Preface to the Second Edition

It has been 5 years since the publication of the first edition of this atlas in 2006. Since then, significant progress has been made in the field of genetic diagnosis and counseling. The first edition of the atlas covered 203 chapters which were revised with current literature and addition of many illustrations, mostly in color. Fifty two new chapters have been added to this edition. Selected references have also been added to the text for the sources of the information.

As with the previous edition, a detailed outline of each disorder is provided, describing the genetics, basic defects, clinical features, diagnostic investigations, and genetic counseling, including recurrence risk, prenatal diagnosis, and management. Relevant references are added in the second edition. The cases are supplemented by case history and diagnostic confirmations by imaging, cytogenetic, biochemical, and/or molecular studies.

I am grateful to the following individuals for their contribution and support of this edition: Dr. Susonne Ursin, my genetic colleague and Chief of Perinatal Genetics, for case studies (Joubert syndrome, Mowatt-Wilson syndrome, otopalatodigital syndrome, rigid spine syndrome, Saethre-Chotzen syndrome, Silver-Russell syndrome); Dr. RMS Riel-Romero for megalencephalic leukoencephalopathy with subcortical cysts; Dr. Amal Anga for Duncan syndrome; Drs. Richard McCall, Phillip Gates, and Anne Hollister, Shreveport Shriners Hospital for Children; Dr. Ghali Ghali, Chairman of Oral and Maxillofacial Surgery; and Dr. Renata Pilatova, Pinecrest Development Center, for providing patients for studies and inclusion into this edition; Dr. Leonard Prouty, Ms. Rhonda Lee Young, and Mr. Jozo Ivancic, LSU Cytogenetics Laboratory for part of the karyotypes used in this edition; Mrs. Lynn Martin, Beverely Gildon, and Diane Dunki-Jacobs-Nolten for nursing care; and Ms. Ashli Daigle and Mrs. Barbara McHenry for their excellent clerical and secretarial help. My apologies in the event that I failed to mention others who have contributed to this edition. Without the patience and encouragement of my dear wife, Cheryl, this edition of the atlas would not have been possible. I would like to express my sincere appreciation to Dr. Joseph Bocchini, Chairman of the Department of Pediatrics, for his encouragement and support. I would like to dedicate this edition of the atlas to the Children's Hospital, Louisiana State University Health Sciences Center in Shreveport, for its excellence in pediatric care and education.

As previously, I would welcome comments, corrections, and criticism from readers.

Harold Chen, Shreveport, LA, USA
October 2011

Preface to the First Edition

This book, *Atlas of Genetic Diagnosis and Counseling*, reflects my experience in 38 years of clinical genetics practice. During this time, I have cared for many patients and their families and taught innumerable medical students, residents, and practicing physicians. As an academic physician, I have found that a picture is truly "worth a thousand words," especially in the field of dysmorphology. Over the years, I have compiled photographs of my patients, which are incorporated into this book to illustrate selected genetic disorders, malformations, and malformation syndromes. A detailed outline of each disorder is provided, describing the genetics, basic defects, clinical features, diagnostic investigations, and genetic counseling, including recurrence risk, prenatal diagnosis, and management. Color photographs are used to illustrate the clinical features of patients of different ages and ethnicities. Photographs of prenatal ultrasounds, imaging, cytogenetics, and postmortem findings are included to help illustrate diagnostic strategies. The cases are supplemented by case history and diagnostic confirmation by cytogenetic, biochemical, and molecular studies, if available. An extensive literature review was done to ensure up-to-date information and to provide a relevant bibliography for each disorder.

This book was written in the hope that it will help physicians improve their recognition and understanding of these conditions and their care of affected individuals and their families. It is also my intention to bring the basic science and clinical medicine together for the readers. *Atlas of Genetic Diagnosis and Counseling* is designed for physicians involved in the evaluation and counseling of patients with genetic diseases, malformations, and malformation syndromes, including medical geneticists, genetic counselors, pediatricians, neonatologists, developmental pediatricians, perinatologists, obstetricians, neurologists, pathologists, and any physicians and health care professionals caring for handicapped children such as craniofacial surgeons, plastic surgeons, otolaryngologists, and orthopedics.

I am grateful to many individuals for their invaluable help in reading and providing cases for illustration. The acknowledgments are provided on a separate page. Without the patience and encouragement of my dear wife, Cheryl, this atlas would not have been possible. I would like to dedicate this book to the Children's Hospital, Louisiana State University Health Sciences Center in Shreveport, for its continued excellence in pediatric care and education.

I would welcome comments, corrections, and criticism from readers.

Harold Chen, M.D., FAAP, FACMG

Biography

Harold Chen, M.D., M.S., FAAP, FACMG

Dr. Chen was born in I-Lan, Taiwan, and was a graduate from the National Taiwan University School of Medicine (M.D. degree) in Taipei, Taiwan. He received M.S. degree in Human Genetics from the University of Michigan Graduate School in Ann Arbor, Michigan. He finished pediatric residency and fellowship training from Wayne State University School of Medicine in Detroit, Michigan. He had been faculty at Wayne State University (Detroit), Wright State University (Dayton, Ohio), and University of South Alabama (Mobile, Alabama). Currently, he is professor of Pediatrics, Obstetrics and Gynecology, and Pathology at the Louisiana State University Health Sciences Center and Chief of Genetic Laboratory Services in Shreveport, Louisiana. Dr. Chen is board-certified in American Board of Pediatrics and American Board of Medical Genetics in Clinical Genetics and Clinical Cytogenetics.

Table of Contents

Acardia 1

Achondrogenesis 11

Achondroplasia 21

Adams–Oliver Syndrome 35

Agnathia 41

Aicardi Syndrome 49

Alagille Syndrome 55

Albinism 61

Alpha-Thalassemia X-linked Mental Retardation Syndrome 71

Ambiguous Genitalia 77

Amniotic Deformity, Adhesions, Mutilations (ADAM) Complex 87

Androgen Insensitivity Syndrome 99

Angelman Syndrome 107

Apert Syndrome 119

Aplasia Cutis Congenita 135

Arthrogryposis Multiplex Congenita 141

Asphyxiating Thoracic Dystrophy 157

Ataxia-Telangiectasia 167

Atelosteogenesis 175

Autism 183

Bannayan–Riley–Ruvalcaba Syndrome 197

Beckwith–Wiedemann Syndrome 203

Acardia

Acardia is a bizarre fetal malformation occurring only in twins or triplets. It is also called acardius acephalus, acardiac twinning, or twin reversed arterial perfusion (TRAP) syndrome or sequence. This condition is very rare and occurs in 1 in 34,600 births or 1 in 100 monozygotic twins (Gillim and Hendricks 1953) and 1 in 30 monozygotic triplets (Van Allen et al. 1983; Napolitani and Schreiber 1960; Moore et al. 1990; Sanjaghsaz et al. 1998; Blenc et al. 1999), and even in quintuplets. Almost all cases reported are monozygotic twins. However, there are reports of dichorionic monozygotic twin gestations with TRAP sequence (French et al. 1998; Gewolb et al. 1983).

Arcadia requires the presence of arterial–arterial anastomosis in the placenta, with retrograde perfusion of poorly oxygenated blood from the normal twin (also called donor or pump twin) to the acardiac twin, venous–venous anastomosis carrying blood back from the acardiac to the donor twin, and circulatory failure of the acardiac twin (Steffensen et al. 2008).

Synonyms and Related Disorders

Acardius acephalus; Acardiac twinning; Twin reversed arterial perfusion sequence

Genetics/Basic Defects

1. Etiology
   a. Rare complication of monochorionic twinning, presumably resulting from the fused placentation of monochorionic twins.
   b. Represents manifestation of abnormal embryonic and fetal blood flow rather than a primary defect of cardiac formation.
   c. Heterogeneous chromosomal abnormalities are present in nearly 50% of the cases, although chromosome errors are not underlying pathogenesis of the acardiac anomaly. Rather, the placental vascular anastomoses are the principal pathogenetic event (Benirschke and des Roches Harper 1977).
      i. 45,XX,t(4;21)del(4p)
      ii. 46,X,i(Xp)
      iii. 47,XX,+2 (Blaicher et al. 2000)
      iv. 47,XX,+11
      v. 47,XY,+G
      vi. 47,XXY
      vii. 69,XXX
      viii. 70,XXX,+15
      ix. 94,XXXXYY
2. Pathogenesis: reversal of fetal arterial perfusion
   a. First hypothesis
      i. A primary defect in the development of the heart
      ii. Survival of the acardiac twin as a result of the compensatory anastomoses that develop
   b. Second hypothesis
      i. The acardiac twin begins life as a normal fetus
      ii. The reversal of the arterial blood flow results in atrophy of the heart and the tributary organs
3. Classification of TRAP sequence (syndrome)
   a. Classification according to the status of the heart of the acardiac twin
      i. Hemiacardius (with incompletely formed heart)
      ii. Holoacardius (with completely absent heart)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_1,
© Springer Science+Business Media, LLC 2012

b. Morphologic classification of the acardiac twin (Gillim and Hendricks 1953; Napolitani and Schreiber 1960; Nicolaidis et al. 1990; Alderman 1973; Thelmo et al. 2007; Obladen 2010)
   i. Acardius amorphous
      a) The least differentiated form
      b) Little more than a lump of connective tissue, covered by edematous skin
      c) No resemblance to classical human form
      d) Anatomical features: presence of only bones, cartilage, muscles, fat, blood vessels, and stroma
   ii. Acardius myelacephalus
      a) Resembles the amorphous type except presence of rudimentary limb formation
      b) Presence of rudimentary nerve tissue in addition to anatomical features in acardius amorphous
   iii. Acardius acephalus
      a) The most common type
      b) Missing head, part of the thorax, and upper extremities
      c) May have additional malformations in the remaining organs
   iv. Acardius anceps
      a) The least atrophied form
      b) Presence of a partially developed fetal head, a thorax, abdominal organs, and extremities
      c) Lacks even a rudimentary heart
   v. Acardius acormus
      a) The rarest type
      b) Presence of a rudimentary head only
      c) Lacks thorax
      d) The umbilical cord inserts in the head and connects directly to the placenta

4. The acardia
   a. Characterized by absence of a normally functioning heart
   b. Acardia as a recipient of twin transfusion sequence
      i. Reversal of blood flow in all various types of acardia, hence the term "twin reversed arterial perfusion (TRAP) sequence" has been proposed.
      ii. Receiving the deoxygenated blood from an umbilical artery of its co-twin through the single umbilical artery of the acardiac twin and returns to its umbilical vein. Therefore, the circulation is entirely opposite to the normal direction.
   c. Usually the severe reduction anomalies occur in the upper part of the body
   d. May develop various structural malformations
      i. Growth retardation
      ii. Anencephaly
      iii. Holoprosencephaly
      iv. Facial defects
      v. Absent or malformed limbs
      vi. Gastrointestinal atresias
      vii. Other abnormalities of abdominal organs
5. The co-twin
   a. Also known as the "pump twin or donor twin."
   b. The donor "pump" twin perfuses itself and its recipient acardiac twin through abnormal arterial anastomosis in the fused placenta.
   c. Increased cardiac workload often leading to cardiac failure and causing further poor perfusion and oxygenation of the acardiac co-twin.
   d. May develop various malformations (about 10%).

Clinical Features

1. Perinatal problems associated with acardiac twinning
   a. Pump-twin congestive heart failure
   b. In utero fetal death of the pump fetus
   c. Maternal polyhydramnios
   d. Premature rupture of membrane
   e. Preterm delivery
   f. Spontaneous abortions
   g. Soft tissue dystocia
   h. Uterine rupture
   i. Postpartum hemorrhage
   j. Increased rate of cesarean section, up to 50%
2. Majority of acardiac twins and their normal twin counterparts are females
3. Nonviable
4. Gross features
   a. Severe reduction anomalies, particularly of the upper body
   b. Characteristic subcutaneous edema
   c. Internal organs: invariably missing

   d. Absent or rudimentary cardiac development: the key diagnostic feature
      i. Pseudoacardia (rudimentary heart tissue)
      ii. Holoacardia (completely lacking a heart)
5. Growth abnormality
6. Cranial vault
   a. Absent
   b. Partial
   c. Intact
7. Brain
   a. Absent
   b. Necrotic
   c. Open cranial vault
   d. Holoprosencephaly
8. Facial features
   a. Absent facial features
   b. Rudimentary facial features
   c. Present with defects
   d. Anophthalmia/microphthalmia
   e. Cleft lip/palate
9. Upper limbs
   a. Absent
   b. Rudimentary
   c. Radial aplasia
   d. Syndactyly/oligodactyly
10. Lower limbs
   a. Absent
   b. Rudimentary/reduced
   c. Syndactyly/oligodactyly
   d. Talipes equinovarus
11. Thorax
   a. Absent
   b. Reduced
   c. Diaphragmatic defect
12. Lungs
   a. Absent
   b. Necrotic or rudimentary
   c. Single midline lobe
13. Cardiac
   a. Absent heart tissue
   b. Unfolded heart tube
   c. Folded heart with common chamber
14. Gastrointestinal
   a. Esophageal atresia
   b. Short intestine
   c. Interrupted intestine
   d. Omphalocele
   e. Incomplete rotation of the gut
   f. Imperforated anus
   g. Ascites
15. Liver
   a. Absent
   b. Reduced
16. Kidney
   a. Absent (bilateral)
   b. Hypoplastic and/or lobulated
17. Other viscera
   a. Absent gallbladder
   b. Absent spleen
   c. Absent to reduced pancreas
   d. Absent adrenal
   e. Absent to hypoplastic gonads
   f. Exstrophy of the cloaca
   g. Skin with myxedematous thickening
18. Umbilical cord vessels
   a. Two vessels
   b. Three vessels
19. Severe obstetrical complications
   a. Maternal polyhydramnios
   b. Preterm labor
   c. Cord accidents
   d. Dystocia
   e. Uterine rupture
20. Severe neonatal complications
   a. Hydrops
   b. Intrauterine demise
   c. Prematurity
   d. Heart failure
   e. Anemia
   f. Twin-to-twin transfusion syndrome
21. Outcome for the normal sib in an acardiac twin pregnancy (Healey 1994).
   a. Unsatisfactory
      i. Adapting to the increasing circulatory load, resulting in the following situations:
         a) Intrauterine growth retardation
         b) Hydrops
         c) Ascites
         d) Pleural effusion
         e) Hypertrophy of the right ventricle
         f) Hepatosplenomegaly
         g) Severe heart failure resulting in pericardial effusion and/or tricuspid insufficiency
      ii. Stillbirth

iii. Prematurity
iv. Neonatal death

b. Mortality for the normal twin reported as high as 50% without intervention (Aggarwal et al. 2002)

Diagnostic Investigations

1. Radiography
   a. Absent or rudimentary skull
   b. Absent or rudimentary thorax
   c. Absent or rudimentary heart
   d. Vertebral anomalies
   e. Rib anomalies
   f. Limb defects, especially upper limbs
2. Pathology
   a. Microcephaly
   b. Severely rudimentary brain
   c. Developmental arrest of brain at the prosencephalic stage (holoprosencephaly)
   d. Hypoxic damage to the holospheric brain mantle with cystic change (hydranencephaly)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: overall recurrence risk of about 1 in 10,000 (The recurrence risk is for monoamniotic twinning (1% for couples who have had one set of monozygotic twins) times the frequency of the occurrence of TRAP sequence with near-term survival (about 1% of monozygotic twin sets))
   b. Patient's offspring: not applicable (a lethal condition)
2. Prenatal ultrasonography (Sherer et al. 1989; Stiller et al. 1989; Langlotz et al. 1991; Donnenfeld et al. 1991; Shalev et al. 1992; Zucchini et al. 1993; Coulam 1996; Schwarzler et al. 1999; Bonilla-Musoles et al. 2001)
   a. Monochorionic placenta with a single umbilical artery in two-thirds of cases
   b. Acardiac fetus
      i. Unrecognizable head or upper trunk.
      ii. Without a recognizable heart or a partially formed heart.
      iii. A variety of other malformations.
      iv. Reversal of blood flow in the umbilical artery with flow going from the placenta toward the acardiac fetus (reversed arterial perfusion). Such a reversal of the blood flow in the recipient twin can be demonstrated in utero by transvaginal Doppler ultrasound as early as 12 weeks of gestation.
      v. Early diagnosis by transvaginal sonography on the following signs:
         a) Monozygotic twin gestation (absence of the lambda sign)
         b) Biometric discordance between the twins
         c) Diffuse subcutaneous edema or morphologic anomalies of one of the twins or both
         d) Detection of reversed umbilical cord flow; cardiac activity likely to disappear as the pregnancy progresses
         e) Absence of cardiac activity, although hemicardia or pseudocardia may be present
   c. The donor fetus
      i. Hydrops
      ii. Cardiac failure (cardiomegaly, pericardial effusion, tricuspid regurgitation)
3. Amniocentesis to diagnose associated chromosome abnormalities (about 10% of pump twins)
4. Management of pregnancies complicated by an acardiac fetus (Donnenfeld et al. 1991; Hanafy and Peterson 1997; Søggard et al. 1999)
   a. Conservative treatment
      i. Monitor pregnancy by serial ultrasonography
      ii. Conservative approach as long as there is no evidence of cardiac circulatory decompensation in the donor twin
   b. Termination of pregnancies
   c. Treatment and prevention of preterm labor by tocolytics
      i. Magnesium sulfate
      ii. Beta sympathomimetics
      iii. Indomethacin
   d. Treatment of pump fetus heart failure involving maternal digitalization
   e. Treatment of polyhydramnios by therapeutic repeated amniocentesis
   f. Selective termination of the acardiac twin
      i. To occlude the umbilical artery of the acardiac twin in order to stop umbilical flow through the anastomosis

a) Intrafunicular injection and mechanical occlusion of the umbilical artery
b) Embolization by steel or platinum coil, alcohol-soaked suture material, or ethanol
c) Hysterotomy and delivery of acardiac twin
d) Ligation of the umbilical cord
e) Hysterotomy and umbilical cord ligation

ii. Fetal surgery: best available treatment for acardiac twinning (Arias et al. 1998)
a) Endoscopic laser coagulation of the umbilical vessels at or before 24 weeks of gestation
b) Endoscopic- or sonographic-guided umbilical cord ligation at 24 weeks of gestation

iii. Summary of acardiac twins treated with invasive procedures reported in the literature
a) Mortality of the pump twin (13.6%)
b) Preterm delivery (50.3%)
c) Delivery before 30 weeks gestation (27.2%)
d) Perinatal mortality if untreated is at least 50%

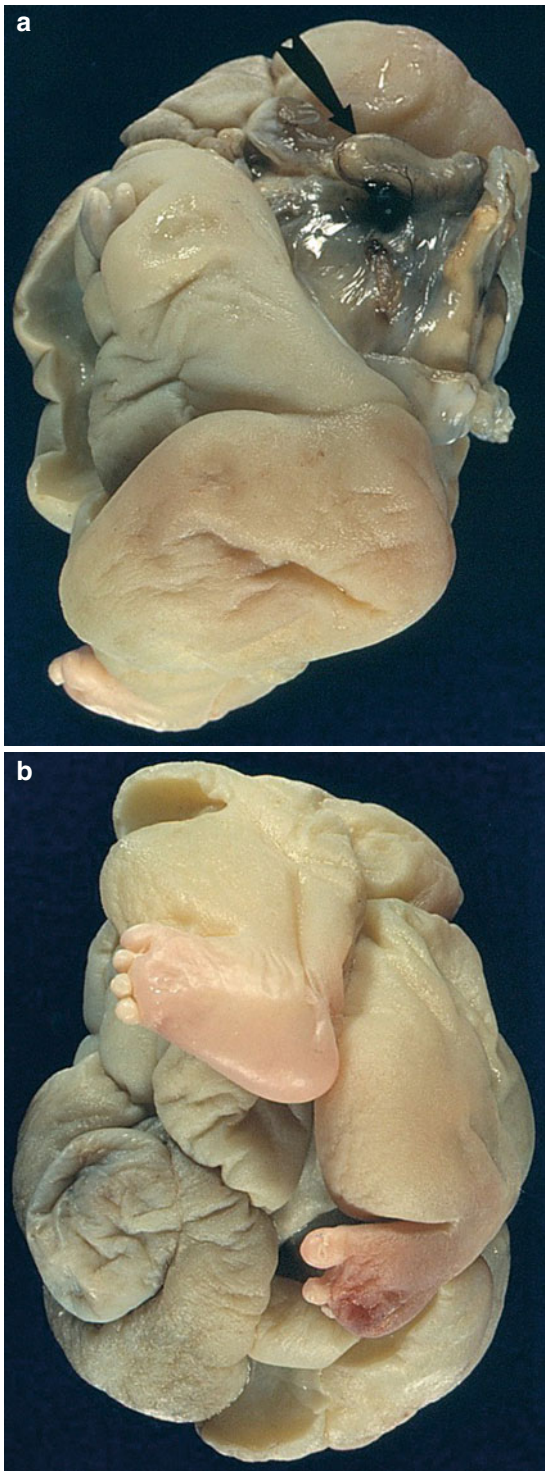

Fig. 1 (**a, b**) Ventral view of an acardiac acephalus fetus (*upper photo*) shows a large abdominal defect, gastroschisis (*arrow*), through which small rudiments of gastrointestinal tract are seen. Dorsal view (*lower photo*) shows a very underdeveloped cephalic end and relatively well-developed lower limbs. The co-twin had major malformations consisting of a large omphalocele, ectopia cordis, and absent pericardium, incompatible with life (Chen et al. 1983)

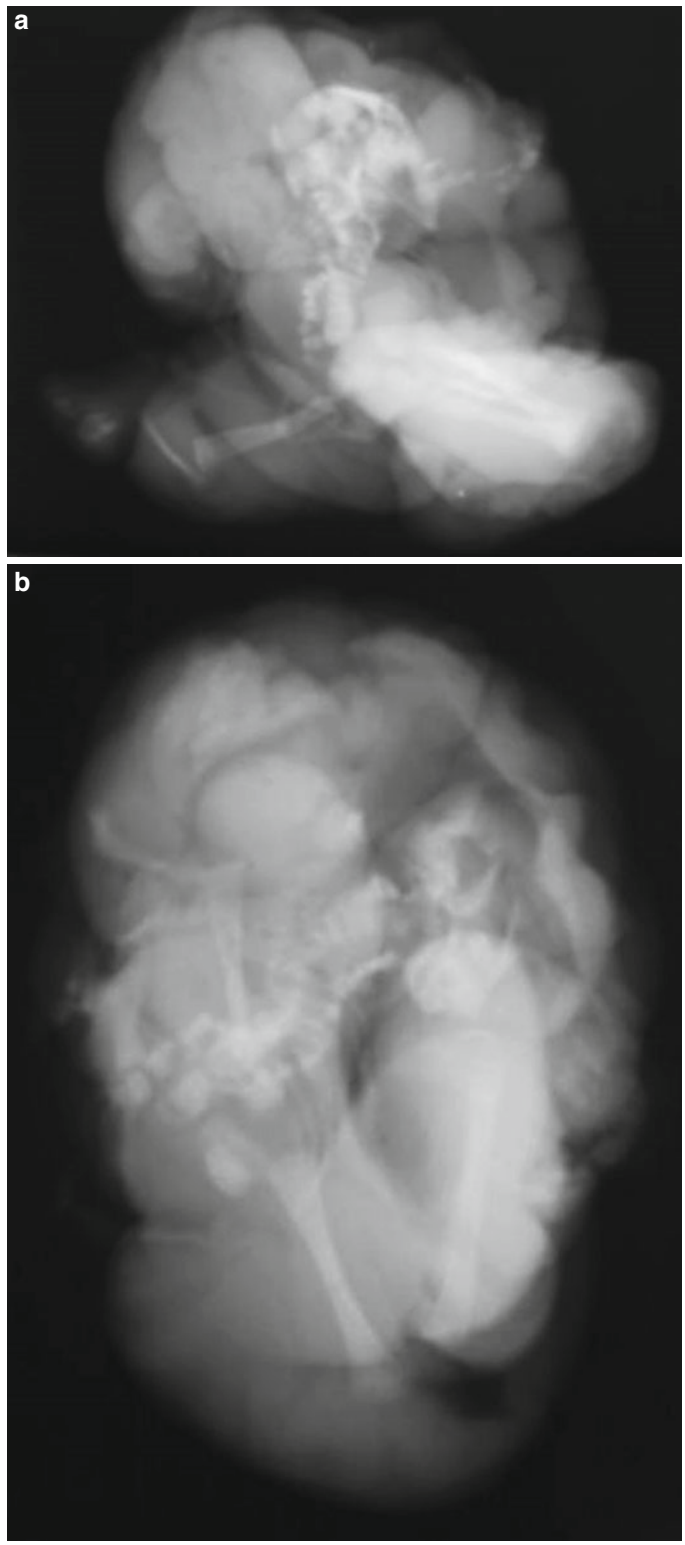

Fig. 2 (**a, b**) Radiographs of the above acardiac fetus showing a missing head, cervical vertebrae and part of upper thoracic vertebrae, rudimental lower ribs, malformed lower thoracic and lumbar vertebrae, and relatively well-formed lower limbs

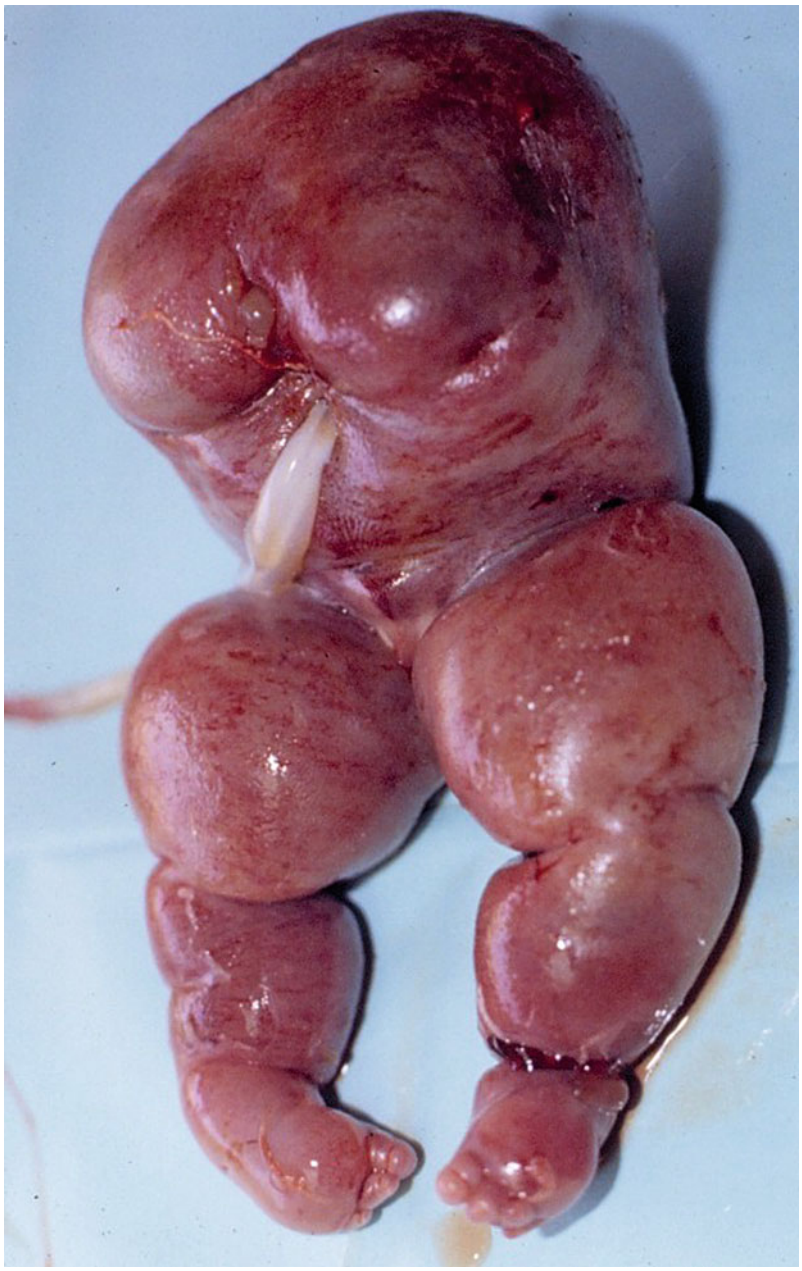

Fig. 3 The head and part of the thorax of this acardiac fetus are completely missing with relatively well-formed lower limbs

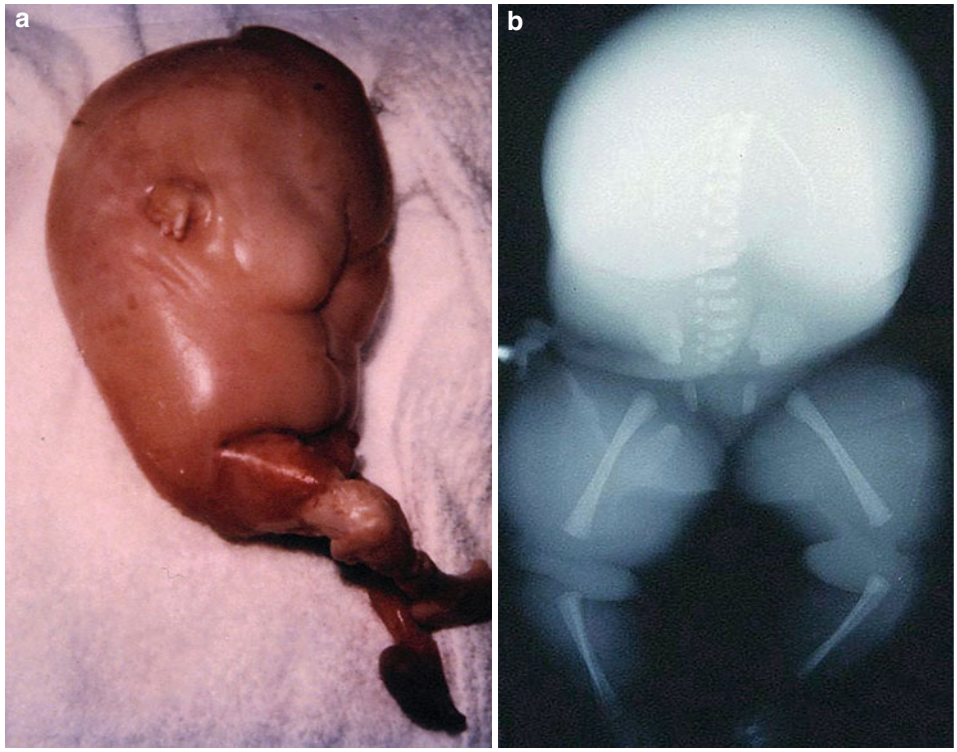

Fig. 4 (**a, b**) Another acardiac fetus with a missing head and part of the upper thorax. Radiograph shows missing head, cervical and part of thoracic vertebrae, and ribs. Pelvis and lower limbs are well formed

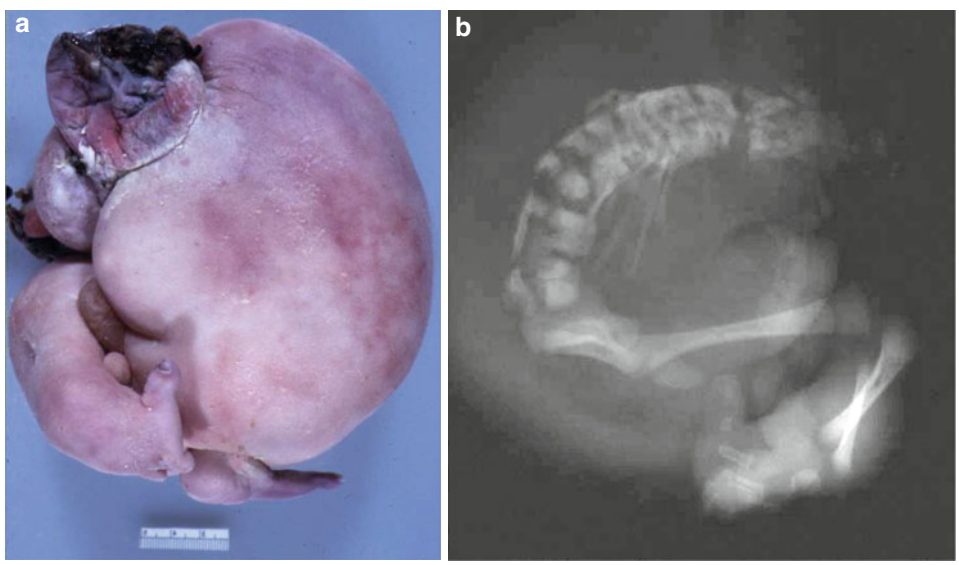

Fig. 5 (**a, b**) Acardius (second twin, 36 weeks gestation) showing spherical body with a small amorphous mass of leptomeningeal and glial tissue at the cephalic end. There were one deformed lower extremity and a small arm appendage. Small intestinal loops, nodules of adrenal glands, and testicles were present in the body. There was no heart or lungs. The placenta was nonoamniotic monochorionic with velamentous insertion of the umbilical cord. The other identical twin was free of birth defects. Radiograph of acardius twin shows a short segment of the spine, a femur, a tibia, and a fibula

Achondrogenesis

Marco Fraccaro first described achondrogenesis in 1952 (Fraccaro 1952). He used the term to describe a stillborn female with severe micromelia and marked histological cartilage changes. The term was later used to characterize the most severe forms of chondrodysplasia in humans, which were invariably lethal before or shortly after birth. By the 1970s, researchers concluded that achondrogenesis was a heterogeneous group of chondrodysplasias lethal to neonates; achondrogenesis type I (Fraccaro-Houston-Harris type) and type II (Langer-Saldino type) were distinguished on the basis of radiological and histological criteria.

Achondrogenesis type I was further subdivided, on the basis of convincing histological criteria, into type IA, which has apparently normal cartilage matrix but inclusions in chondrocytes, and type IB, which has an abnormal cartilage matrix. Classification of type IB as a separate group has been confirmed recently by the discovery of its association with mutations in the diastrophic dysplasia sulfate transporter (*DTDST*) gene, making it allelic with diastrophic dysplasia.

Synonyms and Related Disorders

Achondrogenesis type IA (Houston-Harris type); Achondrogenesis type IB (Fraccaro type); Achondrogenesis type II (Langer-Saldino type)

Genetics/Basic Defects

1. Type IA: an autosomal recessive disorder: caused by mutation in the thyroid hormone recepter interacter 11 (TRIP 11) gene which is mapped on 14q32.12) (Smits et al. 2010)
2. Type IB
   a. An autosomal recessive disorder
   b. Resulting from mutations of the *DTDST* gene, which encodes the SLC26A2 sulfate transporter, is located at 5q32–q33 (Superti-Furga et al. 1996)
3. Type II
   a. Autosomal dominant type II collagenopathy
   b. Resulting from mutations in the *COL2A1* gene, which is located at 12q13.1–q13.3
   c. Report of a familial case of achondrogenesis type II caused by a dominant *COL2A1* mutation and "patchy" expression in the mosaic father (Forzano et al. 2007) suggests that somatic mosaicism can lead to a milder but generalized clinical phenotype.
4. Mutations within the *COL2A1* gene also cause the following skeletal dysplasias (Forzano et al. 2007):
   a. Hypochondrogenesis
   b. Spondyloepiphyseal dysplasia (SED) congenita
   c. SED Namaqualand type
   d. Mild SED with precocious osteoarthritis
   e. Spondyloepimetaphyseal dysplasia, Strudwick type
   f. Kniest dysplasia
   g. Multiple epiphyseal dysplasia with myopia and conductive deafness
   h. Spondyloperipheral dysplasia
   i. Stickler dysplasia type I

Clinical Features

1. Prenatal/perinatal history
   a. Polyhydramnios
   b. Hydrops

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_2,
© Springer Science+Business Media, LLC 2012

c. Breech presentation
d. Perinatal death
2. Achondrogenesis type I
   a. Growth
      i. Lethal neonatal dwarfism
      ii. Mean birth weight of 1,200 g
   b. Craniofacial features
      i. Disproportionately large head
      ii. Soft skull
      iii. Sloping forehead
      iv. Convex facial plane
      v. Flat nasal bridge, occasionally associated with a deep horizontal groove
      vi. Small nose, often with anteverted nostrils
      vii. Long philtrum
      viii. Retrognathia
      ix. Increased distance between lower lip and lower edge of chin
      x. Double chin appearance
   c. Extremely short neck
   d. Thorax
      i. Short and barrel-shaped thorax
      ii. Lung hypoplasia
   e. Heart
      i. Patent ductus arteriosus
      ii. Atrial septal defect
      iii. Ventricular septal defect
   f. Protuberant abdomen
   g. Limbs
      i. Extremely short (micromelia), shorter than type II
      ii. Flipper-like appendages
3. Achondrogenesis type II (Langer-Saldino type)
   a. Growth
      i. Lethal neonatal dwarfism
      ii. Mean birth weight of 2,100 g
   b. Craniofacial features
      i. Disproportionately large head
      ii. Large and prominent forehead
      iii. Midfacial hypoplasia
         a) Flat facial plane
         b) Flat nasal bridge
         c) Small nose with severely anteverted nostrils
      iv. Normal philtrum
      v. Micrognathia
      vi. Cleft palate
   c. Extremely short neck
   d. Thorax
      i. Short and flared thorax
      ii. Bell-shaped cage
      iii. Lung hypoplasia
   e. Protuberant abdomen
   f. Extremely short limbs (micromelia)

Diagnostic Investigations

1. Radiological features
   a. Variable features
   b. No single obligatory feature
   c. Distinction between type IA and type IB on radiographs not always possible
   d. Degree of ossification: age dependent, and caution is needed when comparing radiographs at different gestational ages
   e. Achondrogenesis type I
      i. Skull: Varying degree of deficient cranial ossification consisting of small islands of bone in membranous calvaria
      ii. Thorax and ribs
         a) Short and barrel-shaped thorax
         b) Thin ribs with marked expansion at costochondral junction, frequently with multiple fractures
      iii. Spine and pelvis
         a) Poorly ossified spine, ischium, and pubis
         b) Poorly ossified iliac bones with short medial margins
      iv. Limbs and tubular bones
         a) Extreme micromelia, with limbs much shorter than in type II
         b) Prominent spike-like metaphyseal spurs
         c) Femur and tibia frequently presenting as short bone segments
      v. Subtype IA (Houston-Harris type)
         a) Poorly ossified skull
         b) Thin ribs with multiple fractures
         c) Unossified vertebral pedicles
         d) Arched ilium
         e) Hypoplastic but ossified ischium
         f) Wedged femur with metaphyseal spikes
         g) Short tibia and fibula with metaphyseal flare

vi. Subtype IB (Fraccaro type)
  a) Adequately ossified skull
  b) Absence of rib fractures
  c) Total lack of ossification or only rudimentary calcification of the center of the vertebral bodies
  d) Ossified vertebral pedicles
  e) Iliac bones with ossification only in their upper part, giving a crescent-shaped, "paraglider-like" appearance on X-ray
  f) Unossified ischium
  g) Shortened tubular bones without recognized axis
  h) Metaphyseal spurring giving the appearance of a "thorn apple" or "acanthocyte" (a descriptive term in hematology)
  i) Trapezoid femur
  j) Stellate tibia
  k) Unossified fibula
  l) Poorly ossified phalanges

f. Achondrogenesis type II
  i. Skull
    a) Normal cranial ossification
    b) Relatively large calvaria
  ii. Thorax and ribs
    a) Short and flared thorax
    b) Bell-shaped cage
    c) Shorter ribs without fractures
  iii. Spine and pelvis: relatively well-ossified iliac bones with long, crescent-shaped medial and inferior margins
  iv. Limbs and tubular bones
    a) Short, broad bones, usually with some diaphyseal constriction and flared, cupped metaphyseal ends
    b) Metaphyseal spurs, usually smaller than type I

2. Histologic features
  a. Achondrogenesis type IA
    i. Normal cartilage matrix
    ii. Absent collagen rings around the chondrocytes
    iii. Vacuolated chondrocytes
    iv. Presence of intrachondrocytic inclusion bodies (periodic acid-Schiff [PAS] stain positive, diastase resistant)
    v. Extraskeletal cartilage involvement
    vi. Enlarged lacunas
    vii. Woven bone
  b. Achondrogenesis type IB
    i. Abnormal cartilage matrix: presence of "demasked" coarsened collagen fibers, particularly dense around the chondrocytes, forming collagen rings
    ii. Abnormal staining properties of cartilage
      a) Reduced staining with cationic dyes, such as toluidine blue or Alcian blue, probably because of a deficiency in sulfated proteoglycans
      b) This distinguishes type IB from type IA, in which the matrix is close to normal and inclusions can be seen in chondrocytes, and from achondrogenesis type II, in which cationic dyes give a normal staining pattern.
  c. Achondrogenesis type II
    i. Cartilage
      a) Slightly larger than normal
      b) Grossly distorted (lobulated and mushroomed)
    ii. Markedly deficient cartilaginous matrix
    iii. Severe disturbance in endochondral ossification
    iv. Hypercellular and hypervascular reserve cartilage with large, primitive mesenchymal (ballooned) chondrocytes with abundant clear cytoplasm (vacuoles) ("Swiss cheese-like")
    v. Overgrowth of membranous bones resulting in cupping of the epiphyseal cartilages
    vi. Decreased amount and altered structure of proteoglycans
    vii. Relatively lower content of chondroitin 4-sulfate
    viii. Lower molecular weight and decreased total chondroitin sulfation
    ix. Absence of type II collagen
    x. Increased amounts of type I and type III collagen

3. Biochemical testing
  a. Lack of sulfate incorporation: cumbersome and not used for diagnostic purposes
  b. Sulfate incorporation assay in cultured skin fibroblasts or chondrocytes: recommended in

the rare instances in which the diagnosis of achondrogenesis type IB is strongly suspected but molecular genetic testing fails to detect *SLC26A2* (*DTDST*) mutations

4. Molecular genetic studies
   a. Mutation analysis of the *DTDST* gene, reported in:
      i. Achondrogenesis type IB (the most severe form)
      ii. Atelosteogenesis type II (an intermediate form)
      iii. Diastophic dysplasia (the mildest form)
      iv. Recessive multiple epiphyseal dysplasia
   b. Achondrogenesis type IB
      i. Mutation analysis: testing of the following four most common *SLC26A2* (*DTDST*) gene mutations (mutation detection rate about 60%)
         a) R279W
         b) IVS1 + 2 > C ("Finnish" mutation)
         c) delV340
         d) R178X
      ii. Sequence analysis of the *SLC26A2* (*DTDST*) coding region (mutation detection rate over 90%)
         a) Private mutations
         b) Common mutations
   c. Achondrogenesis type II: mutation analysis of the *COL2A1* gene

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Achondrogenesis type IA and type IB (autosomal recessive disorders)
         a) Recurrence risk: 25%
         b) Unaffected sibs of a proband: two third chance of being heterozygotes
      ii. Achondrogenesis type II
         a) Usually caused by a new dominant mutation, in which case recurrence risk is not significantly increased
         b) Asymptomatic carrier parent (germline mutation for a dominant mutation) may be present in the families of affected patients, in which case recurrence risk can be up to 50%.
   b. Patient's offspring: lethal entities not surviving to reproduction
2. Prenatal diagnosis
   a. Ultrasonography
      i. Polyhydramnios
      ii. Fetal hydrops
      iii. Disproportionally big head
      iv. Nuchal edema
      v. Cystic hygroma
      vi. A narrow thorax
      vii. Short limbs
      viii. Poor ossification of vertebral bodies and limb tubular bones (leading to difficulties in determining their length)
      ix. Suspect achondrogenesis type I
         a) An extremely echo-poor appearance of the skeleton
         b) A poorly mineralized skull
         c) Short limbs
         d) Rib fractures
   b. Molecular genetic studies
      i. Prenatal diagnosis of achondrogenesis type IB and type II by mutation analysis of chorionic villus DNA or amniocyte DNA in the first or second trimester
      ii. Achondrogenesis type IB
         a) Characterize both alleles of *DTDST* beforehand
         b) Identify the source parent of each allele
         c) Theoretically, analysis of sulfate incorporation in chorionic villi might be used for prenatal diagnosis, but experience is lacking.
      iii. Achondrogenesis type II
         a) The affected fetus usually with a new dominant mutation of the *COL2A1* gene
         b) Possible presence of asymptomatic carriers in families of an affected patient
         c) Prenatal diagnosis possible if the mutation has been characterized in the affected family
3. Management
   a. Supportive care
   b. No treatment available for the underlying lethal disorder

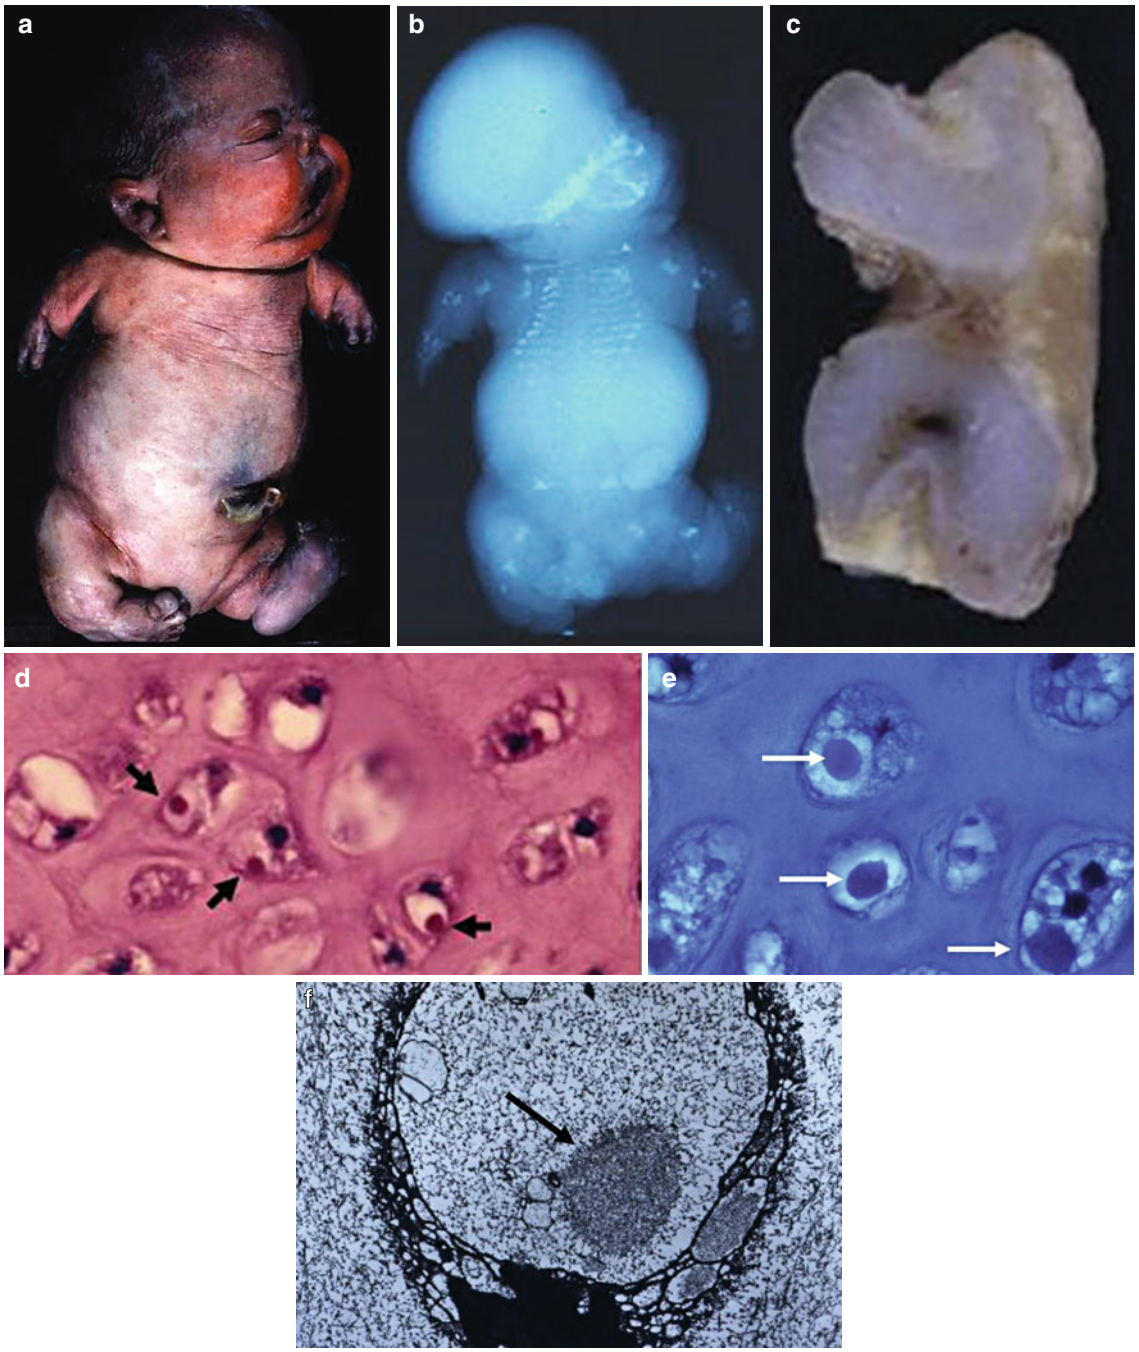

Fig. 1 (**a**–**f**) A neonate with achondrogenesis type I showing large head, short trunk, and extreme micromelia. Radiograph shows unossified calvarium, vertebral bodies, and some pelvic bones. The remaining bones are extremely small. There are multiple rib fractures. The sagittal section of the femora and the humeri are similar. An extremely small ossified shaft is capped by a relatively large epiphyseal cartilage at both ends. Photomicrographs of resting cartilage with high magnification show many chondrocytes that contain large cytoplasmic inclusions which are within clear vacuoles (Diastase PAS stain). Electron micrograph shows inclusion as a globular mass of electron dense material. It is within a distended cistern of rough endoplasmic reticulum

Fig. 2 (**a**–**e**) Achondrogenesis type II. As in type I, this neonate shows large head, short trunk, and micromelia (Potter's pathology of Fetus and Infant, by Gilbert-Barness). Sagittal section of the femur shows much better ossification of the shaft than type I. The cartilage lacks glistering appearance due to cartilage matrix deficiency. Photomicrograph of the entire cartilage shows severe deficiency of cartilage matrix. The cartilage canals are large, fibrotic, and stellate in shape. Physeal growth zone is severely retarded

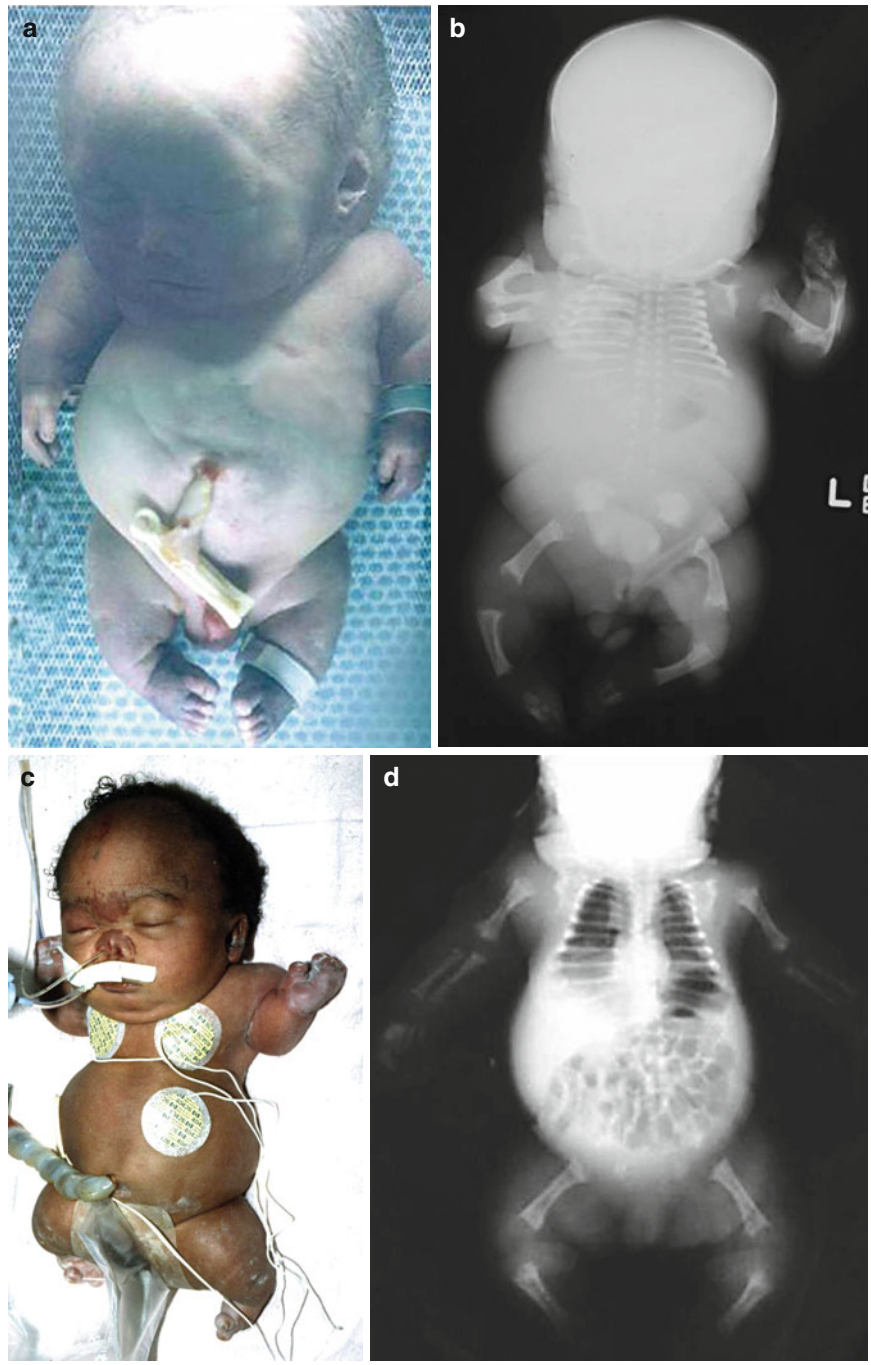

Fig. 3 (**a**–**d**) Two infants with achondrogenesis type II showing milder spectrum of manifestations, bordering the type II and spondyloepiphyseal congenita

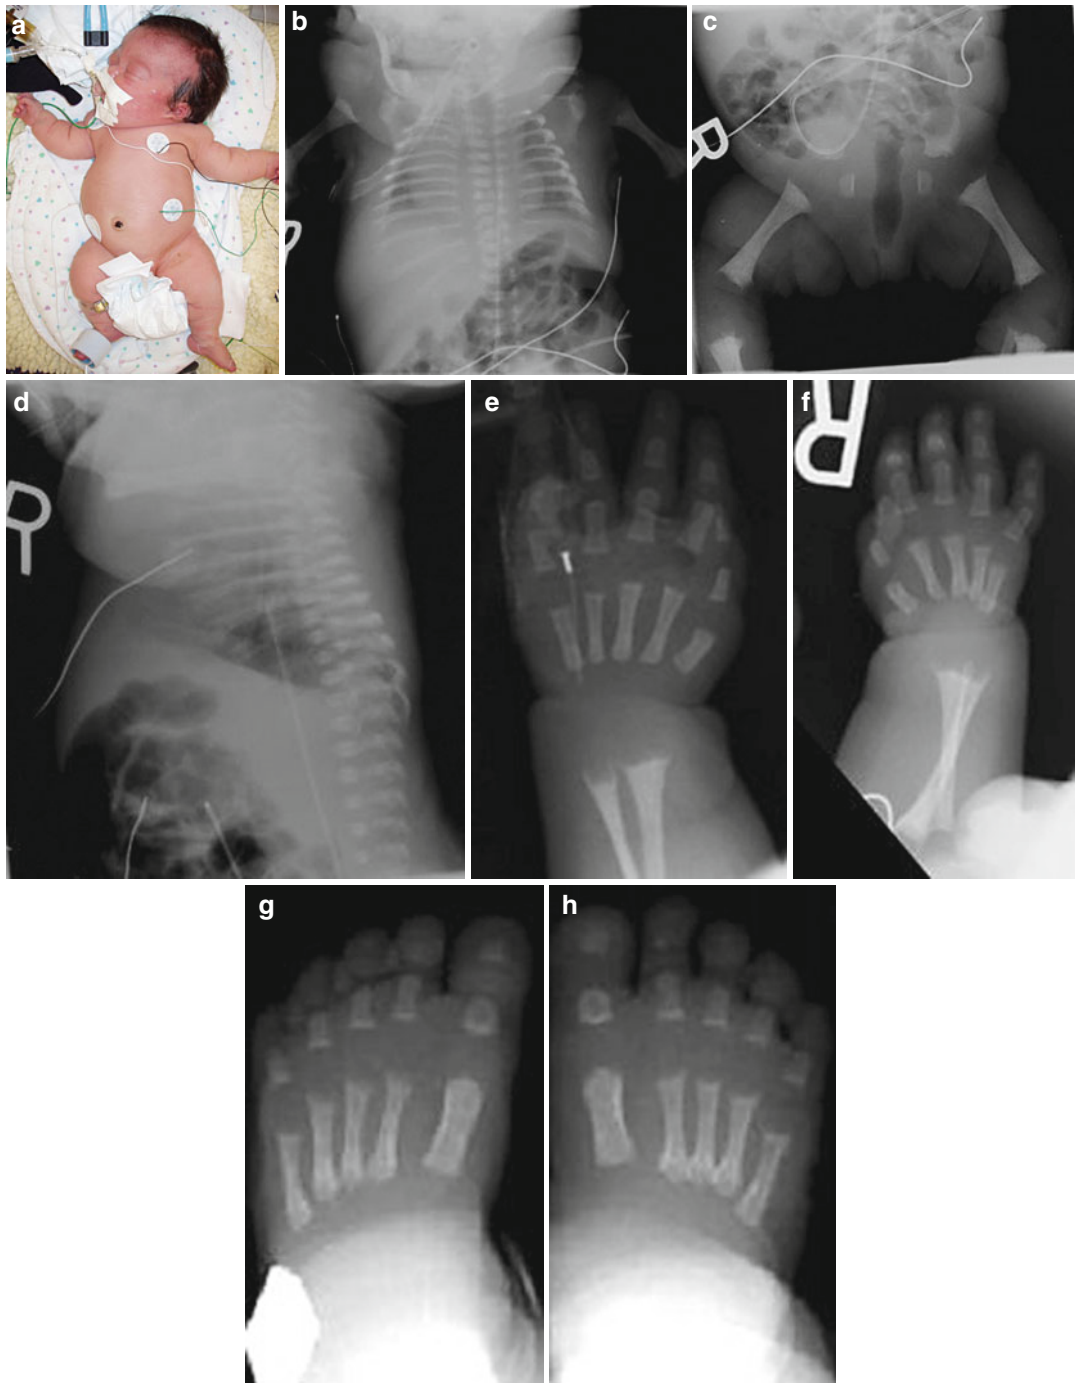

Fig. 4 (**a**–**h**) A newborn girl with achondrogenesis type II showing large head, midfacial hypoplasia, short neck, small chest, and short limbs. The radiographs shows generalized shortening of the long bones of the upper and lower extremities with marked cupping (metaphyseal spurs) at the metaphyseal ends of the bones. This is most evident at the distal ends of the tibia, fibular, radius and ulna, and distal ends of the digits. Radiographs also shows short ribs without fractures and hemivertebrae involving thoracic vertebrae as well as the sacrum. Conformation sensitive gel electrophoresis analysis indicated a sequence variation in the fragment containing exon 19 and the flanking sequences of the *COL2A1* gene (Gly244Asp). Similar mutations in this area have been seen in patients diagnosed with hypochondroplasia and achondrogenesis type II

Achondroplasia

Achondroplasia is the most common form of short-limbed dwarfism. Gene frequency is estimated to be 1/16,000 and 1/35,000. There are about 5,000 achondroplasts in the U.S.A. and 65,000 on Earth. The incidence for achondroplasia is between 0.5 and 1.5 in 10,000 births. The mutation rate is high and is estimated to be between 1.72 and 5.57×10^{-5} per gamete per generation. Most infants with achondroplasia are born unexpectedly to parents of average stature.

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant disorder with complete penetrance
   b. Sporadic in about 80% of the cases, the result of a de novo mutation
   c. Presence of paternal age effect (advanced paternal age in sporadic cases)
   d. Gonadal mosaicism (two or more children with classic achondroplasia born to normal parents)
2. Caused by mutations in the gene of the fibroblast growth factor receptor 3 (*FGFR3*) on chromosome 4p16.3
   a. About 98% of achondroplasia with G-to-A transition and about 1% G-to-C transversion at nucleotide 1138. Both mutations resulted in the substitution of an arginine residue for a glycine at position 380 (G380A) of the mature protein in the transmembrane domain of *FGFR3*.
   b. A rare mutation causing substitution of a nearby glycine 375 with a cysteine (G375C)
   c. Another rare mutation causing substitution of glycine346 with glutamic acid (G346E)
   d. The specific mechanisms by which *FGFR3* mutations disrupt skeletal development in achondroplasia remain elusive
3. Different mutations in *FGFR3* can cause the following spectrum of disorders (Lemyre et al. 1999; Superti-Furga and Unger 2007)
   a. Hypochondroplasia
   b. Severe achondroplasia with developmental delay and acanthosis nigricans
   c. Thanatophoric dysplasia
4. *FGFR3* mutations affect the cartilaginous growth plate in the growing skeleton, therefore disturbing cartilage function during linear bone growth (Richette et al. 2008)
5. Basic defect: zone of chondroblast proliferation in the physeal growth plates
   a. Abnormally retarded endochondral ossification with resultant shortening of tubular bones and flat vertebral bodies, while membranous ossification (skull, facial bones) is not affected
   b. Physeal growth zones show normal columnization, hypertrophy, degeneration, calcification, and ossification. However, the growth is quantitatively reduced significantly.
   c. Achondroplasia as the result of a quantitative loss of endochondral ossification rather than the formation of abnormal tissue
   d. Normal diameter of the bones secondary to normal subperiosteal membranous ossification of tubular bones; the results being production of short, thick tubular bones, leading to short stature with disproportionately shortened limbs

Clinical Features

1. Major clinical symptoms
   a. Delayed motor milestones during infancy and early childhood
   b. Sleep disturbances secondary to both neurological and respiratory complications
   c. Breathing disorders
      i. A high prevalence (75%) of breathing disorders during sleep
      ii. Obstructive apnea caused by upper airway obstruction
      iii. The majority of respiratory complaints due to restrictive lung disease secondary to diminished chest size or upper airway obstruction and rarely due to spinal cord compression
   d. Symptomatic spinal stenosis in more than 50% of patients as a consequence of a congenitally small spinal canal
      i. Back pain
      ii. Lower extremity sensory changes
      iii. Incontinence
      iv. Paraplegia
      v. Onset of symptoms: usually after 20 s or 30 s
   e. Neurologic symptoms classified based on neurologic severity and presentation of spinal stenosis (Lutter and Langer 1977)
      i. Type I (back pain with sensory and motor change of an insidious nature)
      ii. Type II (intermittent claudication limiting ambulation)
      iii. Type III (nerve root compression)
      iv. Type IV (acute onset paraplegia)
   f. Symptoms secondary to foramen magnum stenosis
      i. Respiratory difficulty
      ii. Feeding problems
      iii. Cyanosis, quadriparesis
      iv. Poor head control
   g. Symptoms secondary to cervicomedullary compression
      i. Pain
      ii. Ataxia
      iii. Incontinence
      iv. Apnea
      v. Progressive quadriparesis
      vi. Respiratory arrest
2. Major clinical signs
   a. Disproportionate short stature (dwarfism)
   b. Hypotonia during infancy and early childhood
   c. Relative stenosis of the foramen magnum in all patients, documented by CT
   d. Foramen magnum stenosis considered as the cause of increased incidence of:
      i. Hypotonia
      ii. Sleep apnea
      iii. Sudden infant death syndrome
   e. Symptomatic hydrocephalus in infancy and early childhood rarely due to narrowing of the foramen magnum
   f. Characteristic craniofacial appearance
      i. Disproportionately large head
      ii. Frontal bossing
      iii. Depressed nasal bridge
      iv. Midfacial hypoplasia
      v. Narrow nasal passages
      vi. Prognathism
      vii. Dental malocclusion
   g. A normal trunk length
   h. A thoracolumbar kyphosis or gibbus usually present at birth or early infancy
   i. Exaggerated lumbar lordosis when the child begins to ambulate
   j. Prominent buttocks and protuberant abdomen secondary to increased pelvic tilt in children and adults
   k. Generalized joint hypermobility, especially the knees
   l. Rhizomelic micromelia (relatively shorter proximal segment of the limbs compared to the middle and the distal segments)
   m. Limited elbow and hip extension
   n. Trident hands (inability to approximate the third and fourth fingers in extension produces a “trident” configuration of the hand)
   o. Short fingers (brachydactyly)
   p. Bowing of the legs (genu varum) due to lax knee ligaments
   q. Excess skin folds about thighs
3. Complications/risks
   a. Recurrent otitis media during infancy and childhood
      i. Conductive hearing loss
      ii. Delayed language development
   b. Thoraco-lumbar gibbus
   c. Osteoarthropathy of the knee joints

d. Neurological complications
   i. Small foramen magnum
   ii. Cervicomedullary junction compression causing sudden unexpected death in infants with achondroplasia
   iii. Apnea
   iv. Communicating hydrocephalus
   v. Spinal stenosis
   vi. Paraparesis
   vii. Quadriparesis
   viii. Infantile hypotonia
e. Obesity
   i. Aggravating the morbidity associated with lumbar stenosis
   ii. Contributing to the nonspecific joint problems and to the possible early cardiovascular mortality in this condition
f. Obstetric complications
   i. Large head of the affected infant
   ii. An increased risk of intracranial bleeding during delivery
   iii. Marked obstetrical difficulties secondary to very narrow pelvis of achondroplastic women

4. Prognosis
   a. Normal intelligence and healthy, independent, and productive lives in vast majority of patients. Rarely, intelligence may be affected because of hydrocephalus or other CNS complications.
   b. Mean adult height
      i. Approximately 131 cm ± 5.6 for males
      ii. Approximately 124 cm ± 5.9 for females
   c. Psychosocial problems related to body image because of severe disproportionate short stature
   d. Life span for heterozygous achondroplasia
      i. Usually normal unless there are serious complications
      ii. Mean life expectancy approximately 10 years less than the general population
   e. Homozygous achondroplasia
      i. A lethal condition with severe respiratory distress caused by rib-cage deformity and upper cervical cord damage caused by small foramen magnum. The patients die soon after birth.
      ii. Radiographic changes much more severe than the heterozygous achondroplasia
   f. Normal fertility in achondroplasia
      i. Pregnancy at high risk for achondroplastic women
      ii. Respiratory compromise common during the third trimester
      iii. Advise baseline pulmonary function studies before pregnancy to aid in evaluation and management
      iv. A small pelvic outlet usually requiring Cesarean section under general anesthesia since the spinal or epidural approach is contraindicated because of spinal stenosis
   g. Anticipatory guidance: Patients and their families can benefit greatly from anticipatory guidance published by American Academy of Pediatrics Committee on Genetics (1995) and Clinical Report (2005).
   h. Adaptations of patients to the environment to foster independence
      i. Lowering faucets and light switches
      ii. Using a step stool to keep feet from dangling when sitting
      iii. An extended wand for toileting
      iv. Adaptations of toys for short limbs
   i. Support groups: Many families find it beneficial to interact with other families and children with achondroplasia through local and national support groups.

Diagnostic Investigations

1. Diagnosis of achondroplasia made by clinical findings, radiographic features, and/or *FGFR3* mutation analysis
2. Radiologic Features
   a. Skull
      i. Relatively large calvarium
      ii. Prominent forehead
      iii. Depressed nasal bridge
      iv. Small skull base
      v. Small foramen magnum
      vi. Dental malocclusion
   b. Spine
      i. Caudal narrowing of interpedicular distances in the lower lumbar spine
      ii. Short vertebral pedicles
      iii. Wide disc spaces

iv. Dorsal scalloping of the vertebral bodies in the newborn
v. Concave posterior aspect of the vertebral bodies in childhood and adulthood
vi. Different degree of anterior wedging of the vertebral bodies causing gibbus

c. Pelvis
i. Lack of iliac flaring
ii. Narrow sacroiliac notch
iii. Horizontal acetabular portions of the iliac bones

d. Limbs
i. Rhizomelic micromelia
ii. Square or oval radiolucent areas in the proximal humerus and femur during infancy
iii. Tubular bones with widened diaphyses and flared metaphyses during childhood and adulthood
iv. Markedly shortened humeri
v. Short femoral neck
vi. Disproportionately long fibulae in relation to tibiae

3. Craniocervical MRI
a. Narrowing of the foramen magnum
b. Effacement of the subarachnoid spaces at the cervicomedullary junction
c. Abnormal intrinsic cord signal intensity
d. Mild to moderate ventriculomegaly

4. Histology
a. Normal histologic appearance of epiphyseal and growth plate cartilages
b. Shorter than normal growth plate: The shortening is greater in homozygous than in heterozygous achondroplasia, suggesting a gene dosage effect.

5. Mutation analysis
a. G1138A substitution in *FGFR3* (about 98% of cases)
b. G1138C substitution in *FGFR3* (about 1% of cases)

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Recurrence risk after the conception of an affected child has always been considered very low and less than 30 cases of recurrences among sibs have been reported so far (Natacci et al. 2008). It was possible to demonstrate somatic and germinal mosaicism in the mother (Henderson et al. 2000) and germinal mosaicism in the father (Natacci et al. 2008).
ii. Recurrence risk of achondroplasia in the sibs of achondroplastic children with unaffected parents: presumably higher than twice the mutation rate because of gonadal mosaicism. Currently, the risk is estimated as 1 in 443 (0.2%).
iii. Fifty percent affected if one of the parents is affected
iv. Twenty-five percent affected with homozygous achondroplasia (resulting in a much more severe phenotype that is usually lethal early in infancy) and 50% affected with heterozygous achondroplasia if both parents are affected with achondroplasia

b. Patient's offspring
i. Fifty percent affected (with heterozygous achondroplasia) if the spouse is normal
ii. Twenty-five percent affected with homozygous achondroplasia and 50% affected with heterozygous achondroplasia if the spouse is also affected with achondroplasia. There is still a 25% chance that the offspring will be normal.

2. Prenatal diagnosis
a. Prenatal ultrasonography
i. Suspect achondroplasia on routine ultrasound findings of a fall-off in limb growth (<3rd percentile), increased biparietal diameter (>95th percentile) and low nasal bridge (Cordone et al. 1993; Mesoraca et al. 1996), usually during the third trimester of pregnancy, in case of parents with normal heights. About one third of cases are suspected this way. However, one must be cautious because disproportionately short limbs are observed in a variety of conditions.
ii. Inability to make specific diagnosis of achondroplasia with certainty by ultrasonography unless by radiography late in gestation or after birth
iii. Request of prenatal ultrasonography by an affected parent, having 50% risk of having

a similarly affected child, to optimize obstetric management
iv. Follow pregnancy by a femoral growth curve in the second trimester by serial ultrasound scans to enable prenatal distinction between homozygous, heterozygous, and unaffected fetuses, in case of both affected parents

b. Prenatal radiography
i. Shortened long bones with wide metaphyses
ii. Slim and radiolucent area in the proximal femur
iii. Horizontal acetabular roof
iv. The above features not always detected

c. 3-Dimensional computed tomography scan (3D CT scan) may be used after 30 weeks of gestation (Krakow et al. 2003; Ruano et al. 2004).
i. Slightly flat vertebral bodies with medial spurs
ii. Pointed femora with proximal extremity
iii. Round and square ilia with an oval radiolucent area in the proximal femur

d. On computed tomography and postnatal X-ray, proximal femoral metaphysis appeared rounded, with poor, uneven ossification. Connection to diaphysis was abnormal, with relative overgrowth of the periosteum, creating a new diagnostic sign, called the "collar hoop" sign (Boulet et al. 2009).

e. Prenatal molecular testing
i. Molecular technology applied to prenatal diagnosis of a fetus suspected of or at risk for having achondroplasia
ii. Simple methodology requiring only one PCR and one restriction digest to detect a very limited number of mutations causing achondroplasia
iii. Preimplantation genetic diagnosis
a) Available at present (Moutou et al. 2003)
b) The initial practice raising questions on the feasibility of such a test, specially with affected female patients

3. Management
a. Adaptive environmental modifications
i. Appropriately placed stools
ii. Seating modification
iii. Other adaptive devices

b. Obesity control

c. Obstructive apnea
i. Adenoidectomy and tonsillectomy
ii. Continuous positive airway pressure (CPAP) and bilevel positive airway pressure (BiPAP) for clinically significant persistent obstruction
iii. Extremely rare for requiring temporary tracheostomy

d. Experimental growth hormone therapy (Horton et al. 1992; Shohat et al. 1996; Seino et al. 2000)
i. Resulting in transient increases in growth velocity
ii. Long term result not conclusive

e. Hydrocephalus
i. Observation for benign ventriculomegaly
ii. May need surgical intervention for clinically significant hydrocephalus

f. Kyphosis
i. Adequate support for sitting in early infancy
ii. Bracing using a thoracolumbosacral orthosis for severe kyphosis in young children
iii. Surgical intervention for medically unresponsive cases

g. Surgical decompression for unequivocal evidence for cervical cord compression

h. Decompression laminectomy for severe and progressive lumbosacral spinal stenosis

i. Limb lengthening through osteotomy and stretching of the long bones (Aldegheri et al. 1988; Lavini et al. 1990; Ganel et al. 1979; Ganel and Horoszowski 1996)
i. Controversial
ii. Difficult to achieve the benefits of surgery
a) Need strong commitment on the part of the patients and their families for the time in the hospital and the number of operations
b) A high risk of infection
c) Occurrence of possible severe permanent sequelae (damage to joint and soft tissue)
d) May result in poorer quality of life

j. Potential anesthetic risks related to:
i. Obstructive apnea
ii. Cervical compression

k. Risks associated with pregnancy in women with achondroplasia: relatively infrequent
i. Worsening neurologic symptoms related to increasing hyperlordosis and maternal respiratory failure
ii. Anticipate a scheduled cesarean delivery due to cephalopelvic disproportion
iii. Preeclampsia
iv. Polyhydramnios

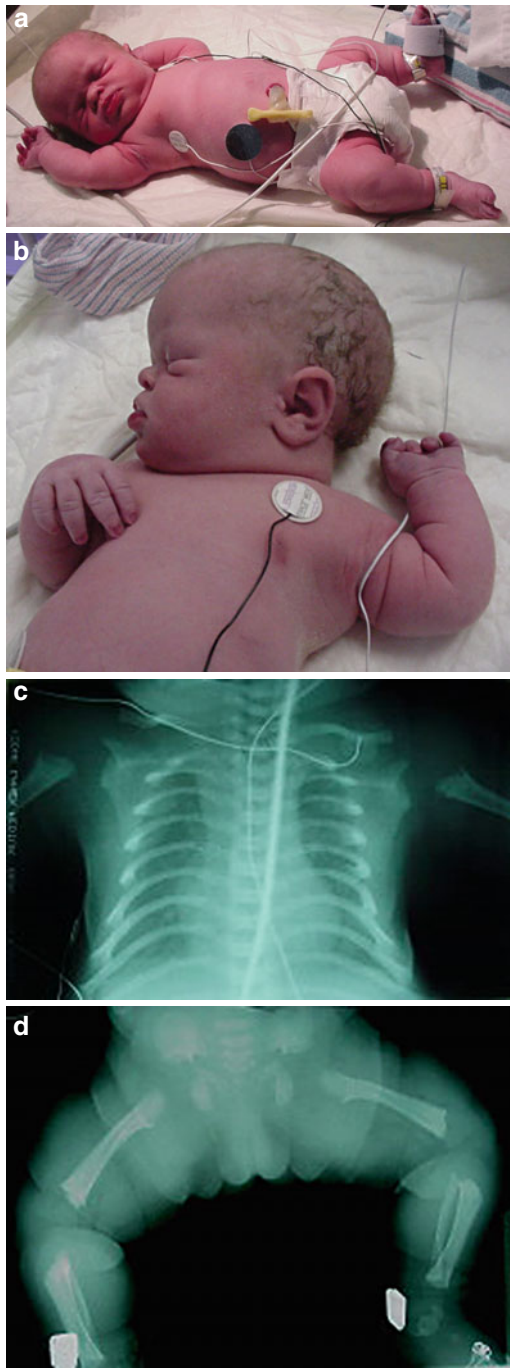

Fig. 1 (**a**–**d**) A newborn with achondroplasia showing large head, depressed nasal bridge, short neck, normal length of the trunk, narrow chest, rhizomelic micromelia, and trident hands. The radiographs showed narrow chest, characteristic pelvis, micromelia, and oval radiolucent proximal portion of the femurs. Molecular analysis showed 1138 G → C transversion mutation which has been observed in approximately 1.9% of achondroplasia chromosomes

Fig. 2 A 4-month-old boy with achondroplasia showing typical craniofacial features and rhizomelic shortening of limbs (confirmed by radiograms). Molecular study revealed 1138 G-to-A transition mutation which has been observed in approximately 98% of achondroplasia chromosomes

Fig. 3 (**a**–**c**) Another achondroplastic neonate with typical clinical features and radiographic findings. Note the abnormal vertebral column with wide intervertebral spaces and abnormal vertebral bodies

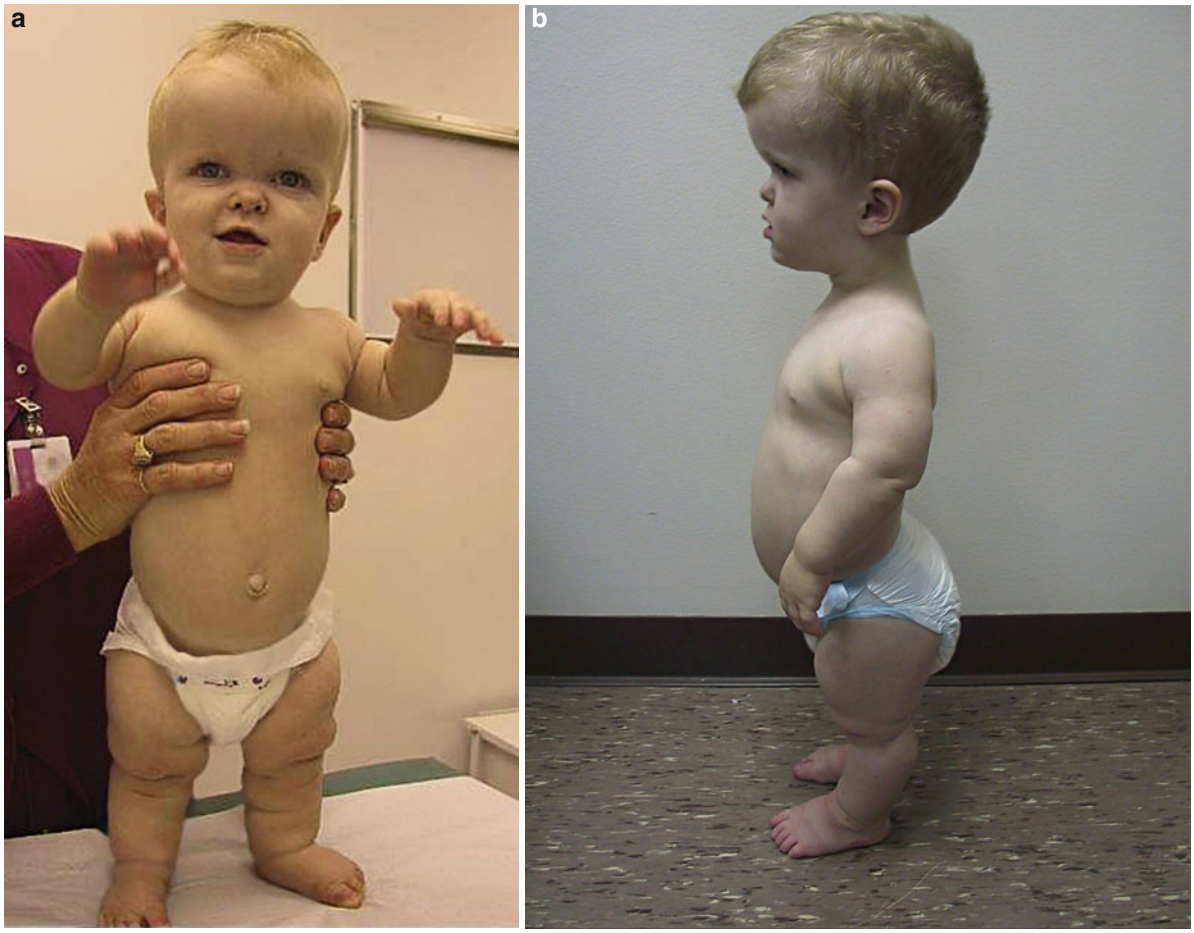

Fig. 4 (**a**, **b**) A boy (7 month and 2 year 7-month old) with achondroplasia showing a large head, small chest, normal size of the trunk, rhizomelic micromelia, and exaggerated lumbar lordosis

Fig. 5 (**a**–**c**) Two older children with achondroplasia showing rhizomelic micromelia, typical craniofacial features, exaggerated lumbar lordosis, and trident hands

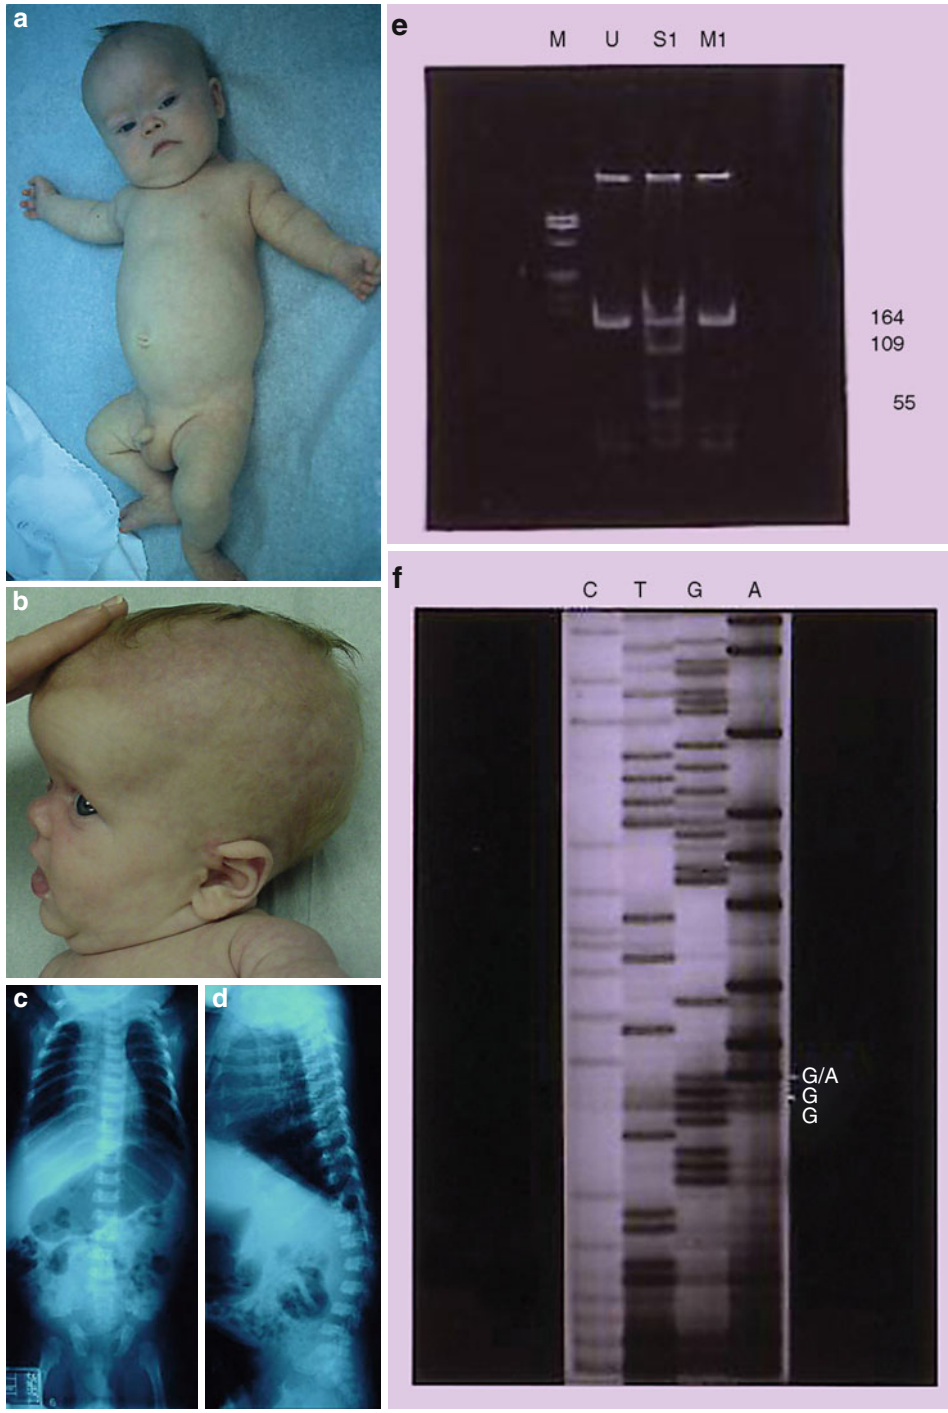

Fig. 6 (**a**–**f**) A boy with achondroplasia and i(21q) Down syndrome presented with diagnostic dilemma. Besides craniofacial features typical for Down syndrome, the skeletal findings of achondroplasia dominate the clinical picture. The diagnosis of Down syndrome was based on the clinical features and the cytogenetic finding of i(21q) trisomy 21. The diagnosis of achondroplasia was based on the presence of clinical and radiographic findings, and confirmed by the presence of a common FGFR3 gene mutation (Gly380Arg) detected by restriction enzyme analysis and sequencing of the PCR products

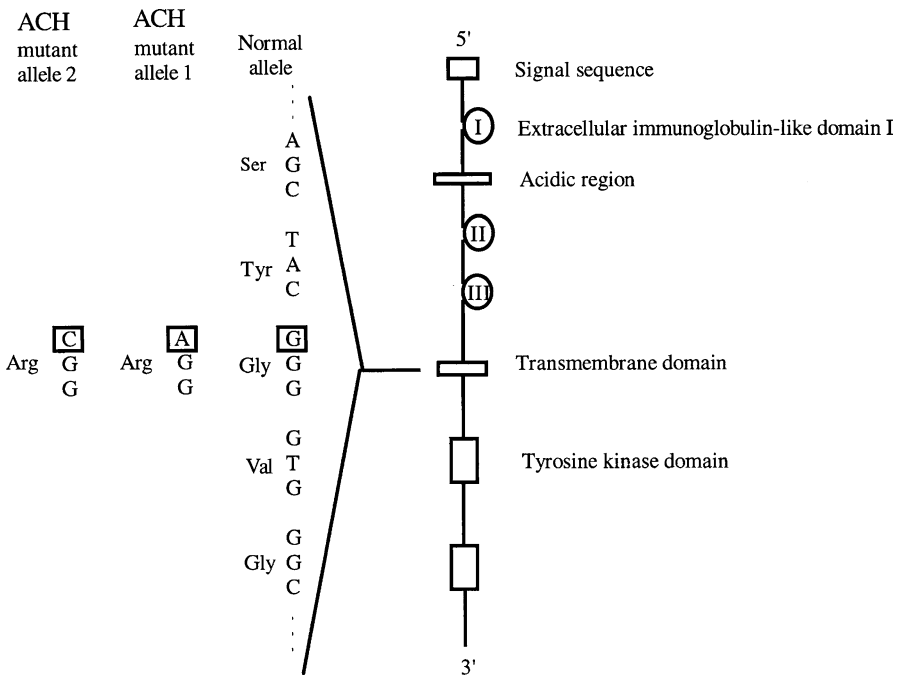

Fig. 7 Schematic of the FGFR3 gene and DNA sequence of normal allele and mutant FGFR3 achondroplasia allele (Modified from Shiang et al. 1994)

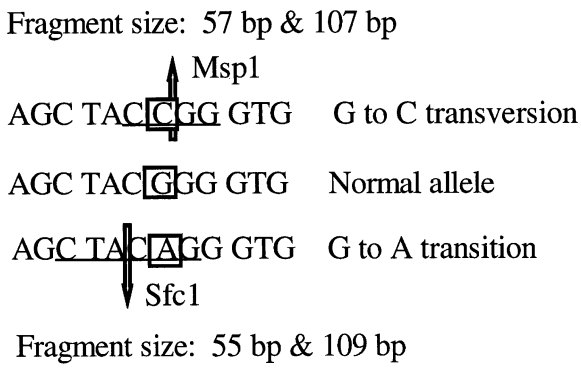

Fig. 8 Nucleotide change in the 1138 C allele creates a Msp1 site and nucleotide change in the 1138A allele creates a Sfc1. The base in the coding sequence that differs in the three alleles is boxed (Modified from Shiang et al. 1994)

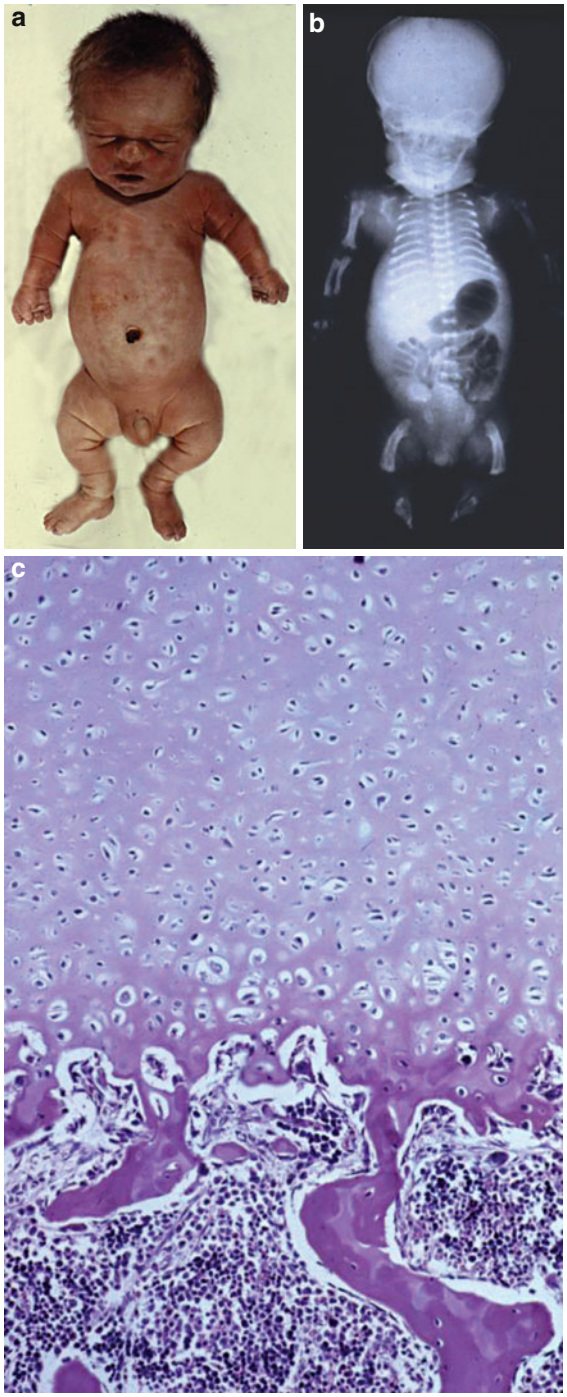

Fig. 9 (**a**–**c**) Homozygous achondroplasia. Both parents are achondroplastic. The large head, narrow chest and severe rhizomelic shortening of the limbs are similar to those of thanatophoric dysplasia. Radiograph shows severe platyspondyly, small ilia and short limb bones. Photomicrograph of the physeal growth zone shows severe retardation and disorganization, similar to that of thanatophoric dysplasia

Adams–Oliver Syndrome

In 1945, Adams and Oliver described congenital transverse limb defects associated with aplasia cutis congenita in a three-generation kindred with typical autosomal dominant inheritance and intrafamilial variable expressivity.

Synonyms and Related Disorders

Aplasia cutis congenita with terminal transverse limb defects

Genetics/Basic Defects

1. Genetic heterogeneity
   a. Autosomal dominant in most cases
      i. The family described by Adams and Oliver, and revisited by Whitley and Gorlin in 1991, illustrates vertical transmission, with multiple affected members spanning four generations and includes male-to-male transmission, consistent with autosomal dominant inheritance
      ii. Reports from over 20 further kindreds provide support for the role of a heterozygous autosomal gene mutation (Snape et al. 2009).
   b. Autosomal recessive in some cases
      i. The combination of aplasia cutis congenita and terminal transverse limb defects within sibships provides evidence for an autosomal recessive mode of inheritance
      ii. Further supported by the occurrence of affected siblings within inbred families
2. Pathogenesis
   a. Trauma
   b. Uterine compression
   c. Amniotic band sequelae
   d. Vascular disruption sequence
      i. Concomitant occurrence of Poland sequence
      ii. Both Poland sequence and Adams–Oliver syndrome: secondary to vascular disruption due to thrombosis of subclavian and vertebral arteries
   e. Massive thrombus from the placenta occluding the brachial artery
   f. Abnormalities in small vessel structures manifesting during embryogenesis
   g. A developmental disorder of morphogenesis
3. Molecular basis of the syndrome remains unknown, although the common occurrence of cardiac and vascular anomalies suggests a primary defect of vasculogenesis (Snape et al. 2009).

Clinical Features

1. Marked intrafamilial and interfamilial variability
2. Terminal transverse limb defects
   a. Most common manifestation (84%)
   b. Usually asymmetrical
   c. Tendency toward bilateral lower limb rather than upper limb involvement
   d. Mild spectrum of defects
      i. Nail hypoplasia
      ii. Cutaneous syndactyly
      iii. Bony syndactyly
      iv. Ectrodactyly
      v. Brachydactyly
   e. Severe spectrum of transverse defects
      i. Absence of the hand

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_4,
© Springer Science+Business Media, LLC 2012

ii. Absence of the foot
iii. Absence of the limb

3. Aplasia cutis congenita
   a. Second most common defect (almost 75%)
   b. Associated with skull defect (64%): the most common site is the vertex, often with scalp defect extending to periosteum, skull, and dura
      i. Small lesion: 0.5 cm in diameter
      ii. Intermediate lesion: 8–10 cm involving the vertex
      iii. Severe lesion: involve most of the scalp with acrania
   c. Skull defect without scalp defect, often mistaken for an enlarged fontanelle
   d. May involve other areas of the body
   e. Severe end of the spectrum of scalp defects
      i. Encephalocele
      ii. Acrania
   f. Most severe manifestations can be associated with a mortality rate of 20–55% (Bjpai and Pal 2003)
      i. Associated with dilated and tortuous scalp veins with significant morbidity
      ii. Associated with hemorrhage or infection
4. Congenital cardiovascular malformations (13.4–20%)
   a. Mechanisms proposed to explain the pathogenesis of congenital cardiovascular malformations
      i. Alteration of mesenchymal cell migration resulting in conotruncal malformations, e.g., tetralogy of Fallot, double outlet right ventricle, and truncus arteriosus
      ii. Alteration of fetal cardiac hemodynamics resulting in different malformations such as coarctation of the aorta, aortic stenosis, perimembranous VSD, and hypoplastic left heart
      iii. Persistence of normal fetal vascular channels resulting in postnatal vascular abnormalities
   b. Diverse vascular and valvular abnormalities
      i. Bicuspid aortic valve
      ii. Pulmonary atresia
      iii. Parachute mitral valve
      iv. Pulmonary hypertension
5. Other associated anomalies
   a. Cutis marmorata telangiectasia congenita (12%)
   b. Dilated and tortuous scalp veins (11%)
   c. Poland anomaly
   d. Encephalocele
   e. Facial features
      i. Hemihypoplasia
      ii. Hypertelorism
      iii. Epicanthal folds
      iv. Microphthalmia
      v. Esotropia
      vi. High arch palate
      vii. Cleft palate
   f. Cryptorchidism
   g. Lymphatic abnormalities
      i. Lymphedema of the leg
      ii. Chylothorax
      iii. Dilated pulmonary lymphatics
      iv. Intestinal lymphangiectasia
      v. Marmorata telangiectasia congenita (a cutaneous vascular abnormality)
   h. CNS abnormalities: unusual manifestation
      i. Mental retardation
      ii. Learning disability
      iii. Epilepsy
   i. Short stature
   j. Renal malformations
   k. Spina bifida occulta
   l. Accessory nipples
6. Major and minor features of Adams–Oliver syndrome (Snape et al. 2009): The presence of two major features is considered sufficient for a diagnosis. The combination of one major and one minor feature should place Adams–Oliver syndrome high in the differential diagnosis of such individuals.
   a. Major features
      i. Terminal transverse limb defects
      ii. Aplasia cutis congenita
      iii. Family history of Adams–Oliver syndrome
   b. Minor features
      i. Cutis marmorata telangiectasia congenita
      ii. Congenital cardiac defect
      iii. Vascular anomaly
7. Differential diagnosis (Snape et al. 2009)
   a. Amniotic band sequence
   b. Moebius and Poland syndromes (McGuirk et al. 2001)
   c. Teratogenic agents such as phenytoin, misoprostol, and ergotamine
      i. Asymmetric bilateral transverse terminal limb defects
      ii. Tend to affect the upper limb more severely than the lower limb (Spranger et al. 1980; Holmes 2002)

d. Limb anomalies
   i. Caused by thalidomide: tends to be symmetrical and longitudinal (Smithells and Newman 1992)
   ii. Caused by chorionic villus sampling during pregnancy (Holmes 2002)
e. Isolated aplasia cutis congenita: substantial heterogeneity based on association with known abnormalities or exposure to teratogens such as methimazole (Frieden 1986)
f. Cutis marmorata telangiectasia congenita
   i. Common in kindreds with Adams–Oliver syndrome
   ii. Can be seen in combination with both terminal transverse limb defects (Maniscalco et al. 2005) and aplasia cutis congenita (Verdyck et al. 2003)
   iii. Can be an isolated finding in otherwise unaffected family members (Scribanu and Temtamy 1975; Toriello et al. 1988)
   iv. Can be associated with skin atrophy and ulcerations, capillary malformations, capillary and cavernous vascular malformations, under- or overgrowth of the affected extremity, macrocephaly and glaucoma, and in association with vascular syndromes including Sturge–Weber and Klippel–Trenaunay (Amitai et al. 2000)

Diagnostic Investigations

1. Radiography
   a. Transverse limb defects
   b. Ectrodactyly
   c. Brachydactyly
   d. Syndactyly
   e. Nail hypoplasia
   f. Skull defect
2. CT scan or MRI of the brain
   a. Polymicrogyria
   b. Ventriculomegaly
   c. Irregular cortical thickening
   d. Cerebral cortex dysplasia
   e. Microcephaly
   f. Arhinencephaly
   g. Periventricular and parenchymal calcium deposits

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant: not increased unless a parent is affected in which case the risk is 50%
      ii. Autosomal recessive: 25%
   b. Patient's offspring
      i. Autosomal dominant: 50%
      ii. Autosomal recessive: not increased unless the spouse carries the gene or is affected
2. Prenatal diagnosis by ultrasonography
   a. Transverse limb defects
   b. Concomitant skull defect
3. Management
   a. Treat minor scalp lesions with daily cleansing of the involved areas with applications of antibiotic ointment
   b. Surgically close larger lesions and exposed dura with minor or major skin grafting procedure (split thickness or full thickness)
   c. Prevent sepsis and/or meningitis from an open scalp lesion which is highly vascular and rarely involves the sagittal sinus predisposing to episodes of spontaneous hemorrhage
   d. Urgent surgical intervention may be required with operative measures that include primary closure, skin grafting, local scalp flaps with or without tissue expansion, and cranial vault reconstruction using split rib grafts and free latissimus dorsi muscle flap (Bajpai and Pal 2003)
   e. Orthopedic care for various degree of limb defects

Zapata, H. H., Sletten, L. J., & Pierpont, M. E. M. (1995). Congenital cardiac malformations in Adams-Oliver syndrome. *Clinical Genetics, 47*, 80–84.

Fig. 1 A 9-month-old boy with Adams–Oliver syndrome showing alopecia, absent eyebrows and eyelashes, scalp defect, tortuous scalp veins, and limb defects (brachydactyly, syndactyly, broad great toes, and nail hypoplasia). Radiography showed absent middle and distal phalanges of second to fifth toes and absent distal phalanges of the great toes

Agnathia

Agnathia is an extremely rare lethal neurocristopathy. The disorder has also been termed agnathia-holoprosencephaly spectrum, agnathia-otocephaly complex, agnathia-astomia-synotia, or cyclopia-otocephaly association. The incidence is estimated to be 1 in 70,000 infants (Schiffer et al. 2002).

The spectrum of agnathia ranges from isolated agnathia, or virtual absence of the mandible, to otocephaly, which refers to a broader malformation of mandibular hypoplasia or agnathia, downward displacement of the ears and/or synotia (approximation of the ears in the midline), with or without aglossia (no tongue), and microstomia (small mouth) (Petrikovsky 1999). Agnathia-otocephaly is a lethal malformation complex characterized by absence of the mandible, microstomia, aglossia, and positioning of the ears toward the midline (Pauli et al. 1981; Bixler et al. 1985). Although ear positioning is variable and the use of the term "otocephaly" does not seem always justified, otocephaly is commonly used to assemble all ear abnormalities with displacement toward the midline (Schiffer et al. 2002). Agnathia-otocephaly can occur alone or in combination with a variety of associated malformations, holoprosencephaly being the most commonly reported association.

