabismus
      ii. Refractive errors
      iii. Amblyopia
      iv. Nystagmus
      v. Anterior segment and fundal changes
   d. Congenital heart defects (two thirds of cases)
      i. Pulmonary valvular stenosis (50%)
      ii. Hypertrophic cardiomyopathy (20–30%): may be present at birth or appears in infancy or childhood
      iii. Atrial septal defect (10%)
      iv. Asymmetrical septal hypertrophy (10%)
      v. Ventricular septal defect (5%)
      vi. Persistent ductus arteriosus (3%)
      vii. Other cardiac defects
         a) Pulmonary artery branch stenosis
         b) Mitral valve prolapse
         c) Ebstein anomaly
         d) Single ventricles
   e. Genitourinary abnormalities
      i. Males: ranging from normal prepubertal virilization to delayed fertility and inadequate secondary sexual development associated with deficient spermatogenesis secondary to earlier cryptorchidism (60%)
      ii. Females: normal or delayed puberty but fertile in majority of cases
   f. Skeletal abnormalities
      i. Characteristic pectus deformity (see detail description below)
      ii. Common features
         a) Cubitus valgus (50%)
         b) Hand anomalies including clinobrachydactyly and blunt fingertips (30%)
         c) Vertebral and sternal anomalies (25%)
         d) Dental malocclusion (35%)
   g. Ectodermal abnormalities
      i. Various skin manifestations
         a) Café-au-lait patches (10%)
         b) Pigmented nevi (25%)
         c) Lentigines (2%)
         d) Keratosis pilaris atrophicans faciei
      ii. Several instances of neurofibromatosis and the Noonan phenotype documented
   h. Bleeding diathesis (about one third of cases with a coagulation defect)
      i. Factor XI deficiency
      ii. Von Willebrand disease
      iii. Platelet dysfunction which may be associated with trimethylaminuria
   i. Lymphatic abnormalities
      i. Congenital dysplasia, hypoplasia, or aplasia of lymphatic channels (20%)
      ii. General lymphedema
      iii. Peripheral lymphedema
      iv. Pulmonary lymphangiectasia
      v. Intestinal lymphangiectasia
      vi. Hydrops fetalis
      vii. Cystic hygroma
   j. Rare associated features
      i. Autoimmune thyroiditis
      ii. Pheochromocytoma
      iii. Ganglioneuroma
      iv. Malignant schwannomas
      v. Congenital contractures
      vi. Chiari malformation with syringomyelia
      vii. Skin and oral xanthomas
      viii. Odontogenic keratosis
   k. Behavioral and developmental abnormalities
      i. Failure to thrive in infancy (40%)
      ii. Motor developmental delay (26%)

iii. Learning disability with specific visual-constructional problems and verbal-performance discrepancy (15%)
iv. Language delay (20%) secondary to perceptual motor disabilities, mild hearing loss (12%), or articulation abnormalities (72%)
v. Intelligence
a) IQ: 64–127 with a median of 102
b) IQ: ten points below that of unaffected family members
c) Mild mental retardation reported in up to 35% of cases

2. Changing phenotype with age (Allanson 1987)
a. Newborn period
i. Marked edema
a) Contributing to a normal-to-high birth weight
b) Rapid reduction after birth simulating failure to thrive
ii. Excess nuchal skin
iii. Sloping and broad forehead
iv. Apparent ocular hypertelorism
v. Downslanting palpebral fissures
vi. A deep philtrum
vii. Mild retrognathia
viii. Posteriorly angulated ears with a thick helix
b. Neonatal period to 2 years
i. Head
a) Relatively large appearance
b) Flat malar eminence
c) Bitemporal narrowing accentuated by lateral supraorbital fullness
d) "Coarse" and occasional asymmetric facial appearance
ii. Eyes
a) Prominent and round
b) Ocular hypertelorism
c) Telecanthus
d) Lessening downslanting of the palpebral fissures
e) Occasional strabismus
f) Thick eyelid hooding the upper iris
g) Sharp arched eyebrows
iii. Nose
a) Depressed nasal root
b) Low nasal bridge
c) Wide nasal base
d) Bulbous nasal tip
e) Anteverted nares
f) Short columella
iv. Deep philtrum
v. Arched upper lip with high and wide peaks of the vermilion border
vi. Ears
a) Posteriorly rotated
b) Occasionally small or square
vii. Neck
a) Short
b) Less excess skin than in the newborn period
c) A low posterior hairline
viii. Often failure to thrive and hypotonia
ix. Occasional hepatosplenomegaly, swarthy skin, and wispy hair
x. 12–18 months of age
a) Changing body shape with stocky and square upper body
b) Occasional presence of an umbilical hernia or diastasis recti
c) The limbs becoming relatively longer and thinner secondary to resolving edema
d) Blunt finger tips
c. Childhood
i. Face
a) Appearance remaining coarse
b) Becoming more triangular as the chin lengthens
c) Forehead becoming lower and may be bossed
d) Flatter malar eminence
ii. Eyes
a) Less prominent eyes with reduced epicanthus
b) Increasing ptosis
c) Increasing lateral supraorbital fullness
d) Higher nasal root and bridge
iii. Full lips with sublabial protrusion
iv. Neck
a) Appearing longer
b) Accentuating webbing
c) Prominent trapezius
v. Thorax
a) Broad
b) An inverted pyramid shape
c) Increasing pectus

d) Upper chest length increases with relatively low-set nipples and axillary webbing which persist to adulthood.
vi. Scapula
a) Round shape
b) Winged scapulae
vii. Limbs
a) Thin
b) Marked cubitus valgus
c) Flat feet
viii. Skin
a) Lentigines
b) Nevi
c) Café-au-lait spots
ix. Often markedly curly or woolly hair
d. Teenage and young adulthood
i. Facial shape becoming increasingly triangular
ii. Facial features becoming sharper
iii. Less prominent eyes with occasional ptosis
iv. Nose
a) Thinner
b) A pinched root
c) Higher bridge
d) Wide base
e) Pointed tip
f) A longer columella
v. Eyebrows becoming sparse
e. Older adulthood
i. Prominent nasolabial folds
ii. Higher anterior hairline
iii. Occasional sloping forehead
iv. Transparent wrinkled skin
f. Prominent abnormalities at all ages
i. Striking blue or blue-green irides
ii. Increased number of fingertip whorls
iii. Posteriorly angulated ears with a thick helix
iv. Characteristic pectus deformity
a) Pectus carinatum superiorly
b) Pectus excavatum inferiorly

3. Disorders clinically related to Noonan syndrome (Tartaglia et al. 2010)
a. LEOPARD syndrome
b. Cardiofaciocutaneous syndrome
i. A rare sporadic multiple congenital anomalies/mental retardation syndrome characterized by:
a) Failure to thrive
b) Severe feeding problems
c) Developmental delay
d) Short stature
e) Distinguished face
f) Abnormalities of the skin gastrointestinal tract and CNS
g) Cardiac defects (pulmonary stenosis, hypertrophic cardiomyopathy)
ii. Genetically heterogeneous, with mutations in the *KRAS*, *BRAF*, *MEK1,* and *MEK2* genes occurring in approximately 60–90% of affected individuals
c. Costello syndrome
i. Clinical features
a) Prenatal overgrowth
b) Followed by postnatal feeding difficulties and severe failure to thrive
c) Distinctive "coarse" facial features
d) Mental retardation
e) Short stature
f) Cardiac defects (pulmonary stenosis, hypertrophic cardiomyopathy)
g) Musculoskeletal (joint laxity) and skin abnormalities
ii. Caused by germline missense mutations in the *HRAS* proto-oncogene
iii. Other causative genes: *KRAS*, *BRAF*, and *MEK1*
d. Neurofibromatosis-Noonan syndrome (NFNS)
i. Most individuals with NFNS harbor an *NF1* mutation and that a single mutation can be sufficient to engender the trait.
ii. Double heterozygosity for *NF1* and *PTPN11* mutations rarely causes NFNS, and it is not yet clear how frequently mutations in other NS disease genes co-occur with *NF1* defects in the disorder.
iii. These findings support the view that NFNS is genetically distinct from NS and emphasize the extreme phenotypic variability associated with lesions in the *NF1* gene.
iv. The identification of specific *NF1* alleles recurring in NFNS, the evidence that these alleles cosegregate with the condition in families, and the observation of a peculiar mutational spectrum strongly suggest that the term "NFNS" does characterize a phenotypic variant of NF1, which manifests with a lower incidence of plexiform neurofibromas, skeletal anomalies, and internal tumors, in association with

hypertelorism, ptosis, low-set ears, and congenital heart defects.
v. Some of the mutations identified in patients with NFNS have also been reported in NF1 without any feature suggestive of NS.

e. Legius syndrome
i. Previously known as neurofibromatosis type 1–like syndrome.
ii. An autosomal dominant disorder.
iii. Clinical features.
a) Multiple axillary freckling
b) Café-au-lait spots
c) Macrocephaly
d) NS–like facial dysmorphism in some individuals
iv. Caused by loss-of-function mutations of the *SPRED1* gene, which encodes a negative modulator of RAS-MAPK signaling (Brems et al. 2007).
v. *SPRED1* mutational analysis of sporadic or familial cases with a diagnosis of NF1 or with a phenotype suggestive of the disorder indicates that mutations account for approximately 0.5–1% of *NF1* mutation-negative cases.

Diagnostic Investigations

1. Growth curves for males and females with Noonan syndrome now available
2. Echocardiography for previously described congenital heart defects
3. Electrocardiography
   a. A wide QRS complex
   b. Left axis deviation
   c. Giant Q wave
   d. A negative pattern in the left precordial leads
4. Radiography: pectus deformity
5. Renal ultrasound for renal anomalies
6. Coagulation studies when needed
7. Chromosome analysis: normal karyotype
8. Molecular genetic testing available clinically
   a. Mutations in the gene *PTPN11* identified in 50% of patients (familial and sporadic cases)
   b. Germline mutations
      i. Detected in 59% of patients with familial Noonan syndrome
      ii. Detected in 37% of individuals with sporadic Noonan syndrome

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Fifty percentage if a parent is affected
      ii. Low risk (<1%) if parents are not affected unless gonadal mosaicism is present in a parent
   b. Patient's offspring: 50% affected
2. Prenatal diagnosis
   a. Ultrasonography for pregnancies at 50% risk: no definitive ultrasonographic diagnostic criteria early in gestation.
      i. Septated cystic hygroma
      ii. Scalp edema
      iii. Polyhydramnios
      iv. Facial features
         a) Posteriorly angulated, apparently low-set ears
         b) Depressed nasal bridge
      v. Pleural and pericardial effusions
      vi. Cardiac defects
         a) Pulmonic stenosis
         b) Hypertrophic cardiomyopathy
      vii. Ascites
      viii. Hydrops fetalis
   b. Molecular genetic testing of fetal DNA extracted from amniocentesis or CVS for *PTPN11* mutations. The disease-causing allele of an affected family member must be identified before prenatal testing can be performed.
   c. Preimplantation genetic diagnosis: may be available for families in which the disease-causing mutation has been identified.
3. Management
   a. Plotting of growth parameters on growth charts for Noonan syndrome.
   b. Ophthalmological care.
   c. Cardiac management of congenital heart defects and hypertrophic cardiomyopathy.
   d. Hearing evaluation and management.
   e. Physical and occupational therapies for hypotonia.
   f. Speech therapy for articulation deficiencies.
   g. Infant stimulation program for developmental delay.
   h. Multidisciplinary developmental intervention program.

i. Hearing aids for sensorineural hearing loss.
j. Orthopedic management of musculoskeletal abnormalities.
k. Growth hormone treatment of short stature: final height not improved substantially in most patients. When long-term GH therapy is intended to promote growth in children with NS, it has to be considered in relation to the genotype, the effective promotion of growth and the potentially increased tumor risk (Binder 2009).
l. Successful pregnancy possible in women with Noonan syndrome.

Fig. 1 (continued)

Fig. 1 Two boys (**a**–**d**; **e**–**f**) with Noonan syndrome showing various features: downslanting palpebral fissures, hypertelorism, short and webbed neck with a low posterior hairline, pectus, and cubitus valgus

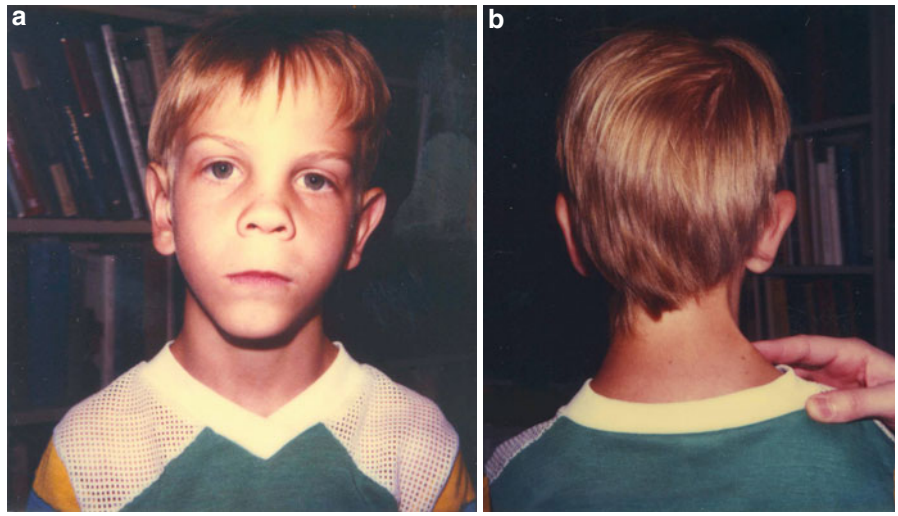

Fig. 2 (**a**, **b**) A boy with Noonan syndrome showing characteristic facial features and webbed neck

Fig. 3 Familial Noonan syndrome in a mother and a daughter

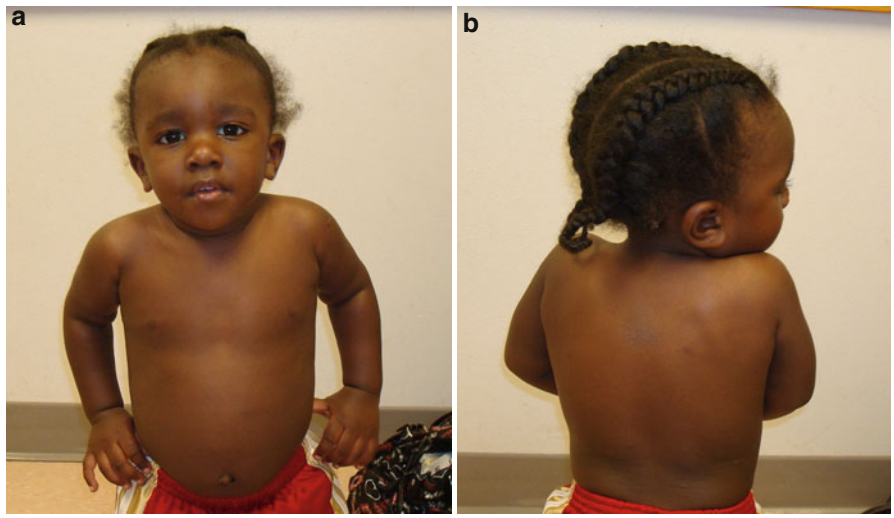

Fig. 4 (**a**, **b**) A 21-month-old boy was evaluated for possible Noonan syndrome because of antimongoloid slant of the palpebral fissures, depressed nasal bridge, slightly low-set ears, short neck, a shield-like chest with distally displaced nipples, and pulmonary stenosis. PTPN11 select exon analysis revealed a heterozygous G>A nucleotide substitution in exon 3, resulting in the replacement of a glycine codon (GGT) with a Serine codon (AGT) at amino acid position 60 of the tyrosine phosphatase SHP-2 protein (p.Gly60Ser or G60S) (c.178G>A)

Oblique Facial Cleft Syndrome

Oblique facial clefts are extremely rare congenital anomalies occurring in about 1/100 to 12/1,000 of facial clefts (Rintala et al. 1980).

Synonyms and Related Disorders

Mandibular process clefts; Naso-ocular clefts; Oculomaxillofacial dysplasia with oblique facial cleft; Oro-aural clefts; Oro-ocular clefts; Tessier clefts

Genetics/Basic Defects

1. Genetic heterogeneity (Richieri-Costa and Gorlin 1994).
   a. Sporadic in most cases
   b. A disruptive event resulting from amniotic band rupture sequence considered as a main etiological agent (Coady et al. 1998)
      i. Twenty six percentage of nonsyndromal craniofacial cleft displays congenital limb anomalies.
      ii. Thirteen percentage of nonsyndromal craniofacial cleft shows evidence of limb ring constrictions.
   c. Occasional association with malformation syndrome (e.g., Fryns anophthalmia-microphthalmia-oblique clefting syndrome)
   d. Rare autosomal recessive inheritance
2. Classification of facial clefts: A universally accepted classification scheme that fully encompasses, accurately describes, and integrates all the various types of orofacial and craniofacial clefts does not exist (Stellzig et al. 1997: Eppley et al. 2005).
   a. The American Association for Cleft Palate Rehabilitation (1962) divided facial clefts into four major groups according to the anatomic location.
      i. Mandibular process clefts
      ii. Naso-ocular clefts
      iii. Oro-ocular clefts
      iv. Oro-aural clefts
   b. Boo-Chai (1990) proposed a subdivision of the oro-ocular group into:
      i. Medial (Type I)
      ii. Lateral (Type II)
   c. Tessier (1976) presented an anatomic classification of the facial clefts by using numbers 0–14 anticlockwise to point the location of the cleft when the orbit is used as the central point.
      i. Commonly used by surgeons because it is purely descriptive and makes no pretense at causation and developmental relationships.
      ii. Proven validity in analyzing complex facial deformities.
      iii. Careful examination in confirming the diagnosis and in managing the patients.
      iv. The Tessier classification includes numbered clefts from 0 (midline cleft of the lip and nose) to 30 (clefting of lower face or a mandibular cleft).
      v. Tessier cleft numbers 4, 5, and 6 are oro-ocular clefts.
      vi. Tessier cleft numbers 7, 8, and 9 are lateral facial or commissural clefts.
      vii. The oblique clefts: indicated by Tessier cleft numbers 3 through 5 (Eppley et al. 2005).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_181,
© Springer Science+Business Media, LLC 2012

3. Classification of orofacial clefts (Tolarová and Cervenka 1998).
   a. Isolated anomaly (61.63%)
      i. Cleft lip
      ii. Cleft lip and palate
      iii. Cleft palate
      iv. Atypical facial cleft
   b. Sequence (3.9%)
      i. Robin sequence
      ii. Holoprosencephaly sequence
      iii. Frontonasal dysplasia sequence
      iv. Amyoplasia congenital disruption sequence
   c. Chromosome aberrations (8.79%)
      i. Trisomy 21 syndrome
      ii. Trisomy 13 syndrome
      iii. Trisomy 18 syndrome
      iv. Other trisomies
      v. Other chromosomal aberrations
   d. Monogenic syndromes (6.02%)
      i. Autosomal dominant
         a) Stickler syndrome
         b) Craniosynostosis syndromes
         c) Van der Woude syndrome
         d) Others
      ii. Autosomal recessive
         a) Smith-Lemli-Opitz syndrome
         b) Meckel syndrome
         c) Others
      iii. X-linked dominant
   e. Known environmental cause (0.2%)
      i. Fetal alcohol syndrome
      ii. Dilantin embryopathy
      iii. Congenital syphilis
   f. Associations (0.79%)
      i. CHARGE association
      ii. VATER association
   g. Multiple congenital anomalies (MCA) (18.5%)
      i. MCA of malformation origin
      ii. MCA of deformation origin
      iii. MCA of malformation and malformation origin
      iv. MCA of other combinations
   h. Conjoined twins
4. Oblique clefts
   a. Considered as late or secondary defects resulting from outgrowth of one or more bone centers in membranous bones
   b. Including certain types of Tessier classification (1976): oblique clefts corresponding to the numbers 3–6 distally or "southward" and 8–11 proximally or "northward" from the orbit in the extreme forms (Rintala et al. 1980)
   c. Arbitrary classification in some instances
   d. Presence of intermediate forms of facial clefts

