stenosis of the subglottic region, ureters, and urethra in addition to skeletal anomalies.

c. Severe end of the spectrum: Affected males with OPD II have more marked skeletal anomalies, CNS anomalies, and other congenital malformations.

d. Most severe end of the spectrum: Affected males with MNS also have severe skeletal anomalies and other congenital malformations similar to OPD II leading to prenatal and perinatal lethality.

5. Genetically related (allelic) disorders
   a. X-linked periventricular nodular heterotopia
      i. Presence of uncalcified nodules of neurons ectopically situated along the surface of the lateral ventricles
      ii. Affected individuals: predominantly heterozygous females; males show early lethality.
      iii. Affected females
         a) Seizures on average at age 14–15 years
         b) Intelligence ranging from normal to borderline functioning
         c) Increased risk for stroke and other vascular problems or coagulopathies
      iv. Germline mutations of *FLNA* leading to null alleles are found almost exclusively in females, whereas missense mutations or mosaicism for truncating mutations can account for affected males or a mild phenotype in females.
   b. A variant of X-linked periventricular nodular heterotopia with marked connective tissue dysfunction (skin fragility, vascular dilatation) described in females has been associated with mutations in *FLNA*, predicted to lead to loss of function.
   c. Gastrointestinal dysmotility associated with periventricular nodular heterotopia associated with *FLNA* mutations
   d. A dual phenotype of periventricular nodular heterotopia and FMD in a female caused by a mutation variably leading to either a substitution or a small deletion as a result of aberrant splicing
   e. Myxomatous cardiac valvular dystrophy associated with X-linked periventricular nodular heterotopia: caused by *FLNA* mutations

Clinical Features

1. Males with OPD I
   a. Skeletal anomalies
      i. Digital anomalies
         a) Thumbs: short, often proximally placed
         b) Distal phalanges of other digits: hypoplastic with a squared (or "spatulate") disposition to the finger tips
         c) Characteristic toes: hypoplasia of the great toe, a long second toe, and a prominent sandal gap
   b. Limitation of joint movement (elbow extension, wrist abduction) in almost all affected individuals
   c. Mild limb bowing
   d. Characteristic facial features
      i. Prominent supraorbital ridges
      ii. Downslanting palpebral fissures
      iii. Ocular hypertelorism
      iv. Broad nasal bridge and nasal tip
   e. Deafness: secondary either to ossicular malformation, neurosensory deficit, or a combination of both
   f. Cleft palate
   g. Oligohypodontia
   h. Normal intelligence
2. Females with OPD I
   a. Exhibit variable expressivity
   b. Some females can be affected to a similar degree as affected, related males.
3. Males with OPD II
   a. Skeletal anomalies
      i. Thoracic hypoplasia
      ii. Limb bowing
      iii. Digital anomalies
         a) Most commonly hypoplasia of the first digit of the hands and feet
         b) Camptodactyly
      iv. Delayed closure of the fontanels
   b. Characteristic craniofacial features
      i. More pronounced than those in OPD I
      ii. Pierre Robin sequence commonly observed
   c. Cardiac septal defects and obstructive lesions to the right ventricular outflow tract in some affected individuals

   d. Associated anomalies
      i. Omphalocele
      ii. Hydronephrosis secondary to ureteric obstruction
      iii. Hypospadias
   e. Central nervous system anomalies
      i. Hydrocephalus
      ii. Cerebellar hypoplasia
      iii. Rare encephalocele and meningomyelocele
   f. Developmental delay: common
   g. Death commonly in the neonatal period secondary to respiratory insufficiency
   h. Survival into the third year of life has been described with intensive medical treatment.
4. Females with OPD II
   a. Usually present with a subclinical phenotype
   b. Characteristic craniofacial features
      i. Prominent supraorbital ridges and a broad nasal root and tip: most common findings
      ii. Occasional conductive hearing loss
   c. Occasional females manifest a phenotype similar in severity to that of males (craniofacial dysmorphism, cleft palate, conductive hearing loss, skeletal and digital anomalies)
5. Males with FMD
   a. Skeletal anomalies
      i. Digital anomalies
         a) Distal phalangeal hypoplasia
         b) Progressive contractures of the hand over the first two decades resulting in marked limitation of movement at the interphalangeal and metacarpophalangeal joints
      ii. Joint limitation at the wrists, elbows, knees, and ankles
      iii. Scoliosis
      iv. Limb bowing
   b. Characteristic craniofacial features
      i. Pronounced supraorbital hyperostosis
      ii. Ocular hypertelorism
      iii. Downslanting palpebral fissures
      iv. Rare cleft palate
   c. Frequent oligohypodontia
   d. Conductive and sensorineural hearing loss in almost all affected individuals
   e. Common underdevelopment of the musculature, most notably around the shoulder girdle and in the intrinsic muscles of the hands
   f. Extraskeletal anomalies
      i. Subglottic stenosis presenting as congenital stridor
      ii. Hydronephrosis
   g. Normal intelligence
6. Females with FMD
   a. Characteristic craniofacial features similar to those of affected males
   b. Digital, subglottic, and urologic anomalies observed in males with FMD either do not occur in females or are observed in markedly attenuated form.
7. Males with MNS
   a. Usually present with a phenotype indistinguishable from, or more severe than, that associated with OPD II
   b. Affected male fetuses born to several women with classic MNS have presented with a lethal phenotype reminiscent of a severe form of OPD II.
   c. Some mildly affected males have been born to clinically unaffected parents.
8. Females with MNS
   a. Skeletal anomalies
      i. Short stature
      ii. Digital anomalies
         a) Typically long phalanges of both hands and feet
         b) Mild distal phalangeal hypoplasia
      iii. Thoracic hypoplasia
      iv. Limb bowing
      v. Joint subluxation
      vi. Scoliosis
   b. Characteristic craniofacial features
      i. Prominent lateral margins of the supraorbital ridges
      ii. Exorbitism
      iii. Micrognathia
   c. Frequent oligohypodontia
   d. Common sensorineural and conductive deafness
   e. Common hydronephrosis secondary to ureteric obstruction
   f. Normal intelligence
   g. Normal pubertal development

Diagnostic Investigations

1. Diagnosis of the OPD spectrum disorders is made by a combination of clinical examination, radiologic studies, family history consistent with X-linked inheritance, and molecular genetic testing (Robertson 2009).
2. Audiometry for hearing loss
3. Renal ultrasound for renal tract anomalies
4. Radiographic studies
   a. Males with OPD I
      i. Skull
         a) Sclerosis of the skull base
         b) Thickening of the calvaria
         c) Underdevelopment of the frontal sinuses
         d) Typically underpneumatized mastoids
         e) Increased mandibular angle
      ii. Spine: Failure of fusion of posterior vertebral or neural arches, particularly in the cervical spine
      iii. Long bones
         a) Mildly bowed upper and lower limbs
         b) Common dislocation of the radial heads
      iv. Hands and feet
         a) Characteristic accessory proximal ossification center of the second metacarpal
         b) Characteristic short, broad first metacarpal and distal phalangeal hypoplasia most marked in the thumb
         c) Presence of accessory carpal bones and fusion of carpal and tarsal bones
      v. Pelvis: typically contracted with a lack of normal flaring of the ilia
   b. Males with OPD II
      i. Skull: findings similar to those in OPD I but delayed in ossification pattern, manifesting as large fontanels in infancy
      ii. Cervical spine
         a) Failure of fusion of the posterior neural or vertebral arches
         b) Segmentation anomalies
      iii. Long bones: bowed upper and lower limbs with splaying of the metaphyses
      iv. Hands and feet
         a) Abnormal modeling of the metacarpals and phalanges, more prominently on the radial side
         b) Hypoplastic or absent great toe
         c) Broad and poorly modeled phalanges and metatarsals
         d) Pelvis: hypoplastic, with lack of normal flaring of the ilia
   c. Females with OPD II
      i. Characteristic sclerosis of the skull base and odontoid process
      ii. Flared metaphyses of the long bones
      iii. Digital anomalies: either absent or presence of hypoplasia of the first metacarpal or metatarsal
   d. Males with FMD
      i. Skull
         a) Sclerosis of the skull base
         b) Marked thickened calvarium
         c) Craniosynostosis
         d) Underpneumatization of the mastoids
         e) Hypoplasia or aplasia of the paranasal sinuses
         f) A spur arising from the anteroinferior tip of the mandible
      ii. Spine
         a) Fusion of vertebral bodies (especially C2-3-4)
         b) Deficiency of the posterior vertebral arches
      iii. Thorax: Ribs can adopt a distorted shape (coat-hanger configuration) even though the thoracic cage is not hypoplastic.
      iv. Long bones: undermodeled and frequently mildly bowed
      v. Hands and feet
         a) Carpal and tarsal fusions: common
         b) Erosion of the carpal bones: observed in adolescence and adulthood
         c) Metacarpals, metatarsals, and phalanges: elongated and poorly modeled
         d) Distal phalanges of the thumb and great toes: hypoplastic
   e. Females with FMD: exhibit the same cranial and long bone features as males, but to a lesser degree
   f. Females with MNS
      i. Skull
         a) Sclerotic skull base
         b) Delayed closure of the fontanels
      ii. Spine
         a) Vertebral bodies: increased in height, especially in the lumbar region
         b) Scoliosis: common

iii. Thorax
  a) Ribs: irregular in contour and form
  b) Clavicle: similarly wavy and irregular, with some expansion of its proximal end
iv. Long bones: bowed both limbs with marked cortical irregularity
v. Hands and feet: elongated and undermodeled phalanges, metacarpals, and metatarsals
vi. Pelvis: exhibits a supra-acetabular constriction with flaring of the ilia

5. Molecular genetic testing
  a. *FLNA* is the only gene currently known to be associated with the otopalatodigital (OPD) spectrum disorders.
  b. Sequence analysis of entire coding region and of select exons: available clinically for confirmation of the diagnosis in the proband and carrier testing of the relatives
  c. Both somatic and germline mosaicism in FLNA leading to periventricular nodular heterotopia (PVNH) have been observed and have been associated with modulation of the severity of the phenotype and survivorship in males (Guerrini et al. 2004; Parrini et al. 2004; Robertson 2007).
    i. Germline mosaicism has been observed in association with OPD I.
    ii. Somatic mutation has been shown to have led to MNS, suggesting similar processes may modulate the expression of OPD spectrum phenotypes (Robertson et al. 2006).

Genetic Counseling

1. Recurrence risk (Robertson 2009)
  a. Sibs of a male proband with OPD I, OPD II, or FMD: Risk depends on the genetic status of the parents.
    i. Mother is a carrier.
      a) A 50% risk to her son to receive the disease gene and express the disease
      b) A 50% risk to her daughter to receive the disease gene and become a carrier with a range of possible phenotypic expression
      c) Mother of an affected child, regardless of proven carrier status, has an increased risk of having an affected male fetus due to presence of maternal germinal mosaicism.
    ii. Father has an *FLNA* mutation.
      a) All female sibs will inherit the mutation.
      b) Male sibs will not inherit the mutation.
  b. Sibs of a proband with MNS: Risk depends upon the genetic status of the mother.
    i. Mother has the gene mutation.
      a) A 50% chance of transmitting the *FLNA* mutation to each child
      b) Male sibs who inherit the mutation will be affected and generally dies prenatally or perinatally.
      c) Female sibs who inherit the mutation will have a range of phenotypic expression.
    ii. Mother is clinically unaffected: Risk to sibs appears to be low but greater than that of the general population due to possible parental germline mosaicism.
  c. Patient's offspring
    i. Males with OPD II do not reproduce.
    ii. Males with OPD I or FMD transmit the disease-causing mutation to all of their daughters and none of their sons.
    iii. Females with OPD I, OPD II, or FMD
      a) A 50% chance of transmitting the disease-causing mutation to each child
      b) Sons who inherit the mutation will be affected.
      c) Daughters will have a range of possible phenotypic expression.
    iv. Males with MNS usually die prenatally or perinatally and do not reproduce.
    v. Females with MNS
      a) A 50% chance of transmitting the disease-causing mutation to each child
      b) Sons who inherit the mutation will be affected and generally die prenatally.
      c) Daughters will have a range of possible phenotypic expression.
2. Prenatal diagnosis
  a. Prenatal ultrasound diagnoses of OPD II in a fetus of an affected mother and in a fetus of a normal mother have been reported.
  b. Prenatal diagnosis and preimplantation genetic diagnosis (PGD) for at-risk pregnancies require prior identification of the disease-causing mutation in the family.

3. Management
   a. Hearing aids for deafness
   b. Stridor in the neonatal period due to laryngeal stenosis rarely requires surgical intervention and is nonprogressive.
   c. Cosmetic surgery to correct the fronto-orbital deformity attempted in some individuals with good results. Regrowth postsurgery does not seem to occur (Kung and Sloan 1998).
   d. Surgery to correct hand and foot malformations and scoliosis
   e. Chest expansion surgery attempted in several individuals with Melnick-Needles syndrome, with only marginal clinical benefit
   f. Continuous positive airway pressure (CPAP) for prevention of airway collapse and sleep apnea secondary to micrognathia and tracheobronchomalacia in severely affected individuals
   g. Anesthetists should be aware of the associated laryngeal stenosis, if intubation and ventilation are required (Leggett 1988; Mehta and Schou 1988).

Fig. 1 (**a**–**d**) A 2-month-old premature (33-week gestation) male infant has multiple congenital anomalies, consisting of marked brachycephaly, widely opened anterior fontanel, short neck with redundant nuchal skin, severe downslanting palpebral fissures, arched eyebrows, a small and flat nose, an extremely small mouth with posterior inverted U-shaped cleft palate, a groove present at philtrum site and lower lip areas, low-set, posteriorly rotated malformed ears, a short sternum, a large umbilical hernia, and hypoplastic scrotum with undescended testicles. Marked limb anomalies are noted: mildly bowed upper arms and forearms, flexed hands with ulnar deviation and overlapping fingers, and duplicated fifth fingers with clinodactyly, bowing of upper and lower legs, and dorsiflexed feet with four toes each with medially deviated great toes and laterally deviated second through fourth toes. Clinical, postmortem, and radiological findings are consistent with otopalatodigital type II syndrome. DNA testing identified two hemizygous missense mutations: c.613 T > C (p.Cys-205-Arg) and c.5290 G > A (p.Ala-1764-Thr) in the *FLNA* gene. The first sequence variation is previously reported to be associated with periventricular heterotropia. The significance of the second sequence variant is unknown. *FLNA* mutations with presumed gain of function are previously reported in association with four other disorders: otopalatodigital syndrome type I and II, frontometaphyseal dysplasia, and Melnick-Needles syndrome

Fig. 2 (**a**–**l**) Radiographs show hypoplastic scapulae, curved humeri, radii, and ulnae, duplicated fourth fingers with four unusually shaped metacarpals and phalanges, markedly bent femora, bent tibiae, unossified fibulae, and four toes in each foot with unusually shaped metatarsals and phalanges

Pachyonychia Congenita

Pachyonychia congenita is a group of rare genetically inherited diseases characterized by nail dystrophy and by varying features of ectodermal dysplasias. There are two major clinical subtypes recognized: type I with oral leukokeratosis and type II with multiple pilosebaceous cysts (Çelebi et al. 1999).

Synonyms and Related Disorders

Jadassohn-Lewandowsky syndrome; Pachyonychia congenita, Jadassohn-Lewandowsky type; Pachyonychia congenita, Jackson-Lawler type

Genetics/Birth Defects

1. Inheritance (Çelebi et al. 1999; Conners et al. 2001)
   a. Type I pachyonychia congenita (Jadassohn–Lewandowsky type)
      i. Autosomal dominant inheritance
      ii. Possible autosomal recessive inheritance
   b. Type II pachyonychia congenita (Jackson–Lawler type): autosomal dominant
2. Etiology
   a. Type I: caused by mutations in genes encoding one of the paired keratins of specialized epidermis, KRT6a or KRT16, resulting in
      i. Fragility of specific epithelia
      ii. Phenotypes of pachyonychia congenita I or focal nonepidermolytic palmoplantar keratoderma with insignificant nail changes
   b. Type II: caused by mutations in genes encoding one of the paired keratins of specialized epidermis, KRT6b or KRT17
      i. Linkage analysis mapped pachyonychia congenita type II phenotype within the type I keratin gene cluster on chromosome 17q12-21
      ii. A germline mutation has been identified in keratin 17 gene (K17).
      iii. Colocalization of K17 with keratin 6b
3. Genotype-phenotype correlation
   a. Differences in type I and type II phenotypes: largely explainable by the difference in expression patterns between the K6a/K16 and K6b/K17 expression pairs
   b. K6b/K17 expresses at higher levels in the pilosebaceous unit than K6a/K16: responsible for the pilosebaceous cysts in type II
   c. Conversely, K6a/K16 more widely expressed in oral epithelia: responsible for the greater predominance of oral leukokeratosis in type I

Clinical Features

1. Presence of intra- and interfamilial phenotypic variation (Feinstein et al. 1988)
2. Pachyonychia congenita type I (56.2% of cases)
   a. The most common subtype
   b. Onset in infancy
   c. Severe nail dystrophy affecting all the nails symmetrically (Dogra et al. 2002)
      i. The best hallmark of the disease

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_189,
© Springer Science+Business Media, LLC 2012

ii. Thickened wedge-shaped nails
iii. Proximal portions of the nails: smooth and normally attached to the lateral nail folds
iv. Distal portions of the nails: may increase to many times the normal thickness, producing a subungual keratinous mass that pushes the nail plate upward, arching it transversally, folding it longitudinally, and elevating it distally
v. Nails commonly shed and regrow with similar but more severe changes.
vi. Projections from the nail beds make the nails susceptible to trauma with consequent chronic paronychial infections.

d. With or without following associated anomalies
i. Focal nonepidermolytic palmoplantar keratoderma (predominantly a feature of type I)
ii. Follicular keratoses observed on
a) Temple
b) Eyebrows
c) Extensor aspect of the proximal parts of the extremities
iii. Hyperkeratosis of palms, soles, knees, and elbows
iv. Localized foot blistering
v. Oral leukokeratosis: a prominent sign
vi. Neonatal teeth
vii. Blister formation on palms and soles
viii. Hoarse voice due to laryngeal involvement (leukokeratosis)
ix. Palmar and plantar hyperhidrosis

3. Pachyonychia congenita type II (24.9% of cases)
a. Nail dystrophy
b. Less pronounced or absent palmoplantar keratoderma and oral changes
c. Follicular keratoses
d. Oral leukokeratosis
e. Multiple pilosebaceous cysts (most useful distinguishing feature for type II but usually occurring at puberty)
i. Epidermoid or infundibular cysts (arising from the hair follicle infundibulum)
ii. Eruptive vellus hair cysts and multiple steatocystomas (characteristic of type II) (arising from the sebaceous duct epithelium)
f. Bullae of palms and soles
g. Palmar and plantar hyperhidrosis
h. Natal or neonatal teeth
i. Pili torti in children
j. Bushy eyebrows
k. Hidradenitis suppurativa

4. Pachyonychia congenita type III (Schafer–Brunauer type) (11.7%)
a. Features of type I and type II
b. Angular cheilosis
c. Leukokeratosis of the cornea
d. Cataracts

5. Pachyonychia congenita tarda (type IV) (7.2%)
a. A rare form of pachyonychia congenita
b. Features of type I, type II, and type III
c. Laryngeal lesions
d. Hoarseness
e. Mental retardation
f. Hair anomalies
g. Alopecia
h. Nail changes occurring in the second or third decade
i. Abnormal painful nails
j. Palmoplantar keratoderma

6. Pachyonychia congenita with early onset nail changes in the absence of other associated features

Diagnostic Investigations

1. Histology and ultrastructure of cutaneous and oral lesions: suggest a keratin disorder (Munro 2001)
2. Molecular analyses of mutations in genes encoding one of the paired keratins of specialized epidermis, K6a/K16 and K6b/K17

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Autosomal dominant inheritance: not increased unless a parent is affected
ii. Autosomal recessive inheritance: 25%
b. Patient's offspring
i. Autosomal dominant inheritance: 50%
ii. Autosomal recessive inheritance: not increased unless the spouse is a carrier

2. Prenatal diagnosis: genomic mutation detection possible in prenatal diagnosis of pachyonychia congenita type I (KRT6a/KRT16) or type II (KRT6b/KRT17) by CVS or amniocentesis

3. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation) has been identified.
4. Management (Dahl et al. 1995)
   a. No ideal treatment for the thickened nail plate available
   b. Vigorous use of topical lubricants and keratolytics
   c. Antiseptic wet dressings for secondarily infected areas
   d. Systemic treatment with acitretin producing variable and inconsistent results with caution of side effects (teratogenicity and hyperostosis)
   e. Custom-fitted footwear for protective support of painful fissures and blisters on the soles
   f. Simple avulsion of the distorted nails is inadequate because the dystrophic nail regrows.
   g. Curettage and electrofulguration or surgical excision of the nail matrix and bed can improve function and appearance.
   h. Surgical excision of focal, hyperplastic epithelial mass results in improvement of hoarseness due to laryngeal obstruction by laryngeal lesions. Additional microsurgery may be necessary for the recurrence of the laryngeal lesions.
   i. Therapeutic small interfering RNAs (siRNAs) for pachyonychia congenita (Leachman et al. 2008)
      i. A new siRNA entering clinical trials in PC patients with the *KRT6A* N171K mutation, with a gene-specific *KRT6A* siRNA study possibly to follow
      ii. This is the first-in-man siRNA therapeutic trial for a skin indication and the first siRNA to target a gene mutation.

Fig. 1 (**a**–**d**) Characteristic nail changes in an 8-month-old girl with pachyonychia congenita type I showing smooth proximal ends and thick distal ends of the nails, producing a subungual keratinous mass that pushes the nail bed upward, arching it transversally, folding it longitudinally, and elevating it distally. The patient also has oral leukokeratosis

Pallister–Killian Syndrome

Pallister–Killian syndrome is a rare sporadic cytogenetic abnormality, caused by a tissue-specific mosaic distribution of an additional isochromosome 12p, first described in three adults by Pallister et al. in 1977 and followed by report of a child by Teschler-Nicola and Killian in 1981 (Pallister et al. 1977; Teschler-Nicola and Killian 1981). The syndrome is also known as Teschler-Nicola/Killian syndrome, Pallister mosaic aneuploidy syndrome, or isochromosome 12p mosaicism. It is the most frequent autosomal tetrasomy in humans (Bresson et al. 1991).

Synonyms and Related Disorders

Isochromosome 12p syndrome; Mosaic tetrasomy 12p syndrome

Genetics/Basic Defects

1. Genetics
   a. Always reported as sporadic
   b. Appears to be associated with increased maternal age
2. Basic cytogenetic defect (Bresson et al. 1991; Yeung et al. 2009).
   a. Caused by tetrasomy 12p
   b. Generally a mosaic
   c. Frequently undetectable by standard cytogenetic analysis of peripheral blood
   d. In the great majority of patients, the i(12p) is maternal in origin, with the underlying mechanism thought to involve a combination of centromere misdivision and nondisjunction at meiosis.
   e. As a result, the i(12p) is present at conception, and mosaicism results from postzygotic mitotic loss (Peltomaki et al. 1987).
   f. There is no apparent correlation between the proportion of tetrasomic cells and the severity of clinical presentation (Schinzel 1991).

Clinical Features

1. Normal or large birth weight (Mathieu et al. 1997)
2. Craniofacial dysmorphism
   a. Brachycephaly
   b. High and broad forehead with frontal bossing
   c. Temporal alopecia
   d. Sparse eyebrows and eyelashes
   e. Hypertelorism
   f. Short nose with anteverted nares
   g. A thick philtrum
   h. A large mouth with down-slanting corners
   i. Full cheeks
   j. Cleft lip/palate
   k. High-arched palate
   l. Micrognathia
   m. Macroglossia
   n. Oral frenula
   o. Delayed dental eruption
   p. Dental anomalies
   q. Low-set and posteriorly rotated ears
   r. Hypertrophy of anthelix crux
   s. Thick earlobes
3. Short neck
4. Diaphragmatic hernia with or without lung hypoplasia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_190,

© Springer Science+Business Media, LLC 2012

5. Imperforate anus
6. CNS/neurologic abnormalities
   a. Severe hypotonia
   b. Mental retardation
   c. Dilated ventricles
   d. Bifrontal cortical atrophy
   e. Absent speech
   f. Poor vision
   g. Epilepsy
7. Congenital heart defects
   a. Ventricular septal defect: the most frequent single malformation
   b. Coarctation of the aorta
   c. Patent ductus arteriosus
   d. Atrial septal defect
   e. Aortic stenosis
8. Limb defects
   a. Talipes
   b. Broad and short hands and fingers
   c. Hypoplastic nails
   d. Abnormal palmar creases
   e. Lymphedema
9. Skin anomalies
   a. Loose/excess skin
   b. Pigmentary dysplasia
   c. Mild hyperkeratosis
   d. Dry skin
   e. Sweating abnormalities
10. Occasional internal organ malformations
    a. Umbilical hernia
    b. Malrotation of the gut
    c. Omphalocele
    d. Abnormalities of urogenital tract including cystic or dysplastic kidneys
    e. Genital anomalies in males
       i. Cryptorchidism
       ii. Small scrotum
    f. Occasional genital anomalies in females
       i. Ambiguous external genitalia
       ii. Hypoplasia of the labia majora
       iii. Absence of the upper vagina and uterus
11. Majority of patients die prenatally, perinatally, or early postnatally, and may die even after 10 or 15 years.
12. Phenotype in older children and young adults: marked phenotypic changes occurring during childhood and adolescence (Horneff et al. 1993)
    a. Coarse and flat facies
    b. Macroglossia
    c. Prognathia
    d. Everted lower lip
    e. Muscular hypertonia
    f. Contractures
    g. Severe psychomotor retardation

Diagnostic Investigations

1. Cytogenetic studies
   a. Demonstration of a supernumerary isochromosome of 12p
   b. Confirmation of 12p tetrasomy by FISH techniques
      i. Using centromere probe on chromosome 12
      ii. Using whole chromosome 12 painting probe
   c. Cytogenetic studies of several tissues because of mosaicism (Mathieu et al. 1997): the mosaicism is usually detected in cultured skin fibroblasts or amniotic cells and rarely in phytohemagglutinin-stimulated lymphocytes, which suggests stimulation of T lymphocytes may distort the percentage of abnormal cells.
      i. Circulating lymphocytes: mosaicism as low as 1–3%
      ii. Amniocytes, chorionic cells and skin fibroblasts: mosaicism ranging from 6% to 100%
2. aCGH (comparative genomic hybridization) can detect partial tetrasomy of 12p in blood without invasive skin biopsy (Theisen et al. 2009).
3. Radiography
   a. Asymmetry of diaphyseal length
   b. Short humerus or femur
   c. Radial notch
   d. Diaphyseal irregularities
   e. Costovertebral defect
4. Echocardiography for congenital heart defect
5. EEG for seizure activities
6. MRI of the brain (Saito et al. 2006)
   a. Normal MRI findings
   b. Abnormal MRI findings
      i. Cortical atrophy with frontal predominance
      ii. Ventricular dilatation
      iii. Hydrocephalus
      iv. Reduced white matter
      v. Thickened cortex
      vi. Micropolygyria

vii. Heterotopic neurons
viii. Agenesis of corpus callosum
ix. Pineal gland tumor
x. Multiple T2-high lesions
xi. T2-elongation in the white matter

7. Postmortem pathologic examinations (Mathieu et al. 1997).
   a. Malpositioned feet
   b. Diaphragmatic defect
   c. Hypoplastic nails
   d. Genital malformation
   e. Imperforate or anteriorly placed anus
   f. Supernumerary spleen
   g. Heart valvular dysplasia
   h. Hypoplasia of the fibula

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low recurrence risk (All cases are sporadic with only one preliminary case report of recurrence.) (Mathieu et al. 1997)
   b. Patient's offspring: not surviving to reproductive age or severely handicapped by profound mental retardation
2. Prenatal diagnosis (Doray et al. 2002)
   a. Ultrasound anomalies
      i. Hydramnios (84%)
      ii. Diaphragmatic hernia (16%)
      iii. Short limbs, predominantly rhizomelic type of micromelia (10%)
      iv. Hydrops fetalis (6%)
      v. Cystic hygroma (3%)
      vi. Increased nuchal translucency (3%)
      vii. Fetal overgrowth (3%)
      viii. Flat fetal facial profile with a small nose and protruding lips (Liberati et al. 2008)
      ix. Ventriculomegaly (3%)
      x. Dilatation of cavum pellucidum (3%)
      xi. Absence of visualization of the stomach (3%)
      xii. Presence of a sacral appendix (3%)
      xiii. Cardiac malformation
      xiv. Hypertelorism
      xv. Short neck
      xvi. Other congenital anomalies
   b. Cytogenetic studies on amniocytes, cells from CVS, or fetal blood cells from cordocentesis
      i. Conventional karyotyping
      ii. FISH using chromosome 12 centromeric and whole chromosome painting probes
         a) Interphase cells
         b) Metaphase cells
3. Management
   a. Supportive treatment
   b. Surgical repair of diaphragmatic hernia or other congenital anomalies in nonlethal cases

Phenylketonuria

Classical phenylketonuria (PKU) is a rare metabolic disorder, resulting from a deficiency of a liver enzyme, phenylalanine hydroxylase. The deficiency of the enzyme leads to elevated phenylalanine (Phe) levels in the blood and various tissues including the brain. The incidence in Caucasians is approximately one in 10,000, giving a heterozygote frequency of one in 50 to one in 70. About one in 15,000 infants is born with PKU in the United States.

Synonyms and Related Disorders

Hyperphenylalaninemia; Phenylalanine hydroxylase deficiency; PKU

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive
   b. Parents: obligatory carriers
2. Basic defect
   a. Deficient activity of the enzyme phenylalanine hydroxylase (PAH), resulting in hyperphenylalaninemia. PAH, a liver-specific enzyme, catalyzes the conversion of phenylalanine to tyrosine, using tetrahydrobiopterin as a cofactor. Chromosomal locus of the *PAH* gene is on 12q24.1.
   b. Identification of more than 400 different mutations in the *PAH* gene (National Institutes of Health Consensus Development Conference Statement 2001)
      i. Deletions
      ii. Insertions
      iii. Missense mutations
      iv. Splicing defects
      v. Nonsense mutations
   c. Compound heterozygotes in most PKU patients, contributing to the clinical heterogeneity and biochemical heterogeneity
   d. Consequences of accumulation of phenylalanine (Phe) and other amino acids in the CNS
      i. Irreversible brain damage from the first few weeks of life
      ii. Severe learning disabilities and associated behavioral and psychological problems

Clinical Features

1. Treated patients
   a. Symptom-free on strict metabolic control using a low-phenylalanine diet for the infants detected by newborn screenings
   b. Normal development with a normal life span when diagnosed early in the newborn period and treated effectively with lifelong dietary control
2. Untreated patients
   a. Profound mental retardation
   b. Psychomotor handicaps
   c. Microcephaly
   d. Delayed speech
   e. Seizures
   f. Light hair and eyes and fair skin secondary to decreased formation of melanin pigment because of compromised tyrosine formation
   g. Musty body or urine odor secondary to excretion of phenylacetic acid into the sweat and the urine

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_191,
© Springer Science+Business Media, LLC 2012

h. Vomiting
i. Irritability
j. Eczema
k. Subtle neurologic findings, sometimes noted even in treated individuals
   i. Hypertonic reflexes
   ii. Intention tremor
l. Behavior problems
   i. Autistic-like behaviors
   ii. Hyperactivity
   iii. Agitation
   iv. Aggression

3. Maternal PKU
   a. Background information
      i. Loss of dietary compliance frequently starting during midchildhood
      ii. Noncompliance on special diet by many affected adolescent females, capable of reproduction, with blood phenylalanine levels above the current recommended therapeutic range
      iii. Loss of follow-up of such females despite effort to identify them
      iv. Teratogenic effect of elevated phenylalanine levels during pregnancy
      v. Fetal anomalies preventable by dietary therapy starting before conception and throughout pregnancy on women with PKU
   b. Abnormalities in the children of women with uncontrolled PKU during pregnancy
      i. Psychomotor retardation (92%)
      ii. Intrauterine growth retardation (40%)
      iii. Microcephaly
      iv. Congenital heart defects (10%)
      v. Postnatal growth retardation
      vi. Neurologic deficits
      vii. Mild craniofacial dysmorphic features
      viii. The frequency of abnormalities directly related to the degree of elevation of maternal phenylalanine levels during pregnancy
      ix. Abnormalities more likely to occur if maternal phenylalanine levels are not controlled during critical periods of embryogenesis and organogenesis early in pregnancy
   c. Currently, the control of phenylalanine levels during pregnancy is recommended at 2–6 mg/dL or 1–4 mg/dL: at least as strict, if not more strict, as that currently recommended for PKU treatment during early childhood.
   d. Women with mild forms of PKU having relatively mild elevations of the phenylalanine are at risk of adversely affecting the fetuses if the mothers are unmonitored and untreated during pregnancies. Because placental gradient favors the fetus, the levels of Phe are higher in the fetus than in the mother.
   e. Effects of uncontrolled maternal PKU occur regardless of the genetic PKU status of the fetus.

Diagnostic Investigations

1. Universal newborn screening from a heel stick bloodspot for PKU (since the 1960s) for early detection and treatment of the disorder (National Institutes of Health Consensus Development Conference Statement 2001)
   a. Guthrie bacterial inhibition assay
      i. Inexpensive
      ii. Simple
      iii. Reliable
   b. Fluorometric analysis
      i. Quantitative and automated test
      ii. Fewer false positive
   c. Tandem mass spectrometry
      i. Quantitative and automated test
      ii. Fewer false positive
      iii. Measurements of tyrosine
      iv. Identification of other metabolic disorders on a single sample
2. Plasma quantitative amino acid analysis especially phenylalanine and tyrosine levels (National Institutes of Health Consensus Development Conference Statement 2001)
   a. Phe concentrations persistently >2 mg/dL in the untreated state
   b. Recommended blood Phe levels in US clinics
      i. 2–6 mg/dL for age <12 years
      ii. 2–10 mg/dL for age >12 years
   c. Frequent monitoring of blood Phe levels
      i. During first year: once a week to once a month
      ii. After first year: once a month to once every 3 months
   d. Recommended blood Phe levels in pregnant maternal PKU
      i. <6 mg/dL achieved at least 3 months before conception
      ii. 2–6 mg/dL during pregnancy

3. MRI of the brain
   a. Hypoplasia of the corpus callosum: a marker for adverse brain development in maternal PKU
   b. Areas of demyelination
4. Molecular genetic testing
   a. Primary purpose
      i. Confirmatory diagnostic testing
      ii. Determine carrier status of at-risk relatives
      iii. For prenatal diagnosis
   b. Methodology
      i. Targeted mutation analysis
      ii. Mutation scanning
      iii. Sequence analysis
      iv. Duplication/deletion analysis
      v. Linkage analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Twenty-five percent affected
      ii. Fifty percent carrier
      iii. Twenty-five percent normal
   b. Patient's offspring
      i. Not increased unless the spouse is also a carrier in which case there will be a 50% risk of having an affected offspring and a 50% of having a carrier offspring
      ii. All offspring of PKU mothers
         a) Carry at least one abnormal gene at the PAH locus inherited from their homozygous affected mothers (obligatory heterozygotes)
         b) Approximately one in 120 (1/4 × 1/30) offspring will be affected by inheriting two abnormal *PAH* genes from both parents depending on the PKU carrier status of the father
2. Prenatal diagnosis
   a. Fetal ultrasonography in noncompliant maternal PKU
      i. Intrauterine growth retardation
      ii. Microcephaly
      iii. Congenital heart disease
   b. DNA mutation analysis on fetal cells by amniocentesis or CVS
      i. Provided the disease-causing mutations in the *PAH* gene identified in an affected family members
      ii. Informative markers available for linkage analysis
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member
3. Management
   a. Dietary phenylalanine restriction: the only known strategy of preventing neurological impairment and mental retardation in patients with PKU
      i. Natural history of the disease modified by a low-phenylalanine diet
      ii. Early strict restriction of phenylalanine intake resulting in normal intelligence
      iii. Phenylalanine-restricted diet required for life
      iv. Special medical foods devoid of or low in phenylalanine supplemented with tyrosine
      v. Restricted diet worth trying in most individuals with previously untreated PKU with possible benefits in the areas of concentration, alertness, mood, irritability, and adaptive behavior (Fitzgerald et al. 2000)
   b. Late-treated PKU: although the severe cognitive impairment associated with untreated PKU can in many cases be partially reversed with dietary treatment, prompt initiation of treatment following newborn metabolic screening is essential for optimal development and the prevention of disability (Grosse 2010).
   c. Adult complications in PKU (Hoeks et al. 2009): consisting of two components, namely high Phe levels (e.g., neurological and neuropsychological problems) and complications occur as a cause of dietary protein restriction (e.g., vitamin deficiencies and osteoporosis)
      i. Adults with PKU who were treated from early infancy have normal intelligence, but their neuropsychological test scores are somewhat lower than those of the general population, their parents, and their unaffected siblings (Weglage et al. 1993).
      ii. Adults with PKU who were continuously treated but relaxed the diet have displayed white matter abnormalities on structural magnetic resonance imaging (Cleary et al. 1994; Sener 2003), which are considered to be indicative of a reduction in myelin (Dyer et al. 1996; Joseph and Dyer 2003). These abnormalities disappear after reintroducing a strict diet.

iii. Neurological investigations in early-treated adults with PKU who discontinued the diet reveal a higher incidence of minor neurological signs including tremor, brisk deep tendon reflexes, or clumsy motor coordination (Thompson et al. 1990; Pietz et al. 1998). In rare cases, severe neurological deterioration may occur after cessation of dietary treatment.

iv. Severe behavior and psychiatric problems are seen in profoundly retarded (untreated) adults with PKU in the third and fourth decade of life (Paine 1957). With introduction of a Phe-restricted diet, these symptoms are sometimes reversible (Baumeister and Baumeister 1998).

v. Vitamin B12 deficiency
   a) Vitamin B12 is only found in animal protein, the sources being meat, fish, and poultry. Since the PKU diet is restricted in protein, vitamin B12 must be provided either combined with the amino acid supplement or from a separate supplement.
   b) Vitamin B12 deficiency can occur when PKU patients relax their diet in adolescence (Robinson et al. 2002). They tend to choose products that are low in animal protein, and amino acid supplements are not taken properly (Hvas et al. 2006).

vi. Osteoporosis: possibly due to long-standing dietary deficiency in protein, calcium, vitamin D, or trace elements, or a primary defect in bone turnover inherent to the disease itself (Modan-Moses et al. 2007)

d. Nutritional management of PKU (Feillet and Agostoni 2010)
   i. Becomes more complex with the multitude of amino acid substitutes available and with the different nutritional issues, such as polyunsaturated fatty acids, micronutrient deficiencies, bone disease, and antioxidant status, that have arisen
   ii. Long-term dietary guidance and monitoring of the nutritional status of patients with PKU should be part of a follow-up program that continues for life.

e. Counseling for maternal PKU
   i. Genetic and nutritional evaluation and counseling, optimally before contemplating pregnancy
   ii. Benefits of dietary phenylalanine restriction in pregnant women with hyperphenylalaninemia: decrease the incidence of following fetal effects (Hanley et al. 1999)
      a) Mental retardation
      b) Microcephaly
      c) Congenital heart disease
      d) Intrauterine growth retardation
   iii. Assistance of women with hyperphenylalaninemia, who are unable or unwilling to maintain blood phenylalanine levels in the range for optimum pregnancy outcome, to obtain adequate means for birth control, including tubal ligation if requested
   iv. Counseling of women with hyperphenylalaninemia who conceive with blood phenylalanine levels greater than 4–6 mg/dL concerning risks to the fetus: offer detailed ultrasonography to detect fetal abnormalities such as growth retardation and congenital heart defects
   v. Close monitoring of serum phenylalanine levels at 2–6 mg/dL during pregnancy of PKU mother and intake of vitamins (folic acid and vitamin B12, in particular) and other nutrients (National Institutes of Health Consensus Development Conference Statement 2001)
   vi. Blood testing for hyperphenylalaninemia indicated to children born to women with features of maternal PKU fetal effects without a known cause

Pierre Robin Sequence

Pierre Robin described a group of patients with cleft palate, micrognathia, and glossoptosis in 1923. The meticulous documentation of the triad of findings led to the recognition of the sequence that bears his name. Pierre Robin sequence is estimated to affect approximately 1 in 8,500 births (Bush and Williams 1983).

Synonyms and Related Disorders

Glossoptosis, micrognathia, and cleft palate

Genetics/Basic Defects

1. Inheritance
   a. Sporadic in most instances
   b. May be familial with autosomal dominant mode of inheritance
   c. Syndromic form: etiologically heterogeneous (Cohen 1999; Taylor 2001)
      i. Monogenic
         a. Stickler syndrome (common cause)
         b. Beckwith-Wiedemann syndrome
         c. Camptomelic syndrome
         d. Cerebrocostomandibular syndrome
         e. Congenital myotonic dystrophy
         f. Distal arthrogryposis-Robin syndrome
         g. Mandibulofacial dysostosis
         h. Miller-Dieker syndrome
         i. Otopalatodigital syndrome II
         j. Robin-oligodactyly syndrome
      ii. Chromosomal
         a. Del(22q) velocardiofacial syndrome (common cause)
         b. Del(4q) syndrome
         c. Del(6q) syndrome
         d. Dup(11q) syndrome
      iii. Teratogenic
         a. Fetal alcohol syndrome
         b. Fetal hydantoin syndrome
         c. Fetal trimethadione syndrome
      iv. Deformation
         a. Oligohydramnios
         b. Uterine structural anomalies
         c. Amniotic band syndrome
      v. Disruption: amniotic band disruption
      vi. Unknown cause:
         a. CHARGE syndrome
         b. Femoral dysgenesis
         c. Moebius sequence
         d. Robin/amelia association
2. Pathogenetically and phenotypically variable (Robin sequences and complexes)
   a. Malformation sequence based on intrinsic mandibular hypoplasia that prevents the normal descent of the tongue interfering with palatal fusion, for example:
      i. Treacher-Collins syndrome
      ii. Del(22q) syndrome
   b. Deformation sequence based on extrinsic mandibular hypoplasia caused by intrauterine constraint
      i. Oligohydramnios (reduced amniotic fluid results in compression of the chin against the sternum restricting mandibular growth and impacting the tongue between the palatal shelves)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_192,
© Springer Science+Business Media, LLC 2012

ii. Mandibular catch-up growth expected after birth when intrauterine deforming forces are no longer acting since micrognathia is based upon intrauterine molding
c. Neurogenic hypotonia leading to lack of mandibular exercise
d. Connective tissue dysplasia: Stickler dysplasia complex
e. Spondyloepiphyseal dysplasia congenita complex
3. Genetic basis of the Pierre Robin sequence (Jakobsen et al. 2006)
a. A comparison among cases in the literature and cases in cytogenetic databases revealed consistency to a certain degree to loci 2q24.1–33.3, 4q32–qter, 11q21–23.1, and 17q21–24.3.
b. No particular candidate genes can be identified for certain from the present study, but GAD67 on 2q31, PVRL1 on 11q23–q24, and the SOX9 gene on 17q24.3–q25.1 are suggested to be important.
5. Developmental delay
a. Usually not present in isolated Robin sequence
b. May be present depending on the underlying syndrome
6. Middle ear diseases associated with cleft palate
a. Otitis media (80%)
b. Auricular anomalies (75%)
c. Hearing loss, mostly conductive (60%)
7. Cleft palate–associated problems
a. Speech defects
b. Velopharyngeal insufficiency
8. "Catch-up growth" of the mandible
a. Normal mandibular growth in patients with Robin sequence secondary to mechanical constraint
b. Deficient mandibular growth in patients with intrinsic mandibular anomalies
9. Other signs and symptoms and associated anomalies depending on the underlying conditions

Clinical Features

1. Classic triads
a. Posterior, U-shaped cleft palate
b. Micrognathia/retrognathia
c. Glossoptosis (observed tendency of the tongue to move posteriorly obstructing the oropharynx)
2. Pierre Robin sequence using different criteria
a. Mandibular deficiency
b. Cleft palate
c. Upper airway obstruction
3. Respiratory difficulty
a. Often the first sign causing concern relating to feeding
b. May not necessarily be present at birth
c. Upper airway obstruction and apnea
i. Glossoptosis associated with retrognathia
ii. Upper airway collapse secondary to:
a. Hypotonic pharynx
b. Laryngomalacia
c. Laryngeal cleft
d. Laryngeal web
d. Complications of continuing airway obstruction
i. Failure to thrive
ii. Pectus excavatum
iii. Decreased pulmonary function
iv. Sudden death
4. Failure to thrive

Diagnostic Investigations

1. Assess respiratory sounds with stethoscope during feeding and at rest.
2. Monitor developmental milestone achievement.
3. Pulse oximetry monitoring to document drops in oxygen saturation
4. Flexible fiber optic nasopharyngoscopy
a. To identify exact mechanism of upper airway obstruction
b. To assess pharyngeal, palatal, lingual, and laryngeal morphology and function during feeding and swallowing
5. Identify the underlying cause of the micrognathia.
6. Orthodontic assessment
7. Hearing assessment
8. Cephalometric radiographs
a. Deformation sequence
i. Mandible
a. Short body
b. Short ramus
c. Increased gonial angle
d. Incomplete catch-up growth
ii. Cranial base angle: decreased
b. Treacher-Collins syndrome
i. Mandible
a. Short body
b. Short ramus

c. Characteristic shape
d. Severely affected growth
ii. Cranial base angle: decreased
c. Del(22q11.2) syndrome
i. Mandible
a. Retrognathia
b. Essentially normal in shape
ii. Cranial base angle: increased
d. Stickler dysplasia complex
i. Mandible
a. Short ramus
b. Antegonial notching of body
ii. Cranial base angle: decreased
e. Spondyloepiphyseal dysplasia congenita complex: short body of mandible
9. Chromosome analysis: del(22q11.2)
10. Molecular diagnosis (Cohen 1999)
a. Treacher-Collins syndrome: mutations in *TCOF1*
b. Stickler dysplasia complex
i. Mutations in *COL2A1*
ii. Mutations in *COL11A1*
c. Spondyloepiphyseal dysplasia congenita complex: mutations in *COL2A1*

Genetic Counseling

1. Recurrence risk
a. Patient's sib: rare unless Pierre Robin sequence is a part of a syndrome
b. Patient's offspring: rare unless Pierre Robin sequence is a part of a syndrome
2. Prenatal diagnosis by ultrasonography demonstrating micrognathia/retrognathia and cleft palate
3. Management
a. Prone positioning of infants believed to help prevent the tongue and mandible from obstructing the airway, leading to generally improved oxygen saturation
b. Nasogastric tube placement for early feeding
c. Occupational therapy directed toward management of the palatal abnormality
d. Surgical intervention for airway obstruction
i. Glossopexy to bring tongue forward and attach it to an anterior structure to prevent the tongue from falling back into the airway
ii. Tracheotomy needed only in cases where conservative treatments fail
iii. Mandibular distraction involving surgical incision of the mandible followed by the application of traction to stimulate new bone growth
iv. Repair of cleft palate
e. Treat middle ear infections
i. Antibiotics
ii. Placement of tympanostomy tubes
f. Speech therapy

Polycystic Kidney Disease, Autosomal Dominant Type

Autosomal dominant polycystic kidney disease (ADPKD) is the most common form of polycystic kidney disease with an estimated incidence of approximately 1/400–1/1,000 individuals worldwide. It roughly accounts for 10% of patients with chronic renal failure requiring hemodialysis or transplantation (Arnaout 2001).

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant with almost complete penetrance
   b. Negative family history in 40% of cases
2. Genetically heterogeneous with at least three different genes now known to cause ADPKD. All three types of ADPKD present with an identical profile of extrarenal manifestations (including liver cysts and aneurysms) (Wilson 2004).
   a. Type I (85–90% of cases): caused by mutations in *PKD1* gene, which is:
      i. Mapped on chromosome 16p13.3
      ii. The most severe form with a lower median survival and a higher risk of progressing to end-stage renal disease
      iii. Closely linked to TSC2, a gene responsible for a major form of tuberous sclerosis
   b. Type II (most of the remaining cases): caused by mutations in *PKD2* gene, which is:
      i. Mapped on chromosome 4q21–q23
      ii. Identified by positional cloning
      iii. Producing milder disease but otherwise phenotypically identical with the *PKD1* disease
   c. A small number of familial cases reported to be unlinked to both the *PKD1* and *PKD2* loci, suggesting the existence of at least one more proposed gene (*PKD3*) which has not been identified
   d. Patients with mutations in both the PKD1 and PKD2 genes (transheterozygotes) have a more severe clinical course than those with mutations in only one of the genes.
3. Mechanism of cyst formation: somatic second-hit model (Wilson 2004)
   a. A germline mutation in one PKD allele in all cells in ADPKD
   b. A random somatic mutation (second hit) occurring in the normal allele causing increased cell proliferation, leading to cyst formation
4. Molecular basis of ADPKD (Rossetti et al. 2002b)
   a. Protein products of the disease gene forming a macromolecular signaling structure, the polycystin complex, that regulates fundamental aspects of renal epithelial development and cell biology
   b. Protein products of PKD1 and PKD2 (polycystin-1 and polycystin-2, respectively
      i. Share sequence homology
      ii. May form components of a receptor/channel complex
   c. Polycstin-1
      i. Predicted to have a receptor-like structure
      ii. May be involved in cell-cell/matrix interactions

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_193,
© Springer Science+Business Media, LLC 2012

iii. May have a regulatory role over a polycystin channel
d. Polycystin-2
i. Similar to and functioning as an ion channel subunit
ii. Causes nonselective cation permeability
e. Basic defect in ADPKD: could be in polycystin-regulated intracellular Ca^{++} levels
5. Disease characteristics.
a. Principal ductal organs with cyst formation
i. Kidneys
ii. Liver
b. Consequences of cyst enlargement
i. Progressive destruction of normal renal tissue
ii. End-stage renal failure in >50% of patients by age 60
c. Systemic involvement
i. Arterial hypertension developing early and observed in >50% of patients
ii. Vascular aneurysms
iii. Cardiac valve defects
iv. Colonic diverticula

Clinical Features

1. Intrafamilial and interfamilial variability in the onset, phenotype, and progression of the disease
a. Due to genetic heterogeneity
i. More common PKD1 (accounting for approximately 85% of cases associated with more severe disease)
ii. Evidence of significant intrafamilial phenotypic variation suggesting modifying factors (such as the angiotensin-converting enzyme insertion/deletion polymorphism) as well as environmental factors that influence the clinical course
iii. Association of the position of the *PKD1* mutation with earlier end-stage renal disease
b. Age of onset
i. Presenting at any age
ii. Generally presenting in the fourth and fifth decades of life
iii. Occasionally presenting in the fetal or neonatal period
2. Onset of disease in the childhood in children who carry *PKD1* gene
a. Frequency of children with renal cysts detectable by ultrasound
i. Sixty percent by 5 years of age
ii. Seventy-five to Eighty percent among children aged 5–18 years
b. Number of renal cysts at 11 years
i. One to ten in 60% of children
ii. More than ten cysts in 40% of children
3. Age at the time of diagnosis and progression of the disease
a. Diagnosis in utero or in the first year of life (intrauterine or infantile onset)
i. Manifesting unusually severe disease
ii. End-stage renal disease during childhood in 18% of cases
b. Diagnosis after the first year of life
i. Increase in the number of cysts over a mean interval of 3.7 years
ii. Systolic hypertension in 9% of cases
iii. None with decreased renal function
4. Renal manifestations (Fick et al. 1994)
a. Development of bilateral renal cysts
i. Primary renal manifestation
ii. Leading to functional changes (impaired renal concentrating capacity, hypertension)
iii. Leading to various clinical manifestations
b. Flank or back pain (about 60%)
c. Acute pain
i. Infected cyst
ii. Ruptured cyst (associated with gross hematuria)
iii. Nephrolithiasis (20–36%)
d. Urinary tract infection (40–68%)
e. Hematuria
f. Mild proteinuria
g. End-stage renal disease
5. Extrarenal manifestations
a. Liver involvement
i. Most common extrarenal manifestation
ii. Liver cysts uncommon before 16 years of age
iii. Liver cysts observed in about 75% of patients older than 60 years
iv. No liver symptoms in most patients with ADPKD
v. Occasionally encountered liver changes
a) Congenital hepatic fibrosis
b) Segmental dilation of the biliary tract

vi. Liver cysts responsible for most of the hepatic complications
vii. Acute complications (Chauvear et al. 2000)
a) Cyst infection
b) Cyst hemorrhage
c) Cyst rupture
d) Cyst torsion
viii. Chronic complications related to progressive increase of the polycystic liver (Chauvear et al. 2000)
a) Abdominal mass
b) Ascites
c) Hepatic venous outflow obstruction (Budd-Chiari syndrome)
d) Portal hypertension with variceal bleeding
e) Inferior vena cava compression
f) Bile duct compression
g) Jaundice
ix. Intrahepatic biliary cysts
a) More common in women
b) Exacerbated by pregnancy

b. Other rare cystic involvement (Fick et al. 1994)
i. Pancreatic cysts (10%)
ii. Arachnoid cysts (5%)
iii. Ovarian cysts

c. Cardiovascular manifestations not uncommon
i. Intracranial berry aneurysms (5–10%)
ii. Dolichoectatic arteries
iii. Aortic root dilatation
iv. Dissections of intracerebral, coronary, thoracic, iliac, aortic, and splenic arteries reported
v. Cardiac valve defects

d. Other noncystic involvement
i. Colonic diverticula (80% of patients with end-stage renal disease)
ii. Hernias (25%)

6. Clinical course in children
a. Clinical spectrum ranging from severe neonatal manifestations mimicking autosomal recessive polycystic kidney disease to renal cysts noted on ultrasound in asymptomatic children
b. Diagnosis made in utero by ultrasound: massively enlarged cystic kidneys
c. Newborn presenting with Potter phenotype and death from pulmonary hypoplasia
d. Newborn with large abdominal masses
e. After neonatal period
i. Hypertension
ii. Abdominal pain
iii. Palpable abdominal mass
iv. Hematuria
v. Renal insufficiency, only rarely
vi. Renal infections

f. Rare extrarenal manifestations
i. Liver cysts
ii. Cerebral vessel aneurysms

g. Prognosis
i. Severe symptoms in neonatal or infantile cases
ii. Milder symptoms in late childhood cases

7. Reproductive issues for adults with ADPKD (Vora et al. 2008)
a. Men with ADPKD
i. Necrospermia
ii. Immotile sperm
iii. Seminal vesicle cysts
iv. Ejaculatory duct cysts

b. Female fertility is not affected
i. Affected women with ADPKD and normal renal function have a high rate of successful uncomplicated pregnancies.
ii. Pregnant women with ADPKD with compromised kidney function should be monitored carefully for the development of hypertension and preeclampsia.

8. Risk factors precipitating faster progression of the disease
a. The *PKD-1* gene
b. Male gender
c. Earlier onset of symptoms
i. Renal enlargement
ii. Hematuria
iii. Proteinuria
iv. Incipient renal failure
v. Hypertension

d. Having >10 renal cysts before age 12 years
e. Having blood pressures above the 75th percentile for age, height, and gender
f. Polycystic liver disease
i. Frequently associated with autosomal dominant polycystic kidney disease
ii. Develops later than renal cysts
iii. Develops earlier and more severe in women than in men

9. End-stage renal disease
   a. The most feared renal complication of ADPKD
   b. Occurs in more than half of patients by the seventh decade of life
10. Differential diagnosis (Wolyniec et al. 2008)
   a. Autosomal recessive polycystic kidney disease: manifests advanced renal insufficiency present already in childhood or early youth (see the chapter on Autosomal Recessive Polycystic Kidney Disease)
   b. Tuberous sclerosis complex (see the chapter)
      i. Cysts in the kidneys observed in 20% of patients with tuberous sclerosis complex
      ii. Associated with characteristic skin and neurological symptoms
   c. Von Hippel-Lindau disease (see the chapter)
   d. Medullary cystic kidney disease
      i. Most commonly occurs as juvenile nephronophtisis
      ii. Associated with chronic renal failure in childhood
   e. Oral-facial-digital syndrome (see the chapter)
   f. Multicystic renal dysplasia in adults
      i. Usually a unilateral disorder
      ii. Frequent presence of calcification in the cyst walls and abnormal structure of parenchyma between the cysts visible on ultrasound
   g. Medullary sponge kidney: lithiasis and nephrocalcinosis commonly observed in the course of the disease
   h. Acquired cystic kidney disease

Diagnostic Investigations

1. Urinalysis
   a. Hematuria
   b. Mild proteinuria
   c. Evidence of infection
2. Sonography
   a. Prenatal presentation
      i. Large hyperechogenic kidneys
      ii. Variable size
      iii. Mixtures of small and large cysts
      iv. Exceptionally uncommon oligohydramnios
   b. Postnatal presentation: invariably large cysts
3. Renal ultrasound and IVP
   a. Enlarged kidneys
   b. Macrocysts and distortion of the collecting system
4. CT scan and/or MRI for renal, hepatic, pancreatic, and ovarian cysts
5. CT scan and/or MRI angiography for intracranial aneurysm
6. Renal function tests
7. Renal ultrasound to assess carrier status
   a. A painless and relatively noninvasive procedure
   b. Detection rate in asymptomatic subjects from families with known ADPKD
      i. Twenty-two percent of cases in the first decade
      ii. Sixty-six percent of cases by the second decade
      iii. Eighty-six percent by age 25
8. Molecular diagnosis (Harris and Rossetti 2010)
   a. Diagnosis of ADPKD before the onset of symptoms is usually performed using renal imaging by either ultrasonography, CT, or MRI. In general, these modalities are reliable for the diagnosis of ADPKD in older individuals.
   b. However, molecular testing can be valuable when a definite diagnosis is required in young individuals, in individuals with a negative family history of ADPKD, and to facilitate preimplantation genetic diagnosis.
   c. Although linkage-based diagnostic approaches are feasible in large families, direct mutation screening is generally more applicable.
   d. Identification and characterization of *PKD1* and *PKD2* provided an opportunity for mutation-based molecular diagnostics to be used for ADPKD. Mutations in *PKD1* account for ~85% of cases and cause more severe disease than mutations in *PKD2*.
   e. As ADPKD displays a high level of allelic heterogeneity, complete screening of both genes is required.
   f. Consequently, such screening approaches are expensive. Screening of individuals with ADPKD detects mutations in up to 91% of cases.
   g. However, only ~65% of patients have definite mutations, with ~26% having nondefinite changes that require further evaluation.
   h. Collation of known variants in the ADPKD mutation database and systematic scoring of nondefinite variants is increasing the diagnostic value of molecular screening.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Not increased in de novo case
      ii. Fifty percent if one of the parent is affected
   b. Patient's offspring
      i. Fifty percent risk of acquiring the disease
      ii. Both sexes of offspring affected equally
2. Carrier testing for family members at risk
   a. Ultrasound and radiography
   b. Molecular mutation analysis of *PKD1* and *PKD2* genes
3. Prenatal diagnosis
   a. Prenatal ultrasonography
      i. Enlarged kidneys (hyperechogenic) with or without cysts: the most common fetal findings
      ii. Absence of urine in the bladder
      iii. May not be evident until the third trimester
      iv. Evidence of uteroplacental insufficiency (Vora et al. 2008)
         a) Intrauterine growth restriction
         b) Oligohydramnios
   b. Molecular mutation analysis of *PKD1* and *PKD2* genes on fetal DNA obtained from amniocentesis or CVS, provided the mutation has been identified in the affected family members or linkage has been established in the family
   c. Preimplantation genetic diagnosis possible, provided the mutation has been identified previously
4. Management (Harris 2002)
   a. No treatment currently directed at the disease process
   b. Monitoring of presymptomatic patients with ADPKD
      i. Monitor blood pressure
      ii. Test renal function
      iii. Advantages
         a) Prevent or control hypertension
         b) Prevent or control infection
         c) Identify potential kidney donors from among the family
         d) Offer advice on reproduction
         e) Provide prenatal diagnosis
   c. Treatment of polycystic kidney disease
      i. Narcotic analgesics for pain
      ii. Antibiotics for infection
      iii. Treatment of nephrolithiasis
         a) Potassium citrate for uric acid lithiasis, hypocitric calcium oxalate nephrolithiasis, and distal acidification defects
         b) Extracorporeal shock wave lithotripsy
         c) Percutaneous nephrostolithotomy
      iv. Needle aspiration of dominant cysts
      v. Laparoscopic cyst decortication
      vi. Open renal cyst decortication
      vii. Therapeutic intervention aimed at slowing the progression of renal failure
         a) Control of hypertension
         b) Control of hyperlipidemia
         c) Dietary protein restriction
         d) Control of acidosis
         e) Prevention of hyperphosphatemia
      viii. Renal dialysis
      ix. Renal transplantation for end-stage renal disease
   i. Treatment of massive polycystic liver disease
      i. Aspiration of cyst fluid
      ii. Stenting
      iii. Cyst fenestration
      iv. Liver resection
      v. Liver transplantation
   j. Treatment of intracranial aneurysms
      i. Asymptomatic aneurysm
         a) Observation and yearly follow-up
         b) Surgery for enlarging aneurysm
      ii. Ruptured or symptomatic aneurysm: surgical clipping at its neck
   k. Management of aortic dissection
      i. Aortic root dilatation
         a) Yearly follow-up
         b) Strict blood pressure control with β-blockade
      ii. Surgery (replacement of the aorta) for aortic root greater than 55–60 mm

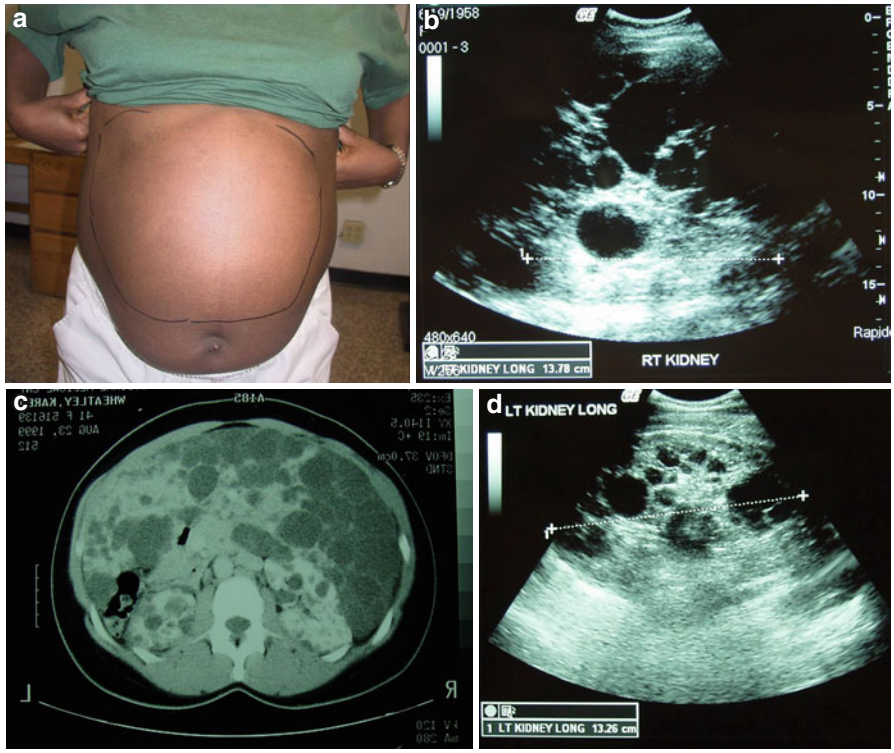

Fig. 1 A lady (**a**) with autosomal dominant polycystic kidney disease and with family history of multiple affected family members. Her liver was markedly enlarged as shown by a pencil mark on the patient's photo. The ultrasonography of the kidneys showed numerous cysts with minimal residual normal appearing cortex. The right kidney (**b**) measured 11 cm, with the largest cyst measuring 2.9 cm. The left kidney measured 13.3 cm in length, with the largest cyst measuring 3.8 cm (image not shown). The abdominal CT scan (**c**) showed marked hepatomegaly which occupies the entire abdomen. Numerous hepatic cysts and renal cysts were evident. Numerous cysts of different sizes were also detected in her brother's enlarged kidneys by ultrasonography (the *left* kidney is shown here on image **d**)

Polycystic Kidney Disease: Autosomal Recessive Type

Autosomal recessive polycystic kidney disease (ARPKD) or polycystic kidney and hepatic disease 1 (*PKHD1*) is an often devastating form of polycystic kidney disease. It is also known as infantile polycystic kidney disease. The incidence of ARPKD is estimated to be 1 in 20,000 live births, and the frequency of the heterozygous carrier state is 1 in 70 (Lonergan et al. 2000).

Synonyms and Related Disorders

Infantile polycystic kidney disease; Polycystic kidney and hepatic disease

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. No clear evidence of genetic heterogeneity
3. Molecular cause (Harris and Rossetti 2004)
   a. Mutations in the *PKHD1* gene on chromosome 6p21.1-p12, encoding a putative receptor protein, fibrocystin (or polyductin)
   b. The ARPKD protein, fibrocystin, is predicted to be an integral membrane, receptor-like protein containing multiple copies of an Ig-like domain (TIG).
   c. Fibrocystin is localized to the branching ureteric bud, collecting and biliary ducts, consistent with the disease phenotype, and often absent from ARPKD tissue.
   d. In common with other PKD-related proteins, fibrocystin is localized to the primary cilia of renal epithelial cells, reinforcing the link between ciliary dysfunction and cyst development.
   e. The majority of patients are compound heterozygotes, and preliminary genotype/phenotype studies associate two truncating mutations with severe disease.
   f. The complexities of *PKHD1*, marked allelic heterogeneity, and high level of missense changes complicate gene-based diagnostics.
4. Genotype-phenotype correlations (Denamur et al. 2010)
   a. All patients carrying two truncating mutations displayed a severe phenotype with perinatal or neonatal demise (Dell and Avner 2011).
   b. Patients who survive have at least one missense mutation.

Clinical Features

1. The most common heritable cystic renal disease manifesting in infancy and childhood (Lonergan et al. 2000)
2. A wide variable clinical spectrum, ranging from severe renal impairment, and a high mortality rate in infancy to older children and adolescents with minimal renal disease and complications of congenital hepatic fibrosis, cholangitis, and portal hypertension
3. Principal manifestations
   a. Fusiform dilatation of renal collecting ducts and distal tubuli
   b. Dysgenesis of the hepatic portal triad
4. Clinical characteristics at presentation
   a. Zero to 1 month
      i. Prenatal diagnosis made
      ii. Positive family history

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_194,

iii. Pneumothorax
iv. Flank mass
v. Hypertension
vi. Renal insufficiency

b. >1 month–1 year
i. Frank mass
ii. Hepatomegaly
iii. Hypertension
iv. Urinary tract infection

c. >1–5 years
i. Hepatomegaly
ii. Portal hypertension

d. >5 years
i. Hepatomegaly
ii. Hypertension
iii. Renal insufficiency
iv. Portal hypertension

e. Predominance of renal abnormalities in younger children

f. Predominance of hepatic disease in older children and adolescents

g. Tendency of inverse relative degrees of kidney and liver involvement
i. Children with severe renal disease usually with milder hepatic disease
ii. Children with severe hepatic disease with milder renal impairment

5. "Potter" phenotype developed in affected fetuses
a. Pulmonary hypoplasia, often incompatible with life
b. Characteristic face
i. Short and snubbed nose
ii. Deep eye creases
iii. Micrognathia
iv. Low-set flattened ears
c. Deformities of the spine and limbs (clubfoot)

6. Renal manifestations
a. Frequent loss of concentrating ability of the kidney
b. Common recurrent urinary tract infections
c. Proteinuria
d. Hematuria
e. Creatinine clearance improving early but declining progressively during adolescence
f. Hypertension early in life but usually regresses
g. Enlarged kidneys
h. End-stage renal disease

7. Hepatic manifestations
a. Congenital hepatic fibrosis
i. Invariably present but only occasionally do hepatic symptoms predominate
ii. Two predominant features characterizing the liver in ARPKD
a) Bile ducts: abnormally/irregularly formed, often increased in number, and dilated intrahepatic bile ducts
b) Portal tracts: enlarged and fibrotic
iii. Normal hepatic parenchyma
iv. Hepatocellular function almost always normal in affected patients, even when they have relatively severe portal tract disease.
v. Not by itself a diagnostic (not pathognomonic) sign. Congenital hepatic fibrosis has been observed in the following situations (Lonergan et al. 2000):
a) Meckel-Gruber syndrome
b) Vaginal atresia
c) Tuberous sclerosis
d) Juvenile nephronophthisis
e) Rarely autosomal dominant polycystic kidney disease

b. Caroli disease
i. Congenital hepatic fibrosis accompanied by a nonobstructive dilation of the intrahepatic bile ducts
ii. Clinical risk of secondary complications
a) Stone formation
b) Recurrent cholangitis: may result from ectatic bile ducts
c) Hepatic abscesses
d) Rare cholangiocarcinoma

c. Hepatomegaly

d. Portal hypertension (Lonergan et al. 2000)
i. The most common sequelae of congenital hepatic fibrosis
ii. Splenomegaly
iii. Variceal bleeding
iv. Hypersplenism
a) Leukopenia
b) Thrombocytopenia
c) Anemia
d) Increased susceptibility to infections resulting from leukopenia associated with splenic sequestration

e. Ascending cholangitis (Lonergan et al. 2000)
i. Presumably caused by entry of nonsterile gastrointestinal contents into the dilated intrahepatic bile ducts
ii. Common in patients with macroscopically dilated bile ducts

iii. Clinical features
a) Abdominal pain
b) Fever
c) Elevation in levels of hepatic enzymes
iv. Tends to recur
v. May lead to hepatic abscess formation, sepsis, and death

8. Cerebral aneurysm, a common feature of ADPKD, reported in an adult with ARPKD
9. Prognosis
a. Thirty to fifty percent of affected neonates die shortly after birth in respiratory insufficiency due to pulmonary hypoplasia.
b. Recent trend with improved prognosis
c. Sixty-seven percent of children who survive the newborn period with life-sustaining renal function at 15 years of age

Diagnostic Investigations

1. Radiography in neonates and infants with moderate to severe renal disease
a. Smoothly enlarged kidneys because of the numerous dilated collecting ducts
b. Abdominal distension
c. Gas-filled bowel loops often deviated centrally
d. Pulmonary hypoplasia and small thorax in the baby with severe kidney disease
e. Pneumothorax common at birth following assisted ventilation
2. Ultrasonography
a. Absence of renal cysts in both parents as demonstrated by ultrasound examination
b. Neonatal ultrasonography with more marked renal cystic disease
i. Massive enlarged kidneys
ii. Increased echogenicity of entire parenchyma
iii. Loss of corticomedullary differentiation
iv. Loss of central echo complex
v. Small macrocysts
vi. Usually small bladder
vii. Increased hepatic echogenicity, mainly in medulla
c. Ultrasonography in children with more prominent hepatic fibrosis
i. Massive kidney enlargement
ii. Increased hepatic echogenicity, mainly in medulla
iii. Macrocysts
a) Less than 2 cm in diameter
b) Tend to become larger and more numerous over time
iv. Enlarged echogenic liver
v. Hepatic cysts
vi. Pancreatic cysts
vii. Splenomegaly secondary to portal hypertension
viii. Hepatofugal-flow duplex and color-flow Doppler
3. CT scan
a. Nonenhanced CT: smooth, enlarged, and low-attenuating kidneys, likely the reflection of the large fluid volume in the dilated ducts
b. CT with contrast
i. Kidneys with a striated pattern representing accumulation of contrast material in the dilated tubules
ii. Linear opacifications representing retention of contrast medium in dilated medullary collecting ducts
iii. Macrocysts appearing as well-circumscribed rounded lucent defects
iv. Time of delay in visualizing the contrast medium in the kidneys, proportionate to the severity of renal impairment
4. Ultrasonography and magnetic resonance cholangiography to investigate the presence of an extent of Caroli disease in children with autosomal recessive polycystic kidney disease
5. MRI of affected children (perinatal, neonatal, and infantile course) (Kern et al. 1999)
a. Kidney appearance
i. Enlarged, humpy but still reniform in shape
ii. Homogeneously grainy parenchyma
b. Signal intensity
i. Hypointense on T1-W spin-echo sequences
ii. Hyperintense on T2-W turbo spin-echo sequences
c. RARE (rapid acquisition with relaxation enhancement)-MR-urography
i. Hyperintense, linear radial pattern seen in the cortex and medulla representing the characteristic microcystic dilatation of collecting ducts
ii. Possible few circumscribed small subcapsular cysts

6. Histopathology of the kidney
   a. Radially arranged cylindrical and fusiform ducts are present throughout renal medulla and cortex, due to a generalized dilatation of collecting ducts.
   b. The portal tracts of the liver are enlarged and contain abundant fibrous tissue and many cistern-like dilated bile ducts. The abnormal changes are the result of ductal plate malformation.
7. Molecular diagnosis
   a. Linkage analysis of the affected family using 6p21 markers demonstrating linkage to the *ARPKD1* gene with the affected proband
   b. 33 different mutations detected on 57 alleles (Rossetti et al. 2003)
      i. 51.1% in ARPKD
      ii. 32.1% in congenital hepatic fibrosis/(Caroli disease)
      iii. Two frequent truncating mutations
         a) 9689delA (9 alleles)
         b) 589insA (8 alleles)
      iv. Mutation detection rate
         a) High in severely affected patients (85%)
         b) Lower in moderate severe ARPKD (41.9%)
         c) Low, but significant, in adults with congenital hepatic fibrosis/Caroli disease (323.1%)
      v. Complications for the prospects for gene-based diagnostics
         a) Large gene size
         b) Marked allelic heterogeneity
         c) Clinical diversity of the ARPKD phenotype
   c. Direct DNA analysis: available clinically
      i. Mutation scanning
      ii. Sequence analysis
      iii. Targeted mutation analysis
      iv. Deletion/duplication analysis
      v. Linkage analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased (theoretical risk 0.7%)
2. Prenatal diagnosis
   a. Ultrasonography in most severely affected fetuses
      i. Enlarged, echogenic kidneys
      ii. Dilated collecting ducts
      iii. Characteristic hepatic ductal plate malformation
      iv. A small or nonvisualized bladder
      v. Oligohydramnios attributable to poor fetal renal output
      vi. Unreliable especially in early pregnancy
   b. Molecular genetic testing by mutation scanning of *PKHD1* is available clinically by analysis of fetal DNA obtained by amniocentesis or CVS. Both disease-causing alleles of an affected family member must be identified or linkage has been established in the family before prenatal testing can be performed. The ARPKD locus mapped to proximal chromosome 6p allowing haplotype-based prenatal diagnosis in "at-risk" family with a previously affected child in whom prior family studies have identified informative linked markers. An absolute prerequisite for these studies is an accurate diagnosis of ARPKD in the previously affected sib (Zerres et al. 1998b; Dell 2011).
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified.
3. Management (Dell 2011)
   a. Initial management of affected infants to focus on stabilization of respiratory function. Mechanical ventilation may be necessary to treat both pulmonary hypoplasia and respiratory compromise from massively enlarged kidneys.
   b. Water and electrolyte balance
   c. Peritoneal dialysis may be required for neonates with oliguria or anuria within the first days of life.
   d. Vigorous treatment of systemic hypertension with antihypertensive agents
      i. ACE inhibitors
      ii. Calcium channel blockers
      iii. Beta blockers
      iv. Judicious use of diuretics (e.g., thiazides, loop diuretics)
   e. Antibiotics for treatment of urinary tract infections

f. Management of renal osteodystrophy in children with ARPKD and chronic renal insufficiency
   i. Calcium supplements
   ii. Phosphate binders
   iii. 1,25-dihydroxyvitamin D3 to suppress parathyroid hormone (PTH)
   iv. Erythropoietin (EPO)
      a) Increases hemoglobin levels
      b) Improves the overall well-being of the child
g. Potential use of recombinant human growth hormone therapy to improve the growth of children with uremia
h. Therapeutic options available for the treatment of portal hypertension in children (Lonergan et al. 2000)
   i. Conservative management
   ii. Control of variceal bleeding
      a) Sclerotherapy effective in controlling bleeding
      b) Banding of varices
      c) Placement of portosystemic shunts occasionally necessary to reduce bleeding and the formation of additional varices
   iii. Prompt management with antibiotics and, when indicated, surgical drainage to help reduce morbidity and mortality associated with ascending cholangitis
   iv. Splenectomy for hypersplenism
   v. Liver transplantation in patients with severe hepatic dysfunction or chronic cholangitis
i. Replacement therapy for renal failure
   i. Renal dialysis
   ii. Renal transplant
j. Combined liver/kidney transplantation

Fig. 1 (**a**, **b**) A newborn with ARPKD showing Potter facies. The spongy appearing cut surface of a kidney from the same patient is due to generalized dilatation of the collecting ducts in both cortex and medulla

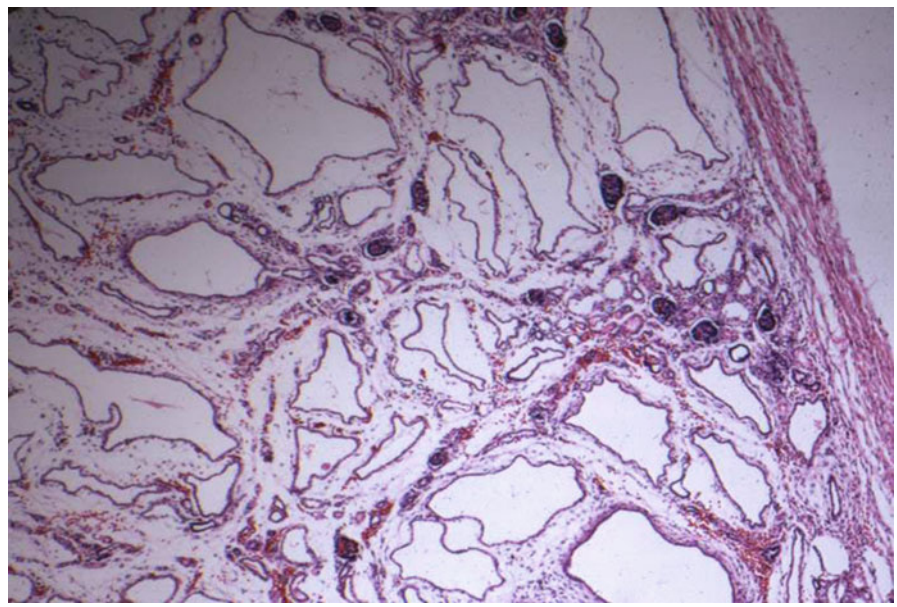

Fig. 2 Photomicrograph of a kidney of a neonate (37 weeks gestation) with ARPKD showing markedly dilated collecting ducts in the medulla (*top*) and the cortex (*bottom*). The infant also had intrahepatic bile duct proliferation and mild cystic changes, and pulmonary hypoplasia

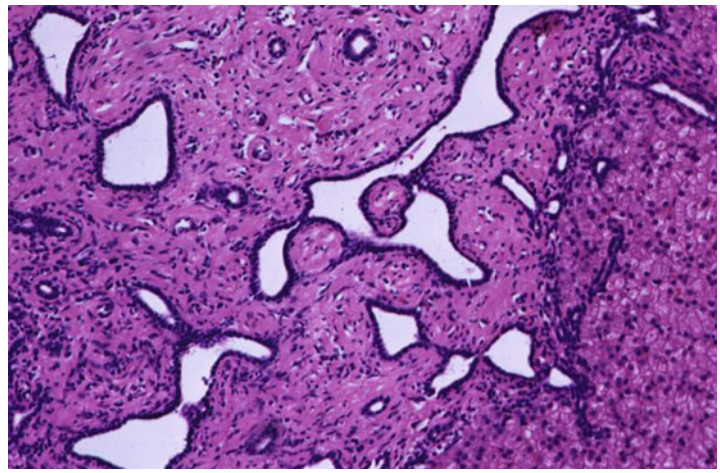

Fig. 3 Photomicrograph of the liver of a 2-year-old girl with congenital hepatic fibrosis, consistent with ARPKD. Note the irregularly dilated branching bile ducts. There is abundant fibrous connective tissue in this enlarged portal tract

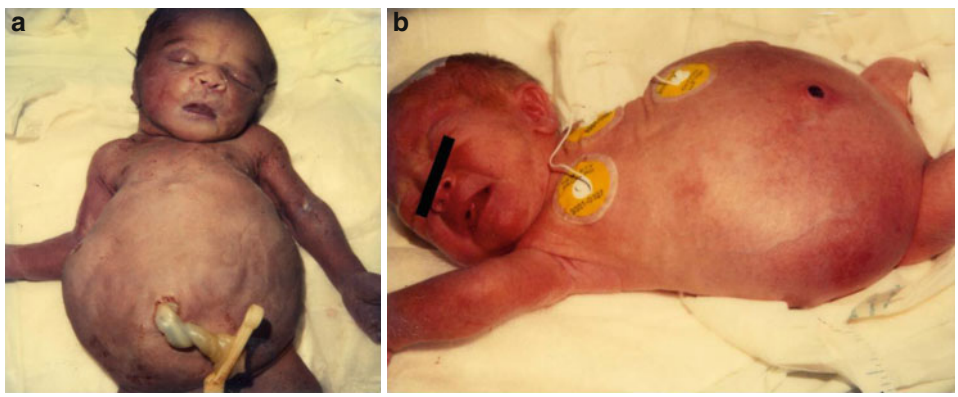

Fig. 4 (**a**, **b**) Two neonates with ARPKD showing markedly distended abdomen

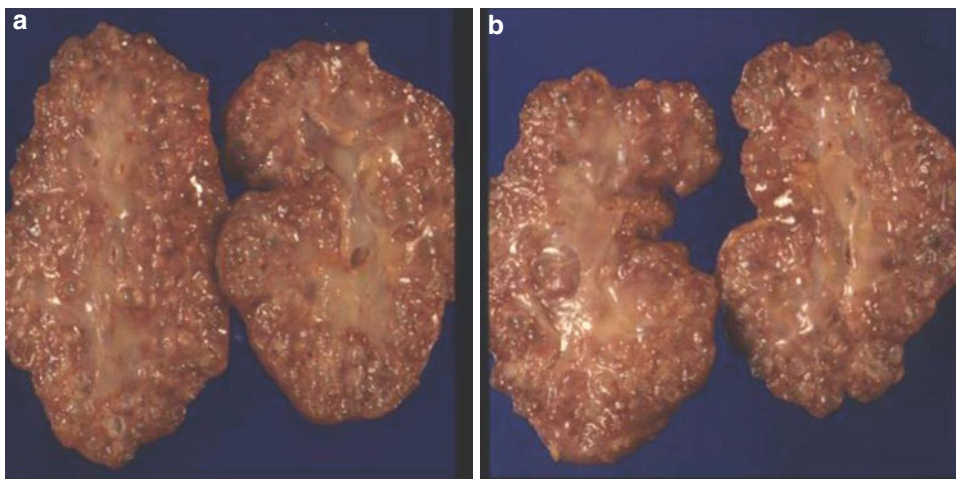

Fig. 5 (**a**, **b**) Kidneys in another neonate with ARPKD

Popliteal Pterygium Syndrome

In 1968, Gorlin et al. described an autosomal dominant form of popliteal pterygium syndrome (PPS), a syndrome comprising cleft lip and palate, popliteal and intercrural pterygia, and digital and genital anomalies. Van der Woude syndrome (VWS) is one of the most common oral cleft syndromes. It accounts for about 2% of all cleft lip and palate cases. Both syndromes are caused by *IRF6* mutations.

In 1972, Bartsocas and Papas reported on four sibs of third-cousin parents with a severe, presumably autosomal recessive form of popliteal pterygium syndrome.

Synonyms and Related Disorders

Bartsocas-Papas syndrome; *IRF6*-Related Disorders including Van der Woude syndrome

Genetics/Basic Defects

1. Interferon regulatory factor 6 (*IRF6*) encodes a member of the IRF family of transcription factors (de Lima et al. 2009)
2. Mutations in *IRF6* cause popliteal pterygium syndrome and Van der Woude syndrome.
3. Popliteal pterygium syndrome
   a. Inherited as an autosomal dominant trait
   b. Exonic mutations in *IRF6* are found in nearly all families with PPS (De Lima et al. 2009).
4. Van der Woude syndrome
   a. Inherited as an autosomal dominant trait with high penetrance (96.7%) but with variable expression
   b. A nonsense mutation in the interferon regulatory factor 6 (*IRF6*) gene in the affected sib of two monozygotic twins discordant for VWS, suggesting *IRF6* as a candidate for VWS (Kondo et al. 2002)
   c. This hypothesis was confirmed in the same study by the detection of *IRF6* mutations in 45 additional unrelated families with VWS. In addition, a unique set of mutations in *IRF6* was discovered in 13 families with PPS, demonstrating that VWS and PPS as allelic, as previously suggested (Lees et al. 1999).
   d. Subsequently, mutations in *IRF6* were identified in 56 additional families with VWS and three with PPS (de Lima et al. 2009).
   e. Exonic mutations in *IRF6* are found in 68% of families with VWS.
5. Bartsocas-Papas syndrome (BPS)
   a. Inherited as an autosomal recessive trait
   b. Early lethality
   c. *IRF6* mutation has not been studied in BPS.

Clinical Features

1. Autosomal dominant popliteal pterygium syndrome
   a. Cleft lip with or without cleft palate
   b. Fistula of the lower lip
   c. Filiform synechiae may connect the upper and lower jaws (syngnathia) or the upper and lower eyelids (ankyloblepharon).
   d. Webbing of the skin extending from the ischial tuberosities to the heels
   e. Bifid scrotum and cryptorchidism in males
   f. Hypoplasia of the labia majora in females

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_195,
© Springer Science+Business Media, LLC 2012

g. Syndactyly of fingers and/or toes
h. Anomalies of the skin around the nails: A characteristic pyramidal fold of skin overlying the nail of the hallux is almost pathognomonic.
i. Normal growth and intelligence

2. Van der Woude syndrome (Gorlin et al. 2001)
   a. Congenital lower-lip fistulae (pits)
      i. Usually bilateral and paramedian
      ii. The phenotype of the lower lip varies from a single barely evident depression to bilateral fistulae of the lower lip.
      iii. Phenotypes of the orofacial cleft vary from a bifid uvula to a complete cleft lip and palate.
   b. Cleft lip with or without cleft palate and cleft palate only
   c. Hypodontia
   d. Less common features
      i. Syndactyly of the fingers
      ii. Syngnathia
      iii. Ankyloblepharon
   e. Normal growth and intelligence
3. Autosomal recessive Bartsocas-Papas syndrome
   a. Oral clefts
   b. Filiform bands between jaws
   c. Ankyloblepharon
   d. Popliteal pterygium
   e. Syndactyly of fingers and toes
   f. Phalangeal anomalies such as hypoplasia and/or synostosis
   g. Nail hypoplasia
   h. Genital anomalies in both sexes
   i. Early lethality is common
   j. Causes of death
      i. Bronchopneumonia
      ii. Respiratory distress
      iii. Sepsis

Diagnostic Investigations

1. Histology of popliteal pterygium (Gorlin et al. 1968)
   a. Bilateral pterygium extending from the heel to the ischial tuberosity
   b. Limiting extension and abduction as well as rotation of the leg
   c. A hard, inelastic subcutaneous cord or fibrous band runs along the free edge of the pterygium
   d. The sciatic nerve lies free within the pterygium deep to the fibrous band about halfway between the free edge and the apex being covered by fibromuscular septa.
   e. The popliteal vessels are normally situated deep in the popliteal space.
   f. Absence of muscle groups or abnormal muscle insertions in many cases
2. Molecular genetic testing by sequence analysis of the *IRF6* coding region (exons 1–9) (Durda et al. 2011)
   a. Detects mutations in approximately 70% of individuals with the Van der Woude syndrome phenotype
   b. Detects mutations in approximately 97% of individuals with the popliteal pterygium syndrome phenotype

Genetic Counseling

1. Recurrence risk for autosomal dominant *IRF6*-related disorders
   a. Patient's sib
      i. Appears to be low when parents are clinically unaffected, but the possibility of incomplete penetrance in a parent or of germline mosaicism need to be considered
      ii. Fifty percent if a parent of the proband is affected or has an *IRF6* mutations
   b. Patient's offspring
      i. Each child of an individual with an *IRF6* mutation has a 50% chance of inheriting the mutation.
      ii. The clinical manifestations of *IRF6*-related disorders are variable and cannot be predicted in the offspring.
2. Prenatal diagnosis
   a. Ultrasonography
      i. Oral cleft
      ii. Popliteal pterygium
   b. Molecular genetic testing
      i. Prenatal diagnosis for pregnancies at increased risk is possible if the disease-causing allele of an affected family member is previously identified.
      ii. Preimplantation genetic diagnosis: may be available for families in which the disease-causing mutation has been identified in an affected family member

3. Management (Gahm et al. 2007)
   a. Early surgical treatment is of importance to enable and preserve oral feeding.
   b. Intranasal flexible fiber intubation with the patient awake is a possible anesthetic strategy to secure the airway prior to surgery in patients with multiple or extensive interalveolar syngnathia.
   c. Surgical removal for synechiae
   d. Cleft lip/cleft palate: surgical and orthodontic management
   e. Speech therapy and audiologic evaluation for cleft palate
   f. Surgery for lip pits for cosmetic purpose
   g. Syndactyly may require surgery.
   h. To accomplish knee extension (Gardetto and Piza-Katzer 2003)
      i. Resect fibrous bands
      ii. Free the sciatic nerve
      iii. Z-lengthening of the Achilles tendon and multiple Z-plasties
      iv. Surgery result: 1 year after surgery, the patient can put his heel on the ground and has almost complete range of motion in the knee and ankle joints.
   i. Orthopedic care and physical therapy may be needed.

Fig. 1 (**a**–c) The newborn was evaluated for multiple congenital anomalies, consisting of ankyloblepharon connecting upper and lower eyelids by fimbria (thin thread-like connective tissue), unilateral cleft lip and palate, thin strings of connective tissue connecting the upper and lower alveolar ridge on both sides, absence of labia majora, hypoplastic labia minor, a clitoral hood, a sacral dimple, popliteal pterygium (webbing of the skin extending from the ischial tuberosities to the heels), skin over the nails of her great toes giving the nail a somewhat triangular shape with a flat base, and syndactyly over second to fifth toes bilaterally. The clinical diagnosis of popliteal pterygium syndrome was confirmed by molecular genetic analysis of *IRF6* gene which showed a missense mutation of exon 4 [c252G > A or p.Arg841His (R84H)]

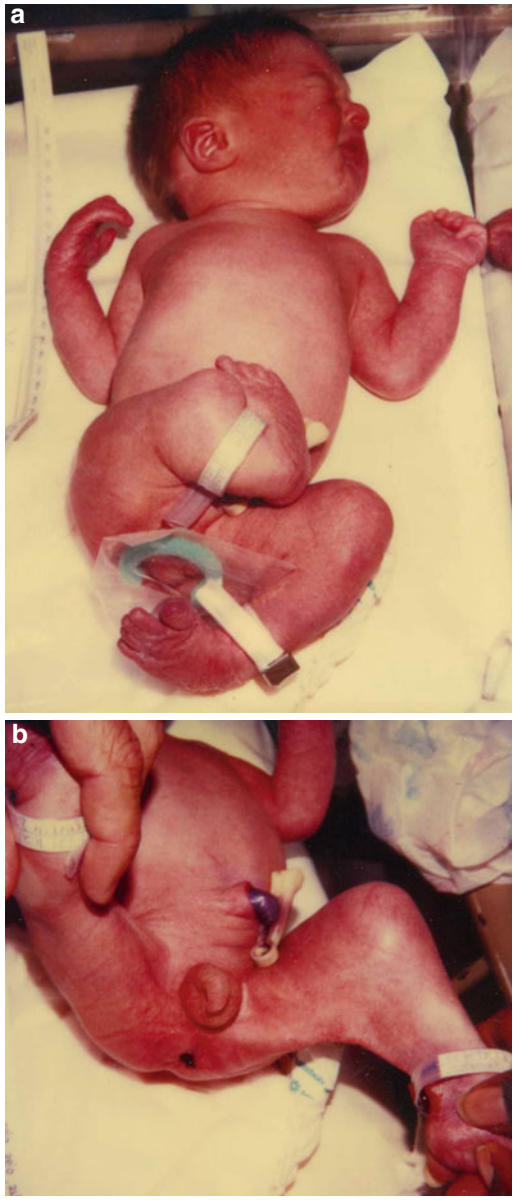

Fig. 2 (**a**, **b**) Another baby with popliteal pterygium syndrome

Prader–Willi Syndrome

Prader–Willi syndrome is a neurogenetic disorder characterized by hypotonia and feeding difficulties in infancy, followed by hyperphagia, hypogonadism, mental retardation, and short stature. It was the first recognized microdeletion syndrome identified with high-resolution chromosome analysis, the first recognized human genomic imprinting disorder, and the first recognized disorder resulting from uniparental disomy. The incidence of Prader–Willi syndrome is approximately 1/10,000–1/15,000 individuals.

Genetics/Basic Defects

1. Inheritance
   a. Usually sporadic events (de novo deletions of 15q11–q13)
   b. Rare familial transmission (balanced translocations involving 15q11–q13) (<1%)
2. A contiguous gene syndrome involving multiple paternally expressed genes
3. Caused by the lack of expression of normally active paternally inherited genes at chromosome 15q11–q13 because of a phenomenon called genomic imprinting
   a. The relevant region on chromosome 15q11–q13: normally expressed on the paternally derived chromosome and imprinted on maternally derived chromosome
   b. The imprinted maternal allele is unable to produce functional protein since the normally expressed paternal copy is often deleted in Prader–Willi syndrome.
4. Molecular subclassification of Prader–Willi syndrome: All involving loss of paternal gene expression from chromosome 15q11–q13 (Buiting 2010)
   a. Paternal deletion 15q11–q13 (de novo) (70% of cases: microdeletion of the actively transcribed segment on the paternally derived chromosome 15q11–q13
   b. Maternal uniparental disomy (UPD15) (25–30% of cases)
      i. Inheritance of two copies of the maternal chromosome without paternal contribution
      ii. In normal individuals, the paternally donated chromosome expresses multiple genes in the Prader–Willi syndrome region while the maternal chromosome is largely silent.
      iii. In case of maternal uniparental disomy, without the presence of a chromosome donated from the father, normal imprinting on the two maternally donated chromosomes leads to the absence of gene expression in this region.
   c. Mutation in the imprinting control center
      i. Deletion of the imprinting center (1% of the cases) of the *SNRPN* (*s*mall *n*uclear *r*ibonucleoprotein *p*olypeptide *N*) gene causing inability to establish the normal methylation status
      ii. Without imprinting center deletion (One percent of cases)

Clinical Features

1. Neonatal presentation
   a. Central hypotonia in infancy
   b. Poor feeding/sucking

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_196,
© Springer Science+Business Media, LLC 2012

   c. Poor weight gain (failure to thrive)
   d. Genital hypoplasia/hypogonadism
   e. Diminished deep tendon reflexes
   f. Abnormal squeaky weak cry
   g. History of fetal inactivity (in utero hypotonia)
2. Developmental delay
3. Mild dysmorphic features
   a. Almond-shaped eyes
   b. Dolichocephaly
   c. Narrow bifrontal diameter
   d. Narrow nasal bridge
   e. Small mandible
   f. Small mouth
   g. High-arched palate
   h. Down-turned lips
   i. Thick viscous saliva
4. Hyperphagia after the 1st–2nd postnatal years
5. Severe obesity without significant intervention
6. Retinal hypopigmentation
7. Small hands and feet (acromicria)
8. Mild to moderate mental retardation
9. Hypothalamic insufficiency suggested by several autonomic dysfunctions that affect appetite regulation, growth, pubertal development, control of breathing, and alertness
10. Behavioral and psychiatric difficulties
    a. Excessive food-seeking behaviors
    b. Obsessions
    c. Compulsions
    d. Mood lability
    e. Depression
11. Other manifestations
    a. Infantile lethargy
    b. Sleep disturbance and/or sleep apnea
    c. Short stature
    d. Hypopigmentation
    e. Skin sores from constant picking
    f. Esotropia/myopia
    g. Speech articulation defects
    h. High pain threshold
    i. Ineffective thermoregulation
    j. Early adrenarche
    k. Osteoporosis
    l. Kyphoscoliosis
12. Prognosis
    a. Obesity: the major cause of morbidity and mortality
    b. Cardiopulmonary compromise (Pickwickian syndrome) resulting from excessive obesity
    c. Most common causes of death: respiratory insufficiency or infections (Tauber et al. 2008)
13. Diagnostic criteria (adapted from Holm et al. 1993): five points for children under 3 years (three from major criteria); eight points for children above 3 years (four from major criteria)
    a. Major Criteria (one point each)
       i. Infantile central hypotonia
       ii. Infantile feeding problems/failure to thrive
       iii. Rapid weight gain between 1 and 6 years
       iv. Characteristic facial features
       v. Hypogonadism (genital hypoplasia, pubertal deficiency)
       vi. Developmental delay/mental retardation
    b. Minor Criteria (1/2 point each)
       i. Decreased fetal movement and infantile lethargy
       ii. Typical behavioral problems
       iii. Sleep disturbance/sleep apnea
       iv. Short stature for the family by age 15 years
       v. Hypopigmentation
       vi. Small hands and feet for height age
       vii. Narrow hands with straight ulnar border
       viii. Esotropia/myopia
       ix. Thick viscous saliva
       x. Speech articulation defects
       xi. Skin picking
    c. Supportive Criteria (no points)
       i. High pain threshold
       ii. Decreased vomiting
       iii. Temperature control problems
       iv. Scoliosis/kyphosis
       v. Early adrenarche
       vi. Osteoporosis
       vii. Unusual skill with jigsaw puzzles
       viii. Normal neuromuscular studies

Diagnostic Investigations

1. Cytogenetic studies
   a. Microscopic or submicroscopic del(15)(q11–q13) confirmed by fluorescence in situ hybridization (FISH probe for *SNRPN*) (60–80%)
   b. Paternally derived chromosome 15 that is deleted

c. De novo events in most cases with cytogenetically normal father's chromosomes
d. Balanced chromosomal rearrangement with break in 15q11–q13 (<1%)

2. Molecular analyses
   a. Uniparental disomy identified by using microsatellite repeat sequences of chromosome 15 in the patient and both parents
      i. Maternal uniparental disomy for chromosome 15 in most of nondeletion cases (20–40%)
      ii. Inheriting both copies of chromosome 15 from the mother
      iii. Absence of the paternally inherited copy of chromosome 15q11–q13
   b. Rare familial Prader–Willi syndrome: associated with very small mutations in 15q11–q13 region leading to the loss of expression of multiple genes from the paternal chromosome
   c. DNA methylation analyses (by Southern blotting and PCR) of the *SNRPN* or PW71 (D15S63) loci to detect absence of paternal methylation patterns on the basis of deletion, uniparental disomy, or defective methylation: detects over 99% of cases and is highly specific
   d. Imprinting defect (Cassidy and Schwartz 2009)
      i. Presumed to be present in individuals with an abnormality in the parent-specific methylation imprint without evidence of a deletion of UPD (Ohta et al. 1999)
      ii. Imprinting defects caused by microdeletions are detected using sequence analysis or MLPA of the PWS-SRO (smallest region of overlap)
      iii. Most imprinting defects are epimutations (i.e., alterations in the imprint, not the DNA) and cannot be detected by sequence analysis (Buiting et al. 1998; Buiting et al. 2003; Horsthemke and Buiting 2006)

Genetic Counseling

1. Recurrence risks (Cassidy and Schwartz 2009; Buiting 2010)
   a. Patient's sib
      i. De novo deletion or maternal uniparental disomy in an affected child: a low recurrence risk (≤1% due to possible paternal balanced insertion or gonadal mosaicism)
         a) Imprinting center mutation in an affected child
         b) No imprinting center deletion: <1%
      ii. With imprinting center deletion: up to 50% recurrence risk
      iii. Apparently de novo balanced chromosome translocation breaking within the PWS/AS critical region: <1%
      iv. Presence of a parental balanced chromosomal rearrangement: up to 25% recurrence risk
   b. Patient's offspring (Cassidy and Schwartz 2009)
      i. With rare exception, individuals with PWS do not reproduce.
      ii. The risk to the child of an affected individual depends on the etiology of the absence of the paternally derived PWS critical region and the sex of the affected individual.
      iii. If the proband has PWS as the result of a deletion, the offspring have a 50% risk of having Angelman syndrome (AS) if the proband is female (reported once) and PWS if the proband is male (never reported).
      iv. If the proband has UPD, there is a theoretical risk of the offspring inheriting two chromosomes 15 from the proband, which could lead to: (1) fetal demise if trisomy rescue does not occur, (2) PWS if the proband is female, and (3) AS if the proband is male. None of these possibilities have been reported. There is a single report of a female with PWS caused by UPD having a normal child (Schulze et al. 2001).
      v. If the proband has PWS as the result of an imprinting mutation, the offspring have a theoretical risk of ≤50% of having PWS (never reported).
      vi. If the proband has a chromosomal translocation, there is a theoretical increased risk to offspring of having PWS or AS, depending on the sex of the proband (never reported).
2. Prenatal diagnosis
   a. High-risk pregnancies
      i. Parents who have had a previous child with Prader–Willi syndrome, caused by deletion or uniparental disomy, are not routinely

offered prenatal testing in subsequent pregnancies but could be offered such testing for assurance.
   ii. Parents who have had a previous child with Prader–Willi syndrome, caused by a defect in the imprinting control center, should be offered prenatal testing because of the high recurrence risk; methylation analysis can also be used in these cases.
   iii. Prenatal testing for an inherited translocation involving chromosome 15 and resulting in a deletion is relevant because of the theoretical 25% risk of Prader–Willi syndrome in the offspring.
b. PWS may be a possibility for low-risk pregnancies in which no family history of Prader–Willi syndrome exists
   i. Cytogenetic study to detect del(15q11–q13) from amniocytes or CVS cells, complemented by FISH probe: Parent-of-origin studies should be performed after confirmation of a deletion to determine if the deletion is paternally derived (fetus has PWS). (If the deletion is maternally derived, the fetus has Angelman syndrome.)
   ii. If trisomy 15 or mosaic trisomy 15 is detected on CVS, and if subsequent amniocentesis reveals 46 chromosomes, the possibility of trisomy rescue leading to PWS (maternal UPD) through loss of a parental chromosome 15 [or leading to Angelman syndrome (maternal UPD) through loss of a maternal chromosome 15] can be considered. In this instance, parent-of-origin (UPD) studies or methylation analysis on amniocytes should be considered (European Collaborative Research on Mosaicism in CVS 1999; Shaffer et al. 2001).
   iii. If an inherited or de novo translocation involving chromosome 15 is present or if a supernumerary chromosome derived from chromosome 15 is detected, FISH (to rule out a deletion) and parent-of-origin studies (to rule out the possibility of UPD) are indicated.
c. Molecular studies of uniparental disomy 15 using microsatellite dinucleotide polymorphism analysis of amniocytes and parental DNA
d. DNA methylation analysis of amniocytes

3. Preimplantation genetic diagnosis (PGD)
   a. May be available for families in which a mutation in the imprinting control element has been identified
   b. Also can be used in cases of familial translocation to rule out UPD
4. Management
   a. Manage feeding problems with special nipples or gavage feeding if needed to assure adequate nutrition, to avoid failure to thrive, and to improve hypotonia
   b. Early intervention programs with speech, physical, and occupational therapies after careful educational, behavioral, and psychological assessments
   c. Dietary control
      i. Monitoring of weight and nutritional counseling
      ii. Low-calorie and well-balanced diet combined with a regular exercise program
      iii. Limit access to food
      iv. Close supervision to minimize food stealing
   d. Management of endocrine problems
      i. Growth hormone treatment improves growth, physical phenotype, and body composition (Cassidy and Driscoll 2009).
      ii. Testosterone treatment in males to improve changes in voice and body hair, beard growth, genital size, body mass and strength, and self-image
      iii. Treatment with estrogen, cycling hormones, or birth control pills in females has resulted in increasing breast size and menstrual periods.
   e. Management of scoliosis as in the general population
   f. Behavioral management
      i. Firm limit setting and enforcement
      ii. Consult with a behavioral psychologist or other behavior specialist for behavioral management programs
   g. Psychiatric management
      i. Psychosis
      ii. Manic-depressive illness
      iii. Obsessive-compulsive disorder
   h. Treatment of complications resulting from excessive obesity
      i. Cardiopulmonary compromise
      ii. Type II diabetes mellitus
      iii. Thrombophlebitis
      iv. Management of skin picking, chronic skin changes, and peripheral edema

Fig. 1 A 10-month-old girl with Prader–Willi syndrome showing severe hypotonia, strabismus, and small hands and feet. Parent-of-origin specific DNA methylation studies at 15q11–q13 for Prader–Willi syndrome revealed the presence of maternal 4.2 kb hybridization band only but not paternal 0.9 kb band consistent with Prader–Willi syndrome. Uniparental disomy DNA analysis revealed that the patient has only maternal alleles based on the Mendelian inheritance of two informative markers (D15S205 and D15S1002) and two partial informative markers (D15S130 and D15S1007), indicative of uniparental disomy for chromosome 15

Fig. 2 A 17-month-old boy with Prader–Willi syndrome showing severe hypotonia. Methylation-specific PCR using SNRPN flanking primers revealed absence of paternal SNRPN and presence of maternal SNRPN, confirming the diagnosis of Prader–Willi syndrome

Fig. 3 An infant with Prader–Willi syndrome [del(15)(q11–q13)] showing hypotonia and failure to thrive

Fig. 4 (**a**, **b**) A girl with Prader–Willi syndrome [del(15)(q11–q13)] showing obesity, short stature, almond-shaped eyes, and small hands and feet

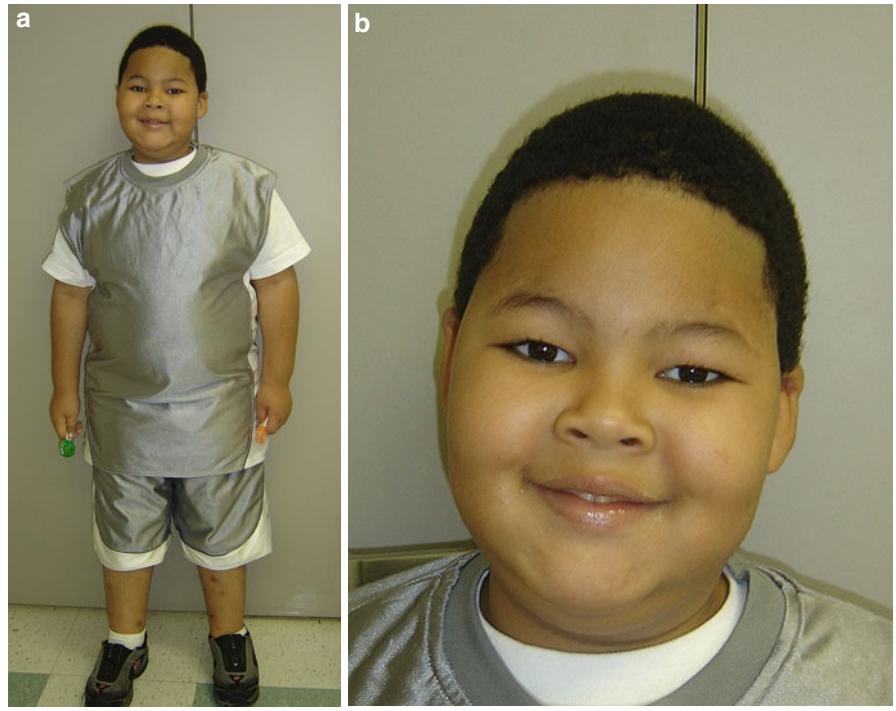

Fig. 5 (**a**, **b**) A boy with Prader–Willi syndrome [del (15)(q11–q13)] showing obesity, almond-shaped eyes, and bitemporal narrowing

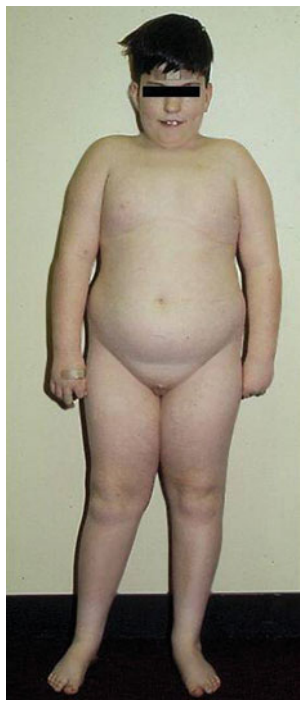

Fig. 6 A boy with Prader–Willi syndrome [del(15)(q11–q13)] showing almond-shaped eyes, bitemporal narrowing, obesity, hypogenitalism, and small hands and feet

Fig. 7 (**a**, **b**) A girl with Prader–Willi syndrome [del (15)(q11–q13)] showing extreme obesity, characteristic facial appearance, small hands and feet, and multiple skin sores from constant picking

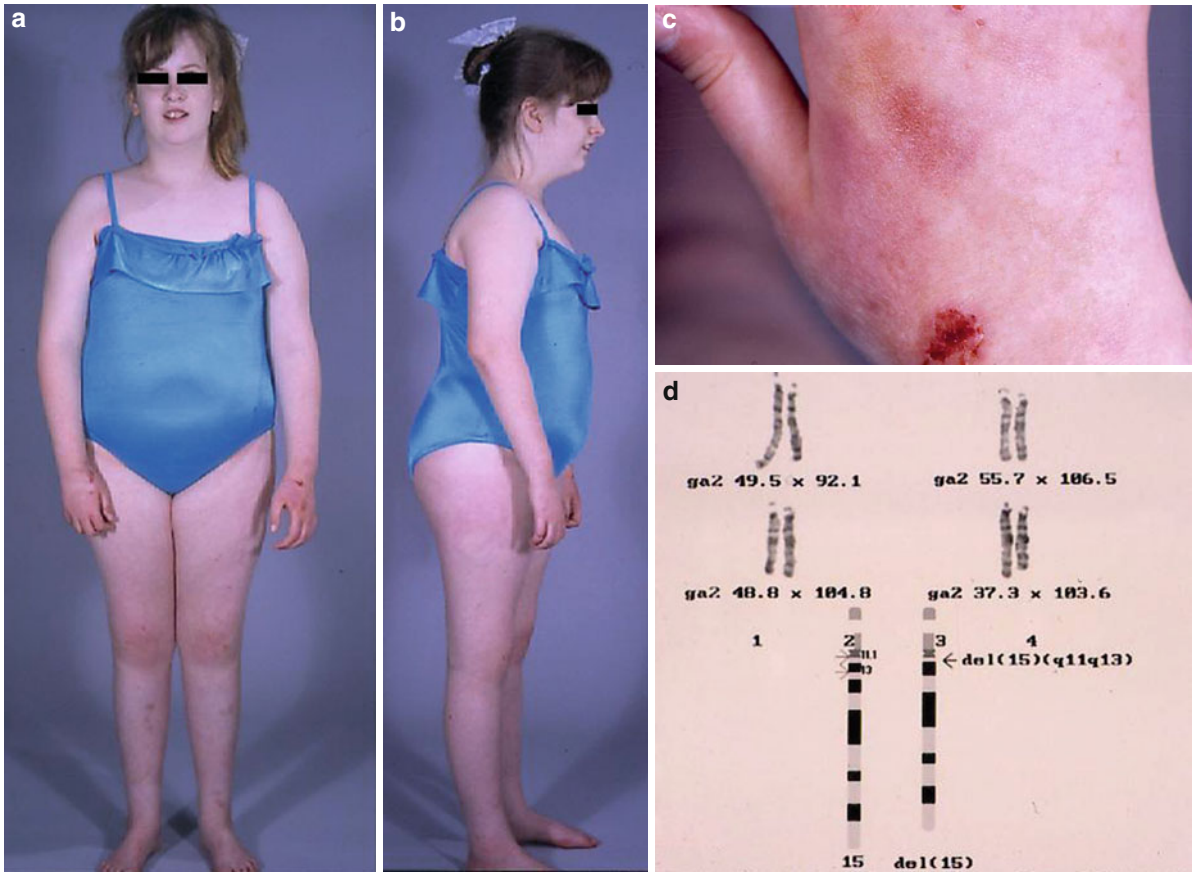

Fig. 8 (**a**–**d**) A patient with Prader–Willi syndrome [del(15)(q11–q13)] (shown by partial karyotypes and ideogram) and trimethylaminuria showing sores on the skin

Fig. 9 A woman with Prader–Willi syndrome [del(15)(q11–q13)] and neurofibromatosis 1 showing obesity and axillary freckles

Progeria

In 1886, Hutchinson described a boy with congenital alopecia, wrinkled atrophic skin, an odd facies, joint contractures, and normal intelligence. Subsequently in 1904, Gilford reported a second patient with similar features and suggested the term progeria, from the Greek word *geras* meaning old age, to describe the premature senile characteristics of the patients. Thus, the syndrome is also known as Hutchinson–Gilford progeria syndrome (HGPS).

Progeria is an extremely rare condition with characteristic clinical findings of premature and accelerated aging. Its incidence was estimated to be one per eight million live births in the United States. Male to female ratio is about 1.5–1. Most reported patients are Caucasians (Badame 1989).

Synonyms and Related Disorders

Hutchinson–Gilford progeria syndrome

Genetics/Basic Defects

1. Inheritance: autosomal dominant inheritance
   a. Advanced paternal age effect observed
   b. Germinal mosaicism responsible for rare instances of affected sibs
2. Basic defects
   a. Caused by mutations in lamin A (*LMNA*) gene
      i. *LMNA* gene encodes two protein products, lamin A/C (lamin A and lamin C), representing major constituent of the inner nuclear membrane lamina.
      ii. Mutations in *LMNA*.
         a) About 90% of patients have an identifiable mutation.
         b) Most common mutation: a de novo single-base substitution, G608G (GGC > GGT) in exon 11. G608G mutation responsible for the majority of progeria arises in the paternal germline (D'Apice et al. 2004)
         c) A second mutation in the same codon, G608S (GGC > AGC)
         d) E145K (exon 2) observed in a phenotypically unusual HGPS
      iii. Mutations in *LMNA* also cause the following different recessive and dominant disorders (Eriksson et al. 2003):
         a) Emery–Dreifuss muscular dystrophy type 1 (EMD1) (autosomal dominant)
         b) Emery–Dreifuss muscular dystrophy type 2 (EMD2) (autosomal recessive)
         c) A familial dilated cardiomyopathy and conduction system defects (CMD1A) (autosomal dominant)
         d) Dunnigan-type familial partial lipodystrophy (FPLD) (autosomal dominant)
         e) Limb-girdle muscular dystrophy type 1B (LGMD1B) (autosomal dominant)
         f) Charcot–Marie–Tooth disorder type 2B1 (CMT2B1) (autosomal recessive axonal neuropathy)
         g) Mandibuloacral dysplasia (MAD) (autosomal recessive)
   b. Hutchinson–Gilford progeria syndrome gene localized to chromosome 1q by observing two

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_197,
© Springer Science+Business Media, LLC 2012

cases of uniparental isodisomy of 1q and one case with a 6-megabase paternal interstitial deletion (Eriksson et al. 2003)

c. Increased hyaluronic acid production by progeric fibroblasts postulated as the underlying metabolic abnormality in progeria
   i. Urinary excretion of hyaluronic acid found to be increased in some patients.
   ii. Elevated levels of hyaluronic acid may result in growth failure and accelerated senescence by inhibiting the growth of blood vessels.
d. Accumulation of type IV collagen due to an interaction between activated T lymphocytes and fibroblasts
e. Current results of microarray analysis: further support the notion that patients with progeria experience an accelerated form of aging
f. Reduced growth capacity in vitro in the skin fibroblasts from progeria patients with conflicting evidence on whether progeric cells can repair single-strand DNA breaks induced by X- or gamma-irradiation
g. Fibroblasts from progeric tissue (Ackerman and Gilbert-Barness 2002)
   i. Inability to subculture
   ii. Having short telomeres
   iii. Uncertain as to whether aging is the consequence of shortened telomeres with reduced cell replication, impaired telomerase activity, or the culmination of the effects of reactive oxygen species
h. Del(1)(q23) reported in a patient with Hutchinson–Gilford progeria
i. Inv ins(1;1)(q32;q44q23) reported in the postmortem skin biopsy specimens from identical twins raising the possibility that a gene for progeria may be located at the break point site of the inserted chromosome segment

Clinical Features

1. General features (Ackerman and Gilbert-Barness 2002)
   a. Normal appearance at birth
   b. Normal intelligence and personality
   c. High-pitched voice
2. Growth
   a. Profound growth failure/failure to thrive starting around 6 months to 1 year of age
   b. Extreme short stature
   c. No rapid growth during puberty
   d. Markedly diminished subcutaneous fat, especially on the face and limbs
   e. Absent sexual maturation
3. Skin
   a. Unremarkable at birth
   b. Generalized nonpitting edema suggestive of scleroderma shortly after birth
   c. "Sclerodermatous" skin over lower abdomen and proximal thighs, in which irregular bumps give appearance of lipodystrophy
   d. Becoming thin, dry, taut, and shiny in some areas, but lax and wrinkled in others, most commonly over the fingers and toes, by the second year
   e. Striking loss of subcutaneous tissue
   f. Prominent venous pattern
   g. Easy bruising
   h. Diminished eccrine sweating in some cases
   i. Progressive freckle-like hyperpigmentation (most evident in sun-exposed areas) and thickened sclerotic areas (usually on the lower parts of the trunk or thighs) after several years
4. Hair
   a. Partial alopecia progressing to generalized alopecia often beginning at birth or in the first year and becoming prominent by the end of the second year
   b. Few remaining hairs: white or blond, fine, and fuzzy
   c. Body hair as well as scalp and facial hair: equally affected
5. Nails
   a. Short, thin, and dystrophic fingernails and toenails
   b. Koilonychia (spoon nails)
   c. Onychogryposis (deformed overgrowth of the nails)
6. A striking facies after few months of life
   a. Typical "plucked bird" appearance related to disproportionate craniofacial growth
   b. Disproportionately large cranium
   c. Relatively small face
   d. Prominent eyes

e. Prominent scalp veins
f. Sparse to absent scalp hair (alopecia, balding, hypotrichosis)
g. Absent eyebrows and eyelashes
h. Thin lips
i. Circumoral cyanosis
j. Protruded ears with absent earlobes
k. "Beaked," pinched nose with sculptured tip
l. Micrognathia

7. Teeth (Yu and Zeng 1991)
   a. Anodontia/hypodontia, especially permanent teeth
   b. Delayed and incomplete dentition
   c. Discoloration (yellowish brownish)
   d. Crowded, rotated, displaced, overlapped, and maloccluded, especially the anterior teeth
   e. High incidence of caries
   f. Poor oral hygiene/gingivitis
   g. Irregularity in size and shape of the odontoblasts
   h. Delayed in ossification of the crown of the permanent teeth
   i. Narrow pulp chambers and root canals
   j. Reticular atrophy of pulp
   k. Calcification along the nerve fibers and the vascular walls
   l. Irregular width of predentin, secondary dentin and cementum
   m. Osteoclastic resorption at apical portion
   n. Incomplete formation of roots of deciduous molars
8. Endocrine manifestations
   a. Incomplete sexual maturation
   b. Occasional hypoplastic nipples
9. Cardiovascular disease
   a. Premature severe atherosclerosis
   b. Premature coronary artery disease
   c. Death from coronary artery disease frequent and may occur before 10 years of age.
   d. Angina pectoris
   e. Myocardial infarction
   f. Congestive heart failure
   g. Epidural hematoma formation after a mild head injury possibly due to progressive atherosclerosis of intracranial vessels
10. Musculoskeletal abnormalities
    a. Generalized osteoporosis with pathologic fractures
    b. Marked delay in bone healing after fractures
    c. Short/dystrophic clavicles
    d. Coxa valga
    e. Arthropathy
    f. Avascular necrosis of the femoral capital epiphysis
    g. Distal phalangeal osteolysis
    h. Delayed closure and persistently patent anterior fontanelle
    i. Joint contractures with contracted hands, elbows, and knees
    j. Dislocation of the hip
    k. Mild flexion of the knees resulting in a wide-gaited "horse-riding" stance and wide-based shuffling gait
    l. Short, tapered distal phalanges
    m. Thin limbs
    n. Muscle atrophy
11. Prognosis (Badame 1989)
    a. Absence of other factors associated with aging such as cancers, cataracts, and senility (not considered to be a phenocopy of normal aging)
    b. Death due to cardiovascular abnormalities in approximately 75% of patients
    c. Main cause of death due to cardiovascular complications
       i. Myocardial infarction
       ii. Congestive heart failure
    d. Other causes of death
       i. Marasmus
       ii. Inanition
       iii. Convulsions
       iv. Accidental head trauma due to thinned cortical bones
    e. Average life expectancy: 13 years (7–27 years)

Diagnostic Investigations

1. Histopathology (Badame 1989)
   a. Skin lesions indistinguishable from scleroderma
      i. Progressive hyalinization of dermal collagen (hyaline fibrosis)
      ii. Loss of subcutaneous tissue
      iii. Decreased sebaceous and sweat glands and hair follicles
   b. Bone lesions
      i. Osteoporosis
      ii. Osteolysis prominent in distal phalanges and clavicles

iii. Skeletal dysplasia manifesting as coxa plana, coxa valga, and attenuated diaphyses with dystrophic metaphyses
iv. Avascular hip necrosis
v. Nonunion of fractures
vi. Hip dislocations

c. Cardiovascular lesions
i. severe, progressive atherosclerosis with widely variable age of clinical manifestation
ii. Presence of atherosclerotic plaques in the large and small arteries
iii. Calcifications in the mitral and aortic valves as well as aorta, coronary, cerebral, subclavian, and axillary arteries
iv. Myocardial ischemia and infarction resulting from the coronary artery disease
v. Diffuse interstitial myocardial fibrosis
vi. Ventricular dilatation and hypertrophy

d. Increased lipofuscin in the brain, adrenal cortex, kidney, testis, liver, and heart

e. Gonads
i. Aspermatogenesis in males
ii. Presence of primordial follicles and corpora albicans in females with evidence of ovulation

f. Arterial biopsy
i. Premature atherosclerosis
ii. Subintimal fibrosis

2. Radiography (Badame 1989)
a. Widespread degenerative changes of bone in the first or second year of life
b. Skull and facial bones
i. Craniofacial disproportion
ii. Patent fontanelles
iii. Wormian bones with fractures
iv. Facial bone hypoplasia
v. Mandibular hypoplasia with dental crowding
vi. Delayed and abnormal dentition

c. Thorax
i. Clavicular resorption
ii. Rib tapering

d. Long bones
i. Indentations
ii. Attenuated cortices
iii. Widened metaphyses
iv. Coxa valga
v. Genu valgum

e. Phalanges
i. Distal resorption, one of the hallmarks of the disease
ii. Radiolucent terminal phalanges (acroosteolysis)

f. Other
i. Osteoporosis
ii. Fish-mouthed vertebral bodies
iii. Soft tissue loss

3. Blood chemistry for hyperlipidemia
a. Increased low-density lipoprotein levels
b. Increased β-lipoprotein and pre-β-lipoprotein levels of high-density lipoprotein
c. Increased serum cholesterol levels

4. Metabolic workup: inconsistent results
a. Insulin resistance
b. Abnormal collagen formation
c. Increased metabolic rate: could be the cause of the failure to thrive seen in progeria
d. Elevated growth hormone levels

5. Urine test
a. Excessive excretion of glycosaminoglycans
b. Excessive excretion of hyaluronic acid (unreliable)

6. Cultured skin fibroblasts
a. Exhibit 76.1% DNA repair capacity compared to normal (Sarkar and Shinton 2001)
b. Decreased cell growth in culture
c. Short telomeres
d. Whether aging is the consequence of shortened telomeres with reduced cell replication, impaired telomerase activity, or the culmination of the effects of reactive oxygen species is uncertain.