Synonyms and Related Disorders

Agnathia-holoprosencephaly spectrum; Agnathia-otocephaly complex

Genetics/Basic Defects

1. Sporadic occurrence in majority of cases
2. Rare autosomal recessive inheritance: two siblings with isolated dysgnathia complex who survived infancy (Baker et al. 2004)
3. Possible autosomal dominant inheritance
   a. Supported by an observation of dysgnathia in mother and daughter (Erlich et al. 2000)
   b. Possibility of a defect in the *OTX2* gene as the basis of the disorder (Matsuo et al. 1995)
4. Teratogenic factors have been described in humans
   a. Salicylate (Benawra et al. 1980)
   b. Amidopyrine (Mollica et al. 1979)
   c. Theophylline (Ibba et al. 2000)
5. A prechordal mesoderm inductive defect affecting neural crest cells
   a. A developmental field defect
   b. Different etiologic agents (etiological heterogeneity) acting on the same developmental field producing a highly similar complex of malformations
6. Possible existence of a mild form of agnathia without brain malformation (holoprosencephaly)
   a. Situs inversus-congenital hypoglossia
   b. Severe micrognathia, aglossia, and choanal atresia
7. A well-recognized malformation complex in the mouse (Juriloff et al. 1985), guinea pig (Wright 1934), rabbit, sheep, and pig

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_5,
© Springer Science+Business Media, LLC 2012

Clinical Features

1. Polyhydramnios due to persistence of oropharyngeal membrane or blind-ending mouth
2. Agnathia (absence of the mandible)
3. Microstomia or astomia (absence of the mouth)
4. Aglossia (absence of the tongue)
5. Blind mouth
6. Ear anomalies
   a. Otocephaly (variable ear positions)
   b. Synotia (external ears approaching one another in the midline)
   c. Dysplastic inner ear
   d. Atretic ear canal
7. Down-slanting palpebral fissures
8. Variable degree of holoprosencephaly: nearly 100 patients reported as having holoprosencephaly and features consistent with the spectrum of agnathia (Kauvar et al. 2010).
   a. Cyclopia
   b. Synophthalmia
   c. Arrhinencephaly
9. Other brain malformations
   a. Cerebellar hypoplasia
   b. Septum pellucidum cavum
   c. Absence of cranial nerves (I–IV)
   d. Absence of the corpus callosum
   e. Meningocele
10. Intrauterine growth retardation
11. Cleft lip/palate
12. Occular malformations
   a. Microphthalmos/anophthalmia
   b. Proptosis (protruding eyes)
   c. Absence of the eyelids
   d. Epibulbar dermoid
   e. Aphakia
   f. Retinal dysplasia
   g. Microcornea
   h. Anterior segment dysgenesis
   i. Uveal colobomas
13. Nasal anomalies
   a. Absence of the nasal cavity
   b. Cleft nose
   c. Blind nasal pharynx
14. Various visceral malformations
   a. Choanal atresia
   b. Tracheoesophageal fistula
   c. Absence of the thyroid gland
   d. Absence of the submandibular and parotid salivary glands
   e. Abnormal glottis and epiglottis
   f. Thyroglossal duct cyst
   g. Carotid artery anomalies
   h. Situs inversus
   i. Cardiac anomalies
   j. Unlobulated lungs
   k. Renogenital anomalies
      i. Unilateral renal agenesis
      ii. Renal Ectopia
      iii. Cystic kidneys
      iv. Horseshoe kidneys
      v. Solitary kidney
      vi. Mullerian duct agenesis
      vii. Cryptorchidism
15. Skeletal anomalies
   a. Vertebral anomalies
   b. Rib anomalies
   c. Tetramelia
16. Anatomical variations
   a. Ears
      i. Absence of the tragus
      ii. Synotia
   b. Mandible
      i. Rudimentary
      ii. Absent
      iii. Two small separate masses
   c. Mouth: microstomia with vertical orientation
   d. Buccopharyngeal membrane: absent to present
   e. Tongue
      i. Small to absent body
      ii. Present in (hypo)pharynx
   f. Absent submandibular glands
   g. Other skull bones: approximated maxillae, palatine, zygomatic, and temporal

Diagnostic Investigations

1. Radiography
   a. Reduced maxilla
   b. Absence of the zygomatic process
   c. Absence of the hyoid bone
   d. Vertebral anomalies
   e. Absence of the ribs
   f. Sprengel deformity
2. Cranial ultrasonography to define holoprosencephaly

3. Postnatal reconstructed CT for detailed 3-D structure of the cranium in agnathia-otocephaly
4. Chromosome analysis
   a. Normal in majority of cases
   b. Unbalanced der(18),t(6;18)(pter → p24.1; p11.21 → qter) in two female sibs with agnathia-holoprosencephaly
5. Autopsy to define postmortem findings

Genetic Counseling

1. Recurrence risks
   a. Risk to patient's sib: not increased unless in a rare autosomal recessive inheritance
   b. Risk to patient's offspring
      i. Not applicable to lethal cases since the patients do not survive to reproductive age
      ii. Autosomal dominant (some case may survive to reproductive age): 50%
2. Prenatal diagnosis by 3-D ultrasonography (Ducarme et al. 2007; Tantbirojn et al. 2008). 3-D imaging by helical computed tomography (CT), and/or MRI imaging (Chen et al. 2003, 2007)
   a. Polyhydramnios: secondary to an atretic, constricted, or obstructed oropharynx that prevents the fetus from swallowing amniotic fluid efficiently or at all
   b. Intrauterine growth retardation
   c. Mandibular absence (agnathia) or major hypoplasia
   d. Holoprosencephaly
   e. Cyclopia, marked hypotelorism or frontal proboscis
3. Management
   a. Although a lethal entity, several survivals beyond infancy have been reported (Brecht and Johnson 1985; Kamiji et al. 1991; Walker et al. 1995; Shermak and Dufresne 1996; Baker et al. 2004). Our third case with agnathia is still surviving with normal neurological development at 20 years of age.
   b. All survivors required tracheotomy immediately soon after delivery since no laryngeal opening is most likely present for endotracheal tube insertion
   c. EXIT (*ex utero* intrapartum treatment) procedure, a technique for safely managing airway obstruction at birth, in which placental support is maintained until the airway can be evaluated and secured (Umekawa et al. 2007)

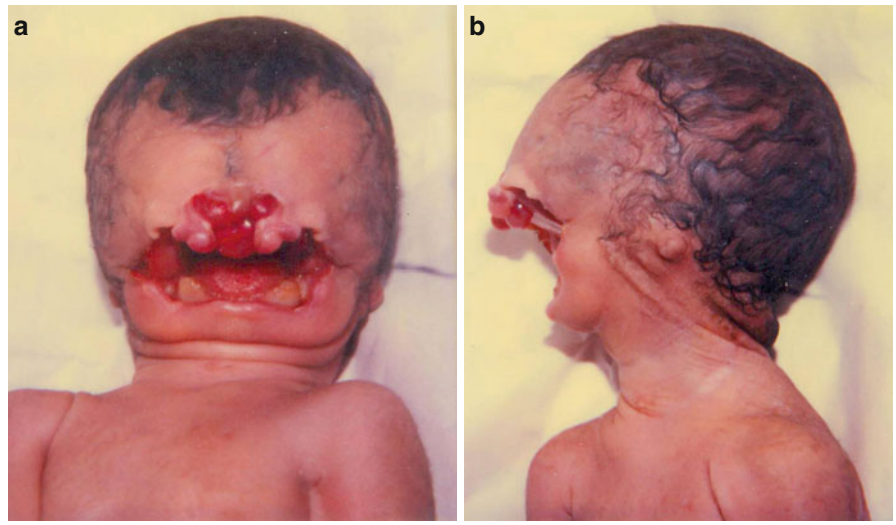

Fig. 1 (**a**, **b**) A neonate (28 week gestation) with agnathia-holoprosencephaly complex showing a large defect involving entire midface area with almost total absence of jaw, absence of eyes and nose, and severe microtia. Absence of olfactory bulbs and grooves (arrhinencephaly) were demonstrated by necropsy. Additional anomalies included 13 pairs of ribs, atresia of left ureter with resultant hydronephrosis, and left renal cortical cysts. Maternal hydramnios was present

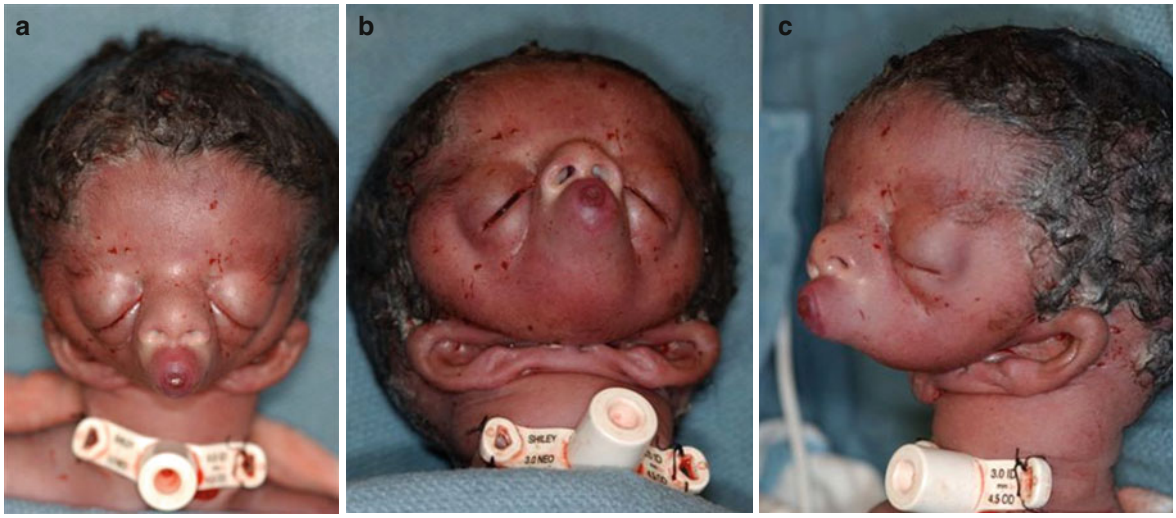

Fig. 2 (**a**–**c**) The female infant was born via elective caesarian section with Apgar scores of 1, 1, 1 at 1, 5 and 10 min respectively. After a failed attempt at nasotracheal intubation, an emergent tracheostomy was performed. However, the infant expired shortly after placement. Postmortem examination of the baby revealed congenital absence of the mandible (agnathia), microstomia with a slit-like oral opening, posterior choanal atresia, proptosis, and external ears placed ventrally with posterior rotation approaching each other in the midline. Amniocentesis revealed normal chromosomes

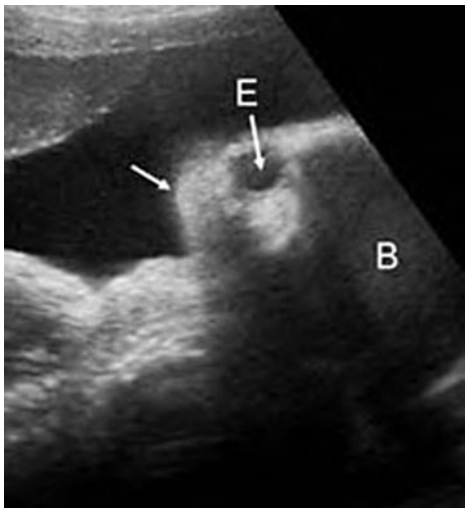

Fig. 3 Prenatal ultrasound showed absence of fetal jaw (*arrow*) (*E* fetal eye, *B* fetal brain)

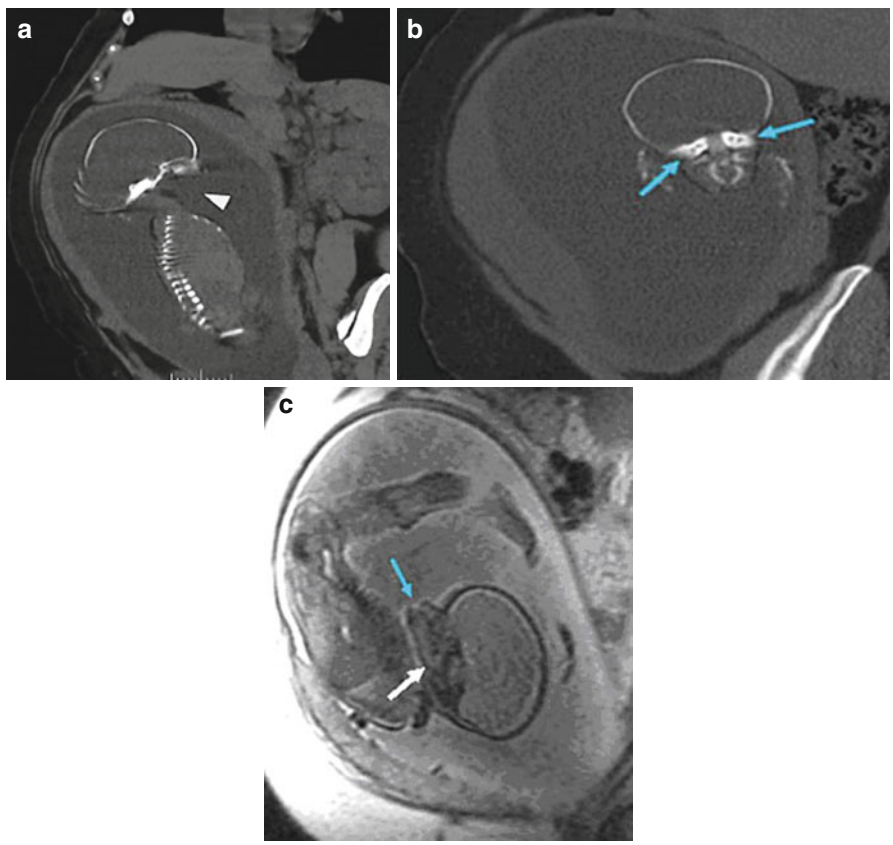

Fig. 4 (**a**–**c**) Maternal abdominal T2 MRI showed agnathia (*blue arrow*) and the lower end of the large horizontal ear meeting at the jaw area (*white arrow*)

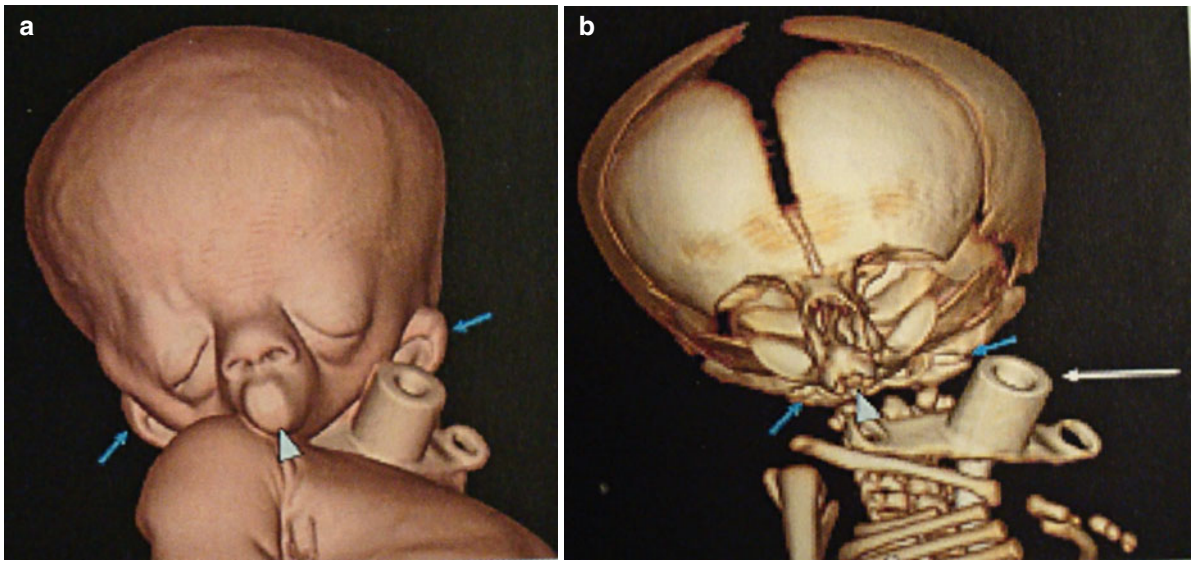

Fig. 5 (**a**, **b**) Postmortem CT scan demonstrated mandibular agnathia with synotia (posterior rotation with ventromedial displacement of the external ear structures approaching fusion near the midline), hypoplasia of the superior maxillary bone and persistece of the inner ears in their initial fetal position

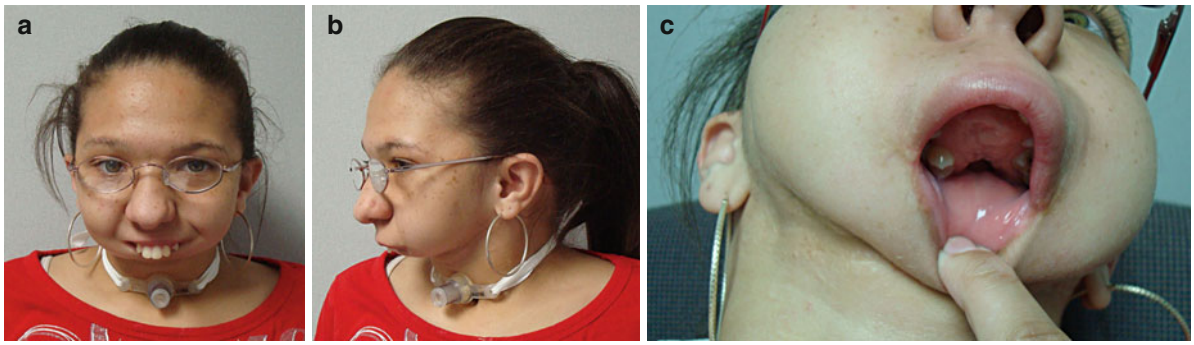

Fig. 6 (**a**–**c**) A 20-year-old female with agnathia with tracheotomy. She has severe microretrognathia due to absence of mandible, cleft palate, Arnold-Chiari malformation, severe bilateral hearing loss, Klippel-Feil syndrome, and scoliosis

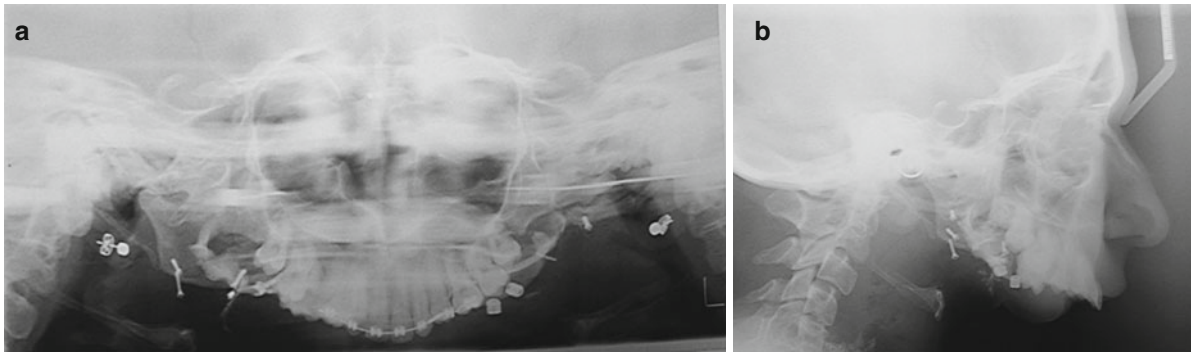

Fig. 7 (**a**, **b**) Radiographs of orofacial structures showed absence of mandible

Aicardi Syndrome

In 1965, Aicardi et al. reported a new syndrome consisting of spasms in flexion, callosal agenesis, and ocular abnormalities. Actual frequency of the condition is not known, but about 1–4% of cases of infantile spasms from tertiary referral centers may be due to Aicardi syndrome.

Synonyms and Related Disorders

Agenesis of corpus callosum with chrioretinal abnormality

Genetics/Basic Defects

1. Inheritance (Aicardi 2005)
   a. An X-linked dominant, lethal in males (Aicardi 1999)
   b. Almost exclusively affects females with two X chromosomes (heterozygous for a particular mutant X-chromosome gene to manifest)
   c. Exceptions
      i. Boys with XXY chromosome constitution (Hopkins et al. 1979; Aicardi 2005; Chen et al. 2009) allowing heterozygous expression of the gene as in the female
      ii. Two phenotypic boys with 46,XY males (Curatolo et al. 1980; Aggarwal et al. 2000): Aicardi has disputed the observations that are too atypical for classification as Aicardi syndrome due to the presence of lissencephaly or chorioretinal lesions not reminiscent of lacunae (Aicardi 1980).
      iii. 5-year-old male was reported to have clinical triad of Aicardi syndrome (Chappelow et al. 2008): Routine cytogenetic analysis showed 46, XY. A chromosome microarray analysis failed to detect any known microdeletion or microduplication. The possibility of low mosaic for 47,XXY Klinefelter cannot be ruled out.
   d. Not known to be a familial condition, except an isolated familial instance involving two sisters (Molina et al. 1989)
   e. The mutation
      i. Seems to arise de novo, accounting for the almost complete absence of familial cases
      ii. Could occur as a postzygotic event in early embryonic development as suggested by the observation of a monozygotic twin in a pair in which only one twin had Aicardi syndrome, the other being unaffected (Costa et al. 1997)
2. A gene responsible for Aicardi syndrome has not been identified
3. Gene map postulated on chromosome Xp22.3 from an observation in an affected girl with t(X;3)(p22;q12)

Clinical Features

1. Classic triad
   a. Pathognomonic chorioretinal lacunae
      i. Multiple, rounded, unpigmented, and yellow-white lesions
      ii. Occasionally unilateral
      iii. May be absent in rare cases
   b. Infantile spasms: the most characteristic type of seizure

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_6,
© Springer Science+Business Media, LLC 2012

i. Frequently asymmetric or even unilateral (Bour et al. 1986)
ii. Often preceded or precipitated by a focal clonic or tonic seizure limited to the side in which the spasms predominate
c. Agenesis of the corpus callosum
2. Other CNS abnormalities
a. Ependymal cysts
b. Choroid plexus papillomas
c. Cortical migration abnormalities
d. Optic disc coloboma
e. Hydrocephaly
f. Porencephaly
g. Cerebellar agenesis
h. Heterotopias
3. Variable neurologic abnormalities
a. Hemiparesis or hemiplegia
i. The most frequent abnormality
ii. Often on the side where the spasms predominate
b. Quadriplegia
c. Hypotonia
d. Hypertonia
e. Development of microcephaly, though head circumference is normal at birth
4. Microphthalmia
5. Extra-CNS tumors
a. Soft palatal benign teratoma
b. Hepatoblastoma
c. Parapharyngeal embryonal cell carcinoma
d. Limb angiosarcoma
e. Scalp lipoma
f. Multiple gastrointestinal polyps
6. Scoliosis or costovertebral anomalies
7. Severe cognitive and physical handicaps
a. Global developmental delay
b. Moderate to severe mental retardation in most patients
c. Unable to ambulate in most children
d. Limited visual ability
8. New diagnostic criteria (Aicardi 1999, 2005)
a. Classic triad
i. Infantile spasms
ii. Chorioretinal lacunae
iii. Agenesis/dysgenesis of the corpus callosum
b. New major features (present in most patients studied by MRI)
i. Cortical malformations, mostly microgyria (probably constant but may not be possible to evidence)
ii. Periventricular and subcortical heterotopia
iii. Cysts around the third ventricle and/or choroid plexuses
iv. Papillomas of choroid plexuses
v. Optic disc/nerve coloboma
c. Supporting features (present in some cases)
i. Vertebral and costal abnormalities
ii. Microphthalmia and/or other eye abnormalities
iii. "Split-brain" EEG (associated suppression-burst tracing)
iv. Gross hemispheric asymmetry
9. Estimated survival rate
a. 76% at 6 years of age
b. 40% at 15 years of age

Diagnostic Investigations

1. Ophthalmological examination
a. Choroid retinal lacunae
b. Optic disc coloboma
2. Electroencephalograms
a. "Split-brain" EEG
b. Asymmetry or asynchrony
c. Quasiperiodicity
d. Hypsarrhythmia
3. CT or MRI of the brain
a. Agenesis or partial agenesis of the corpus callosum
b. Choroid plexus papillomas
c. Cerebellar dysgenesis
d. Cortical heterotopias
e. Porencephaly
f. Agenesis or hypoplasias of the cerebellar vermis
4. Radiography for skeletal malformations
5. Chromosome analysis in case of Klinefelter syndrome
6. Not caused by copy number variants detectable with currently used high-resolution array platform (Wang et al. 2009)
7. Histopathology
a. Multiple brain malformations
i. Complete or partial agenesis of the corpus callosum
ii. Cortical heterotopias

iii. Gyral malformation
iv. Intraventricular cysts
v. Microscopic evaluation of the parenchyma
a) Disordered cellular organization
b) Disruption of the normal layered appearance of the cortex

b. Chorioretinal lacunae
i. Well-circumscribed, punched-out lesions in the retinal pigment epithelium and choroid
ii. Severely disrupted retinal architecture
a) All layers are thinned.
b) Decreased choroidal vessel number and caliber are decreased
c) Presence of pigmentary ectopia and pigmentary epithelial hyperplasia

Genetic Counseling

1. Recurrence risk
   a. Patient's sibs: recurrence not likely (exception with one report of two affected sibs, likely due to gonadal mosaicism in one of the parent).
   b. Patient's offspring: 50% of offspring of affected females are expected to carry the abnormal X chromosome but affected individuals are not expected to survive to reproduce.
2. Prenatal diagnosis: not available currently. The prenatal ultrasonographic findings include:
   a. Arachnoid cysts
   b. Agenesis of the corpus callosum (development of the corpus callosum may not be complete until 22 weeks of gestation)
   c. Ventriculomegaly
3. Management
   a. Anticonvulsants for control of seizures
   b. Specific therapy for infantile spasm
      i. Adrenocorticotropic hormone (ACTH): effective for some patients
      ii. Vigabatrin, a more recently introduced therapy for infantile spasm
         a) An enzyme that breaks down GABA, the major inhibitory neurotransmitter in the brain
         b) Effective for infantile spasm without the serious life-threatening adverse effects of ACTH
         c) Possible ophthalmologic sequelae of constriction of the visual fields
         d) Not currently approved for use in the USA
   c. A multidisciplinary team approach to developmental handicaps
   d. Orthopedic surveillance and treatment of scoliosis
   e. Vigorous treatment of any infection as pulmonary problems are the commonest cause of death

Alagille Syndrome

In 1969, Alagille et al. described a syndrome characterized by chronic cholestasis resulting from paucity of interlobular bile ducts, peripheral pulmonary stenosis, butterfly-like vertebral arch defect, posterior embryotoxon, and peculiar facies. The syndrome is also known as arteriohepatic dysplasia.

Alagille syndrome occurs in approximately 1 in 60,000 live births based on the presence of neonatal cholestasis (Danks et al. 1977). This may be an underestimate as molecular testing has demonstrated that many individuals with a disease-causing mutation do not have neonatal liver disease (Kamath and Poccoli 2003).

Synonyms and Related Disorders

Arteriohepatic dysplasia; *JAG1*-related Alagille syndrome; NOTCH2-related Alagille syndrome

Genetics/Basic Defects

1. Inheritance:
   a. Sporadic in 45–50% of cases
   b. Autosomal dominant
      i. Reduced penetrance
      ii. Variable expressivity
   c. Alagille syndrome gene mapped to 20p12 (Li et al. 1996)
2. Molecular defect
   a. Caused by mutations or deletions of Jagged-1 gene (*JAG1*), encoding a ligand for the NOTCH transmembrane receptor, implicated in cell differentiation (Li et al. 1997)
   b. More than 120 described intragenic mutations of the *JAG1* gene
   c. No clear genotype–phenotype correlation in Alagille syndrome
   d. NOTCH2 mutations were identified in 2/11 individuals with classic Alagelle syndrome who do not have an identifiable *JAG1* mutation (McDaniel et al. 2006)

Clinical Features

1. High variability of phenotypic findings
2. Major features
   a. Neonatal chronic cholestasis
      i. Episodes of jaundice separated by periods of remission
      ii. Pruritus
      iii. Hepatomegaly
      iv. Splenomegaly: may be associated with portal hypertension
      v. Xanthoma: progressive and observed in:
         a) Extensor surface of the fingers
         b) Palmar creases
         c) Nape of the neck
         d) Anal folds
         e) Popliteal fossa
         f) Inguinal areas
   b. Facial features
      i. Broad prominent forehead
      ii. Deep-set, widely spaced eyes
      iii. Long, straight nose
      iv. Underdeveloped mandible

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_7,
© Springer Science+Business Media, LLC 2012

   c. Complex congenital cardiovascular anomalies
      i. Pulmonary artery stenosis (67%)
      ii. Ventricular septal defects
      iii. Patent ductus arteriosus
      iv. Pulmonary valve atresia
      v. Tetralogy of Fallot (7–16%)
      vi. Tricuspid regurgitation
      vii. Right ventricular hypertrophy
   d. Vertebral arch anomalies (butterfly-like vertebrae)
   e. Posterior embryotoxon (prominent Schwalbe's ring)
3. Less frequently associated features
   a. Growth retardation
   b. Neurologic complications from vitamin E deficiency
   c. Mental retardation (2–30%)
   d. Systemic vascular malformations
      i. Coarctation of the aorta
      ii. Middle aortic syndrome
      iii. Arterial hypoplasia (hepatic, renal, carotid, celiac)
      iv. Artery stenosis (renal, subclavian)
      v. Moyamoya disease
      vi. Carotid artery aneurysm
      vii. Intracranial hemorrhage
      viii. Hypoplastic portal vein branch
   e. Renal abnormalities
      i. Interstitial nephritis
      ii. Glomerular intramembranous and mesangial lipidosis
      iii. Tubular dysfunction
      iv. Renal hypoplasia
      v. Renal agenesis
      vi. Horseshoe kidney
      vii. Cystic disease
   f. Small bowel atresia or stenosis
   g. Pancreas
      i. Diabetes
      ii. Exocrine pancreatic insufficiency
   h. Lung: tracheal and bronchial stenosis
   i. Larynx: high-pitched voice
   j. Eye abnormalities
      i. Posterior embryotoxon
      ii. Optic disc drusen
      iii. Angulated retinal vessels
      iv. Pigmentary retinopathy
      v. Iris strands
      vi. Cataract
      vii. Myopia
      viii. Strabismus
      ix. Glaucoma
      x. Fundus hypopigmentation
   k. Skeletal abnormalities
      i. Lack of normal progression of interpedicular distance in the lumbar spine
      ii. Spina bifida
      iii. Shortening of distal phalanges and metacarpal bones
      iv. Clinodactyly
   l. Hepatocellular carcinoma: a rare complication of Alagille syndrome (Bhadri et al. 2005)
4. Prognosis
   a. Characterized by recurrent episodes of cholestasis
   b. Often associated with common respiratory tract infections, especially during the first year of life
   c. Good long survival but mortality rate may be up to 25%

Diagnostic Investigations

1. Biochemical studies (Alagille et al. 1987)
   a. Hypercholesterolemia: Cholesterol levels ranging from 220–1,600 mg% in all children with xanthomas (Garcia et al. 2005)
   b. Hyperphospholipidemia
   c. Hypertriglyceridemia
   d. Prominent increase in the pre-β-lipoprotein and apolipoprotein B levels
   e. Very high total bile acids, gammaglutamyl transferase, and alkaline phosphatase blood levels
2. Ophthalmologic assessment for posterior embryotoxon and other ocular anomalies
3. Abdominal ultrasonography
   a. Evaluation of the hepatobiliary tree and hepatic parenchyma
   b. Evaluation of renal anomalies
4. Radiography for vertebral anomalies
5. Other imagings
   a. Dimethyl iminodiacetic acid scanning
   b. Magnetic resonance cholangiopancreatography
   c. Endoscopic retrograde cholangiopancreatography
   d. Intraoperative cholangiography
6. Echocardiography for cardiovascular malformations
7. Histology (liver biopsy)
   a. Paucity of interlobular bile ducts
   b. Cholestasis in hepatocytes and canaliculi

8. Molecular genetic analysis
   a. Sequence analysis of the *JAG1* gene detects mutations in approximately 70% of individuals who meet clinical diagnostic criteria.
   b. FISH detects a microdeletion of 20p12, including the entire *JAG1* gene, in approximately 5–7% of cases.
   c. Mutations in NOTCH2 gene have been observed in fewer than 1% of individuals with Alagille syndrome (McDaniell et al. 2006)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. A low but slightly increased risk due to parental germline mosaicism in clinically normal appearing parents
      ii. A 50% risk if a parent is affected
   b. Patient's offspring: a 50% risk of having an offspring with Alagille syndrome
2. Prenatal diagnosis
   a. Prenatal ultrasonography
      i. Severe pulmonary artery stenosis
      ii. Progressive severe intrauterine growth retardation
   b. Prenatal molecular diagnosis on fetal DNA obtained from amniocentesis or CVS is available if a disease-causing mutation (demonstrated by molecular genetic testing) or a deletion (detected by FISH) is identified in an affected family member
   c. Preimplantation genetic diagnosis (Renbaum et al. 2007)
      i. A polar body (PB)-based multiplex fluorescent PCR reaction for a female affected with Alagille syndrome
      ii. The protocol included analysis of the Jagged 1 (*JAG1*) familial mutation and five closely linked highly polymorphic markers (D20S162, D20S901, D20S894, and D20S186)
      iii. A reliable diagnosis was possible in all developing embryos
3. Management
   a. Medical care (Alagille et al. 1987)
      i. Low-fat diets with medium-chain triglyceride supplementation
      ii. Hypercaloric diets to severely malnourished patients
      iii. Vitamin supplements
      iv. Pruritus
         a) Antihistamine agents
         b) Cholestyramine or rifampin in management of bile acid-induced pruritus
   b. Surgical care for patients with refractory disease
      i. Biliary diversion
      ii. Eventual orthotopic liver transplantation (Englert et al. 2006; Arnon et al. 2010)
         a) Indications: Progressive hepatic dysfunction, severe portal hypertension, failure to thrive, intractable pruritus, and osteodystrophy
         b) Associated with good long-term graft survival, although it is lower than that in biliary atresia
         c) Death from graft failure, neurological, and cardiac complications was significantly higher than in patients with biliary atresia
         d) The higher rate of mortality and graft failure may be related to the multisystem involvement of Alagille syndrome
      iii. Cardiac surgery for complex congenital heart defects

Albinism

Albinism, derived from the Latin *albus*, is a group of inherited disorders in which melanin biosynthesis is reduced or absent. It involves the skin, hair, and eyes (oculocutaneous albinism) or may be limited primarily to the eyes (ocular albinism). Current classification of albinism is determined by the affected gene, making the previously used terms "partial or complete" and "tyrosinase-positive or tyrosinase-negative" obsolete (King et al. 2007; Summers et al. 1996). The prevalence of all forms of albinism varies considerably worldwide, estimated at approximately 1/17,000 and about 1 in 70 people carry a gene for oculocutaneous albinism (OCA) (Grønskov et al. 2007).

Synonyms and Related Disorders

Chediak–Higashi syndrome; Griscelli syndrome; Hermansky–Pudlak syndrome; Oculocutaneous albinism (OCA) type 1 (tyrosinase-negative OCA, tyrosinase-related OCA); OCA type 2 (tyrosinase-positive OCA); OCA type 3 (Brown albinism); OCA, X-linked

Genetics/Basic Defects

1. Classification of albinism (genetic heterogeneity)
   a. OCA: a common phenotype for a group of recessive genetic disorders of melanin synthesis. Mutations in at least 12 genes are responsible for this phenotype. Mutations in OCA-related genes result in reduction of melanin synthesis by the melanocytes:
      i. Common types of OCA with cutaneous and ocular hypopigmentation without significant involvement of other tissue
         a) Oculocutaneous albinism 1 (OCA1): subdivided into OCA1A, OCA1B, OCA1ts
         b) Oculocutaneous albinism 2 (OCA2)
         c) Oculocutaneous albinism 3 (OCA3)
      ii. Less common types of OCA with more complex manifestations
         a) Hermansky–Pudlak syndrome
         b) Chediak–Higashi syndrome
   b. Ocular albinism:
      i. Ocular albinism 1 (OA1): X-linked recessive
      ii. Autosomal recessive ocular albinism (AROA)
2. Molecular defects causing four known types of OCA (Grønskov et al. 2007)
   a. OCA1 (tyrosinase-related albinism)
      i. Inherited in an autosomal recessive manner
      ii. Caused by mutations of tyrosinase gene (*TYR*) located at 11q14.3.
      iii. Several different types of mutations to the tyrosinase gene (missense, nonsense, and frameshift) are responsible for producing OCA1A and OCA1B.
      iv. OCA1A ("tyrosinase negative" albinism with inactive enzyme) produced by null mutations of the *Tyr* gene:
         a) 0% tyrosinase enzyme activity
         b) Over 100 mutations spanning all parts of the gene reported

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_8,
© Springer Science+Business Media, LLC 2012

c) Compound heterozygotes with different maternal and paternal alleles in majority of patients

v. OCA1B (tyrosinase-related albinism with partially active enzyme) produced by leaky mutations of the *Tyr* gene:
a) "Yellow" form of albinism with 5–10% activity of tyrosinase
b) A base substitution within the gene may result in reduced rather than completely abolished enzyme activity

vi. OCA1ts (tyrosinase-related albinism with thermolabile enzyme):
a) A temperature-sensitive tyrosinase is only partly functional.
b) The first reported cases had a missense substitution within the tyrosinase gene.

b. OCA2 ("tyrosinase-positive" albinism): brown OCA in Africans
i. *OCA2* gene: the pink-eye dilution gene (*p*) located at 15q11.2-q12
ii. Caused by mutations of the P gene on the chromosome 15, homologous to the mouse pinked-eye dilution, or p gene
iii. Inherited in an autosomal recessive manner
iv. The mutated region is also deleted in Prader–Willi syndrome (PWS) and Angelman syndrome (AS), accounting for close linkage of OCA2 to PWS and AS

c. OCA3 (Brown albinism)
i. *OCA3* gene: tyrosinase-related protein-1 gene (*TRP1*) located at 9p23
ii. The gene homologous to the mouse "brown" gene
iii. Mutation of the gene possibly synergistic with a polymorphism or partially active mutation in OCA1 or OCA2
iv. 1 in 8,500 in Africans
v. Rare in white Europeans and Asians

d. OCA4
i. Resulting from mutation in the *SLC45A2* gene, formerly called membrane-associated transporter protein gene (*MATP*), located at 5p13.3
ii. 1 in 85,000 in Japanese
iii. Rare in white Europeans

3. Molecular defects causing other types of albinism
a. XLOA (X-linked ocular albinism, OA1)
i. *GPR143*, located at Xp22.3-22.2, is the only gene known to be associated with XLOA
ii. Intragenic deletions, frameshift mutations, and point mutations identified
iii. Affects males because of X-linked recessive inheritance
iv. 85–90% of obligate carriers show pigmentary mosaicism in the fundi, representing the lionization effect (X-inactivation), although there are no functional sequelae

b. OAR (autosomal recessive ocular albinism)
i. Gene mapping: 6q13-q15
ii. May not be a clinical entity
iii. Tyrosinase in some cases
iv. P protein in some cases

c. Hermansky–Pudlak syndrome (HPS): a bleeding disorder due to absence of dense bodies in platelets
i. Hermansky–Pudlak syndrome 1 is caused by mutations of the *HPS1* gene which is localized to 10q23.
ii. *HPS2* gene was localized to 5q13. Hermansky–Pudlak syndrome 2 is caused by mutation of the *APB1* gene, which is localized to 5q13, resulting in a defect in adapter complex 3 AP-3, β3A subunit.

d. Chediak–Higashi syndrome
i. Immunodeficiency associated with neurologic problems
ii. Defect in *CHS1* gene (lysosomal trafficking regular gene) located at 1q42-44

e. Griscelli syndrome: resulting from mutations in the *RAB27A* gene located or *MYO5A* gene, both located at 15q21

4. Pathophysiology
a. Melanin in the skin
i. Melanin, a photoprotective pigment in the skin, absorbs UV light from the sun, thus preventing skin damage.
ii. Normal skin tans upon sun exposure due to increased melanin pigment in the skin.
iii. Patient with albinism develop sunburn because of the lack of melanin.

b. Consequence of the absence of melanin during the development of the eye
i. Hypoplasia of fovea
ii. Alteration of neural connections between the retina and the brain

c. Melanin pathway
i. Consisting of a series of reactions that converts tyrosine into two types of melanin,

black-brown eumelanin and red-blond pheomelanin
   ii. Tyrosinase: a major enzyme in a series of conversions to melanin from tyrosine and it is also responsible for converting tyrosine to DOPA and then to dopaquinone, which subsequently converts to either eumelanin or pheomelanin
   iii. Two other enzymes involved in the formation of eumelanin: tyrosinase-related protein 1 (TRP1, DHICA oxidase) and tyrosinase-related protein 2 (TRP2, dopachrome tautomerase). Mutation of the TRP1 results in OCA3; mutation of the TRP2 does not cause albinism.
   iv. P protein, a melanosomal membrane protein, believed to be involved in the transport of tyrosine prior to melanin synthesis. Mutation of this *P* gene causes OCA2.
5. Pathogenesis of the ocular features
   a. Development of the optic system highly dependent on the presence of melanin
   b. Ocular features appear if melanin is reduced or absent
   c. Mechanisms
      i. Misrouting of the retinogeniculate projections resulting in abnormal decussation of optic nerve fibers
      ii. Sensation of photophobia and decreased visual acuity caused by light scattering within the eye
      iii. Light-induced retinal damage postulated as a contributing mechanism to decreased visual acuity
      iv. Foveal hypoplasia: the most significant factor causing decreased visual acuity

Clinical Features

1. General clinical features of albinism
   a. Skin, hair, and eye discoloration caused by abnormalities of melanin metabolism (might not be obvious in ocular albinism)
   b. Reduced visual acuity due to foveal hypoplasia (common to all types of albinism, even though a rudimentary annular reflex has been described in a few patients with better visual acuity) (Summers 2009)
   c. Translucent iris due to reduction in iris pigment
   d. Visible choroid vessels due to reduction in retinal pigment
   e. Photophobia due to iris pigmentary abnormalities
   f. Anomalous visual pathway projections due to misrouting of the optic nerves at the chiasm
   g. Nystagmus (Summers 2009)
      i. Due to abnormal decussation of optic nerve fibers
      ii. Typically pendular in nature
      iii. More noticeable with fatigue and illness
      iv. Amplitude of nystagmus diminishes as child matures
   h. Alternating strabismus
   i. Hyperopia, myopia, and astigmatism
2. Oculocutaneous albinism 1 (OCA1)
   a. Incidence: approximately 1 in 40,000 individuals
   b. Oculocutaneous albinism 1A (OCA1A)
      i. Classic "tyrosinase-negative" OCA: complete lack of melanin production throughout life
      ii. Most severe form of OCA
      iii. White hair and white skin that does not tan
      iv. Blue and translucent irides that do not darken with age
      v. Foveal hypoplasia
      vi. No tanning potential
      vii. At risk for sun burning and skin cancer
      viii. Diminished visual acuity as low as 20/400
      ix. Photophobia and nystagmus worst in this subtype
   c. Oculocutaneous albinism 1B (OCA1B)
      i. Yellow mutant type OCA, referred to as Amish albinism, or xanthous albinism
      ii. Variable pigmentation ranging from very little cutaneous pigmentation to nearly normal skin pigmentation
      iii. Increased skin, hair, and eye pigment with age and tan with sun exposure
      iv. Yellow hair pigment develops in the first few years of life and continuously accumulates pigment, principally yellow-red pheomelanin, in the hair, eyes, and skin in the later life
      v. Decreased visual acuity improving with age
   d. Temperature-sensitive albinism (OCA1ts)
      i. A subtype of OCA1B
      ii. Mutation of the tyrosinase gene that produces a temperature-sensitive tyrosinase enzyme

iii. The heat-sensitive tyrosinase enzyme activity is approximately 25% of the normal tyrosinase activity at 37°C. The activity improves at lower temperatures.
iv. Dark hair pigment in the arms and legs (cooler areas of the body) while axillary and scalp hair remains white
v. Pigment is absent in the fetus because of high fetal temperature.

3. Oculocutaneous albinism 2 (OCA2)
   a. "Tyrosinase-positive" OCA
   b. Incidence: approximately 1 in 15,000 individuals
   c. Most prevalent type of albinism in all races and especially frequent among African-American population (1 in 10,000)
   d. Phenotypic variability
      i. Ranging from absence of pigmentation to almost normal pigmentation
      ii. Absence of black pigment (eumelanin) in the skin, hair, or eyes at birth
      iii. Gradual development of pigmentation with age
      iv. Increased pigmentation resulting in improved vision
4. Oculocutaneous albinism 3 (OCA3)
   a. Previously known as red/rufous OCA
   b. Incidence of the disease unknown
   c. Phenotype in African patients
      i. Light brown skin and hair
      ii. Blue-brown irides
      iii. Ocular features not fully consistent with diagnosis of OCA (no iris translucency, nystagmus, strabismus, or foveal hypoplasia)
   d. Phenotype in Caucasians and Asians: not known
5. Oculocutaneous albinism 4 (OCA4)
   a. Cannot be distinguished from OCA2 on clinical findings
   b. Hypopigmentation of the skin and hair
   c. Characteristic ocular changes found in all other types of albinism
      i. Nystagmus
      ii. Reduced iris pigment with iris translucency
      iii. Reduced retinal pigment with visualization of the choroidal blood vessels on ophthalmoscopic examination
      iv. Foveal hypoplasia associated with reduction in visual acuity
      v. Misrouting of the optic nerves at the chiasm associated with alternating strabismus
      vi. Reduced stereoscopic vision
      vii. An altered visual-evoked potential (VEP)
6. Ocular albinism 1 (OA1) (Lewis 2011)
   a. X-linked recessive OA (XLOA)
   b. Incidence of the disease approximately 1 in 50,000 individuals
   c. Extreme variability in clinical expression
   d. Involving eyes only
      i. Decreased visual acuity
      ii. Refractive errors: typical findings
         a) Hypermetropia
         b) Astigmatism
      iii. Hypopigmentation of the fundus and the iris
      iv. Absent foveal reflex (foveal hypoplasia)
      v. Congenital nystagmus
      vi. Photophobia
      vii. Strabismus
      viii. Iris translucency
      ix. Posterior embryotoxon
      x. Loss of stereoscopic vision due to misrouting of the optic tracts
   e. Normal skin
   f. Male manifesting complete phenotype
   g. Carrier females
      i. Normal vision
      ii. Hypopigmented streaks (characteristic patchy hypopigmentation as a result of mosaic inactivation of the affected X chromosomes) in the periphery
      iii. Marked iris translucency
   h. Severity depending on ethnic background: less severe in races exhibiting very dark constitutive skin pigmentation than those more lightly pigmented
7. Autosomal recessive ocular albinism (OAR)
   a. Children with ocular features of albinism and normal cutaneous pigmentation born to normally pigmented parents
   b. Classified as autosomal recessive because both males and females are affected
   c. Not considered a clinical entity
8. Hermansky–Pudlak syndrome
   a. A group of related disorders
      i. Common oculocutaneous albinism

   ii. A platelet storage disorder
   iii. Ceroid-lipofuscin lysosomal storage disease
  b. An autosomal recessive disorder with very variable expression
  c. Incidence of the disease: rare, except in Puerto Rico where its frequency is 1 in 1,800 individuals (Witkop et al. 1990)
  d. Bleeding diathesis resulting from a platelet storage pool deficiency
  e. Patients exhibit severe immunologic deficiency with neutropenia and lack of killer cells (DePinho and Kaplan 1985)
  f. Ceroid storage disease
   i. Accumulation of a Ceroid-lipofuscin material in various organ systems
   ii. Interstitial pulmonary fibrosis
   iii. Granulomatous colitis and gingivitis
   iv. Kidney failure
   v. Cardiomyopathy
9. Chediak–Higashi syndrome (Russell-Eggitt 2001)
  a. An autosomal recessive disorder with variable expression
  b. Consisting of a very rare group of conditions
  c. Severe immune disorder
   i. Abnormal intracellular granules in most cells, especially white cells
   ii. Susceptible to bacterial infections
   iii. Defective neutrophils function
   iv. Episodes of macrophage activation known as accelerated phases:
    a) Fever
    b) Anemia
    c) Neutropenia
    d) Occasionally thrombocytopenia
    e) Hepatosplenomegaly
    f) Lymphadenopathy
    g) Jaundice
  d. Hypopigmentation of skin, hair, irides, and ocular fundi
  e. Bleeding diathesis
   i. Easy bruising
   ii. Mucosal bleeding
   iii. Epistaxis
   iv. Petechiae
  f. Eye symptoms
   i. Photophobia
   ii. Nystagmus
   iii. Reduced stereoacuity
   iv. Strabismus
  g. Often succumb during childhood to severe viral and bacterial infections, bleeding or development of the accelerated phase
  h. May develop a peripheral and cranial neuropathy in survivors
   i. Autonomic dysfunction
   ii. Weakness and sensory deficits
   iii. Loss of deep tendon reflexes
   iv. Clumsiness with a wide-based gait
   v. Seizures
   vi. Abnormal EEG
   vii. Abnormal EMG with decreased motor nerve conduction velocities
10. Griscelli syndrome (Mancini et al. 1998)
  a. A rare disorder
  b. Immune impairment
  c. Neurological deficit
  d. Hypopigmentation of skin and hair
  e. Presence of large clumps of pigment in hair shafts
11. Waardenburg syndrome: a syndrome of sensory deafness and partial albinism, referred to as the albinism-deafness syndrome (Waardenburg 1951)

Diagnostic Investigations

1. Ophthalmologic examination for detection of reduced retinal pigment with visualization of the choroidal blood vessels (OCA1) and foveal hypoplasia
2. Visual acuity reduction
3. Hair bulb incubation assay for tyrosinase activity
  a. OCA1A: no tyrosinase activity
  b. OCA1B: greatly reduced activity of tyrosinase but still present
4. Visual-evoked potential (VEP): an accurate diagnostic test for albinism by demonstrating an asymmetry of VEP between the two eyes secondary to misrouting of optic pathways
5. Electron microscopy of skin and hair bulb: not routinely performed but probably the best diagnostic method for albinism.

c. Chediak–Higashi syndrome
   i. Treat infections
   ii. Bone marrow transplantation: improves immunological status but no effect on ocular and cutaneous albinism

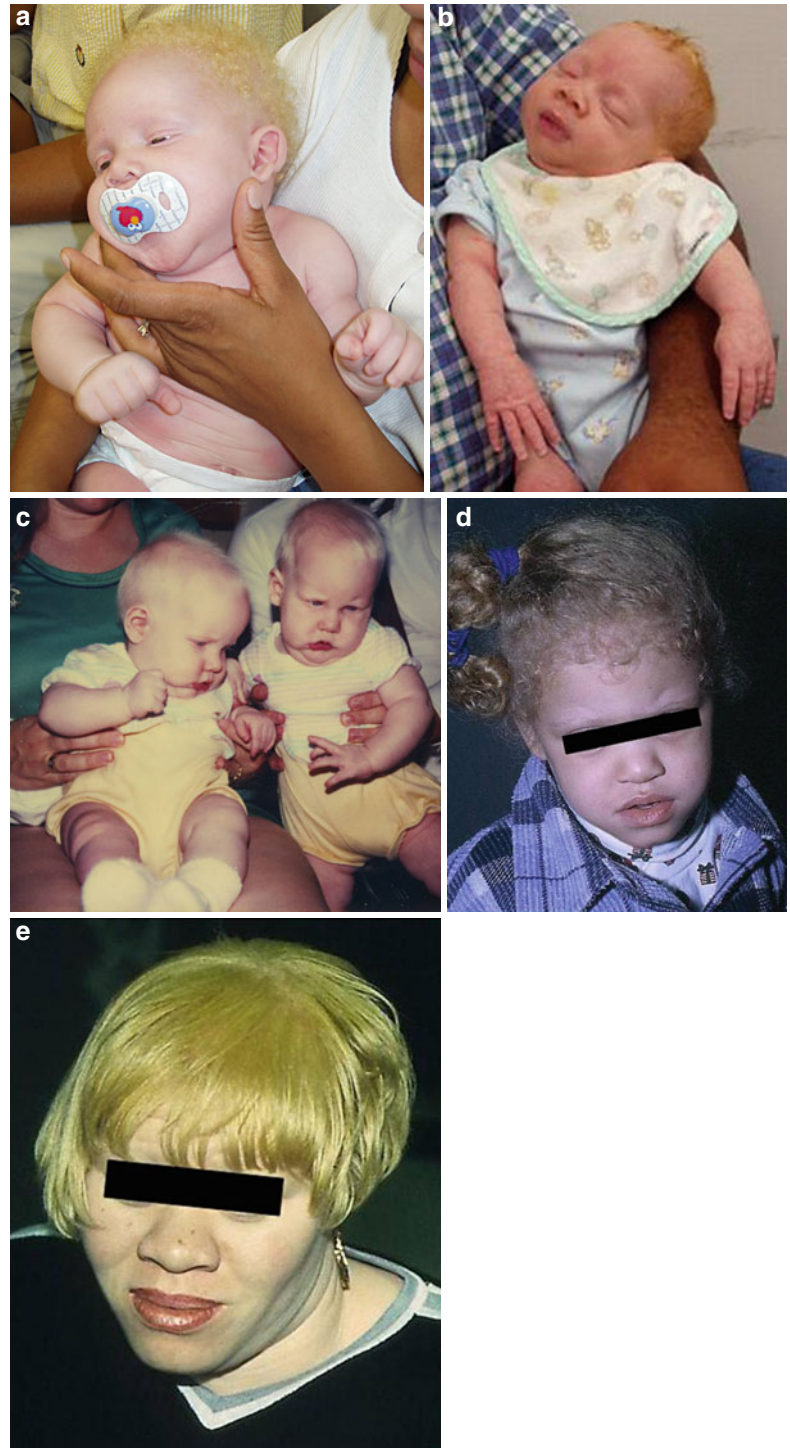

Fig. 1 (**a–e**) Oculocutaneous albinism in different age groups including one set of identical twins

Fig. 2 A 7-month-old infant boy with light skin color, *silverish white* scalp hair, eyebrows, and eyelashes, and absence of nystagmus or strabismus. The infant possesses one detectable mutation in the *OCA2* gene encoding the P protein, namely, V433I: c.1327G > A. This mutation has been reported in the literature and is a known cause of OCA2. The second variation, IVS12-44C > T was noted. A homozygous sequence change (IVS7-17insA) was observed in the *OCA3* gene. The intronic sequence changes in the *OCA2* and *OCA3* genes have not been reported in the literature and therefore clinical significance is unknown. No mutations were observed in the *OCA1* gene, the *OCA4* gene, or the *OA1* gene

Alpha-Thalassemia X-linked Mental Retardation Syndrome

Alpha-thalassemia X-linked mental retardation (ATRX) syndrome, one form of X-linked mental retardation, is characterized by severe mental retardation, typical dysmorphic facies, genital abnormalities, and an unusually mild form of hemoglobin H disease (Gibbons et al. 1995a).

Synonyms and Related Disorders

ATRX syndrome; X-linked mental retardation-hypotonic face syndrome

Genetics/Basic Defects

1. An X-linked recessive disorder
2. The gene involved in the disease, *ATRX*, is mapped to Xq13.3
3. The function of the ATRX protein: unknown but may play a role in gene expression based on the fact that alpha globin expression is perturbed in the patients
4. Genetically related (allelic) disorders
   a. Several X-linked mental retardation (XLMR) syndromes: These disorders should be considered to be in the phenotypic spectrum of ATRX syndromes and there are no compelling reasons to maintain the syndromic names.
      i. Carpenter–Waziri syndrome
      ii. Holmes–Gang syndrome
      iii. Chudley–Lowry syndrome
      iv. XLMR with spastic paraplegia
      v. XLMR with epilepsy
      vi. Nonsyndromic XLMR
   b. ATRX mutations are identified in the following two syndromes but not in the original reported families and therefore the relationship between ATRX syndrome and these two syndromes is unclear.
      i. Juberg–Marsidi syndrome
      ii. Smith–Fineman–Myers syndrome

Clinical Features

1. Central nervous system features
   a. Global developmental delay
      i. Limited expressive language
      ii. Delayed walking until late childhood or unable to ambulate
   b. Generalized hypotonia, a hallmark of the condition, in early childhood, contributing to facial manifestations, drooling, and developmental retardation
   c. Seizures (1/3 of cases)
2. Characteristic craniofacial features
   a. Microcephaly
   b. Upsweep of the frontal hair
   c. Telecanthus or ocular hypertelorism
   d. Small triangular nose with retracted columella
   e. Tented upper lip
   f. Prominent or everted lower lip
   g. Open mouth
   h. Other features
      i. Irregular anatomy of the pinnae
      ii. Wide spacing of the teeth

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_9,
© Springer Science+Business Media, LLC 2012

iii. Tongue protrusion
iv. Coarse facial appearance particularly after the first few years of life

3. Abnormal external genitalia: broad spectrum of possible genital anomalies but the type of genital anomaly appears to be consistent within a family
   a. Often minor anomalies
      i. First-degree hypospadias
      ii. Undescended testes
      iii. Underdevelopment of the scrotum
   b. More severe defects
      i. Second- and third-degree hypospadias
      ii. Micropenis
      iii. Ambiguous genitalia
   c. Occasional gonadal dysgenesis resulting in inadequate testosterone production and ambiguous genitalia or normally appearing female external genitalia
4. Skeletal anomalies
   a. Short stature
   b. Digital anomalies
      i. Brachydactyly
      ii. Clinodactyly
      iii. Tapered digits
   c. Joint contractures
   d. Spine anomalies
      i. Pectus carinatum
      ii. Kyphosis
      iii. Scoliosis
      iv. Dimples over the lower spine
   e. Foot anomalies
      i. Varus and valgus foot deformation
      ii. Pes planus
5. Gastrointestinal features
   a. Gastroesophageal reflux (2/3 of cases): may cause aspiration with a fatal complication in some
   b. Chronic constipation (1/3 of cases)
   c. Report of pseudo-obstruction (gastric pseudovolvulus) resulting from abnormal suspension of the stomach and constipation from colon hypoganglionosis
6. Major malformations: uncommon
   a. Ocular coloboma
   b. Cleft palate
   c. Cardiac defects
   d. Inguinal hernia
   e. Heterotaxy
   f. Asplenia

Diagnostic Investigations

1. Diagnosis is suspected on the basis of characteristic craniofacial, genital, skeletal, other somatic features, and hematological findings and should be confirmed by molecular genetic testing
2. Hematologic studies: demonstration of evidence of alpha-thalassemia
   a. Hb H inclusions (β-globin tetramers) ranging from 0.01% to 30% in erythrocytes demonstrated in most individuals with *ATRX* mutations
   b. Hemoglobin electrophoresis: demonstration of Hb H (not highly sensitive)
   c. Red blood cell indices: microcytic hypochromic anemia in some affected individuals
3. Molecular genetic testing
   a. Sequence analysis and mutation scanning of select exons
   b. Sequence analysis and mutation scanning of all exons and splice junctions
   c. Deletion/duplication analysis
   d. X-chromosome inactivation studies: The finding of nonrandom X-chromosome inactivation is not unique to ATRX syndrome and is therefore not diagnostic
4. Carrier testing in at-risk females possible when the disease-causing mutation in the family is known

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Carrier mother
         a) A 50% chance of transmitting the *ATRX* mutation
         b) Offspring with a 46,XY karyotype who inherit the *ATRX* mutation will be affected
         c) Offspring with a 46,XX karyotype who inherit the mutation are unaffected female carriers
      ii. Sibs of proband with de novo gene mutation: at increased risk of inheriting the disease-causing mutation because of possible germline mosaicism in the mother
   b. Patient's offspring: Affected individual do not reproduce

2. Prenatal diagnosis and preimplantation genetic diagnosis: possible for pregnancies at increased risk for ATRX syndrome when the disease-causing mutation in the family is known
3. Management
   a. Multidisciplinary interventions
      i. Infant stimulation
      ii. Early intervention
      iii. Special education
   b. Management of feeding and gastrointestinal problems
      i. Gavage feeding for difficulty in sucking
      ii. Fundoplication and feeding gastrostomy may be required for gastroesophageal reflux
      iii. Surgical correction of pseudovolvulus
      iv. Prevention of constipation
      v. Consider biopsy to rule out Hirschsprung's disease and colonic hypoganglionosis
      vi. Control of severe drooling
         a) Anticholinergics
         b) Botulinum toxin type A injection of the salivary glands
         c) Surgical redirecting of the submandibular ducts
   c. Seizure control
   d. Genitourinary problems
      i. Orchidopexy for cryptorchidism
      ii. Treat recurrent urinary tract infections
   e. Orthopedic management for musculoskeletal anomalies
   f. Hearing loss management
   g. Alpha-thalassemia
      i. No treatment required for the mild anemia
      ii. Iron not required unless iron stores are shown to be low

Fig. 1 (**a, b**) A 7-year-old boy with global developmental delay and the characteristic facial appearance of ATRX syndrome: upswept frontal hair line, ocular hypertelorism, epicanthal folds, a small triangular upturned nose, open mouth, tented upper lip, prominent everted lower lip, and hypotonic appearing face. He has mild microcytic, hypochromic anemia (mean cell volume 74.8 FL (76–90), MCH 23.6 pg (27–31), MCHC 31.5 g/dl (32–36)). Sequence analysis showed a C > T change at nucleotide 736 in the *XNP* gene (c.736C > T). This change results in the substitution of a cysteine for an arginine at amino acid 246 (R246C). This change is consistent with the diagnosis of ATRX syndrome. His mother has the same *XNP* gene mutation

Fig. 2 A maternal uncle was similarly affected with recurrent pneumonias, anemia, and mental retardation

Ambiguous Genitalia

Most cases of ambiguous genitalia are discovered at birth, occurring approximately once in every 1,000 live births. Genital ambiguity usually is due to virilization of genetic females or undervirilization of genetic males who have normal gonads. Less common are disorders of sexual differentiation that involve gonadal dysgenesis (Chi et al. 2008).

In females, congenital adrenal hyperplasia (CAH), specifically 21-hydroxylase deficiency, is the most common condition leading to inappropriate virilization. In males, defects in testosterone production, metabolism, or peripheral action can lead to ambiguous genitalia. Later presentations of ambiguous genitalia often include previously unrecognized genital ambiguity, inguinal hernia in a girl (e.g., complete androgen insensitivity), delayed or incomplete puberty, primary amenorrhea or virilization in a girl, breast development in a boy, and gross or cyclic hematuria in a boy (unrecognized virilized 46,XX with CAH) (Lee et al. 2006).

Synonyms and Related Disorders

Genetic disorders of sexual differentiation (gonadal dysgenesis, true hermaphroditism, sex reversal); Undervirilization of male infant; Virilization of female infant

Genetics/Basic Defects

1. Normal development of the human reproductive system (Chi et al. 2008)
   a. Sexual differentiation of the fetus begins at 6–7 weeks of gestation
   b. During embryogenesis, the fetus contains both female (müllerian) and male (wolffian) genital ducts
      i. Müllerian ducts: develop into fallopian tubes, uterus, and the upper one third of the vagina
      ii. Wolffian ducts: develop into the vas deferens, epididymis, and seminal vesicles
   c. "Default" pathway of the bipotential gonad and internal structures: female
   d. Presence of the sex-determining region Y gene (SRY) in males: activates a cascade of events that culminates in differentiation of the gonad as a testis which produces the following two key hormones
      i. Testosterone
         a) Function: stimulates wolffian duct differentiation
         b) Production: initially driven by placental human chorionic gonadotrophin (hCG) which subsequently replaced by fetal pituitary gonadotrophins after the first trimester, both acting through the luteinizing hormone (LH) receptor
         c) Local conversion of testosterone to dihydrotestosterone (DHT) by the enzyme 5-α reductase leads to fusion of the labioscrotal folds and formation of the scrotum and penis, both critical events occurring in the first trimester
      ii. Müllerian inhibiting substance (MIS) or anti-müllerian hormone (AMH): stimulates müllerian duct regression
   e. Absence of testosterone and MIS in females leads to:
      i. Involution of the wolffian ducts.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_10,
© Springer Science+Business Media, LLC 2012

ii. Differentiation of the müllerian ducts into female internal genitalia
iii. Needs both X chromosomes to develop normally differentiated and functional ovaries; females with X chromosome deletion (Turner syndrome) have abnormal gonadal differentiation and oocytes loss, leading to streak gonads.

2. Broad categories of ambiguous genitalia
   a. XX baby with virilization
      i. In the virilized XX baby, the gonads are ovaries and the internal genitalia are female.
      ii. The external genitalia are masculinized by circulating androgens to a variable degree, ranging from subtle clitoromegaly to complete labial fusion with urethral tubularization to the tip of the enlarged phallus.
      iii. If exposure occurred late, clitoromegaly without labial fusion is seen. The gonads are not palpable.
      iv. The commonest cause of virilization in the XX "female" is congenital adrenal hyperplasia. This autosomal recessive condition results from an enzymatic defect in adrenal steroidogenesis, leading to accumulation of steroids proximal to the block, which are converted to androgens. The commonest of these is 21-hydroxylase deficiency, followed by 11β-hydroxylase and 3β-hydroxysteroid dehydrogenase deficiency. The serum and urinary steroid profile will help to confirm the diagnosis. Other possible causes include exposure to exogenous androgens, such as from maternal androgens or progestin ingestion, or rarely, maternal androgen-producing tumors.
      v. The majority of true hermaphrodites also have a 46 XX chromosomal makeup, but these form a distinct group.
   b. The XY baby with undervirilization
      i. The undervirilized XY baby presents with a small phallus with severe chordee, posterior hypospadias, poorly formed, bifid scrotum with or without testicular maldescent. Inadequate testosterone production, either as a result of testicular dysgenesis or autosomal recessive enzymatic defects, is rare.
      ii. The commonest cause is a group of disorders known as androgen insensitivity syndrome (AIS), previously also known as testicular feminization syndrome. This is an X-linked disorder resulting from peripheral resistance to androgen action, either from mutations in the androgen receptor gene, or elsewhere in the molecular pathway.
      iii. Whether AIS may, in fact, be due to a defect in the conversion of dihydrotestosterone to 5-α-androstanediol remains to be seen.
      iv. 5-α-reductase deficiency, an autosomal recessive defect resulting in deficient dihydrotestosterone necessary in the virilization of the external genitalia in early embryogenesis, is another cause of undervirilization.
   c. True hermaphroditism
      i. In the true hermaphrodite, both testicular and ovarian tissues coexist.
      ii. The gonads are usually ovary-testis, or ovary-ovotestis.
      iii. The genotype is usually 46 XX, although 46 XY or mosaicism can occur.
      iv. Asymmetry of the gonads, internal and external genitalia is a feature in true hermaphroditism. The right side is more commonly the "masculine" side while the left side is often more "feminine."
   d. Mixed gonadal dysgenesis
      i. In mixed gonadal dysgenesis, there is a testis on one side (more commonly the right side) and a streak gonad on the other.
      ii. The testis may be dysgenetic or initially normal, and the streak gonad histologically is composed of whorls of ovarian stroma without oocytes.
      iii. The karyotype is most commonly 45,X/46,XY, but other mosaic patterns have been described.
      iv. As with true hermaphrodites, asymmetry is a feature in mixed gonadal dysgenesis.
3. XX true hermaphroditism
   a. Mechanisms
      i. Hidden mosaicism with a Y-bearing cell line
      ii. Translocation of Y-material including SRY from paternal Y-to-X chromosome
      iii. An autosomal or X-linked mutation that permits testis differentiation in the absence of SRY
   b. An unusual cause of ambiguous genitalia
      i. Both ovarian and testicular tissue present either in the same or in a contralateral gonad
      ii. Predominantly 46,XX karyotype

c. Several familial forms reported although the great majority of cases are sporadic
   i. Occurring with a higher frequency in South African blacks suggesting a genetic origin
   ii. Several families in which 46,XX males coexist with 46,XX true hermaphrodites strongly suggest that both disorders are alternative manifestations of the same genetic defect
d. SRY-negative true hermaphroditism could be the result of genetic defects at an unknown X-linked or autosomal sex-determining locus
e. Mutations in SRY originated ovotestes development described in 46,XY patients
f. Absence of SRY in gonadal tissue reported in cases of 46,XX true hermaphroditism
g. Possible underestimate of gonadal hidden mosaicism for SRY in XX true hermaphrodites suggesting that true hermaphroditism is a genetically heterogeneous condition

4. Causes of ambiguous genitalia (Chi et al. 2008)
   a. Virilization of female infant
      i. Excessive androgen production: congenital adrenal hyperplasia
         a) 21-α hydroxylase deficiency
         b) 11-β hydroxylase deficiency
         c) 3-β hydroxysteroid dehydrogenase deficiency
      ii. Defects in androgen metabolism: placental aromatase deficiency
      iii. Maternal hyperandrogenism
         a) Maternal androgen production (luteoma of pregnancy, adrenal tumor, untreated CAH)
         b) Progestational agents
   b. Undervirilization of male infant
      i. Defects in testosterone production
         a) Leydig cell hypoplasia/agenesis
         b) Defects in testicular and adrenal steroidogenesis (steroid acute regulatory (StAR) protein deficiency, 3-β hydroxysteroid dehydrogenase deficiency, 17-α hydroxylase/17,20 lyase deficiency, 17-α hydroxysteroid dehydrogenase (ketosteroid reductase) deficiency
      ii. Defects in testosterone metabolism: 5-α reductase deficiency
      iii. Defects in testosterone action: androgen insensitivity syndrome
      iv. Exogenous estrogen/progestin exposure
   c. Genetic disorders of sexual differentiation
      i. Gonadal dysgenesis
         a) 45,X (streak ovaries)
         b) 46,XX gonadal dysgenesis
         c) 46,XY complete and partial gonadal dysgenesis
         d) 45,X/46,XY mixed gonadal dysgenesis
         e) 47,XXY (seminiferous tubular dysgenesis)
      ii. True hermaphroditism
      iii. Sex reversal
         a) XX males (SRY±)
         b) XY female (SRY±)
         c) Smith–Lemli–Opitz Syndrome (SLOS)
         d) *DAX1* mutations
         e) *WT1* mutations

Clinical Features

1. Physical features suggestive of ambiguous genitalia (Lee et al. 2006)
   a. Overt genital ambiguity (e.g., cloacal exstrophy)
   b. Apparent female genitalia with enlarged clitoris and posterior labial fusion (e.g., CAH)
   c. Apparent male genitalia with undescended testes, hypospadias, or micropenis
2. Rules of thumb and clinical significance of internal genitalia (the gonads and the genital ducts) (Low et al. 2003)
   a. Testes descend, ovaries do not: Presence of a palpable gonad implies the presence of testicular tissue on the same side, which implies the presence of the *SRY* gene somewhere in the genome
   b. Testicular descent is directly linked to müllerian duct regression:
      i. Presence of two palpable gonads means there is no uterus.
      ii. With asymmetrical gonadal descent, similar ductal asymmetry internally can be predicted.
      iii. On the side of the descended gonad, there will be wolffian duct derivatives but no müllerian structures. Correspondingly, the contralateral hemi-uterus is likely to be present.
      iv. When there are no palpable gonads, the gonadal and ductal status is unknown.
   c. Presence of a uterus (digitally palpated or ultrasonically detected) means no müllerian

inhibiting substance/anti-müllerian hormone (MIS/AMH) action during the "sensitive" period in early gestation. This implies either no testes, dysgenetic nonfunctional testes, or defects in production or action of MIS/AMH as occurs in the rare syndrome of persistent müllerian duct syndrome (PMDS).

d. Testosterone, as well as MIS/AMH, functions as a locally acting exocrine hormone in the development of the internal genital ducts
   i. Gonadal asymmetry as occurs in true hermaphrodites and mixed gonadal dysgenesis results in corresponding duct asymmetry.
   ii. Circulating androgens in over-androgenized XX babies are insufficient to allow development of male internal genitalia.

3. Rules of thumb and clinical significance of external genitalia (Low et al. 2003)
   a. External virilization, of any degree, is due to the effect of androgens
      i. "Clitoromegaly" in an otherwise phenotypic female is always abnormal, indicating abnormal exposure to androgens
      ii. The genotype may be "XX" with virilization or "XY" with undervirilization
   b. The degree of external virilization proportionally predicts the degree of lower vaginal development
      i. A baby who is incompletely virilized externally, an incomplete vaginal remnant, is likely to be retained
      ii. In a 46 XX "female" baby, the greater the external virilization, the smaller the vaginal remnant and the higher its opening into the posterior urethra
   c. With the exception of the phallus, circulating androgens masculinize the external genitalia only during a critical period (8th–12th weeks)
      i. Scrotal fusion indicates the presence of early circulating androgens while an unfused scrotum means deficient early androgen effect
      ii. An enlarged phallus without urethral/scrotal fusion means there has been a delayed androgen effect (beyond 12 weeks)
      iii. Enlargement of the phallus to normal penile size means continued presence of an androgen effect throughout later gestation (12 weeks to term)

4. True hermaphroditism: contains both ovarian and testicular gonadal tissue separately or, more commonly, together as ovotestis
   a. During intrauterine life: presence of ovarian and testicular tissue with variability in hormonal production results in abnormal differentiation of internal and external genitalia
   b. At birth
      i. Variable degrees of genital ambiguity present in nearly all patients
      ii. Presence of labioscrotal folds, normally developed labia majora in most affected individuals
      iii. A hemiscrotum or even a normal scrotum in a minority of cases
      iv. A phallus of variable length with chordee and urethra generally opens as a urogenital sinus in majority of cases while less severe hypospadias in some cases
      v. Ovaries generally locate in ovarian position while testes locate in the scrotum generally, inguinal canal, or even intra-abdominally
      vi. Location of ovotestis depends on the amount of testicular or ovarian tissue present
      vii. Development of internal genitalia: variable depending on the neighboring gonad
         a) Presence of müllerian derivatives: an ovary is present and ovotestes in most cases
         b) Wolffian structures: observed in association with testes
      viii. A unicornate uterus is usually found
   c. At puberty
      i. Relative production rate of sex hormones vary depending on the composition of the gonads
      ii. Secondary sex characteristics depend on the type of predominant steroid hormone production
      iii. Breast development frequent after puberty
      iv. Menstruation occurring in approximately 50% of patients
      v. Ovulation common
      vi. Pregnancy reported in a few cases
   d. Pregnancy in true hermaphrodites (Schultz et al. 2009):
      i. Complications with preterm labor, neonatal death, or the delivery process itself

ii. Sex of the fetus likely male
iii. Recommendation to remove the remaining gonad(s) due to an increased risk of germ cell malignancies after thorough discussion of the risks, benefits, alternatives, and implications of future sterility and hormone deprivation

5. Recently proposed revised nomenclature (Lee et al. 2006)
   a. Disorders of sex development (DSD) replacing "intersex"
   b. 46,XY DSD replacing "male pseudohermaphrodite, undervirilization of an XY male, and undermasculization of an XY male"
   c. 46,XX DSD replacing "female pseudohermaphrodite, overvirilization of an XX female, and masculinization of an XX female"
   d. Ovotesticular DSD replacing "true hermaphrodite"
   e. 46,XX testicular DSD replacing "XX male or XX sex reversal"
   f. 46,XY complete gonadal dysgenesis replacing "XY sex reversal"

Diagnostic Investigations

1. Approach to the baby with ambiguous genitalia (Low et al. 2003)
   a. History:
      i. Careful history taking: indispensable to an accurate diagnosis
         a) Maternal steroid ingestion
         b) Antenatal diagnosis of an androgen-producing tumor
         c) A positive family history of a known intersex disorder will give important clues to the underlying disorder
         d) Majority of cases, however, will not yield a positive history
   b. Steps in the evaluation of a baby with ambiguous genitalia
      i. Document the degree of external virilization: The greater the degree of virilization, the greater the amount of early androgen exposure (between 8 and 12 weeks) and the greater the extent of vaginal regression.
      ii. Examine the urogenital sinus carefully by pulling it open. If skin tags with a slight bluish hue are seen, then the hymen and therefore the vagina is confirmed present.
      iii. Determine the presence and location of gonads
         a) Palpable gonads predict the presence of SRY, testicular development, and müllerian regression on the ipsilateral side
         b) The degree of testicular descent correlates with the degree of androgen exposure in the second half of pregnancy
      iv. Three possible clinical scenarios
         a) Both gonads palpable and symmetrical: Palpable gonads are almost always testes and the implication, in general, is that the baby is an inadequately virilized male and müllerian duct structures are absent. The differential diagnoses include inadequate testosterone production, receptor deficiency, 5-α-reductase deficiency, minor testicular dysplasia (an exception is the occurrence of bilateral symmetrical ovotestes in a true hermaphrodite).
         b) Gonadal asymmetry with only one gonad palpable: This implies that at least one testis is present. The other may be an ovary, an ovotestis or a streak gonad.
         c) When gonadal asymmetry is encountered, always consider true hermaphroditism or mixed gonadal dysgenesis.
      v. Impalpable gonads
         a) Gonadal and duct status: unknown.
         b) Additional clues may be obtained by careful examination to determine if the external inguinal rings are open, which are felt as inverted V-shaped defects superior and medial to the pubic tubercle. Open external rings indicate a high likelihood of an undescended canalicular testis, while a closed external ring is consistent with the presence of ovaries or extremely dysplastic testes with minimal testosterone production. Per rectal examination is also useful in this circumstance. A gentle examination with the little finger will easily palpate the cervix and confirm the presence of the uterus.
         c) Look for other clues in the general physical examination, such as facial

dysmorphism or developmental abnormalities that may be part of a sex chromosome abnormality. Hyperpigmentation may occur in congenital adrenal hyperplasia.

2. Pelvic ultrasonography: used to detect the presence of a uterus, as well as the presence and position of intra-abdominal gonads. However, visualization may be difficult in the small neonate.
3. Urogenital sinugram: to confirm the presence of and delineate the anatomy of the lower vagina.
4. MRI (Choi et al. 1998)
   a. Female pseudohermaphroditism: shows normal internal female genitalia with masculinized external genitalia
   b. Male pseudohermaphroditism: shows normal or mildly defective testes with incompletely masculinized external genitalia
   c. Gonadal dysgenesis: shows combinations of normal, dysgenetic, and streak gonads; no gonads are evident in gonadal agenesis
   d. True hermaphroditism: shows both testicular and ovarian tissue
5. Hormonal investigations
   a. Serum analysis of 17-hydroxyprogesterone.
   b. Serum profile of adrenal steroids, gonadal androgens, and its precursors.
   c. Human chorionic gonadotrophin stimulation tests may be needed to confirm the normal rise of gonadal hormones with stimulation, while testosterone/dihydrotestosterone ratios reflect 5-α-reductase activity.
6. Chromosomal analysis: to identify the genotype of the affected baby, either as XX, XY, or a mosaic pattern
7. FISH analysis with SRY probes to identify the presence of Y sequences on the X chromosome in cases of 46,XX hermaphroditism and ambiguous genitalia
8. Biopsy of the genital skin for androgen receptor assay
9. Panendoscopy and/or laparoscopy to delineate the internal genitalia
10. Gonadal biopsies on occasion
11. Diagnostic evaluation and potential diagnoses based upon symmetry of genitalia (Mieszczak et al. 2009)
    a. Symmetrical external genitalia
       i. Palpable gonad: gene testing of *SF1*
       ii. Nonpalpable gonad: ultrasound
          a) Uterus (lack of MIH): hormonal assessment (17α-hydroxyprogesterone, androstenedione, testosterone, plasma renin activity) for congenital adrenal hyperplasia and in utero androgen exposure
          b) No uterus (presence of MIH): hormonal assessment (MIH, LH, testosterone, FSH (follicle-stimulating hormone), inhibin B, androstenedione) for Leydig cell hypoplasia, 3β-HSD, 17β-HSD (hydroxysteroid dehydrogenase), androgen insensitivity, 5 α-reductase deficiency, and testicular regression
    b. Asymmetric external genitalia (virilization of labia different on each side): assessment includes:
       i. Fluorescence in situ hybridization for SRY (sex-determining region Y)
       ii. Hormonal assessment
          a) MIH
          b) LH
          c) Testosterone
          d) FSH
       iii. Inhibin B: androstenedione
       iv. Gene testing
          a) *SOX9* (17q24) – male gonadal dysgenesis, campomelic dysplasia, or XY sex reversal
          b) *WT1*(11p13) – XX male (SRY+), Frasier syndrome, or Denys–Drash syndrome with Wilms's tumor
          c) *DAX1* (Xp21.3) – mixed gonadal dysgenesis, XY female (SRY-), or congenital adrenal hypoplasia
          d) *WNT4* – XO/XY
          e) *DHH* – ovotesticular DSD
          f) *ATRX* – α-thalassemia X-linked mental retardation syndrome
          g) *SLOS* – Smith–Lemli–Opitz syndrome
       v. Imaging: ultrasound

Genetic Counseling

1. Recurrence risk: Recurrence risk depends on the inheritance pattern of the disorder (e.g., autosomal recessive disorders – congenital adrenal

hyperplasia, testosterone biosynthetic defects, Leydig cell hypoplasia; autosomal dominant disorders – campomelic dysplasia, Denys–Drash syndrome, Frasier syndrome; X-linked recessive disorders – androgen insensitivity syndrome, male pseudohermaphroditism due to testicular 17,20-desmolase deficiency)
   a. Patient's sib
      i. Autosomal recessive: 25%
      ii. Autosomal dominant: not increased unless a parent is affected or having gonadal mosaicism
      iii. X-linked recessive: 50% of male sibs affected if the mother is a carrier
   b. Patient's offspring
      i. Autosomal recessive: not increased unless the spouse is also a carrier
      ii. Autosomal dominant: 50%
      iii. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal
2. Prenatal diagnosis
   a. Prenatal ultrasonography: Pitfalls in sonographic fetal sex determination (Odeh et al. 2009) include:
      i. Fetuses with malformations of the external genitalia represent a diagnostic challenge
      ii. Clues to the presence of congenital malformations of the external genitalia include:
         a) Nonvisualization of the fetal bladder (Wilcox and Chitty 2001)
         b) Diagnosis of female genitalia at early gestation based on caudal orientation of the genital tubercle, followed at a later time by observation of male genitalia (Borneshtien et al. 1995)
         c) Marked phallic size discrepancy for gestational age; curvature of the phallus; scrotal-phallus malpositions
         d) Nondescended testis in the third trimester
         e) Absence of phallic, labial, or scrotal structures (Mandell et al. 1995)
         f) Abnormalities of the genitalia should also be suspected whenever a mismatch is found between the sonographic fetal sex and the karyotypic fetal sex (Stephens 1984; Cheikhelard et al. 2000)
   b. Prenatal diagnosis is possible for pregnancies at increased risk for various genetic syndromes when the disease-causing mutation in the family is known
3. Management
   a. Ambiguous genitalia: likely the most devastating condition to face any parent of a newborn.
   b. Dealing with emotional, psychosocial, cultural, diagnostic, and treatment issues.
   c. Factors to consider when discussing sex assignment with families (Lee et al. 2006):
      i. Diagnosis
      ii. Genital appearance
      iii. Potential for fertility
      iv. Surgical options
      v. Long-term hormone replacement therapy
      vi. Family views
      vii. Cultural practices
   d. Challenge facing clinicians : come to an accurate and expeditious diagnosis, and then to a rational sex assignment:
      i. The condition is rare
      ii. Clinical diagnosis frequently difficult
      iii. Understanding of normal sexual differentiation is crucial to understanding these disorders
   e. Hormone replacement therapy is often required to induce and sustain puberty, optimize bone mineral accrual and psychosexual development in individuals with ambiguous genitalia (Warne et al. 2005; Nabhan and Lee 2007):
      i. Intramuscular injections of either testosterone cypionate or ethanate are used for pubertal induction for hypogonadal boys. Other testosterone preparations such as gels and patches are available, but there is limited experience of their use for the induction of puberty (Rogol 2005).
      ii. Estrogen replacement orally or injection to induce secondary sexual characteristic development and menses for girls with hypogonadism. A progestin is usually added after breakthrough bleeding or after 1–2 years of continuous estrogen. In women without a uterus, there is no evidence that the addition of cyclic progesterone is beneficial.
   f. Surgical care:
      i. Feminizing genitoplasty, including vaginoplasty and clitoroplasty, in a virilized female
      ii. Surgical reconstruction in undervirilized males who typically have hypospadias: gender

reassignment may be considered in patients with male pseudohermaphrodism and genital inadequacy

iii. Testes in individuals with 46,XY gonadal dysgenesis or fragments of Y-chromosome material raised female should be removed to prevent testicular malignancy

Fig. 1 Vaginal labia agglutination (adhesion) in a female infant

Fig. 3 Penoscrotal hypospadias with a chordee in a male infant

Fig. 2 Vaginal atresia in a female newborn

Fig. 4 Cloacal exstrophy with ambiguous genitalia in an infant

Fig. 5 Ambiguous genitalia with clitoromegaly in a female infant

Fig. 6 Ambiguous genitalia in a female infant with congenital adrenal hyperplasia

Fig. 7 Penoscrotal hypospadias in Smith–Lemli–Opitz syndrome

Fig. 8 A 17-year-old male was followed for 46,XX true hermaphroditism. He was born with low shaft hypospadias and *left* inguinal hernia. He underwent *left* groin exploration and *left* inguinal hernia repair. At operation, the patient was noted to have an odd testicle which looked like a typical ovotestis. Two biopsied specimen were obtained: one revealed immature ovary containing numerous follicles and other a fragment of immature testicle containing seminiferous tubules. He was followed at age of 11. He had Tanner III gynecomastia, Tanner III-IV pubic hair, and Prader 5–8 cc volume testes that were somewhat irregular in size and firm. The LH and FSH were 3.2 and 21 μ/ml (both were normal pubertal levels), respectively. A beta HCG was <3 mIU/ml, and testosterone level 351 ng/dl (normal pubertal levels), estrone 1.3 ng/dl, and estradiol 0.8 ng/dl (normal male levels). His bone age was between 12 and 12.5 years of age

Amniotic Deformity, Adhesions, Mutilations (ADAM) Complex

ADAM complex occurs in 1 of every 5,000–15,000 births and had been demonstrated in 1–2% of malformed infants (Heifetz 1984).

Synonyms and Related Disorders

Amniotic band disruption complex; Amniotic band syndrome; Amniotic constriction band; Congenital ring constrictions; Constriction ring syndrome; TEARS (The Early Amnion Rupture Spectrum)

Genetics/Basic Defects

1. Streeter intrinsic theory (Streeter 1930; Wiedrich 1998)
   a. An intrinsic defect of the subcutaneous germ plasm causes soft tissue to slough. The resulting external healing leads to the constriction ring.
   b. Significant rate of associated anomalies as indirect proof of existence of some genetic force at work to cause the syndrome
2. Torpin extrinsic theory (Torpin 1965) (currently most popular theory)
   a. Early amniotic rupture leading to the formation of mesodermal fibrous strands that entangle limbs and appendages
   b. Amnion rupture without injury to the chorion resulting in amniotic bands
   c. Oligohydramnios playing a major role in the development of the constricting bands
   d. Higher incidence of club feet possibly resulting from continuous pressure on the feet from the undersized uterus
   e. Amniotic bands essentially encircling the affected part resulting in constricting rings
   f. Supporting evidence
      i. Constriction rings often occurring in a straight line across multiple digits as if one external band affects multiple adjacent digits
      ii. Frequent involvement of the central digits
      iii. Occasional attachment of amnion in the constricting ring
      iv. Facial clefting which does not follow developmental planes
3. Other theory: simultaneous occurrence of both extrinsic and intrinsic factors in the development of constriction band syndrome
4. Other factors/mechanisms implicated in the etiology of amniotic band syndrome: The cause of amniotic band syndrome remains elusive and controversial (Bagatin et al. 1997).
   a. Simple oligohydramnios
   b. Fetal hypertension
   c. Venous stasis
   d. Localized fetal ischemia caused by uterine contractions
   e. Intrauterine hemorrhage as the precipitating event
   f. Vascular compromise (lack of distal blood flow demonstrated in association with forearm amputation defects)
   g. Cocaine drug abuse: cocaine acting as a teratogen by inducing fetal hypoxemia through impaired uteroplacental fetal blood flow and directly through its vasoconstrictive properties on the fetal vasculature
   h. Incompetent cervix

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_11,
© Springer Science+Business Media, LLC 2012

i. Amniocentesis implicated. An increased incidence of anomalies related to amniotic band syndrome in association with prenatal amniocentesis in animal models
j. Familial occurrences reported despite no evidence for a genetic predisposition to amniotic band syndrome

Clinical Features

1. The nature and severity of deformities: related to the timing and initiating event of amniotic rupture (Heifetz 1984)
2. Triad of amniotic band syndrome
   a. Amnion-denuded placenta
   b. Fetal attachment or entanglement by amniotic remnants
   c. Fetal deformation, malformation, and/or disruption (Goldfarb et al. 2009)
      i. Fetal deformation
         a) Fetal compression secondary to oligohydramnios (talipes equinovarus, scoliosis, and various joint contractures)
         b) Fetal entanglement by amniotic bands
      ii. Fetal malformation resulting from amniotic band interfering with the normal sequence of embryologic development. Classic malformations include:
         a) Body-wall defects, internal organ abnormalities
         b) Craniofacial abnormalities
      iii. Fetal disruption secondary to cleavage of structures that have already developed normally. Classic disruptive findings are:
         a) Constriction bands
         b) Amputations
         c) Acrosyndactyly
3. Craniofacial disruptions (up to one-third of cases) (Bagatin et al. 1997)
   a. Facial clefting
      i. Most likely associated with swallowing of band at about 5 months of gestation
      ii. Unusual extensions with asymmetric locations, such as oblique facial clefting
   b. Orbital defects
      i. Anophthalmos
      ii. Microphthalmos
      iii. Enophthalmos
      iv. Hypertelorism
   c. Corneal abnormalities
      i. Anomalous eyelid configuration
      ii. Ineffective eye closure
   d. Other ocular abnormalities
      i. Strabismus due to defects in extraocular muscles
      ii. Epiphora related to either lachrymal system involvement or eyelid abnormalities
   e. CNS involvement: usually associated with amniotic band rupture before 45 days of gestation
      i. Neural tube defects (cranioschisis, atypical or asymmetrical meningocele, myelomeningocele, encephalocele, or anencephaly)
      ii. Ventriculomegaly
      iii. Pressure defects of the parenchyma
   f. Calvarial defects
   g. Cleft lip/palate
4. Limb abnormalities
   a. Limb reduction defects
   b. Intrauterine amputations
   c. Ring constrictions with or without distal lymphedema, clubbing, or syndactyly
      i. Deeper rings
      ii. Circumferential rings
   d. Club feet
   e. Digital anomalies: frequently involved
      i. Syndactyly
      ii. Acrosyndactyly
      iii. Digital hypoplasia
      iv. Symphalangism
      v. Symbrachydactyly
      vi. Camptodactyly
   f. Significant neurovascular impairment distal to the constricting band
5. Umbilical cord strangulation by amniotic bands
   a. Common occurrence (10%)
   b. Cord strangulation
   c. Severe strangulation of the umbilical cord at times resulting in fetal death
   d. Stillbirths observed in about 97% of umbilical cord strangulation by amniotic bands
6. Associated anomalies
   a. Hemangiomas
   b. Cardiac defect
   c. Limb/body wall defects

   d. Thoracoabdominal wall defects
      i. Thoracoschisis
      ii. Extrathoracic heart
      iii. Omphalocele
      iv. Gastroschisis
   e. Aplasia cutis
   f. Short umbilical cord
   g. Oligohydramnios sequence
7. Patterson's classification system of congenital ring constriction based on the severity of the syndrome
   a. Simple constriction rings
   b. Constriction rings associated with deformity of the distal part, with or without lymphedema
   c. Constriction rings associated with soft-tissue fusions of distal parts (acrosyndactyly)
   d. Intrauterine amputation
8. Hall's classification system for amniotic band syndrome
   a. Mild constriction without lymphedema
   b. Moderate constriction with lymphedema
   c. Severe constriction with amputation
9. Weinzweig's classification system for amniotic band syndrome (Weinzweig 1995)
   a. Mild constriction without lymphedema
   b. Moderate constriction with distal deformity, syndactyly, or discontinuous neurovascular or musculotendinous structures without vascular compromise
      i. Without lymphedema
      ii. With lymphedema
   c. Severe constriction with progressive lymphaticovenous or arterial compromise
      i. Without soft-tissue loss
      ii. With soft-tissue loss
   d. Intrauterine amputation
10. Lockwood's classification of fetal anomalies in amniotic band syndrome according to their presumed mechanism (Lockwood et al. 1989)
   a. Anomalies caused by interruption of embryonic morphogenesis
      i. Cleft lip and palate
      ii. Omphalocele
      iii. Cardiac anomalies
      iv. Renal agenesis or dysplasia
      v. Bladder exstrophy
      vi. Imperforate anus
   b. Anomalies caused by fetal vascular compromise
      i. Gastroschisis
      ii. Gallbladder agenesis
      iii. Single umbilical artery
   c. Anomalies caused by intrauterine constraint
      i. Club foot
      ii. Clubbed hands
      iii. Abnormal facies
      iv. Valgus-varus deformities
      v. Kyphoscoliosis
   d. Anomalies caused by disruption of normally developed structures
      i. Severe central nervous system or calvarial defect
      ii. Acrosyndactyly
      iii. Amputations
      iv. Constriction bands
      v. Facial clefts (anatomically inappropriate)
      vi. Aplasia cutis
11. Proposed prenatal classification in stages of amniotic band syndrome involving extremities (modified postnatal classification by Weinzweig 1995; Hüsler et al. 2009)
   a. Amniotic bands without signs of constriction
   b. Constriction without vascular compromise (normal vascular Doppler studies, when compared to opposite side) may have distal deformity
      i. Without or only mild lymphedema
      ii. With severe lymphedema
   c. Severe constriction with progressive arterial compromise. The flow has to be measured proximally, at and distally to the constriction band.
      i. Abnormal distal Doppler studies when compared to contralateral extremity
      ii. No vascular flow to extremity
   d. Bowing or fracture of long bones at constriction site
   e. Intrauterine amputation
12. Prognosis
   a. Prenatally diagnosed amniotic adhesion with a grim prognosis
   b. Most cases of cranial and body wall defects incompatible with extrauterine life
   c. Infants born with limited limb abnormalities: better prognosis with good results after surgical repair of the constrictions or syndactyly

Diagnostic Investigations

1. Radiography
   a. Syndactyly with amputation of distal parts
   b. Intrauterine amputation of limbs and digits
2. MRI imagings (Labor et al. 1998)
   a. Delineate the depth of the constriction band
   b. Delineate the extent of the resultant lymphedema
   c. Delineate the integrity of the musculature
   d. Define the vascular anatomy, which may be anomalous; may help to prevent injury to the vessels during surgery.
3. Histology (Day-Salvatore et al. 1995)
   a. Absence of amniotic membrane on the fetal surface of the chorionic sac, including the placental sac
   b. Presence of amnion remnant as a cuff of thick membrane at the base of the umbilical cord at its insertion site
   c. Amniotic squames and cellular debris are frequently embedded in the superficial soft tissue of the chorion indicating chronic amniotic rupture
   d. Constricting bands encircling digits

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased
2. Prenatal diagnosis (Hüsler et al. 2009)
   a. Possible by ultrasonography during second and third trimester
   b. Possible as early as the first trimester in certain cases
   c. Degree of deformity depends on the severity and location of the band formation and the gestational age at amniotic rupture.
   d. Visualization of amniotic sheets or bands attached to the fetus. The diagnosis of amniotic band syndrome should not be made solely on the basis of a membrane observed in the uterine cavity.
   e. Restricted fetal movement
   f. Characteristic asymmetric fetal anomalies
   g. Constriction bands around the limbs
   h. Prenatal natural history of amniotic band sequence without body wall defect
      i. Prematurity
      ii. Preterm rupture of membranes
      iii. Low birth weight (<2,500 g)
      iv. May lead to compromised blood supply to the constricted body parts
      v. Constriction bands may spontaneously resolve (Pedersen and Thomsen 2001)
      vi. Fetal death associated with amniotic band strangulation of the umbilical cord reported (Heifetz 1984; Lurie et al. 2008)
3. Management
   a. Surgery not needed for shallow constriction bands that are not circumferential and without distal swelling
   b. Distal edema or impairment of neurovascular function requiring staged constriction band excision, Z-plasty, or W-plasty
   c. Digital amputation may be required for a ring so constrictive that distal edema is massive.
   d. Multiple plastic surgical procedures required for corrections of the complex craniofacial abnormalities
   e. Procedures for the upper-extremity deformities (Foulkes and Reinker 1994)
      i. Band release, Z- or W-plasty
      ii. Syndactyly/web space release
      iii. Skin graft
      iv. Stump revision
      v. Osteotomy/osteoclasis
      vi. Hardware removal
      vii. Ray resection/transposition
      viii. Distraction osteogenesis
      ix. Pollicization/osteocutaneous transfer
      x. Tendon transfer
      xi. Excision supernumerary digit
      xii. Amputation
   f. Procedures for the lower-extremity deformities (Foulkes and Reinker 1994)
      i. Band release, Z- or W-plasty
      ii. Syndactyly release
      iii. Simple revision
      iv. Amputation/excision toe
      v. Clubfoot procedure
      vi. Hip procedure
      vii. Tibial derotation
      viii. Removal of skin tag

g. Careful follow-up on congenital constriction band of the trunk because the evolution of this condition is benign.
h. Intrauterine release of extremity amniotic band should be indicated in severe cases with risk of intrauterine amputations or irreversible deformities when no other severe disorders are associated (Soldado et al. 2009). The most relevant risks that have to be assumed are premature rupture of membranes and complications related to prematurity.
i. In utero surgical intervention proposed to avoid amputation or permanent damage to the extremity of the fetus, provided the maternal and fetal risks of surgery are small

Fig. 1 A small stillborn fetus (110 g) showing amniotic constriction band at *left* ankle. Amputation and pseudosyndactyly of fingers and toes are present

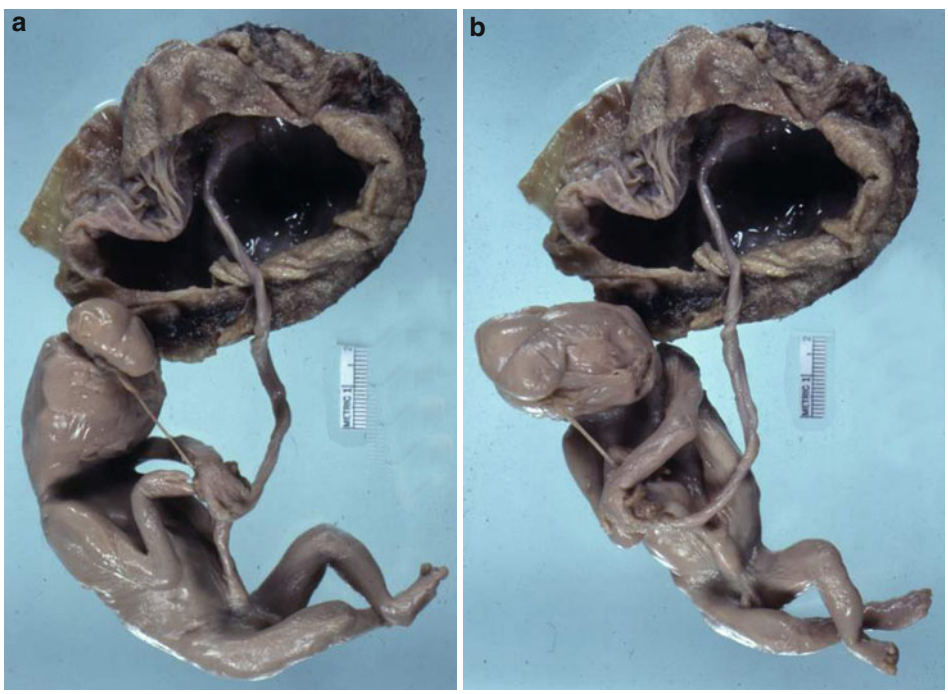

Fig. 2 (**a**, **b**) A small stillborn fetus (60 g) with a fibrous amniotic band constricting a portion of the head and facial cleft

Fig. 3 (**a**, **b**) A small fetus with a large amniotic band which caused anencephaly

Fig. 4 The *left* hand of a 1,100 g fetus showing in utero amputation of the third and fourth fingers

Fig. 6 Cord strangulation by amniotic band

Fig. 5 A placenta with a long strand of amniotic band which was pulled out of the mouth of the premature neonate at birth. The baby did not have amniotic band syndrome

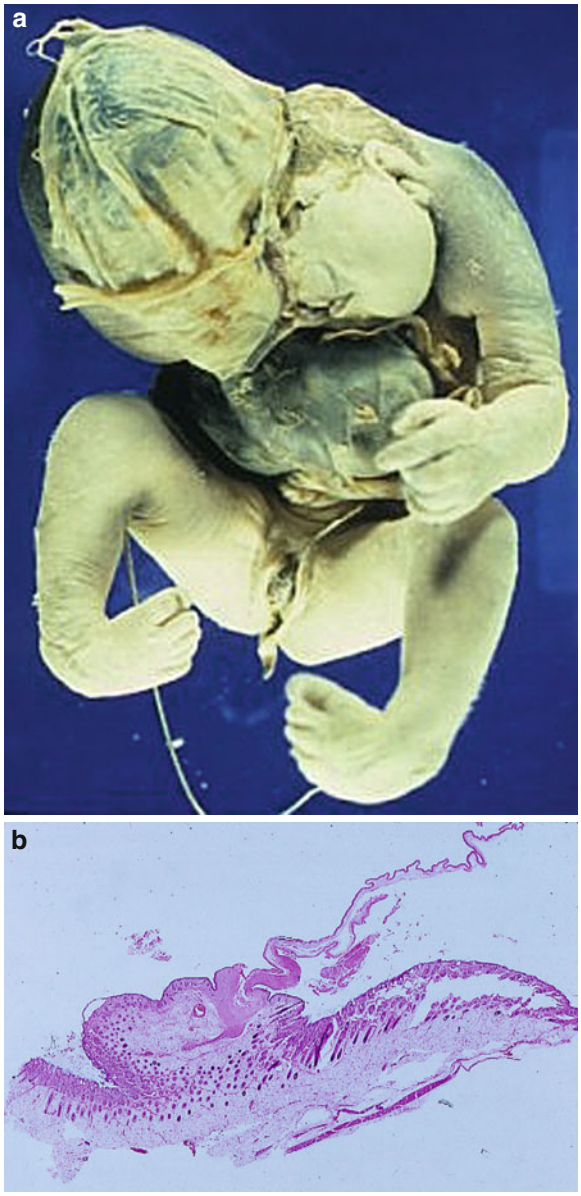

Fig. 7 (**a**, **b**) A fetus with a large meningoencephalocele and an amniotic band attaching to its base. Facial defects, a large gastroschisis, and talipes equinovarus were also present. Histology of the scalp shows an amniotic band fused with the soft tissue of the upper dermis. The amniotic epithelium of the band is visible as a darker line on the surface. The epidermis of the scalp is denuded at the site of band attachment

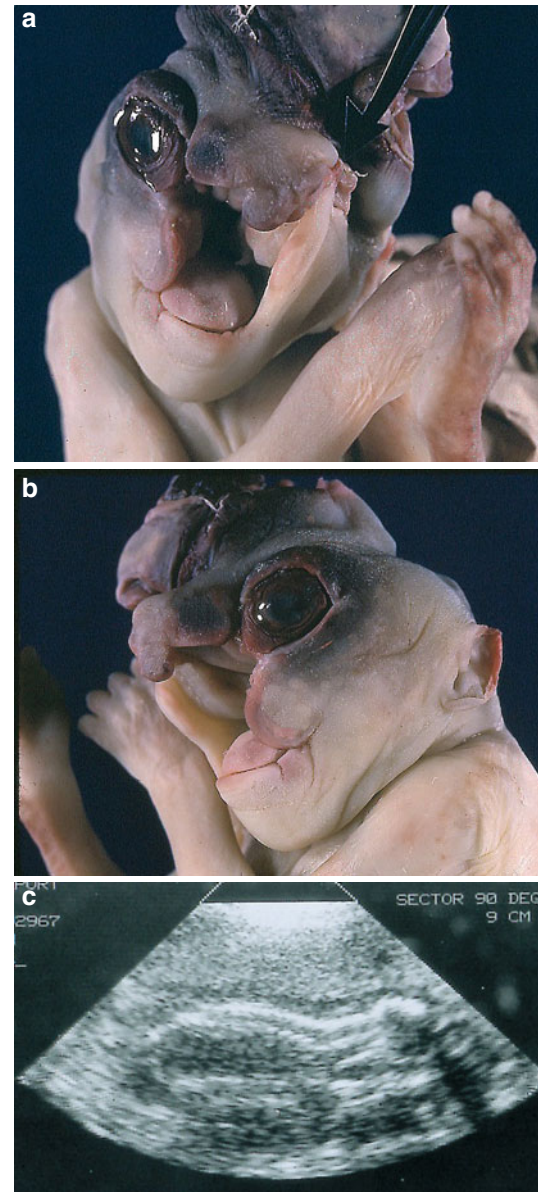

Fig. 8 (**a**–**c**) A fetus with marked craniofacial defects and the site of amniotic band attachment at the base of the skull. The fetus also had amputation of the distal *left* great toe (not shown). Prenatal ultrasonography showed a complex structure arising from the top and front of the craniofacial region

Fig. 9 An infant with marked craniofacial anomalies, a constricting ring of a finger with distal lymphedema, and an amputation of the fifth finger

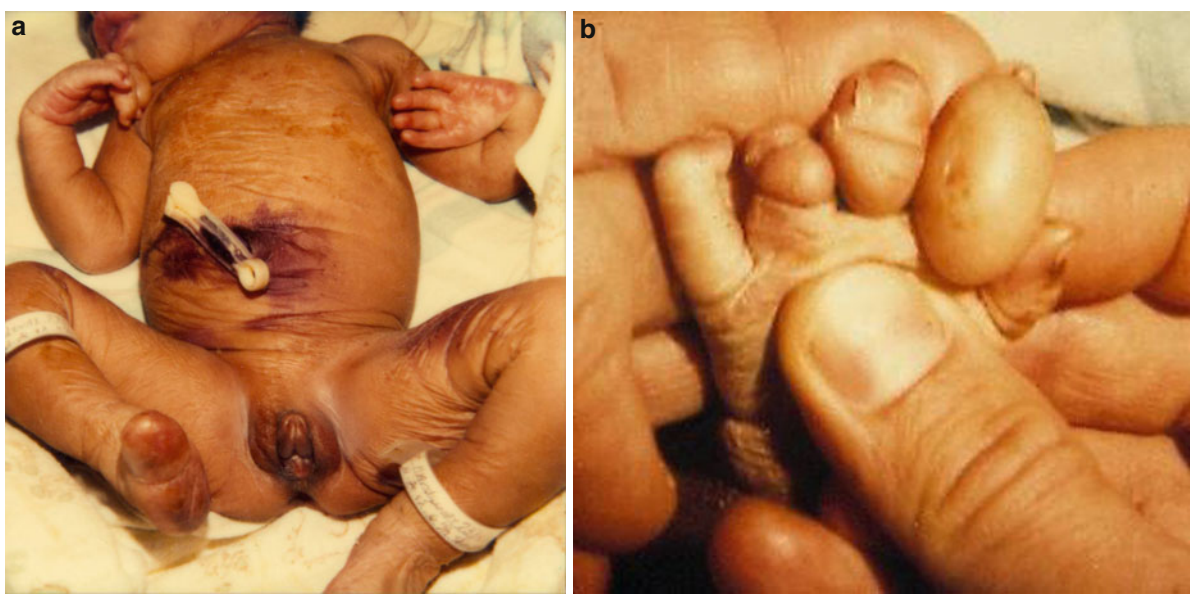

Fig. 10 (**a**, **b**) An infant with club *left* hand with a missing finger, constricting rings with marked distal lymphedema of the *right* index finger, and pseudosyndactyly of the *right* foot

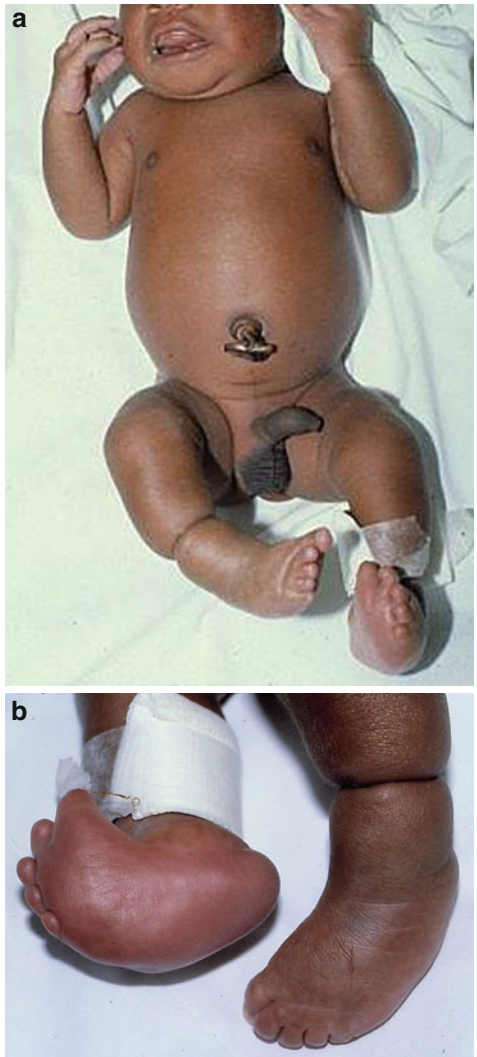

Fig. 11 (**a**, **b**) An infant with deep constricting groove around the lower one-third of both legs. The patient also had terminal amputation and constriction rings of fingers with a small amniotic band still attached to the constricting ring of the second finger (not shown)

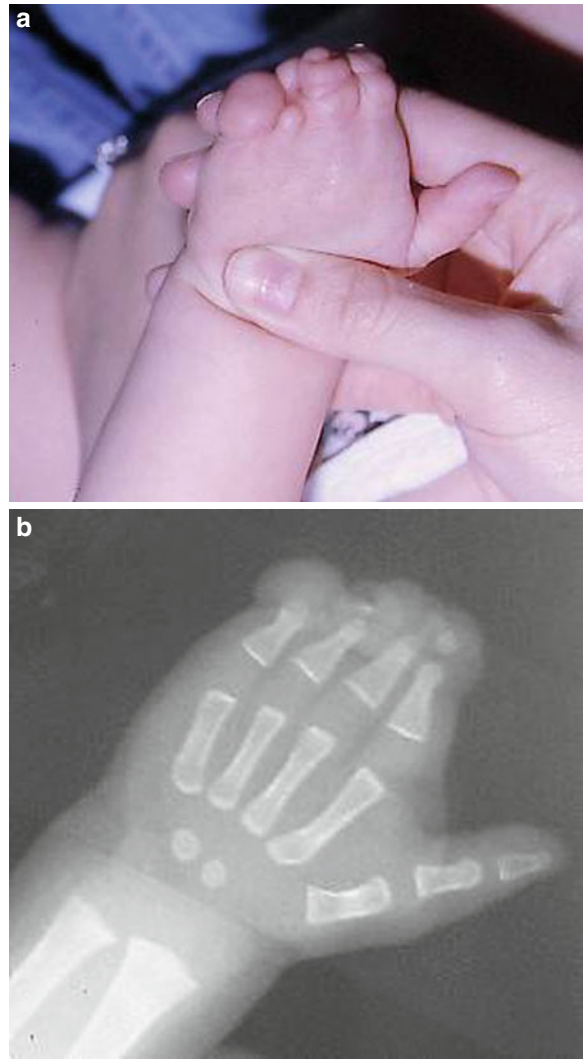

Fig. 12 (**a**, **b**) A hand of an infant with constriction bands of the fingers with amputations, shown by the radiograph

Androgen Insensitivity Syndrome

In 1953, Morris described the clinical phenotype of "testicular feminization" after reviewing 82 cases. Morris's phenotype included a female body habitus with normal breast development, minimal pubic and axillary hair, typically absent or rudimentary vagina or absent uterus. The term "testicular feminization syndrome" was based on the observation of the complete absence of signs of virilization in phenotypic females with testes and a 46,XY karyotype. The change in nomenclature from testicular feminization to androgen insensitivity syndrome (AIS) was prompted by the finding of normal urinary 17-ketosteroid levels, an androgen metabolite as well as by absence of treatment effect when 46,XY women were treated with methyltestosterone, suggesting androgen resistance rather than a deficiency (Wilkins 1950; Speroff and Fritz 2005; Oakes et al. 2009).