Clinical Features

1. Clinical variability
2. Oblique facial clefts
   a. Naso-ocular clefts
      i. Whole stretch from the lip through the nose to the eyelid and orbit
      ii. Nasolacrimal duct always involved
      iii. Defective and upwardly dislocated ala nasi
   b. Oro-ocular clefts
      i. Type I (medial): cleft medial to infraorbital region of the nasolabial groove to end in the inner canthus or the lower eyelid
      ii. Type II (lateral): cleft extending from the angle of the mouth upward to the orbit ending in the lateral canthus or in a coloboma in the midportion of the lower eyelid
      iii. Twice as frequent as the naso-ocular types
   c. Bilateral clefts in 20–35% of cases
   d. Presence of complete or incomplete forms
   e. Possible involvement of palate and extending into the temporal region
3. Concordant clinical signs
   a. Short stature
   b. Sparse eyebrows
   c. Sparse eyelashes
   d. Lower lid coloboma
   e. Abnormal nose
   f. Involvement of the nasolacrimal duct
   g. Malar hypoplasia
4. Other variable clinical signs
   a. Mental retardation
   b. Anophthalmia/microphthalmia
   c. Hemimelia (possibly resulting from in utero vascular accident in some cases)
5. Associated anomalies
   a. Amniotic bands
      i. Amniotic band affecting premaxillary-nasal-ocular areas of the midface producing oblique tissue disruptions
      ii. Intrauterine amputation

iii. Constriction rings
iv. Distal lymphedema
v. Distal pseudosyndactyly
vi. Remnant of amniotic band still attached to the lesion

b. CNS abnormalities
i. Encephalocele
ii. Hydrocephaly

c. Aplasia cutis congenita
d. Talipes equinovarus

Diagnostic Investigations

1. Radiography for craniofacial anomalies
2. Three-dimensional CT scan for visualization of the extent and location of the cleft
3. MRI of the brain for CNS anomalies
4. Blood for chromosome analysis to rule out chromosome etiology

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk not increased since most cases are sporadic, especially in a case where amniotic band rupture sequence is considered to be the etiologic factor
      ii. Recurrence risk possibly increased in occasional cases of autosomal recessive inheritance
   b. Patient's offspring: not increased
2. Prenatal diagnosis: possible by ultrasonographic documenting oblique facial cleft associated with other commonly associated anomalies (CNS anomaly, anophthalmia, and findings of amniotic band disruption sequence)
3. Management
   a. Early orthopedic treatment
      i. To achieve both the proper alignment of the maxillary segments and a reduction of cleft width in cases of unilateral cleft lip, alveolus, and palate
      ii. Presurgical orthopedic devices to approximate the distorted segments and to facilitate lip closure in the treatment of maxillary clefts
   b. Surgical repair of facial cleft (Chiong et al. 1981)
      i. General principle
         a) Accurate approximation of each tissue layer
         b) Meticulous layered closure to prevent loss of anatomical continuity and a depressed scar along the site of the operative procedure
         c) Multiple Z-plasty when the repair crosses lines of minimal skin tension or when there is loss of length
      ii. Closure of the cleft and reconstruction of the underlying bony deficiencies at a very early age
      iii. Followed by subsequent correction of orbital hypertelorism between the ages of 2–5 years
      iv. Followed by orthognathic correction of maxillary and mandibular deformities in the teens
   c. Multidisciplinary approach to early intervention

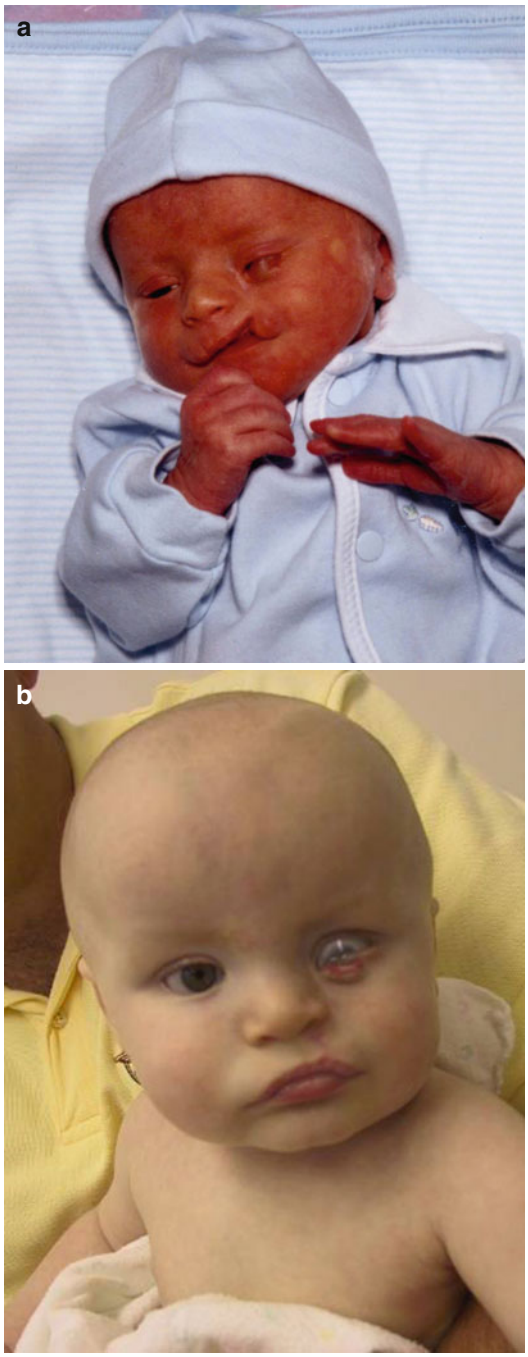

Fig. 1 (**a**, **b**) An infant with oblique facial cleft syndrome (at birth and postoperative) showing unilateral oro-ocular cleft with cleft beginning at the angle of the mouth and ending in a coloboma of the lower eyelid and corneal opacity

Fig. 2 (**a**, **b**) An infant with oblique facial cleft syndrome showing extensive unilateral oro-naso-ocular cleft and encephalocele

Fig. 3 (**a**–**c**) A newborn with oblique facial cleft syndrome associated with amniotic band syndrome and cutis aplasia congenita of the scalp showing bilateral frontonasal clefts, scalp defect, pseudotail, hypertelorism, anophthalmia, clubhands, digital amputation, constriction bands, and an amniotic band still attached to the left finger. The infant also had hydrocephalus, atrial septal defect, and clubfoot

Fig. 4 (**a**–**d**) A 4-year- and 11-month-old boy was seen for Tessier complex orofacial cleft. He was born without right eyeball, absent right nostril, and large oblique orofacial cleft. The photographs show before and after operations

Fig. 5 (**a**–**d**) An infant with Tessier number 7 cleft with a 3D reconstruction CT

Oligohydramnios Sequence

Oligohydramnios is defined as deficiency of amniotic fluid, i.e., decrease in the volume of amniotic fluid. It may result from decreased urinary production or excretion, or fluid loss from rupture of membranes. The incidence is estimated to be 0.5–8% of all pregnancies.

Genetics/Basic Defects

1. Associated maternal conditions (Peipert and Donnenfeld 1991)
   a. Ureteroplacental insufficiency
      i. Antiphospholipid antibodies
      ii. Chronic hypertension
      iii. Collagen vascular diseases
      iv. Diabetic vasculopathy
      v. Maternal hypovolemia
      vi. Preeclampsia/pregnancy-induced hypertension
   b. Drugs
      i. Prostaglandin synthetase inhibitors
      ii. Angiotensin converting enzyme inhibitors
   c. Placental
      i. Abruption
      ii. Twin-to-twin transfusion
   d. Maternal hydration status
2. Associated fetal conditions
   a. Renal malformations
      i. Bilateral agenesis
      ii. Bilateral cystic dysplasia
      iii. Unilateral cystic dysplasia/agenesis
      iv. Meckel syndrome
      v. Infantile polycystic kidneys
      vi. Renal tubular dysgenesis (Lacoste et al. 2006)
         a) Probably an underrecognized disorder
         b) An autosomal recessive disorder
         c) Should be considered for fetuses who present early oligohydramnios, normal or nearly normal kidneys on ultrasound examination, and skull ossification defects
      vii. Posterior urethral valves
      viii. Renal hypoplasia
      ix. Horseshoe kidney
   b. Other congenital anomalies
      i. Amniotic band syndrome
      ii. Branchio-oto-renal syndrome
      iii. Cystic hygroma
      iv. Encephalocele
      v. Endocardial fibroelastosis
      vi. Holoprosencephaly
      vii. Hypophosphatasia (homozygous dominant form)
      viii. MURCS association
      ix. Sacral agenesis (caudal regression)
      x. Sirenomelia
      xi. VATER association
      xii. Others
   c. Chromosome abnormalities
      i. Trisomy 13
      ii. Trisomy 18
   d. Twin-to-twin transfusion syndrome ("stuck twin syndrome")
      i. A complication of monochorionic diamniotic twinning

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_182,
© Springer Science+Business Media, LLC 2012

ii. One twin stucked because of severe oligohydramnios and compressed by the significant polyhydramnios associated with its co-twin
iii. Perinatal mortality associated with severe oligohydramnios/polyhydramnios sequence in a monochorionic twin pregnancy before 28 weeks: 70–100%

e. Intrauterine growth retardation
f. Intrauterine fetal demise
g. Postmaturity possibly caused by a decline in placental function
h. Rupture of membranes: the most common cause of oligohydramnios
   i. Preterm
   ii. Prolonged
i. Idiopathic

3. Dynamic of amniotic fluid
   a. Presence of amniotic fluid throughout gestation
      i. Enables normal development of the fetal respiratory, gastrointestinal, and urinary tracts and musculoskeletal system
      ii. Continued fetal growth in a nonrestricted, sterile, and thermally controlled environment
      iii. Amniotic fluid volume is gestational-age dependent.
   b. Factors contributing to the formation and removal of amniotic fluid
      i. Formation
         a) Fetal urination
         b) Tracheal secretions
         c) Intramembranous pathway including transfers between amniotic fluid and fetal blood perfusing the fetal surface of the placenta, fetal skin, and umbilical cord
         d) Transmembranous pathway involving direct exchange across the fetal membranes between amniotic fluid and maternal blood within the uterus
      ii. Removal: fetal swallowing
   c. Significance of oligohydramnios
      i. A sign of potential fetal compromise
      ii. Associated with an increased incidence of adverse perinatal morbidity and mortality, especially in conjunction with the following:
         a) Structural fetal anomalies
         b) Fetal growth restriction
         c) Post dates pregnancies
         d) Maternal disease

Clinical Features

1. Consequences of severe fetal constraints secondary to early and prolonged oligohydramnios
   a. Potter facies: associated with renal agenesis and any other cause of severe oligohydramnios
      i. Hypertelorism
      ii. Deep crease under the eyes
      iii. Epicanthal folds
      iv. Flat nose
      v. Receding chin
      vi. Low-set, aberrantly folded ears
   b. Lung hypoplasia
      i. Respiratory insufficiency
      ii. Death
   c. Limb positional anomalies
      i. Arthrogryposis
      ii. Spade-like hands
      iii. Talipes equinovarus
   d. Intrauterine growth retardation: one of the most common complications associated with sever oligohydramnios
2. Presence of fetal abnormalities in cases associated with severe oligohydramnios (Shipp et al. 1996)
   a. 50.7% in the second trimester
   b. 22.1% in the third trimester
   c. Rate of aneuploidy: at least 4.4%
3. Correlation of the rate of survivors and the gestation when the severe oligohydramnios is diagnosed
   a. 10.2% survivors in the second trimester
   b. 85.6% survivors in the third trimester

Diagnostic Investigations

1. Ultrasonography
   a. Ultrasonographic modalities to assess oligohydramnios
      i. Single deepest vertical pocket (range: <0.5 to <3 cm)
      ii. Two-diameter pocket (vertical X horizontal <15 cm)
      iii. Amniotic fluid index (AFI) (range: <5 to <8 cm)
   b. Defines oligohydramnios
      i. Amniotic fluid index less than 7 cm
      ii. Absence of a fluid pocket of 2–3 cm in depth
   c. Assesses fetal growth

   d. Visualizes fetal kidneys, collecting system, and bladder
   e. Improves fetal structures by amnioinfusion
2. Chromosome analysis for aneuploidy
3. Autopsy for verification of etiology

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: depends on etiology
   b. Patient's offspring: depends on etiology
2. Prenatal diagnosis
   a. Ultrasonography
   b. Amniocentesis
3. Management
   a. Maternal bed rest
   b. Maternal hydration
   c. Serial amnioinfusions to prevent pulmonary hypoplasia (complications including preterm labor, amnionitis, and perinatal deaths)
   d. The risks of maintaining the fetus in utero must be weighed against the morbidities and mortalities of premature delivery.
   e. Bilateral renal disease with oligohydramnios indicates significant global fetal renal dysfunction and is a risk factor for the development of pulmonary hypoplasia. This is in striking contrast to the dramatic progress that has been made in neonatal intensive care including pulmonary management.
   f. Recent advances in treatment of infants and children with chronic kidney disease and end-stage renal disease has improved prognosis and also for infants with renal insufficiency considerably (Klaassen et al. 2007).

Fig. 3 (**a**–**d**) An infant with caudal regression showing Potter facies, anal atresia, arthrogryposis, and talipes equinovarus

Omphalocele

Omphalocele is a congenital herniation of viscera into the base of the umbilical cord, covered by a membranous sac. The incidence of omphalocele is approximately 1 in 4,000 births.

Genetics/Basic Defects

1. Embryogenesis: Failure of the cranial, caudal, and lateral folds to fuse before myotome invasion is the most likely explanation for the failure of physiologically herniated midgut returning to the abdomen during the first trimester.
2. Inheritance
   a. Usually sporadic
   b. Single-gene disorders associated with omphalocele (Chitayat et al. 1997)
      i. Autosomal recessive disorders
         a) Agonadism with multiple internal malformation
         b) Agonadism, XY, with mental retardation, short stature, retarded bone age, and multiple extragenital malformations
         c) Craniostenosis-mental retardation syndrome of Lin and Gettig
         d) Hydrocephalus with associated malformation
         e) Hydrolethalus syndrome
         f) Malpuech facial clefting syndrome
         g) Omphalocele-exstrophy-imperforate anus-spinal defects (OEIS): also known as exstrophy of the cloaca occurring in about 1 in 100,00–400,000 pregnancies (Carey et al. 1978)
         h) Omphalocele-cleft palate
         i) Opitz C syndrome
      ii. Autosomal dominant disorders
         a) Beckwith–Wiedemann syndrome
         b) Omphalocele
         c) Shprintzen syndrome
      iii. X-linked recessive disorders
         a) Cranioorodigital syndrome
         b) Melnick–Needles osteodysplasty
         c) Omphalocele
         d) Simpson–Golabi–Behmel syndrome
         e) Thoracoabdominal syndrome
   c. Other malformation syndromes associated with omphalocele
      i. Caudal regression
      ii. Cornelia de Lange syndrome
      iii. Amniotic band syndrome
      iv. Limb body wall complex
      v. Megacystic microcolon
      vi. Schisis association
      vii. Skeletal dysplasias
   d. Chromosome disorders associated with omphalocele (25%) (Frolov et al. 2010)
      i. Trisomy 1q
      ii. Trisomy 3q
      iii. Trisomy 13
      iv. Trisomy 18
      v. Trisomy 21
      vi. Trisomy 16
      vii. Add(15)
      viii. Turner syndrome
      ix. Del(4q)
      x. Del(9)(p22)
      xi. Del(18p)

Clinical Features

1. General features
   a. Prematurity
   b. IUGR
2. Herniated sac
   a. Size ranging from 2 to 10 cm
   b. Covering avascular sac consists of fused layers of peritoneum and amnion.
   c. Contents of hernia include thoracic and abdominal viscera.
      i. Liver
      ii. Large intestine
      iii. Small intestine
      iv. Stomach
      v. Gall bladder
      vi. Urinary bladder
      vii. Pancreas
      viii. Spleen
      ix. Internal genitalia
   d. The sac may be torn or ruptured (10–20%).
   e. Necrotizing enterocolitis and malabsorption only if sac is ruptured
3. Umbilical cord inserting into the apex of the sac
4. At increased risk for associated anomalies or syndromes (45–67%)
   a. Cleft lip/palate
   b. Gastrointestinal abnormalities
      i. Diaphragmatic hernia
      ii. Midgut volvulus
      iii. Meckel diverticulum
      iv. Intestinal atresia
      v. Intestinal duplication
      vi. Intestinal malrotation
      vii. Colonic agenesis
      viii. Imperforate anus
   c. Congenital heart defects
   d. Neural tube defects
   e. Genitourinary: exstrophy of the bladder
   f. Limb defects: absent radial ray
   g. Beckwith–Wiedemann syndrome
      i. Macroglossia
      ii. Hypoglycemia
      iii. Organomegaly
      iv. Gigantism
   h. Epigastric omphalocele associated with pentalogy of Cantrell
      i. Cardiac abnormalities
         a) Ventricular septal defect most common
         b) Occasional diverticulum of the left ventricle
      ii. Sternal cleft
      iii. Omphalocele
      iv. Anterior diaphragmatic hernia
      v. Ectopia cordis
5. Prognosis depending on:
   a. Size of the omphalocele
      i. Better prognosis with smaller defects
      ii. Intractable respiratory insufficiency in newborns with large omphaloceles
   b. Presence or absence of the associated anomalies
   c. Presence of chromosome anomalies

Diagnostic Investigations

1. Routine blood work
2. Abdominal radiography
3. Abdominal ultrasound
4. Echocardiography
5. Chromosome analysis
6. Initiate studies for associated single-gene disorder or malformation syndrome

Genetic Counseling

1. Recurrence risk: depends on the mode of transmission and associated chromosome anomalies
2. Prenatal Diagnosis
   a. Elevated maternal serum alpha-fetoprotein
   b. Prenatal 2D ultrasonography
      i. Maternal polyhydramnios
      ii. A circumscribed mass containing liver and/or intestines at the cord insertion site
      iii. Covering sac composed of amnion and peritoneum
      iv. Ruptured omphalocele: a rare complication

v. Identifies other malformations and allows diagnosis of recognizable syndromes such as pentalogy of Cantrell and prune belly syndrome

c. Prenatal 3D ultrasonography
   i. A useful complement to 2D ultrasonography
   ii. Improved definition of omphalocele
   iii. Identifies other malformations and allows diagnosis of recognizable syndromes such as pentalogy of Cantrell and prune belly syndrome
   iv. Allows isolation and better evaluation of the anomalous structure of interest when there is oligohydramnios or fetal contact with the uterine wall or placenta
d. Fetal echocardiography for evaluation of cardiac anomalies
e. Fetal MRI (Mann et al. 2008)
   i. Useful for viewing anatomical details where visualization is limited by maternal body habitus or amniotic fluid volume (Pumberger et al. 2003)
   ii. Volumetric calculations of lung volume (Cannie et al. 2006)
   iii. Evaluation of abdominal contents (Takada et al. 2006)
f. Amniocentesis
   i. Elevated amniotic fluid alpha-fetoprotein
   ii. Positive acetylcholinesterase
g. Chromosome analysis
   i. Amniocentesis
   ii. CVS
   iii. Fetal blood sampling

3. Management (Mann et al. 2008)
   a. Mode of delivery: Owing to the potential intrapartum risk of dystocia, sac rupture, and trauma to abdominal viscera, delivery of fetuses with giant omphaloceles should be by cesarean section.
   b. Attempts at primary repair: difficult due to a small abdominal cavity resulting from extraabdominal location of the viscera in utero
   c. Emergency care
      i. Insertion of an orogastric tube
         a) To decompress the stomach
         b) To prevent swallowed air from causing bowel distention
      ii. Cover the intact omphalocele sac with a sterile dressing and protect it from injury or rupture: Rupture of the sac increases the risk of infection and can lead to intestinal or hepatic trauma but, worse, destroys options for delayed closure strategies.
      iii. Administer intravenous fluids and parenteral antibiotics
      iv. Assess cardiorespiratory status and additional anomalies
   d. Direct primary closure of the abdominal wall for small omphalocele (2 cm)
   e. Staged closure: using a Dacron-reinforced Silastic silo as a temporary housing for the bowel for medium to large omphalocele

Oral–Facial–Digital Syndrome

In 1941, Mohr reported a family in which the propositus had oral (high-arched palate, lobate tongue with papilliform outgrowths), facial (broad nasal root, hypertelorism), and digital (syndactyly, brachydactyly, polydactyly of the hands and feet) findings. This report was the first description of an oral–facial–digital syndrome (OFD). Mohr concluded that the condition was due to sex-linked recessive sublethal gene. A later report of the same family identified a similarly affected individual born to consanguineous parents, thus leading to the conclusion that the condition was inherited as an autosomal recessive trait, now known as OFD II or Mohr syndrome.

A similar phenotype, described by Papillon-Leage and Psaume in 1954, was identified as an X-linked dominant trait, now known as OFD I. After the identification of OFD I and OFD II, the phenotype spectrum was further expanded with extra oral–facial–digital manifestations, leading to the definition of the new types. To date, 13 types have been distinguished based on the characteristic clinical manifestations. The oral–facial–digital syndromes result from the pleiotropic effect of a morphogenetic impairment affecting almost invariably the mouth, face, and digits.