7. Immunofluorescence of cultured fibroblasts with antibodies directed against lamin A demonstrating visible abnormalities of the nuclear membrane in many cells

8. Molecular genetic analysis to detect *LMNA* p.gly608Gly point mutation: clinically available
a. Sequence analysis
b. Targeted mutation analysis

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. The lamin A gene mutations not found in patient's parents suggesting that it

occurs spontaneously in each patient and does not pass from parent to child
   ii. Recurrence risk very low, estimated at 1 in 500 with each subsequent pregnancy due to germline mutations (Wuyts et al. 2005)
   iii. Rare reports of siblings with progeria from consanguineous or nonconsanguineous marriages
   iv. Reported cases of monozygous twins with progeria
 b. Patient's offspring: inability of patients to reproduce
2. Prenatal diagnosis and preimplantation genetic diagnosis: possible in families in which the disease-causing mutation has been identified in a family member
3. Management (Gordon et al. 2011)
 a. Regular diet
 b. Combined nutritional treatment and growth hormone treatment
   i. Improve growth
   ii. Increase the levels of growth factors
   iii. Paradoxically result in a decreased BMR
   iv. Response decreases over time.
   v. Do not prevent the progression of atherosclerotic disease (Abdenur et al. 1997)
 c. Early and definitive surgical intervention for symptomatic oral pathosis
   i. Abnormal facial morphology
   ii. Dermal inelasticity
   iii. Potential anesthetic difficulties
   iv. Progressive ongoing deterioration in the medical condition
 d. Orthopedic cares for musculoskeletal abnormalities
   i. Routine treatment of fractures
   ii. Conservative treatment for hip dislocation. Avoid surgery if possible.
   iii. Routine physical therapy to maintain joint range of motion
 e. Management of cardiovascular complications
   i. Routine anticongestive therapy for congestive heart failure
   ii. Nitroglycerin for angina
   iii. Low doses of aspirin help delay heart attacks and strokes

Fig. 1 (**a**–**h**) A boy with progeria showing short stature; senile appearance; small face in comparison with large cranial vault (craniofacial disproportion); alopecia with prominent scalp veins; absent eyelashes and eyebrows; prominent eyes; beak-like nose; mandibular hypoplasia; absent earlobes; contracted hands, elbows, and knees; short, tapered terminal phalanges; enlarged joints; and dry, brittle, hypoplastic nails

Prune Belly Syndrome

In 1895, Parker described the congenital triad of deficient abdominal musculature, cryptorchidism, and urinary tract abnormalities. Subsequently, the term "prune belly syndrome" was coined for this condition based on the characteristic wrinkled appearance of the abdomen. The incidence of the syndrome is estimated to be 1 in 35,000 to 1 in 50,000 live births.

Synonyms and Related Disorders

Absence of abdominal muscles with urinary tract abnormality and cryptorchidism; Eagle-Barrett syndrome; Potter sequence

Genetics/Basic Defects

1. Etiologies
   a. Questionable genetic inheritance
      i. Questionable autosomal dominant inheritance
      ii. Autosomal recessive inheritance suggested by some authors
   b. Fetal abdominal distension caused by urinary tract obstruction
      i. The most common cause of prune belly syndrome
      ii. Urethral obstruction causing dilatation of the fetal bladder and upper tracts thereby attenuating the abdominal musculature
      iii. Spontaneous relief of the urethral obstruction in some cases prenatally decompresses the abdomen, producing the shriveled, prune like appearance of the baby's abdomen.
      iv. Persistent urethral obstruction causing huge distention of the urinary bladder, bilateral hydronephrosis, and hydroureter complicated by oligohydramnios in more severe cases
   c. Fetal ascites from whatever cause: abdominal decompression during intrauterine life leading to prune belly appearance of the abdomen
   d. Prostatic hypoplasia resulting in a functional urethral obstruction leading to development of the prune belly syndrome (Hoagland 1988)
   e. Primary mesodermal defect simultaneously affecting the formation of abdominal musculature and abnormalities in the lower urinary tract (Mouriquand et al. 2001)
   f. Rare association of chromosome abnormalities
      i. Trisomy 13
      ii. Trisomy 18
      iii. Turner syndrome with fetal ascites (pathogenetic mechanism thought to involve abdominal distention by ascites rather than by urinary obstruction)
      iv. Ring X chromosome lacking *XIST* (Guillen 1997)
      v. Cat-eye syndrome
      vi. Rarely with trisomy 21
      vii. Mosaic unbalanced chromosome constitution of chromosome 16
      viii. Presence of a small additional chromosome fragment
      ix. Interstitial deletion of chromosome 1 [del (1)(q25q32)] (Scarbrough et al. 1988)

2. Pathogenesis: abdominal wall hypoplasia as a nonspecific lesion resulting from fetal abdominal distension of various causes
3. Terminologies
   a. Prune belly: a descriptive term for a wrinkled and flaccid abdominal wall secondary to stretched skin, soft tissues, and muscles of the abdomen
   b. Prune belly syndrome generally used to indicate the condition having prune belly, cryptorchidism, and abnormalities of the urinary tract
4. Causes of urine flow impairment/obstruction (Mouriquand et al. 2001)
   a. Renal causes
      i. Pelviureteric junction anomaly
      ii. Vesicoureteric junction anomaly
      iii. Posterior urethral valves
      iv. Duplex systems
      v. Ureterocele/ectopic ureter
      vi. Urethral atresia
      vii. Cloacal anomaly
      viii. Vesicoureteric reflux
      ix. Megaureter
      x. Megacystis microcolon
      xi. Hypoperistalsis syndrome
   b. Extrarenal causes
      i. Sacrococcygeal teratoma
      ii. Hydrometacolpos
      iii. Other pelvic masses

Clinical Features

1. Broad spectrum in severity
2. Nearly 95% of cases occurring in males
3. Potter face
   a. Mandibular micrognathia
   b. Wide-set eyes
   c. Flattened palpebral fissures
   d. Prominent epicanthus
   e. Flattened nasal bridge
   f. Large, low-set ears with lacking cartilage
4. Abdomen
   a. Partial or complete absence of the abdominal musculature
   b. Thin/lax protruding abdominal wall
   c. Wrinkled abdominal skin
   d. Visible intra-abdominal intestinal patterns through thin abdominal wall
5. Other associated gastrointestinal abnormalities (Woods and Brandon 2007)
   a. Malrotation: midgut anomaly, intestines abnormally rotated or become twisted during embryologic development
   b. Atresia: failure of the intestinal tract to completely form, causing absence of a normal opening
   c. Stenosis: narrowing of the center passage within the intestines
   d. Volvulus: intestines or stomach lack normal attachments of the body, causing the intestines to become twisted, resulting in a lack of blood supply
   e. Clinical symptoms
      i. Bilious vomiting
      ii. Abdominal distention
      iii. Abdominal tenderness
      iv. Failure to pass meconium
      v. Rectal bleeding
      vi. Signs of shock and sepsis
6. Genitourinary anomalies
   a. Urethral obstruction
   b. Dilated/hypertrophic bladder
   c. Dilated urethra, particularly the prostatic urethra
   d. Dilated/tortuous ureters
   e. Renal dysplasia/hypoplasia with cystic changes
   f. Hydronephrosis
   g. Absence or hypoplasia of the prostate
   h. Ventral body wall defects
      i. Cloacal exstrophy
      ii. Bladder exstrophy
      iii. Hypo-/epispadias
   i. Genitalia
      i. Bilateral cryptorchidism in males
      ii. Pseudohermaphroditism in females
   j. Potter sequence
      i. Oligohydramnios
      ii. Potter face
      iii. Pulmonary hypoplasia
      iv. Other deformations
7. Secondary malformations
   a. Gastrointestinal obstruction
      i. Malrotation
      ii. Atresia
      iii. Stenosis
      iv. Volvulus
      v. Splenic torsion

vi. Imperforate anus
vii. Anorectal agenesis

b. Limb and other skeletal abnormalities believed to be the direct result of oligohydramnios with resultant fetal crowding (Green et al. 1993)
i. Talipes equinovarus
ii. Metatarsus adductus
iii. Vertical talus
iv. Hip dislocation
v. Arthrogryposis
vi. Pectus excavatum/carinatum
vii. Congenital muscular torticollis
viii. Bell shape chest
ix. Infantile scoliosis
x. Severe leg maldevelopment
a) Generalized hypoplasia
b) Complete absence
c) Terminal defects

c. Cardiac malformations
i. Tetralogy of Fallot
ii. Ventriculoseptal defect

d. Cleft lip
e. Spina bifida
f. Association with diverse chromosome syndromes
i. Trisomy 13
ii. Trisomy 18
iii. Turner syndrome
iv. Cat-eye syndrome
v. Trisomy 21
vi. Others

8. Grading of patients according to severity of renal and pulmonary malformations (Herman and Siegel 2009)
a. Grade 1: those with oligohydramnios-induced pulmonary hypoplasia and Potter facies
b. Grade 2: moderate-to-marked neonatal and infantile urinary tract involvement without pulmonary hypoplasia or Potter facies
c. Grade 3: mild renal involvement

9. Prognosis
a. High mortality although compatible with long-term survival
i. Stillbirth or death by 1 month of age in 20% of cases
ii. Death by the second year for additional 30% of cases
b. Causes of death (Christopher et al. 1982)
i. Renal failure secondary to renal dysplasia present at birth
ii. Pulmonary complications including lung hypoplasia
iii. Infection associated with urinary stasis or operative interventions

Diagnostic Investigations

1. Renal and bladder ultrasound
2. Contrast voiding cystourethrogram
3. Radiography
a. Hypoplastic lungs with flared lower ribs secondary to the distended abdomen
b. Diffusely distended flanks
c. Dilated/dysplastic calyces of the kidneys
d. Markedly dilated/tortuous ureters
e. Vertical and trabeculated bladder
f. A wide and long posterior urethra
g. Cryptorchidism
4. Histology of the abdominal wall (Moerman et al. 1984a, b)
a. Muscle atrophy (degeneration of already formed muscle), not of primitive muscle
b. The finding supports the theory that the abdominal muscle hypoplasia is a nonspecific lesion, resulting from fetal abdominal distension of various causes.
5. Chromosome analysis for multiple congenital anomalies

Genetic Counseling

1. Recurrence risk
a. Patient's sib: not increased unless in autosomal recessive inheritance (which is still unclear)
b. Patient's offspring: not increased
2. Prenatal diagnosis by 2D and 3D ultrasonography (Leeners et al. 2000; Chen et al. 2010)
a. Signs of fetal abdominal laxity (characteristic abdominal appearance) associated with fetal urinary tract abnormalities
i. Amniotic fluid wave produced by fetal movement

ii. Sinusoidal undulation of the fetal anterior abdominal wall produced by tapping the maternal abdomen
   b. A distended bladder (megacystis) and ureters
   c. Cryptorchidism
   d. Oligohydramnios
   e. Fetal ascites
   f. Lung hypoplasia
   g. Associated anomalies
      i. Other renal anomalies (25%)
      ii. Extrarenal abnormalities (12%)
         a) Anorectal anomalies
         b) VATER syndrome
         c) Esophageal atresia
         d) Pattern compatible to specific chromosomal abnormality
3. Management
   a. Orchidopexy for cryptorchidism
   b. Treatment of vesicoureteral dysfunction
      i. Temporary diversion
      ii. Ureteral reconstruction
   c. Treatment of vesicourethral dysfunction
      i. Reduction cystoplasty
      ii. Internal urethrotomy
      iii. Megalourethra repair
   d. Abdominal wall reconstruction
   e. Vesicoamniotic shunting with percutaneous placed catheters: useful in some lower urinary tract obstructions such as those that occur with prune belly syndrome (Woods and Brandon 2007). However, vesicoamniotic shunt placement for suspected prenatal obstructive uropathy remains controversial (Freedman et al. 1996).

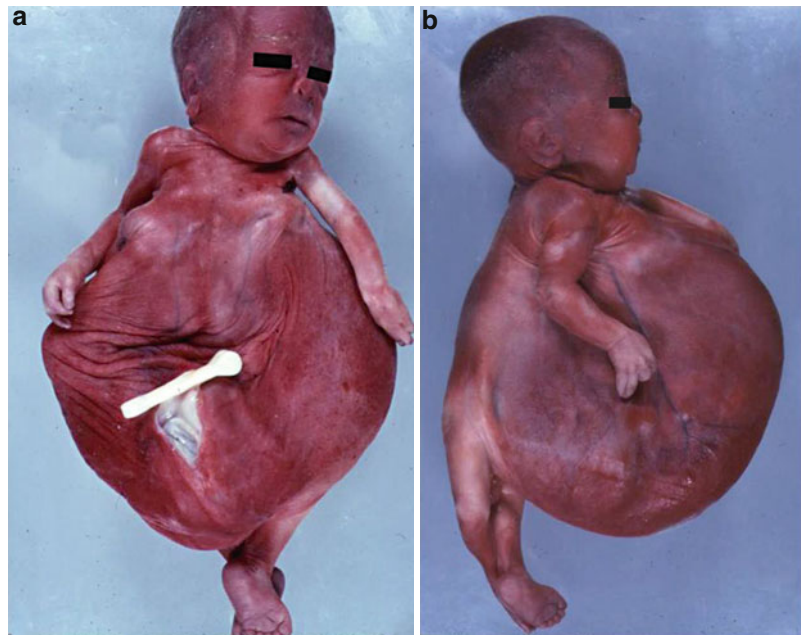

Fig. 1 (**a**, **b**) A premature male neonate with prune belly syndrome due to urethral atresia. He lived for 2 h. There was a massive dilation and hypertrophy of the urinary bladder. Mild hydronephrosis was seen in one kidney but the second kidney was hypoplastic. The anterior abdominal wall showed muscle deficiency. Additional anomalies included imperforate anus with vesicorectal fistula, secundum-type atrial septal defect of the heart, mild coarctation of the aorta, and bilateral talipes equinovarus

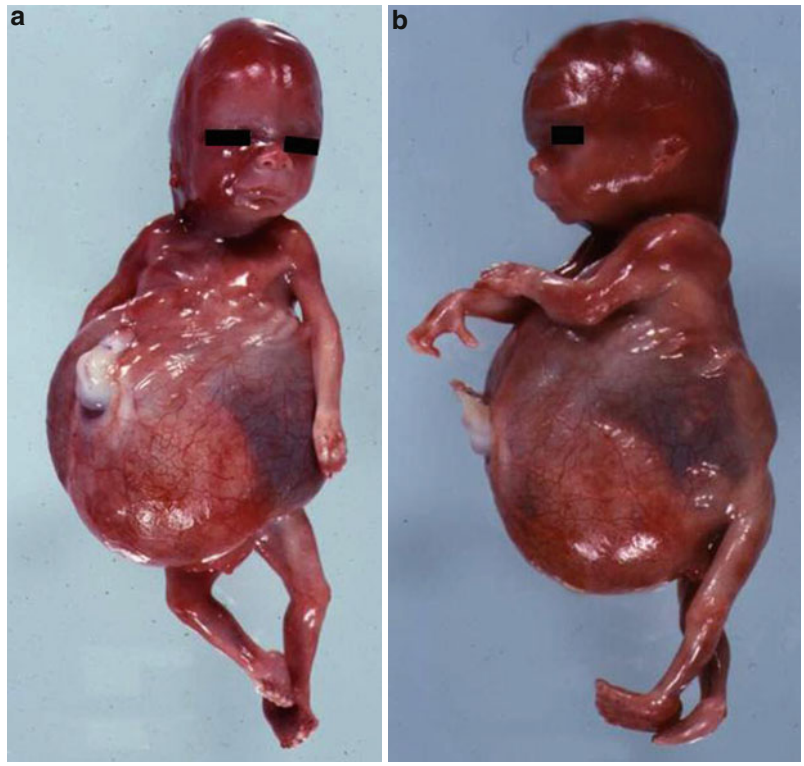

Fig. 2 (**a**, **b**) A male fetus with prune belly syndrome due to severe urethral stenosis. There were marked dilatation of the proximal urethra, bladder, and bilateral ureters. Mild hydronephrosis and cystic renal dysplasia were seen in both kidneys. There were no other anomalies

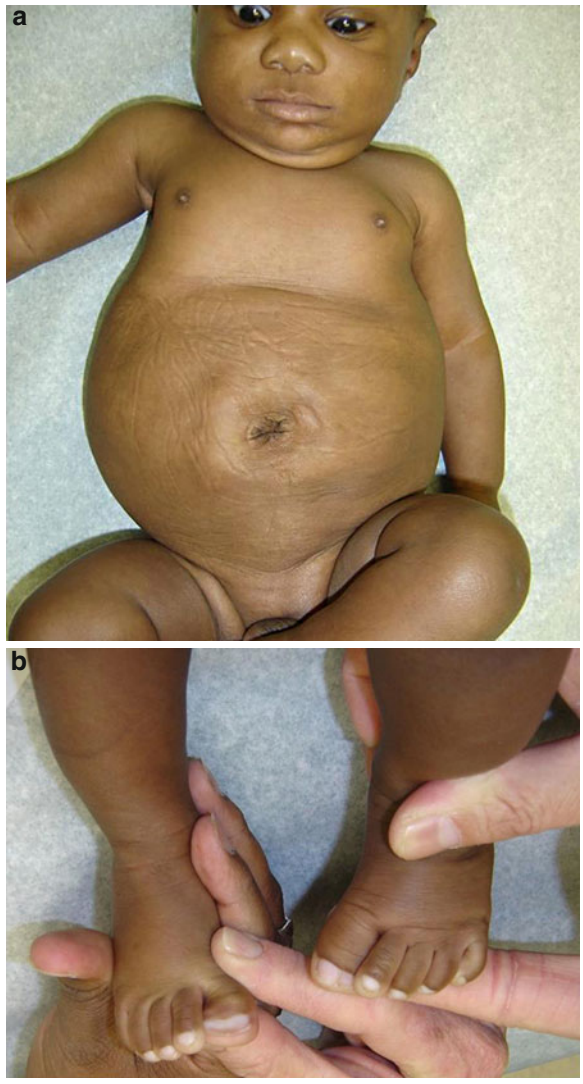
Fig. 3 An infant with prune belly syndrome showing thin, flaccid abdominal wall through which intra-abdominal intestinal patterns are visible

Fig. 4 A postmortem infant with prune belly syndrome showing flaccid and wrinkling abdominal wall with visible intestinal patterns



Figs. 5 (**a**, **b**) A neonate with prune belly syndrome showing wrinkling abdominal wall due to multicystic kidneys. The infant also has duplicated great toes

Pseudoachondroplasia

Pseudoachondroplasia is a type of short-limbed dwarfism, deriving its name from phenotypic similarity to achondroplasia. It is characterized by normal facies, short-limbed dwarfism, joint laxity, and epiphyseal and metaphyseal abnormalities in the growing child.

Synonyms and Related Disorders

Pseudoachondroplastic dysplasia; Peudoachondroplastic spondyloepiphyseal dysplasia

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant with complete penetrance
   b. Autosomal recessive unlikely (Ferguson et al. 1997)
      i. Somatic mosaicism was demonstrated in two pseudoachondroplasia families that were originally considered to represent autosomal recessive inheritance.
      ii. The results suggest that autosomal recessive inheritance is unlikely, and all cases of pseudoachondroplasia should be studied for mutations in *COMP*.
2. Cause
   a. Mutations in the gene encoding cartilage oligomeric matrix protein (*COMP*) on the centromeric region of 19p (19p13.1-p12)
      i. Deletions: Approximately 40–50% of cases of pseudoachondroplasia have deletion mutations in exon 13 of the *COMP* gene.
      ii. Specific base substitutions
      iii. Duplications
   b. Allelic to multiple epiphyseal dysplasia, which is also caused by *COMP* mutations
   c. All mutations associated with pseudoachondroplasia and multiple epiphyseal dysplasia: found in exons encoding the type III repeat region or C-terminal domain of *COMP*
   d. Mutations in extracellular matrix proteins, *COMP*, types II and IX collagens, and matrilin-3
      i. Producing a spectrum of mild to severe chondrodysplasias characterized by epiphyseal and vertebral abnormalities
      ii. Disruption of protein processing and excessive accumulation of some of these proteins in the rough endoplasmic reticulum that appears to compromise cellular function

Clinical Features

1. Normal at birth
2. Normal intelligence
3. Normal craniofacial appearance
4. Waddling gait and diminished linear growth at about 2 years of age
5. Rhizomelic short-limbed dwarfism
   a. Body proportion resembling achondroplasia
   b. Usually detectable at age 2–4 years
6. Spine
   a. Accentuated lumbar lordosis
   b. Scoliosis
   c. Kyphosis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_199,

   d. Chronic compression myelopathy secondary to habitual atlantoaxial dislocation
7. Extremities
   a. Bowing of the long bones
   b. Deformities of the lower limbs
      i. Secondary to ligamentous laxity
      ii. Ranging from genu varum (bowed legs), genu valgum (knock-knees), and genu recurvatum
      iii. A "wind-swept deformity" (bowleg on one side and knock-knee on the other side)
   c. Markedly shortened hands (without trident configuration) and feet
   d. Ulnar deviation of the wrist
   e. Flexion contractures of the elbow and knees
   f. Brachydactyly
   g. "Telescoping" fingers
8. Joint
   a. Lax ligament
   b. Premature osteoarthritis
   c. Contractures of the hips
9. Prognosis
   a. Good survival
   b. Early arthrosis, notably in the hip and knee joints
   c. Possible myelopathy secondary to atlantoaxial dislocations
10. Differential diagnosis (Cohn 2010)
   a. Dominant multiple epiphyseal dysplasia (see the chapter): Mutations in *COMP*, *COL9A1*, *COL9A2*, *COL9A3*, or *MATN3* genes can be demonstrated in about 50% of cases.
   b. Recessive multiple epiphyseal dysplasia (see the chapter)
      i. *SLC26A2* (*DTDST*) is the only gene known to be associated with recessive multiple epiphyseal dysplasia.
      ii. Diagnosis can be confirmed by molecular genetic testing of the *SLC26A2* gene.
   c. Other forms of spondyloepimetaphyseal dysplasia: need complete skeletal survey for diagnosis

Diagnostic Investigations

1. Radiography
   a. Tubular bones
      i. Irregularities and fragmentations of the developing epiphyses
      ii. Shortened tubular bones
      iii. Brachydactyly
      iv. Delayed epiphyseal ossification (delayed bone age)
      v. Small phalangeal epiphyses (miniepiphyses)
      vi. Small, irregular carpal bones
      vii. Irregular, widened (frayed), mushroomed metaphyses
      viii. Coxa vara
   b. Pelvis
      i. Delayed ossification of the capital femoral epiphyses, which become flattened and small when ossified
      ii. Commonly observed sclerosis and irregularity of the acetabular roof
   c. Vertebrae
      i. Characteristic anterior beaking or tonguing (in lateral view of the lumbar spines)
         a) Due to delayed ossification of the annular epiphyses
         b) Vertebrae becoming more normal in appearance after puberty
      ii. Characteristic platyspondyly in childhood
      iii. Kyphoscoliosis
      iv. Lumbar lordosis
      v. Odontoid hypoplasia
      vi. Atlantoaxial dislocations
   d. Ribs: spatulate
2. Histology of growth plates
   a. Irregular arrangement of chondrocytes without column formation
   b. Irregular provisional calcification
   c. Intracytoplasmic inclusions in chondrocytes
3. EM of chondrocytes
   a. Showing distinctive giant rough endoplasmic reticulum cisternae filled with punctuate material
   b. The material composed of alternating electron-lucent and electron-dense layers in a unique lamellar appearance
4. Serum COMP concentration may be suggested as an additional diagnostic marker to aid clinical findings in suspected cases of Pseudoachondroplasia (Liu et al. 2010).
5. Molecular diagnosis
   a. Sequence analysis of selected exons or the entire coding region (Cohn 2010)
      i. Detect p.Asp473del (about 30%)
      ii. Detect missense and small in-frame deletions (about 70%)
   b. Particularly useful in adult patients where radiological diagnosis can be difficult

Genetic Counseling

1. Recurrence risk: according to autosomal dominant inheritance (Cohn 2010)
   a. Patient's sib
      i. Fifty percent if one of the parent is affected
      ii. Not increased if parents are normal
      iii. If the disease-causing mutation identified in the proband cannot be detected in the DNA of either parent, two possible explanations are germ line mosaicism in a parent or a *de novo* mutation in the proband.
         a) The risk to the sibs of the proband depends on the probability of germ line mosaicism in a parent of the proband and the spontaneous mutation rate of *COMP*.
         b) Germ line mosaicism for a *COMP* mutation has been reported (Hall et al. 1987, Ferguson et al. 1997), but the frequency is unknown and the empiric risk to sibs of a proband has not been determined.
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Prenatal ultrasonography unlikely to detect the skeletal changes which will not manifest until about 2 years of age
   b. Prenatal diagnosis and preimplantation genetic diagnosis: possible in the family at risk and the disease-causing *COMP* mutation has been characterized in an affected individual
3. Management
   a. Supportive
   b. Surgical correction of the leg deformities
   c. Hip replacement for severe hip contractures
   d. Cervical stabilization procedures for cervical cord compression with progressive neurologic symptoms and signs

Fig. 1 (**a**–**d**) A girl with pseudoachondroplasia at 2 ½ years (*upper*) with normal craniofacial appearance, mild short stature, and waddling gate and at 6 years (*lowers*) with short limbs, accentuated lumbar lordosis, and short stature

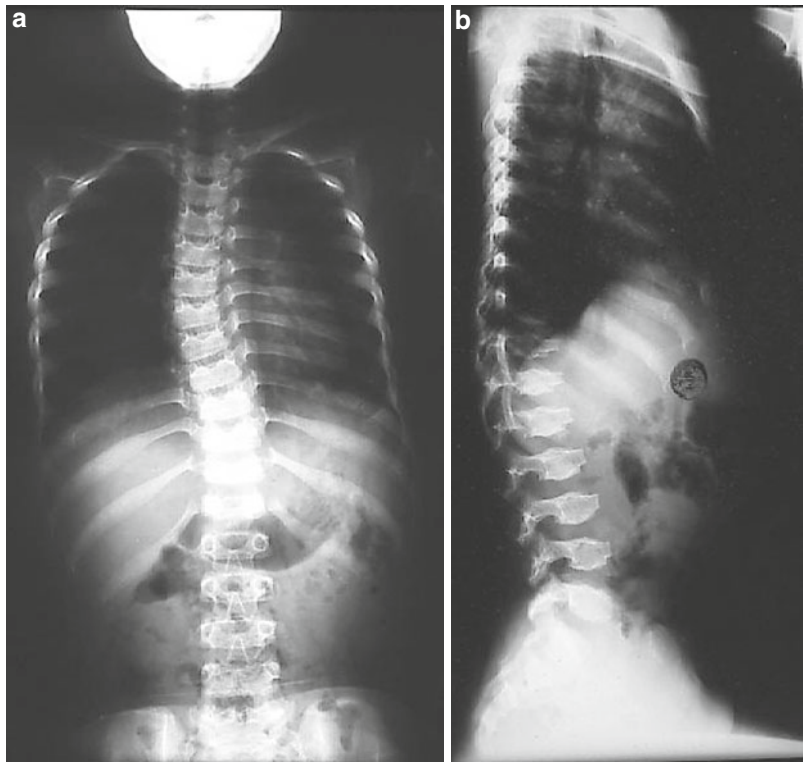

Fig. 2 (**a**, **b**) Radiographs of the spine show characteristic anterior beaking of the lumbar spine and mild scoliosis

Fig. 3 Radiographs of the pelvis and lower extremities showing irregular, horizontal acetabular roof, delayed epiphyseal ossification, and wide mushroom-shape metaphyses

Fig. 4 Radiograph of the upper extremities showing markedly widened and defective metaphyseal and epiphyseal ossifications in the proximal humerus, distal radius, and ulna

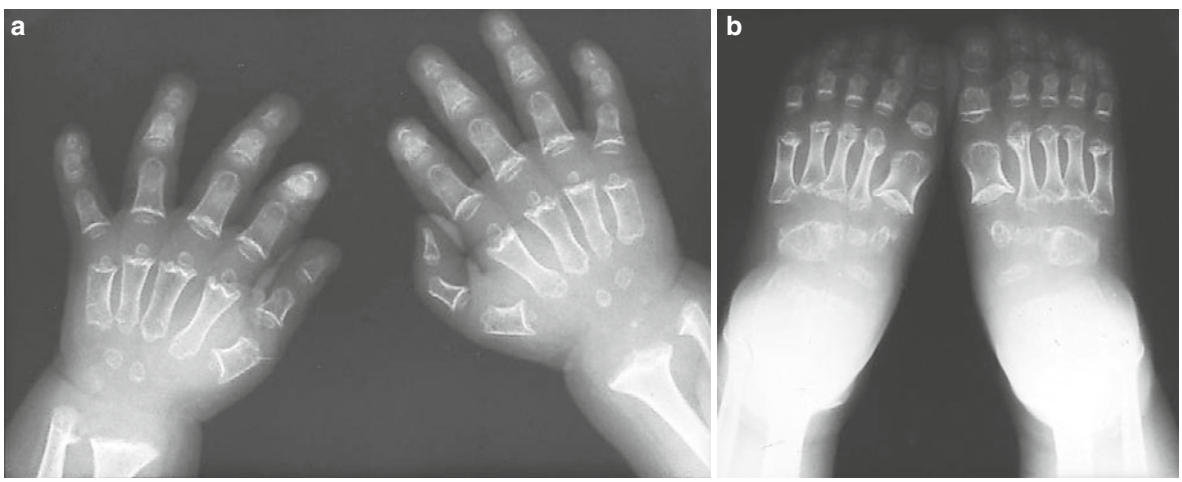

Fig. 5 (**a**, **b**) Radiographs of the hands and feet show grossly disturbed metaphyseal and epiphyseal ossification, short and stubby tubular bones, somewhat widened metacarpals and metatarsals, and small and markedly irregular carpal and tarsal bones

R(18) Syndrome

In 1962, Wang et al. reported the first observation of the ring chromosome 18. Ring chromosome 18 syndrome is a rare chromosome disorder resulting from loss (deletion) of genetic material from one or both ends of a chromosome 18 and joining of the chromosomal ends to form a ring.

Ring chromosome 18 has been reported in many cases of liveborns. The phenotype may vary greatly in range and severity from normal fertile persons in a majority of cases to those with severe malformations, depending upon the amount and location of lost genetic material. Ring chromosome 18 is usually caused by spontaneous (de novo) errors very early in the development of the embryo.

Synonyms and Related Disorders

Mosaic ring chromosome 18 syndrome; Ring chromosome 18 syndrome

Genetics/Basic Defects

1. Formation of a ring chromosome 18.
   a. Ring chromosomes arise from chromosomal breakages occurring on either side of the centromere and subsequent rejoining of the segment containing the centromere.
   b. One of the breakpoints is generally at or adjacent to the centromere. Thus, two types of ring chromosomes may arise:
      i. One derived from the short arm
      ii. One derived from the long arm
2. Supernumerary ring chromosome 18.
   a. The r(18) was additional to the two existing chromosome 18 copies, leading to trisomy for the chromosome 18 segment carried on r(18).
   b. May show the characteristics of trisomy 18 or duplications of 18p or 18q.
3. Mosaic ring chromosome 18.
   a. Ring chromosomes are known to be unstable and are often found in a mosaic state.
   b. Instability of a ring may lead to a monosomic cell line.
4. Haploinsuficiency of several genes have been postulated to play a role in the 18q- and 18p- syndrome phenotypes:
   a. HPE4 (18p11.3): holoprosencephaly
   b. GALNR1 (18q23)
   c. Growth hormone deficiency
   d. MBP (18q23): hypomyelination
5. Phenotypic variability depends on the extent of the deleted chromosome 8 segments: Most patients show the symptoms of 18q- syndrome, 10p- syndrome, or combination of these two.
6. Rare occurrence of a ring chromosome 18 together with a duplication of a segment of chromosome 18 or with a marker chromosome.

Clinical Features

1. Clinical features of r(18) syndrome.
   a. Growth and development
      i. Mental retardation
      ii. Hypotonia
      iii. Short stature

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_200,
© Springer Science+Business Media, LLC 2012

b. Head/brain
   i. Microcephaly
   ii. Dolichocephaly
   iii. Holoprosencephaly
   iv. Cebocephaly
   v. Arhinencephaly
c. Midface: flat
d. Ears
   i. Asymmetric
   ii. Low-set
   iii. Atretic external ear canals
   iv. Prominent antihelix
e. Eyes
   i. Deep-set
   ii. Hypertelorism
   iii. Down slanting palpebral fissures
   iv. Epicanthal folds
   v. Nystagmus
   vi. Strabismus
   vii. Ptosis
   viii. Coloboma
f. Nose
   i. Broad base
   ii. Depressed nasal bridge
   iii. Broad tip
g. Mouth
   i. Micrognathia
   ii. Carp-like down-turned corners
   iii. Thin upper and lower lips
   iv. High/narrow palate
   v. Dental caries
h. Neck: short
i. Chest
   i. Pectus excavatum
   ii. Wide-spaced nipples
j. Congenital heart defect
   i. PDA
   ii. PS
   iii. VSD
   iv. AS
k. Abdomen
   i. Umbilical hernia
   ii. Inguinal hernia
l. Genitourinary
   i. Male genitalia
      a) Cryptorchidism
      b) Hypoplastic scrotum
      c) Micropenis
   ii. Female genitalia: hypoplastic labia minora
m. Musculoskeletal
   i. Spine: scoliosis
   ii. Hands
      a) Clinodactyly
      b) Camptodactyly
      c) Short fingers
      d) Long tapering fingers
      e) Proximally placed thumbs
      f) Single transverse palmar crease
   iii. Legs/feet
      a) Club feet (varus)
      b) Overriding toes
      c) Long/broad toes
      d) Genu valgum
n. Other features
   i. Hypothyroidism
   ii. Hypoparathyroidism
   iii. Growth hormone deficiency
o. Atypical features
   i. Van der Woude syndrome
   ii. Insulin-dependent diabetes mellitus
   iii. Agammaglobulinemia

2. Most patients share the features of del(18q) syndrome which are highly variable depending on the extent of the terminal or interstitial 18q deletion:
   a. Mental retardation
   b. Hypotonia
   c. Microcephaly
   d. Short stature
   e. Flat midface
   f. Carp-shaped mouth
   g. Prominent antihelix and antitragus
   h. Atretic/stenotic ear canals
   i. Proximally placed thumbs
   j. Long tapering digits
   k. Foot deformity
   l. Abnormal male genitalia
3. Some patients share the features of del(18p) syndrome which are highly variable depending on the extent of the terminal or interstitial 18p deletion:
   a. Mental retardation
   b. Speech delay
   c. Hypotonia
   d. Short stature
   e. Midface defects including holoprosencephaly
   f. Ptosis of eyelids
   g. Small mandible
   h. Dental caries

i. Short neck
j. IgA deficiency
4. Some patients share the combined features of del (18p) syndrome and del(18q) syndrome.

Diagnostic Investigations

1. Conventional cytogenetic studies
   a. Nonmosaic r(18)
   b. Mosaic r(18)
2. Molecular cytogenetic studies using fluorescence in situ hybridization (FISH) technique
   a. Ring chromosome positive for chromosome 18 centromeric probe
   b. Absence of 18q subtelomeric probe
3. Microdissection followed by FISH to determine the origin of the marker chromosome
4. Using a number of microsatellite markers to determine the parental origin and possible mode of formation of the r(18)
5. Low IgA

Genetic Counseling

1. Recurrence risk
   a. Patient sibling
      i. A low recurrence risk if both parents are normal phenotypically and karyotypically (in cases of de novo instances in majority of cases).
      ii. Careful chromosome analysis to rule out parental mosaicism which may contribute to a recurrent risk of giving birth to a child with either partial trisomy or monosomy of different regions of chromosome 18.
      iii. A ring chromosome 18 can be transmitted from a phenotypically normal parent with 46, XX or XY/47,XX or XY,+r(18) karyotype to offspring with a 46,XX or XY,r(18) karyotype.
   b. Patient's offspring
      i. Patients with an r(18): 50%
      ii. Patients with mosaic form of an r(18): lower than 50% depends on the percentage of the marker chromosomes
2. Prenatal diagnosis
   a. Prenatal ultrasonography for congenital anomalies
   b. Chromosome analysis by amniocentesis or CVS
      i. Presence of an r(18) chromosome
      ii. FISH with a chromosome 18 probe to identify chromosome 18
3. Management
   a. Mainly supportive
   b. Multidisciplinary team approach with physical, occupational, and speech therapies
   c. Supportive treatment for chronic sinopulmonary infections associated with IgA deficiency
   d. Treat endocrine dysfunction if present
   e. Surgery for congenital anomalies

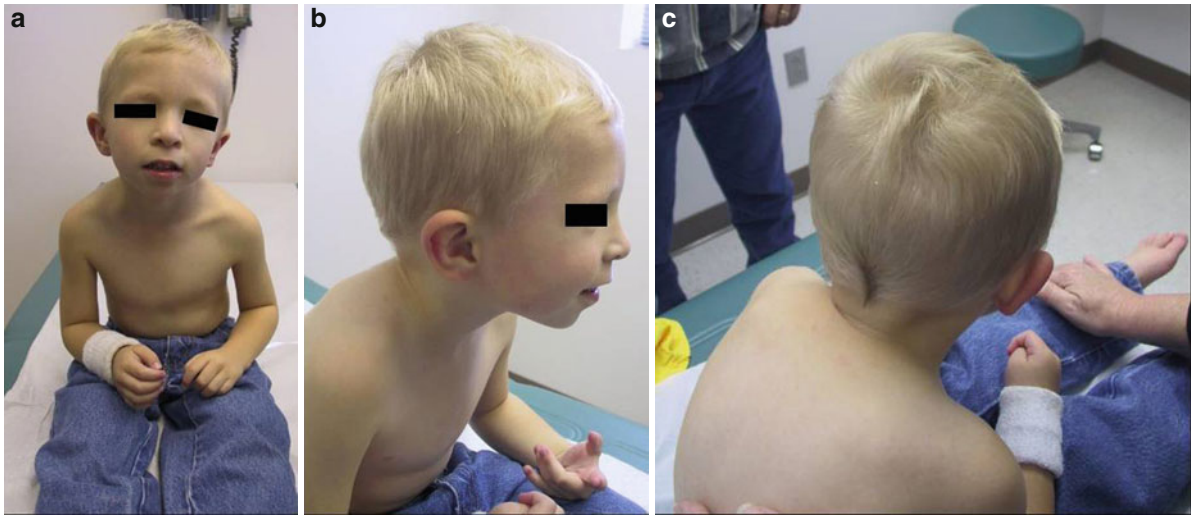

Fig. 1 (**a**–**c**) A 4-year-old boy with de novo r(18) syndrome showing growth deficiency (prenatal and postnatal), speech delay, hypertelorism, downward slanting of the palpebral fissures, strabismus, slightly low-set ears, mild pectus carinatum, clinodactyly of the 5th fingers, and syndactyly of toes. He also has IgA deficiency

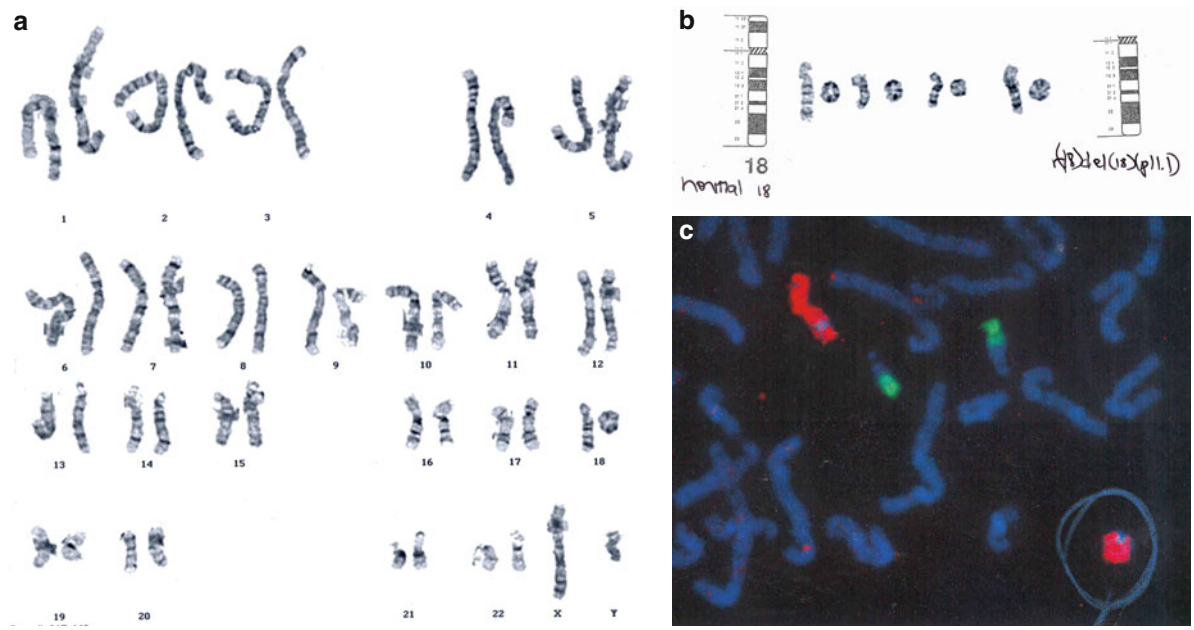

Fig. 2 (**a**–**c**) Chromosome analysis of the patient showed 46,XY,r(18), illustrated by a G-banded karyotype, a partial karyotype with idiograms, and FISH with whole chromosome 18 painting probe

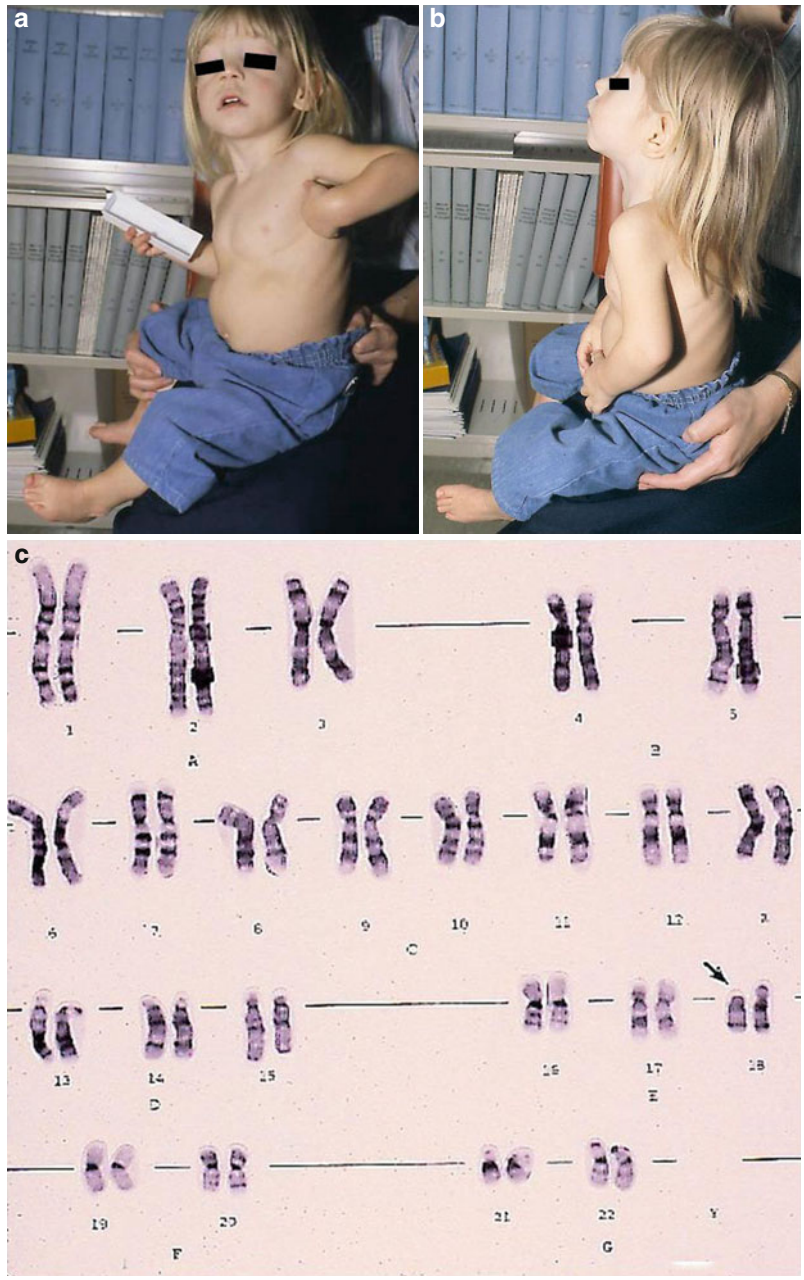

Fig. 3 (**a**–**c**) A girl with del (18p) showing hypotonia, ptosis of the eyelids, and small mandible. The G-banded karyotype shows deletion of the short arm of a chromosome 18

Fig. 4 (**a**, **b**) A boy with del(18q) showing hypotonia, ptosis of the eyelids, and carp-like mouth

Retinoid Embryopathy

Oral retinoids, isotretinoin (Accutane) and etretinate, uniquely effective in the treatment for severe cystic and keratinization disorders, are potent human teratogens.

Synonyms and Related Disorders

Isotretinoin embryopathy

Genetics/Basic Defects

1. Synthetic retinoids (isotretinoin, etretinate, acitretin)
   a. Closely resemble naturally occurring vitamin A, which is essential for the maintenance of visual and reproductive function and for proliferation and differentiation of epithelial tissues
   b. Isotretinoin and etretinate
      i. Released in the United States and Europe in 1982
      ii. Isotretinoin: uniquely effective in severe cystic acne
      iii. Etretinate (and acitretin): uniquely effective in severe psoriasis and other keratinization disorders which proved recalcitrant to all other therapies, account for their availability on prescription despite their teratogenicity
   c. Acitretin released later to replace etretinate as it is more rapidly eliminated from the body
   d. Adverse reactions
      i. Commonly reported adverse reactions: largely dose-related, of early onset, and reversible on discontinuation
         a) Dryness of the lips, mouth, and eyes
         b) Hair loss
         c) Pruitis
      ii. Less common and more severe idiosyncratic reactions
         a) Altered vision
         b) Headache
         c) Joint and muscle pain
         d) Abnormally raised serum transaminases levels
         e) Serum lipid changes
         f) Increased serum triglyceriode and cholesterol levels
         g) An increase in low-density/high-density lipoprotein ratio
      iii. Rare reactions
         a) Mental depression
         b) Severe hepatitis
         c) Diffuse hyperostosis of the spine
         d) Benign intracranial hypertension
   e. Teratogenicity of retinoids
      i. Foreshadowed by animal studies with strong warnings against exposure during pregnancy
      ii. Believed to interfere with the activity and migration of cranial neural crest cells during development and thus cause craniofacial, thymic conotruncal heart, and CNS malformations
      iii. Intellectual deficits

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_201,
© Springer Science+Business Media, LLC 2012

2. Teratogenicity (Chan et al. 1996)
   a. Isotretinoin
      i. Teratogenic during the first trimester fetal exposure within the therapeutic dose range
      ii. Has a short elimination half-life of about 20 h
      iii. Recommended contraception period after cessation of therapy: 1 month
      iv. Risk of teratogenicity for isotretinoin
         a) Exposure within first trimester: about 28%.
         b) Pregnancy occurring within 1 month after cessation of treatment: about 4%.
         c) Pregnancy occurring after 1 month: The risk of fetal malformations returns to baseline (isotretinoin is no longer detectable in the maternal circulation) (Ellis and Krach 2001).
   b. Etretinate
      i. Readily absorbed into adipose tissue and slowly released from it
      ii. Has a long elimination half-life ($\geq$120 days)
      iii. Recommended contraception period after therapy: 2 years
      iv. Risk for teratogenicity for exposure to etretinate
         a) During pregnancy: about 26%
         b) Within 2 years of treatment cessation: about 2%
   c. Acitretin
      i. A shorter elimination half-life of 50 h
      ii. Recommendation of a 2-year contraception period after therapy for acitretin, as in some women, there is conversion of acitretin to etretinate during therapy

Clinical Features

1. Isotretinoin embryopathy (Chan et al. 1996)
   a. Craniofacial abnormalities
      i. Microtia/anotia
      ii. Agenesis or marked stenosis of external ear canals
      iii. Hypertelorism
      iv. Depressed nasal bridge
      v. Micrognathia
      vi. Cleft palate
      vii. Low-set ears
   b. Central nervous system abnormalities
      i. Hydrocephalus
      ii. Dandy–Walker malformation
      iii. Microcephaly
      iv. Microophthalmia
      v. Cerebellar defects
         a) Hypoplasia
         b) Microdysgenesis
      vi. Cortical defects
      vii. Cortical blindness
      viii. Facial nerve palsy
      ix. Optic nerve hypoplasia
      x. Retinal defects
      xi. Spina bifida
      xii. Mental retardation
   c. Cardiovascular abnormalities
      i. Conotruncal malformations
         a) Transposition of the great vessels
         b) Tetralogy of Fallot
         c) Truncus arteriosus
         d) Double-outlet right ventricle
         e) Ventricular septal defect
         f) Atrial septal defect
      ii. Coarctation of the aorta
      iii. Interrupted aortic arch
      iv. Hypoplastic left ventricle
      v. Retroesophageal right subclavian artery
   d. Other abnormalities
      i. Thymic abnormalities
         a) Ectopia
         b) Hypoplasia
         c) Aplasia
      ii. Nystagmus
      iii. Decreased muscle tone
      iv. Hepatic abnormality
      v. Hydroureter
      vi. Simian crease
      vii. Limb reduction
      viii. An increased risk of spontaneous abortions (about 15%) but no long-term effects on fertility
2. Retinate embryopathy
   a. Craniofacial abnormalities
      i. Microtia
      ii. Micrognathia
      iii. Low-set ears
   b. Central nervous system abnormalities
      i. Menigomyelocele
      ii. Anophthalmia
      iii. Brain defect
   c. Skeletal abnormalities
      i. Syndactyly

ii. Shortened or absent digits
iii. Club foot
iv. Multiple synostosis

Diagnostic Investigations

1. Sonogram/CT/MRI of the brain for CNS anomalies
2. Radiography/CT for auditory canal malformations
3. Echocardiography for congenital heart defects
4. Audiological assessment by brainstem auditory evoked response
5. Visual and somatosensory evoked potential to detect cortical response
6. Electroencephalography

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless the mother exposes to retinoid again during the pregnancy
   b. Patient's offspring: not increased unless exposure to retinoid during pregnancy
2. Prenatal diagnosis
   a. History of maternal exposure to retinoid
   b. Prenatal ultrasonography
      i. Craniofacial anomalies
         a) Microtia/anotia
         b) Anophthalmia/microphthalmia
         c) Other facial abnormalities
      ii. CNS anomalies
         a) Microcephaly
         b) Dandy–Walker malformation
         c) Hydrocephalus
      iii. Cardiac defects by fetal echocardiography
      iv. Skeletal abnormalities
3. Management (Atanackovic and Koren 1999b; Abroms et al. 2006)
   a. Pregnancy Prevention Program, developed by the manufacturer and the US Food and Drug Administration since 1988, to prevent fetal exposure to the drug Accutane
      i. Distribute printed material to prescribing physicians to be used in educating their female patients about the serious teratogenic effects
      ii. Instruct physicians to delay therapy until the second or third day of the patient's next normal menstrual period
      iii. Stress to patients, the importance of using two forms of contraception concurrently
      iv. A consent form to be signed by female patients
         a) Acknowledging that they have been instructed through the program
         b) Aware of the need to use two forms of contraception during isotretinoin therapy
         c) Agree to undergo pregnancy testing before, during, and after the therapy
      v. Internet-based, performance-linked system called iPLEDGE (Abroms et al. 2006)
         a) The most recent and most stringent system
         b) To ensure that the drug is dispensed only when there is documentary proof that the patient is not pregnant and is using two forms of birth control
   b. Adhere to strict prescription guidelines, but exposure during pregnancy still occurs. The most common reasons for unwanted or mistimed pregnancies with isotretinoin therapy are (Perlman et al. 2001) as follows:
      i. Unsuccessful attempts at abstinence
      ii. Use of ineffective contraception
      iii. Inconsistent use of contraception
      iv. Unexpected sexual activity
      v. Contraceptive failure
   c. The need to improve pregnancy prevention programs (Crijns et al. 2011)
      i. Taking responsibility and enhancing the performance by health care professionals
      ii. Give explicit instructions
      iii. Monitor the performance and adjusting, if necessary
   d. Surgical shunting for hydrocephalus
   e. Surgical repair of congenital heart defects
   f. Surgical reconstruction of the external ear canal and middle ear
   g. Orthopedic management of limb reduction
   h. Multidisciplinary approach to multiple handicapped conditions

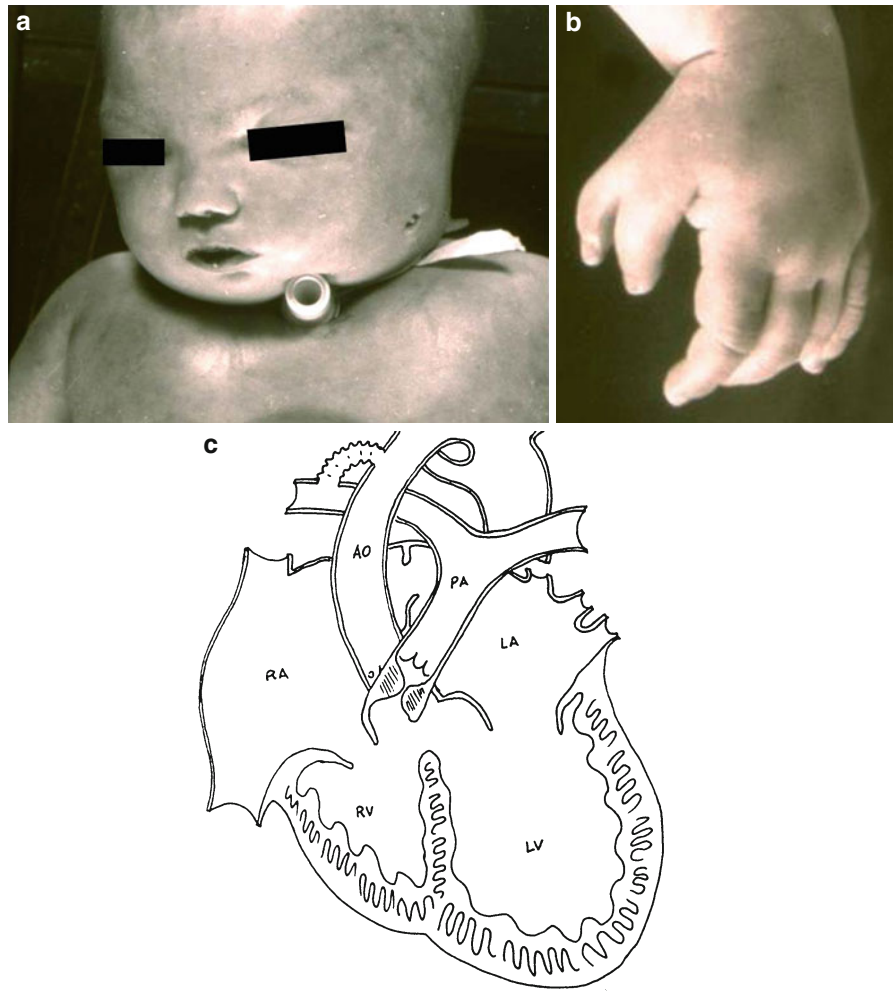

Fig. 1 (**a**–**c**) An infant with isotretinoin embryopathy. The mother took Accutane in the first trimester. Prenatal ultrasound examinations revealed intrauterine growth retardation, apparent ocular hypertelorism, flat nasal bridge, and tetralogy of Fallot. Parents elected to continue the pregnancy. The infant was born with dysmorphic craniofacial features (microcephaly, hypertelorism, flat nasal bridge, microretrognathia, cleft palate, absent ear canals and anotia, duplicated thumb on the left hand, anteriorly placed anus, and tetralogy of Fallot (illustrated in a drawing))

Rett Syndrome

Rett syndrome, a neurodevelopmental disorder affecting girls almost exclusively, was first described by Rett in 1966. The disorder now bears his name and became widely known after a report of 35 cases by Hagberg et al. in 1983. The prevalence is estimated to be 1/10,000–1/15,000 female births; over 95% of cases arise de novo due to the fact that most females with Rett syndrome do not reproduce. Rett syndrome is considered to be one of the most common genetic causes of mental retardation in girls, second only to Down syndrome.

Synonyms and Related Disorders

Autism, dementia, ataxia, and loss of purposeful hand use

Genetics/Basic Defects

1. Inheritance
   a. Sporadic cases (99.5%), occurring almost exclusively in females
      i. A de novo mutation in the child with Rett syndrome
      ii. Disease-causing mutation inherited from one parent who has somatic or germ line mosaicism
   b. Several reports of familial recurrence support X-linked dominant inheritance with lethality in hemizygous males.
2. The region of interest has been localized to Xq28 by linkage analysis from available familial cases.
3. Caused by mutations in the *MECP2* (methyl-CpG-binding protein 2) gene in Xq28
   a. Result in a loss of function by either disrupting the methylated DNA-binding properties of the protein or interfering with its association with transcriptional corepressors
   b. *MECP2* mutations in sporadic or atypical cases
      i. Up to 80% of sporadic affected females
      ii. One third of the clinically atypical cases
   c. *MECP2* mutations in familial cases (lower incidence)
      i. Germ line mosaic mothers
      ii. Asymptomatic carrier mothers due to nonrandom patterns of X-inactivation. The pattern of X-inactivation most likely protects the mutation carriers from expression of the disease by preferential inactivation of the mutant *MECP2* allele.
4. Females with the *MECP2* mutations (Takahashi et al. 2008)
   a. Exhibit a broad spectrum of clinical presentations ranging from classical Rett syndrome to asymptomatic carriers due to differences in X chromosome inactivation (XCI), and mechanisms other than XCI may contribute to the phenotypic heterogeneity associated with *MECP2* mutations
5. Males with the *MECP2* mutations
   a. May suffer from severe neonatal encephalopathy and die from breathing difficulties before their second year
   b. The almost absence of men with classic Rett syndrome suggests a lethal effect of the *MECP2* mutation in hemizygous affected men.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_202,
© Springer Science+Business Media, LLC 2012

c. However, males with Rett syndrome are not always lethal although neurologic impairment is slowly progressive and much more severe in men than in women.
d. Affected men have been reported in association with Klinefelter syndrome and somatic mosaicism.
e. Most *MECP2* mutations have originated in the paternal germ line. The paternal X *MECP2* never passed on from father to their sons.
f. Only way for a male to have Rett syndrome is a de novo mutation of a maternal X or inheritance of a *MECP2* gene mutation from his mother.
g. Some reported *MECP2* mutations may actually represent genetic variant rather than true pathogenetic novel mutations in the *MECP2* gene in males.
h. Genotype-phenotype correlations in males with MECP2 mutations (Moretti and Zoghbi 2006; Villard 2007)
    i. The first group
        a) Boys with Rett syndrome: have XXY karyotype or somatic mosaic and carry the same *MECP2* mutations that cause classic Rett syndrome in girls
        b) The affected boys have severe neonatal encephalopathy and usually die in their first year of life.
        c) These mutations can also lead to a milder phenotype when they are diluted among normally expressing cells.
    ii. The second group
        a) Has mutations that are not found in females with Rett syndrome
        b) These mutations are usually compatible with life into adulthood.
        c) The neurological presentation ranges from severe to mild nonspecific mental retardation.
    iii. The third group
        a) Composed of males having a duplication of the whole *MECP2* gene (and sometimes genes in its vicinity)
        b) The primary clinical features associated with this microduplication are nonspecific, but they comprise a severe phenotype.
        c) Affected individuals experience infantile hypotonia, recurrent respiratory infection, severe mental retardation, absence of speech development, seizures, and spasticity.
6. Clinical phenotypes of MeCP2 dysfunction in Rett syndrome and related disorders (Moretti and Zoghbi 2006; Chahrour and Zoghbi 2007)
    a. Females (loss-of-function of MeCP2)
        i. Classic Rett syndrome
        ii. Atypical Rett (preserved speech or normal hand use)
        iii. Infantile encephalopathy
        iv. Angelman syndrome phenotype
        v. Mental retardation with seizures
        vi. Mild mental retardation
        vii. Learning disability
        viii. Autism
        ix. Normal
    b. Males (loss-of-function of MeCP2)
        i. Infantile encephalopathy
        ii. Classic Rett syndrome (47,XXY or somatic mosaics)
        iii. Mental retardation with motor deficits
        iv. Bipolar disorder, mental retardation, and tremors
        v. Juvenile-onset schizophrenia, mental retardation, and tremors
        vi. Mental retardation, psychosis, pyramidal signs, and macroorchidism
    c. MECP2 gene duplications (overexpression of MeCP2)
        i. Preserved speech variant of Rett syndrome
        ii. Severe mental retardation and clinical features of Rett syndrome
        iii. Nonspecific X-linked mental retardation

Clinical Features

1. Normal prenatal and perinatal history
2. Appropriate head circumference
3. Apparently normal psychomotor development until about 6–18 months of life in affected girls
4. Developmental milestones afterward beginning to slow down and regress with loss of skills already achieved
    a. Deterioration of communicative skills
    b. Social withdrawal
    c. Loss of purposeful hand movement

5. Continued deterioration over the next few years
   a. Loss of language
   b. Poor motor function (truncal and gait apraxia/ataxia)
   c. Stereotypic hand movements (hand wringing and flapping)
   d. Deceleration of head growth (acquired microcephaly)
   e. Autistic behavior
6. Period of stabilization
   a. Severe psychomotor dysfunction
   b. Some patients may make small recoveries in contact and communication skills.
7. Breathing difficulties
   a. Periodic apnea
   b. Hyperventilation
   c. Breath holding
   d. Forced explosion of air/saliva
   e. Bruxism
8. Swallowing difficulties
9. Dystonia and hand and foot deformities as affected girls grow older
10. Later development of scoliosis
11. Osteoporosis at risk for fractures
12. Seizures (epilepsy) in 50% affected females
13. Possible survival into adulthood without further deterioration
14. An increased risk for sudden, unexplained death
    a. Longer corrected QT intervals
    b. T-wave abnormalities
    c. Reduced heart rate
15. Rett syndrome variants (<10% of cases)
    a. Patients with a milder clinical course ("forme fruste" phenotype): considered to be the most common variant of nonclassical Rett syndrome
       i. Less dramatic regression
       ii. Mild learning disability
       iii. Milder mental retardation
       iv. Preserved speech
       v. Ability to walk
       vi. Some hand use
       vii. Usually without seizures
       viii. No apparent symptoms observed in a few women who demonstrate skewed X chromosome inactivation
    b. Patients with a severe phenotype
       i. Lack of normal postnatal developmental period
       ii. Congenital hypotonia
       iii. Infantile spasms
    c. Patients with late regression
    d. Male patients with Rett syndrome
       i. Males with XXY (Klinefelter syndrome)
       ii. Males with somatic mosaicism
       iii. Males with XY (normal karyotype)
16. Clinical stages in classic Rett syndrome (Jedele 2007)
    a. Stagnation stage (6–18 months)
       i. Developmental arrest
       ii. Deterioration of eye contact and possible loss of communication
    b. Rapid destructive stage (1–4 years): developmental regression
       i. Developmental deterioration
       ii. Loss of acquired skills, including fine motor, babbling of words, and active playing
       iii. Loss of purposeful hand use
       iv. Stereotyped hand movements
       v. Apparent cognitive impairment
       vi. Intermittently "in another world"
       vii. Autistic features
       viii. Gait ataxia and apraxia
       ix. Irregular breathing (hyperventilation)
       x. Seizures in only 15%
    c. Pseudostationary stage (preschool–early school years)
       i. Some communication improvements
       ii. "Wake-up" period
       iii. Decreased autistic features
       iv. Preserved ambulation (A few are never ambulant.)
       v. Prominent gait ataxia and hand apraxia
       vi. Slow neuromotor regression
       vii. Seizures most frequent and severe
    d. Late motor deterioration stage (5–25 years)
       i. Decreased mobility (loss of ambulation)
       ii. Severe debilitation in patients who never walked
       iii. Spasticity
       iv. Improved emotional contact
       v. Scoliosis
       vi. Severe wasting and debilitation leading to "frozen stiffness"
       vii. Cachexia and growth retardation
       viii. Staring, unfathomable gaze
       ix. Complete wheelchair dependency
       x. Seizures may lessen or disappear

17. Wide spectrum of clinical features associated with an *MECP2* mutation
    a. Male patients with early-onset lethal encephalopathy
    b. Adult cases with severe mental retardation
    c. Female cases
        i. Asymptomatic
        ii. Mildly mentally retarded
        iii. Severe variant of Rett syndrome with congenital onset
18. Relatively restrictive international diagnostic criteria (Rett syndrome Diagnostic Criteria Work Group 1988)
    a. Apparently normal prenatal and perinatal period*
    b. Normal head circumference at birth
    c. Apparently normal development through age 6 months*
    d. Deceleration of head growth occurring anytime between ages 3 months and 48 months
    e. Loss of acquired hand skills and purposeful hand use between ages 5 months and 30 months, with subsequent development of stereotyped hand movements
    f. Severe impairment of expressive and receptive language together with severe psychomotor retardation
    g. Development of gait apraxia and truncal ataxia between ages 12 months and 48 months

* Clinical criteria "a" and "c" may not be applicable to severely affected females; other criteria will not apply to those who are mildly affected and are identified as having mutations in *MECP2*.

19. Modified diagnostic criteria (proposed by Clarke in 1996)
    a. Necessary criteria
        i. Normal prenatal and perinatal development
        ii. Loss of acquired skills such as communication and speech
        iii. Normal head circumference at birth with acquired microcephaly
        iv. Marked developmental delay
        v. Loss of hand skills
        vi. Autistic features
        vii. Gait apraxia
        viii. Stereotypic hand movements
    b. Supportive criteria
        i. Seizures
        ii. Abnormal EEG
        iii. Apnea
        iv. Hyperventilation
        v. Breathing dysfunction with breath holding
        vi. Scoliosis
        vii. Growth retardation
        viii. Cold feet
        ix. Spasticity with muscle wasting
20. Revised diagnostic criteria for classical and variant Rett syndrome (Hagberg et al. 2002; Williamson and Christodoulou 2006)
    a. Classical Rett syndrome
        i. Necessary criteria
            a) Normal prenatal and perinatal history
            b) Normal psychomotor development for the first 6 months
            c) Normal head circumference at birth
            d) Postnatal deceleration of head growth in most individuals
            e) Loss of purposeful hand skills between 6 months and 2.5 years
            f) Hand stereotypes
            g) Evolving social withdrawal, communication dysfunction, loss of acquired speech, and cognitive impairment
            h) Impairment or deterioration of locomotion
        ii. Supportive criteria
            a) Breathing disturbances during waking hours
            b) Bruxism
            c) Impairment of sleeping pattern from early infancy
            d) Abnormal muscle tone associated with muscle wasting and dystonia
            e) Peripheral vasomotor disturbances
            f) Progressive kyphosis or scoliosis
            g) Growth retardation
            h) Hypotrophic small and cold feet and/or hands
        iii. Exclusion criteria
            a) Evidence of a storage disorder including organomegaly
            b) Cataract, retinopathy, or optic atrophy
            c) History of perinatal or postnatal brain damage

d) Confirmed inborn error of metabolism or neurodegenerative disorder
e) Acquired neurological disorder due to severe head trauma or infection

b. Variant Rett syndrome
i. Inclusion criteria
a) At least three of the six main criteria
b) At least 5 of the 11 supportive criteria
ii. Main criteria
a) Reduction or absence of hand skills
b) Loss or reduction of speech (including babble)
c) Hand stereotypes
d) Loss or reduction of communication skills
e) Deceleration of head growth from early childhood
f) Regression followed by recovery of interaction
iii. Supportive criteria
a) Breathing irregularities
b) Abdominal bloating or air swallowing
c) Bruxism
d) Abnormal locomotion
e) Kyphosis or scoliosis
f) Lower limb amyotrophy
g) Cold, discolored and usually hypotrophic feet
h) Night time screaming and other sleep disturbances
i) Inexplicable episodes of screaming or laughing
j) Apparently diminished sensitivity to pain
k) Intense eye contact and/or eye pointing

Diagnostic Investigations

1. Mutational analyses of *MECP2* gene
   a. Sequence analysis and mutation scanning
   b. Mutations detected in 35–90% of patients (detected in almost every patient with classical Rett syndrome)
   c. Wide spectrum of mutations of the *MECP2* gene
   d. Mutations extending to phenotypes that are not easily recognized as Rett syndrome
   e. No significant correlation exists between the clinical course and mutation type.
   f. *MECP2* mutations have been identified in patients previously diagnosed with the following conditions:
      i. Autism
      ii. Mild learning disability
      iii. Clinically suspected but molecularly unconfirmed Angelman syndrome
      iv. Mental retardation with spasticity or tremor
2. X-chromosome inactivation pattern: not tested routinely
3. EEG: not specific
4. CT and MRI
   a. Cortical atrophy predominantly in the frontal area
   b. No abnormalities in the white matter, basal ganglia, thalamus, or hippocampus
   c. Narrowing of the brain stem in some patients
5. Photon emission CT
   a. Lower cerebral blood flow in the prefrontal and temporoparietal association regions with sparing of the sensorimotor regions
   b. The flow distribution in Rett patients
      i. Similar to that observed in infants of a few months of age
      ii. Suggesting a neurodevelopmental abnormality rather than a neurodegenerative process

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. 50% risk to sibs of inheriting *MECP2* allele from the carrier mother
      ii. Low risk to sibs (<1/300) (Killian 1986) when a mutation present in the proband is not identified in a parent, provided germ line mosaicism is not present in either parent (Amir et al. 1999; Mari et al. 2005)
   b. Patient's offspring
      i. Unlikely to have offspring due to mental retardation and other handicaps
      ii. Reproduction reported in mildly affected females
         a) Each offspring of a carrier female with 50% risk of inheriting the disease-causing mutation
         b) Daughters who inherit the mutation are at high risk of developing classic Rett

syndrome although skewed X chromosome inactivation may result in a milder phenotype.

c) Sons who inherit the mutation may suffer a severe neonatal encephalopathy or severe mental retardation in those who survive beyond the first year of age.

iii. Healthy sisters of a girl with Rett syndrome
   a) Possibility of being carriers of the *MECP2* mutation but with little or no symptoms because of favorable skewed X chromosome inactivation
   b) At risk of transmitting the disease-causing *MECP2* mutation to their own children

iv. No male with a *MECP2* mutation known to reproduce

2. Prenatal diagnosis
   a. Amniocentesis or chorionic villus sampling available to pregnancies at risk for women with a known *MECP2* mutation identified in a family member
   b. Appropriate to offer prenatal diagnosis to couples who have had a child with Rett syndrome or mental retardation due to a *MECP2* mutation, whether or not the disease-causing mutation has been identified in a parent since germ line mosaicism cannot be excluded in either parent
   c. A male fetus with the mutation
      i. May suffer from a severe neonatal encephalopathy
      ii. May survive with a severe mental retardation syndrome
   d. A female fetus with the mutation
      i. Difficult to predict the phenotype in a female fetus with a *MECP2* mutation which can range from apparently normal to severely affected
      ii. At high risk of developing classic Rett syndrome although skewed X chromosome inactivation may result in a milder phenotype
3. Management
   a. No treatment is known to improve the neurologic outcome of Rett patients.
   b. Supportive and symptomatic therapies
      i. Anticonvulsants for seizures
      ii. Chloral hydrate for agitation
      iii. Carbidopa and levodopa for rigidity
      iv. Melatonin for sleep disturbances
      v. Nutritional management to insure adequate caloric and fiber intake
      vi. Management of gastroesophageal reflux
         a) Antireflux agents
         b) Smaller and thickened feedings
         c) Positioning
   c. Occupational and physical therapies
      i. Maintain function
      ii. Prevent scoliosis and deformities
   d. Augmentative communication
   e. Therapeutic horseback riding, swimming, and music therapy

Fig. 1 A girl with Rett syndrome

Fig. 2 A girl with Rett syndrome who has *MECP2* mutation (R106W)

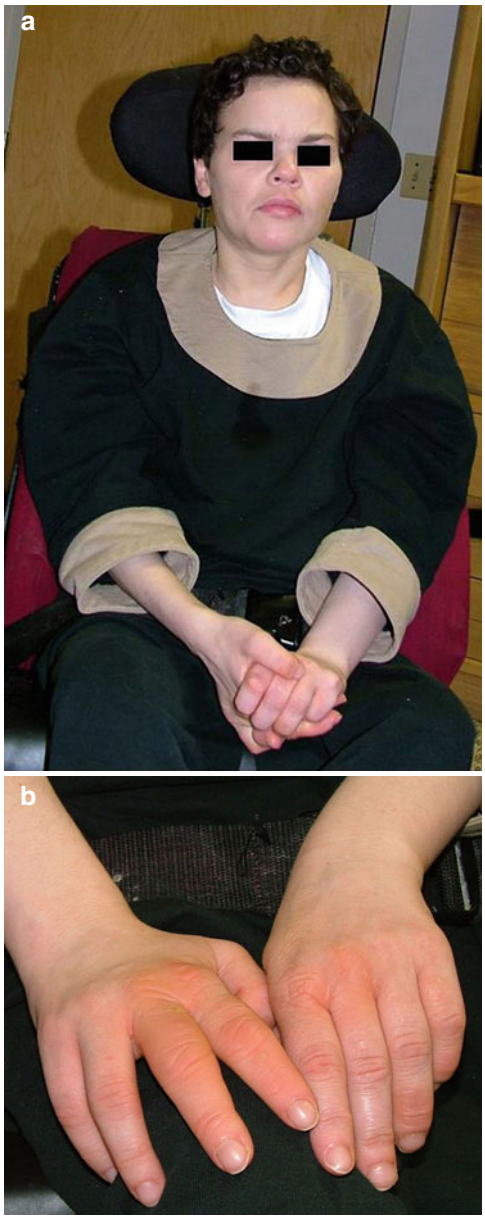

Fig. 3 (**a**, **b**) A 33-year-old female with Rett syndrome showing severe psychomotor retardation and hand wringing so severe that the part of the hand and fingers are red, rough, and swollen from constant irritation by stereotypic hand movement. She was normal developmentally until about 18 months of age when she started to have hand washing/wringing, tip toe walking, fell easily, and lost the skills she already attained. Shortly after, she started to lose eye contact with people and has seizures. DNA sequence analysis identify a nucleotide change of 763 C > T in one copy of the *MECP2* gene which predicts an amino acid change of arginine to a premature translation stop at codon 255 (R255X). This nonsense mutation was previously identified in multiple Rett syndrome patients as a disease-causing *MECP2* mutation

Rickets

Normal bone mineralization requires adequate supplies of calcium and phosphate and normal vitamin D metabolism. Defective supply or function of any of these factors can cause rickets and osteomalacia.

Synonyms and Related Disorders

Familial hypophosphatemic rickets; Nutritional rickets; Vitamin-deficiency rickets; Vitamin D-dependent rickets

Genetics/Basic Defects

1. Causes
   a. Younger than 6 months of age
      i. Hypophosphatasia
      ii. Prematurity
      iii. Primary hyperparathyroidism
      iv. Maternal factors
         a) Vitamin D deficiency
         b) Poorly controlled hyperparathyroidism
         c) Poorly controlled renal insufficiency
   b. Older than 6 months of age
      i. Nutritional rickets in children
         a) Inadequate levels (deficiency) of vitamin D due to either inadequate oral intake or insufficient exposure to sunlight
         b) With resultant decreased calcium absorption in the small intestine
         c) Thereby decreasing the available calcium for epiphyseal cartilage and skeletal mineralization
         d) Secondary hyperparathyroidism due to limited calcium availability and attendant renal phosphate losses contributes to the bone and growth plate pathophysiology that lead to the clinical manifestations of rickets.
      ii. Liver disease (impaired 25-vitamin D formation)
         a) Chronic liver diseases (extrahepatic biliary atresia, total parenteral nutrition, tyrosinemia)
         b) Anticonvulsant therapy
      iii. Malabsorption
         a) Celiac disease
         b) Inflammatory bowel disease
         c) Pancreatic insufficiency
      iv. Renal tubular insufficiency (hypophosphatemia)
         a) Vitamin D-resistant rickets
         b) Vitamin D-dependent rickets
         c) Fanconi syndrome
         d) Lowe syndrome
         e) Cystine storage disease
      v. Chronic renal disease (renal osteodystrophy)
         a) Pyelonephritis
         b) Polycystic kidney disease
         c) Chronic glomerulonephritis
         d) Renal tubular acidosis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_203,
© Springer Science+Business Media, LLC 2012

2. Vitamin D deficiency rickets: caused by low endogenous vitamin D
   a. Selected pediatric populations at high risk for vitamin D deficiency
      i. Dietary factors (breast-fed infants with marginal calcium stores due to low levels of vitamin D in breast milk)
      ii. Skin pigmentation (African American children due to dark skin absorbing ultraviolet radiation less available for vitamin D production)
      iii. Sun screen application
      iv. Insufficient sun exposure (far northern latitudes, during the winter months, cultural traditions)
   b. Other predisposing factors
      i. Severe liver failure
      ii. Nephrotic syndrome
      iii. Severe malnutrition
      iv. Gastrointestinal diseases leading to malabsorption, including impaired fat absorption or enterohepatic recirculation
3. Vitamin D-dependent rickets: caused by reduced activity of 25(OH)1-alphahydroxylase
   a. Vitamin D-dependent rickets type I (1-alpha-hydroxylase mutation): also known as hereditary pseudovitamin D deficiency rickets
      i. Autosomal recessivedisorder
      ii. Commonly found in the French Canadian population
      iii. The gene locus mapped to chromosome 12q14
      iv. Caused by mutation in the vitamin D 1-alpha-hydroxylase gene
      v. Impaired 1 alpha-hydroxylation in the renal proximal tubule that converts 25(OH)D to $1,25(OH)_2D$
   b. Vitamin D-dependent rickets type II (receptor mutation): also known as hereditary vitamin D-resistant rickets
      i. Autosomal recessive inheritance
      ii. Caused by mutations in the vitamin D receptor (VDR) that result in end-organ resistance to active vitamin D (1,25-dihydroxyvitamin D) [$1,25\text{-}(OH)_2D_3$]
      iii. Major defect caused by the mutant VDR: a decrease of intestinal calcium and phosphate absorption which leads to decreased bone mineralization and rickets
      iv. The major biochemical distinction between type I and type II
         a) Low circulating $1,25\text{-}(OH)_2D_3$ levels in patients with type I
         b) High circulating $1,25\text{-}(OH)_2D_3$ levels in patients with type II
4. Familial hypophosphatemic rickets
   a. A heterogeneous disease with an incidence of 1 in 20,000 newborns
   b. Caused by defect in reabsorption of phosphatein the proximal tubule, resulting in hypophos phatemia, defective bone mineralization, normoc alcemic rickets, and short stature
   c. Types of hypophosphatemia
      i. Dominant X-linked hypophosphatemic rickets (also called vitamin D-resistant rickets)
         a) The gene locus: mapped to Xp22.1
         b) The gene responsible: phosphate regulating (*PHEX*) gene with homologies to endopeptidases in the X chromosome (Chandran et al. 2010)
         c) Complete penetrance
         d) This is the most common form of metabolic rickets.
      ii. Autosomal dominant hypophosphatemic rickets
         a) The gene locus: mapped to 12p13
         b) Caused by mutations in *FGF23*
         c) Incomplete penetrance
      iii. Autosomal recessive hypophosphatemic rickets (Farrow et al. 2009; Levy-Litan et al. 2010; Lorenz-Depiereux et al. 2010)
         a) Caused by mutations in Dentin matrix protein-1 (*DMP1*) gene, which is associated with elevated fibroblast growth factor 23 (FGF23), or ectonucleotide pyrophosphatase/phosphodiesterase 1 (*ENPP1*) gene
         b) Surprisingly, *ENPP1* loss-of-function mutations have previously been described in generalized arterial calcification of infancy, suggesting an as yet elusive mechanism that balances arterial calcification with bone mineralization.

iv. Hereditary hypophosphatemic rickets with hypercalcinuria (Pettifor 2008)
a) Caused by *SLC34A3* mutations
b) Gene product: inactivating mutation in NaPi-IIc (renal Na-P_i cotransporter)
c) Elevated $1,25(OH)_2D$

Clinical Features

1. Rickets vs osteomalacia
   a. Rickets: occurs only before fusion of the epiphyses
   b. Osteomalacia: occurs in adults deficient in calcium, phosphate, or vitamin D
2. Signs of rickets in osseous tissues (Wharton and Bishop 2003)
   a. Craniotabes in newborn baby and young infant
      i. Softening of skull bones
      ii. May be present but not pathognomonic
   b. Frontal bossing in early infancy
      i. Expansion of cranial bones relative to facial bones
      ii. Also possibly due to hydrocephalus ("rickets hydrocephalus")
   c. Fontanelle
      i. Delayed closure
      ii. Occasional intracranial hypertension
   d. Wrists: an apparent bracelet of bone around the wrist (specificity 81%)
   e. Rickety rosary: swollen costochondral junctions of ribs (specificity 64%)
   f. Skeletal deformities
      i. Particularly "bow legs" once the child is walking
      ii. Genu valgum generally not due to rickets
      iii. Spinal curvature most likely due to nonrickets cause
      iv. Narrowed pelvic outlet used to cause obstructed labor
   g. Brown tumor: rare fibrous-cystic osteitis associated with the secondary hyperparathyroidism
   h. Limb pain
      i. Bone pain and pseudoparalysis uncommon
      ii. Osteomalacia and the subperiosteal hematoma of scurvy: more likely causes of pain
   i. Teeth
      i. Delayed eruption of teeth
      ii. Enamel hypoplasia: greater susceptibility to caries in the first dentition
3. Nonosseous effect of vitamin D deficiency (Wharton and Bishop 2003)
   a. Symptomatic hypocalcemia with convulsions: particularly in young infants less than 6 months of age born to mothers with untreated osteomalacia, many of whom are subclinical cases.
   b. Myopathy
      i. Proximal myopathy in infants and adolescents
      ii. Heart failure simulating cardiomyopathy with severe hypocalcemia
      iii. Responding to treatment for rickets and inotropes
   c. Myelofibrosis
      i. With pancytopenia or microcytic hypochromic anemia
      ii. Returning to normal when treated with vitamin D
   d. Possible link between early vitamin D deficiency and other disorders in later life
      i. Type I diabetes
      ii. Multiple sclerosis
      iii. Schizophrenia
      iv. Hear disease
   e. Intrauterine and infant growth: Vitamin D supplement in the last trimester of pregnancy improves growth in utero and during infancy in some studies.
4. Vitamin D deficiency rickets
   a. Not clinically apparent before 6 months of age because of prenatal stores of vitamin D imparted by the mother
   b. Decreased linear growth/short stature
   c. Poor weight gain/small for age
   d. Delayed development
   e. Incidental finding on radiograph or physical examinations
   f. Nonspecific musculoskeletal complaints
   g. Bowing of the legs
   h. Seizures
   i. Tetany
   j. Weakness
   k. Drowsiness

l. Development of secondary hyperparathyroidismdue to increasing severity of vitamin D deficiency, progressing to frank osteomalacia and fractures

5. Vitamin D-dependent rickets
   a. Vitamin D-dependent rickets type I (hereditary pseudovitamin D deficiency rickets)
      i. Clinical presentation within the first few months of life
      ii. First clinical sign: acute or chronic hypocalcemia because the major physiologic role of 1,25-dihydroxyvitamin D is to promote intestinal calcium absorption
      iii. Hypocalcemic seizures as early as 4 weeks of age or usually before 2 years of age
      iv. Growth retardation
      v. Bowing of the extremities
      vi. Bone pain secondary to rickets and osteomalacia
      vii. Enamel hypoplasia and oligodentia
      viii. Hypocalcemia accompanied by secondary hyperparathyroidism resulting in hypophosphatemia and occasional aminoaciduria
   b. Vitamin D-dependent rickets type II (hereditary vitamin D-resistant rickets)
      i. Onset of disease: infancy or childhood
      ii. Major clinical findings: hypocalcemia and rickets due to defective intestinal calcium absorption leading to impaired mineralization of newly forming bone and preosseous cartilage.
      iii. Rickets
         a) Often severe
         b) Usually exhibits within months of birth
      iv. Bone pain
      v. Muscle weakness
      vi. Hypotonia
      vii. Occasional convulsions from hypocalcemia
      viii. Often growth retarded
      ix. Enamel hypoplasia, oligodentia, and severe dental caries
      x. Hypocalcemia accompanied by secondary hyperparathyroidism results in hypophosphatemia and occasional aminoaciduria.
      xi. Pneumonia secondary to severe rickets of the chest wall and poor respiratory effort causes death in some infants.
      xii. Alopecia
         a) Sparse body hair in many patients
         b) Alopecia totalis observed in some kindreds, including eyebrows and in some cases eyelashes

6. Hereditary hypophosphatemic rickets
   a. X-linked dominant hypophosphatemic rickets
      i. Characterized by renal phosphate wasting with hypophosphatemia
      ii. Disease severity similar in males and females but differs among individuals (some patients with isolated hypophosphatemia; others with disabling severe bone disease)
      iii. The disease may persist into adulthood.
      iv. Short stature
      v. Rickets with resultant lower-extremity deformities
      vi. Bone pain.
      vii. Enthesopathy (calcification of tendons, ligaments, and joint capsules)
      viii. Dental abscesses
      ix. Cranial abnormalities (e.g., craniosynostosis) (Murthy 2009) and spinal stenosis in some severely affected individuals
   b. Autosomal dominant hypophosphatemic rickets
      i. Isolated renal phosphate wasting
      ii. Short stature
      iii. Impressive windswept deformity (valgus on one side and varus on the other side)
      iv. Marked tendency for fracture with or without trauma
      v. Delayed onset of disease in some patients
      vi. Patients who present as adults: osteomalacia with bone pain, weakness, and fractures
   c. Autosomal recessive hypophosphatemic rickets: severe disease course (Stamp and Baker 1976; Farrow et al. 2009)
      i. Marked hypophosphatemia
      ii. Persistent osteomalacia upon bone biopsy
      iii. Increased bone density by dual-energy X-ray absorptiometry
      iv. Stunted growth
      v. Nerve deafness
      vi. Facial and dental abnormalities
      vii. Learning disabilities

Diagnostic Investigations

1. Vitamin D deficiency rickets
   a. Decreased levels of 25-OH vitamin D (best screening test for vitamin D stores in otherwise healthy individuals)
   b. Normal or increased levels of 1,25 $(OH)_2$ vitamin D
   c. Increased levels of parathyroid hormone
   d. Decreased levels of calcium (hypocalcemia)
   e. Decreased levels of phosphate (hypophosphatemia)
2. Vitamin D-resistant rickets
   a. Renal tubular phosphate leakage and subsequent hypophosphatemia in all affected individuals
   b. Normal levels of 25-OH vitamin D
   c. Normal or decreased levels of 1,25 $(OH)_2$ vitamin D
   d. Normal or increased levels of parathyroid hormone
   e. Normal levels of calcium
   f. Decreased phosphate (hypophosphatemia)
3. Vitamin D-dependent rickets
   a. Elevated or normal levels of 25-OH vitamin D
   b. Low levels of 1,25 $(OH)_2$ vitamin D in type I and elevated levels in type II
   c. Normal or increased levels of parathyroid hormone
   d. Normal or decreased levels of calcium
   e. Decreased levels of phosphorous (hypophosphatemia)
   f. Elevated serum alkaline phosphatase activity
4. Radiographic findings
   a. Cupping, fraying, and widening of the metaphyses: a requirement for diagnosis of rickets
   b. Rachitic rosary (enlargement of the wrists, knees, and costochondral beadings)
   c. Flaring of ribs at diaphragm level (Harrison's groove)
   d. Bowing of the lower extremities in the newly ambulating child
   e. Widening and irregularity of all the physes
   f. Osteopenia (decreased mineralization of the bone matrix) with blurred or nonapparent cortical outlines of the epiphyseal ossification centers
   g. Multiple fractures in various stages of healing
   h. Deformities caused by softening of bone or poor muscle tone
      i. Femoral bowing
      ii. Tibial bowing
      iii. Genu valgum (knock knees)
   i. Genu valgum or varum
   j. Lordosis/kyphosis/scoliosis
   k. Pelvis
      i. Coxa valga
      ii. Protrusio acetabuli
   l. Thorax: hourglass shape
   m. Skull
      i. Postural molding
      ii. Frontal bossing
      iii. Craniotabes
      iv. Delayed closure of anterior fontanel
   n. Dental abnormalities
   o. The zone of provisional calcification appearing as a dense metaphyseal band due to calcium deposit in response to vitamin D therapy
      i. Seen as early as 2–3 weeks after initiation of therapy in children with nutritional rickets
      ii. Seen after 2–3 months in children with renal rickets
      iii. Persistence of deformities caused by bone softening despite successful treatment
5. Histological findings
   a. Primary metabolic abnormality at the zone of provisional calcification
   b. Diminished calcification of cartilage columns in the metaphysis
   c. Continued osteoid production by osteoblasts, but ossification of the osteoid tissue is impaired because of insufficient calcium deposition
   d. Widened, irregularly calcified physis resulting from resorption of osteoid and calcium because of impaired osteoclast function
   e. Metaphyseal broadening or "cupping" likely caused by stress at sites of ligament attachment
   f. Splaying of cartilage cells peripherally
   g. Microfractures of the primary spongiosa by herniation of cartilage into this area
6. Molecular genetic diagnosis
   a. X-linked dominant hypophosphatemic rickets (*PHEX* gene mutations)
      i. Sequencing of entire coding region
      ii. Deletion/duplication analysis

b. Autosomal dominant hypophosphatemic rickets (*FGF23* gene mutations)
   i. Sequencing of entire coding region
   ii. Mutation scanning
   iii. Targeted mutation analysis
   iv. Deletion/duplication analysis
c. Hypophosphatemic rickets, autosomal recessive 1 (*DMP1* gene mutations)
   i. Sequencing of entire coding region
   ii. Deletion/duplication analysis
d. Hypophosphatemic rickets, autosomal recessive 2 (*ENPP1* gene mutations): sequencing of the entire coding region
e. Vitamin D-dependent rickets, type I (*CYP27B1* gene mutations)
   i. Sequencing of entire coding region
   ii. Targeted mutation analysis
   iii. Deletion/duplication analysis
f. Vitamin D-dependent rickets, type II (VDR gene mutations): sequencing of the entire coding region
g. Hereditary hypophosphatemic rickets with hypercalcinuria (*SLC34A3* gene mutations): sequencing of the entire coding region

Genetic Counseling

1. Recurrence risk: depends on the etiology
   a. Vitamin D deficiency rickets: recurrence risk high if conditions leading to vitamin D deficiency exist
   b. Autosomal recessive inheritance
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier or affected
   c. Autosomal dominant inheritance
      i. Patient's sib: not increased unless a parent is affected
      ii. Patient's offspring: 50%
   d. X-linked dominant inheritance
      i. Patient's sib: not increased unless a parent is affected
      ii. Patient's offspring
         a) Affected female: 50% of daughters and 50% of sons will be affected.
         b) Affected male: All daughters will be affected and all sons normal.
2. Prenatal diagnosis
   a. Fetal radiography, particularly in mothers with osteomalacia
      i. Poorly mineralized fetal bones
      ii. Thin cortices of the limb bones and penciled outlines of the vertebral bodies
      iii. Cupped tibial/radial metaphysis with indistinct border to the epiphyseal aspect
   b. Fetal echocardiography
      i. Atrial flutter with heart failure reported in a fetus affected with X-linked dominant hypophosphatemic rickets.
      ii. Causal relationship in this case remained unknown.
   c. Prenatal diagnosis by molecular analysis of cultured fetal cells obtained from CVS and amniocentesis in pregnant women from high-risk families to look for disease-causing mutation, previously identified in an affected individual
      i. X-linked dominant hypophosphatemic rickets
      ii. Autosomal dominant hypophosphatemic rickets
      iii. Autosomal recessive hypophosphatemic rickets, I
      iv. Vitamin D-dependent rickets type I and type II
      v. Hereditary hypophosphatemic rickets with hypercalciuria
3. Management
   a. Hypocalcemia and "simple rickets" (Wharton and Bishop 2003)
      i. Hypocalcemia (early infancy)
         a) IV calcium gluconate to control continuing seizures
         b) Oral calcium daily
         c) Oral calciferol daily
         d) Look for evidence of rickets in the baby (radiographs of the knees and wrists).
         e) Look for maternal osteomalacia (elevated maternal alkaline phosphatase).
         f) Slowly withdraw treatment when the plasma calcium is normal.
         g) Continue prophylactic vitamin D thereafter.
      ii. Rickets without hypocalcemia (early infancy): oral calciferol daily for 2–4 months
      iii. Older infants, toddlers, and adolescents
         a) Oral calciferol
         b) Add oral calcium if dietary deficiency may be a factor.

c) Phosphorus not needed in simple rickets since phosphorus is abundant in the diet
d) Necessary to supplement phosphorus for very preterm babies and in the phosphate-wasting causes of rickets

b. Vitamin D deficiency rickets
   i. Increase dietary intake of vitamin D
      a) The new recommended adequate intake of vitamin D by the National Academy of Sciences to prevent vitamin D deficiency in normal infants, children, and adolescents is 200 IU per day.
      b) An intake of at least 200 IU per day of vitamin D will prevent physical signs of vitamin D deficiency and maintain serum 25-hydroxy-vitamin D at or above 27.5 nmol/L.
   ii. Increased sun exposure
   iii. Prevent other predisposing factors
c. Vitamin D-resistant rickets
   i. Increase dietary intake of vitamin D.
   ii. Increased sun exposure
   iii. Prevent other predisposing factors.
d. Vitamin D-dependent rickets: lifelong treatment with 1-alpha-hydroxyvitamin D or 1,25-dihydroxyvitamin D
e. Dominant X-linked hypophosphatemic rickets: treat bone lesions and impaired longitudinal growth
   i. Medical treatment remains the main pillar of therapy in affected children.
      a) Vitamin D supplement
      b) Oral phosphate supplement: risks of stimulating secondary hyperparathyroidism
   ii. Surgery can be safely performed in XL vitamin D-resistant hypophosphatemic rickets, independent of age or bone maturation (Fucentese et al. 2008).

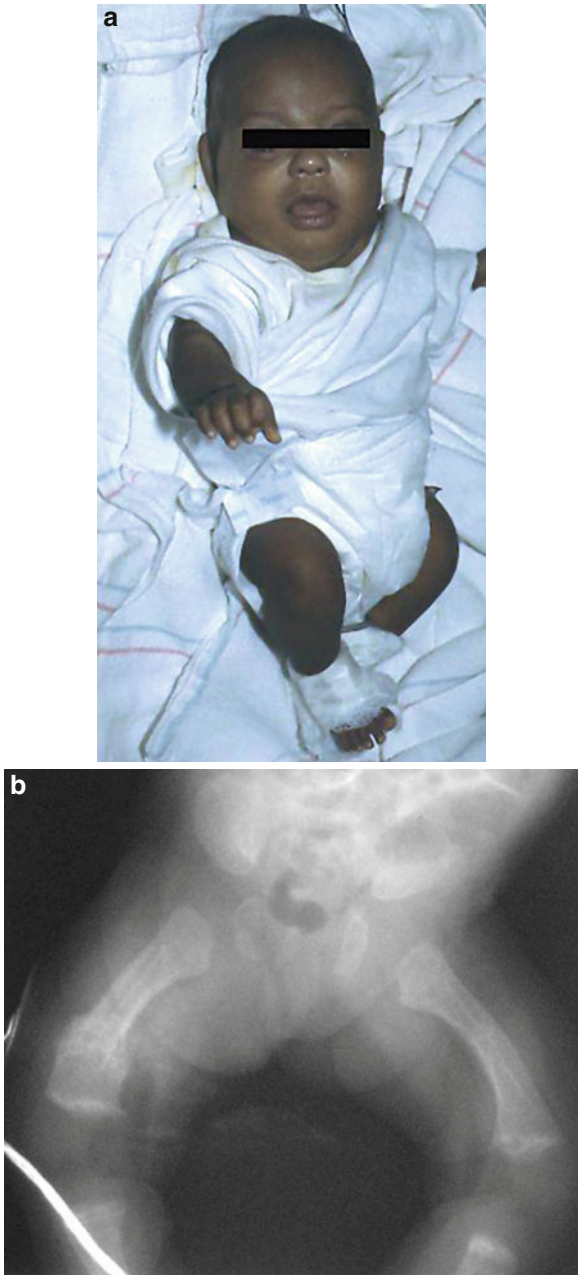

Fig. 1 (**a**, **b**) An infant with healing nutritional rickets. The radiograph shows femoral bowing and a healing fracture with callus formation in the right femur

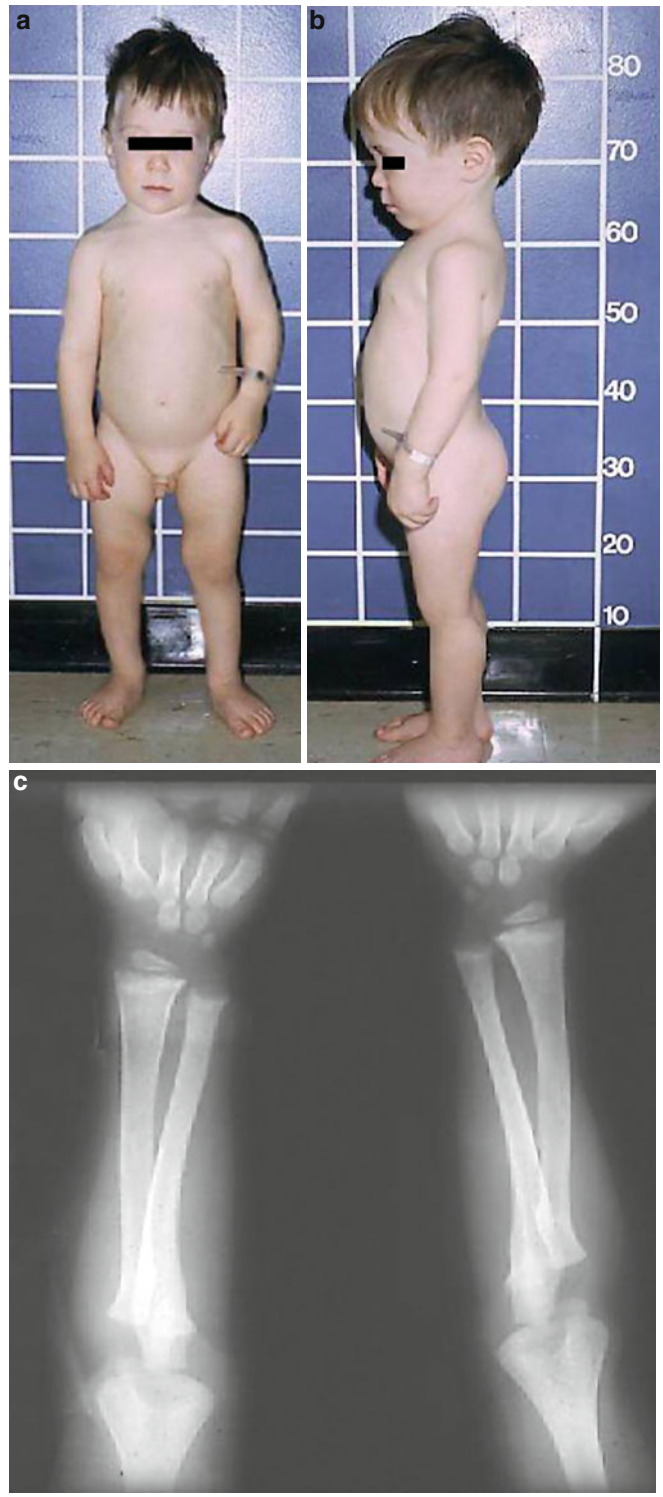

Fig. 2 (**a**–**c**) A boy with vitamin D-resistant rickets showing short stature. The radiograph shows widening, cupping, and fraying of the distal radius and ulna

Fig. 3 (**a**, **b**) Another boy with vitamin D-resistant rickets

Fig. 4 (**a**, **b**) Radiograph from a patient with renal rickets shows widening, cupping, and fraying of the distal radius and ulna

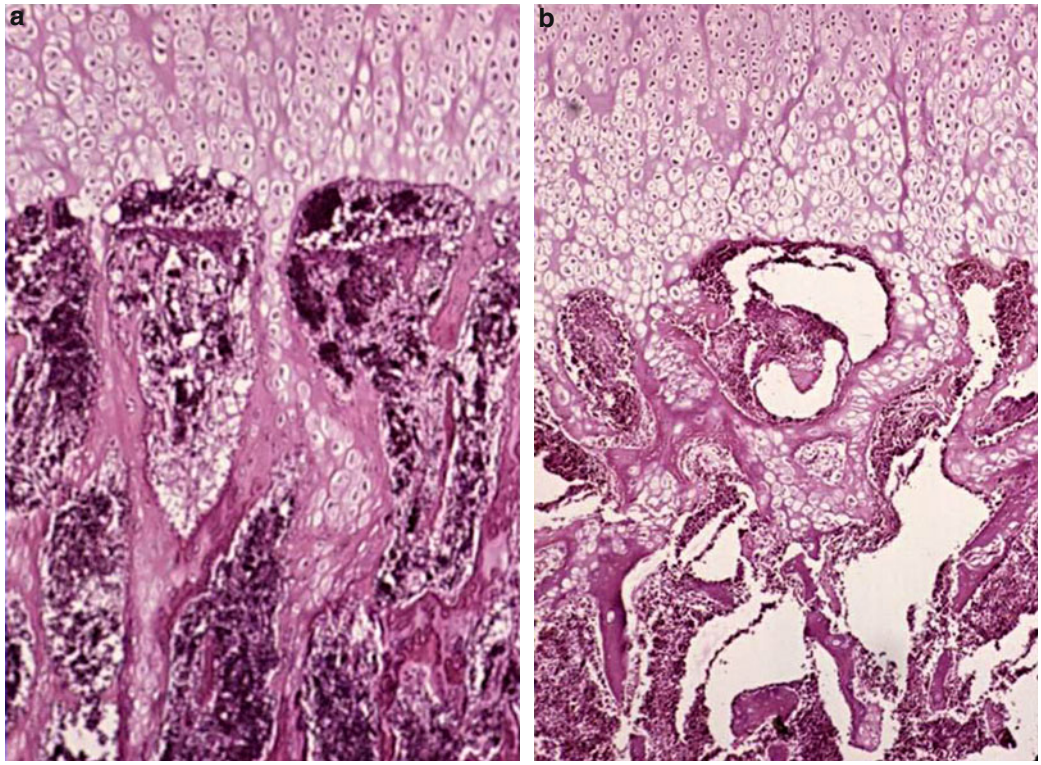

Fig. 5 (**a**, **b**) Photomicrograph of the humerus (*left*) and the rib (*right*) of a female neonate who lived 43 min. Broad cartilage columns with many large chondrocytes are present in the metaphysis. They have broad osteoid seams and are poorly ossified. The abnormal area corresponds to the radiographic metaphyseal irregular lucency. The findings are similar to those of hypophosphatasia, though the changes are milder. The cause of congenital rickets in this case is unknown. The mother did not have history of malabsorption, vitamin D intake deficiency, renal failure, or preeclampsia

Fig. 6 Three sisters with hypophosphatemic rickets showing short stature and bowed legs. They have an affected father

Fig. 7 Two sisters and a brother with hypophosphatemic rickets showing short stature. The brother had severe short stature and bowed legs. The oldest sister had surgeries on her legs to correct the lower leg deformities. The middle sister was mildly affected. Their mother was affected

Rigid Spine Syndrome

The peculiar phenotype caused by the combination of muscle wasting and prominent spinal rigidity was first proposed by (Dubowitz 1965, 1973) and termed "rigid spine syndrome."

Synonyms and Related Disorders

Congenital muscular dystrophy with spinal rigidity

Genetics/Basic Defects

1. *SEPN1* gene mutations resulting in rigid spine congenital muscular dystrophy were first identified by Moghadaszadeh et al. in (Moghadaszadeh et al. 2001).
2. Several different forms of autosomal recessive muscle disorders caused by mutations in the *SEPN1* gene (Rederstorff et al. 2007)
   a. Different forms
      i. Congenital muscular dystrophy with spinal rigidity (RSMD1) (Moghadaszadeh et al. 2001)
      ii. Multiminicore myopathy (MmD) (Ferreiro et al. 2002)
      iii. Desmin-related myopathy with Mallory body-like inclusions (MB-DRM) (Ferreiro et al. 2004)
      iv. Congenital fiber-type disproportion myopathy (CFTD) (Clarke et al. 2006)
   b. Share identical clinical features, despite distinctly different histopathological descriptions of these different disorders
      i. Early weakness of axial muscles
      ii. Development of spinal rigidity and scoliosis
      iii. Severe respiratory insufficiency
   c. These phenotypes are now grouped under the generic term of *SEPN1*-related myopathy (Ferreiro et al. 2002).
3. *SEPN1* gene mutations
   a. *SEPN1* gene, mapped on chromosome 1p35–36 (Moghadaszadeh et al. 1998), codes for selenoprotein N, an endoplasmic reticulum glycoprotein.
   b. Numerous mutations scattered all over the *SEPN1* gene (Deniziak et al. 2007)
   c. Most mutations are nonsense mutations and deletions, likely to induce a loss of function.

Clinical Features

1. Early spine rigidity: a predominant feature (limitation in flexion of dorsolumbar and cervical spine due to contracture of spinal extensors)
2. Diffuse, mild to severe muscle wasting with failure to thrive
3. Muscle weakness/axial hypotonia
   a. Diffuse, more prominent in the neck and trunk
   b. Facial weakness
   c. Finger extensors and trunk flexors weakness
4. Contractures
   a. Limitation in mouth opening
   b. Joint contractures (knees, ankles, elbows, and/or hips)
5. Lumbar scoliosis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_204,
© Springer Science+Business Media, LLC 2012

6. Delay of gross motor milestones evident, though ambulation is eventually achieved and preserved in most patients
7. Nasal speech common due to palatal weakness
8. Impaired respiratory function
   a. Respiratory failure due to skeletal abnormalities and diaphragmatic weakness
   b. Nocturnal hypoventilation may be an early feature and a cause of mortality (Morita et al. 1990; Ras et al. 1994).
   c. May require mechanical ventilation by teens
9. Rare reports of various cardiac involvement (Stübgen et al. (Stübgen 2008a))
   a. Complete heart block
   b. Interventricular septum hypertrophy
   c. Left atrial and ventricular hypertrophy
   d. Cardiomyopathy may occur concomitantly.
10. Differential diagnosis of spine rigidity associated with various neuromuscular and movement disorders (Sponholz et al. 2006)
    a. Classic form of multiminicore disease
    b. Desmin-related myopathy with Mallory body-like inclusions
    c. Emery-Dreifuss muscular dystrophy
    d. Bethlem myopathy
    e. Ullrich congenital muscular dystrophy
    f. Dysferlinopathy
    g. Other congenital myopathies
    h. Mitochondrial myopathies
    i. Metabolic diseases (e.g., lysosomal storage disorders)
    j. Dystonias
    k. Ankylosing spondylitis

Diagnostic Investigations

1. CK serum levels: normal or only mildly elevated (Lisi and Cohn 2007)
2. Muscle biopsy: nonspecific myopathic changes
   a. Fiber diameter variability
   b. Prevalence of type I fibers
   c. Atrophy and internalization of nuclei
   d. Marked fibrosis
   e. Some specimen contain minicores typical of classical minicore myopathies (Ferreiro et al. 2002).
3. Electromyogram: myopathic pattern in spinal muscles
4. MRI imaging of muscles
5. MRI of the brain: normal
6. Antibodies directed against the 70-kDa SEPN1 show absence of the protein in fibroblasts of patients with nonsense mutations.
7. Screening for mutations in the *SEPN1* gene is required to establish the diagnosis of rigid spine muscular dystrophy.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25% affected, given the parents are carriers
   b. Patient's offspring
      i. When the spouse is not a carrier, all offspring obligate heterozygotes.
      ii. When the spouse is a carrier, 50% of offspring affected and 50% of offspring carriers
2. Prenatal diagnosis
   a. Not reported to date
   b. Possible for pregnancies at increased risk if the disease-causing gene mutation has been identified in the family
3. Management (Jungbluth 2007)
   a. No curative treatment currently available
   b. Regular physiotherapy
      i. Promote endurance
      ii. Preserve muscle function
      iii. Prevention of contractures, especially Achilles tendon
   c. Swimming and riding for promoting truncal stability
   d. Management of scoliosis
      i. Conservative approaches often unsuccessful due to the progressive nature of the deformity
      ii. Eventually need to be managed surgically
   e. Mobilization following surgery ought to be early in order to avoid the detrimental effects of prolonged immobilization on muscle strength
   f. Appropriate rehabilitative measures to promote independent ambulation
   g. Management of severe respiratory impairment; mechanical ventilation may eventually be needed.

h. Echocardiography for cardiomyopathy
i. Therapeutic perspectives (Reed 2009)
   i. Recently, (Rederstorff et al. 2007) reported a patient with a homozygous point mutation at the selenocysteine (Sec) codon (c.G1385A) that converted the normal codon UGA to UAA, therefore preventing synthesis of a full-length active SePN protein.
   ii. (Lescure et al. 2008) subsequently "engineered a mutant tRNASec gene carrying a point mutation in the anticodon, thereby restoring the base-complementarity with the SEPN1-mutated codon; in patient-derived primary fibroblasts, the corrector tRNASec gene allowed read-through of the UAA stop codon, thus enabling synthesis of the full-length SePN protein" (Rederstorff et al. 2007).
   iii. This is the first attempt of a therapeutic strategy for rigid spine CMD and other SEPN related disorders, using a mutation-specific approach.

Fig. 1 This 8-year-and-6-month-old boy was evaluated for poor weight gain, hypotonia, and muscle weakness. On examination, he was noted to be very hypotonic with poor head control, inability to flex the spine or the neck and limited rotation of the neck, mild scoliosis, and chest wall asymmetry. Metabolic panel revealed a minimally elevated AST (40 μ/L), a minimally elevated CPK (362 μ/L), and a mildly elevated aldolase (7.8 μ/L). The radiographs of the spine showed straight lateral view of the spine without normal cervical and thoracic curvatures with minimal scoliosis. Because of the radiographs, rigid spine muscular dystrophy, a selenoprotein N1-related myopathy, was suspected. The SEPN1 mutation analysis revealed that the patient is heterozygous for a mutation in exon 1 of the SEPN1 (c.1A > G) and a mutation in exon 7 of the SEPN1 gene (c.943 G > A) which are both known to be pathogenic. The results are consistent with a diagnosis of SEPN1-related myopathy, an autosomal recessive myopathy. Note the myopathic face

Fig. 2 Note the stiff neck and spine with minimal scoliosis

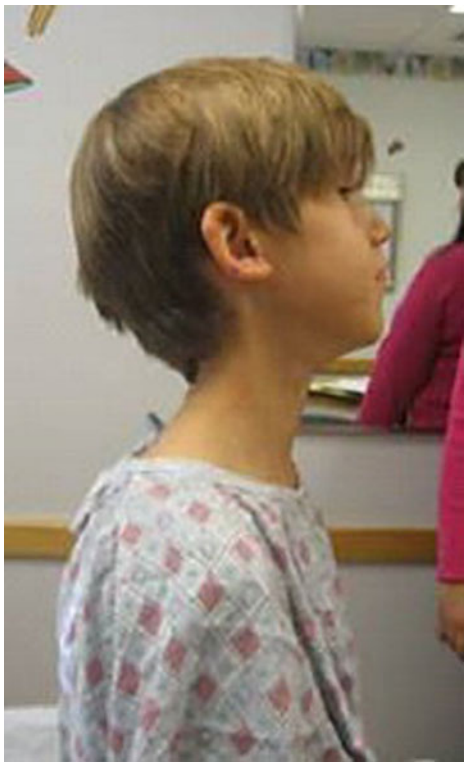

Fig. 3 Note his rigid neck that cannot bend

Fig. 4 Note difficulty in bending his neck and spine

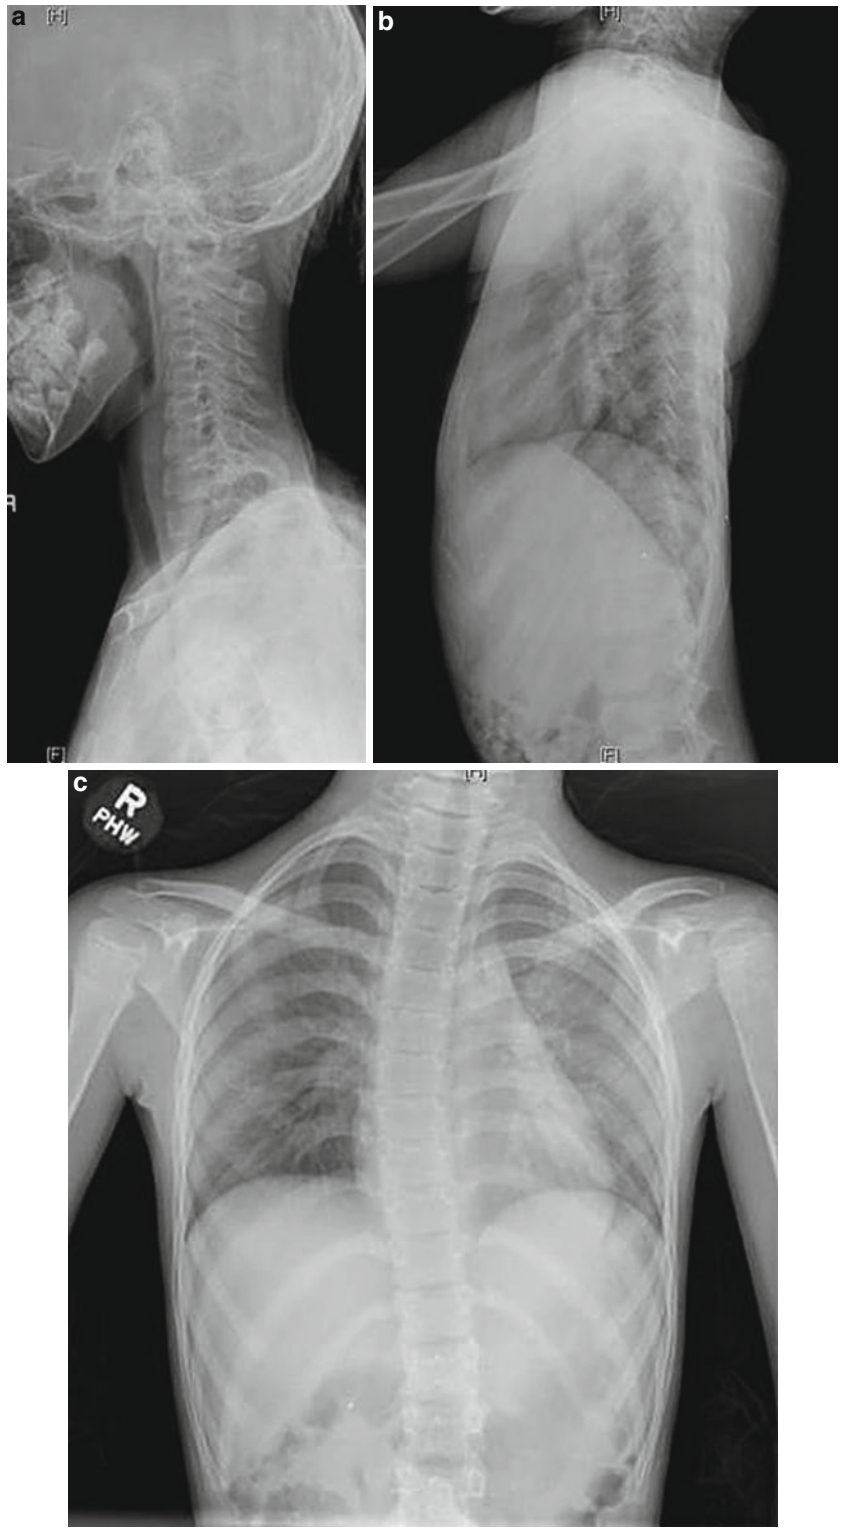

Fig. 5 (**a**–**c**) Radiographs of the spine showed stiff spinal column (lateral views) and mild scoliosis (AP view)

Roberts Syndrome

Roberts syndrome is a rare hereditary disorder characterized by symmetrical reduction of all limbs and a unique cytogenetic abnormality of premature centromere separation, which disrupts the process of chromatid pairing.

Synonyms and Related Disorders

Roberts-SC Phocomelia syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Associated with unique cytogenetic abnormality: premature centromere separation
   a. Disrupts the process of chromatid pairing
   b. Responsible for the development of multiple structural anomalies observed in Roberts syndrome
3. Caused by mutations in *establishment of cohesion 1 homologue 2* (*ESCO2*) on 8p21.1, a human homolog of yeast *ECO1* that is essential for the establishment of sister chromatid cohesion (Vega et al. 2005)
4. Loss of ESCO2 acetyltransferase activity was recently implicated in the molecular mechanism of Roberts syndrome (Gordillo et al. 2008).