AIS probably represents the most common cause of male pseudohermaphroditism. It is an X-linked recessive disorder in 46,XY individuals with normal androgen production and metabolism. The prevalence of AIS is estimated to be 1 in 20,000–1 in 99,000 genetic males (Bangsboll et al. 1992; Boehmer et al. 2001; Grumbach et al. 2003). The prevalence of phenotypic females with inguinal hernias is estimated to be 0.8–2.4% (Gans and Rubin 1962; Nielsen and Bulow 1976).

Synonyms and Related Disorders

Androgen receptor deficiency; Dihydrotestosterone receptor deficiency; Testicular feminization syndrome

Genetics/Basic Defects

1. Inheritance
   a. X-linked recessive inheritance
      i. Affected XY individuals
      ii. Carrier XX females
   b. Manifesting carrier females (about 10% of carrier females)
2. Caused by mutations of androgen receptor (*AR*) gene (mapped to chromosomal locus Xq11-q12) (Lubahn et al. 1988)
   a. Mutations of androgen receptor: responsible for a variable degree of impaired androgen action
   b. De novo mutations
      i. De novo mutation rate close to 30%
      ii. Somatic or germ-line mosaicism observed for "de novo" mutations in which the mutation is present in some of the cells in one of the clinically unaffected parents
   c. Type of mutations
      i. Point mutations
      ii. Complete and partial gene deletions
      iii. Small insertion deletions
   d. Variable expressivity of a particular point mutation attributable to somatic mosaicism for the mutation
3. Pathogenesis
   a. Androgen insensitivity syndrome
      i. The result of an end-organ resistance to androgens caused by an abnormality of the androgen receptor
      ii. Normal production of testosterone and normal conversion to dihydrotestosterone

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_12,
© Springer Science+Business Media, LLC 2012

(DHT) by the normal testes in affected individuals, differentiating this condition from 5α reductase deficiency
iii. Absence of fallopian tubes, uterus, or proximal (upper) vagina in affected individuals because testes produce normal amounts of müllerian-inhibiting factor (MIF)

b. Complete androgen insensitivity syndrome (CAIS)
i. Most severe form
ii. Complete resistance to all actions of testosterone and dihydrotestosterone

c. Incomplete androgen insensitivity syndrome (IAIS): partial resistance to the action of testosterone and dihydrotestosterone

d. Reifenstein syndrome: Variable resistance to the action of testosterone and dihydrotestosterone

e. Mild androgen insensitivity syndrome (MAIS): Resistance to the action of androgen varies in different tissues

Clinical Features

1. Variable phenotypic expression allowing the classification of AIS into complete and partial forms, and a rare group of phenotypically normal men with azoospermia.
2. Complete androgen insensitivity syndrome
   a. Presumptive diagnosis of CAIS (Gottlieb et al. 2007)
      i. Absence of extragenital abnormalities
      ii. Two nondysplastic testes
      iii. Absent or rudimentary müllerian structures (absence of fallopian tubes, uterus, or cervix)
      iv. A short vagina
      v. Under-masculinization of the external genitalia at birth
      vi. Impaired spermatogenesis (sterility) and/or somatic virilization at puberty
   b. External phenotype
      i. Invariably presenting as a normal female external appearance (female habitus)
      ii. Female external genitalia ("testicular feminization"; Tfm)
      iii. Underdeveloped, short blind-ending vagina
      iv. Normal breast and female adiposity development
      v. Unaffected sexual identity and orientation
      vi. Scant or absent pubic and/or axillary hair
   c. Urogenital tract
      i. Absent or rudimentary wolffian duct derivatives (epididymides and/or vas deferens)
      ii. Inguinal or labial masses subsequently identified as testes in a phenotypic female infant or child
      iii. Inguinal hernia: the commonest presentation of CAIS in childhood (Deeb and Hughes 2005)
      iv. 1.1% incidence rate of CAIS in a child with a premenarcheal inguinal hernia while 80–90% of girls with CAIS eventually develop an inguinal hernia (Gans and Rubin 1962; Viner et al. 1997; Sarpel 2005)
   d. Other features
      i. Primary amenorrhea in a phenotypic female adolescent: most typical presentation
      ii. Complete androgen insensitivity syndrome almost always runs true in families (i.e., affected XY relatives usually have normal female external genitalia and seldom have any sign of external genital masculinization, such as clitoromegaly or posterior labial fusion).
3. Partial androgen insensitivity syndrome (PAIS)
   a. Predominantly female external genitalia (incomplete androgen insensitivity syndrome)
      i. Signs of external genital masculinization
         a) Clitoromegaly
         b) Partial fusion of the labioscrotal folds
      ii. Female habitus and breast development
      iii. Normal axillary and pubic hair
      iv. Inguinal or labial testes as in CAIS
      v. Wolffian duct derivatives emptying into the vagina
      vi. Distinct urethral and vaginal openings or a urogenital sinus
      vii. No müllerian duct derivatives
   b. Ambiguous external genitalia (Reifenstein syndrome)
      i. Microphallus (<1 cm) with clitoris-like underdeveloped glans
      ii. Labia majora-like bifid scrotum
      iii. Descended or undescended testes
      iv. Perineoscrotal hypospadias or urogenital sinus
      v. Gynecomastia in puberty

   c. Predominantly male external genitalia (Reifenstein syndrome)
      i. Simple (glandular or penile) or severe (perineal) "isolated" hypospadias with a normal-sized penis and descended testes or severe hypospadias with micropenis
      ii. Bifid scrotum
      iii. Either descended or undescended testes
      iv. Gynecomastia in puberty
4. Mild androgen insensitivity syndrome
   a. Two phenotypic forms at puberty
      i. Impaired spermatogenesis and fertility
      ii. Normal or sufficient spermatogenesis to preserve fertility
   b. Clinical features common to both forms
      i. Male external genitalia ("undervirilized male syndrome")
      ii. Gynecomastia in puberty
      iii. High-pitched voice
      iv. Sparse sex hair
      v. Impotence
5. Manifesting carrier females
   a. Asymmetric distribution and sparse or delayed growth of pubic or axillary hair
   b. A history of late (15 years) or delayed (16 years or older) menarche
6. Differential diagnosis (Oakes et al. 2008)
   a. Mayer-Rokitansky-Kuster-Hauser (MRKH) syndrome (müllerian agenesis)
      i. A more common cause of primary amenorrhea: an incidence rate of 1 in 5,000 (Aittomaki et al. 2001)
      ii. Normal breast development
      iii. Underdeveloped vagina
      iv. Normal axillary and pubic hair (Speroff and Fritz 2005)
      v. A 46,XX karyotype
   b. Swyer syndrome (XY gonadal dysgenesis)
      i. Lack of breast development
      ii. Short stature
      iii. Localize testes and to rule out testicular tumors by ultrasound and MRI

Diagnostic Investigations

1. Diagnostic workup
   a. Diagnosis of CAIS usually based on:
      i. Clinical findings
      ii. Laboratory evaluation
      iii. Imaging studies including transabdominal pelvic ultrasound and MRI: to document internal anatomy
   b. Diagnosis of PAIS and MAIS based on:
      i. Clinical findings
      ii. Laboratory evaluation
      iii. Family history consistent with X-linked recessive inheritance
2. Laboratory investigations
   a. AIS
      i. Chromosome analysis: 46,XY karyotype
      ii. Evidence of normal or increased synthesis of testosterone by the testes
      iii. Evidence of normal conversion of testosterone to 5α-dihydrotestosterone
      iv. Evidence of normal or increased luteinizing hormone production by the pituitary gland
      v. Evidence of deficient or defective androgen-binding activity of genital skin fibroblasts
   b. CAIS, IAIS, Reifenstein syndrome, and MAIS
      i. Chromosome analysis: 46,XY karyotype
      ii. Testosterone: Normal or high male plasma levels and production rates
      iii. Estrogen: Plasma levels and production rates higher than in normal men
      iv. Gonadotropin: Elevated plasma LH levels (may be normal in MAIS)
   c. Additional findings of sporadic cases of predominantly male phenotype of PAIS
      i. Impaired development of the prostate and of the wolffian duct derivatives demonstrated by ultrasonography or genitourography
      ii. Less than normal decline of sex hormone–binding globulin in response to a standard dose of the anabolic androgen, Stanozolol
      iii. Higher than normal levels of anti-müllerian hormone during the first year of life or at the beginning of puberty
3. Histologic investigations
   a. CAIS
      i. Testes: apparently normal in early life but begin to lose their germ cell population in late childhood
      ii. Development of testicular hamartomas (composed of Sertoli and Leydig cells, spindle cells, stroma, and germ cells in varying

proportion), benign and malignant tumors beginning in the postpubertal period
iii. Germinal cell tumors, usually seminomas, in approximately 8% of CAIS cases
b. IAIS
i. Histologic appearance of the gonads similar to that of CAIS
ii. Cryptorchid testes, usually containing spermatocytes and rare observation of spermatozoa in a minority of patients
c. MAIS with oligospermia or azoospermia in phenotypically normal males with testicular biopsy showing:
i. Presence of Sertoli cell only
ii. Arrest of spermatogenesis at the spermatid stage

4. Detection of known mutations of the androgen receptor gene clinically available by sequencing
a. CAIS: detected in >95% of patients
b. PAIS: detected in <50% of patients
c. MAIS: proportion of patients with detected mutations unknown

Genetic Counseling

1. Recurrence risk: genetic counseling according to X-linked recessive inheritance (Gottlieb et al. 2007)
a. Patient's sib
i. Recurrence risk: low but greater than that of the general population because the possibility of germ-line mosaicism exists provided the mother is not a carrier
ii. 50% of sibs inheriting the mutation from the carrier mother
a) Sibs with a 46,XY karyotype who inherit the mutation will be affected
b) Sibs with a 46,XX karyotype who inherit the mutation will be carriers
b. Patient's offspring
i. 46,XY individuals with AIS (i.e., CAIS, PAIS, MAIS): almost always infertile
ii. Manifesting carrier females: 50% risk of transmitting the AR gene mutation in each pregnancy
c. Offspring of a known *AR* mutation carrier female
i. 25% of 46,XY children: affected
ii. 25% of 46,XY children: unaffected
iii. 25% of 46,XX children: carrier
iv. 25% of 46,XX children: not a carrier
v. A wide range of phenotypes observed for the same mutation in different families making genetic counseling more difficult

7. Carrier detection
a. Family pedigree
b. Clinical features
i. Asymmetric distribution and sparse or delayed growth of pubic or axillary hair in manifesting carriers (10% of carriers), resulting from skew X chromosome inactivation
ii. Normal pubic and axillary hair do not rule out the 46,XX carrier state
c. Deficient or defective androgen-binding activity of single-cell clones from a genital skin fibroblast line, provided an affected 46,XY family member is known to have deficient or defective androgen-binding activity in a genital skin fibroblast cell line
d. Molecular genetic testing (Davies et al. 1995)
i. A complete screening strategy of the entire androgen receptor gene needed to find the mutation in a new case of androgen insensitivity syndrome. Once the mutation is identified in the proband, carrier detection of other family members is possible.
ii. Intragenic polyglutamine and polyglycine trinucleotide repeats in the N-terminal region of the androgen receptor may be used as polymorphisms to follow the affected X chromosome through the family and used for carrier status determination.

8. Prenatal diagnosis
a. Request for prenatal diagnosis uncommon
i. Finding of discordance between chromosomal and phenotypic sex by ultrasonographic and cytogenetic analysis
ii. AIS does not affect intellect
iii. Only some treatment modalities available
b. Prenatal diagnosis by mutation analysis: clinically available in families in which the disease-causing allele has been identified in an affected family member
c. Fetal sex determination by amniocentesis or CVS
i. XX fetus: additional testing not warranted
ii. XY fetus: extract DNA for mutation analysis

9. Management (Gottlieb et al. 2007)
a. Psychological support

i. Probably the most important aspect of medical care
ii. Psychologist or psychiatrist consultations to help adjust to child's condition, including support on how to inform the child, over time and in an age-appropriate manner
iii. Androgen Insensitivity Syndrome Support Group (http://www.medhelp.org/www/ais)

b. CAIS
i. Remove testes (gonadectomy) as soon as the diagnosis is made: current recommendation, however, is for removal of gonads after puberty (Oakes et al. 2008).
ii. The rationale for postpubertal gonadectomy: testicular malignancy seldom occurs before puberty unlike that of usual cryptorchid testes.
iii. Estrogen replacement therapy necessary to initiate puberty, maintain feminization, and avoid osteoporosis
iv. Dilatation of short vaginal length (vaginoplasty) to avoid dyspareunia
v. Systemic disclosure of the condition to parents and patients in an empathic setting

c. PAIS with predominantly female genitalia
i. Management issues similar to CAIS
ii. Prepubertal gonadectomy helps avoid discomfort of increasing clitoromegaly at the time of puberty.

d. PAIS with ambiguous genitalia or predominantly male genitalia
i. Sex of rearing based on the genital phenotype, genital reconstructive surgery, and hormone therapy
ii. Sex assignment in infants with ambiguous genitalia requires delicate decision-making by parents and health-care personnel and should be resolved as early as is feasible.
iii. A male sex of rearing demands a therapeutic trial with pharmacologic doses of androgen to predict potential androgen responsiveness at puberty and to facilitate reconstructive surgery.
iv. Reduction mammoplasty for gynecomastia developing in puberty

e. MAIS
i. Reduction mammoplasty often required for gynecomastia
ii. A trial of androgen pharmacotherapy to improve virilization

Angelman Syndrome

In 1965, Angelman reported three children with a similar pattern of severe learning disability, seizures, ataxic jerky movements, easily provoked laughter, absent speech, and dysmorphic facial features. The syndrome, which bears his name, was originally called the "happy puppet" syndrome. The incidence is estimated to be 1 in 12,000 to 1 in 20,000 (Clyton-Smith and Pembrey 1992; Petersen et al. 1995; Steffenburg et al. 1996).

Synonyms and Related Disorders

Happy puppet syndrome

Genetics/Basic Defects

1. Inheritance
   a. Sporadic in most cases
   b. Rare familial transmission (always transmitted through maternal lineage)
2. Caused by deficiency of gene expression from abnormality on the maternally derived chromosome 15 because of genomic imprinting
   a. The relevant region on chromosome 15q
      i. Normally expressed on the maternally derived chromosome
      ii. Normally imprinted on the paternally derived chromosome
   b. Inability of the imprinted paternal allele to produce functional protein since the normally expressed maternal copy is often deleted in Angelman syndrome
3. Genetic mechanisms responsible for the disorder (Buiting 2010)
   a. Chromosome deletions and translocations
      i. Deletion (de novo) of the maternally derived chromosome region 15q11–q13 (~70%), which affects several imprinted genes including *UBE3A* (E6AP-3A ubiquitin-protein ligase gene) and *SNRPN* (small nuclear ribonucleoprotein polypeptide N)
         a) Abnormal methylation analysis with presence of paternal band only
         b) Other diagnostic tests: high-resolution cytogenetics or FISH analysis
      ii. Rare families with deletion due to unique chromosome 15 rearrangement within 15q11–q13 (<1%)
         a) Abnormal methylation analysis with presence of paternal band only
         b) Other diagnostic tests: high-resolution cytogenetics or FISH analysis
   b. *UBE3A* and other presumed single gene mutations (20–25%)
      i. Imprinting of the *UBE3A* gene with paternal silencing in human brain
      ii. Inability to degrade unwanted proteins
      iii. Compromised cellular functions secondary to absence of *UBE3A*
      iv. Resulting in abnormal cortical functioning with severe mental retardation
      v. Diagnostic tests for mutations
         a) Normal methylation analysis with presence of both maternal and paternal bands
         b) Other diagnostic tests: screening of *UBE3A* for mutations

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_13,
© Springer Science+Business Media, LLC 2012

c. Paternal uniparental disomy (UPD) (both copies of a chromosome come from the father) of the chromosome 15 (1–2%)
   i. Affected individuals having two alleles of all genes (both derived from the father) but remain silenced with no production of functional protein
   ii. Milder phenotypic manifestations (lower incidence of seizures)
   iii. Abnormal methylation analysis with presence of paternal band only
   iv. Other diagnostic tests: RFLP analysis
d. Imprinting defects (2–4%)
   i. A mutation within the "imprinting center," located within 15q11–q13 on chromosome 15, renders the imprinting center unable to function properly (2%). Normally imprinting center regulates which segments of DNA are imprinted.
      a) Abnormal methylation analysis with presence of paternal band only
      b) Positive screening for imprinting center for mutation
   ii. Imprinting defect without imprinting center mutation (2%)
      a) Abnormal methylation analysis with presence of paternal band only
      b) Negative screening for imprinting center for mutation
   iii. Mosaic imprinting defect (frequency unknown)
      a) Abnormal methylation analysis with presence of faint maternal band
      b) Usually negative screening for imprinting center for mutation
   iv. Microdeletions reported in the imprinting center
e. No genetic abnormality identified: Patients with clinical features of Angelman syndrome but no demonstrable cytogenetic or molecular abnormality of chromosome 15q11–q13

Clinical Features

1. Consistent cardinal features (100%) (Clayton-Smith and Laan 2003; Williams et al. 2006)
   a. Normal newborn phenotype
      i. Normal prenatal and birth history
      ii. Normal head circumference
      iii. Absence of major birth defects
   b. Developmental delay
      i. Starting around 6 months of age
      ii. Eventually classified as severe developmental delay and/or mental retardation
   c. Profound speech impairment
      i. Absent or minimal use of words
      ii. Receptive and nonverbal communication skills better than verbal capability
   d. Movement or balance disorder
      i. Abnormal ataxic gait
      ii. Puppet-like jerky movements of limbs
      iii. Hand flapping movement
   e. Typical behavioral pattern
      i. An easily excitable personality, often with hand flapping movements
      ii. Short attention span
      iii. A happy, sociable disposition
      iv. Inappropriately happy affect
      v. Bouts of inappropriate laughter
      vi. Hypermotoric behavior
2. Frequent features (>80%)
   a. Delayed, disproportionate growth in head circumference, usually resulting in microcephaly by age 2
   b. Seizures (80%)
      i. Onset usually before 3 years of age (1–5 years)
      ii. Variety of seizures (tonic-clonic, atypical absences, complex partial, myoclonic, atonic, tonic seizures to status epilepticus)
   c. Characteristic EEG with large amplitude slow spike waves and triphasic waves
3. Associated features (20–80%)
   a. Characteristic craniofacial appearance
      i. Flat occiput
      ii. Occipital groove
      iii. Strabismus
      iv. Tongue thrusting
      v. Prognathia
      vi. Wide mouth
      vii. Widely spaced teeth
      viii. Frequent drooling
      ix. Excessive chewing/mouthing behaviors
   b. Swallowing disorder
   c. Feeding problems during infancy
   d. Hypopigmented skin
   e. Light hair and eye color, compared to other family members, seen only in deletion cases

f. Hyperactive lower limb deep tendon reflexes
g. Uplifted, flexed arm position especially during ambulation
h. Increased sensitivity to heat
i. Sleep disturbance
j. Attention to and fascination with water
k. Hypotonia at birth

4. Adolescent and adult phenotype
   a. More striking facial features
      i. Marked mandibular prognathism
      ii. Pointed chin
      iii. Macrostomia
      iv. Prominent lower lip
      v. Deeply set eyes
      vi. Keratoconus secondary to eye rubbing
   b. Scoliosis and joint contractures increasing with age
   c. Improved hyperactivity and concentration
   d. Persistent sociable disposition
   e. A good quality of life maintained despite the above problems
   f. Lifespan not greatly reduced
5. Phenotype–genotype correlations
   a. Patients with chromosome 15 deletions: in general, the most severely affected
      i. Higher incidence of seizures, microcephaly, and hypopigmentation. Severe epilepsy seen in these patients is considered to be the result of the absence of one copy of the *GABA* receptor genes.
      ii. Greater delay in motor milestones
      iii. Absent speech
      iv. Severe clinical features thought to be the result of haploinsufficiency for a number of genes within the 15q11–q13 region
   b. Phenotype in the non-deletion cases: milder than in the deletion cases
   c. Phenotype in the paternal UPD: milder than that of the deletion cases
      i. A low incidence of seizures, microcephaly, and hypopigmentation
      ii. Able to say a few words in many patients
      iii. Better growth parameters
      iv. Less obvious dysmorphic features
      v. Typical behavioral pattern
   d. Imprinting defects
      i. Less likely to have microcephaly, hypopigmentation, or seizures
      ii. More able than the deletion group with less delay in motor milestones and better communication skills
      iii. Growth better than the deletion patients
      iv. Obesity relatively common within this group
   e. Milder phenotype associated with incomplete imprinting defect or cellular mosaicism (displayed as Angelman syndrome methylation pattern)
   f. Point mutations in the *UBE3A*
      i. Phenotype between the deletion group and the UPD group
      ii. Frequently with mild or absence of ataxia, epilepsy, and microcephaly
      iii. Not hypopigmented
      iv. Better motor and communication skills than the deletion group
6. Consensus criteria for the clinical diagnosis of Angelman syndrome by developmental history and clinical findings (Williams et al. 2006)
   a. Developmental history
      i. Normal prenatal and birth history
      ii. Normal head circumference
      iii. Absence of major birth defects
      iv. Feeding difficulties may be present in the neonate and infant
      v. Developmental delay evident by 6–12 months of age
      vi. Sometimes associated with truncal hypotonus
      vii. Unsteady limb movements and/or increased smiling may be evident
   b. Consistent clinical findings (100%)
      i. Developmental delay, functionally severe
      ii. Movement or balance disorder, usually ataxia of gait, and/or tremulous movement of limbs. Movement disorder can be mild. May not appear as frank ataxia but can be forward lurching, unsteadiness, clumsiness, or quick, jerky motions
      iii. Behavioral uniqueness: any combination of frequent laughter/smiling; apparent happy demeanor; easily excitable personality, often with uplifted hand-flapping, or waving movements; hypermotoric behavior
      iv. Speech impairment, none or minimal use of words; receptive and nonverbal communication skills higher than verbal ones
   c. Frequent clinical findings (>80%)
      i. Delayed, disproportionate growth in head circumference, usually resulting in

microcephaly (_2 SD of normal OFC) by age 2 years. Microcephaly is more pronounced in those with 15q11.2–q13 deletions.
ii. Seizures, onset usually <3 years of age. Seizure severity usually decreases with age but the seizure disorder lasts throughout adulthood.
iii. Abnormal EEG, with a characteristic pattern, as mentioned in the text. The EEG abnormalities can occur in the first 2 years of life and can precede clinical features, and are often not correlated to clinical seizure events.

d. Associated clinical findings (20–80%)
i. Flat occiput
ii. Occipital groove
iii. Protruding tongue
iv. Tongue thrusting; sucking/swallowing disorders
v. Feeding problems and/or truncal hypotonia during infancy
vi. Prognathia
vii. Wide mouth, wide-spaced teeth
viii. Frequent drooling
ix. Excessive chewing/mouthing behaviors
x. Strabismus
xi. Hypopigmented skin, light hair, and eye color (compared to family), seen only in deletion cases
xii. Hyperactive lower extremity deep tendon reflexes
xiii. Uplifted, flexed arm position especially during ambulation
xiv. Wide-based gait with pronated or valgus-positioned ankles
xv. Increased sensitivity to heat
xvi. Abnormal sleep-wake cycles and diminished need for sleep
xvii. Attraction to/fascination with water; fascination with crinkly items such as certain papers and plastics
xviii. Abnormal food-related behaviors
xix. Obesity (in the older child)
xx. Scoliosis
xxi. Constipation

7. Differential diagnosis (Williams et al. 2010a)
a. Nonspecific psychomotor delay and/or seizures including cerebral palsy, static encephalopathy, and mitochondrial encephalomyopathy: tremulousness and jerky limb movements seen in most infants with Angelman syndrome are not seen in these conditions
b. Mowat–Wilson syndrome
i. Findings suggesting Angelman syndrome
a) Happy affect
b) Prominent mandible
c) Diminished speech
d) Microcephaly
e) Constipation
ii. Typically results from heterozygous mutations in *ZEB2*
c. Christianson syndrome (Christianson et al. 1999; Gilfillan et al. 2008)
i. An X-linked disorder
ii. Caused by mutations in the *SLC9A6* gene
iii. Clinical features
a) Apparently happy disposition
b) Severe cognitive delays
c) Ataxia
d) Microcephaly
e) Seizure disorder
f) A rapid (10–14 Hz) background frequency EEG, compared to a generalized high amplitude, slow spike/wave (1.5–3 Hz) pattern seen in patients with *SLC9A6* mutations
g) Cerebellar and brain stem atrophy in some cases
h) Individuals with *SLC9A6* disorder may have thinner body appearance and may lose ambulation beyond 10 years of age.
d. Adenylosuccinate lyase deficiency (Spiegel et al. 2006; Gitiaux et al. 2009)
i. Results in accumulation of succinylpurines leading to:
a) Psychomotor retardation
b) Autistic features
c) Hypotonia
d) Seizures
ii. The following behavior profile may mimic Angelman syndrome:
a) Motor apraxia
b) Severe speech deficits
c) Excessive laughter
d) A very happy disposition

e) Hyperactivity
f) A short attention span
g) Mouthing of objects
h) Tantrums
i) Stereotyped movements

e. Pitt–Hopkins syndrome
i. Characteristic features
a) Mental retardation
b) Distinctive facial features including wide mouth
c) Intermittent hyperventilation followed by apnea (Zwier et al. 2007). Diurnal hyperventilation is a salient feature in some and occurs after 3 years of age (Peippo et al. 2006).
ii. Mutation and deletion screening for the TCF4 gene: available

f. Rett syndrome
i. Seizures and severe speech impairment of Rett syndrome: resemble infant girls with Angelman syndrome but children with Angelman syndrome do not have a regressive course and do not lose purposeful use of their hands, as do girls with Rett syndrome.
ii. Testing for mutations of *MECP2*: clinically available

g. Prader–Willi syndrome: Infants with Angelman syndrome who present with feeding difficulties and muscle hypotonia may be misdiagnosed as having Prader–Willi syndrome because the 15q11.2–q13 deletion, detected by comparative genomic hybridization (CGH) or fluorescent in situ hybridization (FISH), was not proven by DNA methylation analysis to be of maternal origin.

h. Other microdeletion syndromes
i. Microdeletion of 22q13.3 deletion (Phelan–McDermid) syndrome (Precht et al. 1998)
a) Nondysmorphic facial features
b) Absent or minimal speech
c) Moderate to severe developmental delay
d) Behavioral features in the autism spectrum
ii. Microdeletions of the 2q23.1 region (van Bon et al. 2010; Williams et al. 2010b)
a) Severe speech delay
b) Seizures
c) Behavioral disorders
d) Microcephaly. Some individuals present with an AS-like phenotype.
e) Other new microdeletion disorders, detected by CGH, may be associated with some features of Angelman syndrome (Brunetti-Pierri et al. 2008; Sharkey et al. 2009).

Diagnostic Investigations

1. Normal metabolic, hematologic, and chemical laboratory profiles
2. Normal brain imagings (MRI, CT) with occasional mild cortical atrophy and dysmyelination
3. Abnormal EEG
a. High amplitude slow spike-wave activities (most common)
b. Hypsarrhythmia (infantile spasm)
4. Cytogenetic studies
a. To detect visible chromosome rearrangement (<1%)
i. Translocation
ii. Inversion
b. High-resolution chromosome studies to demonstrate large del(15)(q11–q13)
c. Fluorescence in situ hybridization (FISH) to identify 15q11–q13 microdeletions, using D15S10 and/or *SNRPN* probes: detects about 70% of patients
5. DNA methylation studies
a. To demonstrate characteristic DNA methylation pattern (i.e., paternal imprint only) of 15q11–q13 cloned DNA sequences using methylation-sensitive restriction endonucleases
i. Diagnose about 80% of classic Angelman syndrome including patients with a deletion, uniparental disomy, or an imprinting defect
ii. Certain maternally inherited genes are extensively methylated and thus inactivated while the paternal alleles are unmethylated and active in normal individuals.
iii. Unmethylated *SNRPN* alleles in patients with Angelman syndrome, caused by:
a) Uniparental disomy
b) Imprinting center defects
c) Typical 15q11–q13 deletion

iv. Inability to distinguish the molecular classes (15q11–q13 deletion, uniparental disomy, or imprinting center defect)

b. *UBE3A* mutation analysis
   a) Detect mutations in the E6-AP ubiquitin-protein ligase gene
   b) Detect additional 11% of patients

6. DNA polymorphisms to demonstrate absence of maternal alleles at 15q11–q13 loci, which may result either from maternal deletion or from paternal uniparental disomy
   a. Determined by analysis of simple sequence repeats (microsatellites) in the parents and affected individual
   b. Determine parental origin of 15q11–q13 and the rest of chromosome 15
   c. Detect patients with deletions and uniparental disomy but not the *UBE3A* mutation class of patients
   d. Detect biparental inheritance of 15q11–q13 with abnormal DNA methylation in patients with imprinting center defects
7. Simple algorithm for genetic testing in patients with clinical suspicion of Angelman syndrome (Clayton-Smith and Laan 2003; Williams et al. 2010a)
   a. Abnormal methylation analysis
      i. FISH analysis or array-CGH
         a) Presence of del(15)(q11.3–q13) (5–7 Mb deletion)
         b) Absence of del(15)(q11–q13)
      ii. RFLP analysis if FISH analysis is negative
         a) Presence of UPD
         b) Absence of UPD
      iii. Angelman syndrome imprinting center deletion analysis (2–200 kb deletions) if UPD is absent
   b. Normal methylation analysis
      i. Screen *UBE3A* mutation (sequence analysis for sequence variants and gene or Intragenic deletion study for partial or whole-gene deletions) in clinically typical patients
         a) If positive, check parents
         b) If negative, keep on reviewing patient's findings
      ii. No further testing required for clinical normal patients (not Angelman syndrome)
8. Currently, about 10% of patients with classic phenotypic features of Angelman syndrome are not amenable to diagnostic testing due to presently unidentified genetic mechanisms.
9. Consensus criteria for the diagnosis of Angelman syndrome by laboratory findings and genetic test abnormalities (Williams et al. 2006)
   a. Normal metabolic, hematologic, and chemical laboratory profiles
   b. Structurally normal brain using MRI or CT (may have mild cortical atrophy or dysmyelination)
   c. Characteristic Angelman syndrome pattern of DNA methylation of the *SNURF-SNRPN* exon 1/promoter. Detects cases due to 15q11.2–q13 deletion, UPD, and imprinting defects (may have mosaic methylation pattern in non-deletion imprinting defects)
   d. Abnormal FISH indicating a deletion of 15q11.2–q13 DNA sequences within the common Angelman syndrome deletion overlap region
      i. Use of a pericentromeric FISH probe enhances the ability to detect subtle translocation.
      ii. Array-CGH can be used to detect the deletion but confirmation by FISH is currently required.
      iii. Class I and II deletions can be distinguished by array-CGH or FISH using appropriate clones.
   e. DNA polymorphism analysis within 15q11.2–q13 showing paternal UPD
   f. Deletion in the Imprinting Center, demonstrated by real-time PCR, single copy FISH, or other analysis methods of the Angelman syndrome Imprinting Center smallest region of overlap (SRO)
   g. Pathogenic DNA sequence change in the *UBE3A* gene
10. Diagnostic approach (van Buggenhout and Fryns 2009)
   a. Cytogenetic study: large deletion/translocation/duplication: Rare (<1%)
   b. Molecular diagnosis: DNA methylation test
      i. Abnormal
         a) FISH and CGH (5–7 Mb deletion) to demonstrate deletion region 15q11.2–q13 (60–70% of the patients)
         b) UPD study to demonstrate paternal UPD (2–5% of the patient)

c) Imprinting Center deletion study to demonstrate: Imprinting Center defect (2–5%)

ii. Normal: Sequence analysis of the *UBE3A* gene detects mutations in about 10% of the patients.

Genetic Counseling

1. Recurrence risks : depending on the genetic mechanism involved and on whether the mother is shown to carry genetic abnormalities of 15q11–q13 (Laan 1999; Buiting 2010; Williams et al. 2008, 2010a)
   a. Reasons of difficulty in providing recurrence risk estimation
      i. Causal heterogeneity of Angelman syndrome
      ii. Maternal germ cell mosaicism
   b. Patient's sib
      i. For proband with a large deletion: <1% risk to sibs. However, germline mosaicism for these large deletions has been reported (Kokkonen and Leisti 2000).
      ii. For proband with an inherited small interstitial deletion or an unbalanced chromosome translocation: The risk to sibs depends on whether the rearrangement is inherited or de novo (Horsthemke et al. 1996; Stalker and Williams 1998). Possibly as high as 50%
      iii. For proband with paternal UPD (in families in which Angelman syndrome is the result of paternal UPD and in which no Robertsonian chromosomal translocation is identified): The risk to sibs of having Angelman syndrome is <1% (The risk figure is based on the lack of recurrence among all known cases of UPD in Angelman syndrome with normal chromosomes).
      iv. For proband with paternal UPD and with predisposing parental translocation: approaching 100% if father has a 15;15 Robertsonian translocation
      v. For proband with imprinting defect
         a) No imprinting center deletion: <1%
         b) With inherited imprinting center deletion: 50%
      vi. For proband with *UBE3A* mutation
         a) De novo mutation: <1%
         b) With inherited mutation from mother: 50%
      vii. For proband without identifiable molecular abnormality: undetermined risk
   c. Patient's offspring: To date, only one individual with Angelman syndrome reported to have reproduced (Lossie and Driscoll 1999)
      i. Females with Angelman syndrome are fully capable of reproduction: The mother and fetus inherited large deletions of maternal 15q11–13.
      ii. Demonstrated paternal-only DNA methylation imprints along 15q11–13.
      iii. *UBE3A* was paternally expressed (not imprinted) in eye tissue from the fetus with Angelman syndrome.
2. Prenatal diagnosis
   a. Possible when the underlying genetic mechanism is as follows:
      i. A deletion
      ii. Uniparental disomy
      iii. An imprinting defect
      iv. A *UBE3A* mutation
      v. A chromosome rearrangement
   b. Combined use of methylation analysis, chromosomal/FISH analysis, and DNA marker studies through analysis of fetal cells obtained by CVS or amniocentesis: to identify the common ~4 Mb deletion, paternal UPD, or imprinting mutation in about 70–80% of cases with Angelman syndrome
   c. Mutation analysis for *UBE3A*
   d. Readily accomplished if a disease-causing mutation is identified and is present in the mother
   e. Preimplantation genetic diagnosis
      i. Available for families in which the underlying mechanism has been identified in the proband to be UBE3A mutations or imprinting center deletions
      ii. The relative hypomethylation of the early embryo makes PGD problematic for DNA methylation testing.
3. Management
   a. Routine management
      i. Feeding difficulties
      ii. Constipation
      iii. Gastroesophageal reflux
      iv. Strabismus

b. Seizure control difficult with antiepileptic drugs, especially in childhood
   i. Sodium valproate as monotherapy or in combination with clonazepam or other benzodiazepines
   ii. Experience with the newer antiepileptic drugs very limited
c. Physical therapy for unstable or nonambulatory children
d. Occupational therapy for improving fine motor and oral-motor control
e. Speech and communication therapy
   i. Augmentative communication aids, such as picture cards or communication boards
   ii. Sign language
f. Consistent behavioral modifications
g. Orthopedic management
   i. Subluxed or pronated ankles
   ii. Tight Achilles tendons
   iii. Scoliosis

Apert Syndrome

Apert syndrome is named after the French physician who described the syndrome acrocephalosyndactylia in 1906. Apert syndrome is a rare autosomal dominant disorder characterized by craniosynostosis, craniofacial anomalies, and severe symmetrical syndactyly (cutaneous and bony fusion) of the hands and feet. It probably is the most familiar and best-described type of acrocephalosyndactyly. Prevalence is estimated at 1 in 65,000 (approximately 15.5 in 1,000,000) live births (Cohen and Kreiborg 1992, 1993a). Apert syndrome accounts for 4.5% of all cases of craniosynostosis.

Synonyms and Related Disorders

Acrocephalosyndactyly types 1 and 2; Apert-Crouzon disease; Vogt cephalodactyly

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. Sporadic in majority (>98%) of cases, resulting from new mutations with a paternal age effect
   c. Rarity of familial cases can be explained by reduced genetic fitness of individuals because of severe malformations and the presence of mental retardation in many cases.
2. Cause
   a. Caused by specific missense substitution mutations, involving adjacent amino acids (i.e., Ser252Trp or Pro253Arg) in the linker between the second and third extracellular immunoglobulins domains of *FGFR2*, which maps to chromosome bands 10q25–q26 (more than 98% of cases with Apert syndrome)
   b. Remaining cases are caused by Alu-element insertion mutations in or near exon 9 of *FGFR2*.
3. Pathogenesis
   a. Unique fibroblast growth factor receptor 2 (*FGFR2*) mutations
      i. Leading to an increase in the number of precursor cells that enter the osteogenic pathway
      ii. Ultimately leading to increased subperiosteal bone matrix formation and premature calvaria ossification during fetal development
   b. Fusion of the cranial sutures
      i. The order and rate of suture fusion determine the degree of deformity and disability.
      ii. Once a suture becomes fused, growth perpendicular to that suture becomes restricted, and the fused bones act as a single bony structure.
      iii. Compensatory growth occurs at the remaining open sutures to allow continued brain growth.
      iv. Complex, multiple sutural synostosis frequently extends to premature fusion of the sutures at the base of the skull, causing midfacial hypoplasia, shallow orbits, a foreshortened nasal dorsum, maxillary hypoplasia, and occasional upper airway obstruction.
   c. Syndactyly of Apert syndrome
      i. A keratinocyte growth factor receptor (KGFR)-mediated effect, provided by the observation of the correlation between KGFR expression in fibroblasts and severity of syndactyly
      ii. Different phenotypic expression in patients with Ser252Trp and those with Pro253Arg.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_14,
© Springer Science+Business Media, LLC 2012

The syndactyly is more severe with Pro253Arg mutation for both hands and feet, whereas cleft palate is significantly more common with Ser252Try mutation.

d. During early infancy (younger than 3 month of age)
   i. Premature closure of the coronal suture area, evident by a bony condensation line beginning at the cranial base and extending upward with a characteristic posterior convexity
   ii. Widely patent anterior and posterior fontanelles
   iii. Presence of a gaping defect of the midline of the calvaria, extending from the glabellar area to the posterior fontanelle via the metopic suture area, anterior fontanelle, and sagittal suture area. The skull with gaping midline defect appears to permit adequate accommodation of the growing brain.
   iv. Normal lambdoidal sutures in all cases
e. During the first 2–4 years of life
   i. Obliteration of the midline defect by coalescence of the enlarging bony islands without evidence of any proper formation of sutures
   ii. Very early onset in fetal life of growth inhibition in the sphenofrontal and coronal suture area, suggested by an extremely short squama and orbital part of the frontal bone together with the posterior convexity of the coronal bone condensation line

Clinical Features

1. History
   a. Headache and vomiting: signs of acute increase of intracranial pressure, especially in cases of multiple suture involvement
   b. Stridor and sleep apnea indicates upper airway problems, due to craniosynostosis of the base of the skull
   c. Visual disturbance due to exposure keratitis and conjunctivitis
   d. Mental retardation in many patients, though patients with normal intelligence have been reported
2. Skull
   a. Craniosynostosis
   b. Coronal sutures most commonly involved, resulting in acrocephaly, brachycephaly, turribrachycephaly, flat occiput, and high prominent forehead
   c. Large late-closing fontanels
   d. Gaping midline defect
   e. Rare cloverleaf skull anomaly in approximately 4% of infants
3. Facial features
   a. Horizontal grooves above the supraorbital ridges that disappear with age
   b. A break in the continuity of the eyebrows
   c. A trapezoid-shaped mouth at rest
   d. Flattened, often asymmetric face
   e. Maxillary hypoplasia with retruded midface
   f. Eyes
      i. Down-slanting palpebral fissures
      ii. Hypertelorism
      iii. Shallow orbits
      iv. Proptosis
      v. Exophthalmos
      vi. Lateral ptosis
      vii. Widened palpebral fissures
      viii. Tearing secondary to exposure keratitis
      ix. Prolonged corneal exposure resulting in corneal scars and opacification
      x. Partially open eye during sleep
      xi. Strabismus
      xii. Amblyopia
      xiii. Optic atrophy
      xiv. Keratoconus
      xv. Ectopic lentis
      xvi. Congenital glaucoma
      xvii. Lack of pigment in the fundi with occasional papilledema
      xviii. Rare luxation of the eye globes as an extreme complication of severe exorbitism, producing possible strangulation of the circulation of the globe and blindness
   g. Mouth
      i. A prominent mandible
      ii. Down-turned corners
      iii. High arched palate
      iv. Bifid uvula
      v. Cleft palate
      vi. Crowded upper teeth
      vii. Malocclusion
      viii. Delayed dentition

ix. Ectopic eruption
x. Shovel-shaped incisors
xi. Supernumerary teeth
xii. V-shaped maxillary dental arch
xiii. Bulging alveolar ridges

h. Ears
i. Apparent low-set ears
ii. Occasional conductive hearing loss
iii. Congenital fixation of stapedial footplate

4. Extremities and digits
a. The upper limbs affected more severely than lower limbs
b. Coalition of distal phalanges and synonychia of the hands (never present in the feet)
c. The glenohumeral joint and proximal humerus affected more severely than the pelvic girdle and femur
d. The elbow involved much less severely than the proximal portion of the upper limb
e. Syndactyly of the hands and feet with partial-to-complete fusion of the digits, often involving second, third, and fourth digits. These often are termed mitten hands and socked feet. In severe cases, all digits are fused, with the palm deeply concave or cup-shaped and the sole supinated.
f. Hitchhiker posture or radial deviation of short or broad thumbs resulting from abnormal proximal phalanx
g. Brachydactyly
h. Contiguous nailbeds (synonychia)
i. Subacromial dimples and elbow dimples during infancy
j. Limited mobility at the glenohumeral joint with progressive limitation in abduction, forward flexion, and external rotation
k. Limited elbow mobility common with decreased elbow extension, flexion, pronation, and supination
l. Short humeri, a constant finding beyond infancy
m. Limited genu valga present in many cases

5. Other skeletal and cartilaginous segmentation defects
a. Congenital cervical spinal fusion (68%), especially C5–C6
b. Aplasia or ankylosis of shoulder, elbow, and hip joints
c. Tracheal cartilage anomalies
d. Rhizomelia

6. CNS
a. Intelligence varying from normal to mental deficiency, though a significant number of patients are mentally retarded. Malformations of the CNS may be responsible for most cases.
b. Common CNS malformations
i. Megalencephaly
ii. Agenesis of the corpus callosum
iii. Malformed limbic structures
iv. Variable ventriculomegaly. Progressive hydrocephalus is uncommon.
v. Encephalocele
vi. Gyral abnormalities
vii. Hypoplastic cerebral white matter
viii. Pyramidal tract abnormalities
ix. Heterotopic gray matter
x. Papilledema and optic atrophy with loss of vision in cases with insidious intracranial pressure increase

7. Cardiovascular (10%)
a. Atrial septal defect
b. Patent ductus arteriosus
c. Ventricular septal defect
d. Pulmonary stenosis
e. Overriding aorta
f. Coarctation of aorta
g. Dextrocardia
h. Tetralogy of Fallot
i. Endocardial fibroelastosis

8. Genitourinary (9.6%)
a. Polycystic kidneys
b. Duplication of renal pelvis
c. Hydronephrosis
d. Stenosis of bladder neck
e. Bicornuate uterus
f. Vaginal atresia
g. Protuberant labia majora
h. Clitoromegaly
i. Cryptorchidism

9. Gastrointestinal (1.5%)
a. Pyloric stenosis
b. Esophageal atresia and tracheoesophageal fistula
c. Ectopic or imperforate anus
d. Partial biliary atresia with agenesis of gallbladder

10. Respiratory (1.5%)
a. Anomalous tracheal cartilage
b. Tracheoesophageal fistula
c. Pulmonary aplasia

d. Absence of right middle lobe of the lung
e. Absence of interlobular lung fissures
11. Skin
a. Hyperhidrosis (common)
b. Acneiform lesions frequent after adolescence
c. Interruption of the eyebrows
d. Hypopigmentation
e. Hyperkeratosis in the plantar surface
f. Paronychial infections more commonly affected in feet than hands and observed more commonly in institutionalized patients
g. Excessive skin wrinkling of forehead
h. Skin dimples at knuckles, shoulders, and elbows
12. At risk for complications resulting from elevated intracranial pressure despite surgical attempts to increase cranial capacity in infancy
13. Early death
a. Upper airway compromise
i. Reduction in nasophrynx size
ii. Choanal patency
iii. Obstructive sleep apnea
iv. Cor pulmonale
b. Lower airway compromise due to anomalies of the tracheal cartilage
14. Differential diagnosis
a. Beare–Stevenson syndrome
i. Mental retardation
ii. Associated cutaneous disorders
a) Cutis gyrata
b) Acanthosis nigricans (hands and feet)
iii. Caused by *FGFR2* mutations
b. Carpenter syndrome (see the chapter)
i. An autosomal recessive disorder
ii. A peculiar face
iii. Preaxial polydactyly of hands, feet, or both
iv. Absence of osseous fusion of hand bones
c. *FGFR3* -associated coronal synostosis syndrome
i. Variable clinical presentation overlapping with Pfeiffer, Jackson–Weiss, or Saethre–Chotzen syndrome phenotypes
ii. Some individuals with a disease-causing mutation may have no clinical problems
d. Jackson–Weiss syndrome
i. Caused by *FGFR2* mutations
ii. Enlarged or broad great toes with varus deviation
iii. Tarsal or metatarsal fusion
iv. Lack of thumb abnormalities
v. Midface hypoplasia
e. Pfeiffer syndrome
i. Identifiable mutations in *FGFR1* and *FGFR2* (~67% of patients)
ii. Hand and foot abnormalities
a) Broad thumbs and halluces
b) Occasional cutaneous syndactyly
iii. Lack of osseous fusion of the phalanges
iv. Craniofacial features
a) Turribrachycephaly
b) Occasional clover-leaf skull
c) Ocular hypertelorism
d) Shallow orbits
e) Sown-slanting palpebral fissures
f) Proptosis
g) Strabismus
h) Low nasal bridge
i) Small nose
j) Maxillary hypoplasia
k) Mandibular prognathism
f. Saethre–Chotzen syndrome (see the chapter)
i. Characteristic facies
ii. Relatively mild cranial deformity
iii. Lack of osseous fusion of the hand bones
iv. Identifiable mutations in the *TWIST* gene (~75% of patients)

Diagnostic Investigations

1. Psychometric evaluation
2. Hearing assessment
3. Imaging studies
a. Skull radiography to evaluate craniostenosis, which usually involves coronal sutures and maxillary hypoplasia
i. Sclerosis of suture line
ii. Bony bridging and beaking along the suture line
iii. An indistinct suture line
iv. Turribrachycephaly
v. Shallow orbits
vi. Hypoplastic maxillae
b. Spine radiography
i. Spinal fusions, most commonly at the levels of C3-4 and C5-6, appearing to be

progressive and occurring at the site of subtle congenital anomalies
ii. Small-sized vertebral body and reduced intervertebral disc space: indicators of subsequent bony fusion

c. Limb radiography
i. Multiple epiphyseal dysplasia
ii. Short humeri
iii. Glenoid dysplasia
iv. Cutaneous and osseous syndactyly
v. Complete syndactyly involving the second and fifth digits (mitten hands)
vi. Multiple progressive synostosis involves distal phalanges, proximal fourth and fifth metacarpals, capitate, and hamate.
vii. Progressive symphalangism of interphalangeal joints
viii. Shortened and radial deviation of distal phalanx
ix. Delta-shaped deformity of proximal phalanx of the thumbs
x. Complete syndactyly involving the second and fifth toes (socked feet)
xi. Fusion of tarsal bones, metatarsophalangeal and interphalangeal joints, and adjacent metatarsals
xii. Delta-shaped proximal phalanx of the first toes
xiii. Occasional partial or complete duplication of the proximal phalanx of the great toes and first metatarsals

d. Computed tomography
i. CT scan with comparative 3-dimensional reconstruction analysis of the calvaria and cranial bases: the most useful radiological examination in identifying skull shape and presence or absence of involved sutures
ii. Precise definition of the pathological anatomy, permitting specific operative planning

e. Magnetic resonance imaging
i. Demonstration of the anatomy of the soft-tissue structures and associated brain abnormalities
ii. Visualization of the spatial arrangement of the bones

4. Molecular analysis
a. Exquisitely specific molecular mechanism with a narrow mutational spectrum
b. More than 98% of cases: caused by specific missense substitution mutations, involving adjacent amino acids (Ser252Trp, Ser252Phe, or Pro253Arg) in exon 7 of *FGFR2*
c. The remaining cases: due to Alu-element insertion mutations in or near exon 9

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. A negligible recurrence risk for patient's sib when parents are not affected except in the case of germinal mosaicism in which the risk for future sibs depends on the proportion of germ cells bearing the mutant allele
ii. 50% risk, if a parent is also affected.
b. Patient's offspring: a 50% recurrence risk for an affected individual to have an affected offspring
c. Advanced paternal age effect in new mutations has been shown clinically and demonstrated conclusively at the molecular level.

2. Prenatal diagnosis
a. Prenatal ultrasonography in low-risk pregnancies with finding of abnormal fetal skull shape
i. Prenatal diagnosis of Apert syndrome suspected with findings of fetal "mitten hands" associated with abnormal skull shape and midfacial hypoplasia and confirmed by molecular diagnosis. Craniosynostosis is usually not detected until the third trimester.
ii. Low yield for testing mutations in the *FGFR2* gene
iii. Mutation identification not helpful in determining the prognosis of a fetus, which is largely determined by the clinical diagnosis and not by the molecular diagnosis
b. Prenatal MRI: a useful and sometimes indispensable, additional diagnostic tool (Weber et al. 2010)
c. Fetoscopy to visualize fetal anomalies comparable to Apert syndrome in a pregnancy at risk: an invasive procedure not used currently
d. Molecular genetic analysis
i. An affected parent with identified mutation of *FGFR2* gene: prenatal diagnosis available on fetal DNA obtained through amniocentesis or chorionic villus sampling

ii. An affected parent without identified mutation of *FGFR2* gene: linkage analysis available to an informative family with at least two affected family members based on an accurate clinical diagnosis and an accurate understanding of genetic relationships in the family

3. Management
   a. Protection of the cornea
      i. Instill lubricating bland ointments in the eyes at bedtime to protect corneas from desiccation
      ii. Artificial teardrops during the day
      iii. Lateral or medial tarsorrhaphy in severe cases to narrow the palpebral fissure cosmetically and protect the corneas and the vision
   b. Upper airway obstruction during the neonatal period
      i. Remove excessive nasal secretions
      ii. Treat upper airway infection
      iii. Humidification with added oxygen
      iv. Judicious use of topic nasal decongestants
      v. Rarely requires orotracheal intubation
   c. Sleep apnea
      i. Polysomography (a sleep recording of multiple physiologic variables), currently the most reliable method for determining the presence of sleep apnea
      ii. Continuous positive pressure
      iii. Tracheostomy indicated in severely affected children
   d. Chronic middle ear effusion associated with bilateral conductive hearing deficit
      i. Antimicrobial therapy
      ii. Bilateral myringotomy and placement of ventilation tubes: the most effective treatment
   e. Craniofacial surgery
      i. Cranium
         a) Removes synostotic sutures
         b) Reshapes the calvaria
         c) Allows more normal cranial development to proceed with respect to shape, volume, and bone quality
         d) Relieves increased intracranial pressure
      ii. Orbits
         a) Correction of ocular proptosis: the primary objective of orbital surgery
         b) Reduction of increased interorbital distance (hypertelorism)
         c) Correction of increased interior malrotation
      iii. Nose
         a) Infants and child: nasal reconstruction focusing on correction of the excessively obtuse nasofrontal angle, flat nasal dorsum, and ptotic nasal tip
         b) Teenager and adult: reduction of the nasal tip bulk
      iv. Midface
         a) Normalization of midface appearance
         b) Expansion of the inferior orbit
         c) Volumetric expansion of the nasal and nasopharyngeal airways
         d) Establishment of a normal dentoskeletal relationship
      v. Mandible: mandibular osteotomies to improve dentoskeletal relations for masticatory and esthetic benefit
   f. Surgical reconstruction of syndactyly
   g. Psychological and social challenges confronted by individuals with Apert syndrome
      i. Emotional adjustment
      ii. Body image development
      iii. Impact of surgery and hospitalization on children with Apert syndrome

Fig. 1 (**a**–**d**) An infant with Apert syndrome showing characteristic facial appearance and typical mitten hands and socked feet

Fig. 2 (**a**–**d**) A 13-year-old girl with Apert syndrome showing characteristic facial appearance and postoperative status of the fingers and toes

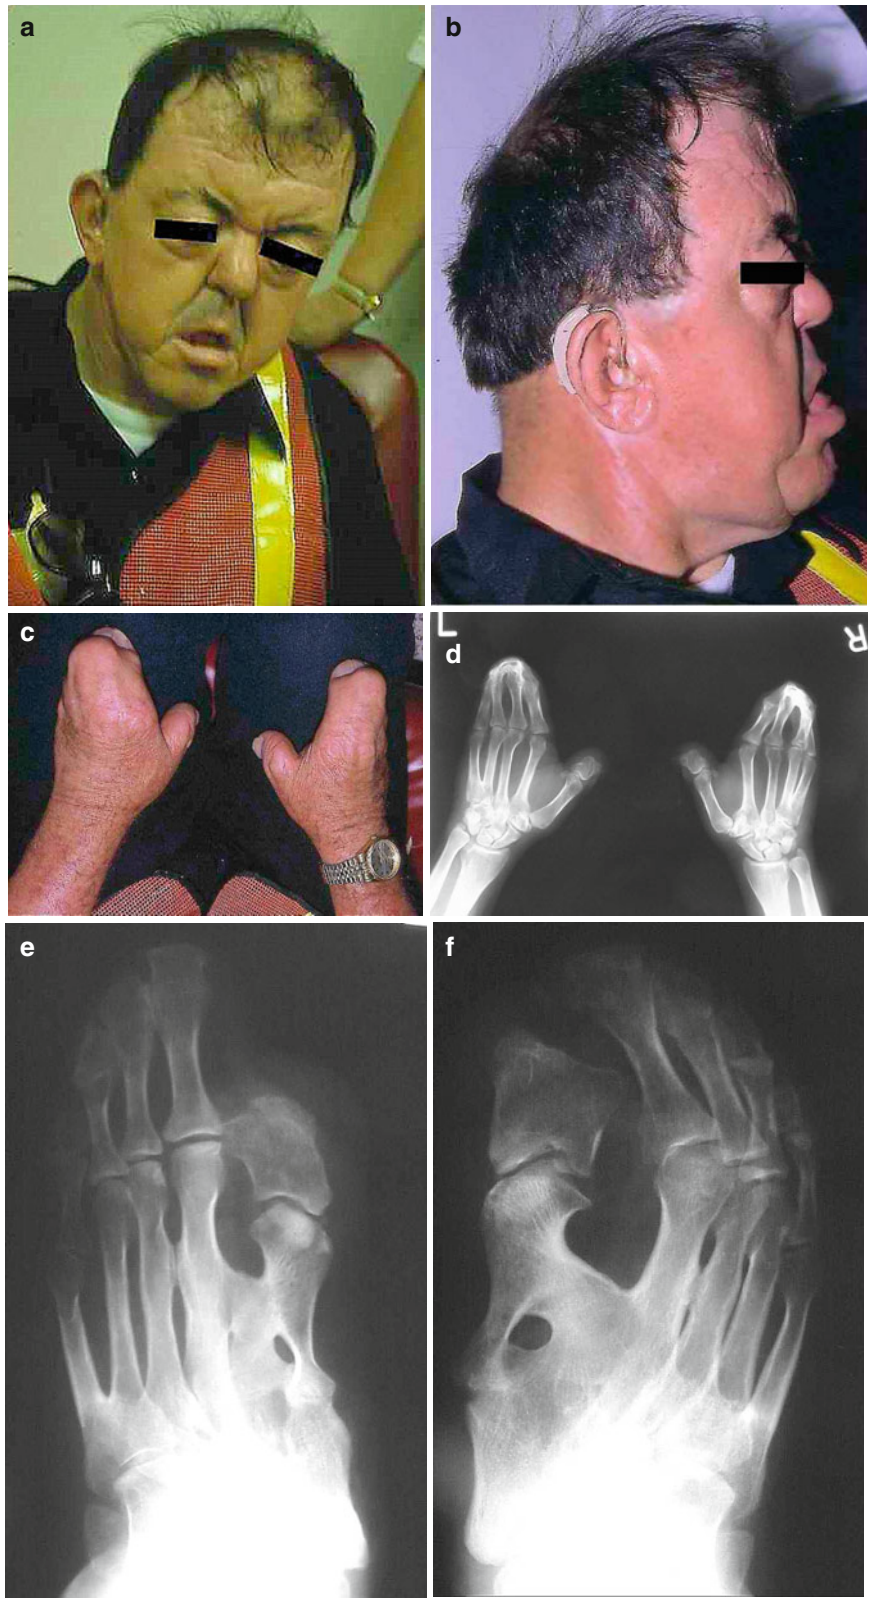

Fig. 3 (**a**–**f**) An adult with Apert syndrome showing typical craniofacial appearance, hearing loss (wearing hearing aids), and mitten hands. Radiographs showed cutaneous and osseous syndactyly, complete syndactyly involving the second through fifth digits (mitten hands), symphalangism of interphalangeal joints, delta-shaped proximal phalanx of the thumbs, complete syndactyly involving the second through fifth digits (socked feet), and partial duplication of the proximal phalanx of the great toes and first metatarsals

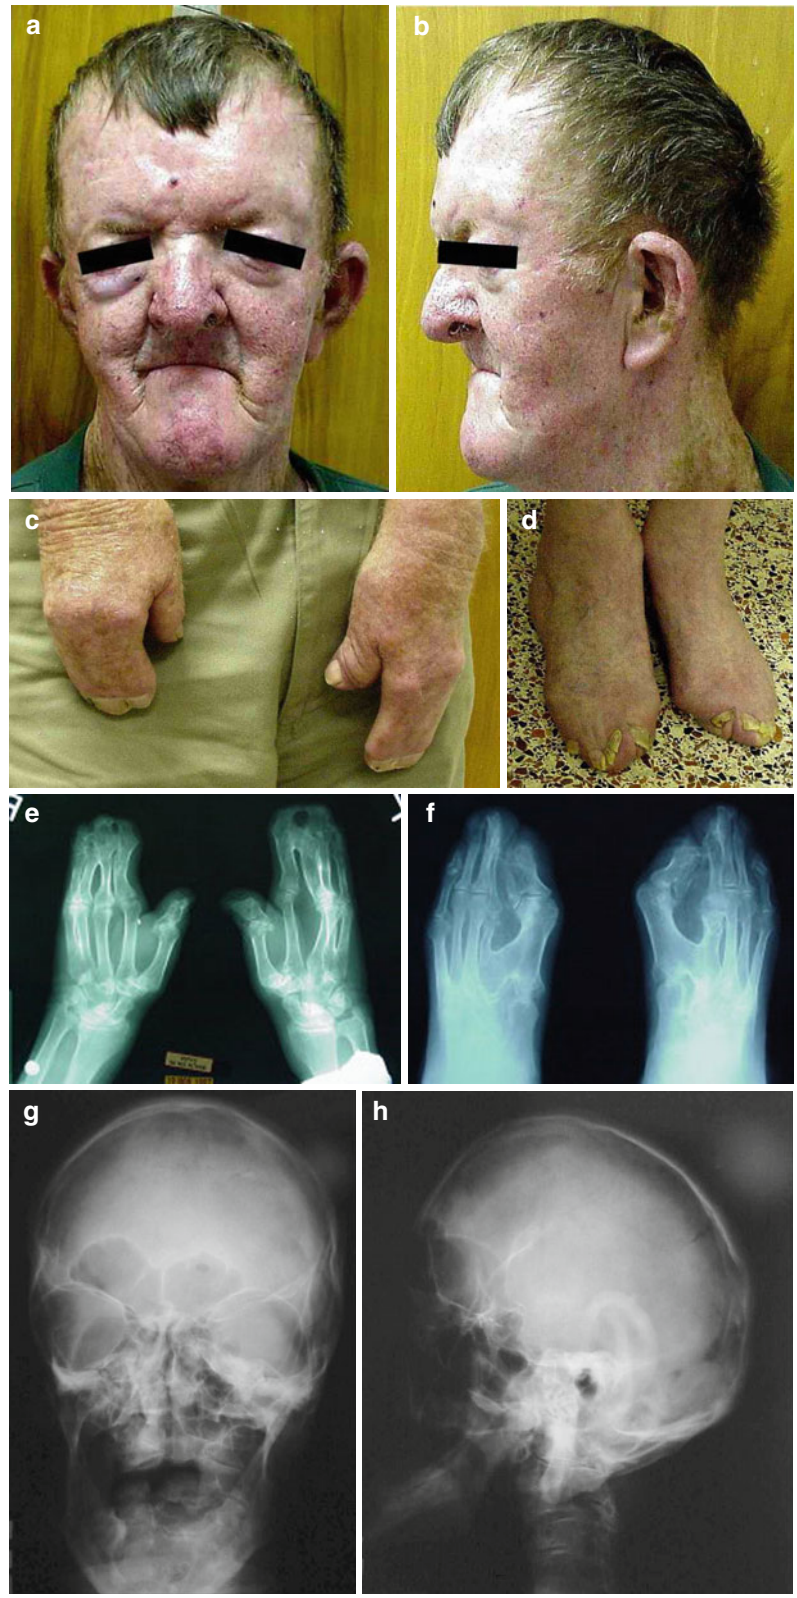

Fig. 4 (**a**–**h**) An adult with Apert syndrome showing typical craniofacial appearance with mitten hands and socked feet. Radiographs of hands and feet and skull showed cutaneous and osseous syndactyly, turribrachycephaly, shallow orbits, and hypoplastic maxilla

Fig. 5 (**a**–**h**) A daughter and a mother with Apert syndrome showing characteristic craniofacial features, mitten hands, and socked feet

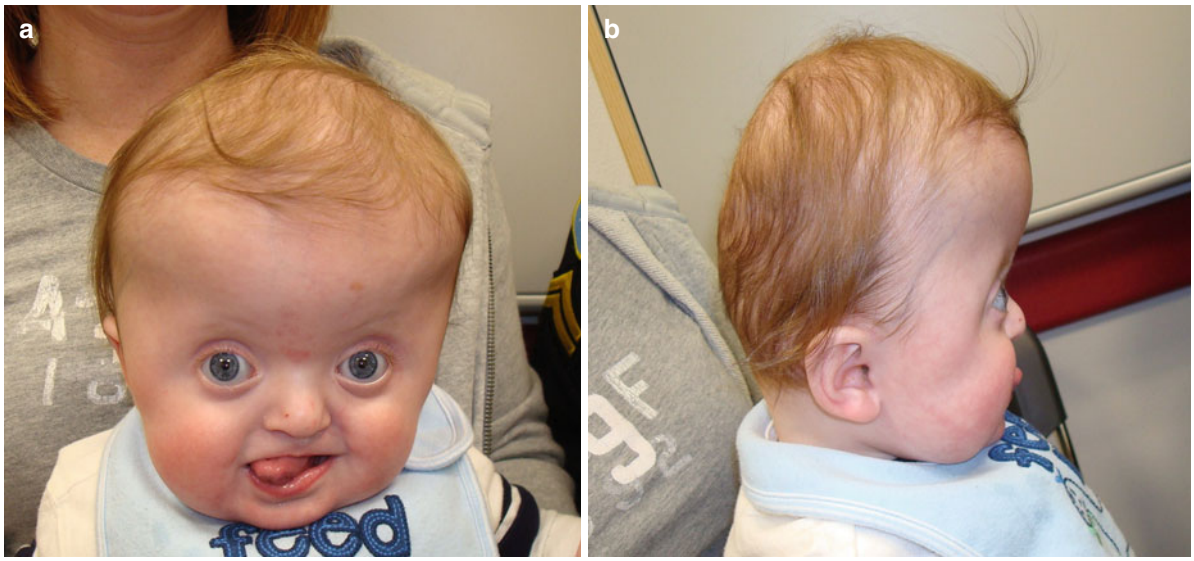

Fig. 6 (**a**, **b**) A 6-month-old male infant was evaluated for Apert syndrome which was diagnosed prenatally. The fetus was noted to have abnormal craniofacial features with mitten hands by ultrasonography. Molecular testing from cultured amniocytes indicated the presence of a C > G transversion at nucleotide 755 (c.755 C > G) of the fibroblast growth factor receptor 2 (*FGFR2*) gene. This change substitutes a tryptophan for a serine at amino acid 252 (p.S252W). The presence of this mutation is consistent with a clinical diagnosis of Apert syndrome. The infant showed severe acrocephaly, palpable coronal suture ridge, ocular hypertelorism with proptotic eyes, low-set ears, depressed nasal bridge, small soft palate cleft, hitchhiker like thumbs, mitten hands, and sock feet

Fig. 7 Mitten-shaped hands with cutaneous syndactyly and synonychia

Fig. 8 Radiograph of the right hand showing coalition of distal phalanges, symphalangism, cutaneous and osseous syndactyly, and delta-shaped deformity of the proximal phalanx of the thumb

Fig. 10 Radiograph of the right foot showing complete cutaneous syndactyly involving the second, third, fourth digits, and delta-shaped deformity of the proximal phalanx of the first toe

Fig. 9 Both feet showing socket-shaped feet, syndactyly of the feet with partial-to-complete fusion of the digits, involving second, third, and forth digits

Aplasia Cutis Congenita

Aplasia cutis congenita (ACC) is a clinical description of the absence of the skin at birth, first described by Cordon in 1767. It is a heterogeneous group of disorders characterized by absence of epidermis, dermis, and, sometimes, subcutaneous tissue, muscle, or bone on one or more parts of the body. The incidence is estimated to be 1 in 10,000 births.

Synonyms and Related Disorders

Aplasia cutis congenita associated with epidermolysis bullosa (simplex, junctional, dystrophic); Congenital scalp defect; Congenital skull and scalp defect

Genetics/Basic Defects

1. Etiological theories
   a. Amniogenic theory (Frieden 1986)
      i. Adhesion of the amniotic membrane to the fetal skin might tear off, leaving absent areas of skin
      ii. Not supported by the study of placentas because most placentas are normal
   b. Vascular theory: assumes thromboplastic material from a fetus papyraceus (mummified dead fetus) as the causes of skin damage
   c. Placental abnormalities
   d. Biomechanical forces on the vertex during the embryogenesis
   e. Intrauterine trauma: a history of trauma in only a minority of cases
   f. Intrauterine infections
      i. Varicella
      ii. Herpes simplex
   g. Intrauterine involution of a hemangioma
   h. Teratogens
      i. Methimazole
      ii. Misoprostol
   i. Genetic factors
2. Frieden's classification of aplasia cutis congenita (Frieden 1986)
   a. Group I: ACC of the scalp without multiple anomalies: sporadic occurrence or autosomal dominant inheritance
   b. Group II: ACC of the scalp with associated limb abnormalities: autosomal dominant inheritance
   c. Group III: ACC of the scalp with associated epidermal, organoid nevus, or epidermal nevus syndrome: sporadic occurrence
   d. Group IV: ACC overlying embryologic malformations: inheritance depending on underlying conditions
   e. Group V: ACC with associated fetus papyraceous or placental infarcts: sporadic occurrence
   f. Group VI: ACC associated with epidermolysis bullosa: autosomal dominant or recessive inheritance depending on the type of the epidermolysis bullosa
   g. Group VII: ACC localized to extremities without blistering: autosomal dominant or recessive inheritance

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_15,
© Springer Science+Business Media, LLC 2012

   h. Group VIII: ACC caused by specific teratogens: scalp (methimazole), any area (varicella, herpes simplex)
   i. Group IX: ACC associated with malformation syndromes
      i. Trisomy 13
      ii. Trisomy 18
      iii. Monosomy 4
      iv. Ectodermal dysplasias
      v. Johanson-Blizzard syndrome
      vi. Focal dermal hypoplasia
      vii. 46,XY gonadal dysgenesis
      viii. Amniotic band disruption complex
3. Aplasia cutis congenita associated with epidermolysis bullosa (Achiron et al. 1992)
   a. Simplex
      i. An autosomal dominant disorder
      ii. Lysis of the epidermis occurring within the cytoplasm of the basal cell layer
   b. Junctional
      i. An autosomal recessive disorder
      ii. Damage at the level of the lamina lucida
   c. Dystrophic (scarring)
      i. An autosomal dominant or recessive disorder
      ii. Defect situated in the anchoring fibrils attaching the basal lamina to the dermis

Clinical Features

1. Aplasia cutis of the scalp (aplasia cutis vertices) (Cambiaghi et al. 1998)
   a. The most common form
   b. Single or multiple noninflammatory ulcers
   c. Occurrence at or near the scalp vertex
   d. Variable in shape and size
   e. Heals leaving a hairless scar
   f. Occurrence
      i. An isolated condition
      ii. Associated with other congenital abnormalities
2. Aplasia cutis with extracranial symmetrical involvement (a distinctive type of "non-scalp" aplasia cutis congenita)
   a. Linear lesions with a symmetrical pattern of distribution on the trunk and limbs
   b. Aplasia cutis with fetus papyraceous: usually associated with in utero death of a monozygotic twin during pregnancy, with or without the presence of a fetus papyraceous (persistence of a mummified dead fetus)
   c. Other terms
      i. Truncal aplasia cutis
      ii. Bilateral abdominal aplasia cutis
3. Associated congenital anomalies
   a. Craniofacial anomalies
      i. Underlying skull bony defect: 15–20% of cases of scalp ACC and as high as 75% in cases of extensive scalp ACC (Burkhead et al. 2009)
      ii. Microphthalmia
      iii. Colobomas
      iv. Myopia
      v. Epibulbar dermoid
      vi. Cleft lip
      vii. Cleft palate
      viii. Ear malformations
   b. CNS malformation
      i. Hydrocephalus
      ii. Mental retardation
      iii. Spastic paralysis
   c. Ectodermal dysplasia
      i. Hypoplasia of the teeth
      ii. Delayed dentition
      iii. Nail hypoplasia
      iv. Skin blisters
      v. Skin hyperpigmentation
      vi. Cutis marmorata
   d. Gastrointestinal abnormalities (Al-Sawan et al. 1999; Lane and Zanol 2000)
      i. Tracheoesophageal fistula/esophageal atresia
      ii. Omphalocele
      iii. Gastroschisis
      iv. Pyloric atresia: especially in association with junctional (atrophicans) type of epidermolysis bullosa
      v. Ileal atresia
      vi. Mesenteric herniation
      vii. Biliary atresia
      viii. Midgut atresia
      ix. Intestinal lymphangiectasia
   e. Musculoskeletal abnormalities
      i. Terminal transverse limb defects (Adams-Oliver syndrome) (Snape et al. 2009)
      ii. Arthrogryposis
      iii. Polydactyly
      iv. Syndactyly

4. Prognosis
   a. Scalp lesion (1–3 cm): resolves spontaneously in majority of cases (85%)
   b. Prognosis usually determined by underlying anomalies and extent of the lesions

Diagnostic Investigations

1. Imaging
   a. Radiography
      i. Scalp/skull
      ii. Hands
      iii. Feet
   b. CT scan or MRI of the brain
2. Karyotyping to detect chromosome abnormality
3. Histology: heterogeneous appearance of lesions
   a. Ulcerated lesions at birth
      i. Complete absence of all layers of skin
      ii. Occasionally extending to the bone or dura
   b. In utero healing of some lesions
   c. Healed lesions
      i. Flattened epidermis
      ii. Proliferation of fibroblasts in a loose connective tissue stroma
      iii. Newly formed capillaries
      iv. Complete absence of adnexal structures
4. Culture/serology
   a. Varicella zoster
   b. Herpes simplex virus
5. Amniotic fluid findings in some cases (Dror et al. 1994)
   a. Elevated amniotic fluid AFP levels
   b. Positive acetylcholinesterase

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant: not increased unless a parent is affected
      ii. Autosomal recessive: 25%
   b. Patient's offspring
      i. Autosomal dominant: 50%
      ii. Autosomal recessive: not increased unless the spouse is a carrier
2. Prenatal diagnosis
   a. Ultrasonography for at risk family with aplasia cutis congenita associated with epidermolysis bullosa and pyloric atresia (Achiron et al. 1992)
      i. Hydramnios
      ii. A dilated stomach
      iii. A deformed external ear
      iv. A contracted fisted hand
   b. Amniocentesis for associated chromosomal abnormality
3. Management
   a. Careful and standard wound treatment for small defects involving only epidermis: usually uneventful healing of the lesion
   b. Control of infection
   c. Control of electrolyte abnormalities, especially with larger wounds
   d. Requires a scalp flap for most lesions
   e. A split-thickness skin grafting or full-thickness pedicle grafts (for defects of the scalp extending to the dura mater)
   f. Reconstruction of skull and scalp for a large lesion involving scalp, skull, and dura
   g. Emergency intervention to control life-threatening hemorrhage
   h. Surgical intervention also useful later in life for revision of scars and correction of alopecia with rotation flaps, simple excision and closure, scalp reduction techniques, or local hair transplantation
   i. Management of associated anomalies

Arthrogryposis Multiplex Congenita

Arthrogryposis multiplex congenita comprises nonprogressive conditions characterized by multiple joint contractures throughout the body at birth. The term encompasses a very heterogeneous group of disorders having the common feature of multiple congenital joint contractures. The overall prevalence of arthrogryposis is approximately 1 in 3,000 live births (Hall 1985a, b; Fahy and Hall 1990).

Synonyms and Related Disorders

Amyoplasia; Distal arthrogryposis (distotarlar dysmorphism, Freeman-Sheldon syndrome, Sheldon-Hall syndrome, Gordon syndrome, Hecht syndrome, Beals syndrome)

Genetics/Basic Defects

1. Major causes
   a. Arthrogryposis as a physical sign observed in many specific clinical conditions
      i. Single gene defects
      ii. Chromosomal abnormalities
      iii. Known or unknown syndromes or conditions
      iv. Environmental effects
   b. Fetal akinesia due to fetal abnormalities
      i. Neurogenic abnormalities: the most common cause of arthrogryposis
         a) Meningomyelocele
         b) Anencephaly
         c) Hydranencephaly
         d) Holoprosencephaly
         e) Spinal muscular atrophy
         f) Cerebro-oculo-facial-skeletal syndrome
         g) Marden-Walker syndrome
      ii. Muscular abnormalities: relatively rare causes of arthrogryposis
         a) Congenital muscular dystrophies
         b) Congenital myopathies
         c) Intrauterine myositis
         d) Mitochondrial disorders
      iii. Connective tissue abnormalities in tendon, bone, joint, or joint lining restricting fetal movements, resulting in congenital contractures. Examples include:
         a) Synostosis
         b) Lack of joint development
         c) Aberrant fixation of joints (as in diastrophic dysplasia and metatropic dwarfism)
         d) Aberrant laxity of joints with dislocations (as in Larsen syndrome)
         e) Aberrant soft tissue fixations (as in popliteal pterygium syndrome)
         f) Failure of normally developed tendon to attach to the appropriate place around the joint or bone in some forms of distal arthrogryposis, resulting in abnormal lack of movement of the joints with secondary contractures at birth.
      iv. Mechanical limitations to movement. Limited space for fetal movement inside the uterus may contribute to development of contractures. Examples include:
         a) Multiple births
         b) Uterine structural abnormalities such as bicornuate uterus
         c) Umbilical cord wrapping

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_16,
© Springer Science+Business Media, LLC 2012

d) Oligohydramnios in renal agenesis
e) Early persistent leakage of amniotic fluid

v. Intrauterine vascular compromise resulting in loss of nerve and muscle function with development of fetal akinesia and secondary joint contractures. Examples include:
a) Severe maternal bleeding during pregnancy
b) Failed attempts at termination of pregnancy

c. Fetal akinesia due to maternal disorders, examples include:
i. Infections
a) Rubella
b) Poliomyelitis
ii. Drugs/chemicals
a) Methocarbamol
b) Alcohol
c) Carbon monoxide poisoning
iii. Trauma
iv. Vitamin deficiency
v. Hyperthermia (e.g., prolonged sauna)
vi. Radiation
vii. Other maternal illnesses
a) Maternal autoantibodies
b) Diabetes mellitus
c) Myotonic dystrophy
d) Maternal multiple sclerosis

2. Pathophysiology
a. Joint development
i. Almost always normal during early embryogenesis
ii. Fetal motion essential for normal development of joints and their contiguous structures
b. Lack of fetal movement
i. Causing extra connective tissue to develop around the joint
ii. Resulting in fixation of the joint
iii. Limiting movement further aggravates the joint contracture.
iv. Contractures secondary to fetal akinesia: more severe in patients who are diagnosed early in pregnancy and who experience akinesia for longer periods of time during gestation

Clinical Features

1. Family history (Hall 1997)
a. Presence of congenital contractures in the family
i. Affected siblings
ii. Other affected family members
b. Marked intrafamilial variability
i. Mildly affected parent
ii. A parent with contractures early in infancy
c. Consanguinity
i. Increasing the chance that the parents will both carry the same disease gene
ii. Observed more frequently in families with rare recessive diseases than in those with common recessive diseases
d. Increased parental age
i. Some chromosomal abnormalities: increasing dramatically with advanced maternal age
ii. Single-gene dominant mutations: increasing with advanced paternal age
e. History of previous miscarriages or stillbirths
2. Pregnancy history
a. Diminished fetal movement
b. Infants born to mothers affected with the following disorders:
i. Myotonic dystrophy: A child who inherits the gene and is severely affected with resistant contractures.
ii. Myasthenia gravis and multiple sclerosis: Children may be born with congenital contractures.
c. Maternal infections leading to CNS or peripheral nerve destruction with secondary congenital contractures
i. Rubella
ii. Rubeola
iii. Coxsackievirus
iv. Enterovirus
v. Akabane
d. Maternal fever or hyperthermia causing contractures due to abnormal nerve growth or migration

e. Exposure to teratogens leading to decreased fetal movement
   i. Drugs
   ii. Alcohol
   iii. Curare
   iv. Methocarbamol
   v. Phenytoin
   vi. Radiation
f. Amniotic fluid volume
   i. Oligohydramnios: causes fetal constraint and secondary deformational contractures
   ii. Polyhydramnios: indicating fetal compromise
g. Uterine abnormalities
   i. Bicornuate uterus with a septum
   ii. Uterine fibroid
h. Other maternal complications
   i. Toxemia
   ii. Severe hypotension at critical time
   iii. Severe hypoxia (e.g., carbon monoxide poisoning) during pregnancy
   iv. Abnormal fetal lies
   v. Threatened abortion
   vi. Attempted termination
   vii. Trauma such as trauma to the abdomen

3. Delivery history
   a. Breech or transverse fetal position
      i. Relatively common
      ii. Usually normal length of gestation
      iii. Induction of labor often prolonged
      iv. Fracture of a limb during traumatic delivery in 5–10% of cases
   b. Abnormal placenta, membranes, or cord insertion in case of amniotic bands or vascular compromise. The umbilical cord may be shortened or wrapped around a limb, leading to compression.
   c. Prematurity
   d. Multiple births or twins
      i. Lack of movement due to uterine crowding
      ii. The death of one twin may lead to vascular compromise in the remaining twin.
4. Common physical characteristics
   a. Involved extremities
      i. Fusiform or cylindrical in shape
      ii. Thin subcutaneous tissue
      iii. Absence of skin creases
   b. Deformities
      i. Usually symmetric
      ii. Severity increasing distally
      iii. Hands and feet typically being the most deformed.
   c. Joint rigidity
   d. Associated joint dislocations, especially the hips and, occasionally, the knees
   e. Muscles
      i. Atrophy
      ii. Absence
   f. Sensation
      i. Usually intact
      ii. Diminished or absent deep tendon reflexes
5. Contractures
   a. Distal joints affected more frequently than proximal joints
   b. Types of contractures
      i. Flexion versus extension
      ii. Limitation of movement (fixed vs passive vs active)
      iii. Complete fusion vs ankylosis and soft-tissue contracture
   c. Intrinsically derived contractures
      i. Frequently associated with polyhydramnios
      ii. Symmetric contractures
      iii. Accompanied by taut skin
      iv. Pterygia across joints
      v. Lack of flexion creases
      vi. Recurrence risk and prognosis dependent on etiology
   d. Extrinsically derived contractures
      i. Associated with positional limb anomalies, large ears, loose skin, and normal or exaggerated flexion creases
      ii. Excellent prognosis
      iii. A low recurrence risk
6. Deformities
   a. Limb deformities
      i. Pterygium (webbing)
      ii. Shortening
      iii. Amniotic bands
      iv. Compression (e.g., due to cord wrapping)
      v. Absent patella
      vi. Dislocated radial heads
      vii. Dimples

b. Face deformities
   i. Asymmetry
   ii. Flat nasal bridge
   iii. Hemangioma
   iv. Jaw deformities including micrognathia and trismus
c. Other deformities
   i. Scoliosis
   ii. Genital deformities
      a) Cryptorchidism
      b) Microphallus
      c) Lack of labia
   iii. Hernias
      a) Inguinal
      b) Umbilical
d. Other features of the fetal akinesia sequence
   i. Intrauterine growth retardation
   ii. Pulmonary hypoplasia
   iii. Craniofacial anomalies
      a) Hypertelorism
      b) Cleft palate
      c) Depressed nasal tip
      d) High nasal bridge
   iv. Functional short gut with feeding problems
   v. Short umbilical cord
e. Absent or distorted crease abnormalities resulting from aberrant form or function in early hand or foot development

7. Malformations
   a. Craniofacial malformations
      i. CNS
         a) Structural malformations
         b) Seizures
         c) Mental retardation
      ii. Skull
         a) Craniosynostosis
         b) Asymmetry
         c) Microencephaly
      iii. Eyes
         a) Small and malformed eyes
         b) Corneal opacities
         c) Ptosis
         d) Strabismus
      iv. Palate
         a) High-arched
         b) Cleft
         c) Submucous cleft
   b. Respiratory problems affecting lung function
      i. Tracheal and laryngeal clefts and stenosis
      ii. Hypoplasia or weak muscles of diaphragm
   c. Limb malformations
      i. Reduction anomalies
      ii. Radioulnar synostosis
      iii. Syndactyly
      iv. Shortened digits
   d. Skin/vasculature abnormalities
      i. Hemangiomas and cutis marmorata
      ii. Cold and blue distal limbs
   e. Cardiac problems
      i. Congenital heart defects
      ii. Cardiomyopathy
   f. Urogenital structural anomalies
      i. Kidneys
      ii. Ureters
      iii. Bladder
   g. Nervous system problems
      i. Loss of vigor
      ii. Lethargy
      iii. Slow, fast, or absent deep tendon reflexes
      iv. Sensory deficits
   h. Muscle malformations
      i. Decreased muscle mass
      ii. Soft muscle texture
      iii. Fibrous bands
      iv. Abnormal tendon attachments
      v. Muscle changing with time
8. Connective tissue abnormalities
   a. Skin webs (pterygia) across joints with limitation of movement
   b. Skin dimples observed frequently over joints where movement is limited
   c. Soft, doughy, thick, or extensible skin
   d. Decreased or increased subcutaneous fat
   e. Inguinal, umbilical, or diaphragmatic hernias
   f. Thickness in joints
   g. Symphalangism
   h. Abnormalities in tendon attachment and length
   i. Associated skin defects including scalp defects, amniotic bands on limbs, and nail defects
9. Disorders with mainly limb involvement (Hall 1997)
   a. Amyoplasia (Bevan et al. 2007)
      i. The most common type of arthrogryposis seen in clinical practice and constitutes about one third of cases.
      ii. Incidence: about 1 in 10,000 live births

iii. A sporadic condition, not observed in siblings or offspring (recurrence risk not increased)
iv. Characterized by typical and symmetric positioning of the limbs
v. Internally rotated and adducted shoulders
vi. Fixed extended elbows
vii. Pronated forearms
viii. Flexed wrists and fingers
ix. A severe talipes equinovarus deformity
x. Muscles: hypoplastic and usually replaced by fibrous and fatty tissue
xi. Normal intelligence

b. Distal arthrogryposes
i. Type I (distotarlar dysmorphism)
a) An autosomal dominant disorder
b) Medially overlapping fingers
c) Tightly clenched fists at birth
d) Ulnar deviation of fingers and camptodactyly in adults
e) Positional foot contractures
f) Usually normal intelligence
ii. Type IIA (Freeman–Sheldon syndrome, also known as whistling face syndrome)
a) An autosomal dominant disorder
b) A mask-like face with a small mouth, giving a whistling face appearance
c) Deep-set eyes
d) Small nose with a broad nasal bridge
e) Epicanthal folds
f) Strabismus
g) High-arched palate
h) Small tongue
i) An H-shaped cutaneous dimpling on the chin
j) Flexion of fingers
k) Equinovarus feet with contracted toes
l) Kyphoscoliosis
iii. Type IIB (Sheldon–Hall syndrome) (Toydemir and Bamshad 2009)
a) An autosomal dominant disorder
b) Contractures of the distal joints of the limbs
c) Triangular face
d) Down-slanting palpebral fissures
e) Small mouth
f) High-arched palate
g) Caused by mutations in either *MYH3*, *TNNI2*, or *TNNT3* (~50% of cases)
iv. Type III (Gordon syndrome)
a) Short stature (90%)
b) Cleft palate
c) Bifid uvula
d) Epicanthal folds
e) Congenital ptosis
f) Short neck
g) Camptodactyly
v. Type IV
a) Scoliosis
b) Finger contractures
vi. Type V
a) Ophthalmoplegia (limited ocular motility)
b) Ptosis
c) Finger contractures
vii. Type VI
a) Sensorineural hearing loss
b) Finger contractures
viii. Type VII (Hecht syndrome)
a) Trismus pseudocamptodactyly
b) Inability to fully open mouth
c) Facultative camptodactyly
ix. Type VIII (autosomal dominant multiple pterygium syndrome)
a) Multiple pterygium
b) Finger contractures
x. Type IX (Beals syndrome, congenital contractural arachnodactyly)
a) An autosomal dominant disorder
b) Joint contractures
c) A long, thin body builds
d) Crumpling ears
e) Lacking cardiovascular and ocular abnormalities of Marfan syndrome
xi. Type X (congenital plantar contractures)

c. Bony fusion likely to be confused with arthrogryposis
i. Symphalangism (e.g., fusion of phalanges)
ii. Coalition (e.g., fusion of the carpals and tarsal bones)
iii. Synostosis (e.g., fusion of long bones)

d. Other associated syndromes and conditions
i. Absence of dermal ridges
ii. Absence of distal interphalangeal (DIP) joint creases
iii. Amniotic bands
iv. Antecubital webbing
v. Camptodactyly

vi. Congenital clapsed thumbs
vii. Familial impaired pronation and supination of forearm
viii. Humeroradial synostosis
ix. Liebenberg syndrome
x. Nail-patella syndrome
xi. Nievergelt-Pearlman syndrome
xii. Poland anomaly
xiii. Radioulnar synostosis
xiv. Tel-Hashomer camptodactyly

10. Disorders with involvement of limbs and other body parts (Hall 1997)
    a. Multiple pterygium syndrome (Chen et al. 1980)
        i. Autosomal recessive type: characterized by multiple joint contractures with marked pterygia, dysmorphic facies (flat, sad, motionless facial appearance), and cervical vertebral anomalies
        ii. Autosomal dominant type: characterized by multiple pterygia with or without mental retardation
    b. Multiple pterygium syndrome (pterygia with flexion contractures) associated with scoliosis, cleft palate, and malignant hyperthermia
    c. Multiple pterygium syndrome, Escobar type (Escobar et al. 1978)
        i. Webbing of the neck that increases with age
        ii. Webbing of the knees and elbows that develops before adolescence
        iii. Multiple joint contractures
        iv. Lumbar lordosis
    d. Lethal multiple pterygium syndrome (Hall 1984c; Chen et al. 1984; Chen 2011)
        i. An autosomal recessive disorder
        ii. Characteristic features
            a) Early lethality
            b) Hydrops fetalis
            c) Cystic hygroma
            d) Dysmorphic facies (hypertelorism, markedly flattened nasal bridge with hypoplastic nasal alae, cleft palate, micrognathia, low-set ears)
            e) Marked webbing and flexion contractures of multiple joints
            f) Short neck
            g) Small chest
            h) Hypoplastic lungs
        iii. Classification by Hall (1984a, b, c and Entezami et al. (1998)
            a) Type I (Gillin-Pryse-Davis syndrome): multiple pterygia, pulmonary hypoplasia, genital anomalies, and marked flexed extremities with a reduced muscle mass
            b) Type II (Chen syndrome) (Chen et al. 1984): multiple pterygia, hygroma colli, facial anomalies, undermodeled long bones, cartilaginous fusion of joints and bony fusion of the spinous processes of the vertebrae, polyhydramnios, hypoplastic lungs and heart, and diaphragmatic hernia
            c) Type III (van Regemorter syndrome): multiple pterygia, pulmonary hypoplasia, facial anomalies, thin extremities with reduced muscle mass, and fusions of the long tubular bones
            d) Type IV (Herva syndrome): multiple pterygia, degeneration of the anterior horn cells of the spinal cord, and observed particularly in Finland
    e. Popliteal pterygium syndrome
        i. An autosomal dominant disorder
        ii. Popliteal webs
        iii. Cleft lip or palate
        iv. Webs in the mouth
        v. Unusual nails
    f. Lethal popliteal pterygium syndrome (Bartsocas-Papas syndrome)
        i. An autosomal recessive disorder
        ii. Severe webs across the knee
        iii. Associated with facial clefting and fused digits (synostosis of the hand and foot bones) in the newborn period
        iv. Usually lethal
    g. Osteochondrodysplasias known to be associated congenital contractures
        i. Camptomelic dysplasia
        ii. Conradi-Hünermann (chrondrodysplasia punctata)
        iii. Diastrophic dysplasia
        iv. Focal femoral dysplasia
        v. Geleophysic syndrome
        vi. Kniest dysplasia
        vii. Metaphyseal dysplasia, Jansen type
        viii. Metatropic dysplasia

ix. Larsen dysplasia
x. Nail-patella syndrome
xi. Oculodentodigital syndrome
xii. Orocraniodigital syndrome
xiii. Osteogenesis imperfecta type II
xiv. Otopalatodigital syndrome
xv. Parastremmatic dysplasia
xvi. Perinatal lethal osteogenesis imperfecta
xvii. Pfeiffer syndrome
xviii. Saul–Wilson syndrome
xix. Synspondylism
xx. Spondyloepiphyseal dysplasia congenita
xxi. Otospondylomegaepiphyseal dysplasia

h. Other associated syndromes and conditions
i. Hand-muscle wasting and sensorineural deafness
ii. Holt–Oram syndrome
iii. Kuskokwim syndrome
iv. Leprechaunism
v. Megalocornea with multiple skeletal anomalies
vi. Möbius syndrome
vii. Nemaline myopathy
viii. Ophthalmomandibulomelic dysplasia
ix. Prader-Willi habitus/osteoporosis/hand contractures
x. Pseudothalidomide syndrome
xi. Puretic-Murray syndrome
xii. Sacral agenesis
xiii. Schwartz-Jampel syndrome
xiv. Sturge–Weber syndrome
xv. Tuberous sclerosis
xvi. VATER (vertebral defects, imperforate anus, tracheoesophageal fistula, radial and renal dysplasia) complex
xvii. Weaver syndrome
xviii. Winchester syndrome
xix. X-trapezoidocephaly with midfacial hypoplasia and cartilage abnormalities

11. Disorders with limb involvement and CNS dysfunction (Hall 1997)
a. Associated chromosome abnormalities
i. Sex chromosome anomalies (45,X, 47, XXY/48,XXXY, 49,XXXXX, 49, XXXXY)
ii. Autosomal trisomies (4p, 8, 8 mosaicism, 9, 9q, 10p, 10q, 11q, 13, 14, 15, 18, 21)
iii. Other chromosome anomalies
b. Cerebro-oculo-facio-skeletal syndrome
i. A common lethal condition
ii. Contractures
iii. Brain anomalies
iv. Dysmyelination
v. Microphthalmia
vi. Cataracts
vii. Renal anomalies
viii. Other visceral anomalies
c. Neu-Laxova syndrome
i. A lethal autosomal recessive disorder
ii. Dramatic contractures
iii. Intrauterine growth retardation
iv. Microcephaly
v. Open eyes
vi. Tight ichthyotic skin
vii. Severe CNS anomalies
d. Restrictive dermopathy
i. A lethal autosomal recessive disorder
ii. Contractures and failure of fetal skin to grow normally restricting fetal movement and leading to secondary contractures
e. Pena-Shokeir phenotype: Phenotype is caused by fetal akinesia rather than a specific syndrome
i. Short, fixed limbs
ii. Pulmonary hypoplasia
iii. Intrauterine growth retardation
iv. Polyhydramnios
v. Short umbilical cord
vi. Unusual craniofacies

12. Other associated syndromes and conditions
a. Adducted thumbs
b. Bowen-Conradi syndrome
c. C syndrome
d. Congenital myotonic dystrophy
e. Congenital myasthenia gravis
f. Faciocardiomelic syndrome
g. Fetal alcohol syndrome
h. FG syndrome
i. Marden-Walker syndrome
j. Meckel syndrome
k. Meningomyelocele
l. Mietens-Weber syndrome
m. Miller–Dieker syndrome
n. Neu-Laxova syndrome
o. Neurofibromatosis
p. Popliteal pterygium with facial clefts
q. Potter syndrome

r. Pseudotrisomy 18
s. Spinal muscular atrophy
t. Syndrome of cloudy cornea, diaphragmatic defects, and distal limb deformities
u. Syndrome of craniofacial and brain anomalies and intrauterine growth retardation
v. Syndrome of cryptorchidism, chest deformity, and contractures
w. Toriello–Bauserman syndrome
x. Walker–Warburg syndrome
y. X-linked lethal arthrogryposis
z. Zellweger syndrome