Synonyms and Related Disorders

Orofacialdigital syndrome (OFD); OFD I (papillon-Leage-Psaume syndrome); OFD II (Mohr syndrome); OPD III (Sugarman syndrome); OFD IV (Mohr-Majewski syndrome); OFD V (Thurston syndrome); OFD VI (Varadi-Papp syndrome); OFD VII (Whelan syndrome); OFD VIII (Edwards syndrome); OFD IX (Gurrieri syndrome); OFD X (Figuera syndrome); OFD XI (Gabrielli syndrome); OFD XII (Moran-Barroso syndrome); OFD XIII (Degner syndrome)

Genetics/Basic Defects

1. OFD I (Papillon-Leage–Psaume syndrome): X-linked dominant (lethal in males): *OFD1* is the only gene currently known to be associated with oral–facial–digital syndrome type I.
2. OFD II (Mohr syndrome): autosomal recessive
3. OFD III (Sugarman syndrome): autosomal recessive
4. OFD IV (Mohr–Majewski syndrome, Baraitser–Burn syndrome): autosomal recessive
5. OFD V (Thurston syndrome): autosomal recessive
6. OFD VI (Varadi–Papp syndrome): autosomal recessive
7. OFD VII (Whelan syndrome): autosomal or X-linked dominant
8. OFD VIII (Edwards syndrome): possibly X-linked recessive
9. OFD IX (Gurrieri syndrome): autosomal recessive
10. OFD X (Figuera syndrome): autosomal dominant
11. OFD XI (Gabrielli syndrome): possibly autosomal recessive
12. OFD XII (Moran–Barroso syndrome): possibly autosomal recessive
13. OFD XIII (Degner syndrome): possibly autosomal recessive

Clinical Features

1. OFD I (Papillon-Leage–Psaume syndrome) (Gurrieri et al. 2007)
   a. Characterized by anomalies of the face, oral cavity, and digits with a high degree of phenotypic variability even within the same family, possibly due to different degrees of somatic mosaicism resulting from random X-inactivation
   b. Abnormalities of the oral cavity: primarily affecting the tongue, palate, and teeth
      i. Lobed tongue often described as bifid or trifid
      ii. Tongue nodules, usually hamartomas or lipomas, also occur in at least one third of individuals.
      iii. Ankyloglossia attributable to a short lingual frenulum common
      iv. Cleft hard or soft palate, submucous cleft palate, or highly arched palate: occurring in more than 50% of affected individuals
      v. Trifurcation of the soft palate reported
      vi. Alveolar clefts and accessory gingival frenula are common. These fibrous bands are hyperplastic frenula extending from the buccal mucous membrane to the alveolar ridge, resulting in notching of the alveolar ridges.
      vii. Dental abnormalities include missing teeth (most common), extra teeth, enamel dysplasia, and malocclusion.
   c. Craniofacial abnormalities
      i. Median pseudoclefting of the upper lip
      ii. Irregular margin of the lips
      iii. Facial asymmetry
      iv. Downslanting palpebral fissures
      v. Ocular hypertelorism
      vi. Telecanthus
      vii. Micrognathia
      viii. Broadened nasal ridge
      ix. Hypoplasia of the malar bones and nasal alar cartilages
      x. Frontal bossing
      xi. Vanishing milia of the face and ears, usually disappear before the third year of life
      xii. Dryness, brittleness, and/or alopecia of the scalp hair
   d. Digital abnormalities
      i. Brachydactyly
      ii. Syndactyly of varying degrees
      iii. Clinodactyly of the fifth finger
      iv. The third (i.e., middle finger) showing variable radial or ulnar deviation
      v. Duplicated hallux (great toe) occurs in fewer than 50% of affected individuals, but if present is usually unilateral.
      vi. Preaxial or postaxial polydactyly of the hands occurring in 1–2% of affected individuals
      vii. Radiographs of the hands often demonstrate fine reticular radiolucencies, described as irregular mineralization of the bone, with or without spicule formation of the phalanges.
   e. Other associated anomalies
      i. CNS anomalies
         a) Microcephaly
         b) Intracerebral cysts
         c) Agenesis of the corpus callosum
         d) Cerebellar agenesis with or without Dandy–Walker malformation
         e) Type 2 porencephaly (schizencephalic porencephaly)
         f) Pachygyria and heterotopias
         g) Hydrocephalus
         h) Cerebral or cerebellar atrophy
         i) Berry aneurysms
      ii. Intelligence: about 50% of individuals with OFD1 with some degree of mental retardation or learning disability
      iii. Polycystic kidney disease: occurring in fewer than 50% of individuals with OFD1. Renal cysts can develop from both tubules and glomeruli, most often in adulthood.
2. OFD II (Mohr syndrome)
   a. Oral anomalies
      i. Cleft tongue
      ii. Tongue hamartomas
   b. Facial anomalies
      i. Bifid nasal tip
      ii. Median cleft of the upper lip
      iii. Ocular hypertelorism

c. Digital anomalies
   i. Bilateral upper extremity hexadactyly
   ii. Polysyndactyly of big toes
d. Features overlapping with OFD I
   i. Orofacial manifestations: tongue nodules, midline clefts of the lip, thick frenula, and dystopia canthorum
   ii. Digital manifestations: clinobrachydactyly, syndactyly, and polydactyly
e. Subtle clinical differences between types I and II
   i. Greater thickness of the alveolar ridge that in type I, which is normal in type II
   ii. Presence of hair and skin abnormalities in type I
   iii. Presence of bilateral polysyndactyly of the halluces in type II rather than unilateral polysyndactyly, which is usually found in type I
   iv. Conductive hearing impairment may occur in type II
   v. Central nervous system can also be affected in this form mainly with porencephaly and hydrocephaly
f. Distinctive difference in the mode of inheritance: OFD type II is caused by mutations of an as yet unidentified autosomal recessive gene vs. X-linked dominant inheritance in OFD type I.
g. Expanding phenotype spectrum in OFD type II: congenital heart defects such as atrioventricular canal and endocardial cushion defects
h. A Y-shaped central metacarpal, usually considered typical of OFD type VI, has also been reported in patients with clinical characteristics falling within the OFD II spectrum, suggesting the existence of transitional OFD types that may turn out to be allelic forms once the genetic defects of all OFD types are discovered.

3. OFD III (Sugarman syndrome): only two reports of this condition
   a. Oral, facial, and digital abnormalities
   b. Continuous alternating (ceaseless seesaw) winking of the eye lids
   c. Myoclonic jerks
   d. Polydactyly: postaxial
4. OFD IV (Mohr–Majewski syndrome, Baraitser–Burn syndrome) (oral–facial–digital syndrome with tibial defects)
   a. Minor facial anomalies
   b. Oral frenula, tongue nodules with or without lobulation
   c. Digital anomalies, including polydactyly and club feet
   d. Long bone anomalies limited to tibial defects (tibial dysplasia)
   e. Hearing loss
   f. Expansion of phenotypic spectrum
      i. Occipitoschisis
      ii. Brain malformation
      iii. Ocular colobomas
      iv. Intrahepatic cyst
      v. Renal cysts
      vi. Anal atresia
      vii. Joint dislocations
5. OFD V (Thurston syndrome)
   a. The mildest form within the OFD group
   b. Midline cleft lip
   c. Bilateral postaxial polydactyly of the hands and feet
   d. Reported exclusively in individuals of Indian ethnicity
6. OFD VI (Varadi–Papp syndrome)
   a. Distinguished features
      i. First report in endogamic gypsies
      ii. Oral, facial, and digital abnormalities
      iii. Cerebellar findings (vermis hypoplasia/aplasia, Dandy–Walker anomaly)
      iv. Y-shaped metacarpals: forked third or fourth metacarpals, indicating central polydactyly
      v. Expanded phenotype spectrum
         a) Penile agenesis
         b) Abnormal clavicles
         c) Absent pituitary gland
         d) Hypothalamic hamartoma with precocious puberty which is almost constantly found in Pallister–Hall syndrome, an autosomal dominant condition characterized by postaxial polydactyly, imperforate anus, and hypothalamic hamartoma. The phenotypic overlap between OFD VI and Pallister–Hall

syndrome has been noted, and lumping of the two conditions as the same entity has been proposed.
   e) GLI3 mutations identified in Pallister–Hall syndrome suggest that GLI3 analysis should also be carried out in patients with OFD VI to find out if these two conditions are allelic.
   f) A single report of neuropathologic findings in OFD VI showed disruption or dysgenesis of glial architecture, suggesting a primary glial cell defect. This observation is interesting in light of the recent discovery that OFD I is caused by a failure of the ciliary system, which is involved in cellular migration during embryogenesis.
7. OFD VII (Whelan syndrome): a single report of mother and daughter
   a. Facial (asymmetry), oral, and digital (polydactyly of hands and feet) anomalies
   b. Laryngeal anomalies
   c. Ear anomalies
   d. Hydronephrosis
   e. Possibly same entity as OFD 1 since mother and daughter later developed cystic kidney disease, although mutation analysis for OFD I failed to detect a pathogenic mutation
8. OFD VIII (Edwards syndrome)
   a. Clinically overlapped with OFD II
      i. Short tibia
      ii. Dystopia canthorum
   b. Distinguished from OFD II by X-linked recessive inheritance
9. OFD IX (Gurrieri syndrome)
   a. Retinal anomaly: a distinctive feature
   b. Digital anomalies: usually consist of hallucal duplication detectable radiologically
   c. Dandy–Walker malformation
10. OFD X (Figuera syndrome)
   a. Orofacial findings
   b. Digital findings
      i. Oligodactyly
      ii. Preaxial polydactyly
   c. Limb anomalies
      i. Mesomelic limb shortening, specifically due to radial hypoplasia
      ii. Fibular agenesis
11. OFD XI (Gabrielli syndrome): in addition to the oral, facial, and digital anomalies, this type is characterized by following craniovertebral anomalies
   a. Oral, facial, and digital anomalies
   b. Additional anomalies
      i. Midline cleft involving the palate, vomer, ethmoid, and crista galli
      ii. Apophysis
      iii. Vertebral malformations
         a) Fusion of vertebral arches in C1, C2, and C3
         b) Clefts of vertebral bodies
12. OFD XII (Moran–Barroso syndrome)
   a. Oral, facial, and digital anomalies
   b. Myelomeningocele
   c. Stenosis of the aqueduct of Sylvius
   d. Cardiac anomalies
13. OFD XIII (Degner syndrome)
   a. Oral, facial, and digital anomalies
   b. CNS anomalies
      i. Psychiatric symptoms (major depression)
      ii. Epilepsy
      iii. Brain MRI findings of leukoaraiosis (patched loss of white matter of unknown pathogenetic origin, possibly of ischemic nature, considered to increase the risk of stroke)

Diagnostic Investigations

1. Diagnostic approach
   a. First, ascertain oral, facial, and digital findings.
   b. Obtain family history to determine if a mode of inheritance can be established.
   c. In patients with clear X-linked dominant transmission and even in sporadic female patients, it is necessary to rule out mutations in the OFD1 gene.
   d. Additional studies to delineate specific type, given the fragmentary nosology of OFD
      i. Brain MRI
      ii. Abdominal ultrasound
      iii. Skeletal survey
      iv. Ophthalmologic evaluation
      v. Audiometric test
      vi. Chromosome analysis to detect submicroscopic rearrangements by array-CGH analysis
2. Diagnosis of OFD I
   a. Established at birth in some infants on the basis of characteristic oral, facial, and digital anomalies

b. Diagnosis is suspected in some patients only after polycystic kidney disease is identified in later childhood or adulthood
c. Molecular genetic testing (sequencing) of *OFD1*, the only gene currently known to be associated with OFD I: clinically available for confirmatory diagnostic testing and prenatal diagnosis of OFDI

3. Diagnosis of OFD VII (includes unilateral cleft lip and hydronephrosis, only been described in one mother–daughter pair, who were later found to have a mutation in *OFD1*): either allelic to OFD1 or demonstrates variable expression of OFD1

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive (OFD types II, III, IV, V, VI, possibly types XI, XII, XIII)
         a) A 25% risk
         b) A 50% risk of being a carrier
      ii. Autosomal dominant (OFD X)
         a) A small recurrence risk if neither parent is affected
         b) A 50% risk if one parent is affected
      iii. X-linked dominant with male lethality (OFD I, OFD VII)
         a) Approximately 75% of affected individuals are simplex cases (no family history of OFD1).
         b) A female proband with OFD1 may have the disorder as the result of a de novo gene mutation; however, the proportion of cases caused by de novo mutations is unknown.
         c) If no family history of OFD1 exists, the risk that the unaffected mother of an affected female will have another female with OFD1 is less than 1%.
      iv. X-linked recessive (OFD VIII): risk to the sibs depending on the carrier status of the mother
         a) Mother is a carrier: a 50% of risk of having a male sib with OFD VIII
         b) Mother is not a carrier: a low recurrence risk
   b. Patient's offspring
      i. Autosomal recessive: a low recurrence risk unless the spouse is also affected or a carrier
      ii. Autosomal dominant: a 50% risk if the spouse is normal
      iii. X-linked dominant with male lethality
         a) At conception, the risk to the offspring of females with OFD1 of inheriting the disease-causing OFD1 allele is 50%; however, most male conceptuses with the disease-causing allele miscarry.
         b) At delivery, the expected sex ratio of offspring: 33% unaffected females, 33% affected females, and 33% unaffected males.
      iv. X-linked recessive
         a) No sons will be affected
         b) All daughters will be carriers
2. Prenatal diagnosis
   a. Prenatal ultrasound
      i. Prenatal diagnosis of OFD type II reported in a fetus
         a) Polydactyly with bifid thumbs in both hands
         b) Bilateral polysyndactyly of halluces
         c) Lateral polysyndactyly and bilateral pes equinovarus
      ii. Prenatal diagnosis of OFD type IV (Mohr–Majewski) possible: findings showing overlap between OFD type II (Mohr) and lethal short-rib–polydactyly syndrome type II (Majewski)
      iii. Prenatal ultrasound examination may detect structural brain malformations and/or duplication of the hallux.
   b. Molecular genetic analysis: prenatal diagnosis for families in which the disease-causing mutation has been identified is clinically available.
3. Management
   a. Surgery
      i. Cleft lip/palate
      ii. Tongue nodules
      iii. Accessory frenula
      iv. Polysyndactyly
      v. Removal of accessory teeth
      vi. Orthodontia for malocclusion
   b. Management of renal disease and seizures
   c. Speech therapy
   d. Special education
   e. Surveillance
      i. Annual monitoring of renal function
      ii. Speech and hearing assessment if cleft palate is present

Fig. 1 Patient 1 with OFD I. Note the lingual frenulum and hypoplastic alar nasi

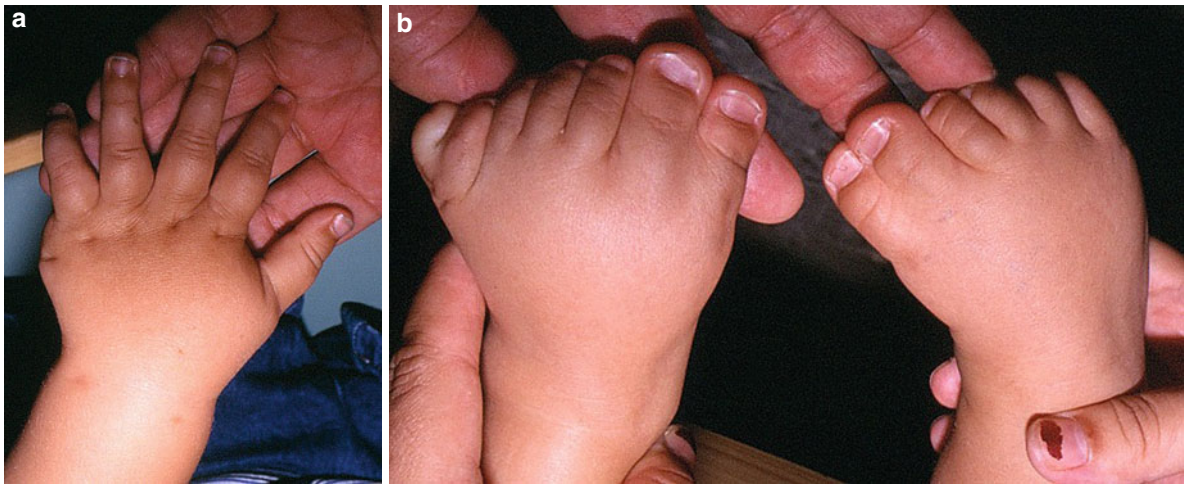

Fig. 2 (**a**, **b**) The patient's bilateral postaxial polydactyly of both hands, duplicated hallux of both feet, and postaxial polydactyly of the *left* foot

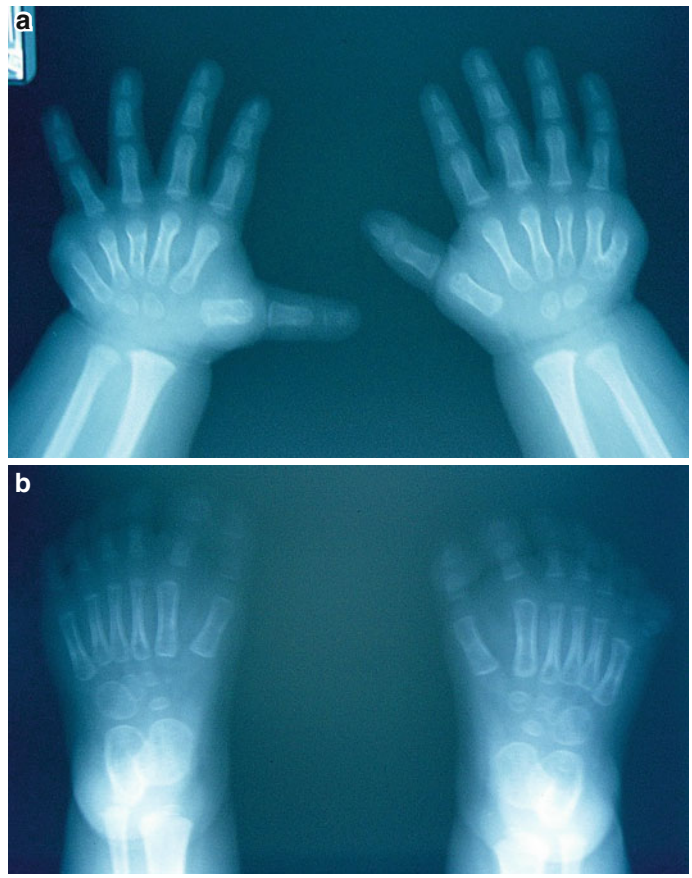

Fig. 3 (**a**, **b**) Radiographs of hands and feet of patient 1

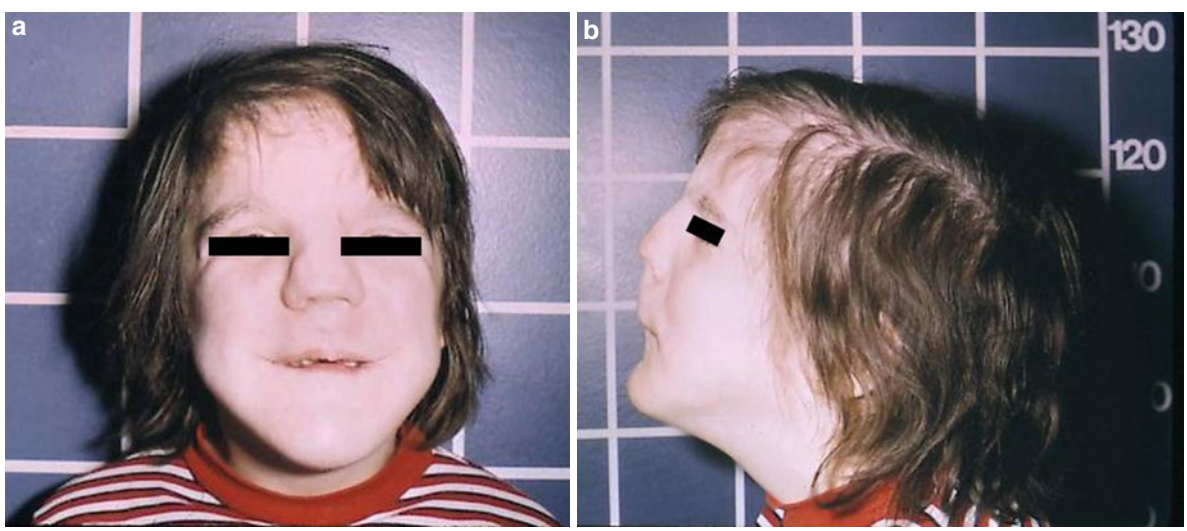

Fig. 4 (**a**, **b**) Patient 2 with OFD II. Note bifid nasal tip, medial cleft of the *upper* lip, and ocular hypertelorism

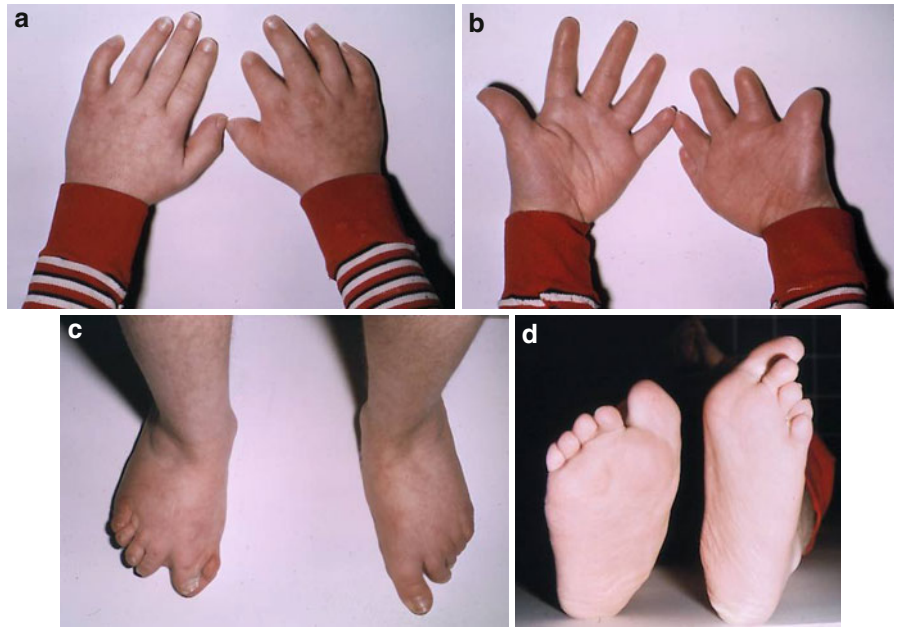

Fig. 5 (**a**–**d**) Note the clinobrachydactyly and syndactyly of the hands and polydactyly of the *right* hallux

Fig. 6 (**a**–**d**) Patient 3 with OFD II. Note the ocular hypertelorism, bifid tip of the nose, lingual frenulum, and brachysyndactyly

Fig. 7 (**a**–**d**) Patient 4 with unclassified OFD. Note frontal bossing, ocular hypertelorism, strabismus, pseudocleft of the upper lip, preaxial polydactyly of the hands, hepatomegaly, and genu valgum

Osteogenesis Imperfecta

Osteogenesis imperfecta (OI) is a generalized, hereditary disorder of connective tissue involving bone, tendon, ligament, fascia, and dentin, resulting from mutations affecting the amount or structure of type I collagen. OI affects about 1 in 10,000 individuals.