Clinical Features

1. Craniofacial malformations: marked variability
   a. Bilateral cleft lip and cleft palate in severe cases
   b. No clefting of the lip or palate in some cases
   c. Hypertelorism secondary to widely spaced orbits
   d. Ophthalmic manifestations
      i. Exophthalmos due to shallow orbits
      ii. Microphthalmia
      iii. Peter anomaly
      iv. Cloudy cornea
      v. Cataracts
   e. Wide nasal bridge
   f. Hypoplastic nasal alae
   g. Hemangiomata of the lip, nose, face, or forehead
   h. Micrognathia
   i. Dark scalp hair becomes thin and silvery blond.
2. Limb defects
   a. Phenotype varies from a complete absence of arms and legs with rudimentary digits to mild growth reduction in the limbs.
   b. Limb reduction defects tend to be symmetric and more severely involved in the upper extremities than the lower extremities.
   c. Presence of phocomelia
      i. Tetraphocomelia: a prominent characteristic of the syndrome
      ii. Two deficient limbs in 11% of cases
      iii. No phocomelia in 2% of cases
   d. Often reduced number of fingers (oligodactyly)
   e. Radial aplasia or dysplasia common
   f. Lack of 1st metacarpal, thumb, or first phalanx
3. Other associated anomalies
   a. CNS anomalies
      i. Mental retardation
      ii. Microcephaly
      iii. Hydrocephalus
      iv. Absent olfactory lobes
      v. Calcification of the basal ganglia
      vi. Encephalocele

vii. Cranial nerve paralysis
viii. Seizures
b. Congenital heart defects
i. Atrial septal defect
ii. Patent ductus arteriosus
iii. Pulmonic stenosis
iv. Aortic stenosis
v. AV canal defect
c. Renal anomalies
i. Polycystic kidneys
ii. Dysplastic kidneys
iii. Horseshoe kidney
iv. Hydronephrosis
v. Renal agenesis
d. Gastrointestinal obstruction
e. Splenogonadal fusion
f. Cryptorchidism
g. Enlarged phallus
h. Failure to thrive
i. Neoplasms
i. Sarcoma botryoides
ii. Malignant melanoma
4. Prognosis
a. Severe cases
i. Often resulting in spontaneous abortions or stillbirths
ii. Few cases survive past one month of life.
b. Phenotypically milder cases
i. Requiring minimal to full time care depending on the degree of mental retardation
ii. May require surgical interventions to correct craniofacial and limb anomalies
5. Differential diagnosis (Gordillo et al. 2009)
a. SC phocomelia (Herrmann et al. 1969)
i. Clinical characteristics
a) Tetraphocomelia
b) Scanty silvery blond hair
c) Microcephaly
d) Mild mental retardation
e) Facial hemangioma
f) Cloudy cornea
g) Hypoplastic nasal alae and ears
ii. Originally thought to differ from Roberts syndrome by
a) Usual absence of midfacial clefting
b) Prolonged survival
c) Lesser degree of mental and physical retardation
d) Relatively milder degree of phocomelia
iii. Now considered to be the same entity as Roberts syndrome (Roberts-SC phocomelia syndrome) based on the following observations (Schüle et al. 2005):
a) The presence of severely and mildly affected individuals in the same sibship raised the suspicion that the two disorders are allelic, representing spectrum of severity.
b) Furthermore, both are characterized by heterochromatin repulsion (HR) or premature centromere separation in mitotic cells (Judge 1973; Freeman et al. 1974a, 1974b; Tomkins et al. 1979).
c) Somatic-cell complementation studies revealed that cells positive for HR (HR+) from individuals with Roberts syndrome and from those with SC do not complement each other, further supporting the notion that the same gene is affected in the two disorders (McDaniel et al. 2000).
b. Thrombocytopenia-absent radius (TAR) syndrome (see the chapter on Thrombocytopenia-Absent Radius (TAR) Syndrome).
i. Absent radii with thumbs present
ii. Hypomegakaryocytic thrombocytopenia
iii. Absent cleft palate
c. Baller-Gerold syndrome
i. Autosomal recessive disorder
ii. Craniosynostosis (brachycephaly)
iii. Ocular proptosis
iv. Bulging forehead
v. Radial ray defect (oligodactyly)
vi. Aplasia or hypoplasia of the thumb and/or aplasia or hypoplasia of the radius
vii. Growth retardation
viii. Poikiloderma
ix. Caused by mutations in *RECQL4*
d. Fanconi anemia (see the chapter on Thrombocytopenia-Absent Radius (TAR) Syndrome).
e. Tetra-amelia, X-linked (Zimmer tetraphocomelia)
i. Tetra-amelia
ii. Facial clefts
iii. Absence of ears and nose
iv. Anal atresia
v. Absence of frontal bones
vi. Pulmonary hypoplasia with adenomatoid malformation
vii. Absence of thyroid

viii. Dysplastic kidneys, gallbladder, spleen, uterus, and ovaries
ix. Imperforate vagina

f. Tetra-amelia, autosomal recessive
i. Caused by mutations in the WNT3
ii. Amelia
iii. Severe lung hypoplasia and aplasia of the peripheral pulmonary vessels
iv. Cleft lip/palate
v. Hypoplasia of the pelvis
vi. Malformed uterus
vii. Atresia of the urethra, vagina, and anus
viii. Diaphragmatic defect
ix. Agenesis of the kidney, spleen, and adrenal glands

g. Splenogonadal fusion with limb defects and micrognathia
i. Autosomal recessive inheritance
ii. Abnormal fusion between the spleen and the gonad or the remnants of the mesonephros
iii. Tetramelia
iv. Mild mandibular and oral abnormalities (micrognathia, multiple unerupted teeth, crowding of the upper incisors, and deep, narrow, V-shaped palate without cleft)

h. DK phocomelia syndrome
i. Autosomal recessive inheritance
ii. Phocomelia
iii. Absence of radius and digits
iv. Thrombocytopenia
v. Encephalocele
vi. Cleft palate and absence of radius and digits
vii. Anal atresia
viii. Abnormal lobation of the lungs
ix. Diaphragmatic agenesis

i. Holt-Oram syndrome (see the chapter)

j. Thalidomide embryopathy (see the chapter on dysmelia)
i. Abnormalities of the long bones of the extremities
a) Upper limb bones are affected in an order of frequency starting with the thumb, followed by the radius, the humerus, the ulna, and finally the fingers on the ulnar side of the hand.
b) In extreme cases, the radius, ulna, and humerus are lacking; the hand bud arises from the shoulders.
c) Legs may be affected but less severely.
ii. The second major group of defects involves the ears (anotia, microtia, accessory auricles) and the eyes (coloboma of the iris, anophthalmia, microphthalmia).
iii. Internal defects commonly involve the heart, kidneys, and urinary, alimentary, and genital tracts.

k. Cornelia de Lange syndrome (see the chapter)

l. Mosaic variegated aneuploidy syndrome
i. Autosomal recessive inheritance
ii. Caused by mutations in *BUB1B* which encodes BUBR1, a key protein in the mitotic spindle checkpoint, which have been found in individuals with this disease
iii. Severe microcephaly
iv. Growth deficiency
v. Mental retardation
vi. Childhood cancer predisposition
vii. Associated with constitutional mosaicism for chromosomal gains and losses
viii. Cytogenetic findings include premature centromere division, in which mitotic cells show split centromeres and splayed chromatids in all or most chromosomes (Plaja et al. 2001).

Diagnostic Investigations

1. Cytogenetics
a. Distinctive abnormality of the constitutive heterochromatin (the RS effect): premature centromere separation (PCS)
i. Detected in
a) Fibroblasts and lymphocytes in neonates
b) Chorionic villi and amniocytes in the fetus
ii. Consists of "puffing" or "repulsion" of the constitutive heterochromatin
a) Chromosome puffing most obvious at the large heterochromatic regions of chromosomes 1, 9, and 16
b) Chromosome repulsion most evident at the short arms of the acrocentrics and the distal long arm of the Y chromosome
iii. A "railroad-track" or "tram-track" appearance of the sister chromatids due to the

absence of a constriction at the centromere in several other chromosomes
    a) This phenomenon, called heterochromatin repulsion, is observed in cells of different tissue origin with several chromosomes in each metaphase showing a visible abnormality.
    b) Most evident in chromosomes containing the largest amount of heterochromatin
  b. Sporadic aneuploidy was noted with the pattern of aneuploidy different in each patient. The possible relationship between centromere "splaying" and aneuploidy is yet to be determined.
  c. Normal karyotypes lacking any microdeletion or chromosomal rearrangement from either leukocytes or fibroblasts in about a fifth of all cases
2. Radiography for phocomelia evaluation
  a. Absence of the radius and fibula: the most common skeletal abnormalities in the upper and lower limbs
  b. Absent, short, deformed, and/or hypoplastic ulna and tibia: the second most common bone defects
  c. Absent, short, deformed, or hypoplastic humerus and femur: the third and least common abnormalities
3. Echocardiography for congenital heart defect
4. Renal ultrasound for renal anomalies
5. MRI of the brain for CNS anomalies
6. Molecular genetic testing: sequence analysis of the *ESCO2* gene available clinically

Genetic Counseling

1. Recurrence risk
  a. Patient's sib: 25%
  b. Patient's offspring: not increased (not surviving to reproduction in severe cases)
2. Prenatal diagnosis for pregnancies at risk (Schulz et al. 2008)
  a. Ultrasonography
    i. Intrauterine growth retardation
    ii. Bilateral phocomelia (tetraphocomelia in majority of cases) of varying degree
    iii. Cleft lip and palate
    iv. Associate anomalies
      a) Hydrocephalus
      b) Congenital heart defects
      c) Renal anomalies
  b. DNA from fetal cells obtained from amniocentesis or CVS
    i. Confirmed by characteristic disjunction of centromeres (premature centromere separation in metaphases)
    ii. Molecular diagnosis of *ESCO2* gene mutations
3. Management
  a. Special education
  b. Cornea grafting
  c. Corrective surgery
    i. Cleft lip/palate
    ii. Limb defects
  d. Prosthetic devices
    i. For underdeveloped or missing limbs
    ii. Used to increase independence

Fig. 1 The G-banded metaphase spread from fibroblast culture of a male infant with Roberts syndrome showing characteristic heterochromatin separation: puffing of the centromeric heterochromatin of some chromosomes and splaying of the Yqh region (arrows). The patient had profound psychomotor retardation, corneal clouding, and tetraphocomelia

Fig. 2 A newborn with Roberts syndrome variant showing bilateral cleft lip and cleft palate, phocomelia, club hands with an appendage-like thumb on the right, and a missing thumb on the left. The infant also had intrauterine growth retardation, hydrocephalus, cloudy cornea, AV canal heart defect, and normal lower extremities. Cytogenetic studies revealed no premature centromere separation. The mother took Diflucan during pregnancy and the teratogenic etiology was a possibility

Robinow Syndrome

In 1969, Robinow et al. described a new dwarfing syndrome characterized by mesomelic shortening of extremities, hemivertebrae, genital hypoplasia, and "fetal facies." The incidence is estimated to be approximately 1 in 500,000.

Synonyms and Related Disorders

Acral dysostosis with facial and genital abnormalities; Costovertebral segmentation defect with mesomelia; Fetal face syndrome; Robinow dwarfism

Genetics/Basic Defects

1. Autosomal recessive form
   a. Phenotype tends to be more severe than the autosomal dominant form.
   b. Caused by different homozygous (and compound heterozygous) missense, nonsense, and frameshift mutations of the *ROR2* gene (Tufan et al. 2005)
   c. *ROR2* gene
      i. Mapped to chromosome 9q22
      ii. Encoding an orphan receptor tyrosine kinase 2 with orthologues in mouse and other species
      iii. Allelic to dominant brachydactyly type B (characterized by terminal deficiency of fingers and toes)
2. Autosomal dominant form (Person et al. 2010)
   a. Caused by missense mutations in *WNT5A*, which result in amino acid substitutions of highly conserved cysteines, are associated with autosomal dominant Robinow syndrome
   b. One mutation has been found in all living affected members of the original family described by Meinhard Robinow and another in a second unrelated patient.

Clinical Features

1. Characteristic craniofacial appearance
   a. Early childhood
      i. Midfacial hypoplasia
      ii. Occasional midline capillary hemangioma
      iii. Eyes
         a) Marked hypertelorism
         b) Prominent eyes giving the appearance of exophthalmos (pseudoexophthalmos)
      iv. A short upturned nose
      v. Mouth
         a) "Tented" upper lip having an inverted-V appearance with tethering in the center
         b) Midline clefting of the lower lip
         c) Gum hypertrophy at birth
         d) Dental crowding/irregular teeth
         e) "Tongue tie" (ankyloglossia) resembling a bifid tongue when the tongue tie is marked
      vi. Ears
         a) Low-set
         b) Simple
         c) Deformed pinna

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_206,
© Springer Science+Business Media, LLC 2012

vii. Resemblance to a fetal face
a) Relatively small face
b) Laterally displaced eyes
c) Forward-pointing alae nasi
d) "Fetal facies" becomes less prominent over time

b. Adulthood
i. Loss of fetal facial proportions
ii. Absent midfacial hypoplasia
iii. Persistent hypertelorism with a broad nasal root and broad forehead

2. Short stature
a. Reduced birth length
b. Not a universal finding with some reports of normal growth

3. Limb abnormalities
a. Mesomelic or acromesomelic limb shortening
b. Shortening of the forearms more striking than the shortening of the legs
c. Occasional Madelung deformity
d. Hands/feet
i. Brachydactyly with shortening of the distal phalanx and nail hypoplasia or dystrophy
ii. Thumbs
a) Displaced
b) Occasionally bifid
c) Partial cutaneous syndactyly
d) Ectrodactyly (especially patients reported from Turkey)

4. Other skeletal abnormalities
a. Chest deformities
b. Kyphoscoliosis
c. Vertebral anomalies
d. Rib defects
e. Pectus excavatum
f. Acrodysostosis
g. Delayed bone age

5. Genital hypoplasia
a. Genital abnormalities: may be present at birth causing concern regarding gender assignment
i. Males
a) Micropenis
b) Normal scrotum and testes
ii. Females
a) Reduced clitoral size
b) Hypoplasia of the labia minor
c) Associated vaginal atresia and hematocolpos
iii. Onset of puberty normal in both sexes
iv. Several reports of both male and female patients having normal children

6. Congenital heart defects (15%)
a. Severe pulmonary stenosis or atresia (the most common cardiac abnormalities)
b. Atrial septal defect
c. Ventricular septal defect
d. Coarctation of the aorta
e. Bicuspid aortic valve
f. Tetralogy of Fallot
g. Tricuspid atresia
h. Double-outlet right ventricle
i. Patent ductus arteriosus

7. Renal abnormalities
a. Hydronephrosis (relatively common)
b. Cystic dysplasia of the kidney

8. Developmental delay but intelligence is usually normal

9. Dermatoglyphics
a. Absent interphalangeal creases
b. Bilateral transverse creases
c. Hypothenar whorl pattern

10. Clinical characteristics of recessive Robinow syndrome: more frequently manifests orthopedic involvement (vertebral/rib anomalies and more severe mesomelic brachymelia) than the dominant form
a. Short stature
b. Mesomelic and acromelic brachymelia
c. Thick abnormally modeled radius and ulna
d. Characteristic face
i. Hypertelorism
ii. Wide palpebral fissures
iii. Broad-based nose with everted nares
iv. Large mouth
v. Gum hypertrophy
vi. Irregular and crowded teeth
e. Costovertebral anomalies
f. Endocrine dysfunction
i. Empty sella
ii. Partial insensitivity of Leydig cells to HCG
iii. Low basal testosterone in prepubertal boys
iv. Defective sex-steroid feedback mechanism
g. Micropenis in males

11. Clinical characterization of autosomal dominant and recessive variants of Robinow syndrome,

based on inheritance pattern in familial cases and presence of rib fusions as diagnostic of the recessive variant (Mazzeu et al. 2007):
   a. Clinical signs present in more than 75% of patients with either form, and therefore the most important for the characterization of this syndrome
      i. Hypertelorism
      ii. Nasal features (large nasal bridge, short upturned nose, and anteverted nares)
      iii. Midfacial hypoplasia
      iv. Mesomelic limb shortening
      v. Brachydactyly
      vi. Clinodactyly
      vii. Micropenis
      viii. Short stature
   b. Hemivertebrae and scoliosis were present in more than 75% of patients with the recessive form but in less than 25% of patients with the dominant form
   c. Umbilical hernia (32.3%) and supernumerary teeth (10.3%) were found exclusively in patients with the dominant form
12. Differential diagnosis of mesomelic dwarfism (Giedion et al. 1975)
   a. With Madelung deformity: dyschondrosteosis
   b. With malformations of long bones depending on various distribution/severity patterns and types of transmission
      i. Ulnofibular
         a) With mild triangular deformity
         b) With extreme variety: boomerang bone disease
      ii. Radio-tibial with "normal" fibula
      iii. Ulno-fibular-mandibular (Langer type, homozygous dyschondrosteosis)
      iv. Ulno-radio-fibular-tarsal with square, triangular, or rhomboid tibia
      v. Ulno-radio-tibial with absent fibula
   c. With associated malformations of spine
      i. Robinow syndrome
      ii. Wegmann syndrome
      iii. Campallia and Martinelli syndrome
      iv. "Spondylo-epiphyso-metaphyseal" dysplasia
   d. With acrodysplasia
      i. Acromesomelic dwarfism
      ii. Ellis-van Creveld syndrome
      iii. Grebe achondrogenesis

Diagnostic Investigations

1. Radiography
   a. Skull
      i. Macrocephaly
      ii. Prominent forehead
      iii. Hypertelorism
      iv. Hypoplastic mandible
      v. Dental anomalies
   b. Spine/ribs: widespread fusion of thoracic vertebrae with frequent hemivertebrae and fusion of the ribs, resembling Jarcho-Levin syndrome (spondylocostal dysostosis) in severe cases (autosomal recessive form)
      i. Hemivertebrae and vertebral fusions
      ii. Fusion of ribs
      iii. Shortened interpeduncular distance
   c. Extremities (long bones): mesomelic shortening
      i. Upper extremities
      ii. Lower extremities
      iii. Ulna shorter than radius
      iv. Luxation of the radius
   d. Hands and feet
      i. Brachymesophalangism of fifth digits
      ii. Clinodactyly of the fifth digits
      iii. Shortening of other phalanges
      iv. Brachymetacarpism
      v. Fusion of carpal bones
      vi. Bifid terminal phalanges (splitting of one or more distal phalanges)
      vii. Fusion of phalanges
      viii. Retarded bone age
2. Renal ultrasound for renal anomalies
3. Echocardiography for congenital heart disease
4. Growth hormone assay for possible growth hormone deficiency
5. DNA mutation analysis: available on clinical basis (Afzal and Taylor 2005)
   a. *ROR2* gene is the gene responsible for autosomal recessive *ROR2*-related Robinow syndrome
   b. Sequence analysis of *ROR2* gene detects 65–100% of affected individuals

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant inheritance: not increased unless a parent is affected
      ii. Autosomal recessive inheritance: 25%
   b. Patient's offspring
      i. Autosomal dominant inheritance: 50%
      ii. Autosomal recessive inheritance: not increased unless the spouse is a carrier
2. Prenatal diagnosis
   a. Ultrasonography: possible by measuring the length of the long bones and the ulna/humerus ratio for the fetus at risk
   b. Prenatal diagnosis: also possible for pregnancies at increased risk for ROR2-related Robinow syndrome by sequencing of entire coding region of *ROR2* gene on fetal DNA obtained by amniocentesis or CVS, provided the disease-causing alleles have been previously identified in the proband (Afzal and Taylor 2005)
3. Management
   a. Anticipate difficult intubation because of midfacial hypoplasia
   b. Orthopedic care for vertebral anomalies and hip dislocation
   c. Orthodontics for dental malalignment
   d. Surgery for cleft lip and palate, inguinal hernia, and undescended testes
   e. Growth hormone therapy if associated with growth hormone deficiency
   f. Testosterone therapy for micropenis not proven useful
   g. Psychologic support

Rubinstein-Taybi Syndrome

In 1963, Rubinstein and Taybi described a new syndrome characterized by broad thumbs and toes, facial abnormalities, and mental retardation. The prevalence of Rubinstein-Taybi syndrome (RTS) is estimated to be 1 in 100,000–1 in 125,000 live births in the Netherlands.

Synonyms and Related Disorders

Broad thumb-hallux syndrome; Broad thumbs and great toes, characteristic facies, and mental retardation; Rubinstein syndrome

Genetics/Basic Defects

1. Inheritance: autosomal dominant
2. Most cases are sporadic (~99%); familial cases are extremely rare (Bartsch et al. 2010).
3. Caused by deletions or heteroallelic mutations of *CREBBP*, the gene for cAMP-responsive element-binding (CREB) protein, which resides on chromosome 16p13.3. CREBBP is a large nuclear protein involved in transcription regulation, chromatin remodeling, and the integration of several different signal transduction pathways. The following mutations of *CREBBP* were reported in patients with Rubinstein-Taybi syndrome:
   a. Chromosomal translocations/inversions
   b. Deletions at the microscopic and submicroscopic levels
   c. Molecular mutations
4. Mutations in the *CREBBP* gene are responsible for:
   a. Rubinstein-Taybi syndrome
   b. t(8;16)-associated acute myeloid leukemia
5. Also rarely caused by mutations in *EP300* gene (located on 22q13.2): individuals reported with mutations in *EP300* have a milder skeletal phenotype, lacking typical broadening and angulation of the thumb and hallux (Bartholdi et al. 2007).
6. No clear phenotypic differences are observed between patients in whom microdeletions or truncating mutations were found.
7. Variable expression and somatic mosaicism contribute to the phenotypic variability of RTS. Somatic mosaicism may be more frequent in RTS than previously assumed (Bartsch et al. 2010).

Clinical Features

1. Characteristic craniofacial features
   a. Microcephaly (35–94%)
   b. Prominent forehead
   c. Down-slanting palpebral fissures
   d. Apparent ocular hypertelorism
   e. High-arched or heavy eyebrows
   f. Long eyelashes
   g. Epicanthal folds
   h. Prominent nose with columella (lower margin of the nasal septum) below the alae nasi
   i. Malpositioned ears with dysplastic helices
   j. Grimacing smile
   k. Hypoplastic maxilla
   l. Mild retrognathia
   m. High-arched palate
2. Skeletal abnormalities
   a. Thumbs
      i. Broad terminal phalanges

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_207,
© Springer Science+Business Media, LLC 2012

   ii. Severe radial angulation deformity ("hitchhiker thumbs") with abnormal shape of proximal phalanx, which prevents opposition and functional gripping strength
  b. Great toes
   i. Broad terminal phalanges
   ii. Angulation deformity with abnormal shape of proximal phalanx or first metatarsal
   iii. Duplicated proximal phalanx
   iv. Duplicated distal phalanx
  c. Short stature (78%)
  d. Fifth finger clinodactyly
  e. Overlapping toes
  f. Broad terminal phalanges of other fingers
  g. Pelvic anomalies
   i. Flat acetabular angles
   ii. Flaring of the ilia
   iii. Notch in the ischia
  h. Stiff gait
  i. Lax ligaments
  j. Hyperextensible joints
  k. Vertebral anomalies
   i. Spina bifida
   ii. Kyphosis
   iii. Lordosis
   iv. Scoliosis
  l. Sternal or rib anomalies
   i. Premature fusion
   ii. Simian sternum
   iii. Pectus excavatum or carinatum
   iv. Forked ribs
   v. Cervical ribs
   vi. Fusion of the first and second ribs
3. History of maternal polyhydramnios (39%)
4. Hypotonia
5. Developmental delay
6. Variable mental retardation
  a. Severe in some patients
  b. Moderate degree in many patients
  c. Mild in some patients
7. Behavioral/psychiatric disorders
  a. Childhood
   i. Short attention span
   ii. Impulsiveness
   iii. Clinically nonsignificant stereotype
   iv. Withdrawal
   v. Nonspecific "maladaptive behavior"
   vi. Repetitive motions
   vii. Resistance to change
   viii. Distractibility
   ix. Aggressive outbursts
   x. Difficulty in sleeping
  b. Adulthood
   i. Mood disorders
   ii. Chronic motor tic disorder
   iii. Obsessive compulsive disorder
   iv. Depressive disorder
   v. Bipolar disorder
   vi. Tourette disorder
   vii. Trichotillomania
   viii. Pervasive developmental disorder
   ix. Self-injurious behaviors
   x. Autistic features
8. Seizures (27–28%)
9. Ophthalmologic problems
  a. Strabismus (60–71%) with subsequent risk of amblyopia
  b. Refractive errors (41–56%)
  c. Lacrimal duct obstructions (38–47%)
  d. Ptosis (29–32%)
  e. Coloboma (9–11%)
  f. Duane retraction syndrome (8%)
  g. Ghost vessels
  h. Peters anomaly
  i. Optic nerve hypoplasia
  j. Cataracts
  k. Corneal opacities
  l. Congenital glaucoma
  m. Retinal abnormalities
10. Dental manifestations (67%)
  a. Talon cusps of secondary dentition
  b. Crowding and malpositioned teeth
  c. Anterior and posterior crossbites secondary to a narrow palate or jaw size discrepancy
  d. Natal teeth
  e. Gingivitis
  f. Hypodontia/hyperdontia
  g. Increased rate of carries
11. Upper airway obstruction during sleep due to:
  a. Hypotonia
  b. Anatomy of the oropharynx and airway
   i. Small nasal passages
   ii. Retrognathia
   iii. Micrognathia
   iv. Hypertrophy of the tonsils and adenoids
   v. Obesity

12. Gastrointestinal problems
    a. Significant gastroesophageal reflux
    b. Feeding difficulties
    c. Constipation
13. Congenital heart disease (24–38%)
    a. ASD
    b. VSD
    c. PDA
    d. Coarctation of the aorta
    e. Pulmonary stenosis
    f. Bicuspid aortic valve
    g. Pseudotruncus
    h. Aortic stenosis
    i. Hypoplastic left heart syndrome
    j. Complex congenital heart defects
    k. Dextrocardia
    l. Vascular rings
    m. Conduction problems
14. Renal anomalies (52%)
    a. Hydronephrosis
    b. Duplications
    c. Vesicoureteral reflux
    d. Urinary tract infections
    e. Renal stones
    f. Nephrotic syndrome
    g. Neurogenic bladder
15. Cutaneous manifestations
    a. Tendency of keloid and hypertrophic scar formation
    b. Ingrown toenails
    c. Toenail paronychia (44%)
    d. Fingernail paronychia (9%)
    e. Pilomatrixomas
    f. Capillary hemangioma
        i. Forehead
        ii. Nape of the neck
        iii. Back
    g. Supernumerary nipples
    h. Hirsutism
    i. Transverse palmar creases
    j. Deep plantar crease between the first and second toes
16. Orthopedic problems
    a. Hypotonia
    b. Lax ligaments
    c. Tight heel cords
    d. Elbow abnormalities
    e. Legg-Perthes disease (3%)
    f. Dislocated patella (2.5%)
    g. Congenital hip dislocation (1.4%)
    h. Slipped capital femoral epiphysis (0.6%)
    i. Congenital or acquired scoliosis, kyphosis, and lordosis
    j. An increased risk of associated thickened filum terminale, tethering of the cord, and lipoma
    k. An increased risk of fractures
17. An increased risk of having benign and malignant tumors as well as leukemia and lymphoma
    a. Oligodendroglioma
    b. Medulloblastoma
    c. Neuroblastoma
    d. Meningioma
    e. Pheochromocytoma
    f. Nasopharyngeal rhabdomyosarcoma
    g. Leiomyosarcoma
    h. Seminoma
    i. Embryonal carcinoma
    j. Odontoma
    k. Choristoma
    l. Dermoid cyst
    m. Pilomatrixomas

Diagnostic Investigations

1. Developmental evaluation
2. Echocardiography for cardiac defects
3. Ophthalmologic examination
4. Renal ultrasound
5. Voiding cystourethrogram
6. Hearing evaluation
7. EEG abnormalities
8. Radiography
    a. Hands
        i. Broad first distal phalanx
        ii. Broad first ray
        iii. Duplicated first distal phalanx
        iv. Delta-shaped proximal phalanges of the thumbs
        v. Mushroom-shaped distal phalanges
        vi. Angulation of the distal phalanges
        vii. Thin tubular bones
        viii. Delayed bone age (74%)
    b. Feet
        i. Broad first distal phalanx
        ii. Broad first ray

iii. Duplicated first distal phalanx
iv. Duplicated first proximal and distal phalanges
v. Delta-shaped first proximal phalanx. A duplicated longitudinal bracketed epiphysis ("kissing delta" phalanx) always involves the proximal phalanx of the great toe.
vi. Angulation deformity of the hallux
vii. Mushroom-shaped distal phalanges
viii. Very small distal phalanges
ix. Thin tubular bones
x. Protruding calcaneus
xi. Synostosis of cuneiform ossicles
xii. Proximally split fifth metatarsal bone

c. Limbs
i. Thin tubular bones
ii. Fractures
iii. Patella luxations

d. Spine
i. Cervical hyperkyphosis
ii. Lumbar hyperlordosis
iii. Scoliosis
iv. Spina bifida occulta: cervical or lumbosacral
v. Spondylolisthesis
vi. Irregular thoracic endplates

e. Skull
i. Microcephaly
ii. Absent sinus frontalis
iii. Deviated nasal septum
iv. Steep skull base
v. Abnormally shaped sella turcica
vi. Foramina parietal permagna
vii. Prominent digital marking

f. Thorax
i. Narrow thoracic aperture
ii. 11 ribs
iii. Fusion of ribs
iv. High diaphragm

g. Pelvis
i. Small iliac wings
ii. Flaring iliac wings
iii. Irregularly formed acetabulum
iv. Symphysiolysis

9. Diagnosis of Rubinstein-Taybi syndrome
a. Made primarily by clinical examination
b. Confirmed by the presence of microdeletion

10. Cytogenetic analysis: chromosome abnormalities observed in about 10% of patients (Breuning et al. 1993; Blough et al. 2000; Petrij et al. 2000b)
a. FISH analysis with cosmids from the *CBP* region to detect chromosome 16p13.3
b. Chromosome abnormalities
i. t(2;16)(p13.3;p13.3)
ii. t(7;16)(q34;p13.3)
iii. Inv(16)(p13.3q13)

11. Clinical testing of *CREBBP* gene: available clinically
a. Fluorescent in situ hybridization (FISH) probes
i. Specific for chromosome region 16p13.3
ii. Containing regions of the cyclic AMP-responsive element-binding protein gene (*CBP* gene)
iii. Microdeletions identified in approximately 10% of patients by five cosmid probes containing almost the entire gene
b. Sequence analysis/mutation scanning available clinically: detects *CREBBP* mutation in another 30–50% of affected individuals
c. Deletion/duplication analysis using array CGH or quantitative multiplex fluorescent-PVR

12. Clinical testing of *EP300* gene: available clinically
a. *EP300* mutations available clinically can identify approximately 3% of affected individuals.
b. Deletion/duplication analysis.

Genetic Counseling

1. Recurrence risk
a. Patient's sib: Accumulating data suggest a recurrence risk of approximately 0.5–1.0% for parents of a child with RTS due to gonadal mosaicism, exceeding the so far empiric estimated risk of 0.1% for siblings (Chiang et al. 2009; Bartsch et al. 2010)
b. Patient's offspring: as high as 50%, particularly in individuals with deletions

2. Prenatal diagnosis: possible for fetuses at risk on fetal cells obtained by amniocentesis or chorionic villus sampling, provided the disease-causing *CREBBP* or *EP300* mutation or deletion in an affected family member is known (Stevens 2009)

3. Preimplantation genetic diagnosis for at-risk pregnancies requires prior identification of the disease-causing mutation in the family (Stevens 2009)

4. Management
   a. Early intervention programs
      i. Physical therapy
      ii. Occupational therapy
      iii. Speech therapy
   b. Management of gastroesophageal reflux
   c. Prophylaxis for subacute bacterial endocarditis for patients at risk
   d. Requires assistance and training in self-help skills but can become self-sufficient in most self-help areas such as feeding, dressing, and toileting
   e. Special education
   f. Behavioral modification
   g. Surgery to correct a delta phalanx deformity
   h. Caution with general anesthesia in children
      i. Challenging to intubate due to airway anomalies
         a) Relatively anterior position of the larynx
         b) Easily collapsible laryngeal wall
      ii. Important to intubate due to the high risk of aspiration during induction and emergence
      iii. Presence of skeletal anomalies
      iv. Cardiac arrhythmia may result from use of cardioactive drugs.
         a) Atropine
         b) Neostigmine
         c) Succinylcholine
         d) Suxamethonium

Fig. 1 (**a**–**l**) A patient with Rubinstein-Taybi syndrome at different ages (childhood and adulthood) showing typical facial appearance (prominent beaked nose with the columella below the alae nasi), broad thumbs, and broad/bifid great toes, which are illustrated by radiographs

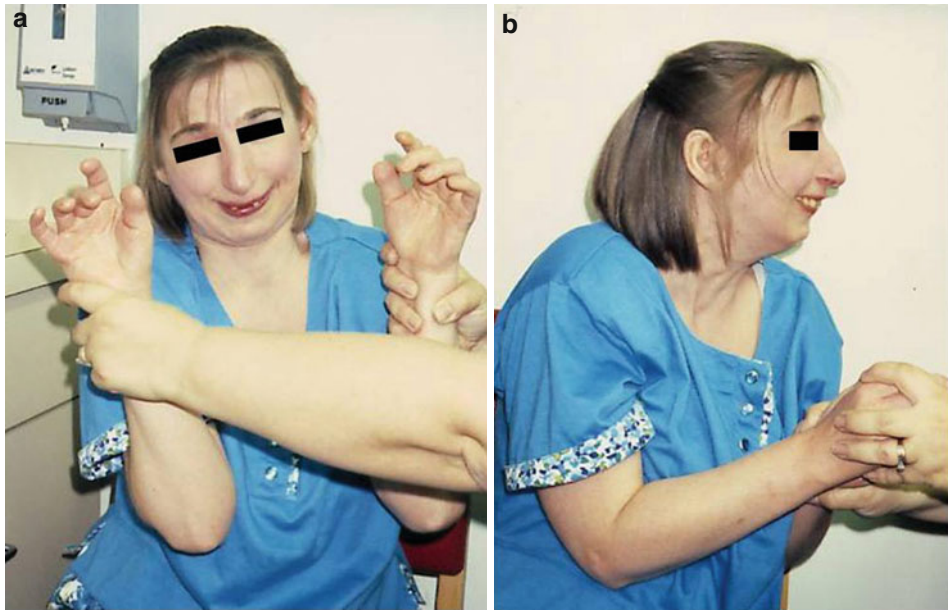

Fig. 2 (**a**, **b**) An adult with Rubinstein-Taybi syndrome showing the characteristic facies and broad thumbs

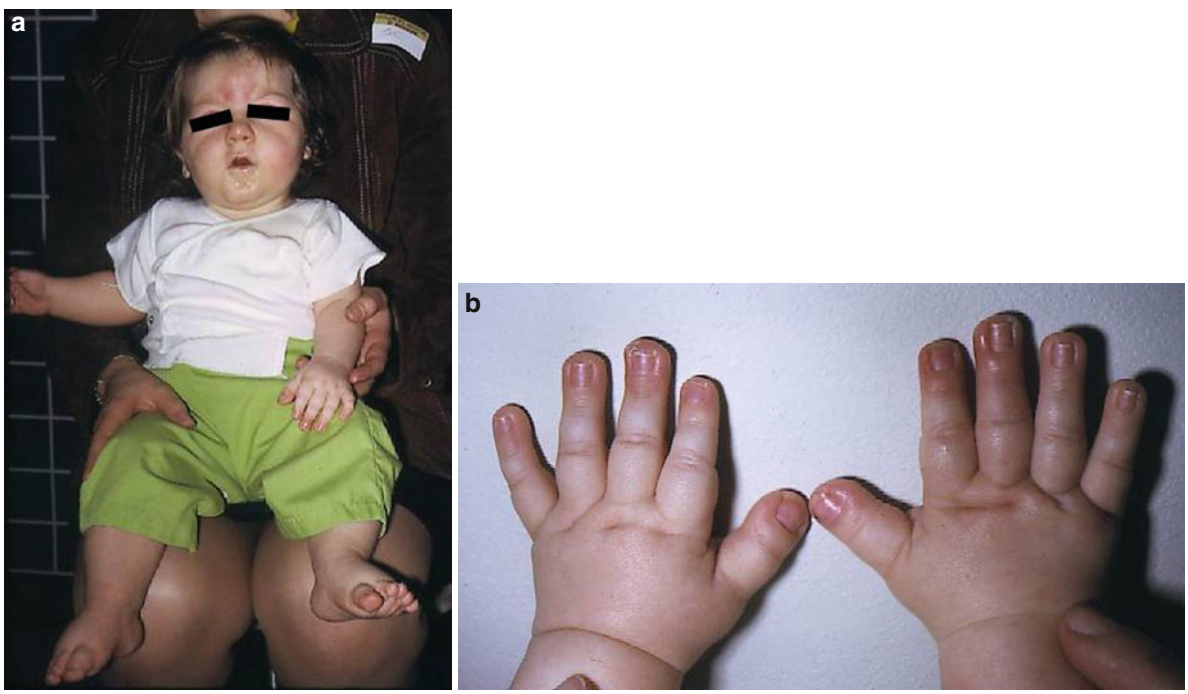

Fig. 3 (**a**, **b**) A young patient with Rubinstein-Taybi syndrome showing characteristic facies, broad thumbs, and great toes

Saethre-Chotzen Syndrome

Saethre in 1931 and Chotzen in 1932 separately described a group of patients with cranial vault dysmorphology ("acrocephaly"), skull asymmetry, and incomplete simple syndactyly of the index and middle fingers and the third and fourth toes.

Saethre-Chotzen syndrome (SCS) is one of the more common forms of syndromic craniosynostosis. Its prevalence was estimated to range from 1:25,000 to 1:50,000, approximately the same prevalence as Crouzon syndrome.

Synonyms and Related Disorders

Acrocephalosyndactyly, Type III; Acrocephaly, skull asymmetry, and mild syndactyly; Chotzen syndrome

Genetics/Basic Defects

1. An autosomal dominant disorder with high penetrance and wide variable expressivity
2. A variety of mutations, including missense and nonsense mutations, small insertions, duplications, and deletions (Gripp et al. 2000; Chun et al. 2002) on the *TWIST* gene, which was mapped at 7p21, lead to heterogeneous symptoms of the syndrome.
3. Also, patients with characteristics of Saethre-Chotzen syndrome but without *TWIST* mutations have been described (de Heer et al. 2005).
   a. Some of these patients harbored the *FGFR3* P250R mutation, nowadays considered to cause a distinct and unique craniosynostosis syndrome, Muenke syndrome (Muenke et al. 1997; Graham et al. 1998).
   b. Strikingly, it was found that all Saethre-Chotzen syndrome patients with large genetic deletions, encompassing the *TWIST* gene and extending onto chromosome 7p, had mental retardation, a rare feature in the syndrome (Johnson et al. 1998; Zackai and Stolle 1998; Chun et al. 2002).

Clinical Features

1. Widely variable phenotype
2. Craniosynostosis (premature fusion of one or more sutures of calvarium) (Paznekas et al. 1998)
   a. Coronal suture (unilateral or bilateral): most commonly affected
      i. Bilateral (59% of cases)
      ii. Unilateral (23% of cases)
   b. Other cranial sutures (21% of cases), such as sagittal, lambdoid, and metopic, and even pansynostosis, may be involved.
      i. Can undergo premature fusion
      ii. Reports of affected individuals with no evidence of pathologic suture
   c. Often presents with an abnormal skull shape
      i. Brachycephaly (short, broad skull)
      ii. Acrocephaly (tall skull)
3. Other craniofacial features
   a. Facial asymmetry (the most conspicuous facial feature), particularly in individuals with unicoronal synostosis
   b. Low frontal hairline
   c. Ptosis of the eyelids: often results from a defective functioning or agenesis of the levator palpebrae muscle
   d. Downslanting of the palpebral fissures

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_208,
© Springer Science+Business Media, LLC 2012

e. Epicanthal folds
f. Strabismus
g. Amblyopia
h. Midface hypoplasia
i. A broad nose with depressed nasal bridge
j. Characteristic appearance of the ears: low-set and rotated ears with small pinna with a prominent superior and/or inferior crus

4. Limb anomalies
   a. Brachydactyly: most frequent finding
   b. Cutaneous syndactyly of the second and third digits of the hands and feet: highly variable degree but nearly diagnostic in the presence of limb anomalies
   c. Clinodactyly of the fifth fingers
   d. Transverse palmar creases often present
   e. Broad digit I of the feet
   f. Hallux valgus
   g. Duplicated distal phalanx of the hallux
   h. Triangular epiphyses of the hallux
5. Other variable clinical features
   a. Short stature
   b. Presence of foramina parietalia permagna (bony defects on both sides of the parietal suture exceeding 1 cm in diameter)
   c. Impressiones digitatae, considered to be an indicator of raised intracranial pressure, often recorded without the presence of increased intracranial pressure
   d. Conductive, mixed, and profound sensorineural hearing loss
   e. Ocular hypertelorism
   f. Occasional blepharophimosis
   g. Lacrimal duct stenosis
   h. Maxillary hypoplasia
   i. High-arched and/or cleft palate
   j. Congenital heart defects
   k. Vertebral fusion
   l. Radioulnar synostosis
   m. Increased risk of cancers (breast, kidney)
6. Intelligence
   a. More commonly normal intelligence
   b. Significant learning disability usually noted in affected individuals with microdeletion in 7p21 but severe delay or mental retardation is not typical
7. Family history of abnormal skull shape and/or a combination of other physical findings: usually present in SCS, however, craniosynostosis is not an obligatory finding (some affected relatives may not have been diagnosed with a craniosynostosis syndrome)
8. Differential diagnosis
   a. Muenke syndrome
      i. Characterized by "nonsyndromic" coronal craniosynostosis caused by the specific point mutation p.Pro250Arg in *FGFR3* (encoding fibroblast growth factor receptor-3)
      ii. Shares features with Saethre-Chotzen syndrome (SCS)
      iii. Individuals with *TWIST1* mutations distinguished from those with the *FGFR3* p.Pro250Arg mutations from a recent study of 39 pedigrees (71 affected individuals) ascertained on the basis of coronal synostosis with the following clinical features:
         a) A low frontal hairline
         b) Ptosis
         c) Small ears
         d) Parietal foramina
         e) Interdigital webbing
         f) Hallux valgus or broad great toe with bifid distal phalanx
   b. Isolated unilateral coronal synostosis
      i. Represents coronal suture fusion with no evidence of other malformations
      ii. Approximately ten times more common than SCS. Coronal synostosis is the second most common form of single-suture fusion after sagittal synostosis.
      iii. Facial asymmetry resembling SCS can result from untreated or incompletely treated isolated unilateral coronal synostosis.
   c. Baller-Gerold syndrome (BGS)
      i. Characteristic clinical features
         a) Coronal craniosynostosis manifesting as abnormal shape of the skull (brachycephaly) with ocular proptosis and bulging forehead
         b) Radial ray defect manifesting as oligodactyly (reduction in number of digits), aplasia or hypoplasia of the thumb, and/or aplasia or hypoplasia of the radius

c) Growth retardation
d) Poikiloderma

ii. *RECQL4*: the only gene currently known to be associated with BGS

iii. Clinical findings overlap with those of Rothmund-Thomson syndrome and Rapadilino syndrome, also caused by mutations in *RECQL4*.

Diagnostic Investigations

1. Diagnosis primarily based on clinical findings
2. Molecular genetic testing
   a. *TWIST1* mutations: identified in 46–80% of affected individuals using a combination of deletion/duplication analysis and sequence analysis (positive in 46–80% of cases)
   b. Consider testing for *FGFR3* (p.Pro250Arg) mutation if no *TWIST1* mutation is identified in an individual with a presumed diagnosis of Saethre-Chotzen syndrome since clinical findings of Muenke syndrome overlap with Saethre-Chotzen syndrome.
3. Cytogenetic analysis: a chromosome translocation or inversion involving 7p21 or ring chromosome 7 reported in occasional patients with atypical findings, including developmental delay

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. A 50% risk if a parent is also affected
      ii. An apparently low risk if the parents are clinically unaffected and do not have a *TWIST1* mutation
         a) Spontaneous mutation rate if the proband represents de novo mutation
         b) Possible parental germ line mosaicism exists although no instances of germ line mosaicism have been reported.
   b. Patient's offspring: a 50% recurrence risk for an affected individual to have an affected offspring
2. Prenatal diagnosis: possible for pregnancies at increased risk if the disease-causing mutation has been identified in the family

3. Management
   a. Cranioplasty in the first year of life
      i. To prevent progressive facial asymmetry in those with asymmetric coronal fusion
      ii. To prevent increased intracranial pressure (ICP) in those with multiple sutural synostosis
      iii. To prevent developmental delay and impaired vision secondary to increased intracranial pressure
   b. Midfacial surgery needed for dental malocclusion, swallowing difficulties, and respiratory problems
   c. Cleft palate surgery usually follows cranioplasty.
   d. Orthodontic treatment and/or orthognathic surgery as needed near the completion of facial growth; developmental intervention
   e. Routine treatment of hearing loss
   f. Prevention of secondary complications
      i. Attention to possible cervical vertebral instability secondary to vertebral anomalies
      ii. Periodic ophthalmologic evaluation for chronic papilledema
      iii. Brain imaging in later life for evidence of increased intracranial pressure
      iv. Routine evaluation for facial asymmetry, psychomotor development, and hearing loss

Fig. 1 (**a**, **b**) A 2-month-old boy was evaluated for trigonocephaly (metopic suture premature synostosis)

Fig. 2 His mother was diagnosed to have Saethre-Chotzen syndrome clinically. Preoperatively, she was noted to have marked forehead asymmetry, retrusion of the right side of the supraorbital region, disproportion of the orbits with the right orbit higher, and temporal fossa hollowness. The diagnosis was confirmed molecularly by detection of a *TWIST* gene mutation (c.396–416 dup mutation, i.e., c.417ins21) which has been previously detected in other Saethre-Chotzen syndrome patients

Fig. 3 (**a**–**c**) Follow-up visit of the child and the mother

Fig. 4 (**a**–**f**) A 42-year-old man was diagnosed to have Saethre-Chotzen since childhood. He was noted to have a brachycephalic skull with midfacial hypoplasia, a high forehead with a low hairline, a small cranial vault, asymmetric face with a curved nose, marked ptosis, down turned upper lip, underbite, repaired cleft palate, an underbite, low-set ears with prominent crus, cutaneous syndactyly and contractures at the proximal interphalangeal joints in the second and fifth digits bilaterally, a single flexion crease in the fifth digit of both hands with unusual palmar creases, short toes with broad great toes bilaterally, minimal cutaneous syndactyly of toes 2–3 bilaterally, and bilateral hearing aids in place. In addition, he had developmental delay, seizures, heart murmur, and toeing-in requiring braces in childhood, keratoconus requiring corneal transplants, hypertension, and colon polyps and spastic colon. Southern blot analysis of genomic DNA showed complete deletion of one allele of the *TWIST* gene. Such mutations are diagnostic for Saethre-Chotzen syndrome

Sagittal Craniosynostosis Associated with Chromosome Abnormalities with a Brief Review on Craniosynostosis

Craniosynostosis, defined as the premature closure of >1 cranial suture with an estimated prevalence of 1 in 2,000–3,000 births (Cohen 2000), comprises a heterogeneous group of birth defects, including isolated forms and syndromic cases.

Sagittal craniosynostosis (or synostosis), usually an isolated congenital abnormality in otherwise normal infants, is characterized by scaphocephaly. It is the most common form of craniosynostosis with prevalence of 1 in 5,000 children, comprising approximately 50% of all craniosynostosis cases (Lajeunie et al. 1996, 2005). Rarely, when sagittal synostosis is a part of a syndrome, it can be due to a chromosome abnormality associated with multiple congenital abnormalities or due to a single gene abnormality such as Crouzon or Carpenter syndrome, invariably associated with obvious facial or digital anomalies, with clinically evident closure of multiple sutures.

Genetics/Basic Defects

1. Classification of craniosynostosis based on suture involvement (Kimonis et al. 2007)
   a. Simple (involving one suture) or complex (involving two or more sutures)
   b. Primary (caused by an intrinsic defect in the suture) or secondary (premature closure of normal sutures because of another medical condition such as deficient brain growth)
   c. Isolated (occurring without other anomalies) or syndromic (accompanied by other dysmorphic features or developmental defects)
   d. Frequencies of the various sutures involved
      i. Sagittal: 40–58%, etiology unknown
      ii. Coronal: 20–29%, estimated one-third caused by single-gene mutations
      iii. Metopic: 4–10%, etiology unknown
      iv. Lambdoidal: 2–4%, etiology unknown
2. Etiologies of nonsyndromic craniosynostosis (Passos-Bueno et al. 2008)
   a. Familial recurrence (Hennekam and Van den Boogaard 1990; Lajeunie et al. 1996, 1998, 2005; Cohen and McLean 2000)
      i. Nonsyndromic coronal synostosis (14%)
      ii. Nonsyndromic sagittal synostosis (6%)
      iii. Nonsyndromic metopic synostosis (3–9%) versus 22% in syndromic metopic synostosis
      iv. Pedigrees from familial recurrence: compatible with:
         a) Autosomal dominant inheritance
         b) Autosomal recessive inheritance
         c) X-linked inheritance
   b. Genetic etiology
      i. Poorly understood
      ii. *EFNA4*: The only gene that when mutated causes only nonsyndromic craniosynostosis (Merrill et al. 2006).
3. Etiologies of isolated (nonsyndromic) sagittal synostosis
   a. Suggestions of possible genetic and environmental factors (Johnson et al. 2000; Zeiger et al. 2002; Lajeunie et al. 2005)
   b. Possible intrauterine pressure on the neurocranium on the etiology of craniosynostosis (Johnson et al. 2000; Kirschner et al. 2002)

c. Preference for (Butzelaar et al. 2009)
   i. Male sex
   ii. Twinning
   iii. Prematurity

4. Etiologies of syndromic craniosynostosis (Passos-Bueno et al. 2008; Jehee et al. 2008)
   a. To date, well over 180 syndromes are associated with craniosynostosis as a major clinical feature. Mendelian and chromosomal alterations are important causative mechanisms.
   b. Mutations associated with syndromic craniosynostosis
      i. Mutations in seven genes (*FGFR1*, *FGFR2*, *FGFR3*, *TWIST1*, *EFNB1*, *MSX2*, and *RAB23*): unequivocally associated with mendelian forms of syndromic craniosynostosis and explain the etiology of about 30% of syndromic cases (Wilkie et al. 2007)
      ii. Mutations in four other genes, *FBN1*, *POR*, *TGFBR1*, and *TGFBR2*: also associated with craniosynostosis, but not causing the major clinical feature of the phenotype and/or with an apparently low penetrance (Sood et al. 1996; Flück et al. 2004; Loeys et al. 2005)
5. Chromosome alterations in the etiology of craniosynostosis (Passos-Bueno et al. 2008)
   a. All types of chromosomal abnormalities have already been described in patients with craniosynostosis, including deletions and duplications in almost all human chromosomes.
   b. Approximately 16% of syndromic cases have been associated with chromosomal abnormalities in conventional cytogenetics studies (Cohen 2000).
      i. A high association of craniosynostosis with duplication 13q21–q34
      ii. A high association of craniosynostosis with deletion 7p15–p21, 9p21–p24, and 11q23–q25 (Brewer et al. 1998, 1999)
      iii. Deletion and/or duplication 1p36 (Gajecka et al. 2005; McDonald-McGinn et al. 2005)
   c. Jehee et al. (2008) screened 45 patients with craniosynostotic disorders with a variety of methods including conventional karyotype, microsatellite segregation analysis, subtelomeric multiplex ligation-dependent probe amplification, and array-based comparative genome hybridization with the following results:
      i. Causative abnormalities were present in 42.2% (19/45) of the samples.
      ii. 27.8% (10/36) of the patients with normal conventional karyotype carried submicroscopic imbalances.
      iii. Sagittal synostosis
         a) Del(1p)
         b) Dup(5)(p15.1–p14.1)
         c) Dup17q
         d) Dup(X)(p11.23)
      iv. Metopic synostosis
         a) Del(1q)
         b) Del(1q)/dup(15q)
         c) Del(9)(p22.3p24.2)
         d) Del(9q)/dup(17q)
         e) Del(11)(q23.3)
         f) Del(X)(p11.3)
         g) Del(Y)(q11)
         h) Der(9)t(9;4)(p22.3;q34)
         i) Der(9)t(9;?)(p21.3;?)
         j) Dup(3)(p25.2)
         k) Dup(6)(q27)
         l) Dup(15)(q13.2)
         m) Dup(22)(q11.23)
         n) Dup(X)(p22.3)
      v. Bilateral coronal synostosis: Dup(3)(q26.33)
      vi. Bilateral coronal and metopic synostosis: Dup(X)(q22.2)
6. Sagittal synostosis associated with chromosome abnormalities
   a. Our patient 1: del(4)(q26 → q28.3ter) and del(13)(q21.2 → q21.31)
   b. Our patient 2: del(13)(q33.1 → qter) and dup(17)(q25.3 → qter) [der(13)(13)(t13;17)(q33.1;q25.3)]
   c. Our patient 3: t(4;18)(p12p11.2)
7. Multiple craniosynostosis involving sagittal and other sutures associated with chromosome abnormalities
   a. Sagittal and metopic synostosis (Hiraki et al. 2006): 46,X,der(Y)(t(Y;1)(q12;p36.3) inherited from father [46,X,t(Y;1)(q12;p36.3)]
   b. Sagittal and bilateral lambdoid synostosis (called craniofacial dyssynostosis, "Mercedes Benz" syndrome, or nonsyndromic multisutural synostosis) (Hing et al. 2009)
      i. Case reported by Shiihara et al. (2004): sagittal and metopic suture synostosis
         a) An unbalanced translocation, 46,XX,der(13)t(5;13)(q33.3;q34)mat resulting in monosomy 13 q34–qter and trisomy 5q33.3–qter

b) FISH analysis showed three MSX2 signals indicating the presence of three copies of the MSX2 gene.

ii. Case reported by Cohen (2000): complex rearrangement of chromosome 5, resulting in three paracentric inversions/two insertions and a duplication of 5q35 inclusive of the MSX2 gene region

iii. Case reported by Tagariello et al. (2006)

a) A de novo–balanced translocation, t(9;11)(q33;p15)

b) Both breakpoint regions were cloned, and the chromosome 11p15 breakpoint was noted to disrupt the *SOX6* gene between exons 6 and 7. However, the potential role of the *SOX6* gene disruption in BLSS remains undetermined.

iv. Case reported by Hing et al. (2009): an Xp11.2 deletion

c. Sagittal, metopic, and coronary synostosis (Hiraki et al. 2008): 46,XX,der(15)(q15.2q22.1)

d. Sagittal, metopic, lambdoid, temporal, and squamosal synostosis (Jehee et al. 2007): De novo interstitial 11q duplication [46,XY,dup(11)(q11–q13.3)(/46,XY] included the duplication of genes FGF3 and FGF4.

Clinical Features

1. Natural history of sagittal synostosis (Chatterjee et al. 2007)
   a. As the condition occurs in utero, diagnosis should be possible at birth with careful attention to the sagittal suture and the deformity that is created.
   b. If uncorrected, sagittal synostosis leads to progression of the scaphocephalic deformity which can be an esthetic problem as well as raised intracranial pressure and speech and language impairment in almost 40% of patients.
2. Clinical features of sagittal synostosis
   a. Scaphocephaly or dolichocephaly due to growth restriction transverse to the sagittal suture resulting in a biparietally narrowed skull and continuing growth of the calvaria in the ventral-dorsal direction resulting in the elongation of the skull
   b. Variable appearance of the elongation of the skull depending on which portion of the sagittal suture is fused
   c. Ridging of the sagittal suture
   d. Frontal bossing: resulting from premature closure of the anterior portion of the sagittal suture (Jane et al. 2000)
   e. Variants of posterior sagittal synostosis (Jane et al. 2000): Closure of the posterior portion of the sagittal sutures occurs less commonly than anterior closure.
      i. Occipital knob: The occipital bone becomes the site of compensatory overgrowth because it is located distal and perpendicular to the fused suture.
      ii. "Golf tee" deformity
         a) An exaggerated form of the occipital knob, simulating a golf tee
         b) The skull is narrower posteriorly and protrudes more prominently. In addition, the unfused anterior portion of the sagittal suture may widen the parietal bone anteriorly, accentuating the occipital narrowing.
      iii. Bathrocephalic deformities: an extreme consequence of premature posterior closure of the sagittal suture
         a) Characterized by the appearance of a podium in the occipital region
         b) The posterior portion of the parietal bone slants inferiorly while the occipital bone juts superiorly.
   f. Complete sagittal synostosis: the most extreme form of the sagittal synostosis, resulting in both anterior and posterior deformity
3. Sagittal synostosis associated with chromosome abnormalities (our cases)
   a. Patient 1 (monosomies 4q and 13q)
      i. Sagittal suture synostosis (palpable bonny ridge along the sagittal suture)
      ii. Ocular hypertelorism
      iii. Proptotic eyes
      iv. Micrognathia
   b. Patient 2 (translocation 4p and 18p)
      i. Sagittal synostosis (scaphocephaly)
      ii. Tetralogy of Fallot
4. Multiple suture synostoses (including sagittal synostosis) associated with chromosome abnormalities: wide variation of clinical features depending on the gain or loss of the chromosome(s) and

chromosome segments involved. Following are some of the examples:

a. Multiple craniosynostoses involving the sagittal and metopic sutures with 1p36.3–pter trisomy (Hiraki et al. 2006)
   i. Borderline mental retardation
   ii. Bitemporal narrowing
   iii. Sloping forehead
   iv. Blepharophimosis
   v. Blepharoptosis
b. Multiple craniosynostoses involving sagittal and bilateral lambdoid sutures: Premature fusion of the sagittal and both lambdoid sutures results in a characteristic head shape with frontal bossing, turribrachycephaly, biparietal narrowing, occipital concavity, inferior displacement of the ears, and ridging of the sagittal and lambdoid sutures (Hing et al. 2009).
   i. Case reported by Shiihara et al. (2004)
      a) Sagittal and bilateral lambdoid sutures
      b) Developmental delay
      c) Atrial septal defect
      d) Patent ductus arteriosus
      e) Unbalanced translocation, 46,XX,der (13)t(5;13)(q33.3;q34)mat resulting in monosomy 13 q34–qter and trisomy 5q33.3–qter
      f) FISH analysis demonstrated three copies of the *MSX2* gene.
   ii. Case reported by Cohen (2000)
      a) Sagittal and bilateral lambdoid sutures
      b) Hypotonia
      c) Ventricular septal defect
      d) Coarctation of the aorta
      e) A complex rearrangement of chromosome 5 resulting in three paracentric inversions/two insertions and a duplication of 5q35 inclusive of the *MSX2* gene region
      f) MSX2 is known to play an important role in cranial bone formation as haploinsufficiency of MSX2 results in parietal skull defects and overexpression causes craniosynostosis.
   iii. Case reported by Tagariello et al. (2006)
      a) Sagittal and bilateral lambdoid sutures
      b) Mild speech delay
      c) A de novo balanced translocation, t(9;11)(q33;p15)
      d) Both breakpoint regions were cloned, and the chromosome 11p15 breakpoint was noted to disrupt the *SOX6* gene between exons 6 and 7.
   iv. Case reported by Hing et al. (2009)
      a) Sagittal and bilateral lambdoid sutures: frontal bossing, brachycephaly, narrow occiput
      b) Hypotonia at birth
      c) Progressive apnea
      d) Seizures
      e) Expired at 4 months of age
      f) Xp11.22 deletion: clinical significance unknown
c. Multiple craniosynostoses involving the sagittal, metopic, and coronary sutures
   i. Cases reported by Hiraki et al. (2008) with a de novo 15q15q22 deletion
      a) Hypotonia
      b) Profound growth and psychomotor retardation
      c) Craniofacial dysmorphic features (bow-shaped eyebrows, downslanting palpebral fissures, mild blepharophimosis, strabismus, nystagmus, optic nerve atrophy, low-set ears with stenotic bilateral ear canals, bulbous nasal tip, hypoplastic alae nasi, upturned nostrils, high-arched palate, bifid uvula, epiglottic hypoplasia, a thin upper lip, and tucked-in lower lip)
      d) Other anomalies (pectus excavatum, accessory nipples, small hands and feet, long fingers, abducted and proximally placed thumbs, clinodactyly of the fifth fingers, four finger creases, overlapping third and fifth over fourth toes, metatarsus adductus)
d. Sagittal, metopic, lambdoid, temporal, and squamosal synostosis (Jehee et al. 2007): de novo interstitial 11q duplication
   i. Developmental delay
   ii. Marked trigonocephalic, turricephalic, and scaphocephalic-shaped skull
   iii. Blue sclerae
   iv. Nystagmus
   v. Strabismus
   vi. Short neck
   vii. Short philtrum
   viii. Supernumerary maxillary lateral incisor
   ix. PDA

x. Patent foramen ovale
xi. Seizures
xii. Recurrent infections
xiii. Mild brachydactyly of the finger
xiv. Clinodactyly of the fifth fingers
xv. Slightly broad thumbs
xvi. Shortened distal phalanges
xvii. Hypoplastic nails

Diagnostic Investigations

1. Radiographic study to demonstrate sagittal synostosis
2. Three-dimensional computed tomographies to discern the characteristics of sagittal synostosis (David et al. 2009)
   a. Anterior type: characterized by a transverse retrocoronal band
   b. Central type: Prematurely fused sagittal suture is marked by a prominent heaped-up appearance.
   c. Posterior type: a significantly elongated occiput as the most striking radiographic feature
   d. Complex type: combined characteristics of anterior, central, and posterior types
3. Conventional karyotype
4. Microsatellite segregation analysis
5. Subtelomeric multiplex ligation-dependent probe amplification
6. Array-based comparative genome hybridization

Genetic Counseling

1. Recurrence risk (Kimonis et al. 2007; Wilkie et al. 2007)
   a. Patient's sib
      i. "Truly nonsyndromic craniosynostosis": thought to be a multifactorial trait with recurrent risk around 5% for coronal and around 1% for sagittal suture fusion
      ii. Autosomal dominant craniosynostosis
         a) Common in craniosynostosis syndromes with a relatively high proportion of new mutations
         b) Genetic counseling for the parents of a child with an apparently new mutation: difficult by uncertainties over the recurrence risk attributable to occult germ line mosaicism in a parent
         c) Negative parental mutation testing: still leaves a small (<1%) risk of recurrence because of potential gonadal mosaicism
      iii. Craniosynostosis associated with chromosome abnormality: recurrent risk depends on whether a de novo event or a parent is a carrier of the abnormality
   b. Patient's offspring
      i. "Truly nonsyndromic craniosynostosis": thought to be a multifactorial trait with recurrent risk around 5% for coronal and around 1% for sagittal suture fusion
      ii. Autosomal dominant craniosynostosis: Mutation carriers have a 50% risk of passing the affected gene to their offspring.
      iii. Chromosome aneuploidy: depends on the type and complexity of the chromosome rearrangement
2. Prenatal diagnosis: Craniosynostoses are rarely detected in utero (Fjortoft et al. 2007).
   a. Prenatal ultrasonography of the cranial suture
      i. Most craniosynostoses are missed during routine US screening examination.
      ii. Most of the prenatal diagnoses made have been severe syndromic synostosis elide mainly on cranial deformity and associated abnormalities, in particular limb malformations. Examples including:
         a) Pfeiffer syndrome
         b) Apert syndrome
         c) Saethre-Chotzen syndrome
   b. Prenatal MRI imaging of the cranial suture
      i. MRI cannot directly visualize calvarial sutures.
      ii. Diagnostic when craniosynostosis is suspected by prenatal ultrasound examination
      iii. Advantage of MRI: allows detection and provides better assessment of brain abnormalities which may be associated with craniosynostosis
   c. Prenatal 3-dimensional CT: useful as it allows direct visualization of the cranial vault sutures, which is not possible with MRI
   d. Prenatal testing strategies
      i. Chorionic villus sampling (typically at 10–14 weeks gestation)

ii. Amniocentesis (typically at 16–18 weeks gestation)
iii. Prenatal chromosome testing for syndromic craniosynostosis due to chromosome abnormality
iv. Molecular genetic testing of syndromic craniosynostosis due to single gene mutation

e. Preimplantation genetic diagnosis
i. A valuable option available for those who have been identified as carriers of the mutation but are interested in ensuring that their children are unaffected without making the decision to terminate a pregnancy in the event of a positive prenatal diagnosis
ii. Molecular testing enables the selection of only genetically normal embryos for use in in vitro fertilization.

3. Management (Adamo and Pollack 2009; Jimenez et al. 2008)
a. Goals of surgery in sagittal synostosis
i. Eliminate the biparietal constriction caused by the fused sagittal suture
ii. Increase the width of the skull
iii. Decrease the anterior-posterior (AP) length of the skull

b. In cases of mild scaphocephaly
i. Perform strip or extended craniectomies to remove the sagittal suture using either open or endoscopic techniques
ii. Then rely on future cranial vault remodeling with brain growth

c. In cases of more marked scaphocephaly
i. Extend the craniectomy to follow along the lambdoid sutures
ii. Add bilateral parietal bone wedge osteotomies

d. The pi technique (Jane et al. 1978): also widely used
i. Bilateral parasagittal strip craniectomies with outfracturing of the temporal bones
ii. Removal of the vertex bone
iii. AP shortening of the calvarial vault, in some instances with bifrontal osteotomies

e. In older children: The bone is more difficult to reshape.
i. A more extensive calvarial reconstructive procedure is performed with bifrontal, biparietal, and occipital bone removal and reconstruction.
ii. The bones are then angulated to reduce frontal bossing, and the grafts are shortened to reduce the AP dimension of the skull.

f. Surgical procedures used for the treatment of sagittal synostosis
i. Strip craniectomy procedure
ii. Total vertex craniectomy
iii. Peninsula craniectomy
iv. Pi procedure
v. Modified Pi procedure
vi. Clamshell procedure
vii. Distraction-contraction procedure
viii. Foreshortening and lateral expansion
ix. Spiral osteotomy technique
x. Parietal bone fixation technique
xi. Reversal exchange technique
xii. Sprint-assisted cranioplasty
xiii. Marchac transposition
xiv. Modified Marchac transposition
xv. Endoscopic craniectomy
xvi. Microscopic craniectomies

Fig. 1 (**a**, **b**) An 8-month-old infant was evaluated for sagittal suture synostosis. Her craniofacial features were characterized by palpable bonny ridge along the sagittal suture, ocular hypertelorism with proptotic eyes, and mild retrognathia. Conventional cytogenetics showed a complex chromosomal rearrangement involving chromosomes 2, 4, and 13, and deletions in chromosomes 4 and 13 [46,XX,ins(2;4)(p21;q31.2q33),del(4)(q26q28.3),t(4;13)(q31.3;q21.32),del(13)(q21.2q21.31)]. Oligonucleotide array CGH analysis showed a 22-Mb deletion in bands 4q26 to 4q28.3 and a 3.5-Mb deletion in 13q21.2 to13q21.31. The karyotype is therefore monosomic for genes in these regions

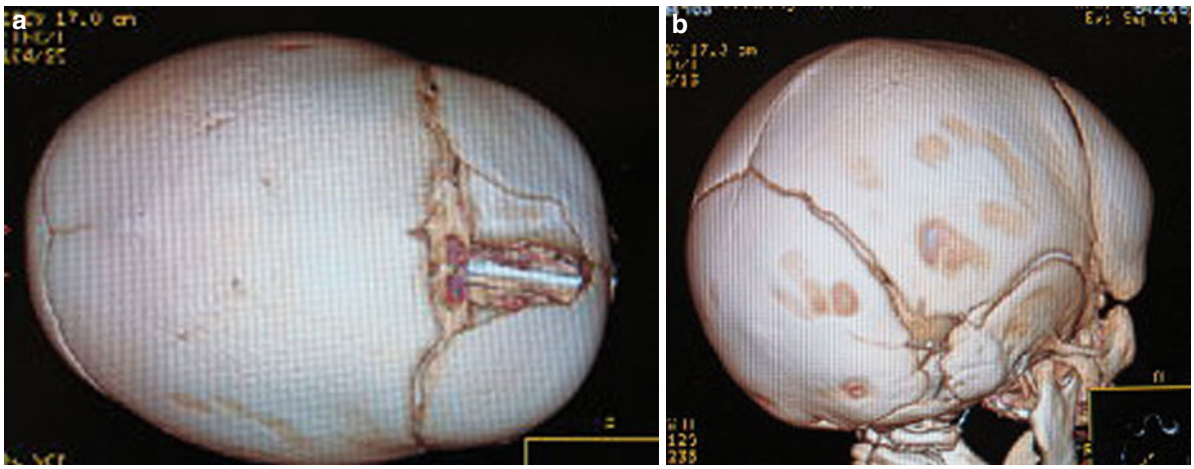

Fig. 2 (**a**, **b**) Three-dimensional CT reconstructions from the same patient shows dolichocephalic skull resulting from premature fusion of the sagittal suture and sagittal ridge

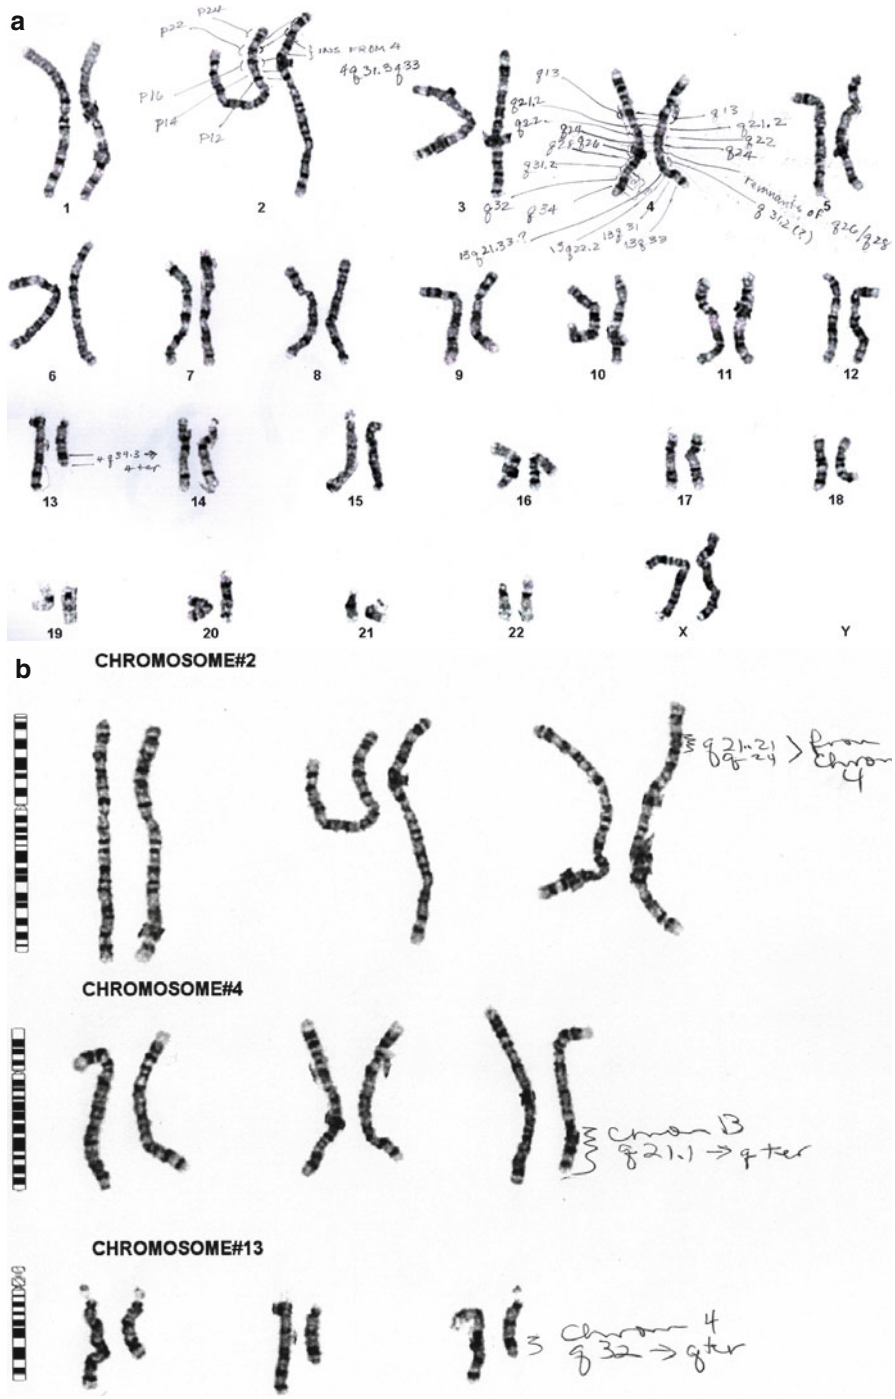

Fig. 3 (**a**, **b**) Her karyotype showed del(4)(q26 → q28.3ter) and del(13)(13q21.2 → q21.31) (Pencil marks are intentionally left here to show the complex chromosome rearrangements)

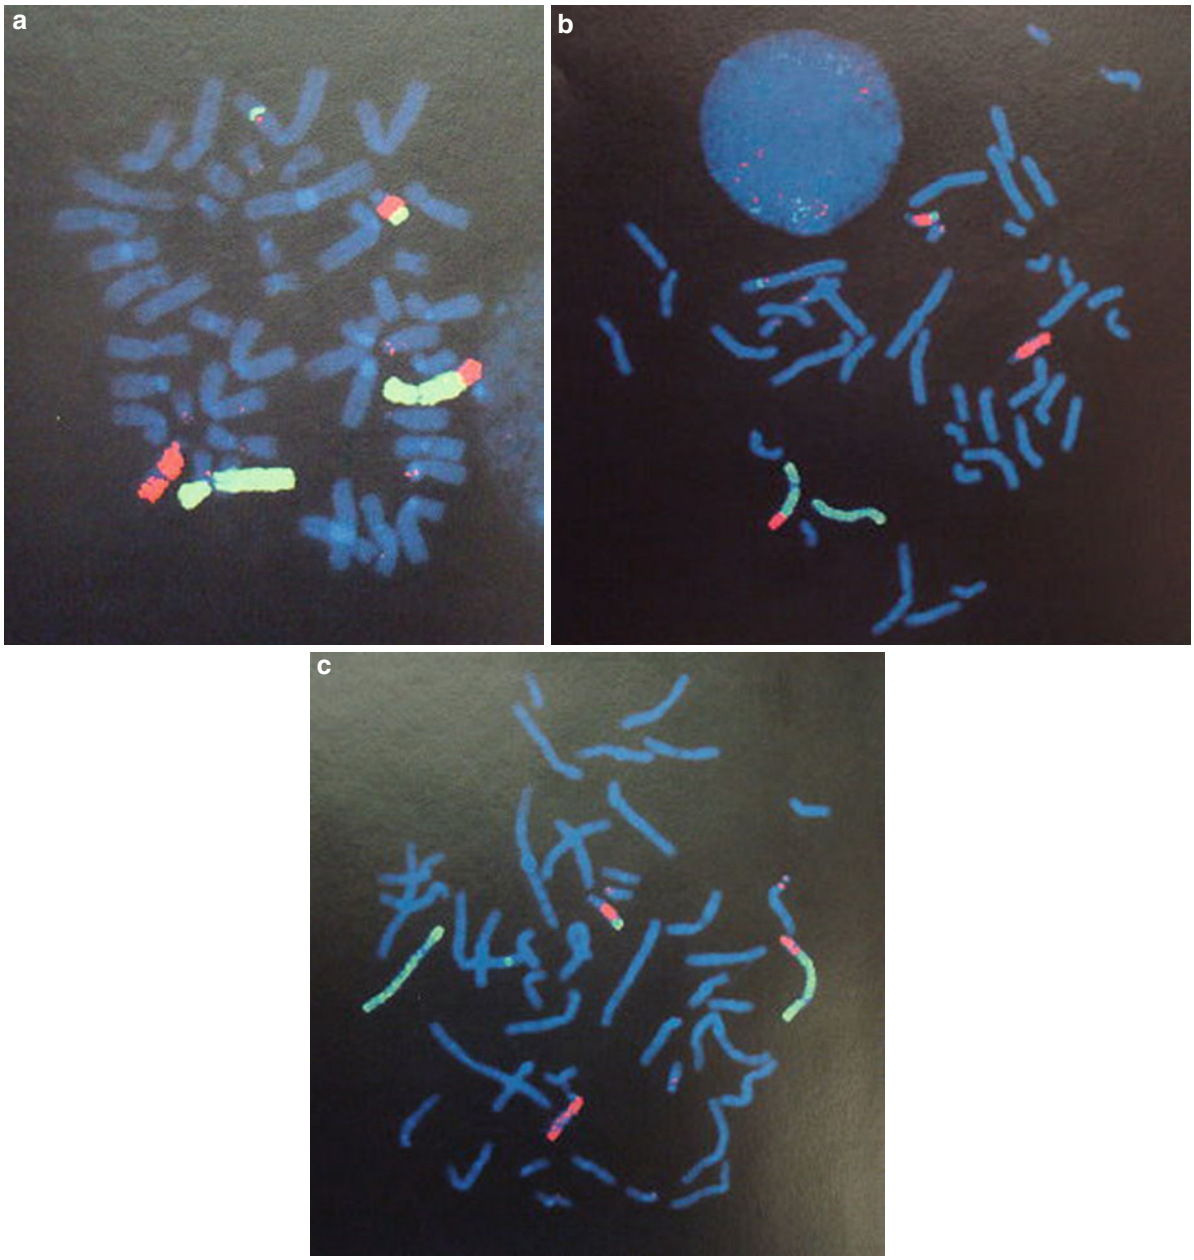

Fig. 4 (**a**–**c**) FISH with wcp2 and wcp4 confirmed an insertion of chromosome 4 material (4q31.2–33) into the short arm of 4q31.1 to 4qter. This translocation was confirmed with FISH subtelomeric probes, showing the qter of the translocation positive for the 13q subtelomere sequences, and the qter of the translocation 13 positive for 4q subtelomere

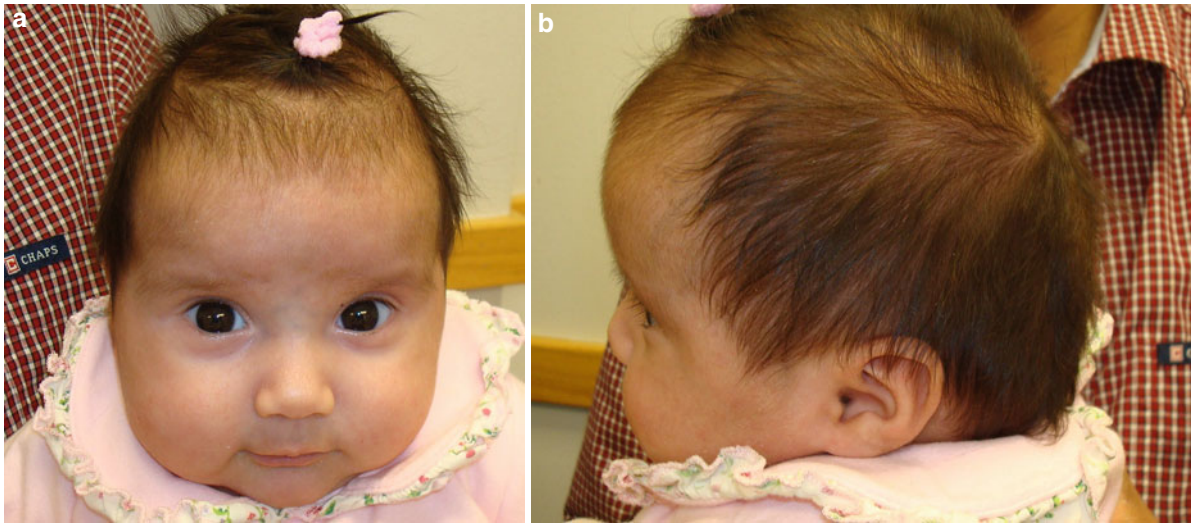

Fig. 5 (**a**, **b**) A 2-month-old infant was evaluated for scaphocephaly (sagittal suture ridge palpable) with Tetralogy of Fallot

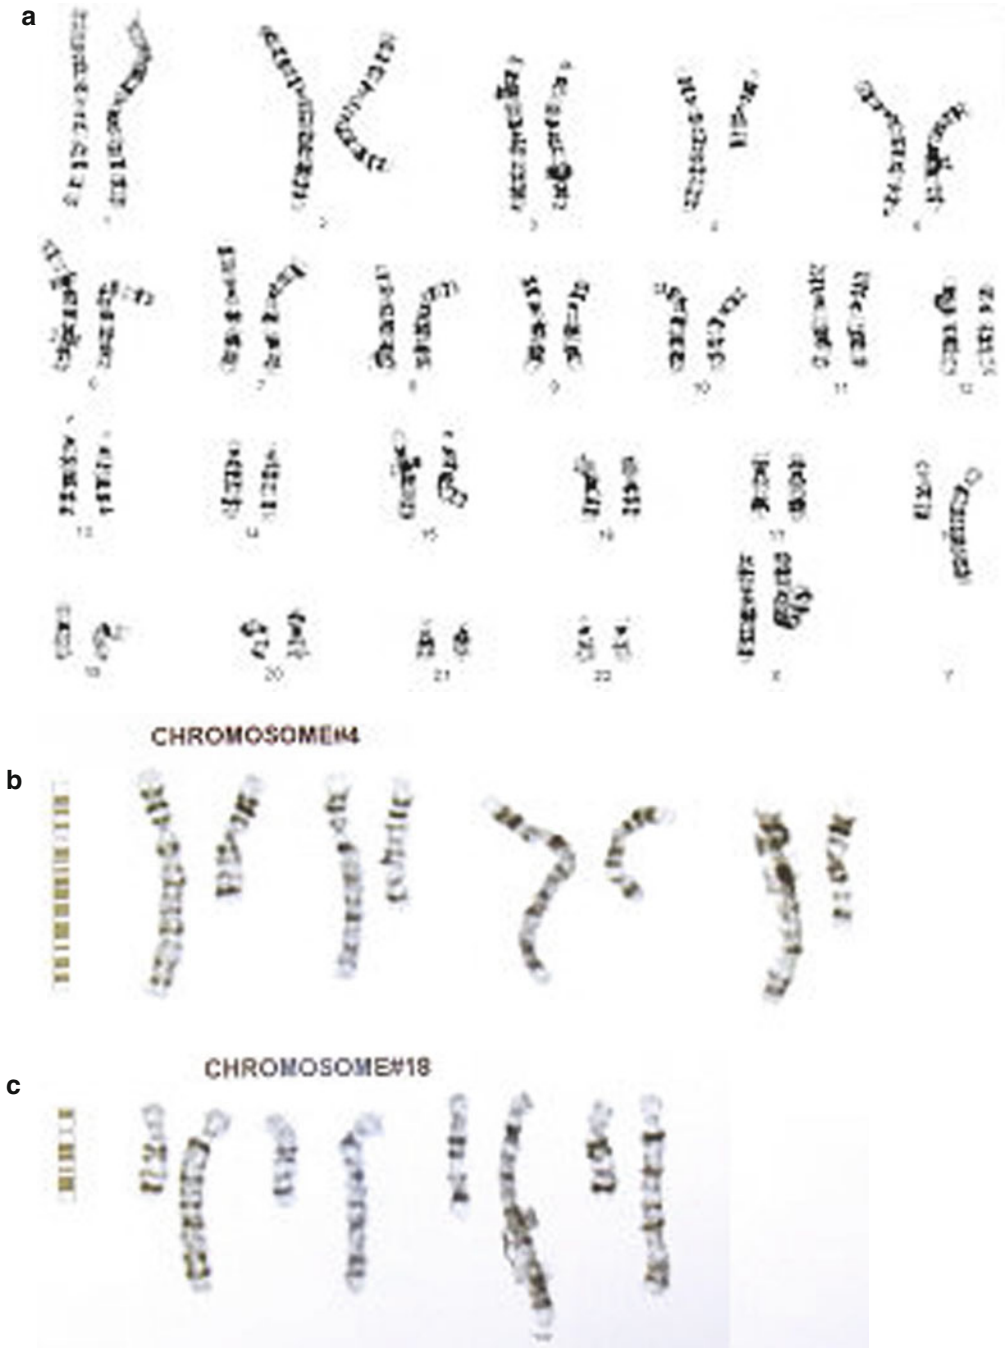

Fig. 6 (**a**–**c**) Her karyotype and ideogram with partial karyotypes showed a balanced translocation t(4;18)(p12;p11.2)

Schizencephaly

Schizencephaly is a rare congenital brain malformation characterized by deep clefts of the cerebral mantle that extend from the cortical surface to the lateral ventricles. The conditions are often associated with convolutional anomalies such as polymicrogyria or nodular subependymal heterotopias.

Genetics/Birth Defects

1. Inheritance
   a. Isolated schizencephaly: mainly sporadic
   b. Rare reports of familial cases
2. Etiology
   a. A developmental defect in the blood vessels supplying the cerebral cortex
      i. Resulting in tissue death and cleft formation due to lack of oxygen (in utero vascular insufficiency)
      ii. With preferential location in the parasylvian regions following the frontoparietal distribution of the middle cerebral artery
   b. Mutations in the homeodomain gene *EMX2* as a possible cause of some cases of schizencephaly
      i. At least some schizencephaly cases result from germline mutations.
      ii. *EMX2*: expressed in restricted areas of the developing mammalian forebrain, including areas that develop into the cerebral cortex
      iii. Discovery of *EMX2* mutations in both sporadic and familial cases of schizencephaly marking an important advance in establishing genetic causes for brain malformations
      iv. Lack of *EMX2* mutations in most schizencephaly patients has increased the likelihood of other genes being involved.
      v. *EMX2* mutations were not confirmed from recent studies on large schizencephaly case series (Tietjen et al. 2007; Merello et al. 2008; Hehr et al. 2010).
   c. Heterozygous mutations in *SIX3* and *SHH* are associated with schizencephaly: a subset of patients with schizencephaly may develop as one aspect of a more complex malformation of the ventral forebrain, directly result from mutations in the *SHH* pathway, and hence be considered as yet another feature of the broad phenotypic spectrum of holoprosencephaly (Hehr et al. 2010)
3. Schizencephaly
   a. Refers to gray matter–lined clefts that extend through the entire hemisphere from the ependymal lining of the lateral ventricles to the pial covering of the cortex
   b. Cleft
      i. A cleft in the cerebral mantle which communicates between the subarachnoid space laterally and ventricular system medially
         a) Unilateral or bilateral cleft
         b) Symmetric or asymmetric cleft
      ii. The sides of clefts generally lined with heterotopic gray matter (an abnormal accumulation of neurons)
   c. Two types of schizencephaly depending on the size of the area involved and the separation of the cleft lips
      i. Type I (closed-lip schizencephaly)
         a) Consisting of a fused cleft

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_210,
© Springer Science+Business Media, LLC 2012

b) This fused pial-ependymal seam forms a furrow in the developing brain and is lined by polymicrogyric gray matter.

ii. Type II (open-lip schizencephaly): presence of a large defect, a holohemispheric cleft in the cerebral cortex filled with cerebral spinal fluid and lined by polymicrogyric gray matter

d. Associated malformations commonly accompanying schizencephaly

i. Mild hypoplasia of the corpus callosum

ii. Total or nearly total absence of cavum septum pellucidum in 70–90% of patients with schizencephaly. 30–50% of patients show associated optic nerve hypoplasia on clinical examination (septo-optic dysplasia with schizencephaly).

iii. Focal cortical dysplasia

iv. Coloboma of the retina

v. Hydrocephalus

4. Syndromes associated with schizencephaly

a. Septo-optic dysplasia-schizencephaly syndrome

i. Clinical features distinct from isolated septo-optic dysplasia

ii. Significant global developmental delay and spastic motor deficits

iii. Seizures and visual symptoms rather than with endocrine abnormalities

b. Other rare schizencephaly syndromes

i. Prenatal cytomegalovirus infection

ii. Vascular disruption related to twinning

c. Schizencephaly (plus polymicrogyria) as part of multiple congenital anomaly/mental retardation syndromes

i. Adam-Oliver syndrome

ii. Aicardi syndrome

iii. Arima syndrome

iv. Delleman (oculocerebrocutaneous) syndrome

v. Galloway-Mowat syndrome

vi. Micro syndrome

Clinical Features

1. Clinical manifestations depend on the size and location of involved brain.

a. A narrow, unilateral cleft

i. Usually present with seizures and mild focal neurological deficits

ii. Otherwise developmentally normal

b. Bilateral clefts

i. Severe developmental delay

ii. Early intractable epilepsy

iii. Severe motor dysfunction

2. Clinical features

a. Mental retardation (varying degree)

b. Developmental delay: moderate to severe if the defects are large

c. Microcephaly (varying degree)

d. Hydrocephalus in some patients

e. Hypotonia in the postnatal period

f. Motor difficulties

g. Seizures in most patients

h. Generalized spasticity

i. Hemiparesis or quadriparesis

j. Blindness secondary to optic nerve hypoplasia

k. Prognosis depending on the size of the clefts and the degree of neurological deficits

i. Patients with type I abnormalities

a) Almost normal

b) May have seizures and spasticity

ii. Patients with smaller, unilateral clefts (clefts in only one hemisphere)

a) Often paralyzed on one side of the body

b) May have normal intelligence

iii. Patients with type II abnormalities

a) Mental retardation

b) Seizures

c) Hypotonia

d) Spasticity

e) Inability to walk or speak

f) Blindness

iv. Patients with bilateral open-lip schizencephaly generally with the worst clinical symptoms

Diagnostic Investigations

1. Ultrasonography of the brain to demonstrate closed-lip or open-lip brain cleft communicating with lateral ventricle(s)
2. Magnetic resonance imaging (MRI) or computed tomography (CT) of the brain

a. Open-lip or closed-lip schizencephaly

b. Associated absence of the septum pellucidum and hypoplasia of the optic chiasm

3. Potential role of diffusion tensor imaging with tractography in providing insights into the

evaluation of white matter tracts in patients with schizencephaly (Sarikaya 2009)

4. Pathology
   a. Clefts most commonly in the Rolandic fissures
   b. Frequently associated with pachygyria, polymicrogyria, or lissencephaly
5. Molecular genetic testing of *EMX2* mutation for familial schizencephaly: not considered to be appropriate and not available clinically

Genetic Counseling

1. Recurrence risk: low unless germline mutation is present in one of the parent
2. Prenatal diagnosis
   a. Ultrasonography and/or fetal MRI of the brain to demonstrate brain clefts connecting to the lateral ventricles
   b. Differential diagnosis of CSF-containing abnormalities in the fetal brain (Oh et al. 2005)
      i. Developmental lesions
         a) Arachnoid cyst
         b) Ventriculomegaly
         c) Monoventricle in holoprosencephaly
         d) Agenesis of the corpus callosum with an interhemispheric cyst
         e) Schizencephaly
      ii. Destructive lesions
         a) Porencephalic cyst
         b) Ventriculomegaly (infection or bleeding)
         c) Hydranencephaly
   c. *EMX2* mutation analysis on amniocytes or CVS: not considered to be appropriate and not available clinically
3. Management
   a. Physical therapy
   b. Seizure control
   c. VP shunt for hydrocephalus

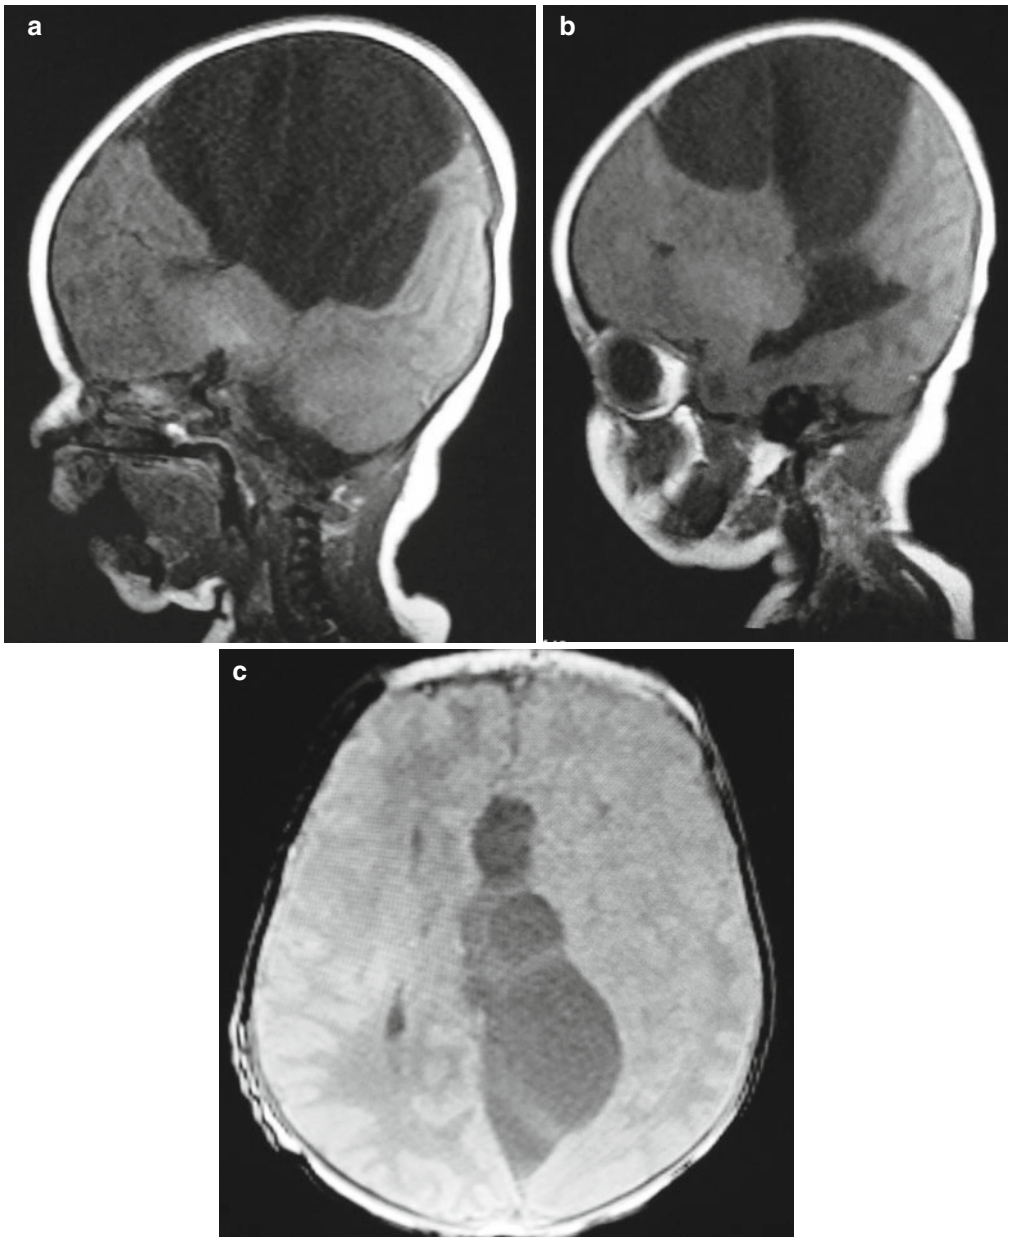

Fig. 4 (**a**–**c**) MRI of the brain of a neonate showed a large open-lip schizencephaly extending to the *right* convexity causing a large gap in the *right* cerebellar hemisphere. There is also absence of the corpus callosum

Schmid Metaphyseal Chondrodysplasia

Schmid metaphyseal chondrodysplasia (SMCD) is a mild hereditary chondrodysplasia resulting from growth plate cartilage abnormalities (Chan et al. 1998).

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. Variable expression
2. Molecular pathogenesis
   a. SMCD: caused by heterozygous mutations in the gene *COL10A1* (mapped to chromosome 6q21-q22), the gene which encodes α1(X) chains of type X collagen, a short-chain collagen whose expression is largely restricted to the hypertrophic chondrocytes of growth plate cartilage (Bateman et al. 2003)
      i. Most mutations reside in the carboxyl-terminal globular domain (CN1) (Ridanpää et al. 2003)
      ii. Two mutations observed In a putative signal peptide cleavage site
   b. Growth plate abnormalities of SMCD: resulting from collagen X haploinsufficiency, a reduction by 50% in collagen X (Bateman et al. 2003)

Clinical Features

1. Mild to moderate short-limbed dwarfism (Beluffi et al. 1982)
2. Bowed legs
3. Waddling gait, often a presenting sign at second year
4. Coxa vara
5. Genu varum
6. Exaggerated lumbar lordosis
7. Flared anterior rib cage
8. Leg pain during childhood
9. Prognosis
   a. Radiological changes appearing early with a tendency to heal and change slowly with time, giving rise to mildly dwarfed patients
   b. Normal intelligence

Diagnostic Investigations

1. Radiography (Lachman et al. 1988)
   a. Hip
      i. Abnormal acetabular roofs
      ii. Enlarged capital femoral epiphyses
      iii. Coxa vara
      iv. Femoral bowing
      v. Abnormal proximal femoral metaphyses
   b. Knee
      i. Abnormal distal femoral metaphyses
      ii. Abnormal proximal tibial metaphyses
      iii. Abnormal proximal fibular metaphyses
   c. Ankle
      i. Abnormal distal tibial metaphyses
      ii. Abnormal distal fibular metaphyses
   d. Wrist
      i. Abnormal distal radial metaphyses
      ii. Abnormal distal ulnar metaphyses
   e. Ribs: anterior cupping, splaying and sclerosis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_211,
© Springer Science+Business Media, LLC 2012

   f. Wide metaphyses with cupping and fraying
   g. Short and stubby long bones
   h. Mild hand involvement: a common feature (Elliott et al. 2005)
      i. Shortening of the tubular bones
      ii. Metaphyseal cupping of the proximal phalanges and metacarpals
   i. Normal spine
2. Histology: variable bone changes (Dimson 1968)
   a. Mild sharp serrations of the metaphyses with increased density of the provisional zone of calcification
   b. Irregularity with flaring and fragmentation and widening of the growth plate
3. Molecular genetic analysis of *COL10A1* mutation (Milunsky et al. 1998)
   a. Mutation analysis
   b. Mutation scanning

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low recurrence risk unless a parent is affected
   b. Patient's offspring: 50%
2. Prenatal diagnosis by amniocentesis or CVS: can be offered to families at-risk for DMCD with a previously characterized disease-causing *COL10A1* mutation
3. Management
   a. Supportive
   b. Orthopedic management of bowed legs: generally does not require orthopedic surgery

Seckel Syndrome

In 1960, Seckel reported 2 personal cases and 13 cases from the literature of a clinical condition characterized by severe intrauterine and postnatal proportionate dwarfism, severe microcephaly, "bird-headed" profile with receding forehead and chin, large and beaked nose, severe mental retardation, and other anomalies (Majewski and Goecke 1982). Seckel syndrome (SCKL) is a rare heterogeneous type of primordial dwarfism with frequency of less than 1 in 10,000 live births.

Synonyms and Related Disorders

Bird-headed dwarfism; Microcephalic primordial dwarfism; Nanocephalic dwarfism; Seckel-type dwarfism

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Genetic heterogeneity
   a. SCKL1: A gene for Seckel syndrome was mapped to human chromosome 3q22.1–q24 in two inbred Pakistani families originating from the same village (Driscoll 2003).
      i. The gene encoding ataxia-telangiectasia and Rad3-related protein (ATR) maps to the critical region to an interval of 5Mbp between markers D3S1316 and D3S1557.
      ii. A synonymous mutation in affected individuals was identified that alters *ATR* splicing.
      iii. The mutation confers a phenotype including marked microcephaly and dwarfism.
   b. SCKL2: Another gene locus was mapped to chromosome 18p11.31–q11.2 in one inbred Iraqi family (Børglum et al. 2001).
   c. SCKL3: A novel locus at 14q23 by linkage analysis in 13 Turkish families. The novel gene locus SCKL3 is 1.18 cM and harbors ménage a trios 1, a gene with a role in DNA repair (Kilinç et al. 2003).
   d. Caused by mutations of the pericentrin gene (*PCNT*) (mapped to 21q22.3) (Griffith et al. 2008; Rauch et al. 2008; Willems et al. 2009)
      i. The gene encodes cetrosomal protein which plays a key role in the organization of mitotic spindles.
      ii. The mutations also can cause microcephalic osteodysplastic primordial dwarfism type II.
   e. Mutations in *CENPJ*, a gene that has hitherto been linked to primary microcephaly only (Bond et al. 2005; Gul et al. 2006), also can cause Seckel syndrome (Al-Dosari et al. 2009).

Clinical Features

1. Broad interfamilial clinical heterogeneity (Arnold et al. 1999)
2. Growth
   a. Severe proportionate short stature of prenatal onset

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_212,

b. Severe postnatal growth deficiency
c. Intrauterine growth retardation
d. Low-birth-weight dwarfism
3. Mental retardation
4. Characteristic craniofacial features
a. Cranial manifestations
i. Severe microcephaly
ii. Premature closure of cranial sutures
b. Receding forehead
c. "Birdlike" face
d. Antimongoloid slant of palpebral fissures
e. Large eyes
f. Beak-like protrusion of the nose
g. Narrow face
h. Receding lower jaw (retrognathia)
i. Micrognathia
j. High-arched or cleft palate
k. Ears
i. Low set
ii. Hypoplastic lobules
l. Dental abnormalities
i. Enamel hypoplasia
ii. Missing permanent teeth
iii. Precocious eruption of teeth
iv. Microdontia
v. Malocclusion
vi. Taurodontism
m. "Dysplastic" ears
5. Associated anomalies
a. Ocular manifestations (Guirgis et al. 2001)
i. Severe myopia and astigmatism
ii. Severe, early onset, bilateral retinal degeneration
iii. Hypotelorism
iv. Bilateral ptosis
v. Microphthalmos
vi. Megacornea
vii. Glaucoma
viii. Retrolental membrane
ix. Macular coloboma
x. Optic hypoplasia
xi. Strabismus
xii. Lens dislocation
b. Skeletal defects
i. Premature closure of cranial sutures
ii. Dislocation of the radial head
iii. Clinodactyly of the 5th fingers
iv. Hip "dysplasia"/dislocation
v. Retardation of ossification
vi. Clubfoot
vii. Hypoplastic patella
viii. Scoliosis
c. CNS anomalies (Shanske et al. 1997)
i. Small cerebrum with simplified, ape-like convolutional pattern (pongidoid micrencephaly)
ii. Dysgenesis of cerebral cortex
iii. Agenesis of corpus callosum
iv. Cerebellar vermis hypoplasia
v. Dorsal cerebral cyst
vi. Arachnoid cyst
vii. Dilated ventricles
viii. Pachygyria
ix. Agyria
x. Intracranial aneurysms
d. Endocrine abnormalities
i. Pituitary gland abnormalities
a) Delayed development
b) Decreased adrenocorticotropic hormone production
c) Decreased growth hormone production
d) Absence of adenohypophysis
e) Hypophyseal hypoplasia
f) Precocious puberty
ii. Adrenal hypoplasia
iii. Hirsutism
e. Hematopoietic abnormalities
i. Acute myelogenous leukemia
ii. Refractory anemia with excess blasts
iii. Pancytopenia
iv. Fanconi anemia
f. Urogenital abnormalities
i. Males
a) Cryptorchidism
b) Hypoplasia of testis
ii. Females
a) Clitoromegaly
b) Hypoplasia of labia majora
g. Features of premature senility
i. Receding hair
ii. Redundant wrinkled skin on the palms
h. Miscellaneous findings
i. Congenital heart defects
a) Patent ductus arteriosus
b) Atrial septal defect
c) Ventricular septal defects
d) Atrioventricular canal defect
ii. Multiple intestinal atresia

6. Seckel-like syndromes (Majewski and Goecke 1982; Arnold et al. 1999)
   a. Microcephalic osteodysplastic primordial dwarfism type I
      i. Distinguished from Seckel syndrome by:
         a) Broad, low "dysplastic" pelvis with poor development of the acetabula
         b) Disproportionately short, broad bowing of humeri and femora with rather unremarkable metaphysis
         c) Agenesis of the corpus callosum and lissencephaly have also been noted.
      ii. Classified as Seckel syndrome by Majewski and Goecke (1982)
   b. Microcephalic osteodysplastic primordial dwarfism type II: differences from the Seckel syndrome include the following (mainly based on X-ray features):
      i. Short limbs with preferential distal involvement (disproportionate shortness of forearms and legs) in the first years of life
      ii. Brachymesophalangy
      iii. Brachymetacarpy I
      iv. Coxa vara
      v. Epiphysiolysis
      vi. Metaphyseal flaring with V-shaped distal femoral metaphyses
   c. Microcephalic osteodysplastic primordial dwarfism type III
      i. Alopecia
      ii. Seckel-like features
         a) Intrauterine growth retardation
         b) Microcephaly
         c) Receding forehead and chin
         d) Large ears
         e) Large prominent nose
         f) Platyspondyly
         g) Long dysplastic clavicles
         h) Hypoplasia of iliac wing and acetabula
         i) Broad femora
      iii. Currently considered to be the same entity as type I (Meinecke et al. 1991)
   d. A variant of osteodysplastic bird-headed dwarfism described by Bangstad et al. (1989)
      i. Progressive ataxia
      ii. Primary gonadal insufficiency
      iii. Endocrine abnormalities
         a) Insulin-resistant diabetes mellitus
         b) Goiter
      e. Chromosome abnormalities
         i. Chromosome instability/breakage (Bobabilla-Morales et al. 2003)
         ii. Deletion 1q22–q24.3
         iii. Interstitial deletion 2q33.3–q34 (Courtens et al. 1997)
         iv. Ring chromosome 4 mosaicism (Anderson et al. 1997)

Diagnostic Investigations

1. Hematological workup indicated in selected patients
   a. Anemia
   b. Pancytopenia
   c. Acute myeloid leukemia
2. Endocrine workup for pituitary and adrenal dysfunction
3. Radiography
   a. Microcephaly with a rather steeply sloping base of the skull
   b. Premature closure of the cranial sutures
   c. Delayed bone age
   d. Hip dysplasia
   e. Elbow dislocation
   f. Dislocation of the radial head
   g. Ivory epiphyses (dense sclerotic areas in the phalanges)
   h. Cone-shaped epiphyses
   i. Disharmonic bone development
      i. Hypoplasia of proximal radii and fibulae
      ii. Absence of epiphyseal ossification centers in fingers and toes
4. Neuropathology and CT/MRI of the brain
   a. Microcephaly
   b. Neuroglial ectopia
   c. Agenesis of the corpus callosum
   d. Micropolygyria
   e. Disproportion of the cerebrum and cerebellum
   f. Dysgenetic cerebral cortex
   g. Hypoplasia of the cerebellar vermis
   h. Dorsal cerebral cyst
5. Growth plate histology
   a. Normal column formation
   b. No structural abnormality of chondrocytes
   c. Decrease in cellularity of chondrocytes

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not likely to have offspring due to severe mental retardation
2. Prenatal diagnosis possible by serial ultrasonography for families at risk for Seckel syndrome
   a. Severe intrauterine growth retardation
   b. Craniofacial abnormalities
      i. Microcephaly
      ii. Receding forehead
      iii. A prominent nose
      iv. Severe micrognathia
   c. Short limbs
3. Management
   a. Symptomatic
   b. Psychosocial support for mental retardation
   c. Dental cares
   d. Orthopedic cares
   e. Treatments for hematological abnormalities

Fig. 2 (**a**–**b**) Two adults with Seckel syndrome showing severe short stature, mental retardation, extreme microcephaly, sloping forehead, a beaked nose, and retro/micrognathia

Severe Combined Immune Deficiency

Severe combined immune deficiency (SCID) is a fatal, heterogeneous group of immune disorder, characterized by T-cell lymphopenia, a profound lack of cellular (T-cell) and humoral (B-cell) immunity, and, in some cases, decreased NK-cell number and function. All infants with SCID develop infections from both common and opportunistic pathogens because protection from maternal antibodies wanes early in life (Buckley et al. 1997; Friedrich et al. 2007). The incidence of SCID is estimated to be 1/100,000 live births, but this may be an underestimate due to some children dying before diagnosis or having unrecognized less severe disease (Stephan et al. 1993; Chan and Puck 2005; McGhee et al. 2005).

Synonyms and Related Disorders

Autosomal recessive SCID (Swiss-type agammaglobulinemia); Bare lymphocyte syndrome; Interleukin (IL)-2 deficient SCID; Janus-associated kinase 3 (JAK3) deficient SCID; Omenn syndrome; Purine nucleoside phosphorylase (PNP) deficient SCID; Reticular dysgenesis; SCID; X-linked SCID; ZAP-70 protein tyrosine kinase (PTK) deficient SCID

Genetics/Basic Defects

1. A heterogeneous syndrome of varied genetic origins (Secord 2009)
   a. X-linked type SCID (X-SCID)
      i. The most common type (50% of all patients with SCIDs), characterized by the absence of the cytokine receptor common γ chain
      ii. A combined cellular and humoral immunodeficiency resulting from lack of T and natural killer (NK) lymphocytes and nonfunctional B lymphocytes
      iii. Caused by a mutation in the X-linked gene *IL2RG*, which encodes the common γ chain, γc (mapped on Xq13), of the leukocyte receptors for interleukin-2 and multiple other cytokines (Fanos et al. 2001)
         a) Significant frequency of de novo mutations accounting for one third of the cases
         b) Occurrence of maternal germ line mosaicism
      iv. Atypical X-SCID: less frequently seen in patients with mutations that result in production of a small amount of gene product or a protein with residual activity
   b. Autosomal recessive type SCID
      i. Formerly known as Swiss-type agammaglobulinemia
      ii. Causes
         a) Adenosine deaminase deficiency (10–20% of all cases of SCID): the *ADA* gene mapped on chromosome 20q13.11 (Arredondo-Vega et al. 1998)
         b) Purine nucleoside phosphorylase (PNP) deficiency: the *PNP* gene mapped on 14q13
         c) Janus-associated kinase 3 (JAK3) deficiency causing autosomal recessive T-B + SCID: the JAK3 gene mapped on 19p13
         d) Interleukin (IL)-2 deficiency
         e) ZAP-70 protein tyrosine kinase (PTK) deficiency: ZAP-70 mapped on 2q12

© Springer Science+Business Media, LLC 2012

f) Bare lymphocyte syndrome
g) Reticular dysgenesis
h) Omenn syndrome

2. Pathophysiology
   a. Varies among various forms of SCID
   b. Common end point in all forms of SCID
      i. Lack of T-cell function
      ii. Lack of B-cell function
   c. Cellular hallmarks differentiating various forms of SCID
      i. X-linked SCID
         a) Absence or near absence of T cells ($CD3^+$) and natural killer (NK) cells leading to lymphopenia
         b) Variable levels of B cells that produce no functional antibodies
      ii. JAK3 deficiency
         a) Absence or near absence of T cells ($CD3^+$) and natural killer (NK) cells leading to lymphopenia
         b) Normal or high levels of B cells that produce no functional antibodies
      iii. ADA deficiency
         a) Death of T and B cells secondary to the accumulation of toxic metabolites in the purine salvage pathway leading to lymphopenia
         b) Decreased or absence of functional antibodies
      iv. PNP deficiency
         a) Death of T cells secondary to the accumulation of toxic metabolites in the purine salvage pathway leading to lymphopenia
         b) Normal number of circulating B cells with poor B-cell function, evidenced by the lack of antibody formation
      v. IL-2 deficiency
         a) Normal or near normal numbers of T cells (both $CD4^+$ and $CD8^+$)
         b) Decreased production of functional antibody
      vi. ZAP-70 PTK deficiency
         a) Absence of $CD8^+$ T cells leading to lymphopenia
         b) No antibody formation
      vii. Bare lymphocyte syndrome
         a) Normal or mildly reduced lymphocyte count
         b) Decreased $CD4^+$ T cells
         c) Normal or mildly increased $CD8^+$ T-cell numbers
         d) Normal or mildly decreased B-cell numbers with decreased antibody production
      viii. Reticular dysgenesis
         a) Absence of myeloid cells in the bone marrow leading to lymphopenia
         b) Presence of functioning red blood cells and platelets
      ix. Omenn syndrome
         a) Presence of normal or elevated T-cell numbers of maternal origin
         b) Usually undetectable B cells
         c) Presence of NK cells
         d) Markedly low total immunoglobulin level with poor antibody production
         e) Elevated eosinophils and total serum immunoglobulin E (IgE) level

3. Molecular defects
   a. X-linked SCID
      i. Mutation of the common gamma chain of the IL receptors (IL-2R, IL-4R, IL-7R, IL-9R, IL-15R) resulting in loss of cytokine function (Cavazzana-Calvo et al. 2000)
      ii. Loss of IL-2R function leading to the loss of a lymphocyte proliferation signal
      iii. Loss of IL-4R function leading to the inability of B cells to class switch
      iv. Loss of IL-7R function leading to the loss of an antiapoptotic signal resulting in a loss of T-cell selection in the thymus and also associated with the loss of a T-cell receptor
      v. Loss of IL-15R function leading to the ablation of NK cell development
   b. JAK3 deficiency
      i. JAK, a protein tyrosine kinase that associates with the common gamma chain of the IL receptors
      ii. Deficiency of JAK3 resulting in the same clinical manifestations as those of X-linked SCID
   c. ADA and PNP deficiencies
      i. Associated with enzyme deficiencies in the purine salvage pathway
      ii. Toxic metabolites responsible for the destruction of lymphocytes that cause the immune deficiency

d. IL-2 deficiency
   i. Molecular defect unknown
   ii. Often associated with other cytokine production defects
e. ZAP-70 PTK deficiency: caused by a mutation in the gene coding for this tyrosine kinase, which is important in T-cell signaling and is critical in positive and negative selection of T cells in the thymus
f. Bare lymphocyte syndrome
   i. Deficiency of major histocompatibility complex (MHC)
   ii. Absent or decreased MHC type I levels
   iii. Decreased MHC type II levels on mononuclear cells
g. Omenn syndrome: believed to be caused by a mutation impairing the function of immunoglobulin and TCR recombinase genes, such as *RAG1* and *RAG2* genes

Clinical Features

1. Age of onset: 3–6 months of life
2. Usual presentation with infections due to lack of T-cell function
   a. Opportunistic organisms
      i. *Pneumocystis carinii* pneumonia
      ii. Systemic candidiasis
      iii. Atypical mycobacterium
      iv. Cryptosporidium
      v. Pneumococcus
   b. Recurrent infections
   c. Persistence of infections despite conventional treatment
3. Failure to thrive
4. Oral or diaper candidiasis
5. Dehydration from chronic diarrhea
6. Fevers
7. Rashes
8. Cough and congestion
9. Increased respiratory rate and effort
10. Absence of tonsils and lymph nodes
11. Absence of lymphadenopathy or increased tonsillar tissue despite serious infections
12. Pneumonias
13. Sepsis
14. Disseminated infections
   a. Salmonella
   b. Varicella
   c. Cytomegalovirus
   d. Epstein-Barr virus
   e. Herpes simplex virus
   f. BCG
   g. Vaccine strain (live) polio virus
15. Recurrent sinopulmonary infections
16. Recurrent skin infections
17. Abscesses
18. Poor wound healing
19. Transplacental transfer of maternal lymphocytes to the infant prenatally or during parturition causing graft-vs-host disease (GVHD), characterized by
   a. Erythematous skin rashes
   b. Hepatomegaly
   c. Lymphadenopathy
20. ADA deficiency and PNP deficiency with later onset and milder or atypical clinical presentation
   a. Diagnosis suspected in patients with
      i. Unexplained T-cell lymphopenia
      ii. Late manifestations of immunodeficiency
         a) Chronic pulmonary insufficiency
         b) History of autoimmunity and neurologic abnormalities
         c) Onset during the first two decades of life and even later
   b. Diagnosis confirmed by finding absent or very low enzyme activity in erythrocytes or in nucleated blood cells
21. Lymphadenopathy or hepatosplenomegaly in Omenn syndrome or bare lymphocyte syndrome
22. Prognosis
   a. Fatal if untreated
   b. Bone marrow transplantation or enzyme replacement to reconstitute the immune system compatible with long survival

Diagnostic Investigations

1. Newborn screening (Adeli and Buckley 2010; Lipstein et al. 2010; Secord 2009)
   a. Newborn screening would not only make the diagnosis at birth but would lead to measures to protect infants from becoming infected before they could receive a transplant.
   b. Newborn screening would also reveal the true incidence of SCID and define the range of conditions characterized by severely impaired T-cell development.

c. Evidence indicates the benefits of early treatment of SCID and the possibility of population-based newborn screening.
d. Better information on optimal treatment and the costs of treatment and screening would benefit policy makers deciding among competing health care priorities.

2. Laboratory workup
   a. X-SCID (Davis and Puck 2005)
      i. Lymphocyte count
         a) Usually very low number of T cells
         b) B cells generally present, but nonfunctional
         c) Low or absent number of NK cells
         d) Typical X-SCID designated as $T^{-}B^{+}NK^{-}$
      ii. Lymphocyte functional tests
         a) Absent antibody responses to vaccines and infections agents
         b) Lacking T-cell responses to mitogens
      iii. Immunoglobulin concentrations
         a) Low serum concentrations of IgA and IgM
         b) IgG generally normal at birth but declines as maternally transferred IgG disappears by 3 months of age
      iv. Thymus: absent thymic shadow on chest radiogram
      v. Molecular genetic testing clinically available: *IL2RF* is the only gene known to be associated with X-SCID.
         a) Sequence analysis
         b) Targeted mutation analysis
   b. Adenosine deaminase deficiency (Hershfield 2009)
      i. Immune function
         a) Lymphopenia, the laboratory hallmark of ADA-deficient SCID, is present at birth. The total blood lymphocyte count is usually lower than 500/μL (normal for neonates: 2,000 to >5,000).
         b) All lymphoid lineages (T-, B-, and NK-cells) are depleted as demonstrated by flow cytometry.
         c) Lower or absent in vitro lymphocyte function, as measured by proliferative response to mitogens and antigens
         d) Low serum immunoglobulins and absence of specific antibody response to infections and immunizations
      ii. Adenosine deaminase (ADA) catalytic activity
         a) Affected individuals who have not been transfused have less than 1% of normal ADA catalytic activity in erythrocyte hemolysates.
         b) Affected individuals who have been recently transfused may require testing of another cell type, such as fibroblasts or leukocytes.
      iii. Biochemical markers of ADA deficiency
         a) Elevated erythrocyte deaminate 2′-deoxyadenosine (dAdo) nucleotides (dAXP): pathognomonic
         b) Reduced erythrocyte S-adenosylhomocysteine hydrolase (AdoHcyase, SAHase) activity (<5% of normal)
         c) Markedly elevated urinary excretion of dAdo
      iv. Molecular genetic testing: *ADA* is the only gene associated with ADA deficiency.
         a) Sequence analysis
         b) Deletion/duplication analysis
   c. ZAP70-related SCID (Capece and Nash 2009)
      i. Lymphocyte counts
         a) T-cell counts: absent or very low CD8+ cells, normal or elevated CD4+ cells, and normal CD3+ cells
         b) B-cell counts: normal B cells and NK cells
      ii. Lymphocyte function
         a) Absence of proliferation of CD4+ cells in response to mitogens (e.g., PHA)
         b) Absence of proliferation of CD4+ cells in response to antigens (e.g., ConA)
         c) Defective $CD4^{+}$ cell-cell activation manifests as impaired Ca^{2+} flux in response to CD3 (OKT3) stimulation.
      iii. ZAP-70 protein expression: absence of ZAP-70 protein in most cases by immunocytochemistry testing of CD4+ T cells
      iv. Immunoglobulin concentrations and function
         a) Severe hypogammaglobulinemia in a majority of affected individuals but normal immunoglobulin levels have been seen
         b) Although functional antibody responses to immunization are present in a few persons, this finding does not indicate that all specific antigenic responses are intact.

v. Molecular genetic testing: Sequence analysis of the *ZAP70* coding region detects missense and nonsense mutations, splice and regulatory region mutations, and insertion mutations.

d. Autosomal recessive SCID (T-B-NK+. *RAG1*/*RAG2*-related): molecular genetic testing of *RAG1*/*RAG2* gene available clinically by sequence analysis or deletion/duplication analysis

3. Chest X-ray
   a. Absent to small thymus shadow
   b. Pneumonia
   c. Typical cupping and flaring of the costochondral junction in patients with ADA deficiency
4. Lymph node biopsy
   a. Paucity of T and B cells
   b. Lack of germinal centers
5. Consider X-SCID in male infants with
   a. Severe recurrent or persistent infections
   b. Infections not responding to ordinary treatment
   c. Infections caused by opportunistic pathogens
   d. Failure to thrive
6. Carrier testing of X-SCID
   a. Testing for known family-specific *IL2RG* mutations
   b. Sequence analysis of the *IL2RG* coding region and splice regions
   c. Southern blot analysis is used to detect large deletions and complex mutations if the family-specific mutation is not known and sequence analysis is uninformative.
   d. X-chromosome inactivation studies on lymphocytes for at-risk females in whom sequence analysis and/or mutation analysis are not an option for carrier testing or are not informative, provided presence of the following two conditions:
      i. Skewed X-chromosome inactivation in lymphocytes
      ii. Non-skewed X-chromosome inactivation in another blood lineage such as granulocytes

Genetic Counseling

1. Recurrence risk
   a. X-SCID
      i. Female germ line mosaicism present if a woman has more than one affected son and the disease-causing mutation in the *IL2RG* gene cannot be detected in her leukocytes
      ii. Over 50% of affected males do not have family history of early deaths in maternal male relatives.
      iii. Patient's sib if the mother is a carrier
         a) Fifty percent of male sibs affected
         b) Fifty percent of female sibs carriers
      iv. Patient's sib is still at increased risk even if the disease-causing mutation has not been identified in the mother's leukocytes since germ line mosaicism has been demonstrated in this condition.
      v. Patient's offspring (offspring of affected males)
         a) Hundred percent of daughters carriers
         b) None of sons affected
   b. Autosomal recessive SCID
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier in which case 25% of the offspring will be affected
2. Prenatal diagnosis
   a. X-SCID
      i. Determination on fetal cells obtained by CVS or amniocentesis
      ii. Analysis of DNA from fetal cells for the known disease-causing mutation, provided
         a) Karyotype revealing 46,XY
         b) The disease-causing *IL2RG* mutation has been identified in a family member.
      iii. Fetal blood sampling for immunological evaluation when the family-specific mutation is not known
         a) Lymphocytopenia
         b) Low numbers of T cells
         c) Poor T-cell blastogenic responses to mitogens
   b. Autosomal recessive SCID
      i. JAK3-deficient SCID (Schumacher et al. 1999)
         a) Immunophenotypic evaluation of cord blood cells at 18–20 weeks of gestation
         b) Direct gene analysis using chorionic villus sampling derived DNA in the first trimester
      ii. ADA deficiency
         a) Prenatal diagnosis established by measuring ADA enzyme activity in amniotic cells or chorionic villi (Aitken et al. 1986)
         b) Prenatal diagnosis and preimplantation genetic diagnosis for at-risk pregnancies require prior identification of the

disease-causing mutations in the family (Hershfield 2009).