13. Prognosis
    a. Poor prognosis for ventilator-dependent neonates
    b. Prenatal factors that potentially predict respiratory insufficiency
        i. Decreased fetal movements
        ii. Polyhydramnios
        iii. Micrognathia
        iv. Thin ribs
        v. Decreased fetal movement often resulting in delayed developmental milestones
    c. Skeletal changes secondary to the original deformities
        i. Scoliosis
        ii. Deformed carpal and tarsal bones
        iii. Under growing of limbs after longstanding contractures
        iv. External genitalia often abnormal (e.g., cryptorchidism, absent labia majora) because of abnormal hip position
    d. Intrinsically or extrinsically derived defects
        i. Extrinsically derived contractures: an excellent prognosis
        ii. Intrinsically derived contractures: a prognosis dependent on etiology
    e. Prognosis depending on the condition's natural history
        i. Developmental landmarks (attainment of motor, social, and language milestones)
        ii. Growth of affected limbs
        iii. Progression of contractures
        iv. CNS damage (lethal, stable, improving)
        v. Asymmetry of contractures (improving, worsening)
        vi. Changes in trunk or limbs
        vii. Intellectual ability
        viii. Socialization
    f. Prognosis depending on the patient's response to therapy
        i. Spontaneous improvement
        ii. Response to physical therapy
        iii. Response to casting
        iv. Types of surgery at appropriate time
        v. Development of motor strength proportionate to limb size

Diagnostic Investigations

1. Lab studies (Hall 1981)
    a. Laboratory tests, in general, are not useful
    b. Creatine phosphokinase (CPK) levels when the following conditions are present:
        i. Generalized weakness
        ii. Doughy or decreased muscle mass
        iii. Progressive worsening
    c. Viral cultures for an infectious process (intrauterine growth retardation, eye involvement, and hepatosplenomegaly)
    d. Immunoglobulin M levels and specific viral titers (e.g., coxsackievirus, enterovirus, Akabane virus) in the newborn for intrauterine infection
    e. Maternal antibodies to neurotransmitters in the infant indicating myasthenia gravis
    f. Cytogenetic study indicated in the following situations:
        i. Multiple organ or system involvement
        ii. Presence of CNS abnormalities, such as microcephaly, mental retardation, lethargy, degenerative changes, or eye anomalies
        iii. Fibroblast chromosome study if lymphocyte chromosomes are normal and the patient has mental retardation without diagnosis
    g. Nuclear DNA mutation analysis to identify certain disorders, such as spinal muscular dystrophy
    h. Mitochondrial mutation analysis to identify certain disorders, such as mitochondrial myopathy
2. Imaging studies
    a. Patient's photographs
        i. To document the extent of deformities (range of motion and position of arthrogryposis)
        ii. To assess progress during treatment
    b. Radiographs to evaluate the following skeletal and joint abnormalities:
        i. Bony abnormalities (e.g., gracile bones, fusions, extra or missing carpals, and tarsals)

ii. Disproportionately short stature (i.e., skeletal dysplasias)
iii. Scoliosis
iv. Ankylosis
v. Absence of patella
vi. Humeroradial synostosis

c. Ultrasonography
i. To evaluate the CNS and other viscera for anomalies
ii. To establish potential muscle tissue

d. CT scan to evaluate the CNS and the muscle mass
e. MRI to evaluate muscle mass obscured by contractures
f. Ophthalmological evaluation for opacity and retinal degeneration

3. Histologic studies (Banker 1985)
a. Neurogenic types
i. Muscle fiber type predominance or disproportion is the most common neurogenic abnormality in arthrogryposis (26%). These are nonspecific alterations.
ii. Dysgenesis of the motor nuclei of the spinal cord and brainstem causes the replacement of fasciculi of muscle fibers by small muscle fibers and adipose tissue. Examples include Pierre Robin syndrome and Möbius syndrome.
iii. Dysgenesis of the CNS: the second most common neurogenic abnormality in arthrogryposis (23%), with disorganization and decrease in neurons of the cortex and motor nuclei of the brainstem and spinal cord. Clinical syndromes with this abnormality include trisomy 18, partial deletion of the long arm of chromosome 18 syndrome, and Zellweger syndrome.
iv. Dysgenesis of the anterior horn, another common neurogenic abnormality in arthrogryposis
v. Spinal muscular atrophy (e.g., Werdnig–Hoffmann disease): another neurogenic abnormality in arthrogryposis

b. Myopathic types
i. Central core disease: a form of arthrogryposis in which the central portion of each muscle fiber contains a zone in which oxidative enzyme activity is absent
ii. Nemaline myopathy indicated by abnormal thread-like structures in muscle cells. In type I nemaline myopathy, nemaline rods are present. In type II, the number of fibers with central nuclei is increased.
iii. Congenital muscular dystrophy indicated by muscle fibers that demonstrate a rounded configuration and conspicuous variation in diameter. Perimysial and endomysial connective tissues are increased markedly.
iv. Mitochondrial cytopathy indicated by numerous ragged-red fibers on muscle biopsy. It is associated with CNS abnormalities consistent with mitochondrial disease (Gordon 1998).
v. Myoneural junction abnormality (e.g., congenital myasthenia gravis): another myopathic type of arthrogryposis

4. Procedures
a. Skin biopsy for culture of fibroblasts to be used for chromosome analysis and metabolic studies
b. Muscle biopsy
i. Probably the most important diagnostic procedure. It should be included in all autopsies and at time of surgery.
ii. Distinguish myopathic from neuropathic conditions by obtaining muscle specimens from normal and affected areas.
iii. Special histopathologic and electron micrographic studies to evaluate fatty and connective tissue replacement of muscle fibers and variations in fiber size, such as decreased fiber diameter. All are nonspecific signs of muscle atrophy.

c. Electromyography (EMG) in normal and affected areas useful in differentiating neurogenic and myopathic causes (Gordon 1998)
d. Nerve conduction tests to measure conduction velocities in motor and sensory nerves. These should be performed when a peripheral neuropathy is suspected.
e. An autopsy to investigate the following:
i. CNS (i.e., brain neuropathology)
ii. Spinal cord (number and size of anterior horn cells, presence or absence of tracts at various levels)
iii. Ganglia and peripheral nerves
iv. Eye (i.e., neuropathology)
v. Muscle tissue from different muscle groups (i.e., electron microscopy and special stains)

vi. Fibrous bands replacing muscle
vii. Tendon attachments
viii. Other visceral anomalies, malformations, deformations, and disruptions

Genetic Counseling

1. Recurrence risk: Recurrence risk depends on whether the contractures are extrinsically or intrinsically derived. Extrinsically derived contractures have a low recurrence risk, while the recurrence risk for intrinsically derived contractures depends on etiology. Arthrogryposis may be inherited in the following ways with different recurrence risks:
   a. Patient's sib
      i. Autosomal recessive: 25%
      ii. Autosomal dominant: not increased unless a parent is affected or having gonadal mosaicism
      iii. X-linked recessive: 50% of male sibs affected if the mother is a carrier
   b. Patient's offspring
      i. Autosomal recessive: not increased unless the spouse is also a carrier
      ii. Autosomal dominant: 50%
      iii. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.
   c. Multifactorial: Combined effects of multiple genes and environmental factors cause multifactorial traits. For most multifactorial diseases, empirical risks (risks based on direct observation of data) have been derived. For example, empirical recurrence risks of neural tube defects for siblings of an affected individual range from 2% to 5% in most populations.
   d. Mitochondrial: A small but significant number of diseases are caused by mitochondrial mutations. Because of the unique properties of mitochondria, these diseases display characteristic modes of inheritance (i.e., inherited exclusively through the maternal line) with wide phenotypic variability. Only females can transmit the disease mutation to their offspring (e.g., distal type IIB arthrogryposis).
   e. Sporadic: For those families in which a specific diagnosis cannot be made, the empiric recurrence risk to unaffected parents of an affected child, or to the affected individual with arthrogryposis, is about 3–5%.
2. Prenatal diagnosis
   a. Prenatal ultrasonography to detect the following:
      i. Diminished fetal movement (main manifestation shared by various conditions with congenital contractures)
      ii. Joint contractures (bilateral fixed flexion deformities of the hands, elbows, shoulders, hips and knees, or talipes)
      iii. Detection of subcutaneous edema (fetal hydrops)
      iv. Cystic hygroma
      v. Increased nuchal translucency
      vi. Abnormal fetal lie
      vii. Polyhydramnios or oligohydramnios
      viii. Other associated anomalies (e.g., distended bladder in early urethral obstruction sequence; microcephaly, hydrocephaly, or hydranencephaly in "cerebral dysgenesis"–induced congenital contractures)
   b. Chromosome analysis by amniocentesis or CVS for chromosome disorders
   c. Molecular genetic analysis for certain genetic disorders with demonstrable mutations
3. Management (Shriner's Manual)
   a. No completely successful approach to treatment
   b. Overall goals
      i. Proper alignment of the lower limbs
      ii. Upper limb function for self-care
   c. Early vigorous physical therapy to stretch contractures
      i. To improve joint motion
      ii. To avoid muscle atrophy
      iii. Excellent functional outcome in patients with amyoplasia or distal arthrogryposis
      iv. May be harmful in diastrophic dysplasia because it may lead to joint ankylosis
      v. Frequent recurrence of deformities following stretching, often requires surgery
   d. Splinting combined with physical therapy
      i. Preferable to continuous casting
      ii. Night splinting after surgical procedures indicated to maintain increased range of motion
   e. Feeding assistance and intubation needed in patients with severe trismus

f. Specific joint problems
   i. Should be addressed with regard to treatment of other joints and the goals for the patient
   ii. Early soft-tissue surgery with osteotomies when the growth is completed
   iii. Tenotomies accompanied by capsulotomies in soft-tissue release procedures
   iv. Long-term bracing and assistive devices usually needed
g. Feet
   i. A rigid talipes equinovarus deformity: the most common deformity
   ii. Goal of treatment: a plantigrade, braceable foot
h. Knees
   i. Goal of treatment: an extended knee for ambulation
   ii. Flexion knee deformities more common than fixed knee deformities and more resistant to treatment
i. Hips
   i. Hip surgery follows foot and knee surgery, especially in the presence of knee extension deformities.
   ii. Hip surgery in patients younger than 1 year to facilitate ambulation. In some patients with bilateral hip dislocations and extremely mobile hips, open reduction may be attempted.
j. Upper extremities
   i. Treatment involves development of self-help skills (e.g., feeding and toileting) and mobility skills (e.g., pushing out of chair and using crutches).
   ii. Consider overall function of the entire extremity rather than function of the individual joints in evaluating the upper extremities.
   iii. Consider upper extremity surgery until the patient is older than 5–6 years.
k. Elbows
   i. Goals: passive or active flexion capability (feeding arm) and extension capability (toilet arm)
   ii. Achieve elbow mobility before correcting a wrist deformity because the elbow is crucial to hand function.
l. Wrists
   i. Stretching and splinting for the major wrist deformity (flexion with ulnar deviation)
   ii. Proximal row carpectomy with or without fusion for a severe deformity
m. Fingers
   i. Passive stretching and splinting for minimal to moderate flexion deformities
   ii. Soft-tissue releases with proximal interphalangeal joint fusions for more severe deformities
   iii. Thumb-in-palm deformity to be corrected to provide opposition-improved grasp
n. Spine
   i. The spine affected in about one third of patients
   ii. Scoliosis beginning early and progressing to become a long, severe, rigid, C-shaped curve. This curve responds poorly to orthoses, as it is progressive.
   iii. Curves greater than 35°: treated with spinal fusion and instrumentation
o. Complications
   i. Anesthesia: difficult to administer because vascular access often is restricted
   ii. Intubation: posing problems for patients with a small underdeveloped jaw, limited movement of the temporomandibular joint, or a narrow airway
   iii. Osseous hypoplasia associated with decreased mechanical use in developing bone: prone to fracture at multiple sites. Multiple perinatal fractures have been observed in osteopenic bones.
p. Physical activity
   i. Limited because of existing orthopedic problems
   ii. As a group, patients cope well socially and participate in social activities corresponding to their needs.
   iii. More restricted walking in patients with flexion contractures of the lower extremities than in those with extension contractures. Flexion contractures of the hips severely impair walking ability.
   iv. Contracture of the elbow causing a significant degree of disability in hand function
   v. Impossible to use crutches in patients with upper extremity involvement associated with severe spinal deformity
   vi. Dependent on help from other people to a higher degree in patients with more severe

joint involvement than those with less severe joint involvement

vii. Independent living with productive lives for most children with normal intelligence despite severe handicaps. However, many remain partially dependent on others, such as parents, relatives, and government subsidy. Dependency is related more closely to personality, education, and overall coping skills than to the degree of physical deformity.

viii. Good family support, a proper educational environment, and promotion of independence at an early age: required to achieve maximal function in addition to appropriate surgical correction

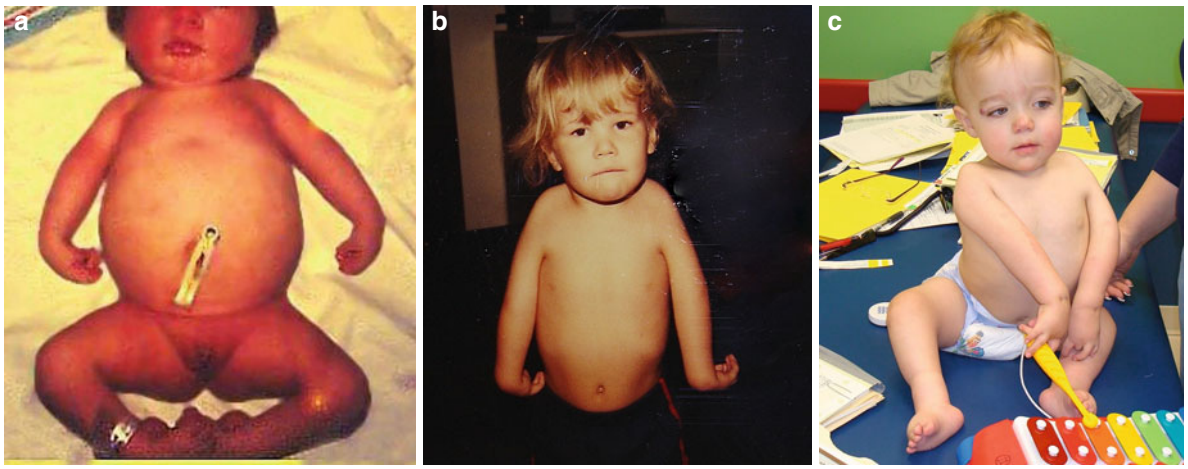

Fig. 1 (**a–c**) Three infants with amyoplasia congenita showing typical, symmetrical positioning of the limbs, internally rotated and adducted shoulders, fixed extended elbows, pronated forearms, flexed wrists and fingers, and severe talipes equinovarus deformity

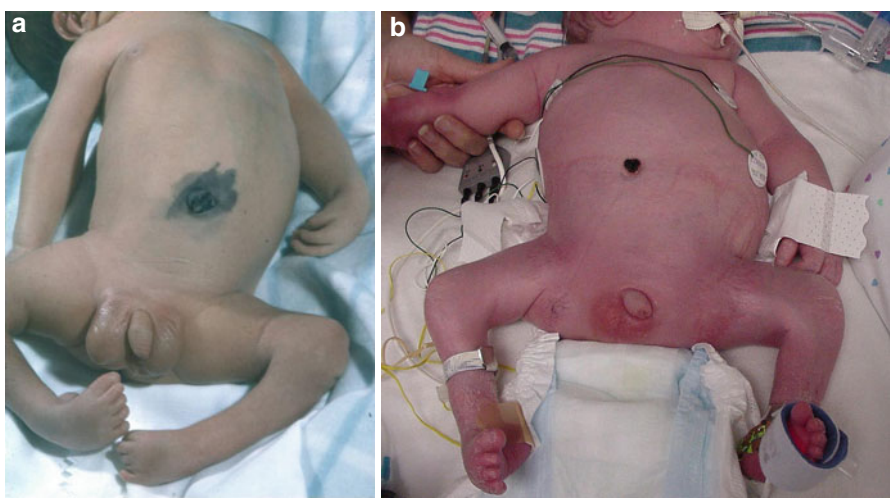

Fig. 2 (**a–b**) Two infants with arthrogryposis multiplex congenita characterized by flexion contractures of the knees and fingers, and equinovarus deformities of the feet

Fig. 3 (**a–b**) An infant with distal arthrogryposis showing predominantly distal contractures with overlapping finger contractures, ulnar deviation of fingers, and clubfeet

Fig. 4 (**a–c**) A 33-year-old female was followed for arthrogryposis multiplex congenita. At birth, flexion contractures of the fingers and hands, dysplastic hips, bilateral rocker bottom feet, and "generalized stiffness" were noted. At recent visit, flexion contractures of the elbows, limitation of supination of the wrists, contractures of the thumbs and PIP joints, and operation scars of webbing release between 1st and 2nd fingers and Achilles tendon release were noted

Asphyxiating Thoracic Dystrophy

In 1955, Jeune et al. described familial asphyxiating thoracic dystrophy (ATD) in a pair of siblings with severely narrow thoraxes. This condition is also known as Jeune syndrome. Incidence is estimated at 1 per 100,000–130,000 live births (den Hollander et al. 2001).

Jeune syndrome, a potentially lethal congenital dwarfism, is a rare autosomal recessive disorder characterized by typical skeletal dysplasias, such as a narrow thorax and micromelia, with respiratory and renal manifestations. Respiratory manifestations vary widely from respiratory failure and infantile death to a latent phenotype without respiratory symptoms.

Synonyms and Related Disorders

Jeune Syndrome

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Genetically heterogeneous
   a. One locus mapped to chromosome 15q13 (Morgan et al. 2003).
   b. Families with both mild and severe forms of ATD mapped to 15q13.
   c. Five consanguineous families sharing a 1.2 cM region of homozygosity between D15S165 and D15S1010.
   d. Mutations in the intraflagellar transport 80 (*IFT80*) gene have been recently identified in 3/39 families originating from Pakistan and Turkey, ascribing ATD to the ciliopathy group (Morgan et al. 2003). However, *IFT80* was excluded in a series of 26 fetuses and children belonging to 14 families diagnosed with either ATD or short rib-polydactyly syndrome, type III (SRP III) (Dagoneau et al. 2009).
   e. *DYNC2H1* Mutations: cause asphyxiating thoracic dystrophy (also cause SRP III) (Dagoneau et al. 2009)
      i. Studying a consanguineous family from Morocco, another locus was mapped to chromosome 11q14.3-q23.1 in a 20.4 Mb region and identified homozygous mutations in the cytoplasmic dynein 2 heavy chain 1 (*DYNC2H1*) gene in the affected children.
      ii. Compound heterozygosity for *DYNC2H1* mutations was also identified in four additional families.
      iii. Among the five families, 3/5 were diagnosed with ATD and 2/5 included pregnancies terminated for SRP type III
      iv. *DYNC2H1* is a component of a cytoplasmic dynein complex and is directly involved in the generation and maintenance of cilia.
      v. ATD and SRP type III are variants of a single disorder belonging to the ciliopathy group.

Clinical Features

1. Wide phenotypic variability
2. Classification of ATD
   a. Lethal form
   b. Severe form
   c. Mild form
   d. Latent form

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_17,
© Springer Science+Business Media, LLC 2012

3. Short-limbed dwarfism
4. Growth retardation
5. Respiratory distress
   a. Respiratory distress secondary to a small thorax
      i. Motionless thorax
      ii. Abdominal respiration
      iii. Considerable supraclavicular, suprasternal, and intercostal space retraction on inspiration
   b. Severe dyspnea and extreme cyanosis in severe cases
   c. Some infants with only respiratory symptoms in conjunction with infection
   d. Some individuals lack respiratory symptoms in infancy or childhood.
6. Chest deformity of varying degree
   a. A long, narrow, and abnormally small thorax with reduced thoracic cage capacity
   b. Lung hypoplasia and respiratory distress usually leading to early death
   c. The symptoms of small thorax usually improves with age for those who survive early childhood
7. Limbs
   a. Variable micromelia and short digits with bulbous terminal phalanges
   b. Occasional postaxial polydactyly of the hands and feet
8. Eyes: occasional retinal degeneration.
9. Occasional intestinal malabsorption.
10. Renal failure developing during infancy, early adolescence, or second decade of life.
11. Polyuria, polydipsia, and hypertension occur during the second or third year of life.
12. Occasional involvement of the liver
    a. Prolonged neonatal jaundice
    b. Polycystic liver disease
    c. Hyperplasia of the bile ducts
    d. Congenital hepatic cirrhosis
13. Occasional involvement of the heart
    a. Cardiac failure secondary to increased pulmonary vascular resistance, thoracic constriction, and alveolar hypoplasia
    b. Possible intrinsic myocardial disease
14. Cystic changes of pancreatic ducts and pancreatic exocrine insufficiency occur in long-term survivors.
15. Occasional involvement of the teeth, nails, and other organs.
16. Prognosis
    a. Difficult to predict in each individual case because frequent pulmonary complications and cystic renal lesions are not always directly related to severity of skeletal changes.
    b. The skeletal dysplasia of this entity is compatible with life, though respiratory failure and infections are often fatal during infancy.
    c. Considerable variation in the severity of thoracic constriction: For those patients who survive infancy, the thorax tends to revert to normal with improving respiratory function. This suggests that the lungs have a normal growth potential and the respiratory problems are secondary to restricted rib cage deformity.
    d. Renal failure: Renal involvement is the major prognostic factor in those patients who survive the respiratory insufficiency during infancy.
    e. Short stature in survivors.
17. Morbidity and mortality
    a. Alveolar hypoventilation
       i. The most common and prominent clinical presentation
       ii. Caused by impaired chest expansion as a result of short horizontally placed ribs
    b. Bilateral microcystic renal disease gradually progressing to tubular atrophy and renal failure
    c. Most patients (approximately 60–70%) dying from respiratory failure in early infancy and early childhood
    d. Chronic renal failure ensuing in survivors
    e. Few patients reaching adolescence or adulthood
18. ATD overlapping with SRP III (Verma-Naumoff syndrome)
    a. Both conditions share the same radiological features (including the polydactyly)
    b. SRP type III (Ho et al. 2000; Superti-Furga and Unger 2007)
       i. More severe condition
       ii. Early prenatal expression and lethality
       iii. Variable malformations
          a) Cleft lip and/or palate
          b) Polycystic kidneys
          c) Gastrointestinal, urogenital, brain, and/or cardiac malformations
       iv. Severely shortened tubular bones having round metaphyseal ends with lateral spikes

Diagnostic Investigations

1. Laboratory studies
   a. Urinalysis
      i. Hematuria
      ii. Proteinuria
      iii. Defective urine concentrating capacity
   b. Arterial blood gas (ABG): hypoxia and hypercarbia in room air reflecting severe restrictive lung disease
2. Imaging studies
   a. Newborn and infant radiography
      i. Small and bell-shaped thorax with reduced transverse and anterior-posterior diameter
      ii. Abnormal clavicles ("bicycle handlebar shaped")
      iii. Short and horizontally oriented ribs with irregular costochondral junctions and bulbous and irregular anterior ends
      iv. Abnormal pelvis
         a) Short squared iliac wings
         b) Trident appearance of acetabular margin
      v. Short limbs relative to trunk
      vi. Variable limb shortening
      vii. Short phalanges, metacarpals, or metatarsals with or without polydactyly
      viii. Premature ossification of the capital femoral epiphyses
   b. Childhood radiology
      i. Relatively larger thorax with growth of ribs compared to infancy
      ii. Short ilium with normal flaring of iliac wings
      iii. Striking cone-shaped epiphyses and early fusion between the epiphyses and metaphyses of the distal and middle phalanges
      iv. Short distal and middle phalanges
      v. Varying shortening of extremities relative to trunk
      vi. Subtypes of ATD
         a) Type I: irregular metaphyseal ends
         b) Type II: smooth metaphyseal ends
3. Pulmonary function test to detect severe restrictive lung disease
4. Histology
   a. Lungs: Hypoplastic due to a marked reduction in the number of alveolar ducts and alveoli (hypoplasia of alveoli)
   b. Cartilages: retarded endochondral ossification in both types
      i. ATD type I: irregular cartilage-bone junction with patchy distribution of physeal growth zone of chondrocytes
      ii. ATD type II: smooth cartilage-bone junctions
   c. Kidneys
      i. Cystic renal dysplasia and hypoplasia
      ii. Nephronophthisis or interstitial nephritis
         a) Diffuse interstitial and periglomerular fibrosis
         b) Round cell lymphocytic infiltration
         c) Hyalinized glomeruli
         d) Pericapsular thickening
         e) Thickened basement membrane
         f) Dilated or atrophic tubules
      iii. Pyelonephritis with scarring
      iv. Distortion of renal parenchyma
   d. Liver
      i. Periportal hepatic fibrosis
      ii. Bile duct proliferation
      iii. Early cirrhosis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: usually lethal, not surviving to reproductive age
2. Prenatal diagnosis by ultrasonography
   a. Detection of affected second- and third-trimester fetuses of at-risk families
   b. Characteristic ultrasonographic findings
      i. Narrow thorax
      ii. Short hypoplastic ribs
      iii. Short tubular bones
      iv. Renal cystic changes
   c. Other ultrasonographic findings
      i. Polyhydramnios
      ii. Absent or feeble fetal respiratory movements
      iii. Increased nuchal translucency
      iv. With or without polydactyly
      v. Ventriculomegaly
      vi. A single umbilical artery
3. Management
   a. Medical care
      i. Supportive care

ii. Mechanical ventilation
   a) Urgently required in the most severe cases, those when respiratory distress develops immediately after birth
   b) Less severe cases gradually progressing to respiratory failure as a result of multiple recurrent pulmonary infections
iii. Treat respiratory infections vigorously with antibiotics, endotracheal suctioning, and postural drainage
iv. Nasogastric or gastrostomy feedings if needed
v. Ursodeoxycholic acid used to control the progression of the hepatic dysfunction

b. Surgical care
   i. Surgery indicated only in the most severe cases in which failure to intervene will result in progressive pulmonary damage and eventual death. No data is currently available on long-term follow-up care of patients who have been surgically treated.
   ii. Expansion thoracoplasty utilizing various surgical techniques (Kaddoura et al. 2001)
      a) Splitting the sternum or the rib cage and maintaining the separation with methacrylate
      b) Rib grafts
      c) Homologous bone grafts
      d) Lateral rib cage expansion using staggered superiosteal rib osteotomies and rigid titanium miniplate and screw augmentation and stabilization
      e) Modified bailey rib approximator to provide a calibrated dynamic separation for the sternum after the primary procedure of midsternotomy and methylmethacrylate sternoplasty
   iii. Dialysis and renal transplantation indicated for renal failure. Recently, cadaver renal transplantation was successful in a 10-year-old boy with Jeune syndrome type 2 (Amirou et al. 1998).
   iv. Surgical complications
      a) Pneumothorax
      b) Mucous plugging of a bronchus
      c) Repeated infections
      d) Progressive herniation of lung through sternal defect
      e) Cardiac insufficiency

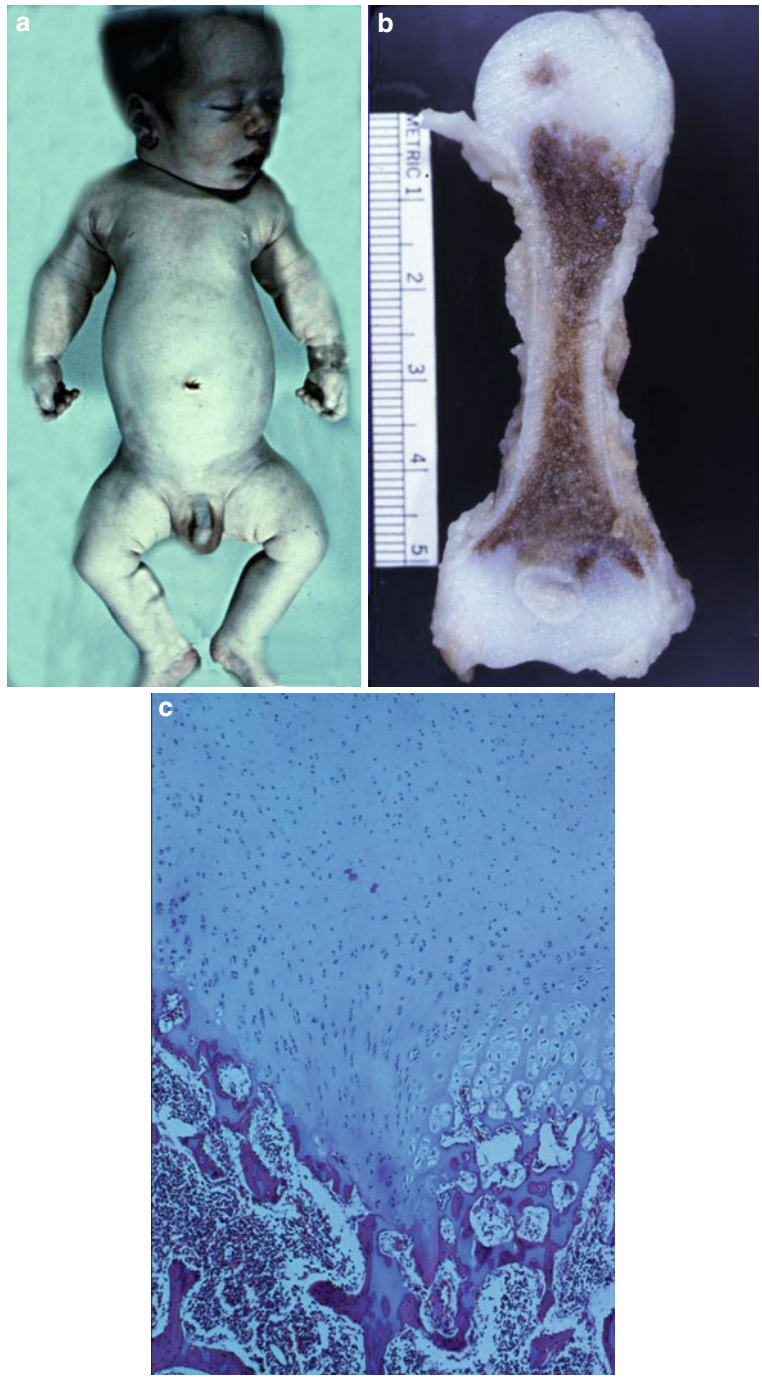

Fig. 1 (**a–c**) A neonate died of respiratory insufficiency. The chest is severely narrow and limbs are mildly shortened (Yang et al. 1976). The longitudinal section of the humerus shows irregular cartilage-bone junctions. There is a premature ossification center in the proximal epiphysis. The photomicrograph of the physeal growth zone shows scattered areas (*left* 2/3rd of the picture) of severe retardation and disorganization. Consequently, the cartilage-bone junction is irregular

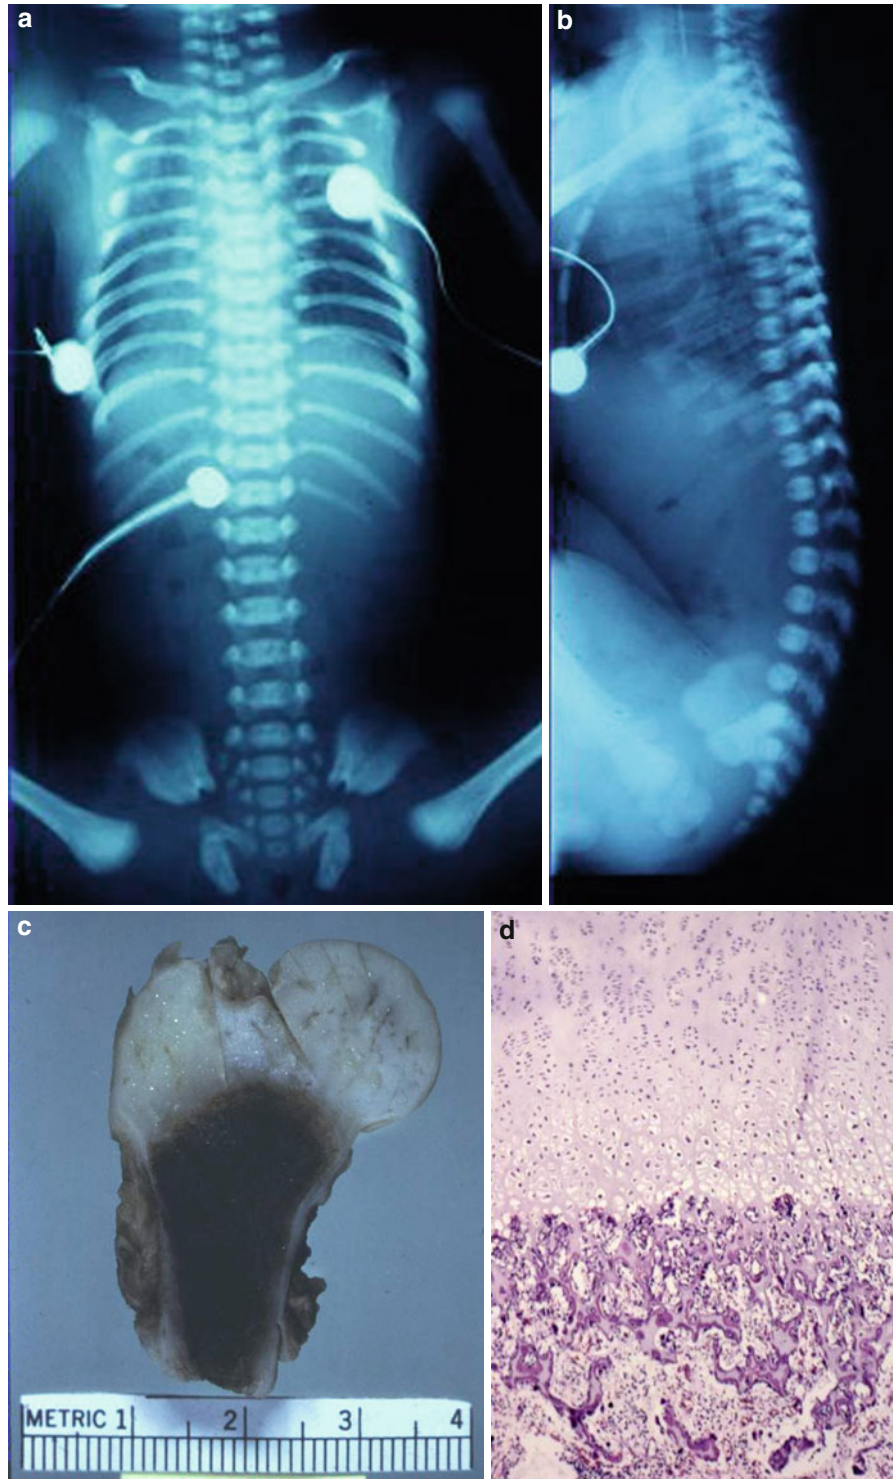

Fig. 2 (**a-d**) Radiographs of the skeletal system of a neonate with type II asphyxiating thoracic dystrophy. The ribs are short. The ilia are vertically shortened. The findings are similar in both types I and II. However, the metaphyseal ends of tubular bones do not show irregularity or spurs as in type I. Photomicrograph of the proximal femur shows generalized retardation and disorganization of the physeal growth zone. The cartilage columns in the metaphysis form a lattice-like meshwork

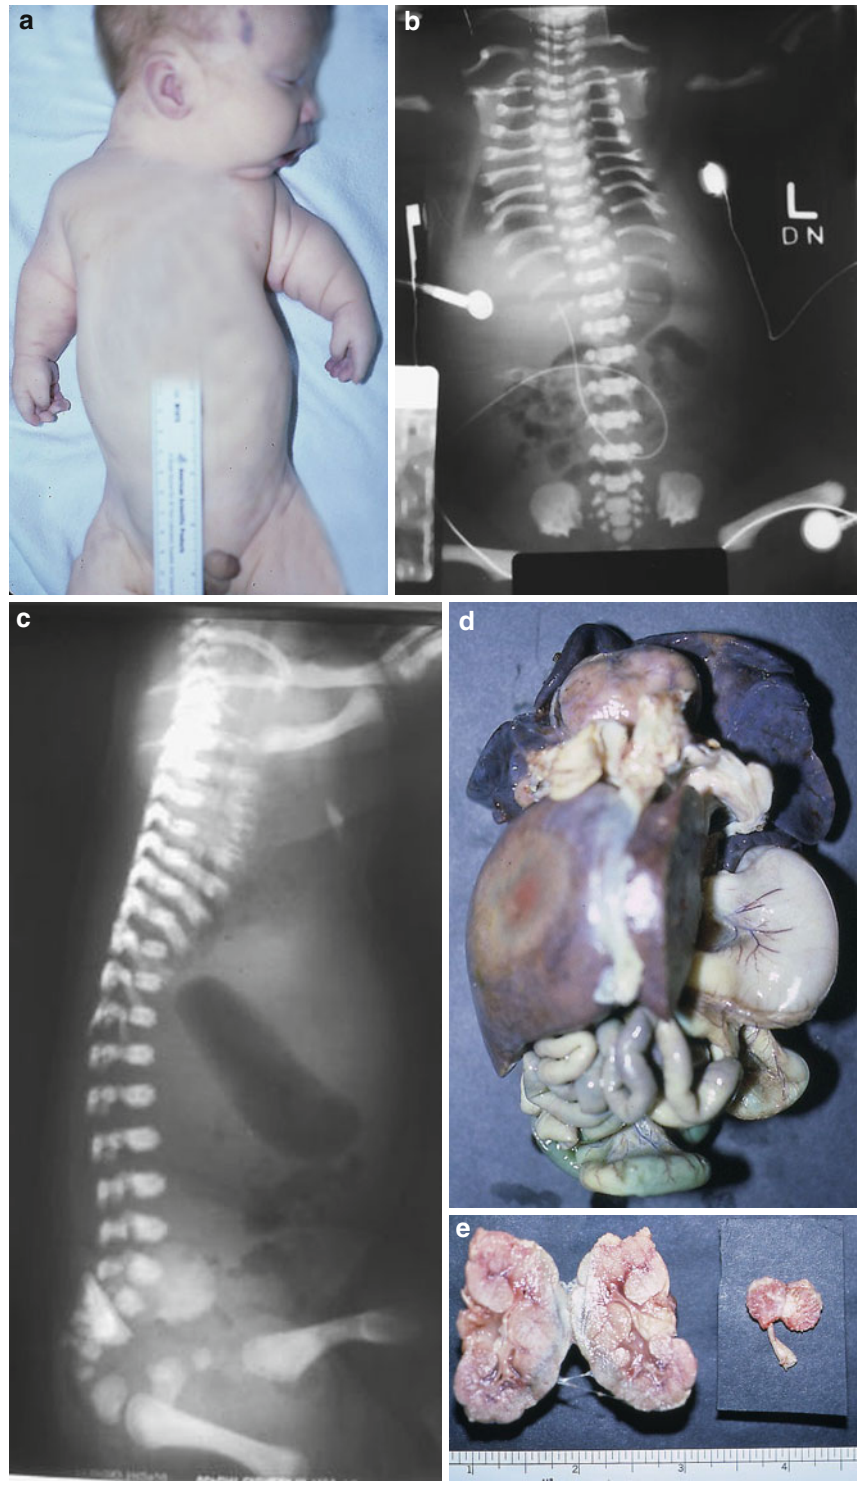

Fig. 3 (**a–e**) An infant with type II asphyxiating thoracic dystrophy showing a narrow thorax and short *upper* extremities. The radiographs showed the handlebar clavicles, short horizontal ribs with widened/cupped anterior rib ends, and *square-shaped* iliac bones with the medial spurs of both acetabular roofs. The necropsy showed lung hypoplasia and renal cystic dysplasia and hypoplasia

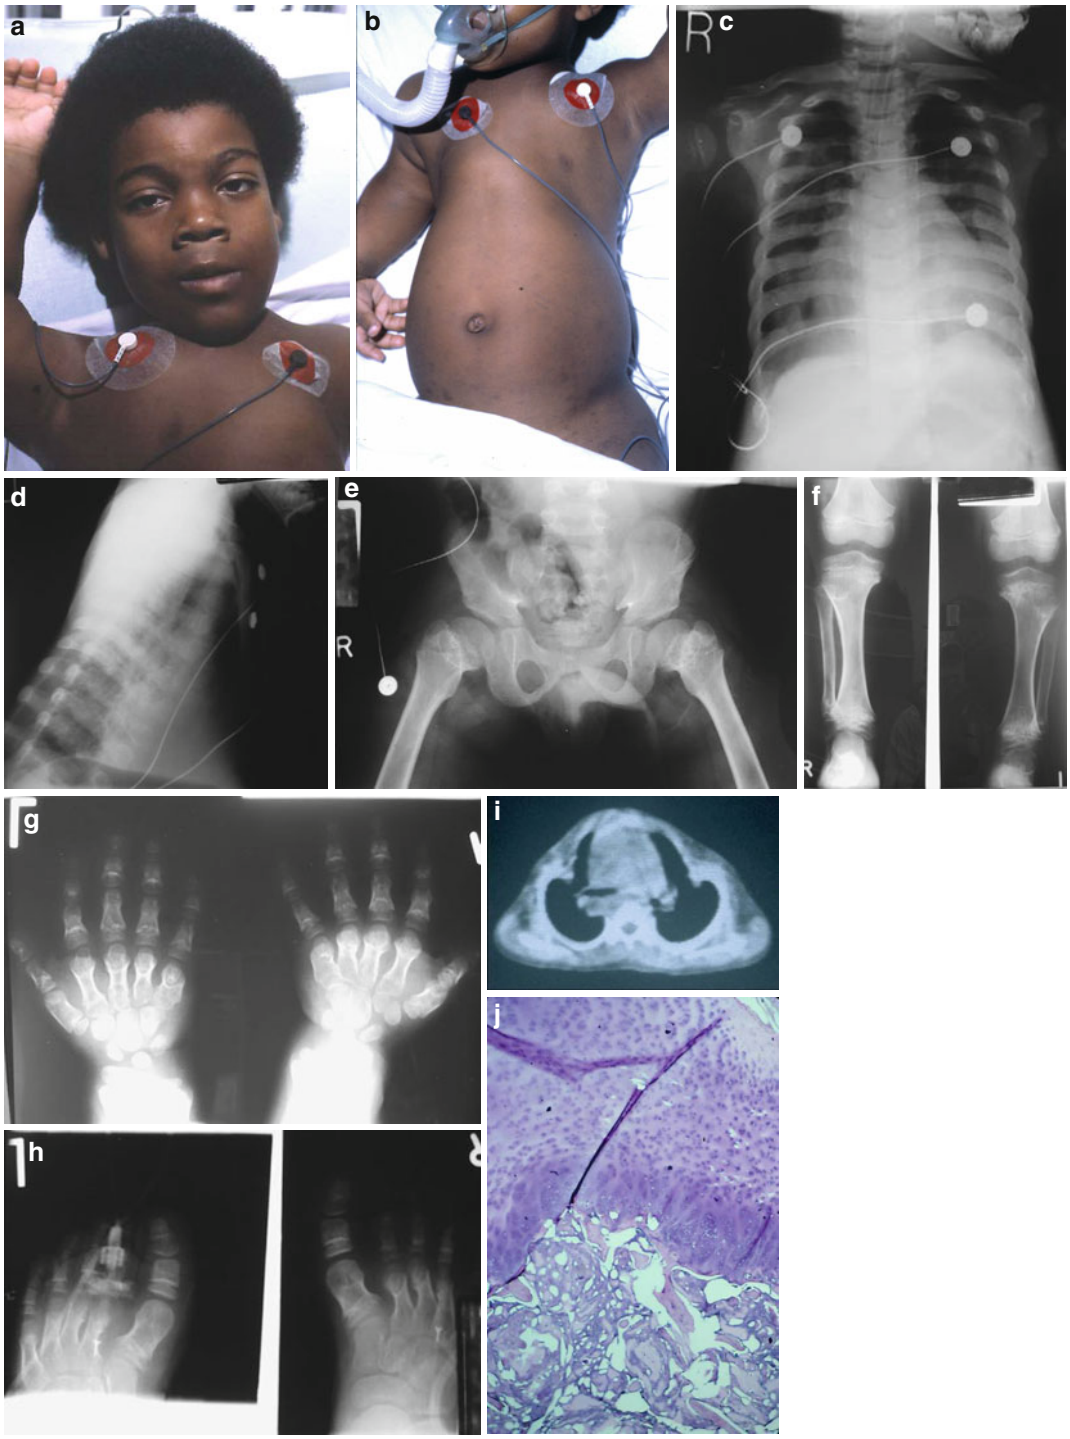

Fig. 4 (**a–j**) A 7-year-old boy with asphyxiating thoracic dystrophy showing a narrow thorax and short limbs. He had dwarfism, postaxial polydactyly, and respiratory distress since birth. Radiographs showed handlebar clavicles, short horizontal ribs, oblique superior acetabular margins, shortened tubular bones, shortened phalanges especially the middle and distal phalanges, and *cone-shaped* epiphyses. CT of the chest showed a narrow thorax, shortened ribs, and lung hypoplasia. Histology of the ribs showed that resting chondrocytes were widely separated by abundant cartilaginous matrix. Histology of a rib physeal growth zone shows greatly reduced number of chondrocytes. In some areas, they are completely nonexistent

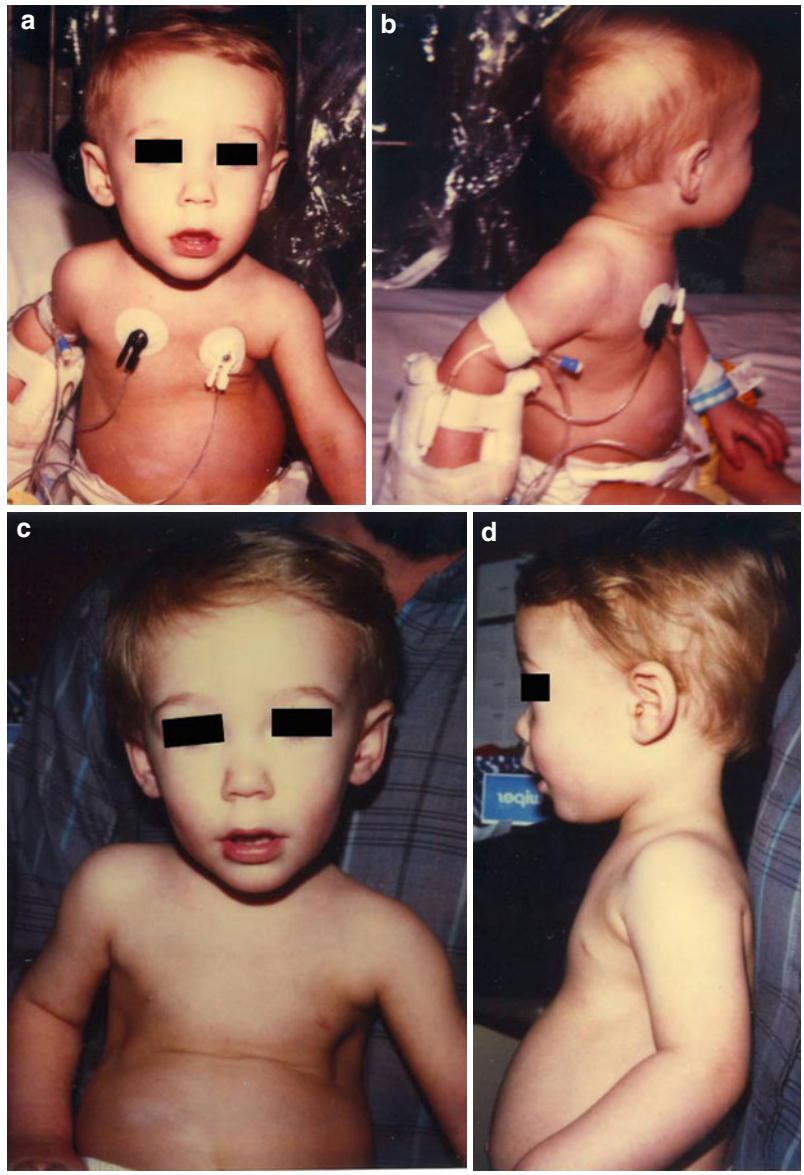

Fig. 5 (**a–d**) A boy with type II asphyxiating thoracic dystrophy at 7 months and 15 months

Ataxia-Telangiectasia

Ataxia-telangiectasia (A-T) is a rare hereditary disorder characterized by progressive cerebellar ataxia, conjunctival telangiectasias, recurrent sinopulmonary infections, radiosensitivity, and a predisposition to malignancy. It is the most common cause of progressive cerebellar ataxia in childhood. The prevalence is estimated to be 1 in 40,000–1 in 100,000 live births.

Synonyms and Related Disorders

Louis–Bar syndrome

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive
   b. Genetic heterogeneity in at least five complementation groups (A–E)
2. Cause
   a. Mutations in the ataxia-telangiectasia mutated gene (*ATM*) which is mapped to 11q22.3
   b. Affected individuals completely lack functional ATM protein
   c. A high prevalence of specific *ATM* mutations in certain ethnic groups (Amish, Mennonite, Costa Rican, Polish, British, Italian, Turkish, Iranian, Israeli) with a founder effect, resulting in a small number of mutations that accounts for the majority of disease-causing mutant alleles
3. Pathophysiology
   a. Basic defect: abnormal sensitivity of A-T cells to x-rays and certain radiomimetic chemicals, leading to chromosome and chromatid breaks. However, sensitivity of A-T cells to ultraviolet irradiation is normal.
   b. Random distribution of breakpoints
   c. Nonrandom chromosome rearrangements selectively affect chromosomes 7 and 14 at sites that are concerned with T-cell receptors and heavy-chain immunoglobulin coding and with the development of hematologic malignancies
   d. Mechanisms responsible for neurologic disease, thymus aplasia, telangiectasias, growth retardation, and impaired organ mutation
      i. Have not been elucidated
      ii. Most likely linked to accelerated telomere loss
4. Range of mutations in the *ATM* gene (Taylor and Byrd 2005)
   a. ATM protein truncating mutations
   b. *ATM* missense mutations
   c. *ATM* splice site mutations
   d. *ATM* founder mutations
   e. New *ATM* mutations
5. Genotype–phenotype correlations (Gatti 2010)
   a. 576ins137nt mutation
      i. Somewhat slower rate of neurological deterioration

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_18,
© Springer Science+Business Media, LLC 2012

ii. Later onset of symptoms
iii. Intermediate radiosensitivity
iv. Little or no cancer risk
b. 8494C>T mutation
i. Milder phenotype
ii. Longer life span

Clinical Features

1. CNS manifestations (Regueiro et al. 2000)
a. Functional neurologic abnormalities rare in infancy
b. Cerebellar ataxia
i. A presenting symptom
ii. Slowly progressive
iii. Truncal ataxia preceding appendicular ataxia and peripheral incoordination
iv. Swaying of the head and trunk while standing and sitting: early sign of ataxia
c. Diminished or absent deep reflexes by school age
d. Hypotonia
e. Dystonia and progressive spinal muscular atrophy affecting hands and feet in affected young adults, resulting in extension contractures
f. Dysarthric speech
g. Flexor plantar response
h. Choreoathetosis in almost all patients
i. Myoclonic jerking and intention tremors in about 25% of patients
j. Drooling
k. Oculomotor apraxia (total or partial loss of the ability to perform coordinated movement or manipulate objects in the absence of motor or sensory impairment) affecting reading (eye tracking) and writing (affected by 7–8 years of age)
l. Intellectual function generally preserved
2. Telangiectasias (dilated small blood vessels)
a. Ocular conjunctiva: most frequently observed
b. Other sites: nose, ears, behind the knees, antecubital fossae, suprasternal notch, dorsum of the hands and feet, and hard and soft palate
c. Usually noticed during 3–6 years of age, i.e., a few years after ataxia
3. Immunodeficiency
a. Frequent sinopulmonary infections
i. Mucopurulent rhinitis, retropharyngeal discharge, otitis media, and sinusitis
ii. Bronchitis and pneumonia
iii. Progress to chronic lung disease: bronchiectasis, pulmonary fibrosis, respiratory insufficiency
b. A small embryonic-like thymus
c. Problems associated with defects in humoral and cellular immunity
i. T-cell deficiency in about 30% of patients
ii. Severe immunodeficiency in about 10% of patients
iii. IgA deficiency
d. Most frequent cause of death in adolescence: bronchiectasis complicated by pneumonitis
4. Malignancy
a. The second most frequent cause of death
b. Eventual malignancy during lifetime in 38% of patients
c. Malignancy of hematologic origin most common (85% of patients)
i. Predominance of malignant lymphomas, usually of B-cell type
ii. Acute lymphocytic leukemia of T-cell origin in younger patients
iii. T-cell prolymphocytic leukemia in older patients
d. Other neoplasms
i. Breast cancer, even in female relatives who do not have ataxia telangiectasia
ii. Gastric cancer
iii. Melanoma
iv. Leiomyoma
v. Sarcoma
5. Ectodermal changes
a. Appearance of premature aging
i. Diffuse graying of the hair
ii. Atrophic and hidebound facial skin
iii. Inelastic ears
iv. Facial wasting
b. Frequent pigmentary changes: hyper-/hypopigmentation with cutaneous atrophy and telangiectasia
c. Partial albinism
d. Vitiligo
e. Café-au-lait spots
f. Seborrheic dermatitis
6. Endocrine manifestations
a. Occasional female hypogonadism associated with ovarian hypoplasia or dysplasia

   b. Male hypogonadism with delayed puberty and characteristic high-pitched voice
7. Clubbing: Observed in 40% of Costa Rican patients not correlated with chronic lung disease, humoral immunodeficiency, or with a particular mutation
8. Other features
   a. Mild postnatal growth retardation
   b. Hypersensitivity to ionizing radiation
   c. Wheelchair-bound by 10 years of age
9. A-T shares similar clinical symptoms and cellular characteristics with two other syndromes: A-T-like disorder (ATLD) and Nijmegen-breakage syndrome (NBS) (Lavin 2008)
   a. Defective protein
      i. A-T: ATM
      ii. ATLD: MRE 11
      iii. NBS: NBS1
   b. Appearance of symptoms
      i. A-T: infancy
      ii. ATLD: first decade
      iii. NBS: infancy
   c. Progression
      i. A-T: rapid
      ii. ATLD: slow
      iii. NBS: rapid
   d. Neurological defect
      i. A-T: cerebellar atrophy
      ii. ATLD: cerebellar atrophy
      iii. NBS: microencephaly
   e. Oculomotor apraxia
      i. A-T: present
      ii. ATLD: present
      iii. NBS: absent
   f. Immunodeficiency
      i. A-T: present
      ii. ATLD: absent
      iii. NBS: present
   g. Telangiectasia
      i. A-T: present
      ii. ATLD: absent
      iii. NBS: absent
   h. Alpha-fetoprotein
      i. A-T: high
      ii. ATLD: normal
      iii. NBS: normal
   i. Growth defect
      i. A-T: absent
      ii. ATLD: absent
      iii. NBS: present
   j. Radiosensitivity
      i. A-T: marked
      ii. ATLD: present
      iii. NBS: present
   k. Cell-cycle checkpoint defect
      i. A-T: present
      ii. ATLD: present
      iii. NBS: present
   l. DNA-repair defect
      i. A-T: present
      ii. ATLD: questionable
      iii. NBS: present
   m. Chromosomal instability
      i. A-T: present
      ii. ATLD: present
      iii. NBS: present
   n. Cancer predisposition
      i. A-T: present
      ii. ATLD: absent
      iii. NBS: present

Diagnostic Investigations

1. Immune workup: presence of significant humoral and cellular immune defects in most patients (Gatti 2010; Regueiro et al. 2000)
   a. Thymic hypoplasia
   b. Low numbers of circulating T-cells
   c. Functional impairment of T-cell-mediated immunity
   d. Selective deficiencies of IgA, IgE, IgG_2, and IgG_4
   e. Low or absent serum levels of IgA in 60% of patients
   f. Low or absent serum levels of IgG2 in 80% of patients
   g. Hyper IgM in approximately 1% of patients, sometimes associated with myeloma-like gammopathy, lymphadenopathy, hepatosplenomegaly, and lymphocytic interstitial pneumonitis
   h. Poor in vivo response to pneumococcal polysaccharides (Sanal et al. 1999)
   i. Immunoblotting for ATM protein (Gatti 2010)
      i. Severely depleted intracellular ATM protein in most patients with A-T
         a) About 90% have no detectable ATM protein

   b) About 10% have trace amounts of ATM protein
   c) About 1% have a normal amount of ATM protein that lacks ATM serine/threonine kinase activity (so-called kinase-dead)
  ii. The most sensitive and specific clinical test, to date, for establishing a diagnosis of A-T
  iii. Small amounts of ATM protein: occasionally associated with a milder prognosis, although there are many exceptions to this and the association needs further validation
2. Increased serum levels of alpha-fetoprotein (AFP) levels in over 90% of older children with A-T
3. Increased plasma levels of carcinoembryonic antigen
4. Colony survival assay by in vitro testing for radiosensitivity on lymphoblastoid cell line to measure the colony survival fraction after 1 Gy of in vitro radiation: sensitivity and specificity exceeding 95% but takes 2–3 months to complete
5. Western blot analysis to detect ATM protein in lysates of a lymphoblastoid cell line
6. DNA-based mutation analysis of the *ATM* gene available clinically
   a. Sequence analysis of the *ATM* coding region
   b. Deletion/duplication analysis
   c. Targeted mutation analysis
   d. Linkage analysis/ethnic haplotype analysis to identify carriers among family members at risk if direct DNA testing fails to identify two disease-causing mutations in the index case
7. Chromosome analysis to identify genetic instability, a hallmark of the A-T phenotype
   a. Types of spontaneous in vitro chromosome aberrations, frequent in both lymphoid and non-lymphoid cells
      i. Chromosome breaks
      ii. Acentric fragments
      iii. Dicentric chromosomes
      iv. Structural arrangements
      v. Telomeric fusions
      vi. An increased rate of telomeric shortening (Metcalfe et al. 1996)
      vii. Aneuploidy
   b. A-T lymphocytes
      i. Increased chromosome breaks. Common breakage points include 7p14, 7q35, 14q12, 14qter, 2p11, 2p12, and 22q11-q12
      ii. Clonal rearrangements involving abnormalities of chromosome 14, especially tandem duplication of 14q at 14q11-q12 and characteristic t(7;14)
   c. Non-lymphoid cells: break points randomly distributed
8. Radiography
   a. Decreased or absent adenoidal tissue in the nasopharynx
   b. Small or absent thymic shadow
   c. Decreased mediastinal lymphoid tissue
   d. Pulmonary changes similar to those seen in cystic fibrosis
9. EEG and nerve conduction velocities
   a. Frequently normal in children
   b. Showing denervation on EEG and reduced nerve conduction in the late stage of the disease, especially in sensory fibers
10. Electrooculography
   a. Shows characteristic oculomotor abnormality of A-T
   b. Differentiates A-T from Friedreich ataxia
11. MRI of the brain
   a. A small cerebellum
   b. Widened sulci
   c. Enlargement of the fourth ventricle
12. Histology
   a. Degeneration of Purkinje and granule cells in the cerebellum: the major pathological marker of A-T in the CNS
   b. Late degenerative gliovascular nodules in the white matter
   c. Lesions of the basal ganglia observed only occasionally
   d. Degeneration of spinal tracts and anterior horn cells often present in late stages
   e. Nucleocytomegaly, a feature of several cell types throughout the body

Genetic Counseling

1. Recurrence risk: counseling according to autosomal recessive inheritance
   a. Patient's sib
      i. A 25% recurrence risk
      ii. Two thirds of unaffected sibs are carriers.
   b. Patient's offspring: most patients with A-T do not reproduce.

2. Prenatal diagnosis
   a. Elevated maternal serum alpha-fetoprotein levels
   b. Demonstration of chromosome breaks in amniocytes
   c. Molecular genetic analysis
      i. Direct DNA mutation analysis on fetal DNA obtained from amniocentesis or CVS for pregnancies at-risk with previously identified specific disease-causing mutation
      ii. DNA-based testing with linkage analysis for at-risk family members if no specific disease-causing mutation identified
      iii. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutations have been identified
3. Management
   a. No specific treatment available
   b. Antibiotics for infections
   c. Prevention of infection by regular injection of immunoglobulins in patients with antibody deficiency
   d. IV IG replacement therapy for individuals with frequent and severe infections and very low IgG levels (Nowak-Wegrzyn et al. 2004)
   e. Aggressive pulmonary hygiene for individuals with chronic bronchiectasis before the final stages of the disease (Tangsinmankong et al. 2001)
   f. Supportive therapy to minimize drooling, choreoathetosis, and ataxia; individual responses to specific medications vary (Perlman et al. 2003)
   g. Beta-adrenergic blockers may improve fine motor coordination in some cases
   h. Controversial use and doses of radiation therapy and chemotherapy
   i. Avoid bleomycin, actinomycin D, and cyclophosphamide
   j. Regular cancer surveillance of heterozygotes essential. ATM heterozygosity is a risk factor for breast and lung cancers.
   k. Desferroxamine: recently shown to increase genomic stability of A-T cells and may present a promising tool in A-T treatment
   l. Early physical therapy, occupational therapy, and speech therapy
   m. A wheelchair: usually necessary by age 10
   n. Although steroids can temporarily improve the neurologic symptoms of A-T in children, the symptoms reappear within days of their discontinuation (Gatti and Perlman 2009)

Atelosteogenesis

In 1982, Maroteaux et al. proposed the term "atelosteogenesis" for a newborn skeletal dysplasia characterized by specific patterns of aplasia/hypoplasia of humeri, femora, spine, and other skeletal elements. Atelosteogenesis encompasses a heterogeneous group of disorders with overlapping phenotypic features.

Synonyms and Related Disorders

Atelosteogenesis type I (giant cell chondrodysplasia, spondylohumerofemoral hypoplasia, boomerang dysplasia); Atelosteogenesis type II (neonatal osseous dysplasia I, De La Chapelle dysplasia); Atelosteogenesis III

Genetics/Basic Defects

1. Atelosteogenesis I (AOI)/boomerang dysplasia (BD)
   a. Inheritance: de novo autosomal dominant mutation, suggested by:
      i. Sporadic in all observed cases
      ii. No familial cases reported
   b. Previously known as spondylohumerofemoral dysplasia and giant cell chondrodysplasia
   c. Caused by mutations in filamin B (*FLNB*) gene, which also causes the following disorders:
      i. Atelosteogenesis type III
      ii. Autosomal recessive spondylocarpotarsal syndrome
      iii. Autosomal dominant Larsen syndrome
   d. A common pathogenesis suggested for atelosteogenesis type I and boomerang dysplasia
      i. Forming a spectrum of findings within the same nosologic entity with boomerang dysplasia
      ii. Similar histopathology in boomerang dysplasia
      iii. Overlapping radiologic features with boomerang dysplasia
2. Atelosteogenesis II (AOII) (Karniski 2001)
   a. Inheritance: autosomal recessive suggested by:
      i. Recurrence in the subsequent pregnancy
      ii. Parental consanguinity
   b. Synonymous with De la Chapelle dysplasia
   c. Phenotypic and radiographic overlap with atelosteogenesis I but with distinctive matrix histopathology with a major disturbance in cartilage matrix macromolecules
   d. Common pathogenetic features with disorders of sulfation of connective tissue matrix macromolecules. An overlap of phenotypic, radiographic, morphological, and cartilage histochemical features with the following conditions:
      i. Diastophic dysplasia
      ii. Achondrogenesis type IB
   e. Caused by mutated diastrophic dysplasia sulfate transporter (*DTDST*; *SLC26A2*) gene which also causes the following recessively inherited chondrodysplasias:
      i. Diastrophic dysplasia
      ii. Multiple epiphyseal dysplasia
      iii. Achondrogenesis IB

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_19,
© Springer Science+Business Media, LLC 2012

f. The *DTDST* gene
   i. Encodes a sulfate transporter that also accepts chloride and possibly bicarbonate as substrates
   ii. Reduced sulfate transport in chondrocytes of individuals with *DTDST* mutations resulting in the under-sulfation of proteoglycans, which in turn leads to abnormal cartilage formation
g. Factors in addition to the intrinsic sulfate transport properties of the DTDST protein may influence the phenotype in individuals with *DTDST* mutations.

3. Atelosteogenesis III (AOIII)
   a. Inheritance: autosomal dominant
   b. Features overlapping with atelosteogenesis I and II but most similar to those of atelosteogenesis I
   c. Caused by mutations in *FLNB* gene
4. Genotype–phenotype correlation in a compound heterozygote (atelosteogenesis type II-diastrophic dysplasia)
   a. Atelosteogenesis type II
      i. R178X mutations of the *SLC26A2* gene
      ii. Features typical of AO II
         a) Severe and progressive cervical kyphosis
         b) V-shaped distal humerus
         c) Bowed radii
         d) Horizontal sacrum
         e) Gap between the first and second toes
   b. Diastrophic dysplasia
      i. R279W mutations of the *SLC26A2* gene
      ii. Features suggestive of diastrophic dysplasia
         a) Cystic swelling of the external ears
         b) Cervical kyphosis
         c) Rhizomelia
         d) "Hitchhiker" thumbs
         e) Bilateral talipes equinovarus
         f) Short toes
   c. Combination of a severe and a mild mutation leads to an intermediate clinical picture, representing an apparent genotype–phenotype correlation.

Clinical Features

1. Atelosteogenesis I
   a. Stillborn or neonatal death due to respiratory distress
   b. Polyhydramnios
   c. Facial dysmorphism
      i. Depressed nasal bridge
      ii. Eyelid edema
      iii. Micrognathia
      iv. Cleft soft palate
   d. Small chest
   e. Protuberant abdomen
   f. Deficient ossification of various bones
      i. Humerus
      ii. Femur
      iii. Thoracic spine
      iv. Hand bones
   g. Rhizomelic micromelic dwarfism
      i. Short and broad hands
      ii. Incurved legs
      iii. Club feet
      iv. Often dislocation of the elbows
   h. Laryngeal hypoplasia: an important role in the respiratory failure and death
2. Boomerang dysplasia
   a. Distinct facial features
      i. Horizontal palpebral fissures
      ii. Broad nasal root
      iii. Hypoplastic nasal septum
      iv. Prominent philtrum
      v. Cleft palate
   b. Small chest
   c. Protuberant abdomen
   d. Marked rhizo/mesomelic shortening of limbs
   e. Well-developed hands (broad, paddle-shaped) and feet
   f. Bowed lower limbs
   g. Calcaneo-valgus deformities
3. Atelosteogenesis II
   a. Lethal in neonatal period
      i. Pulmonary hypoplasia
      ii. Tracheobronchomalacia
      iii. Laryngeal stenosis
   b. Deficient ossification of parts of the skeleton
   c. Facial dysmorphism
      i. Midface hypoplasia
      ii. Depressed nasal bridge
      iii. Epicanthal folds
      iv. Micrognathia
      v. Cleft palate
   d. Small chest
   e. Protuberant abdomen

f. Extremities
   i. Severe rhizomelic limb shortening
   ii. Talipes
   iii. Abducted (hitch-hiked) thumbs and toes
   iv. Ulnar deviation of the fingers
   v. Gap between the first and second toes
4. Atelosteogenesis III
   a. Milder, usually nonlethal
   b. Limb anomalies
      i. Rhizomelic shortening
      ii. Clubfeet
      iii. Short broad thumbs and great toes
   c. Craniofacial abnormalities
      i. Ocular hypertelorism
      ii. A flat nasal bridge
      iii. Micrognathia
      iv. Cleft palate
   d. Small chest
   e. Protuberant abdomen
   f. Multiple dislocations of elbows, hips, and knees
   g. Respiratory and feeding difficulties secondary to laryngomalacia
   h. Apparent cause of death
      i. Respiratory complications
      ii. Cervical spine instability
   i. Long survival possible

Diagnostic Investigations

1. Atelosteogenesis I (Sillence et al. 1997)
   a. Radiography: overlapping radiological features with boomerang dysplasia
      i. Humeri: absent/geometric (AOI), absent (AOI/BD), absent (BD)
      ii. Hand phalanges: presence of distal and absent middle (AOI), hypoplastic middle (AOI/BD), presence of distal and absent proximal/middle (BD)
      iii. Femora: pointed distally (AOI), geometric (AOI/BD), absent (BD)
      iv. Tibia: bowed (AOI), hypoplastic (AOI/BD), bowed/boomerang (BD)
      v. Fibula: absent (AOI), absent (AOI/BD), absent (BD)
      vi. Spine: coronal clefts in the lumbar vertebrae (AOI), coronal clefts in the vertebrae, and uniform lack of ossification of the centra of the vertebral bodies (BD)
      vii. Pelvis: hypoplasia of the ischiopubis (AOI), lack of ossification of ischiopubis (BD), flared ilia with hypoplasia of the inferior one third (AOI, BD), producing a keyhole shape
      viii. Foot: lack of ossification of the calcaneal centers (AOI, BD)
      ix. Ribs: 10–13 pairs (BD)
   b. Histopathology
      i. Uniformly abnormal
      ii. Lack of ossification
      iii. Nonhomogeneous cell distribution with hypocellular and acellular areas
      iv. Occasional multinucleated giant chondrocytes in the relatively acellular areas of resting cartilage (alternatively named "giant cell chondrodysplasia")
      v. Disorganized growth plate in some cases
      vi. Similar histopathology in boomerang dysplasia
2. Boomerang dysplasia
   a. Radiography
      i. Triangular, boomerang-shaped long bones, diagnostic of the syndrome
      ii. Missing some tubular bone ossification centers
      iii. Ossified fingers and toes from the periphery
      iv. Characteristic shaped pelvis
      v. Retarded ossification of the spine, especially cervical and thoracic spine
      vi. Coronal clefts in the lower thoracic and lumbar spine
   b. Histopathology
      i. Chondrocytes in the resting cartilage are irregularly reduced in number with focal acellularity. Multinucleated giant chondrocytes have been noted.
      ii. The physeal growth zones are markedly retarded and disorganized.
3. Atelosteogenesis II (Bonafe et al. 2009)
   a. Radiography
      i. Normal size skull with disproportionately short skeleton
      ii. Spine
         a) Platyspondyly
         b) Hypodysplastic vertebrae
         c) Cervical kyphosis

d) Ossification of the upper thoracic vertebrae and coronal clefts of the lumbar and lower thoracic vertebrae may be incomplete

iii. Pelvis
a) Hypoplastic/flared ilia
b) Flat/horizontal acetabula with a spicule at the medial border of the acetabula
c) Often unossified pubic bones

iv. Long bones
a) Shortened with metaphyseal flaring
b) Distal humerus: sometimes bifid or V-shaped, sometimes pointed and hypoplastic
c) Femur: distally rounded, clubbed distally
d) Tibia: bowed/hypoplastic
e) Fibula: hypoplastic
f) Radius: typically bowed

v. Hands
a) Hitchhiker thumbs
b) Ulnar deviation of the fingers
c) Hand phalanges: irregular size and shape
d) Gap between the first and second toe
e) Hypoplasia of the first metacarpal bone

b. Histopathology
i. Irregularly distributed resting cartilage chondrocytes
ii. Attenuation of cartilage matrix with concentric matrix condensation rings around degenerating chondrocytes
iii. Shortened proliferative and hypertrophic zones
iv. Histopathology of cartilage essentially similar to that of diastrophic dysplasia and achondrogenesis IB reflecting the paucity of sulfated proteoglycans in cartilage matrix

c. Mutation analysis (mutation detection rate about 60%) and sequence analysis (mutation detection rate 90%) of *DTDST* (*SLC26A2*) gene: Mutations in the *DTDST* gene can be found in more than 90% of patients with radiologic and histologic features compatible with the diagnosis of atelosteogenesis II.

d. Carrier testing for AOII
i. Carrier testing available to at-risk family members once the mutation of the *DTDST* gene has been identified in the proband
ii. For the partner of a heterozygous individual. The partners can be screened for the four most common pathogenic alleles, R279W, IVS1 + 2T > C, delV340, and R178X. When these four alleles are excluded, the risk of carrying *DTDST* mutation is reduced from the general risk of 1:100 to about 1:300

4. Atelosteogenesis III
a. Radiography
i. Humeri: pointed distally
ii. Hand phalanges: tombstone-shaped proximal phalanges, widened distal phalanges
iii. Femora: pointed distally
iv. Tibia: short
v. Fibula: absent
vi. Spine: coronal clefts in the lumbar vertebrae, severe thoracolumbar kyphosis with an S-shaped cervical spine in lateral profile
vii. Pelvis: hypoplastic ischiopubis, banana-shaped pubic rami

b. Histopathology: hypocellularity without clustering, acellular areas, or "giant cells"

Genetic Counseling

1. Recurrence risk
a. AOI
i. Patient's sib: low
ii. Patient's offspring: a lethal entity not surviving to reproduce

b. AOII
i. Patient's sib: 25%
ii. Patient's offspring: a lethal entity not surviving to reproduce

c. AOIII
i. Patient's sib: low
ii. Patient's offspring: 50%

2. Prenatal diagnosis
a. Fetal ultrasonography
i. Short limbs (micromelia)
ii. Abnormal facial profile (depressed nasal base, micrognathia, apparent hypertelorism)
iii. Absence of ossification in the humerus, radius, ulna, and cervical and upper thoracic vertebral bodies
iv. Coronal clefts in the ossified vertebral bodies
v. Talipes equinovarus

b. 3D helical computed tomography (Cordier et al. 2008)
i. Not dependent on amniotic fluid volume, fetal position, and not limited at specific fetal parts

ii. Theoretical fetal exposure to radioactivity similar to that of conventional fetal radiological examination
iii. Identifies more characteristic findings than 3D ultrasonography due to its advantage of being able to image the entire skeleton and its possibilities of rereading

c. Fetal MRI using an ultrafast sequence
i. Dysmorphic features
ii. Pulmonary hypoplasia
iii. A large cysterna magna

d. Prenatal diagnosis by analysis of DNA extracted from fetal cells obtained by CVS or amniocentesis or preimplantation genetic diagnosis: Mutation analysis of *DTDST* gene for pregnancy at risk is possible for AOII for families in which the disease-causing mutations have been identified

3. Management
a. AOI and AOII: supportive measures for these two lethal conditions
b. AOIII
i. Ventilatory support and tracheostomy often necessary for respiratory distress due to laryngotracheomalacia
ii. Treat recurrent respiratory tract infections
iii. Cleft palate repair
iv. Conductive hearing loss evaluation and management
v. Orthopedic care for club feet and joint dislocations

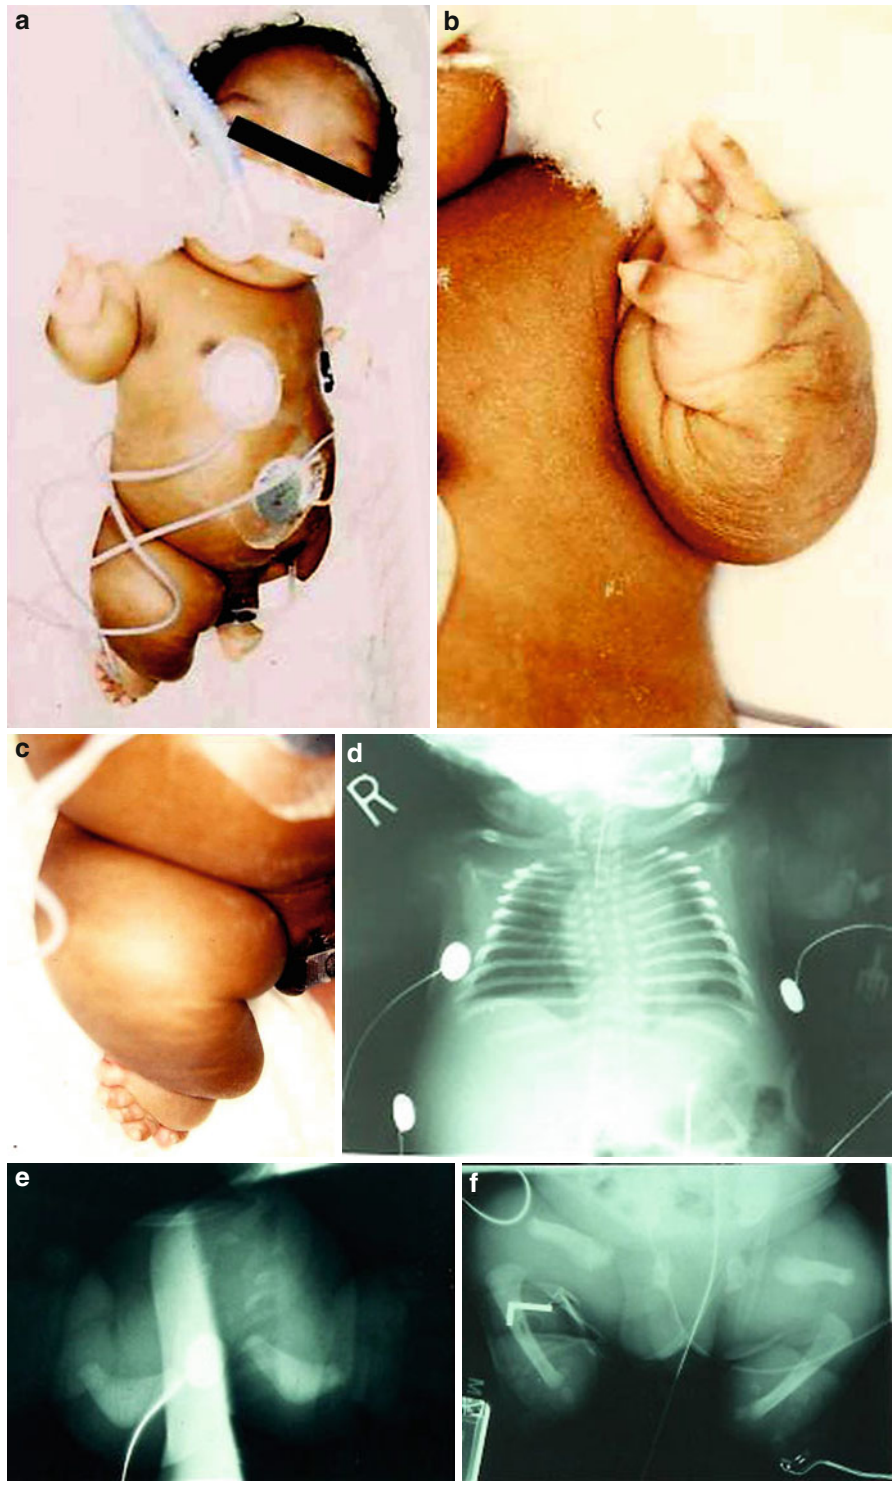

Fig. 1 (**a**–**f**) A male infant with atelosteogenesis I/boomerang dysplasia. Prenatal ultrasound showed polyhydramnios and a short limb dwarf. The infant died at 57 days. He showed relatively large head, hypertelorism, depressed nasal bridge, midfacial hypoplasia, micrognathia, cleft palate, short neck, relatively narrow chest, protuberant abdomen, severe "rhizomelic" micromelia, absent elbow joints, genu varus, and talipes equinovarus. Radiographic features included unossified vertebrae (T6–T9), single boomerang-like long bone (between acromion and wrist), short tapered femora, short bowed tibiae, absent fibulae, calcified distal phalanges, non-ossified carpals, metacarpals, and proximal phalanges, and irregularly ossified tarsals and metatarsals. Histopathology of the cartilage showed disorganized physeal growth zones and irregular areas of hypocellularity in the resting cartilage. Multinucleated giant chondrocytes were not observed

Autism

Autism is a pervasive developmental disorder, defined by impairments in social and communication function, and repetitive and stereotyped behavioral patterns. It occurs in approximately 7–40 out of 10,000 persons.

Autism spectrum disorders (ASDs) represent a heterogeneous group of neurodevelopmental disorders, including autism, Asperger syndrome, childhood disintegrative disorder, and pervasive developmental disorder not otherwise specified, and is characterized by social and communication deficits accompanied by repetitive and stereotype behaviors, with onset before 3 years of age (American Psychiatric Association 1994; DiCicco-Bloom et al. 2006; Caglayan 2010).

Synonyms and Related Disorders

Autistic disorder; Autism spectrum disorders (autism, Asperger syndrome, childhood disintegrative disorder, pervasive developmental disorder)

Genetics/Basic Defects

1. Secondary autism (nongenetic and genetic conditions associated with autism): accounts for a small minority of individuals with autism (<10%) in population-based studies (Miles et al. 2005; Muhle et al. 2004)
   a. Obstetric complications including uterine bleeding, despite absence of demonstrable causal relationship in many studies
   b. Intrauterine exposure to teratogenic drugs in a few affected children
      i. Thalidomide
      ii. Valproate
   c. Elevated cord blood levels of following substances
      i. Neuropeptides substance P
      ii. Vasoactive intestinal peptide
      iii. Pituitary adenylate cyclase-activating polypeptide
      iv. Calcitonin gene-related peptide
      v. Neurotrophin nerve growth factor
   d. Various epidemiologic data
      i. Cerebral palsy (a static motor deficit of brain origin present from early life): present in 2.1–2.9% of individuals with autism and mental retardation
      ii. Congenital rubella infection: present in 0.75% of cases
      iii. Other pre- and postnatal infections (e.g., Hemophilus influenza and cytomegalovirus): may cause autism when they significantly damage the immature brain
      iv. No association between autism and inflammatory bowel disease or with a live MMR vaccination
      v. Epilepsy with the highest association with autism: reported in up to a third of individuals with an autistic spectrum disorder by adulthood
      vi. Behavioral symptoms of autism: frequent in tuberous sclerosis complex and fragile X syndrome but account for only a minority of the total cases of autism
   e. Genetic causes associated with autism
      i. Cytogenetically visible chromosomal abnormalities (~5%)
         a) Angelman syndrome (more commonly associated with autism than Prader–Willi syndrome) can result from the loss or

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_20,
© Springer Science+Business Media, LLC 2012

mutations of the maternally derived *UBE3A* or the *ATP10C* gene in 15q11-q13 region

b) Chromosomal duplication in the Prader–Willi/Angelman region of proximal 15q in about 3% of individuals with autism: more commonly a supernumerary isodicentric 15q chromosome detectable by routine cytogenetic studies or less commonly an interstitial duplication of the region detected by FISH analysis of the *SNRPN* gene

c) Other chromosome abnormalities in 3–5% of individuals with autism

d) A subtelomeric deletion detected by FISH telomere studies in 10% of unselected patients with autism

e) Down syndrome: Autism was found in at least 7% in one study in children with Down syndrome

f) Turner syndrome: known to have specific cognitive and behavioral deficits that overlap with but are also distinct from those found in children with idiopathic autism (Caglayan 2010)

g) Inv dup(15) or idic(15) syndrome: characterized by early central hypotonia, developmental delay and intellectual disability, epilepsy, and autistic behavior with no facial dysmorphic features (Battaglia 2008)

ii. Copy number variants (CNVs) (Miles et al. 2010): Array comparative genomic hybridization (aCGH):

a) Steadily replacing high-resolution chromosome analysis and FISH in the evaluation of children with autism

b) Designed to test for known deletion/duplication syndromes on the entire genome plus assessment of subtelomeric regions

c) Currently, aCGH identifies clinically relevant de novo genomic imbalances in 7–10% of individuals with autism of unknown cause (Sebat et al. 2007; Christian et al. 2008; Kumar et al. 2008; Marshall et al. 2008; Weiss et al. 2008)

d) Examples of CNVs associated with autism: 16p11.2 deletion syndrome in approximately 1% of individuals with autism (Marshall et al. 2008) and 15q13.3 deletion syndrome associated with mental retardation, epilepsy, and ASDs (Ben Shachar et al. 2009; Miller et al. 2009; Pagnamenta et al. 2009)

iii. Single gene causes of autism in which neurologic findings are associated with ASDs (~5%)

a) Fragile X syndrome found in a few percent of children with autism: At least 50% of children with fragile X syndrome have autistic behaviors, including avoidance of eye contact, language delays, repetitive behaviors, sleep disturbances, tantrums, self-injurious behaviors, hyperactivity, impulsiveness, inattention and sound sensitivities

b) Rett syndrome: Children affected with both autism and Rett syndrome (almost universally female sex) have a period of normal development, followed by loss of language with stereotypic hand movements (hand-wringing behavior)

c) Tuberous sclerosis complex: Mentally retarded individuals with tuberous sclerosis complex frequently have autism (almost 50% in some studies)

d) Neurofibromatosis type 1: much less frequently associated with autism than is tuberous sclerosis and fragile X syndrome

e) Duchenne muscular dystrophy: An unexpectedly large proportion of boys with Duchenne muscular dystrophy have autistic spectrum

f) Sotos syndrome: A number of affected individuals diagnosed to have ASDs or autistic features

g) Joubert syndrome: a few affected children diagnosed with autism

h) Other macrocephalic conditions with overgrowth (Simpson-Golabi-Behel syndrome, Beckwith-Wiedemann syndrome)

i) Autism and macrocephaly or autism with no other clinical features: reported to have germline *PTEN* mutations (Herman et al. 2007)

j) Timothy syndrome (an autosomal dominant disorder characterized by lethal cardiac arrhythmias, congenital heart

disease, webbing of fingers and toes, immune deficiency, intermittent hypoglycemia, cognitive abnormalities, and autism) (Splawski et al. 2004)
k) Williams syndrome: Individuals with Williams syndrome show an unusually strong interest in people, including strangers, warm and engaging, and highly empathetic toward others versus profound impairments in social functioning, including difficulties interacting with others, attending to people, and decoding nonverbal cures, and impairments in social emotional reciprocity (Caglayan 2010)
l) Smith–Magenis syndrome: Autistic-type behaviors reported in many affected individuals (Dykens et al. 1997)
m) Smith-Lemli-Opitz syndrome: ~75% of affected children met the criteria for some variants of ASDs (Sikora et al. 2006)
n) Cohen syndrome (an autosomal recessive connective tissue disorder caused by *COH1* gene mutations): autistic features may be relatively common (Karpf et al. 2004)
o) Duchenne muscular dystrophy: 3.1% of patients with ASDs (Hendriksen and Vles 2008)

iv. Metabolic cause associated with autism
a) Mitochondrial cytopathies: 7% of patients with ASDs (Oliveira et al. 2005)
b) Untreated phenylketonuria: an autism frequency of 2.7–5.6% in affected individuals (Baieli et al. 2003; Steiner et al. 2003)
c) Sanfilippo syndrome: prominent behavioral disturbance in affected individuals (Neufeld and Muenzer 2001)
d) Adenylosuccinate lyase deficiency: autistic features in about one-third of patients (Spiegel et al. 2006)

2. Idiopathic autism (inherited autism of unknown cause)
a. Family studies indicates genetics play the major causative role in most individuals with "idiopathic" autism (90–95%)
b. Epidemiologic studies
i. A prevalence of 5–10 cases of classic autism per 10,000 (3–6 per 1,000 if the entire spectrum of autism is included)
ii. A male-to-female ratio of 3:1
a) The preponderance of males suggests an X-linked disorder
b) Linkage to the X chromosome suggested by recent genome-wide screens, although the data are inconsistent
c) Male-to-male transmission of autism in multiplex families (families with more than a single affected family member) ruled out X-linkage in these families
d) No significant associations of autism to Y chromosome based on Y haplotype analysis, although Y chromo some abnormalities have been documented
c. Classification of idiopathic autism
i. Essential autism
a) Defined by the absence of physical abnormalities
b) Seen in about 70% of children with idiopathic autism
c) Associated with better outcome overall
d) More likely a male
e) A higher sibling recurrence risk
ii. Complex autism
a) Defined by the presence of dysmorphic features (microcephaly and/or a structural brain malformation)
b) Seen in about 30% of children with idiopathic autism
c) Associated with a poorer prognosis
d) A lower male-to-female ratio
e) A lower sibling recurrence risk
d. Evidence suggesting genetic basis of autism without a diagnosable cause
i. 25% rate of recurrence in siblings of affected individuals from family studies: much greater than the prevalence rate in the general population
ii. Greater than 60% rate of concordance for classic autism in monozygotic twins, compared with no concordance found between dizygotic twins
e. The identity and the number of genes involved in autistic disorders: remained unknown
i. Multigenic
a) Similar autistic phenotypes may arise from different genes or gene combinations in different families (single-mutation genetic heterogeneity)

b) Example: tuberous sclerosis caused by *TSC1* on chromosome 9q in some families and *TSC2* on 16p in others

ii. Polygenic
   a) Several synergistically acting genes in an affected individual's genome may be required to produce the full autistic phenotype
   b) Lowering of a theoretical threshold by certain sets of genes acting in concert to allow the development of autism, either by themselves or given the right set of environmental or immunologic modifiers
   c) Other related developmental disorders in family members presumed to have inherited some of the susceptibility genes found in the affected family member or to have the same set of susceptibility genes without exposure to the same environmental "trigger factors" for autism

3. Search for candidate genes
   a. Cytogenetics: scrutinize the region involved in visible breakpoints, translocations, duplications, inversions, and deletions for the presence of genes that potentially may be involved in the pathogenesis of autistic spectrum disorders
   b. Whole genome search: microsatellite markers screening in multiplex family uncovers specific chromosomal regions that affected individuals inherit more often than predicted by chance
4. Genes for a monogenic hereditable form of autism (Caglayan 2010; Lintas and Persico 2009)
   a. Neuroligins (*NLGN3*, *NLGN4*) (located at Xq13 and Xq22.33, respectively): gene mutations noted in 1% of individuals with ASDs (Jamain et al. 2003; Lintas and Persico 2009)
   b. *Shanks3* gene (located at 22q13.3): mutations cause ASDs with phenotype characterized mainly by severe verbal and social deficits (Moessner et al. 2007; Aneja and Tierney 2008)
   c. Neurexin 1 gene (*NRXN1*) (located at 2q32): mutations identified in individuals with autism (Yan et al. 2008)
   d. Methyl-CpG-binding protein 2 gene (*MeCP2*) (located at Xq28): de novo mutations occur in 80% of female patients with Rett syndrome
   e. The homeobox A1 gene (*HOXA1*) (located at 7p15.3): autism noted in some patients (Bosley-Salih-Alorainy syndrome) (Herman et al. 2007)
   f. The phosphatase and tensin homologue gene (*PTEN*) (located at 10q23): reported in individuals with macrocephaly and autism (Butler et al. 2005; Herman et al. 2007; Buxbaum et al. 2007)

Clinical Features

1. Early signs of infants with autism (Miles et al. 2005)
   a. Do not care to be held or cuddled
   b. Do not reach out to be picked up
   c. Often "colicky" and hard to console
   d. Typically quieting more readily when left alone
   e. Avoid and fail to initiate eye contact
   f. Stare into space
   g. Sleep disturbances
   h. Usually do not come to medical attention until after the 2nd year when language delays are evident
2. Natural history
   a. Onset of autism: prior to age three
   b. Gradual onset in most children with autism
   c. "Regressive" onset in about 30% of children with autism
      i. Initially begin to talk
      ii. Then often precipitously lose language and become distant
      iii. Refuse to make eye contact within a matter of days and no longer respond to his or her name
      iv. Repetitive movements may develop immediately or by 3 or 4 years of age
   d. About 25% of children who fit diagnostic criteria for autism at age 2 or 3 years
      i. Subsequently begin to talk and communicate
      ii. Blend to varying degrees into the regular school population by 6 or 7 years
   e. Remaining 75% of children with autism continue to have a life-long disability requiring intensive parental, school, and societal support
   f. Fewer than 5% of children with autism completely recover
3. Mental retardation by nonverbal IQ testing in 50–70% of children with autism

4. Seizures develop in about 25% of children with autism
5. Idiopathic autism
   a. About 30% of children have complex autism, defined by presence of the following features
      i. Dysmorphic features
      ii. Microcephaly
      iii. Structural brain malformation
   b. About 70% of children have essential autism, defined by absence of physical abnormalities
6. Behavioral impairments
   a. Impairments in social interaction: separates individuals with autism from individuals around them
      i. Unable to "read" other people, ignoring them and often strenuously avoiding eye contact
      ii. Do not comfort others or seek comfort and do not share interests with others
      iii. Usually prefers to be by himself, engaging in his own, often repetitive, activities at home
      iv. Fail to develop friendships with peers and siblings
      v. Demonstrate a marked deficit in imitating other's actions, which may impede the development of interpersonal synchrony, communication, symbolic play, and the learning of new behaviors
   b. Impairments in communication
      i. Fail to develop reciprocal communication either by speech, gestures, or facial expression in most children with autism
      ii. Fail to use eye gaze to communicate and direct attention in young children
      iii. Display stereotypic speech that may involve echolalia or unusual inflections and intonations when children with autism learn to talk
   c. Repetitive and stereotypic behaviors
      i. Staring or rocking
      ii. Toddlers may have motor "stereotypies"
         a) Movements of fingers
         b) Twirling strings
         c) Flicking pages of books
         d) Licking
      iii. Repetitive whole-body movements
         a) Spinning
         b) Running back and forth
      iv. Complex repetitive movements may last for hours
      v. Develop elaborate rituals in which the order of events, the exact words, and the arrangement of objects must be followed
   d. Other symptoms
      i. Hyper- and hyposensitivities to sensory stimulation of all types (e.g., visual, auditory, tactile, and pain)
      ii. Odd behaviors around foods and their presentation
      iii. Abnormal sleep patterns
      iv. Tantrums and/or self-injurious and aggressive behaviors brought on by a change in routine, an offending touch, or no apparent reason
      v. Impaired motor development with toe walking early in life and general clumsiness
      vi. Total disregard for danger, resulting in high risk of early death, most commonly from drowning
7. Diagnostic criteria for autistic disorder (adapted from DSM-IV) (American Psychiatric Association 1994)
   a. Presence of a total of >6 of the following areas
      i. Qualitative impairment in social interaction (at least two of the following areas)
         a) Marked impairment in the use of multiple nonverbal behaviors, such as eye-to-eye gaze, facial expression body postures, and gestures, to regulate social interaction
         b) Failure to develop peer relationships appropriate to developmental level
         c) Lack of spontaneous seeking to share enjoyment, interests, or achievements with other people (e.g., by lack of showing, bringing, or pointing out objects of interest)
         d) Lack of social or emotional reciprocity
      ii. Qualitative impairment in communication (at least one of the following area)
         a) Delay in, or total lack of, the development of spoken language (not accompanied by an attempt to compensate through alternative modes of communication such as gesture or mime)
         b) Marked impairment in the ability to initiate or sustain a conversation with others in individuals with adequate speech
         c) Stereotyped and repetitive use of language, or idiosyncratic language

d) Lack of varied, spontaneous make-believe, or social imitative play appropriate to developmental level

iii. Restrictive repetitive and stereotypic patterns of behavior, interests, and activities (at least one of the following area)

a) Encompassing preoccupation with one or more stereotyped and restricted patterns of interest that is abnormal either in intensity or focus

b) Apparently inflexible adherence to specific nonfunctional routines or rituals

c) Stereotyped and repetitive motor mannerisms (e.g., hand or finger flapping or twisting, or complex whole-body movements)

d) Persistent preoccupation with parts of objects

b. Delays or abnormal functioning with onset prior to age 3 years (at least one of the following area)

i. Social interaction

ii. Language as used in social communication

iii. Symbolic or imaginative play

c. The disturbance is not better accounted for by Rett syndrome or childhood disintegrative disorder

8. Differential diagnosis with other pervasive developmental disorders

a. Asperger disorder (Asperger 1944; Frith 1991; Miles et al. 2010)

i. A variant of autism typically occurring in high-functioning individuals without mental retardation

ii. Whether Asperger syndrome is the expression of the high end of the autism spectrum or a discrete genetic entity is unclear

iii. Language development

a) Develops better than classic autism

b) Problems with the semantic and pragmatic use of language

iv. Requires all other DSM-IV diagnostic criteria for autism

v. Other characteristics

a) Misdiagnosed early on and in adulthood as odd or eccentric

b) Generally loners

c) Uncomfortable in groups

d) Unable to empathize with others

e) Does not chat

f) Follow a literal interpretation of speech with no understanding of idioms or jokes

g) Maintain a sameness in routine, follow strict rules

h) Have an encompassing preoccupation with one domain, such as the weather or computers

i) Speech may be pedantic or repetitive with odd intonations

j) Clumsiness: common

k) IQ must be within the normal range to qualify for the diagnosis

b. Childhood disintegrative disorder (Heller syndrome)

i. Behavioral, cognitive, and language regression between ages 2 and 10 years after entirely normal early development

ii. Lose previously acquired language, social, and play skills

iii. Cognitive skills usually impaired significantly

iv. The condition may resemble autism in clinical presentation but differs from autism in the pattern of onset, course, and outcome

v. No longer considered one of the pervasive developmental disorders

c. Pervasive developmental disorder, not otherwise specified (PDD-NOS)

i. Onset after age 3 years

ii. Children with autistic symptoms who do not meet full criteria in all three diagnostic domains can be diagnosed with PDD-NOS

a) Includes children with milder symptoms of all three autism diagnostic criteria and those meeting full criteria for autism in two of the three domains

b) Used as an initial or tentative diagnosis for younger children or before diagnostic evaluations are completed

Diagnostic Investigations

1. Cytogenetic studies and molecular genetic analyses (Filipek et al. 2000; Miles et al. 2010)

a. High-resolution or multi-FISH telomere chromosome studies

i. Chromosomal abnormality involving the proximal long arm of chromosome 15

(15q11-q13) observed in more than 1% of autistic individuals. Duplication is usually maternally derived, with one or two extra copies of the area roughly corresponding to the typical Angelman syndrome/Prader–Willi syndrome deletion region:
  a) Pseudodicentric 15 (inverted duplication 15)
  b) Atypical marker chromosomes
ii. Other chromosome abnormality: Cytogenetic abnormalities have been found on virtually every chromosome in individuals with autism

b. aCGH
i. Has replaced high-resolution chromosome analysis as the test of choice for the evaluation of any child with an autism spectrum disorder
ii. Cytogenetic analysis, in addition to aCGH, is recommended when the family history suggests transmission of a balanced chromosome rearrangement

c. Molecular genetic testing (*FMR1*) for full mutations and premutations for fragile X syndrome: unlikely positive in the presence of high-functioning autism

2. Metabolic studies: positive in probably less than 5% of children with autism
a. Metabolic evaluation
i. Quantitative plasma amino acids
ii. Quantitative urine organic acids
iii. Purines, creatine, and guanidinoacetate in the urine
iv. Serum concentration of lactate, pyruvate, creatine kinase, and uric acid

b. Increased serum serotonin in about one-third of individuals with autistic disorder
c. Toxicologic studies
d. Review of child's newborn screening test results
e. Further studies are needed to determine the prevalence of mitochondrial respiratory chain disorders in autism, especially those with recurrent setbacks, hypotonia, and failure to thrive

3. Electrophysiologic studies: epileptiform EEG abnormalities in autistic children with a history of regression and seizures

4. Neuroimaging (MRI) of the brain
a. Indicated when the history and physical examination or neurologic examination suggests a localized lesion, tuberous sclerosis complex, Joubert syndrome, or an early environmental insult
b. Its routine use is controversial because of the expense and need for sedation or anesthesia by an anesthesiologist

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Secondary autism: The recurrence risk is based on information relevant to the primary diagnosis. For example,
  a) Supernumerary isodicentric 15q chromosome: no increased recurrence risk since it is a de novo occurrence
  b) Duplication of proximal 15q: an increased recurrence risk since it may result from segregation of a parental chromosome translocation or a maternally derived interstitial 15q duplication
ii. Idiopathic autism
  a) The empiric aggregate risk to sibs of individuals with autism of unknown cause varies across studies but is generally considered to range from 5% to 10% for autism and 10% to 15% for milder symptoms, including language, social, and psychiatric disorders (Bolton et al. 1994; Lauritsen et al. 2005; Miles et al. 2005; Landa 2008; Selkirk et al. 2009)
  b) For families with $\geq$2 children: the recurrence risk approaches 35% (Ritvo et al. 1989)
iii. Essential autism (Miles et al. 2005)
  a) For male sibs (brothers) of a proband with essential autism: a 7% of risk for autism and an additional 7% risk for milder autism spectrum symptoms
  b) For female sibs (sisters) of a proband with essential autism: a 1% risk for autism and an unknown risk for a milder autism spectrum disorder
iv. Complex autism (Miles et al. 2005): the sib recurrence risk of a proband with complex autism
  a) One percentage for autism
  b) An additional 2% for a milder autism spectrum disorder

b. Patient's offspring: no available data

2. Prenatal diagnosis: may be available for the specific etiology for families at risk of having a child with a chromosomal disorder, copy number variant, or a single gene disorder
3. Management
   a. General goals of treatment
      i. Improve language and social skills
      ii. Decrease stereotypic and disruptive behaviors
      iii. Support parents and families in their adjustment and to educate their children
      iv. Foster independence
   b. Early intervention programs focused on developing the following areas:
      i. Language
      ii. Cognitive and imitation skills
      iii. Social responsiveness
      iv. Appropriate behavior
   c. Behavior modification programs (Prater 2002)
      i. Structure the environment
      ii. Provide consistent responses to behaviors
      iii. Reward a desired behavior (positive reinforcement)
      iv. No reward for undesirable behavior (negative reinforcement)
      v. Apply an adverse stimulus to deter an unwanted response (punishment)
      vi. Reinforcing closer and closer approximations to the desired behavior (shaping)
   d. School-aged children with autism (Bennetto and Rogers 2001)
      i. Need a curriculum that is tailored to individual strengths and needs
      ii. Effective education programs
         a) Well-structured, systematic teaching routines
         b) Consistency and repetition
         c) Concrete and functional learning objectives
   e. Adolescents and adults with autism (Bennetto and Rogers 2001)
      i. Need specific help in vocations and avocations in adult life
      ii. Social skills groups
      iii. Recreational activities
      iv. Individual psychotherapy
      v. Vocational coaching and assistance
   f. Medications: No medications are autism-specific
      i. Antidepressants: Selective serotonin reuptake inhibitors with some success in treating preoccupations, ritualized behaviors, and mood disorders and anxiety
      ii. Stimulant medications: little or no clinical improvement to decrease the activity levels and to improve the attention span of some children
      iii. Antipsychotic medications: New atypical antipsychotic medications may be useful in treating aggressive and hyperactive behavior with fewer side effects
      iv. Anticonvulsant medications: used to treat individuals with autism who suffer from seizures and may be effective in decreasing aggressive behavior and episodic behavioral outbursts, particularly in children with seizure disorder
   g. Treatments for core symptoms of autism spectrum disorders (Levy et al. 2009)
      i. Socialization
         a) Educational curricula (Myers 2009)
         b) Communication and language (Paul 2008): didactic and intensive training, and Milieu teaching
         c) Social-skills training (Seida et al. 2009)
         d) Behavioral treatment (Rogers and Vismara 2008): discrete trial instruction, pivotal response training, and relationship development intervention
      ii. Communication
         a) Communication intervention (Paul 2008): within a comprehensive program (e.g., pivotal response training, or other center), social pragmatics approach, and parent training
         b) Augmentative and assistive communication (Schlosser and Wendt 2008): picture exchange communication system, sign language, and assistive technology (e.g., vocal output devices)
         c) Behavioral (e.g., play, reciprocal communication) (Ospina et al. 2008): Floor time/developmental, individual differences, relationship-based approach, applied verbal behavior
         d) Educational (Myers 2009)
      iii. Behavior
         a) Behavioral intervention (Ospina et al. 2008): discrete trial instruction, and

other comprehensive programs using applied behavior analysis
b) Psychopharmacology (King and Bostic 2006): Selective serotonin reuptake inhibitors, anticonvulsants, atypical antipsychotics, α-2 agonists

h. Complementary and alternative medical treatments (Hess et al. 2008)
i. Biological
a) Supplements – e.g., vitamin B6 or magnesium ion, dimethyl glycine, and cod-liver oil
b) Anti-infectives – e.g., antibiotics, antifungals, and antivirals
c) Immunoglobulins
d) Off-label drugs – e.g., secretin
e) Chelation medications
f) Gastrointestinal medications
g) Elimination or special diets – e.g., gluten free or casein free
h) Hyperbaric oxygen administration
ii. Non-biological
a) Auditory integration training
b) Chiropractic therapy
c) Craniosacral manipulation
d) Facilitated communication
e) Massage and qigong
f) Interactive metronome
g) Reiki
h) Transcranial stimulation
i) Yoga

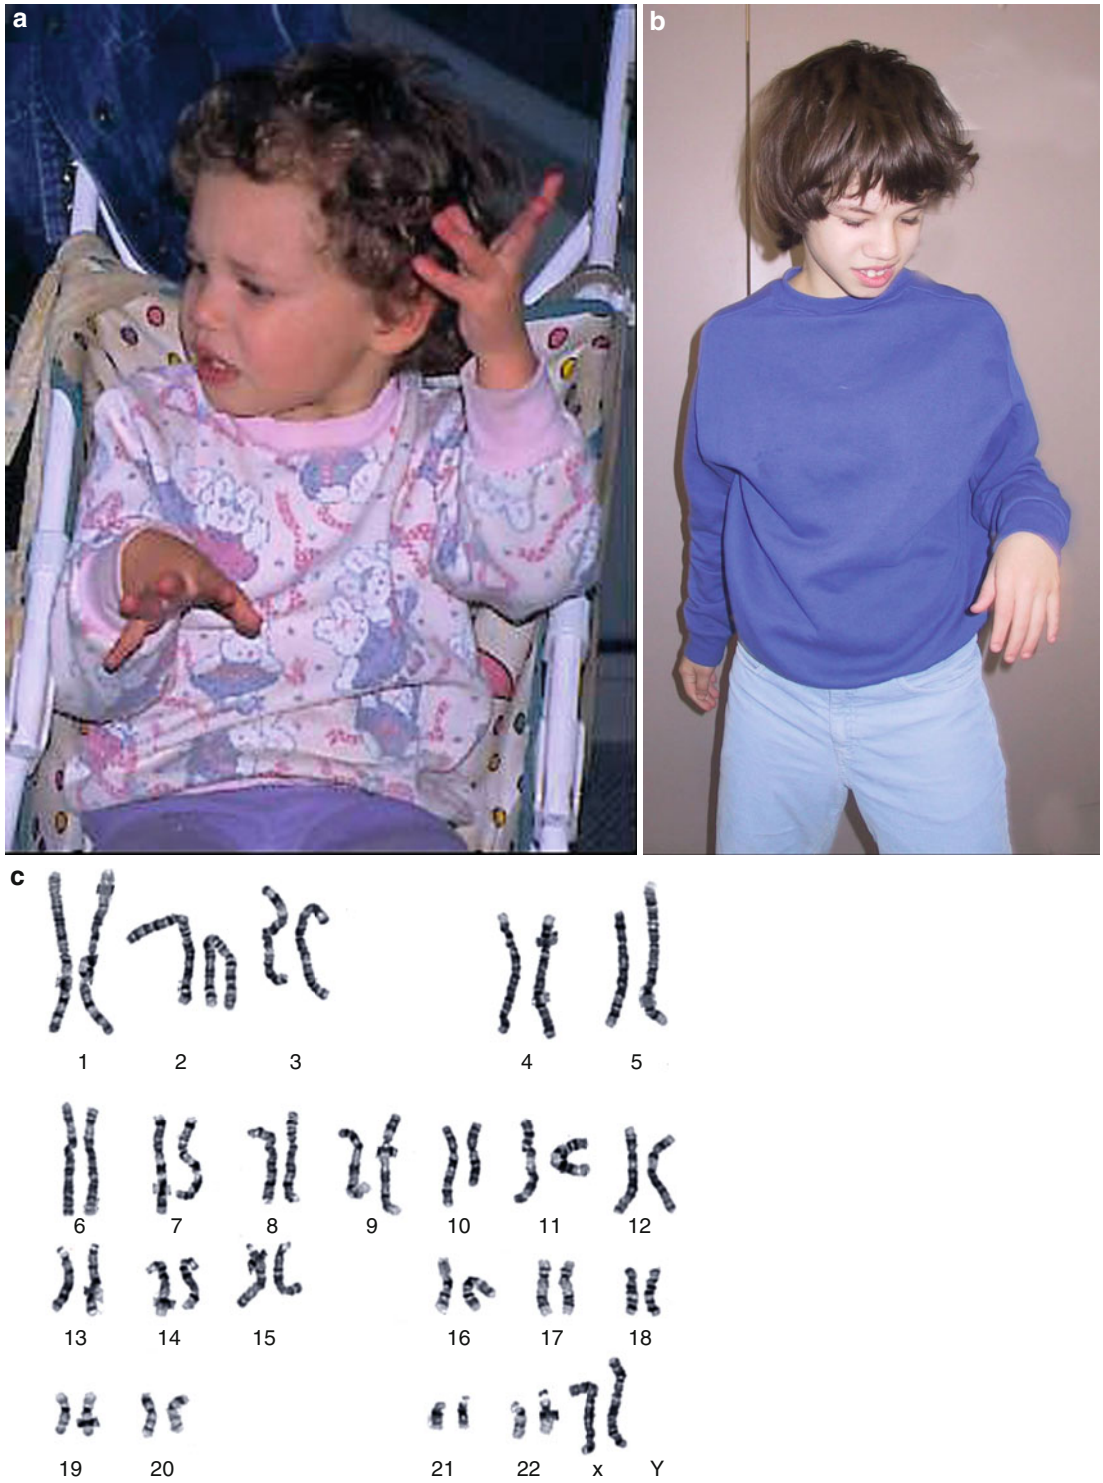

Fig. 1 (**a**–**c**) A girl (at 4 years and 10 years) with autism. Her chromosome study showed a balanced translocation between the short arm of chromosome 3 and the long arm of the chromosome 10 [t(5;10)(p13;q21)] (karyotype shown). Her parents had normal chromosomes

Fig. 2 A 11-year-old girl with autism. During infancy, she did not pay attention to people or environment and often staring into space. She had echolalia and smiled without reason. She walked in time, but had reported spinning, flapping, and rocking

Bannayan–Riley–Ruvalcaba Syndrome

In 1960, Riley and Smith described a mother and her four children with macrocephaly and pseudopapilledema due to a mutation in a single autosomal gene. In 1971, Bannayan described a 3-year-old girl with macrocephaly and numerous subcutaneous lesions ranging from lipolymphangio-hemangiomas to vascular hamartomas. This syndrome was felt to be related to the one reported earlier by Riley and Smith since both lipomatosis and hemangiomatosis are hamartomatous malformations. In 1980, Ruvalcaba, Myhre, and Smith described two patients with macrocephaly, mental retardation, pigmented spotting of the glans penis and shaft, and multiple polyps of the gastrointestinal tract. The cases described by Bannayan, Riley, Ruvalcaba, Myhre, and Smith were later known as the Bannayan–Riley–Ruvalcaba syndrome (BRRS) when Gorlin and colleagues in 1992 coined the term based on evidence of overlap of these syndromes, and later would be linked to mutations in the *PTEN* gene, which also causes Cowden syndrome (CS).