Synonyms and Related Disorders

Osteogenesis imperfecta with blue sclerae; Osteogenesis imperfecta with normal sclerae; Perinatal lethal osteogenesis imperfecta; Progressively deforming osteogenesis imperfecta with normal sclerae

Genetics/Basic Defects

1. Clinicopathological classification (Glorieux 2008; Basel and Steiner 2009): The classification system of Sillence et al. (1979b) divides OI into four severity-based types with type IV representing the most clinically diverse group. It is from this heterogeneous group that types V, VI, VII, and VIII have been identified on the basis of distinct clinical and histological features (Glorieux et al. 2000, 2002; Ward et al. 2002). The most clinically relevant characteristic of all types of OI is bone fragility, the severity of which increases in the order type I < types IV, V, VI, VII, VIII < type III < type II. Heredity follows an autosomal dominant pattern in types I through V, and is autosomal recessive in types VI, VII, and VIII. Mutations affecting collagen type I are usually present in types I through IV and types VII and VIII, but are absent in types V and VI. This classification scheme is likely to change as additional information is gathered on newly described forms caused by *CRTAP* and *LEPRE* mutations.
   a. OI I
      i. Autosomal dominant disorder
      ii. Fresh mutation in 15% of cases
      iii. The most common and mildest form of osteogenesis imperfecta
      iv. Estimated prevalence at between 1 in 10,000 and 1 in 25,000, or may be more frequent because of its relatively mild presentation and the possibility of underdiagnosis
   b. OI II
      i. Autosomal dominant disorder (new mutations in almost all instances)
      ii. The most severe form, resulting in death in the perinatal period
      iii. Autosomal recessive disorder (rare)
      iv. Further subdivided into IIA, IIB (same as type III), and type IIC
      v. Estimated frequency of 1 in 20,000–1 in 60,000 births
   c. OI III
      i. Autosomal dominant disorder
      ii. Autosomal recessive disorder (uncommon)
      iii. The rarest form of OI
      iv. Known as the progressive deforming form
   d. OI IV
      i. Autosomal dominant
      ii. The most clinically diverse group
      iii. Represents the moderately severe spectrum of OI
      iv. Marked intra/interfamilial variability of expression

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_185,
© Springer Science+Business Media, LLC 2012

e. OI V
   i. The moderately deforming form
   ii. Associated mutations: unknown
f. OI VI
   i. The moderately to severely deforming form
   ii. Associated mutations: unknown
g. OI VII
   i. Overlaps with types II and III; milder forms also documented
   ii. Associated mutations: hypomorphic expression of *CRTAP*
h. OI VIII
   i. Overlaps with types II and III; milder forms also documented
   ii. Associated mutations: *LEPRE1*

2. Molecular basis
   a. Type I collagen
      i. Found in the skin, bone, tendons, and ligaments
      ii. Composed of three α chains (two α_1 chains and one α_2 chain)
      iii. Each α chain forms a helix which consists of three amino acids per turn.
      iv. The chains are held together by disulfide bonds at the C-terminal ends of the protein.
      v. There are three amino acids per turn in the helix.
      vi. Every third amino acid is glycine, giving a repeat of Gly-X-Y, where X and Y represent other amino acid residues.
         a) About 10% of the X residues are proline
         b) About 10% of the Y residues are hydroxyproline
      vii. A mutant collagen is produced by missense mutations that result in a substitution of the glycine residue by another amino acid.
   b. OI I
      i. Affected individuals produce only 50% of the normal amount of type I collagen, produced by the normal allele.
      ii. Mechanisms
         a) Splicing in α_1 gene
         b) Null mutation in α_1 gene
   c. OI II, OI III, and OI IV
      i. Affected individuals produce only 25% of the normal amount of type I collagen and 75% of mutant or defective collagen.
      ii. Mechanism: A missense mutation arises in the α_1 gene resulting in a defective α_1 chain which is incorporated into the final collagen molecule and destroys its function.
      iii. Severity of the disease
         a) Related to the position of the missense mutation within the gene and the amino acid substitution that occurs
         b) Generally, the disease is more severe when the mutation is closer to the C-terminal end of the protein.
   d. OI VII
      i. The disease has been assigned to chromosome 3p22–24.1 (Labuda et al. 2002).
      ii. Co-localizing with the gene encoding CRTAP, a cartilage-associated protein, whose expression is 90% reduced in homozygote patients (Morello et al. 2006)
3. OI VIII: caused by *LEPRE1* mutations
4. Allelic connective tissue disorders (Basel and Steiner 2009)
   a. Several patients have been described with joint hypermobility and skin laxity, a clinical phenotype more in keeping with Ehlers-Danlos syndrome but who have an increased disposition to fractures.
   b. Mutations not involving the glycine residues within the triple helix of COL1 and mutations involving cysteine residues have been described in a subset of these patients (Maifait et al. 2007, 2006; Cabral et al. 2007).
   c. N-terminal mutations in COL1 appear to result in abnormal protein folding, which leads to a milder OI/Ehlers-Danlos syndrome p (Makareeva et al. 2006).
5. Very few individuals or families share the same mutation, although more than hundreds of unique mutations of the type I collagen genes have been identified.
6. Phenotypic variations among different families and within same family

Clinical Features

1. OI type I (mild type) (Glorieux 2008)
   a. Fractures
      i. Rarely fracture in utero or in the perinatal period
      ii. Usual onset of fractures: when the child begins to walk

iii. A few to more than 50 fractures before puberty
iv. Number of fractures gradually decreases after puberty.
v. Involve any bones of the body, but primarily long bones of the arms and legs, ribs, and small bones of the hands and feet
vi. Increasing fractures often after menopause in affected women and in the sixth or eighth decades in affected men
vii. Healing rapidly with evidence of good callus formation and without deformity

b. Cranial features
i. Soft thin calvarium
ii. Wide fontanels
iii. Wormian bones
iv. Frontal and temporal bulging
v. Occipital flattening

c. Blue sclera (secondary to a thin sclera allowing partial visualization of the choroid)
i. Readily apparent at birth
ii. Gradually lightens to blue gray in the adulthood

d. Other ocular features
i. Occasional embryotoxon (opacity in the peripheral cornea)
ii. Occasional keratoconus or megalocornea

e. Teeth abnormalities
i. Rare dentinogenesis imperfecta
ii. Hypoplasia of pulp
iii. Yellow or gray teeth
iv. Susceptible to caries
v. Irregular placement
vi. Late eruption

f. Hearing loss
i. Early onset in about 50% of families beginning in late teens
ii. Gradually leading to profound hearing loss in the end of fourth or fifth decades secondary to otosclerosis
iii. Primarily conductive hearing loss in the early phase secondary to fractured and fused bones of the middle ear
iv. Early hearing loss typically of the high-frequency type resulting in a characteristic bifid compliance curve by tympanometry
v. Later hearing loss becoming mixed in type and surgical intervention may be less successful

g. Skin and joint abnormalities
i. Mild joint hypermobility
ii. Easy bruising
iii. Thinner translucent skin
iv. Capillary fragility
v. Inguinal or umbilical hernia
vi. Flat feet
vii. Joint dislocation
viii. Poorly developed muscles
ix. Decreased thrombocyte function leading to increased bleeding

h. Cardiovascular abnormalities
i. Mitral valve prolapse
ii. Aortic valvular insufficiency
iii. Slightly larger than normal aortic root diameter without significant risk of progression to dissection, identified in a small number of patients
iv. Increased bleeding tendency secondary to increased capillary fragility

i. Prognosis
i. Usually normal stature but may lose some height in later decades due to spine involvement
ii. In general, with good orthopedic cares, fractures heal quickly without deformities.
iii. No decrease in fertility or longevity in affected individuals

2. OI type II (perinatal lethal type)
a. Lethality during perinatal period resulting from:
i. Pulmonary insufficiency
ii. Congestive heart failure
iii. Infection

b. Prenatal history
i. Intrauterine growth retardation (dwarfism, low birth weight)
ii. Prematurity
iii. Nonimmune hydrops

c. Short-limbed dwarf
d. Characteristic craniofacial features
i. Extremely soft calvarium
ii. Dark-blue sclerae
iii. Beaked nose
iv. Micrognathia

e. Chest
i. Very small
ii. Beaded ribs
iii. Lung hypoplasia

f. Extremities
   i. Short and deformed limbs
   ii. Bowed legs
g. Hip: flexed and abducted (frog position)
h. Prognosis: death resulting from pulmonary insufficiency, congestive heart failure, or infection
   i. Usually during the first few hours of life
   ii. More than 60% of infants with OI type II during the first day
   iii. Eighty percent within the first month
   iv. Rare survival beyond a year

3. OI type III (progressively deforming type)
   a. Dwarfism and moderate deformities resulting from in utero fractures
   b. Craniofacial features
      i. Typical triangular faces
      ii. Relatively large cranium
   c. Fractures
      i. Very common
      ii. Progressive long bone deformities with growth
      iii. Marked deformities of most bones
   d. Significant kyphoscoliosis leading to cardiopulmonary insufficiency, a major cause of early death in these individuals
   e. Sclerae
      i. Often pale blue at birth
      ii. Generally becomes normal hue by puberty
   f. Abnormal dentinogenesis involving both primary and permanent teeth: common
   g. Hearing loss: common
   h. Prognosis
      i. Death resulting from cardiac decompensation, pulmonary insufficiency, or basilar impression with compression of the brain stem
      ii. Long-term survival possible with multiple fractures and deformities
      iii. Primary objective to lead a satisfying and productive life
      iv. Major limitations (severe bone fragility and deformity, muscle weakness, joint contractures that develop from inactivity, progressive scoliosis resulting in life-threatening cardiopulmonary decompensation, marked short stature)
4. OI type IV (moderately severe type)
   a. Significant intrafamilial and interfamilial phenotypic variation
   b. Fractures
      i. Occurring in utero, during labor and delivery, or in the newborn period
      ii. Fractures at birth, not observed in all affected infants
      iii. Some affected infants with only mild femoral bowing
      iv. Early recognition of these fractures is essential to prevent accusation of child abuse when the first fractures occur, and the previous, now healed, fracture(s) is/are detected by routine skeletal survey.
   c. Variable short stature
   d. Normal white or grayish sclera
   e. Occasional hearing loss
   f. Common dentinogenesis imperfecta
   g. Mild to moderate bone deformity
   h. Severe kyphoscoliosis may compromise cardiopulmonary function.
   i. Prognosis
      i. Life span near normal in the absence of severe cardiopulmonary complications
      ii. Treatment objectives (to minimize the long-term complications of kyphoscoliosis and to assure independence and mobility)
5. OI type V
   a. Represents 4–5% of the OI population seen in hospitals (Rauch and Glorieux 2004)
   b. Moderate to severe bone fragility (Glorieux et al. 2000)
   c. Does not have blue sclera or dentinogenesis imperfecta
   d. Distinctive clinical features
      i. Common occurrence of radial head dislocation/subluxation and calcification of the interosseous membrane between the radius and ulna (Lee et al. 2006; Fassier et al. 2007)
      ii. Frequent development of hypertrophic calluses at fracture sites
      iii. Calcification of the interosseous membranes between the bones of the forearm
      iv. Presence of a radio-opaque metaphyseal band immediately adjacent to the growth plates on x ray
      v. Upon histological examination, the bone organization has an irregular mesh-like appearance, clearly distinct from the normal lamellar pattern

e. The calcified interosseous membrane often severely limits the pronation/supination of the hand and may lead to secondary dislocation of the radial head.
f. The hyperplastic callus that may develop after fractures or surgical interventions may mimic osteosarcoma.

6. OI type VI
   a. Moderate to severe skeletal deformities: may represent in approximately 4% of moderately to severely affected OI patients (Rauch and Glorieux 2004)
   b. Clinically indistinguishable from OI type IV
   c. Does not have blue sclera or dentinogenesis imperfecta (Glorieux et al. 2002)
   d. Inheritance: autosomal recessive
   e. Distinctive histological features: The hallmark is abnormal bone mineralization on histological examination.
      i. The fish-scale-like appearance of the bone lamellae
      ii. The presence of excessive osteoid accumulation on bone-forming surfaces, suggesting a mineralization defect reminiscent of osteomalacia, but there is no abnormality in mineral homeostasis, and growth plate mineralization proceeds normally.
7. OI type VII
   a. Moderate to severe skeletal deformities and bone fragility
   b. Lacks blue sclera and dentinogenesis imperfecta
   c. Coxa vara may be present even in infancy.
   d. Distinctive clinical feature: rhizomelic shortening of the humerus and femur
   e. "Popcorn" epiphyses often seen in severe forms
   f. To date, only been observed in a community of Native Americans in northern Quebec, where it exhibits autosomal recessive inheritance
8. OI type VIII (Shapiro and Sponsellor 2009)
   a. Severe, lethal form
   b. Seen in South African blacks
   c. "Popcorn" epiphyses often seen in severe forms
9. Establishing a diagnosis (Basel and Steiner 2009): The following list of features would be typical in an individual presenting with OI:
   a. Family history of OI or recurrent fractures
   b. Fractures with minimal or no trauma in the absence of other factors, such as inflicted physical abuse or other known disorders of bone
   c. Short stature or stature shorter than predicted based on stature of unaffected family members, often with bone deformity
   d. Blue sclera
   e. Dentinogenesis imperfecta
   f. Progressive, postpubertal hearing loss
   g. Ligamentous laxity and other signs of connective tissue abnormality
   h. Family history of OI, usually consistent with autosomal dominant inheritance
   i. Fractures of varying ages and stages of healing, often of the long bones but may also involve ribs and skull. The metaphyseal chip fractures characteristic of child physical abuse can be seen in a small number of children with OI.
   j. "Codfish" vertebrae, which are the consequence of spinal compression fractures, seen primarily in the adult
   k. Wormian bones, defined as "sutural bones that are 6 mm by 4 mm (in diameter) or larger, in excess of 10 in number, with a tendency to arrangement in a mosaic pattern." Wormian bones are suggestive of, but not pathognomic, for OI. They are present in up to 60% of affected children.
   l. Protrusio acetabuli, in which the socket of the hip joint is too deep and the acetabulum bulges into the cavity of the pelvis causing intrapelvic protrusion of the acetabulum
   m. Low bone density detected by dual energy X-ray absorptiometry. There seems to be a correlation between bone mineral density and fracture risk in OI (Huang et al. 2006; Bachrach 2007).
10. Differential diagnosis (Basel and Steiner 2009)
    a. In utero: Prenatal ultrasound examination of severe OI may lead to following skeletal dysplasias which all present with relative macrocephaly and rhizomelic shortening of the limbs (OI type II with ultrasound findings of crumpled long bones and beaded ribs):
       i. Hypophosphatasia
       ii. Thanatophoric dysplasia
       iii. Campomelic dysplasia
       iv. Achondrogenesis

b. Infancy and childhood
   i. Nonaccidental trauma (child abuse)
   ii. Infantile hypophosphatasia: See the chapter on hypophosphatasia.
   iii. Bruck syndrome
      a) An autosomal recessive condition
      b) Bone fragility
      c) Congenital joint contractures
      d) Clubfeet
      e) Normal or blue sclera
      f) Wormian bones
      g) It results from defects in the lysyl hydroxylase (PLOD2) that hydroxylates the amino-terminal lysyl residues involved in crosslink formation.
   iv. Osteoporosis pseudoglioma syndrome
      a) Bone fragility and fractures
      b) Other skeletal deformities
      c) Pseudoglioma with blindness in infancy
      d) Other anomalies
      e) Caused by mutations in the gene encoding the lipoprotein receptor-related protein
   v. Cole-Carpenter syndrome
      a) Bone deformities
      b) Multiple fractures
      c) Ocular proptosis
      d) Shallow orbits
      e) Orbital craniosynostosis
      f) Frontal bossing
      g) Hydrocephalus
   vi. Hadju-Cheney syndrome
      a) Short stature
      b) Failure to thrive
      c) Conductive hearing loss
      d) Dysmorphic features
      e) Early tooth loss
      f) Genitourinary anomalies
      g) Osteopenia
      h) Pathologic fractures
      i) Wormian bones
      j) Failure of suture ossification
      k) Basilar impression
      l) Vertebral abnormalities
      m) Kyphoscoliosis
      n) Cervical instability
      o) Joint laxity
      p) Dislocation of the radial head
      q) Long-bowed fibulae
      r) Pseudoclubbing
      s) Short distal digits
      t) Acroosteolysis
      u) Hirsutism
   vii. Gerodermia osteodysplastica
      a) Dwarfism
      b) Lax skin
      c) Osteoporosis
      d) Wormian bones
      e) Fractures
      f) Vertebral compression
      g) Wizened facial appearance because of facial skin laxity
   viii. Idiopathic juvenile osteoporosis
      a) Typically presents in preadolescents with fractures and osteoporosis
      b) The fracture susceptibility and osteoporosis usually resolve spontaneously with puberty.
      c) The etiology is unknown.
   ix. Dentinogenesis imperfecta: can occur separately from OI as an isolated familial condition as a result of mutations in the DSPP gene on chromosome 4

11. Importance of diagnosis in the newly affected infant for whom there is no family history
   a. To facilitate genetic counseling
   b. To reassure the family about prognosis
   c. To remove the concern of child abuse in some families (Steiner et al. 1996)
      i. Fractures considered “highly specific” for child abuse: present in 33% (2/6) of cases with OI
         a) Metaphyseal fractures
         b) Posterior rib fractures
         c) Scapular spinous process
         d) Sternal fractures
      ii. Fractures considered “moderately specific” for abuse: present in 50% (3/6) of cases with OI
         a) Multiple fractures, especially bilateral
         b) Fractures of different ages
         c) Epiphyseal separations
         d) Digital fractures
         e) Complex skull fractures

iii. Fractures considered "low specificity" for child abuse: present in 17% (1/6) cases of OI
  a) Clavicular fractures
  b) Long bone shaft
  c) Linear skull fractures

d. General signs of child abuse
  i. Multiple fractures as described
  ii. Clinical findings highly indicative of child abuse
    a) Retinal hemorrhage
    b) Cephalohematoma
    c) Subdural hemorrhage
    d) Evidence of bodily abuse (bruises, lacerations, burns)
    e) Evidence of sexual abuse
  iii. Incompatible history with physical examination
  iv. History of domestic violence, corporal punishment, and child maltreatment

e. Useful for families to have a letter from the child's physician stating the diagnosis of the osteogenesis imperfecta

Diagnostic Investigations

1. Radiography
  a. OI type I
    i. None to multiple fractures with little bone deformities
    ii. Fractures primarily in long bones (may occur with minimal trauma, decreased dramatically in puberty, increase at later ages, normal healing with callus formation)
    iii. Osteopenia (generalized demineralization) which can be documented by densitometry
    iv. Thin bones (cortices)
    v. Little trabeculae with fragility
    vi. Bowing
    vii. Platyspondyly
    viii. Retarded ossification of the cranial vault with multiple Wormian bones
    ix. Flattening of vertical axis
    x. Widening in the transverse axis of the skull
    xi. Small facial bones
    xii. Susceptible to osteoporosis and compression fractures of the vertebrae
    xiii. Pectus carinatum/excavatum

  b. OI type II
    i. Short-limbed dwarfism
    ii. Rhizomelic limb shortening
    iii. Severely retarded (virtual absence) calvarial mineralization
    iv. Generalized osteoporosis
    v. Multiple fractures with callus formation
    vi. Small chest
    vii. Beaded and broad ribs
    viii. Shortened crumpled long bones especially compressed ("telescoped" or "accordion-like") femurs and/or humeri
    ix. Externally rotated and abducted femurs
    x. Bowed lower legs
    xi. Angulated tibiae
    xii. Usually flexed and abducted hip (frog-leg position)
    xiii. Flattened acetabulae and iliac wings
    xiv. Platyspondyly
    xv. Type IIA: short and squared tubular bones, continuous beading of the ribs
    xvi. Type IIB/III: thicker tubular bones, compressed vertebrae, better ossification of the cranial bones, more normally appearing ribs and scapulae
    xvii. Type IIC: thin, deformed tubular bones, severely twisted long tubular bones

  c. OI type III
    i. Undermineralized calvarium with a large fontanel and Wormian bones
    ii. Initially normal or mildly shortening long bones
    iii. Fractures present at birth or during the first year of life with evidence of deformity
    iv. Thin gracile ribs prone to fracture
    v. Gracile long bones showing evidence of intrauterine fractures with callus formation
    vi. Marked angulation or bowing of long bones (especially tibias and femurs, reducing the efficiency of weight bearing and increasing the likelihood of fracture)
    vii. "Accordion-like" short and deformed femurs
    viii. Later metaphyseal and diaphyseal widening with "popcorn" calcification appearance of cystic metaphyses
    ix. Codfish appearance of vertebrae

x. Fractures with minimal trauma and progressive deformities
xi. Severe and generalized osteopenia

d. OI type IV
i. Bowed femurs in the newborn period but tend to straighten with time
ii. Osteopenia/osteoporosis
iii. Thin bones
iv. Fractures with deformities
v. Scoliosis

2. Bone density analysis
a. Still experimental
b. Dual energy X-ray absorptiometry (DEXA)
3. Bone histology
a. Thin cortices
b. Decreased trabecular bone volume
c. Smaller apatite crystals
d. Defective microvascular system
e. Defective collagen fibril diameter
4. Collagen synthesis analyses by cultured fibroblasts from skin biopsy. In OI type I, about half the normal amount of type I procollagen is synthesized.
5. Gene sequence analysis (Basel and Steiner 2009): Genomic DNA can be isolated from peripheral leukocytes in blood or from any other tissue samples.
a. Sequence analysis of *COL1A1* and *COL1A2* cDNA to detect mutations in the coding sequence and sequence analysis of *COL1A1* and *COL1A2* genomic DNA to detect mutations that alter either sequence or stability of mRNA identify between 80% and 85% of mutations in the type I collagen genes.
b. The mutations in most families are unique; only a few recurrent mutations (mostly CpG dinucleotides) are seen in more than one family.
c. Mutation detection rate varies by COLA1-related OI type; a comprehensive database of all 850 known mutations has been published along with a genotype-phenotype correlation.
d. For patients in whom no collagen type I mutation is identified, sequencing of *CRTAP* and *LEPRE1* is available commercially and is a reasonable next step in sequential sequencing to identify a mutation.
e. The importance of identifying these mutations is to establish a genetic risk for future offspring as the parents of an affected individual would be at a 25% risk of conceiving another child with the disorder, and it would be imperative for them to be counseled accurately, and adequately, of antenatal services available to them.