3. Management (Secord 2009)
   a. X-linked SCID and JAK3 PTK deficiency
      i. Fatal disease unless cured by bone marrow transplantation (BMT)
         a) The best results achieved by using an HLA-matched sibling as a donor (success rates of 97%)
         b) Using haploidentical T-cell-depleted BMT from a parent (haploidentical family donors resulting in lower success rates of 52%): lifesaving for the majority of X-SCID patients who lack matched sibling
      ii. Monthly intravenous immunoglobulin replacement therapy required if B cells do not engraft
      iii. Report of in utero transplantation of hematopoietic progenitor cells allowing immune reconstitution in a fetus
      iv. Gene therapy (Hacein-Bey-Abina et al. 2010)
         a) Using autologous bone marrow stem/progenitor cells retrovirally transduced with a therapeutic gene
         b) Successful in reconstituting the immune system in patients with X-SCID
         c) Youngest two of the first ten infants treated in a French study developed leukemia due to retroviral insertional mutagenesis.
         d) After nearly 10 years of follow-up, gene therapy was shown to have corrected the immunodeficiency associated with SCID-X1. Gene therapy may be an option for patients who do not have an HLA-identical donor for hematopoietic stem-cell transplantation and for whom the risks are deemed acceptable. This treatment is associated with a risk of acute leukemia.
   b. ADA deficiency
      i. Usually fatal unless
         a) Keeping affected children in protective isolation, or
         b) Reconstituting the immune system by bone marrow transplantation from a human leukocyte antigen (HLA)-identical sibling donor (therapy of choice but only available for a minority of patients)
      ii. Exogenous enzyme replacement primarily with polyethylene glycol-conjugated ADA (PEG-ADA) replacement therapy (Blaese et al. 1995)
         a) Providing noncurative, life-saving treatment for ADA-SCID patients
         b) Increased peripheral T-cell counts providing a source of T cells for gene correction not available without enzyme therapy
         c) Weight gain and decreased opportunistic infections in most patients
         d) Improved T-cell function as measured by in vitro mitogen responses in most patients
         e) Recovery of consistent immune responses to specific antigens in fewer patients
      iii. The first genetic disorder treated by gene therapy: a clinical trial using retroviral-mediated transfer of the adenosine deaminase (*ADA*) gene into the T cells of children with ADA-SCID
         a) Normalization of the number of blood T cells as well as many cellular and humoral immune responses
         b) Successful gene transfer into long-lasting progenitor cells, producing a functional multilineage progeny (Bordignon et al. 1995)
         c) Safe and effective addition to treatment for some patients
      iv. Combined treatment with PEG-ADA and gene therapy
   c. PNP deficiency and bare lymphocyte syndrome: primarily with bone marrow transplantation when an appropriate donor is available
   d. IL-2 production defects
      i. Primarily with intravenous IL-2 replacement
      ii. Alternatively with bone marrow transplantation when an appropriate donor is available
   e. Omenn syndrome
      i. Primarily with bone marrow transplantation when an appropriate donor is available
      ii. Pretreatment ablative chemotherapy necessary because of maternal cell engraftment
   f. Bone marrow transplantation from a related donor: a life-saving and life-sustaining treatment for patients with any type of severe combined immune deficiency, even when there is no HLA-identical donor

g. Two fetuses successfully treated with gene therapy in utero by an injection of haploidentical $CD34^+$ cells for the γ chain deficiency
h. Psychosocial support for the affected family
i. Avoid live vaccines

Short Rib–Polydactyly Syndromes

Short rib–polydactyly syndromes (SRPS) are a heterogeneous group of recessively inherited lethal skeletal dysplasia. There are four classic subtypes: type I (Saldino–Noonan) (SRPS I), type II (Majewski) (SRPS II), type III (Verma–Naumoff) (SRPS III), and type IV (Beemer–Langer) (SRPS IV).

Synonyms and Related Disorders

SRPS I (Saldino-Noonan syndrome, polydactyly with neonatal chondrodystrophy type I); SRPS II (Majewski syndrome, polydactyly with neonatal chonddrodystrophy type II); SRPS III (Verma-Naumoff syndrome, polydactyly with neonatal chondrodystrophy type III); SRPS IV (Beemer-Langer syndrome, short rib syndrome, Beemer type)

Genetics/Basic Defects

1. Inheritance: autosomal recessive in all four subtypes
2. Different subtypes of SRPS
   a. A great overlap of anomalies present among different subtypes contributing to diagnostic dilemmas in the short rib–polydactyly syndrome group
   b. Possibly represent a continuous spectrum with variable expressivity, suggested by some reports
3. Ciliary abnormalities due to defects in the retrograde transport protein DYNC2H1 in short rib–polydactyly syndrome (Merrill et al. 2009)
   a. Homozygosity by descent mapping in a consanguineous SRPS family identified a genomic region that contained *DYNC2H1*, a cytoplasmic dynein involved in retrograde transport in the cilium. Affected individuals in the family were homozygous for an exon 12 missense mutation that predicted the amino acid substitution R587C.
   b. Compound heterozygosity for one missense and one null mutation was identified in two additional nonconsanguineous SRPS families.
   c. Cultured chondrocytes from affected individuals showed morphologically abnormal, shortened cilia. In addition, the chondrocytes showed abnormal cytoskeletal microtubule architecture, implicating an altered microtubule network as part of the disease process.
   d. These findings establish SRPS as a cilia disorder and demonstrate that DYNC2H1 is essential for skeletogenesis and growth.
4. DYNC2H1 mutations also cause asphyxiating thoracic dystrophy: ATD and SRP type III are variants of a single disorder belonging to the ciliopathy group (Dagoneau et al. 2009)

Clinical Features

1. SRPS I (Saldino–Noonan)
   a. Constant findings
      i. Severely shortened (flipper-like) limbs with postaxial polydactyly
      ii. Small/narrow thorax with short ribs and hypoplastic lungs
      iii. Protuberant abdomen
      iv. Early neonatal death
   b. Common findings
      i. Hydrops fetalis
      ii. Gastrointestinal abnormalities

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_214,
© Springer Science+Business Media, LLC 2012

a) Esophageal atresia
b) Short small intestine
c) Malrotation of the bowel
d) Imperforate anus
e) Persistent cloaca
f) Imperforate anus
g) Pancreatic fibrosis and cysts

iii. Cardiac malformations
a) Transposition of the great vessels
b) Coarctation of the aorta or hypoplastic aortic arch
c) Ventricular septal defects
d) Double-outlet left ventricle

c. Occasional findings
i. Oligohydramnios
ii. Renal dysplasia/cystic disease
iii. Abnormal genitalia
a) Cryptorchidism
b) Hypoplastic penis
iv. CNS malformations
a) Cerebellar hypoplasia
b) Dandy–Walker malformation
v. Bifid epiglottis
vi. Bifid tongue
vii. Cleft upper lip

2. SRPS II (Majewski)
a. Constant findings
i. Extremely short limbs with pre-/postaxial polydactyly of the hands and feet
ii. Small/narrow chest with short ribs and pulmonary hypoplasia
iii. Protuberant abdomen
iv. Median cleft lip or pseudocleft of the upper and lower lip or cleft palate
v. Epiglottis and larynx hypoplasia
vi. Short/ovoid tibias with round ends
vii. Presence of premature ossification centers
viii. Early neonatal death

b. Common findings
i. Polyhydramnios
ii. Hydrops fetalis
iii. Ocular hypertelorism
iv. Broad and flat nose
v. Low-set ears
vi. Ambiguous genitalia
vii. Renal cystic disease

c. Occasional findings
i. Short small intestine
ii. Malrotation of the bowel
iii. Cardiac malformations
iv. Dysplastic pancreas

3. SRPS III (Verma–Naumoff)
a. Constant findings
i. Severely shortened limbs with postaxial polydactyly
ii. Small/narrow thorax with short ribs and hypoplastic lungs
iii. Early neonatal death

b. Common findings
i. Hydrops fetalis
ii. Short cranial base
iii. Bulging forehead
iv. Depressed nasal bridge
v. Flat occiput
vi. Renal cystic dysplasia

c. Occasional findings
i. Congenital heart defects
a) Ventricular septal defect
b) Situs inversus
ii. Epiglottic hypoplasia
iii. Intestinal malrotation
iv. Cloacal developmental abnormalities and ambiguous genitalia

4. SRPS IV (Beemer–Langer)
a. Constant findings
i. Severely shortened limbs with or without postaxial polydactyly
ii. Small/narrow thorax with short ribs and hypoplastic lungs
iii. Early neonatal death

b. Common findings
i. Hydrops fetalis
ii. Macrocephaly with frontal bossing
iii. Ocular hypertelorism
iv. Flat nasal bridge
v. Cleft lip and palate
vi. Protuberant abdomen

c. Occasional findings
i. CNS abnormalities
a) Holoprosencephaly/absence of the corpus callosum/hydrocephalus
b) Dandy–Walker cyst and/or arachnoid cyst
c) Hypothalamic hamartomas
ii. Lobulated tongue with hamartomas

iii. Oral frenula
iv. Congenital heart defects
v. Malrotation of the intestine
vi. Renal malformations
  a) Renal cystic dysplasia
  b) Atresia of the ureter with hydronephrosis and hydroureter
vii. Omphalocele
viii. Inguinal hernia

Diagnostic Investigations

1. Radiography
   a. SRPS I (Saldino–Noonan)
      i. Extreme micromelia with severely dysplastic pointed (or ragged) metaphyses of the long tubular bones, and absence of corticomedullary demarcation
      ii. Narrow thorax with short/horizontal ribs
      iii. Deficient ossification in calvarium, vertebrae, pelvis, and bones of the hands and feet
      iv. Small iliac bones with horizontal acetabula
      v. Postaxial polydactyly
      vi. Short tibiae
   b. SRPS II (Majewski)
      i. Extreme micromelia with smooth rounded metaphyses
      ii. Extremely short horizontal ribs
      iii. Normal pelvis and vertebrae
      iv. Disproportionately shortened ovoid-shaped tibiae
      v. Pre- and postaxial polydactyly, syndactyly, and brachydactyly
      vi. Advanced skeletal ossification–advanced maturation of the proximal femora and humeri
   c. SRPS III (Verma–Naumoff)
      i. Extreme micromelia with severely dysplastic widened metaphyses (bones of the legs) and clear corticomedullary demarcation of the long tubular bones
      ii. Extremely shortened and horizontal ribs
      iii. Small and malformed vertebral bodies
      iv. Shortened cranial base
      v. Short iliac bones with horizontal trident lower margin
      vi. Polydactyly
   d. SRPS IV (Beemer–Langer)
      i. Extreme micromelia with smooth metaphyseal margins
      ii. Extremely shortened and horizontal ribs
      iii. Small, poorly ossified vertebrae and increased intervertebral spaces
      iv. High clavicles and small scapulae
      v. Small iliac bones
      vi. Bowed radii and ulnae
      vii. Tibiae: well tabulated and longer than fibulae
      viii. Postaxial polydactyly
2. Histopathology/necropsy
   a. SRPS I (Saldino–Noonan)
      i. Markedly retarded and frequently deranged endochondral ossification. A large island of fibrous tissue may occupy the center of physeal growth zone. A premature ossification center may be seen in the epiphyseal resting cartilage.
      ii. Lungs: hypoplasia which is easily assessed by abnormally small size and low weight
      iii. Identify associated multiple congenital anomalies listed in the clinical features
   b. SRPS II (Majewski)
      i. Markedly retarded endochondral ossification. The chondrocytes in the physeal growth zones are markedly reduced in number and disorderly arranged
      ii. Lungs: hypoplasia as in type I
      iii. Identify associated multiple congenital anomalies listed in the clinical features.
   c. SRPS III (Verma–Naumoff)
      i. Markedly retarded endochondral ossification as in type II. A single patient showed chondrocytic inclusions which are PAS reactive and diastase resistant.
      ii. Lung: hypoplasia as in type I
      iii. Identify associated multiple congenital anomalies which are less common in this type.
   d. SRPS IV (Beemer–Langer)
      i. Physeal growth zones showing a prominent but disorganized zone of hypertrophy. The vascular penetration of physeal cartilage is irregular.
      ii. Lungs: hypoplasia as in type I
      iii. Identify associated multiple congenital anomalies listed in the clinical features.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: The patients will not survive to reproductive age.
2. Prenatal diagnosis: not always possible to differentiate the subtypes
   a. Ultrasonography for SRPS I (Saldino–Noonan)
      i. Short fetal limbs
      ii. Narrow thorax
      iii. Polydactyly
      iv. Pointed metaphyses
      v. Dysplastic cystic kidneys
      vi. Congenital heart defect
      vii. Genital anomalies
   b. Ultrasonography for SRPS II (Majewski)
      i. With a positive family history of Majewski syndrome
         a) Presence of short fetal limbs
         b) Other skeletal findings
      ii. Without a family history
         a) Short fetal limbs
         b) Disproportionately short tibia
         c) Very narrow fetal chest
         d) Short ribs
         e) Bilateral postaxial polydactyly of the hands and feet
         f) Median cleft lip and palate
         g) Polyhydramnios
         h) Hydrops
         i) Marked shortened humerus and femur
         j) Severe bowing and deformity of the bones of the lower leg and forearm
         k) Hypoplastic lungs
         l) Congenital heart defect
         m) Enlarged echogenic kidneys
         n) Genital anomalies
   c. Ultrasonography for SRPS III (Verma–Naumoff)
      i. Short fetal limbs
      ii. Small/narrow thorax
      iii. Short thin ribs
      iv. Polydactyly
      v. Widened metaphyses with marginal spurs
      vi. Micromelia
   d. Ultrasonography for SRPS IV (Beemer–Langer)
      i. Short fetal bones
      ii. Small/narrow thorax
      iii. Short thin ribs
      iv. Polydactyly
   e. Fetoscopy
      i. To identify fetus with SRPS phenotype
      ii. An invasive procedure currently replaced by ultrasonography
3. Management: supportive therapy only for these lethal entities

Fig. 1 (**a**, **b**) Radiograph of a neonate with Saldino–Noonan syndrome (SRPS I) showing extremely shortened horizontal ribs, very small and dysplastic vertebral bodies and iliac cones, and very short tubular bones with irregular metaphyses

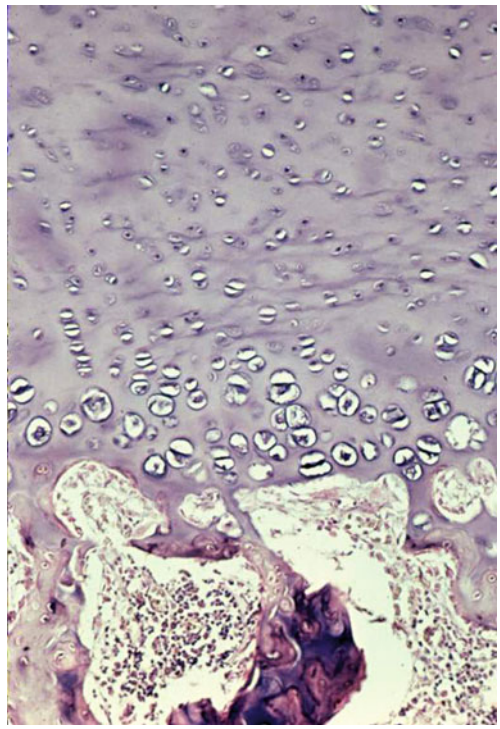

Fig. 2 Photomicrograph of femur (SRPS I) shows markedly retarded and disorganized physeal growth zone

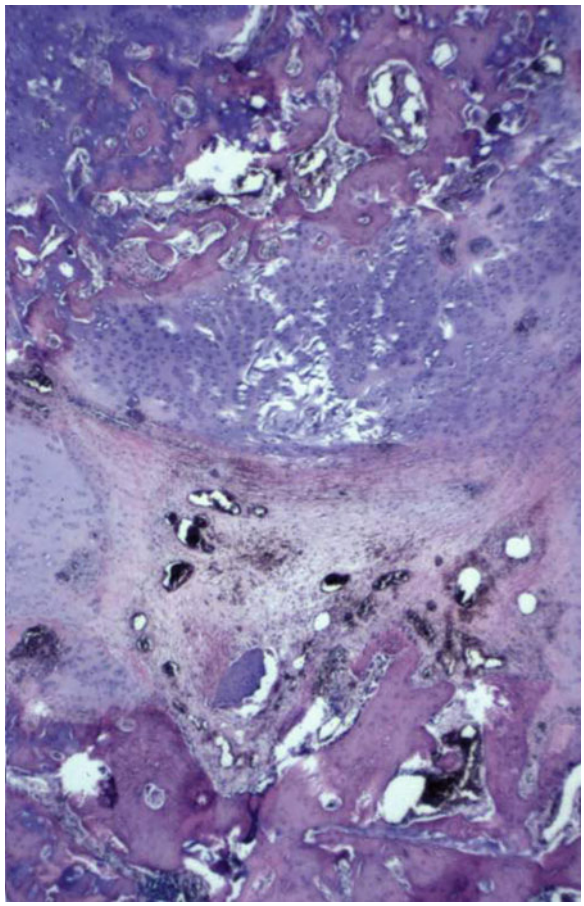

Fig. 3 Photomicrograph of humerus (SRPS I) shows markedly disrupted physeal growth zone by a large cartilage canal-like vascular fibrous tissue. In addition, there is a large premature ossification center (*upper* one third of the picture)

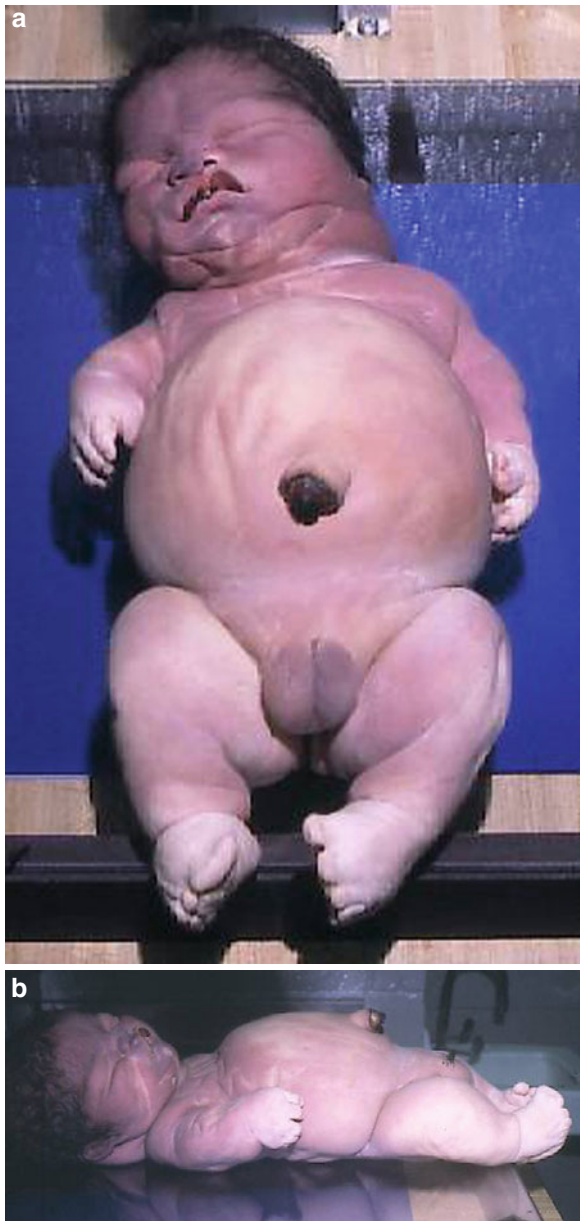

Fig. 4 (**a**, **b**) A neonate with Majewski syndrome (SRPS II) showed hydrops; a large head; hairy forehead; small, malformed, and low-set ears; telecanthus; short nose; a flat nasal bridge; a central cleft of upper and lower lips; short neck; short and narrow chest; markedly distended abdomen with ascites; and extremely short limbs with pre- and postaxial polydactyly, syndactyly, and brachydactyly

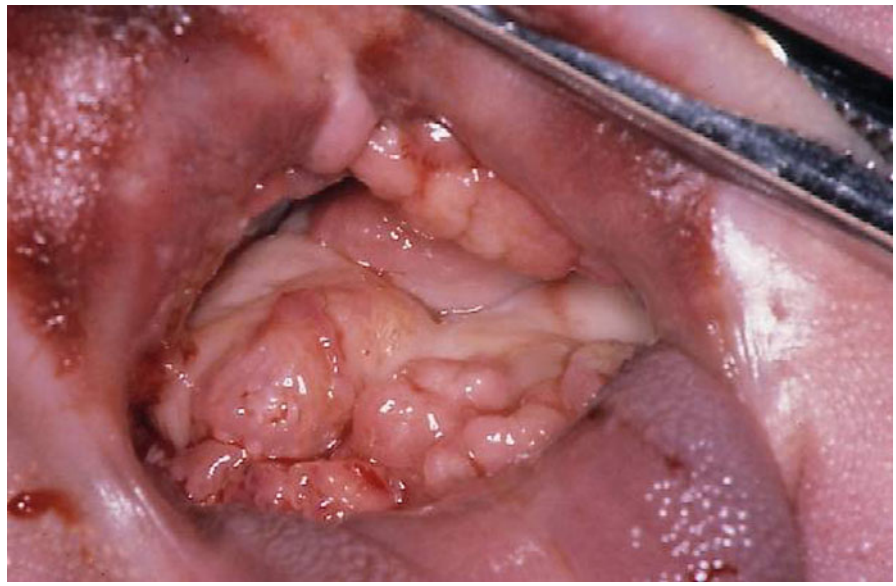

Fig. 5 Mouth of the neonate in Fig. 3 showing lobulated tongue and mucosal frenula

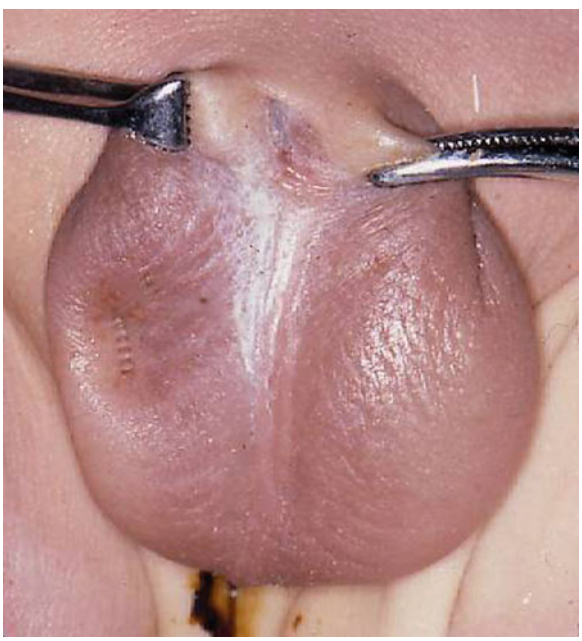

Fig. 6 Ambiguous genitalia with a barely visible micropenis (SRPS II)

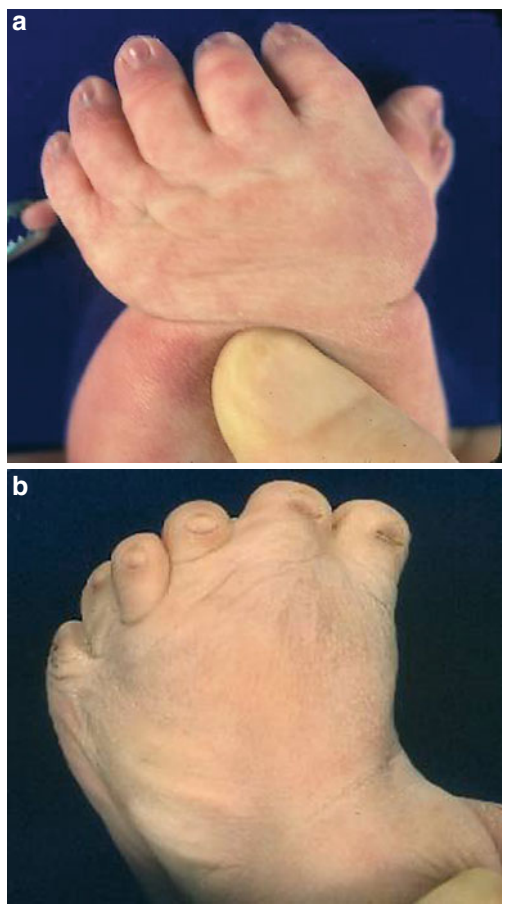

Fig. 7 (**a**, **b**) Hands and feet showed pre- and postaxial polydactyly, syndactyly, and brachydactyly (SRPS II)

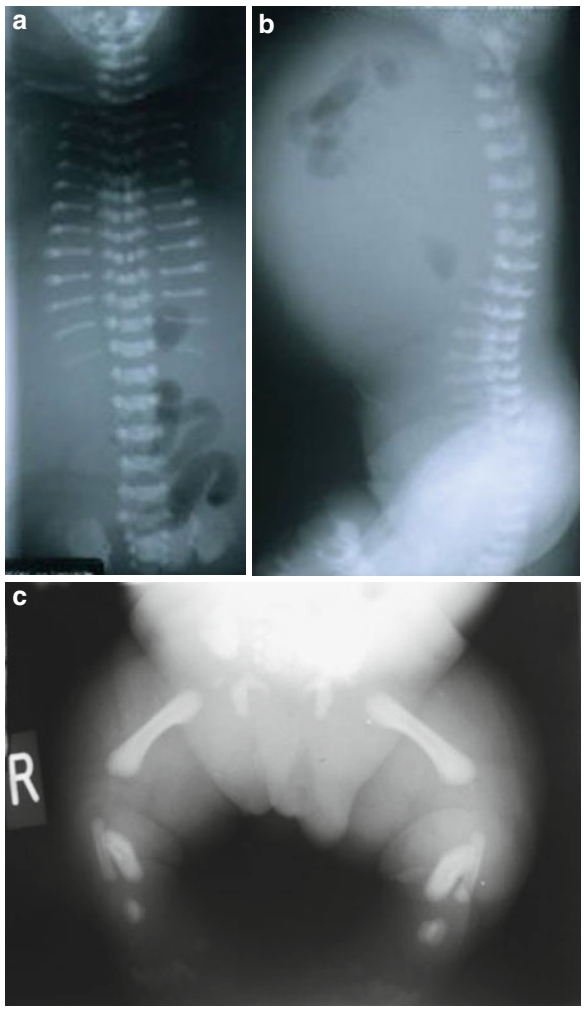

Fig. 8 (**a**–**c**) Radiographs (SRPS II) showing extremely short and horizontal ribs, high clavicles, unremarkable spine and pelvis, and premature ossification of the proximal epiphyses of the humeri, femora, and lateral cuboids. The tubular bones were extremely short, especially the mesomelic segments. The tibiae were disproportionately short and oval in shape

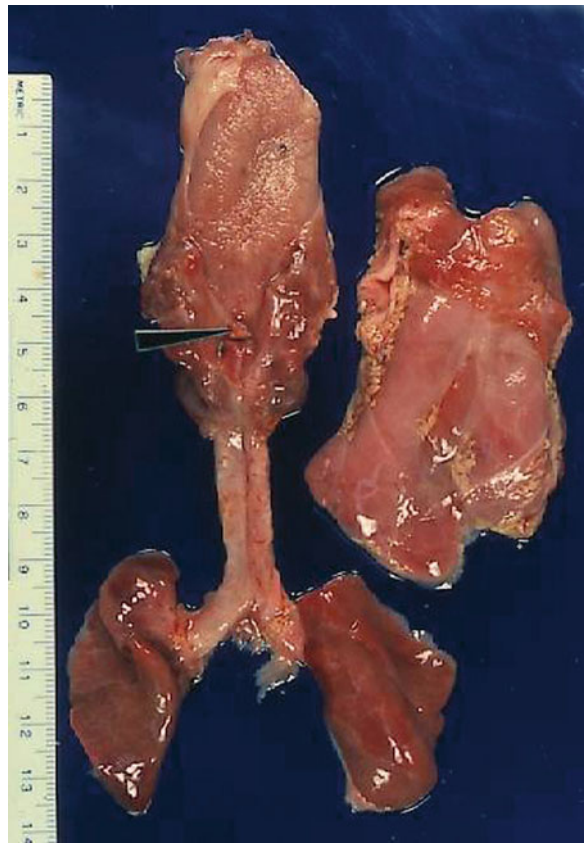

Fig. 9 Respiratory system (necropsy) (SRPS II) showing a small larynx with hypoplastic epiglottis (*arrow*) and remarkably small and hypoplastic lungs. The patient's thymus is juxtaposed for comparison

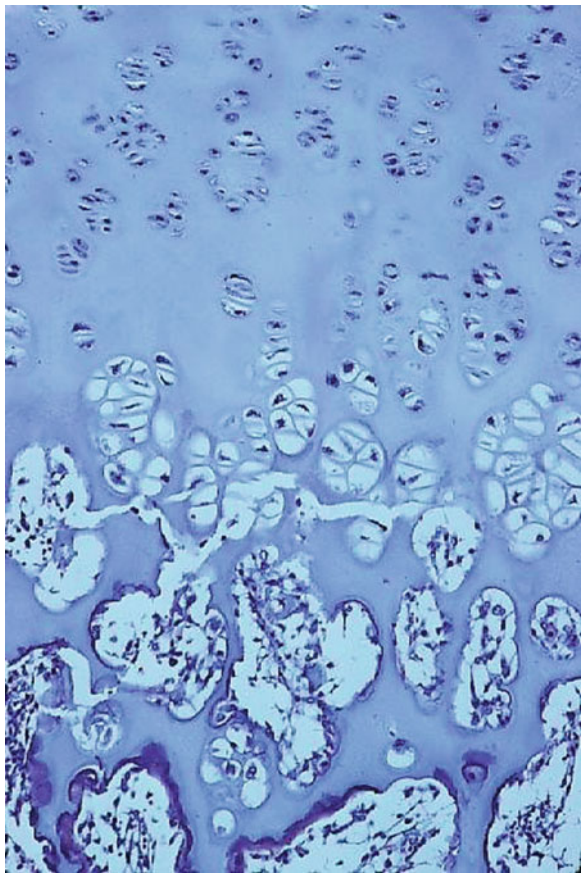

Fig. 10 Photomicrograph of tibia cartilage (SRPS II) (Hematoxylin-eosin, ×108) showing a markedly stunted and disorganized physeal growth zone

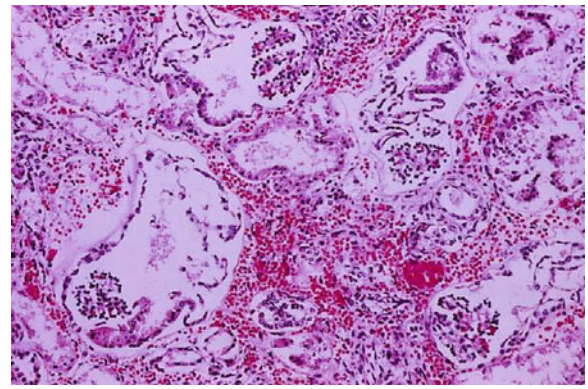

Fig. 11 Photomicrograph of renal cortex showing many dilated glomeruli and mildly cystic renal tubules (SRPS II)

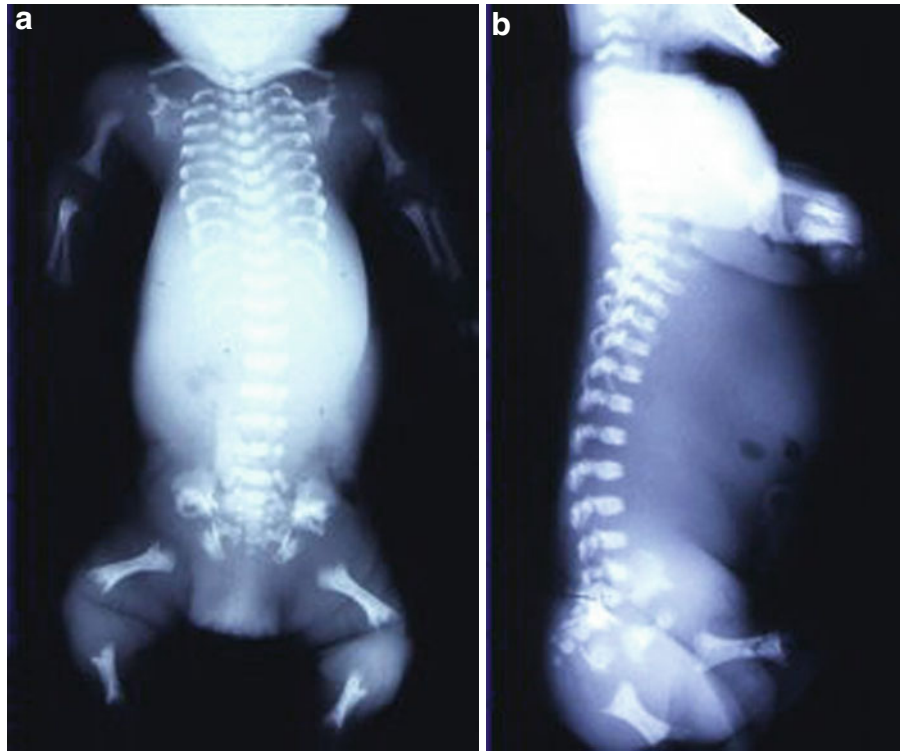

Fig. 12 (**a**, **b**) Radiographs of the skeletal system (SRPS III) showing extremely short and horizontal ribs, small dysplastic vertebral bodies and ilia, short tubular bones with widened metaphyses with longitudinal spurs

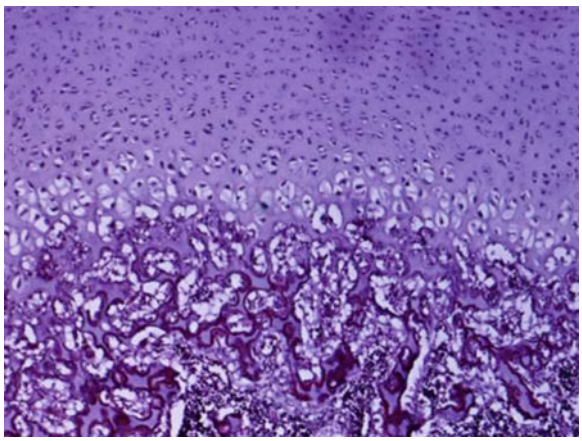

Fig. 13 Photomicrograph of the cartilage of the iliac crest (SRPS III) showing retardation and disorganization of physeal growth zone

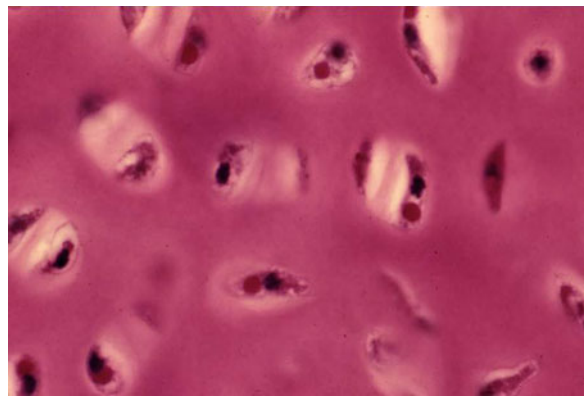

Fig. 14 Higher magnification of the chondrocytes in the resting cartilage and the physeal zone of proliferation frequently show cytoplasmic inclusions (PAS after diastase digestion) (SRPS III)

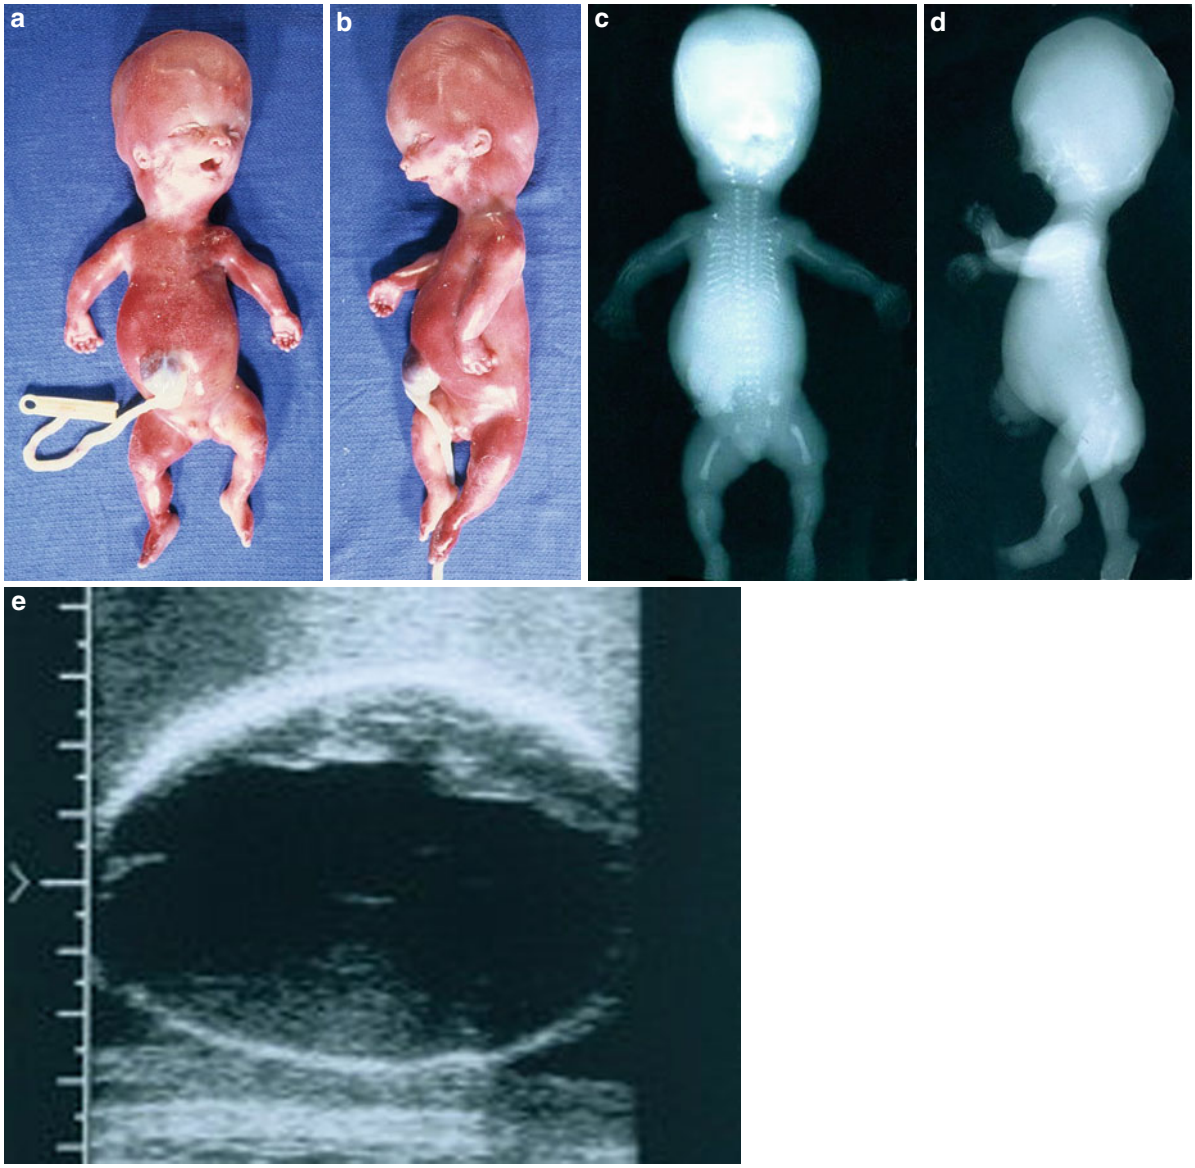

Fig. 15 (**a–e**) A fetus with Beemer–Langer syndrome showing macrocephaly, cystic hygroma, severe micro-/retrognathia with cleft palate, low-set and malformed ears, short limbs, narrow thorax, protuberant abdomen with an omphalocele, and polydactyly. The radiographs show short and horizontal ribs, small scapulae, relatively poorly ossified vertebral bodies, small ilia, short tubular bones with absence of metaphyseal spicules, bowed radii and ulnae, and postaxial polydactyly. The ultrasonography shows porencephalic cyst. The fetus also had a de novo paracentric inversion of chromosome 17q (q12;q25)

Fig. 16 Radiograph of another premature neonate (SRPS IV) showing extremely short and horizontal ribs, small dysplastic vertebral bodies, small iliac wings, and short tubular bone

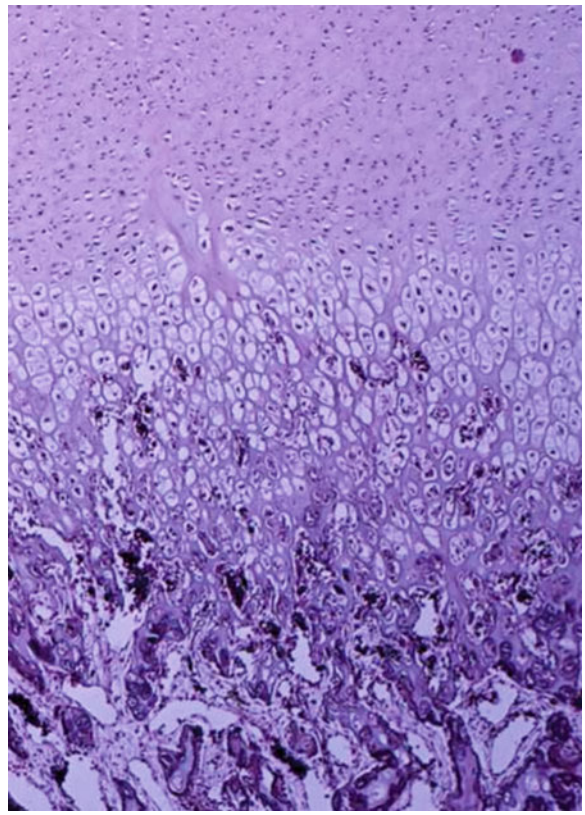

Fig. 17 Physeal growth zone of femur showing prominent but disorganized zone of hypertrophy (SRPS IV)

Sickle Cell Disease

Sickle cell disease (SCD) is the most common single gene disorder in Afro-Americans, affecting approximately 1 in 375 persons of African ancestry. The frequency of sickle cell trait is about 8% in the United States blacks. Sickle blood cells have an increased resistance to malaria. Protection from malaria helps maintain the high prevalence of the sickle gene in areas where malaria is endemic (Fixler and Styles 2002).

Synonyms and Related Disorders

Sickle cell anemia

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Caused by a point mutation at the second nucleotide of codon 6 of the β-globin gene. The base change of A to T causes the amino acid substitution of valine for glutamic acid (GAG to GTG).
   a. Immediate consequence of the mutation: Deoxygenated hemoglobin S polymerizes and distorts the shape of the red blood cell, causing vasoocclusion in the small vessels.
   b. Adverse effects of sickle hemoglobin on the red cell membrane
      i. Oxidative damage
      ii. Cellular dehydration
      iii. Abnormal phospholipid asymmetry
      iv. Increased adherence to endothelial cells
   c. Results of cellular abnormalities
      i. Shortened red cell lifespan causing a lifelong hemolytic anemia
      ii. Intermittent episodes of vascular occlusion causing tissue ischemia and acute and chronic organ dysfunction
3. Sickle cell disease (Lane 1996)
   a. Sickle cell anemia (homozygous sickle cell disease, Hb SS)
      i. Accounts for 60–70% of sickle cell disease in the USA
      ii. The most common form of sickle cell disease
      iii. Caused by inheritance of hemoglobin S from both parents
   b. Other clinically significant sickle cell disorders caused by coinheritance of a sickle gene with a gene for:
      i. β-thalassemia:
         a) The β-thalassemias are divided into β^+-thalassemia (in which some β-globin chains are produced) and β^o-thalassemia (in which there is no β-chain synthesis)
         b) Clinical pictures of patients with hemoglobin S β^+-thalassemia and S β^o-thalassemia resembles sickle cell disease rather than thalassemia, because the sickle β-globin predominates in the presence of underproduction of normal β-globin.
      ii. Hb C
      iii. Hb $D_{\text{Los Angels}}$
      iv. Hb E (HBB Glu25Lys) (Masiello et al. 2007)
         a) One of world's most common hemoglobin variants.
         b) Found primarily in Sri Lanka, Eastern India, Southeast Asia, and Southwest China.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_215,
© Springer Science+Business Media, LLC 2012

c) Individuals homozygous for Hb E have mild anemia and microcytosis and are clinically asymptomatic.
d) Compound heterozygotes for Hb S and Hb E are increasingly found throughout the world due to population migrations and racial intermarriages over the last century.
e) Clinical course of adults with Hb SE disease resembles that of Hb S/β^+-thalassemia.
f) Patients who are compound heterozygotes for Hb E and a β-thalassemia mutation have variable phenotypes from mild to severe; the latter is virtually indistinguishable from β-thalassemia major (Fucharoen and Winichagoon 2000).
g) This is because the Hb E mutation creates a cryptic splice site and therefore manifests also as a mild β^+-thalassemia mutation (Orkin et al. 1982).

v. Hb Lepore
vi. Hb O_{Arab}
vii. Hb C_{Harlem}
viii. Hb Quebec-CHORI

4. Pathophysiology of sickle cell disease (Bookchin and Lew 1996)
   a. Hemolysis: The shortened survival of SS red blood cells results from the following two apparently independent properties of Hb S:
      i. Propensity of the concentrated Hb to polymerization resulting in:
         a) Morphologic sickling
         b) RBC dehydration
         c) A marked decrease in RBC deformability
      ii. Hemoglobin S instability
   b. Erythropoiesis
      i. Submaximal erythropoietic response
      ii. Abnormally low affinity for oxygen of SS cells
      iii. Response of the red cells' glycolytic metabolism to hypoxia

Clinical Features

1. Infection
   a. The most immediate risk for infants diagnosed with sickle cell disease
   b. Prone to many bacterial infections, especially from encapsulated organisms, because of lack of splenic function resulting from progressive infarction of the spleen due to sickling of the red cells
2. Hemolysis
   a. Chronic anemia: Hemolytic anemia develops around 3 months of age.
   b. Jaundice (indirect hyperbilirubinemia)
   c. Aplastic crises
      i. Erythrocyte production by the bone marrow may pause temporarily in children with sickle cell disease.
      ii. Human parvovirus B19 infection responsible for 80% of aplastic crises
   d. Cholelithiasis
      i. Prone to develop pigmented gallstones due to large load of bilirubin from hemoglobin breakdown (chronic hemolysis)
      ii. Presenting symptoms: severe recurrent right upper quadrant pain, episode of cholecystitis, common duct obstruction, or pancreatitis
   e. Delayed growth and sexual maturation
3. Vasoocclusion due to occlusion of the microcirculation by rigid red cells and consequent tissue anoxia and infarction
   a. Recurrent acute pain
      i. Dactylitis (hand and foot syndrome) occurs in 25–45% of the patients and can be the earliest manifestation of sickle cell disease. The syndrome is rare after 4 years of age. It is believed to be due to infarction of the red marrow and associated periosteal inflammation. The clinical manifestations are fever and painful swelling of the hands or feet or both.
      ii. Musculoskeletal pain
      iii. Abdominal pain
   b. Functional asplenia (Lane 1996)
      i. The proportion of children with Hb SS who are functionally asplenic: 1 year (28%), 2 years (58%), 3 years (78%), and 5 years (94%)
      ii. At risk for fulminant septicemia and meningitis with pneumococci and other encapsulated bacteria and death during the first 3 years of life in most patients with Hb SS
   c. Splenic sequestration (10–30% of children with Hb SS most commonly between 6 months and 3 years of life)
      i. Sudden massive collection of blood in the spleen due to sickle cells blocking outflow

ii. Rapid enlargement of the spleen causing acute fall of the hemoglobin level of more than 2 g/dL, despite a persistently elevated reticulocyte count
iii. Mild to moderate thrombocytopenia caused by sequestered platelets
iv. Symptoms
a) Acute pallor
b) Lethargy
c) Increased thirst
d) Abdominal fullness
e) Tachycardia
f) Tachypnea
v. May be associated with other complications of sickle cell disease, such as acute chest syndrome, vasoocclusive pain, bacterial infection, stroke, or aplastic crisis
vi. Increased tendency of recurrence (50%)
vii. High mortality (second leading cause of death in children with sickle cell anemia)

d. Acute chest syndrome (Lane 1996)
i. Appearance of a new pulmonary infiltrate on chest radiography
ii. Causes
a) Infection (bacterial pneumonia, atypical bacterial pneumonia by *Mycoplasma* or *Chlamydia*, viral pneumonia, parvovirus B19)
b) Pulmonary vascular occlusion (in situ pulmonary thrombosis, fat embolism, peripheral thromboembolism)
c) Hypoventilation/atelectasis (thoracic bony infarction, abdominal pain, opioids)
d) Pulmonary edema (intravenous fluids, opioids, pulmonary vascular injury)
e) Bronchospasm
iii. Presenting with varying degrees of fever, cough, tachypnea, pleuritic chest pain, and/or hypoxemia
iv. Occurs in more than 50% of pediatric patients with Hb SS
v. The second leading cause for hospitalization
vi. Predispose to chronic restrictive lung disease with pulmonary hypertension and cor pulmonale (important causes of morbidity and mortality in adulthood)

e. Stroke (Lane 1996)
i. Caused by complete occlusion or severe narrowing of large cerebral vessels
ii. Occurs in 7–8% of children with Hb SS after the first year of life, less commonly in children with Hb SC and sickle β-thalassemia
iii. Presenting symptoms
a) Hemiparesis
b) Monoparesis
c) Aphasia
d) Dysphasia
e) Seizures
f) Semicoma
g) Coma
h) Transient ischemic attack
iv. High rate of recurrence (60–90% have a second stroke within 3 years without transfusion therapy)
v. Silent cerebral infarctions in 10–20% of children with Hb SS without clinically apparent neurologic event

f. Chronic nephropathy: an important cause of mortality in adult patients (Molitierno 2003)
i. Hematuria
a) Persistent microscopic (asymptomatic) hematuria: one of the most prevalent features of the disease
b) Gross hematuria
ii. Significant proteinuria (30%)
iii. Papillary necrosis
iv. Hyposthenuria and enuresis: inability to concentrate urine resulting in a high incidence of enuresis
v. Nephrotic syndrome (40%)
vi. Renal infarction
vii. Pyelonephritis
viii. Renal medullary carcinoma
ix. Hypertension (2–6% in patients with Hb SS)
x. Renal failure (5–18%)

g. Priapism (painful erection)
i. Affects about two thirds of male patients
ii. Recurrent attacks eventuate in impotence in 50% of the patients

h. Bone disorders (Smith 1996)
i. Dactylitis (hand and foot syndrome)
ii. Bone infarction: Manifestations include pain, tenderness, and frequently swelling at the involved site(s).
iii. Aseptic necrosis of the long bones: Manifestations include pain or limitation of motion in the hip, shoulder, or other joints, and during walking and climbing stairs.

i. Proliferative retinopathy
j. Leg ulcers
   i. Most common cutaneous complication in sickle cell anemia
   ii. Causing pain, physical disfigurement, social isolation, vocational adversity, and high utilization of health care resources
   iii. Most common in the ankle area over the medial or lateral malleoli, less common over the dorsum of the foot and near the Achilles tendon
   iv. Universal secondary infections (*Staphylococcus aureus* and *Pseudomonas aeruginosa* most common pathogens)
k. Osteomyelitis
   i. *Salmonella* (most common cause)
   ii. *Staphylococcus aureus*
l. Transfusional hemosiderosis

4. Prognosis
   a. Natural history of sickle cell anemia conducted before mandated newborn screening programs: 15% of children die from acute infections or acute anemic events in the first 5 years of life
   b. Hb SC disease
      i. Clinical manifestations milder than Hb SS disease
      ii. Mild hemolytic anemia
      iii. Risk of overwhelming sepsis and death: less than that in Hb SS disease because of the later onset of splenic dysfunction
      iv. Risk of splenic sequestration up to young adulthood
      v. Splenomegaly
      vi. Vasoocclusion
      vii. Proliferative retinopathy
      viii. Aseptic necrosis of femoral head
   c. Early infectious morbidity and mortality in Hb SS and sickle β^o-thalassemia preventable by:
      i. Presymptomatic diagnosis by neonatal screening
      ii. Extensive parental education
      iii. Prophylactic penicillin for infants with Hb SS and Sβ^o-thalassemia (125 mg by mouth twice a day begun between 2 months and 3 years of age and 250 mg twice daily until at least 5 years of age)
      iv. Timely immunizations (all routine immunizations in a timely fashion; new heptavalent conjugated pneumococcal vaccine administered at 2 months of age; influenza virus vaccines yearly after 6 months of age; meningococcal vaccine for children with splenic dysfunction)
      v. Prompt medical evaluation and management of febrile illness
   d. Sickle cell disease and pregnancy: Affected pregnant women are at risk for:
      i. Crisis
      ii. Toxemia
      iii. Pyelonephritis
      iv. Thrombophlebitis
      v. Spontaneous abortion
   e. Progress toward specific therapies
      i. Transfusion therapy
      ii. Bone marrow transplantation
      iii. Hydroxyurea

Diagnostic Investigations

1. Laboratory studies (Lane 1996)
   a. CBC count
      i. CBC and reticulocyte counts to document anemia and brisk marrow response
      ii. Peripheral blood smear to document presence of sickled erythrocytes, target cells, and Howell–Jolly body (indicating functional asplenism)
      iii. Differential white cell count
      iv. Arterial blood gases to reflect the severity of pulmonary crises
      v. Hemoglobin electrophoresis to document Hb SS or Hb S with another mutant hemoglobin in compound heterozygotes
      vi. Liver function tests, BUN, creatinine, and serum electrolytes
      vii. Fetal hemoglobin
2. Imaging studies (Madani et al. 2007)
   a. Radiography
      i. Performed in patients with respiratory symptoms
         a) Pneumonia
         b) Acute chest syndrome: a new focus of opacity (which may be segmental, lobar or multilobar) or collapse with or without a pleural effusion on a chest radiograph, associated with a variable combination of signs and symptoms

including fever, leukocytosis, hypoxia, and chest pain (Charache et al. 1979)
ii. To detect areas of infarction for painful bones
b. MRI to detect areas of avascular necrosis for the femoral and humeral heads and to distinguish osteomyelitis from bony infarction
c. MRI and MR angiography (MRA) of the brain
i. To detect infarction, ischemia and atrophy (44% prevalence), and vasculopathy (55% prevalence) in children with sickle cell disease (Steen et al. 2003)
ii. Moyamoya (Japanese for a "hazy puff of smoke"): an angiographic pattern of large vessel occlusion and telangiectatica collateral circulation, seen in patients with sickle cell disease (Dobson et al. 2002), as well as other conditions, such as tuberous sclerosis, neurofibromatosis, vasculitides, and infection
d. Abdominal sonogram to document spleen size and the presence of biliary stones
e. Transcranial Doppler ultrasonography useful in selecting patients at risk for stroke

3. Sickle cell anemia (Hb SS)
a. Relative clinical severity
i. Markedly severe hemolysis
ii. Markedly severe vasoocclusion
b. Neonatal screening: hemoglobins FS
c. Hemoglobin electrophoresis (Lane 1996)
i. Hb A: 0%
ii. Hb S: 80–95%
iii. Hb F: 2–20%
iv. Hb A_2: <3.5%
v. Hb C: 0%
d. Thin layer isoelectric focusing
i. Gives better resolution of hemoglobins other than Hb A, Hb S, Hb C, and Hb F
ii. Less experience using this method for screening and more costly
e. High-performance liquid chromatography
i. Differentiates many Hbs (Hbs F, A, S, C, D, E)
ii. Hb S + Hb F + Hb A_2 (probable sickle cell disease)
iii. Hb A + Hb S + Hb A_2 (Sickle cell trait)
iv. Hb A + Hb C (Hb C trait)
v. Hb C (Hb C disease)
vi. Hb S + Hb C (sickle C disease)
vii. Is quantitative (can differentiate sickle trait from sickle β-thalassemia and identify β-thalassemia)
f. Sickle prep
i. Does not distinguish between heterozygote and homozygote
ii. Easy for mass screening
iii. Inappropriate for newborn screening
g. Solubility test
i. Hb S detected by precipitation/turbidity
ii. Does not distinguish sickle cell anemia from other sickle diseases
iii. May give false negative if Hb is low
iv. May give false positive if lipidemia is present
v. Easy to use for mass screening if only the presence of Hb S is desired
vi. Inappropriate for newborn screening
h. DNA diagnosis

4. Sickle β^o-thalassemia
a. Relative clinical severity
i. Moderate severe hemolysis
ii. Moderate severe vasoocclusion
b. Neonatal screening: hemoglobin FS
c. Hemoglobin electrophoresis
i. Hb A: 0%
ii. Hb S: 80–92%
iii. Hb F: 2–15%
iv. Hb A_2: 3.5–7.0%
v. Hb C: 0%

5. Sickle hemoglobin C disease (Hb SC)
a. Relative clinical severity
i. Mild hemolysis
ii. Mild vasoocclusion
b. Neonatal screening: hemoglobins FSC
c. Hemoglobin electrophoresis
i. Hb A: 0%
ii. Hb S: 45–50%
iii. Hb F: 1–5%
iv. Hb A_2: Quantity of A_2 cannot be measured in the presence of Hb C.
v. Hb C: 45–50%

6. Sickle β^+-thalassemia
a. Relative clinical severity
i. Mild to moderate hemolysis
ii. Mild to moderate vasoocclusion
b. Neonatal screening: hemoglobins FSA or FS
c. Hemoglobin electrophoresis

i. Hb A: 5–30%
ii. Hb S: 65–90%
iii. Hb F: 2–10%
iv. Hb A_2: 3.5–6.0%
v. Hb C: 0%

7. Sickle cell trait
   a. Relative clinical severity: normal phenotype
   b. Neonatal screening: hemoglobins FAS
   c. Hemoglobin electrophoresis
      i. Hb A: 50–60%
      ii. Hb S: 35–45%
      iii. Hb F: <2%
      iv. Hb A_2: <3.5%
      v. Hb C: 0%
8. Normal
   a. Relative clinical severity: normal phenotype
   b. Neonatal screening: hemoglobins FA
   c. Hemoglobin electrophoresis
      i. Hb A: 95–98%
      ii. Hb S: 0%
      iii. Hb F: <2%
      iv. Hb A_2: <3.5%
      v. Hb C: 0%
9. Newborn hemoglobinopathy screening
   a. Provided in all 50 states in the USA
   b. The most commonly used screening method: electrophoresis and high-performance liquid chromatography
   c. Fetal hemoglobin present predominantly in young infants
   d. Positive results to be followed by fetal hemoglobin electrophoresis for confirmation
   e. Results with only Hb F and S: suggest the infant has either sickle cell anemia or sickle β^o-thalassemia
   f. Results with Hb F, S, and C: suggest the infant has hemoglobin SC disease
   g. Results with Hb F, S, and A and the infant has not been transfused
      i. Hb S > Hb A: most likely sickle β^+-thalassemia
      ii. Hb A > Hb S: presumed sickle cell trait
      iii. Hb A ≈ Hb S
         a) Study the parents to determine if one of them has the thalassemia trait
         b) Repeat Hb electrophoresis after several months
10. Molecular genetic testing
   a. Carrier testing
      i. Most commonly accomplished by high-performance liquid chromatography
      ii. Isoelectric focusing
      iii. DNA-based assays
   b. Prenatal diagnosis: most commonly use DNA-based assays for the detection of the Hb S mutation
   c. Testing methods
      i. Targeted mutation analysis
         a) Hb S (E6V)
         b) Hb C (E6K)
         c) Hb D (E121Q)
         d) Hb O-Arab (E121K)
      ii. Sequence analysis for Hb mutations

Genetic Counseling

1. Recurrence risk
   a. Homozygous sickle cell disease (Hb SS): The child inherits a sickle (S) gene from each parent.
      i. Risk to patient's sibs: 25%
      ii. Risk to patient's offspring: not increased unless the spouse is a carrier
   b. Sickle hemoglobin C disease (Hb SC): The child inherits an S gene from one parent and a C gene from the other parent.
      i. Risk to patient's sibs: 25% if Hb AS in one parent and Hb AC in other parent
      ii. Risk to patient's offspring: not increased unless the spouse is either Hb AS or Hb AC carrier
   c. Sickle β-thalassemias: The child inherits an S gene from one parent and a β-thalassemia gene from the other parent.
      i. Risk to patient's sibs: 25% if sickle cell carrier in one parent and β-thalassemia carrier in other parent
      ii. Risk to patient's offspring: not increased unless the spouse is a carrier for either Hb S or β-thalassemia gene
2. Prenatal diagnosis
   a. Possible by analysis of DNA extracted from fetal cells obtained by amniocentesis or CVS

b. Both disease-causing hemoglobin alleles of the carrier parents must be identified before prenatal testing.
c. Formal genetic counseling needed when the mother is a known carrier and the father is unknown and/or unavailable for testing.

3. Preimplantation genetic diagnosis (PGD) (El-Toukhy et al. 2010)
   a. PGD for SCD has been performed using PCR and RFLP for detection of the SCD mutation with linked markers (Kuliev et al. 1998, 2005; De Rycke et al. 2001)
   b. The A > T point mutation at codon 7 of the β-globin gene, responsible for SCA can be easily identified by the *Ddel* or *MstII* restriction enzymes
4. Management
   a. Preventive care
      i. Immunizations
         a) *Hemophillus influenzae* type b (Hib) vaccine
         b) 7-valent pneumococcal conjugate vaccine
         c) 23-valent pneumococcal polysaccharide vaccine
         d) Consider quadrivalent meningococcal polysaccharide vaccine
         e) Influenza immunization recommended yearly
      ii. Prophylactic medications
         a) Penicillin prophylaxis: effective in preventing 80% of life-threatening episodes of childhood *Streptococcus pneumoniae* sepsis
         b) Erythromycin prophylaxis: an alternative for individuals allergic to penicillin
         c) Consider folic acid supplementation
      iii. Other preventive strategies
         a) Transcranial Doppler to screen the presence of abnormal velocity of arterial blood flow (at risk for stroke)
         b) Screening for pulmonary hypertension, proteinuria, retinopathy, osteonecrosis, neurocognitive dysfunction, liver disease, growth failure, nutritional deficiency, and gallbladder disease
   b. Acute illness
      i. Infection/fever
         a) Broad-spectrum antibiotics (e.g., ceftriaxone) pending culture results
         b) Vancomycin only for proven or suspected meningitis or other severe illness
      ii. Painful crisis
         a) Oral hydration
         b) Oral analgesics including narcotics, acetaminophen, and ibuprofen
         c) Hospitalization for more severe pain episodes with parental analgesics and hydration
      iii. Splenic sequestration
         a) Emergency transfusion indicated when the signs of cardiovascular instability are present
         b) Splenectomy for multiple or severe episodes of splenic sequestration
      iv. Acute chest syndrome
         a) Treat aggressively with oxygen, analgesics, and antibiotics
         b) Simple transfusion
         c) Exchange transfusion
      v. Stroke
         a) Monitor neurologic status
         b) Aggressive treatment of increased intracranial pressure and seizures
         c) Exchange transfusion generally indicated with the goal of decreasing Hb S percentage to <30% of the total hemoglobin
         d) A preventive chronic transfusion protocol initiated after a CNS event to prevent a second stroke
         e) Prophylactic transfusion with folic acid replacement shown to decrease the incidence of vasoocclusive crisis during pregnancy
      vi. Priapism
         a) Hydration
         b) Analgesia administration
         c) Aspiration and irrigation by a urologist
   c. Surgical care, limited to treat complications
      i. Skin graft to help heal chronic leg ulcers
      ii. Hip replacement or other orthopedic procedures to treat avascular necrosis
      iii. Surgical draining of the penile corpora for resistant priapism
      iv. Cholecystectomy for gallstones
   d. Disease-modulating therapy
      i. Hydroxyurea
         a) Principle: The most prescribed therapy causes myelosuppressive-induced Hb F synthesis by decreasing terminal

differentiation of erythroid stem cells, resulting in decreased sickling and improved red cell survival.

b) Effects of therapy: Patients treated have fewer acute episodes of pain crisis and acute chest syndrome, decreased need for transfusion, and improved survival.

c) Not effective for cerebrovascular complications of sickle cell disease

ii. Other medications that increase the percentage of Hb F, currently under investigation

a) Short-chain fatty acids, such as butyrate or valproic acid

b) 5-azacytidine

iii. Chronic red blood cell transfusion

a) To prevent stroke in patients with an abnormal transcranial Doppler and stroke recurrence

b) To treat chronic debilitating pain and pulmonary hypertension

c) Goal: to maintain the percentage of Hb S between 30% and 50%

d) Complications: iron overload, alloimmunization, and infection

iv. Bone marrow transplant: a curative option for patients with sickle cell disease and other hemoglobinopathies (Bolaños-Meade and Brodsky 2009)

a) Bone marrow transplant from a nonaffected donor, usually a human lymphocyte antigen (HLA)-matched sibling, is the only known curative therapy (Walters et al. 1996, 2000; Vermylen et al. 1998; Bernaudin et al. 2007)

b) Proposed selection criteria: Patients should be less than 16 years of age, have an HLA-identical related donor, and have at least one of the following signs or symptoms: stroke or central nervous system event lasting for more than 24 h, acute chest syndrome, recurrent severe pain episodes, impaired neuropsychological function with an abnormal MRI scan, stage I or II sickle lung disease, sickle nephropathy, bilateral proliferative retinopathy, osteonecrosis of multiple joints, or red blood cell alloimmunization during long-term transfusion therapy (Walters et al. 1996)

v. Gene therapy

a) Principle: A single nucleotide substitution in the pathogenesis of sickle cell disease makes the presence of the sickle cell allele an ideal candidate for gene therapy.

b) Question of the safety of this type of approach: development of leukemia in two patients participating in a clinical trial of gene therapy for X-linked severe combined immunodeficiency disease

Silver–Russell Syndrome

Silver–Russell syndrome (SRS) is a clinically and genetically heterogeneous disorder, characterized by severe prenatal/postnatal growth retardation, characteristic facies, skeletal asymmetry, and other congenital anomalies. The incidence is estimated as 1:50,000–1:100,000 live births.

Synonyms and Related Disorders

Russell-Silver syndrome; Silver-Russell dwarfism

Genetic/Basic Defects

1. Inheritance (Duncan et al. 1990; Preece 2002)
   a. Sporadic occurrence in majority of cases
   b. 19% of cases with more than one affected individuals in the family, providing evidence for a genetic cause
   c. A genetically (and clinically) heterogeneous disorder
      i. Autosomal recessive (17.4%)
      ii. Autosomal dominant (8.7%)
      iii. X-linked dominant (74%)
2. Chromosomal basis (Preece 2002)
   a. Small number of cases with Silver–Russell syndrome reported in association with numerous chromosomal abnormalities
      i. R(15) and deletion of 15q
      ii. Diploid-triploid mixoploidy
      iii. 45,X/46,XY
      iv. XXY
      v. Trisomy 18 mosaicism
      vi. Del(8)(q11-q13)
      vii. Del(18p)
      viii. Dup(1)(q32.1-q42.1)
      ix. Dup(7p12.1-p13)
      x. Distal chromosome 17q (Hitchins et al. 2002)
         a) Balanced translocation (17;20)(q25;q13) inherited from clinically normal father
         b) De novo translocation (1;17)(q31;q25) with breakpoint recently cloned and localized to 17q23.3-q24
         c) Heterozygous deletion of the chorionic somatomammotropin hormone 1 (*CSH1*) gene located within the growth hormone and CSH gene cluster on 17q24.1. The deletion was inherited from the father who appeared clinically normal but had short stature.
   b. Maternal uniparental disomy (UPD) for chromosome 7 (about 7–10% of cases) (Eggermann et al. 2001; Hitchins et al. 2001)
      i. Inheritance of both chromosome 7 from the mother
      ii. A possible novel imprinted region at 7p12-p14, 7q32, and 7q31-ter: UPD can disrupt the balance between imprinted genes and thereby lead to phenotypic manifestations.
      iii. Strong evidence of disruption of imprinted gene expression rather than mutation of a recessive gene underlying the Silver–Russell phenotype in these cases
   c. Genetic and epigenetic disturbances can meanwhile be detected in approximately 50% of patients with typical SRS features (Eggermann et al. 2010).
      i. Nearly one tenth of patients carry a maternal uniparental disomy of chromosome 7 (UPD (7)mat).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_216,
© Springer Science+Business Media, LLC 2012

ii. More than 38% show a hypomethylation in the imprinting control region 1 in 11p15.
iii. More than 1% of patients show (sub)microscopic chromosomal aberrations.
iv. Interestingly, in ~7% of 11p15 hypomethylation carriers, demethylation of other imprinted loci can be detected.

Clinical Features

1. Diagnostic criteria: presence of three major features plus one or more minor features is generally required for a positive diagnosis.
   a. Major criteria
      i. Low birth weight (intrauterine growth retardation)
      ii. Proportionate short stature (postnatal growth retardation): mature height about −3.6 standard deviation scores in both sexes (Davies et al. 1988)
      iii. Small triangular face
      iv. Fifth finger clinodactyly
   b. Minor criteria
      i. Relative macrocephaly due to sparing of cranial growth
      ii. Ear anomalies
      iii. Skeletal asymmetry (face, limb, or body)
      iv. Brachydactyly of the fifth fingers
      v. Bilateral camptodactyly with terminal interphalangeal contractures
      vi. Syndactyly
      vii. Transverse palmar crease
      viii. Downward-slanting corner of the mouth
      ix. Muscular hypotrophy/hypotonia
      x. Motor/neurological delay
      xi. Irregular spacing of the teeth
      xii. Café-au-lait spots
      xiii. Precocious puberty
      xiv. Squeaky voice
      xv. Genital abnormalities
      xvi. Speech delay
      xvii. Feeding difficulties
2. Other manifestations
   a. Significant cognitive impairment (50%)
   b. Gastrointestinal symptoms (77%)
      i. Gastroesophageal reflux disease (34%)
      ii. Esophagitis (25%)
      iii. Food aversion (32%)
      iv. Failure to thrive (63%)
   c. Skeletal anomalies
      i. Large anterior fontanelle (delayed closure)
      ii. Absence of asymmetry
      iii. Syndactyly of the toes
   d. Genitourinary anomalies
      i. Hypospadias
      ii. Posterior urethral valves
   e. Cardiac defects
   f. Various tumors
      i. Craniopharyngioma
      ii. Testicular seminoma
      iii. Hepatocellular carcinoma
      iv. Wilms tumor
   g. Essentially normal pattern of puberty and adolescent growth
   h. Fertility not necessarily impaired, at least in females
   i. Other features
      i. Blue sclera
      ii. Café-au-lait spots
      iii. Excessive sweating
      iv. Hypoglycemia
3. Clinical characterization (Hannula et al. 2001; Binder et al. 2008; Bruce et al. 2009; Eggermann et al. 2010)
   a. Phenotype of maternal UPD7 carriers is generally milder.
   b. 11p15 epimutation (*H19* imprinting control region hypomethylation) carriers usually present the typical picture of SRS.

Diagnostic Investigations

1. Increased serum or urinary gonadotropin levels in the prepubertal age
2. Hypoglycemia
3. Growth hormone studies
4. Metabolic acidosis due to renal tubular acidosis in a few patients
5. Radiography
   a. Delayed bone age
   b. Limb asymmetry
   c. Ivory epiphyses of the distal phalanges
   d. Clinodactyly of the fifth fingers
   e. Short fifth middle phalanges
   f. Pseudoepiphyses at the base of the second metacarpal

6. Chromosome analysis to define chromosome basis
   a. Mosaic trisomy 7 (Flori et al. 2005; Font-Montgomery et al. 2005)
   b. Interstitial deletion of chromosome 7q [del(7)(q21.1q21.3)] (Courtens et al. 2005)
7. Molecular genetic testing (Eggermann et al. 2009; Saal 2007)
   a. Maternal uniparental disomy (UDP) of chromosome 7 (7–10%) clinically available: both maternal isodisomy and heterodisomy have been reported (Bernard et al. 1999; Price et al. 1999).
   b. Genetic or epigenetic mutations in the imprinted region on chromosome 11p15.5: methylation analysis of *H19* (35%) clinically available
   c. 11p15 epimutation and UPD (7) mat carriers do not always show the unambiguous SRS phenotype.
   d. In addition to patients with the classical SRS phenotype fulfilling the SRS-specific scores, genetic testing for the 11p15 epimutation and/or UPD (7) mat should also be considered in case of SRS-like phenotypes, for example, mild IUGR and PNGR (more than −2 SD) associated with a prominent forehead and triangular face or asymmetry as the only clinical signs.
   e. In particular, the lack of IUGR in patients with an SRS-like phenotype should not automatically result in exclusion from molecular testing.

Genetic Counseling

1. Recurrence risk (Saal 2007)
   a. Multiple etiologies of SRS
      i. Maternal uniparental disomy for chromosome 7: both parents are predicted to be unaffected.
      ii. Possible mutations or epigenetic changes that modify expression of genes in the imprinted region of chromosome 11p15.5
      iii. Autosomal dominant inheritance
      iv. Autosomal recessive inheritance
   b. Patient's sibs
      i. Not increased in a nongenetic sporadic case or as the result of maternal uniparental disomy for chromosome 7 (both parents are predicted to be unaffected)
      ii. Increased depending on the inheritance pattern
   c. Patient's offspring
      i. Not increased in a nongenetic sporadic case and probably low in case of maternal uniparental disomy for chromosome 7
      ii. Increased depending on the inheritance pattern
2. Prenatal diagnosis
   a. Ultrasonography of fetus at risk by family history
      i. Delayed fetal skeletal growth may not be evident until the late second trimester.
      ii. Asymmetry of fetal limbs may not be evident until the third trimester
   b. Usually not possible because most occurrences are in a single individual in a family; therefore, most pregnancies are not identified to be at increased risk for recurrence (Saal 2007)
3. Management
   a. Growth deficiency
      i. Optimize caloric intake
      ii. Consider nasogastric or gastrostomy feeding for severe gastroesophageal reflux and failure to thrive
      iii. Consider growth hormone treatment in patients with documented growth hormone deficiency
   b. Dental cares for overcrowding of teeth
   c. Orthopedic management for asymmetry of legs
   d. Early intervention programs including physical therapy for developmental delay due to hypotonia
   e. Special education for learning disabilities
   f. Psychological counseling related to body image and peer relationship

Fig. 1 An infant with Silver–Russell syndrome showing prenatal and postnatal growth deficiency, triangular face, and asymmetry of legs

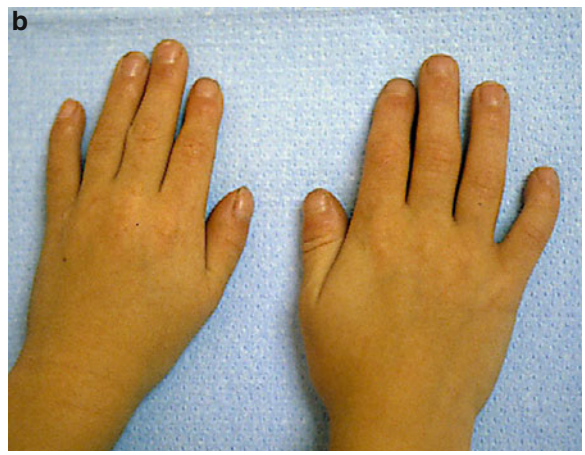

Fig. 2 (**a**, **b**) A girl with Silver–Russell syndrome showing prenatal and postnatal growth deficiency, triangular face, and clinodactyly of the fifth fingers

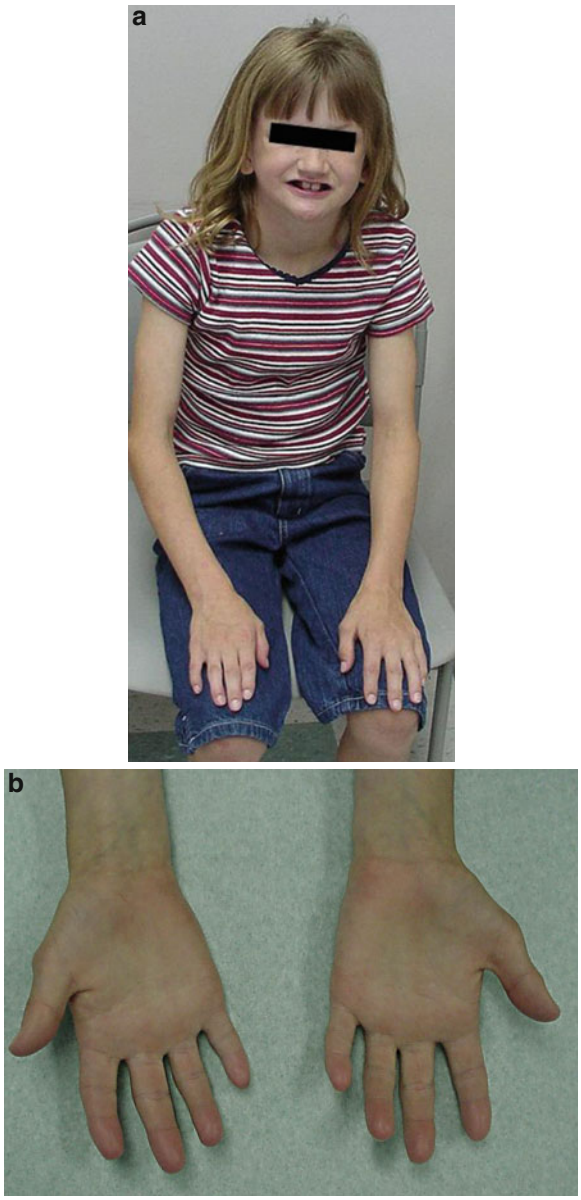

Fig. 3 (**a**, **b**) A girl with Silver–Russell syndrome showing prenatal and postnatal growth deficiency with brachydactyly and clinodactyly of the fifth fingers

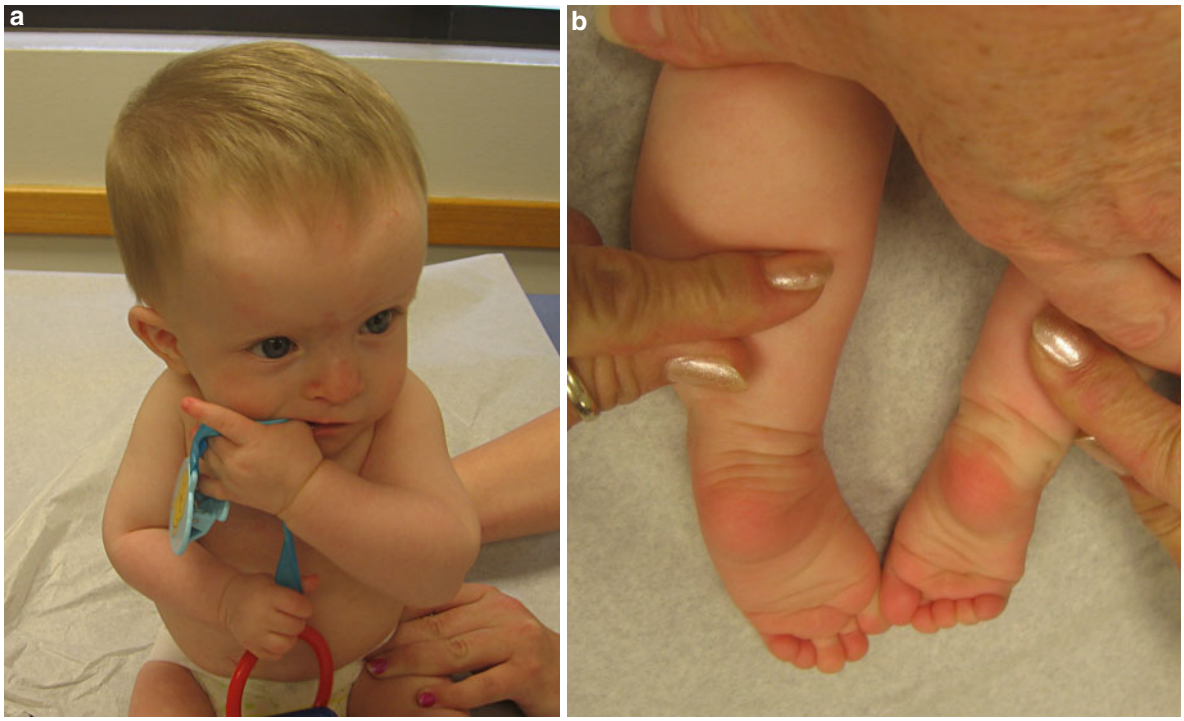

Fig. 4 (**a**, **b**) A 6-month-old male infant was evaluated for intrauterine growth retardation, postnatal growth retardation, a relatively large head, a triangular face, and left side of the body larger than the right. Clinically, he was suspected to have Silver–Russell syndrome. Molecular genetic testing detected loss of methylation at differentially methylated region 1 (DMR1), upstream of the *H19* gene at 11p15. This result is consistent with a diagnosis of Silver–Russell syndrome due to hypomethylation of DMR1

Sirenomelia

Sirenomelia is a rare malformation sequence characterized by a partial or complete fusion of the lower limbs associated with urogenital, anal, lower spine, and other anomalies. The term sirenomelia comes from "siren" or "mermaid" because of the characteristic fusion of the lower extremities. Because of its physical resemblance to the mythical mermaid, the topic of sirenomelia has fascinated public for centuries. Sirenomelia occurs in approximately 1 in 60,000 births.

Synonyms and Related Disorders

Sirenomelia sequence; Sirenomelia mermaid syndrome

Genetics/Basic Defects

1. Sporadic occurrence
2. Incidence of sirenomelia in monozygotic twins markedly increased over dizygotic twins or singletons
3. Cause obscure
   a. Malformations as developmental field defects, probably arising during blastogenesis. Previously considered a vascular disruption anomaly, sirenomelia is a quintessential primary defect of blastogenesis affecting multiple midline primordia during the final stages of granulation at the caudal eminence.
   b. The fusion theory: the lower extremities develop in lateral contact to each other and subsequently become fused.
   c. The classical theory: deficiency of the caudal axial area in the embryo allows the approximation of the side plates where the limbs develop.
   d. The single umbilical artery theory: resulting vascular insufficiency does not allow the normal process of lower limb development.
   e. The vascular steal theory: the sirenomelic malformations result from diversion of the blood flow from caudal structures of the embryo to the placenta. The tissues distal to the diversion receive diminished vascular supply; consequently, the development is arrested at some stage during fetal life.
   f. The extrinsic theory: any mechanical pressure on the caudal portion of the embryo may impede normal rotation of the limb buds as it has been observed in chick embryos exposed to such influences.
   g. The neural tube distention theory: overdistention of the neural tube in the caudal region expands the roof plate of the tube, displacing and laterally rotating the mesoderm, which allows the fusion of the limb buds.

Clinical Features

1. Fusion of the lower limbs
   a. The most striking feature of the syndrome
   b. Fusion of the lower limbs and abnormalities of the feet creating the appearance of a mermaid
   c. Often with rotated feet
   d. Posteriorly located patella
2. Sirtori's classification into three types according to the number of the feet (Sepulveda et al. 1998; Heflin 2007)
   a. Sympus apus (absence of both feet)
      i. The most common form of sirenomelia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_217,
© Springer Science+Business Media, LLC 2012

   ii. Characterized by a completely fused single lower extremity with one femur, no fibulae, and one or two tibia
   iii. Both feet may be absent or rudimentary feet may be present
  b. Sympus unipus or monopus (presence of only one foot)
   i. Characterized by a single fused lower extremity with two femora, two tibia, and two fibulae
   ii. Only one foot is present with a varying number of toes (up to ten) on the single foot.
  c. Sympus dipus (presence of both feet)
   i. Characterized by a single fused lower extremity
   ii. Presence of two distinct feet that appear like a fin or flipper
3. Stocker's more detailed classification into seven subtypes according to the fused bones (Stocker and Heifetz 1987)
  a. Type I: paired femora, tibiae, and fibulae
  b. Type II: a single, fused fibula
  c. Type III: absent fibula
  d. Type IV: partially fused femora and a single fibula
  e. Type V: partially fused femora and absent fibulae
  f. Type VI: a single femur and tibia
  g. Type VII: a single femur and absent tibiae and fibulae
4. Oligohydramnios
5. Single umbilical artery
  a. With hypoplasia of the aorta below the origin of the umbilical artery
  b. Presents virtually in every case of sirenomelia
6. Vascular anomalies
  a. Single umbilical artery
  b. Persistent vitelline artery
  c. Hypoplastic distal aorta
  d. Aberrant femoral arteries
7. Urogenital anomalies
  a. Unilateral or bilateral renal agenesis (the most common finding)
  b. Renal cystic dysplasia
  c. Fusion of the renal pelvis
  d. Absent bladder
  e. Urethral atresia
  f. Ectopic urethra
  g. Posterior urethral valves
  h. Male
   i. Absent external genitalia
   ii. Small/rudimentary phallus
   iii. Absent testis
  i. Females
   i. Absent/ambiguous external genitalia
   ii. Absent ovaries
   iii. Anomalous/rudimentary uterus
   iv. Anomalous vagina
8. Gastrointestinal anomalies
  a. Meckel's diverticulum
  b. Duodenal atresia
  c. Absent gallbladder
  d. Annular pancreas
  e. Omphalocele
  f. Intestinal malrotation
  g. Blind-end colon/rectum
  h. Colon duplication
  i. Absent spleen
  j. Imperforate anus
  k. Limb-body wall complex
9. Cardiac anomalies
  a. Tetralogy of Fallot
  b. Totally anomalous pulmonary venous return
  c. Ventricular septal defect
  d. Atrial septal defect
  e. Truncus arteriosus
  f. Hypoplastic ventricles
  g. Mitral atresia
  h. Transposition of the aorta
  i. Coarctation of the aorta
  j. Hypoplastic left heart
  k. Acardius amorphus
10. Pulmonary anomalies
  a. Pulmonary hypoplasia
  b. Tracheoesophageal fistula
  c. Laryngeal stenosis and tracheal atresia
  d. Cystic adenomatoid malformation
  e. Diaphragmatic hernia
  f. Abnormal lung lobation
  g. Pulmonary agenesis associated with acardius amorphus
11. CNS anomalies
  a. Craniorachischisis
  b. Holoprosencephaly
  c. Hydrocephalus
  d. Arnold-Chiari malformation

e. Absent corpus callosum
f. Meningomyelocele
12. Pelvis/sacral anomalies
a. Dysplastic pelvis
b. Sacral agenesis/dysplasia
13. Vertebral anomalies
a. Hemivertebrae
b. Spina bifida
c. Kyphoscoliosis
14. Upper limb anomalies
a. Absent radius
b. Abnormal thumb
c. Absent limb
d. Preaxial polydactyly
15. Face
a. Potter facies
i. Large, floppy low-set ears
ii. Flat nose
iii. Micrognathia
b. Skin tags
16. Prognosis
a. Generally lethal
i. Stillborn in more than half of cases
ii. Remainder of cases most likely die shortly after birth due to severe associated visceral anomalies, incompatible with life
b. Occasional long term survival possible

Diagnostic Investigations

1. Radiography
a. Classification based on osseous findings
i. Type I (all bones of thigh and lower leg present and unfused)
ii. Type II (fused fibulae)
iii. Type III (absent fibulae)
iv. Type IV (partially fused femora and fused fibulae)
v. Type V (partially fused femora)
vi. Type VI (fused femora and fused tibiae)
vii. Type VII (fused femora and absent tibiae)
b. Rotation of the legs and feet
c. Abnormalities of the vertebrae, especially sacral bones
d. Deficient bony pelvis
2. Angiography for vascular anomalies
3. Chromosome analysis: normal in most cases

Genetic Counseling

1. Recurrence risk
a. Patient's sibs: negligible
b. Patient's offspring: affected individuals do not expect to survive to reproduce.
2. Prenatal diagnosis
a. Ultrasonography
i. Inability to demonstrate separate lower limbs
ii. Identification of varying degree of a single or "fused" lower limb
iii. Lower spine agenesis/dysgenesis
iv. CNS, cardiac, GI, and other abnormalities
v. A single umbilical artery
vi. Oligohydramnios associated with urogenital anomalies, especially renal agenesis/dysgenesis
vii. Prenatal diagnosis of sirenomelia difficult to make because of the associated anhydramnios
b. Color Doppler imaging (Sepulveda et al. 1998)
i. A simple, noninvasive method to detect vascular abnormalities associated with sirenomelia
ii. Two vascular hallmarks of the syndrome in utero
a) Persistence of the vitelline artery: a single large artery arising from the high abdominal aorta to become the single umbilical artery, leaving an atretic or absent distal aorta. Such a vascular abnormality is thought to be responsible for a vascular steal phenomenon and poor perfusion distal to the anomalous artery, leading to the sirenomelia sequence.
b) Absence of renal vessels
c. Prenatal diagnosis by ultrasonography of fetus made as early as first trimester (Monteagudo et al. 2002; Schiesser et al. 2003; van Keirsbilck et al. 2006; Contu et al. 2009)
3. Management (Guidera et al. 1991)
a. Orthopedic treatment of patients with less severe spectrum of caudal regression
i. Soft tissue release
ii. Osteotomies
iii. Separation of the lower limbs. Long term functional results of the separation are unknown.
iv. Orthotics

b. Anticipate extensive reconstruction in the event of survival
c. Goal of orthopedic intervention: proper seating and standing, achievable without amputation
d. Severe form of sirenomelia: a lethal condition

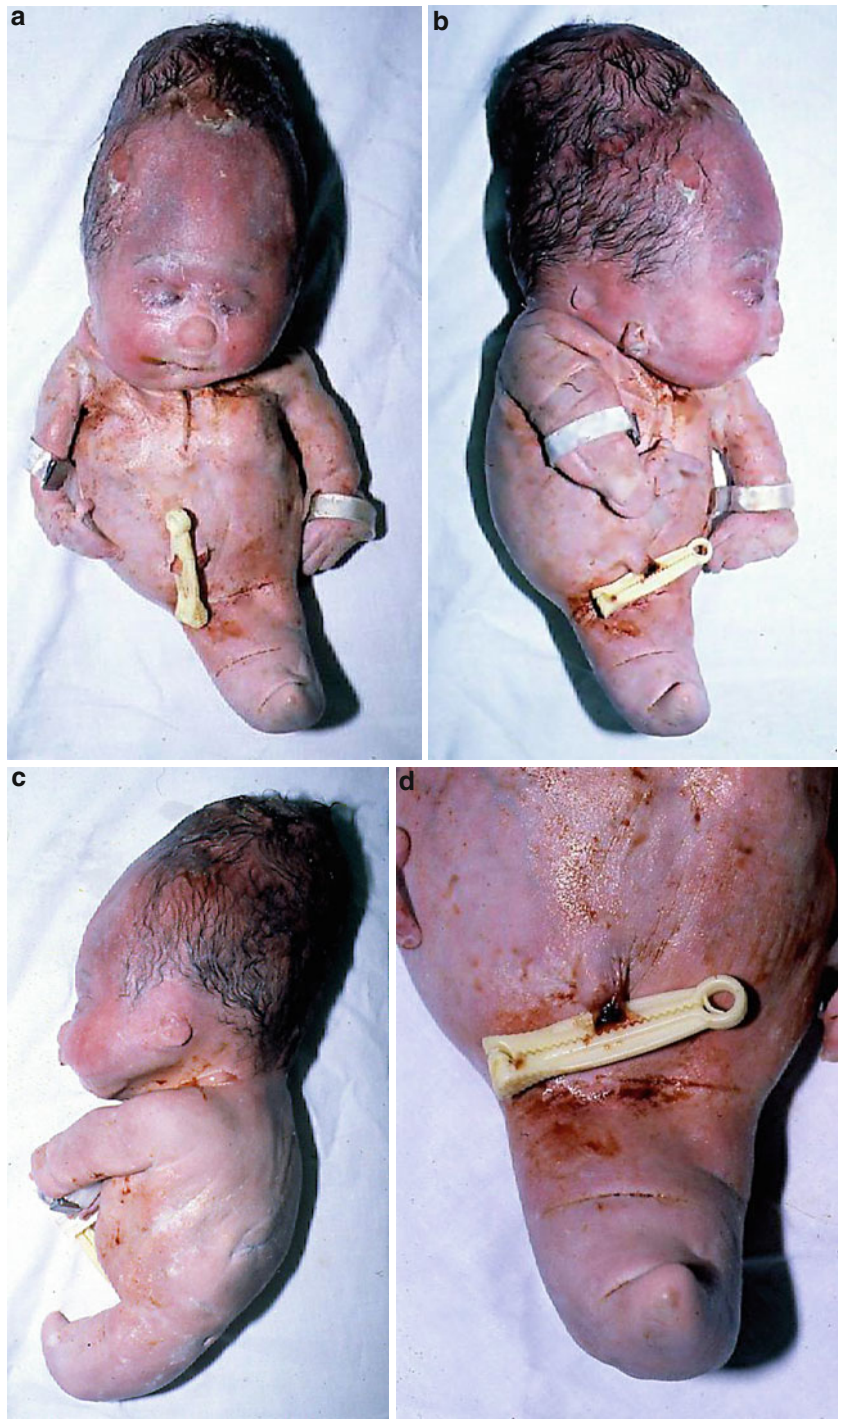

Fig. 1 (**a**–**d**) A stillborn with sirenomelia showing Potter facies, short neck, absent external genitalia, and fused single lower limb with absent feet. This infant also had holoprosencephaly

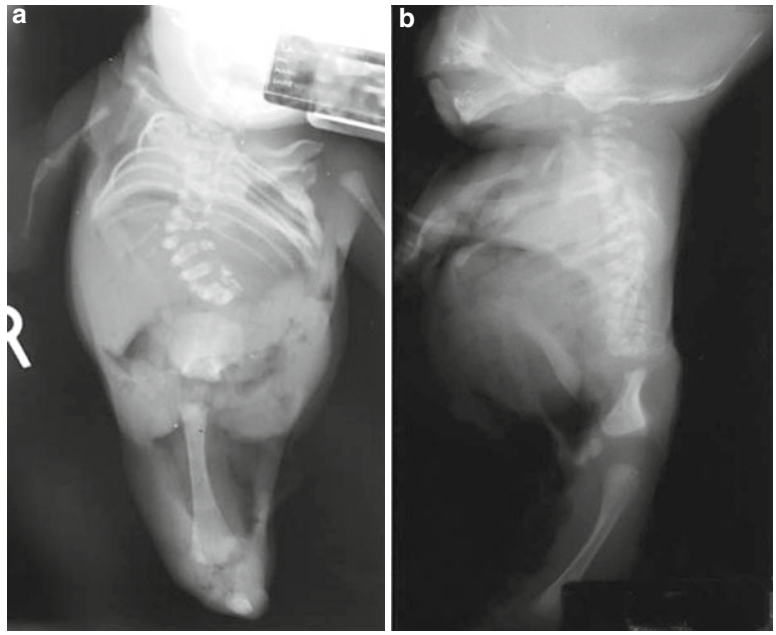

Fig. 2 (**a**, **b**) Radiographs of the previous infant showed vertebral segmentation defects, malformed ribs, absent sacrum, dysplastic pelvic bones, a single femur, and absent tibiae/fibulae/tarsal/metatarsals/phalanges

Fig. 3 A female stillborn (35 weeks gestation) with sirenomelia (monomelia). The infant had a single femur with one bone below knee; agenesis of urinary system (ureters, bladder, and urethra); ectopic rudimentary renal tissue; absence of uterus, vagina, and external genitalia; and imperforate anus

Fig. 4 A male premature neonate with sirenomelia showing fused lower extremities and posterior alignment of the knees and feet. The *left* foot was malformed. Other major anomalies included absence of external genitalia; bilateral renal agenesis; agenesis of the ureters, bladder, urethra, and prostate; esophageal atresia with TE fistula; imperforate anus with absence of the rectum; intestinal malrotation; persistent *left* superior vena cava; bifid cardiac apex; and scoliosis with two hemivertebrae

Smith-Lemli-Opitz Syndrome

In 1964, Smith, Lemli, and Opitz reported three patients with a common distinctive facial appearance, microcephaly, broad alveolar ridges, hypospadias, a characteristic dermatoglyphics pattern, severe feeding disorder, and global developmental delay. The incidence of the Smith-Lemli-Opitz syndrome is estimated to be approximately 1 in 10,000–1 in 40,000 births based on clinical diagnosis and 1 in 60,000–1 in 100,000 births based on biochemical testing. There appears to be strikingly different incidences among various ethnic groups.

Synonyms and Related Disorders

Rutledge multiple congenital anomaly syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Basic defect
   a. Caused by a defect of cholesterol biosynthesis.
   b. Underlying biochemical defect: deficiency of 7-dehydrocholesterol reductase (DHCR7), an enzyme catalyzing the last step of the Kandutsch-Russell cholesterol biosynthesis pathway, resulting in generalized cholesterol deficiency.
   c. Mutations of *DHCR7* gene lead to deficient activity of 7-dehydrocholesterol reductase (DHCR7), the final enzyme of the cholesterol biosynthesis pathway. Functional null alleles of the *DHCR7* locus result in lethal form of Smith-Lemli-Opitz syndrome.
   d. Human *DHCR7* gene has been cloned and localized to 11q12-13.
   e. An example of metabolic deficiency as a cause of a dysmorphic syndrome.
3. Clues pointing to an underlying biochemical defect of cholesterol metabolism
   a. Holoprosencephaly, microcephaly, pituitary agenesis, limb defects, and genital anomalies produced by in utero exposure of rat and mouse pups to chemical inhibitors of the cholesterol biosynthetic pathway
   b. Large adrenal glands with complete absence of lipid in adrenal cortex of patients with Smith-Lemli-Opitz syndrome
   c. Abnormalities of the pituitary-adrenal axis
   d. Suppressed fetal estriol production in pregnancies affected with Smith-Lemli-Opitz syndrome
   e. Neonatal liver disease in severe Smith-Lemli-Opitz syndrome associated with low serum cholesterol level
   f. Male pseudohermaphroditism not caused by dihydrotestosterone receptor defects
   g. Observation of two patients with Smith-Lemli-Opitz syndrome with low plasma cholesterol and elevated levels of 7-dehydrocholesterol (7DHC), the immediate precursor of cholesterol in the Kandutsch-Russell biosynthetic pathway, suggesting that this multiple malformation was caused by a simple Garrodian enzymatic defect
4. Rutledge multiple congenital anomaly syndrome (Rakheja et al. 2003)
   a. Considered a variant of Smith-Lemli-Opitz syndrome

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_218,
© Springer Science+Business Media, LLC 2012

b. Biochemical abnormality of excess 7-dehydrocholesterol and low cholesterol identified in the liver tissue

5. Five additional related human syndromes resulting from impaired cholesterol synthesis (Kelly 2000; Porter 2002)
   a. Desmosterolosis
      i. Autosomal recessive inheritance.
      ii. Caused by mutations in 24-dehydrocholesterol reductase (*DHCR24*) gene.
      iii. Elevated plasma desmosterol.
      iv. Report of a female infant with a lethal syndrome of macrocephaly, thick alveolar ridges, gingival nodules, cleft palate, total anomalous pulmonary venous drainage, ambiguous genitalia, short limbs, and generalized osteosclerosis was found to have markedly increased tissue levels of desmosterol.
      v. Another report of a child with microcephaly, short stature, and delays in speech and psychomotor development was found to have an increased plasma level of desmosterol and markedly increased levels of desmosterol in cultured lymphoblasts.
   b. X-linked dominant chondrodysplasia punctata type 2 (CDPX2) (Conradi-Hünermann syndrome)
      i. Typically in females with a variable combination of bilateral and asymmetric shortening of long bones, punctate calcification of epiphyses, trachea, and larynx, segmental cataracts, and patches of ichthyotic skin that typically follow the lines of Blaschko
      ii. Caused by function-impairing mutations in the sterol-Δ^8 Δ^7-isomerase gene, which maps to Xq11.2-3
      iii. Lethal to males early in gestation
   c. CHILD syndrome (*c*ongenital *h*emidysplasia with *i*chthyosiform erythroderma/nevus and *l*imb *d*efects)
      i. X-linked dominant inheritance
      ii. Cutaneous and bony abnormalities similar to CDPX2
      iii. Report of a patient with classic CHILD syndrome
         a) Manifests the characteristic sterol abnormality of CDPX2
         b) Carries a mutation creating a stop codon in the same sterol-Δ^8-isomerase associated with CDPX2
   d. Greenberg dysplasia (hydrops-ectopic calcification-moth-eaten skeletal dysplasia)
      i. Autosomal recessive inheritance
      ii. A lethal skeletal dysplasia characterized by hydrops fetalis, short-limbed dwarfism, postaxial polydactyly, and abnormal chondro-osseous mineralization
      iii. Radiologic abnormalities
         a) Moth-eaten appearing long bones
         b) Ectopic epiphyseal calcification
         c) Laryngeal and tracheal calcification
         d) Platyspondyly
      iv. Steroid-Δ^{14}-reductase deficiency
   e. Antley-Bixler syndrome (Opitz et al. 2002)
      i. A skeletal abnormality syndrome primarily affecting head and limbs
      ii. Also known as multisynostotic osteodysgenesis with long bone fractures
      iii. A high incidence of genital ambiguity, an anomaly unlikely due to the *FGFR2* mutation, suggesting possible disordered steroidogenesis in early pregnancy
      iv. Elevated two primary precursors of steroid hormones, pregnenolone and progesterone, as are the classical diagnostic metabolites for 17- and 21-hydroxylase deficiencies, suggesting attenuated steroid hydroxylation (including 17,20-lyase activity) at least in the form not associated with *FGFR2* mutations (Shackleton et al. 2004)

Clinical Features

1. General.
   a. Postnatal growth retardation
   b. Failure to thrive
   c. Feeding difficulties requiring gavage feeding in many cases
   d. Abnormal intestinal motility
      i. Pyloric stenosis
      ii. Vomiting
      iii. Gastroesophageal reflux
   e. Feeding intolerance

f. Gastrointestinal irritability
g. Allergy
h. Initial hypotonia/later hypertonia
i. Recurrent otitis media and pneumonias
j. Photosensitivity
k. Adrenal insufficiency uncommon

2. Craniofacial features.
   a. Congenital microcephaly: very common
   b. Metopic prominence and bitemporal narrowing
   c. Capillary hemangioma over the glabella
   d. Eyes
      i. Epicanthal folds
      ii. Ptosis (more than 50% of patients, often with asymmetrical or unilateral ptosis)
      iii. Congenital cataracts
      iv. Optic nerve hypoplasia
   e. Broad nasal bridge and short nasal root with anteverted nares
   f. Micrognathia
   g. Oral
      i. Cleft lip/palate
      ii. High-arched/narrow hard palate
      iii. Broad/ridged alveolar ridges
      iv. Redundant sublingual tissues
      v. Long philtrum
   h. Low-set and posteriorly rotated ears
3. CNS anomalies.
   a. Global psychomotor retardation
   b. Microcephaly (almost universal finding)
   c. Agenesis/hypoplasia of corpus callosum
   d. Cerebellar hypoplasia
   e. Enlarged ventricles
   f. Decreased size of frontal lobes
   g. Pituitary lipoma
   h. Cerebellar hypoplasia with hypoplasia or aplasia of the vermis
   i. Holoprosencephaly sequence (5% of cases)
   j. Seizures
4. Limb anomalies.
   a. Bilateral or unilateral postaxial polydactyly in the hands or feet
   b. Short/proximally placed thumb
   c. Short first metacarpals
   d. Hypoplastic thenar eminences
   e. Subtle "zigzag" alignment of the phalanges of the index finger
   f. Characteristic Y-shaped cutaneous syndactyly of the second–third toes
5. Genital anomalies.
   a. Male (range from normal to the appearance of complete sex reversal)
      i. External genitalia: normal, hypospadias, female appearing, or ambiguous
      ii. Internal genitalia: gonads varying from normal testes to ovotestes to normal ovaries or missing gonads; sex reversal including blind vaginal pouch and rudimentary or bicornuate uterus
   b. Female
      i. Hypoplasia of labia minora
      ii. Hypoplasia of labia majora
6. Congenital heart defects (about 50% of cases).
   a. Endocardial cushion defect (AV canal)
   b. Septal defect
   c. Hypoplastic left heart syndrome
   d. Patent ductus arteriosus
   e. Aortic coarctation
   f. Anomalous pulmonary venous return
   g. Hypertrophic cardiomyopathy
   h. Hypertension
7. Renal anomalies (about 25% of cases).
   a. Renal hypoplasia/aplasia with oligohydramnios sequence
   b. Horseshoe kidney
   c. Renal cortical cysts
   d. Hydronephrosis
   e. Renal ectopia
   f. Ureteral duplication
   g. Fetal lobation
   h. Hypoplastic bladder and ureters
8. Adrenal anomalies.
   a. Adrenal hyperplasia
   b. Adrenal hypoplasia
9. Respiratory tract anomalies.
   a. Laryngomalacia
   b. Tracheomalacia
   c. Sleep apnea
   d. Abnormal pulmonary lobation
   e. Pulmonary hypoplasia
10. Gastrointestinal/hepatic anomalies.
    a. Pyloric stenosis (prominent clinical problem)
    b. Poor feeding/sucking
    c. Gastroesophageal reflux
    d. Constipation
    e. Malrotation
    f. Hirschsprung disease
    g. Cholestatic liver disease

11. Skin.
    a. Photosensitivity
    b. Cutis marmorata
    c. Dry skin/eczema
12. Behavioral disorders.
    a. Hypersensitivity with tactile defensiveness (oral, hands, and feet)
    b. Unusual hyperresponsivity to auditory and visual stimuli
    c. Aggressiveness and self-injury
    d. Severe sleep disturbance
    e. Autistic behavior
13. Prognosis.
    a. Many survive to adulthood.
    b. Many affected children died in the first year from failure to thrive and infections.
14. So-called Smith-Lemli-Opitz syndrome type II, a lethal syndrome resembling the original Smith-Lemli-Opitz syndrome.
    a. Autosomal recessive disorder
    b. Lethal in the newborn period from internal malformations
    c. Most 46, XY "males" with severe hypogenitalism or female appearing external genitalia
    d. Same sterol pattern in most patients
    e. Differences in severity between type I and type II Smith-Lemli-Opitz syndrome: due to severity of the mutations according to subsequent molecular genetic studies
    f. Possibility of genetic heterogeneity of the Smith-Lemli-Opitz syndrome
15. Clinical criteria for the revised severity score (revised Bialer score) by Kelly and Hennekam (2000). The severity score is obtained based on categories of cerebral, ocular, oral, skeletal, and genital defects identified. Based on the severity score, Smith-Lemli-Opitz syndrome phenotype can be divided into three categories: mild (<20), classical (20–50), and severe (>50). Severity score can be correlated with biochemical parameters and provides a basis for establishing a genotype-phenotype correlation.
    a. Brain
        i. Score 1: seizures; qualitative MRI abnormality
        ii. Score 2: major CNS malformations; gyral defects
    b. Oral
        i. Score 1: bifid uvula or submucous cleft
        ii. Score 2: cleft hard palate or median cleft lip
    c. Acral
        i. Score 0: non-Y-shaped minimal toe syndactyly
        ii. Score 1: Y-shaped 2–3 toe syndactyly; clubfoot; upper or lower polydactyly; other syndactyly
        iii. Score 2: any two of the above
    d. Eye
        i. Score 2: cataract; frank microphthalmia
    e. Heart
        i. Score 0: functional defects
        ii. Score 1: single chamber or vessel defects
        iii. Score 2: complex cardiac malformation
    f. Kidney
        i. Score 0: functional defect
        ii. Score 1: simple cystic kidney disease
        iii. Score 2: renal agenesis; clinically important cystic disease
    g. Liver
        i. Score 0: induced hepatic abnormality
        ii. Score 1: simple structural abnormality
        iii. Score 2: progressive liver disease
    h. Lung
        i. Score 0: functional pulmonary disease
        ii. Score 1: abnormal lobation; pulmonary hypoplasia
        iii. Score 2: pulmonary cysts; other major malformations
    i. Bowel
        i. Score 0: functional GI disease
        ii. Score 1: pyloric stenosis
        iii. Hirschsprung disease
    j. Genitalia
        i. Score 1: simple hypospadias
        ii. Score 2: ambiguous or female genitalia in a 46, XY; frank genital malformation in a 46, XX

Diagnostic Investigations

1. Diagnostic biochemical hallmarks of the syndrome
    a. Low serum cholesterol levels (10% of patients with DHCR7 deficiency have normal levels of cholesterol)
    b. Markedly elevated serum levels of 7-dehydrocholesterol (cholesta-5,7-dien-3beta-ol; 7DHC), precursor of cholesterol
2. DHCR7 enzyme assay
3. Analysis of sterol biosynthesis in cultured cells

4. *DHCR7* mutation testing
   a. Sequence analysis
   b. Targeted mutation analysis
   c. Seven most frequent mutations described to date, representing two-thirds of the mutation in analyzed alleles (Jira et al. 2003)
      i. IVS8-1 G > C (31.5%)
      ii. T93M (11.2%)
      iii. R404C (10.7%)
      iv. W151X (6.4%)
      v. V326L (6.3%)
      vi. R352W (3.2%)
      vii. E448K (3.2%)

Genetic Counseling

1. Recurrence risk: Carrier frequency (2%, a reasonable estimate for risk assessment) is relatively high (Porter 2008).
   a. Patient's sibs: 25%
   b. Patient's offspring: not increased
2. Prenatal diagnosis.
   a. Prenatal screening as part of routine triple marker screen for Down syndrome and neural tube defects: abnormally low maternal serum level of unconjugated estriol observed in pregnancies affected with Smith-Lemli-Opitz syndrome (Schoen et al. 2003).
   b. Second trimester ultrasonography. (Goldenberg et al. 2004)
      i. Nuchal edema
      ii. Renal malformation
      iii. Polydactyly
      iv. Ambiguous genitalia
      v. Cerebral malformation
      vi. Cardiac malformation
      vii. Intrauterine growth retardation
   c. Prenatal diagnosis (Jezela-Stanek et al. 2006) can be established by:
      i. Detection of elevated 7-dehydrocholesterol concentrations or SLOS-causing mutations in the DHCR7 gene by analysis in chorionic villus samples or amniocytes
      ii. Amniotic fluid sterol analysis
      iii. Serial measurements of estriol, pregnanetriol, 7-dehydropregnanetriol, and 8-dehydroestriol concentrations in maternal urine samples obtained between 9 and 20 weeks of gestation
   d. Preimplantation genetic diagnosis has been made for SLOS with successful blastomere diagnosis with mutations in the *DHCR7* gene, allowing transfer of mutation-free embryos and successful pregnancies (Liss et al 2008).
3. Management (Porter 2000; Jira et al. 2003).
   a. Therapeutic trials using dietary supplementation of cholesterol
      i. Used to treat complications related to the biochemical disturbance. Clinical benefits of this therapy are limited by presence of developmental problems.
      ii. Currently, most patients being treated with pharmaceutical-grade cholesterol suspended in either soybean oil or Ora-Plus syrup or alternatively with egg yolks.
      iii. Multiple benefits of dietary cholesterol supplementation.
         a) Improved nutrition and growth
         b) Decreased irritability
         c) Increased alertness
         d) Increased sociability
         e) Decreased self-abusive and aggressive behavior
         f) Decreased tactile defensiveness
         g) Decreased photosensitivity
         h) Decreased infections
         i) Improved hearing
         j) Improved muscle tone and strength
      iv. Use of bile acids shown no clear benefit
   b. An alternative therapeutic strategy of treating with simvastatin (an oral HMG-CoA reductase inhibitor) for a median period of 2 years with impressive overall biochemical effect
      i. A decrease of 7DHC and 8DHC
      ii. An increase of cholesterol
      iii. Promising clinical improvement
   c. Fresh frozen plasma, which contains cholesterol-rich lipoproteins, used to provide cholesterol supplementation in very sick patients and the fetuses (Porter 2000)

Fig. 2 (**a**–**f**) A boy with Smith-Lemli-Opitz syndrome showing characteristic facial features (epicanthal folds, ptosis of the eyelids, broad nose with upturned nares, and thick alveolar ridges), ambiguous genitalia (hypospadias), umbilical hernia, transverse palmar crease, and talipes equinovarus

Smith-Magenis Syndrome

Smith-Magenis syndrome (SMS) is a complex multiple congenital anomaly and mental retardation syndrome caused by an interstitial deletion of chromosome 17p11.2.

Synonyms and Related Disorders

Chromosome 17p11.2 deletion syndrome

Genetics/Basic Defects

1. Inheritance.
   a. Autosomal dominant inheritance in virtually all cases of SMS occurring de novo
   b. Rare familial chromosome complex rearrangements leading to deletion(17)(p11.2) and SMS
2. Caused by an interstitial deletion of 17p11.2 in the majority of cases (Potocki et al. 2003).
   a. A common deletion size observed in the majority of patients, derived from nonallelic homologous recombination between low-copy repeat gene clusters during either maternal or paternal gametogenesis
   b. Either smaller or larger sized deletions in about 20–25% of patients
3. Considered a contiguous gene syndrome.
   a. Haploinsufficiency of multiple functionally unrelated genes located in close proximity is responsible for the phenotype.
   b. Deletion of a common interval spanning an estimated 4–5 Mb in majority of patients.
4. Sterol regulatory element-binding protein 1 (SREBF1) has been mapped to 17p11.2 within the SMS critical region. Therefore, the patients are hemizygous for the gene encoding SREBP1 leading to hypercholesterolemia.
5. Rare nondeletion cases (Potocki et al. 2003; Truong et al. 2010).
   a. Report of additional patients without a microdeletion, each harbors a mutation in *retinoic acid induced 1* gene (*RAI1*), which maps within the SMS critical region (Slager et al. 2003).
   b. Haploinsufficiency of *RAI1* results in developmental delay, mental retardation, sleep disturbance, self-abusive behaviors, and most features commonly seen in SMS.
   c. Although *RAI1* is the primary gene responsible for most features of SMS, other genes within 17p11.2 contribute to the variable features and overall severity of the syndrome (Girirajan et al. 2006).
   d. *MYO15* clearly associated with a specific phenotypic feature (sensorineural hearing impairment) in a patient with SMS who harbored a recessive mutation on the nondeleted allele.

Clinical Features

1. Infantile hypotonia (Smith et al. 2010)
2. Feeding difficulties
3. Failure to thrive
4. Developmental delay
5. Distinctive craniofacial features
   a. Brachycephaly
   b. Broad square-shaped face
   c. Prominent forehead
   d. Synophrys

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_219,
© Springer Science+Business Media, LLC 2012

e. Epicanthal folds
f. Upslanted palpebral fissures
g. Deep-set eyes
h. Broad nasal bridge
i. Marked midfacial hypoplasia
j. Short full-tipped nose with reduced nasal height
k. Micrognathia in infancy changing to relative prognathia with age
l. Distinctive appearance of the mouth, with fleshy everted upper lip with a "tented" appearance

6. Otolaryngologic anomalies
   a. Speech delay
   b. Hoarse voice
   c. Velophalangeal insufficiency
   d. Tracheobronchial problems
7. Ocular anomalies
   a. Iris anomalies
   b. Microcornea
   c. Retinal detachment
8. Skeletal abnormalities
   a. Short stature
   b. Scoliosis
   c. Brachydactyly
   d. Flat feet
9. Characteristic neurobehavioral phenotype (Boddaert et al. 2004)
   a. Mental retardation (most patients in moderate range)
   b. Speech delay
   c. Signs of peripheral neuropathy
   d. Inattention
   e. Hyperactivity
   f. Maladaptive behaviors including frequent outbursts and temper tantrums
   g. Attention seeking
   h. Attention deficit
   i. Impulsivity
   j. Distractibility
   k. Disobedience
   l. Aggression
   m. Toileting difficulties
   n. Decreased sensitivity to pain
   o. Self-injurious behaviors
      i. Self-hitting
      ii. Self-biting
      iii. Skin picking
      iv. Inserting foreign objects into body orifices
      v. Yanking fingernails and/or toenails (onychotillomania)
   p. Stereotypic behaviors
      i. Specific to SMS
         a) Spasmodic upper-body squeeze or "self-hug"
         b) Hand licking and page flipping ("lick and flip")
      ii. Additional stereotypes
         a) Mouthing objects or insertion of hand in mouth
         b) Teeth grinding
         c) Body rocking
         d) Spinning or twirling objects
   q. Significant sleep disturbance potentially due to circadian rhythm abnormalities of melatonin (Potocki et al. 2003)
10. Other features
    a. Cardiac defects
    b. Renal and urinary tract abnormalities
    c. Thyroid function abnormalities
    d. Cleft lip/palate
    e. Hearing loss
    f. Seizures
    g. Immune function abnormalities, especially low IgA

Diagnostic Investigations

1. Cytogenetic studies for detection of an interstitial deletion of 17p11.2
   a. G-banded karyotype: may not detect small deletion especially when the indication of cytogenetic study is other than SMS
   b. Molecular cytogenetic analysis by FISH using a DNA probe specific for the SMS critical region
2. Molecular genetic testing of RAI1, the only gene known to account for the majority of features in SMS: available only on a clinical basis
3. Blood chemistry
   a. Hypercholesterolemia
   b. Hypertriglyceridemia
   c. Qualitative immunoglobulins
   d. Thyroid function tests
4. Renal ultrasound for possible renal and urologic anomalies
5. Echocardiogram for possible cardiac defects
6. Radiography of the spine for scoliosis and other vertebral anomalies
7. EEG for clinical seizures

8. MRI and PET imaging (Boddaert et al. 2004)
   a. A significant decrease of grey matter concentration in the insula and lenticular nuclei
   b. A significant hypoperfusion in the same regions
9. Diagnostic strategies (Elsea and Girirajan 2008)
   a. Fluorescent in situ hybridization (FISH): classical methods used to detect the SMS 17p11.2 microdeletion (90% of cases).
   b. Molecular identification (sequence analysis) of a mutation in *RAI1* (remaining 10% of cases).
   c. Whole genome chromosome microarray studies (CGH) will also identify 17p11.2 deletion involving *RAI1*.
   d. Multiplex ligation-dependent probe amplification (MLPA) and real-time quantitative PCR are the newer cost-effective and high-throughput technologies.

Genetic Counseling

1. Recurrence risk (Smith et al. 2010; Smith et al. 2002).
   a. Patient's sib (Elsea and Girirajan 2008)
      i. Less than one percentage if parental chromosome analysis is normal, taking account of possible presence of parental germ line mosaicism
      ii. An increased risk, provided a parent carries a chromosome rearrangement and dependent upon the specific chromosome rearrangement or if mosaicism for either a deletion or *RAI1* mutation is present in either parent (Mosaicism in a parent of an affected child is estimated at 3–5%)
   b. Patient's offspring
      i. Unlikely to have offspring due to severe phenotype
      ii. Theoretically, a 50% risk of having offspring with SMS
2. Prenatal diagnosis: available for pregnancies at risk using a combination of routine cytogenetic studies and FISH.
   a. Amniocentesis
   b. CVS
3. Preimplantation genetic diagnosis may be available for families in which the disease-causing deletion or mutation has been identified.
4. Management.
   a. Early childhood intervention programs.
   b. Special education.
      i. Speech and language
      ii. Physical and occupational
      iii. Sensory integration
   c. Vocational training in later years.
   d. Psychotropic medications to increase attention and decrease hyperactivity.
   e. Behavioral modification.
   f. Administration of β_1-adrenergic antagonist and melatonin helps to manage hyperactivity, enhances cognitive performance, and reduces sleep disorders (de Leersnyder, 2003).
   g. Psychosocial support for the family.

Sotos Syndrome

Sotos syndrome was described by Sotos in 1964 and is relatively common among overgrowth syndromes. It is also known as cerebral gigantism.