Currently, BRRS and CS are considered to be a single entity, with a phenotypic spectrum caused by mutations of the *PTEN* gene, referred to as the *PTEN* hamartoma tumor syndrome.

Synonyms and Related Disorders

PTEN hamartoma tumor syndrome

Genetics/Basic Defects

1. *PTEN* (Phosphatase and Tensin homolog deleted on chromosome 10), a tumor suppressor gene on 10q23.3, has been identified as the susceptibility gene for two hamartoma syndromes, BRRS and CS. Although distinct phenotypically, these two disorders display partial clinical overlap.
2. *PTEN* encodes a dual specificity phosphatase with homology to the focal adhesion molecules tensin and auxilin
3. Germline mutations in the *PTEN* are found in approximately 85% of individuals with classic Cowden Syndrome and in 65% of individuals with BRRS and in other disorders (20%) (Proteus syndrome, Proteus-like syndrome) which are collectively referred to as the "*PTEN* hamartoma tumor syndrome" (PHTS)
4. These phenotypically diverse disorders share several overlapping clinical features and a common genetic etiology, which has led to their gene based classification of PHTS (Marsh et al. 1998, 1999). The broad, apparently difficult to predict, clinical manifestations of PHTS mandate thorough and meticulous phenomic analysis to ensure recognition and then proper diagnosis of patients who are at risk of developing neoplasia (Orloff and Eng 2008)

Clinical Features

1. Clinical feature: Review (Gorlin et al. 1992)
   a. Macrocephaly with a normal ventricular system is common to all BRRS patients
   b. Downslanting of the palpebral fissures (60%)
   c. Strabismus or amblyopia (15%)
   d. Schwalbe lines (35%)
   e. Birth weight above the mean and body length above the 97th percentile in most cases

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_21,
© Springer Science+Business Media, LLC 2012

f. Hypotonia, mild mental retardation, gross motor delay, and speech delay (50%)
   i. Motor delay is, for the most part, transient, and improves with time
   ii. Irreversible myopathic disease in 60% of patients
   iii. Speckling of the glans penis and shaft, cutaneous angiolipomas, lymphangiomyomas, angiokeratomas, joint hyperextensibility, pectus excavatum, scoliosis, and accelerated growth of the metacarpals and of the first and second phalanges (50%)
g. Subcutaneous lipomas (75%)
h. Hemangiomas and cafe´ au lait spots of the trunk and lower extremities (10%)
i. Hamartomatous polyps (45%): limited to the ileum and colon leading to rectal bleeding and intussusception

2. Several clinical features common to CS (Marsh et al. 1999)
   a. Hashimoto's thyroiditis
   b. Vascular malformations
   c. Mental retardation
   d. Main differential features with BRRS
      i. Pigmented macules of the glans penis and shaft, and delayed motor development: seen in BRRS but not seen in CS patients
      ii. Lipomatosis common in BRRS: rarely seen in patients with CS
3. No agreed international criteria for the diagnosis of BRRS exist
   a. Criteria of diagnosis by Marsh et al. (1999) with at least following four features
      i. Macrocephaly
      ii. Lipomatosis
      iii. Hemangiomas
      iv. Speckled penis in males
   b. Criteria by Parisi et al. (2001) with at least two of the following three features
      i. Macrocephaly
      ii. Hamartomas (including at least one lipoma, hemangioma or intestinal polyp)
      iii. Penile macules in males
4. Differential diagnosis
   a. Cowden syndrome
      i. A complex disorder with malignant and benign (hamartomatous) lesions affecting derivatives of all three germ cell layers, affecting the breast, thyroid, uterus, brain, and mucocutaneous tissues
      ii. The lifetime risk for breast cancer: estimated to be 25–50%, with an average age of diagnosis between 38 and 46 years old
      iii. The risk for thyroid cancer (typically follicular, but occasionally papillary) is approximately 10%, while the risk for endometrial cancer, although not well established, has been estimated to be 5–10%
      iv. Associated with germline mutations in *PTEN* (80% in Cowden syndrome probands ascertained by the strict operational diagnostic criteria for Cowden syndrome)
   b. Proteus syndrome and Proteus-like syndrome
      i. A highly variable disorder involving congenital malformations, hamartomatous overgrowth of multiple tissues, connective tissue and epidermal nevi, and hyperostoses which affect patients in a mosaic pattern
      ii. Consensus diagnostic criteria available (Biesecker et al. 1999)
      iii. While initially thought to be unrelated to Cowden syndrome or Bannayan–Riley–Ruvalcaba syndrome, at least two independent reports have identified germline *PTEN* mutations in approximately 20% of patients with Proteus syndrome
      iv. Furthermore, approximately 50% of patients with a Proteus-like syndrome (with significant features of Proteus syndrome, but not meeting diagnostic criteria) were also found to have germline *PTEN* mutations (Zhou et al. 2001)
      v. Thus, at least a subset of Proteus syndrome and Proteus syndrome-like conditions are allelic to Cowden syndrome and Bannayan–Riley–Ruvalcaba syndrome, and are part of the *PTEN* hamartoma tumor syndrome spectrum
   c. Juvenile polyposis syndrome (JPS)
      i. An autosomal dominant disorder
      ii. Characterized by predisposition for hamartomatous polyps in the gastrointestinal tract, specifically in the stomach, small intestine, colon, and rectum
      iii. Untreated polyps lead to bleeding and anemia

iv. Malignant transformation can occur though most juvenile polyps are benign
v. Approximately 20% of individuals with JPS have mutations in the *MADH4* gene and approximately another 20% of individuals with JPS have mutations in the *BMPR1A* gene (Howe et al. 1998, 2001)

d. Peutz–Jeghers syndrome (PJS)
i. An autosomal dominant disorder
ii. Characterized by the association of gastrointestinal polyposis and mucocutaneous pigmentation
iii. Characteristics of polyps
a) Most prevalent in the small intestine but also occur in the stomach and large bowel
b) Often symptomatic with intussusception and rectal bleeding
c) The pigmentation of the perioral region is pathognomonic, particularly if it crosses the vermilion border
d) Hyperpigmented macules on the fingers are also common
e) Molecular genetic testing of *STK11/LKB1* reveals disease-causing mutations in approximately 70% of individuals who have a positive family history and 20–70% of individuals who have no family history of PJS.

Diagnostic Investigations

1. Imaging studies to define extent of the neoplasms
2. *PTEN* molecular genetic diagnosis by full sequencing available on clinical basis
   a. Diagnosis of PHTS made only when a *PTEN* mutation is identified
   b. Detectable *PTEN* gene mutation
      i. 60% of individuals meeting the diagnostic criteria of BRRS
      ii. 80% of individuals meeting the diagnostic criteria for CS
      iii. Preliminary data available suggest that up to 50% of individuals with a Proteus-like syndrome and up to 20% of individuals with Proteus syndrome have *PTEN* mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. 50% if one parent is affected
      ii. Recurrent risk probably negligible if neither parent has the *PTEN* mutation found in the proband since germline mosaicism has not been reported
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis usually performed at approximately 15–18 weeks' gestation or chorionic villus sampling at approximately 10–12 weeks' gestation if the disease-causing allele of an affected family member has been identified
   b. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified in an affected family member
3. Management
   a. Cancer surveillance: the most important aspect of management of an individual with a *PTEN* mutation
      i. Annual physical examination from age 18 years
      ii. Annual urinalysis
      iii. Baseline colonoscopy at age 50 years
   b. Molecular testing of asymptomatic at-risk relatives to identify those who have a family-specific *PTEN* mutation and ensure appropriate surveillance

Fig. 1 The patient, a 6-year-old Caucasian female, was seen for difficulty in walking. She complained significant pain in the *left* lower leg with prominent veins associated with intermittent swelling for the past 4 years. The physical examinations and various imaging studies revealed *left* lower extremity vascular malformation causing significant pain syndrome, swelling, limb dysfunction and gait disturbance and multiple lipomas. The patient was found to have a PTEN deletion which was performed at other institution. The molecular testing confirmed the clinical diagnosis of Bannayan–Riley–Ruvalcaba syndrome. The family history revealed multiple family members affected with lipomatosis (mother, maternal great aunt, and a first cousin)

Fig. 2 Note the vascular malformation affecting *left* lower extremity

Fig. 3 A lipoma noted on the *right* axillary region

Fig. 4 A lipoma noted on the scalp

Fig. 5 A diffuse lipoma noted on the *right* side of the anterior neck

Fig. 6 A lipoma noted on the back of the neck

Fig. 7 A diffuse lipoma noted on the *left* side of the back

Beckwith–Wiedemann Syndrome

The Beckwith–Wiedemann syndrome (BWS) is the most common and the best-known congenital overgrowth syndrome. It was named after Beckwith who, in 1963, described three unrelated patients with exomphalos, hyperplasia of the kidneys and pancreas, and adrenal cytomegaly. Wiedemann in 1964 reported a familial form of omphalocele with macroglossia. The incidence is estimated to be about one in 13,700 births.

Synonyms and Related Disorders

Exomphalos-macroglossia-gigantism syndrome; Wiedemann-Beckwith syndrome

Genetics/Basic Defects

1. Genetics of BWS: complex (Engel et al. 2000)
   a. Pedigree data
      i. Sporadic (85%)
      ii. Familial (15%): autosomal dominant inheritance with variable expressivity, incomplete penetrance, and preferential maternal transmission
   b. Karyotypic data
      i. Chromosome rearrangements influenced by the parent of origin (2%)
         a) Paternally derived 11p15.5 duplications exhibiting atypical clinical features as well as a significant risk of developmental delay
         b) Maternally derived translocations and inversions exhibiting typical features of Beckwith–Wiedemann syndrome
      ii. Normal karyotype (98%)
   c. Molecular data: BWS is caused by alterations in growth regulatory genes on chromosome region 11p15.5, which is subjected to genomic imprinting (an epigenetic mechanism in which gene expression is altered according to the parental origin of the allele).
2. Pathogenesis (Ferry 2010)
   a. Imprinted genes have been implicated in the pathogenesis of both familial and sporadic BWS
   b. A subgroup of BWS patients has loss of methylation at a differentially methylated region (KvDMR1) within the *KCNQ1* gene centromeric to the *IGF2* and *H19* genes
   c. Maternally expressed 11p genes
      i. *CDKN1C* (also known as $P57^{KIP2}$): a member of the cyclin-dependent kinase inhibitor family: a candidate for a maternally expressed growth inhibitory gene in BWS
         a) Germline mutations detected in >40% of familial cases
         b) Mutations infrequent (<5%) in sporadic cases
      ii. *H19*: a maternally expressed gene encoding a biologically active nontranslated mRNA that may function as a tumor suppressor. Deletion of *H19* or transposition from its usual position relative to *IGF2* disrupts normal imprinting.
      iii. *KCNQ1* (also known as *KvLQT1*): serves as an imprinting center, disruption of which could affect transcription and DNA replication through an effect on chromatin structure.
   d. Paternally expressed 11p genes
      i. *IGF2* (the gene for insulin-like growth factor-2): a paternally expressed and

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_22,
© Springer Science+Business Media, LLC 2012

maternally imprinted embryonic growth factor. Many sporadic cases show loss of imprinting of *IGF2* resulting in biallelic expression.

ii. *KCNQ1OT1* gene (also known as *LIT1*): The unmethylated paternal allele of *KvDMR1* permits transcription of the antisense transcript *KCNQ1OT1* and silencing of the *KCNQ1* and *CDKN1C* genes (Murrell et al. 2004).

e. Effect of multiple genes: combination of increased expression of paternally expressed growth promoter genes such as *IGF2* and loss of maternally expressed growth suppressor genes in some patients with paternal uniparental disomy of 11p15

f. Uniparental disomy (mosaic paternal isodisomy) for the band 11p15.5 (10–20% of sporadic cases)

i. Two paternally derived copies of chromosome 11p15 and no maternal contribution for that chromosome region

ii. Resulting from postzygotic mitotic recombination and mosaic paternal isodisomy

iii. All patients with uniparental disomy exhibit somatic mosaicism

3. Clinical findings relevant to molecular etiology (Weksberg et al. 2010)

a. Tumor development

i. Individuals with UPD of 11p15.5 or gain of methylation at the H19. Imprinting center (IC) carry the highest risk to develop Wilms tumor or hepatoblastoma.

ii. Individuals with loss of maternal methylation at IC2 carry a lower tumor risk; as well, the tumors in this molecular subgroup do not include Wilms tumor.

iii. Individuals with mutations in *CDKN1C* seem to have the lowest risk with only a small number of cases reported. In cases with *CDKN1C* mutation, only neuroblastoma has been reported to date.

b. Hemihyperplasia in cases of BWS: Alterations have included mosaicism for UPD 11p15.5 with hemihyperplasia and or molecular alterations at IC2 or IC1.

c. Positive family history: associated with mutations in *CDKN1C* or microdeletions of IC1 and very rarely IC2

d. Omphalocele: associated with an IC2 defect or *CDKN1C* mutation

e. Developmental delay: associated with cytogenetically detectable duplications involving the paternal copy of chromosome 11p15.5

f. A severe BWS phenotype

i. This seems to be associated, at least in certain cases, with very high levels of paternal chromosome 11p15.

ii. An increased frequency of female monozygotic twins discordant for BWS has been reported. These females usually show loss of methylation at IC2.

iii. In contrast, the less frequently observed male monozygotic twins show a broad spectrum of BWS-associated molecular alterations.

g. Sterility/assisted reproductive technologies (ART)

i. This seems to be associated with an increased risk of BWS cases with loss of methylation at IC2.

ii. No specific aspect of subfertility or its treatment has been specifically associated with the increased risk of epigenetic defects associated with BWS after ART.

Clinical Features

1. Variable phenotypic expression (Shuman et al. 2010)
2. Prenatal and postnatal overgrowth (gigantism) (cardinal feature)
   a. Fetus grows at an increased rate during the latter half of pregnancy
   b. Large or above normal size baby at birth
   c. Eventual somatic gigantism in most cases
   d. Advanced bone age
   e. Hemihyperplasia or hemihypertrophy (13%)
3. Performance
   a. Development
      i. Usually normal unless there is chromosome 11p15.5 duplication or serious perinatal complications such as prematurity or uncontrolled hypoglycemia.
      ii. Mild-moderate mental retardation from undetected hypoglycemic episodes during infancy
      iii. Hypoglycemia
         a) Reported in 30–50% of babies with BWS
         b) Likely caused by islet cell hyperplasia and hyperinsulinemia
   b. Seizures in some cases

4. A recognizable facial gestalt: common but often normalizes across childhood
   a. Macroglossia (cardinal feature)
      i. Chronic alveolar hypoventilation
      ii. Anterior open bite
   b. Earlobe grooves or indented ear lesions on the posterior rim of the helix or concha
   c. Facial nevus flammeus
   d. Midfacial hypoplasia
   e. Prominent eyes with infraorbital creases
   f. Full lower face with a prominent mandible
   g. Prominent occiput
5. Abdominal wall defect
   a. Omphalocele (cardinal feature)
   b. Umbilical hernia
   c. Diastasis recti
6. Gastointestinal anomalies
   a. Malrotation anomalies
   b. Dome-shaped defect of the diaphragm
7. Visceromegaly
   a. Fetal adrenocortical cytomegaly: pathognomonic finding for BWS
   b. Hepatomegaly (frequent)
   c. Nephromegaly (frequent)
   d. Cardiomegaly that resolves spontaneously
   e. Occasional clitoromegaly
   f. Hyperplastic pancreas, bladder, uterus, and thymus
8. Neoplasms: overall risk for tumor development in children with BWS estimated at 7.5%
   a. Benign tumors
      i. Adrenal adenoma
      ii. Carcinoid tumor
      iii. Fibroadenoma
      iv. Fibrous hamartoma
      v. Ganglioneuroma
      vi. Myxoma
   b. Malignant tumors: predisposition to embryonal malignancies
      i. Wilms tumor (most frequent)
      ii. Hepatoblastoma
      iii. Adrenocortical carcinoma
      iv. Rhabdomyosarcoma
      v. Neuroblastoma
      vi. Glioblastoma
      vii. Malignant lymphoma
      viii. Pancreatoblastoma
      ix. Teratoma
   c. Clinical findings associated with higher risks of tumor development
      i. Hemihyperplasia
      ii. Nephromegaly
      iii. Nephrogenic rests
9. Additional features
   a. Polyhydramnios
   b. Prematurity
   c. Enlarged placenta
   d. Hemangioma
   e. Other renal anomalies
      i. Medullary dysplasia
      ii. Duplicated collecting system
      iii. Nephrocalcinosis
      iv. Medullary sponge kidney
      v. Cystic changes
      vi. Diverticula
10. Adult phenotype
   a. Hemihyperplasia
   b. Prominent jaw
   c. Enlarge tongue
   d. Ear creases and pits
   e. Enlarged kidneys and other abdominal organs
   f. Normal height
11. Major and minor findings associated with BWS (Weksberg et al. 2010)
   a. Major findings
      i. Abdominal wall defect: omphalocele (exomphalos) or umbilical hernia
      ii. Macroglossia
      iii. Macrosomia (traditionally defined as height and weight >97th percentile)
      iv. Anterior ear lobe creases and/or posterior helical pits (bilateral or unilateral)
      v. Visceromegaly of intra-abdominal organ(s); for example, liver, kidney(s), spleen, pancreas, and adrenal glands
      vi. Embryonal tumor in childhood
      vii. Hemihyperplasia
      viii. Cytomegaly of adrenal fetal cortex, usually diffuse and bilateral
      ix. Renal abnormalities, including medullary dysplasia and later development of medullary sponge kidney (MSK)
      x. Positive family history of BWS
      xi. Cleft palate
   b. Minor findings
      i. Pregnancy-related findings of polyhydramnios, enlarged placenta and/or thickened umbilical cord, premature onset of labor and delivery

ii. Neonatal hypoglycemia
iii. Nevus flammeus
iv. Cardiomegaly/structural cardiac anomalies/cardiomyopathy
v. Characteristic facies
vi. Diastasis recti
vii. Advanced bone age

Diagnostic Investigations

1. Transitory neonatal hypoglycemia (spontaneous regression during the first 4 months of life) (63%)
2. Neonatal polycythemia (20%)
3. Hypercholesterolemia, hyperlipidemia, hypothyroidism, thyroxine-binding globulin deficiency: rare occurrence
4. Periodic abdominal ultrasonography for organomegaly and embryonal tumors, followed by MRI or CT if indicated
5. Radiography
   a. Advanced bone age
   b. Chest radiography to rule out rare neural crest tumors such as thoracic neuroblastoma
6. Echocardiography for suspected cardiac abnormality
7. Chromosome analysis (high resolution and FISH studies)
   a. Normal chromosomes in most patients
   b. Chromosome abnormalities involving 11p15 in $\leq$1% of cases
      i. Paternally derived 11p15 duplication
      ii. Maternally derived translocations and inversions
8. Molecular analysis (Shuman 2010)
   a. Paternal uniparental disomy (UPD) of 11p15 in multiple tissues (10–20%)
      i. Restriction fragment length polymorphism (RFLP) analysis of multiple 11p15 loci
      ii. Methylation studies of multiple imprinted genes on 11p15
   b. Mutation analysis: *P57 ^{KIP2}* (5–10%) (screen for mutation by heteroduplex/SSCP analysis, followed by sequence of *P57 ^{KIP2}* exons)
   c. Molecular testing is typically not indicated for parents or other family members when UPD is found, as these cases arise through post-zygotic somatic recombination.
   d. Parental studies are recommended if genomic alterations are found, that is, karyotype abnormalities, *CDKN1C* mutations or microduplications or microdeletions of the 11p15.5 region (Weksberg et al. 2010).

Genetic Counseling

1. Recurrence risks (Shuman et al. 2010)
   a. Patient's sib: The risk to the sibs of a child with BWS depends on the genetic basis for BWS in the proband
      i. Probably a low recurrence risk in cases of negative family history, normal karyotype, and absence of identifiable molecular etiology
      ii. Up to 50% of recurrence risk in cases of positive family history and normal karyotype
      iii. Up to 50% recurrence risk in cytogenetically detected maternal 11p15 translocation or inversion
      iv. An undetermined recurrence risk in cytogenetically detected paternal 11p15 duplication
      v. A low recurrence risk in cases of paternal 11p15 uniparental disomy as this event arises from a post-zygotic somatic recombination
      vi. 50% recurrence risk if a *CDKN1C* mutation is present in a parent (usually maternally transmitted)
      vii. Four clinically relevant categories identified for approximately 85% of individuals with BWS who have a negative family history and a normal karyotype (Shuman et al. 2010):
         a) Proband with *KCNQ1OT1* hypomethylation (~50–60%): very low recurrence risk since no recurrences of loss of methylation at *KCNQ1OT1* have been reported in first–degree relatives of individuals with BWS who have this molecular lesion.
         b) Proband with paternal uniparental disomy for 11p15 (~10–20%): the recurrence risk is empirically very low because the UPD appears to arise from a post-zygotic somatic recombination.
         c) Proband with a *CDKN1C* mutation (~510%): Both parents should be tested for mutations. Several instances of

transmission of *CDKN1C* mutations from clinically unaffected mothers to affected offspring have been reported as well as two instances of paternal transmission from clinically unaffected fathers. The recurrence risk for such parents may be as high as 50%.

d) Proband with no identifiable primary etiology (~13–15%): The risk to members in these families is unknown but empirically low.

b. Patient's offspring (Shuman et al. 2010)
   i. Negative family history (10–20% of individuals with BWS and no known family history of BWS have paternal uniparental disomy of 11p15) and normal karyotype (5–10% of all individuals with BWS with a normal karyotype have identifiable mutations in *CDKN1C)*: ~85% of individuals with BWS
      a) *KCNQ1OT1* hypomethylation: a low recurrence risk
      b) Uniparental disomy for 11p15: likely a very low risk
      c) Identified *CDKN1C* mutation: The risk to offspring of a female with a *CDKN1C* mutation is 50%; the risk to offspring of a male with a *CDKN1C* mutation is <50%, but too few cases have been reported to generate a risk figure
   ii. Positive family history and normal karyotype: ~10–15% of individuals with BWS
      a) ~50% if transmitting parent is female
      b) <50% if transmitting parent is male
   iii. Monozygous twins (<1% of individuals with BWS): theoretically low

2. Prenatal diagnosis
   a. Indications (Weksberg et al. 2010)
      i. Families having a child with severe manifestations of BWS
      ii. If a cytogenetic or genomic abnormality (e.g., microdeletion, *CDKN1C* mutation) has been identified, prenatal testing may be indicated by CVS or amniocentesis. If such abnormalities are *de novo*, gonadal mosaicism remains a possibility. Epigenetic analysis of amniocytes can be undertaken by methylation-sensitive multiplex ligation probe analysis (MS-MLPA).
      iii. Families, for whom UPD or methylation alterations have been detected in the absence of a transmissible genomic alteration, may also wish to consider prenatal diagnostic testing even though the recurrence risk would be very low. Of note, a recent follow-up study of apparently isolated fetal omphalocele reported BWS in 20% of cases based on clinical or molecular findings (Wilkins-Haug et al. 2009).
   b. Maternal serum alpha fetoprotein screening: may be elevated in a fetus with omphalocele
   c. Prenatal Ultrasonography
      i. Fetal overgrowth (macrosomia)
      ii. Polyhydramnios
      iii. Enlarged placenta
      iv. A long umbilical cord
      v. Macroglossia
      vi. Cleft palate
      vii. Distended abdomen
      viii. Abdominal wall defects
      ix. Organomegaly
      x. Renal anomalies
      xi. Cardiac anomalies
   d. Cytogenetic studies
      i. Possible if a cytogenetic abnormality has been identified in the proband and one parent
      ii. To identify translocations, inversions, and duplications involving 11p15
   e. Molecular analysis
      i. Uniparental disomy
      ii. Mutation analysis of *CDKN1C*, provided the mutation has been documented in the previously affected child

3. Management
   a. Early detection and close monitoring for hypoglycemia to reduce the risk of central nervous system complications
   b. Partial tongue resection for cosmetic purpose and to relieve severe airway obstruction
   c. Surgical risks related to hypoglycemia or difficulty in intubation secondary to macroglossia
   d. Management of abdominal wall defects, gastrointestinal malformations, and renal anomalies
   e. Orthopedic follow-up of hemihyperplasia
   f. Management of structural renal abnormalities
   g. Management of embryonal neoplasms

Fig. 1 (**a**–**e**) Five infants with Beckwith–Wiedemann syndrome showing hemangioma, macroglossia, and umbilical hernia

Fig. 2 (**a**, **b**) An infant with Beckwith–Wiedemann syndrome showing macroglossia, ear crease, and umbilical hernia

Fig. 3 An infant with Beckwith–Wiedemann syndrome and a large omphalocele requiring surgical intervention

Fig. 4 An infant with Beckwith–Wiedemann syndrome prior to partial glossectomy

Fig. 5 A young adult with Beckwith–Wiedemann syndrome showing macroglossia and post-surgical status of umbilical and inguinal hernia repairs

Fig. 6 (**a**, **b**) A 2-month-old infant with macroglossia and posterior ear creases, suspected of having Beckwith–Wiedemann syndrome clinically. Southern blot analysis was utilized to detect abnormal methylation in the imprinting center DMR2, which is located within the BWS critical region on chromosome 1p15. The DNA probe LIT1 was used for the analysis. Hypomethylation of LIT1 was detected. The methylation index was 0.21 (Reference range: 0.40–0.58). The results are consistent with a diagnosis of Beckwith–Wiedemann syndrome

Behcet Disease

In 1937, Behçet first described three patients with oral and genital ulceration and hypopyon. It is most common in the Middle and Far East with a prevalence of 7–8 per 100,000 people, whereas in the United States the prevalence is estimated at 4 per 1,000,000 people.

Synonyms and Related Disorders

Behcet syndrome

Genetics/Basic Defect

1. A complex multisystem inflammatory disease of unknown cause
2. Considered a relapsing and remitting vasculitis of the small- to medium-sized vessels with following protean manifestations:
   a. Aphthous stomatitis
   b. Genital ulceration
   c. Uveitis
   d. Synovitis
   e. Gastrointestinal lesions
   f. Cutaneous lesions
   g. Central nervous system lesions
   h. Cardiac lesions
   i. Vessel lesions
3. Immunopathogenic aspects of Behcet disease (Direskeneli 2001; Krause and Weinberger 2008)
   a. Neutrophil activation
   b. Cellular and humoral immunity
   c. Antigenic stimuli
      i. Herpes simplex virus
      ii. Streptococci and superantigens
      iii. Heat shock proteins (65 kDa, αβ-crystallin)
   d. Genetic predisposition to HLA-B51 and antigen presentation
   e. Retinal-S antigen and HLA-B51 as autoantigens
   f. Vascular disease and antiendothelial cell antibodies
   g. Severity and sex: more severe in men
   h. Tumor necrosis factor-α-1031C allele: associated with disease susceptibility
   i. Polymorphisms in interleukin-10 and CD28 genes: also associated with Behcet disease
   j. Association with endothelial nitric oxide synthase gene polymorphism: ethnic related

Clinical Features

1. Highly variable clinical course with recurrences and remissions
2. Recurrent attacks of oral, genital, ocular, and skin lesions
   a. Oral aphthous ulcers
      i. Keystones to diagnosis of Behcet disease according to the classification criteria
      ii. Often an initial presenting sign
      iii. Occurring on the buccal mucosa, tongue, gingiva, and the soft palate area
      iv. Minor aphthous ulcers: superficial with a diameter of 2–6 mm, appearing as multiple lesions, and developing within

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_23,
© Springer Science+Business Media, LLC 2012

1–2 days. They heal without scarring within 7–10 days and recur at various frequencies.
v. Major aphthous ulcers: deeper and painful lesions leaving scars after healing
vi. Herpetiform aphthous ulcers: numerous lesions grouped as small ulcers

b. Genital ulcers
i. Women: located on the vulva, vagina, and cervix uteri
ii. Men: located on the prepuce and scrotum
iii. Lesions resembling the oral aphthae but tend to be deeper and leaving scars
iv. Differential diagnosis from other genital ulcers (herpes simplex, syphilis, tropical ulcers, and skin infestations)

c. Ocular lesions (70–85%)
i. Generally follow the genital and oral ulceration by a few years
ii. Characterized by severe vasculitis with arterial and venous occlusions
iii. Hypopyon (presence of leukocytes in the anterior chamber of the eye)
iv. Uveitis
v. Hemorrhagic and exudative retinal lesions (retinitis)
vi. Marked vitritis
vii. Choroiditis
viii. Bilateral nongranulomatous inflammation of the iris and ciliary body
ix. Intermittent blurring of vision and loss of vision

d. Skin lesions
i. Pustular vasculitic cutaneous lesions: may evolve as lesions of small vessel necrotizing vasculitis from a neutrophilic vascular reaction to a lymphocytic perivascular reaction
ii. Erythema nodosum-like lesions: usually occurring on the lower extremities but can be seen on the arms, neck, and face
iii. Pseudofolliculitis
iv. Papulopastular lesions: neutrophil-induced, vessel-based reaction
v. Acneiform nodules

3. Articular manifestations
a. Recurrent seronegative arthritis
i. Common findings
ii. A non-specific synovitis
b. Monoarthritis
c. Polyarthritis

4. Gastrointestinal manifestations
a. Ulcerative lesions most frequently occurring in the terminal ileum, caecum, stomach, and intestine
b. Symptoms
i. Abdominal pain
ii. Diarrhea
iii. Melena
iv. Perforation

5. CNS manifestations (about 1% of patients)
a. Headaches
b. Meningitis
c. Meningoencephalitis
d. Cranial nerve palsies
e. Peripheral nerve involvement with vasculitis
f. Cerebellar ataxia
g. Hemiplegia
h. Benign intracranial hypertension
i. Neurologic deficits
j. Cerebral aneurysm
k. Cerebral vasculitis and ischaemic stroke: unusual
l. Personality changes and depression
m. Dementia
n. Hearing and vestibular disturbances

6. Pulmonary manifestations
a. Tracheobronchial ulcerations
b. Pleurisy
c. Embolism
d. Pulmonary arterial aneurysms
e. Pneumonitis
f. Fibrosis

7. Renal involvement: rare
a. Glomerulonephritis
b. Systemic amyloidosis

8. Cardiac manifestations
a. Intracardiac thrombosis
b. Myocardial infarction
c. Pericarditis
d. Endocarditis

9. Vascular manifestations
a. Superficial thrombophlebitis
b. Deep thrombophlebitis
c. Small vessel vasculitis
d. Aneurysm

10. Criteria for clinical diagnosis of Behcet disease, proposed by O'Duffy and Goldstein in 1976, require the presence of recurrent oral or genital aphtha along with two additional systemic findings

for diagnosis and only one for the diagnosis of the incomplete form:
   a. Criteria
      i. Aphthous stomatitis
      ii. Aphthous genital ulceration
      iii. Uveitis
      iv. Cutaneous "pustular" vasculitis
      v. Synovitis
      vi. Meningoencephalitis
   b. Diagnosis: At least three criteria present, one being recurrent aphthous ulceration
   c. Incomplete form: Two criteria present, one being recurrent aphthous ulceration
   d. Exclusion
      i. Inflammatory bowel disease
      ii. Systemic lupus erythematosus
      iii. Reiter's disease
      iv. Herpetic infections
11. The International Study Group criteria were published in 1990 to include positive Pathergy test as one of the criteria to establish the diagnosis of Behcet disease (Ghate and Jorizzo 1999):
   a. Recurrent oral ulceration: minor aphthous, major aphthous, or herpetiform ulceration observed by physician or patient that recurred at least three times in one 12-month period
   b. *Plus 2 of the following criteria* (findings applicable only in absence of other clinical explanations)
      i. Recurrent genital ulceration: aphthous ulceration or scarring observed by physician or patient
      ii. Eye lesions: Anterior uveitis, posterior uveitis, or cells in vitreous on slit lamp examination; or retinal vasculitis observed by ophthalmologist
      iii. Skin lesions: erythema nodosum observed by physician or patient, pseudofolliculitis or papulopustular lesions; or acneiform nodules observed by physician in post-adolescent patients not receiving corticosteroid treatment
      iv. Pathergy test (a non-specific pustule that is an inflammatory reaction to needle pricks in approximately 40% of patients, especially during the exacerbation period): Pathergy test is positive when pricking a sterile needle into the patient's forearm results in an aseptic erythematous nodule or pustule that is more than 2 mm in diameter at 24–48 h.

Diagnostic Investigations

1. Positive skin pathergy test
2. Laboratory findings (Önder and Gürer 2001)
   a. Acute-phase response
      i. Raised erythrocyte sedimentation rate
      ii. Increased serum levels of C-reactive protein
      iii. Elevated plasma complement components, such as C3, C4, C9, and factor B
   b. Disease exacerbations
      i. Elevated IgG, IgA, and IgM
      ii. Elevated C-reactive protein
      iii. Elevated 2-globulin
   c. Interleukin (IL)-8 as a serological marker
3. HLA typing
4. Fluorescein angiography, color Doppler imaging and fundoscopic examination to detect retinal features
5. CT scan (Ceylan et al. 2010)
   a. Effectively demonstrates vascular system involvement that is the main cause of mortality in these patients
   b. Also effective in detecting mediastinal, pleural, and pulmonary parenchymal findings related to the disease
6. MRI and CT scan to detect the neurologic lesions
7. Histopathological features
   a. Pathergy lesions
      i. Leucocytoclastic vasculitis
      ii. Neutrophilic vascular reaction
      iii. Polymorphonuclear leucocyte infiltration
   b. Erythema nodosum-like lesions
      i. Neutrophilic vascular reaction or vasculitis in the dermis and subcutaneous tissue
      ii. Perivascular lymphocytic dermal inflammation
   c. Common histopathological lesions in all organ systems
      i. Vasculitis
      ii. Thrombosis
      iii. Perivascular infiltrates of lymphomononuclear cells
      iv. Neutrophilic vascular reaction
   d. Early cutaneous lesions: neutrophilic vascular reaction or leucocytoclastic vasculitis
   e. Late cutaneous lesions: lymphocytic perivasculitis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased
2. Prenatal diagnosis: no prenatal diagnosis reported
3. Management (Alpsoy and Akman 2009)
   a. Mucocutaneous lesions
      i. Topical corticosteroids: useful for oral and genital ulcers
      ii. Colchicine
         a) Beneficial effects on the mucocutaneous symptoms, presumably by inhibiting neutrophil function
         b) The first choice for treatment of genital ulcers and/or erythema nodosum, especially in female patients
         c) Combination with benzathine penicillin: for patients who are ineffective with colchicine alone, or a male patient, or in the presence of oral ulcers with or without other mucocutaneous lesions
      iii. Treatment with thalidomide: effective for oral and genital ulcers and pseudofolliculitis
      iv. Dapson, zinc sulfate, and rebamipide: can be other choices
      v. Immunosuppressive agents, such as azathioprine and cyclosporine, and biologicals, such as IFN and anti-TNF-α agents: to control the patients with severe mucocutaneous disease or unresponsive to the respected treatments
      vi. Systemic corticosteroids: prescribed for erythema nodosum that is refractory to treatment with colchicine
   b. Ocular lesions
      i. Require special attention and aggressive treatment because of its highest morbidity
      ii. About 25% of patients eventually develop blindness despite therapeutic intervention
      iii. Topical mydriatic agents and corticosteroid drops: given for acute attacks of anterior uveitis
      iv. Colchicine: prescribed to prevent both anterior and posterior uveitis because of its high degree of efficacy and relatively low toxicity
      v. Topical injection of corticosteroids, with systemic administration in some cases: used for acute attacks of posterior uveitis
      vi. Cytotoxic agents (azathioprine, chlorambucil, and cyclophosphamide): help prevent ocular attacks in approximately 50–75% of patients
      vii. Cyclosporine: beneficial in 70–80% of patients with ocular lesions that have been refractory to the conventional therapies
      viii. Subcutaneous human recombinant interferon alpha: an effective and fairly well tolerated therapy for Behcet disease
      ix. Systemic corticosteroids: generally given in acute attacks of posterior uveitis, panuveitis, and retinal vasculitis
      x. Results from therapies: improved vision and decreased pain, saving the individual a potential enucleation
   c. Arthritis
      i. Nonsteroidal anti-inflammatory drugs and colchicine: the first choice and are effective for most cases of arthritis
      ii. Additional use of benzathine penicillin: the next step
      iii. Low dose corticosteroids and azathioprine: used in patients whose arthritis is resistant to treatment with nonsteroidal anti-inflammatory drugs, colchicine, or sulfasalazine
      iv. Interferon alfa: also highly effective
   d. Gastrointestinal lesions
      i. Sulfasalazine, corticosteroids, and azathioprine: the principal drugs
      ii. Anti-TNF-α treatments, especially infliximab: a new and effective alternative
      iii. Bowel rest: obligatory in patients with an acute abdomen and bleeding
      iv. Surgery: considered for patients with bowel perforation and intractable bleeding
   e. CNS lesions
      i. High doses of corticosteroids
      ii. Supplemented with cytotoxic agents
   f. Large-vessel lesions
      i. Treated with a combination of corticosteroids and cytotoxic agents
      ii. Anticoagulants and antiplatelet agents: used for deep venous thrombosis
      iii. Surgery for refractory large-vessel disease

Biotinidase Deficiency

In 1971, Compartz and colleagues first described multiple carboxylase deficiency responsive to biotin administration. Wolf and colleagues further characterized the infantile form of multiple carboxylase deficiency as biotinidase deficiency (BTD) in 1981.

Based on the results of worldwide screening of biotinidase deficiency (Wolf 1991), the incidence of the disorder is one in 137,401 for profound biotinidase deficiency, one in 109,921 for partial biotinidase deficiency, and one in 61,067 for the combined incidence of profound and partial biotinidase deficiency. Carrier frequency in the general population is approximately one in 120.

Synonyms and Related Disorders

Juvenile-onset multiple carboxylase deficiency; Late-onset multiple carboxylase defciency

Genetics/Basic Defects

1. An autosomal recessive disorder affecting the endogenous recycling and release of biotin (vitamin H) from dietary protein: consecutive biotin depletion resulting in low activities of biotin-dependent carboxylases and urinary excretion of organic acids characteristic of multiple carboxylase deficiency
2. Classification of biotinidase deficiency according to residual enzyme activity (Baumgartner and Suormala 1997; Wolf 2001)
   a. Profound biotinidase deficiency (residual activity $<10\%$ of mean normal value)
   b. Partial biotinidase deficiency (residual activity 10–30% of mean control value)
3. Caused by complete or partial absence of the enzyme biotinidase
4. The gene that encodes biotinidase is mapped at 3p25.

Clinical Features

1. Natural history (Wolf 2011)
   a. Individuals with biotinidase deficiency, diagnosed by newborn screening, who are treated with biotin before developing symptoms: develop normally
   b. Individuals with biotinidase deficiency who have recurrent symptoms and metabolic compromise prior to biotin treatment: develop neurologic problems
2. Untreated profound biotinidase deficiency
   a. Symptoms usually develop between ages 1 week and 10 years
   b. Clinical features, also observed in children with many other inherited metabolic disorders, include:
      i. Seizures
      ii. Hypotonia
      iii. Developmental delay
      iv. Breathing abnormalities
         a) Hyperventilation
         b) Laryngeal stridor
         c) Apnea
   c. More specific features
      i. Sensorineural hearing loss
      ii. Optic atrophy

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_24,
© Springer Science+Business Media, LLC 2012

iii. Cutaneous symptoms
  a) Eczematous skin rash
  b) Alopecia
iv. Conjunctivities
v. Chronic and possibly lethal fungal infections (e.g., candidiasis)
vi. Ataxia

d. Symptoms encountered by older children and adolescents
i. Limb weakness
ii. Rare spastic paraparesis
iii. Scotomata

3. Children with untreated partial biotinidase deficiency: usually have mild symptoms which occur only when the child is stressed (e.g., prolonged infection, illness, fasting)

Diagnostic Investigations

1. New born screening (Wolf 2011)
   a. Utilizes a small amount of blood obtained from a heel prick for a colorimetric test for biotinidase activity (Heard et al. 1984; Wolf et al. 1985a; Heard et al. 1986; Wolf 1991)
   b. Detect virtually 100% of affected infants
   c. False positive test results in:
      i. Premature infants
      ii. Samples placed in plastic prior to sufficient drying
   d. Measure biotinidase activity in serum/plasma in infants whose initial screening tests are abnormal
2. Other laboratory findings
   a. Decreased or low normal plasma biotin concentrations in individuals with profound biotinidase deficiency
   b. In most individuals
      i. Metabolic ketolactic acidosis
      ii. Organic aciduria
      iii. Metabolic ketoacidosis
   c. Specific tests
      i. Biotinidase levels: Carriers (heterozygotes) usually have serum enzyme activity levels intermediate between those of affected and those of normal individuals (Wolf et al. 1983)
      ii. Serum ammonia
      iii. Urine organic acids
      iv. Plasma amino acids
      v. Urine ketones
      vi. Blood gas
      vii. Serum chemistries
      viii. Carnitine, and acylcarnitine profiles
3. Imaging studies: MRI of the brain (Desai et al. 2008)
   a. Cerebral edema
   b. Low attenuation of white matter signal
   c. Cerebral atrophy
   d. Compensatory ventricular enlargement
4. Other tests
   a. Ophthalmologic testing
      i. Dilated funduscopy to detect optic atrophy
      ii. Visual field testing and visual evoked potentials to detect degree of optic nerve injury
   b. Audiologic testing
      i. To detect hearing deficits in symptomatic children which can be persistent after treatment
      ii. Brainstem auditory evoked potentials to delineate the abnormality in younger children or in developmentally delayed patients
   c. EEG for seizure activities
5. Molecular Genetic testing: clinically available
   a. Targeted mutation analysis
      i. Real-time PCR of DNA from the blood spot of a newborn screen card can be used to identify a panel of common *BTD* mutations (p.Cys33PhefsX36, p.Gln456His, p.Arg538Cys, p.Asp444His), and p.[Ala171Thr;Asp444His].
      ii. These five mutations that cause profound biotinidase deficiency comprise approximately 60% of the abnormal alleles found in symptomatic individuals and in children identified by newborn screening.
   b. Sequence analysis
      i. Direct sequencing of *BTD* and its intron/exon junctions is available clinically.
      ii. Almost all individuals with partial biotinidase deficiency have the mutation p.Asp444His in one allele of *BTD* in combination with a mutation for profound deficiency in the other allele.
   c. Deletion/duplication analysis: Although deletion testing is offered clinically, no large deletions have been reported in *BTD*.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is also a carrier
2. Prenatal diagnosis possible for pregnancies at increased risk
   a. Biochemical testing (measurement of biotinidase enzyme activity in cultured amniotic fluid cells and in amniotic fluid obtained by amniocentesis) (Secor McVoy et al. 1984; Chalmers et al. 1994)
   b. Molecular genetic testing (analysis of DNA extracted from fetal cells obtained by amniocentesis or CVS), provided both disease-causing alleles of an affected family member have been identified
   c. Request for prenatal diagnosis or preimplantation genetic diagnosis is not common since biotinidase deficiency can be treated and does not affect intellect.
3. Management
   a. Biotin treatment with supplementation with oral biotin in free form
      i. Children with biotinidase deficiency identified by newborn screening: remain asymptomatic with compliance to lifelong biotin therapy
      ii. Effective in preventing symptoms (Möslinger et al. 2001; Weber et al. 2004)
      iii. Compliance with biotin therapy: improves symptoms in symptomatic individuals
   b. Medical care for developmental delay, hypotonia, spasticity, and bulbar dysfunction

Fig. 1 A 11-month-old girl with biotinidase deficiency (0.41 nmol/mL/min) (normal, 3.66–9.21) detected by newborn screening. Her growth and development have been normal with oral biotin supplementation

Fig. 3 A 12-week-old infant boy was found to have a borderline biotinidase activity by newborn screening. DNA analysis showed a heterozygous D444H mutation and, therefore, he is a carrier

Fig. 2 A 26-month-old boy was found to have partial biotinidase deficiency by newborn screening with a biotin level of 6.3 (normal: >16). DNA analysis showed 1 copy of D444H mutation and 1 copy of G68:d7i3 mutations. His growth and developmental have been normal with oral biotin supplementation

Bladder Exstrophy

Bladder exstrophy is a rare developmental anomaly occurring as an isolated defect in about 1/25,000–1/40,000 births (Cacciari et al. 1999).

Synonyms and Related Disorders

Bladder exstrophy and epispadias complex

Genetics/Basic Defects

1. Genetics
   a. Usually an isolated defect
   b. Microduplications at 22q11.21: associated with non-syndromic classic bladder exstrophy (Draaken et al. 2010)
   c. Microduplication at 22q11.2: reported in two patients with bladder exstrophy and hearing impairment (Lundin et al. 2010)
2. Basic defects (Ives et al. 1980)
   a. Probably failure of fusion of the secondary mesoderm (from the primitive streak) in the midline of the anterior abdominal wall, with subsequent rupture of the thin wall consisting only of ectoderm and endoderm
   b. Early rupture (fifth week) resulting in exstrophy of the cloaca, later rupture (7th week) resulting in exstrophy of the bladder

Clinical Features

1. Classical bladder exstrophy (Ben-Chaim et al. 1996)
   a. Diagnosis easily made at birth
   b. Occupy 60% of the patients with the exstrophy-epispadias complex
   c. Bladder plate protruding just beneath the umbilical cord
   d. Posterior bladder wall is exposed through a midline abdominal wall defect
   e. Inferiorly displaced umbilicus located close to the superior margin of the exstrophic bladder
   f. Rectus muscles divergent on either side of the bladder
      i. Leading to the separated pubic bones
      ii. Separation of the pubic bones caused by an outward rotation of the innominate bones and eversion of the pubic rami
   g. Male patients
      i. A short epispadiac phallus with a dorsal urethral plate
         a) Caused by separation of the pubic bones
         b) Possibly caused by a true deficiency of corporeal tissue
      ii. A splayed glans
      iii. Dorsal chordee
   h. Female patients
      i. Genital defect analogous to the male but more easily reconstructed
      ii. Separated mons pubis (both hemiclitori and labia) (split clitoris and exstrophic vagina)
      iii. Predisposing to uterine prolapse, especially after pregnancy and delivery, secondary to pelvic floor defect
   i. Urinary tract abnormalities
      i. Generally normal upper urinary tract
      ii. Occasional abnormalities
         a) Unilateral renal agenesis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_25,
© Springer Science+Business Media, LLC 2012

b) Horseshoe kidney
c) Hydronephrosis
d) Other renal anomalies

j. Internal genitalia: usually normal
k. Fertility and childbearing
i. Documented in both sexes but less common in the males
ii. C-section advised to avoid injury to continence mechanism
iii. Postpartum uterine prolapse common because of aggravation of preexisting abnormal pelvic support
l. Inguinal hernias
i. Incidence: very common
a) 56–82% in boys
b) 11–15% in girls
ii. Incidence of bowel incarceration below 1 year of age: 10–53%
iii. Causes
a) Large internal and external inguinal rings
b) Lack of obliquity of the inguinal canal
m. Anus
i. Anteriorly placed
ii. Fecal continence adversely affected by the divergence of the pelvic musculature
n. Rectal prolapse
i. Virtually always disappears after bladder closure or cystectomy
ii. Represents an indication for surgical management of the exstrophied bladder
o. Spinal abnormalities (6.7%) (Cadeddu et al. 1997)
i. Myelomeningocele
ii. Lipomeningocele
iii. Scimitar sacrum
iv. Posterior laminal defects
v. Vertebral fusion
vi. Hemivertebrae
p. Malignancies
i. Rare late complication of bladder exstrophy, especially in untreated patients whose bladders are left exstrophic for many years
ii. Types of malignancies
a) Adenocarcinoma: the most common type, arising from the precursor cystitis glandularis, a consequence of chronic irritation and inflammation of exposed bladder mucosa
b) Squamous cell carcinoma and rhabdomyosarcoma
c) Adenocarcinoma developing adjacent to the ureterointestinal anastomoses in patients with urinary diversions that mix the urinary and fecal streams
d) The risk of developing colon adenocarcinoma is increased 7,000-fold after ureterosigmoidostomy among patients younger than 25 years of age than the general population
q. Behavioral, social, and school competency problems observed in 70% of adolescents and 33% of school aged children
r. 70% of parents express concern about the children's sexual function or sexual disfigurement
s. Consider all patients with exstrophy-epispadias complex to be latex-sensitive

2. Variants of exstrophy (Cerniglia et al. 1989)
a. Pseudo-exstrophy (exstrophic abdominal wall defect without bladder exstrophy)
b. Duplicate exstrophy
c. Superior vesical fistula and fissure
d. Covered exstrophy and visceral sequestration

Diagnostic Investigations

1. General assessment
2. Cardiopulmonary assessment
3. Renal ultrasound for baseline examination of the kidneys since increased bladder pressure after bladder closure can lead to hydronephrosis and upper urinary tract deterioration (Yerkes 2009)
4. Voiding cystourethrogram (Yerkes 2009)
a. To rule out bilateral vesicoureteral reflux which is present in nearly all patients with classic bladder exstrophy
b. Performed in early childhood to assess bladder capacity in preparation for continence reconstruction

Genetic Counseling

1. Recurrence risk (Ben-Chaim et al. 1996)
a. Patient's sib: The risk of recurrence of exstrophy or epispadias in a given family is 1 of 275 births

   b. Patient's offspring: The risk of a parent with exstrophy producing a child with exstrophy or epispadias is up to 1 of 70 or 500 times the risk of the general population
2. Prenatal diagnosis possible by ultrasonography
   a. Absence of bladder filling in the presence of normal kidneys (bladder never demonstrated on the ultrasound) (71%)
   b. A protuberance on the lower abdomen representing the exstrophied bladder (47%)
   c. A diminutive penis with anteriorly displaced scrotum (57% of the males)
   d. A low-set umbilical insertion (29%)
   e. Abnormal widening of the iliac crests (18%)
   f. Separation of the pubic rami
   g. Difficulty in ascertaining the sex of the fetus
3. Management
   a. Supportive management
      i. Ligate umbilical cord with suture to avoid bladder mucosal damage by an umbilical clamp
      ii. Protect bladder
         a) With clear plastic wrap
         b) Irrigate the bladder surface with sterile saline each time diaper is changed and the wrap replaced
      iii. Initiate prophylactic antibiotics
   b. Goals of the reconstruction of bladder exstrophy (Grady et al. 1999)
      i. Preservation of the kidney function
      ii. Creation of urinary continence
      iii. Reduction in the urinary tract infections
      iv. Creation of functionally and cosmetically acceptable external genitalia
   c. Initial bladder closure
      i. Closure of the pelvic ring
         a) Important for the initial closure
         b) Important for the eventual attainment of urinary continence
      ii. Pelvic osteotomy
         a) Two main approaches: posterior iliac osteotomy and the anterior innominate osteotomy
         b) Reduce the tension on the suture lines to help securing the bladder closure
         c) To restore the pelvic anatomy and thus increase the chances of eventual continence and reduce the likelihood of uterine prolapse
   d. Epispadias repair
      i. Usually performed at 2–3 years of age before the continence procedure
      ii. Contributing significantly to the development of bladder capacity
      iii. Goals
         a) Reconstruction of the urethra and glans penis
         b) Encourage the potential of penile length
         c) Correction of the dorsal chordee
         d) Achieving adequate skin coverage
      iv. Penis is generally reconstructible to cosmetically and functionally acceptable form, despite a short phallus
   e. Bladder neck reconstruction
      i. Usually performed at age of 4–5 years (when toilet training is possible)
      ii. Require anti-reflux procedure since all exstrophy patients have vesicoureteral reflux
      iii. Complete urinary drainage achieved with ureteral stents and suprapubic cystostomy tubes
   f. Ureteral reimplantation
   g. Bladder augmentation and continent diversion for patients who have failed bladder neck reconstruction and have an inadequate bladder capacity
   h. Alternatives for exstrophy reconstruction
      i. For patients with very small bladder plates or hydronephrosis
      ii. Ureterosigmoidostomies
         a) Allow children to achieve continence
         b) Protect upper urinary tracts
         c) Potential complications: recurrent acute and chronic pyelonephritis, urolithiasis, hyperchloremic hypokalemic metabolic acidosis, ureteral obstruction and the late development of colonic malignancy
   i. Repair of inguinal hernias at the time of primary closure of bladder exstrophy

Blepharophimosis, Ptosis, and Epicanthus Inversus Syndrome

In 1921, Komoto reported the first case, known today as blepharophimosis-ptosis-epicanthus inversus syndrome (BPES), with the triad of wide set eyes, ectropion, excessive brow hair, and hypoplasia of the caruncle and the relatives with similar phenotypic features. Later that year, Dimitry described a family with above triad and traced the pedigree of "blepharophimosis syndrome," apparently transmitted in an autosomal dominant manner for the first time. In 1971, Kohn added telecanthus to the triad of this syndrome.

Synonyms and Related Disorders

BPES with Duane retraction syndrome; BPES with/without ovarian failure

Genetics/Basic Defects

1. An autosomal dominant disorder
   a. No known affected family members in about one quarter of cases
      i. New mutation cases
      ii. Minimal expression in affected relatives
   b. A significant number of patients with no identifiable family history of BPES
2. BPES gene *FOXL2*
   a. Mapped to chromosome 3q22–23
   b. Recently mutation of *FOXL2* has been described as a cause of BPES
3. Two forms of BPES
   a. BPES type I
      i. Characterized by hypogonadism and infertility in affected females
      ii. Complete penetrance
      iii. Transmission by males as fertility in affected females is reduced
   b. BPES type II
      i. Not associated with female infertility
      ii. Incomplete penetrance
      iii. Transmission occurs in both males and females
4. *FOXL2* encodes for a transcription factor that is expressed predominantly in the developing eyelid and in the ovary.
5. Mutations of *FOXL2*: detected in patients with both type I and type II BPES
6. Genotype–phenotype correlation
   a. BPES type I: predicted to be the result of a truncated protein either lacking or containing the forkhead domain
   b. BPES type II: predicted to be the result of duplications, within or downstream of the forkhead domain, or other mutations resulting in an extended protein
7. MRI studies of BPES type I patients demonstrate the possible role of *FOX2* in the differentiation of the superior levator muscle of the eyelid.

Clinical Features

1. Clinical triad
   a. Blepharophimosis (profound small and narrow horizontal palpebral fissure): morphologically defined as reduction of both the horizontal and vertical dimensions of the palpebral fissure
   b. Ptosis of the eyelids: severe, bilateral, and symmetric

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_26,
© Springer Science+Business Media, LLC 2012

   c. Epicanthus inversus (a small skinfold which arises in the lower lids and runs upward)
2. Other ocular associations
   a. Patients often assume a chin up, head tilt backward position to clear their visual axis.
   b. Patients often present with raised arched eyebrows because of recruitment of frontalis muscle to compensate for ptosis and visual field defect.
   c. Associated with telecanthus (normal interpupillary distance with abnormally wide intercanthal distance)
   d. Abnormalities of the eyelid margin and lacrimal drainage apparatus
   e. A high incidence of amblyopia
   f. Strabismus
   g. Microphthalmos
   h. Optic disc colobomas
3. Non-ocular associations
   a. Infertility in women with type I BPES due to premature ovarian failure which is defined as the onset of menopause before the age of 40 years
      i. Normal menarche followed by oligomenorrhea and later amenorrhea in most women with BPES type I
      ii. Fertile in early reproductive years
      iii. Soon leading to either ovarian resistance to gonadotrophins or true premature ovarian failure
      iv. Usually with normal secondary sexual characteristics
   b. Broad flat nasal bridge
   c. High-arched palate
   d. Protruding or cup-shaped ears
   e. Cardiac defects
   f. Mental retardation (controversial)
4. Natural history of BPES
   a. Epicanthal folds and telecanthus: improve significantly with time
   b. Ptosis and blepharophimosis: do not improve with time
5. Differential diagnosis
   a. Blepharophimosis
      i. As an isolated clinical finding
      ii. As part of a number of congenital syndromes
   b. Ohdo syndrome
      i. A sporadic condition
      ii. Blepharophimosis
      iii. Ptosis
      iv. Dental hypoplasia
      v. Partial deafness
      vi. Mental retardation
   c. Observed in several aneuploidies such as chromosome 3p deletion (blepharophimosis, ptosis)
   d. Fetal alcohol effects

Diagnostic Investigations

1. Diagnosis based on clinical findings which are present at birth
2. Detection of premature ovarian failure
   a. Secondary amenorrhea
   b. Endocrinologic evaluation of hypergonadotrophic hypogonadism
      i. Elevated follicle-stimulating hormone
      ii. Elevated luteinizing hormone
      iii. Decreased serum concentration of estradiol and progesterone
   c. Ultrasound studies
      i. Small hypoplastic uterus
      ii. Streak ovaries
      iii. Early on, normal presence of primordial follicle but without normal follicular development
      iv. Later on, presence of scars in place of primordial follicles when progress into true premature menopause
3. *FOXL2* mutations detectable in up to 75% of affected individuals

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Low recurrence risk when parents are not affected and do not have a *FOXL2* mutation. However, Germline mosaicism has been observed in BPES and demonstrated at the molecular level.
      ii. 50% risk if a parent is also affected
   b. Patient's offspring
      i. A 50% recurrence risk for an affected individual to have an affected offspring
      ii. Affected female individuals with type I BPES may have infertility

2. Prenatal diagnosis
   a. Available by DNA analysis from fetal cells obtained via amniocentesis (during 15–18 weeks of gestation) and chorionic villus sampling (10–12 weeks of gestation)
   b. Preimplantation genetic diagnosis may be available for families.
   c. The disease-causing allele of an affected family member must be identified before prenatal testing can be performed.
   d. These tests, however, are not commonly done for BPES.
3. Management
   a. Crucial to distinguish two types of BPES to address the infertility issues with patients and for genetic counseling of female patients of child-bearing age
   b. Endocrine and gynecologic evaluation and management recommended in affected females
      i. Hormone replacement therapy as needed
      ii. Need to address concerns of infertility such as adoption or ovum donation for premature ovarian failure
      iii. Referral to a clinical geneticist for an appropriate genetic workup and counseling
   c. Complex and requires coordination required among several specialists, including pediatric ophthalmologist, oculoplastic surgeon, pediatric endocrinologist, reproductive endocrinologist, gynecologist, and genetic counselor
   d. Treatment goals for an ophthalmologist
      i. Promote normal visual development
      ii. Improve cosmesis
      iii. Alleviate abnormal chin-up posture
   e. A comprehensive ophthalmic examination
      i. Visual acuity
      ii. Refraction
      iii. Ocular movements
   f. Diagnosis and treatment of amblyopia and strabismus crucial
   g. Ptosis repair: usually addressed after medial canthoplasty
   h. Timing of surgery for congenital ptosis: controversial
      i. Weighing the balance of early surgery to prevent amblyopia
      ii. Late surgery to allow for more reliable ptosis measurement, which provides a better surgical outcome

Body Stalk Anomaly

Body stalk anomaly, sometimes also called limb body wall complex, is a rare abdominal wall defect due to failure of the development of the body stalk. Prevalence is estimated to be 0.32 per 10,000 births.

Synonyms and Related Disorders

Limb body wall complex

Genetics/Basic Defects

1. Sporadic occurrence in most cases, although concordance in twins has been reported
2. Failure in body folding in cranial, caudal, and lateral axes during the embryonic stage of development (Hiett et al. 1992)
   a. Abnormalities of cranial folding leading to pentalogy of Cantrell consisting of the following:
      i. Cardiac abnormalities
      ii. Sternal cleft
      iii. Upper abdominal defect
      iv. Anterior diaphragmatic hernia
      v. Deficiency of the diaphragmatic pericardium
   b. Abnormalities of caudal folding leading to the following:
      i. Cloacal exstrophy
      ii. Hypogastric omphalocele
      iii. Imperforate anus
      iv. Partial colonic agenesis
      v. Agenesis of one umbilical artery
   c. Abnormalities of lateral folding leading to midline omphalocele
   d. Abnormalities of folding along all three axes resulting in a body stalk anomaly
      i. Failure to obliterate the extraembryonic cavity that continues to communicate with the intraembryonic cavity
      ii. Creation of a large ventral wall defect that is covered by an amnioperitoneal membrane which contains the abdominal viscera and inserts directly into the chorionic plate
      iii. The fetus appearing to be directly attached to the placenta as the umbilical cord is significantly shortened or absent
      iv. Frequent kyphoscoliosis due to limited truncal flexion
3. Possible causes of the anomaly (Becker et al. 2000):
   a. Early amnion rupture before obliteration of the extraembryonic coelom
   b. Abnormal splitting of the embryo at the fourth gestational week
   c. Disturbance of the blood flow due to vascular rupture, as described in cocaine users
   d. A special situation in monozygotic twins
   e. Maternal uniparental disomy of chromosome 16 in a fetus with body stalk anomaly suggesting placental insufficiency or imprinting effects as cause of this anomaly (Chan et al. 2000)
4. Pathogenesis (de Silva et al. 2001)
   a. The umbilical cord, derived from a small mass of mesoderm (body stalk), attaches the embryo to the wall of the blastocysts.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_27,
© Springer Science+Business Media, LLC 2012

   b. Abnormal development of the body stalk resulting in an absent or rudimentary umbilical cord
   c. Consequences
      i. Direct attachment of fetus to the placenta
      ii. Abdominal viscera lying in a sac outside the abdominal cavity covered by amnion

Clinical Features

1. A large anterior abdominal wall defect with a large omphalocele
   a. Outside the abdominal cavity containing thoracic and/or abdominal organs
   b. Covered by amnion
   c. Appears continuous with (adherent to) the placental membranes
2. Absent, rudimentary, or extremely short umbilical cord. A severe type of short umbilical cord syndrome may be a variant of the body stalk anomaly.
3. Two-vessel cord
4. Severe kyphoscoliosis
5. Placenta directly attached to the amnioperitoneal sac
6. Extensive associated anomalies (Giacoia 1992)
   a. Hypoplasia of the lungs
   b. Anal atresia (imperforate anus)
   c. Agenesis of the colon
   d. Intestinal atresia
   e. Exstrophy of the cloaca
   f. Vaginal atresia
   g. Agenesis of uterus and gonads
   h. Absence of external genitalia
   i. Hypoplastic kidneys
   j. Absence of diaphragm
   k. Diaphragmatic hernia
   l. Spina bifida
   m. Dysplastic thorax
   n. Occasional coexistence of the syndrome with limb malformations (mostly lower extremities) and amniotic bands
7. Fetal death caused by abruptio placentae
8. Live-born infant die shortly afterward

Diagnostic Investigations

1. Radiography to document skeletal anomalies
2. Cytogenetic analysis
   a. No specific anomaly
   b. Placental karyotyping: report of a case with placental trisomy 16 and maternal uniparental disomy (UPD)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not surviving to reproductive age
2. Prenatal diagnosis
   a. High maternal serum alpha fetoprotein
   b. Ultrasonography
      i. Can be diagnosed as early as the first trimester by transvaginal sonography
      ii. A large abdominal anterior wall defect with abdominal organs in a sac outside the abdominal cavity in apparent continuity with (adherent to) the placental membranes
      iii. An extremely short or absent umbilical cord
      iv. Severe kyphoscoliosis
      v. Polyhydramnios
      vi. Oligohydramnios
      vii. Two-vessel cord
      viii. Sonographic signs alone expect an unequivocal poor prognosis
   c. Amniocentesis
      i. Elevated amniotic fluid alpha feto-protein level
      ii. Abnormal acetylcholinesterase
      iii. Normal chromosomes
3. Management: newborn with the body stalk anomaly, uniformly fatal

Fig. 1 An extremely premature neonate with body stalk anomaly. Short umbilical cord (7.5 cm with 5 cm fused with placenta) and a large amnioperitoneal sac between the abdomen and the placenta are evident. The sac was filled with internal viscera. In addition, there were anal and urethral atresia, rectovesical fistula, left renal agenesis, lumbosacral meningomyelocele, severe scoliosis, and lumbosacral hypoplasia

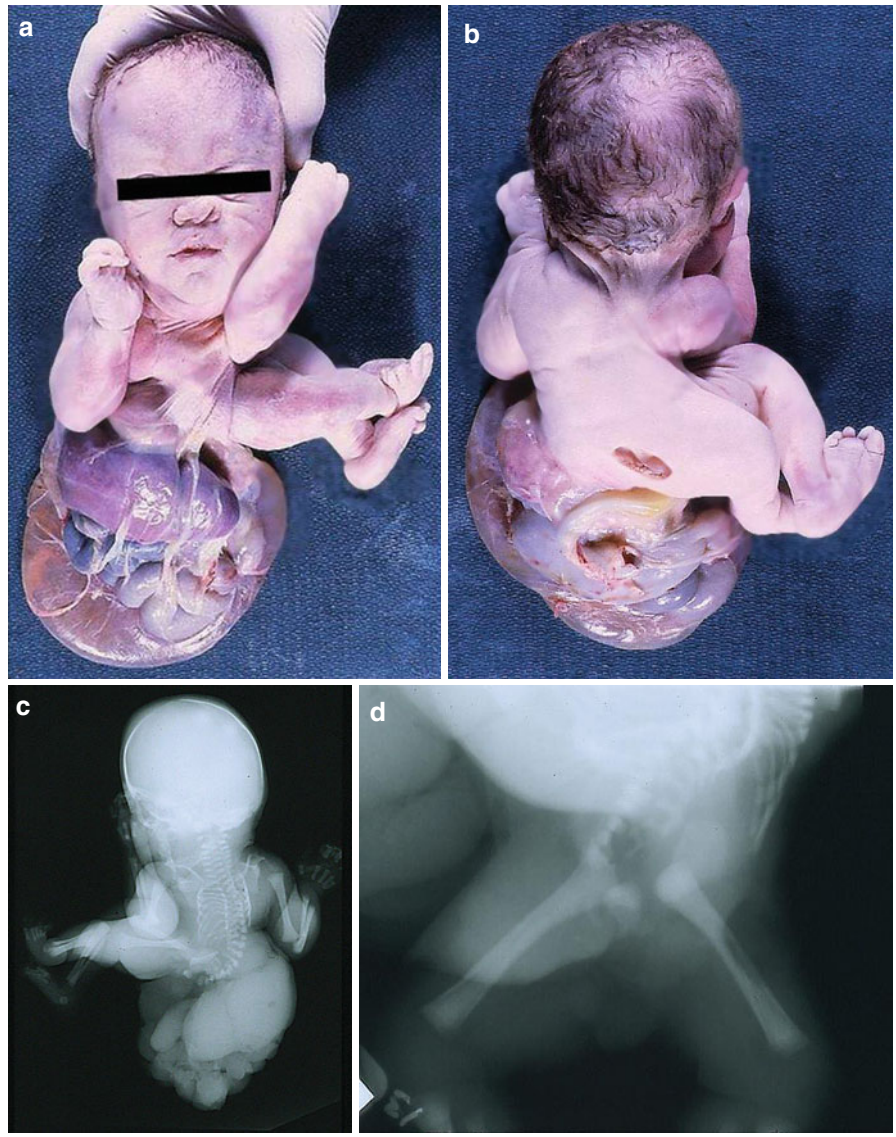

Fig. 2 (**a**–**d**) An infant with body stalk anomaly showing Potter facies, severe kyphoscoliosis, and a large amnioperitoneal sac outside the body. The sac contained abdominal organs. The umbilical cord was absent. Limb and vertebral defects illustrated in the radiographs

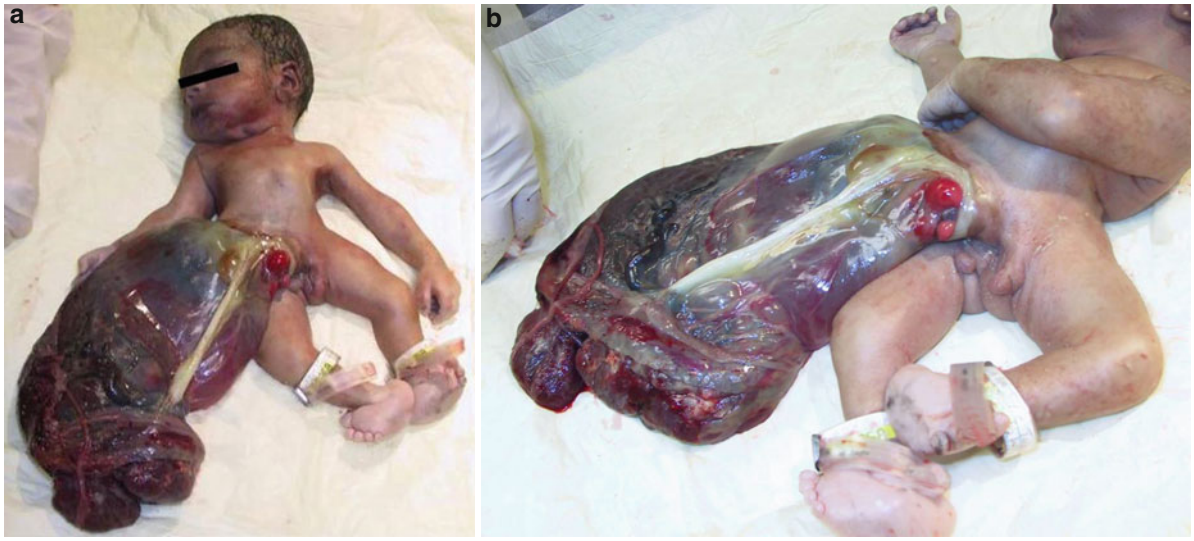

Fig. 3 (**a**, **b**) Another infant with body stalk anomaly showing anterior abdominal wall defect with a large sac containing abdominal organs, exstrophy of the bladder, and clubfeet

Brachydactyly

Brachydactyly, a general term for short digit, refers to disproportionately short fingers and toes and forms part of the group of limb malformations characterized by bone dysostosis. Dysostoses refer to abnormalities of individual bones, either in isolation or in combination with various abnormally formed bones. Dysostosis are usually static and arise during blastogenesis (first 8 weeks of embryonic life) versus osteochondrodysplasias that usually present at a later stage of development, typically affect the skeleton in general, and may continue to evolve as a result of continuous gene functioning throughout life.

Brachydactyly can occur either as an isolated malformation or as a part of a complex malformation syndrome. To date, many different forms of brachydactyly have been identified. Some forms also result in short stature. In isolated brachydactyly, subtle changes elsewhere may be present. Brachydactyly may also be accompanied by other hand malformations, such as syndactyly, polydactyly, reduction defects, or symphalangism.

Synonyms and Related Disorders

Brachydactyly type A1 (Farabee type); Brachymetatarsus IV; Kirner deformity (dystelephalangy); Sugarman brachydactyly; Type 2 (Mohr-Wriedt type); Type A3 (brachydactyly-clinodactyly); Type A4 (Temtamy type); Type A5; Type B; Type C (Haws type); Type D (stub thumb); Type E

Genetics/Basic Defects

1. Isolated brachydactyly: the inheritance is mostly autosomal dominant with variable expressivity and penetrance
2. Causative gene defect identified in the majority of isolated brachydactylies and some syndromic forms of brachydactyly
3. Genomics of isolated brachydactyly
   a. Brachydactyly type A1 BDA1
      i. Caused by mutations in the Indian hedgehog (*IHH*) gene located on chromosome 2q35-36. This supports the hypothesis that *IHH* plays a pivotal role in normal human skeletogenesis.
      ii. Another locus for this phenotype, designated *BDA1B* has been identified on chromosome 5p13.3-p13.2
   b. Brachydactyly type A2 (BDA2)
      i. Caused by mutation in the human bone morphogenetic protein receptor 1B gene (*BMPR1B*) on chromosome 4q21-q20, that affects cartilage formation in a dominant-negative manner
      ii. Sparing of the fourth finger distinguishes the Mohr-Wriedt type BDA2 from BDA2 caused by mutations in *BMPR1B* and concludes that the growth and differentiation factor 5 gene (*GDF5*) on chromosome 20q11.2 is a novel BDA2 causing gene. Mutations in *GDF5* alter the receptor binding affinities and can also cause symphalangism.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_28,
© Springer Science+Business Media, LLC 2012

c. Brachydactyly type A3 (BDA3): no gene or locus has yet been identified.
d. Brachydactyly type A4 (BDA4) (*HOXD13*, mapped on 2q31-q32)
   i. Mutations in the homeobox containing gene (*HOXD13* on chromosome 2q31-q32) can give rise to limb malformations with variable expressivity and a wide spectrum of clinical manifestations including synpolydactyly and brachydactylies types D and E.
   ii. The term "HOXD13 limb morphopathies" for the spectrum of limb disorders caused by *HOXD13* mutations was suggested based on a link between *HOXD13* and two additional limb phenotypes – syndactyly type V and brachydactyly type A4.
e. Brachydactyly type B (BDB)
   i. Caused by heterozygous truncating mutations in the receptor kinase-like orphan receptor 2 gene (*ROR2*) on 9q22 in the majority of cases
   ii. Patients affected with the distal mutations have a more severe phenotype than those with the proximal mutations.
   iii. Homozygous *ROR2* mutations are associated with an extreme form of brachydactyly, with extensive hypoplasia of the phalanges and metacarpals/metatarsals and absence of nails. In addition, there are vertebral anomalies, brachymelia of the arms, and ventricular septal defect, making up the manifestations of the Robinow syndrome, which also has been shown to be caused by mutations in *ROR2*.
   iv. Different mutations in the bone morphogenetic protein (*BMP*) antagonist NOGGIN (*NOG*, mapped on chromosome 4q23-q24) were identified in a subset of *ROR2*-negative patients with BDB and additional occurrence of proximal symphalangism and carpal synostosis.
   v. The BDB phenotype, as well as the location and nature of the BDB mutations, suggest a specific mutational effect that cannot be explained by simple haploinsufficiency.
f. Brachydactyly type C (BDC) (*CDMP1*, mapped on 20q11.2)
   i. Caused by heterozygous mutations of cartilage-derived morphogenetic protein 1 (*CDMP1*), also known as growth/differentiation factor-5 gene (*GDF5*), resulting in loss of function
   ii. Factors other than locus heterogeneity, such as genetic modifiers and/or environmental factors, must play a role in phenotypic variability.
   iii. Non-penetrance in a mutation carrier of heterozygous mutations was identified in additional families with BDC.
   iv. A novel missense mutation was described in the prodomain of *CDMP1* indicating an important function of the prodomain for the folding, secretion, and availability of biologically active *CDMP1*.
   v. Homozygous mutations of *CDMP1* cause the Hunter-Thompson form of chondrodysplasia, a recessive condition that is characterized by severe acromesomelic limb shortness.
g. Brachydactyly type D (BDD): associated with mutations in HOXD13 (Johnson et al. 2003)
h. Brachydactyly type E (BDE) (*HOXD13*, mapped on 2q31-q32)
   i. Brachydactyly type E as an isolated abnormality has not been mapped with confidence.
   ii. The occurrence of brachydactyly type E was one feature of what appeared to be a contiguous gene syndrome due to a cytogenetically visible de novo deletion of 2q37.
   iii. Missense mutations in the homeodomain of *HOXD13* in two cases with distinctive limb phenotypes exhibiting overlap with BDD and BDE have been described.
i. Brachymetatarsus IV: no gene or locus for Kirner deformity has yet been identified.
j. Sugarman brachydactyly: no gene or locus for Kirner deformity has yet been identified.
k. Kirner deformity: no gene or locus for Kirner deformity has yet been identified.

Clinical Features

1. Types of isolated brachydactyly
   a. Brachydactyly type A: shortening is confined to middle phalanges.

i. Brachydactyly type A1 (BDA1) (Farabee type brachydactyly)
   a) Variable short or rudimentary middle phalanges of all digits which are occasionally fused with terminal phalanges
   b) Short proximal phalanges of the thumbs and big toes
   c) An autosomal dominant trait
ii. Brachydactyly type A2 (BDA2) (Mohr-Wriedt type brachydactyly)
   a) Characterized by hypoplasia/aplasia of the second middle phalanx of the index finger and sometimes little finger
   b) Characteristic triangular-shaped middle phalanx ("delta phalanx") in the index fingers and second toes
   c) Radially curved index finger in severely affected cases
   d) Malformation of the proximal phalanx of big toes resulting in fibular deviation of the distal phalanx, while all other toes have rudimentary middle phalanges causing tibial deflection of their distal phalanges
   e) An autosomal dominant trait
iii. Brachydactyly type A3 (BDA3) (brachymesophalangy V, brachydactyly-clinodactyly)
   a) Characterized by shortening of the middle phalanx of the little finger
   b) Slanting of the distal articular surface of the middle phalanx leads to radial deflection of the distal phalanx.
   c) Not always associated with clinodactyly. A single flexion crease of the little finger indicates a short or absent middle phalanx.
   d) This type should be differentiated from other types of crooked little fingers, namely, Kirner deformity and camptodactyly; in the former, there is radial bowing of the terminal phalanx due to curving of its shaft. Camptodactyly is a flexure contracture deformity of the interphalangeal joints.
   e) An autosomal dominant trait with reduced penetrance
iv. Brachydactyly type A4 (BDA4) (brachymesophalangy II and V, Temtamy type brachydactyly)
   a) Brachymesophalangy affecting mainly the second and fifth digits
   b) When the fourth digit was affected, it showed an abnormally shaped middle phalanx leading to radial deviation of the distal phalanx.
   c) The feet also showed absence of middle phalanges of the lateral four toes.
   d) Rare autosomal dominant trait
v. Brachydactyly type A5 (BDA5) (absent middle phalanges of digits 2–5 with nail dysplasia)
   a) Absence of the middle phalanges and nail dysplasia with duplicated terminal phalanx of the thumb
   b) This type can be included in type B brachydactyly.

b. Brachydactyly type B (BDB)
   i. Absence or hypoplasia of the terminal parts of the index to little fingers with complete absence of fingernails
   ii. Intact thumbs frequently showing flattening, splitting, or duplication of the distal phalanges
   iii. Less severely affected digits on the radial side of the hand compared to those on the ulnar side
   iv. Similarly but less severely affected feet
   v. Symmetric deformity
   vi. Accompanied by soft tissue syndactyly, symphalangism, carpal and/or tarsal fusions, and shortening of metacarpals and/or metatarsals
   vii. A rare hand malformation
   viii. An autosomal dominant trait with variable severity (expressivity)
c. Brachydactyly type C (BDC) (brachydactyly with hyperphalangism, Haws type brachydactyly)
   i. Characterized by brachymesophalangy of the index, middle, and little fingers and shortening of the first metacarpal
   ii. The ring finger: usually the longest digit, longer than the index finger (hyperphalangism detected on radiological examination)
   iii. The proximal phalanx of the index finger: an anomalous configuration resulting in its ulnar deflection

iv. Short metacarpals and symphalangism: occasionally present
v. The feet: either normal or show ordinary brachydactyly
vi. Inheritance: autosomal dominant with variable expressivity
vii. Presence of considerable intra- and interfamilial variation

d. Brachydactyly type D (BDD) (stub thumb)
i. Distal phalanx of the thumb alone: characteristically shortened
ii. Various degrees of thumb shortening, either unilaterally or bilaterally
iii. Base of the distal phalanx is broader than the surface of the proximal phalanx to which it articulates, and that the distal end of the bone often shows some hyperplasia.
iv. Short distal phalanx of the thumb results from early closure of its epiphyses.
v. An autosomal dominant trait with reduced penetrance

e. Brachydactyly type E (BDE)
i. Variable shortening of the metacarpals with more or less normal length of phalanges
ii. Occasional shortening of the metatarsals, resulting from hypoplastic and partially fused metacarpal epiphyses, visible on radiographs
iii. Often presence of short terminal phalanges
iv. Hyperextensibility of the hand joints: frequently a striking feature
v. Often relatively high axial triradius
vi. Mild short stature in affected individuals
vii. An isolated type E brachydactyly is inherited as an autosomal dominant trait with variable expressivity and variable involvement of the metacarpals and/or metatarsals, with frequent bilateral asymmetry.
viii. This phenotype is an example of genetic heterogeneity, because in addition to the autosomal dominant isolated type and Albright hereditary osteodystrophy, it also occurs with Turner syndrome.

f. Brachymetatarsus IV (metatarsus IV, short, toes, fourth, short)
i. Short fourth metatarsi resulting in unilateral or bilateral short fourth toes were observed in 206 persons in northeastern India with no instance of short metacarpals, distinguishing this form from BDE.
ii. An autosomal dominant trait with approximately 27% penetrance

g. Sugarman brachydactyly (brachydactyly with major proximal phalangeal shortening)
i. A new form of brachydactyly of which a conspicuous feature was a non-articulating great toe which was set dorsal and proximal to the usual position. The great toes were amputated.
ii. Very short fingers without motion at the proximal interphalangeal joints
iii. The consanguinity in the family and the presence of seven other affected members among the patient's relatives made autosomal recessive inheritance likely.

h. Kirner deformity (dystelephalangy)
i. Malformed little finger consists of radial bowing of the terminal phalanx.
ii. Tip of the little finger points toward the thenar eminence.
iii. Usually bilateral malformations
iv. An autosomal dominant trait with incomplete penetrance

2. Brachydactyly as part of a syndrome (extensive list), for example:
a. Autosomal recessive Robinow syndrome
b. Rubinstein–Taybi syndrome
c. Albright hereditary osteodystrophy
d. Brachydactyly type E with hypertension
e. du Pan syndrome

3. Prognosis
a. Strongly dependent on the nature of the brachydactyly
b. May vary from excellent to severely influencing hand function
c. Often depends on the nature of the associated anomalies if brachydactyly forms part of a syndromic entity

Diagnostic Investigations

1. Radiographic studies
a. To document brachydactyly of hands and feet
b. To document other skeletal anomalies

2. Analysis of affected family members
3. Mutation studies

Genetic Counseling

1. Recurrence risk: The nature of genetic counseling depends both on the pattern of inheritance of the type of brachydactyly present in the family and on the presence or absence of accompanying symptoms. In autosomal dominant inheritance, variability in severity and incomplete penetrance are common in several types of brachydactyly. In autosomal recessive inheritance, variability is usually smaller although variable symptoms may still be present in affected sibs.
   a. Patient's sib
      i. Autosomal dominant inheritance
         a) Recurrence risk of 50% if a parent is affected
         b) Low recurrence risk if both parents are normal
      ii. Autosomal recessive inheritance: risk of recurrence 25%
   b. Patient's offspring
      i. Autosomal dominant inheritance: a 50% risk of offspring affected
      ii. Autosomal recessive inheritance: low recurrence risk unless the spouse is affected or a carrier of brachydactyly mutation
2. Prenatal diagnosis
   a. Usually not indicated for isolated forms of brachydactyly, but may be appropriate in syndromic forms
   b. Molecular studies of chorionic villus samples at 11 weeks of gestation and by amniocentesis after the 14th week of gestation can provide antenatal diagnosis if the causative mutation in the family is known.
3. Management
   a. No specific management or treatment applicable to all forms of brachydactyly
   b. Plastic surgery
      i. Only indicated if the brachydactyly affects hand function or for cosmetic reasons
      ii. Typically not ordered
   c. Physical therapy and ergotherapy may ameliorate hand function.

Fig. 1 A 2 years and 6 months old boy was evaluated for brachydactyly and abnormal shaped thumbs and great toes. He had hitch-hiker shaped thumbs and great toes with short fingers and toes including clinodactyly of the fifth fingers. His sister, mother, and maternal grandmother are similarly but less severely affected. The brachydactyly present in this kindred is consistent with brachydactyly type A1

Fig. 2 His great toes showed hitch-hiker shaped deformities

Fig. 3 His thumbs showed hitch-hiker shaped deformities

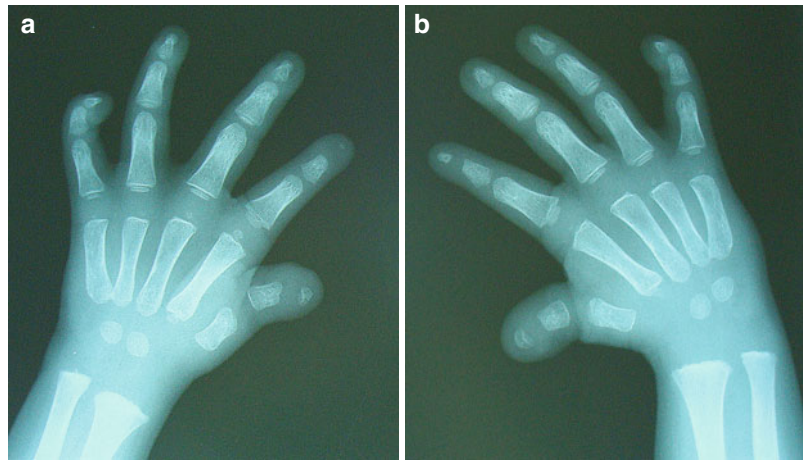

Fig. 4 (**a**, **b**) Radiographs of both hands showed short phalanges, especially short middle and distal phalanges in addition to deformities of the thumbs

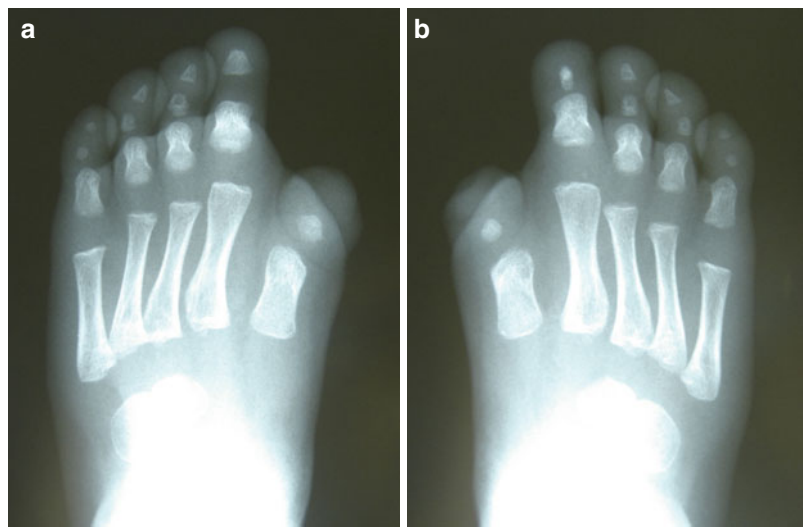

Fig. 5 (**a**, **b**) Radiographs of both feet showed short phalanges, especially middle and distal phalanges, in addition to deformities of the great toes

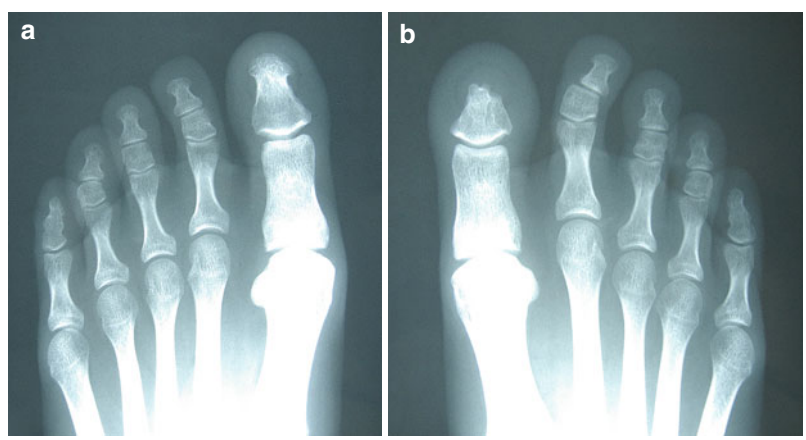

Fig. 6 (**a**, **b**) Radiographs of the feet of his mother

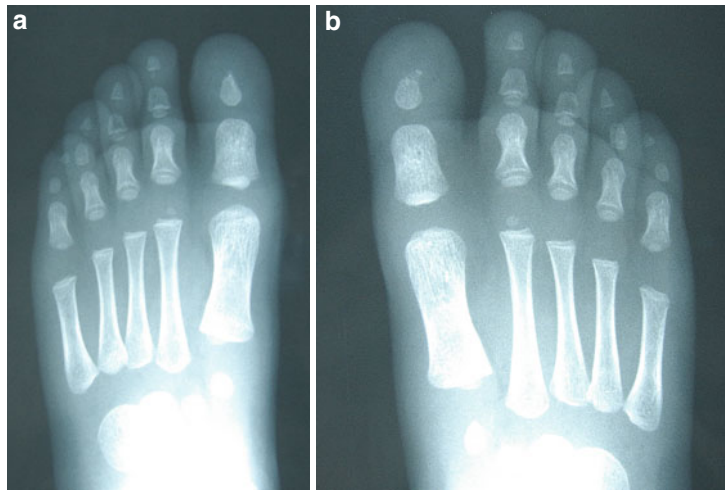

Fig. 7 (**a**, **b**) Radiographs of the feet of his sister

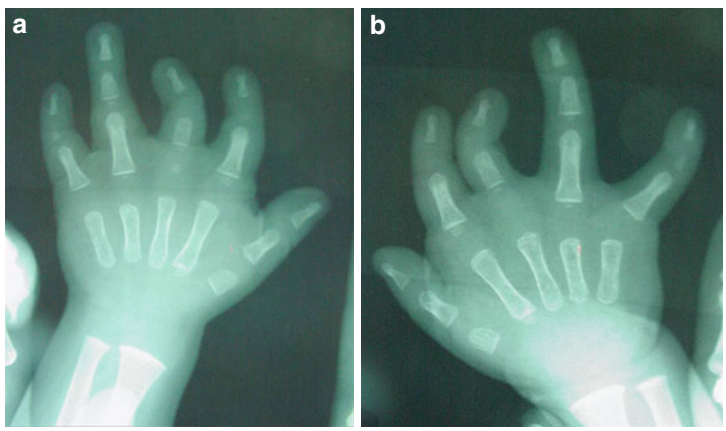

Fig. 8 (**a**, **b**) Radiographs of the hands of a 21-month-old boy, who was evaluated for hand anomalies, showed short first metacarpals, ulnar deviation of the second to third fingers with deficient ossification of the middle phalanges, relatively normal fourth finger (the longest digit and longer than the middle finger), and clinodactyly of the fifth finger with hypoplastic middle phalanges. No carpal bones were apparent. The brachydactyly in this child appears to represent brachydactyly type C

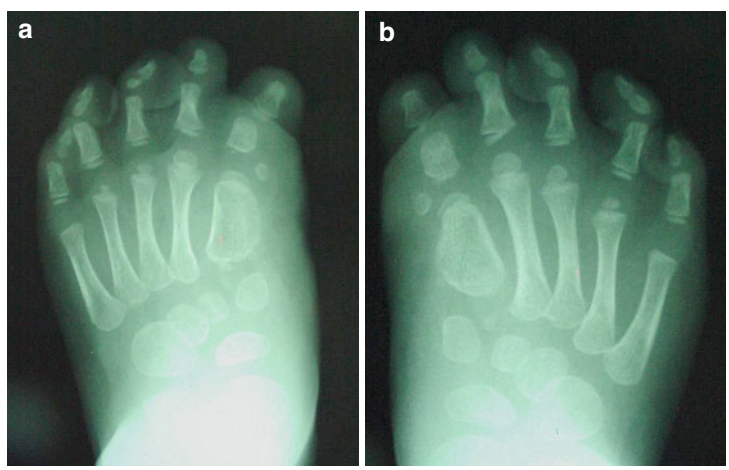

Fig. 9 (**a**, **b**) Radiographs of the feet showed abnormal shaped first metatarsals and short toes with absent or hypoplastic middle phalanges

Branchial Cleft Anomalies

Abnormal persistence of branchial apparatus remnants results in branchial anomalies.

Synonyms and Related Disorders

Branchial cyst; Branchial fistula; Branchial sinus; Branchial remnant presenting as skin tag

Genetics/Basic Defects

1. Embryology of the fetal branchial apparatus
   a. A derivative of a foregut, developed during the second fetal week
   b. Consisting of five paired pharyngeal arches, separated internally by four endodermal pouches and externally by four ectodermal clefts
2. Embryology of the branchial clefts
   a. First branchial cleft
      i. Giving rise to the Eustachian tube, tympanic cavity, and mastoid antrum
      ii. Contributing to the formation of the tympanic membrane
      iii. The only cleft to contribute to the adult structure is the external auditory canal
   b. Second, third, and fourth branchial clefts
      i. Known as the cervical sinus of His (part of an ectodermally lined depression)
      ii. Obliteration of the cervical sinus as the second and fifth branchial clefts merge
   c. Second branchial pouch
      i. Lined by ectoderm
      ii. Contributing to the palatine tonsil and tonsillar fossa
   d. Third branchial pouch: forming the following structures
      i. Inferior parathyroid gland
      ii. Thymus
      iii. Pyriform sinus
   e. Fourth branchial pouch: forming the following structures
      i. Superior parathyroid gland
      ii. Apex of the pyriform sinus
3. Pathogenesis of branchial cleft anomalies: remains controversial
   a. Arising from incomplete obliteration of the cervical sinus of His
   b. Arising from buried epithelial cell rests
4. Genetics: autosomal dominant inheritance in some families

Clinical Features

1. Manifestation of branchial cleft anomalies
   a. Cyst
      i. An epithelial-lined structure without an external opening
      ii. Most common branchial cleft anomalies (75%)
   b. Sinus
      i. A blind tract with an opening externally through the skin on the side of the neck representing persistence of a branchial groove
      ii. A blind tract with an opening internally into the foregut representing persistence of a branchial pouch
   c. Fistula
      i. A tract communicating between the skin externally (a patent abnormal canal

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_29,
© Springer Science+Business Media, LLC 2012

opening externally on the neck surface) and the foregut internally (within the pharyngeal mucosa).
ii. Representing persistence of a branchial groove with its corresponding pouch and without branchial membrane between them.
d. Skin tag: A branchial remnant presenting in the lateral neck
e. Bilateral branchial cleft anomalies
i. Occurring in 2–3% of cases
ii. Often familial
2. First branchial cleft cyst
a. Accounting for only 5–8% of all branchial cleft defects
b. Most commonly seen in middle-aged women
c. Usually manifesting as recurrent abscesses or other inflammation (sinus tract) either around the ear or at the angle of the mandible
d. History of recurrent parotid abscesses unresponsive to antibiotics and drainage
e. Cystic drainage into the external auditory canal
i. Aural fistulas
ii. Auricular swelling
iii. Otitis
iv. Otorrhea
v. A cervical skin tag at birth
f. Occasional sinus tract extending to the hyoid bone
g. Cyst related to the parotid gland
i. Forming abscess and produce parotitis
ii. May be associated with facial nerve palsy
3. Second branchial cleft cyst
a. Most common developmental anomalies arising from the branchial apparatus
b. Cysts
i. Accounting for at least three fourths of branchial cleft anomalies
ii. Typically occurring between 10 and 40 years of age
c. Location of the cysts
i. Most commonly in the submandibular space
ii. Anywhere along a line from the oropharyngeal tonsillar fossa to the supraclavicular region of the neck
d. Signs and symptoms of second branchial cleft cyst
i. Usually appearing as painless, fluctuant masses in the lateral portion of the neck adjacent to the anteromedial border of the sternocleidomastoid muscle at the mandibular angle
ii. Enlarge slowly over time
iii. Painful and tender if secondarily infected
iv. Highly suggestive in a young patient with a history of recurrent inflammation in the region of the mandibular angle
v. Ostium usually noted at birth just above the clavicle in the anterior neck if a fistula is present
e. Fistulas and sinuses
i. Almost always present at birth
ii. With a small pinpoint external opening
iii. May go unnoticed for years if there is no drainage
iv. Symptoms consisting of continuous or intermittent mucoid drainage and recurrent attacks of inflammation that often follow mild trauma or an infection of the upper respiratory tract
v. Occasional formation of cellulitis and abscess
vi. Probing of the track producing irritation of the vagus nerve
vii. Usually unilateral
viii. Found in several members of the same family
4. Third branchial cleft cyst
a. Extremely rare
b. Most cysts located in the posterior cervical space posterior to the sternocleidomastoid muscle
c. Constituting the second most common congenital lesion of the posterior cervical space of the neck after cystic hygroma
d. Usually manifesting as a painless, fluctuant mass in the posterior triangle area of the neck
e. Mass usually distending during a viral infection of the upper respiratory tract
5. Fourth branchial cleft cyst
a. Extremely rare
b. Usually manifesting as a sinus tract rather than a cyst or fistula
c. Majority of the lesions occurring on the left side

Diagnostic Investigations

1. CT scans/MRI imagings
a. First branchial cleft cyst
i. Appearing as a cystic mass either within, superficial to, or deep to the parotid gland

ii. Variable wall thickness and enhancement: increase with recurrent infections
iii. Difficult to differentiate from other cystic mass of the parotid gland

b. Second branchial cleft cyst
i. Typically well-circumscribed, homogeneously hypoattenuated masses surrounded by a uniformly thin wall
ii. Increased mural thickness after infection
iii. "Beaked sign" (a curved rim of tissue or "beak" pointing medially between the internal and external carotid arteries) considered a pathognomonic imaging feature of a second branchial cleft cyst

c. Third branchial cleft cyst
i. Most commonly appearing as a unilocular cystic mass centered in the posterior cervical space
ii. Cyst fluid varying in signal intensity on T1-weighted images depending on the protein concentration and is typically hyperintense relative to muscle on T2-weighted images

d. Fourth branchial cleft cysts
i. Connected with the pyriform sinus
ii. Appearing similar to an external or mixed laryngocele

2. Ultrasonography
a. A fluctuant, compressible, anechoic, or hypoechoic mass
b. May have fine internal debris

3. Sinogram or fistulogram with radiopaque dye
a. To help confirming the diagnosis
b. To identify length and location of the fistulous tract
c. To identify an associated cyst

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. Not increased in de novo case
ii. 50% recurrence risk if a parent is affected with an autosomal dominant disorder

b. Patient's offspring: 50% in autosomal dominant inheritance

2. Prenatal diagnosis by ultrasonography possible by demonstrating a cystic neck mass in the fetus with differential diagnosis including hemangioma, dermoid cyst, neuroblastoma, congenital cystic hygroma, teratoma, epignathus, esophageal duplication, goiter, and laryngocele

3. Management
a. First branchial cleft cyst: complete surgical excision (only curative therapy)
b. Second and third branchial cleft cysts: surgical excision recommended because of increased frequency of secondary infection
c. Recurrence risk uncommon after surgical excision
d. Antibiotics required for treating infections or abscess

Calcinosis Cutis

Calcinosis cutis is a group of disorders characterized by the deposition of crystals of calcium phosphate (hydroxyapatite) in the skin in various areas of the body (Ianello et al. 1998) and can be associated with both normal and elevated calcium levels. Classically, it is divided into dystrophic, metastatic, iatrogenic, and idiopathic types.