Genetic Counseling

1. Recurrence risk for OI I
a. Patient's sib: not increased unless a parent is affected or with gonadal mosaicism
b. Patient's offspring
i. Fifty percent affected if an affected parent marrying a normal spouse
ii. Twenty-five homozygously affected infant (likely to be perinatally lethal or severely affected) if both parents are affected with OI type I
2. Recurrence risk for OI II
a. Patient's sib: an empiric recurrence risk of 2–3% to 6–7% among siblings resulting from parental mosaicism for the mutation that is lethal in the infant who is heterozygous for the same mutation or due to the rare recessive form
b. Patient's offspring: none surviving beyond infancy
3. Recurrence risk for OI III (also called type IIB)
a. Patient's sib
i. Autosomal dominant form: not increased unless a parent is affected or with gonadal mosaicism
ii. Autosomal recessive form: 25%
iii. An empiric recurrence risk of 7–8% (germinal mosaicism, homozygosity of *COL1A2* mutations, and autosomal recessive inheritance)
b. Patient's offspring
i. Autosomal dominant form: 50%
ii. Autosomal recessive form: not increased unless a spouse is a carrier or affected
4. Recurrence risk for OI IV
a. Striking intrafamilial variability making clinical classification difficult for OI IV, OI III, or OI I
b. Patient's sib: not increased unless a parent carries gonadal mosaicism
c. Patient's offspring
i. Fifty percent when an affected parent marrying a normal spouse
ii. Rare possibility of having children with lethal OI phenotype by a parent with OI IV as a consequence of parental mosaicism for the lethal mutations

5. Prenatal diagnosis
   a. OI type I
      i. Identification of the mutant allele including segregation studies with an appropriate family structure (CVS at 11–12 weeks gestation)
      ii. Identification of the nonexpressed allele in mRNA from the fetus
      iii. Direct identification of the mutation (CVS at 11–12 weeks gestation)
      iv. Recognition of fracture or bowing of long bones by ultrasound
   b. Type II
      i. Diagnosis by prenatal ultrasonography accomplished between 14 and 18 weeks gestation (short femurs, fractures, small thoracic cage, minimal calvarial mineralization, or polyhydramnios)
      ii. Analysis of chorionic villi for the presence of abnormal collagens
      iii. Analysis of collagens synthesized by cells grown from chorionic villi
      iv. Direct mutation analysis in families of an identified DNA mutation in a previously affected infant
   c. Type III
      i. Diagnosis by prenatal ultrasonography not feasible until 20–22 weeks gestation
      ii. Direct mutation analysis of collagens synthesized by chorionic villus cells or DNA isolated directly from the tissue
   d. Type IV
      i. Linkage analysis with *COL1A2* polymorphisms in the dominant families
      ii. Direct mutation analysis
      iii. Analysis of proteins produced by cells grown from CVS biopsies
      iv. Little value of ultrasound analysis because of the late appearance of short or deformed bones
   e. *CRTAP*-related OI and *LEPRE1*-related OI: Prenatal diagnosis is available provided the mutations are previously identified in the family member.
6. Management
   a. Improving bone mass
      i. Use of bisphosphonates (cyclic intravenous pamidronate) to decrease the resorption of bone and to increase the formation of bone. Hopefully, early commencement of bisphosphonate treatment will prevent serious deformities.
      ii. Bisphosphonate therapy does not constitute a cure of OI, but is an adjunct to physiotherapy, rehabilitation, and orthopedic care. These drugs have brought clear improvement to the lives of patients suffering from moderate to severe OI. In contrast, children and adolescents with OI who have few fractures and no functional limitations have less to gain from treatment. It therefore appears advisable not to treat such patients unless clinical benefit can be demonstrated in placebo-controlled studies (Glorieux 2008).
      iii. Use of bone marrow transplantation as means of introducing normal mesenchymal stromal cells that have the capacity to differentiate into normal osteoblasts
   b. Fractures
      i. Meticulous orthopedic care
      ii. Corrective osteotomies
      iii. Intramedullary roddings to improve mobility, prevent fractures, and correct and prevent progressive deformity
      iv. Avoid unnecessary immobilization.
      v. Avoid malunions.
   c. Progressive scoliosis in adolescence requires spinal fusion with instrumentation.
   d. Orthotics
      i. To stabilize lax joints such as the ankle and subtalar joints
      ii. To prevent progressive deformities and fractures
      iii. Commonly used devices include ankle-foot, knee-ankle-foot, and forearm orthoses.
   e. Recognition and management of hearing loss
   f. Care of dentinogenesis imperfecta

Fig. 1 A boy with osteogenesis imperfecta type I showing blue sclera

Fig. 2 (**a**–**c**) Familial osteogenesis imperfecta type I in two sibs. Radiographs show fracture of a femur in the boy and that of humerus in the girl. Their father is also affected. Molecular testing revealed c.578^579insC of COL1A1 gene mutation in this family

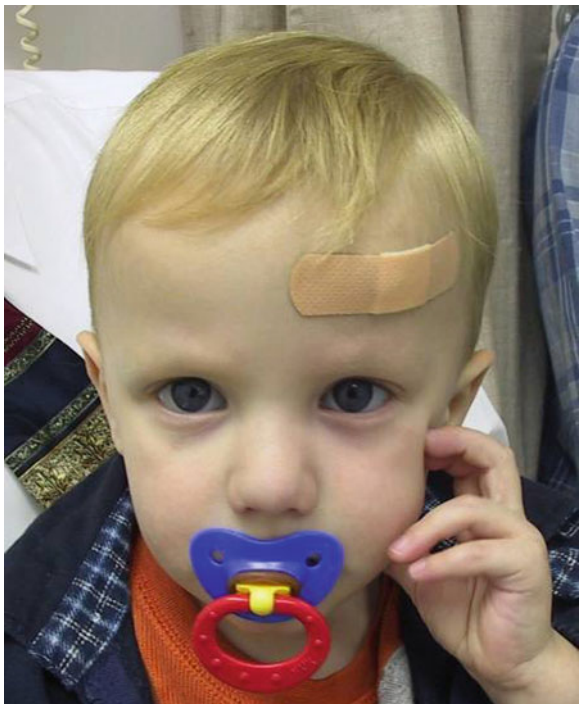

Fig. 3 A 22-month-old boy with osteogenesis imperfecta type I showing blue sclera. He has heterozygous mutation Arg75Stop of the COL1A1 gene by molecular genetic analysis

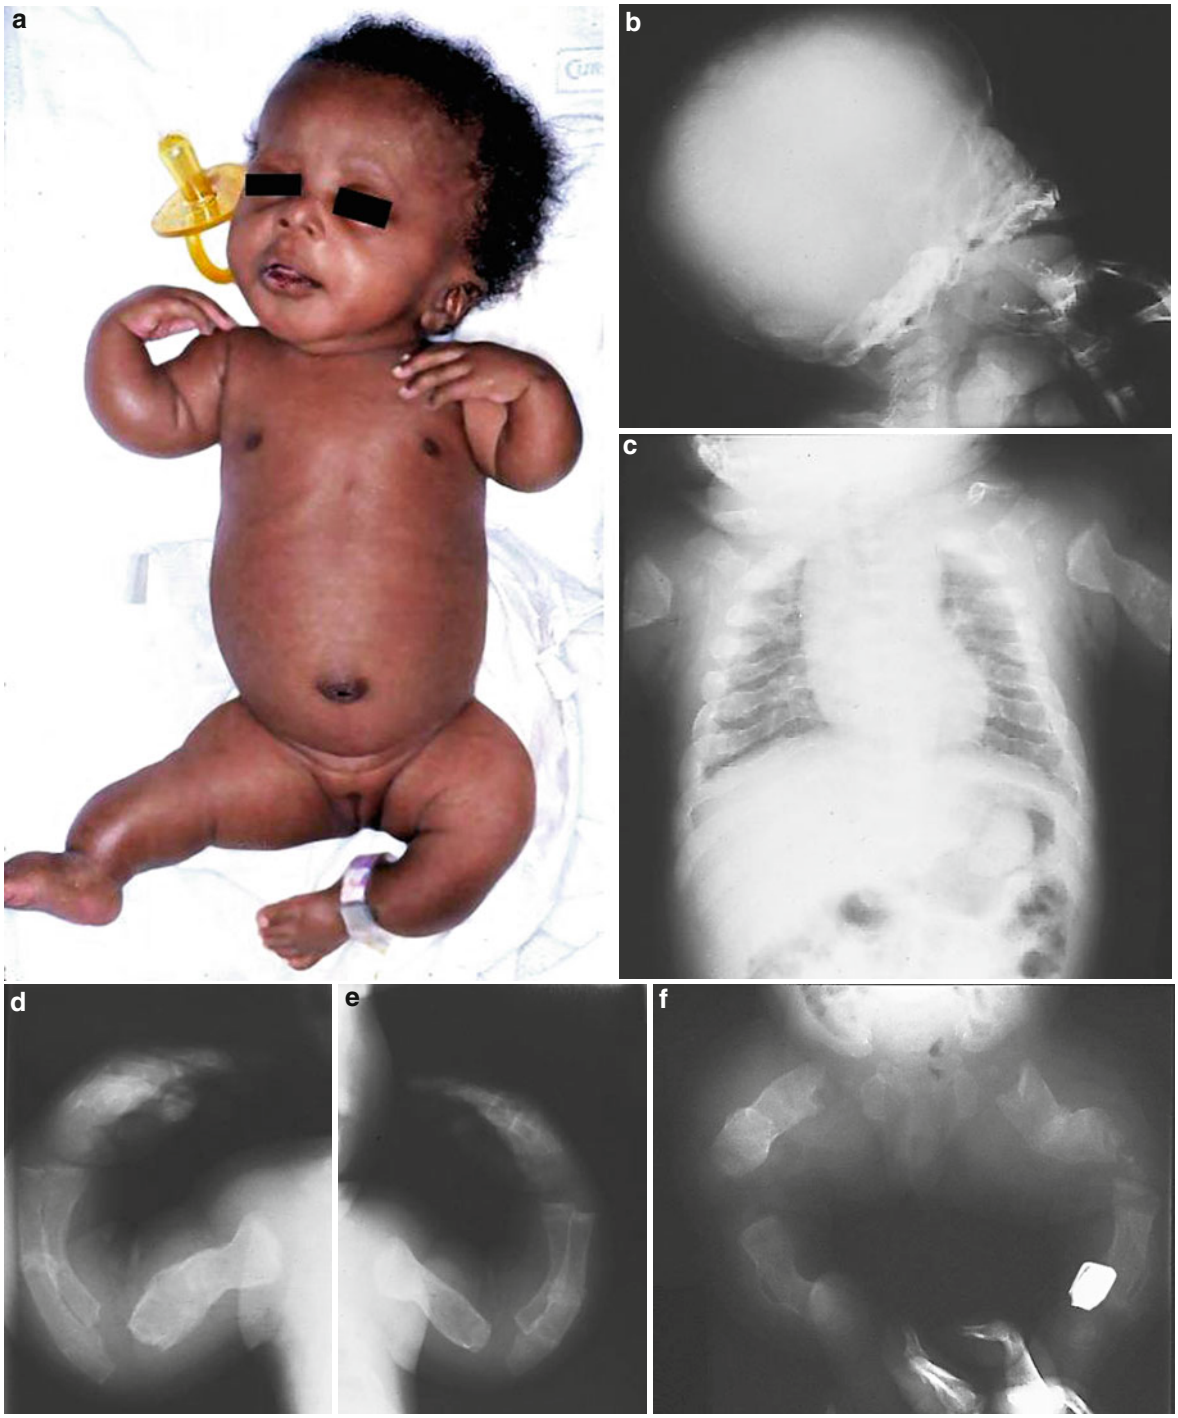

Fig. 4 (**a**–**f**) An infant with osteogenesis imperfecta type II showing severe dwarfism, characteristic craniofacial features, short and deformed limbs, and bowed legs. Radiographs showed short-limb dwarfism, rhizomelic limb shortening, severely retarded calvarial mineralization, multiple fractures with callus formation, beaded and broad ribs, and "telescoped" femurs and humeri

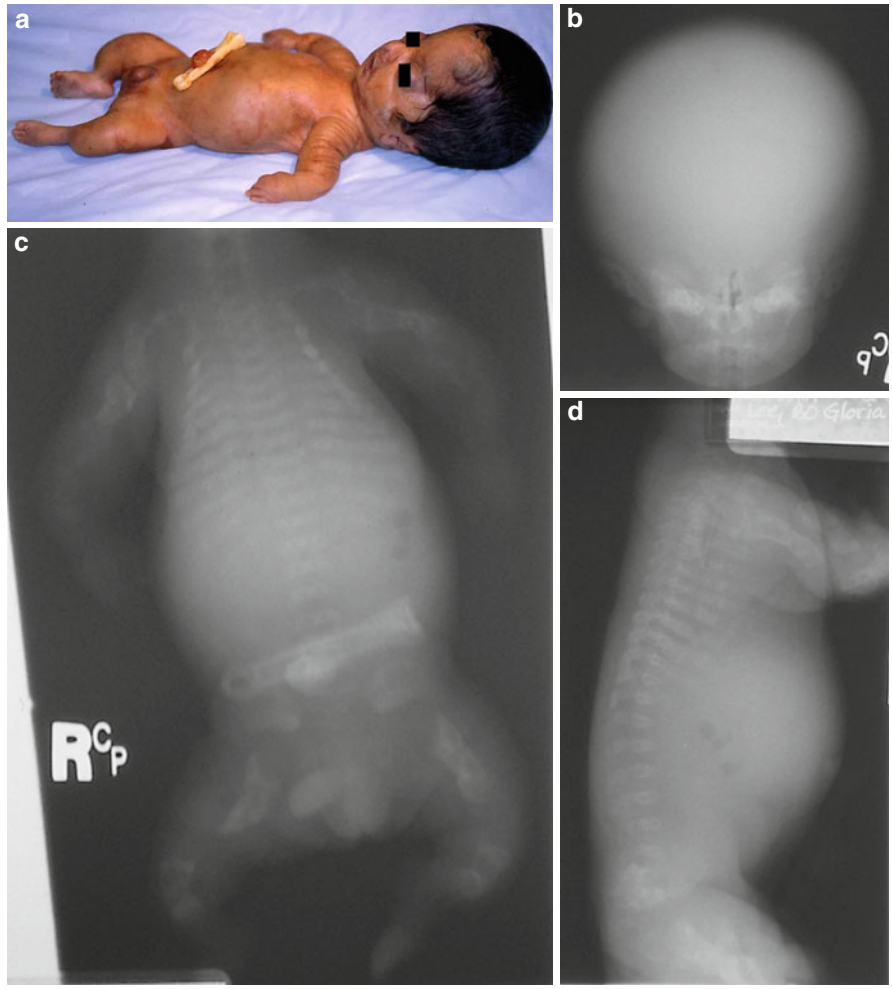

Fig. 5 (**a**–**d**) Another case of osteogenesis imperfecta type II showing the similar features

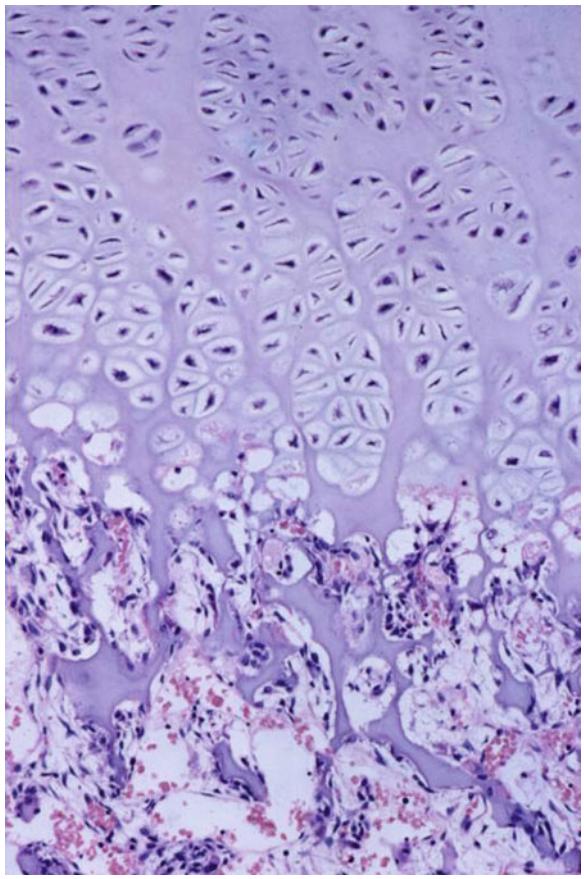

Fig. 6 Photomicrograph of rib of another case with type II osteogenesis imperfecta. The columns of cartilage in the metaphysis are covered by minimal amounts of basophilic primitive woven bone. Normal ossification is absent The physeal growth zone is moderately disorganized