Synonyms and Related Disorders

Cerebral gigantism

Genetics/Basic Defects

1. Inheritance: genetically heterogeneous (Visser and Matsumoto 2003)
   a. Sporadic in majority of cases (>98%)
   b. Autosomal dominant inheritance reported in a few families
   c. Autosomal recessive inheritances postulated in some families
2. Discovery of human *n*uclear receptor *S*ET *d*omain-containing protein 1 (*NSD1*) gene (Hőglund et al. 2003)
   a. Report of a patient with Sotos syndrome who had t(5;8)(q35;q24.1).
   b. Discovery of a partial genomic sequence homologous to mouse *NSD1* near the breakpoint by constructing a BAC/PAC/cosmid contig covering the breakpoint.
   c. Human *NSD1* gene was subsequently isolated and characterized.
3. Molecular defect
   a. The major cause of Sotos syndrome: haploinsufficiency of the *NSD1* gene at 5q35, because the majority of patients had either a common microdeletion including *NSD1* or a truncated type of point mutation in *NSD1*
   b. *NSD1* gene mutations and deletions (Rio et al. 2003)
      i. Japanese patients (66%)
         a) Point mutations (48.5%)
         b) Deletions (18.2%)
      ii. British patients (78%)
         a) Point mutations (70%)
         b) Large deletions (8%)
   c. Size of the deletion correlates with severity of the phenotype.
4. No satisfactory explanation for the overgrowth

Clinical Features

1. Prenatal and postnatal overgrowth (major clinical features)
   a. Large for gestational age at birth
   b. Excessive growth velocity, particularly in the first 3–4 years
   c. Advanced bone age by 2–4 years over chronological age during childhood
   d. Large hands and feet
   e. Excessive heights in some adult patients
2. Performance
   a. Developmental retardation
   b. Mental deficiency of varying degree
   c. Lack of fine motor control
   d. Difficulties in neonatal adaptation and/or feeding
3. Characteristic craniofacial appearance
   a. Dolichocephalic large head
   b. Prominent forehead

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_220,
© Springer Science+Business Media, LLC 2012

   c. Ocular hypertelorism
   d. Downslanting of the palpebral fissures
   e. High-arched palate
   f. Premature teeth eruptions
   g. Pointed chin (prominent mandible)
4. CNS manifestations
   a. Hypotonia
   b. Seizures
   c. Clumsy gait
   d. Mildly enlarged ventricles
   e. Increased subarachnoid spaces
   f. Agenesis/hypoplasia of the corpus callosum
   g. Agenesis of the septal pellucidum
   h. Hypoplasia/atrophy of the cerebellar vermis
   i. Large cisternal magna
   j. Abnormal Sylvian fissure
5. Neoplasms (3.9%)
   a. Benign tumors
      i. Multiple hemangiomas
      ii. Osteochondroma
      iii. Large hairy nevus
      iv. Giant-cell granulomas of the mandible
   b. Malignant tumors
      i. Wilms tumor
      ii. Neuroblastoma
      iii. Hepatocellular carcinoma
      iv. Epidermoid carcinoma of the vagina
      v. Small-cell carcinoma of the lung
6. Other features
   a. Strabismus
   b. Lax joints
   c. Pes planus
   d. Kyphoscoliosis
   e. Asymmetric leg length
   f. Syndactyly
   g. Congenital heart defects
      i. Septal defects
      ii. Persistent ductus arteriosus
      iii. Ebstein malformation
   h. Functional megacolon
   i. Urinary anomalies
      i. Hypoplastic kidney
      ii. Hydronephrosis
      iii. Vesicoureteric reflux
   j. Recurrent hernias
   k. Abnormal dermatoglyphics
7. Social and behavioral difficulties
   a. Emotional immaturity
   b. Poor motor control
   c. Temper tantrums
   d. Good social skills in some patients
8. Weaver syndrome: the major differential diagnosis (Douglas et al. 2003)
   a. Seen less commonly than Sotos syndrome
   b. Caused by *NSD1* mutations in a significant number of patients
   c. Cardinal features
      i. Accelerated growth
      ii. Distinctive facies with micrognathia and a deep horizontal chin crease
      iii. Advanced bone age
      iv. Developmental delay
   d. Additional features
      i. A hoarse low-pitched cry
      ii. Metaphyseal flaring of the femurs
      iii. Deep-set nails
      iv. Prominent finger pads
      v. Camptodactyly

Diagnostic Investigations

1. Glucose intolerance (14%)
2. Radiography: advanced bone age
3. CNS lesions by CAT scan and/or MRI of the brain
   a. Ventricles
      i. Ventriculomegaly
      ii. Prominent trigone of the lateral ventricles
      iii. Prominent occipital horn
   b. Extracerebral fluid
      i. Increased supratentorial space
      ii. Increased posterior fossa space
   c. Midline anomalies
      i. Persistent cavum septum pellucidum
      ii. Persistent cavum vergae
      iii. Cavum velum interpositum
      iv. Macrocisterna magna
      v. Agenesis of corpus callosum
      vi. Hypoplasia (thinning) of corpus callosum
   d. Periventricular leukomalacia
   e. Macrocerebellum
   f. Open operculum
4. Cytogenetic testing
   a. Most affected individuals do not have a cytogenetic abnormality.
   b. Rare cytogenetic abnormality such as a translocation involving 5q35 results in Sotos syndrome (Kurotaki et al. 2003).

5. DNA analysis: NSD1 abnormalities, such as truncating mutations, missense mutations in functional domains, partial gene deletions, and 5q35 microdeletions encompassing NSD1, are identifiable in the majority (49%) of Sotos syndrome cases (Tatton-Brown and Rahman 2007; Cole et al. 2009).
   a. Intragenic sequence analysis/mutation scanning
   b. Deletion/duplication analysis
      i. 5q35 microdeletion analysis/*NSD1* whole gene deletion analysis
      ii. *NSD1* exonic/multiexonic gene deletions

Genetic Counseling

1. Recurrence risk (Tatton-Brown and Rahman 2007)
   a. Patient's sib
      i. Most individuals with Sotos syndrome are the result of de novo mutations.
      ii. No affected siblings of unaffected parents have been reported, indicating that the incidence of germ line mosaicism must be low.
      iii. Therefore, the recurrence risk of unaffected parents approximates to the population risk, which is estimated to be ~1:15,000.
   b. Patient's offspring: a 50% risk as for other autosomal dominant conditions
2. Prenatal diagnosis of fetuses at risk for Sotos syndrome
   a. Ultrasonography in the third trimester
      i. Macrocephaly
      ii. Ventriculomegaly
      iii. Hypoplasia of the corpus callosum
      iv. An enlarged cisterna magna
      v. Overgrowth
      vi. Unilateral hydronephrosis
      vii. Polyhydramnios
   b. Prenatal diagnosis possible by molecular mutation analysis of fetal DNA obtained from amniocytes or CVS of previously identified disease-causing *NSD1* gene: available on a clinical basis
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified.
3. Management:
   a. No specific therapy exists.
   b. Supportive management for cardiac abnormalities, seizures, renal problems, and scoliosis
   c. Referral to appropriate specialist for learning/behavior/speech difficulties

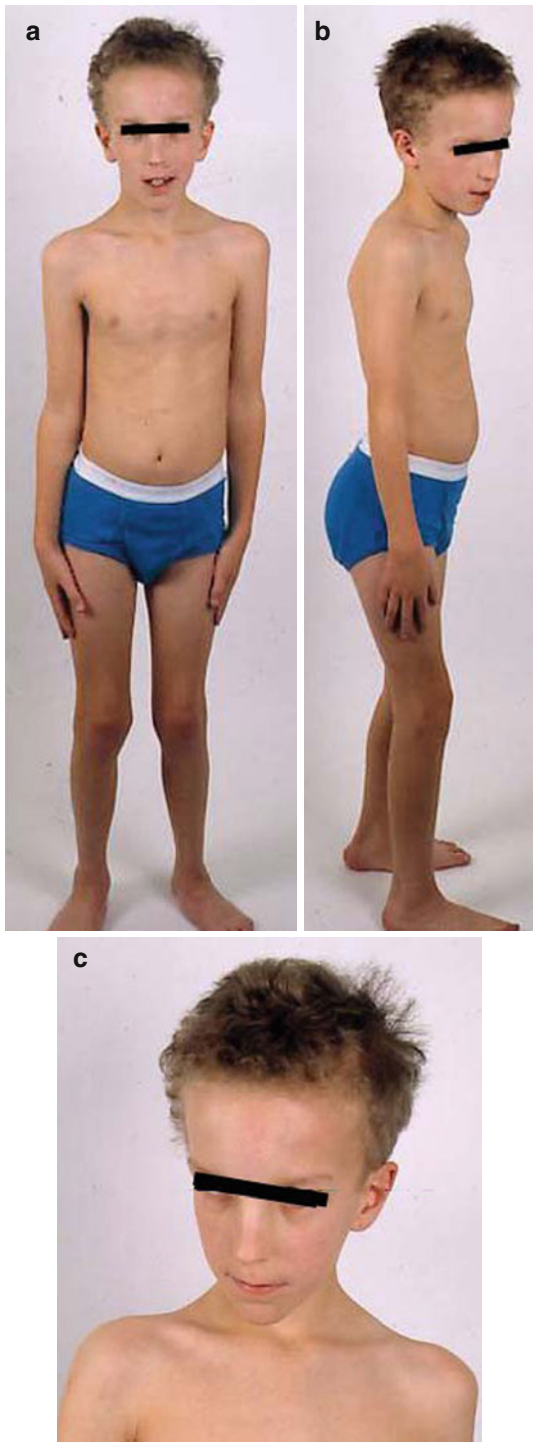

Fig. 1 (**a**–**c**) A child with Sotos syndrome showing excessive growth, a large dolichocephalic head, prominent forehead, downslanting palpebral fissures, and a pointed chin

Fig. 2 The radiograph of the hand from a 20-month-old, showing advanced bone age (3 years)

Fig. 3 (**a**–**c**) A 5-year-old girl with Sotos syndrome showing gigantism, large head, prominent forehead, large hands and feet, and MRI findings of enlarged subarachnoid spaces, mild ventriculomegaly, thinning of the corpus callosum, and mild polymicrogyria

Fig. 4 (**a**–**c**) An adult with Sotos syndrome showing excessive height (compared with other family members), prominent forehead, hypertelorism, a pointed chin, and large hands and feet (compared to normal adult). Chromosome analysis by FISH showed duplicated 4p15.2 and deleted 4q32. Both parents have normal chromosomes

Fig. 5 (**a**–**c**) A 2-year-old girl with Sotos syndrome has excessive height, weight, and head circumference; advanced bone age; and delayed development. The skull is characterized by dolichocephaly, frontal bossing, and deep-set eyes. Molecular study showed two variants of unknown significance: c.1515 T > C(p.N505N) and c.1515 T > C) (p.L1956P). There were no apparent deletions or duplications within the coding region of NSD1

Spinal Muscular Atrophy

Spinal muscular atrophy (SMA) is a disorder characterized by degeneration of lower motor neurons and occasionally bulbar motor neurons leading to progressive limb and trunk paralysis as well as muscular atrophy. It is a clinically and genetically heterogeneous group of neuromuscular diseases. It is the second most common lethal autosomal recessive disorder after cystic fibrosis in Caucasian populations with an overall incidence of 1 in 10,000 live births and a carrier frequency of approximately 1 in 50 (Biros and Forrest 1999).

Synonyms and Related Disorders

Adult SMA; Arthrogryposis multiplex congenita-SMA; Congenital axonal neuropathy; Dubowitz disease; Kugelberg-Welander disease; Werdnig-Hoffman disease

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive in most cases (SMA1, SMA2, SMA3)
   b. Autosomal dominant in both juvenile and adult form, representing 2% of infantile and about 30% of adult SMA
2. Caused by mutation or deletion of *Survival Motor Neuron-1* (*SMN1*)
3. Mutation in all three forms (SMA1, SMA2, and SMA3) mapped to chromosome 5q13 (SMA critical region)
4. SMN deletions
   a. High frequency of *SMN* deletions in SMA patients (92.8%) provides a direct and accurate genetic test for:
      i. Diagnostic confirmation of SMA
      ii. Prenatal prediction of SMA
   b. Homozygous deletion of *SMN* observed in:
      i. Atypical forms of SMA associated with congenital heart defects
      ii. Arthrogryposis
      iii. Some cases of congenital axonal neuropathy
      iv. Some patients affected with adult form of SMA
   c. Rare cases of homozygous *SMN* exon 7 deletion or conversion reported in asymptomatic relatives of haploidentical type II or III SMA patients
   d. Absence of deletion of the *SMN* gene or linkage to chromosome 5q in:
      i. SMA associated with diaphragmatic involvement
      ii. SMA with olivopontocerebellar atrophy
      iii. Autosomal dominant form of SMA
      iv. Amyotrophic lateral sclerosis
      v. Post-polio syndrome
5. Molecular-phenotype correlation (Lorson et al. 2010; MacKenzie 2010)
   a. Phenotype of SMA associated with disease-causing mutations of the *SMN* gene spans a continuum without a clear delineation of subtypes.
   b. The severity of the SMA phenotype inversely correlated with:
      i. *SMN2* copy number: The greater the *SMN2* copy number (both in infants and children

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_221,
© Springer Science+Business Media, LLC 2012

with spinal muscular atrophy and in mouse models), the milder the disease.
ii. The level of full-length SMN protein produced by *SMN2* (~10–15% compared with *SMN1*)

Clinical Features

1. Existing classification system based on age of onset of symptoms: useful for prognosis and management
   a. Congenital axonal neuropathy
      i. Prenatal onset of SMA
      ii. Decreased fetal movement
      iii. Maternal polyhydramnios
      iv. Severe muscle weakness (hypotonia)
      v. Absence of movement
      vi. Joint contractures
      vii. Facial diplegia
      viii. Ophthalmoplegia
      ix. Respiratory failure requiring immediate endotracheal intubation and ventilation
      x. Death from respiratory failure within days
   b. Arthrogryposis multiplex congenita-SMA
      i. Prenatal onset of SMA
      ii. Decreased fetal movement
      iii. Maternal polyhydramnios
      iv. Breech presentation
      v. Severe muscular weakness (hypotonia)
      vi. Arthrogryposis multiplex congenita
      vii. Absence of movement except for extraocular and facial movement
      viii. Death from respiratory failure before 1 month of age
   c. SMA1 (acute spinal muscular atrophy, Werdnig-Hoffman disease)
      i. Represents about 30% of all SMA cases
      ii. Onset before 6 months of age
      iii. The most severe form with fatal outcome
      iv. Severe generalized muscular weakness (hypotonia)
      v. Lack of motor development
      vi. Mild joint contractures at the knees and rarely at the elbows
      vii. Most severely affected neonates
         a) Difficulty in sucking and swallowing
         b) Abdominal breathing
      viii. Facial muscles spared completely with a bright, normal expression
      ix. Ocular muscles and the diaphragm not involved until late in the course of the disease
      x. Fasciculation of the tongue seen in most but not all cases
      xi. Intercostal paralysis with severe collapse of the chest: the rule
      xii. Affected children unable to sit without support
      xiii. Absence of tendon reflexes (areflexia)
      xiv. Normal intelligence
      xv. Usually die within 2 years due to the following:
         a) Feeding difficulty
         b) Breathing difficulty
   d. SMA2 (chronic infantile spinal muscular atrophy, Dubowitz disease)
      i. Represent about 45% of SMA cases
      ii. Onset between 6 and 12 months
      iii. The intermediate form (a more slowly progressive generalized disease with a variable prognosis)
      iv. Poor muscle tone at birth or within first 2 months of life
      v. Slow attainment of motor milestones
         a) Not sitting independently by age 9–12 months
         b) Not standing by 1 year of age
      vi. Frequent tongue fasciculations and atrophy
      vii. Common finger trembling and general flaccidity
      viii. Diminished or absent deep tendon reflexes
      ix. Intact sensation
      x. Loss of the ability to sit independently by the mid-teens
      xi. Slow or arrest of clinical progression
      xii. Severe scoliosis if untreated
      xiii. Defect in respiratory ventilation
      xiv. Highly variable life expectancy, ranging up to adult life in some cases
   e. SMA3 (juvenile spinal muscular atrophy, Kugelberg-Welander disease)
      i. Represents abut 8% of all SMA cases
      ii. Childhood onset after 12 months (usually after 18 months to 30 years of life)
      iii. The mild chronic form

iv. Motor milestones
  a) Ability to walk but frequent fall on walking
  b) Trouble walking upstairs and downstairs at age 2–3 years
v. Muscle weakness
  a) Proximal muscle weakness associated with muscle atrophy
  b) Legs more severely affected than the arms
vi. Normal sensation
vii. No evidence of upper motor neuron involvement
viii. Hypertrophy of the calves in about 25% of cases
ix. Prognosis generally correlates with the maximum motor function attained.

f. SMA4 (adult SMA)
  i. Adult onset (after 20 or 30 years of age)
  ii. Muscle weakness (after 30 years of age)
  iii. Clinical features similar to those described for SMA3 with evidence of lower motor neuron involvement
    a) Tongue fasciculations
    b) Muscle atrophy
    c) Depressed deep tendon reflexes
    d) Normal sensation

2. Consider diagnosis of SMA in infants presenting with the following clinical features:
  a. During neonatal period
    i. Severe hypotonia
    ii. Absent movement
    iii. Contractures, usually of a mild degree
    iv. Evidence of anterior horn cell (i.e., lower motor neuron) involvement
      a) Tongue fasciculations
      b) Absence of deep tendon reflexes
    v. Respiratory failure
    vi. Variable cranial nerve involvement usually apparent late in the course
      a) Ophthalmoplegia
      b) Facial diplegia
  b. After neonatal period
    i. Poor muscle tone
    ii. Symmetric muscle weakness
      a) Sparing the ocular muscles
      b) Involving the facial muscles and diaphragm late in the course of the disease
    iii. Delayed acquisition of motor skills
    iv. Evidence of anterior horn (i.e., lower motor neuron) involvement
      a) Tongue fasciculations (seen in only 65% of patients)
      b) Absence of deep tendon reflexes
    v. Normal reaction to sensory stimuli
    vi. Normal intelligence

3. Natural history (Lorson et al. 2010; MacKenzie 2010)
  a. Clinical features of the disease are caused by specific degeneration of α-motor neurons in the spinal cord, leading to muscle weakness, atrophy, and, in the majority of cases, premature death.
  b. Most afflicted infants and children, while largely neurologically and completely cognitively intact, grow progressively weaker over time, with many ultimately succumbing to respiratory failure at a young age.
  c. The natural history of SMA has been altered over the past several decades, primarily through supportive care measures, but an effective treatment does not presently exist.

4. Other forms of severe spinal muscular atrophy not linked to *SMN* gene (Wang et al. 2007)
  a. Scapuloperoneal spinal muscular atrophy
    i. Autosomal dominant (gene mapped on 12q24.1-q24.31)
    ii. Clinical presentations
      a) Congenital absence of muscles
      b) Progressive weakness of scapuloperoneal and laryngeal muscles
  b. Pontocerebellar hypoplasia with spinal muscular atrophy
    i. Autosomal recessive
    ii. Clinical presentations
      a) Onset at 0–6 months
      b) Cerebellar and brainstem hypoplasia
      c) Absent dentate nucleus
      d) Neuronal loss in basal ganglia
      e) Cortical atrophy
  c. X-linked infantile spinal muscular atrophy with arthrogryposis
    i. X-linked (gene mapped on Xp11.3-q11.2)
    ii. Clinical presentations
      a) Onset at birth or infancy
      b) Contractures
      c) Death before 2 years of age

d. Spinal muscular atrophy with respiratory distress type 1
   i. Autosomal recessive (gene mapped on 11q13.2-q13.4)
   ii. Clinical presentations
      a) Onset within the first 3 months of age
      b) Eventuation of the right or both hemidiaphragms
      c) Finger contractures
      d) Pes equines foot deformities

Diagnostic Investigations

1. Increased serum creatine phosphokinase (CK) activity in about half of the patients with type III SMA
2. Electromyography (EMG)
   a. During voluntary effort
      i. Spontaneous discharge activity in resting muscle
      ii. Increased amplitude
      iii. Prolonged duration of motor unit potentials
   b. Severe denervation commonly found in older patients
   c. Nerve conduction velocity
      i. Generally considered normal
      ii. Some decrease in velocity in severe case
3. Muscle histology
   a. Denervation changes with small groups of atrophic muscle fibers associated with markedly hypertrophied fibers.
   b. Small angular fibers randomly intermixed with normal-sized fibers
   c. Atrophic fibers arranged in groups
      i. Usually of uniform fiber type based on the myosin ATPase reaction
      ii. Considered as an extensive collateral reinnervation of previously denervated muscle fibers by sprouts from surviving motor neurons
   d. In SMA type III, but not in infantile SMA (type I or II)
      i. Markedly hypertrophic fibers
      ii. Excessive variation in fiber size
      iii. Internal nuclei
      iv. Observation of degenerative changes with necrosis and regenerative fibers associated with proliferative interstitial connective tissue
         a) Interpreted as "pseudomyopathic" changes
         b) Usually found in patients with high serum levels of CK activity suggesting the presence of a myopathic process secondary to neurogenic process
         c) These pseudomyopathic changes not observed in other human neurogenic diseases, suggesting that they can be specific to the molecular mechanism resulting in or associated with juvenile SMA
4. Neuropathologic features found at autopsy of SMA patients
   a. Loss of the large anterior horn cells of the spinal cord (most striking feature)
   b. Severe degree of central chromatolysis in the remaining surviving motor neurons, appearing as large ballooned cells without stored substances
   c. Other anterior horn cells
      i. Pyknotic
      ii. Presence of occasional figures of neuronophagia associated with astrogliosis
      iii. Small anterior roots
5. Molecular diagnosis of SMA (Prior and Russman 2011)
   a. The following relatively simple DNA tests enable confirmation of a suspected clinical diagnosis of SMA or prediction of the outcome of a pregnancy in families with a history of SMA (Biros and Forrest 1999).
      i. SSCP analysis
      ii. PCR followed by restriction enzyme digestion
   b. Mutation analysis of *SMN1* available on clinical basis
      i. Used to detect deletion of exons 7 and 8 of *SMN1*
      ii. Homologous deletions of exon 7 of *SMN1* in 95% of cases with clinical diagnosis of SMA
      iii. Compound heterozygotes for deletion of *SMN1* exon 7 and an intragenic mutation of *SMN1* in 2–5% of patients with a clinical diagnosis of SMA
   c. Sequence analysis of all *SMN1* exons and intron/exon borders available on clinical basis
      i. Used to identify the intragenic *SMN1* mutations present in the 2–5% of patients who are compound heterozygotes
      ii. Limitations
         a) Cannot determine whether the point mutation is in the SMN1 gene or the SMN2 gene, unless one of these genes is absent

b) Does not detect exonic duplications
c) Cannot detect deletions of whole exons if more than one SMN gene copy is present

d. Duplication analysis to determine *SMN2* copy number
i. *SMN2* copy number ranges from 0 to 5
ii. Quantitative PCR: currently used for accurate determination of *SMN2* copy number

e. SMA carrier testing (gene dosage analysis) available clinically
i. Mutation analysis not reliable for carrier detection since it does not quantitate the number of *SMN1* gene copies
ii. A PCR-based dosage assay (called SMA carrier testing or *SMN* gene dosage analysis) allows for the determination of the number of *SMN1* gene copies, thus permitting highly accurate carrier detection.
iii. Dosage analysis to differentiate carriers from non-carriers

f. Linkage analysis available on clinical basis
i. Available to families in which direct DNA testing is not informative
ii. May be used for confirmation of carrier testing results and prenatal testing results

6. Newborn screening: An effective technology exists for newborn screening of SMA (Prior et al. 2010).

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Autosomal recessive inheritance: 25%
ii. Autosomal dominant inheritance: not increased unless a parent is affected

b. Patient's offspring: only milder forms of SMA likely to reproduce
i. Autosomal recessive inheritance
a) All offspring: carriers
b) Recurrence risk not increased unless the spouse is affected or a carrier
ii. Autosomal dominant inheritance: 50%

2. Prenatal diagnosis
a. Possible to detect fetuses at 25% risk when the disease-causing *SMN* mutations in both parents are known
b. Mutation analysis on fetal DNA obtained from CVS or amniocentesis
c. Linkage analysis
i. Many diagnostic laboratories still perform linkage analysis in addition to direct SMN^T mutation analysis in families where the previously affected child lacks both copies of SMN^T, since there are people in the normal population who lack both copies of SMN^T but not clinically affected.
ii. The only option available to the families where no deletion has been observed but the clinical findings are consistent with 5q SMA

d. Preimplantation genetic diagnosis: available clinically for families in which the disease-causing mutations have been identified in an affected family member

3. Management (Iannaccone 2007; Sendtner 2010)
a. Treat and prevent complications of weakness and maintain quality of life.
b. Several organ systems affected by weakness
i. Respiratory (restrictive lung disease)
a) Noninvasive ventilation support using new technology for patients with sufficient orofacial muscle strength. Long-term ventilatory support is not usually considered.
b) A new awareness of the importance of identifying sleep-disordered breathing
c) A new multidisciplinary approach to standard of care
ii. Gastrointestinal (dysphagia): feeding gastrostomy for children with difficult in sucking and swallowing
iii. Orthopedic (progressive deformities)
a) Orthosis to allow to sit upright rather than bedridden
b) Option of surgical repair for the severe scoliosis

c. Therapy development
i. Previous therapy approaches have focused on upregulation of SMN expression from a second SMN (*SMN2*) gene that gives rise to low amounts of functional SMN protein.
ii. Drug development to target disease-specific mechanisms at cellular and physiological levels is in its early stages, as the pathophysiological processes that underlie the main disease symptoms are still not fully understood.
iii. Human induced pluripotent stem cell technology for generation of large numbers of

human motor neurons could help to fill this gap and advance the power of drug screening.

iv. In parallel, advances in oligonucleotide technologies for engineering *SMN2* pre-mRNA splicing are approaching their first clinical trials, whose success depends on improved technologies for drug delivery to motor neurons.

v. If this obstacle can be overcome, this could boost therapy development, not only for SMA but also for other neurodegenerative disorders.

Fig. 1 A 2 1/2-week-old white male died of respiratory failure associated with congenital spinal muscular atrophy (Werdnig–Hoffman disease). There was generalized muscle atrophy including respiratory muscle

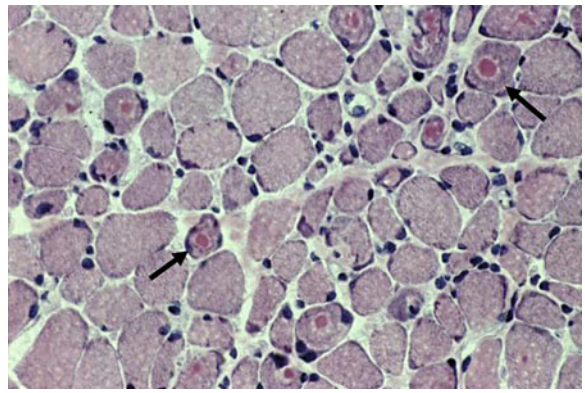

Fig. 3 Residual muscle seen in a 14-year-old female showed chronic denervative change with presence of scattered target fibers (*arrows*) (H & E ×400)

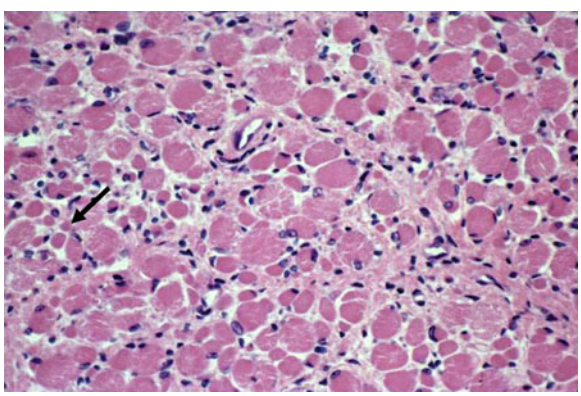

Fig. 2 Quadriceps muscle shows many exceedingly atrophic muscle fibers which tend to be in groups (*arrow*). No degenerative muscle fibers are present (H & E, ×100)

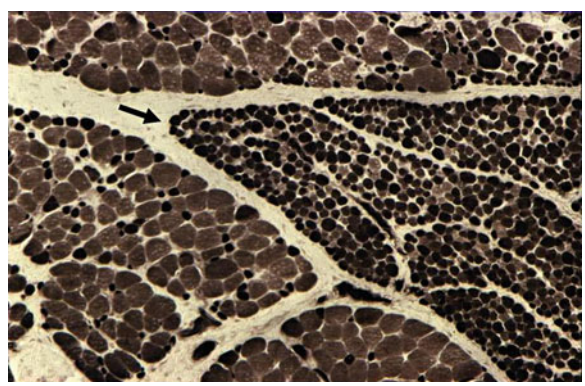

Fig. 4 Biopsy of quadriceps muscle from a 10-month-old girl shows a group atrophy involving several entire fascicles (*arrow*). Both type I (light-stained) and type II (dark-stained) fibers are affected. This is accompanied by an enervative phenomenon (the large muscle fibers all stain pale) (Myosin ATPase, at 9.4, ×50)

Fig. 5 (**a**, **b**) A 3-month-old infant boy with Werdnig-Hoffman disease showing generalized hypotonia. He had a small chest with diaphragmatic breathing, fasciculation of the tongue, and absence of deep tendon reflexes. Molecular genetic analysis revealed homozygous exon 7 deletion and homozygous exon 8 deletion for the survival motor neuron genes (*SMN*)

Fig. 6 A 27-month-old girl with SMA1. She could not stand holding or independently and had foot drops, absence of deep tendon reflexes, and muscle weakness. She was confined to a wheelchair. Molecular genetic analysis revealed homozygous exon 7 deletion and homozygous exon 8 deletion for the *SMN* gene

Fig. 7 A 5-year-old girl with SMA showing tongue fasciculation

Fig. 8 A 30-year-old man with Kugelberg-Welander disease showing muscle weakness and had been confined to a wheelchair for some time. He had trouble standing and began to walk at 6 years of age. Molecular genetic diagnosis revealed homozygous exon 7 deletion and homozygous exon 8 deletion

Spondyloepiphyseal Dysplasia

Spondyloepiphyseal dysplasia (SED) refers to a group of disorders with primary involvement of the vertebrae and epiphyseal centers resulting in a short-trunk disproportionate dwarfism. Two major types (congenita and tarda) will be discussed here.

Synonyms and Related Disorders

SED congenita; SED tarda

Genetics/Basic Defects

1. Genetic basis of SED
   a. SED congenita
      i. Autosomal dominant inheritance
      ii. Spondyloepiphyseal dysplasia congenita gene mapped to chromosome 12q13
      iii. Gonadal mosaicism reported
      iv. Advanced paternal age recognized as a risk factor
   b. SED tarda
      i. X-linked recessive inheritance
         a) Most common
         b) The gene mapped to Xp22.12-p22.31
      ii. Autosomal recessive inheritance
      iii. Autosomal dominant inheritance
2. Molecular basis of SED (Cole et al. 1993)
   a. SED congenita
      i. Caused by mutations in *COL2A1* gene, which encodes the α1(II) chain of type II collagen. The gene was mapped on chromosome 12.
      ii. The mutations result in abnormal type II collagen, which is the major collagen of nucleus pulposus of the spine, hyaline cartilages, fibrocartilages, and vitreous humor of the eyes.
      iii. Other skeletal dysplasias affected by collagen II abnormalities
         a) Autosomal forms of SED tarda
         b) Achondrogenesis type II
         c) Hypochondrogenesis
         d) Kniest dysplasia
         e) Stickler dysplasia
         f) Spondylometaepiphyseal (Strudwick) dysplasia
   b. SED tarda, X-linked form (Christie et al. 2001; Savarirayan et al. 2003)
      i. Caused by mutations in *SEDL* (SED late) gene (designated "sedlin"), mapped on Xp22.12-p22.31
      ii. *SEDL* gene encodes a protein of 140 amino acids with a role in vesicular transport.
      iii. Over 30 novel mutations affecting the *SEDL* gene recognized: the most common type of *SEDL*-gene disruption being deletion, representing 50% of identified mutations

Clinical Features

1. SED congenita
   a. Clinical features present at birth
   b. Short newborn with disproportionately shortened trunk
   c. Delayed motor development
   d. Short neck

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_222,
© Springer Science+Business Media, LLC 2012

e. Cervical myelopathy resulting from atlantoaxial instability, odontoid hypoplasia, and spinal cord compression, often presenting at age 5–10 years
   i. Delayed motor development
   ii. Decreased endurance
   iii. Progressive motor weakness
   iv. Hypotonia
   v. Sleep apnea
   vi. Alterations in respiration
   vii. Pyramidal tract signs (spasticity, hyperreflexia, Babinski sign, and clonus)
f. Respiratory insufficiency may develop secondary to thoracic dysplasia.
g. Barrel-shaped chest with pectus carinatum deformity
h. Protuberant abdomen
i. Spine abnormalities
   i. Lumbar lordosis
   ii. Thoracic kyphoscoliosis evident in adolescence
j. Hip abnormalities
   i. Hip flexion contractures
   ii. Coxa vara
      a) An almost universal finding
      b) Varying severity
      c) Progressive
      d) Associated progressive hip dislocation if ligamentous laxity present
   iii. The delayed ossification of the capital femoral epiphysis predisposing the hip to deformation with flattening, lateral extrusion, hinge abduction, and premature osteoarthritis
k. Knee abnormalities
   i. Valgus alignment of the knees often associated with overgrowth of the medial femoral condyle
   ii. Rare genu varum
l. Other clinical features
   i. Gait problems often attributed to hip and knee deformities
   ii. Clubfeet (talipes equinovarus) present in some patients
   iii. Ocular anomalies
      a) Myopia and retinal detachment (>50%): important clinical findings in many patients
      b) Cataracts
      c) Buphthalmos secondary glaucoma and strabismus
      d) Clear corneas
   iv. Deafness
   v. Cleft palate
   vi. Abdominal or inguinal hernias

2. SED tarda
   a. X-linked recessive form
      i. Normal appearance at birth
      ii. Variable age of onset
         a) Hip and trunk features appearing around 4 years of age
         b) Diagnosis not recognized until the adolescent years in some patients
      iii. Only males are affected.
      iv. Mild disproportionate trunk shortening
      v. Barrel-shaped chest
      vi. Atlantoaxial instability secondary to odontoid hypoplasia
      vii. Progressive joint and back pain with osteoarthritis commonly involving hip, knee, elbows, and shoulder joints
      viii. Hip involvement
         a) Hip pain or stiffness presenting around the first or second decade of life
         b) Changes mimic bilateral Legg-Calve-Perthes disease
         c) Varying degrees of coxa magna, flattening, extrusion, and subluxation
         d) Osteoarthritis of the hip, a common sequelae
      ix. Kyphoscoliosis
      x. Lumbar lordosis
      xi. Epiphyseal involvement
         a) Primarily in the shoulders, hips, and knees
         b) Symmetrical and bilateral
      xii. Rare association with nephrotic syndrome
      xiii. Craniofacial appearance, vision, and hearing not affected in X-linked SED tarda
      xiv. Normal intelligence
      xv. Normal life span
   b. Autosomal recessive form
      i. Onset between the age of 4 and 10 years
      ii. Short stature
      iii. Waddling gait
      iv. Disproportionately short trunk
      v. Accentuated spinal curvatures
      vi. Restricted mobility of the hip joints
      vii. Hip pain becomes worse with increasing age.

c. Autosomal dominant form
   i. Clinical features identical to those in the recessive form of SED tarda
   ii. Hip pain and waddling gait noted after the fourth year of life
   iii. Mild shortness of the trunk
   iv. Progressive hip changes causing considerable discomfort

Diagnostic Investigations

1. Radiography
   a. SED congenita
      i. A generalized delay in the development of ossification centers
         a) Absent epiphyseal centers of the distal femur and proximal tibia, os pubis, calcaneus, and talus, which are usually present at birth
         b) Femoral heads usually not visible on radiographs until patients are aged 5 years
         c) Femoral capital epiphyses: flattened and irregular in shape when they appear on radiographs
      ii. Vertebral abnormalities
         a) Varying degrees of platyspondyly
         b) Oval, trapezoid, or pear-shaped vertebrae resulting from posterior wedging of vertebral bodies
         c) Incompletely fused ossification centers of the vertebral bodies
         d) End plate irregularities and intervertebral disk spaces narrowing become obvious with an increased anteroposterior diameter of the vertebral bodies in adolescents and young adults.
         e) Exaggerated lumbar lordosis
         f) Progressive kyphoscoliosis developing in late childhood
         g) Odontoid hypoplasia or os odontoideum leading to atlantoaxial instability: common
      iii. Pelvic abnormalities
         a) Short and small iliac crests with horizontal acetabular roofs and delayed ossification of the pubis
         b) Small iliac bones with lack of normal flaring of the iliac wings
         c) Deep acetabular fossae appearing empty due to the severely retarded ossification of femoral heads
         d) Varying severity of coxa vara
         e) Delayed ossification of the femoral head predisposing hip to deformation with flattening, lateral extrusion, hinge abduction, and premature osteoarthritis
      iv. Tubular bone abnormalities
         a) Delayed ossification centers of the distal femur and proximal tibia leading to flattening and irregularity
         b) Genu valgum usually present with overgrowth of the medial femoral condyle
         c) Relatively short and broad long tubular bones
         d) Presence of some metaphyseal flaring especially in the region of the distal femur and proximal and distal humerus
         e) Delayed or disorganized ossification of carpal and tarsal centers with occasional extra epiphyses
   b. SED tarda, X-linked recessive form
      i. Radiographic changes usually apparent in children older than 4–6 years (not evident at birth)
      ii. Changes suggestive of atlantoaxial instability, platyspondyly, kyphoscoliosis, and epiphyseal involvement similar to those seen in patients with SED congenita
      iii. Predominantly affecting the spinal vertebral bodies and epiphyses during skeletal growth
      iv. A mound of bone ("donkey hump") typically present in the central and posterior portions of the superior and inferior end plates on lateral radiographs in patients with X-linked recessive type of SED tarda (not features of the autosomal dominant or recessive types of SED tarda). However, absence of ossification at the upper and lower anterior margins of the vertebral bodies is considered to be the distinctive radiographic feature.
      v. Symmetric epiphyseal involvement primarily in the shoulders, hips, and knees
      vi. Delayed ossification predisposing the weight bearing joints of the lower extremities to deformation and premature osteoarthritis

vii. Changes in the hip (dysplastic changes of femoral heads and neck), mimic bilateral Legg-Calve-Perthes disease
viii. Presence of varying degrees of coxa magna, flattening, extrusion, and subluxation
ix. Minor skeletal changes in carrier women with X-linked recessive SED tarda in a 6-generation kindred from Arkansas
a) Subtle abnormal shape of the pelvis and knees
b) Premature occurrence of degenerative changes in the spine leading to frequent complaint of arthralgia in the middle age

c. SED tarda, autosomal recessive form
i. Irregular upper and lower plates of the vertebral bodies
ii. Anteriosuperior ossification defects of some vertebras
iii. Less frequent findings
a) Additional ossification defects of the anterioinferior edges of the vertebral bodies
b) Anterior protrusion f central portions of the vertebral bodies
iv. Femoral heads
a) Well-developed capital femoral epiphyses in the younger child
b) Progressive flattening and destruction of the femoral heads with advancing age
c) Milder abnormalities in the knee joints
d) Small and irregular carpal bones
e) Slightly short and irregular metacarpals and phalanges in some patients

d. SED tarda, autosomal dominant form
i. Accentuated dorsal flattening of the vertebral bodies in the younger patient
ii. Platyspondyly with a rectangular shape of the vertebral bodies in the older patient
iii. Mild and slowly progressive deformities of capital femoral epiphyses and knee epiphyses
iv. Slightly short phalanges and metacarpals with narrowing of the joint spaces

2. MRI
a. To delineate cord compression due to C1–C2 instability
b. To evaluate severe spinal deformities prior to surgical intervention
c. To evaluate the condition of the epiphyseal centers prior to reconstructive procedures

3. CT scan
a. To assess the configuration of bones and joints prior to surgical intervention
b. To reconstruct three-dimensional images for help in surgical planning of severe cases

4. Hip arthrography
a. To document congruity of the femoral head or hinged abduction
b. To evaluate severe varus deformity of the femoral neck

5. Laboratory features of SED congenita
a. Fine metachromatic inclusions in the peripheral lymphocytes
b. Normal urinary excretion of acid mucopolysaccharides including keratosulfate
c. Histopathology
i. Mildly disorganized physis (epiphyseal growth plate)
ii. Chondrocytes containing PAS-positive cytoplasmic inclusions
iii. Ultrastructurally, the inclusions correspond to the accumulations of finely granular material in dilated cisterns of rough endoplasmic reticulum.

6. Molecular genetic analysis
a. Mutations in *COL2A1* gene in SED congenita
b. Mutation in *SEDL* gene in X-linked recessive SED tarda (Tiller and Hannig 2011)
i. Sequence analysis clinically available
ii. Mutation types
a) Deletions
b) Splice mutations
c) Missense mutations
d) Nonsense mutations
iii. Detected in >80% of affected males with X-linked spondyloepiphyseal dysplasia tarda
iv. Molecular genetic testing in new patients relied largely on mutation screening by sequencing the entire coding region.
v. Carrier testing of at risk female relatives available once the mutation has been identified in the proband

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Spondyloepiphyseal dysplasia congenita (autosomal dominant): recurrence risk low unless presence of parental gonadal mosaicism
      ii. Spondyloepiphyseal dysplasia tarda, X-linked
         a) The risk to sibs depends on the carrier status of the mother.
         b) When the mother is a carrier: a 25% risk of having an affected brother; a 25% risk of having an unaffected brother; a 25% risk of having a carrier sister; a 25% risk of having a noncarrier sister
         c) When the mother is not a carrier: The risk to sibs is low (the risk of gonadal mosaicism in mothers not yet known).
      iii. Spondyloepiphyseal dysplasia tarda, autosomal recessive: 25%
      iv. Spondyloepiphyseal dysplasia tarda, autosomal dominant: low unless a parent is affected
   b. Patient's offspring
      i. Spondyloepiphyseal dysplasia congenita, autosomal dominant
         a) When the spouse is not affected: 50% of offspring will be affected.
         b) When the spouse is also affected with spondyloepiphyseal dysplasia congenita: 50% of offspring are heterozygous and affected; 25% are homozygous, which is ordinarily fatal in the first few months of life and 25% are unaffected.
      ii. Spondyloepiphyseal dysplasia tarda
         a) Autosomal recessive form: recurrence risk to offspring low unless the spouse is a carrier
         b) Autosomal dominant form: 50%
      iii. Spondyloepiphyseal dysplasia tarda, X-linked recessive
         a) None of the sons of an affected male will be affected.
         b) All daughters of an affected male are carriers.
2. Prenatal diagnosis
   a. Molecular genetic diagnosis on fetal DNA from amniocytes or CVS available in families at risk for SED congenita, provided the disease-causing mutation (*COL2A1*) is identified in the proband
   b. Molecular genetic diagnosis on fetal DNA from amniocytes or CVS possible in families at risk for X-linked SED tarda, provided the disease-causing mutation (*SEDL*) is identified in the proband
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified in an affected family member.
3. Management
   a. SED congenita
      i. Supportive care including psychosocial support
      ii. Tracheostomy for severe respiratory difficulties to maintain adequate ventilation
      iii. Posterior atlantoaxial fusion for patients with signs and symptoms of atlantoaxial instability measuring 8 mm or more or myelopathy
      iv. Brace for scoliosis initially
      v. Posterior spinal fusion for severe scoliosis or for patients resistant to bracing
      vi. Surgical correction for hip and knee abnormalities
      vii. Surgical correction of equinovarus deformities unmanageable by physical therapy or serial casting
   b. SED tarda, X-linked type
      i. Supportive care
         a) Avoid activities and occupations that place undue stress on the spine and weight bearing joints to prevent premature arthritis.
         b) Chronic pain management
         c) Psychosocial support for the patient and family
      ii. Bracing for scoliosis
      iii. Posterior spinal fusion for severe scoliosis
      iv. Posterior stabilization for atlantoaxial instability
      v. Valgus or valgus-extension intertrochanteric osteotomy to improve hip congruity
      vi. Total joint arthroplasty for osteoarthritis in adulthood

vii. Management of hip dysplasia
   a) Acetabular augmentation if the acetabulum is insufficient to contain the enlarged femoral head (coxa magna)
   b) May require hip replacement

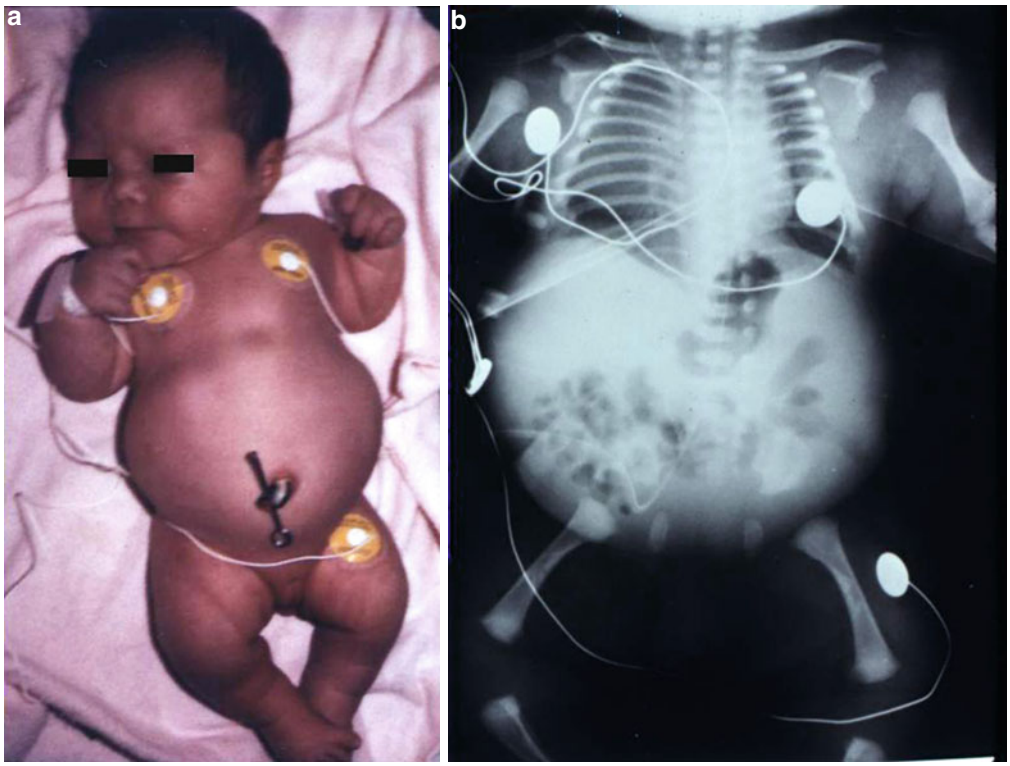

Fig. 1 (**a**, **b**) A neonate with SED congenita showing moderately shortened limbs, short trunk, and large head. Radiograph shows small oval vertebral bodies, reniform ilia, and moderately shortened limb bones

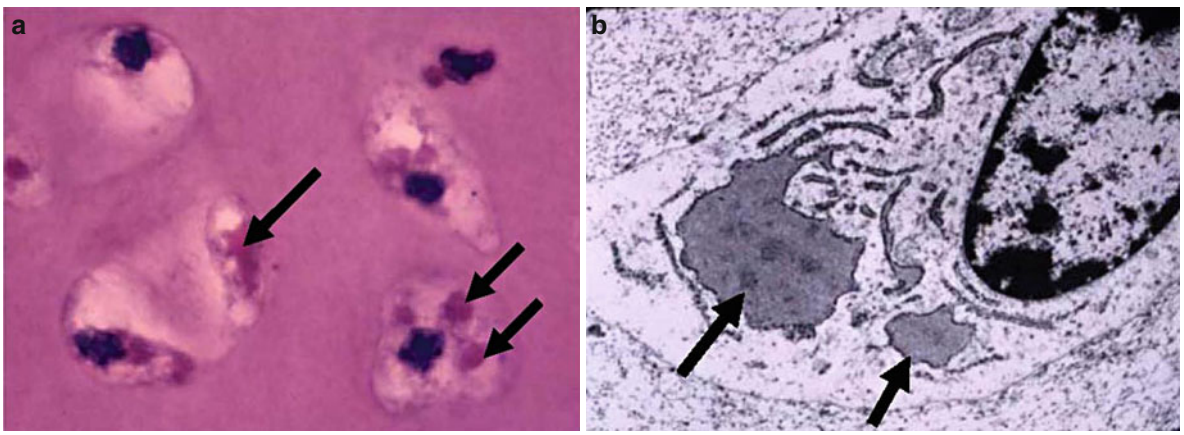

Fig. 2 (**a**, **b**) Photomicrograph of a neonate with SED congenita shows frequent presence of cytoplasmic inclusions in the chondrocytes of resting cartilage and the zone of proliferation. The cytoplasmic inclusion is a dilated rough endoplasmic reticulum containing finely granular material

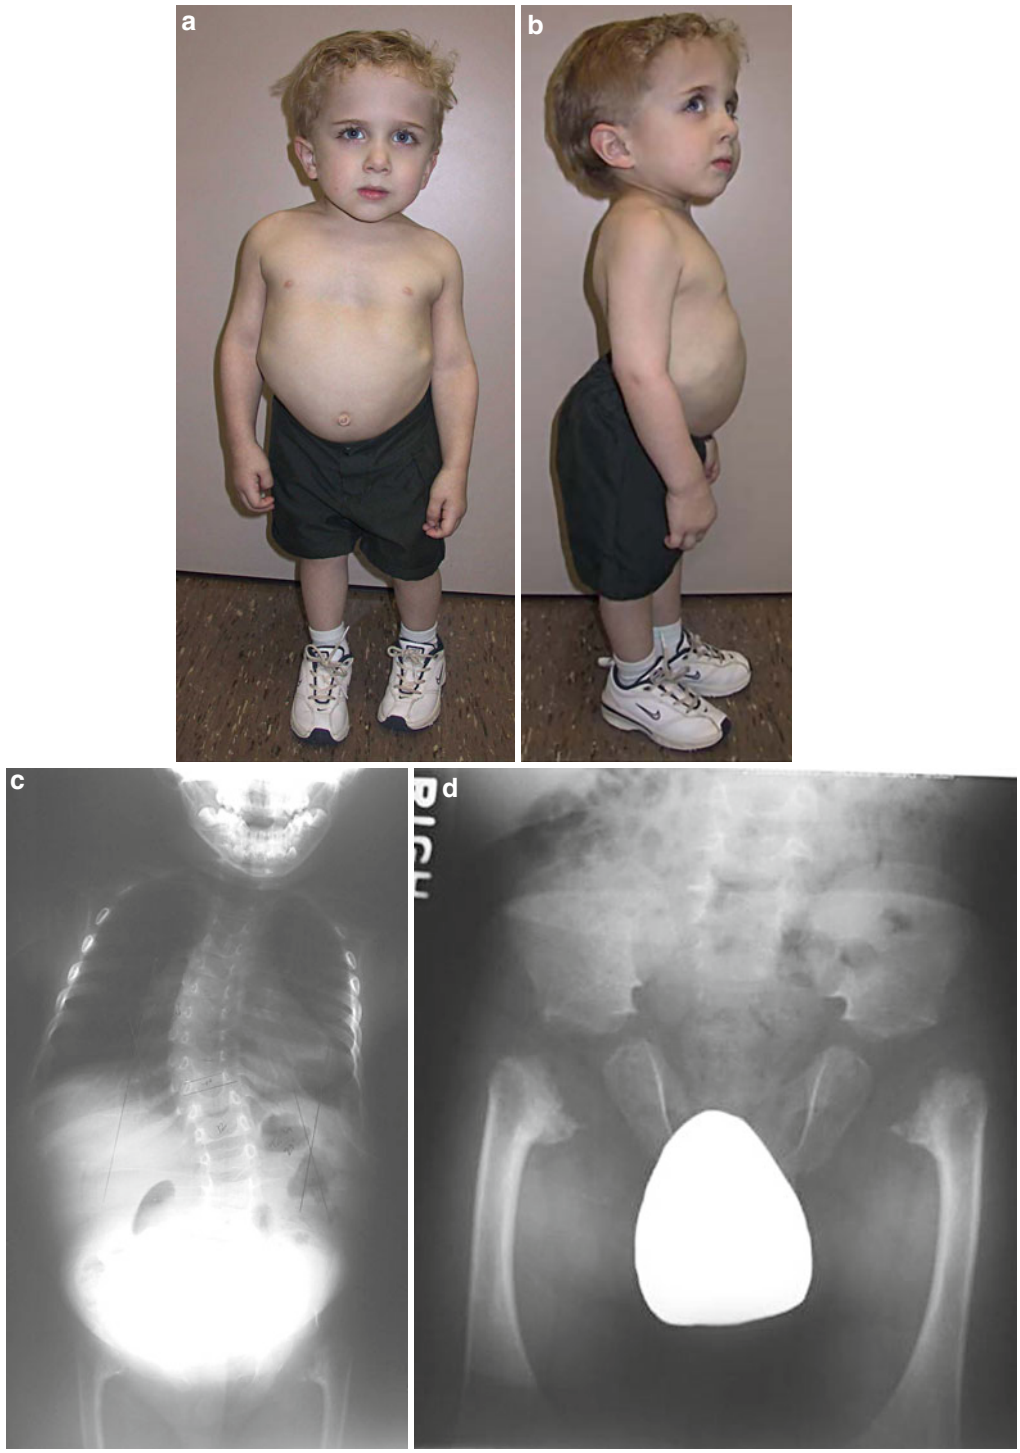

Fig. 3 (**a**–**d**) A boy with SED congenita showing short trunk, short, broad chest with pectus excavatum, globoid abdomen, and hyperlordosis. Radiographs showed lack of ossification of the femoral epiphysis, short femoral neck, generalized platyspondyly, and thoracolumbar scoliosis

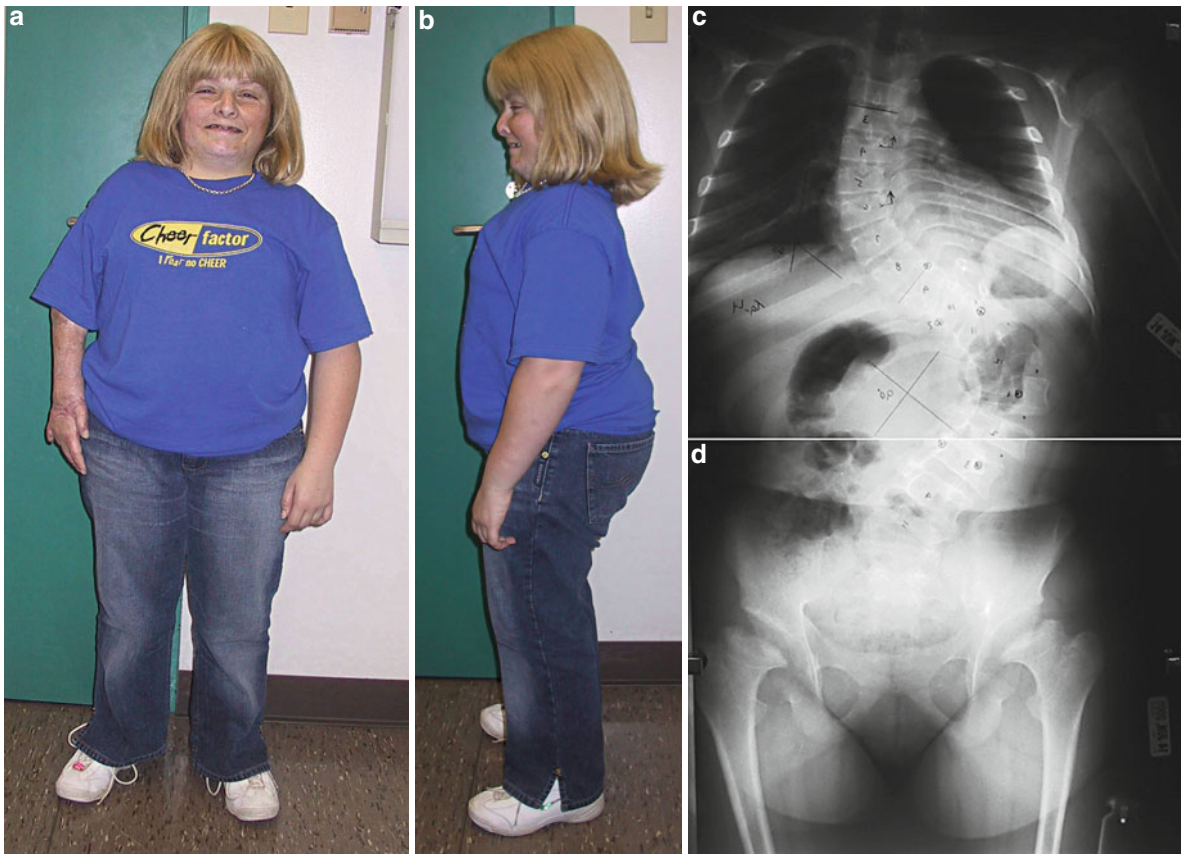

Fig. 4 (**a**–**d**) An adult with SED showing short-trunk dwarfism. Radiographs showed flat vertebral bodies, severe scoliosis, and retarded ossification of femoral head and neck

Fig. 5 (**a**–**d**) A 9-year-old boy with spondyloepiphyseal dysplasia tarda showing kyphosis. The spinal radiographs showed anterior body projection, widening of vertebral body spaces, and lumbar kyphosis. Femoral epiphysis was poorly developed (flat epiphyses) and acetabular sockets were not well formed

Stickler Syndrome

In 1965, Stickler et al. described a family with progressive myopia, retinal detachment and blindness, and premature degenerative changes in various joints. The disorder was subsequently termed "hereditary progressive arthroophthalmopathy." The incidence is estimated to be about 1 in 10,000 (Admiraal et al. 2002).

Synonyms and Related Disorders

Hereditary progressive arhroophthalmopathy

Genetics/Basic Defects

1. Inheritance: autosomal dominant with wide variation in expression
2. Association of the Stickler syndrome with following collagen gene mutations:
   a. *COL2A1* gene mutations (Hoornaert et al. 2010)
      i. Observed in membranous or type I vitreous phenotype (afibrillar phenotype)
      ii. The presence of vitreous anomalies, retinal tears or detachments, cleft palate and a positive family history was shown to be good indicator for a COL2A1 defect.
      iii. Stickler syndrome type 1 is predominantly caused by loss-of-function mutations in the COL2A1 gene as >90% of the mutations were predicted to result in nonsense-mediated decay.
   b. *COL11A1* gene mutations (Richards et al. 2010)
      i. Observed in beaded or type II vitreous phenotype
      ii. Stickler syndrome type II (Marshall syndrome)
         a) More severe facial features (short nose, midfacial flattening)
         b) High myopia
         c) Less risk of retinal detachment
         d) Moderate hearing impairment
      iii. Some mutations in *COL11A1* have been classified as Marshall syndrome, but as demonstrated by Annunen et al. (1999), the short nose, anteverted nares, midfacial hypoplasia, and flat nasal bridge that are common in cases of Marshall syndrome with *COL11A1* mutations, are also often present in young individuals with mutations in *COL2A1*, making differential diagnosis based on facial phenotypes difficult (Marjava et al. 2007).
   c. *COL11A2* gene mutations
      i. Cause nonocular Stickler syndrome type III
         a) Stickler-like facial features
         b) Mild to moderate deafness
         c) Normal eyes
      ii. Also found in patients with a recessively inherited variant denoted as otospondylomegaepiphyseal dysplasia (OSMED)
      iii. Also cause autosomal dominant nonsyndromic deafness (DFNA13)
   d. *COL9A1* mutations (autosomal recessive Stickler syndrome): vitreous syneresis with an optically empty vitreous due to progressive gel liquefaction (Van Camp et al. 2006)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_223,
© Springer Science+Business Media, LLC 2012

3. Genotype-phenotype correlations
   a. Type I Stickler syndrome: ocular Stickler syndrome with mutations in *COL2A1* (chromosome locus: 12q13.11-q13.2)
   b. Type II Stickler syndrome: ocular Stickler syndrome with mutations in *COL11A1* (chromosome locus: 1p21)
   c. Type III Stickler syndrome: nonocular Stickler syndrome with mutations in *COL11A2* (chromosome locus: 6p21.3)

Clinical Features

1. Considerable clinical variability within families and between families, explainable in part by locus and allelic heterogeneity
2. Ocular features
   a. Myopia
      i. Congenital
      ii. Nonprogressive
      iii. Of high degree
   b. Abnormalities of vitreous formation and gel architecture
      i. Pathognomonic of Stickler syndrome
      ii. A prerequisite for diagnosis
      iii. Vitreous anomalies
         a) Characteristic congenital "membranous" vitreous anomaly (type I phenotype) in type I Stickler syndromes
         b) Sparse and irregularly thickened bundles of fibers throughout the vitreous cavity (type II phenotype) in type II Stickler syndrome
   c. Retinal detachment: the most serious ophthalmologic complication
   d. Cataracts
   e. Strabismus
   f. Open-angle glaucoma
   g. No ocular abnormalities in Stickler syndrome type III
3. Hearing impairment (Admiraal et al. 2002)
   a. Considerable variability
   b. Conductive hearing impairment
      i. Resulting from recurrent otitis media
      ii. Secondary to cleft palate
   c. Sensorineural hearing impairment
      i. Type I Stickler syndrome with mutations in the *COL2A1* gene
         a) Occurring in 50–60%
         b) Typically mild to moderate degrees
         c) Predominantly affecting higher frequencies
         d) No tangible progression beyond presbycusis
      ii. Type II Stickler syndrome (Marshall syndrome) with the mutations in the *COL11A1* gene
         a) Occurring in 80–100%
         b) More severely affected
         c) Starting at a younger age or congenital in origin
         d) Showing progression
      iii. Type III Stickler syndrome with mutations in the *COL11A2* gene
         a) A typical feature
         b) Hundred percent penetrance
         c) Mild to moderate impairment
         d) Nonprogressive when accounted for presbycusis
         e) Showing different audiometric configurations
4. Associated anomalies
   a. Orofacial anomalies
      i. Facial bone hypoplasia
         a) Flat midface
         b) Depressed nasal bridge
         c) Maxillary hypoplasia
         d) Mandibular hypoplasia (Pierre-Robin anomaly)
      ii. High arched/cleft palate
      iii. Bifid uvula
      iv. Abnormal teeth
      v. Malocclusion
   b. Generalized musculoskeletal abnormalities
      i. Joint hyperextensibility
      ii. Enlarged joints
      iii. Premature osteoarthritis
      iv. Slender extremities
      v. Long fingers
      vi. Hypotonia
      vii. Relative muscle hypoplasia
      viii. Kyphosis

ix. Scoliosis
x. Pectus carinatum
xi. Accessory carpal ossicles
xii. Hip dislocation
xiii. Coxa valga
xiv. Genu valga
xv. Talipes equinovarus

c. Mitral valve prolapse
i. Fifty percent of patients in one series
ii. 0% in another series

5. Intelligence: normal
6. Clinical features seen in different types of Stickler syndrome (Li and Thorne 2010)
a. Type I
i. Ocular
a) Myopia
b) Vitreoretinal degeneration
c) Cataracts
d) Retinal detachment
ii. Musculoskeletal
a) Mild degenerative changes
b) Hypermobility
iii. Auditory: Normal to slight hearing impairment
iv. Craniofacial: cleft palate

b. Type II
i. Ocular
a) Congenital nonprogressive myopia
b) Cataracts
ii. Musculoskeletal
a) Mild degenerative changes
b) Hypermobility
iii. Auditory: early-onset sensorineural hearing loss
iv. Craniofacial: cleft palate

c. Type III
i. Ocular: none
ii. Musculoskeletal: early-onset osteoarthritis
iii. Auditory: high-tone sensorineural hearing loss
iv. Craniofacial: Pierre-Robin sequence

7. Differential diagnosis (Snead and Yates 1999; Bowling et al. 2000)
a. Wagner hereditary vitreoretinal degeneration
i. Consisting solely of ocular abnormalities
a) Myopia
b) Vitreous degeneration
c) Preretinal avascular membranes
d) Retinal degeneration and thinning
ii. No increased risk of retinal detachment or systemic abnormalities

b. Weissenbacher-Zweymüller syndrome and otospondylomegaepiphyseal dysplasia (OSMED)
i. Pierre-Robin sequence
ii. Snub nose
iii. Proximal limb shortening resolved by adulthood
iv. Dumbbell-shaped femora and humeri
v. Coronal vertebral clefts
vi. Sensorineural hearing loss
vii. No eye abnormalities
viii. *COL11A2* mutations
ix. Appears to represent the same entity as nonocular Stickler syndrome

c. Erosive vitreoretinopathy
i. Autosomal dominant eye disorder
ii. Phenotype resembling Wagner syndrome but lacking any systemic abnormalities
iii. Condition mapped to 5q13-q14 suggesting it may be an allelic variant of Wagner syndrome

d. Marshall syndrome
i. Autosomal dominant disorder
ii. Clinical phenotype
a) Cataracts
b) Myopia
c) Abnormal vitreous
d) Midfacial hypoplasia
e) Congenital deafness
iii. Associated with *COL11A1* mutation in a family affected with Marshall syndrome

e. Kniest dysplasia
i. Ocular abnormalities
a) Severe myopia
b) Vitreous veils
c) Perivascular lattice
d) Retinal detachment
e) Cataracts
ii. Systemic findings
a) Short trunk dwarfism
b) Kyphoscoliosis
c) Deafness
d) Depressed nasal bridge
e) Cleft palate

f. Spondyloepiphyseal dysplasia
g. Marfan syndrome

h. Goldmann-Farve syndrome
   i. A rare recessively inherited condition
   ii. Ocular abnormalities
      a) Night blindness
      b) Retinal detachment
      c) Pigmentary choroidoretinal degeneration
      d) Vascular sheathing in the fundus
i. Jansen syndrome
   i. Ocular abnormalities similar to Wagner syndrome
   ii. Absent systemic abnormalities
j. Congenital retinoschisis
   i. A sex-linked recessive trait
   ii. Usually occurring in emmetropic or hyperopic patients
   iii. Membrane-like structures in midvitreous

Diagnostic Investigations

1. Audiological testing for hearing loss
2. Radiographic features
   a. Generalized spondyloepiphyseal dysplasia
   b. Flattening of the epiphyses
   c. Narrowing of the diaphyses
   d. Flaring or widening of the metaphyses
   e. Wedging of the tubular bones
   f. Coxa valga
   g. Widening of femoral neck
   h. Acetabular protrusio
   i. Chondrolysis
   j. Avascular necrosis
   k. Premature arthritic changes
   l. Anterior maxillary and mandibular underdevelopment
3. Clinically available molecular genetic testing for mutations affecting four different genes (COL2A1, COL11A1, COL11A2, and COL9A1)
   a. Sequence analysis
   b. Deletion/duplication analysis

Genetic Counseling

1. Recurrence risk (Robin et al. 2010)
   a. Variable clinical expression of Stickler syndrome may complicate the genetic counseling (Faber et al. 2000).
      i. Exercise caution on assuming a de novo mutation: radiographic studies and clinical examination of the parents including formal testing of hearing and vision
      ii. Mutation search whenever possible
      iii. Uncertainty in predicting clinical consequences of inheriting a mutation
   b. Patient's sib
      i. Autosomal dominant inheritance (COL2A1, COL11A1, COL11A2-related Stickler syndrome)
         a) A 50% risk if a parent has Stickler syndrome
         b) A low recurrence risk if the parents are clinically affected and the disease-causing mutation not identified
      ii. Autosomal recessive inheritance (*COL9A1*): a 25% risk
   c. Patient's offspring
      i. Autosomal dominant: a 50% risk
      ii. Autosomal recessive: risk not increased unless the spouse is a carrier
2. Prenatal diagnosis
   a. Ultrasonographic demonstration of Pierre-Robin sequence as a part of Stickler syndrome
   b. Mutation analysis on amniocytes or CVS cells in at-risk families with known mutations
   c. Linkage analysis of the 3'VNTR polymorphism on the involved gene (*COL2A1*) using amniocytic DNA
   d. Preimplantation genetic diagnosis for at-risk pregnancies require prior identification of the disease-causing mutations in the family
3. Management (Bowling et al. 2000)
   a. Early evaluation of at-risk patients for the development of the following complications
      i. Retinal tears
      ii. Retinal detachment
      iii. Cataracts
      iv. Glaucoma
   b. Long-term monitoring
   c. Cleft palate repair with appropriate feeding techniques
   d. Corrective lenses for myopia
   e. Avoid contact sports which may lead to retinal detachment
   f. Laser photocoagulation of vitreoretinopathy as preventive treatment for retinal detachment

g. Surgical repair of retinal detachments and remove cataracts with possible lens implantation
h. Glaucoma management
i. Corrective treatment for strabismus
j. Hearing aids for hearing loss
k. Speech therapy
l. Symptomatic treatment for arthropathy
    i. Joint pain management
    ii. Appropriate splints for strengthening and stabilizing lax joints
    iii. Braces or aids to assist daily activities
    iv. Hydrotherapy or other physical therapy modalities to increase range of motion, endurance, and strength
m. Management for mitral valve prolapse
    i. Antibiotics prophylaxis
    ii. Beta-blocker for symptomatic patients

Sturge-Webber Syndrome

Sturge-Weber syndrome comprises of vascular malformations of the central nervous system and the port-wine stain or nevus flammeus of the face in a trigeminal nerve distribution. The syndrome is also known as encephalotrigeminal angiomatosis. The incidence is estimated to be approximately 1 in 50,000 (Sturge 1879; Parkes Weber 1922; Thomas-Sohl et al. 2004).

Synonyms and Related Disorders

Encephalofacial or Encephalotrigeminal angiomatosis

Genetics/Basic Defects

1. Genetics
   a. A sporadic, nonfamilial disease
   b. Uncertain inheritance: only a few familial clusters of the syndrome reported; most of these have not exhibited the clear-cut autosomal dominant inheritance pattern
   c. Proposed to represent a genetically mosaic condition. Lesions in the Sturge-Weber syndrome result from somatic mutations in affected areas, such as the port-wine stain or leptomeningeal angioma, but not in blood or normal skin (Huq et al. 2002).
   d. A potential role of fibronectin in the pathogenesis of Sturge-Weber syndrome. The gene expression findings in fibroblast supported the hypothesis of a somatic mutation underlying the disorder.
   e. A novel synonymous mutation (c.1229G > A) (p.K420K) of RASA1 was identified in a Chinese patient with sporadic Sturge-Weber syndrome (Zhou et al. 2011): Further study is needed.
2. Basic defect: caused by residual embryonal blood vessels and their secondary effects on surrounding brain tissue
3. Pathophysiology: Neurologic dysfunction of the syndrome results from secondary effects of residual embryonal blood vessels on surrounding brain tissue.
   a. Hypoxia
   b. Ischemia
   c. Venous occlusion
   d. Thrombosis
   e. Infarction
   f. Vasomotor phenomenon
   g. Seizures

Clinical Features

1. Variable natural history of the disease (Mirowski et al. 1999)
2. Three cardinal features (Comi 2003)
   a. Capillary malformation (port-wine stain, cutaneous angioma) in the upper trigeminal neural distribution
      i. Involves the ophthalmic branch of the trigeminal nerve, in particular, the upper eyelid and supraorbital region
      ii. May extend into the maxillary and mandibular regions

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_224,
© Springer Science+Business Media, LLC 2012

iii. May be associated with soft tissue and bony overgrowth
iv. May be hidden in scalp or mouth
v. May be absent in the forme fruste of Sturge-Weber syndrome

b. Ocular abnormalities
i. Ipsilateral to the port-wine stain
ii. Can be seen with V1 or V2 involvement
iii. Glaucoma (60%)
iv. Buphthalmos
v. Vascular malformations of the conjunctiva, episclera, choroids, and retina

c. Leptomeningeal vascular malformation (angioma)
i. May be unilateral (more common) or bilateral
ii. Usually ipsilateral to port-wine stain
iii. Capillary and venous anomalies of leptomeninges
iv. No correlation between the size of facial and CNS malformations

3. CNS manifestations
a. Seizures (75–90% of cases)
b. Mental retardation present in approximately 50% of cases
c. Contralateral hemiplegia or hemisensory deficits
d. Contralateral homonymous hemianopsia (impaired vision in half of the visual field)
e. Headaches
f. Developmental delay
g. Learning disorders
h. Attention deficit hyperactivity disorder

4. Soft tissue and skeletal overgrowth (60–83%) (Greene et al. 2009)
a. Often exhibit localized cutaneous growths, either pyogenic granuloma or fibrovascular nodules
b. Do not combine venous, lymphatic, or arterial anomalies in an extremity, although simple diffuse venous varicosities have been seen
c. Often erroneously diagnosed as having either Klippel-Trenaunay syndrome (extremity capillary-lymphatico- venous malformation with overgrowth) or Parkes Weber syndrome (extremity capillary-arteriovenous malformation with overgrowth)

5. Long-term outcome (Arzimanoglou et al. 2000)
a. Distribution of port-wine stain
i. Cranial: 98%
ii. Extracranial: 52%
b. Glaucoma (60%)
c. Seizures (83%)
d. Developmental delay usually associated with seizures
i. With seizures: 43%
ii. Without seizures: 0%
e. Presence of behavior and emotional problems
i. With seizures: 85%
ii. Without seizures: 58%
f. Require special education
i. With seizures: 71%
ii. Without seizures: 0%
g. Employability
i. With seizures: 46%
ii. Without seizures: 78%
h. Normal fertility
i. Indications of progressive nature
i. Increasing duration of seizures and postictal deficits
ii. Increase in atrophy or of calcified lesions or both

Diagnostic Investigations

1. Radiography
a. Asymmetric skull
b. Double contour "gyriform" patterns of intracranial calcifications
i. Classic "tram-line," "tram-track", or "trolley-track" intracranial calcifications
a) Considered pathognomonic prior to modern neuroimaging
b) Often a late finding
c) May not be present initially
ii. Distribution
a) In the subcortical region, primarily in the parietal and occipital regions
b) Unilateral (80%) or bilateral (20%)

2. EEG to evaluate seizure activities
3. Angiographic findings
a. Lack of superficial cortical veins
b. Nonfilling dural sinuses
c. Abnormal, tortuous vessels

4. CT scan findings (Di Rocco and Tamburrini 2006)
a. Intracranial dense gyriform or "tram-truck" calcifications which more commonly affect the parieto-occipital cortical area and/or the choroid plexus and are usually absent in early infancy

   b. Diffuse high attenuation of the superficial and deep white matter, presumably due to microcalcifications
   c. Gyriform enhancement after iodinated contrast enhancement, expression of the pial angiomatosis
   d. Brain atrophy, consequence of vascular steal phenomena of the pial angioma on the surrounding cortical structures
   e. Thickening of the calvarium, more frequently observed in patients with early onset symptoms as an indirect feature of loss of the brain substance
   f. Abnormal draining veins
   g. Enlarged ipsilateral choroid plexus
   h. Blood-brain barrier breakdown during seizures
5. MRI findings: the gold standard imaging modality for the identification of structural brain abnormalities (Di Rocco and Tamburrini 2006)
   a. Leptomeningeal enhancement with Gd-diethyltriaminepentaacetic acid on T1-weighted images is considered one of the most important signs that help define the extent of the vascular malformation; however, its absence does not exclude the diagnosis (Elster and Chen 1990).
   b. Enlarged choroid plexus
   c. Sinovenous occlusion
   d. Cortical atrophy
   e. Accelerated myelination
6. Single-photon emission computed tomography to measure cerebral blood flow (Pinton 1997)
   a. Hyperperfusion early (before 1 year)
   b. Hypoperfusion late (after 1 year)
7. Positron emission tomography (PET) for hypometabolism
8. Histology
   a. Thickened and discolored leptomeninges
   b. Abnormal venous structures
   c. Calcifications
      i. Cerebral vessel walls
      ii. Perivascular tissue
      iii. Rarely within neurons

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low
   b. Patient's offspring: low
2. Prenatal diagnosis: not been reported
3. Management (Thomas-Sohl 2004)
   a. Medical care
      i. Medications for recurrent headaches/migraine
         a) Ibuprofen: first choice
         b) Abortive therapy with sumatriptan
         c) Preventive therapy with propranolol or nortriptyline
      ii. Management of glaucoma to control the intraocular pressure and prevent progressive visual loss and blindness
         a) Beta blocker drops: first choice
         b) Adrenergic drops or carbonic anhydrase inhibitor drops: second choice
      iii. Anticonvulsants for seizure (partial epilepsy most prevalent in children) control
         a) Carbamazepine: first choice
         b) Valproate, topiramate, phenobarbital, phenytoin
      iv. Strokelike episodes: aspirin
      v. Neurobehavioral problems
         a) Methylphenidate: first choice
         b) Clonidine: second choice
         c) Dextroamphetamine or risperidone
      vi. Dermatologic laser therapy for port-wine stain
   b. Surgical care
      i. Surgery (trabeculectomy) for glaucoma if medications fail to lower intraocular pressure
      ii. Option of early surgery for patients with Sturge-Weber syndrome with drug-resistant epilepsy
         a) Focal cortical resection
         b) Hemispherectomy
         c) Corpus callosotomy
         d) Vagal nerve stimulation
      iii. Lesionectomy provided that the pial angioma is unilateral and the resection can be complete

Tay-Sachs Disease

Tay-Sachs disease is a hereditary neurodegenerative disorder resulting from excess storage of GM2 ganglioside within the lysosomes of cells, caused by deficiency of hexosaminidase A. The incidence of the disease is estimated to be 1 in 3,600 in Ashkenazi Jews with carrier frequency of 1 in 30 and 1 in 360,000 in other population with carrier frequency of 1 in 300. Tay-Sachs disease is the most frequently occurring sphingolipidoses.

Synonyms and Related Disorders

GM2-gangliosidosis type 1; Hexosaminidase A deficiency

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Biochemical defect: deficiency of the isoenzyme β-hexosaminidase A (Hex A)
3. Genetic basis
   a. Mutations in the *HEXA* gene (on chromosome 15q23-q24) that codes for the subunit of the β-hexosaminidases result in the deficiency of Hex A (αβ) that results in Tay-Sachs disease.
   b. Over 100 different mutations have been identified in the *HEXA* gene to date.
   c. Presence of a small number of common mutations in populations where the carrier frequency is high (Sutton 2002)
      i. Ashkenazi Jews (Bach 2001)
         a) Two common mutations associated with Tay-Sachs disease [a four base-pair insertion into exon 11 of the *HEXA* gene (1278insTATC) accounting for 75–80% of all mutations in this population; a splice site mutation in intron 12 (1421+1G → C) accounting for 15% of mutations]
         b) One mutation associated with a late-onset form of the disease (G269S in 3% of carriers)
         c) Pseudodeficiency polymorphism (R247W in 2% of carriers)
      ii. Pennsylvania Dutch
         a) An intron 9 splice site mutation (1,073 +1G → A)
         b) Pseudodeficiency allele (R247W)
      iii. Cajuns in Southern Louisiana
         a) An intron 9 splice site mutations (1,073 +1G → A)
         b) Four base-pair insertion in exon 11 (1278insTATC)
      iv. French Canadians in Eastern Quebec
         a) A large (7.6 kb) deletion at the 5′ end of the gene
         b) A splice site mutation in intron 7 (805 +1G → A)
         c) Common 4 base-pair insertion in exon 11 seen in Ashkenazi Jews (1278insTATC)

Clinical Features

1. Classic infantile acute-onset Tay-Sachs disease
   a. Natural history (Sutton 2002)
      i. Appears normal at birth
      ii. Normal motor development in the first few months of life

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_225,
© Springer Science+Business Media, LLC 2012

iii. Progressive weakness and loss of motor skills beginning around 2–6 months of life
iv. Followed by decreased social interaction, increased sensitivity to noise (hyperacusis), and an increased startle response to noise
v. Progressive neurodegeneration
vi. Uniformly fatal: death from pneumonia usually occurring between 2 and 5 years of age

b. Clinical features
i. Delayed development
ii. Poor feeding
iii. Lethargy
iv. Hypotonia
v. Hyperreflexia
vi. Opisthotonos
vii. Hyperacusis
viii. A cherry red spot on the fovea centralis of the macula, representing loss of ganglion cells in the foveal area with the remaining ones filled with the ganglioside
ix. Progressive neurodegeneration
a) Developmental regression
b) Macrocephaly secondary to accumulation of storage material within the brain after about 15 months of age. There is no evidence of hepatosplenomegaly or other peripheral evidence of storage disease.
c) Myoclonic seizures, most during the first year of life
d) Progressive macular degeneration leading to blindness, usually by 1 year of age
e) Deafness
f) Spasticity
g) Complete disability

2. Subacute (juvenile) Tay-Sachs disease (2–18 years of age) (Maegawa et al. 2006): characterized by progressive neurologic deterioration that mainly affects motor and spinocerebellar function leading to:
a. Progressive spasticity with seizures and dementia
b. A vegetative state by late childhood or mid-teens
3. Late-onset (adult) Tay-Sachs disease (Shapiro et al. 2008)
a. A chronic, progressive, lysosomal storage disorder caused by a partial deficiency of beta hexosaminidase A (HEXA) activity
b. Deficient levels of HEXA result in the intracellular accumulation of GM_2-ganglioside, resulting in toxicity to nerve cells
c. Clinical manifestations primarily involve the central nervous system (CNS) and lower motor neurons, including:
i. Ataxia
ii. Weakness
iii. Spasticity
iv. Dysarthria
v. Dysphagia
vi. Dystonia
vii. Seizures
viii. Psychosis
ix. Mania
x. Depression
xi. Cognitive decline
d. The prevalence of peripheral nervous system: a predominantly axon loss polyneuropathy affecting distal nerve segments in the lower and upper extremities (27% of cases)

Diagnostic Investigations

1. Diagnosis and carrier testing
a. Indications for carrier testing
i. Fully or partially Jewish
ii. Pennsylvania Dutch
iii. Cajuns of Southern Louisiana
iv. French Canadians of Eastern Quebec
b. Preconceptional counseling for at-risk couples
c. Enzyme assay
i. Using fluorimetric study measuring activity of both Hex A and Hex B in either serum or leukocytes
ii. Decreased activity of Hex A with normal or increased activity of Hex B in carriers
iii. Limitations of serum assay
a) Overlapping of the values between carriers and noncarriers
b) Unreliable in pregnant women and in women taking oral contraceptives
c) Inability to distinguish carriers of pseudodeficiency alleles from carriers of disease-causing mutations
iv. Clarification of abnormal or inconclusive results of enzyme assay by:
a) Enzyme assay on leukocytes

b) DNA mutation analysis for common mutations and pseudodeficiency alleles

d. Molecular genetic testing (Kaback and Desnick 2011)
   i. Targeted mutation analysis: using a panel of common *HEXA* mutations when assay of HEX A enzymatic activity is abnormal:
      a) In a symptomatic individual in order to identify the disease-causing mutations
      b) In an asymptomatic individual to evaluate for the presence of a pseudodeficiency allele
   ii. Sequence analysis/mutation scanning: to identify *HEXA* mutations in an individual who:
      a) Is affected but had only one or neither mutation identified using a panel of standard mutations, or
      b) Has carrier-level enzymatic results but did not have a mutation identified using a panel of standard mutations

2. CT scan of the brain: areas of low density in the basal ganglia and cerebral white matter
3. MRI of the brain: an increased signal in the basal ganglia and cerebral white matter on T_2-weighted images
4. MR spectroscopy (Aydin et al. 2005)
   a. Demonstrates an increase in myoinositol/creatine and choline/creatine ratios with a decrease in the N-acetyl aspartate/creatine ratio
   b. The spectroscopy findings support demyelination, gliosis, and neuronal loss in the neuropathological process of Tay-Sachs disease.
5. Characteristic neuropathological findings (Kaback et al. 1993)
   a. Pathologic changes are restricted to the nervous system.
   b. Ballooning of neurons with massive intralysosomal accumulation of lipophilic membranous bodies
   c. Nature and structure of the stored intraneuronal material : GM2 ganglioside
   d. Abnormal cytoplasmic inclusion bodies identified in fetal spinal cord at 12 weeks and retina and spinal ganglia during 19th–22nd week of gestation (Adachi et al. 1974)
   e. Cisternae of the endoplasmic reticulum: the primary site of lipid accumulation in neurons during the fetal stage of Tay-Sachs disease (Adachi et al. 1974)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring
      i. Acute infantile form: not surviving to reproductive age
      ii. Late-onset form may reproduce: risk not increased unless the spouse is a carrier
2. Prenatal diagnosis (Kaback and Desnick 2011) is available when HEX A enzyme assay has shown both parents to be heterozygous, and molecular genetic testing has ruled out the presence of a pseudodeficiency allele in either parent:
   a. Enzyme analysis (absence of hexosaminidase A) on cultured amniocytes or chorionic villus cells
   b. DNA analysis when one of the common mutations had been identified in the family
      i. Preferred method of prenatal diagnosis
      ii. Less prone to error
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified in an affected family member.
3. Management
   a. No effective treatment to alter the natural history
   b. Primarily supportive
      i. Provide adequate nutrition and hydration
      ii. Manage infections
      iii. Protect airway
      iv. Control seizures
      v. Bowel management
   c. Enzyme replacement therapy and bone marrow transplantation: not yet successful
   d. Options to modify 25% risk of having an affected child with each pregnancy if both partners are found to be carriers (Sutton 2002)
      i. Prenatal diagnosis by amniocentesis or chorionic villus sampling
      ii. Egg or sperm donation
      iii. Preimplantation genetic diagnosis
      iv. Adoption

Fig. 1 A cherry red spot on the fovea centralis of the macula from the fundus of an infant with Tay-Sachs disease

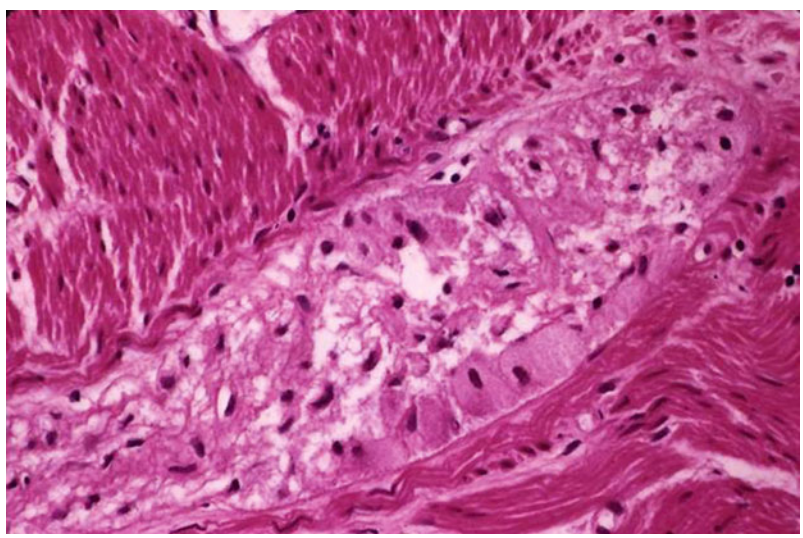

Fig. 2 Myenteric plexus of the rectum (H & E, ×400) showing many enlarged ganglion cells with abundant foamy cytoplasm due to ganglioside storage. Rectal biopsy can be a good source of neurons in confirming neuronal storage disease. In this patient, Tay-Sachs disease was confirmed by electron microscopic examination of ganglion cells

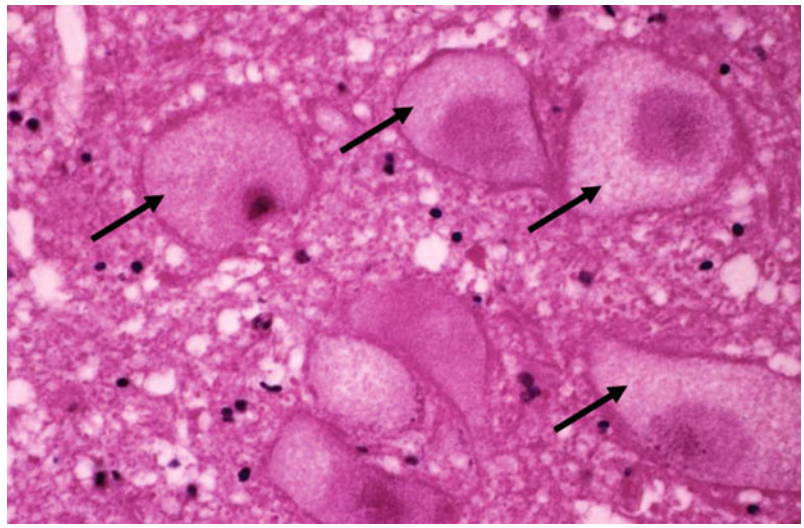

Fig. 3 A section of medulla showing a group of neurons with markedly distended foamy cytoplasm (*arrows*) due to accumulation of GM_2 ganglioside (H & E, ×1,000)

Tetrasomy 9p Syndrome

Tetrasomy 9p syndrome, a clinically diagnosable condition, is a rare cytogenetic disorder characterized by tetrasomy 9p associated with a distinctive patterns of multiple congenital anomalies. In 1973, Ghymers et al. first described the syndrome.

Synonyms and Related Disorders

Supernumerary isochromosome 9p syndrome

Genetics/Basic Defects

1. Caused by de novo supernumerary isochromosome 9p (presence of four copies of the short arm of the chromosome 9)
   a. Pure tetrasomy 9p
   b. Tetrasomy involving the varying segment of the short arm of chromosome 9
2. Cytogenetic types of tetrasomy 9p
   a. Presence of an extra dicentric chromosome 9 consisting entirely of 9p
   b. Presence of an extra dicentric chromosome 9 consisting of 9p and the proximal part of 9q
   c. Mosaicism involving tetrasomy 9p: mosaic of i(9p) cells
3. Hypotheses proposed to explain tetrasomy 9p
   a. A meiosis I disturbance with nondisjunction and rearrangement in two of the four chromatids of a bivalent 9, resulting in the formation of an isochromosome 9p
   b. Meiosis II nondisjunction followed by rearrangements (isochromosome formation) with duplication of the short arm and loss of the acentric long arm at the subsequent mitosis
   c. Dicentric vs monocentric (de Azevedo Moreira et al. 2003)
      i. Using conventional cytogenetics and banding techniques revealed an additional dicentric 9p chromosome in most cases.
      ii. Using molecular studies using a chromosome 9 classic satellite probe shows an error in the division of centromere 9 by a double-break event, resulting in the formation of a monocentric isochromosome 9p.

Clinical Features

1. Craniofacial abnormalities
   a. Delayed closure of the anterior fontanel
   b. Ocular hypertelorism
   c. Telecanthus
   d. Strabismus
   e. Enophthalmos/microphthalmia
   f. Epicanthal folds
   g. Prominent beaked or bulbous nose
   h. Down-turned corners of the mouth
   i. Microretrognathia
   j. Low-set, malformed ears
   k. Cleft lip/palate
   l. High-arched palate
2. Cardiac anomalies
   a. Ventricular septal defect
   b. Atrial septal defect
   c. Patent ductus arteriosus
   d. Persistent left superior vena cava

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_226,
© Springer Science+Business Media, LLC 2012

   e. Double outlet of the right ventricle
   f. Hypoplastic right ventricle
   g. Hypoplastic left heart ventricle
3. Lung anomalies
   a. Lung hypoplasia
   b. Abnormal lobulation of the lung
4. Renal anomalies
   a. Renal hypoplasia
   b. Multicystic dysplasia
   c. Hydroureter
   d. Hydronephrosis
5. Genital anomalies
   a. Cryptorchidism
   b. Genital hypoplasia
   c. Micropenis
   d. Hypoplastic shawl-like scrotum
   e. Ambiguous genitalia
6. Gastrointestinal anomalies
   a. Intestinal malrotation
   b. Hirschsprung disease
7. CNS anomalies
   a. Psychomotor retardation
   b. Hypotonia
   c. Microcephaly
   d. Brachycephaly
   e. Hydrocephalus
   f. Cerebral hypoplasia
   g. Dandy-Walker cyst
   h. Absence of olfactory bulbs
   i. Hypoplastic cerebellum
8. Skeletal anomalies
   a. Growth retardation
   b. Short stature
   c. Short neck
   d. Dysplastic fingernails
   e. Limb anomalies
   f. Clinodactyly of the fifth fingers
   g. Club feet
   h. Articular dislocations
   i. Shortened hands and feet
9. Other features
   a. Single umbilical artery
   b. Failure to thrive
   c. Redundant skin
   d. Widely spaced nipples
   e. Single palmar crease
   f. Sacral dimple
10. The severity of the phenotype correlates with size of the tetrasomic region and the degree of tissue mosaicism for the tetrasomy 9p.

Diagnostic Investigations

1. Cytogenetic studies to identify supernumerary marker chromosomes (Tan et al. 2007)
   a. Conventional and high-resolution analyses
   b. A whole-chromosome paint probe for chromosome 9 to identify the supernumerary chromosome, using the fluorescence in situ hybridization (FISH) technique (Callen et al. 1992; Crolla et al. 1998)
   c. Microdissection and reverse FISH (micro-FISH) (Mahjoubi et al. 2005; de Pater et al. 2006)
   d. Multiplex-FISH (M-FISH) technique (Uhrig et al. 1999)
   e. Centromere-specific multicolor-FISH assays (Nietzel et al. 2001)
   f. AcroM-FISH technique (Langer et al. 2001)
2. Echocardiography for cardiovascular malformations
3. Radiography
   a. Microcephaly
   b. Hypertelorism
   c. Hypoplastic first and 12th ribs
   d. Kyphoscoliosis
   e. Clinodactyly and brachymesophalangy of the fifth fingers
   f. Delayed ossification of pubic bones and ischiopubic synchondrosis
   g. Delayed ossification of femoral heads
   h. Spina bifida occulta
   i. Generalized osteoporosis
4. Ultrasonography of renal abnormalities

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: patient not surviving to reproductive age

2. Prenatal diagnosis
   a. Ultrasonography (Tan et al. 2007)
      i. Intrauterine growth retardation
      ii. Genitourinary/renal anomalies
      iii. Cleft lip/palate
      iv. CNS anomalies
         a) Dandy-Walker malformation
         b) Ventriculomegaly
         c) Hypoplastic/absent vermis
         d) Agenesis of corpus callosum
      v. Limb malformations
      vi. Vertebral anomalies
      vii. Cardiac anomalies
      viii. Genitourinary anomalies
      ix. Polyhydramnios/oligohydramnios
   b. Chromosome analysis of amniocytes, CVS, or fetal blood: Microdissection and pre-G-banded FISH is important in determining the origin of supernumerary marker chromosome in prenatal diagnosis.
3. Management
   a. Early intervention programs for mild developmental delay with minor anomalies
   b. Supporting care for severe cases with early death

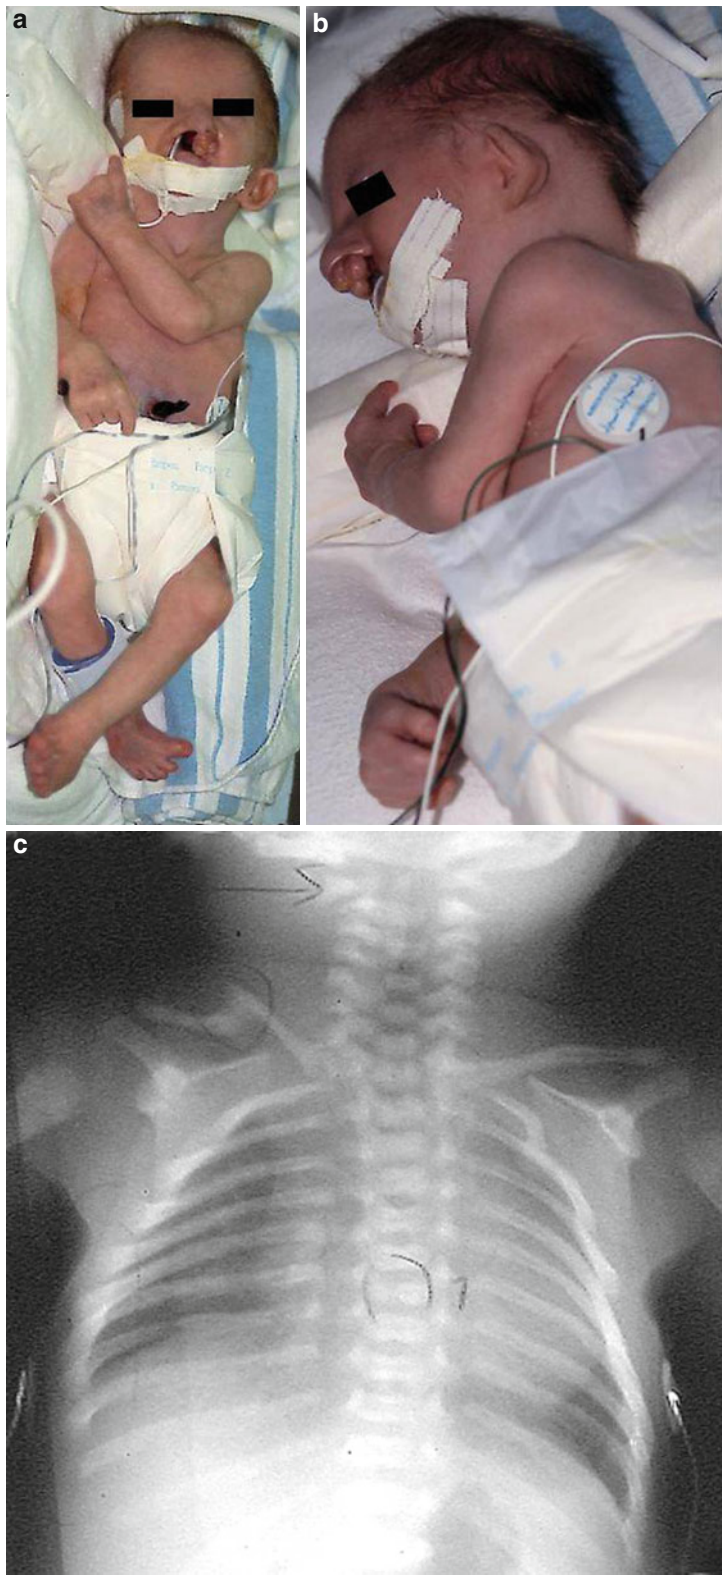

Fig. 1 (**a**–**c**) An infant with tetrasomy 9p syndrome presenting with widened anterior fontanel, microbrachycephaly, a broad nasal root, telecanthus, bilateral cleft lip and palate, retromicrognathia, small eyes, low-set lop ears, and a skin tag on the antihelix of the right ears. In addition, the infant had short neck with excess nuchal fold, bilateral webbing of the anterior axillary folds, pectus excavatum, congenital heart defects, right hydronephrosis, diastasis recti with an umbilical hernia, a right inguinal hernia, sacral dimple with a tag, micropenis, bilateral metatarsus adductus, bilateral transverse palmar creases, clinodactyly of the fifth fingers, short thumbs, and hypoplastic nails. Chest X-ray showed hemivertebrae in the thoracic spine and fractured right clavicle with callus formation. A rectal biopsy confirmed the diagnosis of Hirschsprung disease

Thalassemia

The term thalassemia was first applied to the anemias encountered frequently in people of the Italian and Greek coasts and nearby islands. The term now refers to a group of inherited disorders of globin chain synthesis. Thalassemia comprises of a group of hemoglobinopathies, which are classified according to the specific globin chain (α or β) whose synthesis is impaired. Thus, α- and β-thalassemia are depression of synthesis of the respective chain.

Synonyms and Related Disorders

Alpha-thalassemia (Hb H disease or alpha-thalassemia intermedia, Hb Bart's hydrops fetalis or alpha thalassemia major); Beta-thalassemia (beta-thalassemia major or Cooley anemia or homozygous beta-thalassemia, beta-thalassemia intermedia or compound heterozygote, beta-thalassemia minor or beta-thalassemia trait)

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. α-thalassemia (Vichinsky 2010)
   a. Normal fetal hemoglobin synthesis
      i. Early in gestation, embryonic hemoglobins (Gower1, Gower2, and Portland), which do not contain α-globin chains, are the predominant hemoglobins.
      ii. They are rapidly replaced by fetal and then adult hemoglobin, which contain α-globin chains.
      iii. Therefore, α-thalassemia mutations become phenotypically evident by 12 weeks of gestation.
   b. Synthesis of α-chains is directed by four α-genes, two on each chromosome 16.
   c. α-thalassemia represents a group of conditions with reduced or absent synthesis of one to all four of α-globin genes.
      i. α-thalassemia-2 (α-/αα): resulting from deletion of one of the two α-globin genes
      ii. α-thalassemia-1 (−−/αα): resulting from deletion of both α-globin genes
      iii. Hb H disease (−−/−α): resulting from deletion of three α-globin genes
      iv. Hb Bart's hydrops fetalis (−−/−−): resulting from deletion of all four α-globin genes: Physiologically nonfunctional homotetramers γ_4 and β_4 make up most of the hemoglobin in the erythrocytes in infants with the Bart's hydrops fetalis syndrome.
   d. When both α-genes on a single chromosome are inactive, the designation α^o-thalassemia is used. When there is some production of α-globin chains, α^+-thalassemia is designated.
3. β-thalassemia
   a. Synthesis of β-chains: directed by a single β-gene on each chromosome 11
   b. Caused by the reduced (β^+) or absent (β^o) synthesis of the β-globin chains of the hemoglobin tetramer which is made up of two α-globin and two β-globin chains ($\alpha_2\beta_2$).
   c. Mutations in β-thalassemia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_227,
© Springer Science+Business Media, LLC 2012

i. In contrast to the α-thalassemias, most of the common β-thalassemia mutants are caused by point mutations rather than by gene deletion.
ii. Single base–pair mutations in the DNA alter processing of messenger RNA: most common
iii. Chain terminator defects
iv. Frameshift mutations
v. Polyadenylation mutations
vi. Promoter mutations

d. β^{o}-thalassemia
i. The mutations prevent β-globin chain synthesis entirely.
ii. Absent β-globin synthesis in β^{o}-thalassemia homozygotes
iii. Accounts for about one-third of thalassemia patients

e. β^{+}-thalassemia
i. The mutations prevent β-chain synthesis partially.
ii. β-globin synthesis reduces to 5–30% of normal levels in β^{+}-thalassemia homozygotes.

f. β^{+}/β^{o}-thalassemia compound heterozygotes

4. Pathogenesis (Yaish 2010)
a. Basic defect in all types of thalassemia: imbalanced globin chain synthesis
b. A decrease in the rate of production of a certain globin chain (α, β, γ, δ) impedes hemoglobin (Hb) synthesis and creates an imbalance with the other globin chain that normally produce globin chains.
c. Consequences of impaired production of globin chains
i. Result in less Hb deposit in each RBC, leading to hypochromasia
ii. Deficiency in Hb causes RBCs to be smaller, leading to the classic hypochromic microcytic features of thalassemia.

5. Phenotype-genotype correlation (Cao and Galanello 2010)
a. Homozygosity or compound heterozygosity for β-thalassemia most commonly results in the clinical phenotype of transfusion-dependent thalassemia major.
b. However, a consistent proportion of homozygotes develop milder forms, called thalassemia intermedia, which range in severity from thalassemia major to the β-thalassemia carrier state.
c. Ascertained molecular mechanisms leading to thalassemia intermedia
i. β-thalassemia mutations
a) Mild mutation
b) Silent mutation
c) Mild/silent mutation
ii. Coinherited α-thalassemia
a) Single α-globin gene deletion (−α/αα)
b) Deletion of two α-globin gene (−α/−α or – /αα)
c) Point mutations of the major α-2-globin gene
iii. Genetic determinant of high Hb F production
a) Due to the β-thalassemia mutation per se (δβ-thalassemia, β-promoter deletion)
b) Coinherited Agamma or Ggamma promoter mutation (−158 Ggamma (A → T); −196 Agamma (C → T))
c) Heterocellular HPFH, BCL11A on chromosome 2, and HBS1L-MYB region on chromosome 6

Clinical Features

1. α-thalassemia (Harteveld and Higgs 2010)
a. The most common genetic disorder of hemoglobin synthesis, affects up to 5% of the world's population (Vichinsky 2010)
b. Found in people of African descent, Indochina, Malaysia, and China
c. Severity of resulting anemia quite variable ranging from asymptomatic carriers to a fatal in utero disease: depends on the number of functioning α-genes
i. α-thalassemia-2 or silent carrier α-thalassemia (α-/αα) (deficiency of only one globin gene)
a) Twenty-five percent of African Americans
b) 3.4% of Greek Americans
c) Slight microcytic red blood cells
d) Borderline or minimal anemia
ii. α-thalassemia-1 or α-thalassemia trait (– /αα) (deficiency of two globin genes)
a) Fifteen to twenty percent of Thai
b) Mildly anemic

c) Microcytic red blood cells
d) Slight variation in red blood cell size
e) Mild splenomegaly
f) Work capacity not impaired
g) Same phenotypic effect in the individual homozygous for α-thalassemia-2 (α−/α−): This form is much more common in black populations.

iii. Hb H disease or α-thalassemia intermedia (–/−α) (deficiency of three globin genes)
a) One percent of Thai
b) Significant hypochromic anemia in the neonatal period
c) Microcytic anemia
d) Reticulocytosis
e) Jaundice
f) Splenomegaly (may be severe and occasionally complicated by hypersplenism)
g) Growth retardation may be seen in children.
h) Hemolysis precipitated by infections or oxidant drugs (e.g., iron, sulfonamides)
i) Leg ulcers
j) Gallstones
k) Folic acid deficiency
l) Needs occasional transfusions, splenectomy, or avoidance of precipitating drugs
m) Severity of clinical features: related to the molecular basis of the disease: Patients with nondeletional types of Hb H disease are more severely affected than those with the common deletional types of Hb H disease

iv. Hb Bart's hydrops fetalis or α-thalassemia major (–/–) (deficiency of all four globin genes)
a) Most severe form of α-thalassemia
b) Incompatible with life unless intrauterine blood transfusion is given because not enough functional hemoglobin is produced to sustain tissue oxygenation
c) Profound oxygen deprivation in utero with resulting heart failure (hydrops fetalis)
d) Stillborn or die soon after birth
e) Pale edematous infant with signs of cardiac failure (edema and ascites) and prolonged intrauterine anemia
f) Massive hepatosplenomegaly
g) Severe erythroblastic anemia
h) Retardation in brain growth
i) Skeletal and cardiovascular anomalies
j) Enlargement of the placenta

2. β-thalassemia (Cao and Galanello 2010)
a. Found largely in people of African and Mediterranean descent, Far East, Middle East, and the Asian subcontinent
i. Highest incidence
a) Cyprus (14%)
b) Sardinia (12%)
c) Southeast Asia
ii. The high gene frequency of beta-thalassemia in these regions
a) Most likely related to the selective pressure from *Plasmodium falciparum* malaria, as it is indicated by its distribution quite similar to that of present or past malaria endemics. Carriers of beta-thalassemia are indeed relatively protected against the invasion of *Plasmodium falciparum*.
b) However, because of population migration and, to a limited extent, slave trade, beta-thalassemia is, at present, also common in Northern Europe, North and South America, Caribbean, and Australia.

b. Clinical features dependent on reduced (β^+) or absent (β^o) synthesis of β-globin
i. β-thalassemia major (also known as Cooley's anemia or homozygous β-thalassemia)
a) Due to inheritance of two β-thalassemia alleles, one on each copy of chromosome 11
b) Generally recognized to be a homozygous state for whichever thalassemia gene is involved
c) Clinically a severe disorder
d) Infants born free of significant anemia, protected by prenatal Hb F production
e) Onset: 6–12 months
f) Diagnosis: evident by 2 years of age
g) Manifestations in early childhood: anemia, pallor, growth retardation, tiredness, abdominal swelling due to hepatosplenomegaly, infection, and jaundice

h) Manifestations in childhood and adult: severe anemia, infection, tiredness, growth retardation, distinctive facies, hepatosplenomegaly, cardiomegaly, abdominal pain, leg ulcers, osteoporosis, and iron overload
i) At significant risk for developing overwhelming, often fatal infection after splenectomy (postsplenectomy syndrome)
j) Severe anemia usually necessitating chronic blood transfusions
k) Prognosis: average survival of children with untreated thalassemia major (<4 years)

ii. β-thalassemia intermedia (compound heterozygotes)
a) Due to inheritance of two β-thalassemia mutations (one mild and one severe or two mild mutations) or occasionally due to inheritance of complex combinations such as α-β-thalassemia
b) Affected individuals: either compound heterozygotes for two different thalassemia genes or heterozygotes for a structural variant plus a thalassemia gene. Homozygotes for the milder β^+-thalassemia also have thalassemia intermedia.
c) Less severe clinical phenotype: cardiomegaly, osteoporosis, fractures, arthritis, and splenomegaly in some patients
d) Significant anemia but usually do not require chronic blood transfusions

iii. β-thalassemia minor (also known as β-thalassemia trait or heterozygous β-thalassemia)
a) Due to presence of a single β-thalassemia mutation and a normal β-globin gene on the other chromosome
b) Clinically asymptomatic but may have mild or minimal anemia

iv. Silent carrier β-thalassemia
a) No symptoms except for possible low RBC indices
b) Mutation causing thalassemia is very mild and represents β+-thalassemia.

Diagnostic Investigations

1. Screening tests for thalassemias
   a. Low MCV
      i. Increased Hb A_2 and/or Hb F: indicate β-thalassemia syndrome
      ii. Normal Hb A_2 and Hb F, and ferritin >20 ng/mL: suggest possible α-thalassemia syndrome
   b. Normal MCV, normal electrophoresis: thalassemia syndrome unlikely
2. α-thalassemia: More difficult to diagnose because characteristic elevations in Hb A_2 ($\alpha_2\delta_2$) or Hb F ($\alpha_2\gamma_2$), seen in β-thalassemia, do not occur.
   a. α-thalassemia-2
      i. Laboratory notation: FA + Bart's
      ii. Small amount of Hb Bart's (1–2%) in affected infants at birth
      iii. Remainder of the hemoglobin: Hb F and Hb A ($\alpha_2\beta_2$)
      iv. Hb F and Hb Bart's: disappear after a few months of age
      v. Minimal microcytosis: remains
   b. α-thalassemia-1
      i. Laboratory notation: FA + Bart's (impossible to differentiate the two forms of α-thalassemia from the electrophoretic pattern)
      ii. Slightly larger amount of Hb Bart's in cord blood (3–5%)
      iii. Hb F and Hb Bart's: disappear after birth
      iv. Unequivocal microcytosis: Mean red cell volume of 65–70 fl/cell remains.
      v. Abnormally low Hb A_2 proportion
   c. Hb H disease
      i. Reduction in α-chain does not affect the production of β-chain which is produced in excess and tends to form tetramers (β^4 or Hb H).
      ii. Hb A + Hb H (β^4) + Hb Bart's (γ^4)
      iii. Presence of Heinz bodies: inclusions representing β-chain tetramers (Hb H), which are unstable and precipitate in the RBC, giving the appearance of a golf ball
   d. Hb Bart's hydrops fetalis
      i. Hypochromic macrocytes with nucleated red blood cells

ii. γ^4 (Bart's hemoglobin): nonfunctional as an oxygen transporter

3. β-thalassemia
   a. β-thalassemia major
      i. Small, thin, and distorted red blood cells containing markedly reduced amounts of hemoglobin
      ii. Peripheral blood smear
         a) Severe microcytic hypochromic anemia (no anemia at birth)
         b) Anisocytosis
         c) Poikilocytosis (speculated teardrop and elongated cells)
         d) Abundant nucleated red cells (i.e., erythroblasts)
         e) Occasional immature leukocytes
      iii. Hemolytic anemia
      iv. Hemoglobin profile: predominant Hb F
      v. In patient with homozygous β^o-thalassemia: absent Hb A with normal amounts of Hb A_2
      vi. In newborn with β^+-thalassemia: Hb F (about 90%) decreases with advancing age but always considerably higher than normal (10–90%).
   b. β-thalassemia intermedia
      i. Intermediate Hb concentration (8–10 gm/dL)
      ii. Microcytic hypochromic anemia
      iii. Hb F (5–99%)
   c. β-thalassemia minor
      i. Mild hypochromic microcytosis
      ii. Target cells
      iii. Mild to minimal anemia (hemoglobin concentration average 1–2 gm/dL below normal)
      iv. Elevation of Hb A_2 and Hb F (70–99%) during early years of life
      v. Anemia worsen during pregnancy
4. Imaging studies
   a. Chest X-ray to evaluate cardiac size and shape
   b. Skeletal survey
      i. Skeletal response to marrow proliferation
         a) Expanding marrow space
         b) Thinning of cortical bone
         c) Resorption of cancellous bone
         d) Resulting in generalized loss of bone density
         e) Frequent small lucencies resulting from focal proliferation of marrow
         f) "Periosteal response" caused by perforation of the cortex by hypertrophic and hyperplastic marrow subperiosteally
      ii. Classic facies observed in thalassemia major
         a) Classic "hair-on-end" appearance of the skull
         b) Maxilla overgrowth resulting in maxillary overbite
         c) Prominent upper incisors
         d) Separation of the orbits
      iii. Various bone deformities seen in ribs, long bones, and flat bones
      iv. Premature fusion of the epiphyses
   c. MRI/CT scans to evaluate the amount of iron in the liver in patients on chelation therapy
5. Carrier screening
   a. α-thalassemia (Vichinsky 2010)
      i. Commonly, microcytosis using an MCV <82 fL and/or hypochromia (MCH <27 pg) is often used as a population screening technique.
         a) Anemia is unreliable and is often not present in adults with two α-globin gene deletions.
         b) Once iron deficiency is ruled out or corrected, microcytosis should be further evaluated in the individual and his or her partner in order to determine their risk for hydrops.
      ii. Molecular diagnosis for α-globin mutations: essential for at-risk couples
   b. β-thalassemia
      i. Ongoing in several at-risk populations in the Mediterranean (Cao et al. 2002)
      ii. Carrier testing relies on hematological analysis: When the hematological analysis indicates a beta-thalassemia carrier state, molecular genetic testing of *HBB* can be performed to identify a disease-causing mutation.
6. Molecular genetic testing for α- and β-thalassemias
   a. α-thalassemia (Galanello and Cao 2008)
      i. *HBA1*, the gene encoding α_1-globin, and *HBA2*, the gene encoding α_2-globin, are the two genes most commonly associated with α-thalassemia.

ii. Molecular genetic testing of *HBA1* and *HBA2* detects deletions in about 90% and point mutations in about 10% of affected individuals.

b. β-thalassemia (Cao and Galanello 2010)
   i. Molecular genetic testing of the gene encoding the hemoglobin subunit beta (HBB): available clinically
      a) Targeted mutation analysis
      b) Sequence analysis

Genetic Counseling

1. Recurrence risk
   a. α-thalassemia
      i. Patterns of inheritance of the α-thalassemia when both parents are α-thalassemia-1 (−−/αα)
         a) 25% normal
         b) Fifty percent α-thalassemia-1
         c) Twenty five percent Hb Bart's (hydrops fetalis)
      ii. Patterns of inheritance of the α-thalassemia syndrome when one parent is α-thalassemia-1 (−−/αα) and the other parent is α-thalassemia-2 (α-/αα)
         a) Twenty-five percent normal
         b) Twenty-five percent α-thalassemia-1
         c) Twenty-five percent α-thalassemia-2
         d) Twenty-five percent Hb H disease
      iii. If the carrier of α^{+}-thalassemia is a homozygote, clearly, the risk of Hb H disease is 1:2 (50%) (Harteveld and Higgs 2010)
      iv. Patient's offspring: not increased unless the spouse is a carrier
      v. Twenty-five percent of African Americans have heterozygous α-thalassemia-2 (α-/αα). Thus, 1.5% are homozygotes for α-thalassemia-2 (α-/α-). But since the more severe α-thalassemia-1 is not present, subsequent children are not at risk of having Hb H or Bart's hydrops fetalis.
   b. β-thalassemia
      i. Patient's sib: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier

2. Prenatal diagnosis: available to all families at risk of either severe α-thalassemia or β-thalassemia
   a. α-thalassemia
      i. Ultrasonography (Tongson et al. 1998)
         a) Hepatosplenomegaly (>90%)
         b) Cardiomegaly (>90%)
         c) Edematous placenta (>90%)
         d) Ascites (>90%)
         e) Oligohydramnios (82%)
         f) Subcutaneous edema (75%)
         g) Decreased fetal movement (74%)
         h) Cord edema (63%)
         i) Enlarged umbilical vessel (62%)
         j) Pericardial or pleural effusion (15%)
      ii. Molecular hybridization technique to detect complete absence of α-genes in fetal amniocytes in a pregnancy at risk for homozygous α-thalassemia-1 and the hydrops fetalis syndrome
      iii. Quantitative polymerase chain reaction for the rapid prenatal diagnosis of homozygous α-thalassemia (Hb Bart's hydrops fetalis)
   b. β-thalassemia
      i. Available to couples who are carriers of β-thalassemia and their hemoglobin gene mutations have been identified by DNA analysis
      ii. Direct DNA analysis by molecular hybridization methods for the presence of the thalassemia mutation from fetal cells obtained by amniocentesis and chorionic villus biopsy
      iii. DNA analysis of fetal nucleated RBCs from maternal peripheral blood
      iv. Approach to prenatal diagnosis complicated by presence of the heterogeneity of thalassemia mutations
      v. Preimplantation genetic diagnosis available for at-risk pregnancies requires prior identification of the disease-causing mutations in the family.

3. Management
   a. α-thalassemia (Segel et al. 2002)
      i. No therapy necessary for patients with α-thalassemia trait
      ii. Avoid exposure to oxidant medications (e.g., iron, sulfonamides) which accelerate precipitation of Hb H and exacerbate hemolysis

iii. Prompt treatment of infection especially in postsplenectomy
iv. Hb H disease
  a) Folate supplementation
  b) Chronic transfusion therapy (consider iron chelation therapy to avoid iron overloading)
  c) Splenectomy in rare instances of hypersplenism
  d) Allogeneic bone marrow transplantation limited to the most severely affected patients
v. Bart's hemoglobinopathy
  a) Usually results in neonatal death
  b) Patients rarely salvaged by intrauterine transfusions and subsequent stem cell transplantation
  c) The diagnosis, management, and prognosis of homozygous α-thalassemia/hydrops fetalis is changing; advances in antenatal diagnosis, intrauterine intervention, and postnatal therapy have resulted in long-term survival of children previously felt to have an invariably fatal disease(Singer et al. 2000; Weisz et al. 2009; Vichinsky 2010).

b. β-thalassemia
  i. No specific therapy required for β-thalassemia trait
  ii. Regular blood transfusions in thalassemia major
    a) Correct the anemia
    b) Suppress erythropoiesis
    c) Inhibit increased gastrointestinal absorption of iron
  iii. Treatment of individuals with thalassemia intermedia
    a) Symptomatic treatment
    b) Splenectomy
    c) Folic acid supplementation
    d) Treatment of extramedullary erythropoietic masses (radiotherapy, transfusions, or hydroxyurea in selected cases)
  iv. Iron chelation with desferrioxamine to eliminate the iron overload secondary to multiple blood cell transfusions and to increase iron absorption
  v. Bone marrow transplantation
    a) From an HLA-identical sib
    b) Outcome dependent on pretransplantation clinical conditions, specifically the presence of hepatomegaly, extent of liver fibrosis, and magnitude of iron accumulation
    c) Risk of chronic graft-versus-host disease of variable severity: 5–8%
  vi. Cord blood transplantation (Kelly et al. 1997)
    a) Human umbilical cord blood contains hematopoietic stem cells capable of reconstituting bone marrow.
    b) Possibility of using cord blood obtained from unrelated donors with a decrease in the incidence of graft-versus-host disease
  vii. Attempts to increase Hb F production by following agents: variable without substantial effects
    a) 5-azacytidine
    b) Erythropoietin
    c) Butyrate compounds
    d) Hydroxyurea
  viii. Hematopoietic stem cells to correct the molecular defect by transfer of a normal gene via a suitable vector or by homologous recombination: currently under investigation

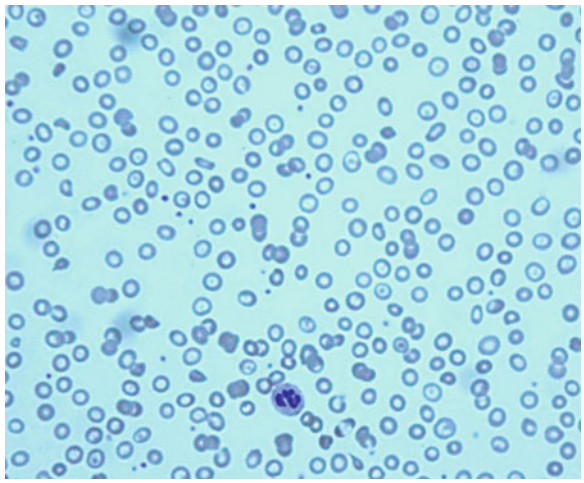

Fig. 1 Peripheral blood smear from a 58-year-old woman with microcytic anemia and frequent target cells (codocytes). Hemoglobin electrophoresis showed an AA pattern with an increased hemoglobin A_2 (5.8% by HPLC) consistent with beta$^+$- thalassemia trait

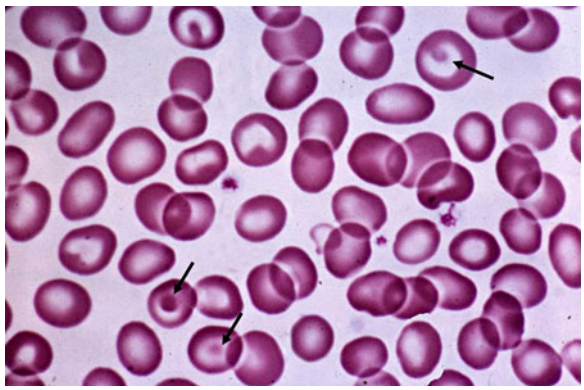

Fig. 2 Peripheral blood smear from a patient with alpha-thalassemia minor shows hypochromia, target cells (*arrows*), and anisopoikilocytosis (Wright-Giemsa stain, ×1,000)

Thanatophoric Dysplasia

Thanatophoric dysplasia was originally described by Maroteaux et al. in 1967. The term "thanatophoric" was coined to mean "death bearing" in Greek. Thanatophoric dysplasia is probably the most common lethal neonatal dwarfism with an estimated incidence of 0.2–0.5 per 10,000 births.