Synonyms and Related Disorders

Calcinosis cutis (dystrophic, metastatic, iatrogenic, or idiopathic types)

Genetics/Basic Defects

1. Dystrophic calcinosis cutis (Nunley and Jones 2009)
   a. A common form of calcinosis cutis
   b. Localized or generalized
   c. Absence of calcium or phosphorus metabolic abnormalities
   d. Depositions of calcium salts: secondary to local inflammation, tissue damage, and degeneration
   e. Localized tissue damage
      i. Trauma
      ii. Burn
      iii. Inflammatory processes
         a) Acne
         b) Insect bites
      iv. Varicose veins
      v. Infections: Necrotic tissue produced by an infectious process may subsequently become calcified.
         a) Onchocerciasis
         b) Cysticercosis
         c) Histoplasmosis
         d) Cryptococcosis
         e) Intrauterine herpes simplex infection
      vi. Tumors: Benign and malignant tumors may develop calcification.
         a) Pilomatrixoma
         b) Calcifying epithelioma of Malherbe
         c) Epithelial cysts
         d) Syringomas
         e) Basal cell carcinomas
         f) Rarely in melanocytic nevi, malignant melanoma, atypical fibroxanthoma, hemangioma, pyogenic granuloma, seborrheic keratoses, neurilemomas, and trichoepitheliomas
   f. Generalized tissue damage
      i. Connective tissue diseases
         a) Dermatomyositis
         b) Scleroderma
         c) Lupus erythematosus
         d) Systemic sclerosis
         e) Calcinosis cutis, Raynaud phenomenon, esophageal dysfunction, sclerodactyly, telangiectasias (CREST) syndrome
      ii. Panniculitis
      iii. Porphyria cutanea tarda
      iv. Subcutaneous fat necrosis of the newborn
      v. Inherited disorders
         a) Ehlers–Danlos syndrome
         b) Werner syndrome
         c) Pseudoxanthoma elasticum
         d) Rothmund–Thomson syndrome
2. Metastatic calcinosis cutis
   a. Precipitation of calcium salts in normal tissue due to increased serum calcium and phosphate

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_30,
© Springer Science+Business Media, LLC 2012

levels as a result of an underlying defect in calcium and/or phosphate metabolism
   b. Generally indicates chronic renal failure
   c. Calcification usually widespread and affects predominantly blood vessels, kidneys, lungs, and gastric mucosa
   d. Cutaneous and subcutaneous tissues may be involved: a rare complication
   e. Some of the factors involved are:
      i. Factors involved in increased serum calcium levels:
         a) Primary or secondary hyperparathyroidism
         b) Paraneoplastic hypercalcemia
         c) Albright hereditary osteodystrophy
         d) Destructive bone disease (malignancies, Paget disease)
         e) Excessive vitamin D intake
         f) Milk-alkali syndrome
         g) Sarcoidosis
         h) Chronic renal failure
         i) Calciphylaxis
      ii. Factor involved in increased serum phosphate levels: chronic renal failure
3. Iatrogenic causes: secondary to a treatment or procedure
   a. Parenteral calcium: extravasation of intravenously administered calcium chloride or calcium gluconate
   b. Parental inorganic phosphate
   c. Tumor lysis syndrome
   d. Repeated heel sticks in the newborn
   e. Prolonged use of calcium-containing electrode paste
      i. Electromyography
      ii. Electroencephalography
      iii. Brain auditory evoked potential
4. Idiopathic calcinosis cutis (Ogretmen et al. 2002)
   a. Also known as calcinosis cutis universalis
   b. Sporadic occurrence
   c. Characterized by calcium deposits in dermis, subcutis, and muscles without any metabolic disorder or tissue injury
   d. An uncommon type and may be solitary of multiple
   e. Causes
      i. Idiopathic calcinosis of scrotum/penis/vulva
      ii. "Milia-like" idiopathic calcinosis cutis with or without Down syndrome
      iii. Subepidermal calcified nodule
      iv. Tumoral calcinosis
      v. Calcinosis cutis circumscripta
      vi. Transplant-associated calcinosis

Clinical Features

1. Dystrophic calcinosis cutis (Nunley and Jones 2009)
   a. Most common type of calcinosis cutis
   b. Large and widespread deposits: termed calcinosis universalis
   c. Dystrophic calcification occurring locally and consists of only a few deposits of calcium salts termed "calcinosis circumscripta"
2. Metastatic calcinosis
   a. First manifestations
      i. Bone demineralization
      ii. Non-visceral and/or visceral calcification, mostly with mural deposits in arteries and arterioles
   b. Calcium deposition
      i. Frequently widespread
      ii. Large deposits frequently found around large joints, such as knees, elbows, and shoulders, in a symmetrical distribution
      iii. Visceral organs: deposition of calcium in the lungs, kidneys, blood vessels, and stomach occurring more frequently than deposition within the skin or muscle
      iv. Calciphylaxis: characterized by progressive vascular calcification, soft tissue necrosis, and ischemic necrosis of the skin
3. Iatrogenic calcinosis cutis
   a. Calcification generally localized at the site of an invasive procedure
   b. Diffuse deposition may occur
4. Idiopathic calcinosis cutis
   a. Uncommon
   b. Calcification deposit
      i. Most commonly localized to one general area
      ii. Observed in dermis, subcutis, and muscles without any metabolic disorder or tissue injury

Diagnostic Investigations

1. Laboratory studies (Nunley and Jones 2009)
   a. Serum calcium, inorganic phosphate, alkaline phosphatase, and albumin levels

i. Elevated serum calcium and alkaline phosphatase levels with a decrease in the inorganic phosphate level: suggestive of hyperparathyroidism
ii. An albumin value: needed to interpret the significance of hypocalcemia or hypercalcemia
iii. Serum blood urea nitrogen and creatinine concentrations: needed to measure renal function

b. Abnormal complete blood cell count with differential: suggest an underlying malignancy or lupus erythematosus
c. Abnormal plasma bicarbonate or arterial pH value: indicates the presence of a metabolic alkalosis (milk-alkali syndrome)
d. Parathyroid hormone concentration: direct measurement for hyperparathyroidism
e. Abnormal creatine kinase and aldolase value
i. Dermatomyositis
ii. Myositis
iii. Rhabdomyolysis
f. Serum amylase or lipase levels: to assess pancreatic disease
g. Antinuclear antibody testing: helpful in screening for lupus erythematosus
h. Presence of SCL-70 (topoisomerase) antibody: portends a poor prognosis for scleroderma patient
i. Vitamin D levels: to evaluate for excess vitamin D. A test of the 24-hour urinary excretion of calcium and/or inorganic phosphate may be useful.

2. Imaging studies
a. Radiographic examination: to demonstrate the extent of tissue calcification
b. Bone scintigraphy with radiolabeled phosphate compounds (technetium Tc 99m methylene diphosphonate [MDP]): to evaluate non-visceral soft tissue calcification (Bhattacharya et al. 2005)
c. CT for the identification of visceral and non-visceral calcification, particularly in assessing tumoral calcinosis
d. MRI: to evaluate characteristic patterns of calcific deposits, particularly in evaluating granulomatous foreign-body reaction in tumoral calcinosis

3. Biopsy and histopathologic examination of a cutaneous lesion
a. Observation of granules and deposits of calcium in the dermis, with or without a surrounding foreign-body giant cell reaction
b. Massive calcium deposits: may be located in the subcutaneous tissue
c. Calcium deposition: frequently found within the walls of small- and medium-sized blood vessels in areas of necrosis
d. Calcium deposition: may be confirmed on Von Kossa and alizarin red stains

Genetic Counseling

1. Recurrence risk
a. Patient's sib
i. No increase in sporadic cases
ii. Autosomal recessive: a 25% recurrence risk (e.g., Rothmund–Thomson syndrome, Ehlers–Danlos syndrome types VI–VII, familial hyperphosphatemic tumoral calcinosis)
iii. Autosomal dominant: not increased unless a parent is affected, in which case a 50% recurrence risk (e.g., pseudoxanthoma elasticum, Ehlers–Danlos syndrome types I–IV)
iv. X-linked recessive: 50% of male sibs affected if the mother is a carrier (e.g., Ehlers–Danlos syndrome type V)

b. Patient's offspring:
i. Autosomal recessive: not increased unless the spouse is also a carrier
ii. Autosomal dominant: a 50% risk
iii. X-linked recessive: all daughters of affected males will be carriers. All sons of an affected male will be normal.

2. Prenatal diagnosis: not reported
3. Management
a. Medical management: limited with variable benefit; should attempt to correct the underlying problems
i. Intralesional corticosteroids: may be beneficial because of their anti-inflammatory and inhibitory effects on fibroblast activity
ii. Probenecid and colchicines: beneficial in some individuals
iii. Magnesium or aluminum antacids: may be effective phosphate binders in patients with hyperphosphatemia but the use of these agents in patients with renal insufficiency may result in magnesium or aluminum toxicity

iv. Sodium etidronate and diphosphonates: may reduce bone turnover and inhibit the growth of ectopic hydroxyapatite crystals. Paradoxical hyperphosphatemia may result from prolonged treatment
v. Myo-inositol hexaphosphonate is a dietary substance shown to inhibit the crystallization of calcium salts in animal studies and potentially could be of benefit in humans
vi. Warfarin: has shown benefit in some individuals
vii. The use of the calcium-channel blocker diltiazem over at least 5 years has variable benefits. The therapeutic effect is believed to be the antagonism of the calcium-sodium ion pump
viii. Response to intravenous immunoglobulin in some patients with dystrophic calcification (Schanz et al. 2008)

b. Surgical removal
   i. Indications
      a) Pain
      b) Recurrent infection
      c) Ulceration
      d) Functional impairment
   ii. Initial test removal of a test site before pursuing a large excision because the surgical trauma may stimulate calcification
   iii. Recurrence common after excision
c. Electric shock wave lithotripsy
   i. Anecdotally successful in dermatomyositis-induced tissue calcification
   ii. Complete relief of associated pain although reduction in the size of the calcification is minimal

Fig. 1 (**a–d**) A 4-year-old boy has had numerous hard nodules in his neck, arms, legs, and trunk since early infancy. The subcutaneous hard nodules were tender and began to multiply and eventually became ulcerated. Recently he complained restricted arm and leg movement

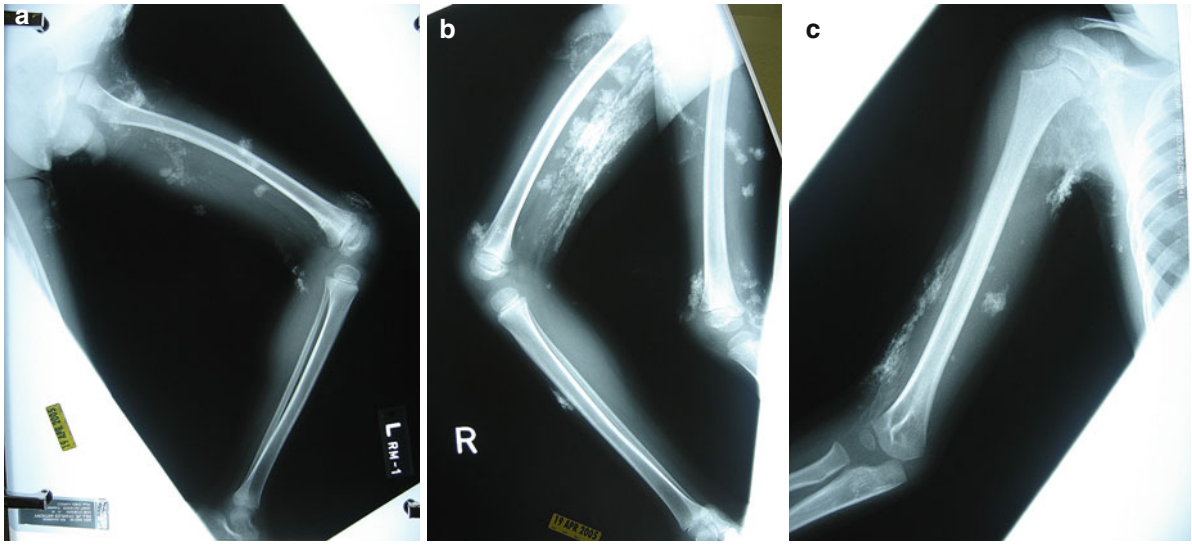

Fig. 2 (**a–c**) Radiologic studies revealed numerous subcutaneous calcifications throughout the body (only arm and legs are illustrated here). *GNAS1* gene mutation testing revealed no sequence variation

Campomelic Dysplasia

Campomelic dysplasia is a rare, often lethal congenital osteochondrodysplasias associated with skeletal malformations and sex reversal. The term "campomelia" derives from Greek, meaning bent or curved limb. Since most patients die in the neonatal period due to respiratory distress, patients with campomelic dysplasia are most often sporadic but few familial cases have been reported. The incidence of campomelic dysplasia is reported to be 0.05–0.9 per 10,000 births (Iravani et al. 2000).

Synonyms and Related Disorders

Acampomelic campomelic dysplasia; Campomelic dysplasia with autosomal sex reversal; Camptomelic dysplasia

Genetics/Basic Defects

1. Inheritance: autosomal dominant
2. Etiology (Kwok et al. 1995): can be caused by heterozygous intragenic *SOX9* mutations or chromosomal aberrations (translocations, inversions, or deletions) affecting *SOX9* or the putative enhancer region (Wada et al. 2009)
   a. Assignment of a locus *CMPD1* to 17q24.3-q25.1 was based on characterization of three independent de novo chromosome 17 translocations in campomelic dysplasia patients.
   b. XY sex reversal of two of these translocation patients placed an autosomal sex-determining locus, *SRA1*, in the same region.
   c. *SOX9*, a gene related to the mammalian Y chromosome sex-determining gene SRY, was mapped to this region and found to be near the translocation breakpoint of a sex-reversed campomelic dysplasia patient.
   d. Subsequent identification of de novo mutations in sex-reversed campomelic patients demonstrated that SOX9 is the gene responsible for both campomelic dysplasia and autosomal sex reversal.
   e. SOX9 mutations.
      i. Disrupt skeletogenesis and chondrocytic differentiation
      ii. Produce defective testicular development often resulting in sex reversal with female phenotype in chromosomal XY males
   f. Proof of *SOX9* being responsible for both campomelic dysplasia and XY sex reversal: demonstration of de novo heterozygous loss-of-function mutations within the SOX9 coding region in non-translocation campomelic dysplasia patients (Iravani et al. 2000).
   g. Isolation of the *SOX9* gene on chromosome 17q by positional cloning in combination with positional candidate information from the vicinity of breakpoints in campomelic dysplasia patients with reciprocal de novo translocations (Moyer et al. 1977).
   h. Report of a familial acampomelic dysplasia caused by an inherited deletion mapping upstream of the *SOX9* gene (Lecointre et al. 2009).

Clinical Features

1. Clinically a heterogeneous disorder (Houston et al. 1983; Iravani et al. 2000)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_31,
© Springer Science+Business Media, LLC 2012

a. Long-limbed variety
   i. Bent bones of normal thickness, may be slightly shortened
   ii. Rarely involves the upper limbs
b. Short-limbed variety
   i. Bent bones are short and wide
   ii. Two skull types
      a) Craniosynostotic type with cloverleaf skull
      b) Normocephalic type
c. Acampomelic campomelic dysplasia
   i. The eponymous feature "campomelia" (the bending of the long bones): not an obligatory feature of the syndrome
   ii. Absence of campomelia in about 10% of campomelic dysplasia cases

2. Prenatal history
   a. Polyhydramnios (30% of cases) in the third trimester common
   b. Growth retardation
3. Extreme hypotonia at birth
4. Characteristic craniofacial features
   a. Frequent macrodolichocephaly
   b. Cloverleaf skull
   c. Wide fontanel
   d. Short, narrow, and upslanted palpebral fissures
   e. Ocular hypertelorism
   f. Flat nasal bridge
   g. Long philtrum
   h. Micrognathia (Pierre Robin sequence)
   i. Cleft palate in two third of the cases
   j. Low-set and posteriorly rotated ears
   k. Prominent nuchal folds
   l. Hearing loss (deaf) in survivors
5. Prominent and characteristic musculoskeletal features
   a. Congenital bowed lower limbs (anterior bowing of the tibiae) with pretibial skin dimples. Pretibial dimples appear to result from the loss of subcutaneous tissue secondary to marked stretching of the skin overlying the apexes of the bony curvatures during fetal life
   b. Short limbs
   c. Short neck
   d. Pterygium coli
   e. Narrow thorax
   f. Kyphoscoliosis
   g. Talipes equinovarus
   h. Hand anomalies
      i. Brachydactyly
      ii. Clinodactyly
      iii. Camptodactyly
   i. Congenital dislocation of the hips
   j. Winging of the scapula
   k. Fewer ribs
6. Genitalia
   a. Genotypic XY males (three fourth of karyotypic males with sex reversal)
      i. External genitalia: range from an unambiguous female external genitalia to hypospadias with a bifid scrotum and an enlarged clitoris
      ii. Internal genitalia: various combinations of internal Mullerian and Wolffian duct structures
   b. Genotypic XX females: remain phenotypic female
7. CNS
   a. Mental retardation in survivors
   b. Large brain
   c. Hydrocephalus (25%)
   d. Polygyria
   e. Absent olfactory bulbs and/or tracts
   f. Dysgenesis of the corpus callosum
   g. Gross cellular disorganization, especially of cerebral peduncle, thalamus, and caudate nucleus
8. Respiratory insufficiency secondary to
   a. Robin sequence
   b. Narrow airways due to laryngotracheobronchomalacia (the most characteristic finding)
   c. Hypoplastic lungs
   d. A small bell-shaped thorax
9. Occasional abnormalities
   a. Congenital heart diseases
      i. Patent ductus arteriosus
      ii. Ventricular septal defects
      iii. Coarctation of the aorta
      iv. Tetralogy of Fallot
   b. Renal anomalies
      i. Hydronephrosis
      ii. Hydroureter
      iii. Renal hypoplasia
      iv. Renal cortical and medullary cysts
   c. Ear anomalies
      i. Hypoplastic cochlea and semicircular canals
      ii. Anomalies in incus and stapes
10. Cause of death
   a. Usually due to respiratory insufficiency

i. Primarily owing to airway and pulmonary defects, lack of laryngotracheobroanchial cartilages and hypotonia
ii. Resulting in apneic spells, atelectasis, aspiration, and pneumonia

b. A high rate of neonatal death
i. Most deaths occurring neonatally (77%)
ii. 90% of deaths before 2 years

11. Life expectancy varies depending on the severity of the phenotype
a. Young infants who survive
i. Feeding difficulties
ii. Stridor
iii. Retractions
iv. Frequent otitis media
v. Bronchitis
vi. Poor growth
b. Infants who survive several years
i. May be mentally retarded
ii. May show variable breakpoints within the vicinity of chromosome 17 (q21-q25)
iii. Oldest reported survivor: 17 years of age with an IQ of 45
c. Complications of survivors of campomelic dysplasia (Mansour et al. 2002)
i. Recurrent apnea
ii. Upper respiratory infections
iii. Progressive kyphoscoliosis
iv. Mild to moderate learning difficulties
v. Short stature
vi. Dislocation of the hips
d. Possible explanations for the survival of patients with campomelic dysplasia
i. Mosaicism of the *SOX9* mutations
ii. Chromosomal rearrangements involving chromosome 17q (q23.3-q25.1) shown to cause campomelic dysplasia without disrupting the *SOX9* gene, resulting in a milder phenotype

Diagnostic Investigations

1. Radiography (skeletal survey)
a. Affected infants
i. Tubular bones
a) Bowed femora and tibiae
b) Short fibulae
c) Radioulnar dislocation
ii. Thorax
a) Severe hypoplastic, bladeless scapulae
b) Thin short clavicles
c) Nonmineralized sternum
d) Small thoracic cage with slender and/or decreased number of ribs (usually 11 pairs)
iii. Spine
a) Abnormal cervical vertebrae
b) Kyphoscoliosis
c) Nonmineralized thoracic pedicles
iv. Pelvis
a) Dislocation of the hips
b) Narrow iliac wings
c) Poorly developed ischiopubic rami
d) Coxa vara
v. Hands and feet
a) Short first metacarpal bone
b) Talipes equinovarus
vi. Skeletal maturation
a) Delayed bone age
b) Delayed ossification of proximal tibial and distal femoral epiphysis and talus
b. Survivors
i. Hypoplastic scapulae
ii. Defective ischiopubic ossification
iii. Absent or hypoplastic patellae
iv. Spinal dysraphism
c. Considerable radiographic overlap with ischiopubic-patella syndrome
2. Hearing screening
3. Gonadal histology (Cameron et al. 1996)
a. Similar to XY gonadal dysgenesis
b. Ranging from dysplastic testicular tissue to poorly differentiated ovarian tissue with a few primordial follicles
4. Histology of growth plate: unremarkable epiphyseal resting cartilage
5. Cytogenetic analysis
a. Abnormal in about 5% of patients (Unger et al. 2008)
i. A de novo reciprocal translocation with one breakpoint in chromosome region 17q24.3-q25.1 where SOX9 is located: rarely the translocation may be familial, thus parental karyotypes should be obtained
ii. A de novo interstitial deletion of 17q
b. Identification of the sex reversal
6. Molecular analysis of *SOX9* mutation (Unger et al. 2008)

a. Sequence analysis: to detect coding regions and splice mutations (positive in about 90%)
b. Deletion analysis: to detect partial or whole-gene deletions (positive in about 5%)

Genetic Counseling

1. Recurrence risk (Unger et al. 2008)
   a. Patient's sib
      i. An affected parent (non-mosaic): a 50% risk
      ii. Not increased unless somatic or gonadal mosaicism or SOX9 deletion is present in one of the parent
         a) Unaffected mother with somatic mosaicism for the *SOX9* mutation has been reported (Wagner et al. 1994)
         b) An unaffected father of three affected children was reported to have germline, but not somatic, mosaicism (Cameron et al. 1996)
         c) A *SOX9* deletion in a mildly/minimally affected father of two affected children has been reported (Smyk et al. 2007)
      iii. Proband with an unbalanced chromosome constitution
         a) If neither parent has the chromosome rearrangement: a negligible risk
         b) If a parent has a balanced chromosome rearrangement: an increased risk, dependent on the specific chromosome rearrangement and the possibility of other variable
   b. Patient's offspring: provided the patient survives to the reproductive age
      i. A 50% risk to offspring when the proband has a non-mosaic *SOX9* mutation
      ii. Risk to offspring depends on the proband's cytogenetic abnormality involving *SOX9*
2. Prenatal diagnosis
   a. Possible by ultrasonography as early as 18 weeks of gestation.
      i. Ultrasonographic findings
         a) Symmetrical anterior bowing of femurs and tibias
         b) Hypoplastic or absent scapulae
         c) Small thorax compared to the abdomen
         d) Bilateral talipes equinovarus
         e) External genitalia not compatible with 46, XY karyotype
         f) Polyhydramnios
         g) Fetal growth retardation
         h) Large head with internal hydrocephalus
         i) Sagittal scan of the face showing a flat nasal bridge, elongated philtrum, and micrognathia
      ii. Major differential diagnosis of ultrasonographic features
         a) Osteogenesis imperfecta
         b) Hypophosphatasia
         c) Unclassifiable varieties of congenital bowing of the long bones
   b. Amniocentesis result of 46,XY with ultrasonographic finding of female external genitalia.
   c. Identification of *SOX9* mutation in the fetus: Prenatal diagnosis for pregnancies at risk as a result of a mildly affected parent or potential somatic or germline mosaicism requires prior identification of the disease-causing mutation in a previously affected child or the mildly affected parent.
3. Management
   a. Supportive medical care
   b. Orthopedic treatment of the musculoskeletal malformations to prevent additional morbidity
      i. Hip dislocation
      ii. Bracing or spinal fusion for spinal deformity
      iii. Serial casting or surgical correction for foot deformity
   c. Gonadodectomy advocated in surviving phenotypic females with Y chromosome fragments owing to the increased risk of gonadoblastoma

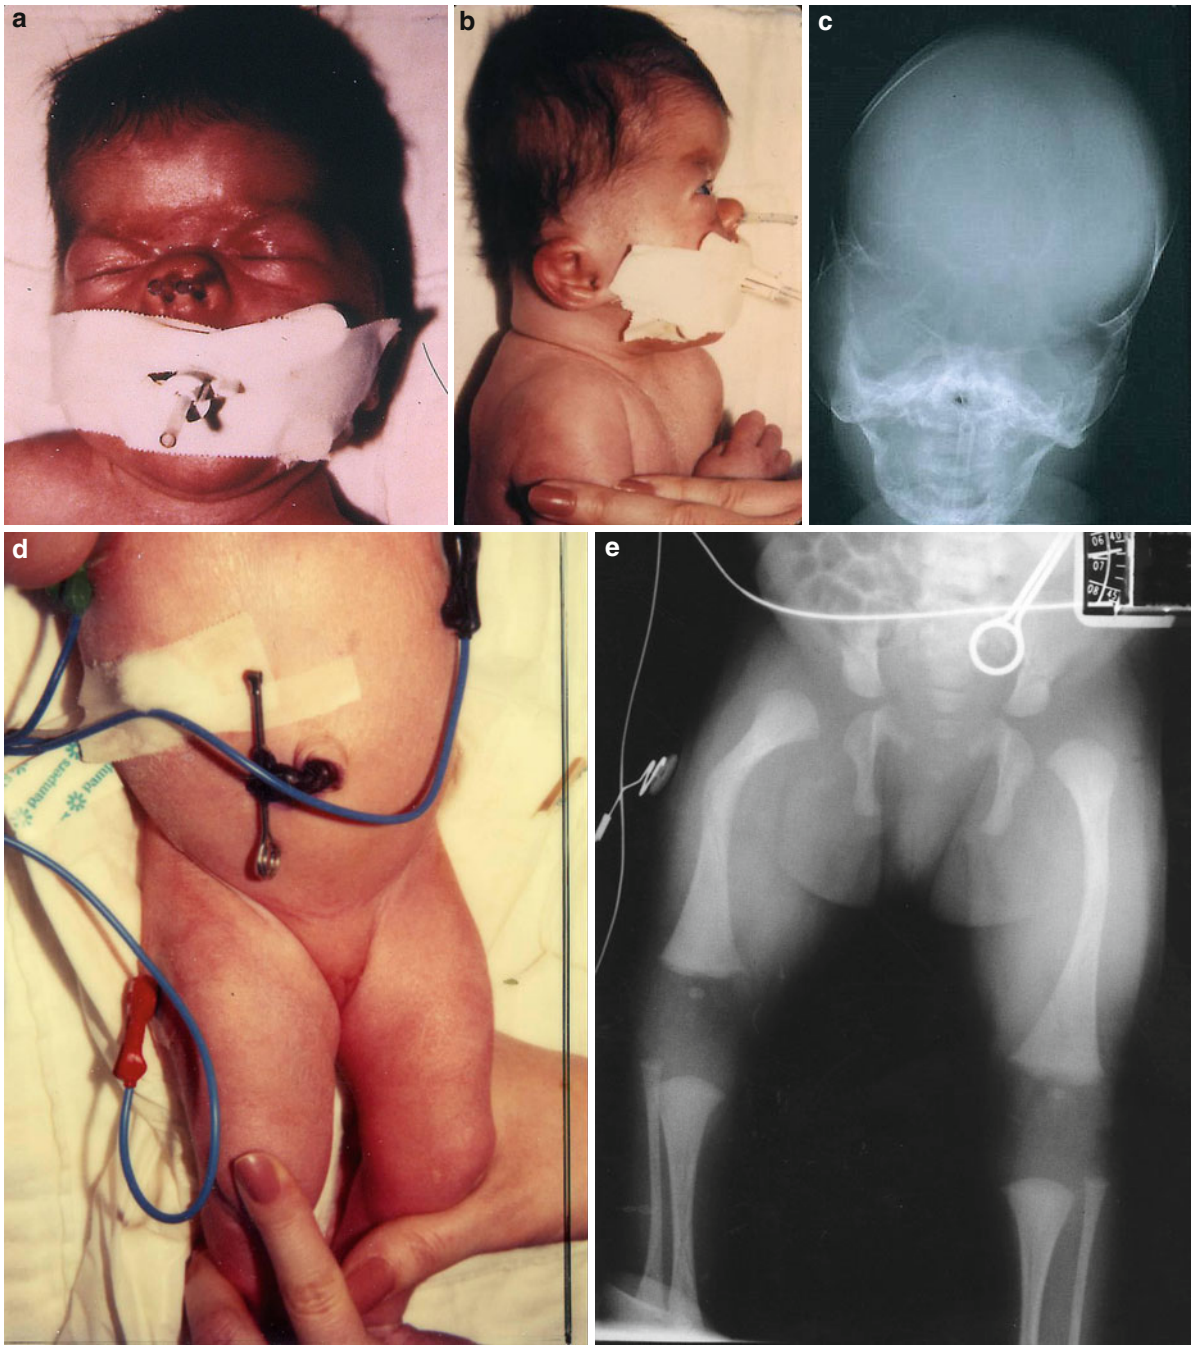

Fig. 1 (**a–e**) A neonate with campomelic dysplasia showing cloverleaf skull and bowed femurs, illustrated by radiographs

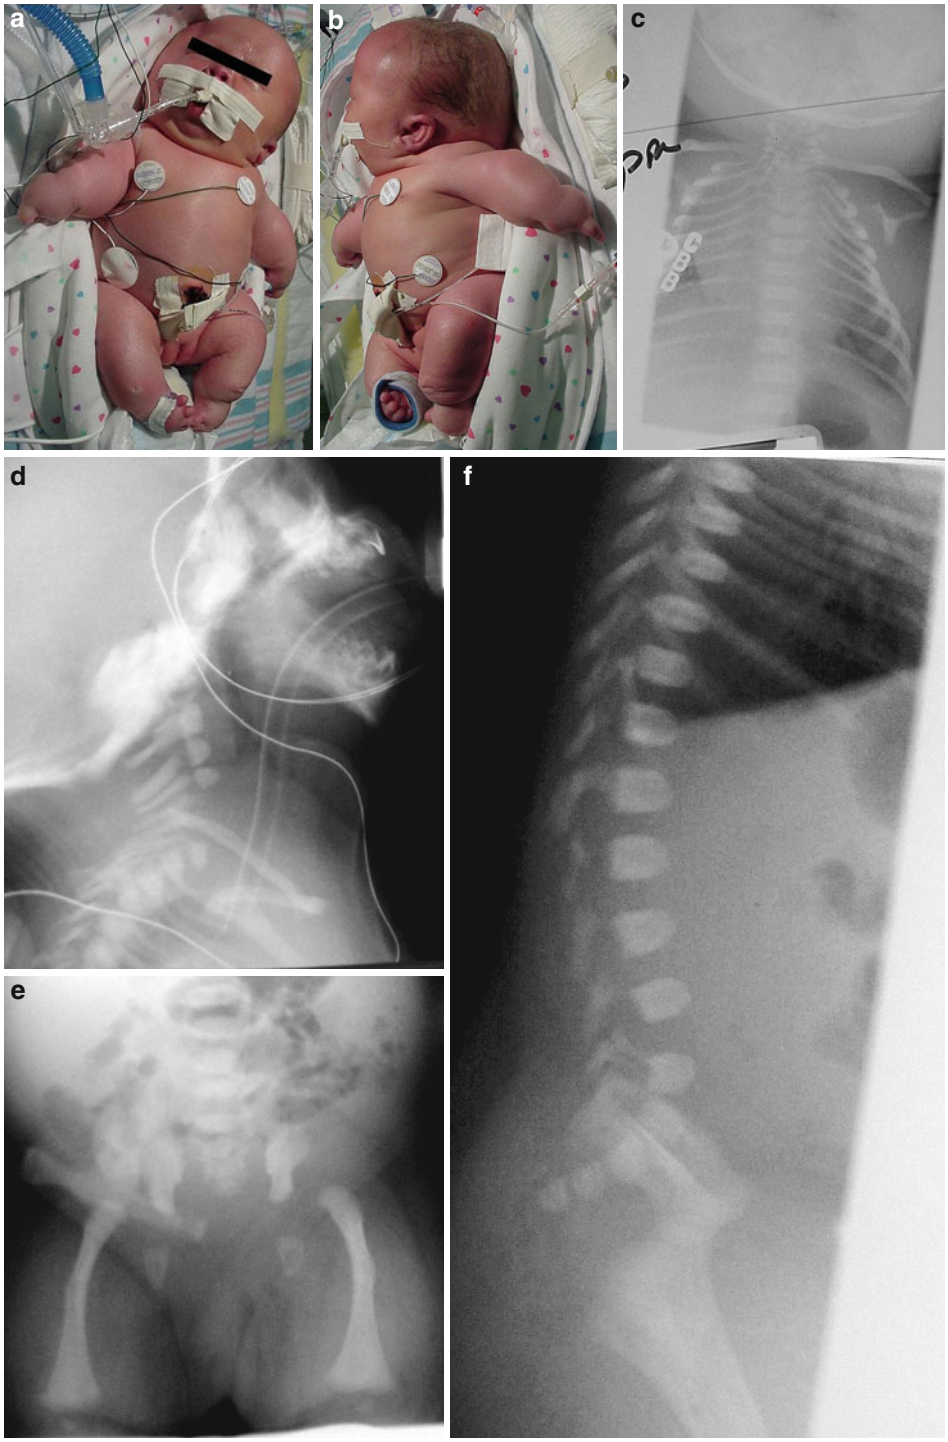

Fig. 2 (**a–f**) An infant with campomelic dysplasia showing bowing of the limbs with pretibial skin dimples, hypoplasia of cervical vertebra and scapula, 11 pairs of ribs, nonmineralized pedicles, *vertical*/*narrow* iliac wings, and bowing of femurs

Fig. 3 (**a–c**) A neonate with campomelic dysplasia showing large head, flat face, flat nasal bridge, low-set ears, micrognathia, and bowed lower legs with pretibial dimples. The radiograph showed bowing of the femora, tibia, and fibulas

Carpenter Syndrome

Carpenter in 1901 described two living siblings and one stillborn sibling with peculiar facies, acrocephaly, brachydactyly, syndactyly of the hands, and preaxial polydactyly and syndactyly of the toes. Temtamy in 1966 documented 12 additional cases (10 of which were familial) and proposed the eponymous designation "Carpenter syndrome."

Synonyms and Related Disorders

Acrocephalopolysyndactyly type II

Genetics/Basic Defects

1. An autosomal recessive inheritance: unlike other acrocephalosyndactyly syndromes or acrocephalopolysyndactyly syndrome
2. Caused by mutations in *RAB23*, a negative regulator of hedgehog signaling involved in cranial suture development (Jenkins et al. 2007)

Clinical Features

1. Craniofacial anomalies (Perlyin and Marsh 2008)
   a. Craniosynostosis (abnormal fusion of the cranial sutures): the basic abnormality of the craniofacial skeleton in Carpenter syndrome
      i. Premature closure of the sagittal, metopic, and lambdoid sutures, with coronal suture often remaining patent until the remaining sutures became synostotic (Marsh and Vannier 1995)
      ii. Pattern of craniosynostosis at birth may vary among affected siblings.
   b. Cranial configuration (Marsh and Vannier 1995)
      i. Acrocephalic
      ii. Often asymmetric
   c. Marked absence or underdevelopment of the anterior cranial fossa and bulging of the middle cranial fossa
   d. Maxillofacial manifestations (Carpenter 1901; Temtamy 1966; Der Kaloustian et al. 1972; Poole 1993; Puri et al. 1980)
      i. Brachycephaly
      ii. Flat facies with midface hypoplasia
      iii. Eyes
         a) Hyper/hypotelorism
         b) Shallow orbits
         c) Epicanthal folds
         d) Corneal opacity
         e) Microcornea
         f) Optic atrophy
      iv. Fat nasal bridge
      v. High-arched palate
      vi. Teeth
         a) Missing teeth
         b) Delayed loss of deciduous teeth
      vii. Ears
         a) Low-set/malformed ears
         b) Preauricular pits
         c) Conductive hearing loss
         d) Sensorineural hearing loss
      viii. Short muscular neck
2. Acral anomalies
   a. Polydactyly of the great toes
   b. Clinodactyly of the fingers

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_32,
© Springer Science+Business Media, LLC 2012

c. Brachydactyly of the hands and feet
d. Syndactyly of the hands and feet
3. Neurologic findings: presence of phenotypic variability
a. Dilatation of ventricles
b. Discernible brain abnormalities
4. Growth
a. Short stature
b. Obesity
5. Other features
a. Cardiovascular defects
i. Atrial septal defect
ii. Ventricular septal defect
iii. Pulmonic stenosis
iv. Tetralogy of Fallot
v. Transposition of the great vessels
vi. Patent ductus arteriosus
b. Abdomen
i. Umbilical hernia
ii. Omphalocele
c. Genitourinary tract anomalies
i. Cryptorchidism
ii. Hydronephrosis
iii. Hydroureter
d. Other skeletal anomalies
i. Spine
a) Pilonidal dimple
b) Absent coccyx
c) Spina bifida occulta
d) Scoliosis
ii. Pelvis
a) Coxa valga
b) Decreased hip joint mobility
c) Flared ilia
iii. Limbs
a) Genu valgum
b) Lateral displacement of patellae
e. Endocrine features
i. Hypogenitalism
ii. Precocious puberty
f. Learning disability

Diagnostic Investigations

1. Radiography/CT scan of the skull
a. Craniosynostosis
i. Sagittal suture
ii. Metopic suture
iii. Lambdoidal suture
iv. Coronal suture
b. Cranial configuration: acrocephalic and often asymmetric
2. Radiography of the hands and feet
a. Polysyndactyly
b. Brachydactyly
c. Clinodactyly
3. Molecular genetic testing of *RAB23* mutations: not available clinically at present

Genetic Counseling

1. Recurrence risk
a. Patient's sib: 25%
b. Patient's offspring: not increased unless the spouse is also a carrier, in which case there is a 50% risk of having an affected offspring
2. Prenatal diagnosis: may be suspected in a pregnancy at risk with abnormal ultrasonography demonstrating abnormal craniofacial shape with polysyndactyly of the hands and feet
3. Management
a. Correction of skull malformations within the first year of infancy
b. Correction of other anomalies
i. Congenital heart defects
ii. Polysyndactyly
c. Care for eyes, vision, and hearing impairments
d. Intervention programs
i. Speech therapy
ii. Occupational therapy
e. Dietary control for obesity

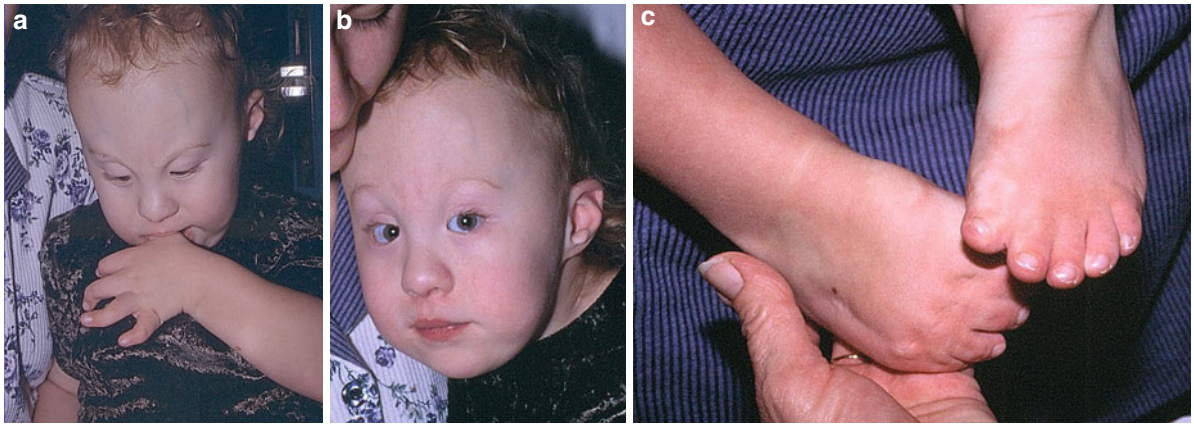

Fig. 1 (**a–c**) A two and a half year old girl had cone-shaped head, postaxial polydactyly of the hands and extra big toes of both feet (surgically excised at one month of age). The patient also had no opening of the anterior fontanel which was surgically repaired. She was noted to have brachycephaly, shallow orbits, high forehead, scanty eyebrows, lateral displacement of inner canthi, operation scars on the coronal sutures and sagittal suture, low-set malformed ears, small chin, high-arched palate, and operation scar for the umbilical hernia. Fingers and toes were abnormal with brachydactyly, clinodactyly, syndactyly, and polydactyly (surgically excised)

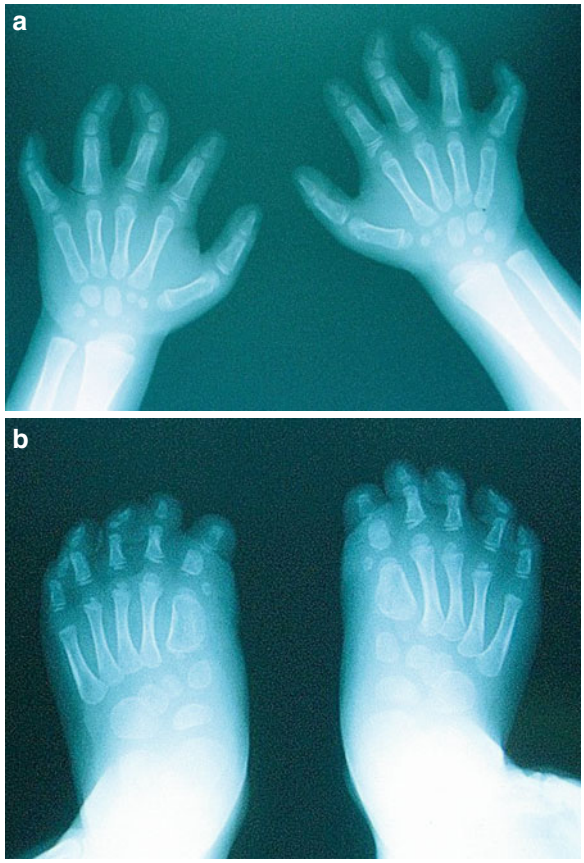

Fig. 2 (**a**, **b**) X-ray of hands and feet

Fig. 3 Patient at 10 years of age

Cat Eye Syndrome

Cat eye syndrome is a clinically recognizable congenital malformation syndrome consisting primarily of colobomas, anal anomalies, preauricular anomalies, cardiac and renal defects, and mild to moderate mental retardation. The name "cat eye" was introduced because of iris colobomas resembling the pupils of the cat.

Synonyms and Related Disorders

Schmid-Fraccaro syndrome; Chromosome 22 partial tetrasomy inv dup(22)(q11)

Genetics/Basic Defects

1. Historic background
   a. In 1965, an extra bisatellited marker chromosome was described in patients with cat eye syndrome phenotype (Schachenmann et al. 1965).
   b. Later in 1981, the marker was determined to be an inverted dicentric duplication of a part of chromosome 22 [inv dup(22)(pter → q11::q11 → pter)].
2. Molecular and cytogenetic bases
   a. Associated with the presence of three copies (trisomy) or four copies (tetrasomy) of a segment of chromosome 22q11.2, usually in the form of a bisatellited, isodicentric supernumerary chromosome (Footz et al. 2001)
   b. Formation of transient or unstable dic r(22) during early fetal development, which subsequently are lost from most cells, resulting in cat eye syndrome features
   c. The minimal common duplication required to produce features of cat eye syndrome (the cat eye syndrome critical region): defined by the dic r(22) patient, breakpoints between proximal locus ATP6E and distal locus D22S57, and covering approximately 2 Mb of 22q11.2
   d. Maternal origin of the supernumerary chromosome in cases studied
   e. Direct correlations between the extent of duplicated chromosome 22 materials and the severity of the cat eye syndrome remain difficult
   f. Human homolog of insect-derived growth factor, *CECR1*,: a candidate gene for features of cat eye syndrome
3. 22q11.2 region (Jezela-Stanek et al. 2009)
   a. Highly susceptible to chromosomal rearrangement: mediated by low-copy repeats causing nonallelic homologous recombination (Stankiewicz and Leepski 2002)
   b. A variety of clinical disorders are associated with either increased or decreased gene dosage (McDermid and Morrow 2002).
      i. Most common: DiGeorge/Velocardiofacial syndrome caused by microdeletion of 22q11.2
      ii. Other well characterized but less frequently recognized disorders
         a) Cat eye syndrome (CES) because of 22pter-q11 trisomy/tetrasomy
         b) Emanuel syndrome – the result of unbalanced 11, 22 chromosomal translocation, resulting in der (22)(22pter-22q11: 11q23-11qter) (Zakai and Emanuel 1980)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_33,
© Springer Science+Business Media, LLC 2012

iii. Other 22q11.2 rearrangements have been recognized recently.
  a) Microduplication 22q11.2 (Yobb et al. 2005; Kriek et al. 2006; Courtens et al. 2008)
  b) Triplication 22q11.2 (Yobb et al. 2005)
  c) Deletion of CES critical region (Kriek et al. 2006)
  d) 22q11.2 distal deletion (Ben-Shachar et al. 2008)
  e) Aberrations resulting in CES phenotype: proximal 22q duplication (Lindsay et al. 1995; Feenstra et al. 2006) or interstitial duplication 22q11 (Ensenauer et al. 2003)

Clinical Features

1. Marked phenotypic variability
2. Major features
   a. Preauricular skin tags and/or pits: most consistent features
   b. Ocular coloboma
   c. Congenital heart defect
      i. Ventricular septal defect
      ii. Total anomalous pulmonary venous connection
      iii. Atrial septal defect
      iv. Patent ductus arteriosus
      v. Pulmonary stenosis
      vi. Aortic malformation
      vii. Tricuspid atresia
      viii. Hypoplastic left heart syndrome
   d. Anorectal malformations
      i. Anal atresia or imperforate anus
      ii. Anal stenosis
      iii. Anorectal atresia
      iv. Ectopic anus
      v. Associated rectal fistulas
   e. Urogenital malformations
      i. Male external genital malformation
      ii. Renal agenesis/hypoplasia
      iii. Hydro(uretero)nephrosis
      iv. Vesicoureteral reflux
      v. Female genital malformation
      vi. Renal dysplasia or polycystic kidney
      vii. Bladder defects
      viii. Renal cystic malformation
      ix. Ectopic/horseshoe kidney
3. Minor features
   a. Craniofacial abnormalities
      i. Microcephaly
      ii. Ocular abnormalities
         a) Downslanting palpebral fissures
         b) Hypertelorism
         c) Ocular motility defect
         d) Epicanthal folds
         e) Microphthalmia
      iii. Oral abnormalities
         a) Micrognathia
         b) Cleft palate or absent uvula
      iv. Low-set or dysplastic ears
   b. Skeletal abnormalities
      i. Arm or hand deformity
      ii. Leg or foot deformity
      iii. Scoliosis or chest deformity
      iv. Vertebral anomaly
      v. Congenital dislocation of the hip
      vi. Rib or sternal anomaly
   c. Abdominal abnormalities
      i. Umbilical hernia
      ii. Malrotation of the gut
      iii. Hirschsprung or megacolon
      iv. Biliary atresia or choledochal cyst
      v. Volvulus
      vi. Meckel diverticulum
4. Neurodevelopmental outcome
   a. Growth and development
      i. Short stature
      ii. Mental development: markedly variable
         a) Normal-borderline normal
         b) Mild-moderate retardation
         c) Severe mental retardation
   b. Neurological abnormalities
      i. Dysregulation of muscle tone
      ii. Visual defect
      iii. Hearing impairment
      iv. Ventricular dilatation
      v. Abnormal slow EEG
      vi. Seizures
      vii. Spasticity
      viii. Cerebral or cerebellar atrophy
      ix. Hyperactive behavior
      x. Ataxia
      xi. Facial nerve palsy

Diagnostic Investigations

1. Chromosome analysis from blood and other tissues
   a. Conventional
   b. FISH
2. Radiography for limb defect
3. Echocardiography for congenital heart defects
4. Renal ultrasonography for renal anomalies
5. Developmental evaluation

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a small recurrence risk because of possible presence of germline mosaicism
   b. Patient's offspring
      i. Patients with an inv dup(22): 50%
      ii. Patients with mosaic form of an inv dup(22): lower than 50%, depends on the percentage of the marker chromosomes
2. Prenatal diagnosis by amniocentesis or CVS
   a. Presence of a bisatellited, dicentric supernumerary chromosome
   b. FISH with a chromosome 22-specific cosmid probe to identify chromosome 22
3. Management
   a. Supportive
   b. Surgery
      i. Congenital heart defect
      ii. Anorectal anomalies
      iii. Urogenital anomalies
      iv. Gastrointestinal anomalies
      v. Skeletal anomalies
   c. Potential anesthetic risks (Devavaram et al. 2001)
      i. Potential difficult airway management
      ii. Congenital heart disease
      iii. Renal and hepatic dysfunction

Celiac Disease

Celiac disease is a gastrointestinal disorder characterized by chronic inflammation of the small intestine that can develop in genetically susceptible individuals ingesting proteins in wheat (gliadin), rye (secalin), and barley (hordein), collectively called gluten. The prevalence of celiac disease in the United States and Canada is as high as 0.5–1%, similar to earlier estimates outside North America.

Synonyms and Related Disorders

Celiac sprue; Gluten sensitive enteropathy

Genetics/Basic Defects

1. Pathogenesis
   a. Celiac disease occurs in genetically susceptible individuals who ingest gluten, a protein found in certain grains
   b. Gluten causes an abnormal T cell–mediated immune response and inflammatory injury to the mucosa of the small intestine, resulting in malabsorption of nutrients in these individuals
   c. Gliadin fraction of gluten is mainly responsible for this intestinal damage
   d. Approximately 97% of individuals with celiac disease have genetic markers on chromosome 6 called human leukocyte antigen (HLA) DQ2 and HLA DQ8, compared with 40% of the general population
   e. An individual's intolerance to gluten is lifelong and self-perpetuating because of this genetic predisposition
2. A multifactorial disorder with complex genetics (Sollid and Lie 2005)
   a. Interplay between genetic and environmental factors
      i. Gluten (consisting of the gliadin and glutenin subcomponents): a critical environmental component
      ii. Both HLA and non-HLA genes: considered to be predisposing genetic factors
      iii. HLA as a necessary but not sufficient genetic factor for celiac disease development
         a) HLA-DQ as the chief locus mediating the HLA-linked effect in celiac disease
         b) The great majority of the patients carry a variant of DQ2 (*DQA1*05*/*DQB1*02*)
         c) A minority of the patients carry DQ8 (*DQA1*03*/*DQB1*0302*)
   b. HLA molecules
      i. The role of the molecules: to bind and present peptide fragments to T cells
      ii. Different HLA molecules thus present different sets of peptides
      iii. Gluten-reactive T cells of the celiac intestinal mucosa uniquely recognize gluten peptides in the context of DQ2 and DQ8, suggesting that these HLA molecules predispose to celiac disease by preferentially presenting gluten peptides to CD4 T cells

Clinical Features

1. Variable clinical presentations may lead to difficulty in diagnosis (Westerberg et al. 2006)
   a. Signs and symptoms in children
      i. Abdominal distention/bloating
      ii. Chronic diarrhea
      iii. Delayed puberty
      iv. Growth failure
   b. Signs and symptoms in adults
      i. Abdominal pain
      ii. Chronic diarrhea
      iii. Infertility or recurrent spontaneous abortion
      iv. Iron deficiency anemia
      v. Irritable bowel syndrome
      vi. Peripheral neuropathy
      vii. Persistent fatigue/malaise
      viii. Weight loss
   c. Associated conditions
      i. Autoimmune disorders
      ii. Dermatitis
      iii. Down syndrome
      iv. Epilepsy
      v. Idiopathic dilated cardiomyopathy
      vi. Immunoglobulin A deficiency
      vii. Immunoglobulin A nephropathy
      viii. Microscopic colitis
      ix. Osteoporosis or other bone diseases
      x. Thyroid diseases
      xi. Turner syndrome
      xii. Type I diabetes mellitus
2. Changing celiac disease pattern
   a. Less frequent so-called classic/typical celiac disease with a malabsorption syndrome in childhood. The symptomatic cases (about 10%) are considered to be the tip of the iceberg (Kaukinen et al. 2002).
   b. Increasingly common to diagnose children who have subtle or no gastrointestinal or non-gastrointestinal symptoms (Ravikumara et al. 2006)

Diagnostic Investigations

1. Initial serology tests before eliminating gluten from diet (Hill et al. 2005; Rostom et al. 2006; Westerberg et al. 2006)
   a. IgA-tissue transglutaminase (tTG) antibody and endomysial antibody (EMA) (performed to identify candidates for duodenal biopsy)
   b. Total serum IgA (performed to identify individuals with IgA deficiency).
2. Serologic tests are helpful in screening at-risk populations for celiac disease (Rashid et al. 2009)
   a. Helpful in screening at-risk populations for celiac disease, such as:
      i. First- and second-degree relatives of patients with celiac disease
      ii. Individuals with type 1 diabetes mellitus and other autoimmune endocrinopathies
      iii. Individuals with atypical symptoms
   b. Anti-deamidated gliadin-related peptide (a-DGP) antibodies IgA and IgG: detects antibodies binding synthetic deamidated gliadin-related peptides (DGPs) (Liu et al. 2007; Niveloni et al. 2007)
   c. An over-the-counter home self-testing kit for celiac disease has recently been marketed in Canada. Using a tiny blood sample obtained by a pinprick of the fingertip, the home blood test identifies the tTG antibodies present in the blood of those with celiac disease. This test is for screening only and should not replace a medical diagnosis.
3. Final diagnosis of celiac disease is based on the biopsy findings of typical histologic alterations of the small intestinal mucosa of patients eating gluten.
4. A clinical response on a gluten exclusion diet: considered to be important in diagnosis.
5. Recent recommendations also include HLA genotyping as a diagnostic adjunct (Hill et al. 2005).
   a. DQ2 heterodimer (encoded by specific *HLA-DQA1**05 alleles and specific *HLA-DQB1**02 alleles) and/or
   b. DQ8 heterodimer (encoded by specific *HLA-DQA1**03 and *HLA-DQB1**0302 alleles)
   c. Clinical molecular testing by targeted mutation analysis to determine *HLA-DQA1* and *HLA-DQB1* genotypes to detect the presence or absence of the celiac disease-associated alleles, *HLA-DQA1**0501, *HLA-DQA1**0505, *HLA-DQB1**0201, *HLA-DQB1**0202, and *HLA-DQB1**0302 (Snyder et al. 2008).
6. Informing an individual that she or he is the carrier of predisposing genes has an ethical aspect, and the possibility of a psychological impact of an HLA test

in relation to celiac disease must be considered (Sollid and Lie 2005). The presence of celiac disease predisposing HLA alleles means little, whereas the absence of the same HLA alleles makes celiac disease an improbable disorder for that patient.

Genetic Counseling

1. Recurrence risk (Snyder et al. 2008)
   a. Patient's sib
      i. The overall empiric risk for celiac disease in sibs of a proband is 7–20% if the HLA haplotype is not known (Treem 2004).
      ii. If the HLA haplotype of the parents is known, the risk to the sibs can be refined.
      iii. Sibs who share the same celiac disease-susceptibility HLA haplotype with the proband have a risk of developing celiac disease that approaches 40% (Treem 2004).
      iv. The risk to a sib of having celiac disease is estimated at 23.6% when multiple family members are affected (Gudjónsdóttir et al. 2004).
      v. If a parent of the proband has the DQ2 celiac disease-susceptibility haplotype in *cis* configuration or the DQ8 celiac disease-susceptibility HLA haplotype, the risk to each sib of inheriting the celiac disease-susceptibility HLA haplotype is 50%.
      vi. If one parent of the proband has half of the DQ2 heterodimer (*HLA-DQA1**0501 or *0505) and the other parent has half of the DQ2 heterodimer (*HLA-DQB1**0201 or *0202), the risks to sibs are as follows:
         a) Risk of inheriting both HLA haplotypes and having the full DQ2 heterodimer encoded in *trans* configuration: 25%
         b) Risk of inheriting half of the DQ2 heterodimer (*HLA-DQA1**0501 or *0505) or (*HLA-DQB1**0201 or *0202): 50%
         c) Risk of inheriting neither the *HLA-DQA1**0501 or *0505 nor the *HLA-DQB1**0201 or *0202 celiac disease-susceptibility haplotype: 25%.
   b. Patient's offspring
      i. The overall risk for celiac disease in offspring of a proband is 5–10% if the celiac disease-susceptibility HLA haplotype is not known.
      ii. The risk increases when the offspring has the DQ2 celiac disease-susceptibility HLA haplotype and/or the DQ8 celiac disease-susceptibility HLA haplotype (Treem 2004).
      iii. The risk is lower when only half of the DQ2 heterodimer (i.e., the *DQA1* sequence variant **or** the *DQB1* sequence variant, but not both) is present (Qiao et al. 2005).
      iv. Each child of an individual with the DQ2 celiac disease-susceptibility HLA haplotype or the DQ8 celiac disease-susceptibility HLA haplotype has a 50% chance of inheriting the celiac disease-susceptibility HLA haplotype.
      v. The child of a proband who has the DQ2 celiac disease-susceptibility HLA haplotype in the *trans* configuration will inherit one of the celiac disease-susceptibility HLA haplotypes from the affected parent.
      vi. Because the DQ2 or DQ8 heterodimer is found in 30–40% of the general population, testing the proband's reproductive partner is appropriate.
2. Prenatal diagnosis: While technically possible, prenatal testing of celiac disease-susceptibility HLA haplotypes does not seem relevant in this complex disorder (Snyder et al. 2008)
   a. The genetic change is common in the general population
   b. The genetic change is predisposing to, but not predictive of, celiac disease
   c. A highly effective treatment is available
3. Management
   a. Gluten-free diet
      i. Many patients cope easily.
      ii. Some patients may find that the dietary restrictions are laborious, negatively influencing their quality of life.
      iii. Requires strict adherence to a gluten-free diet for life for symptomatic and asymptomatic children with characteristic histological findings on small bowel biopsy.
      iv. Compliance with the gluten-free diet is often incomplete among celiac disease patients.
      v. When maintained on a long-term gluten-free diet (including wheat starch-based gluten-free flours), there is probably no increase in mortality, morbidity, or malignancies (Holmes et al. 1989) in patients with celiac

disease over the population in general, although there are conflicting reports whether gluten-free food completely eliminates all risks (Green et al. 2003).

b. Treat nutritional deficiencies and osteoporosis
c. A need for future alternative treatments

Fig. 1 A 3-year-old girl was healthy until 1 year of age when she developed severe watery diarrhea and abdominal distention for approximately a year and 9 months. She was diagnosed to have gluten-induced gastroenteropathy. The diarrhea stopped immediately upon withdrawal of gluten. She has been healthy since then. Her 18-month-old brother was admitted to a local hospital at 11 days of age for 6 days including 3 days of intensive care stay for a respiratory syncytial virus bronchiolitis. He again developed RSV infection at 2 months of age. In addition, he developed severe watery diarrhea with abdominal distention which improved upon discontinuation of gluten from his diet. He has since been healthy. HLA allelic variants associated with celiac disease were detected in both siblings: DQ2 heterodimer (HLA DQA1*05/DQB1*02). These alleles are present in 96–99% of confirmed celiac disease

Cerebral Palsy

Cerebral palsy (CP) is currently considered as a clinically defined symptom complex applied to individuals with a static, nonprogressive motor impairment of early onset that is cerebral in origin. It describes a group of motor impairment syndromes secondary to genetic and acquired disorders of the developing brain. Therefore, it is not a single entity with respect to pathogenesis but rather an etiologically heterogeneous entity with multiple possible causes that result in an aberration or injury to the maturing central nervous system. The motor disorders of cerebral palsy are often accompanied by disturbances of sensation, cognition, communication, perception, and/or behavior, and/or by a seizure disorder. The prevalence is estimated between 1.5 and 2.5 per 1,000 live births.

Synonyms and Related Disorders

Ataxic-hypotonic CP; Dyskinetic CP; Mixed CP; Monoplegic/hemiplegic CP; Spastic diplegic CP; Spastic quadriplegic CP; Spastic triplegic CP

Genetics/Basic Defects

1. Components of CP classification (Bax et al. 2005)
   a. Motor abnormalities
      i. Nature and typology of the motor disorder
         a) Tonal abnormalities assessed on examination (e.g., hypertonia or hypotonia)
         b) Diagnosed movement disorders (e.g., spasticity, ataxia, dystonia, or athetosis)
      ii. Functional motor abilities: motor function in all body areas, including oromotor and speech function
   b. Associated impairments
      i. Presence or absence of associated non-motor neurodevelopmental or sensory problems
         a) Seizures
         b) Hearing or vision impairments
         c) Attentional, behavioral, communicative, and/or cognitive deficits
      ii. The extent to which impairments interact in individuals with cerebral palsy
   c. Anatomic and radiological findings
      i. Anatomic distribution (the parts of the body affected by motor impairments or limitations), e.g.,
         a) Limbs
         b) Trunk
         c) Bulbar region
      ii. Radiological findings: the neuroanatomic findings on computed tomography or magnetic resonance imaging, e.g.,
         a) Ventricular enlargement
         b) White matter loss
         c) Brain anomaly
   d. Causation and timing
      i. Clearly identified cause
         a) Usually postnatal CP (e.g., meningitis or head injury)
         b) Brain malformations
      ii. Presumed time frame during which the injury occurred, if known

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_35,
© Springer Science+Business Media, LLC 2012

2. Etiologies: Distribution of observed diagnoses is noted by Shevell et al. (2003):
   a. Single cause
      i. Periventricular leukomalacia (13.8%)
      ii. Asphyxia (12.4%)
      iii. Cerebral dysgenesis (17.1%)
      iv. Intracranial hemorrhage (5.5%)
      v. Vascular (9.2%)
      vi. Infection (5.1%)
      vii. Atrophy (1.8%)
      viii. Toxins (1.1%)
   b. Multiple causes
      i. Periventricular leukomalacia (24.9%)
      ii. Asphyxia (21.7%)
      iii. Cerebral dysgenesis (17.1%)
      iv. Intracranial hemorrhage (12.9%)
      v. Vascular (9.7%)
      vi. Infection (6.5%)
      vii. Trauma (1.8%)
      viii. Atrophy (1.8%)
      ix. Toxins (2.2%)
3. Common etiologies of cerebral palsy (Russman and Ashwal 2004; Dodge 2008)
   a. Prenatal onset
      i. Brain malformations
      ii. Intrauterine infection such as cytomegalovirus infection
      iii. In utero stroke
      iv. Toxemia
      v. Placental abruption
   b. Perinatal onset
      i. Hypoxic–ischemic encephalopathy
      ii. Viral encephalitis
      iii. Meningitis
      iv. Kernicterus
      v. Trauma
   c. Postnatal onset
      i. Infection
      ii. Accidental head trauma
      iii. Anoxic insult
      iv. Child abuse
      v. Progressive hydrocephalus
4. Occurrence of CP phenotype has been seen in a variety of recognizable genetic syndromes including (Fisher and Russman 1974):
   a. Coffin–Lowry syndrome
   b. Cerebro-oculo-facio-skeletal syndrome
   c. Rett syndrome
   d. Angelman syndrome
   e. Hereditary spastic paraplegia
   f. Pelizaeus–Merzbacher spectrum
   g. West syndrome (infantile spasm and status dystonicus)
5. Recently described metabolic conditions associated with cerebral palsy phenotype (Schaefer 2008)
   a. Glucose transport disorders
   b. Molybdenum cofactor deficiency (sulfite oxidase deficiency)
   c. Serine biosynthesis disorder
   d. Glycine cleavage encephalopathy
   e. Creatine biosynthesis disorder
   f. Neurotransmitter disorders
   g. Nonlactic acidemia Leigh syndrome
   h. Adenylosuccinate lyase deficiency
   i. Congenital disorders of glycosylation
   j. Glutamate transporter EAAT1
   k. 2-methylbutyryl-CoA dehydrogenase deficiency
   l. Mitochondrial disorders (Fryer et al. 1994)
      i. Report of a family, affected with Leigh's encephalopathy and the mitochondrial DNA (mtDNA) mutation 8993, presented with nonspecific delayed development or cerebral palsy.
      ii. There was some correlation in this family between the disease severity and the proportion of mutant mtDNA in the blood.
      iii. This mutation appears to segregate to high levels of mutant mtDNA rapidly within pedigrees.
      iv. The mother of a severely affected child has a high risk of having further children with a high proportion of mutant mtDNA and a severe phenotype.
6. Types of cerebral palsy (Shevell et al. 2003)
   a. Spastic quadriplegic (35.5%)
   b. Spastic hemiplegic (31.3%)
   c. Spastic diplegic (18.0%)
   d. Mixed (5.5%)
   e. Ataxic–hypotonic (5.5%)
   f. Spastic monoplegic (2.7%)
   g. Dyskinetic (0.9%)
   h. Worster-Drought (also called bilateral perisylvian or opercular) syndrome (0.9%)

Clinical Features

1. Prenatal and perinatal history (Green et al. 2003)
   a. Prenatal history: potential pregnancy complications
      i. Maternal illnesses during pregnancy
      ii. Exposure to toxins (e.g., alcohol or drugs)
      iii. Prenatal care
      iv. Fetal movements
      v. History of trauma
   b. Perinatal history
      i. Gestational age at delivery
      ii. Delivery type and presentation
      iii. Length of labor
      iv. Birth weight
      v. Apgar scores
      vi. Cord gas pH
      vii. Presence of intraventricular hemorrhage
      viii. Procedures done during hospitalization
      ix. Ability to feed
      x. Degree of tone
2. Developmental history
   a. Age of attainment of developmental milestones
   b. Age-appropriate developmental function
   c. Assessment of gross motor function
      i. Head control
      ii. Trunk control
      iii. Rolling
      iv. Sitting
      v. Crawling
      vi. Standing
      vii. Cruising
      viii. Walking
   d. Assessment of fine motor function
      i. Handedness
      ii. Hand-to-mouth movements
      iii. Bimanual activities
      iv. Grasping
      v. Writing
      vi. Feeding
   e. Assessment of language ability
      i. Babbling
      ii. Size of vocabulary
      iii. Ability to string words together
      iv. Counting
      v. Naming of body parts, colors, alphabet, and comprehension
   f. Current social and personal skills
3. Other histories
   a. Nutritional status, including feeding style, ability, and content
   b. Medications and allergies
   c. Past surgeries
   d. Presence of seizures
   e. Tone and body movement patterns
   f. Bowel and bladder concerns
   g. Visual and hearing concerns
   h. General health
   i. Immunization history
   j. Positioning devices
   k. Bathing equipment
   l. Wheelchair and seating equipment
   m. Adaptive devices
   n. Communication devices
   o. Computers
   p. Environmental control units
   q. Transportation systems
   r. Educational information
      i. Early intervention programs
      ii. School environment
      iii. Special services
      iv. Individualized education plan
      v. Adaptive physical education and recreation
      vi. Vocational and vocational activities in adults
4. Criteria for diagnosis (Paneth 2008): presence of one or more of the following four types of neurologic impairment of the motor system:
   a. Spasticity
      i. Commonest neurologic abnormality
      ii. Characterized by increased muscle tone manifesting as increased resistance to stretch that is velocity dependent
      iii. Generally accompanied by hyperreflexia, which may include prolonged or sustained clonus, as well as pathologic reflexes such as an abnormal Babinski response (Sanger et al. 2003)
      iv. When spasticity affects the lower limbs:
         a) Internal rotation and adduction of the hips is often seen, leading to the typical flexed posture and pigeon-toed gait of CP

b) Spasticity of the gastrocnemius muscle in the calf leads to another characteristic finding of toe walking due to plantar flexion

b. Dyskinesia
   i. Stereotyped, involuntary movements accentuated with effort
   ii. Presence of two forms of dyskinesia
      a) Dystonia in which abnormal postures due to sustained muscle contractions are the essential feature.
      b) Choreoathetosis, in which abnormal movements predominate, consists of two related motor disorders: choreiform movements are rapid and jerky, whereas athetoid movements have a writhing quality. Athetoid CP is characteristic of children who suffered kernicterus in the neonatal period. With control of rhesus hemolytic disease, and better management of all forms of neonatal hyperbilirubinemia, this form of cerebral palsy has become very rare. Patients with the dystonic form of cerebral palsy generally have spasticity as well, whereas patients with choreoathetoid cerebral palsy often have varying tone, with hypertonia and hypotonia both found.
c. Hypotonia.
d. Ataxia.
   i. Usually presence of both truncal and gait ataxia, which can both be observed (e.g., wide-based gait) and elicited by examination (e.g., inability to accurately place finger on nose)
   ii. Intention tremor commonly seen
   iii. Fine motor skills are particularly limited
   iv. Tone is usually hypotonic in this form of cerebral palsy

5. Musculoskeletal features
   a. Hip assessment should include evaluation for contractures involving flexion, internal and external rotation, adduction, and leg length discrepancies
   b. The knee should be tested for hamstring contracture
   c. The foot and ankle should be tested for contractures and tibial torsion
   d. The back should be examined for posture, spinal curves, or asymmetries
   e. The upper extremities should be assessed for resting posture and spontaneous movement
   f. An occupational therapy evaluation of grip and fine motor coordination often is beneficial
6. Neurologic features
   a. CP is a disorder of movement resulting in a delay in the development of gross motor skills
   b. Focus on tone
      i. If movement has a velocity-dependent component, it is spastic
      ii. In addition to the deep tendon reflexes (which are often increased in spastic CP) and the Babinski, or plantar, response (which is often upgoing)
7. Spastic cerebral palsy
   a. Spasticity
      i. Definitions
         a) An increase in the physiologic resistance of muscle to passive motion
         b) Hypertonicity that increases with increased velocity of movement (or having an increased stretch reflex)
      ii. Most common of cerebral palsy (70–80% of children who have cerebral palsy are spastic) (Panteliadis 2004)
      iii. A part of the upper motor neuron syndrome characterized by:
         a) Hyperreflexia
         b) Clonus
         c) Extensor plantar responses
         d) Persistent primitive reflexes
   b. Cause: damage to the pyramidal parts of the brain
   c. Subdivision of spastic cerebral palsy: according to the area of the body involved
      i. Diplegia
         a) 50% of children with spastic cerebral palsy have diplegia (Berker and Yalçin 2008).
         b) The most common type seen in premature infants (Schaefer 2008).
         c) Greater involvement of legs than arms.
         d) Children with spastic diplegia are late in attaining all gross motor skills, but the delay in standing and walking are most notable. Generally, there is only mild functional impairment of the upper

extremity. In a prospective study, being able to sit independently at 2 years was a good predictive sign of future ambulation. Children who could not sit by age 4 did not ambulate.

ii. Quadriplegia
   a) 30% of children with spastic cerebral palsy have quadriplegia (Berker and Yalçin 2008)
   b) The only type associated with asphyxia in term infants (Schaefer 2008)
   c) All four extremities, the trunk, and muscles that control the mouth, tongue, and pharynx get affected
   d) Children with spastic quadriplegia present a much broader spectrum of disability
   e) The severity of motor involvement affects the delay in developmental milestones
   f) About one-fourth of children with spastic quadriplegia have only mild involvement, with minimal functional limitation with regard to mobility or self-care
   g) About one-half are moderately impaired
   h) These patients are unable to achieve complete independence but are able to function reasonably well
   i) About one-quarter of patients are severely involved, require total care, and are unable to ambulate
   j) Independent sitting at 2 years and suppression of obligatory reflexes are good prognostic signs for eventual ambulation

iii. Hemiplegic/monoplegia
   a) Most likely causes (focal traumatic, vascular, or infectious lesion).
   b) Not typically associated birth asphyxia (Schaefer 2008).
   c) 20% of children with cerebral palsy have hemiplegia (Berker and Yalçin 2008).
   d) One-sided (unilateral) involvement: a unilateral brain infarct with posthemorrhagic porencephaly apparent on MRI.
   e) Upper extremity generally more affected than the lower.
   f) Exhibit definite hand preference before 1 year of age, compared with most children who display handedness at about age 2.
   g) Display either an asymmetric crawl or no crawl at all.
   h) Almost all children with spastic hemiplegia do ambulate. Most become independent with activities of daily living, using some aids.
   i) Seizures, mild mental retardation, learning difficulties, and behavioral disturbances may complicate the management and integration into society.

iv. Double hemiplegic: both sides, arms > legs

d. Children with spastic syndromes, in general, often show white matter injury on imaging
e. Most closely linked to periventricular leukomalacia but may also be secondary to congenital human immunodeficiency virus, dopa-responsive dystonia, hereditary spastic paraplegia, or spinal pathology, arginase deficiency, and Sjögren–Larsson syndrome, with characteristic appearances on imaging

8. Dyskinetic cerebral palsy
   a. Dyskinetic cerebral palsy accounts for approximately 10–15% of all cases of cerebral palsy (Berker and Yalçin 2008).
   b. The most probable etiology: hyperbilirubinemia or severe anoxia that causes basal ganglia dysfunction.
   c. Choreoathetoid (hyperkinetic) and chorea: the main movement disorders seen in dyskinetic children.
   d. Dysarthria, dysphagia, and drooling accompany the movement problems.
   e. Children with dyskinetic cerebral palsy typically suffer from severe neuromuscular dysfunction. The abnormal movements are first noticed in the hands and fingers, but abnormal movements are usually noted in all extremities by 18 months of age. The writhing, involuntary movements give way to dystonia. As a result, all of their gross motor milestones are significantly delayed. Only about one-half of these children are able to walk, and they normally do not walk until after 3 years of age.

Children who are able to walk usually develop the coordination necessary to perform their activities of daily living. Those who do not walk typically require almost total care.

f. Abnormal movements that are most obvious when a patient initiates a movement. These abnormal movements are caused by inadequate regulation of muscle tone and coordination.
g. When the patient is relaxed, there is usually full range of motion with decreased tone.
h. The patient often has a "cogwheel" type resistance, without changes in the deep tendon reflexes. Tone decreases when the patient is supine, and tone may "shake loose."
i. There are two main types of dyskinetic movement.
   i. The first is dystonia, in which abnormal shifts of general muscle tone are induced by movement. These patients tend to retain abnormal posture in the same stereotyped patterns.
   ii. The second main type of dyskinetic movement is choreoathetoid, in which the initiation of movement in one extremity leads to movement of other muscle groups. These patients exhibit slowly writhing involuntary movements in combination with abrupt, irregular, jerky movements.

9. Ataxic cerebral palsy
   a. Ataxic CP is the disturbance in the coordination of voluntary movements caused by muscle dyssynergia.
   b. Usually caused by cerebellar dysfunction.
   c. Ataxia becomes apparent toward the age of 2–3 years.
   d. Generally seen in association with spastic diplegic cerebral palsy.
   e. Now often categorized in the group of dyskinetic CP.
10. Mixed cerebral palsy
   a. Ataxia and dystonia occurring together with spasticity.
   b. The damage, usually, is more global, and the patients are quadriplegic.
11. Extrapyramidal cerebral palsy syndromes
   a. Characterized by rigidity, elicited clinically by passive stretch independent of velocity or dystonia, which is often action-induced twisting or fixed postures
   b. Arm use is typically more affected than leg function
   c. Children with extrapyramidal syndromes, in general, frequently have basal ganglia abnormalities on imaging
   d. May result from genetic metabolic disorders such as glutaric aciduria type 1 (caudate/putamen), mitochondrial disorders such as Leigh syndrome (globus pallidus/caudate/putamen), kernicterus (globus pallidus), or hypoxic–ischemic encephalopathy (putamen/thalamus)
12. Associated conditions in children with cerebral palsy (Ashwal et al. 2004)
   a. Mental retardation (52%)
      i. Cognitive and neuropsychological function in children with CP are commonly impaired
      ii. In general, no absolute relation between the type of CP and severity of cognitive impairment. However, the following correlations are noted:
         a) Greater degree of mental impairment in spastic quadriplegia than in spastic hemiplegia
         b) Severity of cognitive deficits appears to correlate with motor deficits associated with spastic cerebral palsy in contrast to dyskinetic cerebral palsy where this relation is lacking
         c) Greater intellectual impairment in cerebral palsy in the presence of epilepsy, abnormal EEG, or abnormal neuroimagings
   b. Speech and language disorders (38%)
      i. Anarthric or dysarthric speech and other impairments related to oral motor dysfunction are common due to bilateral corticobulbar dysfunction (i.e., articulation disorders and impaired speech intelligibility present in 38%)
      ii. Inability to develop the linguistic skills necessary to develop more complex speech patterns due to impaired mobility which causes limited interaction with individuals in the environment
      iii. Language (as opposed to speech) deficits in CP closely related to verbal intellectual limitations associated with mental retardation

iv. Oral motor problems may lead to potential serious impacts on nutrition and growth, oral health, respiration, and self-esteem
a) Feeding difficulties
b) Swallowing dysfunction
c) Drooling

c. Ophthalmologic defects (28%)
i. Visual impairments and disorders of ocular motility are common
a) Strabismus
b) Amblyopia
c) Nystagmus
d) Optic atrophy
e) Refractive errors
ii. Visual perceptual problems more likely in those due to periventricular leukomalacia

d. Hearing impairment (12%)
i. More commonly in children with following etiologies:
a) Low birth weight
b) Kernicterus
c) Neonatal meningitis
d) Severe hypoxic–ischemic insults
ii. Greater risk in children with CP who have mental retardation or abnormal neuroimaging studies

e. Epilepsy (43%)

13. Clues to the so-called cerebral palsy of unknown etiology (Dodge 2008)
a. Family history (familial spastic paraplegia)
b. Normal deep tendon reflexes (transient toe walking)
c. Calf hypertrophy with positive Gower sign (muscular dystrophy)
d. Regression, lethargy, unusual vomiting
i. Ichthyosis (Sjögren–Larsson syndrome)
ii. Severe self-mutation (Lesch–Nyhan syndrome)
e. Recurrent stroke, cardiomyopathy, hypoglycemia (mitochondrial disorders)
f. Multiple anomalies
g. Lissencephaly (Miller–Dieker syndrome)
h. Acquired microcephaly, hand wringing (Rett syndrome)

14. Medical complications associated with cerebral palsy (Dougherty 2009)
a. Spasticity
b. Joint contractures, misalignment secondary to muscle spasticity
c. Hip dislocation
d. Osteoporosis
e. Intellectual disability (seen in 30–50% of individuals)
f. Seizures
g. Gastroeosphageal reflux
h. Dysphagia or aphagia
i. Failure to thrive/malnutrition
j. Hearing loss

15. Possible source of pain (dodge 2008)
a. Cranial
i. Increased intracranial pressure
ii. Migraines and other headaches
b. Ophthalmologic
i. Corneal abrasion
ii. Glaucoma
c. Dental
i. Abscesses
ii. Temporomandibular joint pain
d. Gastrointestinal
i. Gastroesophageal reflux
ii. Constipation
e. Musculoskeletal
i. Hip dislocation
ii. Scoliosis
f. Neuromuscular (muscle spasms)
g. Urologic
i. Urolithiasis
ii. Bladder spasms
h. Other (Decubitus ulcers)

16. Proposed diagnostic criteria of cerebral palsy (Kavčič and Vodušek 2005)
a. Possible CP
i. Mandatory inclusion criteria
a) Disorder of movement and posture manifesting as spastic diplegia, spastic hemiplegia, spastic tetraplegia, ataxia, dystonia, choreoathetosis – alone or in any combination
b) Onset early in life
c) No evidence of progression
ii. Mandatory exclusion criteria
a) Active disease that could explain the foregoing features
b) Chromosomal disorders
iii. Supportive features
a) Other signs of brain dysfunction that could be caused by the same pathological process as the foregoing disorders of

movement and posture (epilepsy, learning disorders, disorders of speech, vision or hearing)
- b) Born after multiple pregnancy
- c) Vanishing twin syndrome
- d) Intrauterine growth retardation
- e) Major antenatal placental abruption
- f) Preterm birth
- g) Acute intrapartum hypoxia
- h) Reduced fetal heart rate variability from the onset of labor
- i) Extensive chorioamnionitis
- j) Congenital coagulation disorders
- k) Autoimmune disease of the mother
- l) No child with the same/similar clinical picture in a family

b. Probable CP: Mandatory inclusion criteria:
- i. Disorder of movement and posture as in possible CP
- ii. Onset early in life
- iii. No evidence of progression or other disease that could explain the foregoing features at school age

c. Definite CP: Mandatory inclusion criteria:
- i. Disorder of movement and posture as in probable CP
- ii. Plus still no evidence of progression unrelated to aging or other disease that could explain the foregoing features at age 18 or older

17. Prognosis (Blair et al. 2001)
    a. Most persons with cerebral palsy survive to adulthood except those with profound intellectual deficit
    b. Survival strongly associated with degree of intellectual deficit
    c. Mortality declines with age during childhood
    d. Cause of death usually due to respiratory problems such as aspiration pneumonia

Diagnostic Investigations

1. EEG
    a. For features suggesting presence of epilepsy or epileptic syndrome
    b. Probably not very helpful in determining the etiology of cerebral palsy
2. Neonatal audiometric screening
3. MRI (preferred to CT scanning) (Russman and Ashwal 2004)
    a. Higher yield of suggesting an etiology and timing of insult leading to CP
    b. MRI abnormalities in children with cerebral palsy
        - i. Acquired lesions
            - a) Periventricular leukomalacia with other areas of injury
            - b) Diffuse encephalopathy (cortical/subcortical atrophy/ventriculomegaly)
            - c) Focal ischemic/hemorrhagic (e.g., infarct porencephaly)
            - d) Multicystic encephalomalacia
            - e) Trauma (at birth or later)
            - f) Infection
        - ii. Malformations
            - a) Cortical dysplasia/polymicrogyria
            - b) Schizencephaly
            - c) Pachygyria/lissencephaly
            - d) Complex brain malformation
            - e) Agenesis/hypoplasia of the corpus callosum
            - f) Arachnoid cyst
            - g) Vermian/cerebellar hypoplasia
            - h) Hydrocephalus/holoprosencephaly/hydranencephaly
        - iii. Miscellaneous or unknown
            - a) Miscellaneous etiologies
            - b) Delayed/abnormal myelination
        - iv. Normal
4. Metabolic and genetic testing (Russman and Ashwal 2004; Schaefer 2008)
    a. Features of family history that might prompt a genetics/metabolic workup
        - i. Thromboses/vascular accidents
        - ii. Mental retardation/developmental disabilities
        - iii. Seizures
        - iv. Cerebral palsy
        - v. Neuromotor disorders
        - vi. Tumors
        - vii. Neurobehavioral disorders
        - viii. Joint contractures/stiffness
        - ix. Congenital anomalies
        - x. Infertility
        - xi. Recurrent miscarriages/stillborns
        - xii. Adult-onset neurodegenerative conditions

   b. Features on medical history and physical examination prompting a genetics/metabolic workup (Schaefer 2008)
      i. Neuroregression
      ii. Seizures/change in seizure type
      iii. Late onset/acquired microcephaly
      iv. Macrocephaly
      v. Pigmentary changes
      vi. Major and minor dysmorphic features
      vii. Congenital anomalies
   c. Metabolic or genetic causes for CP to occur infrequently (0–4%; true incidence unknown)
   d. Neuroimaging studies showing 7–11% of children with cerebral palsy have a brain malformation suggest the presence of additional risk for genetic and possibly a metabolic etiology
   e. Metabolic studies
   f. High-resolution chromosome analysis
   g. Chromosome microarray analysis
5. Recognizable genetic syndromes known to be associated with a cerebral palsy phenotype
   a. MECP2 mutation study for Rett syndrome
   b. Chromosome 15 anomaly and UBE3A mutation studies for Angelman syndrome
   c. L1CAM mutation study for hereditary spastic paraplegia
   d. PLP1 mutation study for Pelizaeus–Merzbacher spectrum
   e. ARX (X-linked aristaless-related homeobox gene) mutation study for West syndrome

Genetic Counseling

1. Recurrence risk: Recurrence risk depends on the underline genetic disorders (rare) of cerebral palsy
   a. Patient's sib
      i. Recurrence risk is low in most cases caused by hypoxic or ischemic injury to the brain
      ii. Autosomal recessive: 25%
      iii. Autosomal dominant: not increased unless a parent is affected or having gonadal mosaicism
      iv. X-linked recessive disorder: 50% of male sibs affected if the mother is a carrier
      v. Mitochondrial: All sibs are at risk of being affected if the mother has the mitochondrial DNA mutation
   b. Patient's offspring
      i. Autosomal recessive: not increased
      ii. Autosomal dominant: 50%
      iii. X-linked recessive: all daughters of affected males will be carriers. All sons of an affected male will be normal.
      iv. Mitochondrial:
         a) Offspring of males with a mtDNA mutation are not at risk
         b) All offspring of females with a mtDNA mutation are at risk of inheriting the mutation
         c) A female harboring a heteroplasmic mtDNA point mutation may transmit a variable amount of mutant mtDNA to her offspring, resulting in considerable clinical variability among sibs within the same nuclear family (Poulton and Turnbull 2000; Chinnery 2006)
2. Prenatal diagnosis: not reported to date
3. Management
   a. Management strategy and rehabilitation of the child with cerebral palsy (Berker and Yalçin 2008)
      i. Support growth and nutrition
      ii. Therapy for vision
         a) Rehabilitation
         b) Glasses
         c) Surgery
      iii. Dental hygiene
      iv. Gastointestinal problems
         a) Medications for reflux
         b) Gastrostomy
         c) Antireflux surgery
      v. Therapy for motor function
         a) Physical therapy
         b) Occupational therapy
         c) Adaptive seating
         d) Bracing
         e) Wheeled motility
         f) Orthopedic surgery
         g) Sports-recreation
      vi. Oromotor therapy
         a) Chewing
         b) Swallowing
         c) Speech
      vii. Seizure prevention

viii. Spasticity and dyskinesia
  a) Medical treatment
  b) Botulinum toxin

b. Timing of rehabilitative measures
  i. Infancy
    a) Goal: supportive measures for prolonging and optimizing physical status and life
    b) Methods: nutritional support and infant stimulation and positioning
  ii. Childhood
    a) Goal: strategies to obtain maximum independent mobility
    b) Methods: medication to minimize spasticity, exercise, Botulinum toxin, bracing
  iii. Preschool
    a) Goal: maximum independent mobility
    b) Methods: minimize deformity, medication, exercise, Botulinum toxin, bracing, orthopedic surgery
  iv. Adolescence
    a) Goal: education, vocation, and integration into the community
    b) Methods: schooling, sports, psychosocial support

c. Effects of physiolotherapy (Berker and Yalçin 2008)
  i. Physiolotherapy to improve:
    a) Postural control: decreasing spasticity and contracture
    b) Muscle strength: increasing muscle elasticity and joint laxity
  ii. Range of motion
    a) Joint alignment: increasing coordination/agility
    b) Motor control: balance
    c) Muscular/cardiovascular endurance and mobility skills: transitions, use of assistive devices

d. Oral sensorimotor therapy
  i. May be effective in promoting oral motor function
  ii. Not shown to be effective in promoting oral feeding efficiency, caloric intake, weight gain, or pharyngeal motility and airway protection during feedings

e. Gastrostomy tube feeding (Rogers 2004)
  i. An important alternative nutritional source for children with cerebral palsy
  ii. Relative indications
    a) Dysphagia resulting in undernutrition
    b) Aspiration with associated respiratory disease
    c) Insufficient fluid intake and/or refusal of oral medications
    d) Excessive effort or stress during oral feedings.

f. Early intervention programs
  i. Work to optimize development
  ii. Goals: improve function and encourage independence
  iii. Improve family interaction
  iv. Provide family support
  v. Provide education in how to promote development
  vi. The Individuals with Disabilities Education Act mandates early intervention for all children 0–3 years old who demonstrate developmental delay
    a) These programs are typically multidisciplinary and may take place in centers or in the family's home.
    b) The therapists directly provide hands-on therapy to the child or educate the family on how to provide the interventions themselves.

g. Management of spasticity
  i. The management of spasticity is a large part of the treatment of children with cerebral palsy.
  ii. Daily range of motion shown to decrease muscle tone for several hours after it is done and may delay or prevent contractures.
  iii. Use of heat or cold can modify tone in the short term, but either modality is impractical for long-term use.
  iv. Casting and splinting often used as adjuncts to regular range of motion: Casting for 2–3 weeks can decrease tone and improve range of motion for several months.
  v. Cyclical use of electrical stimulation has been found to decrease upper extremity contractures and improve agonist/antagonist balance, but these affects last only for hours.
  vi. Medications.

h. Management of seizures

i. Complemental and alternative therapies (Liptak 2005)
   i. Hyperbaric oxygen (delivery of 100% oxygen)
      a) Theory/benefits: awakens dormant brain tissue surrounding the original injury
      b) Adverse effects: ear trauma, pneumothorax, fire and explosions
      c) Evidence: improvements in the treated children in uncontrolled studies, improvement in treated and controls in controlled study
      d) Comments: more evidence is required
   ii. Adeli suit (originally developed for Russian cosmonauts to counteract the adverse effects of zero gravity, including muscle atrophy and osteopenia)
      a) Theory/benefits: resistance across muscles improves strength, posture, and coordination
      b) Adverse effects: discomfort from suit, expense for intensive therapy and travel to centers that prescribe the suit
      c) Evidence: no conclusive evidence
   iii. Patterning (passively putting children through certain repeated normal motions)
      a) Theory/benefits: passively repeating steps in normal development overcome brain injuries.
      b) Adverse effects: time, energy, and expenses required
      c) Evidence: results of uncontrolled studies are inconsistent; controlled trials show no benefits
      d) Comments: not recommended
   iv. Electrical stimulation (elicits muscle contraction): more evidence required
   v. Threshold electrical stimulation
      a) Theory/benefits: increased blood flow from electrical current leads to stronger muscles
      b) Adverse effects: expense for units, generally safe
      c) Evidence: subjective improvements in some uncontrolled trials; inconclusive in controlled trials
   vi. Functional neuromuscular stimulation
      a) Theory/benefits: increased muscle contraction improves strength and function
      b) Adverse effects: expense, infection from needles, discomfort
      c) Evidence: somewhat more positive than for threshold stimulation but still inconclusive
   vii. Conductive education (interventions including promoting independent functioning using repetition and verbalization by the child)
      a) Theory/benefits: problems with motor skills are due to problems of learning. New abilities are created out of teaching
      b) Adverse effects: not known
      c) Evidence: benefit shown in uncontrolled trials, mixed results in controlled trials
      d) Comments: conductive education implemented in many different ways making generalizations from a single program difficult
   viii. Hippotherapy (equine-assisted therapy)
      a) Theory/benefits: riding a horse improves muscle tone, head and trunk control, mobility in the pelvis, and equilibrium
      b) Adverse effects: trauma from a fall, allergies
      c) Evidence: beneficial effects on body structures and functioning shown by uncontrolled and controlled trials
      d) Comments: increases social participation
   ix. Craniosacral therapy (a cranial rhythm linked with movements in the sacrum transmitted through the dura of the spinal cord by light corrective pressure applied to various points along the craniosacral axis)
      a) Theory/benefits: used to remove impediments to the flow of cerebrospinal fluid within the cranium and spinal cord
      b) Adverse effects: none known
      c) Evidence: no studies showing efficacy, some question the basis of the intervention
   x. Feldenkrais intervention method
      a) Theory/benefits: gentle change of position and directed attention to relax muscles, improve movement, posture, and functioning

b) Adverse effects: none known
c) Evidence: no studies showing efficacy

xi. Acupuncture
a) Theory/benefits: help to restore the normal flow of Qi (energy)
b) Adverse effects: forgotten needles, pain, bruising, and infection
c) Evidence: improvements in several areas shown by uncontrolled and some controlled studies
d) Comments: appears promising, but more studies needed

Fig. 1 A 10-year-old girl with cerebral palsy secondary to anoxic encephalopathy

Fig. 2 The patient, a 14-year-old boy, was diagnosed with diplegia cerebral palsy. He was born 27 weeks gestation by C Section and was one of the fraternal twins. He had a grade IV intraventricular bleed. Birth weight was 2 lbs. 1 oz. He was in NICU for 2 months

Fig. 3 The patient, a 14-year-old boy, was diagnosed with triplegia cerebral palsy. He was born 32 weeks gestation and on the ventilator for several weeks

Cerebro-Costo-Mandibular Syndrome

Cerebro-costo-mandibular syndrome, a rare congenital syndrome, consists of severe micrognathia, often with the Pierre Robin anomaly, posterior rib-gap defects, and developmental delay (Smith et al. 1966). It is also known as "rib-gap syndrome," "rib-gap defect with micrognathia syndrome," and "Smith–Theiler–Schachenmann syndrome."

Synonyms and Related Disorders

Rib gap defects with micrognathia

Genetics/Pathogenesis

1. Cause: unknown
2. Inheritance
   a. Sporadic in majority of cases
   b. Familial occurrence in a few instances
      i. Autosomal recessive pattern
      ii. Autosomal dominant pattern
3. Pathogenesis of the rib gaps (Megier et al. 1998)
   a. Not well understood.
   b. Rib abnormality results from a lack of fusion between two mesenchymal tissues derived from the somatic mesoderm (posteriorly) and the lateral plate mesoderm (anteriorly).
   c. Defective organization of the somite results in discontinuities of the ribs.

Clinical Features

1. Variable inter- and intrafamilial expression
2. Cardinal signs
   a. Rib abnormalities
      i. Posterior rib gaps
         a) Present in almost all affected newborn infants
         b) Showing great variability in severity
         c) Disappear in time
         d) Sometimes replaced by callus or pseudo-arthroses
      ii. Segmentation defects and rudimentary rib development, fusion of most ribs to the vertebrae, and absence of any normal costovertebral articulations
      iii. Thin ribs
      iv. Agenetic ribs
   b. Micrognathia/Pierre Robin anomaly
   c. Cerebral abnormalities
      i. Microcephaly
      ii. Agenesis of the corpus callosum
      iii. Dilated lateral ventricles
      iv. Porencephalic cyst
      v. Variable degree of mental retardation probably secondary to hypoxia following respiratory distress
3. Other skeletal anomalies
   a. Vertebral anomalies including hemivertebrae
   b. Hip dislocation
   c. Subluxation of the elbows

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_36,
© Springer Science+Business Media, LLC 2012

   d. Pectus carinatum
   e. Hypoplasia of the sternum, clavicles, and pubic rami
   f. Epiphyseal stippling
   g. Abnormal phalanges and toes
   h. Clubfoot
4. Intrauterine growth retardation
5. Postnatal growth deficiency
6. Respiratory distress
7. Feeding difficulties
8. Language delay
9. Conductive deafness
10. Palatal defect
    a. Short soft palate
    b. Cleft palate
11. Dental defects
12. Laryngeal and tracheal abnormalities
13. Pterygium coli
14. Renal anomalies
    a. Renal cysts
    b. Ectopia
15. Congenital heart defects
16. Prognosis
    a. Mental retardation often among the late survivors
    b. High mortality (40% in the first year of life, 50% in the first month of life) mostly due to respiratory insufficiency secondary to rib abnormalities and flail chest

Diagnostic Investigations

1. Radiography
   a. Rib malformations
      i. Multiple gaps consisting of fibrous or cartilaginous tissue
      ii. Thin ribs
      iii. Agenetic ribs
   b. Vertebral anomalies
   c. Other associated skeletal anomalies
   d. Micrognathia
2. Three-dimensional CT of costo-thoracic skeleton: demonstration of variable gaps in the posterior ribs and absence of ribs (Su et al. 2010)
3. Cranial ultrasonography for cerebral abnormalities
4. Histology of rib gaps: undifferentiated fibrous connective tissue and muscles, instead of cartilage and bone

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Not increased in sporadic cases and in a fresh mutation case of an autosomal dominant disorder
      ii. 25% in an autosomal recessive disorder
   b. Patient's offspring: not increased unless the patient survives and is affected with an autosomal dominant disorder in which case there is a 50% risk of having an affected child
2. Prenatal diagnosis by ultrasonography: difficult to establish
   a. Small mandible
   b. A narrow short chest
   c. Defective ribs
   d. Growth retardation
   e. Vertebral anomalies
   f. Limb anomalies
   g. Increased nuchal translucency
   h. Cystic hygroma
   i. Polyhydramnios
3. Management
   a. Treatment of respiratory distress.
   b. Nasogastric tube feeding.
   c. Tracheostomy may be required.
   d. Surgery for cleft palate.
   e. Early intervention and multidisciplinary team approach.
   f. Orthopedic care for skeletal anomalies.