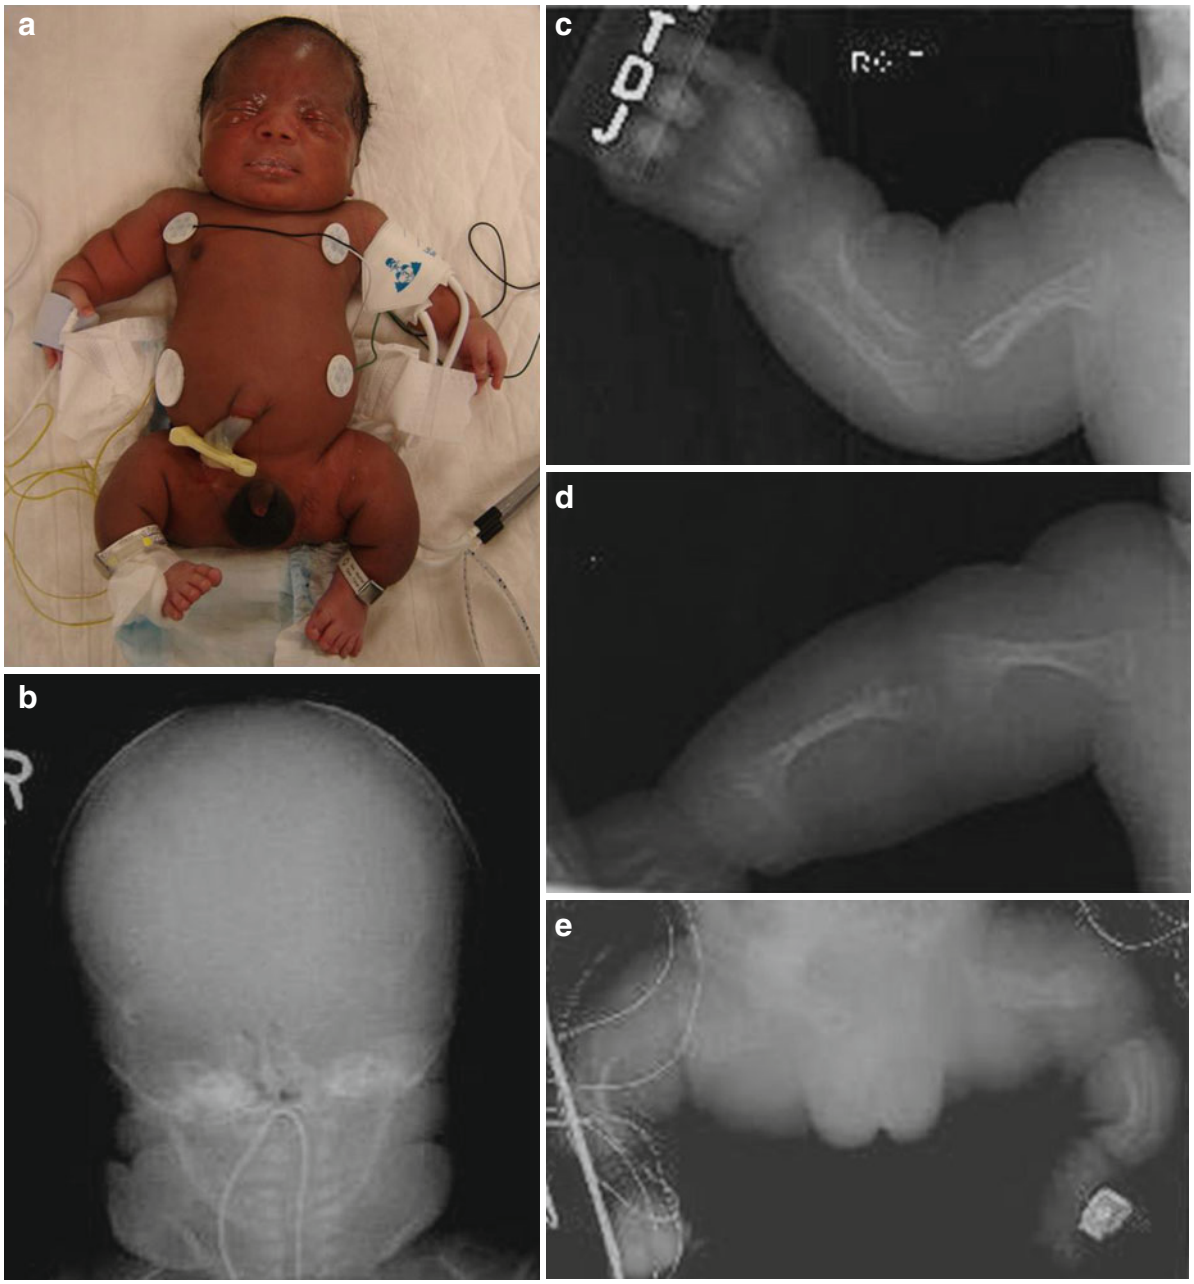

Fig. 7 (**a**–**e**) A neonate with osteogenesis type III showing short-limbed dwarfism, large head, short neck, short thigh, and curbed lower legs. Radiographs showed generalized osteopenia; poor mineralization of the skull; thin ribs with sixth, seventh, and eighth rib fractures with callus formation; short limbs; and bowed femurs with multiple fractures with callus formation. Molecular study showed heterozygous mutation of COL1A2 gene (del of three base pairs [GTT] at cDNA position c.763–765). This mutation has been reported in patients with osteogenesis imperfecta type III

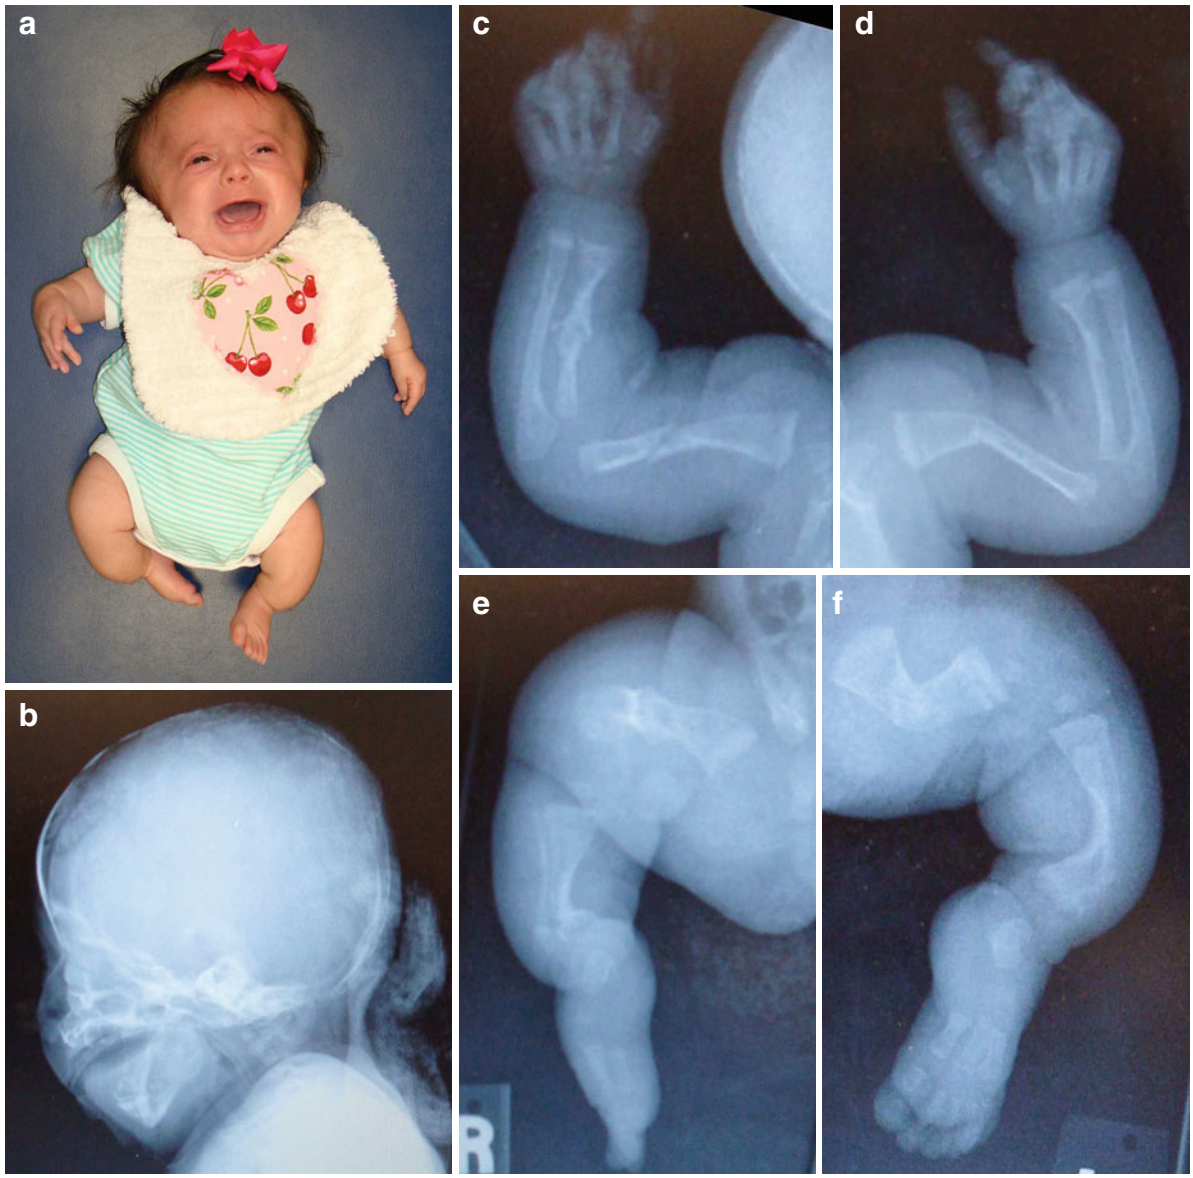

Fig. 8 (**a**–**f**) A neonate with osteogenesis type III showing short-limbed dwarfism, large head, short neck, and short and curbed upper and lower extremities. Radiographs showed generalized osteopenia, poor mineralization of the skull, and short and bowed limbs with multiple fractures with callus formation. Molecular study by sequence analysis indicated a variation in the fragment containing exon 21 and the flanking sequences of the *COL1A2* gene. Sequencing revealed a nucleotide G to A substitution that converted a codon for Glycine-289 (GGA) to a codon for glutamic acid (GAA) at cDNA position c.866. The patient thus showed a heterozygous mutation of *COL1A2* gene (Gly289Glu). This mutation has not been reported previously

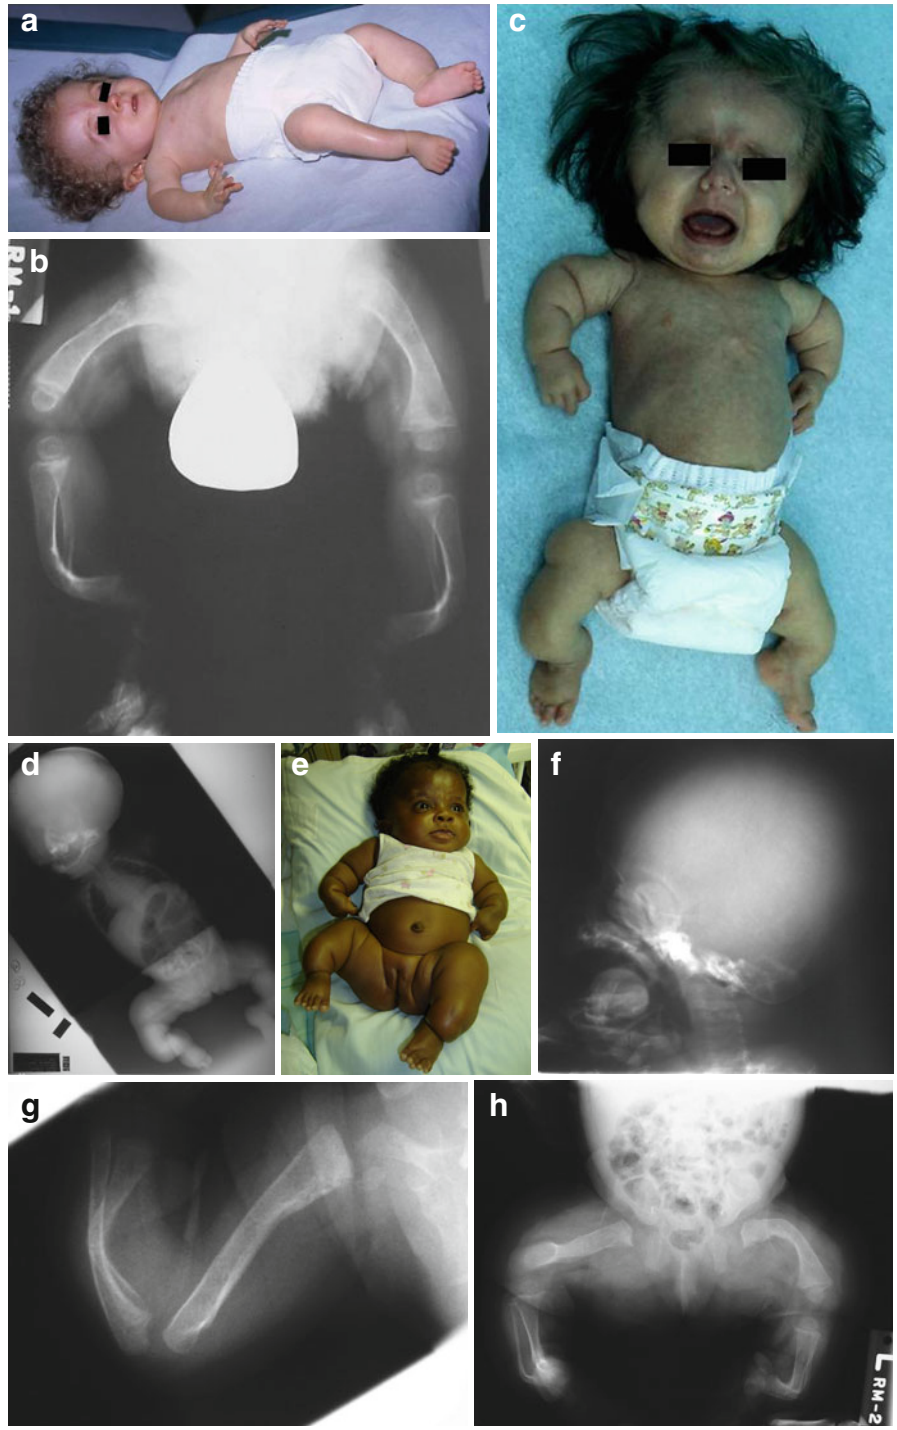

Fig. 9 (**a**–**h**) Three other infants with osteogenesis imperfecta type III showing dwarfism, moderate deformities resulting from in utero fractures, and typical triangular face with relatively large cranium. Radiographs showed undermineralized calvarium with a large fontanel and marked angulation or bowing of long bones, especially tibias and femurs

Fig. 10 An infant girl with osteogenesis imperfecta type IV

Fig. 11 (**a**–**d**) A girl with Cole-Carpenter syndrome showing ocular proptosis, craniosynostosis, and bone fragility with fractures

Osteopetrosis

Osteopetrosis is a heterogeneous group of sclerosing bone diseases due to impaired bone and cartilage resorption, resulting from absence or defective function of osteoclasts (Steward 2003). The overall incidence of these conditions is difficult to estimate, but autosomal recessive osteopetrosis has an incidence of 1 in 250,000 births, and autosomal dominant osteopetrosis has an incidence of 1 in 20,000 births (Stark and Savarirayan 2009).

Synonyms and Related Disorders

Albers-Schonberg disease; Infantile malignant osteopetrosis; Ostoclast-poor osteopetrosis

Genetics/Basic Defects

1. Inheritance of recognized subtypes of human osteopetrosis (Stark and Savarirayan 2009; Steward 2003, 2010)
   a. Autosomal recessive osteopetrosis
      i. Classic (infantile malignant osteopetrosis): Vacuolar proton pump deficiency (*ATP6i/TCIRG1*) (locus 11q13.3-q13.5)
      ii. Neuropathic (osteopetrosis and infantile neuroaxonal dystrophy): CLC-7 chloride pump deficiency (loss of function *CLCN7* mutations) (locus 16p13.3) and *OSTM1* mutations (cause an extremely severe form of autosomal recessive osteopetrosis with frequent CNS involvement (Pangrazio et al. 2006)
      iii. Autosomal recessive osteopetrosis with renal tubular acidosis (Jacquemin et al. 1998)
         a) Caused by mutations in *CA2*, the gene encoding carbonic anhydrase II
         b) Generalized osteosclerosis
         c) Cerebral calcifications
         d) Associated with intellectual disability
      iv. Autosomal recessive osteopetrosis secondary to *PLEKHM1* mutations: mild phenotype and can regress with increasing age (van Wesenbeeck et al. 2007)
   b. More benign osteopetrosis primarily affecting adults: two subtypes based on radiographic features
      i. Autosomal dominant osteopetrosis type I (locus 11q12-13)
      ii. Autosomal dominant osteopetrosis type II (Albers-Schőnberg disease): dominant negative *CLCN7* mutations (Most patients have this type.)
   c. Intermediate forms: Children presenting beyond 2 years of age often have a slower progressive disease.
      i. An autosomal recessive disease with milder mutations: carbonic anhydrase isoenzyme type II deficiency (CAII) and *CLCN7* mutations
      ii. Early diagnoses of the more severe end of the autosomal dominant spectrum
   d. RANKL deficiency (Askmyr et al. 2008)
      i. Recently discovered in a screen of 40 patients with recessive osteopetrosis with unknown genetic defects (Sobacchi et al. 2007)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_186,
© Springer Science+Business Media, LLC 2012

ii. Characterized by a decrease in osteoclast numbers
iii. Less severe with a slower progression than the classical malignant forms of osteopetrosis
iv. The gene that is mutated encodes RANKL, one of the osteoclast-promoting cytokines produced by stromal cells in the bone marrow.

e. Osteopetrosis associated with ectodermal dysplasia, lymphedema, and immunodeficiency
i. X-linked (Smahi et al. 2002)
ii. Resulting from a hypomorphic mutation in IKBKG [also known as NEMO (NF-kB essential modulator)]
iii. Most hypomorphic mutations do not cause osteopetrosis but mild ectodermal dysplasia and immunodeficiency in males.

f. Osteopetrosis with agenesis of corpus callosum: autosomal recessive

g. Dysosteosclerosis
i. Autosomal recessive
ii. X-linked also reported

2. Basic defects: Absence or defective function of osteoclasts results in defective remodeling of bone with partial or complete obliteration of marrow cavities, producing bone which is dense but has an increased tendency to fracture.

3. Potential clinical consequences of aberrant resorption and remodeling of bones caused by defective osteoclast function (Steward 2010)

a. Fractures
i. Undertubulated bones break easily.
ii. Common fracture sites (Cheow et al. 2001)
a) Long bones of the arms and leg
b) Posterior ribs
c) Acromial processes

b. CNS and eye involvements (Abinun et al. 1999; Steward 2003)
i. Bony overgrowth, or lack of remodeling, results in compression of nerves or blood vessels that pass through bones, especially the optic nerve (resulting in partial or complete visual loss) and, more rarely, the auditory and facial nerves.
ii. Arteries or venous sinuses within the skull can also be constricted, as can the foramen magnum.
iii. Early fusion of bones may result in craniosynostosis.
iv. Some patients have primary neurometabolic (neuronopathic) forms of osteopetrosis and may have abnormal retinal pigmentation and cerebral atrophy.

c. Cytopenia/pancytopenia (Steward et al. 2005)
i. Bony encroachment on medullary cavities results in extramedullary hemopoiesis with hepatosplenomegaly and the potential for hypersplenism.
ii. Anemia and thrombocytopenia result and blood films often show a markedly leukoerythroblastic picture, with a high white blood cell count and high numbers of circulating stem cells.

d. Growth: Most children with osteopetrosis fall below the tenth percentile on growth charts, and some have severe dwarfism (Gerritsen et al. 1994; Driessen et al. 2003).

e. Hypocalcemia: Defective osteoclast function can disturb calcium homeostasis, which may manifest as symptomatic hypocalcemia in the first few months of life, despite high total body calcium reserves (Gerritsen et al. 1994; Srinivasan et al. 2000).

f. Respiratory compromise (Wong et al. 1978)
i. The skull base, choanal bones, and jaw are often severely affected, which produces persistent snuffling, noisy breathing, and upper airway obstruction, and may predispose patients to pulmonary arterial hypertension.
ii. Patients often suffer increased ear, nose, and throat infections and respiratory infections.

g. Dentition (Luzzi et al. 2006)
i. Tooth eruption often delayed
ii. Poor tooth quality
iii. Osteomyelitis of the jaw can occur.

h. Other organ system involvement: The genes involved may have roles in other organs. For example, a small proportion of children have a severe neurometabolic disease and abnormalities of lymphocytes and immunoglobulin production are now recognized in some variants (Villa et al. 2009; Mazzolari et al. 2009).