Synonyms and Related Disorders

Thanatophoric dysplasia type I (thanatophoric dwarfism, lethal short-limbed platyspondylic dwarfism, San diego type, platyspondylic lethal skeletal dysplasia, San Diego type); Thanatophoric dysplasia type II (cloverleaf skull with thanatophoric dwarfism, thanatophoric dysplasia with kleeblattschaedel, thanatophoric dysplasia with straight femur and cloverleaf skull)

Genetics/Basic Defects

1. Genetic heterogeneity
   a. Sporadic in most cases
   b. A new autosomal dominant mutation
   c. Caused by mutations in the transmembrane domains of the fibroblast growth factor receptor 3 (*FGFR3*)
2. Having the most extreme micromelia and the most extensive craniofacial involvement compared to two other short limb skeletal dysplasias (achondroplasia and hypochondroplasia) which are also caused by mutations of *FGFR3*
3. Pathogenesis for the phenotypic features of thanatophoric dysplasia
   a. Normal function of *FGFR3*: to regulate endochondral ossification by "putting the brakes on growth"
   b. "Gain-of-function" type of known mutations on *FGFR3*
      i. Primarily affects the cranial base and nasal capsule (endochondral bones)
      ii. With secondary effect on membrane bones which articulates with endochondral bones
4. Two major forms (TD1, TD2) of thanatophoric dysplasia, postulated based on subtle differences in skeletal radiographs and the underlying genetic mutation
   a. TD1
      i. Curved femora
      ii. Very flat vertebral bodies
      iii. Very few TD1 patients with cloverleaf skull
      iv. Molecular defect consisting of a stop codon mutation or missense mutation in the extracellular domain of the FGFR3 protein, resulting in a newly created cysteine residue (Arg248Cys, most common)
   b. TD2
      i. Straight femora
      ii. Taller vertebral bodies
      iii. Most TD2 patients with cloverleaf skull (severe craniosynostosis)
      iv. Molecular defect consisting of a single nucleotide substitution resulting in replacement of lysine with glutamine at position 650 (Lys650Glu) in the tyrosine kinase 2 domain of the receptor
5. Activating mutations in the *FGFR3* gene can cause following conditions:
   a. Achondroplasia

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_228,
© Springer Science+Business Media, LLC 2012

b. Thanatophoric dysplasia type I and type II
c. Hypochondroplasia
d. Severe achondroplasia with developmental delay and acanthosis nigricans

Clinical Features

1. Unique and homogeneous clinical features observed in patients with TD1
2. General features
   a. Virtually lethal neonatally
   b. A few reports with survival up to 4–5 years of age with aggressive neonatal intervention
      i. Markedly limited growth potential
      ii. Markedly delayed cognitive development
      iii. Respiratory insufficiency
      iv. Neurologic abnormalities
      v. Long-term medical care and chronic ventilator dependence
3. Craniofacial features
   a. Head
      i. Disproportionally large (macrocephaly)
      ii. Frontal bossing
      iii. With or without cloverleaf (Kleeblattschdel) anomaly of the skull resulting from premature closure of cranial sutures
   b. Facial features
      i. Bulging eyes
      ii. Hypertelorism
      iii. Severely depressed or indented nasal bridge
4. Short neck
5. Chest
   a. Extremely narrow
   b. Constricted thoracic cage
   c. Reduced size of the thoracic cavity
   d. Short ribs
   e. Hypoplastic lungs
6. Protuberant abdomen
7. Limbs
   a. Extremely short
   b. Thickened skin
   c. Excessive skin folds
   d. Usually outstretched arms
   e. Externally rotated legs with abducted thighs
   f. Syndactyly
8. Early death in most children secondary to:
   a. Chest constriction and consequent respiratory insufficiency
   b. Foramen magnum stenosis resulting in failure of respiratory control
9. A few children with longer survival (up to 9–10 years)
   a. Respiratory insufficiency
      i. Reduced chest circumference
      ii. Upper cervical cord compression resulting from a diminutive foramen magnum
   b. Markedly limited growth potential
   c. Markedly delayed cognitive development
   d. Seizures
   e. Hearing loss
   f. Additional CNS anomalies (Baker et al. 1997)
      i. Hydrocephalus
      ii. Polymicrogyria
      iii. Neuronal heterotopia
      iv. Megalencephaly
      v. Cerebral gyral disorganization
      vi. Hippocampal malformation
      vii. Temporal lobe malformations
      viii. Nuclear dysplasia
      ix. Abnormal axonal bundles
      x. Cerebellar hypoplasia in the small posterior fossa
      xi. Partial agenesis of the corpus callosum
      xii. Spinal stenosis
      xiii. Hyperreflexia
      xiv. Clonus
   g. Acanthosis nigricans, an associated rare skin disorder
10. Differential diagnosis (Schild et al. 1996)
   a. Achondroplasia
      i. Autosomal dominant disorder
      ii. Rhizomelic shortening of the bones, less prominent than thanatophoric dysplasia
      iii. Macrocrania
      iv. Heterozygous achondroplasia
         a) Compatible with normal life span
         b) Normal intelligence
      v. Homozygous achondroplasia with two affected parents
   b. Campomelic dysplasia
      i. Autosomal recessive disorder
      ii. Typical anterior bowing of the lower limbs
      iii. Hypoplastic fibula
      iv. Hypoplastic scapulae
      v. A sex reversal phenomenon (phenotypical female with male karyotype)
   c. Osteogenesis imperfecta type II and type III

i. Varying degree of bone demineralization
ii. Shortened long bones with multiple fractures
iii. Blue sclerae
iv. Polyhydramnios frequently associated with type II

d. Hypophosphatasia
i. Demineralization of bone tissue
ii. Lack of calcification of the fetal skull
iii. Mild to moderate shortening of limb bones
iv. Difficult to differentiate from osteogenesis imperfecta if fractures are present

e. Achondrogenesis
i. Severe micromelia
ii. Poor ossification of the vertebral bodies, cranium, pelvis, and sacrum
iii. Narrow and shortened thorax
iv. Frequent complications with fetal hydrops and hydramnios

f. Short rib-polydactyly and other rare skeletal dysplasia syndromes

Diagnostic Investigations

1. Radiographic features
a. Skull
i. Relatively large calvarium
ii. A small foramen magnum
iii. Trilobed skull with a towering calvarium and bitemporal bulging in the cloverleaf skull type (type II)

b. Ribs
i. Very short ribs with cupped anterior ends
ii. Short ribs (type II)

c. Vertebrae
i. Flat vertebral bodies (platyspondyly)
ii. Increasing intervertebral disc space
iii. "Inverted U–shaped or H-shaped" vertebral bodies
iv. Narrow interpedunculate distance at the lumbar level
v. Taller vertebral bodies (type II)

d. Pelvis
i. Short
ii. Small sacrosciatic notches

e. Tubular bones
i. Extremely shortened long bones of the limbs
ii. Rhizomelic shortening of the limbs
iii. Flared metaphyses
iv. "Telephone receiver"–like curved femora in the noncloverleaf type
v. Relatively straight femora (type II)

2. Histologic features
a. Generalized disruption of endochondral ossification
i. Hallmark of the histologic findings
ii. Physeal growth zone shows minimal proliferation and hypertrophy of chondrocytes with absence of column formation.
iii. Lateral overgrowth of metaphyseal bone around the physis
iv. Mesenchymal cells extending inward from the perichondrium as a narrow band at the periphery of the physeal zone (the so-called fibrous band)
v. Increased vascularity of the resting cartilage

b. Brain
i. Neuronal migration abnormalities of the temporal lobe
ii. Hydrocephalus
iii. Partial agenesis of the corpus callosum
iv. Upper cord compression
v. Spinal stenosis

3. DNA mutation analysis of *FGFR3*
a. TD1
i. 742C → T (Arg248Cys): most common
ii. Tyr373Cys
iii. Ser249Cys
iv. Other missense mutations
v. Stop codon mutations

b. TD2: missense mutation of 1948A → G (Lys650Glu) in TD2

c. Clinical testing
i. Targeted mutation analysis
ii. Sequence analysis of select regions of FGFR3 or of the entire *FGFR3* coding region

Genetic Counseling

1. Recurrence risk
a. Patient's sib: about 2%
b. Patient's offspring: not surviving to reproduction age

2. Prenatal diagnosis
a. Ultrasonography
i. Hydramnios in most cases

ii. Megacephaly with or without cloverleaf-shaped skull
iii. Progressive hydrocephaly
iv. Hypoplastic thorax disproportionately small in relation to the abdomen
v. Small chest and lung measurement to predict severe pulmonary hypoplasia
vi. Short ribs
vii. Short limbs with curved "telephone handle–shaped" or straight femurs
viii. Excessive skin giving fetus a "boxer's face" appearance
ix. Flattened vertebrae with increased intervertebral spaces, giving the vertebral bodies the form of an "H"

b. Prenatal radiography for documenting characteristic skeletal anomalies
c. DNA mutation analysis of *FGFR3* in fetal cells from amniocentesis or CVS
d. Prenatal and preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified

3. Management
a. Limited intervention
i. Appropriate because of the inevitable lethal outcome
ii. Aggressive neonatal management, at times, not even resulting in short-term survival
b. Debatable issues about the level of intensity of medical care for unanticipated long-term survival
i. Long-term medical care
ii. Chronic ventilator support
iii. Requiring extensive health maintenance measures
iv. Anticipate frequent medical exacerbations requiring recurrent hospitalizations
v. Possibility of lethal complication, an ever present concern
vi. Special education programs for the longer survivals

Fig. 1 (**a**–**c**) Front views of three infants showing frontal bossing, flat facies, short neck, micromelia, and small chest

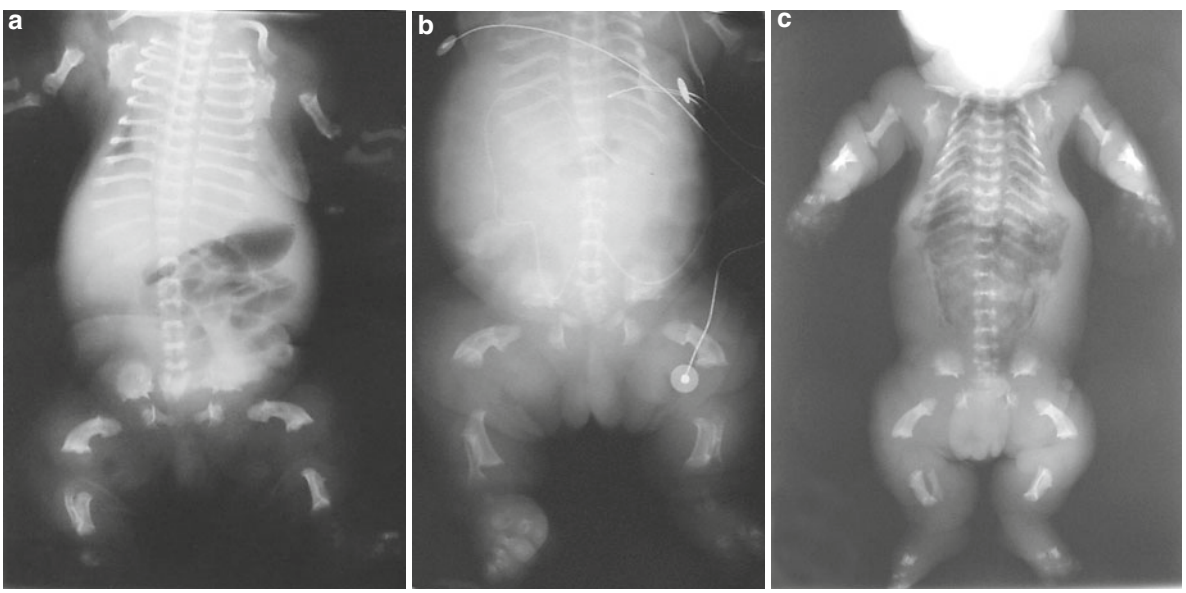

Fig. 2 (**a**–**c**) AP radiographic views of three infants with typical findings of TD1 showing profound platyspondyly, decreased thoracic volume, characteristic pelvic configuration, micromelia, and so-called "telephone receiver" femoral bowing

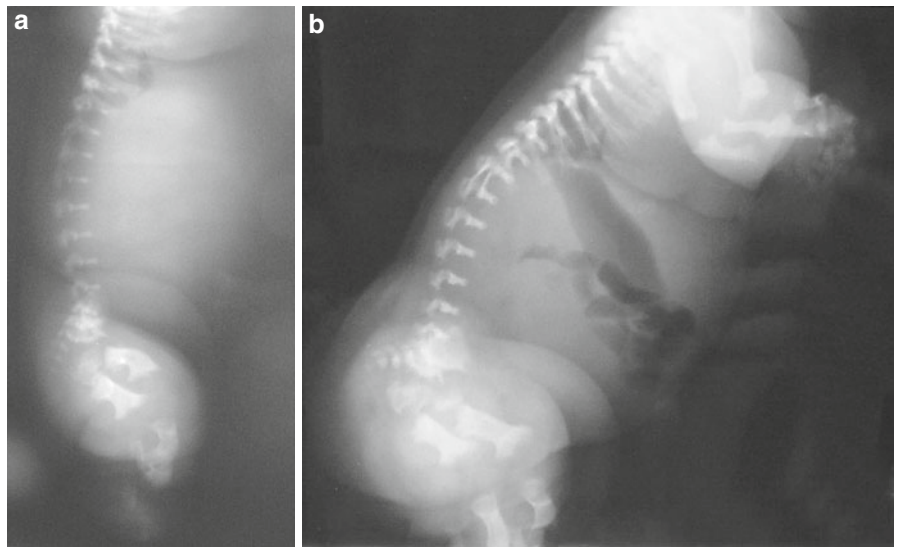

Fig. 3 (**a**, **b**) Lateral radiographic views of the spines of two infants with typical TD1 showing extreme platyspondyly and short ribs

Fig. 4 Gross appearance of a femur resembling a "telephone receiver"

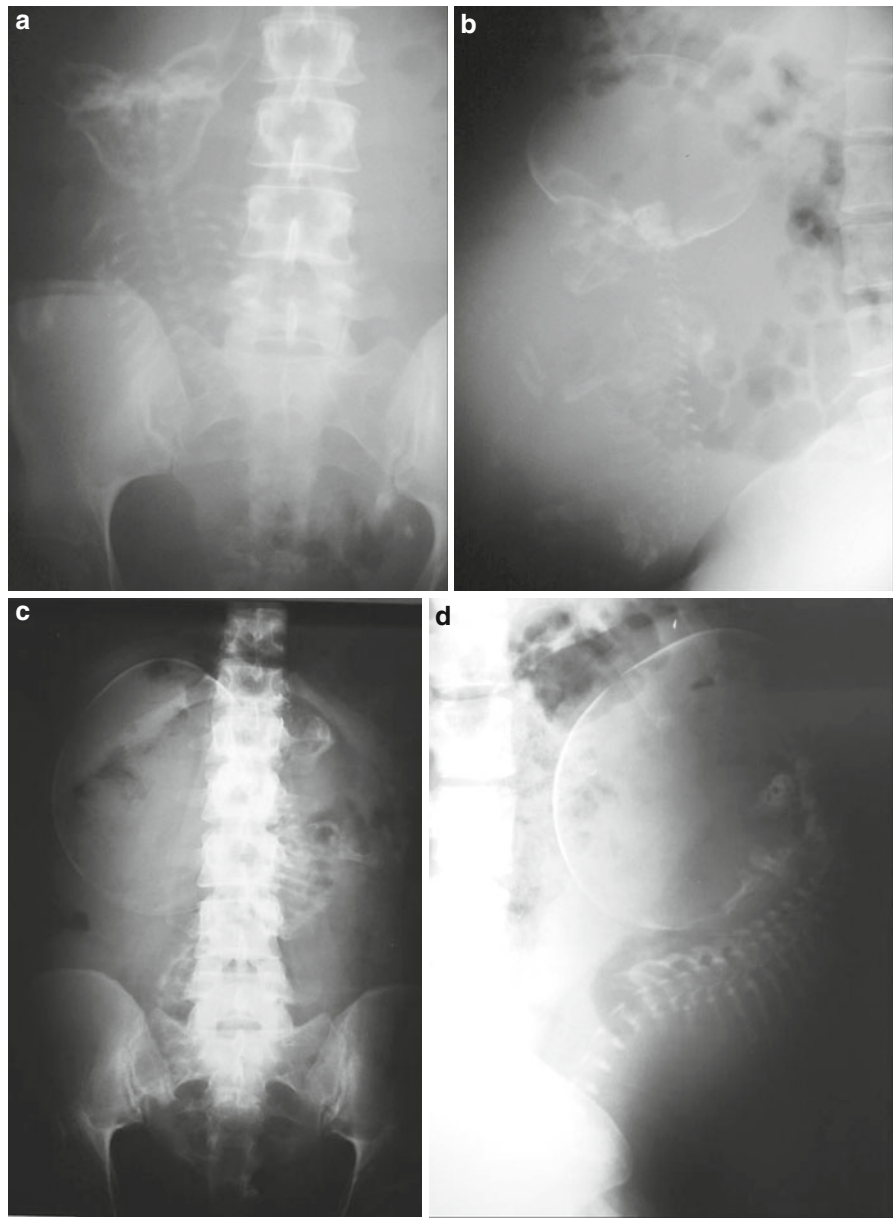

Fig. 5 (**a**–**d**) Prenatal radiographs of two fetuses affected with thanatophoric dysplasia showing platyspondyly, short ribs, and micromelia

Fig. 6 Thanatophoric dysplasia in identical twin fetuses. The pregnancy was terminated following ultrasonographic diagnosis at 22 weeks' gestation. The placenta was diamniotic monochorionic, consistent with monozygotic pregnancy

Fig. 7 Thanatophoric dysplasia with cloverleaf skull in a neonate. The head is large and trilobed. The narrow chest and rhizomelic shortening of limbs are similar to those of classic thanatophoric dysplasia. Radiograph revealed platyspondyly and small ilium that are similar to those of classic thanatophoric dysplasia (not shown). However, the femur is straight and not as curved as seen in the classic type

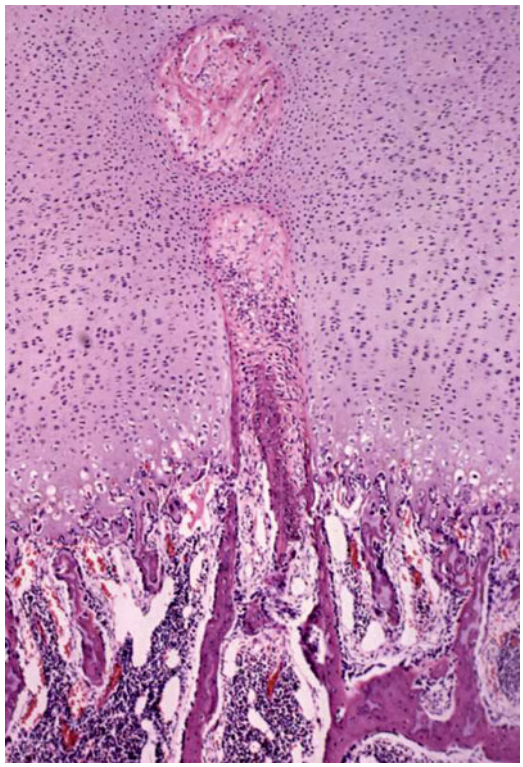

Fig. 8 Photomicrograph of the cartilage-bone junction, cloverleaf skull type of thanatophoric dysplasia. The physeal growth zone is markedly retarded and disorganized. Similar changes are seen in the classic type thanatophoric dysplasia. A partially ossified cartilage canal is present at the center of physis. It is more prominent in size and number in cloverleaf type than in classic type

Fig. 9 A neonate with short limb dwarfism, characterized by flat face, short neck, short chest, and micromelia. A single sequence mutation (Nt742C > T) was identified in the *FGFR3* gene. This causes the substitution of arginine for cysteine at codon 248 (C248R). This mutation has been previously reported in thanatophoric dysplasia type I

Thrombocytopenia-Absent Radius Syndrome

Thrombocytopenia-absent radius (TAR) syndrome is a congenital malformation syndrome characterized by bilateral absence of the radii and congenital thrombocytopenia.

Synonyms and Related Disorders

TAR syndrome

Genetics/Basic Defects

1. Genetic inheritance: unknown but autosomal recessive inheritance was suspected based on the following observations
   a. Families with at least two affected children born to unaffected parents
   b. Rare instances of association with consanguinity
2. Associated with an interstitial microdeletion of 200 kb on chromosome 1q21.1 in all 30 investigated patients with TAR syndrome, detected by microarray-based comparative genomic hybridization (Klopocki et al. 2007)
   a. Analysis of the parents revealed that this deletion occurred de novo in 25% of affected individuals.
   b. The phenotype develops only in the presence of an additional as-yet-unknown modifier.
3. Etiology of thrombocytopenia: unknown but is considered to be the result of a decreased production of platelets from the bone marrow

Clinical Features

1. Thrombocytopenia (100%)
   a. May be transient
   b. Symptomatic in over 90% of cases within the first 4 months of life
      i. Purpura
      ii. Petechiae
      iii. Epistaxis
      iv. Gastrointestinal bleeding
         a) Hematemesis
         b) Melena
      v. Hemoptysis
      vi. Hematuria
      vii. Intracerebral bleeding
   c. More severe thrombocytopenia can be precipitated by stress, infection, gastrointestinal disturbances, or surgery (Fayen and Harris 1980).
   d. Platelet count tends to rise as the child gets older and may approach normal levels in adulthood (spontaneous improvement of platelet counts after 1 year).
2. Upper extremity anomalies (100%) (Hall 1987)
   a. Bilateral absence of the radius (100%): the most striking skeletal manifestation
   b. Hand anomalies
      i. Presence of the thumbs (100%)
         a) An important clinical feature distinguishing TAR syndrome from other disorders featuring radial aplasia, which are usually associated with absent thumbs
         b) Relatively functional thumbs

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_229,

© Springer Science+Business Media, LLC 2012

c) Thumbs often adducted
d) Thumbs often hypoplastic
ii. Radially deviated
iii. Limited extension of the fingers
iv. Hypoplasia of the carpal and phalangeal bones
c. Associated ulnar anomalies
i. Usually short
ii. Usually malformed
iii. Absent ulna
a) Absent bilaterally in about 20% of cases
b) Absent unilaterally in about 10% of cases
d. Associated humeral anomalies
i. Often abnormal in about 50% of cases
ii. Absent humeri in about 5–10% of cases (rare phocomelia)
e. Associated shoulder and arm anomalies
i. One arm shorter than the other in about 15% of cases
ii. Hypoplasia of muscles and soft tissue in the arm and shoulder
iii. Abnormal shoulder joint secondary to abnormal humeral head
3. Lower limb anomalies (47%)
a. Correlation exists between the severity of skeletal changes in the lower limbs and the severity of abnormalities of the upper limbs.
b. Variable involvement but usually milder than the upper limbs
i. Dislocation of the patella and/or of the hips
ii. Knee involvement
a) Dysplasia: rare severe knee dysplasia due to agenesis of cruciate ligaments and menisci
b) Ankylosis
c) Subluxation
iii. Hip dislocation
iv. Coxa valga
v. Absent tibiofibular joint
vi. Femoral or tibial torsion
vii. Lower limb phocomelia
viii. Valgus and varus foot deformities
ix. Abnormal toe placement
x. Severe cases with lower limb phocomelia
4. Cow's milk intolerance (62%)
a. Presentation symptoms
i. Persistent diarrhea
ii. Failure to thrive
b. Thrombocytopenia episodes
i. Precipitated by introduction of cow's milk
ii. Relieved by its exclusion from the diet
5. Urogenital anomalies (23%)
a. Horseshoe kidney
b. Absent uterus
6. Cardiac anomalies (22–33%)
a. Tetralogy of Fallot
b. Atrial septal defect
c. Ventricular septal defect
7. Other associated congenital anomalies
a. Facial capillary hemangiomata in the glabella region
b. Micrognathia
c. Cleft palate
d. Intracranial vascular malformation
e. Sensorineural hearing loss
f. Epilepsy
g. Other skeletal anomalies
i. Scoliosis
ii. Cervical rib
iii. Fused cervical spine
iv. Short stature
h. Neural tube defect
8. Prognosis
a. Variable clinical course among patients
b. Survival related to the severity and duration of thrombocytopenia
c. Good prognosis after surviving the first year of life
d. Early diagnosis and treatment with platelet therapy minimize mortality risks.
e. Mental retardation secondary to intracranial bleed (7%)
f. Good hand and upper extremity functions, especially if bilateral radial aplasia is the only skeletal abnormality
9. Differential diagnosis (Hedburg and Lipton 1988 Greenhalgh et al. 2002)
a. Holt-Oram syndrome
i. An autosomal dominant condition caused by mutations in the *TBX5* gene
ii. Often with a family history of heart and limb defects
iii. Absence of the thumb associated with radial aplasia
iv. Absence of thrombocytopenia
b. Roberts syndrome
i. An autosomal recessive trait
ii. Pre- and postnatal growth retardation

iii. Facial clefting
iv. Genitourinary abnormalities
v. Limb defects involving upper or lower limbs or both
vi. Characteristic chromosome abnormality in the majority (79%) of cases
  a) Premature centromeric separation (PCS)
  b) "Puffing" of the chromosomes caused by repulsion of the heterochromatic regions near the centromeres of chromosomes 1, 9, and 16 with splaying of the short arms of the acrocentric chromosomes and of distal Yp.33
  c) Evidence of abnormal mitosis
vii. Postulated that TAR syndrome and Roberts syndrome might be part of the same condition, with TAR syndrome being the milder and Roberts the severer variant

c. Fanconi anemia
  i. An autosomal recessive disorder
  ii. Bone marrow failure
  iii. Skeletal defects
  iv. Cutaneous pigmentation
  v. Microcephaly
  vi. Short stature
  vii. May present with thrombocytopenia
  viii. Upper limb abnormalities also involve the radial ray.
  ix. Hypoplastic thumbs may be accompanied by radial hypoplasia but absence of the radius is associated with absence of the thumbs.
  x. Spontaneous chromosome breakage, a consistent feature of Fanconi anemia and is a reliable diagnostic test

d. Aase syndrome
  i. Radial hypoplasia
  ii. Triphalangeal thumbs
  iii. Hypoplastic anemia, similar to Blackfan-Diamond syndrome
  iv. Thrombocytopenia not a feature

e. Thalidomide embryopathy
  i. May present with radial anomalies of the upper limb
  ii. Malformations of the lower limbs showing a less consistent pattern
  iii. Diagnosed based on:
    a) Phenotype
    b) History of exposure to thalidomide during pregnancy
    c) Increasing use of thalidomide as a therapeutic agent for the treatment of conditions such as Beçhet disease, graft versus host disease, multiple myeloma, and Kaposi sarcoma

f. Rapadilino syndrome
  i. Absent thumbs and radial aplasia/hypoplasia
  ii. Patellar aplasia/hypoplasia
  iii. Cleft palate

g. Other syndromes with limb reduction abnormalities predominantly involving the upper extremities (Donnenfeld et al. 1990)
  i. Adams-Oliver syndrome
    a) Transverse limb defects
    b) Aplasia cutis congenita
    c) Growth deficiency
  ii. Aglossia-adactylia
    a) Absence/hypoplasia of digits
    b) Absence/hypoplasia of the tongue
  iii. Amniotic band sequence
    a) Limb constriction or amputation
    b) Asymmetric facial clefts
    c) Cranial defects
    d) Compression deformities
  iv. CHILD syndrome
    a) Unilateral hypomelia
    b) Ichthyosiform erythroderma
    c) Cardiac septal defect
  v. Cornelia de Lange syndrome
    a) Micromelia
    b) Growth deficiency
    c) Facial dysmorphism
  vi. Femur-fibula-ulnar syndrome
    a) Femoral/fibular defects associated with malformations of the arms
    b) Amelia
    c) Peromelia at the lower end of the humerus
    d) Humeroradial synostosis
    e) Defects of the ulna and ulnar rays
  vii. Poland anomaly
    a) Unilateral defect of pectoralis major muscle
    b) Ipsilateral limb abnormalities
  viii. VATER association (vertebral, anal, tracheoesophageal, renal, and radial anomalies)
  ix. Weyers ulnar ray/oligodactyly syndrome
    a) Deficient ulnar and fibular rays
    b) Oligodactyly
    c) Hydronephrosis

h. Megakaryocytic aplasia
   i. Amegakaryocytic thrombocytopenia
   ii. Congenital hypoplastic thrombocytopenia with microcephaly
   iii. Thrombocytopenia associated with trisomy 13 and trisomy 18

Diagnostic Investigations

1. Hematological studies
   a. Blood platelet counts: thrombocytopenia
   b. Anemia secondary to bleeding
   c. Eosinophilia
   d. Leukemoid reaction (Hall 1987)
      i. Reported in about 60–70% of patients during the first year of life
      ii. White blood counts >35,000 per mm^3 with a shift to the left, particularly with the stress and infections
      iii. Usually associated with worse thrombocytopenia and often with hepatosplenomegaly
   e. Bone marrow aspirates
      i. Normal or hypercellular bone marrow
      ii. Hypomegakaryocytic thrombocytopenia (<100,000 platelets per mm^3) (Hall 1987)
         a) Absence of megakaryocytes in two thirds of cases
         b) Decreased in number of megakaryocytes, which are small, immature, basophilic, and vacuolated, in the rest of cases
2. Chromosome analysis: normal to differentiate from chromosome abnormality syndrome
3. Array comparative genomic hybridization (aCGH) (Toriello 2009)
   a. Individuals with TAR syndrome have a minimally deleted 200-kb region at chromosome band 1q21.1, which is distinct from the region involved in the 1q21.1 deletion/duplication syndrome.
   b. Deletion of this segment is necessary but not sufficient to cause the phenotype.
   c. Identification of the 200-kb minimally deleted region is sufficient to verify the diagnosis of TAR syndrome in individuals with bilateral absence of the radius and presence of thumbs.
4. Radiography
   a. Upper extremities
      i. Bilateral radial aplasia
      ii. Radial club hand
      iii. Hypoplastic carpals and phalanges
      iv. Thumb and fingers always present
      v. Hypoplastic ulnae, humeri, and shoulder girdles
      vi. Syndactyly and clinodactyly of fingers and toes
   b. Lower extremities
      i. Hip dislocation
      ii. Femoral torsion
      iii. Tibial torsion
      iv. Knee dysplasia
      v. Absent patella
      vi. Valgus and varus foot deformities
      vii. Abnormal toe placement
      viii. Overriding toes

Genetic Counseling

1. Recurrence risk (Toriello 2009)
   a. The mode of inheritance of TAR syndrome is unknown.
   b. Presence of the minimally deleted 200-kb region at chromosome band 1q21.1 is necessary but not sufficient to cause the phenotype.
   c. Approximately 75% of probands have inherited the 200-kb minimally deleted region from one of his/her unaffected parents; the deletion occurs de novo in about 25% of probands.
   d. Sibs of a proband are at increased risk of also having TAR syndrome, although the recurrence risk appears to be less than 25%.
   e. Although reports of parent-to-child transmission have been published, no empiric risk figures are available.
   f. Patient's offspring
      i. Offspring of a proband are at increased risk of also having TAR syndrome.
      ii. Although reports of parent-to-child transmission have been published, no empiric risk figures are available.
      iii. The risk to each child of an individual with TAR syndrome of inheriting the 200-kb minimally deleted region at 1q21.1 is 50%. However, the presence of the deletion alone is not sufficient to cause TAR syndrome.
2. Prenatal diagnosis: reported mostly in pregnancies with a prior affected sibling (Donnenfeld et al. 1990; Toriello 2009)

a. Ultrasonography
   i. Bilateral radial aplasia
   ii. Club hands with normal thumbs and metacarpals
b. Cordocentesis to evaluate fetal platelet count (thrombocytopenia) and anemia
c. Identification of the interstitial microdeletion 1q21.1 in an unaffected parent and detection of the same microdeletion in a terminated fetus with upper limb deformities (Uhrig et al. 2007). Physical examination of the fetus revealed malformed upper extremities and absence of both radii, with opposable thumbs in an adducted position.
d. Prenatal diagnosis for pregnancies at increased risk for TAR syndrome is possible using molecular genetic testing to detect the 200-kb minimally deleted region and ultrasound examination to evaluate the limbs.

3. Management (McLaurin et al. 1999; Wu et al. 2003)
   a. Platelet infusions
      i. Remains the only real option for treatment of thrombocytopenia
      ii. To prevent the intracerebral hemorrhage, which was previously the main cause of mortality
      iii. Potential risks of platelet transfusion
         a) Infection (hepatitis viruses, HIV)
         b) Anaphylaxis
         c) Hemolytic reaction
   b. Injury prevention strategies
      i. Avoid contact sports
      ii. Use appropriate protective gear (helmet, padding)
   c. Splenectomy usually effective for the treatment of thrombocytopenia in adults
   d. Bone marrow transplantation as an option for patients who continue to remain thrombocytopenic with bleeding despite platelet transfusions
   e. Physical and occupational therapies to improve function and quality of life
   f. Management of the upper extremity
      i. Postpone surgery till later as thrombocytopenic-related bleeding problems are less frequent in older individuals.
      ii. Prosthetic fitting is generally rejected by patients as most patients are able to perform tasks by approximating themselves closely enough to an object to use their own hands.
      iii. Adaptive devices for feeding, dressing, and toileting are generally well tolerated.
   g. Management of the lower extremity
      i. Rejection of any lower extremity intervention by most patients
      ii. Use of power wheelchair or motorized cart for ambulation

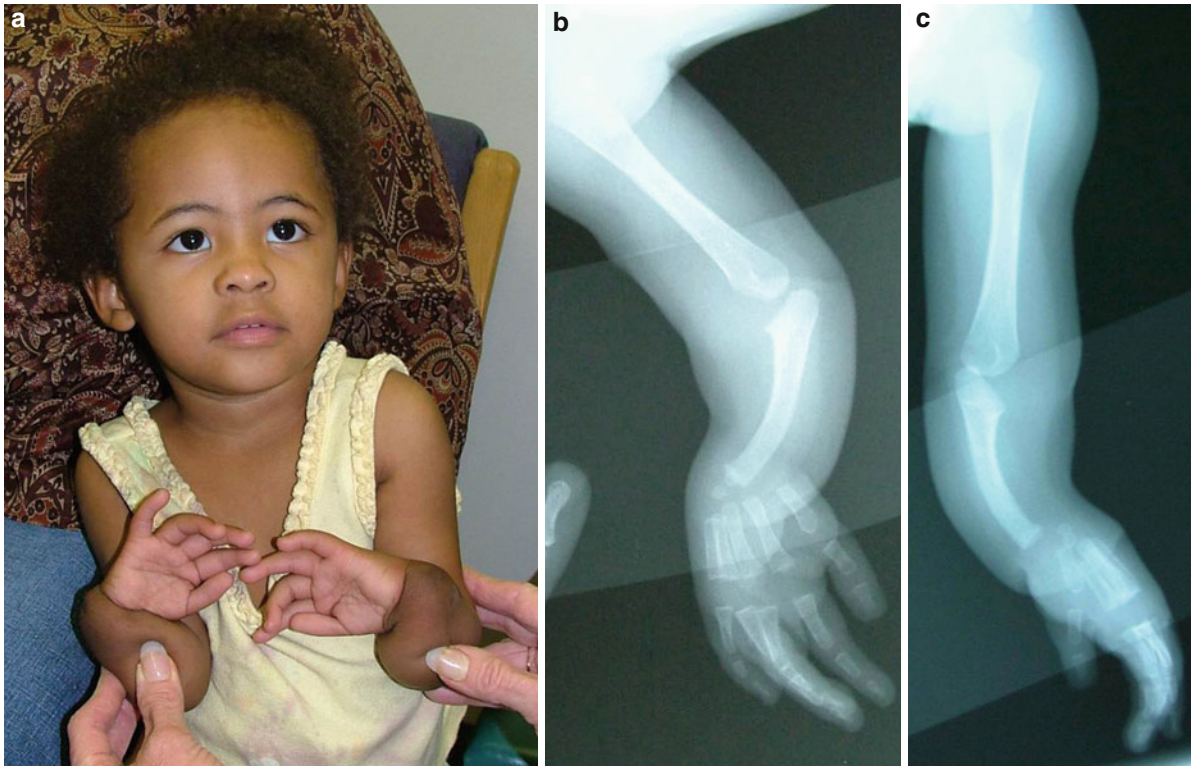

Fig. 1 (**a**–**c**) A 2 1/2-year-old girl with TAR syndrome showing club hands with fingerlike thumbs and radial aplasia, illustrated by radiographs. The patient had thrombocytopenia early in life

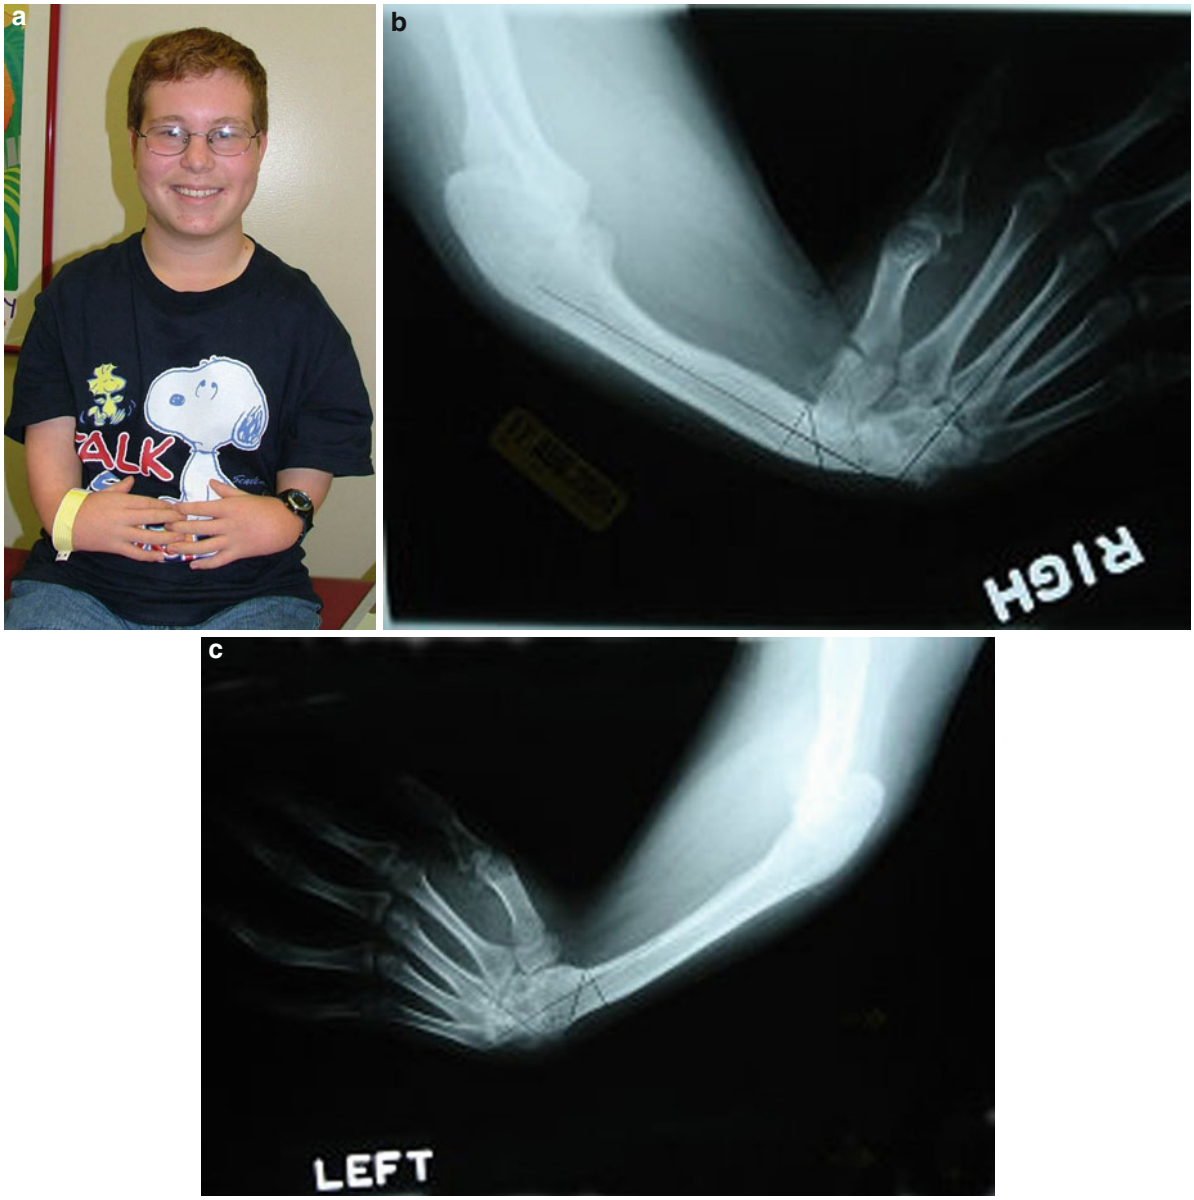

Fig. 2 (**a**–**c**) A 14-year-old boy with TAR syndrome showing similar clinical and radiographic features

Fig. 3 (**a**–**c**) An 8-month-old boy was noted to have club hands with radial aplasia. Platelet count was 28,000 at birth. He was diagnosed to have thrombocytopenia necessitating repeat platelet infusions

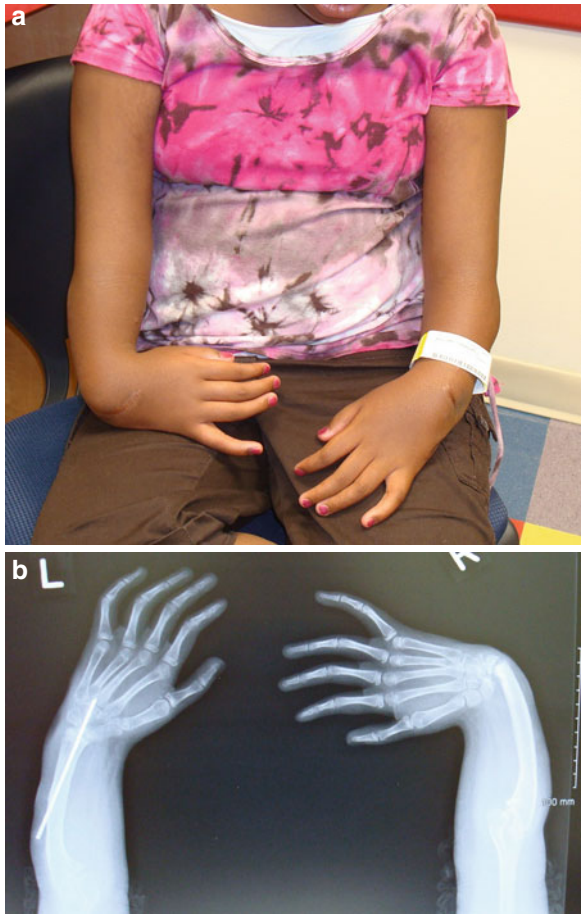

Fig. 4 (**a**, **b**) An 8-year-old girl with TAR syndrome showing similar clinical and radiographic features

Treacher-Collins Syndrome

Treacher-Collins syndrome (TCS), also called Treacher Collins-Franceschetti syndrome or mandibulofacial dysostosis, is an autosomal dominant disorder affecting the development of structures derived from the first and second branchial arches during early embryonic development (Poswillo 1975). The incidence is estimated to be 1 in 50,000 live births.

Synonyms and Related Disorders

Mandibulofacial dysostosis; Treacher Collins-Franceschetti syndrome

Genetics/Basic Defects

1. Inheritance
   a. An autosomal dominant disorder
      i. Rare incomplete penetrance
      ii. Wide variability
   b. Forty percentage of cases have a previous family history.
   c. Sixty percentage of cases possibly arise from de novo mutations of *TCOF1*.
2. The *Treacher Collins-Franceschetti syndrome 1* (*TCOF1*) gene
   a. The only gene currently known to be associated with TCS
   b. Mapped to chromosome 5q32-q33.1
   c. Encoding a serine/alanine–rich protein, called "treacle" (Jones et al. 1999)
   d. A complete coding sequence of the Treacher Collins-Franceschetti syndrome 1 gene (*TCOF1*) has been identified.
   e. Mutations in the *TCOF1* gene (Marszalek et al. 2002)
      i. Type of mutations
         a) Deletions
         b) Insertions
         c) Missense mutations
      ii. Two mutations affecting splicing of the primary transcript are located in:
         a) Introns 3 (304+5 G → C)
         b) Introns 22 (3550+1G → A)
      iii. Most mutations result in a premature termination codon, producing a truncated protein devoid of the nuclear localization signals (NLSs).
3. Pathogenesis (Trainor et al. 2009)
   a. General cranioskeletal hypoplasia occurs due to generation of insufficient neural crest cells.
   b. Insufficient neural crest cell number is a consequence of neuroepithelial progenitor cell death.
   c. Tcof1/Treacle is an important spatiotemporal regulator of ribosome biogenesis.
   d. Haploinsufficiency of Tcof1/Treacle results in deficient ribosome biogenesis, which is incapable of meeting the proliferative needs of the neuroepithelium.
   e. Deficient ribosome biogenesis leads to nucleolar stress activation and stabilization of p53, which causes the high degree of neuroepithelial apoptosis and consequent loss of neural crest cells.
   f. In an experimental animal-based strategy, genetic and/or chemical inhibition of p53-dependent apoptosis can restore the normal complement of neural crest cells and prevent the development of TCS craniofacial anomalies.

Clinical Features

1. Interfamilial and intrafamilial variability
2. Eyes
   a. Antimongoloid slant of the palpebral fissures
   b. Colobomata and hypoplasia of the lower lids and lateral canthi
   c. Partial absence of eyelid cilia
   d. Hypertelorism
3. Ears (Posnick and Ruiz 2000)
   a. External ear anomalies
      i. Symmetric
      ii. Normal
      iii. Absent
      iv. Malformed
      v. Malposed
   b. External auditory canal abnormalities
      i. Symmetric (88%)
      ii. Atretic (54%)
      iii. Stenotic (31%)
      iv. Normal (15%)
   c. Middle ear cavity ossicular deformities
      i. Symmetric (96%)
      ii. Hypoplastic (85%)
   d. Conductive hearing loss results from variable degrees of hypoplasia of the external auditory canals and ossicles of the middle ears.
4. Nose/mouth
   a. Respiratory compromise in severely affected patients as a result of the following two factors (Posnick and Ruiz 2000):
      i. Presence of maxillary hypoplasia, which tends to constrict the nasal passages and results in a degree of choanal stenosis or atresia
      ii. Presence of mandibular micrognathia and a retropositioned tongue obstructing the oropharyngeal and hypopharyngeal spaces
   b. Nasal deformity
   c. Macrostomia
   d. Cleft palate with or without cleft lip
   e. High-arched palate
   f. Malocclusion
   g. Open bite
5. Facial bone malformations: the most characteristic findings
   a. Hypoplasia of the malar bones
      i. Often with clefting through the arches
      ii. Limited formation of the residual zygomatic complex
   b. Orbits
      i. Hypoplastic lateral aspects of the orbits
      ii. Dysplastic inferior-lateral orbits
   c. Maxilla and mandible
      i. Characteristically hypoplastic (malar hypoplasia)
      ii. Variable effects on the temporomandibular joints and the muscles of mastication
      iii. Anterior open bite malocclusion
      iv. A steep (clockwise-rotated) occlusal plane
6. Sleep apnea and sudden infant death syndrome
7. Differential diagnosis (Dixon 1995)
   a. Nager acrofacial dysostosis
      i. Features similar to those of TCS
         a) Zygomatic hypoplasia
         b) Downward slanting of the palpebral fissures
         c) Micrognathia
         d) Anomalies of the external ears
         e) Cleft palate
      ii. Limb defects (not observed in TCS)
         a) Often asymmetrical
         b) Preaxial limb defects
         c) Hypoplastic or absent thumbs
         d) Radial hypoplasia or aplasia
         e) Radioulnar synostosis
   b. Miller acrofacial dysostosis
      i. Facial features similar to TCS and Nager syndrome
      ii. Limb defects
         a) Postaxial limb defects
         b) Most commonly with absence or incomplete development of the fifth digital ray of all four limbs
   c. Oculoauriculovertebral (OAV) spectrum
      i. OAV spectrum
         a) Sporadic occurrence in vast majority of cases
         b) One to two percentage of cases with a previous family history
         c) Includes hemifacial microsomia and Goldenhar syndrome

ii. Hemifacial microsomia
  a) Primarily affecting development of the ear, mouth, and mandible
  b) Wide variable expression
  c) Affecting primarily only one side of the face
iii. Goldenhar syndrome
  a) Facial involvement
  b) Vertebral anomalies
  c) Epibulbar dermoids

Diagnostic Investigations

1. Radiography and CT for evaluation of craniofacial abnormalities
   a. Mandibular hypoplasia
   b. Bilateral condylar hypoplasia
   c. Coronoid process absence/hypoplasia
   d. Maxillary bone hypoplasia
   e. Malar bone hypoplasia
   f. Narrowed frontal bone
   g. Maxillary sinus walls hypertrophy
   h. Auricular canals atresia
   i. C1-C2 fusion
   j. Temporal muscle hypotrophy
   k. Masseter muscle hypotrophy
   l. Lateral pterygoid hypotrophy
   m. Decreased oropharyngeal space
   n. Conchae hypertrophy
2. Audiological evaluation for hearing impairment
3. DNA diagnosis: Direct sequencing of the coding and flanking intronic regions of *TCOF1* detects mutations in about 90–95% of patients (Katsanis and Cutting 2006).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low unless a parent is affected in which case the risk to the sibs is 50% or has germline mosaicism
   b. Patient's offspring: 50%
2. Prenatal diagnosis available for pregnancies at increased risk for TCS
   a. Two-dimensional and preferably three-dimensional sonography (Hsu et al. 2002)
      i. Polyhydramnios
      ii. Demonstration of characteristic facies of TCS
         a) Downward slanting palpebral fissures
         b) Micrognathia
         c) Abnormal appearance of the nose with narrow nostrils
         d) Cleft lip/palate
         e) Low-set dysplastic ears
         f) Abnormal fetal swallowing
   b. Amniocentesis or CVS
      i. To detect *TCOF1* mutation
      ii. The disease-causing allele of an affected individual must be identified before prenatal testing can be performed.
      iii. The presence of a *TCOF1* mutation detected by prenatal diagnosis does not predict the specific malformations or severity of the disease.
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified in an affected family member.
3. Management
   a. Multidisciplinary team (Thompson et al. 2009)
      i. Geneticist
      ii. Neonatologist
      iii. Pulmonologist
      iv. Ophthalmologist
      v. Otolaryngologist
      vi. Audiologist
      vii. Speech pathologist
      viii. Dentist/orthodontist
      ix. Radiologist
      x. Psychologist/social worker
      xi. Craniofacial surgeons
   b. Severe case
      i. Secure airway by tracheostomy if necessary
      ii. A gastrostomy for feeding
   c. To promote normal language development
      i. Cleft palate repair
      ii. Evaluation by an otolaryngologist, audiologist, and speech pathologist
   d. Orthodontic alignment of the teeth
   e. Craniofacial reconstruction
      i. Zygomatic and orbital reconstruction
      ii. Maxillomandibular reconstruction

iii. Nasal reconstruction
iv. Soft tissue reconstruction
v. External ear reconstruction
vi. External auditory canal and middle ear reconstruction

Fig. 1 (**a**, **b**) A child and the father with Treacher-Collins syndrome. The faces are characterized by an antimongoloid slant of the palpebral fissure, colobomata and hypoplasia of the lower lids, and small and receding chins

Fig. 2 An infant and his mother with Treacher-Collins syndrome showing similar features. The infant is mildly affected

Fig. 3 (**a**–**d**) A newborn and a child with Treacher-Collins syndrome showing antimongoloid slant of the palpebral fissures, coloboma and hypoplasia of the lower lids, and microtia

Fig. 4 (**a**–**c**) Another infant with typical Treacher-Collins syndrome

Trimethylaminuria

Trimethylaminuria, also called fish odor syndrome, is a metabolic disorder characterized by a distinctive decaying fish odor of sweat, urine, breath, and other body secretions due to presence of abnormal amounts of the dietary-derived tertiary amine, trimethylamine (TMA).

Synonyms and Related Disorders

Fish-odor syndrome

Genetics/Basic Defects

1. Inheritance (Rehman 1999)
   a. Autosomal recessive
   b. The incidence of heterozygous carriers of the allele for impaired N-oxidation is estimated to be of the order of 1%.
2. Basic defect
   a. Caused by deficiency of the flavin-containing mono-oxygenase isoform 3 (FMO3). A defect in hepatic N-oxidation of dietary-derived TMA causes excess excretion of TMA, leading to affected individuals to have a body odor resembling rotten fish (Basarab 1999).
   b. Caused by loss-of-function mutations in the *FMO3* gene (mapped on 1q24.3) encoding an isoform of flavin-containing mono-oxygenase have been shown to underlie trimethylaminuria/fish odor syndrome (Lunden 2002).
   c. Common variants in the FMO3 gene lead to greatly reduced enzyme activity in vivo, shown to cause mild to transient trimethylaminuria
   d. Also can be caused by liver, kidney, and/or gastrointestinal dysfunction, including dietary carnitine overloading secondary to the gut-generated substrate overwhelming the hepatic enzymes' oxidizing capacity
   e. Trimethylaminuria reflects how genetic constitution can adversely influence interactions with one's diet (Mitchell 2001).
3. TMA (Lunden 2002)
   a. Derived from the intestinal bacterial degradation of foods rich in choline and carnitine, such as egg yolk, liver, kidney, soybeans, peas, and saltwater fish
   b. Readily absorbed from the gut and is normally oxidized by the liver FMO3 to odorless trimethylamine N-oxide which is then excreted in the urine
   c. Impaired oxidation of TMA, thought to be the cause of the fish odor syndrome, is responsible for the smell of rotting fish.
4. FMO3
   a. One of the major enzyme systems protecting humans from the potentially toxic properties of drugs and chemicals
   b. Converts nucleophilic heteroatom-containing chemicals and endogenous materials to polar metabolites, which facilitate their elimination
   c. N-oxygenates trimethylamine to trimethylamine N-oxide which is excreted in a detoxication and deoderation process
   d. Prevalent polymorphisms of the human FMO3 may contribute to low penetrance and predispositions to diseases associated with adverse environmental exposures to heteroatom-containing

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_231, 2025
© Springer Science+Business Media, LLC 2012

chemicals, drugs (e.g., tricyclic antidepressants, ranitidine, amphetamine, methamphetamine, clozapine, chlorpromazine, methimazole), and endogenous amines

5. Classification of the disorder (Mitchell 2001)
   a. Primary genetic form
      i. The best understood of the various forms of the disorder
      ii. Accounts for a large proportion of the known cases
      iii. Human FMO3
         a) Highly polymorphic
         b) Some mutations, either alone or in combination, are associated with dysfunctional enzyme activity and the metabolic disorder.
         c) Two relatively common polymorphisms (P153L and E305X) appear to account for the majority of severe cases of trimethylaminuria.
         d) Some other mutations are associated with inactivation of FMO3.
         e) Combinations of intragenic polymorphisms within FMO3 appear to determine a modified and less severe form of the condition.
         f) Some mutations appear to be benign.
   b. Acquired form
      i. Several cases of clinical and biochemically diagnosed trimethylaminuria have been reported to emerge in adult life.
      ii. No previous history in childhood
      iii. No familial background
      iv. Possible mechanism: Viral hepatitis may have been responsible for precipitation of the condition possibly by insertion of viral DNA into the genome thereby affecting normal expression of the human *FMO3* gene.
   c. Transient childhood forms
      i. A transient or mild form of trimethylaminuria may occur during early childhood.
      ii. Compound heterozygosity for several mutations has been detected by molecular analysis in some cases.
   d. Transient form associated with menstruation
      i. Fish odor intensifies with onset of menstruation.
      ii. Trimethylaminuric condition deepens just prior to the onset of menstruation.
   e. Precursor overload
      i. Overload of precursors, such as choline, lecithin, and carnitine, saturates the existing levels of flavin monooxygenase.
      ii. Exposure to unusually high levels of such precursors may hasten a fish odor syndrome, especially if the individual is a haplotype for certain mutations.
   f. Disease states that impair trimethylamine metabolism
      i. Advanced liver disease
      ii. Advanced renal disease
      iii. Association with temporal lobe epilepsy and behavioral disturbances
      iv. Bacterial vaginosis with fish odor in vaginal secretions
   g. Exacerbating factors
      i. Pyrexic states
      ii. Stress
      iii. Puberty
      iv. Sweating
      v. Exercise
      vi. Emotional upsets
      vii. Menstruation
      viii. Oral contraceptives
      ix. Foods rich in choline

Clinical Features

1. Present from birth but manifests itself with the introduction of a diet, including foods that contain high amounts of choline or trimethylamine N-oxide (Chalmers et al. 2006)
2. Unmistakable, strong fishy body odor from excess unmetabolized trimethylamine in the urine, sweat, and other body secretions (breath, saliva, vaginal secretions)
3. Skin sores induced by choline-rich foods
4. Serious social/behavioral problems resulting from strong body odor (Mitchell 2001)
   a. Subject to ridicule, loss of confidence, and school disruption
   b. Destructive to personal, working, and career lives of the affected individuals
   c. Clinical depression
   d. Attempted suicide
5. Highly variable severity of the syndrome

Diagnostic Investigations

1. Demonstration of elevated TMA after a choline-rich diet by gas chromatography-mass spectrometry measurement. TMA challenge test (with a 600 mg TMA oral challenge dose and analysis of 0–8 h urine samples) is useful in confirming unequivocally the trimethylaminuric patients as well as indicating the status of the parents as carriers.
2. Mass spectroscopy and proton nuclear magnetic resonance (NMR) spectroscopy
   a. Have the advantage of being able to detect TMA and TMA *N*-oxide simultaneously with great sensitivity
   b. NMR has further advantage of requiring no prior extraction or separation of metabolites and thus measurement can be done directly on urine samples
3. Increase in urinary excretion of trimethylamine with decreased trimethylamine oxide
4. Sequence analysis of *FMO3* gene to detect mutations (>99%): clinically available
5. Combination of the proton nuclear magnetic resonance (NMR) spectroscopy to assess activity of the mutant enzyme with gene sequence and expression technology provides a powerful means of determining genotype-phenotype relationships in trimethylaminuria (Murphy 2000).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis: possible by demonstrating the previously characterized mutation in the fetal DNA obtained by amniocentesis or CVS
3. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified
4. Management (Rehman 1999; Mitchell 2001; Chalmers et al. 2006)
   a. Restriction of dietary sources of trimethylamine: the main therapeutic approach (Chen and Aiello 1993; Phillips and Shephard 2008)
      i. Restriction of trimethylamine (milk obtained from wheat-fed cows)
      ii. Restriction of its precursors including choline-rich food
         a) Egg yolk
         b) Liver
         c) Kidney
         d) Peas
         e) Beans
         f) Peanuts
         g) Soya products
         h) Brassicas (include cabbage, broccoli, and turnip)
         i) Legumes
         j) Fish
      iii. Trimethylamine N-oxide source
         a) Some saltwater fish (cod, skate)
         b) Cephalopods (include cuttlefish, squid, and octopus)
         c) Crustaceans (include crabs, lobsters, and shrimp)
      iv. Dietary restriction appears to be successful in the management of the majority of patients.
      v. Appears to be most effective in mild to moderate forms of fish odor syndrome arising from particular mutations or haplotypes
   b. Suitable diet include:
      i. Dark green leafy vegetables
      ii. Fortified bread and cereals
      iii. Orange juice
   c. Freshwater fish may be eaten freely.
   d. Avoid exacerbation factors such as pyrexia and stress.
   e. Vitamin supplementation with riboflavin, a precursor of the FAD cofactor for flavin monooxygenase function, in an attempt to maximize any residual activity
   f. Drug treatment: Occasionally a short course of metronidazole, neomycin, and lactulose may suppress production of TMA by reducing the activity of gut microflora in some patients (Fraser-Andrews 2003).
   g. Copper-chlorophyllin tablets to moderate gut flora activity and complex TMA
   h. Use of "malodor suppressants" in hygiene products and soaps and body lotions with a low pH (3.5–6.5) to disguise the offensive smell of trimethylamine
   i. Counseling of the social/behavioral problems
   j. Gene therapy and enzyme induction with drugs provide hope for the future.

Fig. 1 (**a**–**d**) A 12-year-old girl with trimethylaminuria showing multiple sores on the hands and legs. At age 4, she developed unpleasant fish odor and constant scratching of her skin. Trimethylaminuria was diagnosed based on markedly increased urinary TMA by gas chromatography after loading with choline. The patient started with a baseline level of 0.28 mg TMA mg/mg creatine that is 4 times of control. After 8, 16, and 24 h of loading with choline, the values went up to 2.8 mg (41×), 3.99 mg (57×), and 9.93 mg (95×), respectively. In addition, the diagnosis of Prader–Willi syndrome was made at age 9 because of relative obesity, hypotonia, delayed psychomotor development, almond-shaped eyes, small hands and feet, and presence of chromosome abnormality of del(15)(q11q13)

Triploidy

Triploidy is defined as the presence of three sets of haploid (69) chromosomes. Triploid fetuses occur in about 1% of recognized pregnancies, 1 in 100,000 live borns, and constitute about 15% of all fetuses with chromosome abnormalities. There is a slight excess of males (M1.5:F1). Most triploid fetuses often result in spontaneous abortions between 7 and 17 weeks of gestation. However, rare instances of a live triploid infant have been reported (Allen and Pritchard 2000).

Synonyms and Related Disorders

Partial hydatidiform mole of the placenta; Triploid fetus (69,XXY, 69,XXX, diploid/triploid mosaicism)

Genetics/Basic Defects

1. Origin of triploidy (Allen and Pritchard 2000; Benn et al. 2001)
   a. Diandric origin of the triploid fetuses (type I)
      i. Mechanisms of paternal origin of the supernummary haploid set
         a) Dispermy: fertilization of a haploid egg by two haploid sperms (dispermy) accounting for 66% (most common mechanism leading to triploidy)
         b) Faulty meiotic division in the male: fertilization of a normal ovum by a diploid sperm (diandry) (about 24%)
      ii. Characteristics of diandric fetuses
         a) Relatively normal fetal growth
         b) Slight macrocephaly
         c) Marked syncytiotrophoblastic hyperplasia
         d) Hydatidiform changes of the placental villi (partial mole) (large cystic placenta)
   b. Digynic origin of triploid fetuses (type II)
      i. Mechanisms of maternal origin of the supernummary haploid set
         a) Mitotic errors in female germ cell precursors: fertilization of a diploid ovum by a normal sperm (digyny) (about 10%)
         b) Errors in maternal meiosis: an error at meiosis I or II or incorporation of the second polar body postulated
      ii. Characteristics of digynic fetuses
         a) Generally marked fetal (asymmetric) growth retardation
         b) Relative macrocephaly
         c) Small, non-cystic placenta
         d) Maternally derived triploidy was often found in those fetuses that survived until late pregnancy.
2. Diploidy/triploidy mosaicism
   a. Mechanisms (Phelan et al. 2001)
      i. Postzygotic maldivision of a triploid or diploid zygote
      ii. Incorporation of the second polar body into a daughter nucleus of the developing embryo
      iii. Fertilization of a diploid ovum with incorporation of the second diploid polar body
      iv. Fertilization of the first polar body and ovum by individual spermatozoa with suppression of one second polar body
      v. Dispermy or diploid sperm fertilization with incorporation of an independently fertilized second polar body

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_232,
© Springer Science+Business Media, LLC 2012

vi. Chimera formation by union of diploid and triploid embryos
vii. Vanishing twin and chimerism
b. Characteristics of diploid/triploid fetuses: rarer and less severe phenotype than true triploidy

3. Triploidy and in vitro fertilization (IVF)/ intracytoplasmic sperm injection (ICSI) (Dayal et al. 2009)
a. Diandric triploidy is observed with spontaneous as well as conventional IVF and is assumed to be the most common form of triploidy (Jun et al. 2006).
b. Intracytoplasmic sperm injection, by its virtue of injecting a single sperm into a single oocyte, negates the potential for dispermic triploidy.
c. Digynic triploidy occurs secondary to failed meiosis II expulsion of the second polar body and subsequent fertilization of a diploid oocyte. Cytogenetic evidence of three pronuclei post-ICSI zygotes that result from failed extrusion of the second polar body (Tsuchiya et al. 2002).
d. Mechanistically, this may occur with a damaged metaphase plate or oocyte cytoskeleton (Kimura and Yanagimachi 1995), after abnormal spindle formation or increased female age (Spandorfer et al. 1998; Tsuchiya et al. 2002). The latter etiologies may represent an occult oocyte factor.

Clinical Features

1. Prenatal history
a. IUGR
i. Asymmetrical (digynic)
ii. Symmetrical (diandric)
b. Prematurity
c. Hydrops
d. Polyhydramnios
e. Oligohydramnios
f. Partial hydatidiform mole (placenta)
2. Craniofacial features
a. Dysplastic calvarium
b. Microcephaly
c. Large posterior fontanelle
d. Ocular hypertelorism or hypotelorism
e. Epicanthal folds
f. Exomphalos
g. Microphthalmia
h. Iris and choroid colobomas
i. Midfacial hypoplasia
j. Arhinia
k. Small upturned nose
l. Choanal atresia
m. Single nostril (in holoprosencephaly)
n. Micrognathia
o. Cleft lip/palate
p. Low-set ears
q. Short neck
r. Thick nuchal fold
s. Cystic hygroma
3. CNS
a. Hypotonia
b. Arnold-Chiari malformation
c. Posterior fossa cyst (Dandy-Walker malformation)
d. Holoprosencephaly
e. Hydranencephaly
f. Hydrocephalus (20%)
g. Absent corpus callosum (15%)
h. Absent gyri of the brain
i. Hypoplastic cerebellum
j. Absent first cranial nerve
k. Encephalocele
l. Lumbosacral meningomyelocele (20%)
4. Gastrointestinal malformations
a. Omphalocele
b. Ventral wall defects
c. Incomplete rotation of colon
d. Agenesis of gallbladder
e. Meckel diverticulum
f. Duodenal atresia
g. Malfixation of cecum
h. Inguinal hernia
5. Endocrine abnormalities
a. Adrenal hypoplasia
b. Thyroid hypoplasia
c. Lingual thyroid
d. Thymic hypoplasia
e. Leydig cell hyperplasia
f. Gonadal dysgenesis
6. Genitourinary abnormalities
a. 69,XXY triploid fetus
i. Varying degree of ambiguous genitalia (40%)
ii. Hypospadias (40%)
iii. Cryptorchidism (85%)
iv. Micropenis (75%)

v. Scrotal abnormalities (60%) including bifidity, scrotal hypoplasia, or agenesis
vi. Leydig cell hyperplasia (20%)
b. 69,XXX triploid fetus
i. Gonadal dysgenesis
ii. Renal abnormalities
a) Multicystic kidneys
b) Hydronephrosis
c) Glomerulosclerosis
7. Gastrointestinal abnormalities
a. Omphalocele
b. Diaphragmatic hernia
c. Gastroschisis
d. Malrotation
e. Gallbladder hypoplasia
f. Pancreas hypoplasia
8. Cardiovascular anomalies
a. VSD
b. ASD
c. PDA
d. PA
e. Tetralogy of Fallot
f. Truncus arteriosus
g. Aberrant right subclavian artery
h. Cardiomegaly
9. Respiratory tract abnormalities
a. Small chest
b. Pulmonary hypoplasia
c. Absent lung lobation
d. Congenital cystic adenomatoid malformation of the lung
10. Prognosis
a. Majority die early in gestation.
b. Very few surviving into the third trimester
c. The fetuses rarely survive to delivery.
i. Profoundly malformed
ii. Growth-restricted
iii. Survival measured in hours to days
d. Fetuses with extra maternal haploid set of chromosomes appear to survive longer in utero than those with extra paternal haploid set of chromosomes (Allen and Pritchard 2000).
e. Some cases of diploid/triploid mixoploidy survive after the neonatal period, which is exceptional.
11. Diploid/triploid mosaicism (Van De Laar et al. 2002)
a. A well-known malformation syndrome
b. Common features
i. Mental retardation
ii. Growth retardation
iii. Body and/or facial asymmetry
iv. Hypotonia
v. Truncal obesity
vi. Prominent forehead
vii. Depressed nasal bridge
viii. Micrognathia
ix. Malformed low-set ears
x. Syndactyly
xi. Clinodactyly
xii. Transverse palmar creases
xiii. A small phallus
xiv. Cryptorchidism
xv. Precocious puberty
c. Additional features
i. Sandal gap
ii. Short halluces
iii. Seizures
iv. Respiratory distress
v. Microstomia
vi. Irregular skin
vii. Feeding difficulties
viii. Muscular atrophy of the limbs
d. Rarer and less severe than true triploidy in which infants can survive beyond neonatal period till over 20 years
e. Presence of a normal diploid cell line and a second triploid cell line in varying degrees and with varying tissue distribution

Diagnostic Investigations

1. Karyotype of fetus and newborn
a. 69,XXX (one third of cases)
b. 69,XXY (Two thirds of cases)
c. Diploid/triploid mosaicism
i. Less severe phenotype
ii. More compatible with life
iii. Harder to diagnose clinically
iv. Peripheral lymphocyte cultures showing a normal karyotype only
v. Need fibroblast culture to show the cell line with triploid complement
d. Molecular determination of the origin of the extra haploid set of chromosomes
i. Fluorescent polymerase chain reaction (F-PCR) analysis of short tandem repeats (STRs) located on chromosomes such as 21, 18, and 13 (Bán et al. 2002)

ii. Assessment of numerous polymorphic DNA markers

2. Radiography
   a. Poor ossification of calvarium
   b. Craniolacunae
   c. Chondrodysplasia punctata-like calcification
   d. Vertebral fusions
   e. Harlequin orbits
   f. Gracile ribs
   g. Upswept clavicles
   h. Diaphyseal overtubulation of long bones
   i. Vertical ilia
   j. Proximal radioulnar synostosis
   k. Asymmetry of occipitoparietal calvaria (50%)
3. CT and MRI of the brain
   a. Cortical hypoplasia
   b. Agenesis of corpus callosum (15%)
   c. Hypoplasia of basal ganglia/occipital lobe
   d. Dandy-Walker anomaly
   e. Arnold-Chiari malformation
4. Histopathology of the placenta
   a. Partial hydatidiform mole change of villi on gross and microscopic examination
   b. The partial mole is caused by a triploidy (Devriendt 2005).
   c. The villi with molar change show hydropic swelling of the stroma, and trophoblastic proliferation (hyperplasia) is also present in scattered areas.
   d. Irregular cystic cavitation may be seen in larger hydropic villi.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: The true recurrence risk for cytogenetic abnormalities in subsequent offspring is uncertain but may be slightly increased and higher than expected (Graham et al. 1989).
   b. Patient's offspring: a lethal condition not surviving to reproduce
2. Prenatal diagnosis
   a. First-trimester markers screening (De Graaf et al. 1999)
      i. Low serum marker pregnancy-associated plasma protein A (PAPP-A)
      ii. Low serum marker free β-chain of chorionic gonadotrophin (free β-hCG)
   b. Second trimester maternal serum screening (Benn et al. 2001)
      i. High maternal serum hCG associated with triploidy
         a) Nearly always indicating placenta with partial mole (93%)
         b) A high frequency of open neural tube defects or ventral wall defects (29%)
         c) With either XXX or XXY karyotype
      ii. Low hCG associated with triploidy
         a) Infrequently associated with a molar placenta (9%)
         b) Not appear to be associated with open neural tube defects or ventral wall defects
         c) An excess of XXX over XXY karyotypes
      iii. Large placentas with molar changes (diandry) generally associated with increased maternal serum AFP (MSAFP) and high hCG levels
      iv. Those with digyny and small monocystic placentas generally associated with normal MSAFP and low hCG
   c. Isolation of nucleated red blood cells from the maternal peripheral circulation at the first trimester (12 weeks gestation): FISH analysis using X and Y and other chromosome-specific probes (De Graaf et al. 1999)
   d. Amniocentesis/CVS
      i. Triploidy
      ii. Diploidy/triploidy mosaicism
   e. Ultrasonography of structural anomalies compatible with triploidy
      i. Severe, early-onset asymmetrical growth restriction in the late first and early second trimester (the head size remains almost normal whereas the remainder of the fetal body and skeleton is severely growth-restricted)
      ii. Oligohydramnios, asymmetric growth restriction, and a small placenta when the third set of chromosomes is maternal
      iii. Large, hydropic-appearing placenta consistent with partial moles (60–80%) when the third set of chromosomes is paternal
      iv. Most common sonographic abnormalities
         a) Large thickened placenta containing multiple sonolucent areas
         b) Characteristic sharply defined, large and small cystic spaces within the placenta

c) Hydrops
d) Ventriculomegaly
e) Dandy-Walker malformation
f) Holoprosencephaly
g) Agenesis of the corpus callosum
h) Micrognathia
i) Echogenic bowel
j) Omphalocele
k) Renal malformations
l) Thickened nuchal folds
m) Neural tube defects
n) Club feet
o) Syndactyly of the third and fourth fingers

f. Preimplantation genetic diagnosis in conjunction with in vitro fertilization by a single sperm injection: a viable approach when there are clinical or genetic indications of repeated dispermy, unreduced (diploid) spermatozoa, or unreduced (diploid) oocytes (Pergament et al. 2000)

3. Management
   a. No treatment available for true triploidy, a lethal condition.
   b. Supportive therapy for diploid/triploid mosaicism who may survive beyond neonatal period.

Fig. 1 (**a**–**e**) A newborn with triploidy (69,XXY) showing woolly hair, distinctive facial appearance (epicanthal folds, microphthalmia, beaked nose, small mouth, receding jaw, low-set and malformed ears), partial syndactyly between third-fourth fingers and toes, and ambiguous genitalia. The infant also had bilateral coloboma and cataracts, short neck, loud continuous heart murmur along the *left* sternal border, and bilateral transverse palmar creases. The infant died at 25 h

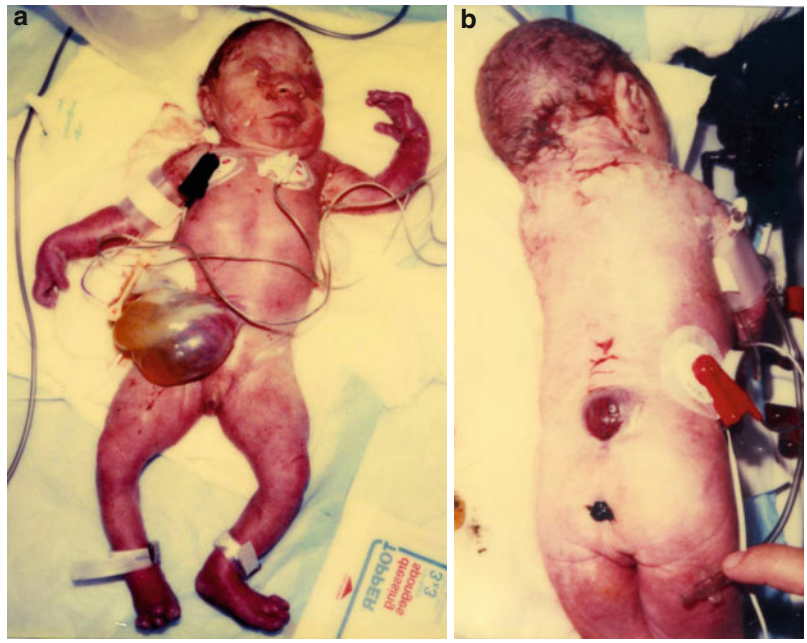

Fig. 2 (**a**, **b**) An infant with triploidy showing abnormal craniofacial features, omphalocele, thick nuchal fold, and lumbosacral meningomyelocele

Fig. 3 (**a**–**c**) An infant with triploidy (69,XXX) showing low-set/malformed ears, syndactyly of two-three-four fingers, spina bifida, and pulmonary hypoplasia at autopsy. The infant also had a large ventricular septal defect

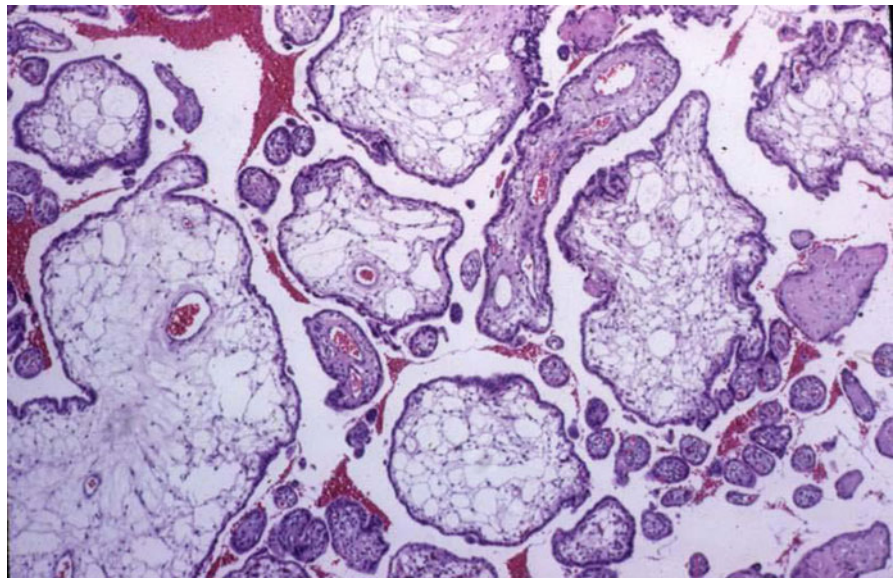

Fig. 4 Partial mole of triploidy placenta. Many villi are enlarged, hydropic, and hypovascular. Prominent infolding and nests of trophoblastic cells in the villous stroma are seen in other areas

Fig. 5 A G-banded karyotype showing 69,XXX

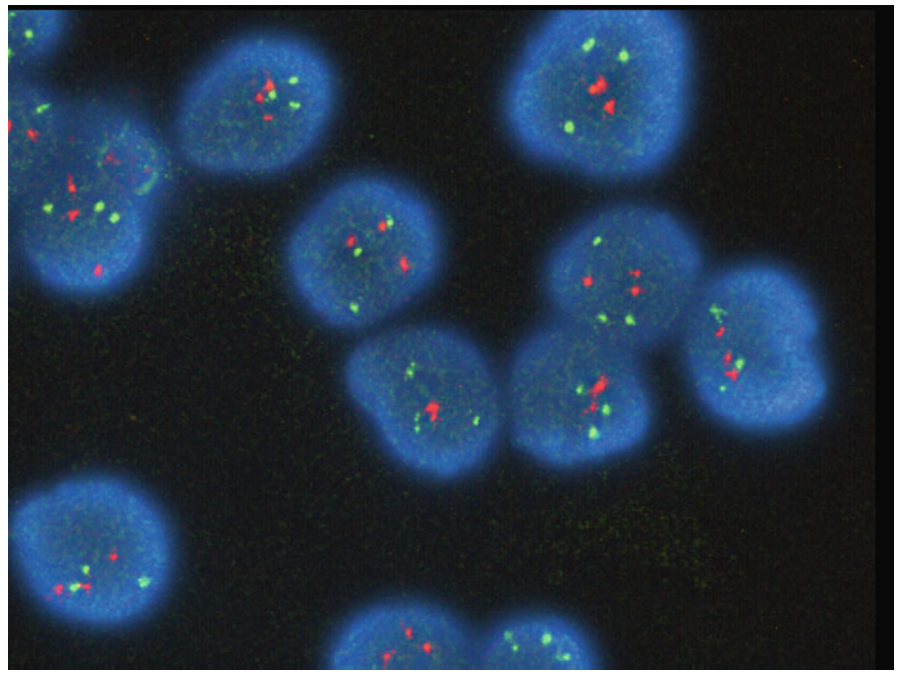

Fig. 6 Triploidy for all chromosomes shown by multicolor FISH on interphase cells. Three copies of chromosome 13 (*green*) and chromosome 21 (*orange*) are shown here

Trismus-Pseudocamptodactyly Syndrome

The trismus-pseudocamptodactyly syndrome, a relatively rare hereditary disorder, is characterized by inability to open the mouth fully, pseudocamptodactyly, mild foot deformities, and mild short stature. This malformation syndrome was first reported by Hecht and Beals and Wilson et al. in 1969 (Hecht and Beals 1969; Wilson et al. 1969). The term Dutch–Kentucky syndrome was coined for trismus pseudocamptodactyly by Mabry et al. because the earliest affected member was a young Dutch girl who emigrated to the southern United States soon after the American Revolution.

Syonyms and Related Disorders

Dutch–Kentucky syndrome; Hecht–Beals syndrome

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. High penetrance
   c. Variable expression
2. Caused by a single mutation, p.R674Q, in *MYH8* (myosin heavy chain 8) gene (Toydemir et al. 2006a)
3. Pathogenesis
   a. Possible mechanisms of trismus
      i. The shortened lengths of certain mastication muscles presumed to be responsible for the clinical manifestations.
         a) Temporalis muscle
         b) Internal pterygoid muscle
         c) Masseter muscle
      ii. Enlarged coronoid processes
         a) Resulted from tension exerted by short temporal muscle tendon units
         b) Impinging on the body of the zygomatic bone and inner margin of the arch, thereby limiting mandibular excursion
      iii. Secondary to an abnormal ligament between the maxilla and that of the mandible anterior to the masseter muscles
      iv. Fibrotic abnormality of the masseter muscle mass in the vicinity of the ascending ramus
   b. Pseudocamptodactyly of fingers
      i. More appropriate term than camptodactyly because of
         a) Not associated with progressive deformities
         b) Not associated with fixed joint contractures
      ii. Caused by a shortening of the flexor digitorum profundus muscle tendon units, involving all fingers
   c. Foot deformities explainable by a shortening of the various muscle tendon groups in the leg and foot
   d. Several individuals with this mutation also had a so-called variant of Carney complex (a high incidence of myxomas, skin pigmentation disorders, endocrine tumors, or overactivity in schwannomas that manifest with cardiac myxomas and spotty skin pigmentation) (Veugelers et al. 2004), suggesting that the pathogenesis of trismus-pseudocamptodactyly syndrome and Carney complex might be shared. However, none of the individuals with

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_233,
© Springer Science+Business Media, LLC 2012

trismus-pseudocamptodactyly syndrome studied had features of Carney complex, and p.R674Q was not found in 49 independent cases of Carney complex that were screened. The findings show that distal arthrogryposis syndromes share a similar pathogenesis and are, in general, caused by disruption of the contractile complex of muscle (Toydemir et al. 2006a).

e. The trismus found in trismus-pseudocamptodactyly syndrome can also be present in Freeman–Sheldon syndrome (also known as distal arthrogryposis type 2A) and Sheldon–Hall syndrome (also known as distal arthrogryposis type 2B). Both of these conditions are caused by mutations in the *MYH3* gene (Toydemir et al. 2006b), confirming the hypothesis that the distal arthrogryposis syndromes are caused by aberrant function of the contractile complex of fast-twitch myofibers.

Clinical Features

1. Highly variable expression
2. Two main clinical features
   a. Limited excursion of the mandible
      i. Trismus (restricted opening of the mouth)
         a) Present at birth and persisting throughout life
         b) Greatly variable degree of restricted opening of the mouth
         c) The mouth opening is measured between the incisal edges of the central upper and lower incisors (in millimeter).
         d) Children: less than the value for normal children (36.6 ± 5.7 for age 7 years to 47.2 ± 6.4 for age 18 years)
         e) Adults: less than the value for normal adults (53.8 ± 6.5 for males, 50.4 ± 5.9 for females)
      ii. Mastication problems
      iii. Feeding problems with inadequate caloric intake
      iv. Swallowing difficulty (dysphagia)
      v. Difficulty with dental care
      vi. Delayed in speech development
      vii. Difficulty in endotracheal intubation for general anesthesia
   b. A flexion deformity of the fingers
      i. Clenched fists may be present at birth.
      ii. Typically crawling on the knuckles later in infancy
      iii. Occurring with wrist extension (pseudocamptodactyly) which is reversed by wrist flexion
      iv. Flexion of the fingers when the hand is dorsiflexed in minimally affected patients
      v. Pronounced flexion with ulnar deviation of the fingers in severely affected patients
3. Other clinical features
   a. Lower extremity and foot deformities (5% of cases)
      i. Mild calcaneovalgus
      ii. Equinovarus
      iii. Metatarsus varus
      iv. Camptodactyly
      v. Vertical talus
      vi. Hammertoe deformities
      vii. Shortening of both the gastrocnemiae and hamstring muscles
   b. Soft-tissue syndactyly occasionally present
   c. Mild short stature
4. Differential diagnosis of restricted mouth opening and/or (pseudo)camptodactyly
   a. Restricted mandibular opening caused by
      i. Intra-articular processes
         a) Trauma
         b) Infection
         c) Ankylosis
      ii. Extra-articular processes
         a) Soft tissue and bony obstructions
         b) Neurologic disorders such as tetanus
   b. Trismus in temporomandibular joint dysfunction
   c. Trismus caused by hypoplasia and fibrosis of the muscles around the mouth in Freeman–Sheldon syndrome
   d. Trismus and camptodactyly in patients with distal arthrogryposis who may have hyperextension of the metacarpophalangeal joints but also have contractures of the hips and feet, and short stature
   e. Trismus with a fixed facies secondary to hypoplasia or atrophy of small muscle fibers in Schwartz–Jampel syndrome
   f. A new arthrogryposis syndrome with facial and limb anomalies
      i. An autosomal dominant disorder

ii. Small mouth and jaw with limited jaw movement in infancy
iii. Associated with short stature and severe flexion contractures of the hands and feet

g. Digitotalar syndrome
i. An autosomal dominant disorder
ii. Flexion deformities
iii. Ulnar deviation and narrowing of the fingers
iv. Soft-tissue webbing causing abnormal positions of the thumbs
v. A vertical talus

Diagnostic Investigations

1. Radiography
   a. Enlargement of the coronoid processes
   b. Normal hands and forearms
2. Manometry for demonstrating abnormal swallowing
3. Histology of the affected muscles showing presence of fibrous tissue along with some muscle atrophy
4. Molecular genetic testing of *MYH8* mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected (A mildly affected parent may be missed) or has germinal mosaicism (Bonapace et al. 2010)
   b. Patient's offspring: 50%
2. Prenatal diagnosis: not been reported but possible in family at risk by *MYH8* mutation analysis of fetal DNA obtained from amniocentesis of CVS, provided the mutation has been previously identified in the affected family member
3. Management
   a. Use a flattened nipple to assist feeding in infancy.
   b. Anesthetic implications
      i. Limited excursion of the mandible
      ii. Potentially difficult or impossible to apply artificial ventilation and endotracheal intubation
      iii. Inhalational anesthesia with spontaneous breathing recommended for minor surgery
      iv. Bullard laryngoscope, an excellent device for intubating patients with limited mouth opening
      v. Fiber-optic nasotracheal intubation
      vi. Needs for emergency tracheostomy and cricothyrotomy
   c. Surgical release in the severe cases of trismus
      i. Bilateral coronoidotomies with excision of accessory fibrous tissue
      ii. Bilateral excision of hypertrophic coronoid processes
      iii. Surgical release of the shortened muscle–tendon units
      iv. Ongoing physical therapy with postsurgical stretching of the jaw opening on a daily basis to avoid relapse
   d. Surgical flexor slide-through procedure on the flexion tendons of the forearms

Fig. 1 Facial appearance of a child and his mother with trismus pseudocamptodactyly

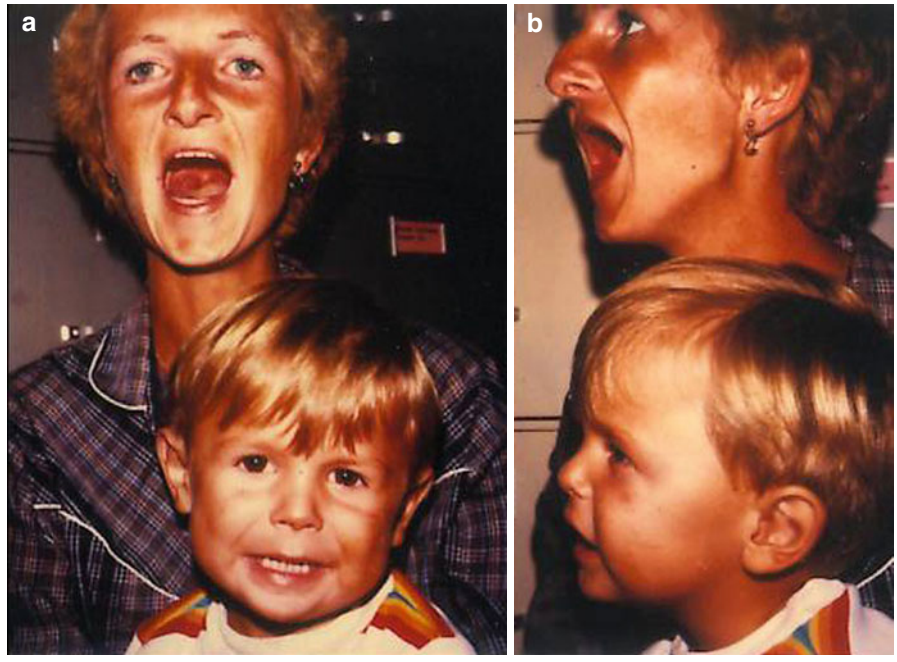

Fig. 2 (**a**, **b**) Front and lateral views of the child and his mother illustrating maximal abilities to open their mouth. The mother and the child both had *MYH8* mutations (p. R674Q)

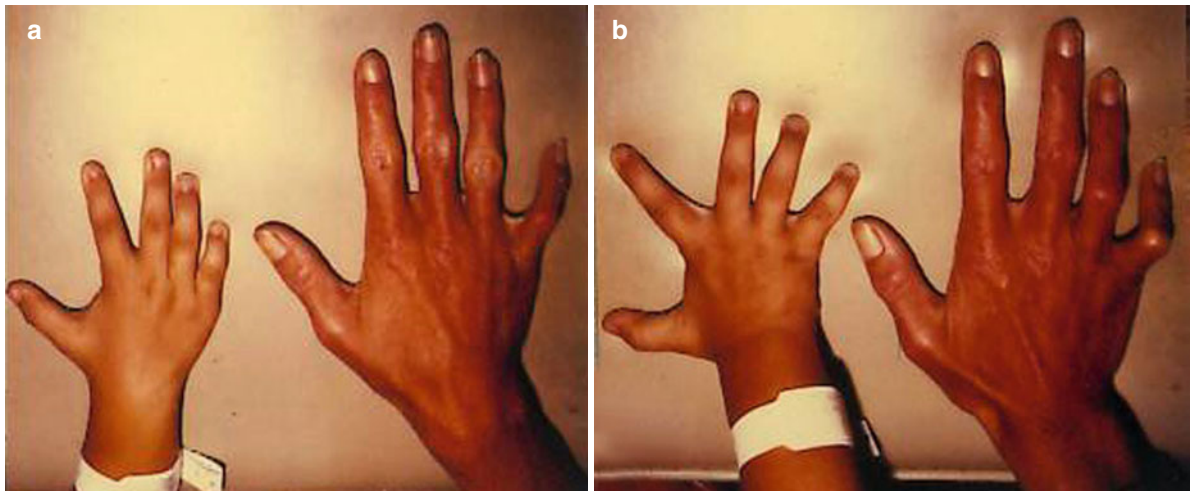

Fig. 3 (**a**, **b**) Hands of the child and his mother demonstrating no contractures of fingers on neutral positions but flexion contractures of fingers on dorsiflexion. Interphalangeal webbings are also seen

Fig. 4 (**a**, **b**) Marked flexion contractures of fingers on dorsiflexion in the mother and her brother

Fig. 5 Affected father and son in different family showing trismus and flexion contractures of fingers on dorsiflexion

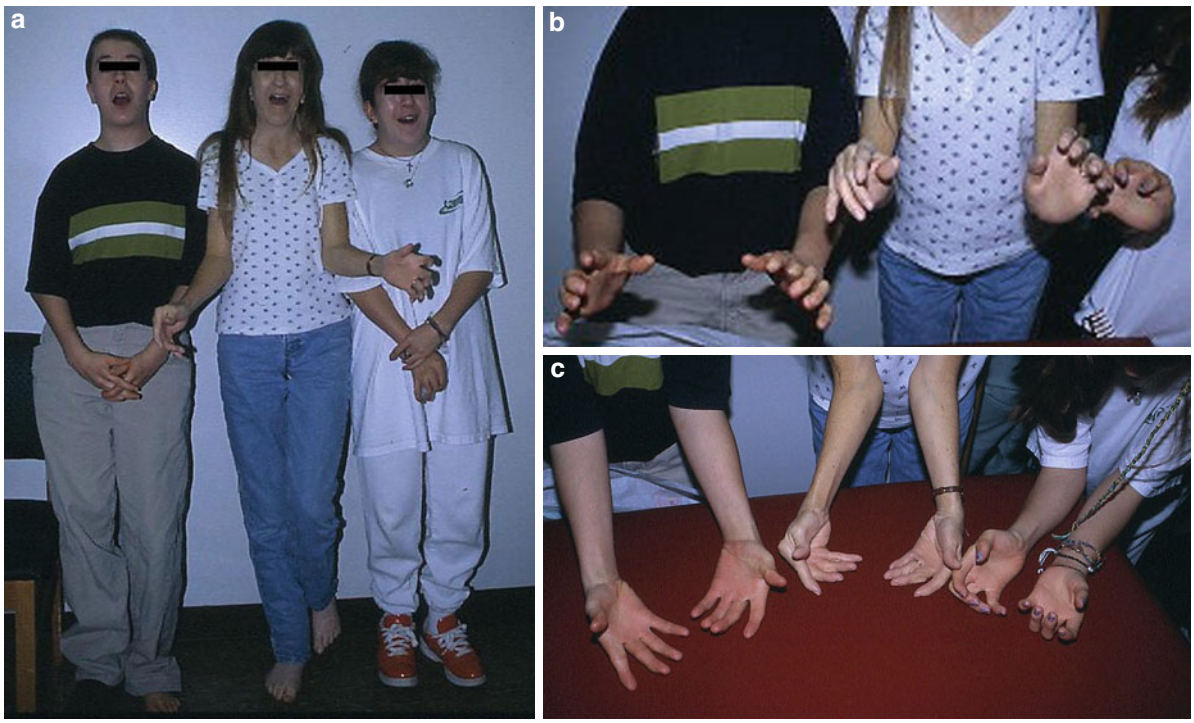

Fig. 6 (**a**–**c**) Affected three individuals in two generations in different family showing trismus and flexion contractures of fingers on dorsiflexion

Trisomy 8 Mosaicism Syndrome

In 1971, de Grouchy et al. first described trisomy 8 mosaicism which was further delineated by Fryns et al., Sanchez and Yunis, Schinzel, and Riccardi in 1977. This syndrome, also known as Warkany syndrome, is a well-recognized syndrome despite its phenotypic variability.

Synonyms and Related Disorders

Warkany syndrome

Genetics/Basic Defects

1. Trisomy 8 mosaicism: chromosome complement mosaic for chromosome 8 (presence of a chromosomally normal cell line in addition to the trisomic 8 cell line)
2. Origin of trisomy 8 mosaicism
   a. Different from the common autosomal trisomies that usually result from maternal meiotic errors
   b. Trisomy 8 in spontaneous abortions: meiotic origin in the majority of cases
   c. Postzygotic (mitotic) nondisjunction error in a diploid conceptus: the most likely origin of trisomy 8 in the live-born population
   d. Postzygotic (mitotic) nondisjunction error in a diploid conceptus, followed by nonrandom distribution of aneuploid cells between the different compartments
   e. Affected fetuses usually show a pattern of absence, or low levels of trisomy in cytotrophoblast cells (STC villi), high levels in extraembryonic mesoderm (LTC villi), and again low levels of trisomic cells in AF cells and/or fetal blood lymphocytes.
   f. LTC villi are more likely to reflect the true fetal chromosomal constitution than STC villi.

Clinical Features

1. Wide range of phenotypic variation
2. Central nervous system
   a. Intelligence: range from normal to mental retardation
   b. Agenesis of the corpus callosum
   c. Arrhinencephaly
3. Craniofacial features
   a. Skull
      i. Asymmetrical skull
      ii. Microcephaly
      iii. Hydrocephaly
      iv. Prominent forehead
      v. Flattened occiput
      vi. Low posterior hairline
   b. Eyes
      i. Ocular hypertelorism
      ii. Deep-set eyes
      iii. Strabismus
      iv. Corneal clouding
      v. Cataracts
      vi. Amblyopia
   c. Nose
      i. Plump nose with broad base
      ii. Prominent nares
   d. Mouth
      i. Micrognathia
      ii. Everted lower lip

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_234,
© Springer Science+Business Media, LLC 2012

   iii. High palate
   iv. Cleft soft palate
4. Chest
   a. Pectus excavatum
   b. Widely spaced nipples
5. Heart: congenital heart disease
6. Gastrointestinal tract
   a. Meckel diverticulum
   b. Hirschsprung disease
   c. Anal anomalies
7. Genitourinary tract
   a. Cryptorchidism
   b. Unilateral renal agenesis
   c. Wilms tumor
   d. Ureteral anomalies
   e. Perineal anomalies
   f. Inguinal hernia
   g. Genital hypoplasia in males
8. Skeletal system
   a. Short stature
   b. Abnormal clavicle
   c. Absent or dysplastic patellae
   d. Joint contracture or limitation
   e. Vertebral anomalies
   f. Narrow pelvis
   g. Rib anomalies
   h. Scoliosis
   i. Camptodactyly of second through fifth fingers and toes
9. Skin
   a. Deep palmar skin furrows
   b. Deep plantar skin furrows: a hallmark of the syndrome
10. Fertility: an increased risk of infertility for males and females with trisomy 8
11. Life expectancy: usually normal

Diagnostic Investigations

1. Traditional cytogenetic diagnosis
   a. Detection of mosaic trisomy 8 from various tissue
   b. Abnormal cell line tends to disappear from lymphocytes with age.
   c. In older patients, aneuploidy can sometimes be demonstrated in fibroblast cultures only.
2. Interphase fluorescent in situ hybridization (FISH) using a chromosome 8 centromere-specific probe
3. Array comparative genomic hybridization (array-CGH)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: recurrence risk not increased
   b. Patient's offspring
      i. An increased risk of spontaneous abortion for trisomic conceptuses
      ii. Fetuses with complete trisomy 8: nonviable
      iii. Chromosomally normal pregnancies possible
2. Prenatal diagnosis
   a. Prenatal cytogenetic diagnosis of mosaicism
      i. Metaphase analysis of cultured cells from either amniotic fluid or chorionic villi: currently the standard technique (analysis of 30 colonies needed to exclude 10% mosaicism with a 95% confidence level)
      ii. Interphase fluorescent in situ hybridization (FISH) with a centromere-specific probe: to further define the level of mosaicism
      iii. Array comparative genomic hybridization (array-CGH): enables faster results than standard cell culture and metaphase analysis (capable of detecting mosaicism at levels as low as 7%)
   b. Problems in genetic counseling
      i. Prediction of phenotype difficult since clinical severity is not related to the level of mosaicism
      ii. Problems in detecting trisomy 8 mosaicism in chorionic villi
         a) Do not necessarily reflect a constitutional mosaicism of the fetus
         b) Most likely represent confined placental mosaicism (a chromosomally abnormal cell line limited to the trophoblast tissue and/or extraembryonic mesoderm, with a normal karyotype in the fetus proper)
         c) Possible false-negative cases of trisomy 8 mosaicism in short-term culture villi, as well as cultured amniotic fluid cells

   d) Follow-up investigations in fetal blood cells recommended when trisomy 8 mosaicism is encountered in chorionic villi
  iii. Problems in detecting trisomy 8 mosaicism in amniotic fluid
    a) Amniocentesis: not the best way to reveal trisomy 8 mosaicism
    b) Cases of missed trisomy 8 mosaicism reported
3. Management
  a. Mostly supportive
  b. Surgical management may be needed for those individuals with major malformations

Fig. 1 (**a**–**d**) An infant boy with trisomy 8 mosaicism showing typical craniofacies (prominent forehead, ocular hypertelorism, plump nose with broad base, micrognathia) and characteristic deep plantar skin furrows. Chromosome analysis showed trisomy 8 mosaicism (only trisomy 8 karyotype is shown here)

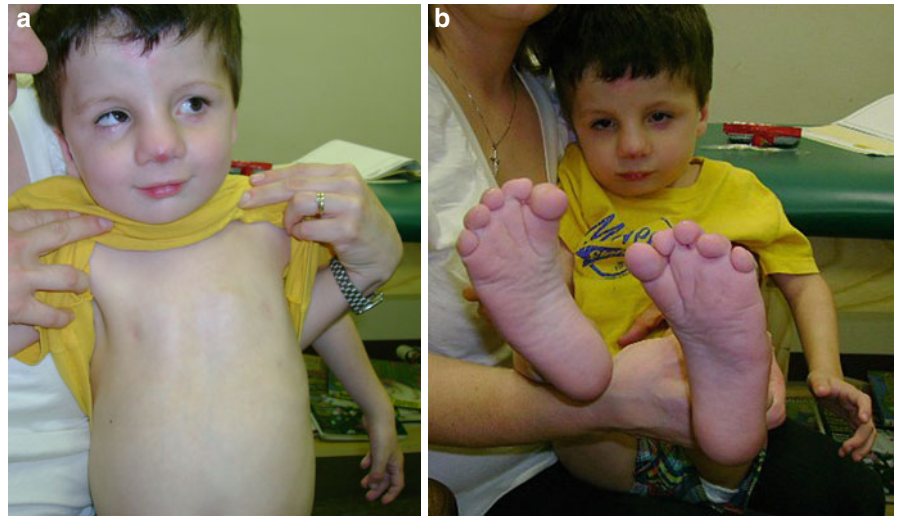

Fig. 2 (**a**, **b**) A 2-year-and-6-month-old boy with trisomy 8 mosaicism showing typical craniofacial features (prominent forehead, ocular hypertelorism, plump nose with broad base, micrognathia) and characteristic deep plantar furrows in both feet

Fig. 3 Another child with trisomy 8 mosaicism with typical phenotype

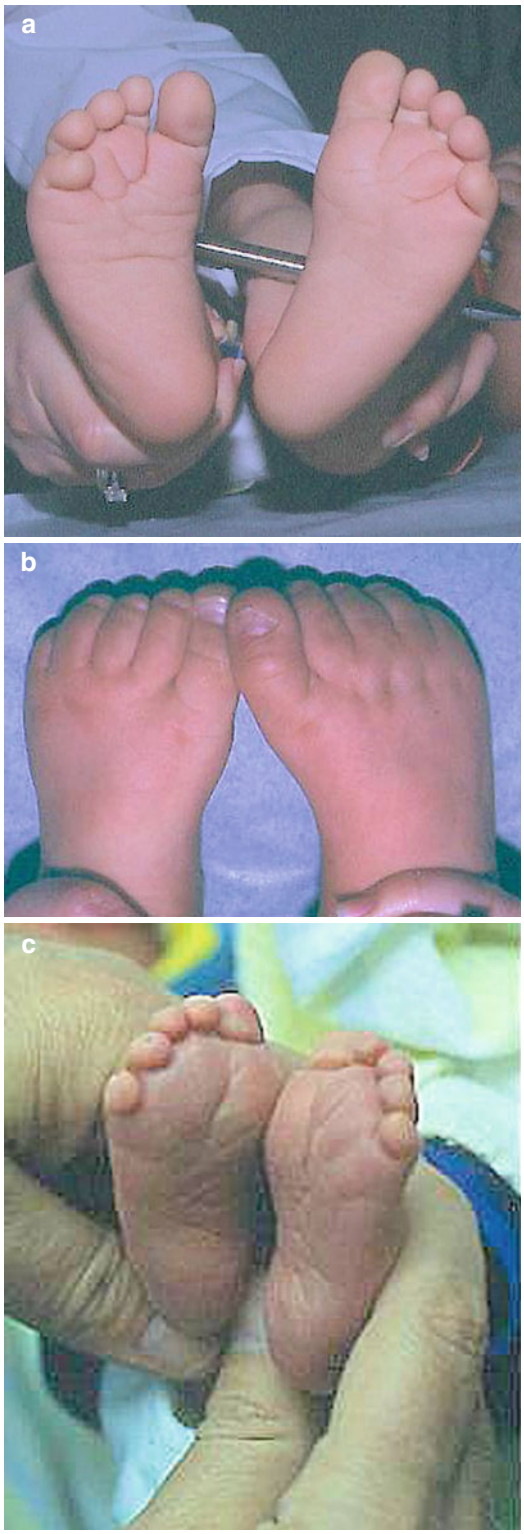

Fig. 4 (**a**–**c**) Two infants with trisomy 8 mosaicism showing characteristic deep plantar furrows in both feet

Trisomy 13 Syndrome

In 1960, Patau et al. first recognized the relation of trisomy 13 to a clinical syndrome. Incidence is estimated to be 1/4,000–1/10,000 live births.

Synonyms and Related Disorders

Patau syndrome

Genetics/Basic Defects

1. Trisomy 13
   a. Mechanism: due to meiotic nondisjunction
      i. Maternal origin of the extra chromosome (90%)
      ii. Stage of nondisjunction: mostly maternal meiosis I (vs. meiosis II in trisomy 18)
      iii. Paternal origin of the extra chromosome (10%): The majority is primarily postzygotic mitotic errors.
   b. Frequency: 75% of cases
2. Translocation trisomy 13
   a. Mechanism: de novo (75%) or familial transmission (25%)
   b. Frequency: 20% of cases
   c. Trisomy 13 due to t(13;13): The structural abnormalities are usually isochromosomes originating in mitosis.
3. Mosaic trisomy 13
   a. Mechanism: due to postzygotic (postfertilization) mitotic nondisjunction
   b. Frequency: 5% of cases
   c. Variable phenotype from full trisomy to near normal
   d. Variable mental retardation with longer survival
   e. Trisomy 13/triploidy mosaicism: a rare event
4. Partial trisomy 13
   a. Partial trisomy of proximal segment with nonspecific clinical features and little similarity to full trisomy 13
   b. Partial trisomy of distal segment with specific clinical features

Clinical Features

1. General
   a. Low birth weight
   b. Thrombocytopenia
2. CNS
   a. Severe mental retardation
   b. Holoprosencephaly
   c. Seizures
   d. Central apnea
3. Craniofacial abnormalities
   a. Microcephaly
   b. Wide sagittal sutures
   c. Wide fontanels
   d. Scalp defect (aplasia cutis congenita, 50%)
   e. Capillary hemangioma of the forehead
   f. Ocular abnormalities
      i. Microphthalmia/anophthalmia
      ii. Colobomas
      iii. Retinal dysplasia
   g. Cleft lip/palate
   h. Abnormal auricles
   i. Low-set ears
   j. Sensorineural and conductive deafness

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_235,
© Springer Science+Business Media, LLC 2012

k. Recurrent otitis media
l. Abundant nuchal skin folds
4. Cardiovascular abnormalities
a. Ventricular septal defect
b. Atrial septal defect
c. Patent ductus
d. Coarctation of the aorta
e. Dextrocardia
5. Gastrointestinal abnormalities
a. Omphalocele
b. Malrotation
c. Umbilical hernia
d. Inguinal hernia
e. Accessory spleen
f. Heterotopic pancreatic tissue
g. Meckel's diverticulum
h. Diaphragmatic defects
i. Large gallbladder
6. Genitourinary abnormalities
a. Polycystic kidneys
b. Cryptorchidism
c. Hypospadias
d. Bicornuate uteri
e. Abnormal fallopian tubes
f. Hypoplastic ovaries
7. Skeletal abnormalities
a. Polydactyly
b. Posterior prominence of heel
c. Flexed fingers
d. Hypoplasia of pelvis
e. Shallow acetabulum
f. Thin posterior ribs
g. Flexion deformity of large joints
h. Limb deficiency (5.3%)
i. Radial aplasia
j. Hyperconvex narrow fingernails
8. Dermatoglyphics
a. Transverse palmar crease
b. t′
c. Hallucal arch fibular or loop tibial
9. Others
a. Thymic cyst
b. Persistence of fetal hemoglobin
10. Prognosis
a. Majority of trisomy 13 conceptuses
i. Abort during pregnancy
ii. Stillborn
b. Twenty-five percent die by 24 h of life
c. Forty-five percent die by 1 month of life
d. Sixty percent die by 6 months of life
e. Seventy-two die by 1 year of age
f. Usual mode of death: primary apnea
g. Survivals up to 11 and 19 years old reported
11. Mosaic trisomy 13
a. The phenotype ranges
i. Typical features of trisomy 13
ii. More mild mental retardation or even normal intellectual function (rare), milder physical features, and longer survival
b. The range in clinical severity is likely due to the varying proportion of trisomy 13 cells and their distribution within the body.
12. Partial trisomy 13 of the proximal segment
a. Severe mental retardation
b. Large nose
c. Short upper lip
d. Receding mandible
e. Clinodactyly of the fifth fingers
13. Partial trisomy 13 of the distal segment
a. Severe mental retardation
b. Bushy eyebrows (synophrys) with long incurved lashes
c. Frontal capillary hemangioma
d. Long philtrum
e. Prominent antihelix

Diagnostic Investigations

1. Cytogenetic studies
a. Conventional technique
b. FISH of interphase cells for rapid diagnosis
c. Parental karyotyping in case of translocation trisomy 13
d. Trisomy 13 mosaicism
2. Echocardiography for cardiovascular anomalies
3. EEG: hypsarrhythmia
4. CT/MRI for central nervous system anomalies
5. Radiography
a. Wide anterior fontanel
b. Presence of a cervical rib
c. Absence of the 12th rib
d. Anomalies of rib morphology
e. Low acetabular angle
f. Long distal phalanges
g. Cranial bone abnormalities in case of holoprosencephaly
h. Clefting of the vertebral bodies

i. Abnormal postsphenoid component of the sphenoid bone
j. Agenesis of the nasal bones

6. Placenta: Partial molar change of the placenta may rarely occur in trisomy 13 (Has et al. 2002).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Trisomy 13: about 1 in 4,000
      ii. De novo translocation: about 1 in 4,000
      iii. Familial translocation: 5–15%
      iv. Mosaicism: 1 in 4,000
   b. Patient's offspring: not surviving to reproductive age
2. Prenatal diagnosis
   a. Prenatal ultrasonography: prevalence of ultrasound abnormalities (91%)
      i. General
         a) IUGR (48%)
         b) Single umbilical artery
         c) Polyhydramnios (15%)
         d) Oligohydramnios (12%)
      ii. Cranium and CNS abnormalities (58%)
         a) Holoprosencephaly (39%)

Trisomy 18 Syndrome

Edwards et al. and Smith et al. independently described trisomy 18 syndrome in 1960 (Edwards et al. 1960; Smith et al. 1960). It is the second most common autosomal trisomy after trisomy 21. Prevalence is approximately 1 in 6,000–8,000 live births.

Synonyms and Related Disorders

Edwards syndrome

Genetics/Basic Defects

1. Caused by an extra chromosome 18 resulting from nondisjunction in meiosis
   a. Maternal origin of an extra chromosome 18 in 90% of cases
   b. An error in maternal meiosis II is the most frequent cause of nondisjunction for chromosome 18, unlike all other human trisomies that have been studied, which show a higher frequency in maternal meiosis I.
   c. Increased incidence with advanced maternal age
2. Types of trisomy 18
   a. Full trisomy 18 in 95% of cases
   b. Rare mosaicism and translocation cases: translocation trisomy giving rise to partial trisomy 18 syndrome
3. Preponderance of females with trisomy 18 in live-borns (sex ratio 0.63) (sex ratio defined as the number of males divided by the number of females) compared to fetuses diagnosed prenatally (sex ratio 0.90) indicating a prenatal selection against trisomy 18 males after the time of amniocentesis (Nicolaidis and Petersen 1998)
4. The smallest extra region necessary for expression of serious anomalies of trisomy 18: Two critical regions, one proximal (18q12-q21.2) and one distal (18q22.3-qter), which work jointly to produce the typical trisomy 18 phenotype.

Clinical Features

1. Prenatal history (Chen 2011)
   a. Maternal polyhydramnios possibly related to defective fetal sucking and swallowing reflexes in utero
   b. Oligohydramnios secondary to renal defects
   c. Disproportionately small placenta
   d. Single umbilical artery
   e. Intrauterine growth retardation
   f. Weak fetal activity
   g. Fetal distress
2. Clinical history
   a. Apneic episodes
   b. Poor feeding
   c. Marked failure to thrive
3. Physical growth: profound growth retardation
4. Central nervous system (CNS)
   a. Inevitable profound delay in psychomotor development and mental retardation (100%)
   b. Neonatal hypotonia followed by hypertonia
   c. Jitteriness
   d. Apnea

    x. Defective falx cerebri
    xi. Frontal lobe defect
    xii. Abnormal gyri
    xiii. Migration defect
    xiv. Arachnoid cyst

5. Cranial
    a. Microcephaly
    b. Elongated skull
    c. Narrow bifrontal diameter
    d. Wide fontanels and cranial sutures
    e. Prominent occiput
6. Facial
    a. Microphthalmia
    b. Ocular hypertelorism
    c. Epicanthal folds
    d. Short palpebral fissures
    e. Iris coloboma
    f. Cataracts
    g. Corneal clouding
    h. Abnormal retinal pigmentation
    i. Short nose with upturned nares
    j. Choanal atresia
    k. Micrognathia/retrognathia
    l. Microstomia
    m. Narrow palatal arch
    n. Infrequent cleft lip and cleft palate
    o. Preauricular tags
    p. Low-set, malformed ears (faun-like with flat pinnae and a pointed upper helix)
7. Skeletal
    a. Severe growth retardation
    b. Characteristic hand posture, with clenched hands with the index finger overriding the middle finger, and the fifth finger overriding the fourth finger
    c. Camptodactyly
    d. Radial hypoplasia or aplasia
    e. Thumb aplasia
    f. Syndactyly of the second and third digits
    g. Arthrogryposis
    h. Rocker-bottom feet with prominent calcanei
    i. Talipes equinovarus
    j. Hypoplastic nails
    k. Dorsiflexed great toes
    l. Short neck with excessive skin folds
    m. Short sternum
    n. Narrow pelvis
    o. Limited hip abduction
    p. Severe kyphoscoliosis and tendency to spontaneous fracture of long bones emerging later
8. Cardiac malformations in more than 90% of infants with trisomy 18
    a. Ventricular septal defects
        i. Present in about two-thirds of cases
        ii. Large defect unlikely to undergo spontaneous closure
    b. Polyvalvular heart disease pulmonary and aortic valve defects)
    c. Double outlet right ventricle
    d. Atrial septal defects
    e. Patent ductus arteriosus
    f. Overriding aorta
    g. Coarctation of aorta
    h. Hypoplastic left heart syndrome
    i. Tetralogy of Fallot
    j. Transposition of great arteries
    k. Endocardial fibroelastosis
    l. Persistent left superior vena cava
    m. Absent right superior vena cava
    n. Dextrocardia
9. Pulmonary
    a. Pulmonary hypoplasia
    b. Abnormal lobation of the lung
10. Gastrointestinal
    a. Omphalocele
    b. Malrotation of the intestine
    c. Ileal atresia
    d. Common mesentery
    e. Meckel diverticulum
    f. Esophageal atresia with or without tracheoesophageal fistula
    g. Diaphragmatic eventration
    h. Prune belly anomaly
    i. Diastasis recti
    j. Abnormal lobulation of the liver

k. Absent or hypoplasia of gallbladder
l. Absent appendix
m. Accessory spleens
n. Exstrophy of cloaca
o. Pyloric stenosis
p. Common mesentery
q. Megacolon
r. Imperforate or malpositioned anus
s. Pilonidal sinus
t. Umbilical, inguinal, or diaphragmatic hernias

11. Genitourinary
    a. Micromulticystic kidneys
    b. Double ureters
    c. megaloureters
    d. Hydroureters
    e. Hydronephrosis
    f. Horseshoe kidneys
    g. Ectopic kidney
    h. Unilateral renal agenesis
    i. Cryptorchidism, hypospadias, and micropenis in males
    j. Hypoplasia of labia and ovaries, bifid uterus, hypoplastic ovaries, and clitoral hypertrophy in females
12. Endocrine
    a. Thymic hypoplasia
    b. Thyroid hypoplasia
    c. Adrenal hypoplasia
13. Dermatoglyphics
    a. Increased number of simple arches (6 or more) on the finger tips
    b. Transverse palmar crease
    c. Increased atd angle
    d. Clinodactyly of the fifth fingers with a single flexion crease
14. Prognosis
    a. Approximately 95–97.5% of conceptuses with trisomy 18 die in embryonic or fetal life.
    b. Only 30% of live fetuses at midtrimester amniocentesis surviving to term
    c. Five to ten percent of affected children survive beyond the first year.
    d. Rare reports of long survival into 20s
    e. High mortality rate secondary to cardiac and renal malformations, feeding difficulties, sepsis, and central apnea caused by CNS defects
    f. Severe psychomotor and growth retardation invariably present for those who survive beyond infancy.
    g. Milder nonspecific phenotype in mosaic trisomy 18 correlates with the proportion of normal cells in the body

Diagnostic Investigations

1. Conventional cytogenetic study to detect full trisomy, mosaic trisomy, or rare translocation type trisomy 18
2. Echocardiography for cardiac anomalies
3. Barium swallow for gastrointestinal anomalies
4. Ultrasound for genitourinary anomalies
5. Skeletal radiography
    a. Phocomelia
    b. Absent radius
    c. Tight flexion of the fingers with second over the third and the fifth over the fourth
    d. Talipes equinovarus
    e. Short sternum
    f. Hemivertebrae
    g. Fused vertebrae
    h. Short neck
    i. Scoliosis
    j. Rib anomaly
    k. Dislocated hips
6. Histopathological study of temporal bone (auditory organ) (Tadaki et al. 2003)
    a. External ear: arctation or atresia of external acoustic meatus (38%)
    b. Middle ear
        i. Anomalies of auditory ossicles (61%)
            a) Incus or malleus
            b) Stapes
        ii. Absence or aberration of tensor tympani muscle or its tendon (31%)
        iii. Complete absence or hypoplasia of stapedial muscle or its tendon (28%)
    c. Inner ear
        i. Hypoplasia of the ductus semicirculares (37%)
        ii. Shortened cochlea (22%)
        iii. Anomalies of stria vascularis (22%)
        iv. Absence or hypoplasia of lymphatic valve in utricle (21%)
        v. Enlargement of canaliculus cochleae (11%)
    d. Facial nerve: geniculate ganglion cells displaced into the internal auditory meatus (53%)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. De novo full trisomy 18: 1% or less
      ii. Low-grade parental mosaicism has been reported in two occasions in sporadic cases of trisomy 18.
      iii. A parent being a balanced carrier of a structural rearrangement: increased recurrence risk pending on the type of structural rearrangement and the pattern of segregation
   b. Patient's offspring: unlikely to survive to reproduction
2. Prenatal diagnosis
   a. Prenatal screening in families without history of trisomy 18 using maternal serum markers
      i. Low human chorionic gonadotropin hCG) and low unconjugated estriol (uE3) in maternal serum during midtrimester: useful predictors for an increased risk for trisomy 18
      ii. Possible future first-trimester biochemical screening for trisomy 18: reduced levels of pregnancy-associated plasma protein A (PAPP-A) and free beta–human chorionic gonadotropin (beta-hCG) at 8–13 weeks gestation. The mean MOM in affected pregnancies was 0.25 for PAPP-A and 0.34 for free beta-hCG.
      iii. Screening for trisomy 18 using a combination of maternal age, PAPP-A, and beta-hCG: reported to achieve a detection rate of 76.6% with a false-positive rate of 0.5% (Biagiotti et al. 1998)
   b. Prenatal ultrasonography: The majority of fetuses with trisomy 18 have detectable structural abnormalities.
      i. First-trimester sonographic findings (Sepulveda et al. 2010)
         a) Nuchal translucency (77–91%)
         b) Absent/hypoplastic nasal bone (53%)
         c) Generalized subcutaneous edema (49%)
         d) Omphalocele (21%)
         e) Abnormal posturing of hands (6%)
         f) Megacystis (4%)
         g) Cardiac defect (4%)
         h) Pleural effusions (4%)
         i) Echogenic yolk sac (4%)
      ii. Oligohydramnios/polyhydramnios (12%)
      iii. Intrauterine growth retardation (29%)
      iv. Two-vessel umbilical cord (40%)
      v. CNS
         a) Abnormally shaped fetal head (strawberry or lemon) (43%)
         b) Microcephaly
         c) Dandy-Walker malformation (posterior fossa enlargement associated with cerebellar hypoplasia)
         d) Enlarged cisterna magna
         e) Choroid plexus cysts (43%)
         f) Neural tube defects (9%)
      vi. Micrognathia
      vii. Thickened nuchal skin fold
      viii. Cystic hygroma or lymphangiectasia (14%)
      ix. Omphalocele (20%)
      x. Esophageal atresia
      xi. Cardiac defects (37%): septal defects with polyvalvular disease
      xii. Renal anomalies (9%)
         a) Polycystic kidneys
         b) Horseshoe and ectopic kidneys
      xiii. Limb abnormalities
         a) Clenched hands with overlapping index finger (89%)
         b) Forehand and hand abnormalities such as a short radial ray
         c) Rocker-bottom feet
         d) Club feet
   c. 3D/4DUS offers diagnostic advantages for most anomalies associated with trisomy 18, especially anomalies of the extremities and face (Zheng et al. 2008).
   d. Amniocentesis or CVS by conventional cytogenetic or FISH techniques
      i. Straight trisomy 18
      ii. Trisomy 18 mosaicism: 54% risk for an abnormal outcome, including phenotypically abnormal offspring, IUGR, or fetal demise. The risk is increased with increasing percentage of amniotic fluid trisomic cell line.
   e. Culturing fetal hematopoietic stem-progenitor cells from maternal blood during pregnancy: a new strategy holding great promise for noninvasive prenatal genetic diagnosis
3. Management
   a. Genetic counseling in prenatally diagnosed trisomy 18

i. Traumatic experience in the lives of all couples having a fetus with trisomy 18
ii. Emotional upheaval persisting for variable time periods after the diagnoses and the decisions concerning the pregnancy outcomes

b. Medical care of trisomy 18 infants
   i. Supportive
   ii. Treat infections
      a) Otitis media
      b) Upper respiratory infections (bronchitis, pneumonia)
      c) Urinary tract infections
   iii. Nasogastric and gastrostomy supplementation for feeding problems
   iv. Orthopedic management of scoliosis secondary to hemivertebrae
   v. Primarily medical management of congenital heart disease
   vi. Diuretic and digoxin for congestive heart failure
   vii. Referral for early intervention including physical and occupational therapy
   viii. Psychosocial management: Discuss implications, possible outcomes, and available supportive services in the community.
   ix. Severe developmental delay exhibited by long-term survivors presenting the greatest challenge to parental coping during the childhood years
   x. Informed and empathetic care to families undergoing a complex grieving process that combines both the reactive grief predominant in chronic illness and the preparatory grief associated with impending death (Van Dyke and Allen 1990)

c. Surgical care of trisomy 18 infants: Because of the extremely poor prognosis, surgical repair of severe congenital anomalies such as esophageal atresia or congenital heart defects is not likely to improve the survival rate of infants and should be discussed with families.