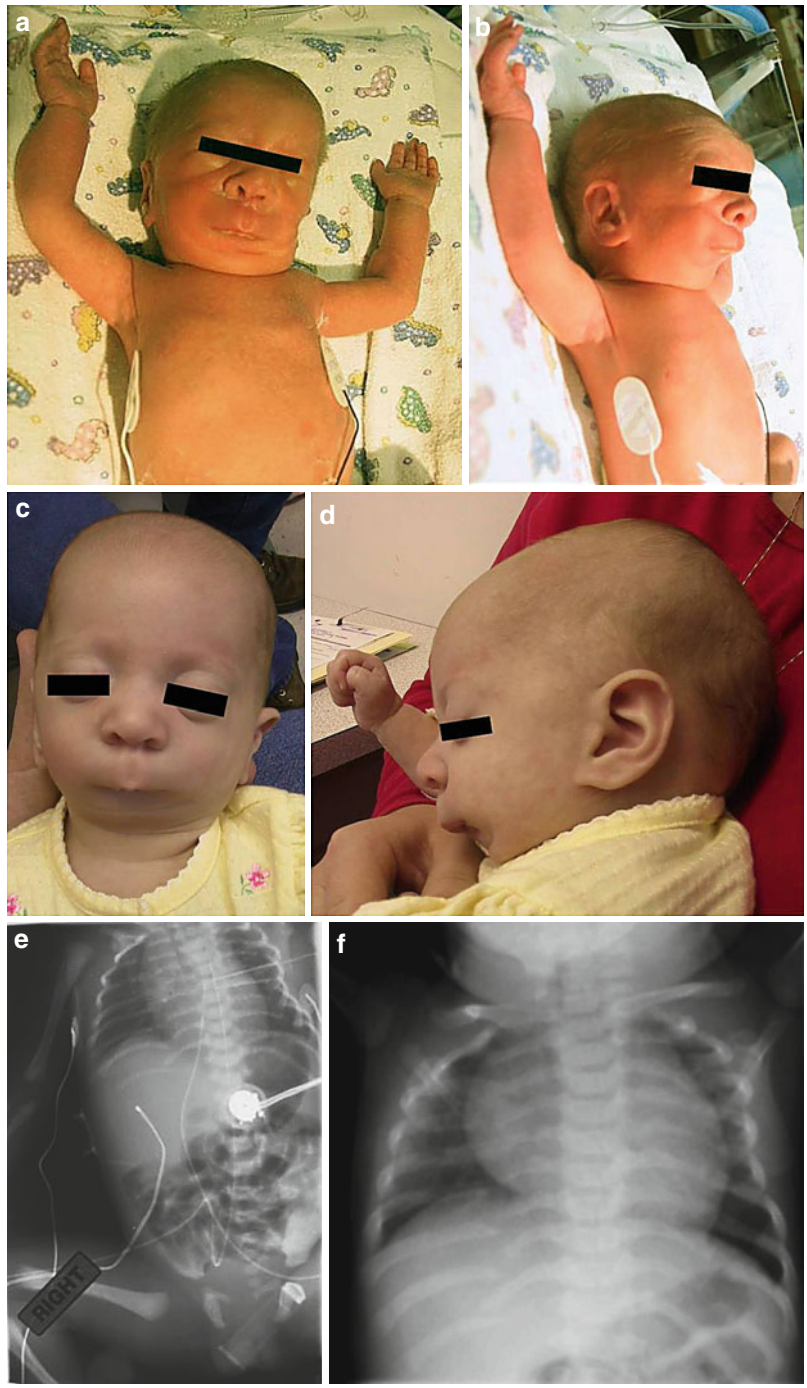

Fig. 1 (**a**–**f**) An infant with cerebro-costo-mandibular syndrome (at birth and 12 weeks of age) showing severe micro/retrognathia and malformations of the ribs with multiple gaps and segmentation defects

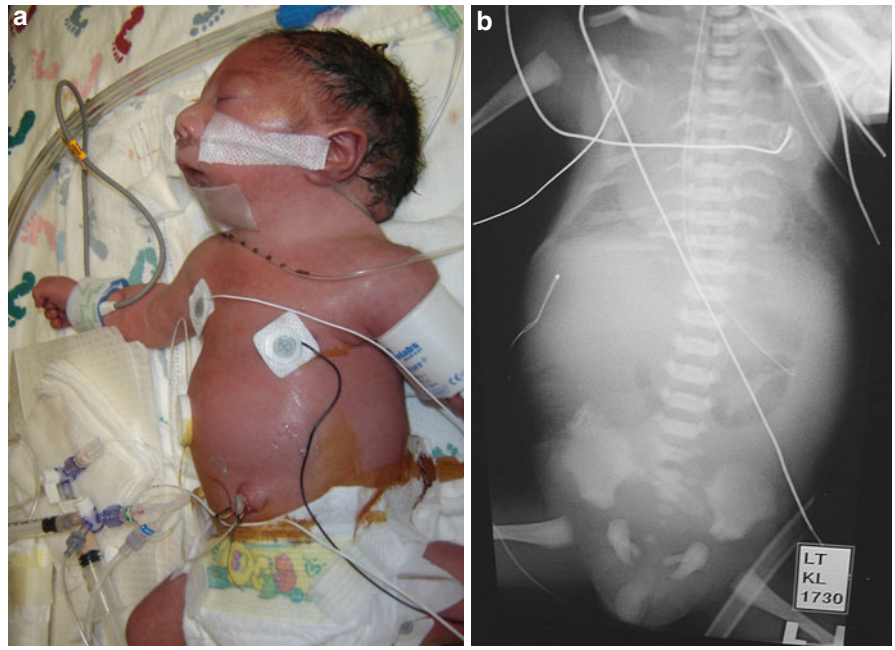

Fig. 2 (**a**, **b**) Another infant with cerebro-costo-mandibular syndrome showing severe micro/retrognathia, a narrow chest, and rib malformations with multiple gaps

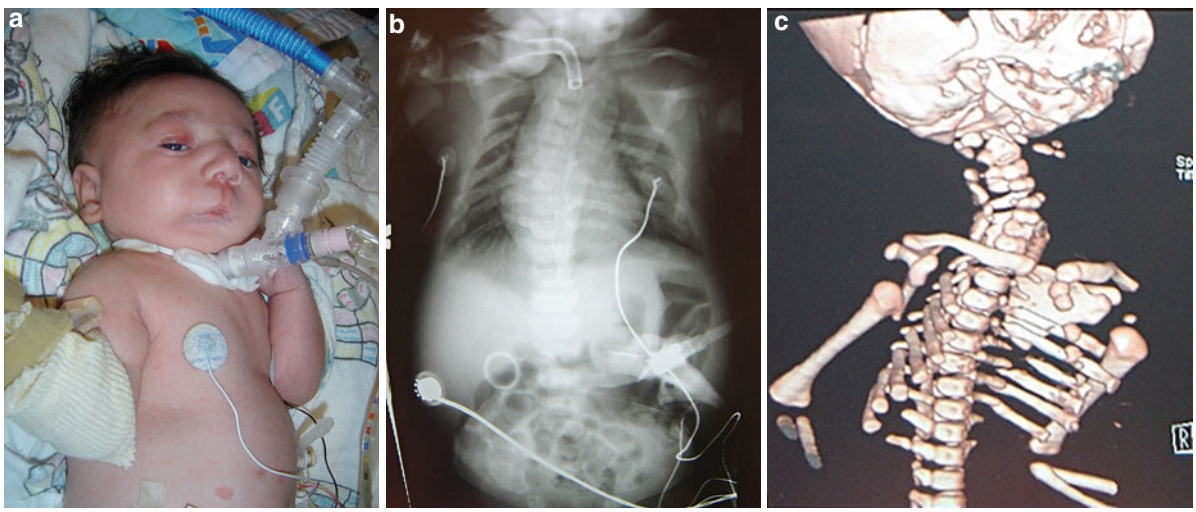

Fig. 3 (**a**–**c**) A neonate presented with severe respiratory distress, requiring tracheostomy. He has severe retromicrognathia and a small chest. Radiographs showed malformations of the ribs with multiple gaps and segmentation defects. A 3-D CT showed variable gaps in the posterior ribs and absence of several ribs

Charcot–Marie–Tooth Disease

Charcot–Marie–Tooth (CMT) disease is the most common inherited peripheral neuropathy. It is a pathologically heterogeneous group of hereditary motor and sensory neuropathies (HMSN), characterized by slowly progressive weakness and atrophy, primarily in the distal leg muscles. The incidence is estimated to be approximately 1 in 2,500.

Synonyms and Related Disorders

Hereditary motor and sensory neuropathy

Genetics/Basic Defects

1. Charcot–Marie–Tooth disease type 1 (CMT1) (Barisic et al. 2008; Bird 2009; Pareyson and Marchesi 2009; Szigeti and Lupski 2009)
   a. Also called hereditary motor and sensory neuropathy type I (HMSN I)
   b. The most common subtype (accounting for about 50% of CMT)
   c. A demyelinating neuropathy
   d. Autosomal dominant-demyelinating form
      i. CMT1A (90% of CMT1 patients): caused by *PMP22* duplication or point mutations (17p11.2–12)
      ii. CMT1B (5–10%): caused by mutations of the myelin protein zero (*MPZ*/*PO*) gene (1q22)
      iii. CMT1C: caused by mutations of *SIMPLE*/*LITAF* gene (16p13.1–p12.3)
      iv. CMT1D: caused by mutations of early growth response gene 2 (*EGR2*) gene (10q21.1–q22.1)
      v. CMT1E: *PMP22* (17p11.2)
      vi. CMT1F: *NEFL* gene (8p21)
2. Charcot–Marie–Tooth disease type 2 (CMT2)
   a. Also called hereditary motor and sensory neuropathy type II (HMSN II)
   b. An axonal neuropathy
   c. Accounting for 20–40% of CMT
   d. Autosomal dominant-axonal form: disease gene loci
      i. CMT2A1: *KIF1B* (1p36.2)
      ii. CMT2A2: *MFN2* (1p33–p36)
      iii. CMT2B: RAB7 (3q21)
      iv. CMT2C: unknown (12q23–q24)
      v. CMT2D: *GARS* (7p15)
      vi. CMT2E: *NEFL* (8p21)
      vii. CMT2F: *HSPB1* (*HSP27*) (7q11–q21)
      viii. CMT2G: unknown (12q12–q13.3)
      ix. CMT2H/K: *GDAP1* (8q13–q21.1)
      x. CMT2I/J: *MPZ* (1q22–q23)
      xi. CMT2L: *HSPB8*/*HSP22* (12q24.3)
   e. Autosomal recessive-axonal form CMT
      i. CMT2B1: *LMNA* (1q21.2)
      ii. CMT2B2: *Med25* (19q13.3)
      iii. CMT2H/2 K: *GDAP1* (8q13–q21.1)
3. Intermediate form of autosomal dominant CMT (rare)
   a. DI-CMTA: unknown (10q24.1–q25.1)
   b. DI-CMTB: *DNM2* (19p12–p13.2)
   c. DI-CMTC: *YARS* (1p34–p35)
   d. DI-CMTD: *MPZ* (1q22)

4. Autosomal recessive-demyelinating form of CMT4
   a. CMT4A: The first locus identified: 8q13–q21.1 (corresponding gene, *GDAP1*)
   b. CMT4B1: *MTMR2* (11q22)
   c. CMT4B2: *MTMR13/SBF2* (11p15)
   d. CMT4C: *KIAA1985/SH3TC2* (5q32)
   e. CMT4D (HSMN-Lom): *NDRG1* (8q24.3)
   f. CMT4E: *EGR2* (10q21.1–q22, 17p)
   g. CMT4F: *PRX* (19q13.1–q13.2)
   h. CMT4G: unknown (10q23.2)
   i. CMT4H: *FGD4* (12p11.21–q13.11)
   j. CMT4J: *FIG4* (6q21)
5. Autosomal recessive-axonal form of CMT4
   a. CMT4C1 (AR CMT2B1): lamin A/C (1q21.2–q21.3)
   b. CMT4C2 (AR-CMT2C or AR-CMT2H): unknown (8q21.3)
   c. CMT4C3 (AR-CMT2B2): *ARC92/ACID1* (MED25) (19q13.3)
   d. CMT4C4 (AR-CMT2K): *GDAP1* (8q13–q21.1)
6. X-linked dominant form of CMT (CMT1X): accounting for 10–20% of CMT (the second most common form of inherited demyelinating neuropathy, next to CMT1A)
   a. CMTX1: caused by mutations in the gene for the gap junction protein 1 (*GJB1*) or connexin 32 (*Cx32*) on Xq13.1
   b. CMT3A(Dejerine– Sottas syndrome): PMP-32 (17p11.2–12)
      i. Also called hereditary motor and sensory neuropathy type III (HMSN III).
      ii. A severe demyelinating neuropathy.
      iii. Autosomal dominant new mutations (*PMP22* mutations).
      iv. Clinical symptoms overlapping with CMT1: These two disorders may represent a spectrum of related clinical phenotypes that can arise from allelic missense point mutations in the *PMP22* gene.
      v. Allelic mutations in the *MPZ* gene similarly identified in sporadic patients with DSS, also implying that CMT type 1 and DSS constitute a spectrum of peripheral neuropathy phenotypes with common genetic bases.
   c. CMT3B: *MPZ* (1q22–q23)
   d. CMT3C: unknown (8q23–q24)
   e. DSS-EGR: *EGR2* (10q21–q22)
   f. CMT3D or CMT4F: *periaxin* (19q13.1–q13.2)
7. X-linked recessive form of CMT
   a. CMTX2: unknown (Xp22.2)
   b. CMTX3: unknown (Xq26.3–q27.1)
   c. CMTX4 (Cowchock syndrome): unknown (Xq24–q26.1)
   d. CMTX5: unknown (Xq22.3)
8. Autosomal dominant-distal hereditary motor neuropathy (HMN) form of CMT
   a. Distal HMN I: unknown (7q34–q36)
   b. Distal HMN II: *HSP22*, *HSP27* (12q24.3, 7q11–q21)
   c. Distal HMN V (HMN 5A): *GARS* (7p15)
   d. Distal HMN V (Silver syndrome, HMN 5B): *BSCL2* (11q12–q14)
   e. Distal HMN VII A: unknown (2q14)
   f. Distal HMN VII B: *DCTN1* (2p13)
   g. Distal HMN ALS4: *SETX* (9q34)
9. Autosomal recessive-distal HMN form of CMT
   a. Distal HMN III: unknown (11q13)
   b. Distal HMN IV: unknown (11q13)
   c. Distal HMN VI : *IGHMBP2* (11q13.2–q13.4)
   d. Distal HMN-Jerash: unknown (9p21.1–p12)
10. Autosomal dominant-hereditary sensory and autonomic neuropathy (HSAN)
    a. HSAN I: *SPTLC1* (9q22.1–q22.3)
    b. HSAN 1B associated with cough and gastroesophageal reflux: unknown (3p22–p24)
11. Autosomal recessive–HSAN form
    a. HSAN II: *HSN2* (12p13.33)
    b. HSAN III (Riley–Day syndrome): *IKBKAP* (9q31)
    c. HSAN IV: *TRKA/NGF* (1q21–q22)
    d. HSAN V: *TRKA/NGF* (1q21–q22), *NGFβ* (1p13.2–p11.2)
    e. HSAN with deafness and global delay: unknown
    f. HSAN with spastic paraplegia: unknown (5q15.31–q14.1)
    g. X-linked HSAN associated with deafness: unknown (Xq23–q27.3)
12. Problems in classification of inherited neuropathies
    a. *PMP22* deletion causes HNPP.
    b. PMP22 duplication causes CMT1A.
    c. Deletion and duplication of *PMP22* causes HNPP and CMT1A, respectively, establishing a singular genetic mechanism as the cause of the two most common inherited neuropathies.

d. *PMP22* mutations cause DSS, CMT1A, and HNPP.
e. *MPZ* mutations cause DSS, CMT1B, and a CMT2-like phenotype.
f. *GJB1* mutations cause CMT1X.
g. *EGR2* mutations cause CMT1 and DSS.

Clinical Features

1. Family history (Jani-Acsadi et al. 2008)
   a. Autosomal dominant
      i. Multiple generations affected
      ii. Male-to-male transmission
      iii. Females and males affected
   b. Sporadic: only one member in the family affected
   c. Autosomal recessive
      i. Consanguinity
      ii. Multiple children affected
      iii. Parents unaffected
   d. X-linked
      i. No male-to-male transmission
      ii. Males may be more severely affected than females
2. Clinical phenotype of all forms of CMT
   a. Generally similar
   b. Clinical presentation with distal leg weakness and atrophy
   c. Followed by hand involvement
3. Presence of a wide range of variation and severity of symptoms in the affected areas and in the rate of progression of symptoms
4. CMT1A
   a. Accounting for 90% of CMT1 patients
   b. A wide range of variation in clinical presentation and severity among affected members of large families with CMT1A
   c. CMT1A *PMP22* duplication
      i. Asymptomatic patients
         a) Observed in some family members in large pedigrees
         b) No symptoms
         c) Normal neurologic examination including ability to walk on their heels and normal stretch reflexes
         d) Slow MNCV
         e) Duplication of *PMP22* confirming the diagnosis of CMT1A
      ii. Symptomatic patients
         a) Onset: first decade or early in the second decade
         b) Presenting symptoms in infants and children: walking on their toes and have severe tightness of the heel cord
         c) Occasional patients born with foot deformities including clubfeet
         d) Other symptoms: abnormal gait, foot deformities, or loss of balance
         e) Muscle weakness starting in the feet and legs
         f) Frequently trip over objects on the floor and sprain ankles as a result of weakness of the dorsiflexor muscles of the feet, innervated by the peroneal nerves
         g) Difficulty or inability to walk on heels
         h) Tight heel cords
         i) Foot drops with each step, forcing the patient to flex the hip, giving the steppage or equine gait
         j) Pes cavus deformity developing with age
         k) Atrophy of the legs, due to wasting of the peroneal muscles giving the stork legs or "inverted champagne bottle" appearance
         l) Weakness of the intrinsic hand muscles usually occurring late in the course of the disease
         m) Claw hands
         n) Mild sensory loss to pricking pain in the legs in some patients
         o) Frequently decreased vibratory sense
      iii. Associated symptoms
         a) Enlarged (auricular, ulnar, and peroneal) nerves in 20–25% of the patients, not related to the age of the patient or the severity of the disease.
         b) Tremor in 40% of the patients.
         c) Hip dysplasia with hip pain and a limp.
         d) Restrictive lung disease usually not a major problem in patients with CMT1.
         e) Other associated features: spastic paraparesis, deafness, optic atrophy, Marfan-like appearance, and absence of eyebrows.

f) Exacerbation of the weakness in 50% of the patients with early-onset disease during pregnancy and delivery.
g) Certain medication and neurotoxic substances may aggravate the neuropathy in patients with CMT.

d. CMT1A point mutations in *PMP22*
i. Show severe disease in childhood
ii. Found in patients that have been diagnosed with the Dejerine–Sottas syndrome

5. CMT1B
a. Accounting for less than 10% of CMT1 patients
b. *MPZ* mutations identified in CMT1B, DDS, or congenital hypomyelination phenotype
c. Differentiating from CMT1A
i. An earlier onset of the symptoms manifested by delayed ability to walk
ii. Proximal leg weakness without decreasing ambulation
iii. Slower motor NCVs

6. CMT2
a. Neuronal type (a progressive peripheral motor and sensory neuropathy)
b. Clinical phenotype similar to the type 1 CMT
i. Symptoms
a) Tingling
b) Numb feeling
c) Pain
d) Muscle cramp
e) Loss of muscle strength: distal weakness with feet involvement first
f) Walking instability
g) Increased loss of strength
h) Increased sensory loss
ii. Signs
a) Atrophied hands
b) Atrophied legs
c) Postural tremors
d) Fasciculations
e) Pes cavus
f) Claw toes
g) Steppage gait
h) Leg atrophy
i) Short calf muscles
j) Abnormal Romberg sign
k) Absent biceps, triceps, knee, and ankle jerks

c. Other characteristics
i. Generally a later onset of the symptoms than seen in type 1
ii. Pes cavus and short calf muscles: predominantly present in patients with early-onset disease
iii. Less involvement of the hand muscles
iv. No clinical evidence of palpable enlarged nerves
v. No sensory deterioration
vi. Normal or slightly diminished motor nerve conduction velocities

7. Autosomal recessive CMT (CMT4)
a. Progressive motor and sensory neuropathy
b. Rare heterogeneous forms with a broad spectrum of clinical severity
c. Presentation of symptoms in infancy by delay in walking
d. Early and rapidly progressive deformities of the feet and spine
e. A high incidence of associated features such as sensorineural hearing loss
f. Weakness beginning in the feet but affecting both distal and proximal muscles
g. No enlargement of superficial nerves
h. Presence of three pathologic forms

8. X-linked CMT (CMTX)
a. Inheritance
i. Dominant form in 90% of cases
ii. Recessive form in 10% of cases
b. A disease-causing mutation and a family pedigree consistent with X-linked dominant inheritance
i. Presence of a disease-causing mutation in the *GJB1* (*Cx32*) gene
ii. Lack male-to-male transmission
c. Males and females with peripheral motor and sensory neuropathy
i. Affected males
a) More severe phenotype than the affected females
b) More severe progressive peripheral motor and sensory neuropathy than that seen in CMT1A
c) Moderately slow median nerve MNCV: 34.5 +/− 6.2 m/s
d) Reduced motor and sensory nerve amplitudes (median nerve CMAP): 3.7 +/− 3.7 mV

ii. Affected females
a) Normal, or mild to moderate signs and symptoms
b) Moderately slow MNCV: 45.8 +/− 7.3 m/s
c) Reduced motor and sensory nerve amplitudes (median nerve CMAP): 7.8 +/− 3.4 mV

d. Signs and symptoms
i. Typical presenting symptom: weakness of the feet and ankles
ii. Initial physical findings: depressed or absent tendon reflexes with weakness of foot dorsiflexion at the ankle
iii. Typical adult patients
a) Bilateral foot drop
b) Symmetrical atrophy of muscles below the knee with stork leg appearance
c) Pes cavus
d) Atrophy of intrinsic hand muscles especially the thenar muscles of the thumb
e) Absent tendon reflexes in both upper and lower extremities
f) Proximal muscles usually remaining strong
g) Mild to moderate sensory loss (deficits of position, vibration, and pain/temperature) commonly occurring in the feet

e. Other characteristics
i. Symptoms typically develop between ages 5 and 25 years
ii. Onset commonly within the first decade in males
iii. Earlier onset with delayed walking in infancy as well as later onset beyond the fourth decades possible
iv. Mild symptoms may be overlooked by patient and physician.
v. Severe motor slowing in most families, consistent with a demyelinating form of the disease
vi. A predominant axonal type also been described

9. Dejerine–Sottas syndrome (DSS)
a. The syndrome still used to define the rare cases of severe hypo-demyelinating neuropathy of early onset
b. Criteria for diagnosis
i. Early onset of the disease by age 2 years with delayed motor milestones.
ii. Severe motor, sensory, and skeletal muscle deficits, frequently extending to proximal muscles. Sensory ataxia and scoliosis also present.
iii. Very low conduction velocities, usually <12 m/s.
iv. Nerve biopsy reveals severe hypomyelination and basal lamina reduplication, with multiple onion bulb formation.
v. Presence of the enlarged nerves
c. De novo point mutations in either *MPZ* or *PMP22* found in most DSS cases
d. May be a variant of CMT1A or CMT1B

10. Congenital hypomyelination (CH)
a. An ill-defined and extremely rare disease merging into Dejerine–Sottas disease.
b. A clinical syndrome characterized by infantile hypotonia due to distal muscle weakness is flexia and very slow NCVs. Severe weakness may lead to early death.
c. Severe contractures of joints or arthrogryposis multiplex congenita in severe cases.
d. Mutation analysis showing *MPZ* mutations, suggesting some of the DSS and CH are part of a spectrum of the demyelinating form of CMT1B.

11. Hereditary neuropathy with liability to pressure palsies (HNPP)
a. Also called familial recurrent polyneuropathy or tomaculous neuropathy
b. Clinical manifestations
i. Periodic/transient/recurrent episodes of numbness, muscular weakness, and atrophy
ii. Palsies after relatively minor compression or trauma of the peripheral nerves (the axillary, median, radial, ulnar, and peroneal nerves)
c. Nerve conduction abnormalities mainly localized at common entrapment sites
d. Nerve biopsy: occurrence of focal myelin thickenings (tomacula) in several fibers
e. Commonly associated with deletion of *PMP22* gene

Diagnostic Investigations

1. Two types of CMT, currently distinguishable by the value of motor nerve conduction velocity (MNCV) of median nerve on electrophysiologic examination and nerve biopsy findings
   a. Demyelinating form (CMT1)
      i. Slowing of MNCV (15–30 m/s)
      ii. Hypertrophy of peripheral nerves with onion bulb formation and segmental demyelination
   b. Axonal form (CMT2)
      i. Normal or mildly slow MNCV (>40 m/s)
      ii. Normal size nerves
      iii. No evidence of segmental demyelinations
2. Motor nerve conduction velocity of the median nerve (MNCV)
   a. Uniform conduction slowing
      i. CMT1A
      ii. CMT1B
      iii. CMT4
      iv. Dejerine–Sottas syndrome
   b. Multifocal conduction slowing
      i. CMTX
      ii. Hereditary neuropathy with liability to pressure palsies (HNPP)
   c. Incompletely characterized electrophysiology
      i. *PMP22* point mutations
      ii. *MPZ* point mutation
      iii. *EGR2* mutations
   d. Usually normal in CMT2
3. EMG testing: evidence of an axonal neuropathy in CMT2
   a. Positive waves
   b. Polyphasic potentials
   c. Fibrillations
   d. Reduced amplitudes of evoked motor and sensory responses
4. Compound motor action potentials (CMAP): greatly reduced in CMT2
5. Nerve biopsy
   a. CMT1A
      i. Regression of onion bulb
      ii. Significantly increased ratio of axon diameter/total fiber diameter, indicating arrested remyelination
   b. CMT1B
      i. Demyelinating process with onion bulb formation (sural nerve biopsy).
      ii. Ultrastructural finding of uncompacted myelin is consistent with the accepted function P_o as a homophilic adhesion molecule.
   c. CMT2
      i. No histological evidence of well-formed onion bulbs on the nerve biopsies
      ii. Loss of myelinated fibers with signs of regeneration, axonal sprouting, and atrophic axons with neurofilaments
   d. Autosomal recessive-demyelinating CMT with three pathologic forms:
      i. Classical onion bulbs
      ii. Basal laminar onion bulbs
      iii. Focally folded myelin sheaths
   e. CMTX
      i. Nerve hypertrophy or onion bulb formation: rare
      ii. A primary axonal neuropathy with axonal sprouting in most affected individuals
      iii. Prominent demyelination consistent with a CMT1 phenotype in some cases
   f. Congenital hypomyelination: hypomyelination (few thin myelin lamella) without active myelin breakdown products and early onion bulb formations
   g. Hereditary neuropathy with liability to pressure palsies (HNPP): demyelination and remyelination with tomacula or sausage-like thickening on the myelin sheath
6. Molecular genetic testing
   a. CMT1
      i. CMT1A
         a) Sequence analysis for point mutations in the *PMP22* gene
         b) Mutation scanning for point mutations in the *PMP22* gene
      ii. CMT1B
         a) Sequence analysis for point mutations in the *MPZ* gene
         b) Mutation scanning for point mutations in the *MPZ* gene
      iii. CMT1C: direct DNA/linkage analysis for point mutation in *LITAF*
      iv. CMT1D
         a) Sequence analysis for point mutations in the *EGR2* gene
         b) Mutation scanning for point mutations in the *EGR2* gene

b. CMT2E: sequence analysis for mutations in *NEFL*
c. CMT4
   i. CMT4E: molecular genetic testing for *EGR2*
   ii. CMT4F: molecular genetic testing for *PRX*
d. CMTX: sequence analysis to detect mutations in the *GJB1* coding region (accounting for about 90% of mutations in patients with CMTX)
e. Molecular genetic testing approach
   i. In cases of HNPP
      a) Test for the *PMP22* deletion (since this is by far the major cause)
      b) If negative, then sequence *PMP22*
   ii. In CMT patients with uniform slowing of motor NCVs between 10 and 35 ms
      a) Test for the *PMP22* duplication (since this is the major cause of CMT1)
      b) If negative, sequence *PMP22*, *MPZ*, *GJB1*, and *EGR2*
   iii. In DSS with appropriately slowed NCVs
      a) Test for the duplication: usually negative
      b) Sequence *PMP22*, *MPZ*, *GJB1*, *EGR2*, and *PRX* genes
   iv. In cases where CMT1X is the most likely diagnosis (based on intermediate slowing of NCVs, no male-to-male transmission)
      a) Sequence *GJB1* alone: the appropriate initial test
      b) If negative, sequence *MPZ* and *NEFL*
   v. In cases of suspected CMT2
      a) Probably premature to test for *MPZ* and *NFEL* mutations alone (the only commercially available tests)
      b) Await a comprehensive battery in the future

Genetic Counseling

1. Recurrence risk (Bird 2009)
   a. Patient's sib
      i. Autosomal dominant CMT
         a) Majority of CMT1 patients carry the *PMP22* duplication and represent de novo mutation cases: recurrence risk to sib not increased unless a parent is affected, in which case the recurrence risk is 50%
         b) Patients with de novo *MPZ* mutation: recurrence risk to sibs not increased unless a parent is affected, in which case the recurrence risk is 50%
      ii. Autosomal recessive CMT: 25%
      iii. X-linked dominant CMT (patients with Cx32 mutation)
         a) A carrier mother has a 50% risk of transmitting the disease-causing mutation with each pregnancy. Sons who inherit the mutation will be affected. Daughters who inherit the mutation will be carriers and may or may not be affected.
         b) A noncarrier mother: recurrence risk to sibs low but not zero since the risk of germ-line mosaicism in mothers is not known.
   b. Patient's offspring
      i. Autosomal dominant CMT: Patients with *PMP22* duplication, *PMP22* deletion, or *MPZ* mutation will have a 50% risk of transmitting the disease to the offspring.
      ii. Autosomal recessive CMT: not increased unless the spouse is a carrier or affected.
      iii. X-linked dominant CMT (patients with Cx32 mutation)
         a) All the daughters of an affected male inherit the mutation but may or may not have symptoms.
         b) None of his sons will be affected.
2. Prenatal diagnosis available to pregnancies at risk for CMT1A, CMT1B, CMT2E, CMT4E, CMT4F, and CMTX
   a. Identify the disease-causing allele of an affected family member before prenatal diagnosis
   b. Mutation analysis of fetal DNA obtained from amniocentesis or CVS
   c. CMT1
      i. Prenatal diagnosis of CMT1A by FISH
         a) Parental blood samples confirmed to be duplicated for *PMP22* by FISH
         b) Interphase FISH assay performed on amniotic fluid specimens and chorionic villus samples to detect a submicroscopic 17p12 duplication in the fetus with CMT1A
      ii. Preimplantation diagnosis for CMT1A: selection of healthy embryos is made based on the presence of the nonduplicated haplotype and heterozygosity of a marker

d. CMT2E: molecular genetic testing of DNA extracted from fetal cells obtained from amniocentesis or CVS for testing of *NEFL* mutation when both disease-causing alleles of an affected family member are identified
e. CMT4E and CMT4F: molecular genetic testing of DNA extracted from fetal cells obtained by amniocentesis or CVS for testing of *EGR2* and *PRX* mutations, respectively, when both disease-causing alleles of an affected family member are identified
f. CMTX
   i. Prenatal diagnosis available to pregnancies of women who are heterozygotes for a disease-causing *GJB1* mutation that has been identified in an affected family member
   ii. Amniocentesis or CVS
      a) Determination of the fetal sex
      b) DNA extracted from cells from male fetuses tested to determine if a disease-causing mutation is present

3. Management
   a. No specific treatment to reverse or slow the natural disease process
   b. Supportive care (Jani-Acsadi et al. 2008)
      i. Musculoskeletal dysfunctions: scoliosis, foot deformities, and hand atrophy
         a) Evaluation by physiatry
         b) Physical therapy
         c) Occupational therapy
         d) Orthotics and assistive devices
         e) Corrective surgery
      ii. Respiratory dysfunction
         a) Pulmonary evaluation
         b) Continuous positive airway pressure (CPAP)
         c) Bi-level positive airway pressure (BiPAP)
         d) Scoliosis correction
      iii. Sensory dysfunction
         a) Pain control
         b) Topical medications (lidocaine patch)
         c) Antidepressants: tricyclics (amitriptyline, nortriptyline, desipramine)
         d) Anticonvulsants: gabapentin, pregabalin
         e) Lamotrigine, carbamazepine
      iv. Iatrogenic neurology
         a) Avoid medications that are known to cause nerve damage: chemotherapeutic drugs (vincristine, cis-platinum, mivacurium), Taxol, cisplatin, isoniazid, and nitrofurantoin
         b) Refer to CMTA Web site regarding updated lists of medication (www.charcot-marie-tooth.org)

Fig. 1 (**a**, **b**) Two patients with Charcot–Marie–Tooth disease showing stork-like legs and pes cavus deformities

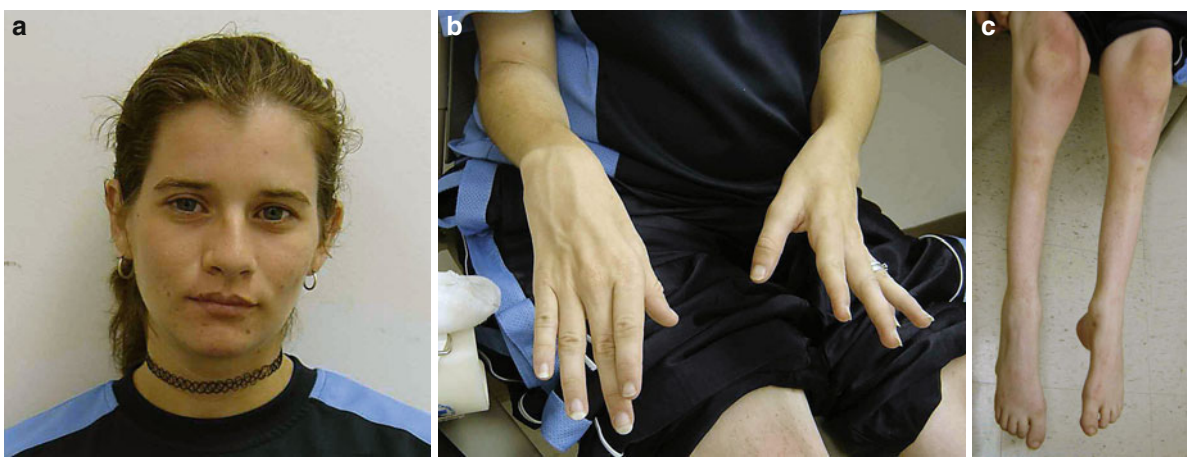

Fig. 2 (**a**–**c**) A 23-year-old female with Charcot–Marie–Tooth disease showing stork legs with muscle wasting, pes cavus deformities, and foot drop. She has absent deep tendon reflexes. Her onset of disease began in the third grade with a history of tripping, falling, and clumsiness. Family history revealed affected individuals in three generation

Fig. 3 An 11-year-old girl was evaluated for "stork-like legs." She was noted to have loss of balance, tip-toe walking, and muscle weakness, particularly in her lower extremities. On examination, she was noted to have claw hands (finger contractures at PIP), "stork-like" legs, muscle weakness in the lower extremities, tight heel cord, pes cavus, and absent deep tendon reflexes. The motor nerve and sensory nerve conduction tests showed severe prolonged latency and severe reduced amplitude. The left median, radial, tibial, and peroneal motors, median, ulnar, radial, and sural sensories were absent. The study showed electrophysiologic evidence of a severe sensorimotor polyneuropathy. A complete CMT molecular evaluation showed her to possess one known recessively inherited mutation in the *GDAP1* gene and one or more DNA variants of unknown significance

Fig. 4 A 26-year-old mother was diagnosed to have Charcot–Marie–Tooth disease type 1A at 15 years of age with complaints of weakness and pain in the arms, shoulders, hips, and neck and had a slight decrease in the pulmonary function test. Her DNA testing showed duplication of peripheral myelin protein n*PM-22*) gene, inherited from her father. The 5-month-old daughter is asymptomatic and carries no *PMP22* gene mutation

Fig. 5 A 31-year-old man with Charcot–Marie–Tooth disease type 1A, confirmed molecularly to have *PMP22* gene mutation associated with 17p12 microduplication. A son died at 3 month of age of ACTA1-related nemaline myopathy. The baby's chromosome microarray analysis showed 17p12 and 16q23.1 microduplications. Duplication of *PMP22* gene on 17p12 is associated with Charcot–Marie–Tooth disease type 1A. The clinical significance of 16q23.1 is unclear

CHARGE Syndrome

CHARGE syndrome is a genetic disorder characterized by a specific and a recognizable pattern of anomalies, namely, *C*oloboma, *H*eart defects, *A*tresia of choana, *R*etardation of growth and/or development, *G*enitourinary defects, and *E*ar anomalies and/or deafness. The pattern of anomalies associated with CHARGE syndrome was described independently by Hall and Hittner et al. in 1979. However, the acronym "CHARGE association" was coined by Pagon in 1981. At present, with its recognizable pattern and definition CHARGE is referred to as a syndrome (Pampal 2010; Zentner et al. 2010). The prevalence is estimated to be approximately 1 in 10,000 (Jongmans et al. 2006; Lalani et al. 2006).

Synonyms and Related Disorders

Coloboma, heart defects, atresia of choana, retardation of growth and/or development, genitourinary defects, and ear anomalies and/or deafness

Genetics/Basic Defects

1. Sporadic in almost all cases (Zentner et al. 2010)
2. Familial in a small number of cases with parent-to-child transmission of *CHD7* mutations (Lalani et al. 2006; Delahaye et al. 2007; Jongmans et al. 2008; Vuorela et al. 2008; Wincent et al. 2008; Pauli et al. 2009)
   a. Parents generally have a mild CHARGE phenotype or are asymptomatic
   b. Their children display more severe defects (a full spectrum of CHARGE features)
   c. Somatic mosaicism for a CHD7 mutations has been described in an asymptomatic mother of two affected siblings (Jongmans et al. 2008)
   d. Germ-cell mosaicism has also been described in an asymptomatic father of two affected children (Pauli et al. 2009)
3. Cause: De novo mutations in the gene encoding chromodomain helicase DNA binding protein 7 (*CHD7*), located on chromosome 8q12.1, are the major cause of CHARGE syndrome.
4. Individuals with *CHD7* mutations: more commonly have the following findings compared to those without the mutations:
   a. Ocular colobomas
   b. Temporal bone anomalies (semicircular canal hypoplasia/dysplasia)
   c. Facial nerve paralysis
5. Pathogenetic mechanism: Haploinsufficiency for *CHD7* is the most likely pathogenic mechanism underlying CHARGE syndrome:
   a. Nonsense or frameshift mutations: majority of *CHD7* disruptions
   b. Chromosomal abnormalities
      i. Interstitial deletion of 8q12.2-q13 (Arrington et al. 2005)
      ii. A balanced translocation disrupting 8q12 (Johnson et al. 2006)
      iii. Several chromosomal abnormalities not involving CHD7 have been reported to confer a phenotype similar to those seen in CHARGE patients (Clementi et al. 1991; North et al. 1995; Wieczorek et al. 1997; De Krijger et al. 1999; Lev et al. 2000)
   c. Recently, CHARGE patients without detectable single-base mutation were found to have

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_38,
© Springer Science+Business Media, LLC 2012

heterozygous deletions of CHD7 (Wincent et al. 2009). In fact, CHD7 deletion was originally detected by array-CGH (Vissers et al. 2004). Alterations in copy number have been reported but represent only a small fraction of the reported disruptions of CHD7 (Bergman et al. 2008).

d. Other conditions with CHD7 mutations having significant clinical overlap with CHARGE syndrome
   i. Kallmann syndrome (Ogata et al. 2006; Kim et al. 2008; Jongmans et al. 2009)
   ii. Omen-like syndrome (Gennery et al. 2008)
   iii. 22q11.2 deletion syndrome (Sanka et al. 2007)

Clinical Features

1. Major criteria
   a. Eye anomalies
      i. *C*oloboma (80–90%) of the iris, choroid disc, and optic nerve
      ii. Microphthalmia/anophthalmia
      iii. Secondary retinal detachments and cataracts
      iv. Total or partial vision loss
      v. Superior palpebral ptosis, epicanthus, and telecanthus
   b. Choanal *A*tresia (50–60%)
   c. *E*ar anomalies/deafness (90%)
      i. External ears
         a) Asymmetry
         b) Posteriorly rotated
         c) Dystopia
         d) Prominent
         e) Increased width
         f) Decreased height
         g) Cup-shaped
         h) "Snipped-off" helical fold
         i) Prominent antihelix discontinuous with the antitragus
         j) Triangular concha
         k) Small or absent lobes
      ii. Middle ears
         a) Chronic serous otitis media approaching 100%
         b) Eustachian tube anomalies associated with choanal atresia or palatal cleft
         c) Ossicular malformations
         d) Conductive hearing loss
      iii. Inner ears
         a) Cochlear defects
         b) Sensorineural hearing loss
      iv. Temporal bone malformations
   d. Cranial nerve dysfunction (70–90%)
      i. Cranial nerve I: anosmia
      ii. Cranial nerve II: unilateral or bilateral facial palsy
      iii. Cranial nerve VIII: sensorineural deafness and vestibular problems
      iv. Cranial nerves IX and/or X: velopharyngeal incoordination and swallowing problems
2. Minor criteria
   a. *H*eart disease (cardiovascular malformations) (75–85%)
      i. Conotruncal defects (e.g., tetralogy of Fallot)
      ii. AV canal defects
      iii. Aortic arch anomalies
      iv. Others
         a) Double outlet right ventricle
         b) Hypoplastic left/right heart
   b. Growth and mental *R*etardation (70–100%)
      i. Growth deficiency
      ii. Short stature
      iii. Delayed motor milestones
      iv. Hypotonia
      v. Mental retardation
   c. *G*enital anomaly (70–80%)
      i. Hypogonadotropic hypogonadism and delayed puberty
      ii. Males: micropenis, cryptorchidism, delayed/incomplete pubertal development
      iii. Females: hypoplastic labia, delayed/incomplete pubertal development
   d. Orofacial cleft
      i. Cleft lip/palate (15–20%)
      ii. Laryngeal cleft
   e. Tracheoesophageal fistula/esophageal atresia (15–20%)
   f. Distinctive face (70–80%)
      i. Broad forehead
      ii. Square face
      iii. Facial asymmetry
      iv. Ptosis
      v. Arched eyebrows
      vi. Shallow supraorbital ridges
      vii. Iris coloboma
      viii. High nasal bridge
      ix. Full nasal tip

x. Microretrognathia
xi. Cleft lip/palate
xii. Laterally protruding ears
xiii. Prognathism, prominent mandibular mentum, and generalized facial narrowing with advancing age
xiv. Occasional broad or webbed neck with sloping shoulders

3. Occasional findings
   a. Thymic/parathyroid hypoplasia: DiGeorge sequence without chromosome 22q11 deletion (rare)
   b. Renal anomalies (15–25%)
      i. Dysgenesis
      ii. Horseshoe/ectopic kidney
      iii. Hydronephrosis
   c. Hand anomalies
      i. Polydactyly, ectrodactyly, thumb hypoplasia (rare)
      ii. Altered palmar flexion creases (50%)
   d. General appearance
      i. Webbed neck (rare)
      ii. Sloping shoulders (occasional)
      iii. Accessory or hypoplastic nipples (rare)
   e. Abdominal defects
      i. Omphalocele (rare)
      ii. Umbilical hernia (15%)
   f. Spine anomalies (rare)
      i. Scoliosis
      ii. Hemivertebrae
   g. CNS malformations
      i. Midline defects (corpus callosum agenesis, arhinencephaly, septal agenesis, meningoencephalocele, partial vermis agenesis) (22%)
      ii. Asymmetry (cerebral, ventricular, cerebellar) (18%)
      iii. Hindbrain anomalies (brain stem hypotrophy demonstrated by CT scan or MRI, vermian agenesis) (14%)
4. Different diagnostic criteria for CHARGE syndrome (Sanlaville and Verloes 2007; Pampal 2010)
   a. Clinical criteria (Pagon et al. 1981): presence of four criteria out of six, and at least one major
      i. Major criteria
         a) Choanal atresia
         b) Ocular coloboma
      ii. Minor criteria
         a) Heart defects of any type
         b) Retardation (of growth and/or of development)
         c) Genital anomalies
         d) Ear anomalies (abnormal pinnae or hearing loss)
   b. Diagnosis criteria of CHARGE (Verloes 2005): typical CHARGE (presence of either all three major signs or two major signs with two minor signs); partial CHARGE (two majors plus one minor); and atypical CHARGE (two majors but no minors or one major plus two minors)
      i. Major signs
         a) Ocular coloboma
         b) Choanal atresia
         c) Hypoplastic semicircular canals
      ii. Minor signs
         a) Rhomboencephalic dysfunction (brain stem and cranial nerve III–XII anomalies, including sensorineural deafness)
         b) Hypothalamo-hypophyseal dysfunction (including growth hormone and gonadotrophin defects)
         c) Mental retardation
         d) Malformation of mediastinal organs (heart, esophagus)
         e) External or middle ear malformations
   c. Diagnostic criteria of CHARGE (Blake and Prasad 2006): presence of either all four major signs or three major signs plus three minor signs
      i. Major signs (classical four Cs)
         a) Coloboma (of iris, retina, choroid, disc; microphthalmia)
         b) Choanal atresia/stenosis (unilateral or bilateral, membranous or bony)
         c) Cranial nerve dysfunction: facial palsy (unilateral or bilateral), sensorineural deafness and/or swallowing problems
         d) Characteristic ear anomalies: external ear (lop or cup-shaped); middle ear (ossicular malformations, chronic serous otitis), mixed deafness, cochlear defects
      ii. Minor signs
         a) Characteristic CHARGE facies (sloping forehead, flattened nasal tip)
         b) Orofacial cleft (cleft lip and/or palate)
         c) Cardiovascular malformations: all types, especially conotruncal defects (e.g., tetralogy of Fallot), AV canal defects, and aortic arch
         d) Tracheoesophageal fistula: all types

e) Genital hypoplasia: males (micropenis, cryptorchidism); females (hypoplastic labia); both males and females (delayed, incomplete pubertal development)
f) Developmental delay: delayed motor milestones, language delay, mental retardation
g) Growth deficiency: short stature, growth hormone deficiency

iii. Occasional signs
a) Renal anomalies: duplex system, vesicoureteric reflux
b) Spinal anomalies: scoliosis, osteoporosis
c) Neck/shoulder anomalies: sloping, Sprengel deformity, kyphosis
d) Hand anomalies: fifth finger clinodactyly, camptodactyly, cutaneous syndactyly

d. Another major diagnostic criteria by Amiel et al. (2001): emphasized the importance of temporal bone imaging in the diagnosis of the disease along with characteristic clinical findings

Diagnostic Investigations

1. Audiology, tympanometry, BAER, and CT of temporal bones for evaluation of hearing loss (Blake and Prasad 2006)
2. Visual analysis and electroretinogram and functional vision testing: to identify and document severity of visual loss
3. Dilated fundoscopic exam for colobomas
4. Nasal pharyngeal feeding tube passage and CT scan of upper airway for evaluation of choanal atresia
5. Blood urea nitrogen, creatinine, electrolytes, and calcium: to evaluate renal function and exclude hypocalcemia (if present, evaluate T-cells for signs of DiGeorge sequence)
6. Hormonal studies
   a. Luteinizing hormone releasing hormone and human chorionic gonadotropin tests in cases of hypogenitalism
   b. Growth hormone (GH) stimulation levels to exclude GH deficiency as a cause of growth retardation
   c. Prepubertal bone age X-ray, followed by screening for hypogonadotrophic hypogonadism in early puberty for growth
7. Echocardiography for cardiovascular malformations
8. Holter monitoring: to detect cardiac rhythm abnormalities
9. Abdominal ultrasound and voiding cystourethrogram: to exclude renal anomalies
10. Skeletal survey: to exclude skeletal anomalies, especially cervical spine anomalies and scoliosis
11. Head CT scan and/or MRI for brain malformations and defective formation of the ossicles of the middle ear, cochlear, and semicircular canals. Olfactory bulbs and tracts imaging may be pathognomonic for CHARGE syndrome (Chalouhi et al. 2005).
12. Chromosome analysis for associated chromosomal anomalies
13. FISH to exclude 22q11 deletion
14. *CHD7* gene mutation testing available clinically
15. Comparative genomic hybridization for patients with CHARGE syndrome but with normal *CHD7* mutation analysis results

Genetic Counseling

1. Recurrence risk (Lalani et al. 2009)
   a. Patient's sib
      i. A parent affected or with a CHD7 mutation: a 50% risk
      ii. Neither parent affected: the empiric risk is approximately 1–2% due to germ-line mosaicism. Typically, CHARGE syndrome is caused by a *CHD7* de novo mutation, the risk to the sibs is small. However, several sib pairs born to unaffected parents have been reported (Jongmans et al. 2006; Lalani et al. 2006), likely due to germ-line mosaicism confirmed in a report (Pauli et al. 2009).
   b. Patient's offspring
      i. Severely affected individuals do not reproduce
      ii. Each child of a mildly affected individual: a 50% risk of inheriting the mutations
2. Prenatal diagnosis
   a. Ultrasonography: difficult unless in the pregnancy at risk
   b. Molecular genetic testing: possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis or CVS, provided the disease-causing allele

of an affected family member has been identified prior to prenatal diagnosis
   c. Preimplantation genetic diagnosis: possible for families in which the disease-causing mutation has been identified
3. Management
   a. Feeding problems/failure to thrive
      i. Use of antispasmodics
      ii. Nissen fundoplication
      iii. Gastrostomy tube for feeding
   b. Developmental delay/mental retardation
      i. Early infant intervention
      ii. Special education
   c. Respiratory problems: may require tracheostomy for aspiration of secretions
   d. Choanal stenosis/atresia
      i. Airway stabilization and circulatory support
      ii. Requires surgical opening for the posterior choanae by placing stents to keep the nasal passages open if there is obstructed breathing
      iii. Choanoplasty
   e. Congenital heart defects: corrective surgery when indicated
   f. Colobomas: requires ophthalmologic care
   g. External ear anomalies/hearing loss
      i. Hearing aids for deafness
      ii. Surgery for ear canal and temporal bone abnormalities
   h. Management of other associated anomalies

Fig. 1 (**a**, **b**) A boy with typical CHARGE association at ages 11 (*front view*) and 15 (*lateral view*). The patient had bilateral colobomas, choanal atresias, growth and mental retardation, hypogonadism, and ear anomalies with hearing loss

Cherubism

In 1933, Jones first described familial occurrence of painless enlargement of the jaws in three siblings. Later in 1938, Jones reported observations on the same family under the title "familial multilocular cystic disease of the jaws" and coined the term "cherubism" after the cherubs of Renaissance art for the full round cheeks and the upward cast of the eyes giving the children a peculiarly grotesque, cherubic appearance.

Cherubism is a benign maxillary bone dysplasia of childhood, usually showing an autosomal dominant inheritance with variable penetrance and spontaneously resolving after puberty. The prevalence of cherubism is 1 or less in 10,000.

Genetics/Basic Defects

1. Inheritance (Faircloth et al. 1991)
   a. Autosomal dominant with variable penetrance
   b. Familial in 80% of cases
   c. Males affected twice as often as females
   d. 80% overall penetrance
      i. 100% in males
      ii. 50–70% in females
   e. Variable expressivity
2. Cause
   a. Gene responsible for cherubism: mapped to chromosome region 4p16.3 (Mangion et al. 1999)
   b. Caused by mutations in the gene encoding SH3-binding protein *SH3BP2*
      i. Familial cherubism: all mutations are present in exon nine and affect three amino acids within a conserved six amino acid sequence (Hatani and Sada 2008)
      ii. Sporadic cherubism: description of a *SH3BP2* mutation in a case of nonfamilial case (Imai et al. 2003) and in an aggressive case of sporadic cherubism (Carvalho et al. 2008)
      iii. Novel mutations in the *SH3BP2* gene have been described in sporadic central giant cell lesion (which is indistinguishable histologically from cherubism), suggesting that both conditions share the same genetic alteration (Carvalho et al. 2009)

Clinical Features

1. Variable size of the jaw lesions in cherubism
   a. Minor lesions of both jaws
   b. Massive involvement of both jaws
2. Natural history:
   a. Classically normal at birth.
   b. Onset usually between 14 months and 5 years. However, the severe cases are evident at birth.
   c. Progresses until puberty.
   d. Usually progression stops after puberty.
   e. Regression of the bone lesions (involution of the disease) without treatment in some cases.
   f. Rapidly growing and extensively deforming lesions of the maxilla and the mandible including the coronoids and condyles in severely affected individuals.
3. Characteristic "eyes raised to heaven" cherubic appearance: an appearance of the cherubs portrayed in Renaissance art
   a. Fullness of the lower half of the face (cheeks and jaw)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_39,
© Springer Science+Business Media, LLC 2012

   b. Retraction of the lower lids by the stretched skin over the cheeks pulling down the lower eyelids. Consequently, a thin line of sclera is exposed beneath the iris and the eyes appear to be raised heavenward in a manner reminiscent of a "the cherubs in Renaissance paintings"
4. Painless hard enlargement of the jaws
5. Exclusively affecting maxilla and mandible
   a. Mandible usually involved
   b. Involvement of the maxilla in 60% of cases
   c. Painless lesions
   d. Bilateral enlargement with loss of bone in the jaws and its replacement with large amount of fibrous tissue
   e. Dental effect by bone lesion
      i. Premature loss of deciduous teeth
      ii. Displacement of permanent dentition
   f. Swelling usually abates by the third decade, whereas radiographic changes commonly persist into the fourth decade
6. Submandibular lymph node enlargement in 45% of cases
7. Ocular manifestations (Carroll and Sullivan 2001)
   a. Lower lid retraction
   b. Proptosis
   c. Diplopia
   d. Globe displacement
   e. Visual loss due to optic nerve atrophy
   f. Rare extension of lesion into the orbits
8. Rare upper airway involvement
   a. Displaced tongue affecting speech, mastication, swallowing, and respiration
   b. Obstructive apnea
9. Extremely rare extrafacial skeletal involvement
   a. Upper humerus
   b. Bilateral triquetral bones
   c. Anterior ribs
   d. Upper femoral necks
10. Rare associated syndromes
   a. Noonan syndrome
   b. Ramon syndrome
      i. Cherubism
      ii. Short stature
      iii. Mental retardation
      iv. Gingival fibromatosis
      v. Epilepsy
   c. Fragile X syndrome
   d. Craniosynostosis
11. Functional impairment (Tiziani et al. 1999)
   a. Mastication problems
   b. Speech difficulty
   c. Tooth alteration
   d. Loss of normal vision
12. Psychological consequences
13. Differential diagnosis
   a. Four main types of fibrous dysplasia
      i. Monostotic fibrous dysplasia: Only one bone is affected.
      ii. Polyostotic: Multiple bones are affected.
      iii. McCune-Albright syndrome:
         a) Polyostotic form
         b) Accompanied by pigmentary lesions
         c) Endocrine dysfunction presenting as precocious puberty in females
      iv. Craniofacial form of fibrous dysplasia:
         a) Only bones of the craniofacial complex are affected.
         b) Onset in the second decade in majority of patients.
         c) Generally unilateral lesions, tend to become static once skeletal maturity is reached.
         d) Clinically difficult to differentiate from cherubism if the skeletal abnormalities are localized to the jaws.
         e) Molecularly different from cherubism.
   b. Infantile cortical hyperostosis
      i. Diagnosed in the first 6 months of life
      ii. Radiographically does not produce cystic areas
      iii. Characterized by thickening of the mandibular lower border
      iv. Does not have bilateral expression
   c. Osteitis fibrosa cystica secondary to hyperparathyroidism
      i. Increased serum alkaline phosphatase
      ii. Increased serum calcium
      iii. Decreased serum phosphorus
      iv. Increased urinary phosphorus
   d. Various tumors of the jaws

Diagnostic Investigations

1. Orthodontic assessment: commonly required as the jaw distortion leads to permanent dental abnormalities

   a. Malocclusive bite
   b. Premature loss of deciduous teeth
   c. Wide-spaced, misplaced, unerupted, or absent permanent teeth
2. Ophthalmologic examination: for rare individuals who may have
   a. Lower lid retraction
   b. Proptosis
   c. Diplopia
   d. Globe displacement
   e. Visual loss caused by optic atrophy
3. Serum alkaline phosphatase levels may be elevated (Kozakiewicz et al. 2001)
4. Radiography (Tiziani et al. 1999)
   a. Extensive involvement of the mandible and the maxilla
   b. Multilocular radiolucent areas in the mandible and maxilla with expansion of the bony cortex
      i. Often very extensive
      ii. With a few irregular bony septa
      iii. Multilocular rarefactions replaced by sclerosis with progressive calcification in the adult
   c. Absent and displaced teeth in the involved areas
5. CT scan
   a. Superior in making the diagnosis
   b. Determining the degree of severity
6. Histological changes in cherubism
   a. Replacement of the normal bony architecture with proliferating fibrous tissue containing numerous giant cells (Ayoub and El-Mofty 1993)
   b. Mononuclear fibroblastic stroma
      i. Nonneoplastic fibrous lesions rich in multinucleated giant cells identified as osteoclasts
      ii. Irregular bone formation
   c. A peculiar perivascular cuffing of collagen: considered by some to be pathognomonic for the condition (Adante and Breen 1996)
   d. Histological resemblance to the following disorders (Mangion et al. 1999):
      i. Giant cell tumor
      ii. Giant cell granulomas
      iii. Ossifying fibroma
      iv. Fibrous dysplasia of the jaw
      v. Paget disease of bone
7. Molecular genetic testing (Baskin et al. 2011)
   a. To confirm the diagnosis in a proband with the suggestive clinical findings and typical radiologic and/or histologic manifestations.
   b. Sequence analysis: *SH3BP2* sequence variants in exon 9 detects an estimated 80% of mutations.

Genetic Counseling

1. Recurrence risk (Baskin et al. 2011)
   a. Patient's sib: The risk depends on the genetic status of the parents
      i. An affected parent: a 50% risk
      ii. Clinically unaffected parents and/or the parents not detected to have a disease-causing mutation: a low recurrence risk but greater than that of the general population because of the possibility of germ-line mosaicism
   b. Patient's offspring: a 50% risk of inheriting the mutation
2. Prenatal diagnosis
   a. Ultrasonography: not possible since the lesion is postnatal in nature
   b. Molecular analysis possible on fetal DNA obtained by amniocentesis or CVS if the disease-causing mutation (*SH3BP2*) has been identified in an affected family member
   c. Preimplantation genetic diagnosis: possible for families at risk in which the disease-causing mutation has been identified
3. Management
   a. Although cherubism represents a benign and localized maxillary dysplasia, it requires prompt surgical but conservative treatment and careful follow-up to avoid permanent lesions (malocclusion and/or edentulism) (Mortellaro et al. 2009)
   b. Observation
      i. Generally self-limiting lesions and subside with age
      ii. Surgical intervention required only in cases with esthetic or functional problems
   c. Tracheostomy to secure the airway for upper airway obstruction
   d. Teeth extraction from the sites of fibrous changes
   e. Curettage alone or in combination with surgical contouring: considered the treatment of choice
   f. Resection of the orbital lesions may be required to improve visual impairment
   g. Prompt recurrence likely if surgery is performed at an early age

h. Radiation therapy ineffective and contraindicated in view of the following risks:
   i. Osteoradionecrosis
   ii. Interference with dentofacial growth and development
   iii. Affect on future surgical procedures
i. Experimental use of calcitonin to treat cherubism described recently

Chiari Malformation

In 1891, Chiari first described a dysplasia of the nervous system consisting of herniation of the cerebellar tonsils into foramen magnum. There are three types of Chiari malformations. The commonest ones are type I and type II, and the latter has been named the Arnold–Chiari malformation. (De Reuck and Theinpont 1976)

Synonyms and Related Disorders

Chiari malformation type I with syringomyelia; Chiaari malformation type II (Arnold-Chiari malformation)

Genetics/Basic Defects

1. Classification of Chiari malformations according to the severity
   a. Type I (CMI) (the milder malformation)
      i. Ectopia of the cerebellar tonsils (caudal herniation of the cerebellar tonsils and inferior cerebellum through the foramen magnum)
      ii. Usually an isolated feature encountered in adults
   b. Type II (CMII) (the more severe malformation)
      i. Downward displacement of the cerebellar medulla and fourth ventricle into the spinal canal
      ii. Almost always associated with meningomyelocele
      iii. May be associated with polygyria, cortical heterotopia, and dysgenesis of the corpus callosum
   c. Type III (CMIII) (the most severe malformation) (Caldarelli et al. 2002)
      i. Downward displacement of most of the cerebellum into a high cervical/low occipital encephalocele
      ii. Malformation consisting of anatomical anomalies typical of Chiari type II malformation with those of a high cervical/occipital encephalocele
2. Acquired Chiari I malformation caused by conditions leading to increased intracranial pressure
   a. Head injury
   b. Hydrocephalus
   c. Craniosynostosis
3. Brainstem dysfunction, sensory disturbance, and motor loss caused by impaction of the tonsils against the cervicomedullary structures

Clinical Features

1. Patients with Chiari I malformation
   a. Asymptomatic in majority of patients
   b. General symptoms
      i. Headache
      ii. Fatigue
      iii. Memory loss
      iv. Pressure on the neck
      v. Back pain
      vi. Insomnia
      vii. Poor circulation
      viii. Nausea
      ix. Menstrual problems
      x. Sexual alterations

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_40,
© Springer Science+Business Media, LLC 2012

xi. Hypothermia
xii. Bronchial aspirations
xiii. Respiratory alterations
xiv. Drop attacks
xv. Rare reports of sudden death

c. Ocular symptoms
i. Loss of vision
ii. Intolerance of bright light
iii. Diplopia

d. Otolaryngologic symptoms
i. Vestibular manifestations
a) Imbalance
b) Swaying
c) Dizziness
d) Positional vertigo
e) Spontaneous vertigo
f) Nystagmus
g) Hearing loss
h) Tinnitus
ii. Alterations of cranial pairs
a) Dysphagia
b) Dysphonia
c) Alterations in tongue mobility
d) Loss of smell
e) Facial hyposthesia
iii. Sleep apnea

e. Cerebellum compression symptoms
i. Ataxia
ii. Nystagmus
iii. Gait difficulties
iv. Opisthotonos
v. Horner's syndrome
vi. Paralysis of the last cranial nerves
vii. Hypotonia
viii. Trembling
ix. Dysarthria
x. Dysmetria

f. Associated CNS anomalies
i. Stenosis of the aqueduct of Silvia
ii. Meningomyelocele
iii. Syringomyelia (cystic dilation of the spinal cord)

g. Symptoms associated with syringomyelia
i. Known to accompany 50–70% of patients with Chiari I malformations
ii. Obstructed cerebrospinal fluid at the site of cerebellar tonsillar herniation shows perivascular movement of CSF from the spinal subarachnoid space into the spinal cord with each Valsalva maneuver and causes syringomyelia
iii. Tingling, hyposthesia, and burning sensation in the extremities
iv. Thermalgesic anesthesia
v. Alteration in muscular reflexes
vi. Areflexia
vii. Alteration of kinesthesia
viii. Motor skill dysfunction
ix. Headache or nonradicular pain in the shoulder, back, and limbs
x. Headache usually suboccipital and upper cervical in location and is exacerbated by Valsalva maneuvers
xi. Associated with the development of a painful, rapidly progressive, or left-curving scoliosis
xii. Recent reports of spontaneous radiographic improvement of childhood Chiari malformations and syringomyelia

h. Chiari I malformation in children and adolescents (Genitori et al. 2000)
i. Natural history of an asymptomatic Chiari I malformation in children
a) Not well understood
b) Rarely reported to resolve spontaneously
c) Asymptomatic at the time of diagnosis in many children
d) Degree of tonsillar ectopia correlating well with the presence of neurologic signs and symptoms
e) Rare reports of sudden death
ii. Group I (asymptomatic)
a) Age at diagnosis: 3 months to 17 years
b) Associated conditions: hydrocephalus, craniofacial syndromes, epilepsy, occult spinal dysraphism
iii. Group II (brain stem compression)
a) Age at diagnosis: 7 months to 26 years
b) Associated conditions: craniofacial syndromes, hydrocephalus, precocious puberty
c) Symptoms: neck pain, vertigo, headache, numbness, swallowing difficulties, apnea, opisthotonos, brachialgia, hyposthenia, spasticity, and hemifacial pain
iv. Group III (presence of syringomyelia). Symptoms are:
a) Numbness
b) Sensory loss

c) Neck pain
d) Vertigo
e) Scoliosis
f) Hyposthenia
g) Headache
h) Muscle hypotrophy
i) Swallowing difficulties
j) Limb pain

2. Patients with Chiari II malformation
   a. Almost invariably associated with myelomeningocele (90%)
   b. Brain stem signs in 20% of patients with Chiari II malformation in children and adolescence
      i. Vertigo
      ii. Bioccipital headache
      iii. Cerebellar dysfunction
      iv. Progressive paresis of the arms
3. Patients with Chiari III malformation (Caldarelli et al. 2002)
   a. Rarest of the Chiari malformations
   b. Associated with a high cervical or occipital encephalocele
   c. Prognosis for nearly all reported patients
      i. Various degree of developmental delay
      ii. Epilepsy
      iii. Hypotonia
      iv. Spasticity
      v. Upper and/or lower motor neuron deficits
      vi. Lower cranial nerve dysfunction
   d. CNS anomalies usually observed in an occipital encephalocele
      i. A small cranial fossa
      ii. Caudal displacement of cerebellar tonsils and vermis
      iii. Medullary kinking
      iv. Tectal beaking
      v. Obvious hydrocephalus

Diagnostic Investigations

1. CT or MRI
   a. Chiari I malformation
      i. Incidental detection in asymptomatic individuals
      ii. Herniation of the tonsils >5 mm below the foramen magnum on MRI considered diagnostic
   b. Chiari II malformation (Gammal 1988)
      i. Caudal cerebellum (100%)
      ii. Kinking of medulla on spinal cord (79%)
      iii. Elongation of brainstem and low medulla, stretched aqueduct, and fourth ventricle (75%)
      iv. Beaking of quadrigeminal plate (60%)
      v. Large massa intermedia (55%)
      vi. Large fourth ventricle (25%)
      vii. Hydromyelia (15%)
   c. Chiari III malformation (Caldarelli et al. 2002)
      i. An occipitocervical meningoencephalo-cele protruding through a bony defect involving the lower occipital squama and/or the posterior arch of the first cervical vertebrae
      ii. A small posterior cranial fossa with low tentorial attachment
      iii. Scalloping of the clivus
      iv. Massive herniation of the hypoplastic cerebellar structures into the malformation
      v. Beaking of the tectal plate
      vi. Dysgenesis of the corpus callosum
      vii. Severe ventricular dilatation (hydrocephalus)
2. Brainstem auditory evoked potentials (BAEP) (Koehler et al. 2001)
   a. Consistently abnormal in symptomatic Chiari II malformation
   b. Showing a positive predictive value of 88% in predicting central neurologic sequelae in newborns and infants

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased
2. Prenatal diagnosis
   a. Prenatal ultrasound diagnosis of Chiari I malformation (Iruretagoyena et al. 2010)
      i. A lip of cerebellum is downwardly displaced with the tonsils, but the fourth ventricle remains in the posterior fossa
      ii. Enlarged third ventricle
      iii. Cerebellar hypoplasia with marked cystic enlargement of the fourth ventricle
      iv. This condition may coexist with syringomyelia, which is a cyst formation on the cervical portion of the spinal cord

b. Prenatal ultrasound diagnosis of Chiari II malformation
   i. Classic "lemon and banana" signs, the gold standard in the early screening of Chiari II malformation
   ii. Clivus-supraocciput angle below fifth centile of nomogram in cases of Chiari II malformation
c. Strategy for fetal sonographic and MRI diagnosis of CMII when ultrasound study shows ventriculomegaly/hydrocephalus
   i. Presence of myelomeningocele by ultrasound: suspect CMII
   ii. Absence of myelomeningocele by ultrasound: proceed to MRI
   iii. Presence of tight posterior fossa by MRI
      a) Presence of myelomeningocele: suspect CMII
      b) Absence of myelomeningocele: suspect CMII (with open defect) or conditions other than CMII, such as craniosynostosis, swollen hindbrain, and tumor
   iv. Absence of tight posterior fossa by MRI: CMII not likely
d. Prenatal ultrasound and MRI diagnosis of Chiari III malformation (Smith et al. 2007)
   i. Repeat US at 19 weeks demonstrated neural tissue in the cyst, consistent with an encephalocele.
   ii. MR imaging at 23 weeks confirmed the presence of an occipital encephalocele, demonstrated additional bony defect in the upper cervical spine, and identified abnormal morphology and position of the brainstem consistent with the diagnosis of Chiari III.
   iii. Postnatal MRI and CT confirmed the fetal MRI findings and demonstrated the utility of fetal MRI in the early evaluation of sonographically detected posterior fossa abnormalities.

3. Management
   a. Chiari I malformation
      i. Conservative treatment for asymptomatic patients
      ii. Main treatment consisting of decompressing the structures trapped in the foramen magnum
         a) Suboccipital craniectomy with or without dural patch grafting and cervical laminectomies: the most often used procedure
         b) Syringosubarachnoid shunt when indicated
      iii. Shunting of hydrocephalus
      iv. Major preexisting sensory or motor deficits: poor prognosticators for functional recovery
   b. Chiari II (Arnold–Chiari) malformation
      i. Seen most often in children with myelomeningocele
      ii. Shunting of hydrocephalus often resolves brainstem symptoms and surgical decompression may not be necessary.
      iii. Surgical decompression of posterior fossa and upper cervical spine may be required if brainstem compression symptoms remain after shunting.
      iv. Surgical intervention indicated to prevent further deterioration of the motor function and to diminish the progress of spasticity and scoliosis from tethered cord syndrome
   c. Chiari III malformation (Caldarelli et al. 2002)
      i. Primary closure of the malformation: usually the treatment of choice
      ii. CSF shunting of the associated hydrocephalus postponed to a later phase
      iii. Neonates often require intensive care treatment for the associated severe respiratory distress

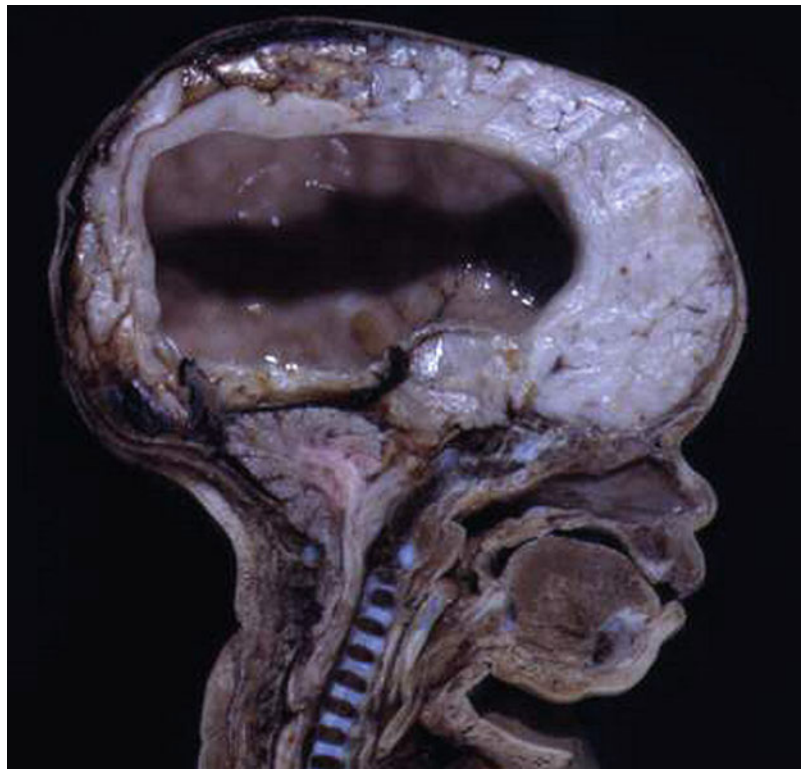

Fig. 1 Sagittal section of a neonate with a large ruptured lumbar meningomyelocele. Arnold–Chiari malformation is evident: The brain stem and lower portion of cerebellum herniate through the foramen magnum and overlap the cervical cord which is severely flattened. The brain shows hydrocephalus

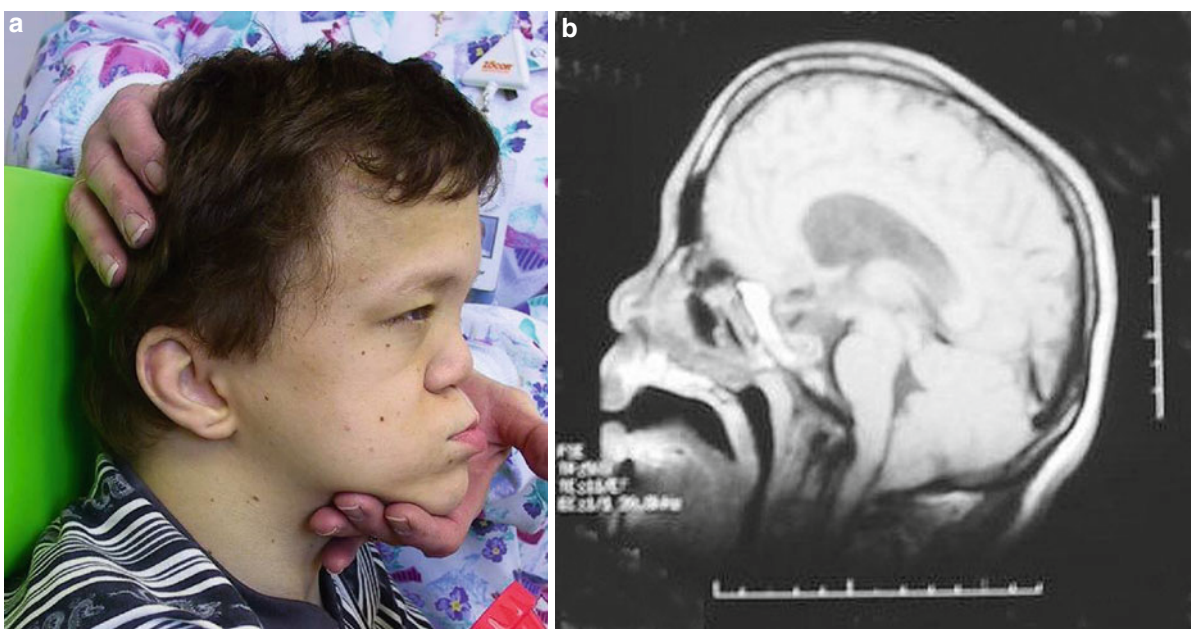

Fig. 2 (**a**, **b**) A patient with multiple congenital anomalies (mental retardation, flat facial plane, epicanthus inversus, blepharophimosis, cataracts, nystagmus, elbow flexion contractures, and vertical talus) with Chiari I malformation (MRI of the brain)

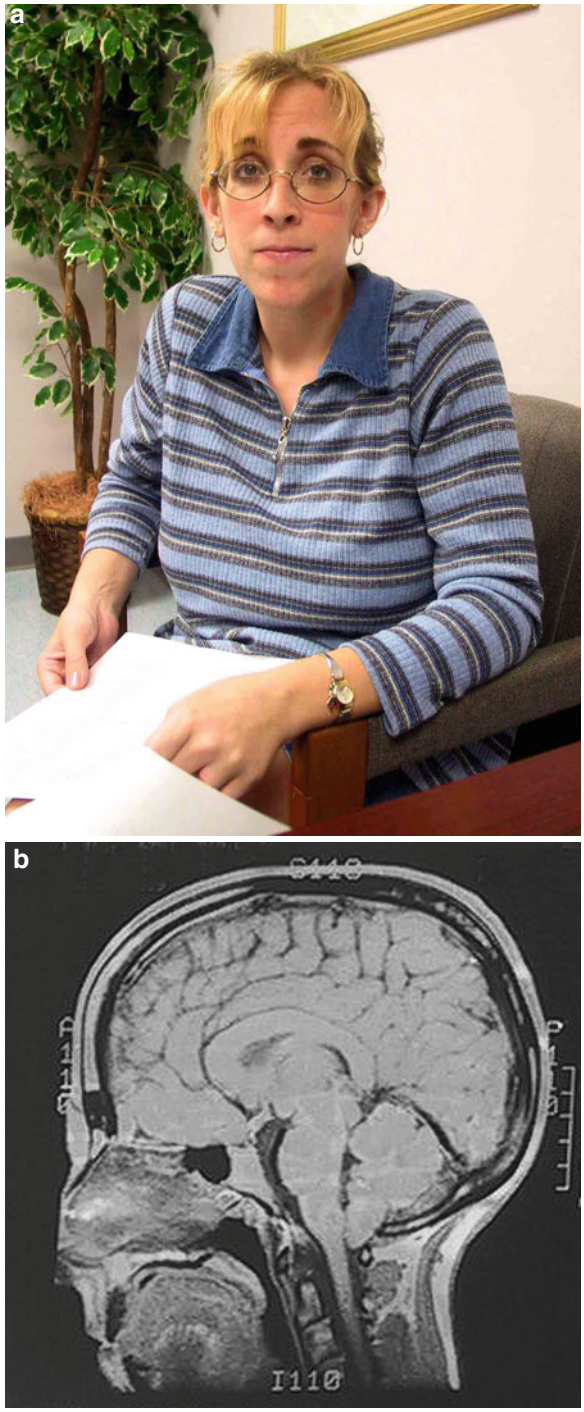

Fig. 3 (**a**, **b**) A 28-year-old female with Chiari I malformation with normal phenotype but complaining headache, dizziness, and neck pain worsened by pregnancy

Chondrodysplasia Punctata

Chondrodysplasia punctata (CDP) refers to the radiographic appearance of punctate calcifications, due to abnormal cartilaginous stippling, the result of calcium deposition in the areas of enchondral bone formation, described in a variety of chondrodysplasias.

Synonyms and Related Disorders

Chondrodystrophia calcificans punctata; Conradi-Hunermann syndrome; Conradi-Hunermann-Happle syndrome; Happle syndrome; Rhizomelic form of Chondrodysplasia punctata

Genetics/Basic Defects

1. Genetic heterogeneity of chondrodysplasia punctata
   a. Rhizomelic chondrodysplasia punctata type I (RCDP1)
      i. Autosomal recessive disorder
      ii. Caused by mutations in *PEX7*, mapped at 6q22–q24, which encodes the cytosolic peroxisomal targeting signal type 2 (PTS2)-receptor protein peroxin 7
      iii. Genotype–phenotype correlations
         a) Classic RCDP1: all patients homozygous for the L292X mutation
         b) Phenotype determined by the other allele if the patients are compound heterozygotes for L292X and another mutation
         c) A milder phenotype associated with several *PEX7* alleles
   b. Rhizomelic chondrodysplasia punctata type 2 (RCDP2)
      i. Autosomal recessive disorder
      ii. Caused by mutations in the gene that encodes peroxisomal dihydroxyacetone phosphate acyltransferase (DHAPAT)
   c. Rhizomelic chondrodysplasia punctata type 3 (RCDP3)
      i. Autosomal recessive disorder
      ii. Caused by mutations in the gene (mapped at 2q31) that encodes peroxisomal alkyl-dihydroxyacetone phosphate synthase (ADHAPS)
   d. Relatively mild autosomal dominant Conradi–Hünermann syndrome
      i. Chondrodysplasia punctata, tibia-metacarpal type
      ii. Chondrodysplasia punctata, humero-metacarpal type
   e. X-linked dominant type only in females (Conradi–Hünermann–Happle syndrome) (CDPX2) (Becker et al. 2001)
      i. Lethal in males
      ii. Caused by mutations of the 3β-hydroxysteroid-Δ^8-Δ^7-isomerase (also called emopamil-binding protein, EBP)
      iii. The gene encoding EBP mapped to Xp11.22–p11.23
      iv. EBP: catalyzes an intermediate step in the conversion of lanosterol to cholesterol
      v. Presence of gonadal and somatic mosaicism in CDPX2

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_41,
© Springer Science+Business Media, LLC 2012

f. X-linked recessive type with a deletion of the short arm of the X chromosome (CDPX1)
   i. Caused by defects in arysulfatase E, a vitamin K-dependent enzyme
   ii. The locus of the disease identified through the characterization of patients with chromosomal abnormalities involving the Xp22.3 region
   iii. The gene of CDPX1, named *ARSE*, encoding a new sulfatase (arylsulfatase E), showing a high sequence homology to steroid sulfatase
   iv. Point mutations of the *ARSE* gene detected in the DNA of karyotypically normal patients with chondrodysplasia punctata

2. Causes of stippled cartilaginous calcifications (Borochowitz 1991)
   a. Peroxisomal disorders
      i. Zellweger syndrome
         a) A peroxisomal disorder
         b) An autosomal recessive inheritance
         c) Associated stippled calcifications of the epiphyses, particularly common in the patella
         d) Severe hypotonia
         e) Characteristic facies with a high forehead, hypertelorism, epicanthal folds, Brushfield spots, and shallow supraorbital ridges
         f) Club foot deformity
         g) The affected infants usually die early in infancy.
         h) Involvement of other organ systems, especially the brain (migrational disorders) and kidneys (cortical cystic disease of the kidneys)
      ii. Rhizomelic chondrodysplasia punctata
   b. Genetic disorders
      i. Conradi–Hunermann chondrodysplasia punctata
      ii. X-linked dominant chondrodysplasia punctata
      iii. Smith-Lemli-Opitz syndrome
      iv. Greenberg dysplasia (cholesterol biosynthesis disorder)
         a) An autosomal recessive disorder
         b) Appears to be caused by an error of sterol metabolism at the level of 3β-hydroxysteroid-Δ14 reductase
         c) Non-immune hydrops fetalis
         d) Mid-face hypoplasia
         e) Micrognathia
         f) Rhizo-mesomelic dwarfism with relatively long and broad hands and feet
         g) Narrow thorax
         h) Protuberant abdomen
         i) Radiographic findings of grossly irregular and deficient ossification of the short tubular bones, fragmented ossification at the ends of the long tubular bones, small pelvic bones with irregular "moth-eaten" contours, platyspondyly with multiple ossification centers of the vertebral bodies, and deficient ossification of the calvaria
      v. CHILD syndrome
         a) Congenital hemidysplasia
         b) Ichthyosiform erythroderma
         c) Limb defects (unilateral hypomelia with ipsilateral epiphyseal stippling)
      vi. Dappled diaphyseal dysplasia (lethal short-limbed dysplasia, type Carty)
         a) An autosomal recessive disorder
         b) All cases were stillborn or died in utero
         c) Fetal hydrops
         d) Polyhydramnios
         e) Short limbs with relatively long hands and feet
         f) Small thorax
         g) Protuberant abdomen
         h) Radiographic findings of fragmented appearance of the ribs, small islands of ossification from disruption of the facial bones, axial and appendicular skeleton, and absent ossification of the calvaria
      vii. Acrodysostosis
      viii. Binder syndrome
      ix. De Barsy syndrome
         a) Cutis laxa
         b) Corneal clouding
         c) Mental retardation
         d) Stippled epiphysis
      x. GM1 gangliosidosis
      xi. Galactosialidosis
      xii. Fibrochondrogenesis
      xiii. Mucolipidosis II

xiv. De Lange syndrome
xv. X-linked ichthyosis
xvi. Keutel syndrome
  a) Stippled epiphysis (knees, elbows)
  b) Brachytelephalangism
  c) Pulmonary stenosis
xvii. Osebold-Remondini syndrome
xviii. Hypothyroidism
xix. Chromosome translocation
xx. Trisomy 21 and 18
xxi. Turner syndrome
xxii. Brachytelephalangic chondrodysplasia punctata
  a) An X-linked recessive disorder
  b) Male infants affected with a very small nose, anteverted and grooved nares
  c) Benign type of chondrodysplasia punctata
  d) Also observed in a patient with Xp terminal deletion with ichthyosis and mental retardation
  e) Distal phalangeal hypoplasia: the most characteristic radiological sign of this form
xxiii. Chondrodysplasia punctata, metacarpal type
  a) Including tibial-metacarpal type and humeral-metacarpal type
  b) An autosomal dominant disorder
  c) Named for a specific long bone but with overlap in the long bone involved
  d) All have short metacarpals
  e) Affected children with a hypoplastic midface, a depressed nasal bridge, small mouth, micrognathia, short neck, and short limbs
  f) Radiographically, with short metacarpals associated with short tibias in the tibia-metacarpal type and short humeri in humero-metacarpal type
xxiv. Sheffield-type chondrodysplasia punctata
  a) Heterogeneous group of patients with punctate epiphyses, particularly in the calcaneus and spine
  b) A benign course
  c) Distal phalangeal hypoplasia
  d) Probably not a specific entity but rather a heterogeneous group of disorders that can be included in other entities
xxv. Pacman dysplasia
  a) A single case report with peculiar bone dysplasia, stippling in many areas, short bowed bones, and periosteal cloaking
  b) Osteoclasts with an unusual appearance reminiscent of the Pacman figures in computer games on bone histology
  c) The entire coccygeal and sacral regions replaced by stippling
  d) Dense stippling also observed in the thoracic region
  e) Considerable stippling also observed in the epiphyses of the proximal femur, talus, calcaneus, cuboid, and the bones of the hand
  f) Wide periosteal cloaking of many bones and poor ossification
  g) Bowed femora
  h) Superior inferior sagittal clefting in the AP views in the upper spine

c. Vitamin K disorders
  i. Warfarin embryopathy
    a) Associated with maternal use of warfarin sodium
    b) Consistent features: saddle nose deformity, hypertelorism, frontal bossing, high-arched palate, short neck, and short stature
    c) Other features: rhizomelia, micromelia, flexion contractures, optic atrophy, psychomotor retardation, cataracts, congenital heart disease, and renal anomalies
  ii. Vitamin K epoxide reductase deficiency
d. Acquired in utero
  i. Fetal alcohol syndrome
  ii. Phenacetin intoxication
  iii. Fetal hydantoin syndrome
  iv. Femoral hypoplasia unusual facies syndrome
  v. Maternal diabetes
  vi. Maternal systemic lupus erythematosis
  vii. Febrile illness
e. Other conditions involving unusual calcification that may be confused with puncta
  i. Amelia and other absence deficiency
  ii. Cerebrocostomandibular syndrome
  iii. Dysplasia epiphysealis hemimelica

iv. Calcifying arthritis
v. Metachondromatosis

3. Etiological classification of chondrodysplasia punctata to aid clinician to reach an accurate diagnosis when CDP is detected (Irving et al. 2008)
   a. Group 1 (Inborn errors of metabolism)
      i. Group 1a (Abnormalities of peroxisomal function)
         a) Rhizomelic CDP1 (*PEX7*, 6q22-q24)
         b) Rhizomelic CDP2 (*DHAPAT*, 1q42)
         c) Rhizomelic CDP3 (*AGPS*, 2q31)
         d) Zellweger syndrome (*PEX1*, *PEX2*, *PEX3*, *PEX5*, *PEX6*, *PEX10*, *PEX12*, *PEX13*; 7q21, 8q, 6q, 12p13.3, 6p21.1, 1p36, 17q11.2, 2p15 respectively)
      ii. Group 1b (Abnormalities of cholesterol synthesis)
         a) Greenberg dysplasia/HEM (*LBR*, 1q42.1)
         b) CDP Conradi-Hunermann (CDPX2) (*EBP*, Xp11.23–p11.22)
         c) CHILD syndrome (*NSDHL*, *EBP*; Xq28, Xp11.23–p11.22 respectively)
      iii. Group 1C (Other metabolic disorders)
         a) Mucolipidosis type II
         b) Mucopolysacharidosis type III
         c) GM1 gangliosidosis
   b. Group 2 (Disruption of vitamin K metabolism)
      i. Warfarin embryopathy
      ii. Familial multiple coagulation factor deficiency (*VKORC1*, *GGCX*; 16p11.2, 2p12 respectively)
      iii. Maternal vitamin K deficiency
      iv. Fetal phenytoin exposure
      v. Keutel syndrome (Keutel et al. 1972; Monroe et al. 1999) (*MGP*, 12p13.1–p12.3)
         a) Abnormal calcification with cartilaginous calcification of the ears, nose, trachea, bronchi and ribs
         b) Peripheral pulmonary stenosis
         c) Sensorineural hearing loss
         d) Short-terminal phalanges
         e) Developmental delay and seizures, secondary to intracerebral calcification
      vi. CDP X-linked recessive/brachytelephalangic (CDPX1) (*ARSE*, Xp22.3)
   c. Group 3 (Chromosomal abnormalities)
      i. Trisomy 21
      ii. Trisomy 18
      iii. Other chromosomal aberrations
   d. Unknown etiology
      i. Maternal systemic lupus erythematosus
      ii. Fetal alcohol syndrome
      iii. CDP-TM (tibial-metacarpal type) (Rittler et al. 1990)
      iv. Dappled diaphyseal dysplasia
      v. Astley-Kendall dysplasia (Astley and Kendall 1980)
      vi. Pacman dysplasia (Miller et al. 2003)

Clinical Features

1. Recessive rhizomelic form
   a. Classic RCDP1
      i. Skeletal abnormalities
         a) Severe symmetric shortening of the proximal limb segments (more severe in humeri than femora)
         b) Stippled (punctate) epiphyses involving knees, hips, elbows, shoulders, hyoid bone, larynx, sternum, and ribs
      ii. Peripheral calcifications
      iii. Facial dysmorphism
         a) Frontal bossing
         b) A short, saddle nose
      iv. Ocular features
         a) Cataracts: the most common ocular defect developing in virtually all patients: usually present at birth or appear in the first few months of life and are progressive
         b) Optic atrophy
         c) Posterior embryotoxon
         d) Strabismus
         e) Adhesions between iris and cornea in the ring of Schwabe
      v. Severe failure to thrive with profound postnatal growth deficiency
      vi. Gross developmental retardation
      vii. Contractures and stiff, painful joints, causing irritability in infancy
      viii. Other complications
         a) Seizures
         b) Recurrent respiratory tract infections caused by neurological compromise, aspiration, immobility, and a small chest with restricted expansion
         c) Spastic quadriplegia

d) Ichthyotic skin changes
e) Cleft soft palate
f) Cervical spine stenosis
g) Congenital heart disease
h) Ureteropelvic junction obstruction

ix. A high mortality
a) About 60% survive the first year.
b) About 39% survive the second year.
c) Only a few survive beyond age 10.

b. Mild RCDP1
i. Only a few patients reported
ii. Consistent features
a) Chondrodysplasia
b) Cataracts
iii. Variable expression
a) Punctate calcifications
b) Rhizomelia
c) Mental and growth deficiency

2. X-linked dominant form (CDPX2)
a. Phenotype
i. Usually a mild form of the disease identified in adult females
ii. May be a stillborn
iii. Occurring almost only in females
iv. Presumably lethal in males, although a few affected males have been reported
b. Lyonization (skewed X-chromosome inactivation) in females resulting in phenotypic variability and asymmetric findings
c. Showing increased disease expression in successive generations (anticipation): another striking clinical feature of CDPX2 that may be associated with skewed methylation
d. Skin lesions
i. The hallmark of the X-linked dominant form
ii. Congenital ichthyosiform erythroderma, distributed in a linear or blotchy pattern
iii. Systematized atrophoderma mainly involving the fair follicles
iv. Circumscribed alopecia
v. Sparse eyebrows and lashes
vi. Nails: flattened and split into layers
e. Epiphyseal calcification in the first year of life
f. Limb shortening
i. Rhizomesomelic
ii. Usually asymmetric
iii. Severely affected infants with bilateral findings resembling those of RDCP1
g. Other later signs
i. Palmoplantar keratosis
ii. Follicular atrophoderma
iii. Segmental cataracts
iv. Tooth and bone abnormalities

3. X-linked recessive chondrodysplasia punctata, brachytelephalangic type (CDPX1)
a. Clinical reports available so far are mainly those of patients who are nullisomic for Xp22.3 in which chondrodysplasia punctata is part of a complex phenotype due to a "contiguous gene syndrome"
b. Wide spectrum of manifestations, ranging from aborted fetus, neonatal death, midfacial hypoplasia, and brachytelephalangy
c. Facial anomalies with severe nasal hypoplasia
d. Short stature
e. Cardinal manifestations
i. Epiphyseal stippling
ii. Hypoplasia of the distal phalanges
f. Abnormalities of proximal and middle phalanges after healing of the punctate calcifications: typical diagnostic signs
g. Without limb shortening or cataracts
h. Presence of ichthyosis attributed to the involvement o of the STS gene in the patients with Xp deletion
i. Mild ichthyosis that improves with age: may be part of the CDPX phenotype

4. Chondrodysplasia punctata, tibia-metacarpal type
a. Symmetrical rhizomelic shortness of the upper limbs
b. Punctate epiphyseal calcifications noted at birth
c. Abnormal face (flattened mid-face and nose)
d. Short hands
e. Normal height
f. Normal mentation

Diagnostic Investigations

1. Radiography
a. Classic RCDP1
i. Bilateral shortening of the humerus and to a lesser degree the femur
ii. Punctate calcifications in the epiphyseal cartilage at the knee, hip, elbow, shoulder, hyoid bone, larynx, sternum, and ribs
iii. Radiolucent coronal clefts of the vertebral bodies that represent unossified cartilage

iv. Abnormal epiphyses and flared and irregular metaphyses secondary to resolved punctate calcification after age 1–3 years

b. Tibia-metacarpal type
   i. Shortened and bowed tibia and radii
   ii. Overgrowth of the fibulae
   iii. Ulnar hypoplasia
   iv. Calcific stippling of the proximal bones
   v. Punctate calcifications of the trachea, thyroid cartilage, entire spine, and sacrum
   vi. Clefting (coronal and/or sagittal) of the vertebral bodies
   vii. Symmetrical brachymetacarpy: shortened 2nd, 3rd, and 4th metacarpals
   viii. Shortened radial head
   ix. Patella dislocation

2. Biochemical/molecular studies
   a. RCDP1 (Braverman et al. 2010)
      i. Deficiency of red blood cell plasmalogens
      ii. Increased plasma concentration of phytanic acid
      iii. Deficiencies in plasmalogen biosynthesis and phytanic acid hydroxylation in cultured skin fibroblasts
      iv. PEX7 receptor defect in RCDP1 predicted by the following:
         a) Deficiency of plasmalogens in red blood cells
         b) Increased plasma concentration of phytanic acid
         c) Normal plasma concentration of very long chain fatty acids
      v. Molecular genetic analysis: *PEX7* gene mutation analysis and sequencing
   b. RCDP2
      i. Deficiency of the peroxisomal enzyme dihydroxyacetone phosphate acyltransferase (DHAPRT) in cultured skin fibroblasts
      ii. *DHAPRT* gene mutation analysis by sequencing of coding regions
   c. RCDP3: deficiency of the peroxisomal enzyme, akkyl-dihydroxyacetone phosphate synthase (ADAPS) in cultured skin fibroblasts
      i. Deficiency of the peroxisomal enzyme, akkyl-dihydroxyacetone phosphate synthase (ADAPS) in cultured skin fibroblasts
      ii. *ADHAPS* gene mutation analysis
   d. X-linked dominant form (CDPX2)
      i. Diagnosis confirmed by measuring the plasma concentration of sterols which show accumulation of precursors, 8(9)-cholesterol and 8-dehydrocholesterol
      ii. Identify molecular defect in human *EBP* in CDPX2 patients
   e. X-linked recessive form (CDPX1): ARSE gene mutation analysis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive RCDP1: 25%
      ii. Autosomal dominant form: not increased unless one of the parents is affected
      iii. X-linked recessive form: 50% of brothers affected when the mother is a carrier
      iv. X-linked dominant form
         a) 50% of sisters and brothers (lethal) affected when the mother is a carrier
         b) Possibility of an apparently normal mother being a carrier to be considered when examining seemingly sporadic cases
   b. Patient's offspring
      i. Autosomal recessive RCDP1: do not reproduce
      ii. Autosomal dominant form: 50%
      iii. X-linked recessive form: 50% risk of daughters to be carriers; none of sons will be affected
      iv. X-linked dominant form: affected mother: 50% of sons affected (lethal in male); 50% of daughters affected
2. Prenatal diagnosis
   a. Radiography
      i. Stippling of the bones of the extremities and pelvis
      ii. Abnormalities of the vertebral bodies
   b. Ultrasonography
      i. Rhizomelic form
         a) Severe rhizomelic limb shortening
         b) Punctuate epiphyseal calcifications
         c) Associated sonographic findings: profound hypoplasia of the humeri,

metaphyseal flaring, a flattened midface, joint contracture, clubfoot deformity, and hydramnios

ii. Nonrhizomelic form
   a) Asymmetric, variable limb shortening without a clear pattern of rhizomelia or mesomelia
   b) Calcifications in the long bone epiphyses, which may be recognizable in the second trimester or may not be recognizable even in the third trimester
   c) Other sonographic findings: spinal deformities, frontal bossing, a depressed nasal bridge, ascites, and polyhydramnios

iii. X-linked dominant form
   a) Growth retardation
   b) Skeletal asymmetry
   c) Polyhydramnios

c. Assays of plasmalogen biosynthesis in cultured chorionic villi or amniocytes for pregnancies at 25% risk for RCDP1
d. Enzyme activity of alkyl-dihydroxyacetone phosphate synthase (ADHAPS) and subcellular localization of peroxisomal thiolase performed on uncultured chorionic villi
e. Molecular prenatal diagnosis in X-linked dominant chondrodysplasia punctata to identify disease-causing *EBP* mutation in the fetus

3. Management
   a. Mainly supportive
   b. G-tube placement for poor feeding and recurrent aspiration
   c. Cataract extraction to preserve vision
   d. Orthopedic procedures to correct contractures to improve function
   e. X-linked dominant form
      i. Emollients for ichthyosis
      ii. Splinting for clubbed feet
      iii. Surgery for polydactyly
      iv. Ophthalmological care for cataracts

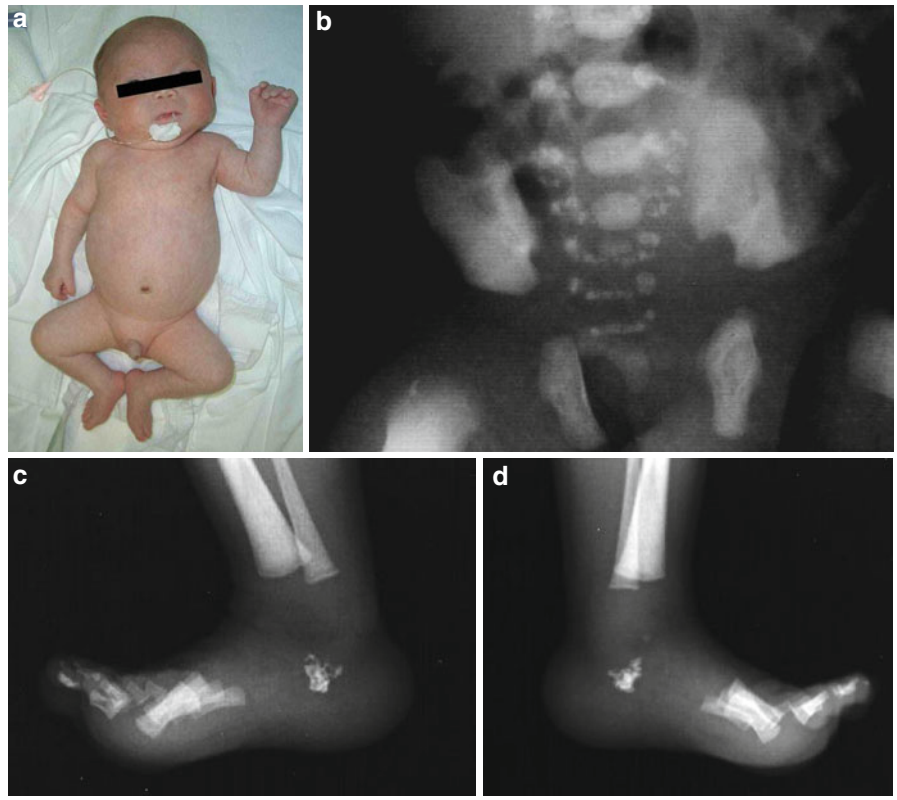

Fig. 1 (**a**–**d**) Patient 1 (a Japanese newborn boy) with X-linked recessive form of chondrodysplasia punctata. Radiographs show paravertebral and calcaneus punctate calcification

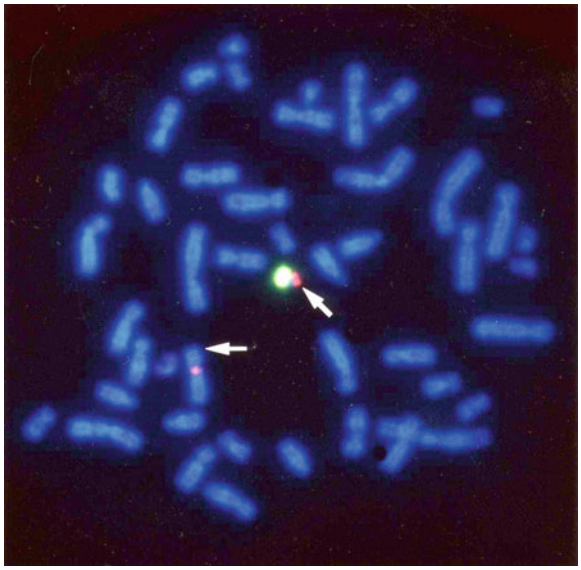

Fig. 2 FISH (patient 1) with a SHOX (short stature homeobox containing gene) probe for Xp22.3 (a pink signal) and Yp11.3 (a pink signal) showing a deleted pink Xp22.3 signal. The pink signal in the X chromosome is an X peri-centromere probe (SXZ1) and the green signal is a Yq12 probe (DXZ1)

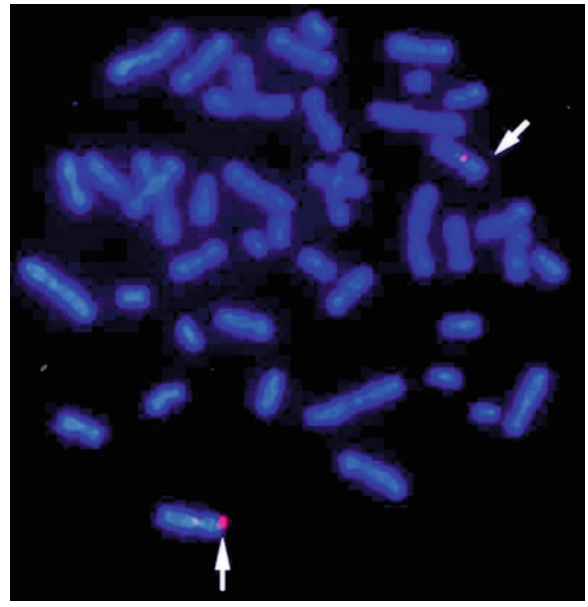

Fig 3 The mother of patient 1 is a carrier of del(X)(p22.3p22.3) (SHOX-). Her FISH showed that a red signal (a probe for Xp22.3; SHOX gene) is deleted in one of her X chromosomes

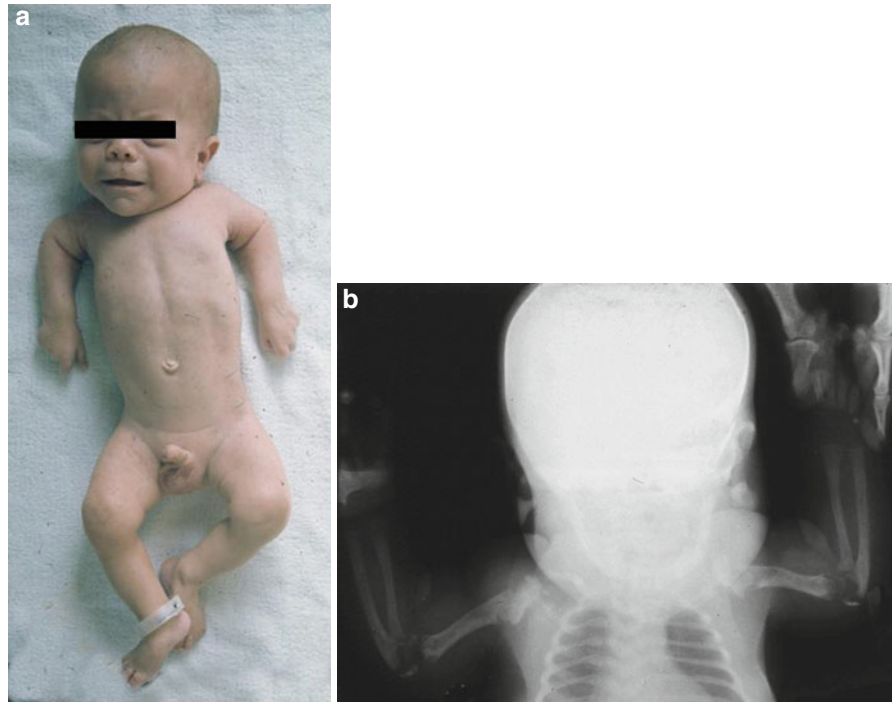

Fig. 4 (**a**, **b**) A neonate with rhizomelic form of chondrodysplasia punctata, showing short humeri and punctate calcifications in the shoulder and/or elbow joints illustrated by radiograph

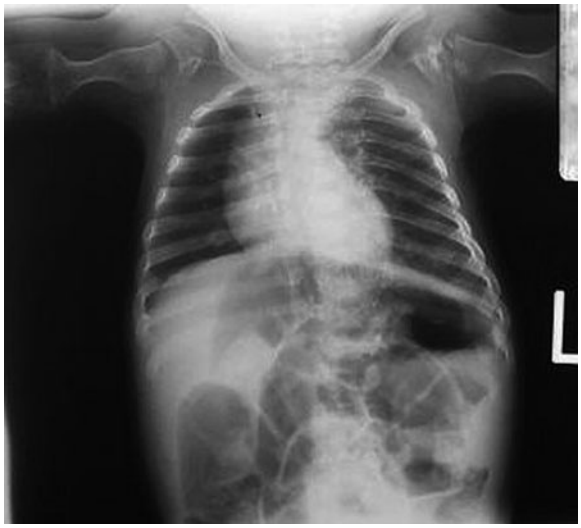

Fig. 5 Radiograph of another neonate with rhizomelic form of chondrodysplasia punctata, showing similar radiographic features

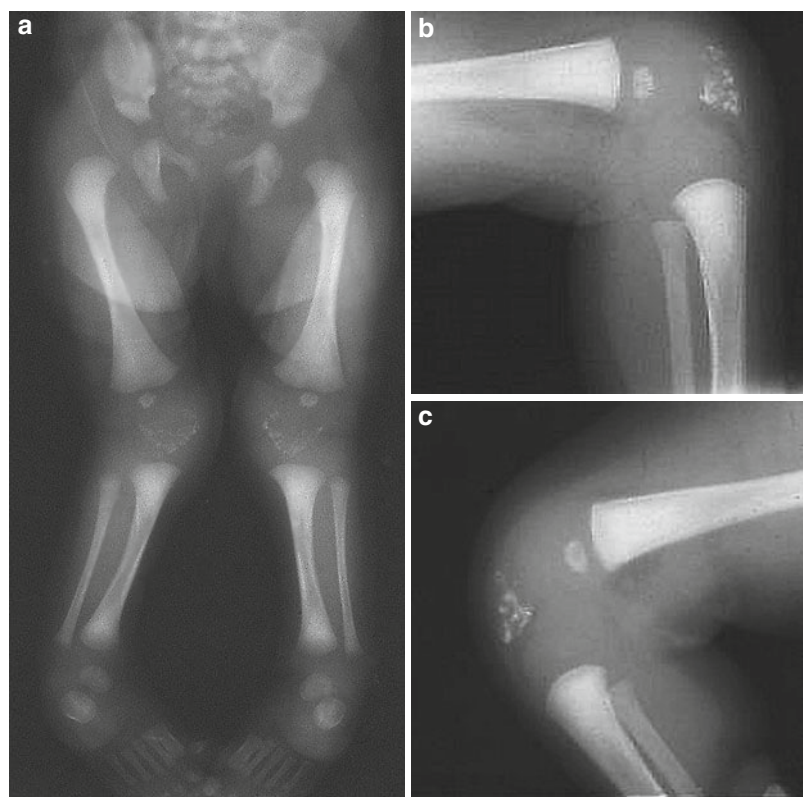
Fig. 6 (**a**, **b**) Another neonate with chondrodysplasia punctata showing depressed nasal bridge and underdeveloped nasal cartilage. The infant has punctate calcifications in the proximal femoral heads



Figs. 7 (**a**–**c**) Radiographs of a child with an autosomal dominant chondrodysplasia punctata showing punctate calcifications in the knees

Chromosome Abnormalities in Pediatric Solid Tumors

Consistent chromosome abnormalities have been described in many pediatric solid tumors. These findings led to direct molecular investigation and a better understanding of tumor pathogenesis. Clinical correlation often produced useful prognostic information (Karnes et al. 1992).