Clinical Features

1. Malignant infantile osteopetrosis (Steward 2003)
   a. Usually diagnosed during the first year of life
   b. Signs and symptoms
      i. Presenting signs
         a) Blindness
         b) Failure to thrive
         c) Seizures due to hypocalcemia
         d) Infections
         e) Pathologic fractures
      ii. Neurovascular involvement: The most serious consequences of the osteopetrosis are cranial nerves, blood vessels, and the spinal cord compression by either gradual occlusion or lack of growth of skull foramina.
      iii. Visual impairment
         a) Optic atrophy: Some degrees of optic atrophy are present in most patients. Blindness is observed in many children with severe forms of autosomal recessive osteopetrosis.
         b) Nystagmus
         c) Strabismus
         d) Proptosis
         e) Limited extraocular movement
      iv. Compression of facial and trigeminal nerves
         a) Produce paralysis, spasm, or neuralgia
         b) Involvement of the trigeminal nerve tends to occur in type I autosomal dominant osteopetrosis.
         c) Involvement of the facial nerve predominant in type II disease
      v. Hearing loss
         a) Poor drainage of the middle ear
         b) Narrowing of the internal acoustic meatus
         c) Osteosclerosis
      vi. Blood vessel compression
         a) Stenosis of arterial supply (internal carotid artery, vertebral artery)
         b) Stenosis of venous supply
      vii. Craniofacial features
         a) Macrocephaly
         b) Frontal bossing
         c) Hypertelorism
         d) Exophthalmos
         e) Flat nasal bridge
         f) Chronic rhinitis
         g) Jaw: a frequent site of osteomyelitis
         h) Obligate mouth breathing in most children secondary to obstruction of the upper airway
      viii. Compromised nutritional state due to difficulty in eating and breathing resulting from limited posterior nasophrynx from bony overgrowth
      ix. Psychomotor retardation
         a) Secondary to hydrocephalus
         b) Secondary to apnea due to upper airway obstruction
         c) Common in carbonic anhydrase isoenzyme type II deficiency
      x. Bone marrow failure
         a) Results from bone marrow encroachment
         b) Leads to extramedullary hematopoiesis and hepatosplenomegaly (abdominal protuberance)
         c) Frequently progresses to hypersplenism and pancytopenia
         d) Signs secondary to thrombocytopenia (petechiae, ecchymoses, epistaxis, melena, gingival bleeding, intracerebral hemorrhages)
         e) Carries a high mortality
2. Autosomal dominant osteopetrosis type I
   a. Chronic bone pain
   b. Cranial nerve palsies
   c. Hearing loss
   d. Not associated with increased fracture rate
3. Autosomal dominant osteopetrosis type II (Albers-Schőnberg disease)
   a. Originally described by Albers-Schőnberg in 1904
   b. The most common form of osteopetrosis
   c. The prevalence: 5.5 in 100,000
   d. The term "benign osteopetrosis": a misnomer for autosomal dominant osteopetrosis type II because of the possibility of severe clinical complications
   e. Most prominent symptoms
      i. Bone pain

   ii. Multiple fractures: frequent (78%), perhaps due to the reduced elasticity of the brittle bone
   iii. Mandibular osteomyelitis
  f. Other signs
   i. Hip osteoarthritis
   ii. Thoracic or lumbar scoliosis
   iii. Hearing loss
   iv. Visual loss
   v. Optic atrophy
   vi. Facial palsy
   vii. Multiple dental abscesses
4. "Intermediate" form of osteopetrosis
  a. Usually diagnosed during the first decade and survive into adulthood
  b. Short stature
  c. Frontal bossing
  d. Mild hepatosplenomegaly
5. Carbonic anhydrase isoenzyme type II deficiency
  a. Most cases have been reported from Middle East or the Mediterranean region.
  b. Osteopetrosis with renal tubular acidosis (usually distal type)
  c. Short stature
  d. Fractures
  e. Psychomotor retardation
  f. Cranial nerve compression (>50%)
  g. Optic atrophy and visual loss
  h. Cerebral calcifications
  i. Minor hematological impairment
  j. Craniofacial features
   i. Micrognathia
   ii. Narrow prominent nose
   iii. Poorly developed philtrum
  k. Abnormal dentition
   i. Peg-shaped carious teeth with malocclusion
   ii. Delayed eruption of the teeth
   iii. Retained primary dentition
  l. Visual failure
  m. Episodic hypokalemic paralysis in some patients
6. Vacuolar proton pump deficiency
  a. Visual failure
  b. Symptomatic hypocalcemia in the first month (50%)
   i. Early or late neonatal convulsions
   ii. Irritability
   iii. Jittering episodes
  c. Fractures
  d. Mild to severe hematological impairment
  e. Hepatosplenomegaly
  f. Failure to thrive
  g. Poor growth
  h. Reduced life span
7. ClC-7 chloride pump deficiency: severe osteopetrosis
8. Neuronopathic osteopetrosis
  a. Causing rapid neurodegeneration and death within the first year
  b. Widespread axonal spheroids and accumulation of ceroid lipofuscin
  c. Often accompanied by severe hematological impairment
  d. Gross hepatosplenomegaly
  e. Severe anemia/thrombocytopenia
  f. High arched palate
  g. Gum hypertrophy
  h. Hyperreflexia
  i. Clonus
  j. Opisthotonos
  k. Fisting
  l. Poor head control
  m. Irritability
  n. Early death
9. Autosomal recessive osteopetrosis with renal tubular acidosis (Whyte 1993)
  a. A milder course
  b. Renal tubular acidosis
  c. Cerebral calcifications
  d. Fractures
  e. Short stature
  f. Dental abnormalities
  g. Cranial nerve compression
  h. Developmental delay
10. X-linked osteopetrosis, lymphedema, anhidrotic ectodermal dysplasia, and immunodeficiency (OLEDAID)
  a. Common variable immune deficiency in association with a particular subtype of osteoclast-poor autosomal recessive osteopetrosis (Guerrini et al. 2008)
  b. Leukocyte adhesion deficiency syndrome (Kilic and Etzioni 2008; Mory et al. 2008)
11. Osteopetrosis with agenesis of corpus callosum: possible variant to neuronopathic osteopetrosis
12. Dysosteosclerosis
  a. Bone fractures
  b. Developmental delay with occasional mental retardation

c. Cranial nerve impingement
   i. Visual loss (optic atrophy)
   ii. Hearing loss
   iii. Facial nerve paralysis
d. Osteomyelitis of the mandible
e. Macular atrophy of the skin
f. Flattened fingernails

13. Differential diagnosis (Manusov et al. 1993)
a. Hyperostosis corticalis generalisata (van Buchem syndrome)
   i. Diffuse/widespread sclerosis of the cortex, usually sparing spine
   ii. Hyperphosphatasemia
b. Oculo-dento-osseous dysplasia
   i. An autosomal dominant disorder
   ii. Enlarged mandible
   iii. Focal osteosclerosis in the pelvis
   iv. Other findings
      a) Microphthalmia
      b) Large jaw
      c) Hypoplasia of tooth enamel
c. Osteitis deformans (Paget disease)
   i. Localized osteosclerosis in one or a few regions of the skeleton
   ii. Local pain
   iii. Bone marrow biopsy finding
d. Progressive diaphyseal dysplasia (Camurati-Engelmann disease)
   i. An autosomal dominant disorder with variable expression
   ii. Caused by domain-specific mutations of the TGFB gene located on chromosome 19q13 encoding transforming growth factor β-1
   iii. Major clinical features
      a) Leg pain
      b) Muscular weakness
      c) Waddling gait
      d) Failure to thrive
   iv. Major radiographic features
      a) Fusiform sclerosis of cortical surfaces and subendosteum
      b) Sclerosis of the skull base
e. Pyknodysostosis
   i. An autosomal recessive disorder
   ii. Generalized osteosclerosis
   iii. Open fontanel
   iv. Associated with mental retardation and dwarfism
f. Heavy metals (lead, bismuth)
   i. Presence of radiodense lines (Harris lines)
   ii. Elevated levels of heavy metals
g. Mastocytosis
   i. Poorly demarcated sclerosis in the pelvis, ribs, vertebrae, skull, and proximal long bones
   ii. Not uniformly symmetric
   iii. Elevated histamine level
h. Renal osteodystrophy
   i. Widespread sclerosis of the skeleton
   ii. Increased density less clear
   iii. Elevated serum parathyroid hormone
   iv. Elevated renal function test
i. Metastatic carcinomas (breast, prostate, lung, kidney, and thyroid)
   i. Dispersed in random fashion
   ii. Bone marrow biopsy often diagnostic
j. Osteosclerosis or myelofibrosis
   i. Diffuse increased bone density with a smooth and even density
   ii. Bone marrow biopsy finding

Diagnostic Investigations

1. Laboratory work-up for infantile malignant osteopetrosis (Lam et al. 2007)
a. Anemia
b. Leukopenia
c. Thrombocytopenia
d. Reticulocytosis
e. Pancytopenia
f. Hypocalcemia
g. Inconsistent hypophosphatemia
h. Defective superoxide generation in peripheral leukocytes
i. Secondary hyperparathyroidism with elevated serum calcitriol: common (Key et al. 1984; Cournot et al. 1992)
j. Increased serum acylphosphatase (ACP)
k. Presence of the brain isoenzyme of creatine kinase (BB-CK) in the serum is a biochemical marker for osteopetrosis
l. ACP and BB-CK originate from osteoclasts (Whyte et al. 1996)

2. Radiographic features
a. Pathognomonic radiographic findings of osteopetrosis (Landa et al. 2007)
   i. Generalized sclerosis

ii. Endobone (bone within bone) formation
iii. Vertebral end plate thickening

b. Malignant infantile osteopetrosis
i. Increased density of the entire skeleton
ii. Complete absence of the medullary canal in severe cases
iii. Lack of remodeling gives rise to metaphyseal widening or a "club-shaped" appearance of the long bones
iv. "Bone within a bone" phenomena or "endobones" seen especially in the pelvis, vertebrae, hands, and feet
v. Transverse radiolucent bands within the metaphyseal regions of the long bones: attributed to periodic variations in the ability to resorb bone
vi. Longitudinal striations in the long bones: attributed to periosteal elevation by trauma or microfractures
vii. Increasingly thickened skull with a "hair-on-end" appearance
viii. Common occurrence of fractures
a) Especially epiphyseal separations and femur fractures
b) Diaphyseal and metaphyseal fractures: usually transverse or short oblique pattern

c. Various subtypes of osteopetrosis
i. Vacuolar proton pump deficiency
a) Generalized increased bone density
b) Bone-within-bone appearance due to periosteal new bone formation
c) Modeling deformities
d) Pseudorickets (widened and irregular metaphyses)
e) Metaphyseal lucencies in some children
f) Fractures: common particularly affecting acromial processes, long bones, posterior ribs, and pubic bones
ii. Carbonic anhydrase isoenzyme type II deficiency
a) Thick sclerotic skull base
b) Generalized osteopetrosis
c) Faulty modeling of metaphyses
d) Transverse striations in metaphyses
e) Arcuate striations in iliac bones
f) Bone-within-bone appearance
g) Sandwich vertebrae
h) Intracranial calcifications
iii. Neuronopathic osteopetrosis
a) Typical findings of severe malignant infantile osteopetrosis
b) Mild to severe cerebral atrophy
iv. Osteopetrosis with agenesis of the corpus callosum
a) As with neuronopathic osteopetrosis
b) Absence of the corpus callosum
v. Dysosteosclerosis
a) Thickening and sclerosis of cranial vault, base of skull, ribs, and clavicle
b) Sclerotic long bones with splayed submetaphyseal clear zones
c) Platyspondyly
d) Retarded white matter myelination
e) Intracerebral calcifications

d. Autosomal dominant osteopetrosis type I
i. Generalized/diffuse osteosclerosis affects especially the cranial vault
ii. Sclerotic skull base
iii. Vertebral bodies comparatively normal but the vertebral arches appearing dense

e. Autosomal dominant osteopetrosis type II (Albers-Schőnberg disease)
i. A spectacular radiological appearance with the segmental distribution of dense bone
ii. Characterized by diffuse osteosclerosis, predominantly involving spine, pelvis, and skull base
a) Thickened vertebral end plates ("sandwich vertebrae," Rugger-Jersey spine)
b) Classic "bone-within-bone" appearance/endobone structures (especially in pelvis)
c) Thickened (dense) skull base
iii. Common sclerotic bands in the metaphyses
iv. Fractures
a) Common (78%)
b) Heal slowly
v. Mandibular osteomyelitis
vi. Hip osteoarthritis (27%)
vii. Thoracic or lumbar scoliosis (24%)
viii. Cranial nerve encroachment leading to hearing loss, bilateral optic atrophy, and/or facial palsy (16%)

3. Major pathologic features
   a. General features for malignant infantile osteopetrosis
      i. Obliteration of the marrow spaces by unresorbed primary trabecular bone and calcified cartilage
      ii. The cartilage cores not remodeled despite an increased number of osteoclasts
      iii. Absent or diminished ruffled border of the osteoclast by electron microscopy
   b. Vacuolar proton pump deficiency: increased osteoclasts
   c. ClC-7 chloride pump deficiency: normal numbers of osteoclasts (in mice)
   d. Neuronopathic osteopetrosis
      i. Autofluorescent neuronal ceroid lipofuscin
      ii. Widespread eosinophilic neuroaxonal spheroids
   e. Autosomal dominant osteopetrosis type I: normal appearance of trabecular bone remodeling
   f. Autosomal dominant osteopetrosis type II (Albers-Schőnberg disease)
      i. Defective trabecular bone remodeling.
      ii. Increased number of osteoclasts.
      iii. Frequent delayed healing of fractures.
      iv. Increased total acid phosphatase probably reflects the increased number of osteoclasts that are unable to resorb bone.
      v. Observation of large multinucleated osteoclasts suggests a defect in osteoclast function rather than differentiation, as in infantile osteopetrosis.
   g. Intermediate form
      i. Mild to marked increased bone density of the axial skeleton and long bones
      ii. Defects of modeling seen especially at the distal femurs which may have "Erlenmeyer flask" deformity
      iii. Frequent coxa vara and pathologic long bone fractures
      iv. Problematic dental malocclusion and caries

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive disorder: 25%
      ii. Autosomal dominant disorder: low unless one of the parent is affected or has gonadal mosaicism
      iii. X-Linked recessive
         a) Carrier mother: 50% of male sibs affected; 50% of female sibs carriers
         b) Noncarrier mother: still with a small risk of having further affected offspring due to gonadal mosaicism
   b. Patient's offspring
      i. Autosomal recessive disorder: low unless the spouse is a carrier
      ii. Autosomal dominant disorder: 50%
      iii. X-linked recessive
         a) No sons will inherit the mutant allele and therefore will not be affected with osteopetrosis.
         b) All daughters will be carriers for osteopetrosis.
2. Prenatal diagnosis
   a. Prenatal radiography (Oğur et al. 1995; Stark and Savarirayan 2009): possible for families with severe autosomal recessive osteopetrosis and unknown mutations (66)
      i. Made at the 25th week of pregnancy at risk for autosomal recessive osteopetrosis
      ii. Fetal radiographic findings
         a) Marked sclerosis of osteopetrotic bone
         b) Metaphyseal splaying and clubbing of both femurs
   b. Prenatal diagnosis available for pregnancies with a 25% risk for fetuses affected with malignant osteopetrosis by amniocentesis or CVS
      i. Using linked microsatellite markers in the region of chromosome 11q12-13
      ii. DNA mutation analysis of fetal DNA for the pregnancy at risk for malignant autosomal recessive osteopetrosis by amniocentesis or CVS when the mutation is previously characterized in the family
   c. Preimplantation diagnosis is theoretically possible in families, in whom the genetic mutation has been identified.
   d. If a family decides to continue with an affected pregnancy, hematopoietic stem cell transplantation before the age of 3 months can be planned with the aim of improving neurological outcomes (Stark and Savarirayan 2009).

3. Management (Wilson and Vellodi 2000)
   a. Supportive care
   b. Blood transfusion for anemia secondary to a failure of bone marrow development
   c. Risk of recurrent infections viewed as an indication for bone marrow transplantation
   d. Optical nerve decompression successful only in mildly affected older children
   e. Early insertion of ventilatory "grommet" tube for hearing impairment secondary to a combination of bony compression of the nerve, sclerosis of the middle ear ossicles, and/or chronic middle ear effusion
   f. Nasal gastric feeding for children with chronic anemia and feeding problems caused by bulbar nerve involvement, nasal congestion, and recurrent infections
   g. A high risk of anesthetic morbidity and mortality in patients with malignant osteopetrosis primarily related to airway and respiratory factors
   h. Manage osteomyelitis
      i. Pus drainage
      ii. Appropriate antibiotic therapy
      iii. Surgical debridement
      iv. Reconstruction if indicated
   i. Orthopedic cares: complicated by the difficulty of working with extremely hard, brittle, marble bone (Landa et al. 2007)
      i. Fracture fixation
         a) Difficulty inserting pins and screws
         b) Failure of load-bearing plate devices
         c) Increased time to union
      ii. Arthroplasty
         a) Iatrogenic fracture during implant placement
         b) Increased risk of osteomyelitis
         c) Obliteration of medullary canal by cortical bone
      iii. General considerations
         a) Overheating and breakage of drill bits
         b) Longer surgical time
   j. Corticosteroids and calcitriol (1,25-hydroxyvitamin D) with some short-term initial benefit but with debatable long-term benefit
   k. Recombinant human gamma interferon (Eapen et al. 1998)
      i. Enhances bone resorption and leukocyte function
      ii. Effects on morbidity and survival remain unclear.
   l. Bone marrow or peripheral blood stem cell transplantation
      i. Rational: Osteoclasts are derived from hematopoietic stem cells.
      ii. Long-term disease-free survival has been achieved in approximately 70% of infants receiving transplants from matched sibling donors (Cheow et al. 2001).
         a) Repopulating the bones with functioning osteoclasts by successful infusion of donor marrow
         b) Beginning the process of remodeling and restoration of normal calcium homeostasis
         c) Radiographic changes of osteopetrosis expected to gradually returning to normal 4 months to 2 years following bone marrow transfusion
         d) Improvement and resolution of the rachitic changes: the first observation after bone marrow transplantation
         e) Immune recovery
         f) Improved growth
   m. Improving results with the use of high-dose peripheral blood stem cell grafts for infantile osteopetrosis from alternative donors, including those from parents mismatched for up to one half of their HLA-type (haploidentical)
   n. Hematopoietic stem cell transplantation in patients with osteopetrosis: associated with disease-specific problems that require careful management, including the potential for life-threatening posttransplant hypercalcemia, a high prevalence of pulmonary arterial hypertension and, in at least one subtype of disease, failure to reverse osteosclerosis despite successful donor cell engraftment (Steward 2010)

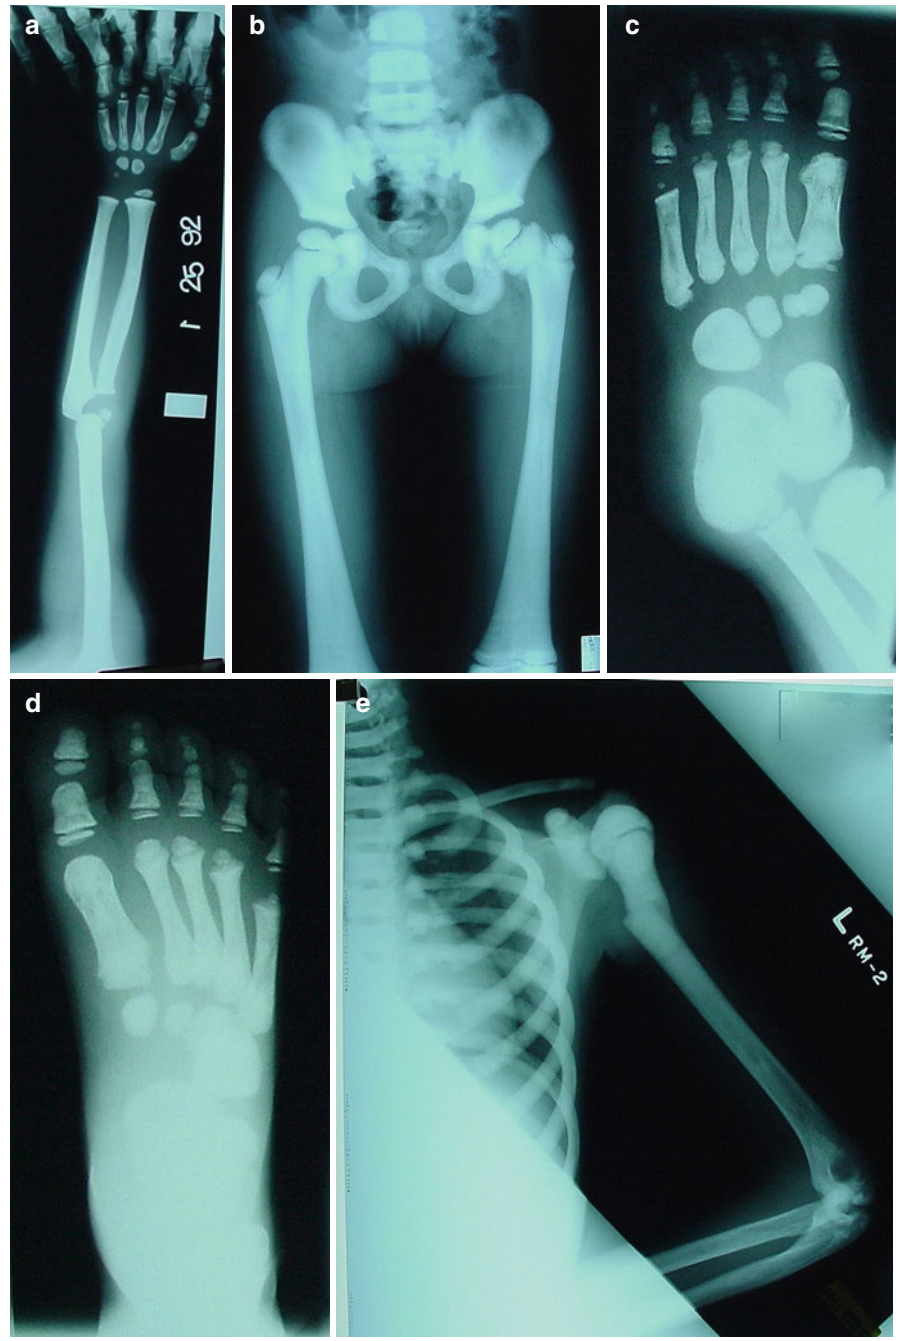

Fig. 1 (**a**–**e**) Radiographs of a girl with Albers-Schőnberg syndrome at 3 years (arm, pelvis, and foot) and at 10 years (arm and chest) showing sclerotic bones with loss of corticomedullary differentiation, fracture at the left humerus, and endobone appearance of phalanges of the hands and feet