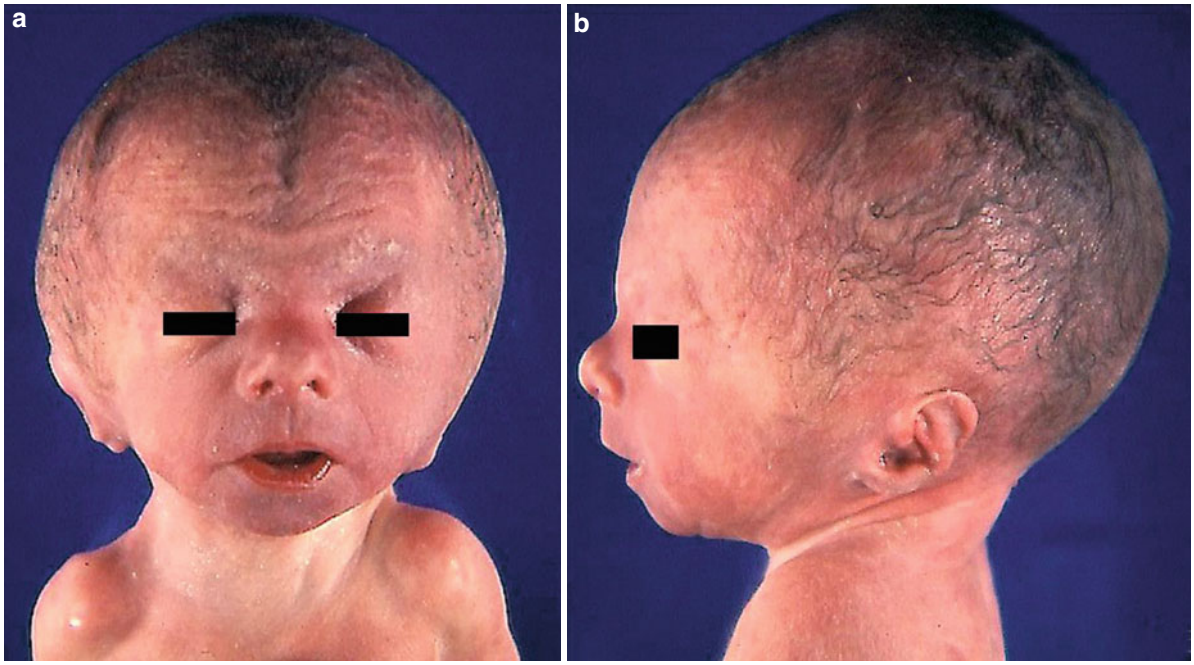

Fig. 2 (**a**, **b**) An infant with trisomy 18 showing small eyes, microstomia, low-set/malformed ears, and short neck

Fig. 3 An infant with trisomy 18 showing micro/retrognathia, short neck, and characteristic finger grasping pattern

Fig. 4 (**a**–**c**) Three infants with trisomy 18 showing reduction malformations of the upper extremities

Fig. 5 (**a**–**d**) Two infants with trisomy 18 showing small eyes, micro/retrognathia, and low-set/malformed ears

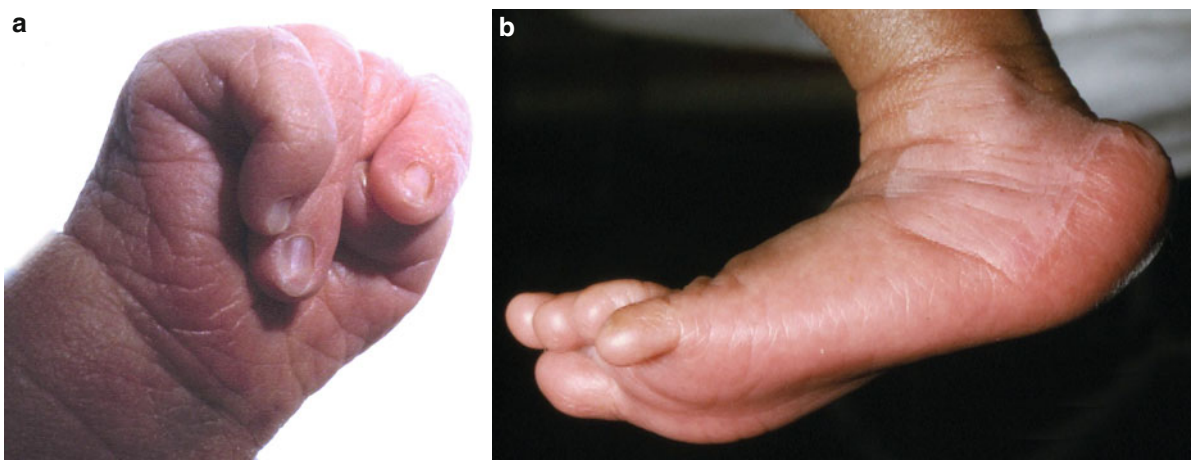

Fig. 6 (**a**, **b**) Typical hand grasping pattern (*left*) and rocker-bottom feet with prominent calcaneus (*right*) observed in trisomy 18

Fig. 7 Trisomy 18 karyotype (47,XY,+18)

Fig. 8 Translocation trisomy 18 karyotype [46,XX,+18,der (13)t(13;18)(q10;q10)]

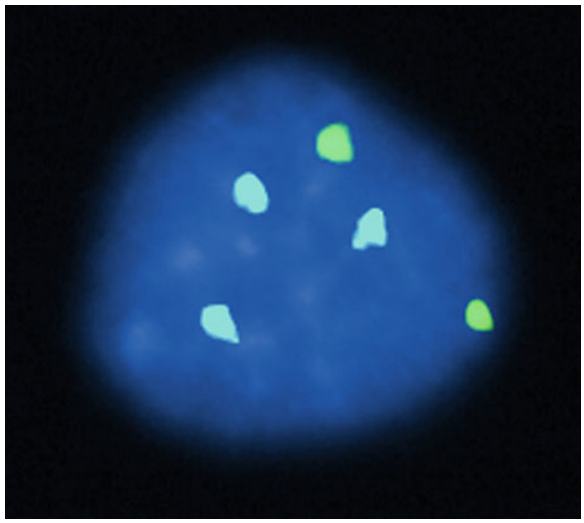

Fig. 9 Trisomy 18 shown by FISH (CEP X/SpectrumGreen, CEP 18/SpectrumAqua, Vysis/Abbott) on an uncultured amniocyte. Three copies of the aqua signal are present in the cells (CEP 18). Two copies of the green signal (CEP X) confirm a female fetus

Tuberous Sclerosis

Tuberous sclerosis is the second most common neurocutaneous syndrome after neurofibromatosis. The term "tuberous sclerosis" derived from the "tubers" (swellings or protuberances) and areas of "sclerosis" (hardening) of the cerebral gyri that calcifies with age. The classic description of the syndrome includes Bogt's triad: mental retardation, seizures, and adenoma sebaceum (a misnomer) or facial angiofibromas. Tuberous sclerosis affects about 1 in 6,000 newborns (Osborne et al. 1991).

Synonyms and Related Disorders

Tuberous sclerosis complex

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
      i. Almost complete penetrance
      ii. Extremely variable in its manifestations and severity
   b. Sporadic (new mutations) in two thirds of cases
2. Caused by mutations in either of the following two tuberous sclerosis complex (*TSC*) genes (Curatolo et al. 2008)
   a. *TSC1*
      i. Located on chromosome 9q34
      ii. Encodes protein, hamartin (TSC1), a protein implicated in regulating cell adhesion via interactions with cortical actin filaments and a plasma membrane binding protein ezrin-radixin-moesin, part of a Rho-mediated signaling pathway
      iii. Approximately 50% of tuberous sclerosis families show linkage to *TSC1*.
      iv. Mutations occurrence: 10–15% of sporadic cases
      v. Most described mutations in the *TSC1* gene result in a truncated protein.
      vi. Phenotype: less severe
   b. *TSC2*
      i. Located on chromosome 16p13.3
      ii. Encodes protein, tuberin (TSC2), a protein implicated in regulating cytoplasmic vesicle transport to the cell membrane
      iii. Approximately 50% of families show linkage to *TSC2*.
      iv. Mutation occurrence: 75–80% of sporadic cases
      v. Many mutations in the *TSC2* gene are large (contiguous) deletions, which may involve the *PKD1* gene, resulting in a severe phenotype called very early onset polycystic kidney disease.
      vi. Phenotype: more severe
3. Both *TSC1* and *TSC2*
   a. Have properties consistent with tumor suppressor genes functioning according to Knudson's "two-hit" hypothesis (Yeung 2003)
   b. The clinical variability occurs secondary to the random nature of the second "hit" in individuals carrying a germ line mutation.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_237,
© Springer Science+Business Media, LLC 2012

c. Loss of heterozygosity for *TSC1* or *TSC2* gene
   i. Suggests that 1 mutation is acquired embryonically and another is acquired later on somatically (two-hit hypothesis)
   ii. Observed in 41% of all hamartomas including renal angiomyolipomas, cardiac rhabdomyomas, and subependymal giant cell astrocytomas

4. Hamartin and tuberin
   a. Widely expressed in the brain
   b. May interact as part of a cascade pathway that modulates cellular differentiation, tumor suppression, and intracellular signaling
5. Mosaicism in tuberous sclerosis reported
   a. Somatic mosaicism: The mutation is not found in all cell lines.
   b. Gonadal mosaicism: The mutation found only in gonadal cells and is therefore transmitted to offspring while parents are spared from any disease manifestation.
6. Genotype-phenotype correlations (Dabora et al. 2001)
   a. Overlap of many clinical features exists among the patients with *TSC1* and *TSC2* mutations.
   b. Sporadic patients with TSC1 mutations
      i. On average, milder phenotypic manifestations compared with patients with TSC2 mutations
      ii. Lower frequencies of seizures
      iii. Lower frequencies of moderate to severe mental retardation
      iv. Fewer subependymal nodules and cortical tubers
      v. Less severe kidney involvement
      vi. No retinal hamartomas
      vii. Less severe facial angiofibroma
   c. Some features are rare or not seen at all in *TSC1* patients.
      i. Grade 2–4 kidney cysts or angiomyolipomas
      ii. Forehead plaques
      iii. Retinal hamartomas
      iv. Liver angiomyolipomas
   d. Both germ line and somatic mutations are less common in TSC1 than TSC2.
   e. Patients without mutation
      i. Milder than patients with TSC2 mutations
      ii. Somewhat distinct from patients with TSC1 mutations

Clinical Features

1. Characteristic cutaneous features (virtually 100% of cases) (Schwartz et al. 2007)
   a. Hypomelanotic macules ("ash-leaf spots") (87–100% of cases)
      i. One of the earliest skin lesions (often present at birth)
      ii. Commonly on trunk and buttocks, rarely on the face, and best appreciated by the Wood's fluorescence lamp
      iii. Not specific to tuberous sclerosis because they are seen in unaffected children
      iv. Smaller depigmented spots over the anterior shins: characteristically distributed in a "confetti" fashion (clustered skin lesions with a reticulated appearance)
   b. Shagreen patches (a form of collagenomas) (20–80%)
      i. Elevated discolored skin lesions commonly over lumbosacral region, observed in about 21% of patients
      ii. Age at presentation: birth to adulthood
   c. Facial angiofibromas (47–90%)
      i. One of the most common and specific cutaneous manifestations
      ii. Causing the most disfigurement among the skin lesions
      iii. Red to brown nodules, observed over the nose and cheeks in bilaterally symmetrical butterfly distribution. Rarely segmental tuberous sclerosis may present as unilateral facial angiofibromas.
      iv. Age of presentation
         a) Usually appear after 2 years of age
         b) Increase in size and number of facial angiofibromas with time
         c) Observed in about 80% of adults with tuberous sclerosis
      v. Chance of small and discrete papules of facial angiofibromas to become confluent and fungating lesions
   d. Forehead fibrous plaque (15%)
      i. Large fibromas without angiomatous appearance on the scalp or the forehead areas

ii. Yellowish-brown or skin-colored plaques of variable size and shape usually located on the forehead or scalp
iii. Present at any age and can be seen at birth or early infancy

e. Periungual fibromas (17–87%)
i. Skin-colored or reddish nodules seen on the lateral nail groove, nail plate, or along the proximal mail folds
ii. More commonly found on the toes than on the fingers
iii. Characteristically appear during puberty and persist through life

f. Café au lait spots: seen in 15–30% of patients with tuberous sclerosis

g. "Confetti-like" macules (2.8%)
i. Multiple, 1–2 mm white spots symmetrically distributed over extremities
ii. Present at the second decade or adulthood

h. Molluscum fibrosum pendulum (skin tags) (23%)
i. Multiple soft pedunculated skin growths on neck, rarely in axilla or groin
ii. More common during first decade of life, rarely during infancy

2. CNS abnormalities (the most common manifestations of the disorder)
a. Epilepsy
i. The major neurologic manifestation, affecting 85% of patients
ii. Onset usually at few months of age
iii. Typically with initial classic hypsarrhythmia and infantile spasms, which transform into adult-type partial complex or tonic-clonic seizures
iv. Carries a poor prognosis with cognitive impairment
v. Intractable seizures

b. Presence of cortical "tubers" (O'Callaghan 2008)
i. A pathognomonic sign
ii. Tubers are developmental abnormalities of the cerebral cortex.
iii. The lesions have lost the normal six-layered laminar architecture of the cerebral cortex and contain dysplastic neurones, astrocytes, and characteristic giant cells.
iv. Tubers can be identified in fetal life and persist throughout life.
v. Tubers do not increase in number after birth, although they may become more visible on magnetic resonance imaging as the brain myelinates in the first 2–3 years of life.

c. Subependymal nodules (abnormal neuronal and glial elements): the most common cerebral lesion

d. Cortical or subcortical white matter tubers (70% of cases)
i. Composed of abnormal giant astrocytes
ii. Found in 90% of patients with tuberous sclerosis
iii. Large cortical tubers may occasionally block the foramen of Monro resulting in hydrocephalus.

e. Subependymal giant cell astrocytomas
i. The most common CNS tumors (6–14%)
ii. Subependymal nodules, small hamartoma lining the ventricles, may calcify.
iii. A radiologically confirmed cortical tuber or calcified subependymal nodule are highly suggestive of tuberous sclerosis.
iv. Rare malignant transformation of these astrocytomas, accounting for 25% of deaths in tuberous sclerosis

f. Other abnormalities
i. Cerebral atrophy
ii. Cerebral infarct
iii. Cerebral aneurysm
iv. Arachnoid cyst
v. Chorea (rare manifestation) (Sha et al. 2009)

3. Developmental disorders (>50%)
a. Childhood
i. Learning disabilities
ii. Behavioral problems
iii. Pervasive developmental disorder
iv. Autism more common in childhood
v. Hyperactivity or attention deficit hyperactivity disorder (ADHD)
vi. Aggression

b. Adulthood: mental retardation present in less than 50% of the affected individuals

4. Ocular involvement (at least 50% of the patients)
a. Retinal and optic nerve astrocytic hamartomas (the most frequent manifestations)
b. Retinal phakoma

i. Astrocytomas of the retina
ii. Often called "mulberry lesions"
iii. Absence of the normal "red reflex" in the newborn suggests the presence of retinal phakoma.

c. Visual loss resulting from
i. Macular hamartoma
ii. Vitreous hemorrhage
iii. Papilledema or optic atrophy secondary to intracranial tumors

d. Rare sector hypopigmentation of the iris, vitiligo, or poliosis of the eyelid and eyelashes

5. Dental involvement: important findings
a. Pitting of the dental enamel
i. Invariably present in the permanent teeth
ii. Seen in the primary (deciduous) teeth (30%)
iii. Rarely produce symptoms

b. Gingival angiofibromas (50% of children; 70% of adults)

6. Neoplasms affecting heart, kidneys, lungs, and other organ systems
a. Cardiac rhabdomyomas (Caldemeyer and Mirowsk 2001)
i. The commonest cardiac tumors of childhood and are often associated with TSC
ii. The earliest diagnostic finding in some patients detected on prenatal sonography
iii. Detected by echocardiography, rarely causing problems
iv. Observed in two thirds of affected children. However, more than 80% of children with cardiac rhabdomyomas have tuberous sclerosis.
v. Usually resolve spontaneously or regress with age
vi. A rare cause of prenatal and neonatal cardiac failure, mostly from dysrhythmias
vii. Rare tumor obstruction to cardiac valves or chambers

b. Renal cysts or angiomyolipomas (70–80% of patients)
i. Bilateral multiple renal angiomyolipomas (70%)
a) Diagnostic of tuberous sclerosis
b) Renal angiomyolipomas are benign tumors but contain vascular tissue, which may cause bleeding, hypovolemic shock, and renal failure.
ii. Epithelial cysts (20%)
iii. Polycystic kidney disease (2–3%)
iv. Rare occurrence of renal cell carcinoma (<1%)
v. Malignant angiomyolipoma (<1%)
vi. Benign adenomatous hamartoma (oncocytoma) (<1%)
vii. Lymphangioleiomyomatosis of the renal sinus: rare

c. Pulmonary manifestations (Caldemeyer and Mirowsk 2001)
i. Lymphangio(leio)myomatosis (1–6% of patients)
a) Observed almost exclusively in young female patients, suggesting that a hormonal component is involved in the development of pulmonary sequelae (Lendvay and Marshall 2003)
b) Affects between 26% and 39% of women with TSC
c) Progressive, diffuse interstitial disease, detected by chest radiographs which show diffuse reticular pattern and multiple cyst lesions in the lungs
d) Often complicated by pneumothorax from rupture of subpleural pulmonary cysts
e) The end-stage disease shows "honeycomb" lungs.
f) No effective treatment that reverse the progression of the lung disease (one of the causes of early mortality in TSC patients (Hancock and Osborne 2002))
ii. Multifocal micronodular pneumocyte hyperplasia
a) Affects men and women
b) May accompany lymphangioleiomyomatosis

d. Hamartomas and polyposis of the stomach, intestine, and colon
i. Almost never cause significant symptoms
ii. Occasional GI bleeding leading to positive tests for fecal occult blood

e. Hepatic cysts and angiomyolipomas (up to 24%)
i. Asymptomatic and nonprogressive
ii. Marked female predominance

f. Vascular lesions (Salerno et al. 2010)
   i. Aneurysms
      a) Aorta
      b) Pulmonary artery
      c) Intracranial arteries (internal carotid, middle cerebral)
      d) Axillary artery
      e) Subclavian artery
      f) Iliofemoral artery
   ii. Stenotic-occlusive disease
      a) Aorta
      b) Common iliac artery
      c) Coronary artery
      d) Moyamoya disease
      e) Renal artery
      f) Mesenteric arteries
g. Arterial aneurysms reported in the brain, aorta, and axillary arteries
h. Musculoskeletal manifestations
   i. Sclerotic and hypertrophic lesions of bone
      a) Mostly an incidental finding
      b) Occasionally palpable and associated with pains
      c) Common locations including calvarium, pelvis, vertebrae, and long bones
   ii. Bone lucencies
      a) Nonspecific hamartomas
      b) Found in the phalanges of the hands and feet
      c) Usually asymptomatic
      d) Involvement in two thirds of patients

7. Pregnancy does not increase the risk of developing renal and pulmonary complications in women with tuberous sclerosis (Mitchell et al. 2003).
8. Diagnostic criteria of tuberous sclerosis complex (first proposed in 1992). The presence of one of the primary diagnostic criteria is considered sufficient to diagnose tuberous sclerosis complex.
   a. Primary features
      i. Facial angiofibromas
      ii. Multiple ungula fibromas (or periungual fibromas in the absence of trauma)
      iii. Cortical tuber (histologically confirmed)
      iv. Subependymal nodule or giant cell astrocytomas (histologically confirmed)
      v. Multiple calcified subependymal nodules protruding into the ventricle (radiographic evidence)
      vi. Multiple retinal astrocytomas (retinal hamartomas)
   b. Secondary features
      i. Affected first-degree relative
      ii. Cardiac rhabdomyoma (histologic or radiographic confirmation)
      iii. Other retinal hamartomas or achromic patch
      iv. Cerebral tubers (radiographic confirmation)
      v. Noncalcified subependymal nodules (radiographic confirmation)
      vi. Shagreen patch
      vii. Forehead plaque
      viii. Pulmonary lymphangiomyomatosis (histologic confirmation) (lymphangioleiomyomatosis)
      ix. Renal angiomyolipoma (radiographic or histologic confirmation)
      x. Renal cysts (histologic confirmation)
   c. Tertiary features
      i. Hypomelanotic macules (three or more ash-leaf spots)
      ii. "Confetti" skin lesions
      iii. Renal cysts (radiographic evidence)
      iv. Randomly distributed enamel pits in deciduous or permanent teeth
      v. Hamartomatous rectal polyps (histologic confirmation)
      vi. Bone cysts (radiographic evidence)
      vii. Pulmonary lymphangiomyomatosis (radiographic evidence)
      viii. Cerebral white-matter "migration tracts" or heterotropias (radiographic evidence)
      ix. Gingival fibromas
      x. Hamartoma of other organs (histologic confirmation)
      xi. Infantile spasms
   d. Diagnostic criteria
      i. Definitive: either 1 primary, 2 secondary, or 1 primary plus 2 tertiary features
      ii. Probable: either 1 secondary plus 1 tertiary or 3 tertiary features
      iii. Suspect: either 1 secondary or 2 tertiary features
9. The Tuberous Sclerosis Consensus Conference: devised the above clinical diagnostic criteria in 1998 (Roach et al. 1998; (Lendvay and Marshall 2003)

a. Major features
   i. Facial angiofibromas or forehead plaque
   ii. Nontraumatic ungual or periungual fibroma
   iii. Hypomelanotic macules (three or more)
   iv. Shagreen patch (connective tissue nevus)
   v. Multiple retinal nodular hamartomas
   vi. Cortical tuber
   vii. Subependymal nodule
   viii. Subependymal giant cell astrocytoma
   ix. Cardiac rhabdomyoma, single or multiple
   x. Lymphangiomyomatosis
   xi. Renal angiomyolipoma
b. Minor features
   i. Multiple, randomly distributed pits in dental enamel
   ii. Hamartomatous rectal polyps
   iii. Bone cysts
   iv. Cerebral white matter radial migration lines
   v. Gingival fibromas
   vi. Nonrenal hamartoma
   vii. Retinal achromic patch
   viii. "Confetti" skin lesions
   ix. Multiple renal cysts
c. Diagnostic criteria
   i. Definitive diagnosis: presence of two major features or one major feature plus two minor features
   ii. Probable diagnosis: presence of one major feature plus one minor feature
   iii. Possible diagnosis: presence of one major feature or two or more minor features

10. Prognosis
    a. The mild form of tuberous sclerosis: live full life without loss of function
    b. The severe form: significant morbidity and mortality from seizures, mental retardation, and associated cardiac, retinal, renal, and pulmonary pathology
    c. Association with sudden death (Byard et al. 2003; Noone et al. 2009)
       i. Cardiac arrhythmia
       ii. Epilepsy
       iii. Intratumoral hemorrhage
       iv. Additional complications
          a) Cardiac outflow obstruction
          b) Obstructive hydrocephalus
          c) Aneurysm rupture
          d) Spontaneous pneumothorax

Diagnostic Investigations

1. Cutaneous evaluation including Wood's lamp
2. Ophthalmologic evaluation for hamartomas
3. Echocardiography to identify rhabdomyomas
4. ECG for cardiac arrhythmias
5. EEG for seizures
6. Radiography of the skull (Caldemeyer and Mirowsk 2001)
   a. Calcification frequently seen in subependymal nodules and giant cell astrocytomas
   b. Less commonly seen in cortical and white matter tubers
   c. Calcification increases with the age of the patient.
7. Plain chest radiographic films: diffuse reticular pattern in lymphangiomyomatosis of the lung
8. Pulmonary CT scan
   a. Diffuse interstitial changes with infiltrates
   b. Cystic changes
9. Body CT (Avila et al. 2010)
   a. The number of sclerotic bone lesions seen at body CT is of value in the diagnosis of TSC and in the differentiation of patients with sporadic lymphangioleiomyomatosis from those with TSC/lymphangioleiomyomatosis.
   b. The CT finding of multiple sclerotic bone lesions might be added to the diagnostic criteria of TSC.
10. Renal ultrasound/CT/MRI
    a. Assess angiomyolipomas
    b. Assess renal cysts
11. Neuroimagings by MRI or CT of the brain
    a. Calcification best detected on computed tomography
    b. Magnetic resonance imaging more sensitive for detecting small subependymal nodules and cortical and white matter tubers, especially when not calcified
       i. Extent and number of cortical tubers
       ii. Subependymal gliomas
       iii. Dilated lateral ventricles
       iv. Hamartomatous foci
       v. Vascular dysplastic lesions such as aneurysms
       vi. Identify subependymal giant cell astrocytomas before occurrence of obstructive hydrocephalus

12. Histologic findings
    a. Angiofibromas
        i. Atrophic sebaceous glands with dermal fibrosis and dilation of some capillaries
        ii. "Glial" appearance of fibrosis due to the large size and stellate shape of the fibroblasts
        iii. Absence of elastic tissue in the angiofibromas
    b. Ungual fibromas
        i. Fibrosis
        ii. Rare capillary dilation
    c. Shagreen patches
        i. Increased dense sclerotic mass of broad collagenous bundles
        ii. Normal collagen bundles sometimes arranged in an interwoven pattern
        iii. Reduced elastic tissue
    d. Hypopigmented ash-leaf macule
        i. Normal melanocytes numbers with decreased pigmentation
        ii. Smaller melanosomes with defective melanization by electron microscopy
13. Molecular testing of the TSC1 and TSC2 genes: clinically available (Northrup and Au 2009)
    a. Complicated by the large size of the two genes, the large number of disease-causing mutations, and the high rate of somatic mosaicism (10–25%) (Sampson et al. 1997; Verhoef et al. 1999)
    b. Sequence analysis
    c. Deletion/duplication analysis: A deletion of the two contiguous genes (*TSC2* and *APKD1*) likely responsible if a child with tuberous sclerosis is found to have polycystic kidney disease

Genetic Counseling

1. Recurrence risk
    a. Patient's sib
        i. One to four percent recurrence risk (in case of unaffected parents) due to germ line mosaicism and nonpenetrance of the disorder
        ii. Fifty percentage if one of the parent is affected
    b. Patient's offspring: 50%
2. Prenatal diagnosis (Milunsky et al. 2009)
    a. Prenatal ultrasonographic detection of cardiac lesions consistent with rhabdomyoma
        i. Fifty percentage risk for tuberous sclerosis in the fetus
        ii. Cardiac rhabdomyomas (Bader et al. 2003)
            a) The most common cardiac tumor diagnosed in utero and in children
            b) Favorable natural history of tumors detected prenatally: Most tumors regress after the third trimester.
            c) In rare cases, there is progression in utero with a fetal demise risk of 4–6%.
    b. Prenatal diagnosis/preimplantation genetic diagnosis for at-risk pregnancies requires prior identification of the disease-causing mutation in the family.
3. Management
    a. Multidisciplinary team approach
    b. Early intervention programs
    c. Assess intellectual function and educational needs
    d. Psychiatric and behavioral problems (Muzykewicz et al. 2007)
        i. The most common formal diagnoses were anxiety disorders (28%), mood disorders (26%), adjustment disorders (21%), ADHD (21%), and mental disorders not otherwise specified due to general medical condition (42%).
        ii. Citalopram demonstrated efficacy in treating anxiety and depression.
        iii. Risperidone, in treating problematic behaviors
    e. Pharmacologic management of behavioral problems
    f. Treat cardiac failure or cardiac arrhythmias
    g. Anticonvulsants for seizure control
        i. Treatment for infantile spasm is difficult because it is often intractable to conventional antiepileptic drugs.
            a) ACTH among other anticonvulsant therapies with variable benefits
            b) Vigabatrin
        ii. Early control of seizures has a crucial role in preventing subsequent epileptic encephalopathy, and in reducing the cognitive/behavioral consequences of seizures, but does not guarantee for a normal mental outcome in children with TSC (Bombardieri et al. 2010).
    h. Rapamycin and clinical trials (Orlova and Crino 2010)

i. Rapamycin
   a) A macrolide antibiotic that has important regulatory effects on cell growth, proliferation, and inflammation via its inhibitory action on mammalian target of rapamycin
   b) Has been used as an immunomodulatory agent following organ transplantation and has a moderate-risk side effect profile
ii. Both preclinical and clinical trial data suggest that rapamycin may provide a possible therapy for TSC: The benefits may only be realized during active therapy.
   a) Reduction of angiomyolipomas volume
   b) Modest improvement of pulmonary function testing

i. Surgical care
   i. Laser treatment of facial angiofibromas
   ii. Removal of ungual fibromas by laser, diathermy, liquid nitrogen, or dermabrasion
   iii. CSF shunting to relief raised intracranial pressure
   iv. Epilepsy surgery: Unifocal onset seizures and mild to no developmental delay at the time of surgery are predictive of excellent long-term outcome.
      a) Focal cortical resection (tuberectomy)
      b) Lobar or multilobar resection
      c) Corpus callosotomy
   v. Vagus nerve stimulation
   vi. A partial nephrectomy or selective embolization preferable to total nephrectomy for treating angiomyolipomata
   vii. Cystic renal lesions rarely required surgery
   viii. Renal transplantation for end-stage renal insufficiency resulting from replacement of renal parenchyma by angiomyolipomas and growing cysts or from the removal of the kidneys for intractable hemorrhage (Papaioannou et al. 2003)
      a) Offers prolonged survival
      b) Appears to be the treatment of choice in such patients

Young, J. M., Burley, M. W., Jeremiah, S. J., et al. (1998). A mutation screen of the TSC1 gene reveals 26 protein truncating mutations and 1 splice site mutation in a panel of 79 tuberous sclerosis patients. *Annals of Human Genetics, 62* (Pt 3), 203–213.

Fig. 1 (**a**, **b**) An ash-leaf spot is observed in a child affected with tuberous sclerosis, inherited from his mother who has characteristic facial angiofibromas with symmetrical "butterfly" distribution on the nasolabial folds and cheeks

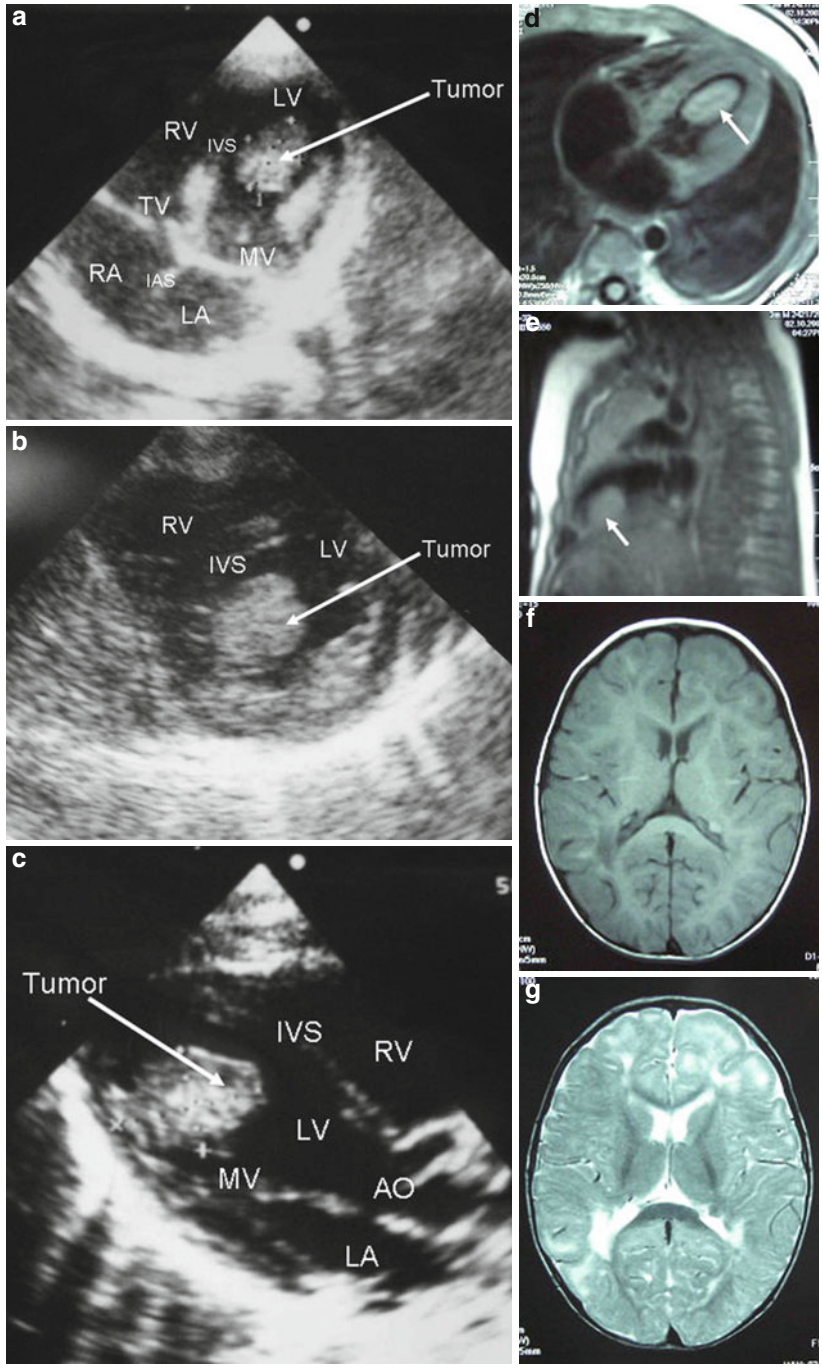

Fig. 2 A 3-month-old infant was found to have small angiofibromatous skin lesions on the cheek, two depigmented spots on the back, and a white round lesion in the left fundus. Echocardiography showed a tumor (measured 2 cm × 1 cm) in the left ventricular cavity (**a**, four chamber view; **b**, short axis view; **c**, long axis view). MRI with T1-enhanced images (**d**, **e**) showed the same rhabdomyoma (*arrow*) in the left ventricular cavity. T1-enhanced (**f**) and T2-enhanced (**g**) images of the brain showed many lesions at subcortical white matter indicated by high or low signals. Some lesions can be seen in the periventricular region. Abbreviations: AO *aorta*, IAS *interatrial septum*, IVS *interventricular septum*, LA *left atrium*, LV *left ventricle*, MV *mitral valve*, RA *right atrium*, RV *right ventricle*, TV *tricuspid valve*

Fig. 3 (**a**, **b**) Severe facial angiofibromas in symmetrical butterfly distribution over nose and cheek with a large forehead plaque. Some angiofibromas have become confluent and fungating lesions

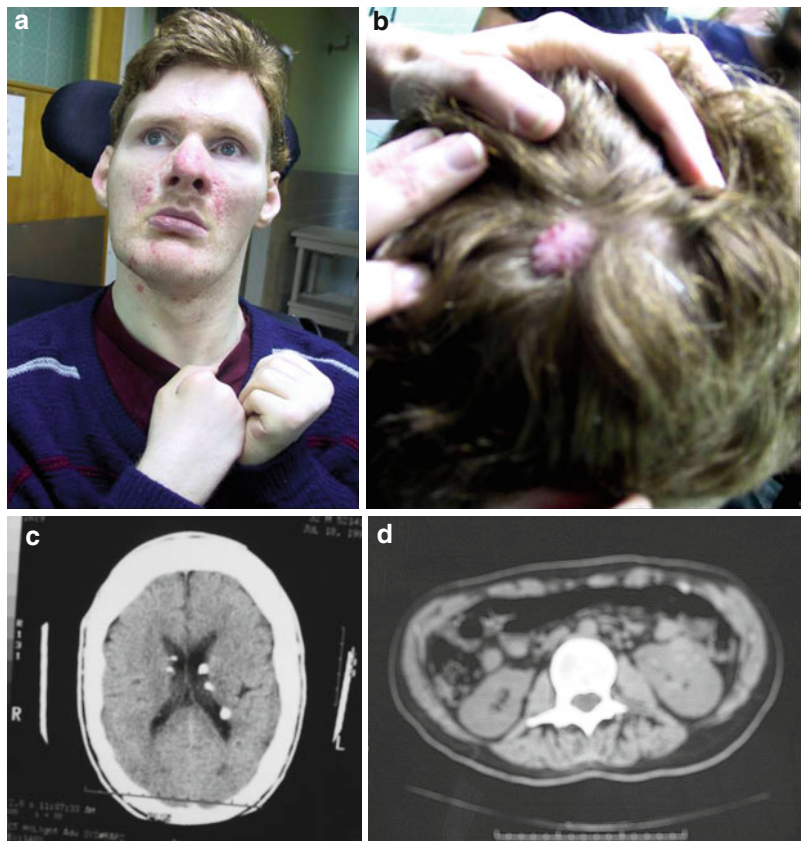

Fig. 4 (**a**–**d**) An adult with tuberous sclerosis showing typical facial angiofibromas and a scalp plaque. CT of the brain showed presence of calcified subependymal nodules. CT scan of the abdomen demonstrates an enlarged left kidney. Histologic examination of the tumor showed renal cell carcinoma

Fig. 5 (**a**, **b**) Two adults with tuberous sclerosis showing typical facial angiofibromas and mental retardation

Fig. 6 (**a**–**c**) An adult with tuberous sclerosis with typical facial angiofibromas and mental retardation. A plain skull X-ray film and a CT of the brain demonstrated intracranial calcifications

Fig. 7 (**a**, **b**) An adult with tuberous sclerosis showing typical facial features. Periungual (*fourth finger*) and ungual (*thumb*) fibromas were present

Fig. 8 (**a**–**c**) An adult with tuberous sclerosis showing typical facial angiofibromas, a scalp plaque, and a large depigmented lesion on the back

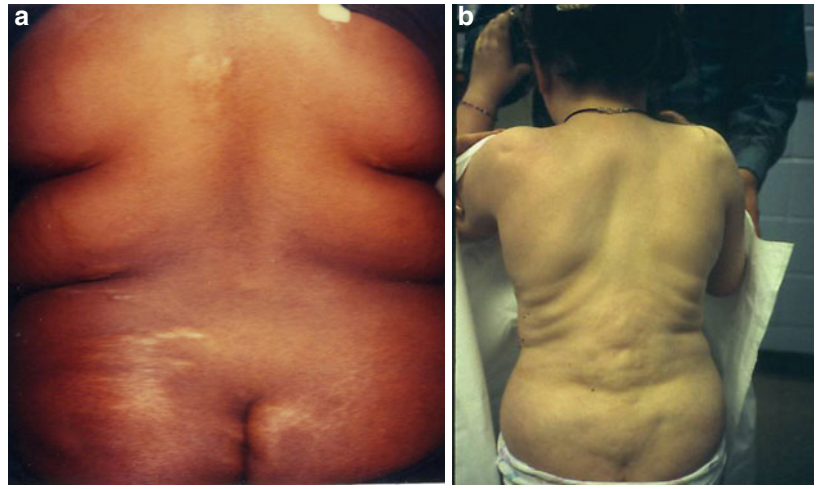

Fig. 9 (**a**, **b**) Shagreen patches are seen in upper back and lower back in two different patients with tuberous sclerosis

Turner Syndrome

In 1938, Turner reported a syndrome of sexual infantilism, short stature, webbed neck, cubitus valgus, and primary amenorrhea in seven female patients. Later in 1954, it was observed that the ovaries were usually replaced by streaks of stroma without follicles; hence, the name gonadal agenesis. Negative sex chromatin was discovered in 1954; only one X chromosome was demonstrated cytogenetically in these patients in 1959.

About 99% of 45,X fetuses abort spontaneously, usually before 28 weeks, and only 1% of these fetuses survive to term. Despite this, Turner syndrome is a relatively common chromosome disorder affecting 1 in 2,500 female live births. About 10% of all spontaneous abortuses have a 45,X karyotype.

Synonyms and Related Disorders

45,X Turner syndrome; 45,X/46,XX mosaic Turner syndrome; 45,X/46,X,r(X) ring chromosome X mosaic Turner syndrome; 46,X,i(X)(q10) isochromosome Xq syndrome

Genetics/Basic Defects

1. Caused by complete or partial X chromosome monosomy in all or some of the body cells
2. Short stature and skeletal manifestations (short fourth metacarpals, cubitus valgus, Madelung deformity, high-arched palate, and short neck) are attributed to haploinsufficiency of the *SHOX*, the short-stature homeobox-containing gene on the pseudoautosomal region of the sex chromosomes (Xp22 and Yp11.3). *SHOX* gene is also known as *PHOG* gene for pseudoautosomal homeobox-containing osteogenic gene, lying on the very tip of the short arm of both sex chromosomes (Binder et al. 2000).
3. Chromosome locus (Wolff et al. 2010)
   a. A majority of genes associated with the physical features observed in Turner syndrome are located on Xp (Xp11.2-p22) (Zinn et al. 1998)
   b. Loci contributing to ovarian function reside in Xq (Xq24) (Schlessinger et al. 2002)
4. Karyotype findings associated with Turner syndrome (Wolff et al. 2010)
   a. Prenatal
      i. Approximately 1–2% of conceptuses have a 45,X karyotype.
      ii. The fetuses typically have ultrasound findings such as cystic hygroma or nuchal thickening.
      iii. A majority of cases with mosaicism for a 45,X cell line and a cell line with a second structurally normal sex chromosome result in the birth of a child with a normal phenotype (Chang et al. 1990; Koeberl et al. 1995)
   b. Postnatal
      i. Apparently nonmosaic monosomy X is found in ~45% of patients with Turner syndrome postnatally.
      ii. A structural chromosome abnormality or mosaicism for 45,X and another cell line is found in the lymphocytes of the remaining patients with Turner syndrome
5. Presence of Y chromosome material (Wolff et al. 2010)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_238,
© Springer Science+Business Media, LLC 2012

a. Mosaicism for a cell line with a normal or abnormal Y chromosome is identified in 6–11% of patients with Turner syndrome with standard cytogenetic techniques.
b. Risk of developing gonadoblastoma (Cools et al. 2006)
   i. A gonadoblastoma is a neoplasm composed of germ cells and sex cord elements with an excellent prognosis if detected early.
   ii. Gonadoblastoma can progress to dysgerminoma with metastatic potential.
   iii. A gonadoblastoma susceptibility locus has been proposed for the pericentromeric region of the Y chromosome (Tsuchiya et al. 1995; Lau 1999)
   iv. The neoplasm does not appear to correlate with the presence of *SRY*.
   v. Presence of occult Y chromosome mosaicism
      a) Eight percentage of cases detected by molecular or standard cytogenetic techniques: Of these 12% of cases had gonadoblastoma
      b) Zero to four percentage of cases detected by FISH using a probe for the Y centromere (DYZ3) (Hanson et al. 2002; Wiktor and Van Dyke 2005)

6. Pathogenesis (Ogata and Matsuo 1995)
   a. Gonadal dysgenesis: Oocytes undergoing accelerated degeneration during the first meiosis, resulting in loss of nearly all oocytes by late childhood
   b. Somatic stigmata
      i. Lymph fluid stasis caused by lymphatic hypoplasia results in distension of the main and tributary lymphatic ducts and generalized lymphedema.
      ii. Distended lymphatics and lymphedema cause mechanical extension of surrounding tissues, giving rise to deformations recognized as lymphatic obstruction stigmata:
         a) Webbed neck
         b) Low posterior hairline
         c) Rotated auricles
         d) Puffy hands and feet
         e) Redundant skin
         f) Nail hypoplasia
         g) Whorl dominant finger tip pattern

7. Phenotype-karyotype correlation
   a. Absence or deletion of the short arm of the X chromosome correlates with Turner stigmata:
      i. Short stature
      ii. Broad chest
      iii. Widespread nipples
      iv. Webbing of the neck
      v. Peripheral lymphedema at birth
      vi. Short fourth metacarpals
      vii. Hypoplastic nails
      viii. Multiple pigmented nevi
      ix. Coarctation of the aorta
   b. Absence or deletion of the long arm of the X chromosome correlates with infertility and gonadal dysgenesis.
   c. The degree of mosaicism correlates with the presence of clinical features of Turner syndrome.
   d. Severe phenotype associates with a small or tiny ring X chromosome which lacks the *XIST* (X-inactive-specific transcript) at Xq13 (Cervantes et al. 2001):
      i. Loss of *XIST* results in functional X disomy for the sequences contained in the ring.
      ii. Some r(X), ascertained because of severe phenotypes, undergo X inactivation.

Clinical Features

1. Skeletal manifestations (Hall and Gilchrist 1990; Ogata and Matsuo 1995)
   a. Short stature (100%): an invariant feature in the 45,X Turner syndrome
   b. Characteristic growth pattern
      i. Intrauterine growth retardation
      ii. Progressive decline in growth velocity in childhood
      iii. Lack of pubertal growth spurt
      iv. Delayed growth cessation
   c. Cubitus valgus
   d. Madelung deformity of the wrist (a bayonet-like deformity of the wrist) with decreased extension and supination
   e. Hypoplastic nails
   f. Short fourth metacarpals
2. Characteristic craniofacial features
   a. Down slanting of the palpebral fissures
   b. Epicanthal folds

c. Occasional ptosis and strabismus
d. Midfacial hypoplasia
e. Broad nasal bridge
f. High-arched palate
g. Micrognathia
h. Rotated auricles

3. Teeth
   a. Crowding
   b. Malocclusion
4. Neck
   a. Short and broad neck
   b. Webbed neck (pterygium colli) with low posterior hairline from the resolution of the cystic hygroma that was present in fetal life
5. Chest
   a. Shield chest
   b. Increased internipple distance
6. Congenital heart defects (30%)
   a. Coarctation of the aorta
   b. Bicuspid aortic valve
   c. Aortic stenosis
   d. Aneurysm (aortic root dilatation)
   e. Cystic medial necrosis of the aorta
7. Vascular anomalies
   a. Multiple intestinal telangiectasia
   b. Hemangiomas
   c. Lymphangiectasia
   d. Venous ectasias
   e. Intermittent and recurrent gastrointestinal bleeding
   f. Protein-losing enteropathy secondary to gastrointestinal lymphangiomas
   g. Chylous fluid accumulation in the abdomen and chest
8. Peripheral lymphedema in the newborn infant involving dorsum of the hands and feet
9. Nail dysplasia
   a. Concave fingernails
   b. Upturned toenails
10. Skin
    a. Redundant skin
    b. Multiple pigmented nevi
    c. Tendency of hypertrophic scarring or keloid formation
11. Gonadal dysgenesis
    a. Sexual infantilism: one of the most common clinical findings
    b. Primary amenorrhea (the rule)
    c. Spontaneous menstruation occurring in about 5% of patients. Some of these women even give birth (3–5%).
    d. Delayed pubertal development in most patients
    e. Up to 30% of patients with at least some pubertal development indicating the presence of follicles in their ovaries in adolescence
    f. A high frequency of miscarriage reported among the spontaneous pregnancies of women with Turner syndrome
    g. Progressive ovarian failure
    h. Infertility/sterility
12. Genitourinary lesions
    a. Horseshoe and ectopic kidneys
    b. Ureteropelvic obstruction
    c. A double collecting system
    d. A bifid renal pelvis
    e. Hydronephrosis
    f. Vaginal agenesis: rare
13. Hypertension (common even without cardiac or renal malformations)
14. Conductive and sensorineural hearing losses
15. Autoimmune disease
    a. A markedly increased incidence of thyroid antibodies
    b. Autoimmune hypothyroidism
    c. Impaired serum glucose tolerance in 25–60% of patients
    d. Diabetes mellitus in 5% of patients
    e. An increased incidence of inflammatory bowel disease
       i. Regional enteritis
       ii. Ulcerative colitis
    f. Rheumatoid arthritis
    g. Acute hyperthyroidism: rare
16. Abnormal dermatoglyphics
    a. Predominant digital whorls
    b. Distal triradii
17. Psychosocial aspects
    a. Significantly higher verbal level than performance level attributed to a specific space-form perception deficit
    b. Arithmetic subtests: most difficult among verbal subtests
    c. Difficulty in performance
       i. Reading
       ii. Figure drawing

iii. Geometry
iv. Arithmetic

18. Presence of Y chromosome material in some cases of Turner syndrome
    a. A high risk of developing gonadoblastoma and dysgerminoma
    b. Requiring preventive removal of the dysgenetic gonads
19. Mosaic patients with a structurally abnormal X chromosome
    a. Classic Turner phenotype
        i. X-derived marker in majority of cases
        ii. Usually a large ring X chromosome that includes *XIST* not associated with a severe phenotype, although a low IQ or even mental retardation has been observed in some cases
    b. Severe phenotype
        i. Mental retardation
        ii. Dysmorphic features uncharacteristic of Turner syndrome
        iii. Observed in patients associated with a small or tiny ring X chromosome lacking the *XIST* gene at Xq13

Diagnostic Investigations

1. Endocrine study
    a. Very low estrogen levels
    b. Elevated pituitary gonadotrophins after puberty
2. Karyotype analyses
    a. 45,X
        i. Observed in 50% of cases
        ii. Maternal origin of the X chromosome in two thirds of cases
    b. Structurally abnormal sex chromosome, such as i(Xq)
    c. Mosaicism with a second cell line containing a normal or abnormal X or Y
        i. Most common forms of mosaicism (Saenger et al. 2001)
            a) 45,X/46,XX
            b) 45,X/46,X,i(Xq)
        ii. Containing a sex marker chromosome in about 20% of cases
            a) Sex marker chromosome: usually an X chromosome
            b) Second cell line containing a structurally abnormal Y chromosome in 6% of cases
    d. Determination of the chromosomal origin of sex marker chromosomes
        i. Fluorescence in situ hybridization (FISH)
        ii. Primed in situ labeling (PRINS) diagnostic for repetitive sequences in specific human chromosomes
    e. Painting probes and libraries and PCR to detect "hidden" mosaicism (Fernández-García et al. 2000; Oliveira et al. 2009)
        i. Classical alpha-satellite probes for the X (CEP-X) chromosome and Y chromosomes (CEP-Y) (Vysis)
        ii. Whole chromosome painting probes (WCP-X, WCP-Y) (Vysis)
        iii. XIST-digoxigenin (Oncor) hybridizing specifically to Xq13.2 indicating the X-inactivation center
        iv. DXZ4-biotin (Oncor) hybridizing specifically to a cluster of 50–100 copies of a 3-kb repeat in the Xq24 region
        v. Subchromosomal painting libraries (SCPL116 specific for the short arm of the X chromosome, SCPL102 specific for the long arm of the X chromosome)
        vi. Using PCR to detect Y chromosome–specific sequences
3. Identification of specific X and Y sequences
    a. Important for establishing phenotype-karyotype correlations
    b. Important for adequate genetic counseling
    c. PCR to identify the presence or absence of specific Y sequences
4. Echocardiography for cardiovascular malformations
5. Renal ultrasound for renal anomalies
6. Radiography
    a. Madelung deformity
        i. Prominent and dorsally dislocated but reducible distal ulna
        ii. Short and bowed radius
        iii. Carpal articular surface of the radius tilted in a volar and ulnar direction producing a triangular configuration and premature fusion of the ulnar side of the radial growth plate
    b. Short fourth metacarpals and metatarsals
    c. Short distal phalanges with tufting
    d. Carpal bone fusion
    e. Pes cavus

f. Irregular tibial metaphyses with mushroom projections on the medial surface of the proximal tibial metaphyses
g. Spine
   i. Schmorl's nodes (abnormalities of cartilaginous end plates)
   ii. Scheuermann's disease of the vertebrae (osteochondrosis of vertebral epiphyses in juveniles)
   iii. Scoliosis
   iv. Lack of lumbar lordosis
   v. Congenital hip dislocation
h. Skull
   i. Midfacial hypoplasia
   ii. An obtuse cranial base angle
   iii. Short cranial base
i. Osteoporosis

7. Other investigations
   a. Blood pressure measurement for hypertension
   b. Thyroid function
   c. Audiology for conductive and sensorineural hearing loss
   d. Orthodontic evaluation
   e. Orthopedic evaluation
   f. Glucose intolerance

Genetic Counseling

1. Recurrence risk: The mode of inheritance is sporadic.
   a. Patient's sib: low
   b. Patient's offspring: rarely pass to offspring due to infertility
2. Prenatal diagnosis
   a. Maternal serum screening
      i. Slightly decreased levels of α-fetoprotein and unconjugated estriol
      ii. Elevated hCG and inhibin A
   b. Ultrasonographic screening
      i. Fetal hydrops
      ii. Increased nuchal translucency
      iii. Fetal cystic hygroma
      iv. Coarctation of the aorta
      v. Left-sided cardiac defects
      vi. Brachycephaly
      vii. Lymphedema
      viii. Renal anomalies
      ix. Intrauterine growth retardation
      x. Polyhydramnios
      xi. Oligohydramnios
   c. Karyotype of fetal cells from amniocentesis or CVS using standard cytogenetic, FISH, or microarray analysis
      i. A karyotype consistent with diagnosis of Turner syndrome
      ii. Phenotype of the individual cannot be predicted based on the karyotype
      iii. Follow laboratory guideline recommendations for prenatal diagnosis of Turner syndrome (Wolff et al. 2010)
3. Management (Davenport 2010)
   a. Psychosocial counseling
      i. Degree of parental understanding and appropriate attitudes toward the patient with Turner syndrome depends, in general, on good family relationships, socioeconomic level of the family, and appropriate physician's counseling
      ii. Short stature: a major concern when entering school
      iii. Pubertal failure and sterility: major concerns to the parents and patients at pubertal age
      iv. Webbed neck less frequent concern cosmetically unless that defect is marked and visible
      v. Occasional parental rejection and over protectiveness
      vi. Child's adjustment to the disease influenced by parental personalities and their ability to cope with the implications of the syndrome
      vii. Development of a high degree of social competency permitting patients to be integrated into a society where they will be self-sufficient and self-sustaining
   b. Estrogen replacement therapy
      i. To induce near normal pubertal development
      ii. To prevent osteoporosis
      iii. To reduce the risk of developing cardiovascular disease
   c. Growth hormone (GH) therapy (with or without anabolic steroids) for short stature
      i. Standard of care for girls with Turner syndrome (Bondy 2007)
      ii. Girls treated with GH at 5.7 years (mean) averaged 7.2 cm taller than those in the control group (Stephure 2005)

d. Pregnancies among women with Turner syndrome: rare (Hovatta 1999; Cabanes et al. 2010; Mortensen et al. 2010)
   i. The most serious maternal complications
      a) Worsening of preexisting hypertension
      b) Aortic dissection
   ii. A high risk of miscarriages and stillbirths among spontaneous pregnancies
   iii. Seventy five percentage of spontaneous pregnancies: normal karyotype

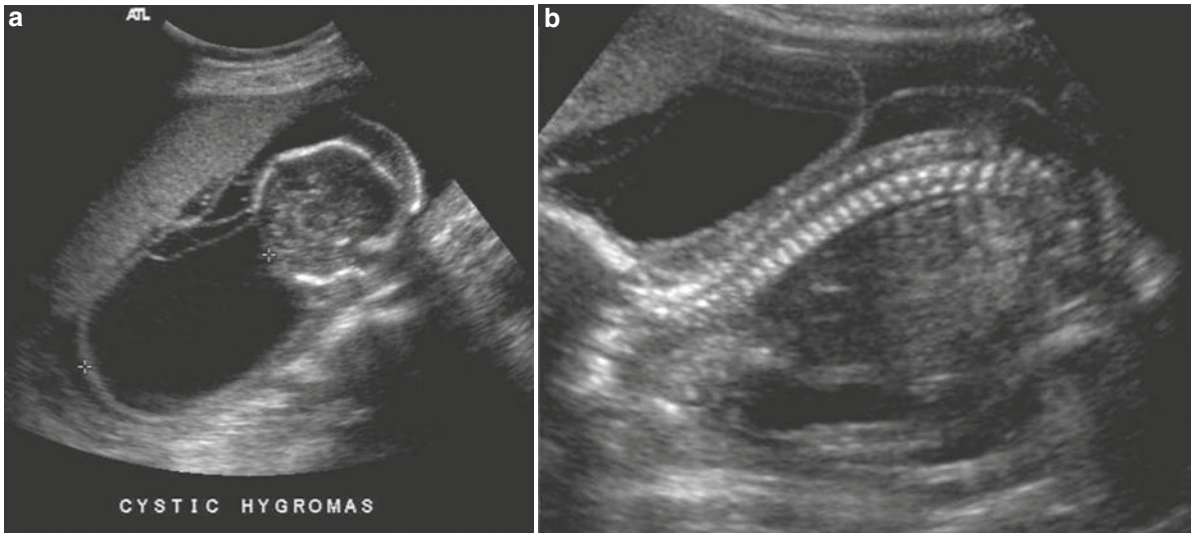

Fig. 1 (**a**, **b**) A multiseptated cystic hygroma is observed in a fetus with Turner syndrome at 18 weeks of gestation

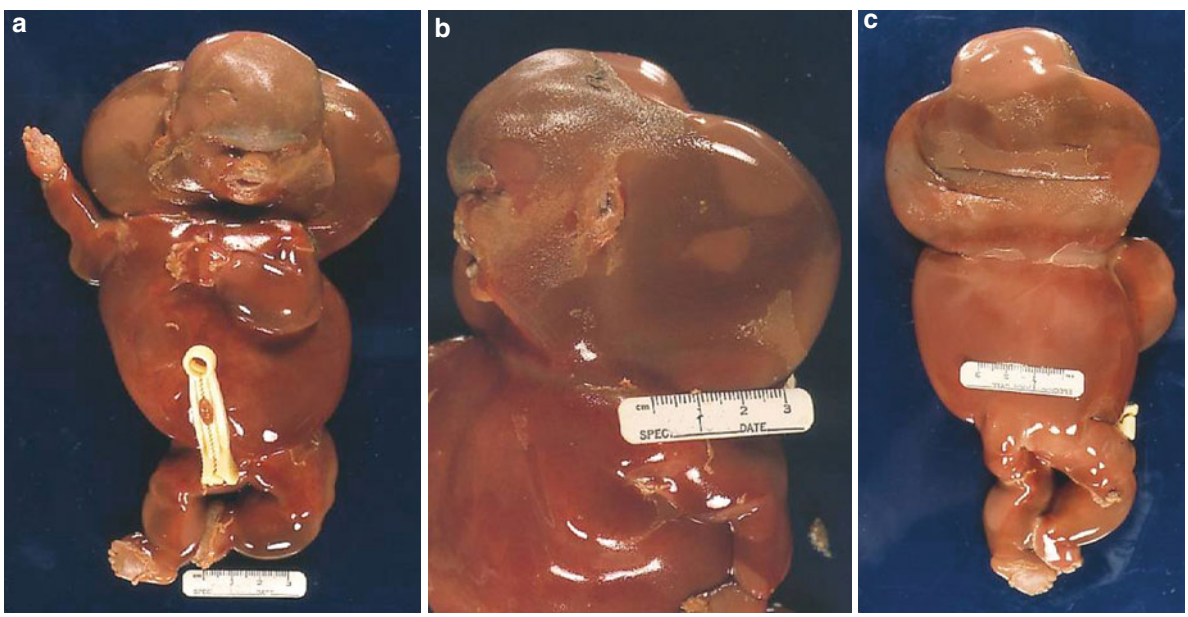

Fig. 2 (**a**–**c**) A 45,X fetus showing massive cystic hygroma and hydrops fetalis

Fig. 3 (**a**–**c**) A newborn with 45,X showing classic facial features, webbed neck, shield chest, and wide space between nipples

Fig. 4 (**a**, **b**) A 45,X newborn with classic facial features (epicanthal folds, down-slanting palpebral fissures, flat nasal bridge, receding chin, low-set/posteriorly rotated ears) and excessive nuchal skin folds

Fig. 5 (**a**, **b**) Two patients with Turner syndrome shield chest

Fig. 6 A patient with Turner syndrome showing short and webbed neck and low hairline

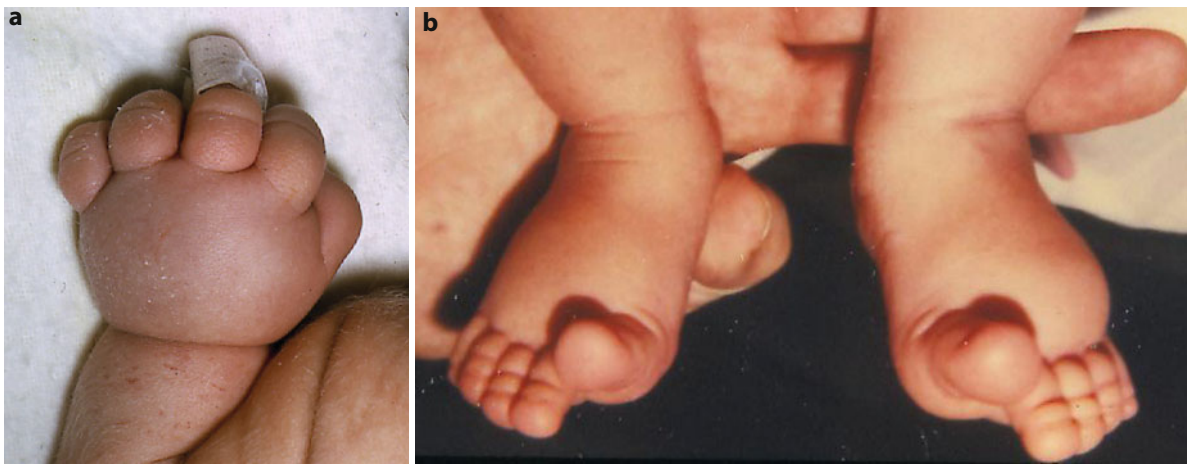

Fig. 7 (**a**, **b**) Two 45,X newborns with severe lymphedema of the dorsum of hand and feet and toenail hypoplasia

Fig. 8 (**a**–**d**) A 45,X girl showing short stature, classic facial features, severe webbed neck, shield-like chest, and widely spaced nipples

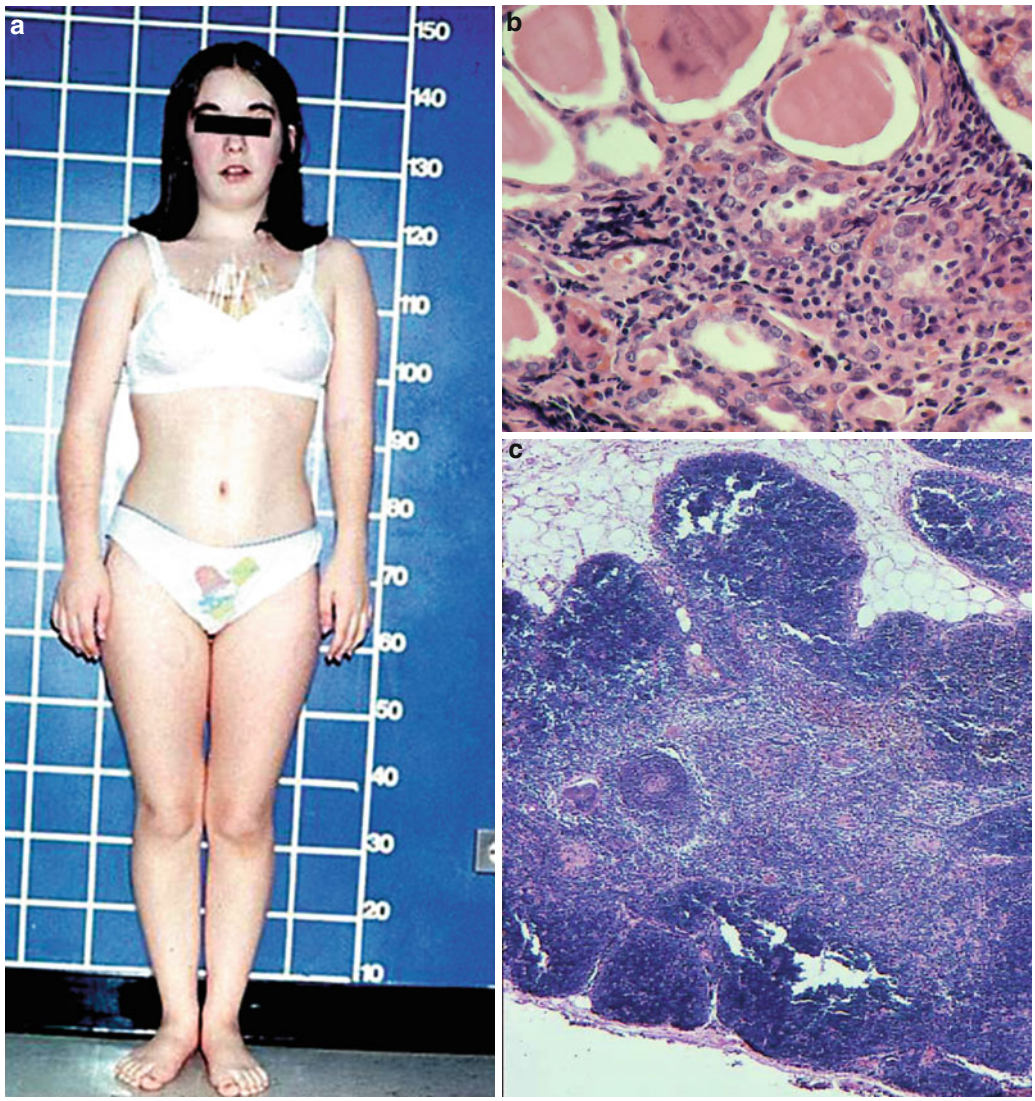

Fig. 9 (**a**–**c**) A 45,X/46,XX patient showing short stature, characteristic facial features, webbed neck, lymphocytic thyroiditis, and follicular formation of thymus medulla

Fig. 10 (**a**–**c**) An adult patient with 45,X/46,XX mosaic Turner syndrome showing webbed neck with low posterior hairline and short metacarpals, illustrated by hand radiograph

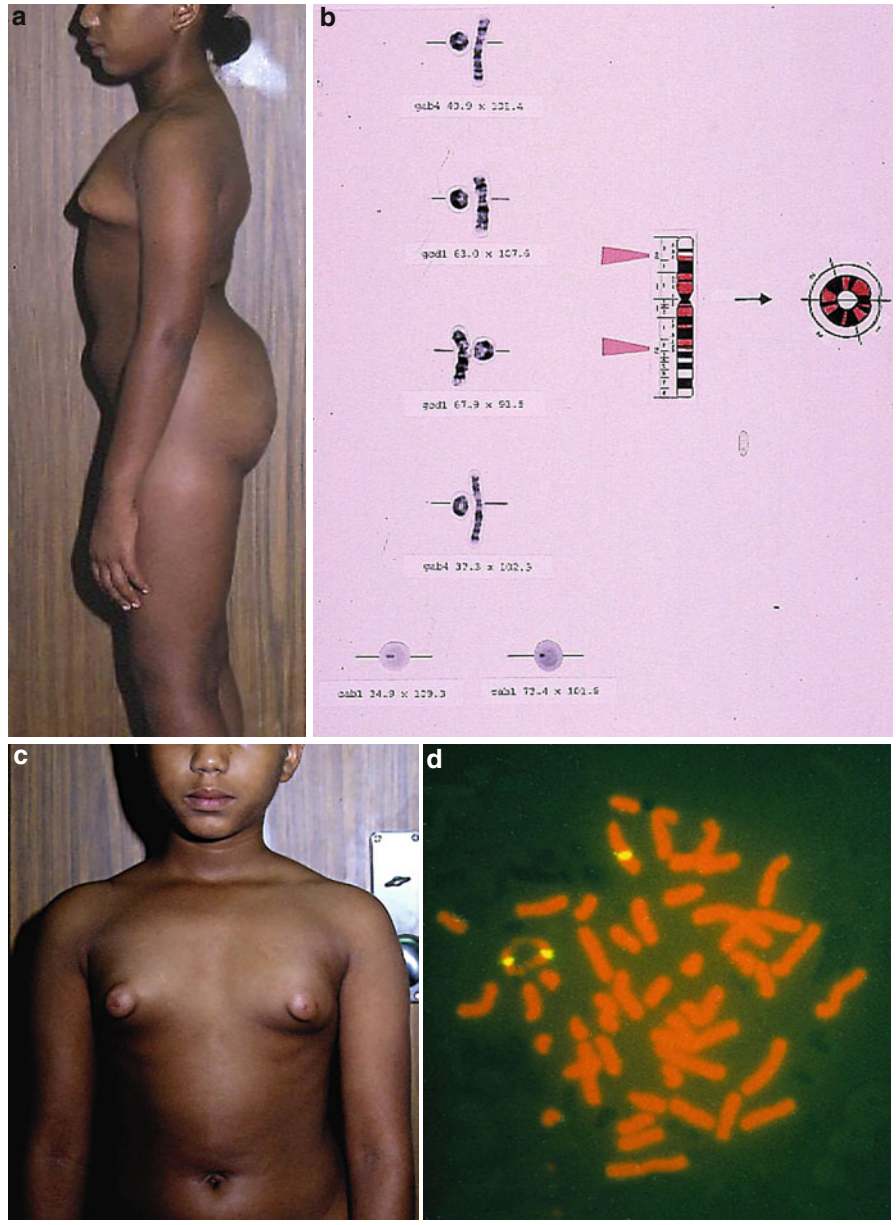

Fig. 11 (**a**–**d**) A girl with 45, X/46,X,r(X) ring chromosome X Turner mosaicism. The ring chromosome is illustrated by partial karyotype with ideogram and FISH with an X chromosome centromeric probe

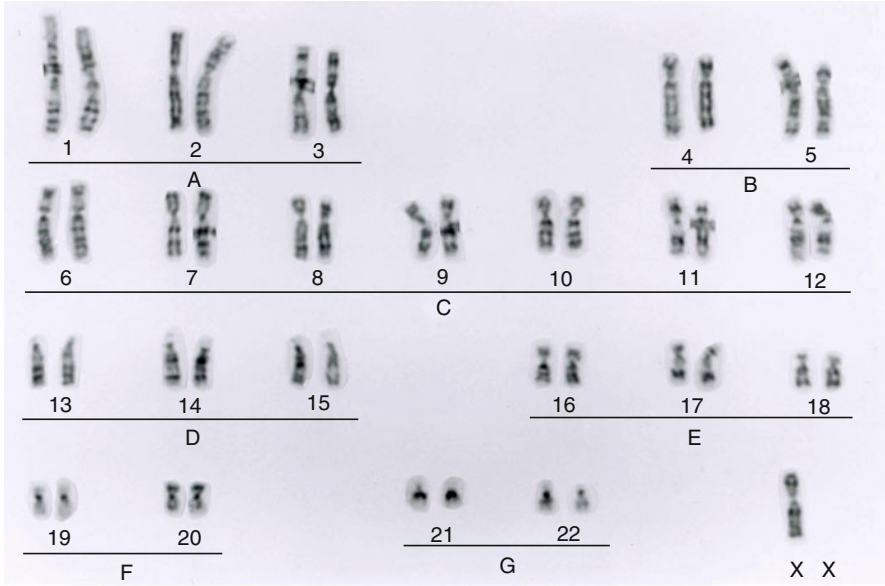

Fig. 12 45,X karyotype

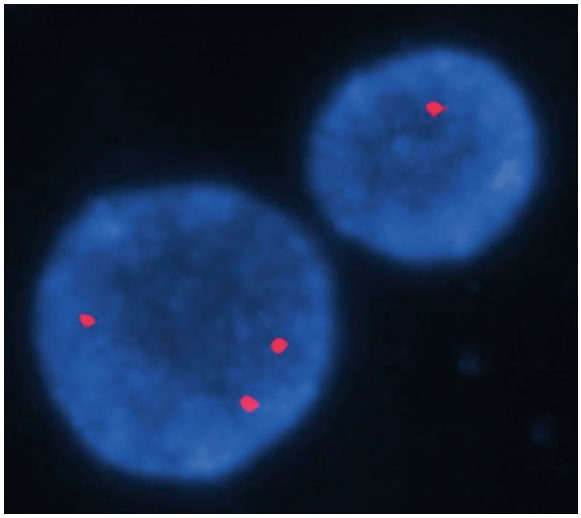

Fig. 13 FISH showing a mosaic fetus with XXX/X (CEP X/SpectrumOrange). Three copies of the orange signal are in the XXX cells and one copy in the monosomy X cells

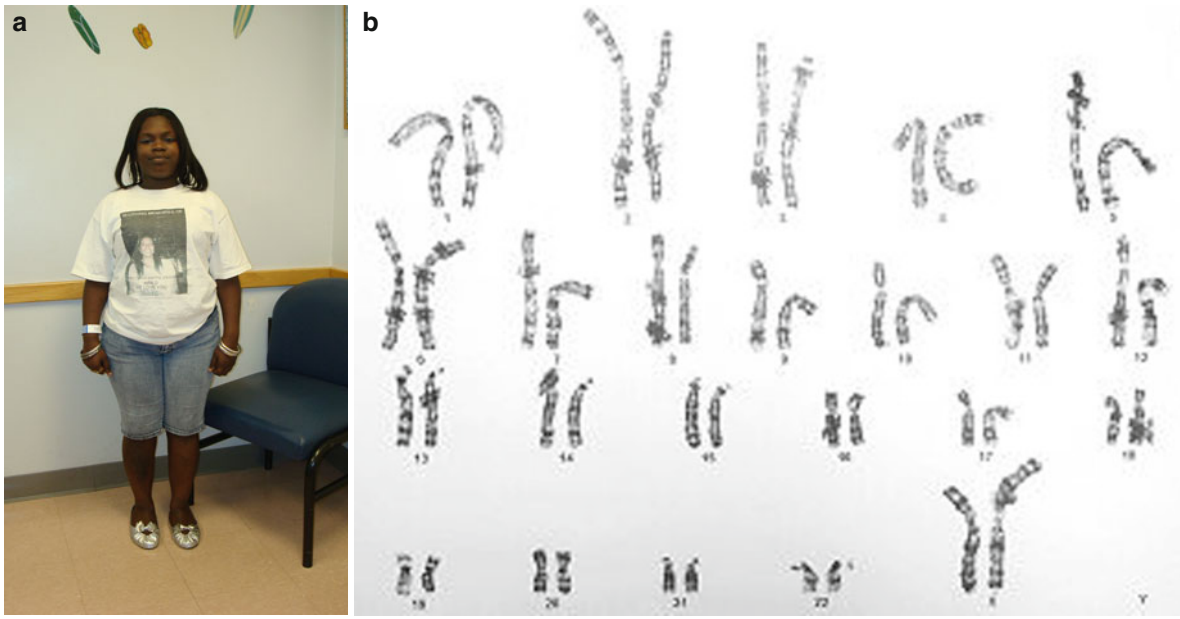

Fig. 14 (**a**, **b**) This 18-year-old adolescent girl was evaluated for absence of menarche. She was noted to have Turner stage II breasts, absence of axillary hair, and scanty pubic hair. However, she has average stature for her age. The karyotype shows 46,X, i(X)(q10) confirming the diagnosis of isochromosome Xq syndrome

Twin–Twin Transfusion Syndrome

Twin–twin transfusion syndrome results from imbalance in the net flow of blood leading to intrauterine blood transfusion from one twin to another twin as a serious complication in 10–30% of monochorionic diamniotic twin pregnancies (Banek et al. 2003; Weber and Sebire 2010).

Genetics/Basic Defects

1. Cause: a serious complication of monozygotic, monochorionic twin pregnancy through placental vascular anastomoses (unilateral arteriovenous anastomoses), resulting in transfusion of blood from one fetal twin to another twin (Banek et al. 2003)
2. Pathogenesis
   a. Imbalance in net blood flow through transplacental fetofetal transfusion, resulting in a discrepancy in blood volume distribution in two twins
   b. The donor twin
      i. Becoming hypovolemic, hypotensive, and oliguric
      ii. Leading to oligo-/anhydramnios and growth restriction
   c. The recipient twin
      i. Becoming hypervolemic, hypertensive, and polyuric
      ii. Leading to polyhydramnios and congestive heart failure

Clinical Features

1. Donor twin
   a. Birth weight: small for gestational age
   b. Pallor and anemic
   c. Poor peripheral perfusion
   d. Oligohydramnios in the amniotic sac secondary to hypovolemia and decreased urine output
   e. Stuck twin phenomenon (the twin appears in a fixed position against the uterine wall) resulting from severe oligohydramnios
   f. Hydrops fetalis secondary to anemia and high-output heart failure
2. Recipient twin
   a. Birth weight: larger at birth
   b. Plethoric and ruddy
   c. Jaundice
   d. Polyhydramnios in the amniotic sac secondary to hypervolemia and increased fetal urine output
   e. Hydrops fetalis secondary to hypervolemia
   f. Hypertension
   g. Hypertrophic cardiomegaly
   h. Right-sided heart failure with tricuspid regurgitation and right ventricular outflow tract obstruction
   i. Increased risk of cardiac malformations
   j. Intravascular coagulation
3. Staging of twin–twin transfusion syndrome (Bebbington 2010)
   a. Stage 1: Polyhydramnios in recipient sac (MVP >8 cm) and oligohydramnios in the donor sac (MVP <2 cm)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_239,
© Springer Science+Business Media, LLC 2012

   b. Stage 2: No visible bladder in the donor twin
   c. Stage 3: Doppler abnormality consisting of absent or reverse flow in the umbilical artery, reverse flow in the ductus venosus or pulsatile flow in the umbilical vein
   d. Stage 4: Ascites or hydrops in either fetus
   e. Stage 5: Demise of either fetus
4. Prognosis
   a. Premature delivery in case of mild to moderate twin–twin transfusion syndrome
   b. Guarded with possible serious maternal and fetal complications
   c. Antenatal death as well as neonatal death secondary to preterm delivery
   d. Survival rate for those diagnosed before 28 weeks: 20–45%
5. Antenatal factors that predict poor outcome
   a. Early gestational age at diagnosis with delivery before 28 weeks of gestation
   b. Fetal polyhydramnios requiring multiple therapeutic amniocenteses
   c. Fetal hydrops
   d. Absent or reversed diastolic flow in umbilical artery Doppler studies
6. Neonatal complications (Blickstein 1990)
   a. Neurologic sequelae in 25% of surviving twin in case of fetal demise in other twin
   b. Divergent intrauterine growth in association with subsequent physical and mental deficiencies in the smaller twins
   c. Thrombocytopenia suggested as the cause of cataracts, impaired hearing, and growth retardation of the donor twin
   d. Intrauterine growth deficiency of the brain and profound neonatal hypoglycemia implicated as reasons for cerebral impairment of the donor twin, resulting in subsequent lower intelligence compared with its co-twin
   e. Circulatory overload with heart failure if severe hypervolemia occurs
   f. Occlusive thrombosis due to hyperviscosity
   g. Polycythemia that may lead to severe hyperbilirubinemia and kernicterus
   h. Brain damage with cerebral palsy, microcephaly, or encephalomalacia
7. Maternal complications
   a. Secondary to multiple gestations
      i. Preeclampsia
      ii. Preterm labor
      iii. Hemorrhage
      iv. Diabetes
   b. Maternal mirror syndrome
      i. A rare complication associated with fetal hydrops
      ii. Also known as "Ballantyne syndrome" or "triple edema syndrome"
      iii. A syndrome of severe water retention that "mirrors" fetal hydropic changes
      iv. Frequent occurrence in the mid-trimester

Diagnostic Investigations

1. Difference in birth weight: inter-twin difference >20% (heavier twin = 100%) (Quintero 2003)
2. CBC to demonstrate inter-twin differences of hemoglobin level (difference ≥5 g/dL) (Quintero 2003)
   a. Anemia: frequently in donor twin at birth
   b. Polycythemia frequently in recipient twin at birth
3. Blood chemistry
   a. Hypoglycemia in either twins
   b. Hypocalcemia, hypoproteinemia in donor twin
   c. High creatinine in either twins with renal dysfunction
4. Thrombocytopenia in either twins
5. Hyperbilirubinemia in polycythemic recipient twin
6. Imagings
   a. Cranial ultrasound: intraventricular hemorrhage and periventricular leukomalacia in premature twins
   b. Chest radiography; pleural effusions and cardiomegaly in hydrops fetalis
   c. Echocardiography
      i. Myocardial dysfunction/hypertrophy
      ii. Valvular insufficiency
      iii. Pericardial effusion
   d. Renal ultrasound: abnormal renal echogenicity indicating hypoxic-ischemic cortical necrosis
   e. Abdominal ultrasound: Ascites in hydrops fetalis
7. Demonstration of transplacental vascular connections: an important criterion for the diagnosis of the twin–twin transfusion syndrome (Blickstein 1990)
   a. Donor twin
      i. Placenta
         a) Pale
         b) Swollen
         c) Atrophied

ii. Amniotic membrane showing amnion nodosum in the presence of oligohydramnios
b. Placenta of the recipient twin
i. Red
ii. Congested
iii. Hypertrophied
8. Surgical pathologic assessment of vascular anastomoses in monochorionic placentas with strong clinical correlation of placental types and occurrence of twin–twin transfusion (Bermúdez et al. 2002)
a. Type A (placenta without vascular anastomoses): 0%
b. Type B (placenta with only deep arteriovenous anastomoses): 81%
c. Type C (placenta with only superficial anastomoses): 1%
d. Type D (placenta with combined deep arteriovenous and superficial anastomoses): 18%
9. Sonographic criteria for determining chorionicity
a. Dichorionic
i. Separate placentas
ii. Well-visualized septum
b. Monochorionic diamniotic
i. One placenta
ii. A paper-thin, reflective hair-like septum (only small parts visible)
c. Dichorionic diamniotic: septum readily seen with a thickness similar to one wall of the umbilical cord

Genetic Counseling

1. Recurrence risk
a. Patient's sib: not increased unless in another pregnancy with monochorionic twinning (twin–twin transfusion syndrome affects 10–15% of monochorionic twins)
b. Patient's offspring: not increased unless in pregnancy with monochorionic twinning
2. Prenatal diagnosis (Blickstein 1990)
a. Ultrasonography
i. Divergent fetal size: striking differences in the sizes of the twins
a) Disparity in size of inter-twin abdominal circumference (difference >18 mm)
b) Disparity in size or in the number of vessels in the umbilical cords: The donor twin may have a single umbilical artery. The size of the umbilical cord of the recipient twin may be much larger than that of its co-twin.
ii. Divergent size of amniotic sacs (Quintero 2003)
a) Presence of polyhydramnios (largest pocket >8 cm) in one sac (the recipient twin persistently has a distended bladder and produces a large amount of urine)
b) Presence of oligohydramnios (largest pocket <2 cm or stuck twin) in other sac (the donor twin produces little urine)
iii. "Stuck twin" sign: a growth-retarded fetus tightly enwrapped within its membrane and trapped or stuck against the uterine wall due to oligohydramnios
iv. Determination of monozygosity
a) Like-sex twins
b) Monochorionic diamniotic placentation (absence of twin peak sign, thin separating membrane, and single placenta showing divergent echogenicity of the cotyledons supplying the two cords)
v. A hydropic placenta: a marker of anemia, even before the fetus itself becomes hydropic (de Laat et al. 2009)
vi. Evidence of hydrops in either twin
vii. Evidence of congestive cardiac failure in the recipient twin
viii. A sonographic staging classification for twin–twin transfusion syndrome allowing for the grading of the severity of the disease by standardized criteria (Quintero 2003)
a) Stage I: visible bladder of the donor twin, normal Doppler studies
b) Stage II: not visible bladder of the donor twin (during the length of examination, usually 1 h), not critically abnormal Doppler studies
c) Stage III: critically abnormal Doppler studies in either twin, characterized as absent or reverse end-diastolic velocity in the umbilical artery, reverse flow in the ductus venosus, or pulsatile umbilical venous flow
d) Stage IV: ascites, pericardial or pleural effusion, scalp edema, or overt hydrops of one or both twins
e) Stage V: presence of one or both demised twins

b. Echocardiography
   i. Possible advantages
      a) Assessment of cardiovascular adaptation to inter-twin transfusion
      b) Early recognition of deterioration
      c) Evaluation of antenatal management
   ii. Fetal heart rate monitoring: A silent, sinusoidal pattern in tracings of the fetal heart rate may indicate signs of fetal anemia.
   iii. Doppler studies
      a) Detection of arterio-arterial anastomoses in monochorionic twins
      b) Doppler velocimetry of the umbilical arteries: inter-twin differences in systolic/diastolic ratio >0.4 predicting growth discordancy of at least 350 g
   iv. Ultrasound-guided fetal blood sampling
      a) Establishing the diagnosis of monozygosity when blood group studies are performed on both twins
      b) Allowing an accurate antenatal assessment of the inter-twin hemoglobin difference and consequently establishing the diagnosis of twin–twin transfusion
      c) Revealing the degree of fetal anemia in the donor twin
c. Fetoscopy
   i. Plethora donor twin
   ii. Pale recipient twin

3. Management
   a. General approach
      i. Monochorionic twining at high risk for twin–twin transfusion syndrome
      ii. Requiring close obstetrical monitoring
      iii. Requiring specialized care in neonatal intensive care unit
   b. Postpartum therapies
      i. Directed towards the problems of each twin, such as prematurity, anemia, polycythemia, and hydrops fetalis
      ii. Severely anemic donor twin: requires packed red blood cell transfusions or partial exchange transfusions
      iii. Polycythemic recipient twin: requires partial exchange transfusion to lower serum hematocrit
   c. Prenatal therapies (van Gemert et al. 2001; Ropacka et al. 2002; Gardiner et al. 2003; Walker et al. 2007)
      i. Treating the mother with digoxin with favorable results when the recipient twin is showing signs of cardiac failure
      ii. Treatment options
         a) Prevent preterm labor and preterm premature rupture of the membranes from polyhydramnios (amniodrainage and septostomy)
         b) Isolate the twin circulations (cord ligation and selective laser photocoagulation)
      iii. Serial amniodrainage (amnioreduction): currently the most widely used therapy because it is simple and requires commonly available skills and equipment
         a) Removing large volumes of amniotic fluid from the recipient twin's sac
         b) Reducing the amniotic fluid volume, thereby reducing the risk of preterm labor or ruptured membranes
         c) Overall perinatal survival with serial aggressive amnioreduction: about 60% in uncontrolled published series
         d) Double survival rate (50%) and single survival rate (20%) in severe twin–twin transfusion syndrome presenting before 28 weeks of gestation
         e) Fail to address the underlying cause of twin–twin transfusion syndrome
         f) Complications: uterine contractions, premature rupture of membranes, chorioamnionitis, abruptio placenta, and inadvertent septostomy resulting in iatrogenic monoamniotic twins
      iv. Amniotic septostomy: intentionally puncturing the intertwine septum
         a) To create a hole in the intertwine membrane between the anhydramniotic donor's sac and the hydramniotic recipient's sac
         b) Restoring normal amniotic fluid pressure gradient, allowing fluid to move along a hydrostatic gradient from the hydramnios sac into the oligohydramnios sac
         c) Also an inadvertent occurrence during amnioreduction procedure
         d) Limited experience

v. Endoscopic laser coagulation of all placental vascular anastomosis (Wee and Fisk 2002)
   a) Reduces and abolishes intertwine transfusion by ablating chorionic plate anastomoses, producing functionally dichorionic pregnancies
   b) Proponents arguing that the procedure reduces the risk of neurological injury in survivors
   c) Overall survival rate (58%) with single survival of 32% and double survival of 42% for cases presenting prior to 18 weeks
   d) Rare fetal complications (relationship to the procedure not established): aplasia cutis, limb necrosis, amniotic bands, and microphthalmia/anophthalmia
vi. Selective feticide by cord occlusion (umbilical cord ligation): used as a last resort in cases in which both twins are at risk because of the serious condition of one twin
   a) Considered in case of monochorionic twin pregnancy in which one twin is a nonviable fetus, especially the condition is compromising the nonaffected fetus
   b) A typical example in twin reversed arterial perfusion sequence. The relatively normal twin risks high-output cardiac failure, complications of polyhydramnios, and death in utero.
   c) Another example of twin–twin transfusion syndrome, in which one fetus has major congenital anomalies or in utero–acquired abnormality, such as demonstrable cerebral lesions, terminal cardiac failure, or other conditions with a poor prognosis
   d) Benefits of selective termination of the affected twin: arrest the fetofetal transfusion process and protect the survivor
vii. In general, twin–twin transfusion syndrome diagnosed before 26 weeks of gestation has significantly better survival rates and fewer neurological sequelae after laser ablation therapy than amnioreduction. Twin–twin transfusion syndrome diagnosed after 26 weeks can best be treated by amnioreduction or delivery.

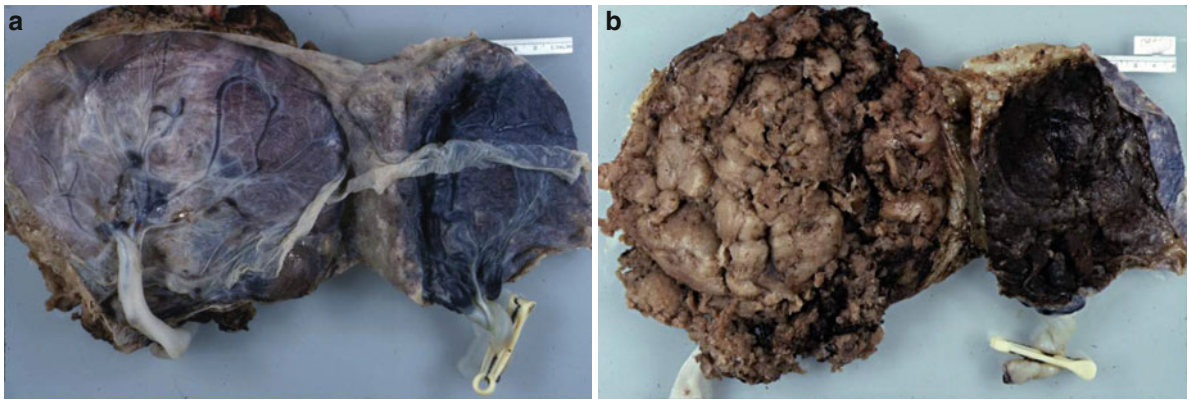

Fig. 1 (**a**, **b**) Diamniotic monochorionic twin placenta with features of twin–twin transfusion (the placental discs are not fused in this case): The placenta corresponding to the recipient twin (*right*) is small but plethoric and dark in color. The placenta of the donor twin (*left*) is large but anemic, pale, and edematous. The amniotic sacs were removed at the margins of the placental discs. The root of the thin monochorionic septum between the two sacs is shown on the fetal surface (first picture). The color difference between the two placentas is better shown on the maternal surface (second picture)

Fig. 2 The donor twin (*right*) showing smaller and pallor and the recipient twin (*left*) showing larger and plethoric at birth

Ulnar-Mammary Syndrome

Ulnar-mammary syndrome was originally described by Gilly in 1882 in a woman with mammary hypoplasia, inability to lactate, and absence of the third to fifth digits and ulna. Later in 1978, Pallister et al. reported a complex malformation syndrome in a young woman with abnormal development of ulnar rays, forearms, mammary gland tissue, axillary apocrine glands, teeth, palate, vertebral column, and urogenital system. Ulnar-mammary syndrome is a pleiotropic disorder affecting limb, apocrine gland, teeth, hair, and genital development.

Synonyms and Related Disorders

Pallister ulnar-mammary syndrome; Schinzel syndrome

Genetics/Basic Defects

1. Inheritance: autosomal dominant with variable expression
2. A gene for ulnar-mammary syndrome mapped to chromosome 12q23-q24.1
3. Caused by mutations that disrupt the DNA-binding domain of the T-box gene, *TBX3*
4. Mutations in human *TBX3* alter limb, apocrine, and genital development in ulnar-mammary syndrome (Bamshad et al. 1997).
5. No obvious phenotypic differences between those who have missense mutations and those who have deletions or frameshifts

Clinical Features

1. Posterior limb defects
   a. Widely variable
   b. Ulnar ray defects in most patients
      i. Hypoplasia of the terminal phalanx of the fifth digit
      ii. Hypoplasia or complete absence of the ulna and third, fourth, and fifth digits
   c. Postaxial digital duplications
   d. Camptodactyly
   e. Digital fusion
2. Apocrine gland abnormalities
   a. Mammary gland abnormalities: variable
      i. Hypoplasia to aplasia of the mammary glands and hypoplasia of the nipples
      ii. Accessory nipples
      iii. Inability to nipple feed
      iv. Normal breast development and lactation
   b. Decreased ability to sweat
   c. Reduced body odor
   d. Absent axillary perspiration
   e. Sparse axillary hair
3. Genital abnormalities: hypogenitalism
   a. Affected males
      i. Delayed puberty
      ii. Diminished to absent axillary hair
      iii. Micropenis
      iv. Cryptorchidism
      v. Small testes
      vi. Shawl scrotum
      vii. Reduced fertility
   b. Affected females
      i. Diminished to absent axillary hair
      ii. Imperforate hymen in some affected females

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_240,
© Springer Science+Business Media, LLC 2012

4. Dental abnormalities
   a. Misplaced teeth
   b. Absent teeth
   c. Hypodontia
5. Other abnormalities
   a. Delay puberty
   b. Short stature
   c. Obesity
   d. Scanty lateral eyebrows
   e. Subglottic stenosis
   f. Pyloric stenosis
   g. Renal agenesis/malformation
   h. Pulmonary hypoplasia
   i. Inguinal hernia
   j. Anal atresia/stenosis
   k. Musculoskeletal abnormalities
      i. Short forearms
      ii. Hypoplastic humeri, scapulae, and clavicles
      iii. Hypoplastic pectoralis major muscles
      iv. Short, stiff, and crooked terminal phalanges of fourth to fifth toes
6. Differential diagnosis
   a. Hand-foot-uterus syndrome
      i. Autosomal dominant disorder
      ii. Allelic to ulnar-mammary syndrome speculated
      iii. Manifestations similar to ulnar-mammary syndrome include the following:
         a) Digital hypoplasia
         b) Carpal fusion
         c) Supernumerary nipples
         d) Genital anomalies
   b. Split hand/split foot syndrome: a causal relationship to ulnar-mammary syndrome suggested
   c. Scalp-ear-nipple syndrome: overlapping manifestations with ulnar-mammary syndrome
      i. Mammary hypoplasia
      ii. Diminished axillary perspiration
      iii. Dental abnormalities
      iv. Digital syndactyly: characteristic limb anomaly found in this syndrome (vs limb deficiency or duplications in ulnar-mammary syndrome)

Diagnostic Investigations

1. Radiography
   a. Short and stiff fifth finger
   b. Absent fifth finger ray
   c. Absent fourth finger ray
   d. Absent fourth to fifth finger rays
   e. Absent third to fifth finger rays
   f. Camptodactyly
   g. Hypoplastic/absent/deformed ulna
   h. Hypoplastic/absent/deformed radius
   i. Hypoplastic humerus, scapula, clavicle, and pectoralis major muscle
   j. Absent xiphisternum
   k. Postaxial polydactyly
   l. Short, stiff fourth and fifth toes
2. Endocrine investigations for hypogenitalism
3. Mutation analysis
   a. Missense mutations (L143P and Y149S)
   b. Nonsense mutation (Q360TER, S343TER)
   c. Splice-site mutations (IVS2 + 1G → C, IVS6 + 2T → A) producing a truncated protein product
   d. Frameshift mutations of small duplications

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Ultrasonography and fetoscopy: possible to pregnancy at risk with presence of obvious fetal skeletal anomalies
   b. Mutation analysis of amniocytes and CVS: possible to families with identified mutation causing ulnar-mammary syndrome
3. Management
   a. Orthopedic management of limb defects
   b. Orchiopexy for cryptorchidism
   c. Testosterone management for hyogonadism in male patients
   d. Bottle feeding of infants born to mothers who has hypoplastic or absent nipples

Fig. 1 A newborn (**a**, **b**) with ulnar mammary syndrome showing ulnar hypoplasia (missing fourth and fifth fingers) (**c**), ectrodactyly, syndactyly, and hypoplasia of the breast and nipples (**d**). The infant also had cryptorchidism, anal atresia, pulmonary hypoplasia, pyloric stenosis, and bilateral renal hypoplasia

Urofacial Syndrome

Urofacial syndrome, also known as Ochoa syndrome is characterized by severe voiding dysfunction and peculiar facies, i.e., inversion of facial expression with grimacing while smiling (Ochoa and Gorlin 1987; Ochoa 1992, 2004).

Synonyms and Related Disorders

Ochoa syndrome

Genetics/Basic Defects

1. Autosomal recessive inheritance based on:
   a. Affected siblings
   b. Normal parents
   c. Presence of consanguinity
2. Mutations with a loss of function in the *Heparanase 2* (*HPSE2*) gene were identified in all urofacial syndrome patients originating from Colombia, the United States, and France (Pang et al. 2010)
   a. HPSE2 encodes a 592 aa protein that contains a domain showing sequence homology to the glycosyl hydrolase motif in the heparanase (*HPSE*) gene, but its exact biological function has not yet been characterized.
   b. Complete loss of HPSE2 function in urofacial syndrome patients suggests that HPSE2 may be important for the synergic action of muscles implicated in facial expression and urine voiding.
3. Biallelic mutations in *HPSE2* gene on chromosome 10q23-q24, predicted to abolish activity of heparanase 2, cause urofacial syndrome in families from different ethnic groups (Daly et al. 2010).

Clinical Features

1. Characteristic facial expression
   a. Inversion of the facial expression when attempting to smile or laugh
   b. Facial grimace while smiling
   c. Smile looking like weeping
   d. Peculiar facial expression on smiling
2. Urinary manifestations
   a. Bladder dysfunction
      i. Intermittent urinary flow
      ii. Residual urine after voiding
      iii. Enuresis
      iv. Polyuria
   b. Urinary tract infection
   c. Hydronephrosis
3. Constipation
4. The urinary abnormalities may lead to renal deterioration and ultimate failure if untreated.

Diagnostic Investigations

1. Renal ultrasonography
2. Renal scan
3. Voiding cystourethrogram (VCUG)
4. Urodynamic studies

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier or affected

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_241,

© Springer Science+Business Media, LLC 2012

2. Prenatal diagnosis: not yet reported
3. Management (Aydogdu et al. 2010)
   a. Intermittent urinary catheterization
   b. Appendicovesicostomy may be required for continent urinary diversion.
   c. Nocturnal bladder emptying with an indwelling nighttime catheter for polyuria
   d. Antibiotic prophylaxis
   e. Anticholinergic therapy
   f. Intravesical botulinium toxin injection
   g. Bowel management
   h. Augumentation cystoplasty

Fig. 1 This 7-year-old girl presented with vague abdominal discomfort associated with nausea, nonbilious vomiting, and weight loss for past 8–10 weeks duration. Abdominal CT revealed bilateral hydronephrosis. Note the "grimace" facial appearance after smiling

Fig. 2 Patient's CT scan of the abdomen showed bilateral hydronephrosis

Fig. 3 Patient's VCUG showed smooth bladder wall

VATER (VACTERL) Association

VATER association is an acronym for the following nonrandom association of defects: *V*ertebral defects, *A*nal atresia, *T*racheoesophageal fistula with *E*sophageal atresia, and *R*enal or *R*adial defects. VACTERL association is an expanded acronym to include *C*ardiac defects and *L*imb defects. Diagnosis of VACTERL association is made if three out of the seven above defects are present in an infant. The incidence is estimated to be 1.6 cases in 10,000 live births.

Genetics/Basic Defects

1. Etiologic heterogeneity
   a. Isolated cases in most cases
   b. Reports of rare familial cases (single gene disorders)
   c. Reports of chromosome abnormality cases
   d. Recognized syndromes or phenotypes
   e. Observed more frequently in infants of diabetic mothers
2. Pathogenesis: suggestion of a defective mesodermal development during embryogenesis due to a variety of causes, leading to overlapping manifestations (Khoury et al. 1983)
3. Molecular basis of VACTERL association
   a. Report of a family in which a female infant was born and died at age 1 month due to renal failure. The mother and sister later developed classic mitochondrial cytopathy, associated with the A-to-G point mutation at nucleotide position 3,243 of mitochondrial DNA (Damian et al. 1996).
   b. Mitochondrial NP 3243 point mutation considered not a common cause of VACTERL association (Damian et al. 1996)
   c. Sonic hedgehog in the human: a possible explanation for the VATER association (Arsic et al. 2002)
   d. Recently, microdeletions of the FOX gene cluster at 16q24.1, comprising four genes, *FOXF1*, *MTHFSD*, *FOXC2*, and *FOXL1*, were reported to cause a phenotype resembling VACTERL association, with vertebral anomalies, gastrointestinal atresias (esophageal, duodenal, and anal), congenital heart malformations, and urinary tract malformations, as well as a rare lethal developmental anomaly of the lung, alveolar capillary dysplasia (Shaw-Smith, 2010)

Clinical Features

1. *V*ertebral anomalies
   a. Hemivertebrae
   b. Fused vertebrae
   c. Hypersegmentation of the vertebrae
   d. Hypersegmentation of the ribs
   e. Scoliosis
   f. Sacral anomalies
   g. Incomplete pedicle
   h. Sternal anomalies
2. *A*nal and urachal anomalies
   a. Anal atresia with or without fistula
   b. Persistent urachus

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_242,
© Springer Science+Business Media, LLC 2012

3. *C*ardiac anomalies
   a. Ventricular septal defects
   b. Patent ductus arteriosus
   c. Tetralogy of Fallot
   d. Transposition of the great arteries
   e. Other cardiovascular anomalies
      i. Right aortic arch
      ii. Double aortic arch
      iii. Coarctation of the aorta
      iv. Dextrocardia
      v. Total anomalous pulmonary venous drainage
      vi. Left superior vena cava
      vii. Congenital mitral stenosis
      viii. Right anomalous coronary artery
      ix. Single umbilical artery
4. *T*racheoesophageal fistula
5. *E*sophageal atresia
6. *R*enal anomalies
   a. Renal agenesis/dysgenesis
   b. Ectopic kidney
   c. Horseshoe kidney
   d. Ureteral/urethral anomalies
   e. Hydronephrosis
   f. Renal ectopia
   g. Vesicoureteral reflux
   h. Posterior urethral valves
   i. Ureteropelvic junction obstruction
7. *L*imb defects
   a. Radial aplasia/dysplasia
   b. Hypoplastic thumbs
   c. Triphalangeal thumb
   d. Preaxial polydactyly
   e. Syndactyly
   f. Radioulnar synostosis
8. Other associated abnormalities
   a. Failure to thrive
   b. Short stature
   c. Wide cranial suture
   d. Large fontanel
   e. Potter facies
   f. Ear anomalies
   g. Cleft palate
   h. Gastrointestinal anomalies
      i. Malrotation
      ii. Meckel diverticulum
      iii. Duodenal atresia
      iv. Pyloric atresia
      v. Ileal atresia
      vi. Pancreatic heterotopia
      vii. Vermiform appendix agenesis
      viii. Omphalocele
      ix. Inguinal hernia
   i. Genital anomalies
      i. Hypospadias
      ii. Cryptorchidism
      iii. Bifid scrotum
      iv. Micropenis
   j. Neurological anomalies
      i. Tethered cord
      ii. Spinal dysraphia
      iii. Occipital encephalocele
   k. Anomalies more commonly associated with CHARGE association

Diagnostic Investigations

1. Radiography for vertebral and limb defects
2. Echocardiography for congenital heart defects
3. GI investigation for TE fistula or esophageal atresia
4. Renal ultrasonography for renal dysplasia
5. Urological evaluation of urogenital defects
6. Chromosome analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: low recurrence risk unless in a single gene disorder
   b. Patient's offspring: low recurrence risk unless in a single gene disorder
2. Prenatal diagnosis by ultrasonography revealing multiple congenital anomalies compatible to VACTERL association
   a. Vertebral anomalies
   b. Anorectal anomalies
   c. Congenital heart defects
   d. TE fistula or esophageal atresia
   e. Renal anomalies
   f. Limb defects
3. Management
   a. Medical care
   b. Surgical care
      i. TE fistula and/or esophageal atresia
      ii. Major cardiac defects
      iii. Urogenital anomalies
      iv. Skeletal and limb defects

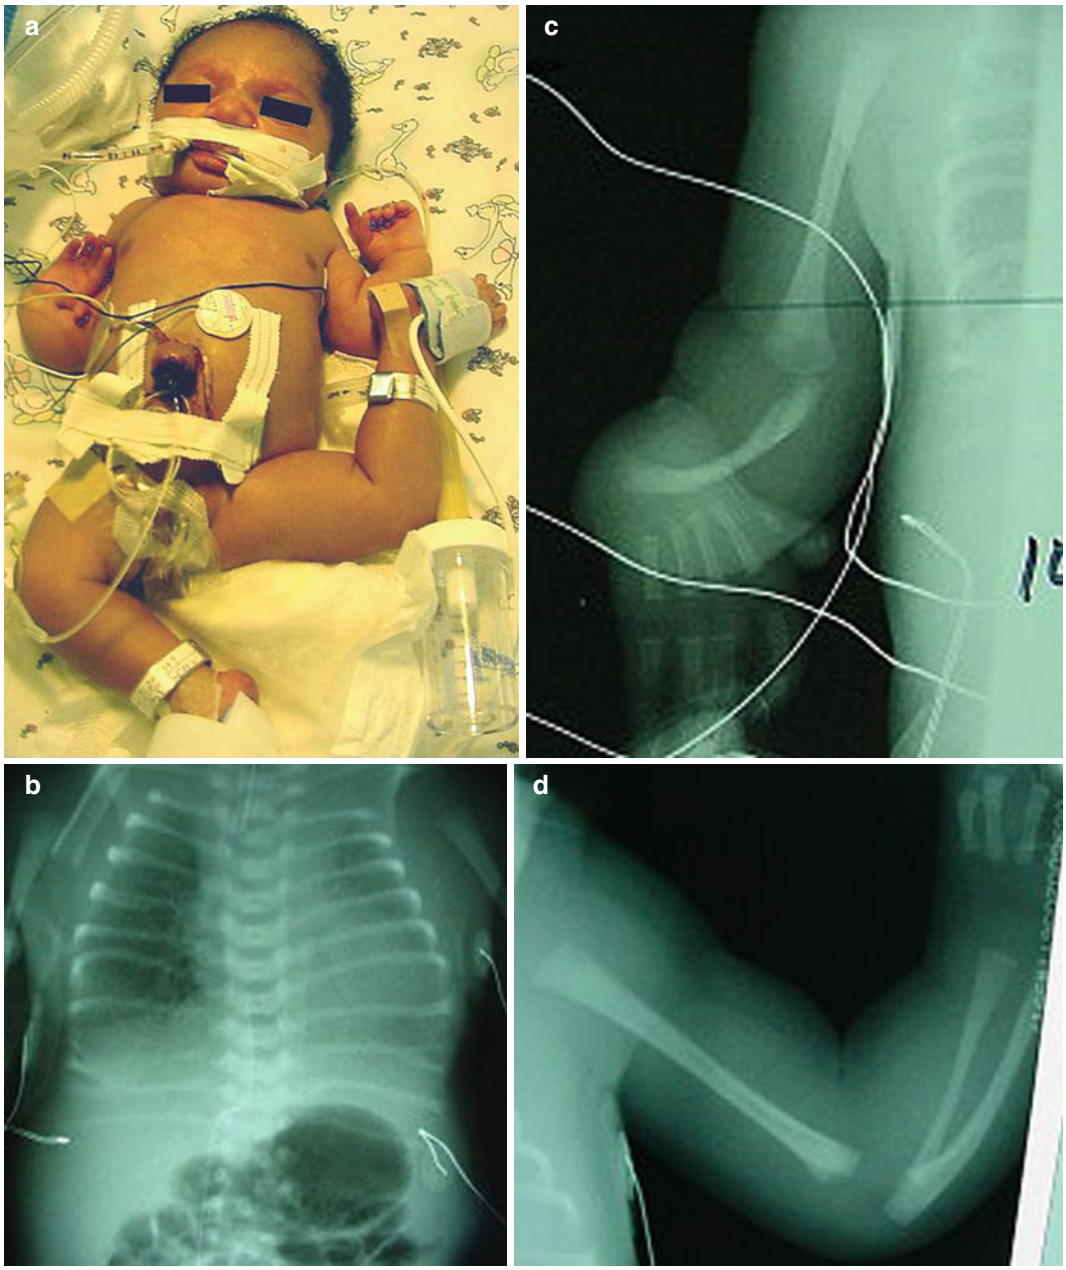

Fig. 1 (**a**–**d**) An infant with VATER association showing club hands, abnormally rotated left lower limb, fused/split ribs, hemivertebrae, radial aplasia on the right, and radioulnar fusion on the left elbow

Fig. 2 (**a**, **b**) A child with VATER association showing club hands and missing thumbs. Radiograph showed absence of the first phalanges and metacarpals and radial aplasia

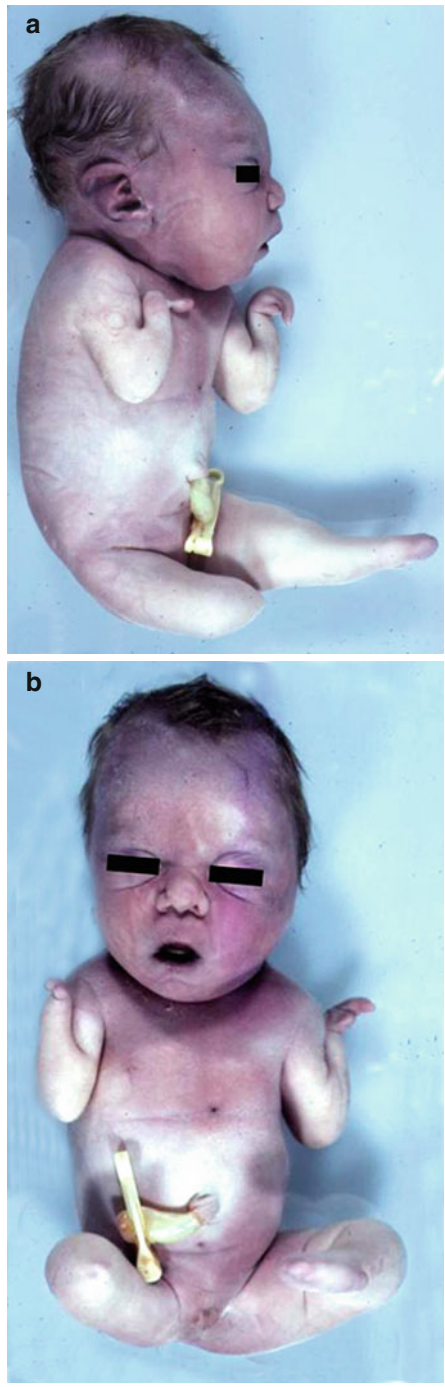

Fig. 3 (**a**, **b**) A male neonate with VATER association showing phocomelia, rudimentary external genitalia, and anal atresia, congenital heart anomalies (type 2 truncus arteriosus, tricuspid valve atresia, ventricular septal defect, large atrial septal defect), type 1 tracheoesophageal fistula, nonlobated lungs, agenesis of kidneys and ureters, malrotation of bowel, and vesicocolonic fistula were demonstrated in the necropsy

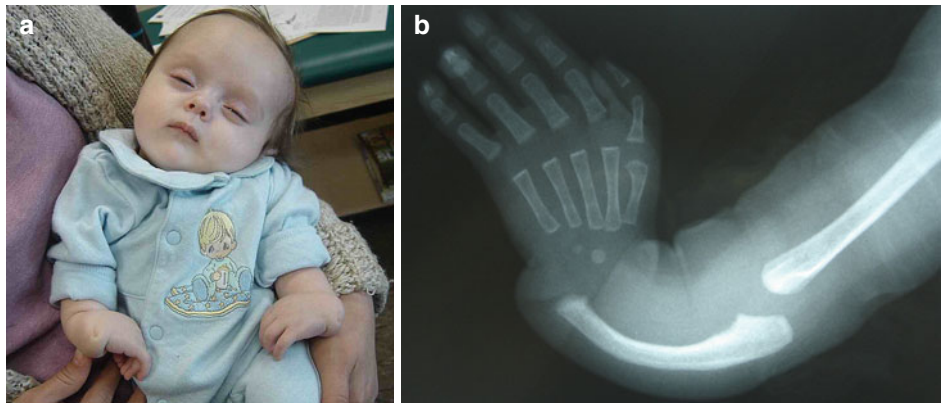

Fig. 4 (**a**, **b**) An infant with club hands and radial aplasia, illustrated by a radiograph

Fig. 5 (**a**–**c**) A girl with VATER association showing a remnant left thumb, anal atresia, and colostomy

Von Hippel–Lindau Disease

Von Hippel-Lindau disease (VHL) is a rare hereditary cancer syndrome. The prevalence is estimated at 1 in 85,000 with an incidence of 1 in 45,500 live births (Friedrich 2001).

Synonyms and Related Disorders

Angiomatosis retinae; Von Hippel-Lindau syndrome

Genetics/Basic Defects

1. Inheritance (Schimke et al. 2009)
   a. Autosomal dominant
   b. Reduced penetrance (95% penetrance at age 60)
   c. Positive family history in up to 80% of cases
   d. Sporadic new mutation in about 20% of cases
   e. Parental mosaicism described
2. Molecular pathogenesis of VHL disease
   a. VHL disease
      i. Caused by deletions or mutations in a tumor suppressor gene, the *VHL* gene, located on chromosome 3p25-26, which encodes an ubiquitin ligase that is involved in the cellular response to hypoxia
      ii. Two-hit theory of Knudson in a familial cancer syndrome such as VHL disease (Lubensky et al. 1998)
         a) Prediction of the genotype of each neoplasm which consists of an allele with an inherited germ line mutation and loss of the second wild-type allele through allelic deletion
         b) Loss of heterozygosity at chromosome 3p at the *VHL* gene region has been demonstrated in different VHL disease-associated tumors
      iii. A germ line mutation in the *VHL* gene (Hes et al. 2003)
         a) Predisposes carriers to tumors in multiple organs
         b) Consistently detected in 100% of classic families with more than one affected family member or classic sporadic patients with multiple VHL-related tumors
         c) Missense mutations leading to an amino acid substitution in *VHL* gene product pVHL, observed in 40% of the families with an identified *VHL* gene germ line mutation
         d) Microdeletions, insertions, splice site, and nonsense mutations, all predicted to lead to a truncated protein: observed in 30% of the families
         e) Large deletions including deletions encompassing the entire gene: account for the remaining 30% of the *VHL* gene germ line mutations
      iv. Somatic mutations (Hes et al. 2003)
         a) Independent somatic alteration of both alleles of the VHL tumor suppressor gene leading to tumorigenesis in nonfamilial (VHL-related) tumors

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_243,
© Springer Science+Business Media, LLC 2012

   b) Somatic VHL gene mutations and allele loss: frequent events in sporadic clear cell renal cell carcinomas and sporadic central nervous system hemangioblastoma, uncommon in sporadic (i.e., nontumor syndrome associated) pheochromocytoma
b. *VHL* gene
   i. Mapped on chromosome 3p25
   ii. Involved in blood vessel formation by regulation of the activity of hypoxia-inducible factor (HIF)-1α
c. Patients with VHL disease
   i. With a positive family history: have inherited an inactive *VHL* allele from an affected parent
   ii. Without a positive family history: have a parent who is mosaic for a *VHL* mutation, presumably as the result of a de novo mutation during early development
d. Angiogenesis of VHL tumors: critical role of inactivation of *VHL* gene
   i. Overexpression of vascular endothelial growth factor (VEGF) resulting in hypervascularization
   ii. Negative regulation of hypoxia-inducible mRNAs including VEGF mRNA by VHL protein
e. Tumor development in VHL disease
   i. Linked to inactivation or loss of the remaining wild-type *VHL* allele in a susceptible cell, leading to loss of the *VHL* gene product pVHL
   ii. Inactivation of *VHL* gene contributing to tumorigenesis of the VHL tumor since VHL protein is required for the downregulation of transcription activity of certain genes

Clinical Features

1. Great variation in the clinical presentation with variable age of onset (Schimke et al. 2009)
2. Classification of VHL disease (Schimke et al. 2009; Sano and Horiguchi 2003)
   a. VHL type 1
      i. Typical VHL manifestations such as hemangioblastomas of the CNS and/or retina and clear cell renal cell carcinomas
      ii. Without pheochromocytoma
      iii. Truncating or null mutations in the VHL gene (deletions or frameshift, nonsense, or splice site mutations) observed in approximately 96–97% of patients with type 1 VHL
   b. VHL type 2
      i. With pheochromocytomas
      ii. Missense mutations observed in 92–98% of patients with type 2 VHL
   c. Subtypes of type 2 VHL
      i. VHL type 2A
         a) VHL without predisposition to renal cell carcinoma and pancreatic neuroendocrine tumor
         b) Specific mutations (Y98H, Y112H, V116F, L188V) in the *VHL* gene conferring an increased risk for VHL disease
      ii. VHL type 2B
         a) VHL with predisposition to renal cell carcinoma and pancreatic neuroendocrine tumor
         b) Specific mutations (R167Q, R167W) in the *VHL* gene conferring an increased risk for VHL disease
      iii. VHL type 2C
         a) VHL with only pheochromocytoma manifestation
         b) Specific mutations (V155L, R238W) in the *VHL* gene conferring an increased risk for VHL disease
3. Tumors/cysts linked to VHL disease, typically develop in the second, third, and fourth decades of life
   a. Retinal angioma/hemangioblastoma
      i. Responsible for the first manifestation of VHL in 50% of the patients
      ii. Retinal lesions
         a) Formerly called retinal angiomas
         b) Histologically identical to hemangioblastomas
         c) Identified in about 70% of the patients
         d) Bilateral in about 50% of the patients
         e) Multiple in about 66% of the patients
      iii. Complications when the condition is unrecognized and untreated at early stage
         a) Majority of retinal angiomas eventually hemorrhage
         b) Resulting in massive exudation and retinal detachment
         c) Ultimate development of neovascular glaucoma and blindness

b. Cerebellar hemangioblastomas (80% of CNS hemangioblastoma) (Friedrich 2001)
   i. The most common initial manifestation (34.9%)
   ii. Cumulative occurrence: 60.2%
   iii. The most common cause of death (47.7%)
   iv. Symptoms and signs
      a) Headache
      b) Slurred speech
      c) Nystagmus
      d) Positional vertigo
      e) Labile hypertension (without pheochromocytoma)
      f) Vomiting
      g) Wide-based gait
      h) Dysmetria
c. Spinal hemangioblastoma (20% of CNS hemangioblastoma) (Friedrich 2001)
   i. More specific for VHL disease
   ii. About 80% of cases are caused by VHL.
   iii. Cumulative occurrence (14.5%)
   iv. Symptoms and signs
      a) Pain
      b) Sensory and motor loss secondary to cord compression
d. Renal lesions
   i. Renal cysts: precursor lesions to clear cell renal cell carcinomas (75% of patients with VHL) which is a frequent cause of death
   ii. Hemangioblastoma
   iii. Renal cell adenoma
   iv. Renal cell carcinoma (20–40%)
e. Pheochromocytomas (tumor of adrenal medulla)
   i. Type 1 families
      a) Absence of pheochromocytomas
      b) Most type 1 families are affected by deletions or premature termination mutations
   ii. Type 2 families (7–20% of families)
      a) Presence of pheochromocytomas
      b) Most type 2 families are affected by missense mutations.
   iii. Arg238trp and arg238gln mutations: associated with a 62% risk for pheochromocytoma
   iv. Location of tumors
      a) Usually located in one or both adrenal glands
      b) May present anywhere along the sympathetic axis in the abdomen or thorax (paragangliomas) or head and neck (chemodectomas)
   v. Symptoms and signs
      a) Sustained or episodic hypertension
      b) Asymptomatic
f. Pancreatic lesions
   i. Type of lesions
      a) Simple pancreatic cysts
      b) Serous cystadenomas
      c) Pancreatic neuroendocrine tumors
   ii. Rarely causing endocrine or exocrine insufficiency unless the lesion is extensive
   iii. Occasionally causing biliary obstruction secondary to cysts in the head of the pancreas
g. Liver lesions
   i. Hemangiomas
   ii. Cyst
   iii. Adenoma
   iv. Carcinoid of the common bile duct
h. Splenic lesions
   i. Hemangiomas
   ii. Cyst
i. Pulmonary lesions
   i. Hemangiomas
   ii. Cyst
j. Bladder hemangioblastoma
k. Endolymphatic sac tumors of the inner ears (labyrinth)
   i. Tinnitus or vertigo
   ii. Deafness
l. Papillary cystadenomas of the epididymis in males
   i. Relatively common in males
   ii. Unilateral: rarely causing problem
   iii. Bilateral: infertility
m. Papillary cystadenomas of the broad ligament in females: much less common
n. Skin lesions
   i. Nevus
   ii. Café au lait spot
o. Bone lesions
   i. Hemangioma
   ii. Cyst

4. Diagnosis of VHL disease usually made on clinical grounds (Sanfilippo et al. 2003)
   a. A positive family history of VHL disease plus one of the following lesions (hemangioblastoma or visceral lesion):
      i. Retinal hemangioblastoma
      ii. Cerebellar hemangioblastoma

iii. Pheochromocytoma
iv. Renal cell carcinoma
v. Multiple pancreatic cysts

b. A negative family history of VHL disease needs one of the following (Friedrich 2001):
i. Two or more retinal or cerebellar hemangioblastomas, or
ii. One hemangioblastoma plus one visceral tumor

5. Prognosis
a. Life expectancy: <50 years
b. Most common causes of death
i. Renal cell carcinoma
ii. Cerebellar hemangioblastoma
c. Improved prognosis in patients with:
i. Earlier diagnosis
ii. Regular monitoring for predictable complications
iii. Followed by early interventions

Diagnostic Investigations

1. Biochemical test: elevated urinary catecholamines (VMA, metanephrine, and total catecholamine) suggesting pheochromocytoma even in the absence of hypertension
2. Eye examinations (Sanfilippo et al. 2003)
a. Ophthalmoscopy
b. Fluorescein angiography, a valuable tool useful in detecting subclinical fundus lesions
3. Radiography for rare associated bone cysts and osseous hemangiomas
4. Ultrasound examinations
a. Evaluation of the epididymis and broad ligament
b. Screening of the kidneys
5. CAT scan
a. To document the presence of CNS and visceral tumors
i. CNS hemangioblastomas
a) Cystic lesions (75%)
b) An enhancing lesion with multiple cystic areas (15%)
c) An enhancing solid mass (10%)
ii. Retinal hemangiomas too small to be depicted on CT scans, the diagnosis mainly dependent on the results of an ophthalmoscopic examination
iii. Papillary endolymphatic sac tumors presenting as a thin peripheral rim of calcification, representing the expanded cortex of petrous bone
b. Low sensitivity in the detection of renal cell carcinoma associated with VHL
i. Not reliable in differentiating cystic renal cell carcinomas, cancers within a cyst, and atypical cysts
ii. Impossible to differentiate a renal cell adenoma from a renal cell carcinoma
6. MRI to document the presence of CNS and visceral tumors
a. MRI appearances of a CNS hemangioblastoma: a well-demarcated cystic lesion with a highly vascular mural nodule that always abuts on the pia mater
b. Spinal hemangioblastomas: intramedullary tumors in most patients (75%) but may be radicular (20%) or intradural extramedullary (5%)
c. Pheochromocytoma: high signal intensity on T2-weighted MRI, differentiating it from adrenal cortical nodules
d. Endolymphatic sac tumors: high signal intensity with T1 imaging on MRI as a mass on the posterior wall of the petrous part of the temporal bone
7. Radionuclide studies
a. To provide an indication of metabolic activity of CNS tumors by positron emission tomography (PET) with 2-[fluorine 18]-fluoro-2-deoxy-D-glucose (FDG)
b. To detect bone metastases resulting from primary malignant tumor of bone of VHL
c. To assess renal function prior to resection of renal tumors
d. To detect pheochromocytoma using iodine-131 metaiodobenzylguanidine (^{131}I MIBG)
8. Angiography
a. Hemangioblastoma: a hypervascular lesion with intense and prolonged early enhancement of the mural nodule associated with dilated feeding vessels
b. Endolymphatic sac tumors
i. Hypervascular on angiography and the blood supply is derived from the external carotid artery

ii. Large tumors with an additional blood supply from the internal carotid artery and posterior circulation

9. Histologic features of VHL tumors (Sano and Horiguchi 2003)
   a. High degree of vascularization
   b. Presence of a clear cell component
10. NIH group recommendation for monitoring VHL patients and family members (Friedrich 2001)
   a. Birth to 2 years
      i. Annual physical examination
      ii. Annual ophthalmologic examination
   b. 2–10 years: urinary catecholamines every 1–2 years
   c. 11–19 years
      i. Biannual MRI of the brain and spine
      ii. Annual ultrasound examination of abdomen
      iii. CT scans of abdomen every 6 months if renal cysts or tumor present
   d. 20–59 years: annual CT scan of abdomen
   e. 60 years and above without VHL
      i. MRI of the brain and spine every 3–5 years
      ii. CT scan of the abdomen every other year
   f. Not necessary to monitor the family members identified previously with an empiric risk of 50% of being affected but are found not to have inherited the mutation
11. Molecular genetic analysis
   a. Considered standard for the evaluation of patients and families with suspected VHL disease: detects mutations in nearly 100% of affected individuals
   b. Clinical testing
      i. Sequence analysis
      ii. Deletion/duplication analysis
   c. Identification of *VHL* gene germ line mutations
      i. Identification of constitutional *VHL* gene deletions by FISH using probes from the *VHL* gene critical region in 3p25.3
         a) Offers a comprehensive way to screen for the presence of germ line deletions because it enables visualization of individual cells
         b) May identify mosaicism or cryptic translocation events that cannot be readily detected by other molecular strategies in patients with submicroscopic germ line deletions and a normal karyotype
         c) Enable to identify a de novo mosaic for the *VHL* gene deletion
      ii. Molecular diagnosis accomplished in virtually all families with classic VHL disease (families with multiple tumors) and in the majority of isolated patients with multiple VHL-associated tumors
         a) Qualitative and quantitative southern blotting to detect partial or complete gene deletions responsible for 28% of all cases
         b) DNA-sequence analysis of the protein-encoding region (all three exons) to detect point mutations in the remainder (72%) of the cases
   d. Mosaicism
      i. A potential cause for failure of molecular diagnosis in VHL
      ii. Individuals with mosaicism:
         a) Asymptomatic
         b) Manifesting as a single-system disease
         c) Manifesting as a multisystem disease
   e. Identification of a mutation in a proband allows the identification of mutation carriers among family members who do not yet exhibit any clinical manifestation of VHL

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. A small risk of having a sib with VHL since parental mosaicism accounts for some apparently sporadic or new cases of VHL
      ii. A 50% risk of having a sib with VHL disease if one of the parent is clinically affected or has a disease-causing *VHL* gene mutation
   b. Patient's offspring
      i. A 50% risk of inheriting the VHL disease-causing mutation
      ii. An individual mosaic for a disease mutation is at increased risk of having affected offspring, despite negative testing for the mutation by routine DNA diagnostic tests
2. Prenatal diagnosis available by molecular genetic testing of fetal DNA obtained from amniocentesis or CVS for pregnancies at 50% risk when the

disease-causing mutation has been identified in the affected parent

3. Preimplantation genetic diagnosis for at-risk pregnancies requires prior identification of the disease-causing mutation in the family
4. Management
   a. Ocular management (Sanfilippo et al. 2003)
      i. Laser photocoagulation therapy or cryotherapy of retinal lesions
      ii. Several treatment strategies on the horizon that show promise for the ocular management of VHL disease
         a) Vascular endothelial growth factor (VEGF) inhibitors
         b) Use of radiotherapy, such as brachytherapy or linear accelerator–based radiosurgery
   b. In general, pancreatic NET with or without VHL disease shows a slow-growth phenotype and patients have a good prognosis. VHL patients at lower metastatic risk from pancreatic neuroendocrine tumor should be spared the risks of surgical resection (Tamura et al. 2010).
   c. Surgery: the mainstay of treatment for the tumors arising in patients with VHL disease (Sanfilippo et al. 2003)
      i. Renal cell carcinomas
         a) Partial nephrectomy or radiofrequency ablation to spare renal function if tumor involvement is not extensive
         b) Total nephrectomy often necessary for extensive tumor involvement
      ii. Resection of symptomatic brain stem hemangioblastomas, in general, is a safe and effective management strategy in patients with VHL disease. Most patients maintain their preoperative functional status, although long-term decline in functional status may occur due to VHL disease–associated progression (Wind et al. 2011).
      iii. Pregnant patients with spinal hemangiomas and VHL must be closely monitored for neurological compromise, as pregnancy can exacerbate both symptomatic and previously asymptomatic lesions. Patients must be evaluated on a case-by-case basis for surgical intervention, which should be carefully considered if clinical function begins to decline (Hayden et al. 2009).
   d. Stereotactic radiosurgery has been proposed as an alternative treatment strategy for CNS hemangioblastomas (Wind et al. 2011).

Waardenburg Syndrome

Waardenburg syndrome is a rare autosomal dominant disorder characterized by patchy depigmentation, sensorineural hearing loss, and other developmental defects. There are four types of this syndrome. Types I and II are more common than types III and IV. The overall syndrome affects about 1 in 42,000 people (Waardenburg 1951).

Synonyms and Related Disorders

Klein-Waardenburg syndrome (Waardenburg syndrome with upper limb anomalies); Waardenburg syndrome with dystopia canthorum; Waardenburg syndrome with or without neurologic involvement; Waardenburg syndrome without dystopia canthorum; Waardenburg-Shah syndrome (Waardenburg syndrome with Hirschsprung disease)

Genetics/Basic Defects

1. Inheritance: genetic heterogeneity
   a. Autosomal dominant
      i. Type I (Waardenburg syndrome): presence of dystopia canthorum (lateral displacement of the inner canthi of the eyes in the presence of normal interpupillary distance)
      ii. Type II (Waardenburg syndrome with ocular albinism; absence of dystopia canthorum)
      iii. Type III (Klein-Waardenburg syndrome; presence of musculoskeletal abnormalities)
   b. Autosomal recessive: Type IV (Shah-Waardenburg syndrome or Waardenburg-Hirschsprung disease)
2. Cause (Read and Newton 1997)
   a. Type I and Type III: mutations in *PAX3* (paired box) gene on chromosome 2q35
   b. Type II
      i. Mutations in *MITF* (microphthalmia associated transcription factor) gene on chromosome 3p12-p14.1
      ii. Mutations in *SOX10* gene (encoding the Sry BOX10 transcription factor) on chromosome 22q13 (Bondurand et al. 2007; Iso et al. 2008)
      iii. Homozygous deletions of *SNAI2* in two patients (Sanchez-Martin et al. 2002)
   c. Type IV
      i. Mutations in the genes for endothelin-3 (*EDN3*) on chromosome 20q13.2-q13.3 or endothelin B receptor (*EDNRB*) on chromosome 13q22
      ii. Mutations in *SOX10* gene
3. Pathogenesis: None of the following theories explains all the features of Waardenburg syndrome (Dourmishev et al. 1999).
   a. Deficient neural crest theory
      i. Developmental abnormality of the neural crest as a cause of the disease
      ii. Supported by the association of Waardenburg syndrome with aganglionic megacolon
   b. As a part of the first arch syndrome theory
   c. A relationship of Waardenburg syndrome with status dysraphicus theory
   d. Intrauterine necrosis theory
4. Genotype-phenotype correlations: Specific mutations in the *PAX3* gene correlate with the expression of different features of Waardenburg syndrome.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_244,
© Springer Science+Business Media, LLC 2012

Clinical Features

1. Wide clinical spectrum
2. Facial appearance
   a. Dystopia canthorum (lateral displacement of the medial canthi)
   b. Bushy eyebrows with synophrys
   c. A narrow nose with prominent nasal root
   d. Marked hypoplasia of the nasal bone
   e. Short philtrum
   f. Short/retro positioned maxilla
3. Congenital sensorineural deafness (deaf-mutism): Waardenburg syndrome is the most common syndromal cause of deafness and is responsible for 2–3% of congenital deafness.
4. Pigmentary abnormalities
   a. Cutaneous pigmentary abnormalities
      i. Achromatic spots, with sharply defined irregular borders and containing scattered islands of hyperpigmention, resemble those of piebaldism.
      ii. Hyperpigmented macules on normally pigmented skin that have been described as a "patchy skin" and give the cases a "dappled appearance"
   b. Hair pigmentary abnormalities
      i. White forelock (may be evident at birth, soon afterwards, or develop later)
      ii. Premature graying of the scalp hair and of the eyebrows, cilia, or body hair
   c. Fundus pigmentary abnormalities
      i. Albinotic fundi (generalized decrease in retinal pigment)
      ii. Pigmentary mottling in the periphery
   d. Partial albinism
   e. Heterochromia (different color) of the iris
   f. Bilateral isohypochromia iridis (pale blue eyes)
   g. Ocular albinism (type II)
5. Musculoskeletal abnormalities (type III, Klein-Waardenburg syndrome) (Goodman et al. 1982)
   a. Ortho-osteomyo-dysplasia of the upper limbs
   b. Bilateral upper limb defects
   c. Flexion contractures
   d. Fusion of the carpal bones
   e. Syndactyly
6. Congenital aganglionic megacolon association (type IV, Shah-Waardenburg syndrome)
7. Occasional associated anomalies (da-Silva 1991)
   a. Cleft lip/palate
   b. Neural tube defects
   c. Facial asymmetry
   d. Facial palsy
   e. Hypokalemic periodic paralysis
   f. Preauricular pit
   g. Hypoplasia of the middle ear ossicles
   h. Blepharoptosis
   i. Microphthalmia
   j. Hypertelorism
   k. Iris coloboma
   l. Fixed dilated pupil, anterior lenticonus
   m. High-arched palate
   n. "Cupid bow" configuration of the upper lip
   o. Prognathism
   p. Microcephaly
   q. Mental retardation
   r. Esophageal atresia with tracheoesophageal fistula
   s. Imperforate anus
   t. Bifid spine
   u. Vertebral agenesis
   v. Absence of vagina and right adnexal uteri
   w. Syndactyly
   x. Cardiovascular anomalies
   y. Polythelia
   z. Urinary anomalies
   aa. Hyperkeratosis of palms and soles
   bb. Black forelock
   cc. Hyperpigmented skin lesions
8. Diagnostic criteria for Waardenburg type I and type II as proposed by the Waardenburg Consortium. To be affected with Waardenburg type I, an individual must have two major or one major plus two minor criteria. To be affected with Waardenburg type II, an individual should show two major features (with one major feature of an affected first-degree relative who should show two major features) (more stringent criteria by Liu et al. 1995) (Read and Newton 1997; Konno and Silm 2001).
   a. Major criteria
      i. Congenital sensorineural hearing loss
      ii. Pigmentary disturbances of iris
         a) Complete heterochromia iridium (two eye of different color)

b) Partial or segmental heterochromia (segments of blue or brown pigmentation in one or both eyes)
c) Hypoplastic blue eyes (characteristically brilliant blue in both eyes)
iii. Hair hypopigmentation (white forelock)
iv. Dystopia canthorum
v. Affected first-degree relatives
b. Minor criteria
i. Congenital leucoderma (several areas of hypopigmented skin)
ii. Synophrys or medial eyebrow flare
iii. Broad and high nasal root
iv. Hypoplasia of alae nasi
v. Premature graying of hair (scalp hair predominantly white before age 30)

Diagnostic Investigations

1. Audiologic evaluation for hearing loss
2. Histochemical studies of achromic skin
   a. Absent melanocytes
   b. Presence of only a few dihydroxyphenylalanine (dopa)-positive cells
3. Ultrastructural findings of depigmented skin
   a. Absence or dramatically reduced melanocytes
   b. Dendritic cells containing poorly melanized melanosomes
   c. Absence of melanosomes in the keratinocytes
4. Chromosome abnormalities observed in type I Waardenburg syndrome (Konno and Silm 2001)
   a. Inversion 2q35-q36.1
   b. Deletion 2q35-q36.2
   c. Del(2)(q34;q36.2)
5. Molecular studies of mutations for different types of Waardenburg syndrome (Konno and Silm 2001; Milunsky 2009)
   a. Testing methods
      i. Sequence analysis for gene mutations
      ii. Deletion/duplication analysis for gene deletions
   b. Different types of Waardenburg syndrome
      i. Waardenburg syndrome type I: *PAX3* gene mutation
      ii. Waardenburg syndrome type II: 15–20% of cases have heterozygous mutation in the *MITF* gene.
      iii. Waardenburg syndrome type III: interstitial deletion of chromosome 2 (2q35-q36.2) including the *PAX3* gene
      iv. Waardenburg syndrome type IV:
         a) Mutations in the gene encoding endothelin-3 (Edn 3) or one of its receptors, the endothelin-B receptor (Ednrb)
         b) Mutations in *SOX10*

Genetic Counseling

1. Recurrence risk
   a. Autosomal dominant inheritance
      i. Patient's sibs: not increased unless one of the parent is also affected or has germinal mosaicism (Kapur and Karam 1991)
      ii. Patient's offspring: 50%
   b. Autosomal recessive inheritance
      i. Patient's sibs: 25%
      ii. Patient's offspring: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis
   a. Possible when a mutation has been defined in the family
   b. Impossible to predict how severe the fetus will be affected
3. Preimplantation genetic diagnosis: available for families in which disease-causing mutation has been identified
4. Management (Konno and Silm 2001)
   a. No effective treatment available
   b. Photoprotection to protect the amelanotic areas from burning with sun exposure
      i. Sunscreens
      ii. Camouflage
         a) Hair dye
         b) Dermablend
   c. Autologous grafts or transplants of autologous cultured melanocytes used to repigment the areas of hypomelanosis (piebaldism)
   d. Important to diagnose and improve hearing loss: auditory habilitation with a cochlear implant with excellent prognosis (Cullen et al. 2006)
   e. Folate supplementation during pregnancy advisable for a fetus at risk for Waardenburg type I, although the risk for neural tube defect is low

Weill–Marchesani Syndrome

Weill–Marchesani syndrome (WMS), a rare connective tissue disorder, was first described by Weill in 1932 and further delineated by Marchesani in 1939 (Weill 1932; Marchesani 1939). It is also known as spherophakia-brachymorphia syndrome or congenital mesodermal dysmorphodystrophy.

Synonyms and Related Disorders

Congenital mesodermal dysmorphodystrophy; Glaucoma-lens ectopia-microspherophakia-stiffness-shortness syndrome; Spherophakia-brachymorphia syndrome

Genetics/Basic Defects

1. Despite clinical homogeneity, two modes of inheritance have been reported.
2. Autosomal dominant inheritance
   a. Caused by heterozygous mutations within the fibrillin-1 gene which is mapped to chromosome 15q21.1
   b. Autosomal dominant WMS and Marfan syndrome appear to be allelic conditions at the fibrillin-1 locus.
3. Autosomal recessive inheritance with occasional brachymorphism in heterozygotes
   a. Homozygosity mapping of an autosomal recessive WMS gene to chromosome 19p13.3–p13.2
   b. Missense *ADAMTS10* (a disintegrin-like and metalloprotease with thrombospondin motifs 10) mutation (c.73G>A; p.Ala25Thr) was recently identified to cause recessive Weill–Marchesani syndrome.
   c. ADAMTS10 is a member of the extracellular matrix protease family and is expressed in skin, fetal chondrocytes, and fetal and adult hearts.

Clinical Features

1. Unable to distinguish autosomal recessive and autosomal dominant WMS by clinical features alone
2. Proportionate short stature
   a. Heights of adult males: 142–169 cm
   b. Heights of adult females: 130–157 cm
3. Ophthalmological features
   a. Microspherophakia (small spherical lens): most important clinical feature of the syndrome
   b. Ectopia lentis: usually results in downward displacement of the lens
   c. Lenticular myopia: usually the first ophthalmologic finding and is progressive
   d. Secondary glaucoma
      i. Resulting from pupillary block in most cases due to forward movement of the lens or by dislocation of the lens into the anterior chamber
      ii. The most serious complication because it can lead to blindness
4. Presenile vitreous liquefaction has been described in a large family with autosomal dominant WMS.
5. Skeletal features
   a. Brachydactyly
   b. Enlarged interphalangeal joints
   c. Joints stiffness

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_245,
© Springer Science+Business Media, LLC 2012

   d. Pectus excavatum
   e. Scoliosis
6. Occasional cardiac features
   a. Mitral valve prolapse
   b. Mitral valve insufficiency
   c. Mitral valve stenosis
   d. Pulmonary hypertension
   e. Subvalvular fibromuscular aortic stenosis
   f. Congenital pulmonic valve stenosis
   g. Patent ductus arteriosus
   h. Ventricular septal defect
   i. Prolonged QT interval
7. Normal intelligence

Diagnostic Investigations

1. Confirmation by molecular genetic testing in addition to clinical features
   a. *ADAMTS10* sequence analysis available clinically to identified homozygous mutations in autosomal recessive WMS
   b. Significance of mutations in *FBN1* in autosomal dominant WMS is unclear.
2. Carrier testing for relatives at risk requires prior identification of the disease-causing mutations in the family.
3. ECG to detect prolonged QT interval
4. Electron microscopy and immunological studies of skin fibroblasts from WMS patients suggest that the syndrome is associated with impairment of the extracellular matrix.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant inheritance
         a) Fifty percent risk if one parent is affected
         b) Recurrence risk: small if neither parent is affected
      ii. Autosomal recessive inheritance: 25% affected; 50% carriers
   b. Patient's offspring
      i. Autosomal dominant inheritance: 50% risk
      ii. Autosomal recessive inheritance: 100% obligatory carriers for a disease-causing mutation in the *ADAMTS10* gene
2. Prenatal diagnosis: available for pregnancies at risk for autosomal recessive WMS provided prior identification of the disease-causing mutations in the family is known
3. Management
   a. Early detection and removal of an ectopic lens to decrease the possibility of pupillary block and glaucoma
   b. Medical treatment of glaucoma: difficult because of paradoxical response to miotics and mydriatics
   c. Surgical management of glaucoma
      i. Peripheral iridectomy to prevent or relieve pupillary block
      ii. Trabeculectomy in advanced chronic angle closure glaucoma
   d. Airway management: difficult during anesthesia because of stiff joints, poorly aligned teeth, and maxillary hypoplasia
   e. Periodic ophthalmic examinations for early detection and removal of an ectopic lens
   f. Avoid ophthalmic miotics and mydriatics to prevent inducing pupillary block.

Fig. 1 (**a**–**c**) A 14-year-old female with Weill–Marchesani syndrome. She had short stature, spherophakia, and brachydactyly. She was again followed at 30 years of age with findings of short stature, shallow orbits, small eyes, myopia, brachydactyly, and enlarged and stiff interphalangeal joints. Her daughter has small lens/cornea, short stature, and brachydactyly

Williams Syndrome

In 1961, Williams et al. described children with a constellation of abnormalities including "unusual" facial features, growth retardation, supravalvular aortic stenosis, and cognitive impairment. In 1962, Beuren described a series of children with similar features, dental anomalies, peripheral pulmonary artery stenosis, and friendly personalities. Consequently, Williams syndrome is also known as Williams-Beuren syndrome. These characteristics are observed in virtually every patient with Williams syndrome, now known to be caused by a microdeletion of chromosome 7q11.23. The incidence of the syndrome is estimated to be between 1 in 20,000 and 1 in 50,000 live births.

Synonyms and Related Disorders

Chromosome 7q11.23 deletion syndrome; Williams–Beuren syndrome

Genetics/Basic Defects

1. Inheritance
   a. Sporadic new deletion in most cases
   b. Rare autosomal dominant transmission of microdeletion involving the Williams syndrome critical region in a few cases
2. Association of the elastin (*ELN*) gene disruption by chromosome translocation or partial deletion involving chromosome 7q11.23 and the supravalvular aortic stenosis: the first clue to the location of the Williams syndrome microdeletion
3. Caused by the haploinsufficiency of genes within a microdeletion of the long arm of chromosome 7 (7q11.23)
4. Deletions in the *ELN* gene (Osborne 1999; Donnai and Karmiloff-Smith 2000)
   a. Mechanism: deletions typically caused by unequal recombination during meiosis
   b. Deletion with equal frequency on the maternally or paternally inherited chromosome 7
   c. A total of at least 16 genes mapped within the commonly deleted interval
   d. *ELN* gene mapped approximately at the center of the deletion
   e. Responsible for supravalvular aortic stenosis and other vascular stenoses
   f. Possibly responsible for some of the connective tissue problems
      i. Lax joints
      ii. Premature aging of the skin
      iii. Joint contractures
      iv. A hoarse voice
      v. Bladder and bowel diverticula
      vi. Hernias
   g. Majority of patients with Williams syndrome with large deletion spans (approximately 1.5 Mb of DNA), which contain many genes that contribute to the additional clinical symptoms not seen in patients with isolated supravalvular aortic stenosis
   h. Genetic studies demonstrate that isolated nonsyndromic supravalvular aortic stenosis is associated with intragenic deletions within the *ELN* gene, while Williams syndrome involves deletions spanning the entire *ELN* gene (Lashkari et al. 1999).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_246,
© Springer Science+Business Media, LLC 2012

i. Other genes identified in the commonly deleted region: e.g., *LIMK1*, *CYLN2*, *GTF21RD1*, and *STX1A* (Jurado 2003)

Clinical Features

1. Characteristic dysmorphic facies, frequently referred to as elfin facies (100%). Effort must be made to curtail the use of "elfin facies" to denote a resemblance to a mythological creature since the term is not well received by family members (Lashkari et al. 1999; AAP 2001).
   a. Periorbital fullness
   b. Stellate lacy iris pattern
   c. Short nose with bulbous nasal tip
   d. Flat nasal bridge
   e. Prominent full cheeks
   f. Long philtrum
   g. Wide mouth
   h. Full lips
   i. Mild micrognathia
   j. Long narrow face and long neck in older children and adults
2. Cardiovascular diseases
   a. Supravalvular aortic stenosis (80%), often a progressive condition that may require surgical repair
   b. Generalized arteriopathy (narrowing of arteries secondary to abnormal elastin protein, an important component of elastic fibers in the arterial wall)
      i. Peripheral pulmonary artery stenosis often present in infancy and usually improves over time
      ii. Possible worsening over time of the coarctation of the aorta, renal artery stenosis, and systemic hypertension
      iii. Possible narrowing of any arterial wall since elastin protein is an important component of elastic fibers in the arterial wall
   c. Other congenital cardiac defects
      i. Mitral valve prolapse (11.6%)
      ii. Bicuspid aortic valve (15%)
      iii. Aortic hypoplasia
      iv. Septal defects
      v. Left ventricular hypertrophy
3. Variable mental retardation (75%)
4. Characteristic cognitive/behavioral profile (90%)
   a. Characteristic behavioral pattern
      i. Relative preservation of linguistic abilities
      ii. Gross deficiencies in visual-spatial processing and motor skills
   b. Motor disabilities affecting balance, strength, coordination, and motor planning
   c. Delayed speech acquisition, followed by excessive talking ("cocktail party" verbal abilities)
   d. Overfriendliness and an empathetic nature
   e. Uncontrollable loquacity
   f. Behavioral problems
      i. Hypersensitivity to sound (hyperacusis)
      ii. Sleep problems
      iii. Attention deficit/hyperactivity disorder (ADHD)
      iv. Anxiety
      v. Distractability
      vi. Inflexibility
      vii. Rituralism
5. Idiopathic infantile hypercalcemia (15%)
   a. Symptoms and signs of hypercalcemia (usually resolves during childhood)
      i. Extreme irritability
      ii. Vomiting
      iii. Constipation
      iv. Muscle cramps
   b. Possible lifelong persistence of abnormal calcium and vitamin D metabolism
   c. Hypercalcinuria predisposing to nephrocalcinosis
6. Other features
   a. Growth
      i. Postterm birth (>41 weeks)
      ii. Failure to thrive
      iii. Short stature (50%)
      iv. Hypothyroidism
      v. A premature and abbreviated pubertal growth spurt
   b. CNS
      i. Muscle hypotonia early
      ii. Muscle tone increases with age; hypertonia in some cases
      iii. Poor coordination
      iv. Awkward gait
      v. Chiari I malformation
      vi. Hyperreflexia of the lower extremities
   c. EENT
      i. Ocular findings
         a) Strabismus

b) Hyperopia
c) Stellate iris
d) Retinal vessel tortuosity
ii. Chronic otitis media
iii. Dental abnormalities
a) Hypodontia/Microdontia
b) Malocclusion
c) Overbite
d) Excessive interdental spacing
e) Small roots
f) High incidence of caries
iv. A hoarse or brassy voice
d. GI
i. Difficulty feeding
ii. Gastroesophageal reflux/vomiting
iii. Prolong colic
iv. Bowel diverticula
v. Hernias
vi. Rectal prolapse
vii. Constipation
viii. Peptic ulcers
e. Genitourinary (18%)
i. Bladder diverticula: the most common defects
ii. Renal artery stenosis
iii. Renal agenesis
iv. Duplicated kidneys
v. Horseshoe kidney
vi. Renal cysts
vii. Nephrocalcinosis
viii. Vesicouriteral reflux
f. Orthopedic problems
i. Low/hoarse voice
ii. Hernias
iii. Joint laxity mostly during infancy
iv. Joint contractures may develop by childhood and adolescence (50%).
v. Radioulnar synostosis
vi. Kyphosis
vii. Lordosis
viii. Scoliosis
ix. Hallux valgus
x. Hypoplastic nails
xi. Clinodactyly of fifth fingers

Diagnostic Investigations

1. Echocardiography for cardiac lesions
2. Ultrasonography
   a. Bladder and kidneys
   b. Intravascular ultrasound imaging: to detect vascular wall thickening with secondary lumen narrowing
3. Serum creatinine level
4. Blood calcium levels to detect hypercalcemia during early infancy
5. Thyroid function test
6. Ophthalmologic evaluation for strabismus and retinal vessel tortuosity
7. Urinalysis to detect hypercalcinuria
8. Renal ultrasound for possible nephrocalcinosis if hypercalcinuria is noted
9. Radiography: osteosclerosis of the metaphyses of long bones, the skull vault, or lamina dura of the alveolar bone in adolescence and adulthood, if overt hypercalcemia is present
10. Full cytogenetic studies
    a. Larger deletions detectable by standard cytogenetic techniques, especially by high-resolution chromosome analysis
    b. To rule out possible chromosomal rearrangements involving the 7q11.23 locus as well as any other cytogenetic abnormalities
11. Fluorescence in situ hybridization (FISH) with a cosmid probe corresponding to *ELN* for diagnostic testing: remains the most widely used laboratory test
    a. Ninety-nine percent of the patients with a hemizygous submicroscopic deletion of 7q11.23 detectable by FISH
    b. Cases undetectable by FISH
       i. Rare cases with a smaller deletion which does not fully encompass the FISH probe
       ii. Cases with phenocopies of Williams syndrome with same clinical phenotype produced by mutation or deletion of other gene(s)
       iii. Cases with a Williams syndrome–like phenotype associated with various cytogenetic rearrangements
12. Other diagnostic laboratory tests (Pober 2010)
    a. Microsatellite marker analysis
    b. Multiplex ligation-dependent probe amplification
    c. Quantitative polymerase-chain-reaction assay
    d. Array comparative genomic hybridization

Genetic Counseling

1. Recurrence risk
   a. Patient's sib (Lashkari et al. 1999)
      i. Recurrence risk low (<1%) (most cases are sporadic and neither parent is affected)
      ii. Presence of a small theoretical risk of germ line mosaicism in an unaffected parent (Kara-Mostefa et al. 1999)
      iii. If a parent is affected, the risk is 50%.
   b. Patient's offspring: 50% recurrence risk of having an affected offspring in individuals who have the deletion of the Williams syndrome critical region (parent-to-child transmission observed occasionally)
2. Prenatal diagnosis by amniocentesis or CVS
   a. Rarely utilized because most cases are sporadic and no prenatal indicators exist for low-risk pregnancies
   b. Utilized for pregnancies at 50% risk of having Williams syndrome
   c. FISH probe covering approximately 180 kb of the critical region deleted in the Williams syndrome including *ELN* gene, lim-kinase1 (*LIMK1*), and the D7S613 locus
3. Management
   a. Management of hypercalcemia (Lashkari et al. 1999)
      i. Limit high calcium food
      ii. Avoid preparations containing vitamin D
   b. Supravalvular aortic stenosis (a life-threatening component of the phenotype): surgically correctable
   c. Early dental care
   d. Education and vocational concerns
      i. Early daily learning activities and strategies
         a) Auditory cues
         b) Music activities, singing/rhyming songs, and toys with soft sounds
         c) Teaching communication skills through daily routines
         d) Use of language expansions and parallel talk
      ii. Special education for older children
      iii. Restrictive levels of care required for most adult patients
   e. Social and emotional concerns
      i. At increased risk for exploitation and abuse
      ii. Teaching of appropriate social skills
   f. Psychotherapy
      i. Verbally oriented psychotherapy
      ii. Group therapy

The metaphase cells show only one chromosome 7 homologue with the orange signal (normal chromosome 7). The hemizygous deletion is shown on the chromosome with only the green loci [internal control probes for D7S486 and D7S522 (7q31)]

Wolf-Hirschhorn Syndrome

Wolf-Hirschhorn syndrome (WHS) is a chromosome 4p deletion syndrome, first described by Cooper and Hirschhorn in 1961, followed by the report of Wolf et al. in 1965 (Wolf et al. 1965). The incidence is estimated to be approximately 1 in 50,000 births.

Synonyms and Related Disorders

Chromosome 4p16.3 deletion syndrome; Pitt-Rogers-Danks syndrome

Genetics/Basic Defects

1. Caused by the deletion of the distal short arm of chromosome 4
   a. Variable size of the deletion
   b. Deletion of the terminal band (4p16.3): essential for full expression of the phenotype
   c. Identification of a 165 kb minimal critical region (WHSCR) within 4p16.3
   d. Mechanism of deletions
      i. De novo deletions (75%): interstitial deletion of preferential paternal origin in 85–90%
      ii. Deletions resulting from unusual cytogenetic abnormality (12%) such as ring chromosome 4
      iii. Deletions resulting from unbalanced product of a parental chromosomal rearrangement, usually of a reciprocal translocation (10–15%)
2. Types of chromosome abnormalities
   a. Detectable by conventional cytogenetic technique: large deletions
   b. Detectable only by molecular methods
      i. Terminal microdeletions
      ii. Interstitial microdeletions
      iii. Cryptic translocations
3. Genotype-phenotype correlation (Zollino et al. 2003, 2008)
   a. Patients with a large 4p16.3 deletion, averaging between 5 and 18 Mb: causing the widely recognizable WHS phenotype
      i. Severe mental and growth retardation
      ii. Major malformations
      iii. Seizures
      iv. Characteristic facial appearance with wide forehead, large and protruding eyes, hypertelorism, prominent glabella, down-turned mouth, and micrognathia
   b. Patients with a 4p16.3 microdeletion not exceeding 3.5 Mb
      i. Milder phenotype
      ii. Lack major congenital malformations
   c. Patients with a very large deletion exceeding 22–25 Mb, causing a severe phenotype that can hardly be defined as typical WHS
   d. Using genotype-phenotype correlation analysis in eight informative patients, Zollino et al. (2003) characterized the following distinctive WHS clinical signs that represent the minimal diagnostic criteria for this condition, and mapped this basic phenotype outside the currently defined WHSCR and designated as a new critical region, WHSCR-2.
      i. Presence of typical facial appearance
      ii. Mental retardation
      iii. Growth delay

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_247,
© Springer Science+Business Media, LLC 2012

iv. Congenital hypotonia
v. Seizures

4. *LETM1*
   a. A gene deleted in WHS, encodes mitochondrial protein
   b. Current evidence suggests that at least some (neuromuscular) features of WHS may be caused by mitochondrial dysfunction.

Clinical Features

1. Maternal gestational history
   a. Intrauterine growth retardation
   b. Decreased fetal movements
   c. Small placenta
2. Developmental history
   a. Delayed psychomotor development
   b. Difficulty in ambulation, often with ataxic gait
   c. Seizures (50% of cases)
3. Behavior history
   a. Stereotypes
      i. Holding the hands in front of the face
      ii. Hand washing or flapping
      iii. Patting self on chest
      iv. Rocking
      v. Head shaking
      vi. Stretching of legs
   b. Absence of speech
   c. Babbling or guttural sounds, occasionally modulated in a communicative way
   d. Comprehension limited to simple orders or to a specific context
   e. Affect disorder that improves over time
   f. Walking with or without support
   g. Self-feeding
   h. Helps in dressing and undressing self
   i. Improved abilities and adaptation to new situations
   j. Communicative abilities and verbal comprehension with extension of the gesture repertoire and decreased occurrence of withdrawal and anxiety behaviors
4. Growth: Severe growth retardation (short stature)
5. CNS
   a. Profound mental retardation
   b. Microcephaly
   c. Seizures (50–100%)
   d. Congenital hypotonia with muscle hypotrophy particularly of the lower limbs
   e. Malformation (33%)
      i. Hypoplasia of cerebellum
      ii. Cavum or absent septum pellucidum
      iii. Agenesis of corpus callosum
      iv. Hypoplasia or absence of olfactory bulbs and tracts
      v. Microgyria
      vi. Migration defects
      vii. Hydrocephalus
6. Skull
   a. Frontal bossing
   b. High frontal hairline
   c. Hemangioma over forehead or glabella
   d. Scalp defect with or without underlying bony defect
7. Face: characteristic dysmorphic features collectively described as “Greek warrior helmet” facies (prominent glabella, hypertelorism, broad beaked nose, and frontal bossing)
8. Eyes
   a. Hypertelorism
   b. Down-slanting palpebral fissures
   c. Epicanthal folds
   d. Strabismus
   e. Coloboma
   f. Proptosis due to hypoplasia of orbital ridges
   g. Ectopic pupils
   h. Esotropia
   i. Ptosis
   j. Microphthalmia
   k. Megalocornea
   l. Sclerocornea
   m. Cataracts
   n. Hypoplastic anterior chamber and ciliary body of iris
   o. Persistence of lenticular membrane
   p. Hypoplastic retina with formation of rosettes
   q. Cup-shaped optic disks
   r. Congenital nystagmus
   s. Early-onset glaucoma
   t. Rieger anomaly
9. Nose
   a. Broad or beaked nose
   b. Nasolacrimal duct stenosis or atresia

10. Mouth
    a. Short upper lip
    b. Short philtrum
    c. Cleft lip or palate
    d. Bifid uvula
    e. Carplike mouth
    f. Micrognathia
    g. Retrognathia
11. Ears
    a. Low-set ears
    b. Large, floppy, or misshapen ears
    c. Microtia
    d. Preauricular dimples
    e. Chronic otitis media with effusion
    f. Sensorineural hearing loss
12. Cardiovascular
    a. Atrial septal defect
    b. Ventricular septal defect
    c. Persistent left superior vena cava
    d. Valve abnormalities
    e. Complex cardiac defects
13. Pulmonary
    a. Bilateral bilobed or trilobed lungs
    b. Lung hypoplasia secondary to diaphragmatic hernia
14. GI anomalies
    a. Diastasis recti
    b. Umbilical or inguinal hernias
    c. Accessory spleens
    d. Absent gallbladder
    e. Diaphragmatic hernia
    f. Intestinal malrotation
15. Genitourinary anomalies (25%)
    a. Hypoplastic kidneys
    b. Cystic dysplastic kidneys
    c. Unilateral renal agenesis
    d. Hydronephrosis
    e. Exstrophy of the bladder
    f. Hypoplastic external genitalia
    g. Cryptorchidism and hypospadias in males
    h. Hypoplastic müllerian derivatives (i.e., agenesis of vagina, cervix, or uterus; hypoplastic uterus; ovarian streaks) in females
16. Skeletal anomalies (60–70%)
    a. Long slender fingers with additional flexion creases
    b. Long narrow chest
    c. Hypoplastic widely spaced nipples
    d. Hypoplasia or duplication of thumbs and great toes
    e. Talipes equinovarus
    f. Hypoplasia of pubic bones
    g. Vertebral and rib anomalies
    h. Defective calvarium ossification
    i. Scoliosis
    j. Kyphosis
    k. Osteoporosis
    l. Delayed bone maturation
    m. Sacral dimple
17. Infection-prone, immunodeficiency
18. Malignant hematological disorders
    a. Myelodysplastic syndrome
    b. Leukemia
19. Dermatoglyphics
    a. Hypoplastic dermal ridges
    b. Transverse palmar creases (25%)
    c. Excess of digital arches
    d. t or t′
20. Pitt-Rogers-Danks syndrome (PRDS)
    a. Phenotypic overlap with WHS
        i. Prenatal and postnatal growth retardation
        ii. Microcephaly
        iii. Seizures
        iv. Developmental delay
        v. Facial features
            a) A wide mouth
            b) Short upper lip
            c) Flat philtrum
            d) Beaked nose
            e) Prominent eyes
            f) Maxillary hypoplasia
    b. Microdeletion of 4p16.3 detected in most cases
    c. Current evidence suggests that PRDS is not a separate clinical entity but may represent the milder end of the WHS spectrum (Battaglia and Carey 1998).
21. Fetal phenotype
    a. Major anomalies
        i. Intrauterine growth retardation
        ii. Microcephaly
        iii. Cleft palate
        iv. Corpus callosum agenesis
        v. Ventricular septal defect

vi. Diaphragmatic hernia
vii. Renal hypoplasia

b. Minor anomalies
i. Scalp defect
ii. Hypertelorism usually with a prominent glabella
iii. Pulmonary isomerism
iv. Common mesentery
v. Hypospadias
vi. Sacral dimple

22. Prognosis
a. Crude infant mortality rate: 17%
b. Mortality rate in the first 2 years: 21%
c. Cases with large de novo deletions are more likely to die than those with smaller deletions.
d. Follow-up of patients, spanning 23 years, showed a slow but constant evolution over time, in all areas (Battaglia et al. 2008).
i. There was an improvement of the motor, and the communicative skills, and of the verbal comprehension with extension of the gesture repertoire, and a reduction of isolation and anxiety
ii. Forty-five percent of patients were able to walk, either independently or with support (range: 2–12 years); 18% could help dressing and undressing themselves and doing simple household tasks
e. Causes of death
i. Birth anoxia
ii. Withdrawal of treatment after premature delivery
iii. Lower respiratory tract infections
iv. Sudden unexplained death
v. Congenital anomalies, such as congenital heart disease, dysplastic kidneys, renal hypoplasia, diaphragmatic hernia, and pulmonary hypoplasia

Diagnostic Investigations

1. Conventional cytogenetic studies: most common method to detect chromosome arm 4p deletions (60–70% of deletions)
2. High-resolution cytogenetic studies: to detect smaller deletions of chromosome band 4p16.3
3. Fluorescence in situ hybridization (FISH) using Wolf-Hirschhorn critical region probe: detecting >95% of deletions. Molecular cytogenetic studies using FISH allow the diagnosis to be made in patients with very small deletions or cryptic translocations. FISH uses genetic markers that have been precisely localized to the area of interest. The absence of signal from either the maternal or the paternal allele for the marker is indicative of monosomy for that chromosomal region.
4. Array comparative genomic hybridization (aCGH)
a. A new technology that can analyze the entire genome at a significantly higher resolution over conventional cytogenetics to characterize unbalanced rearrangements
b. 33 patients with WHS were analyzed using aCGH (South et al. 2008).
i. Observation of a much higher than expected frequency of unbalanced translocations (15/33, 45%)
ii. 7 of these 15 cases were cryptic translocations not detected by a previous karyotype combined with WHS-specific FISH
5. Immune workup
a. Common variable immunodeficiency
b. Immunoglobulin A (IgA) and immunoglobulin G2 (IgG2) subclass deficiency
c. IgA deficiency
d. Impaired polysaccharide responsiveness
e. Normal T cell immunity
6. Radiography
a. Delayed bone maturation
b. Microcephaly
c. Hypertelorism
d. Micrognathia
e. Anterior fusion of vertebrae
f. Fused ribs
g. Dislocated hips
h. Proximal radioulnar synostosis
i. Clubfeet
7. Echocardiography to detect heart defects
8. Renal ultrasound to detect renal anomalies
9. MRI and CT scans to demonstrate underlying brain pathology including agenesis of corpus callosum and ventriculomegaly
10. EEG for seizure monitoring
11. Swallowing study for feeding difficulty

12. Comprehensive audiologic and otologic evaluation to rule out possible hearing impairment
13. Ophthalmologic examination
14. Developmental testing
    a. Speech and motor evaluation
    b. Appropriate psychometric evaluation
15. Growth charts are available from 0 to 4 years of age, based on the study of 101 individuals (Anntonius et al. 2008). Use of these specific growth charts is recommended because standard growth charts are inapplicable for patients with WHS.

Genetic Counseling

1. Recurrence risk
    a. Patient's sib
        i. De novo deletion cases: no significant increased risk
        ii. Deletion resulting from a parental chromosomal rearrangement: increased risk for unbalanced product in offspring
    b. Patient's offspring: reproduction unlikely due to mental retardation
2. Prenatal diagnosis available to families in which one parent is known to be a carrier of a chromosome rearrangement by amniocentesis, CVS, or PUBS
    a. Ultrasonography to detect in utero manifestation of distinct phenotype
        i. Severe intrauterine growth retardation
        ii. Microcephaly
        iii. Hypertelorism, usually with prominent glabella
        iv. Micrognathia
        v. Cleft lip and palate
        vi. Diaphragmatic hernia
    b. Chromosome analysis
        i. Conventional karyotyping
        ii. FISH
        iii. Whole chromosome painting
3. Management
    a. Multidisciplinary team approach
        i. Early intervention program to improve motor development, cognition, communication, and social skills
        ii. Speech, physical, and occupational therapies
        iii. Appropriate school placement
    b. Manage feeding difficulties and failure to thrive
        i. Gavage feeding
        ii. Gastrostomy
        iii. Occasional gastroesophageal fundoplication
    c. Anticonvulsants for seizure control
    d. Orthopedic care for skeletal abnormalities
        i. Clubfoot
        ii. Scoliosis
        iii. Kyphosis
    e. Care for possible immunodeficiency

Fig. 1 (**a**–**e**) A patient with Wolf–Hirschhorn syndrome at different ages showing characteristic facial features consisting of prominent glabella, hypertelorism, beaked nose, and frontal bossing, collectively described as "Greek warrior helmet" facies

Fig. 2 (**a**–**c**) A girl with WHS showing characteristic face and deletion of WHS locus (FISH)

Fig. 3 (**a**–**f**) Four children with WHS showing characteristic facial features of the syndrome

Fig. 4 (**a**–**d**) Two siblings with WHS showing characteristic features of the syndrome

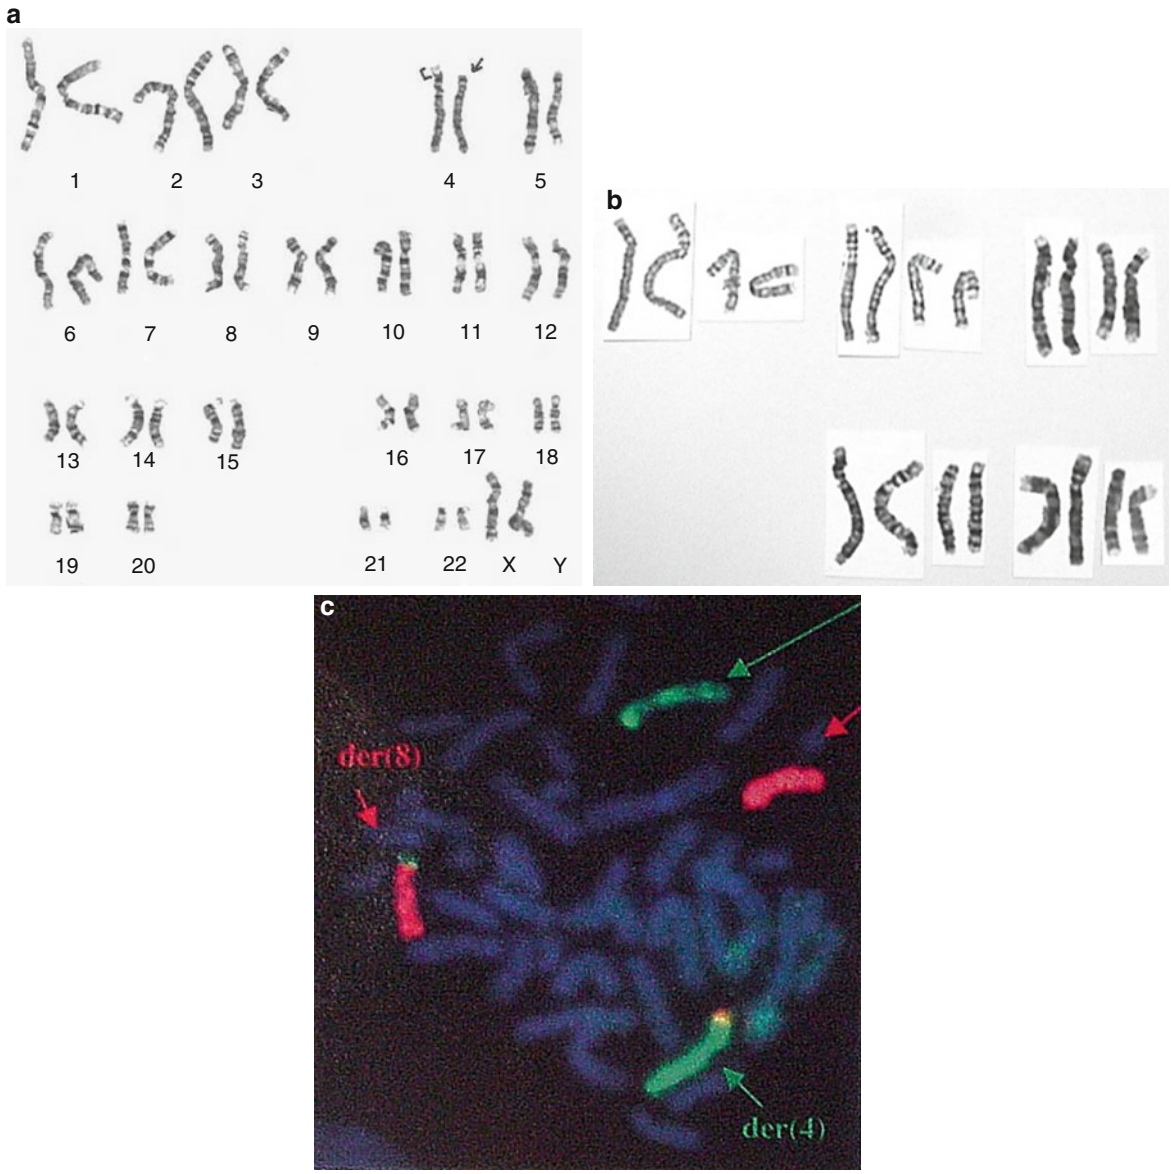

Fig. 5 (**a**–**c**) Karyotype of the sister showing deletion of 4p, derived from the mother with balanced translocation (4p;8p) (partial karyotypes). FISH analysis with whole chromosome paint specific for chromosome 4 (wcp4/SpectrumGreen) and chromosome 8 (wcp8/SpectrumOrange) demonstrated a t(4;8) in all metaphases analyzed. These results confirmed a reciprocal translocation between chromosome 4 and chromosome 8 in the mother

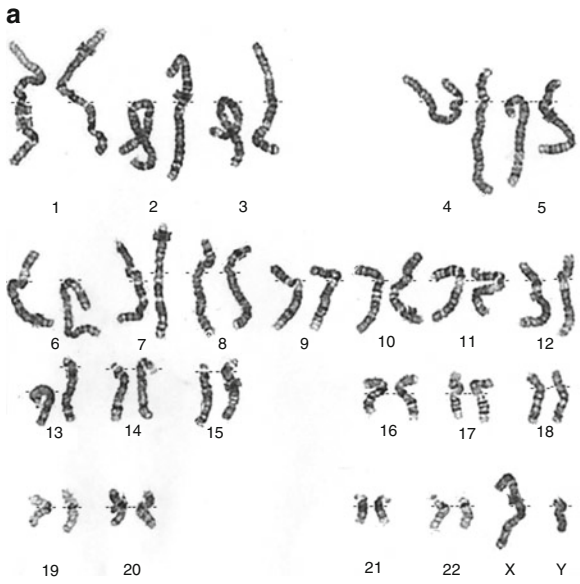

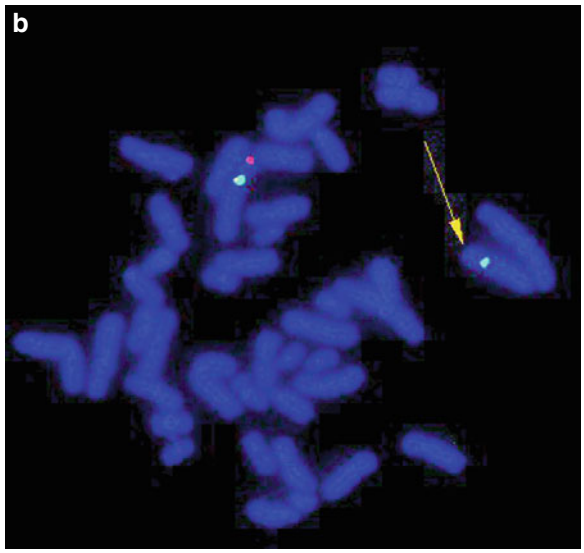

Fig. 6 (**a**, **b**) Karyotype and FISH of another patient with Wolf–Hirschhorn syndrome (4p-)

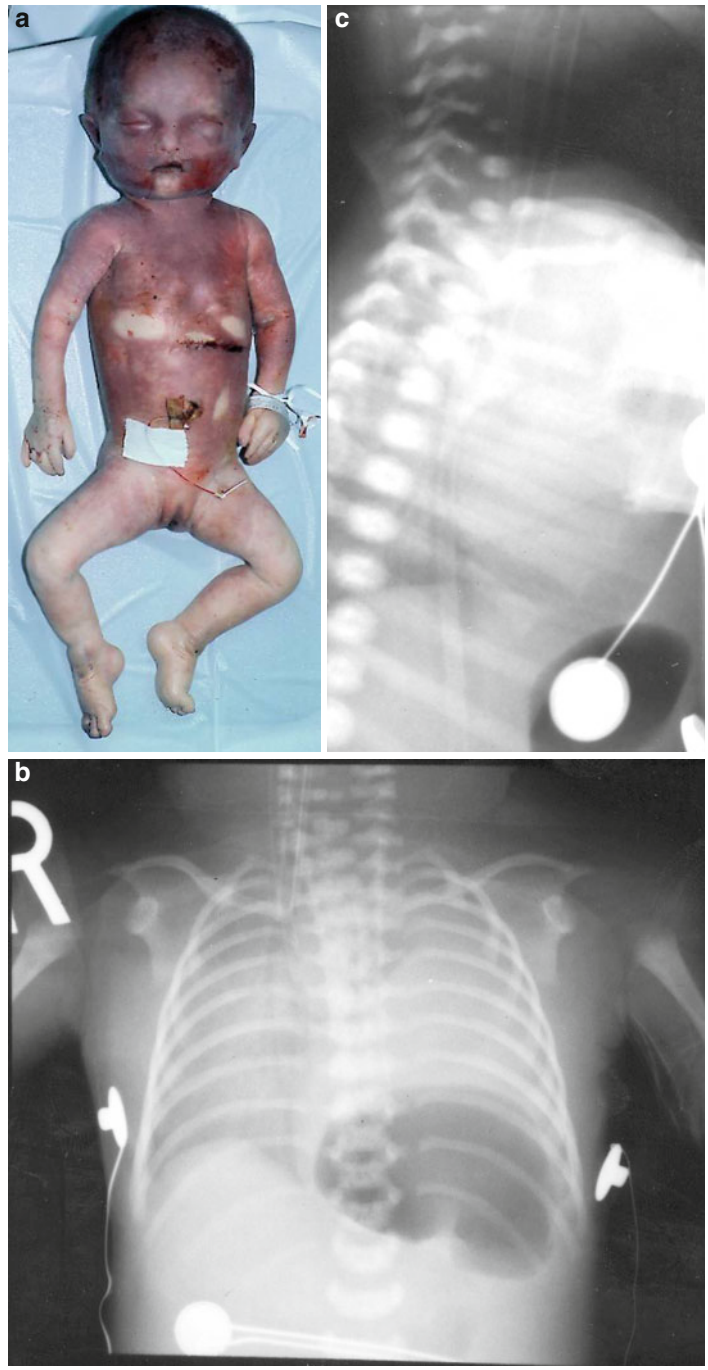

Fig. 7 (**a**–**c**) A fetus with WHS showing broad triangular-shaped nasal root, and the flat facial profile resembling "Greek warrior helmet." The radiographs show hypoplasia of the cervical vertebral bodies

X-Linked Agammaglobulinemia

X-linked agammaglobulinemia (XLA) was first described by Bruton in 1952 (Bruton 1952). It is a prototypical humoral immunodeficiency characterized by early onset of bacterial infections, profound hypogammaglobulinemia, and marked decrease of the peripheral B-lymphocyte population. Associated infections, particularly bacterial meningitis and pneumonia, are often life threatening.

Synonyms and Related Disorders

Agammaglobulinemia tyrosine kinase; B-cell progenitor kinase; Bruton-type agammaglobulinemia; Immunodeficiency 1

Genetics/Basic Defects

1. An X-linked recessive disorder
2. The responsible gene for XLA (named as Bruton's tyrosine kinase, *BTK*), mapped on Xq21.3-Xq22, is mainly involved in early B-cell maturation through its function in pre-B-cell receptor signaling pathway, and its absence causes an arrest in B-cell development.
3. Mutations in the *BTK* gene cause XLA.
4. No clear genotype phenotype correlation exists
5. Female XLA can result from heterozygous *BTK* gene abnormality and extreme nonrandom inactivation of X chromosome on which normal *BTK* gene is located.

Clinical Features

1. Presenting manifestations
   a. Infections in affected boys after the decline of passively transferred maternal antibodies: the major presenting feature
      i. Most frequently respiratory tract and gastrointestinal tract infections (91%), often protracted and recurrent, presenting as otitis media, pneumonitis, and diarrhea
      ii. Other common infections
         a) Conjunctivitis
         b) Sinusitis
         c) Skin infection
      iii. *S. pneumoniae* and *H. influenzae*: the most common organisms found prior to diagnosis and may continue to cause sinusitis and otitis after diagnosis and the initiation of gamma globulin therapy
      iv. Monoarticular or oligoarticular arthritis (20%) affecting large joints: the most common being knees, shoulders, ankles, wrists, and elbows
      v. Central nervous system infections (16%): meningitis/encephalitis
      vi. Septicemia (10%) excluding bacterial meningitis and associated bacteremia
      vii. Virtually, all patients had infections at more than one anatomic site and on more than one occasion.
   b. Neutropenia (10%): always occur in association with infection, and in all cases resolved after treatment with antibiotics and γ-globulin

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_248,
© Springer Science+Business Media, LLC 2012

   c. Failure to thrive: a relatively infrequent occurrence
   d. Fever of unknown origin
   e. Complications of immunizations such as paralytic poliomyelitis following live virus vaccine and vaccinia gangrenosum following smallpox vaccination
2. Age at onset of symptoms
   a. By age 4 months (25%)
   b. By age 8 months (50%)
   c. By age 12 months (75%)
   d. By age 18 months (90%)
3. Chronic complications
   a. Chronic pulmonary disease (46%): the most frequent long-term complication of XLA
      i. Obstructive pulmonary disease (half of cases)
      ii. Combined obstructive and restrictive disease (half of cases)
   b. Sensory neurologic disorders
      i. Hearing loss (32%) as a consequence of chronic otitis media and meningoencephalitis
      ii. Delayed acquisition of speech (14%)
      iii. Learning disorders (15%)
      iv. Significant motor dysfunction as a consequence of encephalitis
         a) Hemiparesis
         b) Ataxia
         c) Diplegia
         d) Quadriplegia
4. Miscellaneous illnesses
   a. Dermatomyositis-like syndrome occurred in association with arthritis and with meningitis/encephalitis.
   b. Viral infections
      i. Disseminated enterovirus infection
      ii. Disseminated adenovirus infection
   c. Hematologic abnormalities: uncommon in treated patients
      i. Chronic Coombs' positive hemolytic anemia
      ii. Transient neutropenia and transient thrombocytopenia in conjunction with infection: resolved when the infection resolved
      iii. Insulin-dependent diabetes mellitus
5. Complications of γ-globulin therapy
   a. Rash
   b. Fever
   c. Apparent anaphylactic-like symptoms
   d. Acrodynia secondary to γ-globulin preparations containing mercury as a preservative
6. Causes of death
   a. Cardiorespiratory failure (38%): consequence of chronic pulmonary disease and cor pulmonale
   b. Severe viral infections (50%)
   c. Fulminant necrotizing hepatitis
   d. Aspiration as a consequence of poliomyelitis-related neurologic impairment
   e. Systemic staphylococcal infections

Diagnostic Investigations

1. Clinical clues to the diagnosis of XLA
   a. Chronic or recurrent nature of infections
   b. Infections at more than one anatomic location
   c. Family history of immunodeficiency
   d. An important clinical clue: absent or barely detectable tonsils and cervical lymph nodes
   e. About 60% of individuals with XLA are recognized as having immunodeficiency when they develop a severe, life-threatening infection such as pneumonia, empyema, meningitis, sepsis, cellulitis, or septic arthritis
2. Clinical laboratory findings in affected individuals
   a. Concentration of serum immunoglobulins
      i. The serum IgG concentration: typically less than 200 mg/dL
      ii. The serum concentrations of IgM and IgA: typically less than 20 mg/dL (Although decreased serum concentration of IgG and IgA can be seen in children with a constitutional delay in immunoglobulin production, low serum IgM concentration is almost always associated with immunodeficiency.)
   b. Antibody titers to vaccine antigens: Affected individuals fail to make antibodies to vaccine antigens like tetanus, *H. influenzae*, or *S. pneumoniae*.
   c. Lymphocyte cell surface markers: markedly reduced numbers of B lymphocytes (CD 19+ cells) in the peripheral circulation (<2% in almost all patients): the most distinctive laboratory finding
   d. Bruton's tyrosine kinase protein (measured by flow cytometry) is absent in most of the patients.
   e. Severe neutropenia: seen in about 10–25% of individuals at the time of diagnosis, usually

in association with pseudomonas or staphylococcal sepsis. Neutropenia is generally not seen after the initiation of gamma globulin therapy.

3. Molecular genetic testing
   a. Mutations in *BTK*: detectable by sequence analysis in approximately 90% of males with early-onset infections, hypogammaglobulinemia, and absent B cells
   b. Duplications or deletions in *BTK* gene: detectable by duplication/deletion analysis in 10% of affected males
   c. Molecular genetic testing of the *BTK* gene is the most reliable way to identify female carriers of XLA.
4. Diagnosis considered established only in those individuals who have a mutation in the *BTK* gene or who have a maternal uncle or cousin with absent B cells

Genetic Counseling

1. Recurrence risk
   a. Obligatory carriers: Mothers who have an affected son and one other affected relative in the maternal line (e.g., brother, uncle, nephew)
   b. Negative family history in 50% of affected males: two possibilities exist regarding his mother's carrier status and carrier risks of extended family members
      i. The mother is a carrier of a disease-causing mutation (80–85% of cases).
      ii. The mother is not a carrier and the affected male has a de novo disease-causing mutation (15–20% of cases).
   c. Patient's sib
      i. When the mother is a carrier
         a) A 50% chance of transmitting the *BTK* mutation by the mother in each pregnancy
         b) Male sibs who inherit the mutation will be affected.
         c) Female sibs who inherit the mutation will be carriers.
      ii. When the mother's carrier status is unknown and if the proband is the only affected individual in the family, the mother has an approximately 80% chance of being a carrier.
         a) Male sibs have a 40% chance of being affected.
         b) Female sibs have a 40% chance of being carriers.
      iii. When the mother is not a carrier (no evidence of her son's BTK disease-causing mutation present in DNA extracted from her leukocytes) and if the affected son represents a single case in the family, the male sibs are still at increased risk (<5%) of being affected because of the possibility of the presence of germ line mosaicism.
   d. Patient's offspring
      i. No sons will inherit the mutant allele and therefore will not be affected.
      ii. All daughters will inherit the mutant allele and will be carriers.
2. Prenatal diagnosis: available to pregnancies of women who are carriers
   a. The usual procedure: to determine fetal sex by performing chromosome analysis on fetal cells obtained by chorionic villus sampling (CVS) at about 10–12 weeks of gestation or by amniocentesis usually performed at about 15–18 weeks of gestation
   b. If the fetal karyotype is 46,XY and if the disease-causing mutation has been identified in a family member, DNA from fetal cells can be analyzed for the known disease-causing mutation.
   c. Preimplantation genetic diagnosis (PGD): available for families in which the disease-causing mutation has been identified in an affected family member. However, the reliability of PGD for XLA has not yet been proven.
3. Management
   a. Gamma globulin replacement (weekly subcutaneous injection or intravenous infusion every 2–4 weeks) and aggressive use of antibiotics
      i. Improve the outlook for affected patients: a remarkable improvement in the health and well-being after therapy is started
      ii. Acute, life-threatening infections: rare in patients with XLA who are receiving intravenous gamma globulin
      iii. Chronic lung disease and enteroviral infections still develop in some patients.

b. Inactivated polio vaccine rather than live oral polio vaccine is given to children with XLA and their sibs.
c. Molecular genetic testing of at-risk male relatives as soon after birth as possible to ensure that gamma globulin replacement therapy is initiated in affected individuals
d. Adults with XLA: become productive members of society and excel in many areas despite the disease impacts on the daily lives

Fig. 1 A 5-year-old boy was evaluated for immune deficiency because of recurrent respiratory tract infections (two pneumonias since late infancy) and one episode of meningitis. Recent immunoglobulin levels revealed IGA of <5 mg/dL (22–159), IGG of 115 mg/dL (141–1,135), and IGM of 11 mg/dL (47–200). Flow cytometry (immune deficiency panel) showed CD3, 92.9% (3,498); CD4, 43% (1,645); CD8, 46% (1,747); CD4/CD8, 1:1.1; CD19, 0.1% (4); and CD16 + CD56+, 6.2% (233). These findings are consistent of B-cell defect with normal T cell subsets and normal NK cells. Bruton's tyrosine kinase mutation analysis revealed a novel mutation in the splice site of exon 6 (g.58919 G > C). Previously, a mutation at this splice site (g.58919) G > A has been reported in the BTKBASE. The impact on protein structure and function for this mutation, assessed using a splice site prediction software, would be the same as that reported for g.58919 G > A. The patient currently receives intravenous immunoglobulin (610 mg/kg) and is responding well

Fig. 2 A 3-year-old male, a brother of the above patient, was also evaluated for immune deficiency because of recurrent upper respiratory infections in the first 2–3 months of life, three pneumonias in later infancy, and a pneumococcus meningitis recently. Recent immunoglobulin levels were IGA of <5 mg/dL, IGG of 184 mg/dL, and IGM of 10 mg/dL. Flow cytometry (immune deficiency panel) revealed CD3, 8% (1,979); CD4, 55% (1,365); CD8, 27% (679); CD4/CD8 ratio, 2:1; CD19+, 1.4% (34); and CD16+ CD56+, 11% (270). The patient currently receives intravenous infusion of immunoglobulin (680 mg/kg) and responds well

X-Linked Ichthyosis

X-linked ichthyosis is a relatively common genetic disorder of keratinization. It is the second most common type of ichthyosis after vulgaris. The incidence is estimated to be between 1 in 2,000 and 1 in 6,000 male live births.

Synonyms and Related Disorders

Placental steroid sulfatase deficiency; Steroid sulfatase deficiency

Genetics/Basic Defects

1. Inheritance
   a. X-linked recessive
   b. Usually affects males only
   c. Transmitted by carrier females (about 1 in 2,000 women are carriers of steroid sulfatase (STS) enzyme deficiency)
   d. Most apparently, sporadic cases appear to be inherited based on biochemical analysis (as their mothers showed low values of STS enzyme activity).
   e. Reports of a few affected female patients
2. Etiology (Janniger and Schwartz 2001)
   a. Caused by a deficiency of STS enzyme
   b. The *STS* gene
      i. Mapped on the distal part of the short arm of the X chromosome (Xp22.3)
      ii. Close to the pseudoautosomal region
      iii. Unlike most X-chromosome genes, the *STS* gene escapes the X-inactivation process.
3. Molecular defects
   a. Deletion of the entire steroid sulfatase (*STS*) gene: the most common molecular defect in X-linked ichthyosis (XLI) patients (observed in 90% of patients)
   b. Partial deletion or point mutation (observed in 10% of patients)
   c. The deletion of *STS* gene may occasionally extend to involve neighboring genes (interstitial and terminal deletions of Xp22.3), resulting in a contiguous gene defect and may be associated with the following conditions. Depending on the length of the deletion, these disorders occur independently from each other or in combination as a contiguous gene syndrome (Aviram-Goldring et al. 2000).
      i. Kallmann syndrome (hypogonadotropic hypogonadism and anosmia)
      ii. X-linked chondrodysplasia punctata
      iii. Short stature
      iv. Mental retardation
      v. Ocular albinism
      vi. Ichthyosis
4. Segregation analysis of paternal transmission of the affected X chromosome (Toral-Lopez et al. 2008): *STS* gene deletion may occur in male meiosis as a result of:
   a. An intrachromosomal event
   b. Recombination between S232 sequences on the same DNA molecule, or
   c. During the process of DNA replication

Clinical Features

1. Cutaneous manifestation (Hernandez-Martin et al. 1999; Jasmi and Al-Khenaizian 2002)
   a. Generalized scaling of the skin (ichthyosiform hyperkeratosis)
      i. Early onset: usually at birth or within 4 months of life
      ii. Large, dark-brown polygonal scales
         a) Usually symmetrically distributed
         b) More prominent on the trunk and the extensor aspects of the limbs
         c) Usually the flexures less affected
      iii. Face usually free from scales, except in the preauricular areas, giving the classic "unwashed appearance," which is considered by many to be pathognomonic
      iv. Sparing palms and soles in most cases
   b. Normal nails and hair
   c. Seasonal influence
      i. Improve during the summer
      ii. Worsen during dry, cold weather
2. Extracutaneous manifestations
   a. Corneal opacities
      i. The most common extracutaneus features
      ii. Secondary to deposits of cholesterol sulfate crystals
      iii. Asymptomatic (not affecting the visual acuity)
      iv. Occurring in the posterior capsule of Descemet's membrane or the corneal stroma (Aviram-Goldring et al. 2000)
      v. More frequent during the second and third decades of life
      vi. Observed in 10–50% of affected males and carrier females
   b. Cryptorchidism
      i. Occurring in 10–20% of patients (versus the incidence of cryptorchidism in the normal population of 1%)
      ii. Possible mechanisms
         a) A deficit in the STS enzyme
         b) A genetic disturbance located on the short arm of chromosome X close to the *STS* gene
   c. Patients at an increased risk of testicular cancer development
   d. CNS manifestations
      i. Epileptic seizures
      ii. Reactive psychological disorders
   e. Clinical manifestations as a part of the contiguous gene syndrome expression
      i. Kallmann syndrome
      ii. Short stature
      iii. Mental retardation
      iv. X-linked chondrodysplasia punctata
   f. Other rare manifestations
      i. Pyloric hypertrophy
      ii. Congenital abdominal wall defect
      iii. Acute lymphoblastic leukemia
3. Steroid sulfatase deficiency during pregnancy in carrier females
   a. Leads to an overall decrease in the levels of estrogen
   b. Causes poor cervical dilatation and prolonged labor
   c. Frequently necessitates a caesarean section

Diagnostic Investigations

1. Direct biochemical demonstration of STS deficiency (undetectable levels of STS activity) from the following tissue (Hernandez-Martin et al. 1999; Jasmi and Al-Khenaizian 2002):
   a. Placenta
   b. Skin fibroblasts
   c. Leukocytes
   d. Keratinocytes
2. Demonstration of an increase in substrates of STS
   a. Dihydroepiandrosterone sulfate (DHEAS)
   b. Cholesterol sulfate
3. Electrophoresis: rapid migration of serum cholesterol sulfate (negatively charged and carried by low-density lipoprotein (LDL) particles) toward the positive pole during electrophoresis
4. Molecular genetic diagnosis yielding reliable results in most affected patients
   a. Detection of complete deletion of the STS gene in most patients
      i. Fluorescence in situ hybridization (FISH)
      ii. Southern blotting
      iii. Multiplex polymerase chain reaction (PCR)

b. Partial deletion by FISH: may provide a false negative FISH result
c. A very small number of cases carrying point mutations instead of deletions at the *STS* gene: undetectable by Southern blot or PCR
d. Carrier detection
   i. STS enzyme assay
   ii. FISH technique especially useful in carrier detection since the enzymatic assay often provides inconclusive results

Genetic Counseling

1. Recurrence risk
   a. Patient's sib (given that the mother is a carrier)
      i. 50% of male sibs affected
      ii. 50% of female sibs carriers
   b. Patient's offspring
      i. Affected male patients
         a) Male offspring normal
         b) All female offspring carriers
      ii. Affected female patients (heterozygous)
         a) 50% of male offspring affected
         b) 50% of female offspring carriers
      iii. Affected female patients (homozygous)
         a) All male offspring affected
         b) All female offspring carriers
2. Prenatal diagnosis
   a. Maternal plasma demonstrating low or undetectable estriol levels in routine maternal serum screening, which is associated with the following conditions (Braunstein et al. 1976; Kashork et al. 2002):
      i. Placental steroid sulfatase deficiency
      ii. Fetal death
      iii. Miscarriages
      iv. Anencephaly
      v. Fetal adrenal hypoplasia
      vi. High-dose corticosteroid therapy
      vii. Aneuploidies
         a) Down syndrome
         b) Triploidy
      viii. Smith-Lemli-Opitz syndrome in rare cases
   b. Maternal urine and plasma profile of affected fetuses indicating a primary placental sulfatase deficiency (low estriol levels) (Basler et al. 1992)
   c. Amniocentesis (Aviram-Goldring et al. 2000)
      i. Elevated sulfated steroids in the amniotic fluid
      ii. FISH to detect deletion in one copy of X chromosome at region Xp22.3 using steroid sulfatase probe
   d. Skin biopsy through fetoscopy to measure sulfated steroid
3. Management (Hernandez-Martin et al. 1999)
   a. Most patients have disease limited to the skin.
   b. Spontaneous improvement in most cases with age and during summer months and hardly require any treatment
   c. Attempt to diminish the abnormal cohesion of corneocytes by facilitating their separation in the milder forms
      i. Topical keratolytics
      ii. Emollients
      iii. Hydrating agents
   d. Retinoids for potential treatment in severely affected patients
   e. Liarozole, a imidazole derivative which inhibit cytochrome P450 to increase the level of endogenous retinoid acid by blocking its P450-dependent catabolism
   f. Examination of male patients to detect cryptorchidism which has an increased risk of testicular cancer

Fig. 1 A sporadic case of X-linked ichthyosis showing thick, large, polygonal, dark-brown scales involving the extensor

Fig. 2 X-linked ichthyosis affecting three boys in a family

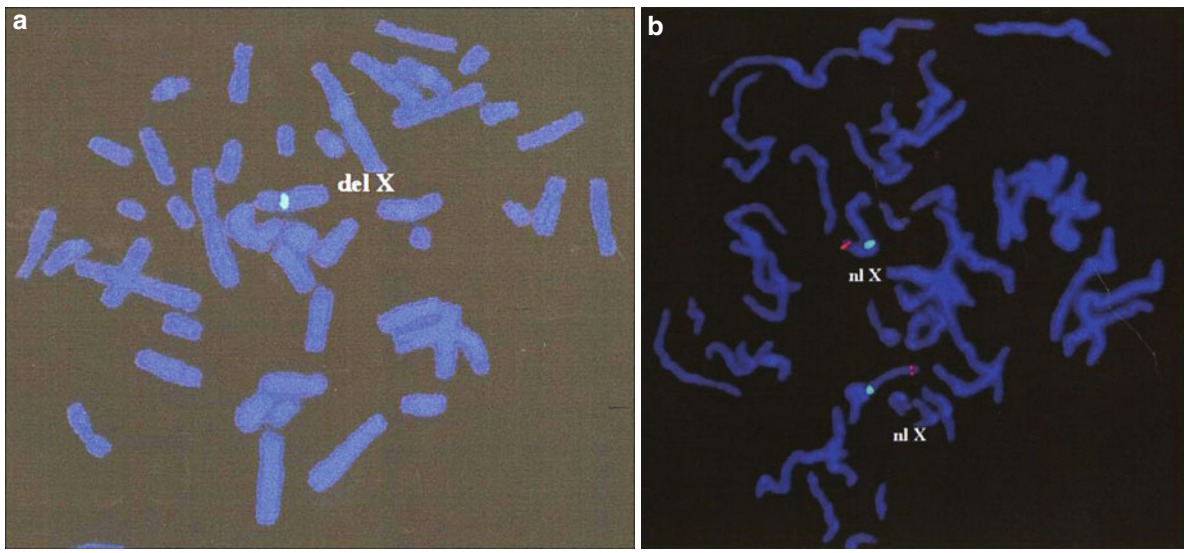

Fig. 3 (**a**, **b**) Abnormal FISH analysis showed a deletion in the steroid sulfatase critical region on the X chromosome [del(X)(p22.3p22.3)(STS-)] in a male fetus (*left photo*). The case was ascertained because of undetectable UE3 from maternal serum screen. The *right photo* (FISH) showed a normal XX control

XX Male

46,XX maleness (XX male syndrome) is a rare disorder occurring in about 1 in 20,000–25,000 newborn males (De la Chapelle 1972; Rajender et al. 2006). Three clinical categories of sex-reversed 46,XX individuals have been identified: (1) XX males with normal external or internal genitalia; (2) XX males with ambiguity, usually detected at birth by external genital ambiguities such as hypospadias, micropenis, or clitoromegaly; and (3) XX true hermaphrodites, who carry internal or external genital ambiguities detected at birth (Valetto et al. 2005). Recently, the term "46,XX testicular DSD (disorder of sex development)" has been proposed for XX male or XX sex reversal (Lee et al. 2006; Hughes et al. 2006; Hughes 2008).

Synonyms and Related Disorders

46,XX disorder of sex development; 46,XX sex reversal syndrome

Genetics/Basic Defects

1. Sex differentiation: Please see the chapter on XY Female Syndrome (Vilain 2009).
2. The *SRY* gene (Valetto et al. 2005)
   a. Located in the short arm of Y chromosome (Yp11.32) near the pseudoautosomal boundary of the Y chromosome
   b. Encodes the sex-determining region Y protein
   c. Has many predicted properties of the testis-determining factor (TDF) (Sinclair et al. 1990)
   d. XX transgenic mice carrying the murine *SRY* gene developed as phenotypic male mice (Koopman et al. 1991).
   e. Loss-of-function mutations in the *SRY* gene: can cause a complete sex reversal (genetically male individuals developing as XY females, presenting a streak gonad lacking germ cells) (Jager et al. 1990; Hawkins et al. 1992)
   f. The gene most commonly known to be associated with 46,XX testicular DSD
      i. Presence of Y chromosome material including *SRY* in some XX individuals: leads to testis determination and the development of a male phenotype
      ii. The majority of XX males carry the *SRY* gene as a result of an illegitimate XY chromosomal interchange during paternal meiosis (Fechner et al. 1993).
      iii. *SRY*-negative individuals resulting from *SRY* gene mutation
   g. Several genetic mishaps conceive the 46,XX male genotype (Rizvi 2008).
      i. An original 47,XXY configuration with the loss of the Y chromosome early in embryogenesis
      ii. A loss-of-function gene mutation on an autosomal chromosome or on the X chromosome that leads to an aberrancy in the testis differentiation pathway
      iii. Possibility that 46,XX males actually have a "hidden" cell line with a Y chromosome present ("cryptic mosaicism")
      iv. Translocation of the Y chromosome fragment containing the SRY gene to the short

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_250,
© Springer Science+Business Media, LLC 2012

arm of an X chromosome or an autosome by unequal interchange between homologous regions during paternal meiotic division (Rego et al. 1996)
   a) The affected individual has male sexual characteristics because of the Y fragment, with the testis-determining factor, being located on the autosome or X chromosome, despite the XX sex chromosome pattern.
   b) If the translocation is in a "pseudoautosomal region" proximal to the SRY gene, there may be no significant outcome.
   c) Only if the translocation involves the SRY region of the Y chromosome then the X chromosome will "act" like a Y chromosome in determining the phenotypic gender of the person.
3. Pathogenesis of 46,XX sex reversal syndrome: currently not clear with the following hypotheses (Wang et al. 2009):
   a. Hypothesis of target gene mutation (Liu et al. 2005)
      i. The structural gene that determines human gender may be located in the autosome, which is regulated by the inhibition of X chromosome and the activation of Y chromosome.
      ii. 46,XX individuals, due to defects of the inhibition of X chromosome, result in spontaneous activation of the downstream gene in the absence of *SRY* gene, transform into 46,XX males.
   b. Hypothesis of overexpression of *SOX9* gene (SRY box-related gene 9 located in 17q24.3-q25.1): Upregulation of *SOX9* expression caused by chromosomal abnormalities or mediated by other bypass activation (e.g., PGD2) may result in the occurrence of the SRY-gene-negative 46,XX male patient.
   c. Hypothesis of Xp-Yp translocation: Abnormal exchange of the ends of X-Y chromosomes (Xp-Yp translocation) occurred during paternal sperm meiosis resulting in X-type sperm containing SRY gene, which could lead to 46,XX offspring when combining with eggs.
4. Approximately 85% of individuals with 46,XX testicular DSD (Queipo et al. 2002; Zenteno-Ruiz et al. 2001)
   a. *SRY* positive
   b. Phenotypically males with unambiguous male genitalia at birth
   c. Not diagnosed until puberty when they fail to proceed normally
5. Remaining 15% of individuals with 46,XX testicular DSD (Zenteno-Ruiz et al. 2001; Kusz et al. 1999)
   a. Genital ambiguity
   b. *SRY* positive in only a minority of cases
6. A proposed classification of causes of 46,XX disorders of sex development (DSD) (Hughes 2008)
   a. Disorders of gonadal (ovarian) development
      i. Gonadal dysgenesis
      ii. Ovotesticular DSD
      iii. Testicular DSD (e.g., *SRY*+, *dup SOX*9, RSP01)
   b. Androgen excess
      i. Fetal
         a) 3β-hydoxysteroiddehydrogenase 2 (HSD3B2)
         b) 21-hydroxylase (CYP21A2)
         c) P450 oxidoreductase (POR)
         d) 11β-hydoxylase (CYP11B1)
         e) Glucocorticoid receptor mutations
      ii. Fetoplacental
         a) Aromatase (*CYP19*) deficiency
         b) Oxidoreductase (*POR*) deficiency
      iii. Maternal
         a) Maternal virilizing tumors (e.g., luteomas)
         b) Androgenic drugs
   c. Other
      i. Syndromic associations (e.g., cloacal anomalies)
      ii. Müllerian agenesis/hypoplasia (e.g., MURCS)
      iii. Uterine abnormalities (e.g., MODY5)
      iv. Vaginal atresia (e.g., KcKusick-Kaufman)
      v. Labial adhesions

Clinical Features

1. Natural history (Vilain 2009)
   a. Approximately 80% of patients
      i. Present after puberty with normal pubic hair and normal penile size, but small testes, gynecomastia, and sterility resulting from azoospermia

ii. The small testes are usually soft but may become firmer with age.
iii. A minority have cryptorchidism and/or anterior hypospadias (Boucekkine et al. 1994).
iv. Gender role and gender identity are reported as male for the common, unambiguous presentation, but systematic psychosexual assessment has not been performed on a significant number of individuals with 46,XX testicular DSD.

b. Approximately 20% of patients: ambiguous genitalia noted at birth, typically penoscrotal hypospadias with or without chordee.
c. Untreated patients: similar to typical consequences of testosterone deficiency
i. Low libido and possible erectile dysfunction
ii. Decrease in secondary sexual characteristics, such as sparse body hair, infrequent need to shave, and reduced muscle mass
iii. Increase in fat mass with lower muscle strength
iv. Increased risk of osteopenia
v. Increased risk of depression

2. SRY-positive 46,XX males
a. Present after puberty
i. Shorter-than-average stature (De la Chapelle 1972)
ii. Gynecomastia
iii. Small testes
iv. Azoospermia
b. Rarely present with atypical genitalia and are less likely than individuals with *SRY*-negative 46,XX males to have gynecomastia (Ferguson-Smith et al. 1990; Boucekkine et al. 1994; Ergun-Longmire et al. 2005)
3. SRY-negative 46,XX males
a. Tend to present with ambiguous genitalia at birth, such as penoscrotal hypospadias and cryptorchidism
b. If untreated, almost always develop gynecomastia around the time of puberty
4. Genotype-phenotype correlations
a. Presence of *SRY* : often associated with the presence of normal male external genitalia
b. Absence of *SRY* : more often associated with ambiguous genitalia (Grigorescu-Sido et al. 2005)
c. Genotype-phenotype correlation: not entirely reliable because a small number of individuals with *SRY*-negative 46,XX males have normal external genitalia (Vilain et al. 1994; Zenteno et al. 1997; Kolon et al. 1998; Vernole et al. 2000; Abusheikha et al. 2001)
5. Long-term outcome: most had male sexual potential and male sex identity as long as testicular tissues were preserved (Kojima et al. 2009)
6. Differential diagnosis
a. Syndromic XX testicular DSD
b. Isolated XX testicular DSD
c. Sex chromosome abnormalities
i. Klinefelter syndrome
ii. 46,XX/46,XY
iii. 45,X/46,XY
d. Mosaic duplication of 17q23.1-q24.3 including *SOX9* gene
e. 46,XX ovotesticular DSD
f. 21-hydroxylase deficiency causing congenital adrenal hyperplasia
g. Prenatal exposure of a pregnancy to androgens with an XX karyotype can cause virilization resulting in an infant with ambiguous genitalia that may look similar to those of a male with 46, XX testicular DSD and genital ambiguity.
i. Externally administered androgens such as danazol
ii. Endogenously produced androgens by the mother

Diagnostic Investigations

1. Routine cytogenetic studies: 46,XX karyotype (Vilain 2009)
2. Endocrine studies
a. Hypergonadotropic hypogonadism secondary to testicular failure (Pérez-Palacios et al. 1981)
i. Moderately elevated basal serum concentrations of LH and FSH
ii. Usually decreased serum testosterone concentration
iii. HCG stimulation test
a) Low to subnormal testosterone response
b) Little or no elevation of serum testosterone concentration
b. Preservation of hypothalamic-pituitary axis: GnRH stimulation test shows a normal LH and FSH response (not warranted for diagnosis).

3. Testicular biopsies (De la Chapelle 1981)
   a. Decrease in size and number of seminiferous tubules
   b. Peritubular fibrosis
   c. Absence of germ cells
   d. Hyperplasia of Leydig cells
4. Molecular genetic testing
   a. Fluorescence in situ hybridization (FISH) using commercially available FISH probe to locate *SRY* gene on the short arm of one X chromosome
   b. PCR amplification
      i. Used when FISH fails to detect the *SRY* region
      ii. More likely to detect a small amount of Y chromosome translocated onto the X chromosome
      iii. To detect the Y chromosome material in an individual who is an XX-*SRY*-positive/XX-*SRY*-negative mosaic
   c. Comparative genomic hybridization (CGH) method to identify the small unbalanced chromosome rearrangement implicated in an XX male (Rigola et al. 2002)

Genetic Counseling

1. Recurrence risk (Vilain 2009)
   a. Patient's sib
      i. Sibs of a proband with *SRY* translocation to an X chromosome
         a) Proband with a de novo translocation (in most cases): has a low risk to XX sibs (<1%). No instances of germline mosaicism have been reported, but it remains a possibility.
         b) Proband with familial translocation (father carrying two copies of SRY, one translocated to his X chromosome and one on his Y chromosome): XX sibs will have 46,XX testicular DSD or XX true hermaphroditism; XY sibs will not be affected.
      ii. Sibs of a proband with *SRY* translocation to an autosome
         a) Proband with a de novo translocation: risk to sibs not increased
         b) Proband with familial translocation (father carrying an *SRY* gene translocated onto an autosome): XX sibs of a proband each have a 50% chance of inheriting the translocated *SRY* gene and will have 46,XX testicular DSD or XX true hermaphroditism.
      iii. Sibs of a proband with SRY-negative 46,XX testicular DSD: 25% risk
   b. Patient's offspring
      i. Men with SRY-positive 46,XX testicular DSD: infertile
      ii. Men with SRY-negative 46,XX testicular DSD: infertile
2. Prenatal diagnosis
   a. Available for pregnancies at risk for SRY-positive 46,XX DSD from fetal cells obtained by amniocentesis or CVS using FISH
   b. Fetal karyotype discordant with the phenotypic sex observed by ultrasound examination in most cases
   c. An *SRY*-positive result decreases but does not exclude the likelihood of ambiguous genitalia.
   d. Has been described in several cases (Margarit et al. 1998; Trujillo-Tiebas et al. 2006)
3. Management
   a. Testosterone replacement therapy: low-dose testosterone therapy: initiate after age 14 years
      i. Testosterone enanthate injection: preferred
      ii. Transdermal patches and gels
   b. Reduction mammoplasty for gynecomastia for:
      i. Failure of regression of gynecomastia after testosterone replacement therapy
      ii. Presence of gynecomastia causing psychological distress
   c. Male-to-female transsexual operation for an XX male patient who is eager to live as a female (Kurita et al. 2006)
      i. Resection of the penis
      ii. Repositioning of the urethra
      iii. Vaginal construction
   d. Calcium, exercise, vitamin D, biphosphonates, or calcitonin for osteopenia
   e. Psychological support

Fig. 1 (**a**–**c**) A 19-year-old phenotypically male patient has been evaluated for slightly high-pitched voice, gynecomastia, cryptorchidism on the right, a small atrophic testis on the left, and penile hypospadias. Chromosome study revealed 46,XX

XXX Syndrome

Females with a 47,XXX karyotype were first described by Jacobs et al. in 1959. The incidence of 47,XXX among female newborns is approximately 1 in 1,000 live births (Pennington et al. 1980). It is the most common female chromosomal abnormality. As some individuals are only mildly affected or asymptomatic, it is estimated that only 10% of individuals with trisomy X are actually diagnosed (Tartaglia et al. 2010).

Synonyms and Related Disorders

Trisomy X syndrome

Genetics/Basic Defects

1. Etiology: An extra chromosome X is responsible for 47,XXX.
2. Mechanism of the origin for the 47,XXX condition
   a. Almost all 47,XXX result from maternal nondisjunction.
   b. Typically at meiosis I
   c. The risk of trisomy X increases with advanced maternal age.
   d. Postzygotic nondisjunction occurs in approximately 20% of cases.
3. The phenotype in trisomy X is hypothesized to result from overexpression of genes that escape X-inactivation, but genotype-phenotype relationships remain to be defined (Tartaglia et al. 2010).

Clinical Features

1. No specific phenotype exists in 47,XXX females (Chudley et al. 1990).
2. A higher incidence of minor anomalies
   a. Epicanthal folds
   b. Upslanting palpebral fissures
   c. Ear abnormalities
   d. Clinodactyly
3. Growth and development (Otter et al. 2010)
   a. Birth weights tend to be slightly lower than the general population.
   b. The physical phenotype shows earlier growth and longer legs.
   c. Taller in older children
   d. Relative microcephaly
   e. Hypotonia
   f. At risk for mild speech/language and motor delays and learning disabilities
   g. The behavioral phenotype often shows auditory processing disorders, disorders in language development, and problems in forming stable interpersonal relationships.
   h. Psychiatric disorders seem to be more common in triple X syndrome.
   i. Quality of life seems to increase after leaving school.
   j. Intelligence
      i. Normal range
      ii. Lower intelligence quotients (10–15 points) in comparison to unaffected sibs
4. Gonadal structures and function
   a. Heterosexual
   b. Normal secondary sexual characteristics

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_251,
© Springer Science+Business Media, LLC 2012

c. Normal menstruation
d. Fertility usually normal
e. Late menarche
f. Occasional amenorrhea
g. Premature ovarian failure
h. Sterility with streak gonads

5. Congenital anomalies reported in a very small number of patients
   a. Urogenital tract abnormalities
   b. Brain abnormalities including seizures
   c. Skeletal abnormalities
   d. Congenital heart defects
   e. Craniofacial abnormalities
6. Adaptation status: variable (Harmon et al. 1998)
   a. At risk for intellectual and psychological problems
   b. 47,XXX women during adolescence and young adulthood
      i. Less well adapted
      ii. With more stress
      iii. With work, leisure, and relationship problems
      iv. With a lower IQ
      v. With more psychopathology when contrasted with the comparison group
   c. Most 47,XXX women
      i. Self-sufficient
      ii. Functioning reasonably well
7. Differential diagnosis prior to definitive karyotype results includes (Tartaglia et al. 2010):
   a. Fragile X
   b. Tetrasomy X
   c. Pentasomy X
   d. Turner syndrome mosaicism

Diagnostic Investigations

1. Chromosome analysis
2. Psychological and psychiatric evaluation when needed

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring (Dewhurst 1978)
      i. An increased risk of a cytogenetically abnormal child but the extent of the risk cannot yet be determined
      ii. Majority of offspring normal
2. Prenatal diagnosis by fetal karyotyping from amniocytes or CVS, followed by detailed ultrasonographic examinations of multiple organ systems to screen for possible associated congenital malformations (Bağci et al. 2010)
3. Management
   a. Infancy/toddler: assess milestones
   b. Childhood
      i. Assess school performance
      ii. Provide intervention if needed
         a) Speech/language therapy
         b) Physical/occupational therapy
         c) Educational remediation
   c. Adolescence: usually no intervention needed
   d. Adulthood: annual physical examination

Fig. 2 A girl with 47,XXX showing normal phenotype

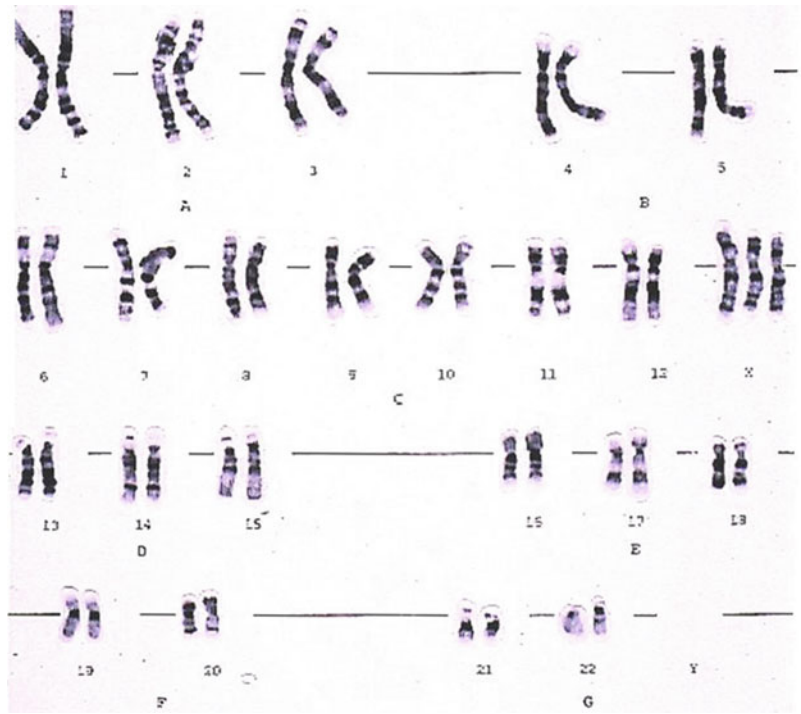

Fig. 3 47,XXX karyotype

XXXXX Syndrome

49,XXXXX (pentasomy X) is a rare sex chromosome aneuploidy. The birth prevalence of pentasomy X is estimated to be one in 85,000 females (Martini et al. 1993).

Synonyms and Related Disorders

49,XXXXX syndrome; Penta X syndrome

Genetics/Basic Defects

1. Etiology: three extra X chromosomes are responsible for the pentasomy X syndrome (Archidiacono et al. 1979).
2. Occurrence of a 49,XXXXX complement: secondary to sequential nondisjunctions in meiosis I and meiosis II in the mother
   a. Involves the survival of both X chromosomes in a single oocyte through both meiotic divisions (Deng et al. 1991)
      i. Once between homologous X chromosomes at the first meiosis
      ii. Twice between sister chromatids in both X chromosomes in the secondary oocytes at the second meiosis
   b. Followed by the fertilization by a sperm contributing the fifth chromosome X
3. Formation of four Barr bodies
   a. Lyon hypothesis
      i. Inactivation of all X chromosomes but one
      ii. Accounts for the viability of the X chromosome aneuploidies
   b. Inactivation of four X chromosomes resulting in four Barr bodies
4. Effect of supernumerary X chromosomes: a direct relationship between the number of supernumerary X chromosomes and phenotypic abnormalities and mental retardation, with each additional chromosome increasing the severity
   a. Affects somatic development most significantly
      i. Skeletal abnormalities
      ii. Cardiovascular abnormalities
   b. Delays sexual development
   c. Affects cognitive development
      i. Severe mental retardation
      ii. Language delay (both expressive and receptive language)
      iii. Behavioral problems

Clinical Features

1. Growth and development
   a. Prenatal growth retardation
   b. Small birth weight
   c. Low postnatal weight
   d. Failure to thrive
   e. Hypotonia
   f. Short stature
   g. Delayed psychomotor retardation
   h. Mental retardation
2. Craniofacial features
   a. Microcephaly
   b. Flattened occiput
   c. Epicanthus
   d. Upslanting palpebral fissures
   e. Ocular hypertelorism
   f. Uncoordinated eye movements

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_252,
© Springer Science+Business Media, LLC 2012

   g. Flat broad nose
   h. Cleft palate
   i. Low-set ears
   j. Malformed teeth
3. Skeletal abnormalities
   a. Short neck
   b. Lax joints
   c. Multiple dislocations
      i. Shoulders
      ii. Elbows
      iii. Hips
   d. Radioulnar synostosis
   e. Spinal abnormalities
   f. Clinodactyly of the fifth fingers
   g. Lower leg abnormalities
      i. Genu valgum
      ii. Talipes
      iii. Metatarsus varus
   h. Delayed bone age
4. Congenital heart defects
   a. Ventricular septal defect
   b. Patent ductus arteriosus
5. Abnormal lobulation of the lungs
6. Renal hypoplasia
7. Sexual development
   a. Delayed puberty
   b. Incomplete secondary sexual development
   c. Small uterus
   d. Hypoplastic/absent ovaries
      i. Composed mainly of stroma and atrophic follicles
      ii. Absence of ova
      iii. Unilateral absence of an ovary reported
   e. Reduced fertility
8. Normal external genitalia
9. Dermatoglyphics
   a. Finger-dermal-ridge hypoplasia and a low total ridge count, consistent with the inverse proportion between the number of X chromosomes and the total ridge count (exceptions exist)
   b. Transverse palmar creases

Diagnostic Investigations

1. Chromosome analysis
   a. 49,XXXXX karyotype
   b. Fluorescence in situ hybridization (FISH), using DNA probe for α-satellite sequence in chromosome X (DXZ1), reveals five signals representing the presence of XXXXX.
2. Radiography
   a. Dislocations of the elbows and/or hips
   b. Radioulnar synostosis
   c. Clinodactyly

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not reported due to severe mental retardation
2. Prenatal diagnosis
   a. Ultrasonography: bilateral radioulnar synostosis
   b. Amniocentesis and CVS
      i. Chromosome analysis
      ii. FISH using DNA probe (DXZ1) applied to uncultured amniocytes
3. Management
   a. Physical/occupational therapy
   b. Speech therapy

XXXXY Syndrome

49,XXXXY syndrome was first described by Fraccaro and Lindsten in 1960. The incidence is estimated to be approximately 1 in 85,000 newborn males (Pallister 1982).

Synonyms and Related Disorders

49,XXXXY syndrome

Genetics/Basic Defects

1. Etiology: three extra X chromosomes are responsible for the 49,XXXXY syndrome.
2. Mechanism
   a. All four X chromosomes are of maternal in origin.
   b. Resulting from successive nondisjunctions in maternal meiosis I and II, fertilized by a normal Y sperm (Deng et al. 1991)
   c. Inactivation of three out of four X chromosomes results in three Barr bodies (Lyon hypothesis).
3. Effect of supernumerary X chromosomes: a direct relationship between the number of supernumerary X chromosomes and phenotypic abnormalities and mental retardation, with each additional chromosome increasing the severity
   a. Somatic development most significantly affected
      i. Skeletal abnormalities
      ii. Cardiovascular abnormalities
   b. Gonadal development in males: particularly susceptible to extra genetic material
      i. Addition of a single X chromosome to a 46, XY karyotype resulting in seminiferous tubal dysgenesis rendering infertile such males with Klinefelter syndrome
      ii. Additional extra X chromosomes in polysomy X males such as 48,XXXY and 49,XXXXY can result in not only infertility but also hypoplastic and malformed genitalia.
   c. Affects cognitive development
      i. Severe mental retardation
      ii. Language delay (both expressive and receptive language)
      iii. Behavioral problems

Clinical Features

1. "Classic triad"
   a. Mental retardation
   b. Radioulnar synostosis
   c. Hypogonadism
2. Growth and development
   a. Growth retardation
   b. Severe speech impairment
   c. Varying degree of mental retardation
3. Craniofacial features
   a. Microcephaly
   b. A full, round face
   c. Ocular hypertelorism
   d. Upslanted palpebral fissures
   e. Epicanthus
   f. Broad nasal bridge
   g. Micrognathia
   h. Prognathism
   i. High-arched or cleft palate
   j. Irregular teeth implantation
   k. Malformed ears
4. Webbed and short neck

5. Congenital heart defects
   a. Patent ductus arteriosus
   b. Atrial septal defect
   c. Pulmonic stenosis
   d. Tetralogy of Fallot
6. Skeletal abnormalities
   a. Short stature
   b. Proximal radioulnar synostosis
   c. Proximal tibiofibular synostosis (Nishimura et al. 2008)
   d. Vertebral anomalies
   e. Clinodactyly of the fifth fingers
   f. Coxa valga
   g. Genu valgum
   h. Pes planus
7. Genital abnormalities
   a. Hypoplastic male genitalia
   b. Micropenis
   c. Hypospadias
   d. Small testes
   e. Hypogonadism
   f. Infertility
8. Dermatoglyphics
   a. Decrease in total finger ridge count
   b. Transverse palmar creases
9. Psychological profile
   a. Timid and shy
   b. Emotional disturbances with low frustration level
   c. Strong reaction to minor changes
   d. Adaptive function higher than cognitive function
10. The phenotypic presentation of the boys with 49, XXXXY (Gropman et al. 2010)
    a. Shares some characteristics with 47, XXY
    b. Other unique and distinctive features
       i. Previously unappreciated intact nonverbal skills are evident in conjunction with moderate to severe developmental dyspraxia.
       ii. Variability in clinical and cognitive functioning may reflect skewed X inactivation, mosaicism, or other factors that warrant further investigation

Diagnostic Investigations

1. Chromosome analysis showing 49,XXXXY
2. Radiography
   a. Elbows
      i. Proximal radioulnar dysostosis
      ii. Radioulnar dislocation without synostosis
      iii. Elongated upper radius
      iv. Wide, club-shaped proximal ulna
   b. Wrists and hands
      i. Elongated distal ulna
      ii. "Pseudoepiphyses"
      iii. Clinodactyly of the fifth fingers
      iv. Brachymesophalangia V
      v. Retarded bone age
      vi. Corner defect in capitate
      vii. Poor modeling of the fifth metacarpals
   c. Pelvis and hips
      i. Coxa valga
      ii. Narrow iliac wings
   d. Knees
      i. Shallow intercondylar fossa
      ii. Genu valgum
   e. Ankles and feet
      i. Gap between the first and second toes
      ii. Short wide distal phalanx of the great toes
   f. Skull
      i. Sclerotic cranial sutures
      ii. Thick cranial vault
      iii. Ocular hypertelorism
      iv. J-shaped sella
      v. Prognathism
   g. Spine
      i. Scoliosis
      ii. Thoracic kyphosis
      iii. Square vertebral bodies
   h. Sternum
      i. Thick
      ii. Abnormal segmentation
3. Echocardiography for congenital heart defects
4. MRI of the brain (Hoffman et al. 2008)
   a. Varying degree of brain volume loss
   b. Abnormalities in white matter
5. Histology of testicular biopsies: dysgenesis of testicular germ cells and tubules leading to fibrosis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: no offspring due to infertility of the condition

2. Prenatal diagnosis
   a. Ultrasonographic markers
      i. Polyhydramnios
      ii. Cystic hygroma
      iii. Clubfoot
      iv. Micropenis
   b. Amniocentesis and CVS
      i. Chromosome analysis
      ii. FISH using DNA probe (DXZ1) applied to uncultured amniocytes
3. Management
   a. Early intervention and stimulation programs
      i. Speech/language therapy
      ii. Physical/occupational therapy
   b. Testosterone replacement therapy

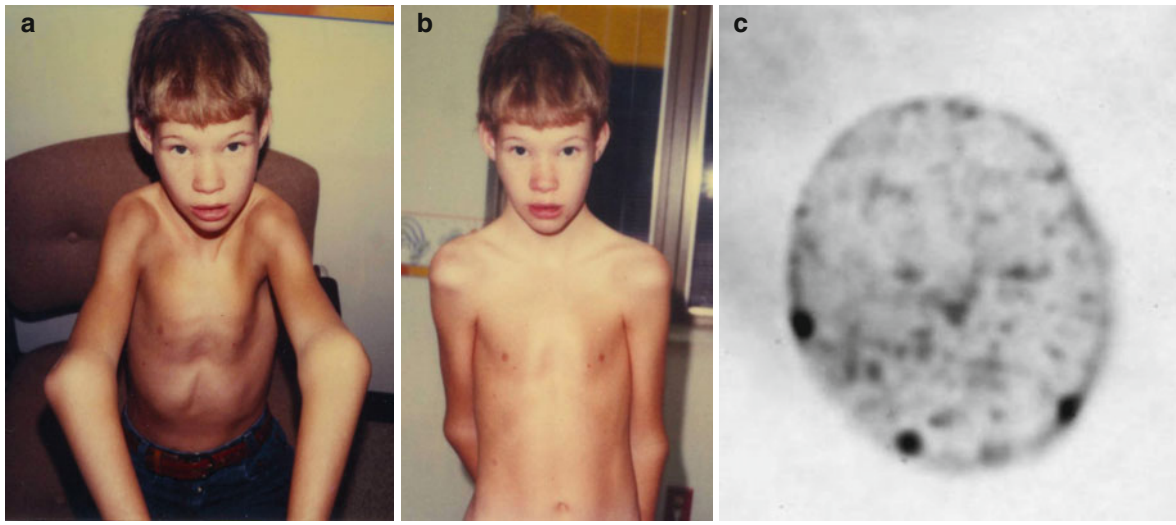

Fig.1 (**a**–**c**) An older boy with 49,XXXXY showing bilateral dislocation of the elbows, radioulnar synostosis, and three Barr bodies (buccal smear)

Fig. 2 (**a**, **b**) A younger boy with 49,XXXXY showing a full, round face. He also has incontinentia pigmenti achromians

XY Female

XY females are completely sex-reversed individuals who are phenotypically females with 46,XY karyotype, failure to develop secondary sex characteristics, amenorrhea, and "streak gonads."

Synonyms and Related Disorders

46,XY disorder of sex development; 46,XY sex reversal syndrome

Genetics/Basic Defects

1. Sexual differentiation (Michala and Creighton 2010): Genetic sex is determined at conception, when the ovum is fertilized by an X or Y chromosome containing spermatozoon (Ahmed and Hughes 2002).
   a. Testicular development
      i. The presence of the Y chromosome directs testicular development, through a switch gene present on its short arm, called the *SRY* gene (Sinclair et al. 1990).
      ii. This, along with other testes-determining factors (TDFs), will guide the differentiation of the undifferentiated gonad into testicular tissue (Cameron and Sinclair 1997).
      iii. Further genital differentiation is promoted by hormones that are produced by testicular tissue and that will lead to virilization.
      iv. Sertoli cells produce anti-Müllerian hormone (AMH), which triggers the regression of Müllerian structures while Leydig cells secrete testosterone, which promotes the development of Wolffian structures into the vas deferens, seminal vesicles, and epididymis (Rey and Picard 1998).
      v. Testosterone is further converted into dihydrotestosterone (DHT), a potent androgen, in the periphery, leading to the virilization of the external genitalia (Zhu et al. 1998).
   b. Ovarian development
      i. Ovarian tissue develops in the absence of TDFs and in the face of the antitesticular action of the genes *DAX1*, *Rspo1*, and *WNT4*.
      ii. Ovaries do not produce hormones during fetal life and the development of female genitalia is independent of hormone production.
      iii. The fetus is recognizable as male or female at 12 weeks and this can be identified ultrasonographically from the second trimester of pregnancy onwards (Odeh et al. 2009).
2. *SRY* gene and its mouse homologue, *Sry* (Schäffler et al. 2000)
   a. The sex-determining region on the Y chromosome
      i. Mapped to the short arm of the Y chromosome
      ii. Encodes for a testis-determining factor (TDF)
      iii. Candidate gene narrowed down to a 35-kb interval on the Y chromosome adjacent to the pseudoautosomal boundary which contains a Y chromosomal–specific sequence, named SRY (sex-determining region Y gene)
      iv. Demonstration that mice transgenic for Sry developed into sex-reversed males despite an XX karyotype provided the confirmation of SRY being the TDF that directs the undifferentiated gonad into a testis.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_254,
© Springer Science+Business Media, LLC 2012

b. Deletions or mutations occurring in the *SRY*
   i. Result in failure of testis development
   ii. Sex differentiation along the female pathway
3. Mechanism of male to female sex reversal (abnormalities of XY sex determination)
   a. Mutations in the SRY gene resulting in XY females with gonadal dysgenesis (vs. translocation of this gene sequence to X chromosome giving rise to XX males)
      i. Increasing variety of unique mutations within SRY gene reported in patients with gonadal dysgenesis/XY reversal. These patients are, in general, normal 46,XY females with complete gonadal dysgenesis.
      ii. SRY gene mutations noted in 15–20% of cases with complete gonadal dysgenesis
         a) Most mutations are located in the High Mobility Group (HMG) box.
         b) De novo mutations affect only one individual in a family in the majority of cases.
         c) Phenotypic variability is associated with different mutations.
      iii. About one third of the *SRY* mutations reported are inherited.
         a) No apparent explanation available to explain why an inherited SRY mutation which results in sex reversal in the offspring is associated with a normal male phenotype in the father and sometime in brothers and uncles.
         b) Paternal mosaicism for the mutant *SRY* provides an explanation for the other familial cases of XY gonadal dysgenesis.
      iv. Eighty percent of patients with sporadic or familial 46,XY gonadal dysgenesis lack a mutation or deletion of the SRY gene, indicating that other autosomal or X-linked genes have a role in sex determination.
   b. *Sox9*
      i. Another gene involved in sex determination identified by positional cloning of a chromosomal breakpoint has been identified in the XY female with campomelic dysplasia, a condition in which three quarters of XY patients show genital and gonadal malformations.
      ii. Belongs to a family of SRY-box-related (SOX) genes which encode proteins with at least 60% amino acid homology to the HMG box of the SRY protein
   c. *Atrx*
      i. The gene responsible for the ATR-X syndrome causes α-thalassemia, severe mental retardation, and multiple congenital anomalies which may include 46,XY gonadal dysgenesis and undermasculinization.
      ii. The C-terminal region of the protein has been lost in most cases where there has been gonadal dysgenesis associated with ATR-X syndrome.
   d. Deletions of variable portions of the short arm of chromosome 9 (*DMRT-1* identified as a candidate gene) result in partial or complete gonadal dysgenesis in XY females.
   e. Sex-reversing Xp duplication (Xp21) (Bardoni et al. 1994)
4. Classification of 46,XY disorders of sex development (DSD) (Hughes 2008; Mendonca et al. 2009)
   a. 46,XY DSD due to gonadal (testicular) development
      i. Gonadal agenesis
      ii. Complete or partial gonadal dysgenesis (e.g., *SRY*, *SOX9*, *SF1*, WT1, DHH)
      iii. Ovotesticular DSD
      iv. Embryonic testis regression syndrome
      v. Gonadal dysgenesis associated with syndromic phenotype
   b. Disorders of androgen syndromes
      i. Disorders of androgen synthesis
         a) LH receptor mutations
         b) Smith–Lemli–Opitz syndrome
         c) Steroidogenic acute regulatory protein mutations
         d) Cholesterol side-chain cleavage(*CYP11A1*)
         e) 3β-hydoxysteroid dehydrogenase 2 (*HSD3B2*)
         f) 17α-hydroxylase/17,20-lyase (*CYP17*)
         g) P450 oxidoreductase (*POR*)
         h) 17β-hydoxysteroid dehydrogenase(*HSD17B3*)
         i) 5α-reductase 2 (*SRD5A2*)
      ii. Disorders of androgen action
         a) Androgen insensitivity syndrome
         b) Drugs and environmental modulators
   c. Others
      i. Syndromic associations of male genital development (e.g., cloacal anomalies, Robinow, Aarskog, hand-foot-genital, popliteal pterygium)

ii. Persistent Müllerian duct syndrome
iii. Vanishing testis syndrome
iv. Congenital hypogonadotropic hypogonadism
v. Cryptorchidism (*INSL3*, *GREAT*)
vi. Environmental influences
vii. Nonclassical forms
a) Isolated hypospadias (*CXorf6*)
b) 46,XY gender identity disorders (male to female transsexualism)

Clinical Features

1. Clinical presentation of an XY female (Berkovitz 1992; Michala and Creighton 2010)
a. Primary amenorrhea with delayed puberty (Swyer syndrome)
i. 46,XY females (individuals with 46,XY complete gonadal dysgenesis)
ii. Diagnosis usually not made until puberty when the patient presents with delayed pubertal development
iii. Unambiguous female phenotype with completely female external genitalia
iv. Gonadal dysgenesis (streak gonads)
v. Well-developed Müllerian structures: Lack of secretion of anti-Müllerian hormone (AMH) results in the normal development of the uterus, fallopian tubes, and vagina
vi. Absence of testicular development
vii. Absence of Wolffian structures
viii. Absence of other somatic abnormalities
ix. Absence of secondary sexual characteristics
x. Amenorrhea
xi. High risk of developing gonadal tumors
a) Gonadoblastoma
b) Dysgerminoma
b. Primary amenorrhea with normal breast development and absent or scanty pubic and axillary hair (complete androgen insensitivity syndrome): Please see the chapter
c. Ambiguous genitalia at birth or virilization at puberty: Possible causes:
i. Mixed gonadal dysgenesis
ii. 5α-reductase deficiency
iii. 17β-hydroxysteroid dehydrogenase deficiency
iv. Partial androgen insensitivity syndrome
v. Leydig cell hypoplasia
d. Inguinal hernia: Possible causes:
i. Complete androgen insensitivity syndrome
ii. 5α-reductase deficiency
iii. 17β-hydroxysteroid dehydrogenase deficiency
iv. Partial androgen insensitivity syndrome
e. Discordant phenotype to karyotype following prenatal diagnostic testing: can be due to all conditions
f. Testing following the diagnosis of an affected sibling: can be due to all conditions
2. Differential diagnosis
a. Individuals with 46,XY partial gonadal dysgenesis (also called 46,XY mixed gonadal dysgenesis or dysgenetic male pseudohermaphroditism)
i. Majority of patients present in the newborn period for evaluation of ambiguous genitalia
ii. Partial testicular determination. The extent of masculinization of the external genitalia depends on the extent of testicular differentiation.
iii. Dysgenetic gonads
iv. Presence of Müllerian and Wolffian structures
v. Regarded as the clinical spectrum of 46,XY gonadal dysgenesis
b. Individuals with 46,XY embryonic testicular regression syndrome (also called true agonadism or gonadal agenesis)
i. A term used to describe the spectrum of genital anomalies resulting from regression of testis development from 8 to 14 weeks of gestation
ii. Regression of the fetal testes between 8 and 10 weeks of gestation
a) Complete absence of gonads
b) Rudimentary Müllerian and/or Wolffian ductal structures
c) Hypoplastic uterus
d) Female genitalia with/or without ambiguity
iii. Regression of the testes after the critical period of male differentiation (around 12–14 weeks)
a) Anorchia
b) Partial testicular regression resulting in a male phenotype as in anorchia but with small rudimentary testes

Diagnostic Investigations

1. Karyotype analysis
   a. 46,XY in phenotypic females
   b. To exclude 45,X/46,XY and other forms of mosaicism, served to exclude the more common forms of gonadal dysgenesis
2. Molecular analysis for *SRY* gene
   a. Nucleotide substitutions (missense/nonsense)
   b. Deletions
   c. Insertions
3. Ultrasonography/laparotomy
   a. Complete gonadal dysgenesis
      i. Streak gonads
      ii. Presence of Müllerian ducts
      iii. Absence of Wolffian ducts
   b. Partial gonadal dysgenesis
      i. Dysgenetic gonads
      ii. Presence of Müllerian and Wolffian structures
4. Gonadal histology
   a. Streak gonads
      i. Absence of primordial follicles
      ii. Wavy ovarian stroma intermixed with fibrous tissue
   b. Gonadal tumors observed in about 30% of cases
      i. Gonadoblastomas: usually benign
      ii. Dysgerminoma
      iii. Embryonal carcinoma: more life-threatening
5. Biochemical findings
   a. Elevated levels of FSH and LH
   b. Low levels of estradiol
   c. No elevation of androgen levels

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: recurrence risk depending on whether the inheritance is X-linked recessive, male-limited autosomal dominant, or autosomal recessive
   b. Patient's offspring: The patients are nonreproductive.
   c. To rule out the disease in siblings because of the presence of familial aggregation
2. Prenatal diagnosis: demonstration of the sexual discrepancy between fetal karyotype (XY) and ultrasonographic fetal phenotype (Bretelle et al. 2002)
   a. To exclude sample error and placental mosaicism
   b. Detailed fetal ultrasound examination to check for syndromic gender discrepancy such as:
      i. Campomelic dysplasia (skeletal malformation)
      ii. Denys–Drash syndrome
      iii. Smith–Lemli–Opitz syndrome
         a) Microcephaly
         b) Abnormal cholesterol metabolism
      iv. Alfi syndrome
         c) Craniostenosis
         d) Trigonocephaly
         e) Multiple congenital anomalies
   c. Prenatal diagnosis possible by SRY analysis for XY gonadal dysgenesis (SRY-negative XY female and SRY-positive XY female)
      i. FISH using SRY probe on metaphase chromosomes
      ii. Sequencing of entire coding region
3. Management
   a. Removal of gonads to avoid malignancy
   b. Initiate cyclic hormonal therapy with estrogen and progesterone at puberty
   c. Vaginoplasty should be performed in adolescence to prevent the risk of vaginal stenosis
   d. Psychological counseling
      i. Raise as a female
      ii. Information regarding the condition and the karyotype should be provided to the patient and her family
      iii. Increase patient's knowledge about medical and surgical history and karyotype
      iv. Counseling for sexual function
      v. Achievement of pregnancy in some patients following in vitro fertilization with a donor egg

Fig. 1 (**a**–**c**) A patient with 46,XY female with gonadal dysgenesis at 42 years of age. Patient has short stature (4'6"), primary amenorrhea, lack of secondary sex characteristics (absent axillary hair, poor breast development), but normal female external genitalia. Laparotomy revealed absent Wolffian structures and presence of uterus and streak gonads which were excised

XYY Syndrome

In 1961, Sandberg described an XYY man. The incidence is estimated to be approximately 1 in 1,000 live male newborns and more frequent in infertile population (Martin 2008).

Genetics/Basic Defects

1. Caused by an additional Y chromosome in males (Rives et al. 2003)
2. Mechanisms of the extra Y chromosome in 47,XYY males
   a. Paternal nondisjunction at meiosis II after a normal chiasmate meiosis I (84%)
   b. Postzygotic mitotic error or nondisjunction at meiosis II after a nullichiasmate meiosis I (16%)
3. Spermatogenesis
   a. Normal spermatogenesis in majority of XYY males
      i. The supernumerary Y chromosome probably lost at the early stage of spermatogenesis
      ii. A large proportion of primary spermatocytes containing only one Y chromosome
   b. Altered spermatogenesis in a proportion of XYY males: Persistence of the supernumerary Y chromosome through meiotic prophase increases spermatocyte degeneration.
4. A higher incidence of the XYY complement in the institutions for the retarded, the mentally ill, the criminally insane, and the aggressive offender: controversial and biased

Clinical Features

1. Earlier observation of the association between the additional Y chromosome and aggressive behavior: considered to be due to selection bias and has since been challenged (Linden et al. 2002)
2. No consistent physical stigmata or medical disorders
3. Growth and development
   a. Increased growth velocity during earliest childhood
   b. Tall stature
   c. Larger tooth size
   d. At risk for mild speech/language and motor delays and learning disabilities
4. Intelligence
   a. Normal range
   b. IQ: 10–15 points lower than siblings
5. Behavioral profile
   a. Childhood temper tantrums
   b. No increased incidence of aggression
   c. Heterosexual
6. Normal reproduction
7. Normal adult adaptation
8. Low fertility

Diagnostic Investigations

1. Chromosome analysis to detect 47,XYY
2. Psychological and psychiatric evaluations when needed

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_255,
© Springer Science+Business Media, LLC 2012

3. Studies of sperm karyotypes or FISH analysis of sperm: The majority of sperm are chromosomally normal in 47,XYY men (Martin et al. 2001).
4. EEG (Tomiero et al. 2011)
   a. Normal background activity and sleep organization
   b. Particular local spikes and sharp waves localized mostly over the vertex and/or central-temporal regions which increased during sleep

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: Patient generally has chromosomally normal children, despite the high theoretical risk of aneuploidy.
2. Prenatal diagnosis: fetal karyotyping from amniocytes or CVS
3. Management (Bender et al. 1984; Linden et al. 2002)
   a. The extra Y chromosome represents a risk factor for motor and language development, but the environment remains a primary force in shaping child's development.
   b. The increased frequency of prenatal detection of 47,XYY by amniocentesis necessitates the importance of making accurate information about the developmental prognosis of these individuals.
   c. Infancy and toddler: assess developmental milestones
   d. Childhood: assess school performance and provide intervention if needed
   e. Adolescence: no intervention needed
   f. Adulthood annual physical examination