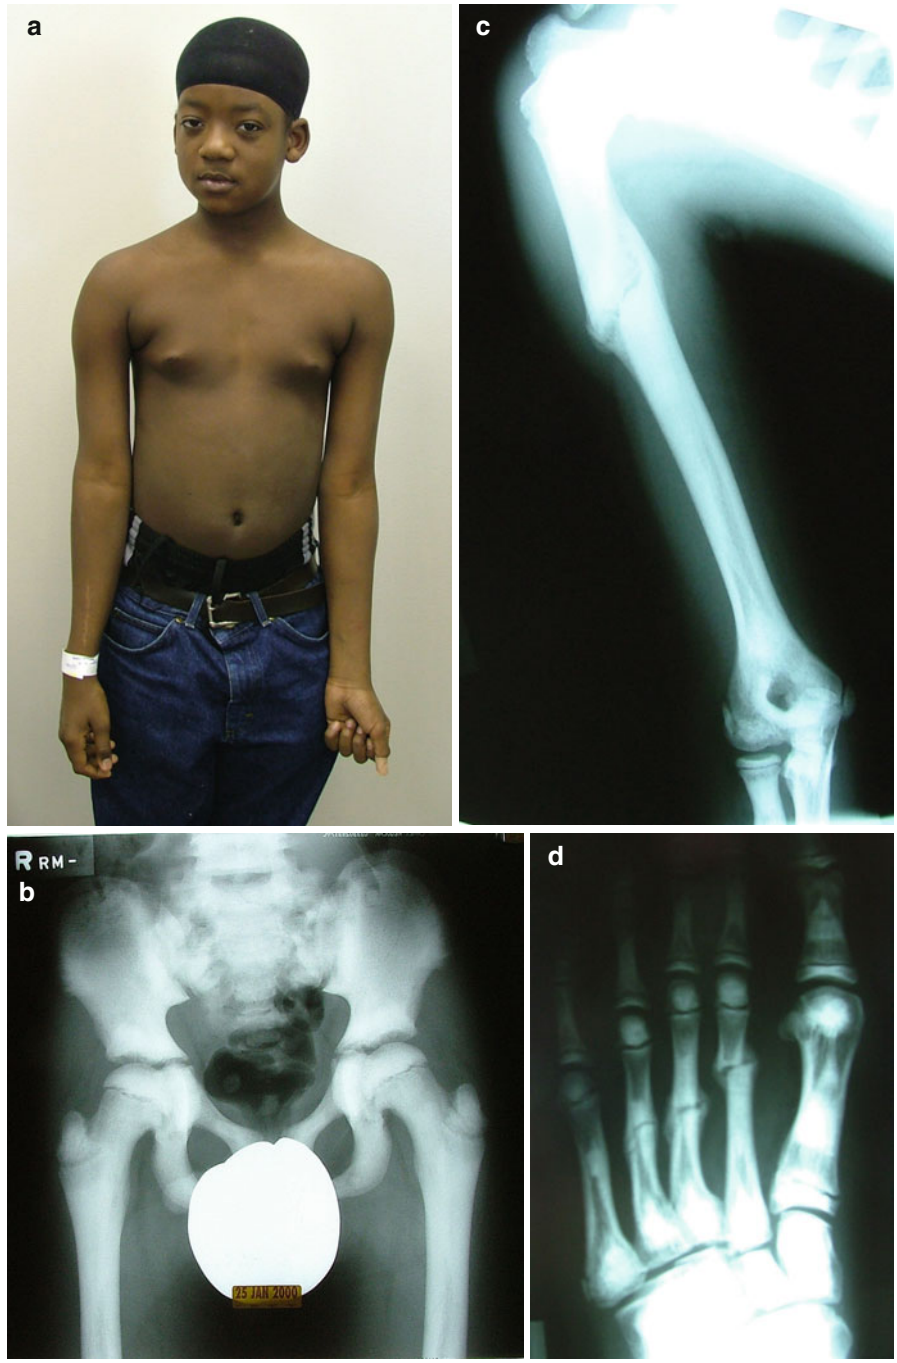

Fig. 2 (**a**–**d**) A 14-year-old boy with osteopetrosis showing sclerotic bones with loss of corticomedullary differentiation and multiple fractures, illustrated by a series of radiographs

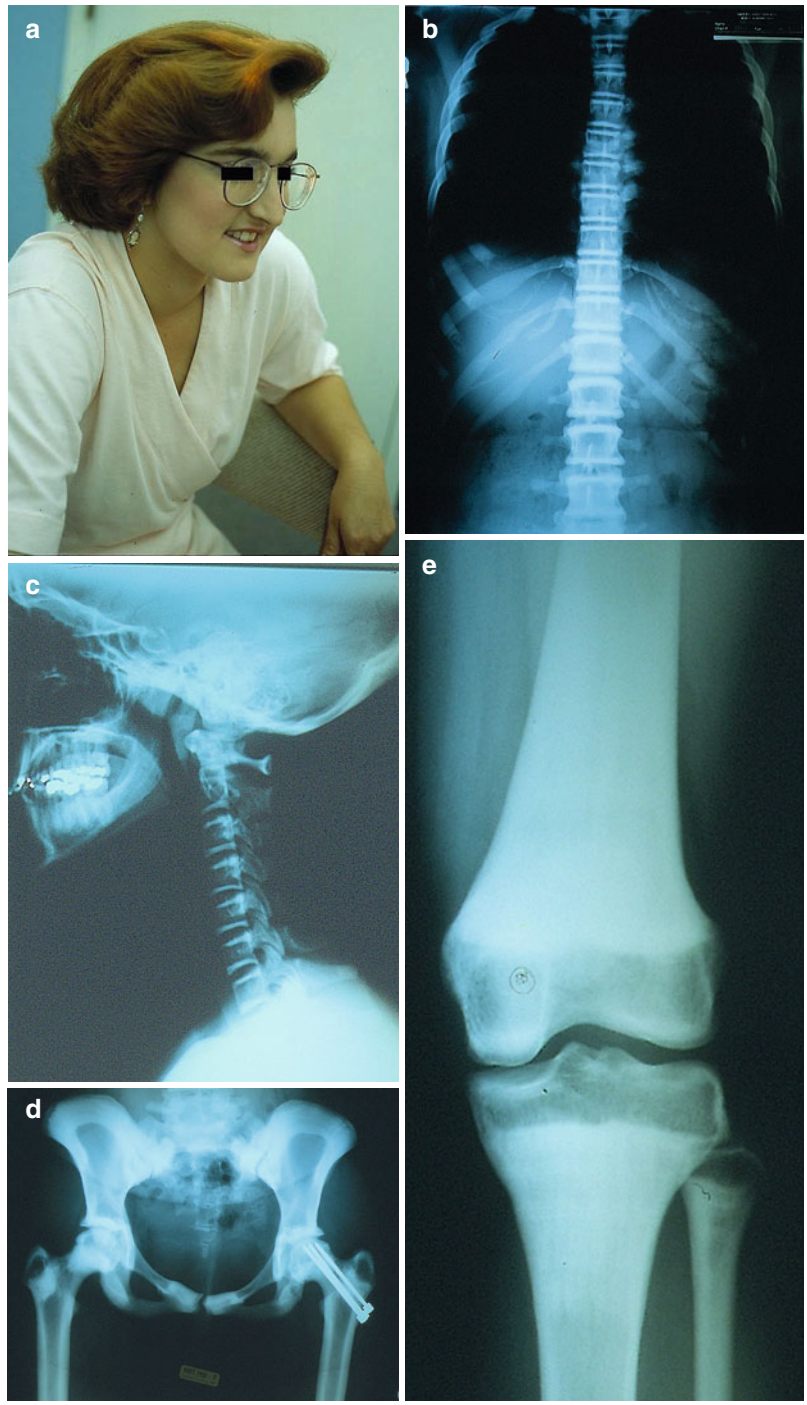

Fig. 3 (**a**–**e**) An adult female with osteopetrosis showing generalized sclerotic bones with loss of corticomedullary differentiation including sandwich cervical vertebrae, illustrated by radiographs

Osteopoikilosis

Osteopoikilosis was first described by Albers-Schonberg in 1915. It is a benign, usually asymptomatic condition diagnosed radiographically by the presence of multiple symmetrical circular/ovoid sclerotic opacities of the ischia, pubic bones, and the epimetaphysial regions of the short tubular bones. The incidence is estimated as 1/50,000 (Cazzola et al. 1989).

Synonyms and Related Disorders

Buschke–Ollendorff syndrome; Melorheostosis; Osteopathia striata

Genetics/Basic Defects

1. Inherited in an autosomal dominant pattern
2. Caused by loss of function mutation of LEM domain-containing three gene (*LEMD3*)
3. Usually occurs in isolation
4. Osteopoikilosis in association with elastic or collagen connective tissue nevi of the skin, known as Buschke–Ollendorff syndrome (dermatofibrosis lenticularis disseminate)
5. In some families and individuals, osteopoikilosis can occur with other osteosclerotic skeletal disorders, such as melorheostosis and osteopathia striata.

Clinical Features

1. Osteopoikilosis
   a. Presence of multiple osteosclerotic lesions in different parts of the skeleton (Lagier et al. 1984; Chigira et al. 1991)
      i. Epiphyses and metaphyses of long tubular bones
      ii. Hands and wrists
         a) Phalanges
         b) Carpal bones
         c) Metacarpals
      iii. Feet/ankles
         a) Phalanges
         b) Metatarsals
         c) Calcaneus
         d) Navicular bones
      iv. Pelvis
      v. Scapulae
   b. An uncommon disorder
   c. Evident at any age (uncommon before the age of 3 years) and persists for life
   d. Symmetric distribution
   e. Generally asymptomatic
   f. Joint inflammation and pain in about 15–20% of cases (Borman et al. 2002)
   g. Osteopoikilosis reported to coexist with other rheumatologic pathologies:
      i. Rheumatoid arthritis (Cazzola et al. 1989; Ureten 2007)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_187,
© Springer Science+Business Media, LLC 2012

   ii. Reactive arthritis (Mesci 2006)
   iii. Discoid lupus erythematosus (Bicer et al. 2002)
   iv. Familial Mediterranean fever (Kavukcu et al. 2003)
2. Melorheostosis
   a. A sporadic sclerosing bone condition
   b. Manifesting in a sclerotomal distribution
   c. Frequently affecting one limb
   d. Usually asymptomatic
   e. Pain, stiffness, leg-length discrepancy, and deformity in severe case
   f. Radiographically, presence of cortical hyperostosis with thickening, resembling dripping candle wax
3. Osteopathia striata
   a. Occurs in isolation or with cranial sclerosis
   b. A key radiographic feature: longitudinal striation of the metaphyses of the long bones
   c. Clinical features ranging from mild skeletal manifestation to multisystem organ involvement, even with the same family
      i. Typical features
         a) Macrocephaly
         b) Cleft palate
         c) Hearing loss
      ii. Additional features
         a) Cardiac malformations
         b) Developmental delay
         c) Cranial nerve palsies
         d) Anal malformations
         e) Cataracts
         f) Nervous system malformations
4. Buschke–Ollendorff syndrome
   a. A rare, autosomal dominant disorder
   b. Typically a benign disorder that combines osteopoikilosis together with skin lesions consisting of connective tissue nevi (Buschke and Ollendorff 1928) or juvenile elastomas (Uitto et al. 1981)

Diagnostic Investigations

1. Radiographic features
   a. Often detected incidentally at radiographic examination
   b. Numerous, small, well-defined circular or ovoid sclerotic foci in a symmetric distribution
      i. Usually seen in (Amezcua-Guerra et al. 2005):
         a) Epiphyses of short tubular bones
         b) Metaphyseal regions of long tubular bones
         c) Carpal bones
         d) Metacarpals
         e) Metatarsals
         f) Tarsal bones
         g) Sacrum
         h) Scapulae
         i) Iliac bones
      ii. Rarely involved in (Mesci 2006):
         a) Skull
         b) Spine
         c) Ribs
         d) Clavicles
2. CT scan and MRI: used to support the diagnosis
3. Radionuclide bone scans
   a. Typically normal
   b. Occasionally abnormal (Appenzeller et al. 2007), especially in younger patients (Borman et al. 2002; An et al. 2004)
4. Bone biopsy: focal condensations of compact lamellar bone within spongiosa (Benli et al. 1992)
5. Molecular genetic diagnosis of *LEMD3* gene mutation is not currently available clinically.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a low recurrence risk if parents are not affected
   b. Patient's offspring: a 50% of risk of having an affected offspring if the spouse is normal
2. Prenatal diagnosis: has not been reported
3. Management
   a. Usually no treatment is required for the condition
   b. Supportive treatment for joint inflammation or joint pain

Fig. 1 A 12-year-old boy with osteopoikilosis which was noticed incidentally from pelvic radiographic examination

Fig. 2 Pelvic radiograph showed small, oval osteosclerotic bone lesions at femoral head and neck and around the acetabulum of the pelvis and symphysis pubis

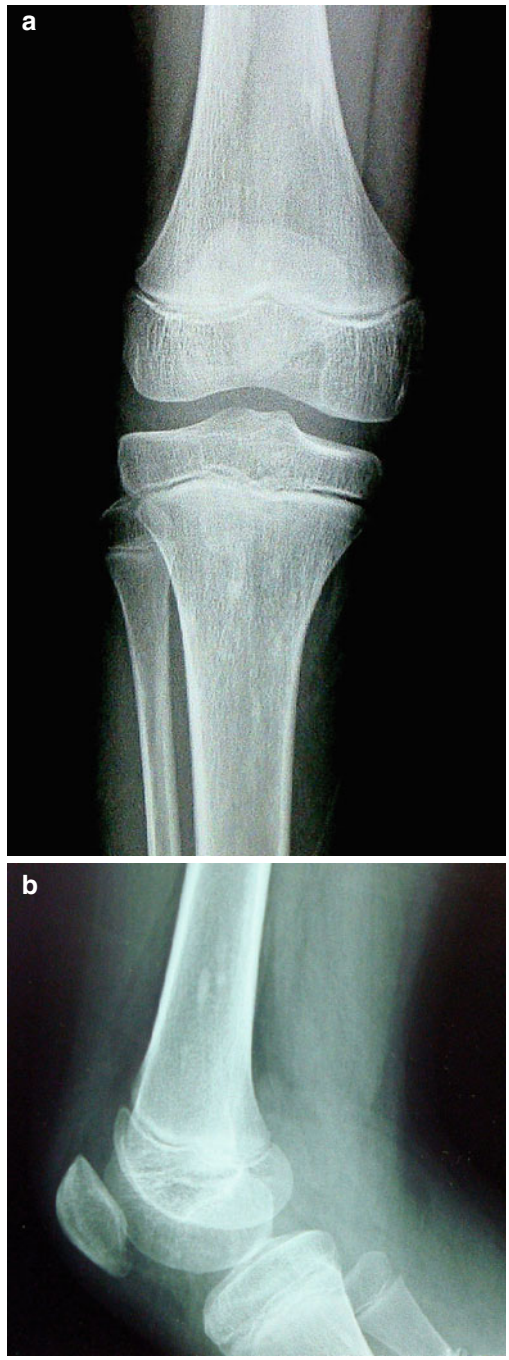

Fig. 3 (**a**, **b**) Oval osteosclerotic bone lesions on proximal tibia and distal femur

Fig. 4 A 9-year-old boy complained pain on both ankles and feet. He was diagnosed to have osteopoikilosis from radiographic findings

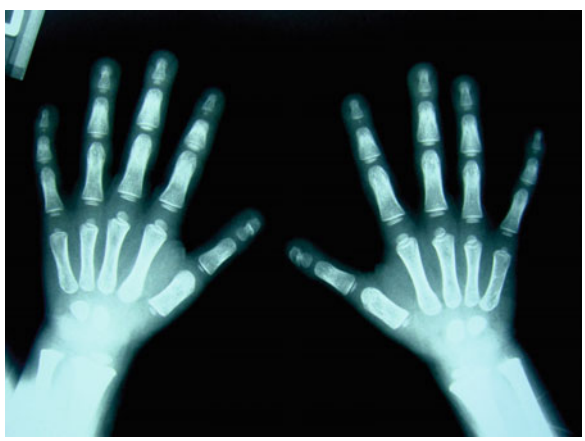

Fig. 5 Hand radiograph at age of 4 showing multiple sclerotic lesions along axis of phalanges and metacarpals

Fig. 6 Feet radiograph at age of 9 showing multiple sclerotic lesions along the axis of several phalanges

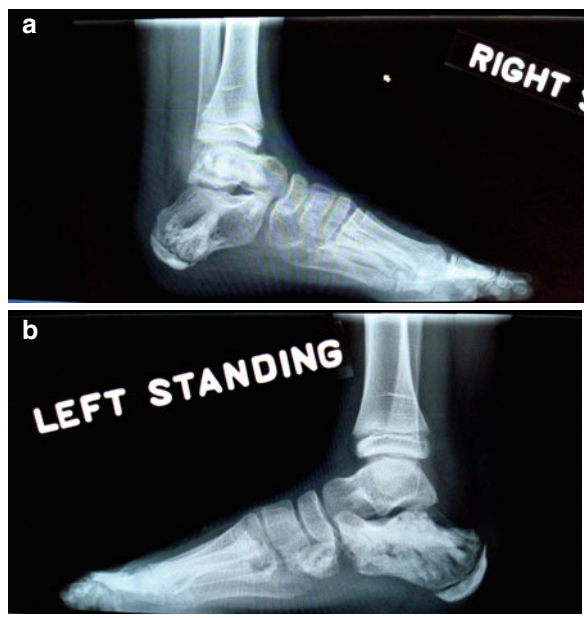

Fig. 7 (**a**–**b**) Lateral view of feet at age of 9 showing multiple sclerotic lesions at calcaneus and talus bones

Otopalatodigital Spectrum Disorders

Otopalatodigital spectrum disorders, a heterogeneous group of disorders characterized primarily by a skeletal dysplasia of variable severity, include otopalatodigital syndrome type I (OPD I), otopalatodigital syndrome type II (OPD II), frontometaphyseal dysplasia (FMD), and Melnick-Needles syndrome (MNS).

Dudding et al. in 1967 described three male sibs with conduction deafness, cleft palate, characteristic facies, and a generalized bone dysplasia. In retrospect, the male patient described by Taybi (1962) may have the same condition. The syndrome is now known as OPD I.

Fitch et al. in 1976 described a familial syndrome of cranial, facial, oral, and limb anomalies in which two male infants have microcephaly, abnormal ears, antimongoloid slant, small mouth, cleft palate, flexed overlapping fingers with syndactyly of the second to the fifth toes, and normal karyotype. The name OPD II was proposed for this syndrome by Fitch et al. (1983).

Gorlin and Cohen in 1969 described a male patient with extraordinarily marked frontal hyperostosis giving great prominence to the supraciliary ridges, underdeveloped mandible, cryptorchidism, subluxated radial heads, and metaphyseal dysplasia resembling that in Pyle disease (metaphyseal dysplasia).

Melnick and Needles in 1966 described families having multiple cases in multiple generations of a severe congenital bone disorder characterized by typical facies (exophthalmos, full cheeks, micrognathia, and malalignment of teeth), flaring of the metaphyses of long bones, S-like curvature of bones of legs, irregular constrictions in the ribs, and sclerosis of base of skull.

In 2000, Verloes et al. presented clinical evidence for a single entity encompassing FMD, MNS, and OPD I and II. Later, mutations in *FLNA*, a gene encoding the cytoskeletal protein filamin A, were found to be associated with otopalatodigital spectrum disorders.

Synonyms and Related Disorders

Frontometaphyseal dysplasia; Melnick-needles syndrome; Otopalatodigital syndromes type I and type II

Genetics/Basic Defects

1. Inherited as X-linked disorders (Robertson 2009)
2. Mutations in *FLNA*, a gene encoding the cytoskeletal protein filamin A, mapped on Xq28, were found to be associated with otopalatodigital spectrum disorders.
3. Different mechanisms contribute to the pathogenesis of these conditions based on the contrast in phenotypic consequences between loss-of-function mutation (leading to periventricular nodular heterotopia) and clustered missense mutations (leading to otopalatodigital spectrum disorders).
4. The four otopalatodigital spectrum disorders are likely allelic based on previous clinical observations, despite remarkably diverse phenotypic presentations.
   a. Mild end of the spectrum: Affected males with OPD I have cleft palate and mild skeletal anomalies with conductive deafness caused by ossicular anomalies.
   b. Intermediate end of the spectrum: Affected males with FMD have a propensity to develop