Synonyms and Related Disorders

CNS primary tumor; Neuroblastoma; Other pediatric solid tumors; Retinoblastoma; Wilms tumor

Genetics/Basic Defects

1. Somatic mutation theory of cancer (Mertens et al. 1994)
   a. Resulting from the accumulation of specific genetic changes
   b. Several lines of evidence
      i. Monoclonal origin of most tumors, suggesting that they derive from a single progenitor cell
      ii. Several tumors occurring not only sporadically but also as familial hereditary traits
      iii. Mutagenic nature of most carcinogenic agents, at least in experimental systems
      iv. Acquired genetic changes in the tumor cells, many of which are detectable at the chromosome level and several of these mutations have been shown to be tumorigenic in experimental animals
2. Chromosome abnormalities in neoplastic cells
   a. Technical improvement in basic cytogenetic techniques
      i. Use of colchicine to arrest dividing cells in metaphase and hypotonic solutions to improve spreading of the chromosomes
         a) Description of the correct chromosome number in humans
         b) The first specifically neoplasia-associated chromosome aberration, the Ph1 chromosome in chronic myeloid leukemia
      ii. Introduction of chromosome banding techniques
         a) Possible to identify individual chromosome pairs
         b) To detect and characterize even subtle rearrangements.
   b. Clonal chromosome aberrations in neoplasms
      i. Primary aberrations
         a) Nonrandomly associated with particular tumor types
         b) Sometimes observed as the sole karyotypic deviation
         c) Thought to constitute early and essential events in carcinogenesis
         d) Increased genomic instability thought to be one of the consequences of the acquisition of a primary cancer chromosome rearrangement
         e) Many primary aberrations affect cellular oncogenes, often fusing them with other genes to encode hybrid proteins or

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_42,
© Springer Science+Business Media, LLC 2012

disrupting the normal control sequences of the oncogene, causing its inappropriate expression
ii. Secondary aberrations
a) Occurrence of new abnormalities facilitated by primary aberrations
b) Nonrandom
c) Distribution of the secondary aberrations dependent on both the primary abnormality and the tumor type in which they occur
iii. Cytogenetic noise
a) Resulting from acquired instability
b) Random changes with little or no selective value

3. Mechanisms by which chromosomal aberrations arise (Albertson et al. 2003)
a. Aberrations that lead to aneuploidy
i. Polyploidy
ii. Aneuploidy
iii. Reciprocal translocation
iv. Nonreciprocal translocation
v. Amplification (double minutes)
vi. Amplification (HSR)
vii. Amplification (distributed insertions)
b. Aberrations that leave the chromosome apparently intact
i. Loss of heterozygosity (LOH) (somatic recombination)
ii. Loss of heterozygosity (duplication/loss)
4. Identification of specific chromosome rearrangements in neoplasms
a. Leukemia and lymphoma
i. Crucial for more detailed studies utilizing molecular genetic techniques
ii. Possible to compare cytogenetic findings with morphologic, immunologic, and clinical parameters such as the response to therapy and survival
iii. Diagnostic and prognostic implications of karyotyping
b. Solid tumors
i. In general, more complex karyotypes observed in solid tumors
ii. Have distinct patterns of primary and secondary aberrations closely associated with histopathologic entities
iii. Identification of only a few genes as a consequence of recurrent structural rearrangements
iv. Fusion of transcription factor gene with other loci, a common feature
v. Tumor suppressor genes
a) Important in solid tumors
b) Thought to encode inhibitors of unrestrained growth
c) Behave in a recessive manner at the cellular level (i.e., loss or structural disruption of both wild-type alleles is required to unleash a neoplastic phenotype)
5. Retinoblastoma (RB) (Mertens et al. 1994)
a. A prototype tumor for understanding basic concepts in cancer genetics
b. Genetics of retinoblastoma
i. Thought to be a single gene disorder caused by mutation of the *RB1* gene
ii. Sporadic, nonhereditary form in most cases
a) Unilateral or unifocal retinoblastoma
b) A mutation in the RB1 locus occurred later in embryogenesis
iii. Hereditary form (one third of tumors)
a) Bilateral or multifocal retinoblastoma
b) Predisposition inherited as an autosomal dominant trait
c) Mutations inherited from a carrier parent in 25% of the cases
d) A new mutation occurring very early in embryogenesis in 75% of cases
e) Overall estimates of the penetrance of the trait: 85–95%
c. Retinoblastoma gene, *RB1*
i. The first cancer-predisposition gene to be cloned
ii. Chromosome map: 13q14
iii. More than 100 different mutations reported to date
a) Missense mutations
b) Nonsense mutations
c) Splice-site mutations
d) Small and large deletions
d. Knudson's "two-hit hypothesis" of tumorigenesis
i. In the unaffected individual, both RB1 genes are intact and serve as guardians of the retina.
ii. Retinoblastoma develops as a result of two separate mutations.
iii. Sporadic tumors: two separate mutations occurring somatically in the same retinal cell
iv. Heritable retinoblastoma: The first mutation is germinal and the second somatic.

e. Inherited form of retinoblastoma
   i. Critical gene for retinoblastoma located in band 13q14, suggested by cytogenetic analyses of tumor cells and lymphocytes
   ii. Homozygous loss of DNA markers from 13q14 in tumor cells from individuals with familial retinoblastoma vs. heterozygous loss of these DNA markers in normal cells, suggested by molecular genetic investigations

6. Neuroblastoma (NB)
   a. A malignant tumor derived from undifferentiated neural crest cells that are committed to differentiate into the sympathetic nervous system
   b. Inheritance
      i. Sporadic in most cases
      ii. A few clustered familial cases reported indicating an autosomal dominant inheritance with incomplete penetrance
   c. Molecular biology (Lee et al. 2003)
      i. The amplification (i.e., increased number of DNA copies) of the oncogene MYCN (N-myc), located on chromosome 2p24, and changes in the normal diploid chromosomal content
         a) Both are correlated with disease prognosis and disease recurrence
         b) The amplification can be in the form of the double minute chromosomes, which are extragenomic segments of DNA, or in homogeneously staining chromosomal regions
      ii. Variable DNA content of neuroblastoma
         a) Near-triploid DNA index regardless of any clinical or biologic features predicts a smaller risk of progression to higher-stage diseases
         b) Diploid/tetraploid index tends to predict higher risk of progression or multiple relapses
      iii. Other molecular markers (receptors for nerve growth factors) associated with neuroblastoma
         a) Trk A: associated with favorable neuroblastomas
         b) Trk B: expressed in unfavorable neuroblastomas

7. Wilms' tumor (WT)
   a. Biological pathways leading to the development of Wilms' tumor
      i. Complex
      ii. Involvement of several genetic loci
         a) Two genes on chromosome 11p; one on chromosome 11p13 (the Wilms' tumor suppressor gene, *WT1*) and the other on chromosome 11p15 (the putative Wilms' tumor suppressor gene, *WT2*)
         b) Loci at 1p, 7p, 16q, 17p (the *p53* tumor suppressor gene), and 19q (the putative familial Wilms' tumor gene, *FWT2*)
   b. Inheritance
      i. Sporadic in majority of cases (>95%)
      ii. Familial predisposition to Wilms' tumor is rare, affecting only1.5% of patients with Wilms' tumor
   c. Association with specific genetic disorders or recognizable syndromes
      i. WAGR syndrome
         a) Large constitutional deletions of chromosome 11p13
         b) Tumor suppressor gene: *WT1*
         c) Mechanism of gene inactivation: hemizygous deletion
         d) Wilms' tumor incidence: >30%
         e) Associated features: aniridia, genitourinary abnormalities
         f) Mental retardation
         g) Associated aniridia: caused by deletion of the *PAX6* gene in the 11p13 region in close proximity to *WT1* gene
      ii. Denys–Drash syndrome
         a) Chromosomal loss: 11p13
         b) Tumor suppressor gene: *WT1*
         c) Mechanism of gene inactivation: mutation (DNA binding domain)
         d) Wilms' tumor incidence: >90%
         e) Associated features: pseudohermaphroditism, mesangial sclerosis, renal failure
      iii. Beckwith–Wiedemann syndrome
         a) Chromosomal loss: 11p15
         b) Tumor suppressor gene: (*WT2*/*BWS*)
         c) Mechanism of gene inactivation: unknown
         d) Wilms' tumor incidence: 5%
         e) Associated features: organomegaly, hemihypertrophy, umbilical hernia,

neonatal hypoglycemia, other tumors such as hepatoblastoma
iv. Perlman syndrome
a) Renal dysplasia
b) Multiple congenital anomalies
c) Gigantism
d) Wilms' tumor
v. X-linked Simpson–Golabi–Behmel syndrome
a) Overgrowth disorder
b) Caused by mutations in the *GPC3* gene located on Xq26
c) Overlapping physical features with Beckwith–Wiedemann syndrome
d) Wilms' tumor and other embryonal tumors

8. Primary tumors of the central nervous system (Martens 1994)
a. Primitive neuroectodermal tumors (PNETs)
i. Homozygous inactivation of the *TP53* gene, a tumor-suppressor gene located in 17p, secondary to i(17p): implicated in the development of several tumor types
ii. Molecular analyses indicating the existence of a second tumor-suppressor gene, distinct from and distal to the *TP53* locus, that might be pathogenetically involved in a subset of primitive neuroectodermal tumors
b. Gliomas
i. A tumor suppressor gene in 22q implicated as an essential event in the genesis of a number of neurogenic neoplasms
ii. A candidate for such a role is *NF2*, thought to be mutated in neurofibromatosis type 2, a dominantly inherited disorder predisposing for gliomas, neurinomas, and meningiomas

Clinical Features

1. Only retinoblastoma, neuroblastoma, and Wilms' tumor will be discussed here.
2. Retinoblastoma (Martens 1994)
a. The most common malignant ocular tumor in childhood and affects approximately 1 in 18,000 children under 5 years of age in the USA (Devesa 1975)
b. A rare malignant tumor arising from cells of the embryonal neural retina
c. Develops only in infants and young children
d. Unifocal retinoblastoma: presence of a single retinoblastoma
e. Multifocal retinoblastoma: presence of more than one tumor
i. Unilateral: occurrence of multiple RB tumors in one eye
ii. Bilateral: occurrence of RB tumors in both eyes
iii. "Trilateral"retinoblastoma: occurrence of bilateral retinoblastoma plus a pinealoma
f. Presenting signs
i. White papillary reflex (leukocoria): the most common presenting sign
ii. Strabismus: the second most common presenting sign
iii. Less common signs
a) Poor vision
b) Orbital swelling
c) Unilateral mydriasis
d) Heterochromia iridis
e) Glaucoma
f) Orbital cellulitis
g) Uveitis
h) Hyphema or vitreous hemorrhage
i) Nystagmus
g. Retinoma-associated eye lesions ranging from retinal scars to calcified phthisical eyes resulting from spontaneous regression of retinoblastoma (include benign retinal tumors called retinocytoma or retinoma)
h. Patients with germline RB1 mutations: at an increased risk of developing tumors outside the eye
i. Pinealomas
ii. Osteosarcomas
iii. Soft tissue sarcomas
iv. Melanomas
3. Neuroblastoma (Davidoff and Hill 2001; Lee et al. 2003)
a. The most frequently occurring solid tumor in children
b. Responsible for 8–10% of all cancers in children and approximately 15% of all pediatric cancer deaths
c. 40% of cases diagnosed in children under 1 year of age who have a very good prognosis
d. 60% in older children and young adult who have a poor prognosis despite advanced medical and surgical management

e. Amplification of *MYCN* gene found in neuroblastomas:
   i. A powerful prognostic indicator
   ii. Associated with:
      a) Advanced stages of disease
      b) Rapid tumor progression
      c) Poor outcome
f. Clinical presentation
   i. Variable presentation
      a) Localized disease (one third to one fourth of cases)
      b) Metastatic disease (two third to three fourth of cases)
      c) Asymptomatic in small number of patients
   ii. Retroperitoneal and abdominal tumors (62–65%)
      a) A palpable mass
      b) Abdominal pain (34%)
      c) Weight loss (21%)
      d) Anorexia
      e) Vomiting
      f) Symptoms related to mass effect
   iii. Thoracic tumors (14%)
      a) Dysphagia
      b) Cough
      c) Respiratory distress
   iv. Pelvis (5%) and paraspinal tumors that compress the spinal cord
      a) Urinary dysfunction
      b) Constipation
      c) Fetal incontinence
      d) Lower extremity weakness
   v. Neck tumors
      a) Horner syndrome: present in patients with lesions in the cervical or upper thoracic sympathetic ganglia (1.7%)
      b) Airway distress
   vi. Liver metastasis
      a) Hepatomegaly
      b) Jaundice
      c) Abnormal liver function tests
      d) Abdominal pain
   vii. Bone metastases and bone marrow involvement
      a) Bone pain
      b) Palpable bony nodules
      c) Anemia
      d) Purpura
   viii. Fever (28%)
   ix. Lymph node metastases: palpable lymphadenopathy
   x. Retrobulbar and orbital metastases: periorbital ecchymoses
   xi. Severe diarrhea refractory to standard treatment due to production of vasoactive intestinal peptide by tumor cells (4%)
   xii. Acute cerebellar encephalopathy (2%)
      a) Cerebellar ataxia
      b) "Dancing eyes and dancing feet syndrome" (involuntary eye fluttering and muscle jerking)
      c) Myoclonic jerks
   xiii. Symptoms related to high catecholamine levels (0.2%)
      a) Hypertension
      b) Palpitations
      c) Flushing
      d) Sweating
      e) Malaise
      f) Headache

4. Wilms' tumor (Martens 1994)
   a. The most common kidney cancer in childhood
   b. Represents about 6% of all childhood cancers in the USA
   c. Clinical presentation
      i. Presence of an asymptomatic abdominal mass: the most common presentation
         a) Usually affects one kidney with multiple tumor foci in 8% of cases
         b) Bilateral in 6% of cases
      ii. Hypertension, gross hematuria, and fever observed in 5–30% of patients
      iii. Hypotension, anemia, and fever in a small number of patients who have hemorrhaged into their tumor
      iv. Rare respiratory symptoms related to the presence of lung metastases in patients with advanced-stage disease
   d. Association with congenital malformations
      i. Found in 60% of the bilateral cases and 4% of the unilateral cases
      ii. WAGR
      iii. Denys–Drash syndrome
      iv. Beckwith–Wiedemann syndrome
      v. Perlman syndrome
      vi. Beckwith–Wiedemann syndrome

vii. X-linked Simpson–Golabi–Behmel syndrome
e. Likelihood of developing Wilms' tumor in aniridia patients
i. Aniridia patients without other anomalies: 1–2%
ii. Aniridia patients with WAGR syndrome: 25–40%

Diagnostic Investigations

1. Cytogenetic and molecular genetic techniques used in analyzing tumor materials from patients (Cooley et al. 2009)
a. Conventional and molecular cytogenetic techniques most commonly used (Varella-Garcia 2003)
i. Metaphase cytogenetics or karyotyping (G-, Q-, and R-bandings):
a) Protein digestion and/or special dye generating banding pattern specific for each chromosome
b) Identification of numerical and structural chromosomal anomalies
ii. Fluorescence in situ hybridization (FISH)
a) A small, labeled DNA fragment used as a probe to search for homologous target sequences in chromosome or chromatin DNA
b) Identification of the presence, number of copies per cell, and localization of probe DNA
c) Applicable to interphase cells
iii. Comparative genomic hybridization (CGH)
a) Comparative hybridization of differentially labeled total genomic tumor DNA and normal reference DNA to normal human metaphases used as templates
b) Detection of variant DNA copy numbers at the chromosome level
c) Applicable to fresh or preserved specimens
iv. Multicolor karyotyping (M-FISH, SKY)
a) Hybridization with 24 differentially labeled, chromosome-specific probes allowing the painting of every human chromosome in a distinct color
b) Detection of rearrangements involving one or more chromosomes within individual metaphase spreads
c) Accurate origin identification of all segments in complex rearrangements
d) Clarification of marker chromosomes
b. Other techniques
i. Flow cytometry
ii. Reverse transcriptase-polymerase chain reaction (RT-PCR)
iii. Quantitative PCR
iv. Southern blot analysis of gene rearrangements
v. Loss of heterozygosity analysis (LOH)
vi. Restriction landmark genome scanning
vii. Representational difference analysis
viii. cDNA gene expression microarrays
ix. Proteomic methods
a) Matrix assisted laser desorption ionization-time of flight (MALDI-TOF)
b) Surface enhanced laser desorption ionization-time of flight (SELDI-TOF)
2. Cytogenetic studies in retinoblastoma
a. Cytogenetically visible changes of 13q14: infrequent in retinoblastoma
b. Deletions or unbalanced translocations leading to loss of 13q14 band (10%)
c. Monosomy 13 (10%)
d. i(6p), mostly detected as a supernumerary isochromosome (one third of cases)
e. Gain of 1q material (one third of cases)
f. Cytogenetic aberrations in retinoblastoma
i. Secondary to *RB1* mutations
ii. More related to tumor progression than to tumor establishment
3. Other studies for retinoblastoma
a. Indirect ophthalmoscopy to examine the fundus of the eye to detect retinomas, preferably by a retinal specialist
b. Imaging studies (CT, MRI, ultrasonography) to support the diagnosis and stage the tumor
c. Histopathological examination to confirm the diagnosis
d. Direct DNA testing of the RB1 gene in WBC DNA
i. Identify a germline mutation in about 80% of individuals with a hereditary predisposition to retinoblastoma

ii. Probability of detection of the RB1 gene mutation in an index case dependent on the following:
a) Whether the tumor is unifocal or multifocal
b) Whether the family history is positive or negative
c) The sensitivity of the testing methodology

4. Cytogenetic studies in neuroblastoma (Davidoff and Hill 2001; Lee et al. 2003)
a. Identification of multiple cytogenetic abnormalities in neuroblastoma
i. Allelic losses on chromosomes 1p (particularly 1p36), 11q, 14q, 7q, 2q, 3p, and 19q
ii. Allelic gains on chromosomes 17q, 18q, 1q, 7q, and 5q
b. Hyodiploid, triploid, or "near triploid", or "near-tetraploid" in modal chromosome number
i. Majority (55%) with triploid or "near-triploid" (a chromosome number between 58 and 80)
ii. Remainder with "near-diploid" (35–57 chromosomes) or "near-tetraploid" (81–103 chromosomes)
c. Frequent partial 1p monosomy (70–80% of cases) with most commonly deleted region being between 1p32 and 1p36
d. Gain on the long arm of chromosome 17 (17q)
i. Probably the most common genetic abnormality in neuroblastomas
ii. Occurring in approximately 75% of primary tumors
iii. Most often resulting from an unbalanced translocation of this region to other chromosomal sites, most frequently 1p or 11q
iv. A powerful independent finding of adverse outcome
e. Deletions of the long arms of chromosomes 11 (11q) and 14 (14q)
i. Appears to be common in neuroblastomas
ii. Both inversely related to *MYCN* amplification
f. Frequent presence of extrachromosomal double minute chromatin bodies (DMs) or homogeneously staining regions (HSRs)
i. Cytogenetic evidence of gene amplification
ii. Amplified region derived from the distal short arm of chromosome 2 (2p24) that contains the *MYCN* proto-oncogene

5. Other studies for neuroblastoma
a. Imaging studies
i. Chest radiography
ii. Ultrasound
iii. CT
iv. MRI
v. Radionucleotide bone scan
b. Blood tests
i. Elevated urinary and serum catecholamine metabolites
a) Homovanillic acid (HVA)
b) Vanillylmandelic acid (VMA)
ii. Abnormal liver function tests
c. Molecular genetic testing (Castel et al. 2007)
i. Array CGH analysis: a pangenomic technique allowing insights into gains and losses with high resolution
ii. Multiplex ligation-dependent probe amplification (MILPA)

6. Cytogenetic studies in Wilms' tumor
a. A near-diploid chromosome count
b. Triploid-tetraploid karyotypes in a few cases with tendency to have an anaplastic morphology
c. Numerical aberrations
i. Mainly involving gains of chromosomes
a) Trisomy 12: particularly frequent
b) Followed by trisomies 8, 6, 7, 13, 20, and 17
d. Structural rearrangements
i. Involve all chromosomes except the Y chromosome
ii. Recombinations of 11p (>20%)
a) Vast majority of the breakpoints assigned to 11p13 and 11p15, indicating these loci are important in sporadic Wilms' tumor
b) Loss of heterozygosity studies indicating that alleles from 11p13 and 11p15 are often lost in Wilms' tumor
iii. Loss of the long arm of chromosome 16 occurring in about 20% of Wilms' tumors: associated with poor prognosis independent of stage or tumor histology

7. Other studies in Wilms' tumor
   a. Renal ultrasound to monitor Wilms' tumor
   b. Abdominal CT scanning to determine the tumor's origin, lymph node involvement, bilateral kidney involvement, and invasion into major vessels (e.g., inferior vena cava or liver metastases)
   c. Chest radiography to detect lung metastases
   d. Histopathological examination to confirm the diagnosis
   e. Further studies of certain patients with either Wilms' tumor or associated anomalies (Coppes and Egeler 1999)
      i. Hemihypertrophy/Beckwith–Wiedemann syndrome: uniparental disomy studies to evaluate constitutional or somatic alterations of 11p15
      ii. WAGR syndrome: molecular evaluation of the 11p13 region if chromosomal studies do not reveal a deletion
         a) Fluorescence in situ hybridization (FISH)
         b) Pulsed-field electrophoresis
      iii. Denys–Drash syndrome: molecular evaluation of *WT1* to determine whether the patient indeed carries a constitutional mutation. If the mutation is present, family members need to be screened.
      iv. Aniridia
         a) Cytogenetic analysis and molecular evaluation of the WAGR region by FISH or pulsed field to rule out contiguous deletion of *Pax6* and *WT1*
         b) No further screening for Wilms' tumor if *Pax6* mutation is identified in isolated cases of aniridia
8. Cytogenetic studies of primary tumors of the central nervous system (Martens 1994)
   a. Primitive neuroectodermal tumors
      i. Near-diploid in most tumors
      ii. I(17q): the most consistent rearrangement
   b. Gliomas
      i. Mostly astrocytomas and ependymomas
      ii. No specific structural rearrangement found
      iii. Loss of 1p and gain of 1q found in a subset of tumors
      iv. Loss of chromosome 22 common in childhood gliomas
      v. Loss of material from chromosome 22, either numeric or structural aberrations, found recurrently in rhabdoid tumors, meningiomas, and neurinomas
9. Cytogenetic studies in hepatoblastoma (Mertens et al. 1994)
   a. Trisomy 2 or duplications of part of 2q: detected in half of the cases
   b. Trisomy 20
   c. Duplication of 8q through either i(8q) formation or trisomy 8
10. Cytogenetic studies in sarcomas
   a. Ewing sarcoma/primitive neuroectodermal tumor (Davidoff and Hill 2001)
      i. Reciprocal translocation t(11;22)(q24;q12)
         a) Characteristic primary rearrangement
         b) Found in nearly 90% of the tumors
         c) Causing a fusion of the transcription factor gene *FLI1* on chromosome 11 with *EWS* on chromosome 22 (*FLI1-EWS*, a fusion transcript). Only the chimeric gene expresses on the derivative chromosome 22 which contains a sequence encoding a DNA-binding domain from *FLI1*
      ii. t(21;22)(q22;q12), *ERG-EWS*
      iii. t(7;22)(p22;q12), *ETV1-EWS*
      iv. t(17;22)(q12;q12), *E1AF-EWS*
      v. t(2;22)(q33;q12), *FEV-EWS*
   b. Additional chromosome changes
      i. Trisomy 8
      ii. Der(16)t(1;16)(a10-q21;q10-13), leading to gain of 1q and loss of 16q
   c. Congenital or infantile fibrosarcoma (Mertens et al.1994)
      i. t(12;15)(p13;q25), *ETV6-NTRK3*
      ii. Hyperdiploid with few or no structural rearrangements
      iii. Nonrandom numerical changes
         a) Trisomies 11 and 20, the most frequent changes, followed by:
         b) Trisomies 17 and 8
   d. Osteosarcoma (Mertens et al. 1994)
      i. Highly complex karyotypes in the majority of cases
      ii. Chromosome number in the triploid-tetraploid range
      iii. Most common numeric aberrations involving −3, −10, −13, and −15

iv. Structural rearrangements involving chromosome arms 1p, 1q, 3p, 3q, 7q, 11p, 17p, and 22q
v. Presence of many undefined chromosome markers

e. Rhabdomyosarcoma (Mertens et al. 1994)
i. The most common soft tissue sarcoma in childhood
ii. Alveolar subtype
a) Most contain 1 or 2 recurring translocations, namely, t(2;13)(q35-37;q14) or the rare t(1;13)(p36;q14), shown to juxtapose the *PAX3* gene on chromosome 2 with the *FKHR* gene on chromosome 13, leading to the formation of a hybrid transcription factor (*PAX3-FKHR*)
b) Found in about 70% of the alveolar tumors
c) Only occasionally described in other subtypes
iii. Embryonal subtype: numerical changes with +2, +8, +11, and +20, found in 35–50% of cases

11. Other common, recurrent translocation in solid and soft tissue tumors of childhood (Davidoff and Hill 2001)
a. Alveolar soft part sarcoma: t(X;17)(p11;q25), *ASPL-TFE3*
b. Inflammatory myofibroblastic tumor: 2p23 translocations, *ALK-TPM3*
c. Desmoplastic small round cell tumor
i. t(11;22)(p13;q12), *WT1-EWS*
ii. t(11;22)(q24;q12), *FLI1-EWS*, *ERG-EWS*
d. Synovial sarcoma
i. t(X;18)(p11.23;q11.2), *SSX1-SSXT*
ii. t(X;18)(p11.21;q11), *SSX2-SSXT*
e. Malignant melanoma of soft part (clear cell sarcoma): t(12;22)(q13;q12), *ATF1-EWS*
f. Myxoid liposarcoma
i. t(12;16)(q13;p11), *CHOP-TLS*(*FUS*)
ii. t(12;22)(q13;q12), *CHOP-EWS*
g. Extraskeletal myxoid chondrosarcoma: t(9;22)(q22;q12), *CSMF-EWS*
h. Dermatofibrosarcoma protuberans and giant cell fibroblastoma: t(17;22)(q22;q13), *COLIAI-PDGFB*
i. Lipomas: t(var;12)(var;q13-15), var, *HMGI-C* (Cooper 1996)
j. Leiomyomas: t(12;14)(q13;15), *HMGI-C*, (Cooper 1996)

12. Other primary chromosome changes in solid tumors (Sandberg 1988)
a. Benign tumors
i. Meningioma and acoustic neuroma
a) −22
b) 22q−
ii. Mixed tumors of salivary glands
a) t(3;8)(p21;q12)
b) t(9;12)(p13-22;q13-15)
iii. Colonic adenomas
a) 12q− and/or +7
b) 12q− and/or +8
iv. Cortical adenoma of the kidney
a) +7
b) +17
c) −Y
b. Adenocarcinomas
i. Bladder
a) i(5p)
b) +7
c) −9/9q−
d) 11p−
ii. Prostate: del(10)(q24)
iii. Lungs (small cell carcinoma): del(3)(p14p23)
iv. Colon
a) 12q−
b) +7
c) +8
d) +12
e) 17(q11)
f) 17p–
v. Kidney: del(3)(p11p21)
vi. Uterus: 1q−
vii. Ovary
a) 6q−
b) t(6;14)(q21;q24)
viii. Endometrium
a) Trisomy 1q
b) +10
c. Embryonal and other tumors
i. Testicular (germ cell tumors): i(12p)
ii. Malignant melanoma
a) Del(6)(q11q27)
b) i(6p)
c) Del(1)(p11p22)
d) t(1;19)(q12;q13)

iii. Mesothelioma: del(3)(p13p23)
iv. Glioma: −22

13. Potential prognostic markers of neoplastic disease (Barcus et al. 2000)
    a. Breast cancer: allelic loss at 1p22-p31 (lymph node metastasis and tumor size >2 cm)
    b. Bladder cancer
        i. LOH RB (high grade/muscle invasion)
        ii. Genomic alterations (2q−, 5p+, 5q−, 6q−, 8p−, 10q−, 18q−, 20q+) (higher grade)
    c. Cervical carcinoma: LOH on chromosome (advanced stage)
    d. Colorectal cancer
        i. LOH at 18q21 or p53 expression (recurrence/poor survival)
        ii. *MSI* (microsatellite instability)and *K-ras* mutations in normal appearing colonic mucosa (predictive of colorectal cancer)
        iii. P16-hypermethylation (shorter survival in Stage T3N0M0 tumors)
    e. Gastric cancer
        i. LOH p53 (invasive disease)
        ii. LOH of 7q (D7S95) (poor prognosis (in Stage III/IV))
    f. Glioma: chromosome 22q loss (astrocytomas progression)
    g. Head and neck squamous cell carcinoma
        i. LOH of 14q (poor outcome)
        ii. LOH on 2q (poor prognosis)
        iii. LOH on 17p (chemoresistance)
    h. Melanoma: LOH in plasma (advanced stage/tumor progression)
    i. Neuroblastoma
        i. N-myc amplification (poor prognosis)
        ii. TrkA expression (good prognosis)
        iii. High telomerase expression (aggressive behavior)
    j. Neuroblastomas, 4s-: N-myc amplification, 1p deletion, 17q gains, elevated telomerase activity (poor prognosis)
    k. Non-small cell lung cancer
        i. Allelic imbalances on 9p (poor prognosis)
        ii. LOH 11p (poor prognosis)
    l. Primitive neuroectodermal tumor
        i. LOH of 17p (metastatic disease)
        ii. C-myc amplification (poor prognosis)
    m. Prostate cancer: LOH on 13q (advanced stage)
    n. Retinoblastoma: LOH at RB1 locus (tumoral differentiation, absence of choroidal invasion)

14. Chromosome abnormalities observed in some solid tumors (Cooley et al. 2009)
    a. Genitourinary
        i. Renal
            a) Clear cell round cell carcinoma (RCC): −3 or del(3p), del(3p) with gain 5q, del(3p) with loss 5q, −14/del (14q)
            b) Papillary RCC: +7, +17, −Y, 9p−
            c) t(Xp11.2) RCC: (X;17)(p11.2;q25), t (X;17) (p11.2;q23), t(X;1)(p11.2;p34)
            d) t(6;11) RCC: t(6;11)(p21;q12)
            e) Chromophobe RCC: loss 1, 2, 6, 10, 13, 17, 21
            f) Oncocytoma: 1p−, t(11q13)
            g) Rabdoid: −22/22q−
            h) Congenital mesoblastic nephroma: t (12;15)(p12;q25), +11, +17, +20
        ii. Bladder, papillary: del(9)(p21), 8p−, +7, +17
        iii. Wilms' tumor: 16q−, +1q, 1p−, −22, 17p−
        iv. Prostate: +17q31, 8p22−, +8q24, 10q−, 17p13−
    b. Gastrointestinal
        i. Liver
            a) Hepatoblastoma: +20, +2, +8, t (1q12q21)
            b) Hepatic mesenchymal hamartoma: t(11;19)(q13;q13.4), t(19q13.4)
        ii. Salivary gland
            a) Pleomorphic adenoma: t(3;8)(p21;q12)
            b) Mucoepidermoid cancer: t(11;19) (q21;p13)
            c) Warthin tumor: t(11;19)(q21;p13)
    c. Breast
        i. Invasive intraductal: dmin (double minute), hsr (homogeneously staining region)
        ii. Secretory breast: t(12;15)(p13;q25)
    d. CNS
        i. Astrocytic tumors: +7, −10/10q−, 9p21−, 19q−
        ii. Glioblastoma: +7, 10q−, 9p−
        iii. Anaplastic: 1p−, 19q−, der(1;19)(q10;p10)
        iv. Mixed oligoastocytoma: +7, −10/10q−, 15q−
        v. Oligoastrocytoma: 19q−, 1p−

e. Ependymoma
   i. Spinal: +7, −22q, 14q−
   ii. Intracranial: +1q, 6q−, +7, 9p−
f. Mudulloblastoma: i(17q), 17p−, −10/10q−, +7
g. Supratentorial primitive neuroectodermal tumor +1q, 16q−, 19p−
h. Atypical teratoid/rhabdoid tumor: −22 or del (22q11.23)
i. Meningioma: −22 or del(22q11.2), 1p−,−14/14q−
j. Choroid plexus tumors
   i. Carcinoma: loss 2, 3, 4, 5, 6, 8, 10, 11, 13, 14, 15, 16, 17, 18, 19, 22
   ii. Papilloma: gain 7, 8, 9, 12, 14, 15, 17, 18, 19, 20
k. Small round cell tumors
   i. Alveolar RMS: t(2;13)(q37;q14), t(1;13)(p36;q14), t(X;2)(q13lq35); t(2;2)(q35;p23)
   ii. Embryomal rhabdomyosarcoma: gain 2, 7, 8, 11, 12, 13, 20; loss 1p, 3p, 9q, 10q, 16q, 17p, 22
   iii. Neuroblastoma: del(1p), del(11q) w/o *MYCN* amp, del(1p), +17q, *MYCN* amp, triploidy w/o above abnormalities
   iv. Ewing sarcoma/peripheral neuroectodermal tumor: t(11;22)(q24;q12) & variants, t(21;22)(q22;q12), del(9p), 17p−, der(1;16)(q10;p10)
   v. Desmoplastic small round cell tumor: t(11;22)(p13;q12)
   vi. Clear cell sarcoma: t(12;22)(q13;q12)
   vii. Retinoblastoma: del(13q14), gain 1q, 6p
   viii. Lymphomas: Specific translocations
l. Bone, soft tissue
   i. Congenital fibrosarcoma/congenital mesoblastic nephroma: t(12;15)(p12;q25), +11, +17, +20
   ii. Synovial sarcoma: t(X;18)(p11.2;q11.2)
   iii. Lipoma: t(3;12)(q27–28;q14–15), variants
   iv. Liposarcoma
      a) Myxoid, round cell: t(12;16)(q13;p11)
      b) Myxoid: t(12;22)(q13;q12), variant
      c) Well differentiated: rings, markers, dmin
m. Leiomyoma: t(12;14)(q15;q24)
   i. Alveolar soft part sarcoma: der(17)t(X;17)(p11.2;q25)
   ii. Extraskeletal myxoid chondrosarcoma: t(9;22)(q22;q12), t(9;17)(q22;q11.2), t(9;15)(q22;q21), t(3;9)(p11;q22)
n. Dermal tumors
   i. Dermatofibrosarcoma protuberans: der(22)t(17;22)(q22;q13.1) or r(22)t(17;22)
   ii. Giant cell fibroblastoma: t(17;22)(q22;q13.1)
   iii. Bednar tumor: der (22)t(17;22) (q22;q13.1) or r(22)t(17;22)
   iv. Hidradenoma: t(11;19)(q21;p13)
o. Non-small cell lung cancer: 3p−, +7, *EGFR* high copy number or amplification
p. Dysgerminoma, ovary: i(12p), 12p overrepresentation
q. Testicular germ cell tumors, seminoma, nonseminoma: i(12p), 12p amplification

Genetic Counseling

1. Recurrence risk
   a. Retinoblastoma
      i. Predisposition to retinoblastoma which is caused by germline mutations in the *RB1* gene: transmitted in an autosomal dominant fashion
      ii. Use *RB1* mutation analysis to clarify the genetic status of at-risk sibs and offspring when a previously characterized germline cancer-predisposing mutation is available
      iii. Use indirect testing using polymorphic loci linked to the *RB1* gene in some families to clarify genetic status of at-risk family members if *RB1* direct DNA testing is not available or is uninformative
      iv. Use empiric recurrence risk estimates in all families in which direct DNA testing of *RB1* and linkage analysis are unavailable or uninformative
      v. Risk to patient's siblings
         a) When there is an existing family history: a 45% chance for siblings of bilaterally affected cases and a 30% chance for siblings of unilaterally cases to develop disease
         b) When there is absence of any family history: 2% risk for siblings of bilaterally

affected cases and 1% for siblings of unilaterally affected cases to develop disease
c) There is an additional risk to siblings in the absence of any family history or documented mutation in parental leukocyte DNA because of germline mosaicism. If neither parent has the cancer-predisposing *RB1* germline mutation that was identified in the index case, germline mosaicism in one parent is possible and the risk to each sib of having retinoblastoma is 3–5%.
d) If the index case has mosaicism for an *RB1* cancer-predisposing mutation (the mutation arose as a post-zygotic event) and that neither parent has an *RB1* germline mutation, the risk to the sibs is not increased and thus it is not warranted to test the sibs for the *RB1* mutation identified in the index case.

vi. Risk for patient's offspring
a) About 45% by the age 6 years (consistent with an autosomal dominant inheritance with 90% penetrance) for the offspring of survivors of hereditary (multifocal, bilateral) retinoblastoma
b) About 2.5% for the offspring of survivors of unilateral retinoblastoma
c) The low (∼1%), but not negligible, risk to the offspring of index cases with unifocal disease and a negative family history reflects the possibility of a germline *RB1* mutation with low penetrance or mutational mosaicism.

b. Genetic counseling for retinoblastoma in the presence of positive family history (Vogel 1979; Isidro et al. 2011)
i. Multiplex disease (>2 affected members): The index patient had retinoblastoma and one or more close relatives are also affected
a) Affected individuals definitely carry a germline mutation
b) A 50% chance exists that a known carrier will pass the mutant copy of the retinoblastoma gene to each child and there is 50% penetrance, there is a 50% × 90% = 45% chance that each child will develop retinoblastoma

ii. Multiplex disease (>2 affected members): The index patient did not develop retinoblastoma as a child but a parent is known to be a carrier
a) Approximately 10% risk that an asymptomatic son or daughter of a known carrier is also a carrier
b) The risk that his or her offspring will inherit a mutation is about 5% and the risk of the disease is 90% × 5% = 4.5%

iii. Simplex disease (only one family member affected): The index patient had multifocal retinoblastoma
a) The patient very likely has a germline mutation
b) The risk to each offspring is 50% for being a carrier and 45% for developing the disease

iv. Simplex disease (only one family member affected): The index patient had unifocal retinoblastoma (one tumor in one eye only)
a) A 12% risk exists that the patient carries a germline mutation (i.e., has hereditary retinoblastoma) and an 88% risk that he or she does not (nonhereditary retinoblastoma)
b) The risk for the first child of the index patient is 6% for being a carrier and 5.4% for developing the disease
c) If the first child does not develop retinoblastoma, the risk for the next child is less
d) If at least one child develops retinoblastoma, the index patient definitely has the hereditary type of the disease and risk for family members are as described for mutiplex families

v. Simplex disease (only one family member affected): Two unaffected parents have one child with retinoblastoma
a) The risk of the parents' second child's developing retinoblastoma is about 1% if the first child had unifocal disease and about 6% if the first child had multifocal disease
b) These risks decrease with every unaffected child that passes the years of highest risk (year 0–5) without developing the disease

vi. Simplex disease (only one family member affected): The index patient is an adult of childbearing age who did not develop retinoblastoma but a sibling had retinoblastoma
  a) A small risk exists that one of the parents is an asymptomatic carrier and the index patient is also an asymptomatic carrier
  b) The carrier risk for the index patient is 0.1% if the affected sibling had unilateral retinoblastoma and 0.6% if the affected sibling had bilateral retinoblastoma
  c) The risk that the first child of the index patient will develop retinoblastoma is approximately half of these numbers, i.e., 0.05% or 0.3%, respectively

c. Neuroblastoma
  i. Risk for patient's sibling: low unless a parent has hereditary form of neuroblastoma
  ii. Risk for patient's offspring: 50%

d. Wilms' tumor
  i. Risk for patient's sibling: low unless a parent has hereditary form of Wilms' tumor
  ii. Risk for patient's offspring: 50%

2. Prenatal diagnosis
  a. Retinoblastoma
    i. Prenatal testing possible if the germline *RB1* mutation in the parent is known or if *RB1* linkage analysis is informative in the family
    ii. Mutation analysis on fetal DNA obtained from amniocentesis or CVS
    iii. Use prenatal ultrasonography to detect intraocular tumors if the disease-causing RB1 mutation is identified in the fetus
  b. Adrenal neuroblastoma (Kesrouani et al. 1999)
    i. Prenatal diagnosis adrenal neuroblastoma by ultrasonography usually made in the 3rd trimester
    ii. Sonographic appearance of the adrenal neuroblastoma varies
      a) Solid
      b) Purely cystic (50%)
      c) Mixed echo pattern (related to necrosis, hemorrhage, or spontaneous tumoral involution)
      d) Fetal hydrops
      e) Hydropic placenta with metastases in the placenta
    iii. Needle biopsy for selection of the group with favorable biological parameters (N-myc, DNA index)
    iv. Frequently producing catecholamines and hence maternal symptoms could aid the diagnosis
    v. Elevated catecholamines in the amniotic fluid
  c. Wilms' tumor by prenatal ultrasonography
    i. A solid echogenic mass with a clearly defined capsule
    ii. Areas of hemorrhage and necrosis may be seen within the mass.

3. Management
  a. Surgeries for most solid tumors
  b. Determining the genetic changes present in the tumor of an individual patient: becoming increasingly important for managing the oncology patient
  c. Retinoblastoma (Chintagumpala et al. 2007)
    i. Goals of treatment: preservation of sight and life
    ii. Management of intraocular disease
      a) Enucleation
      b) External beam radiation (EBR) therapy
      c) Brachytherapy: involves the placement of a radioactive implant
      d) Thermotherapy
      e) Chemothermotherapy
      f) Laser photocoagulation
      g) Cryotherapy
      h) Chemotherapy
    iii. Management of extraocular disease: Patients with extraocular disease, having a very poor prognosis with respect to survival, may benefit from a combination of conventional chemotherapy and EBR and those with distant metastatic disease may benefit from high-dose chemotherapy and EBR in conjunction with bone marrow stem cell transplantation
  d. Neuroblastoma (Lee et al. 2003)
    i. Localized, low-risk disease:
      a) Primary curative surgery
      b) Minimal therapy: low-dose radiation or chemotherapy
      c) Supportive care with surveillance

ii. Intermediate-risk patients: combination therapy with radiation, chemotherapy, and surgery
iii. High-risk patients
   a) Combination of radiation, myeloablative chemotherapy, and surgery (delayed)
   b) Autologous bone marrow transplant
   c) Research protocols

e. Wilms' tumor: The usual approach in most patients is nephrectomy followed by chemotherapy with or without postoperative radiotherapy.

Cleft Lip and/or Cleft Palate

Cleft lip and/or palate (CL/CP) is the most common craniofacial malformation with an estimated incidence of approximately 1 in 700 to 1 in 1,000 live births among Caucasians. (Carinci et al. 2000). CL/CP may occur as an isolated finding or may be found in association with other congenital malformations.

Genetics/Basic Defects

1. Environmental agents (De La Pedraja et al. 2000)
   a. Cleft lip and cleft palate
      i. Alcohol
      ii. Anticonvulsants (phenytoin, sodium valproate)
      iii. Isotretinoin
      iv. Steroids
      v. Methotrexate
      vi. Maternal infections in the first trimester
         a) Rubella
         b) Toxoplasmosis
      vii. Maternal smoking
   b. Isolated clefts
      i. Little evidence linking to any single teratogenic agent, except anticonvulsant phenytoin
      ii. Use of phenytoin during pregnancy is associated with a tenfold increase in the incidence of cleft lip
   c. Cleft lip: Incidence of cleft lip in infants in mothers who smoke during pregnancy is twice that of those born to nonsmoking mothers
2. Genetic factors
   a. Syndromic clefts associated with malformations involving other developmental regions
      i. About 25% of neonates with CL/CP show associated malformations, syndromes or aneuploidy (Berge et al. 2001)
      ii. Van der Woude syndrome: the most commonly recognized syndrome associated with CL/CP, an autosomal dominant disorder characterized by CL/CP and blind sinuses or pits of the lower lip
      iii. Microdeletion of chromosome 22q11.2 (velocardiofacial syndrome, DiGeorge syndrome, and conotruncal anomaly face syndrome): currently the most common syndromic diagnoses among patients with clefts of the secondary palate alone
      iv. Other syndromes associated with clefts of the secondary palate alone:
         a) Stickler syndrome
         b) Ectrodactyly–ectodermal clefting (EEC) syndrome
         c) Popliteal pterygium syndrome
   b. Nonsyndromic cleft of the lip and/or palate (Carinci et al. 2000)
      i. An embryopathy derived from failure in fusion of the nasal process and/or palatal shelves
      ii. Genetic factors play an important role in the etiology of cleft lip and/or palate since one in five patients in different populations has a positive family history of CL/CP
      iii. Isolated CL/CP is considered multifactorial in origin and demonstrates strong familial aggregation with a significant genetic component
      iv. No evidence of classic Mendelian inheritance attributable to any single gene,

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_43,
© Springer Science+Business Media, LLC 2012

although a number of genes or loci have been implicated, including transforming growth factor-alpha, retinoic acid receptor alpha, *BCL3*, *MSX-1* and several regions on chromosome 6p23-24 (OFC1), 2q13 (OFC2), 19q13.2 (OFC3), and other loci such as 4q25–4q31.3 and 17q21

c. Molecular signaling events in embryonic palatal development (Yu et al. 2009)
   i. Failure of palatal shelf formation
      a) Recent studies have identified several molecular networks operating between the palatal shelf epithelium and mesenchyme during different steps of palatogenesis
      b) These networks include signaling molecules and growth factors such as sonic hedgehog (Shh), members of the transforming growth factor β (TGfβ) super family, including bone morphogenetic proteins (Bmps) and Tgfβs, fibroblast growth factors (Fgfs) and their receptors (FgfR), effectors and targets
   ii. Fusion of the palatal shelf with the tongue or mandible
      a) Severe reduction of the expression of *Jagged 2* (*Jag2*), thereby encoding a ligand for the Notch family receptors and ectopic Tgfβ3 production in the nasal epithelia of mice
      b) Mutations in TBX22 have been reported in families with X-linked cleft palate and ankyloglossia
   iii. Failure of palatal elevation
      a) Mutations of *Pax9, Pitx1*, or *Osr2* can lead to failed palatal shelf elevation and cleft palate defect
      b) The implication of GABA in palate development was demonstrated by genetic studies of mice lacking the β3 subunit of the GABA receptor that developed CP without other craniofacial malformations
   iv. Failure of palatal shelves to meet after elevation: Mutations in *Msx1* and *Lhx8* and conditional inactivation of *Tgfbr2* in CNC cells or *Shh* in the epithelium all result in retarded palatal shelf development
   v. Persistence of middle edge epithelium: Mutations of *CDH1*/E cadherin, which deletes the extracellular cadherin repeat domains required for cell-cell adhesion, have recently been associated with CL/CP in families with hereditary diffuse cancer

Clinical Features

1. Classification of different types of orofacial clefting
   a. Cleft lip with or without cleft palate (CL/CP)
      i. Unilateral cleft lip
      ii. Unilateral cleft lip and cleft palate
      iii. Bilateral cleft lip
      iv. Bilateral cleft lip and cleft palate
   b. Cleft palate only
      i. Cleft palate
      ii. Submucous cleft palate
      iii. Velopharyngeal insufficiency
      iv. Robin sequence and robin complexes
   c. Median clefts
      i. Median cleft lip
      ii. Persistent infranasal furrow
      iii. Median frenular cleft
      iv. Median mandibular cleft
   d. Alveolar clefts (oral-facial-digital syndromes)
   e. Tessier type clefts including lateral and oblique facial clefts
2. Racial difference in CL/CP (De La Pedraja et al. 2000)
   a. Whites: approximately 1 in 1,000 births
   b. African Americans: 0.41 per 1,000 births
   c. Asians: approximately twice of whites
3. Sex difference in CL/CP and isolated clefts of the secondary palate (De La Pedraja et al. 2000)
   a. Children born with CL/CP: 60–80% are males
   b. Isolated clefts of the secondary palate: more frequently in females
4. Sites of clefts
   a. Isolated cleft lip: 21%
   b. CL/CP: 46%
   c. Clefts of the secondary palate alone: 33%
   d. Unilateral clefts
      i. More common in the left than the right (2:1)
      ii. Much more common than bilateral (9:1)
      iii. Associated with palatal clefts in 68% of cases
   e. Bilateral clefts of the lip: associated with palatal clefts in 86% of cases

5. Types of cleft lip
   a. Microform
      i. Presence of a vertical groove and vermilion notching
      ii. Associated with varying degrees of lip shortening
   b. Unilateral incomplete cleft lip
      i. Present with varying degrees of lip disruption
      ii. Associated with an intact nasal sill or Simonart band (a band of fibrous tissue from the edge of the red lip to the nostril floor)
   c. Complete cleft lip: characterized by disruption of the lip, alveolus, and nasal sill
6. Incidence of cleft lip +/− palate (CL/CP) and cleft palate alone (CPA) (Robin et al. 2006)
   a. Overall incidence of CL/CP and CPA: 1–2/1,000 children
   b. CPA: about 1/1,500
      i. More common if submucous CP/CA is included
      ii. Bifid uvula occurs in 1 of 80 patients and often occurs in isolation, with no clefting of the palatal muscles
   c. Incidence of CL/CP: varies by race
      i. Highest among American Indians, at 3.6 cases per 1,000 live births
      ii. Lowest among African Americans, with 0.3 cases per 1,000 live births
      iii. The incidence of CPA does not vary by race
   d. Of all CL/CP and CPA
      i. 20% of all clefts are isolated cleft lip (18% unilateral, 2% bilateral)
      ii. 50% are CL/CP (38% unilateral, 12% bilateral)
      iii. 30% are CPA
   e. CL/CP is twice as common in males; CPA is twice as common in females
7. Secondary medical problems with the presence of cleft plate
   a. Difficulty in sucking
   b. Inadequate intake of formula
   c. Aspiration
   d. Deviated nasal septum (airway obstruction)
   e. Hearing impairment
   f. Recurrent ear infections
   g. Malocclusion
   h. Abnormal craniofacial growth
   i. Inability to generate a pressure gradient between the oral and nasal chambers (hinders sucking in most infants)
   j. Speech dysfunction
      i. The most serious untoward consequence associated with cleft palate
      ii. Hypernasality or escape of sound into the nasal cavity associated with the production of many consonant phonemes and vowels in the English language except m, n, and ng
   k. Cosmetic disfigurement associated with orofacial clefting

Diagnostic Investigations

1. Speech and hearing evaluation
2. Echocardiography for associated cardiac anomalies
3. Karyotyping if indicated, especially to detect del (22)(q11.2)
4. Molecular genetic analysis for a known mutation in a syndromic CL/CP

Genetic Counseling

1. Recurrence risk (Chen 1988; Tolarova 1972)
   a. Recurrence risk for nonsyndromic CL +/− CP
      i. Unaffected parent
         a) No previously affected child: about 0.1% (general population risk) (Bonaiti-Pellie and Smith 1974; Kirschner and LaRossa 2000)
         b) With one previously affected child: about 4%
         c) With two previously affected children: about 14%
      ii. One affected parent
         a) No previously affected child: about 4%
         b) With one previously affected child: about 12%
         c) With two previously affected children: about 25%
      iii. Two affected parents
         a) No previously affected child: about 35%
         b) With one previously affected child: about 45%
         c) With two previously affected children: about 50%
   b. Recurrence risk for nonsyndromic CP
      i. Unaffected parent

a) No previously affected child: about 0.04% (general population risk) (Kirschner and LaRossa 2000)
b) With one previously affected child: about 3.5%
c) With two previously affected children: about 13%

ii. One affected parent
a) No previously affected child: about 3.5%
b) With one previously affected child: about 10%
c) With two previously affected children: about 24%

iii. Two affected parents
a) No previously affected child: about 2.5%
b) With one previously affected child: about 40%
c) With two previously affected children: about 45%

c. Presence of a microform such as a forme fruste cleft lip, submucous cleft palate, or bifid uvula suggest genetic factors within the family, which would alter the inheritance risks (e.g., striking association with lower-lip pits in the van der Woude syndrome).

d. Recurrence risk for CL/CP with associated anomalies
i. Mendelian diseases and syndromes
a) Autosomal dominant inheritance (e.g., Apert syndrome)
b) Autosomal recessive inheritance (e.g., Smith-Lemli-Opitz syndrome)
c) X-linked inheritance (e.g., oto-palato-digital syndrome)

ii. Chromosome disorders (e.g., trisomy 13)

2. Prenatal diagnosis
a. Prenatal ultrasonography
i. CL/CP not reliably diagnosed until the soft tissues of the fetal face become distinct by 13–14 weeks by transabdominal (TA) sonography and by transvaginal (TV) sonography slightly earlier
ii. Fetal palate best seen in the axial plane
iii. Fetal lips optimally visualized in the coronal view
iv. To demonstrate isolated CL/CP
v. To demonstrate associated anomalies (limb and spine anomalies, most common with 33%; cardiovascular anomalies, 24%)

b. Fetal echocardiography in case of fetal cardiac anomalies
c. Fetal karyotyping in case of associated fetal anomalies

3. Management
a. Medical
i. A highly specialized multidisciplinary approach from birth to adulthood
ii. Airway management
iii. Establishment of feeding
iv. Speech, hearing, and language therapies

b. Surgical
i. Primary surgery on the lip: usually carried out around the age of 3 months followed by palatal repair at around 6 months
ii. Preventative and restorative dental care
iii. Orthodontics
iv. Secondary surgery in the form of alveolar bone grafting
v. Pharyngeal flap or sphincter pharyngoplasty for velopharyngeal incompetence

c. Psychological issues (Endrica and Kapp-Simon 1999)
i. Parental stress
ii. Parent-child relationship
iii. Behavioral and emotional adjustment
iv. Self-concept and personality
v. Cosmetic disfigurement
vi. Social functioning
vii. Congnitive development and adjustment
viii. Cleft Lip and Palate Association (CLAPA), a helpful source of support and information for both families and professionals

d. Recent observation suggests beneficial effects of folic acid supplementation during pregnancy in the prevention of facial clefting

Cleidocranial Dysplasia

Cleidocranial dysplasia is a generalized skeletal dysplasia affecting not only the clavicles but almost the entire skeletal system. It is characterized by aplasia or hypoplasia of the clavicles, enlarged calvaria with frontal bossing, multiple Wormian bones, delayed tooth eruption, supernumerary unerupted teeth, distal phalanges with abnormally pointed tufts, hypoplasia of the pelvis, and numerous other abnormalities (Jensen 1990)

Synonyms and Related Disorders

Cleidocranial dysostosis

Genetics/Birth Defects

1. Inheritance: autosomal dominant
2. About 20–40% of cases represent new mutations (Martinez-Frias et al. 1988)
3. Cause
   a. Caused by mutations in *CBFA1* (*RUNX2*) gene resulting in haploinsufficiency. Types of mutations identified are:
      i. Deletion
      ii. Insertion
      iii. Missense
      iv. Nonsense
   b. The gene for cleidocranial dysplasia called core-binding factor A1 (*CBFA1*) (a member of the runt family of transcription factors), mapped to 6p21. The alternative gene name is called *RUNX2*
   c. *CBFA1* encodes a transcription factor that activates osteoblast differentiation and plays a role in differentiation of chondrocytes
4. Germline line mosaicism has been reported (Pai et al. 2007)
5. No significant genotype/phenotype correlations observed

Clinical Features

1. Significant intra- and interfamilial variability of phenotypic expression (Mundlos 1999)
2. Abnormal craniofacial growth
   a. Head
      i. Abnormally large, wide-open fontanels at birth
      ii. A large brachycephalic head
      iii. A broad forehead with frontal bossing
      iv. Delayed closure of the fontanels and sutures
      v. Poorly developed midfrontal area showing a frontal groove owing to incomplete ossification of the metopic suture
      vi. Soft skull in infancy
   b. Face
      i. Frontal and parietal bossings, separated by a metopic groove
      ii. A depressed nasal bridge
      iii. Hypertelorism with possible exophthalmos
      iv. A small, flattened facial appearance (midface hypoplasia) with mandibular prognathism
      v. An anatomic pattern of dentofacial deformity consistent with the diagnosis of vertical maxillary deficiency (short face syndrome, type 2)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_44,
© Springer Science+Business Media, LLC 2012

   c. Oral/dental
      i. High arched palate
      ii. Clefts involving soft and hard palates
      iii. Persistence of the deciduous dentition with delayed eruption of the permanent teeth: a relatively constant finding
      iv. Impaction of supernumerary permanent teeth
      v. Crowding/malocclusion
      vi. Dentigerous cysts
3. Otolaryngologic manifestations (Segal and Puterman 2007)
   a. Hypoplasia of the maxilla and zygoma resulting in small face and sometimes asymmetric
   b. Small or absent mastoid air cells
   c. A high rate of Eustachian tube dysfunction
   d. A higher prevalence of submucosal cleft palate
   e. Narrow external auditory canals
   f. Increase rates of recurrent childhood ear infections and various degrees of hearing loss
   g. Clumping of the ossicles, stapes fixation, and sclerosis of the footplate have been described (Hawkins et al. 1975)
4. Shoulders and thorax
   a. Ability to bring shoulders together
   b. Dimplings in the skin secondary to mild hypoplasia of the clavicles
   c. Sloping, almost absent shoulders secondary to severe hypoplasia or absence of the clavicles
   d. Narrow thorax: may lead to respiratory distress during early infancy
5. Mildly disproportionate short stature with short limbs comparing to the trunk and more apparent in the upper limbs than the lower
6. Spine
   a. Scoliosis
   b. Kyphosis
7. Hands
   a. Brachydactyly
   b. Short distal phalanges
   c. Tapering fingers
   d. Nail dysplasia/hypoplasia
   e. Short, broad thumbs
   f. Clinodactyly of the fifth fingers
8. Other abnormalities
   a. Hearing loss
   b. Abnormal gait
   c. Joint hypermobility
   d. Muscular hypotonia
9. Intelligence: normal
10. Cesarean section often required in the pregnant female due to dysplastic pelvis

Diagnostic Investigations

1. Radiographic findings: generalized failure of midline ossification
   a. Skull
      i. Delayed closure of the anterior fontanel (open fontanel) and sagittal and metopic sutures, often open for life
      ii. Unossified areas of the skull becoming smaller with increasing age
      iii. Multiple Wormian bones formation, particularly around the lambdoid suture
      iv. Small or absent nasal bones
      v. Segmental calvarial thickening
      vi. Underdeveloped maxilla
      vii. Delayed union of the mandibular symphysis
      viii. Platybasia
      ix. Small cranial base
      x. A large foramen magnum
      xi. Hypoplastic sinuses (paranasal, frontal, mastoid)
   b. Clavicles
      i. Absent clavicles: rare
      ii. Pseudarthrosis of one or both clavicles
      iii. Hypoplasia of the acromial end: common
      iv. Two separate fragments
      v. Absent sternal end with presence of the acromial end
      vi. Bilaterality is the rule but not always the case
   c. Chest
      i. Small bell-shaped thoracic cage
      ii. Short, oblique ribs
      iii. Presence of cervical ribs
      iv. Scapula often hypoplastic with deficient supraspinatus fossae and acromial facets
      v. Associated deficiency in musculature
   d. Pelvis
      i. Widened pubis symphysis resulting from delay in ossification during adulthood
      ii. Hypoplasia and anterior rotation of the iliac wings
      iii. Wide sacroiliac joints
      iv. Delayed ossification of the pubic bone
      v. Large femoral epiphyses

vi. Unusual shape of femoral head reminiscent of a "chef's hat"
vii. Broad femoral necks
viii. Frequent coxa vara

e. Spine
i. Hemivertebrae
ii. Posterior wedging
iii. Spondylolysis and spondylolisthesis
iv. Syringomyelia
v. Spina bifida occulta of the cervical, thoracic, or lumbar region

f. Tubular bones
i. Presence of both proximal and distal epiphyses in the second metacarpals and metatarsals leading to excessive growth and length
ii. Frequent cone-shaped epiphyses and premature closure of epiphyseal growth plates leading to shortening of bones
iii. Wide epiphyses
iv. Unusually short distal phalanges and the middle phalanges of the second and fifth fingers
v. Poorly developed terminal phalanges giving a tapered appearance to the digit
vi. Occasional hypoplasia, dysplasia, and aplasia of nails

g. Dentition: impacted, supernumerary teeth

2. Cytogenetic study: visible complex chromosome rearrangements occasionally seen (Purandare et al. 2008)
3. Molecular genetic studies of mutations involving *RUNX2* (Mendoza-Londono and Lee 2009)
a. Sequence analysis
b. Deletion/duplication analysis

Genetic Counseling

1. Recurrence risk
a. Patient's sib: not increased unless a parent is affected with the disorder or has germ line mosaicism
b. Patient's offspring: 50%
2. Prenatal diagnosis
a. Ultrasonography (Stewart et al. 2000; Hermann et al. 2009)
i. Hypoplastic clavicles
ii. Less calcified cranium than expected for gestational age
iii. Other craniofacial and skeletal anomalies
b. Prenatal diagnosis and preimplantation genetic diagnosis: Direct DNA testing possible for those families with a known mutation in the *RUNX2*
3. Management (Cooper et al. 2001)
a. Hearing evaluation
b. Evaluate the presence of submucous cleft palate
c. Evaluation of obstructive sleep apnea
d. Medical and surgical therapy for upper airway obstruction, recurrent and chronic sinusitis and otitis
e. Monitor skeletal and orthopedic complications
f. Early surgical and orthodontic intervention of unerupted permanent teeth to induce eruption
g. Orthognathic surgery to correct midface hypoplasia to reduce or correct significant upper respiratory complications and malocclusions
h. Surgical and orthodontic management of vertical maxillary deficiency (Dann et al. 1980)

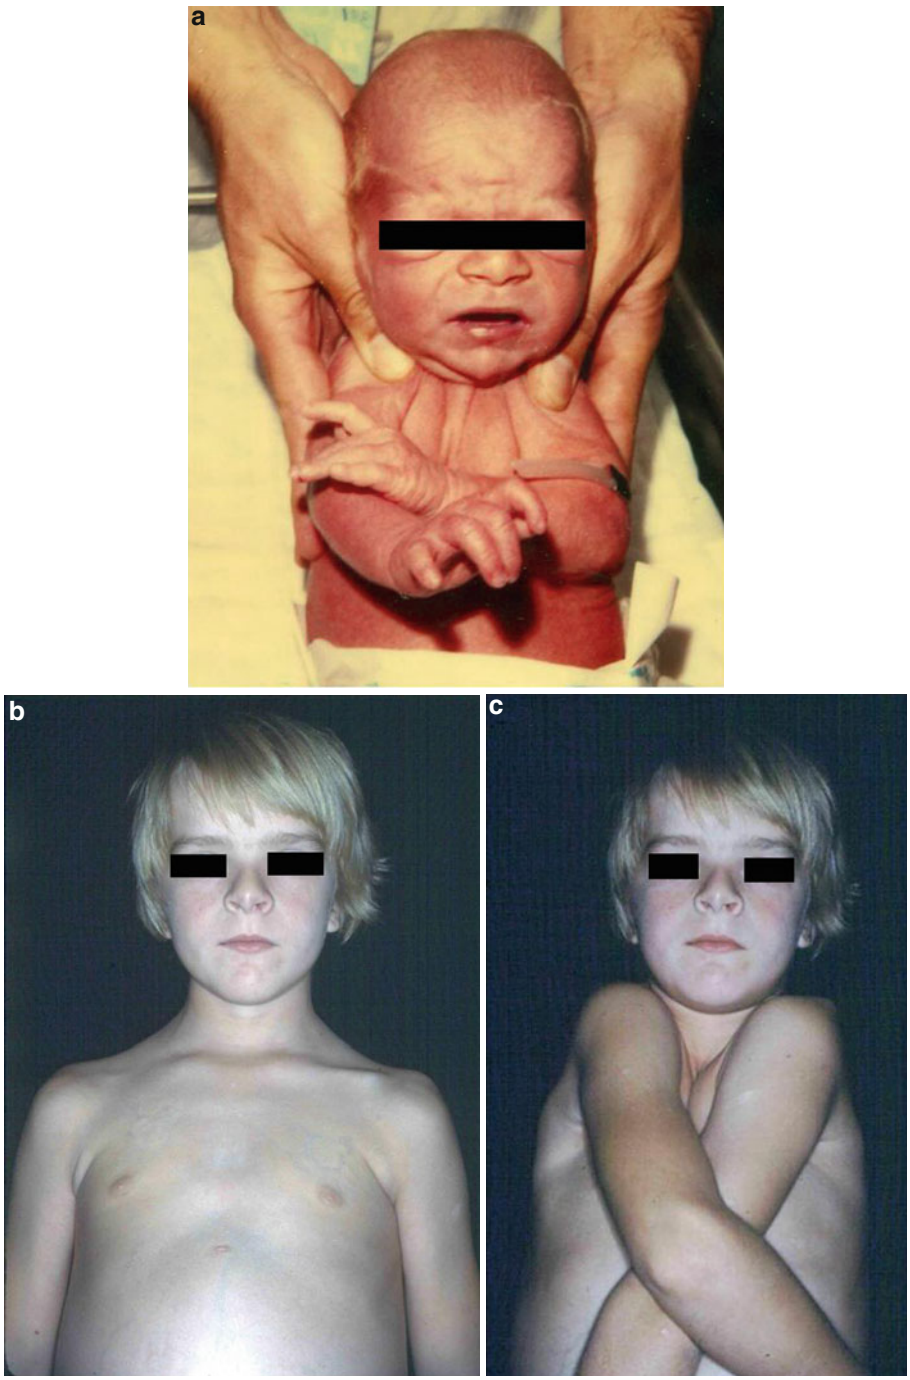

Fig. 1 (**a**–**c**) An infant and a child with cleidocranial dysplasia showing a large brachycephalic skull, frontal bossing, a large anterior fontanel, widely spaced eyes, flat nasal bridge, and easily proximated shoulders

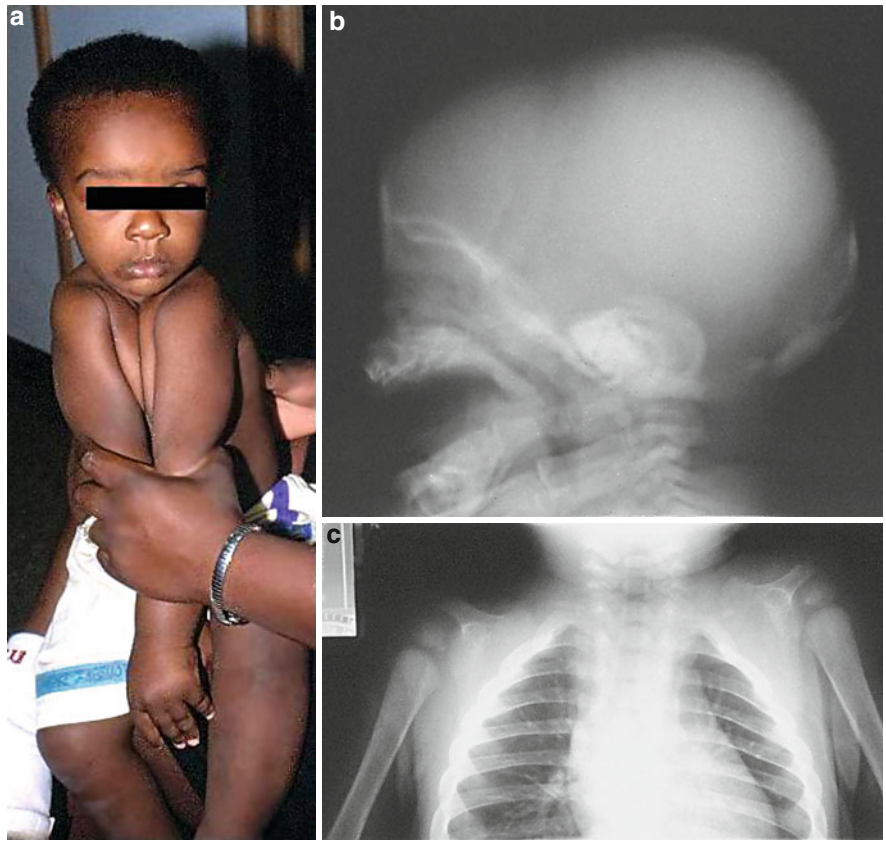

Fig. 2 (**a**–**c**) A child with cleidocranial dysplasia showing prominent forehead, wide anterior fontanel and cranial sutures, wide eyes, depressed nasal bridge, and easily proximated shoulders. Radiographs show poorly ossified skull, wide fontanels, cone-shaped thorax, and absence of clavicles

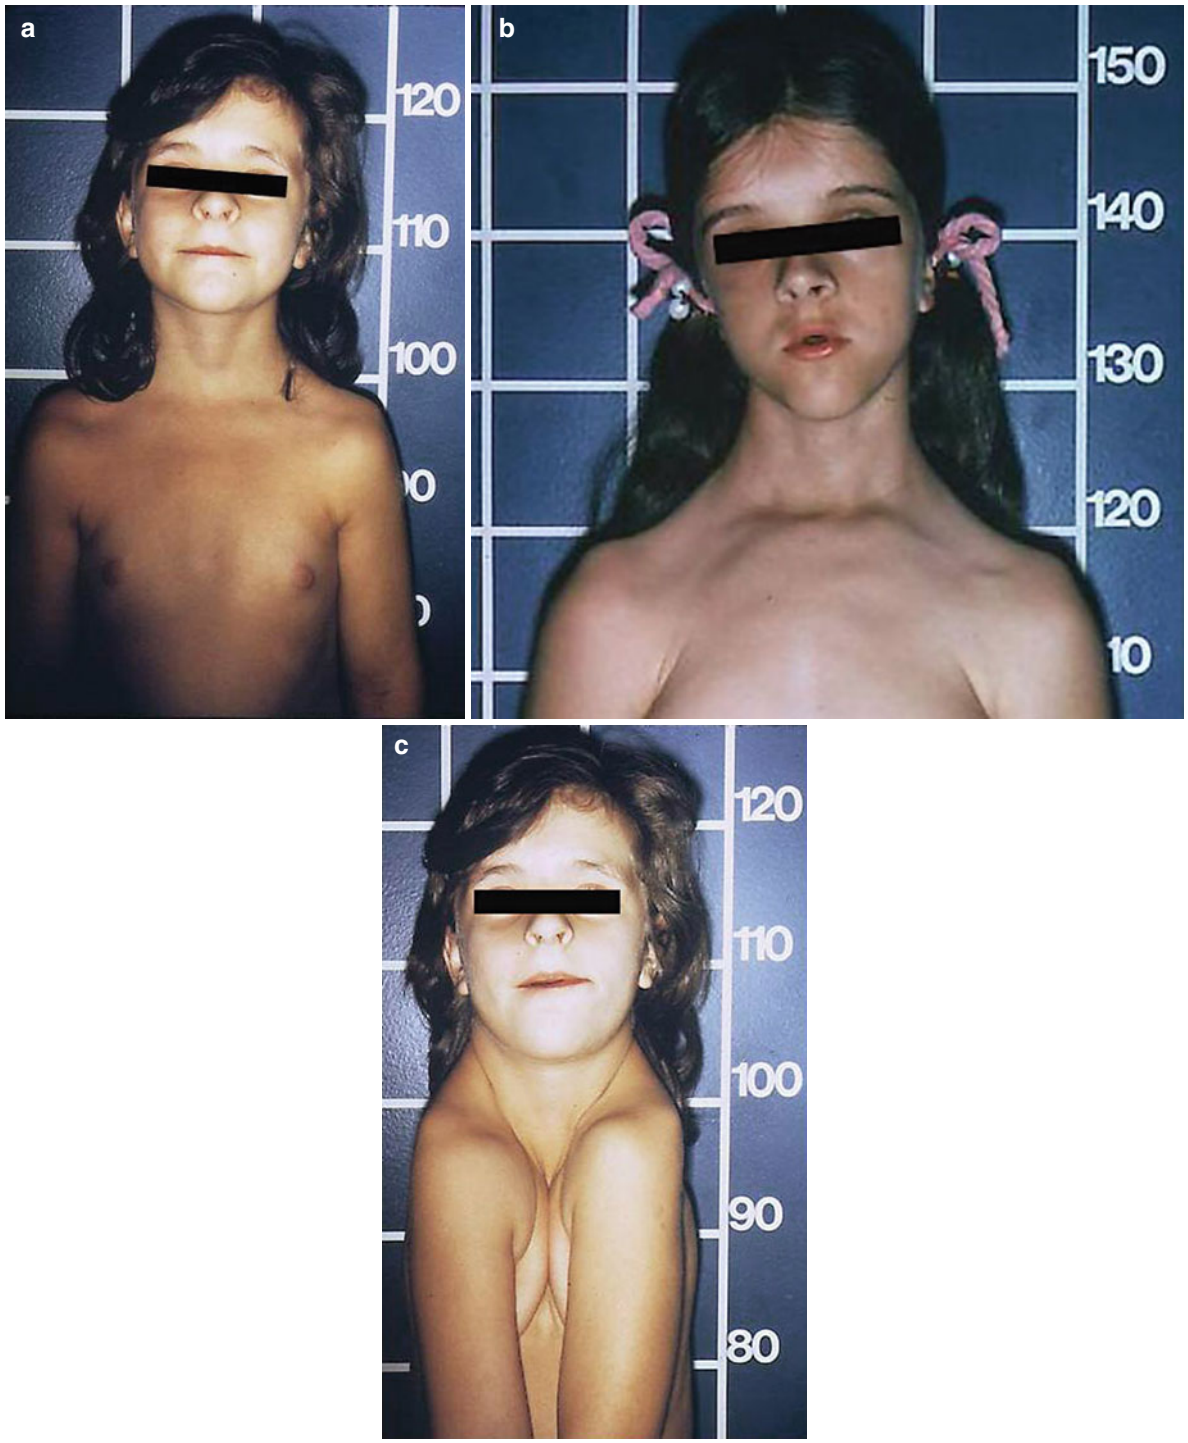

Fig. 3 (**a**–**c**) A girl with cleidocranial dysplasia at different ages showing short stature, frontal bossing, wide cranial sutures, wide set eyes, depressed nasal bridge, and sloping and easily proximated shoulders

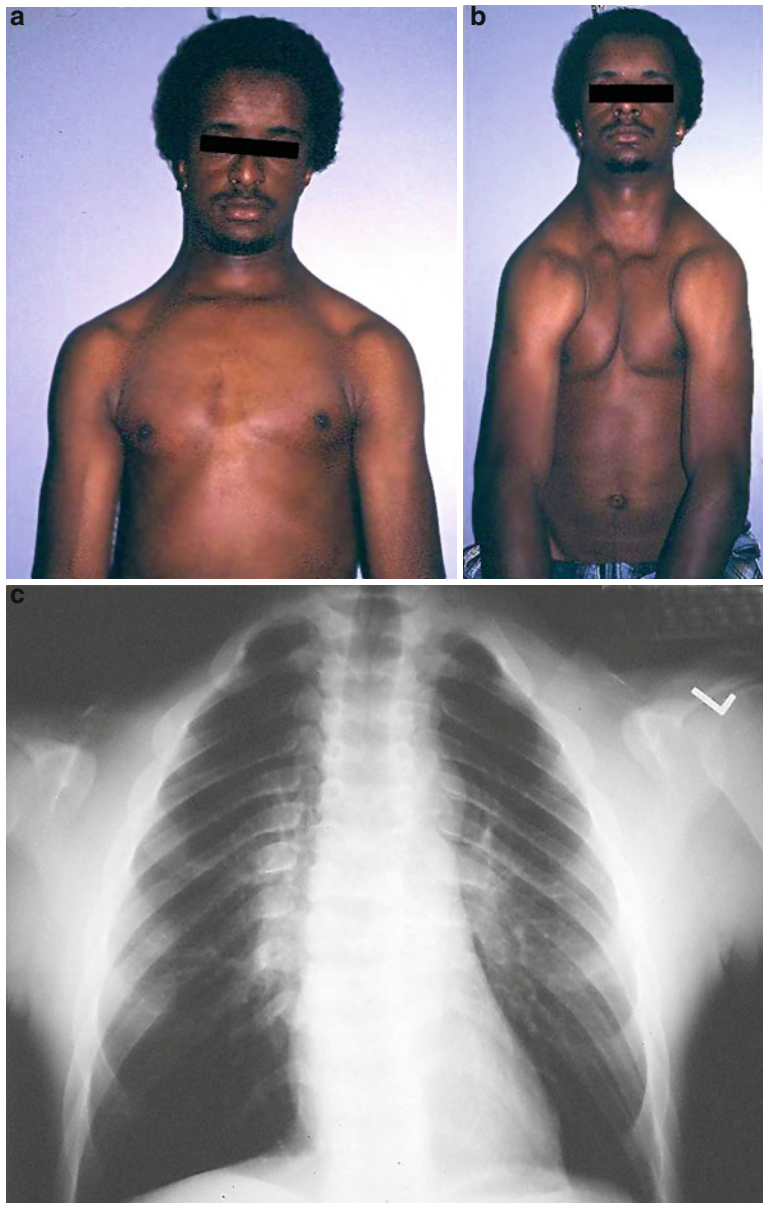

Fig. 4 (**a**–**c**) An adult with cleidocranial dysplasia showing widened cranial sutures, a characteristic face, and sloping and easily proximated shoulders. Radiograph showed a cone-shaped thorax with absent clavicles

Fig. 5 (**a**–**e**) A father and a son with cleidocranial dysplasia showing characteristic clinical findings and a dysplastic left clavicle presenting as two separate fragments, illustrated by radiograph

Fig. 6 (**a**–**d**) Another adult patient with cleidocranial dysplasia, showing typical clinical and dental features (radiograph)

Cloacal Exstrophy

Cloacal exstrophy is a rare congenital malformation resulting in exstrophy of the urinary, intestinal, and genital systems and is associated with anomalies of other organ systems. The term OEIS complex (omphalocele, exstrophy of the bladder, imperforate anus, and spinal defects) are used to describe the spectrum of malformations in cloacal exstrophy (Kaya et al. 2000). The incidence of cloacal exstrophy is estimated to be 1/200,000–1/400,000 live births (Dick et al. 2001), although the true incidence may be as high as 1 in 10,000–50,000, taking into account lack of diagnosis in stillborn infants (Keppler-Noreuil 2001).

Synonyms and Related Disorders

OEIS complex (omphalocele-exstrophy of the bladder-imperforate anus-spinal defects)

Genetics/Basic Defects

1. Genetics
   a. Recurrence of OEIS complex in siblings can be explained by the following mechanisms:
      i. Autosomal recessive inheritance
      ii. Multifactorial determination
      iii. Gonadal mosaicism for a dominant mutation
      iv. Environmental factors
      v. Subclinical maternal disorder
      vi. An unbalanced translocation between 9q and Y chromosome resulting in a 9q34.1-qter deletion, as a potential cause (Thauvin-Robinet et al. 2004)
      vii. Mutations in a group of homeobox genes such as HLXB9 and HOX family which are involved in the development of embryonic mesoderm (Manner and Kluth 2005)
   b. Higher incidence of OEIS complex in monozygotic twins than in dizygotic twins suggests a possible genetic contribution to the occurrence of these defects.
2. Basic defects of OEIS complex (Lee et al. 1999)
   a. Resulting from a single localized defect in the early caudal mesoderm at approximately 29 days of development
   b. Resulting in the following sequence of events:
      i. Failure of cloacal septation leading to a persistence of the cloaca with a rudimentary mid-gut and imperforate anus
      ii. Failure of breakdown of the cloacal membrane leading to exstrophy of the cloaca, omphalocele, and lack of fusion of the pubic rami
      iii. The lumbosacral somites giving rise to abnormal vertebrae in which there is protrusion of the dilated spinal cord (hydromyelia) and a cystic, skin-covered mass in the lumbosacral region
3. Cloaca and cloacal exstrophy
   a. Cloaca
      i. A transient embryological structures
      ii. The term “cloaca” literally means “sewer” in Latin
      iii. The term used to represent the emptying of the gastrointestinal and urogenital tracts into a common sinus

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_45,
© Springer Science+Business Media, LLC 2012

iv. Defined as a common chamber (orifice) in the perineum into which the urinary, genital and intestinal tract drain
b. Cloacal exstrophy: The common orifice empties onto the anterior abdominal wall

Clinical Features

1. Classic exstrophy of the cloaca (Lee et al. 1999)
   a. Lower abdominal defect
   b. Exposure of intestinal and bladder mucosa
   c. Accompanied by the following anomalies
      i. Omphalocele
      ii. Imperforate anus
      iii. Urogenital anomalies
2. Gastrointestinal malformations
   a. Omphalocele
   b. Imperforate anus
   c. Rectovestibular/rectovesical fistula
   d. Small bowel anomalies
      i. Foreshortened small bowel
      ii. Rotational anomalies
   e. Meckel diverticulum
   f. Inguinal hernias
3. CNS malformations
   a. Spina bifida: the most common CNS malformation
      i. Leptomeningocele
      ii. Myelomeningocele
      iii. Meningocele
      iv. Spina bifida occulta
      v. Cord tethering
   b. Craniosynostosis
4. Skeletal malformations
   a. Vertebral anomalies
      i. Presence of extra vertebrae
      ii. Hemivertebrae and associated scoliosis
      iii. Absent vertebrae
   b. Pubic diastasis
   c. Lower extremity anomalies
      i. Clubfoot deformities
      ii. Limb deficiencies
5. Genitourinary malformations
   a. Bladder anomaly
      i. Open
      ii. Separated into two halves
      iii. Flanking the exposed interior of the cecum
      iv. Openings to the remainder of the hindgut
      v. Prolapse of the terminal ileum as a "trunk" of bowel onto the cecal plate
   b. Renal anomalies
      i. A single kidney
      ii. Rudimentary kidney
      iii. Pelvic ectopic kidney
      iv. Ureteropelvic junction obstruction
      v. Malrotation
      vi. Crossed renal ectopia
   c. Ureteral anomalies
      i. Duplication
      ii. Ectopic insertion
      iii. Distal stricture and megaureter
   d. Male genitalia anomalies
      i. Small and bifid penis
      ii. Hemiglans located caudal to each hemibladder
   e. Female genitalia anomalies
      i. Bifid clitoris
      ii. Uterine duplication
      iii. Vaginal duplication
      iv. Vaginal agenesis
6. Prognosis
   a. Used to be uniformly fatal malformation in its worst form
   b. Currently with an 80–100% survival rate due to early surgical repair but accompanied by lifelong severe morbidity

Diagnostic Investigations

1. Evaluation of associated malformations
2. Karyotyping for genetic sex
3. Renal ultrasonography for renal and upper urinary tract anomalies
4. Voiding cystourethrography to assess bladder capacity in early childhood in preparation for continence reconstruction
5. Radiographic studies to demonstrate spinal dysraphism (Dick et al. 2001)
   a. Plain spinal radiographs
   b. Myelography
   c. CT
   d. CT myelography
   e. Spinal MRI to identify occult abnormalities that predispose to symptomatic spinal cord tethering

Genetic Counseling

1. Recurrence risk (Mathews et al. 1998)
   a. Patient's sib: recurrence in subsequent pregnancies noted in one report
   b. Patient's offspring: Lack of offspring from patients with cloacal exstrophy making the determination of inheritance difficult
2. Prenatal diagnosis by ultrasonography
   a. Elevated maternal serum α-fetoprotein (AFP) in OEIS complex. The open ventral wall defect likely results in AFP leakage.
   b. Ultrasonography (Austin et al. 1998)
      i. Major ultrasound criteria
         a) Non-visualization of the bladder (91%)
         b) A large midline infraumbilical anterior wall defect or cystic anterior wall structure (persistent cloacal membrane) (82%)
         c) Omphalocele (77%)
         d) Lumbosacral myelomeningocele (68%)
      ii. Minor (less frequent) ultrasound criteria
         a) Lower limb defects (23%)
         b) Renal anomalies (23%)
         c) Ascites (14%)
         d) Widened pubic arches (18%)
         e) A narrow thorax (9%)
         f) Hydrocephalus (9%)
         g) A single umbilical artery (9%)
   c. Early prenatal diagnosis with fetal MRI (Gobbi et al. 2008)
3. Management (Mathews et al. 1998)
   a. Appropriate parental counseling and referral to a center with significant expertise in the management of cloacal exstrophy when prenatal diagnosis is made
   b. Medical stabilization of the infant
      i. Fluid and electrolyte replacement
      ii. Parenteral nutrition
      iii. Moisten the exstrophied bladder and bowel with saline and cover them with a protective plastic dressing
      iv. Daily prophylactic antibiotics
   c. Gender assignment
      i. Evaluation of the genitalia
      ii. Decision limited to the genetic male patients with cloacal exstrophy
         a) Male gender assignment appropriate for male patients with adequate bilateral or unilateral phallic structures
         b) Male neonates with minimal phallic structures: appropriate to raise as female subjects with early excision of the gonads
         c) Appropriate hormonal manipulation to improve psychosexual dysfunction
         d) Improvements in phallic reconstruction eventually allow most genetic male patients to be assigned male gender.
      iii. Initial sexual reassignment to be done in conjunction with extensive family counseling as well as continued counseling for the parents and children
   d. Management of gastrointestinal malformations
      i. Closure of omphalocele
      ii. Combined with gastrointestinal diversion or reconstruction
         a) Ileostomy with resection of the hindgut remnant
         b) Colostomy
   e. Management of genitourinary malformations
      i. Bladder closure
      ii. Initial bladder excision and urinary diversion
      iii. Further augmentation or urinary diversions to achieve continence
   f. Management of CNS malformations
      i. Closure of myelomeningocele
      ii. Cord untethering
      iii. Spinal fusion
      iv. Cranial expansion for craniosynostosis
   g. Management of orthopedic malformations
      i. Manage myelodysplasia
      ii. Pelvic osteotomies
      iii. Various orthopedic devices to assist with ambulation

Clubfoot

Clubfoot, or talipes equinovarus, is one of the most common congenital deformities affecting the lower limbs in approximately 1–2 in 1,000 live births. The incidence is higher in Hispanics and lower in Asians. Although clubfoot is recognizable at birth, the severity of the deformity can vary from mild to an extremely rigid foot that is resistant to manipulation (Dobbs and Gurnett 2009).

Synonyms and Related Disorders

Talipes equinovarus

Genetics/Basic Defects

1. Pathogenesis
   a. Genetic cause: suggested because it tends to run in families (Lochmiller et al. 1998)
   b. Oligohydramnios: suggested as a cause from early amniocentesis data (CEMAT Group 1998)
   c. Osseous deformities (Shapiro and Glimcher 1979), muscle abnormalities (Herceg et al. 2006), and arrested fetal development (Fukuhara et al. 1994): hypothesized to play a role in pathogenesis
2. Etiology (Dobbs and Gurnett 2009)
   a. Most commonly as an isolated birth defect and considered idiopathic (Wynne-Davies 1964): various theories on etiologies include:
      i. Vascular deficiencies (Hootnick et al. 1982)
      ii. Environmental factors
         a) Early amniocentesis (<13 weeks gestation): associated with an increased risk in talipes equinovarus (an uncommon risk factor), compared to midgestational amniocentesis or chorionic villus sampling (Philip et al. 2004)
         b) Partially associated with amniotic fluid leakage: suggesting that oligohydramnios occurring at a critical gestational period may be detrimental to foot development (Tredwell et al. 2001)
         c) Environmental exposure to cigarette smoke in utero: an independent risk factor (Honein et al. 2000)
      iii. In utero positioning (Dunn 1972)
      iv. Abnormal muscle insertions (Bonnell and Cruess 1969)
   b. Genetic factors suggested by:
      i. Thirty-three percent concordance of identical twins and the fact that nearly 25% of all cases are familial (Lochmiller et al. 1998)
      ii. Differences in clubfoot prevalence across ethnic populations with the lowest prevalence in Chinese (0.39 cases per 1,000 live births) and the highest in Hawaiians and Maoris (seven per 1,000) (Beals 1978; Chung et al. 1969)
   c. Multifactorial and possibly polygenic causation suggested (Lochmiller et al. 1998; Wynne-Davies 1972)
   d. Prevalence of additional congenital anomalies
      i. Chromosomal abnormalities (e.g., trisomy 18 syndrome) in patients with clubfoot (24–50%) (Bakalis et al. 2002; Gurnett et al. 2008)
      ii. Distal arthrogryposis
      iii. Myelomeningocele

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_46,
© Springer Science+Business Media, LLC 2012

e. Recent identification of a rare mutation in the transcription factor PITX1 in a large family with idiopathic clubfoot: importance of genes involved in early limb development (Gurnett et al. 2008)
   i. *PITX1*: the first gene implicated in clubfoot that explains the specific involvement of the foot, since *PITX1* is expressed nearly exclusively in the hindlimb and is responsible for rapid evolutionary changes in pelvic morphology in lower vertebrates (Shapiro et al. 2004).
   ii. Specific involvement of the foot also appears to exclude many of the skeletal muscle contractile genes that are responsible for distal arthrogryposis (Sung et al. 2003a, b; Toydemir et al. 2006; Veugelers et al. 2004) in the causation of idiopathic clubfoot, as mutations in these genes cause both upper and lower extremity involvement and were not identified in idiopathic clubfoot patients (Gurnett et al. 2009).

3. Multifactorial inheritance
   a. Most infants with clubfoot (idiopathic congenital clubfoot) have no identifiable genetic, cytogenetic, syndromal, or extrinsic cause. The idiopathic congenital clubfoot is primarily caused by a multifactorial inheritance.
   b. The observed percentages of talipes equinovarus in relatives of an affected child are consistent with a multifactorial mode of inheritance (Wynne-Davies 1965, 1972)
      i. Monozygotic twins with about 32.5% rate of concordance (both twins affected with clubfoot)
      ii. First degree relatives (parents and siblings) occurrence rate
         a) 2.14%
         b) About 17 times as high as the population rate
      iii. Second degree relatives (aunts and uncles) occur
         a) 0.61%
         b) About six times as high as the population rate
      iv. Third degree relatives (cousins)
         a) 0.2%
         b) Near the incidence in the general population
4. Part of a genetic syndrome
   a. An autosomal recessive inheritance of clubfoot: for example,
      i. Diastrophic dwarfism
      ii. Larsen syndrome
      iii. Smith-Lemli-Opitz syndrome
   b. An autosomal dominant inheritance of clubfoot: for example,
      i. Distal arthrogryposis type 2A (Whistling-face syndrome)
      ii. Distal arthrogryposis type 1
      iii. Freeman-Sheldon syndrome
   c. An X-linked recessive inheritance of clubfoot: for example, Pierre-Robin syndrome
   d. Other syndromic clubfoot: for example,
      i. Meningomyelocele/spina bifida
      ii. Sacral agenesis
      iii. Constriction band syndrome
      iv. Congenital myopathy
5. Part of a cytogenetic abnormality: Numerous cytogenetic abnormalities produce individuals with multiple anomalies including clubfoot
6. Extrinsic causes
   a. Teratogenic agents
      i. Sodium aminopterin
      ii. Position in utero at the time of d-tubocurarine paralysis
   b. Loss of amniotic fluid during gestation
   c. Mechanical forces or positional influence (restriction of fetal foot movement by the uterus)
   d. Drugs

Clinical Features

1. Bilateral in about 50% of cases
2. Three major components of talipes equinovarus
   a. Equinus (limitation of extension) of the ankle and subtalar joint
   b. Hindfoot and midfoot varus
   c. Forefoot adduction
3. Evaluation of the foot, ankle, and leg
   a. "Down and in" appearance
   b. Shorter and wider than the normal foot
   c. Flexible, softer heel due to hypoplastic calcaneus
   d. Concave medial border
   e. Transverse plantar creases or clefts at the midfoot and at the posterior part of the ankle
   f. Highly convex lateral border

g. Internally rotated heel making the soles of the feet facing each other in cases of bilateral deformities
h. Internal rotation of the leg
i. Variable rigidity of the foot
j. Calf and foot atrophy (more obvious in older child than in infant)
k. Mild hypoplasia of the tibia, fibula, and bones of the foot
l. Pronounced tightness of the Achilles tendon with very little dorsiflexion
m. Range of motion of the joints

4. Idiopathic clubfoot
   a. An isolated deformity of the foot and leg
      i. Identifiable in utero
      ii. Consists of four components
         a) Equinus
         b) Hindfoot varus
         c) Forefoot adductus
         d) Cavus
   b. When untreated, children with clubfoot walk on the sides and/or tops of their feet, resulting in (Dobbs and Gurnett 2009):
      i. Callus formation
      ii. Potential skin and bone infections
      iii. Inability to wear standard shoes
      iv. Substantial limitations in mobility and employment opportunities
   c. By far the most common form
   d. Occurring more common in males than in females (2 ~ 2.5:1)
   e. Normal upper limbs
   f. Associated features
      i. Joint laxity
      ii. Congenital dislocation of the hip
      iii. Tibial torsion
      iv. Ray anomalies of the foot (oligodactyly)
      v. Absence of some tarsal bones
      vi. A history of other foot anomalies in the family
5. Various associated anomalies in syndromic talipes equinovarus

Diagnostic Investigations

1. Plain radiography
   a. Limitations
      i. Risk of ionizing radiation
      ii. Proper positioning difficult
      iii. Lack of ossification in some involved bones
         a) Only talus, calcaneus, and metatarsals are ossified in neonates
         b) Cuboid ossification at 6 months
         c) Cuneiforms ossification at 1 year
         d) Navicular ossification after 3 years
   b. Assessment
      i. Hindfoot equinus (plantar flexion of the anterior calcaneus)
      ii. Hindfoot varus (calcaneus rotated around the talus into a varus, i.e., toward midline, position)
      iii. Forefoot varus (increased forefoot supination on dorsoplantar view)
   c. Common measurements
      i. Anteroposterior talocalcaneal angle (typically $<20^\circ$ in a clubfoot)
      ii. Talar-first metatarsal angle
         a) Up to about 30° of valgus in a normal foot
         b) Mild-to-severe varus in a clubfoot
      iii. Medial displacement of the cuboid ossification center on the axis of the calcaneus representing either of the following:
         a) Angular deformity of the calcaneus
         b) Medial subluxation of the cuboid on the calcaneus
2. CT scan
   a. Limitations
      i. Risk of ionizing radiation
      ii. Lack of ossification of the tarsal bones
      iii. Susceptible to motion artifact
   b. Advantage: better assessment of complex 3-dimensional deformity by 3-dimensional reconstructions
3. MRI
   a. Limitations
      i. Need for patient sedation
      ii. Loss of signal caused by ferromagnetic effects of fixation devices
   b. Advantages
      i. Capability of multiplanar imaging
      ii. Excellent depiction of following:
         a) Ossific nuclei
         b) Cartilaginous anlage
         c) Surrounding soft-tissue structures
   c. Findings
      i. Plantar flexion
      ii. Varus angular deformity of the talus, calcaneus, and cuboid

Genetic Counseling

1. Recurrence risk: depends on underline etiology
   a. Patient's sib
      i. Multifactorial trait: approximately 2.1% (first degree relatives)
      ii. Autosomal recessive: 25%
      iii. Autosomal dominant: not increased unless a parent is affected
      iv. X-linked recessive: 50% of male sibs affected if the mother is a carrier
      v. Chromosomal: increased risk, especially a parent is a translocation carrier
   b. Patient's offspring
      i. Multifactorial: approximately 2.1%
      ii. Autosomal recessive: not increased unless the spouse is also a carrier
      iii. Autosomal dominant: 50%
      iv. X-linked recessive: All daughters of affected males will be carriers. All sons of an affected male will be normal.
      v. Chromosomal: increased risk
2. Prenatal diagnosis
   a. Ultrasonography: Wide variation in the accuracy of ultrasonography
      i. Isolated clubfoot
         a) Better prognosis especially detected in the 3rd trimester of pregnancy
         b) Poor correlation between the prenatal appearance of the foot on ultrasound findings and the severity of the talipes at birth
      ii. Complex clubfoot: associated with syndromic, neuromuscular, or chromosomal conditions
3. Management
   a. Traditional nonoperative approach
      i. Appropriate initial management for all children with clubfoot
      ii. Splintage begins at 2–3 days after birth
      iii. Order of correction
         a) Forefoot adduction
         b) Forefoot supination
         c) Gentle correction of equinus
      iv. Two methods most widely performed and with highest reported long-term success rates
         a) Kite and Lovell method
         b) Ponseti method
      v. "Montpellier" method: remains popular in France
   b. Ponseti method: currently widely utilized with high success rate in treating clubfoot
      i. Goal
         a) To reduce or eliminate deformity (equinus, hindfoot varus, forefoot adductus, and cavus)
         b) To attain functional, pain-free, plantigrade foot with good mobility and without calluses, and without need to wear modified shoes
      ii. Techniques
         a) Serial manipulation
         b) A specific technique of cast application
         c) Possible percutaneous Achilles tenotomy
      iii. Significant risk factors for the recurrence of clubfoot deformity after correction with the Ponseti method
         a) Noncompliance of the parents
         b) Lower educational level of the parents
      iv. Outcome
         a) Appears to be effective
         b) Requires only a reasonable amount of time out of the lives of the patient and his or her parents
         c) Frequently include some minimal invasive surgery
   c. Kite and Lovell method
      a) Starting with stretching of the foot through longitudinal traction applied to the foot
      b) Less often requires minimally invasive surgery
      c) More time-consuming
   d. "Montpellier" method
      i. Require fairly extensive physical therapy
      ii. Demand substantial parental time and attention
      iii. Long-term results yet to be confirmed
   e. Operative approach
      i. Should be considered only after a suitable trial of manipulating the foot and holding it in a suitable cast or other device has failed
      ii. Operative treatment
         a) Incisions
         b) Medial plantar release
         c) Posterior release
         d) Lateral release
         e) Reduction and fixation
         f) Intraoperative assessment
         g) Wound closure

h) Revision surgery
i) Postoperative evaluation

iii. Treatment of residual deformity
a) Residual forefoot adduction
b) Residual cavus
c) Angulation of the heel for residual varus or valgus
d) Dynamic forefoot supination
e) Residual toeing-in
f) Dorsal bunion (a painful swelling of the bursa of the first joint of the big toe)
g) Overcorrected foot
h) Skin problems

f. Complications of treatment
i. Failure to correct (undercorrection) resulting from:
a) Selection of inappropriate procedure
b) Inadequate performance of an appropriate procedure

ii. Overcorrection resulting from:
a) Selection of an inappropriate procedure
b) Overzealous release of appropriate structures
c) Inappropriate release of normal structures

iii. Recurrence of deformity

Collodion Baby

Collodion baby is a descriptive term for infants born encased in a membrane-like thick scale resembling oiled parchment or collodion. The presence of a collodion membrane at birth represents a defect in skin barrier function and is usually the initial presentation of a congenital ichthyosiform disorder, most often autosomal recessive congenital ichthyosis (ARCI). Thus, neonates born with the features of collodion baby subsequently develop lamellar ichthyosis (LI), nonbullous congenital ichthyosiform erythroderma (NCIE), or other forms of ichthyosis (Akiyama 2006). However, in 10% of neonates spontaneous healing occurs (Raghunath et al. 2003). Collodion baby is a rare congenital condition accounting for 1 in 50,000–1 in 100,000 deliveries.

Synonyms and Related Disorders

Collodion fetus; Ichthyosis congenita; Lamellar exfoliation of newborn; Lamellar ichthyosis

Genetics/Basic Defects

1. Etiology (Taïeb and Labrèze 2002)
   a. The presence of a collodion membrane at birth (Hackett et al. 2010)
      i. Represents a defect in skin barrier function
      ii. Usually the initial presentation of a congenital ichthyosiform disorder, most often autosomal recessive congenital ichthyosis
   b. Common severe phenotype (not associated with noncutaneous features)
      i. Autosomal recessive nonbullous congenital erythrodermic ichthyosis (50% of cases) including harlequin fetus. Harlequin ichthyosis represents the most severe end of the phenotypic spectrum
      ii. Autosomal recessive lamellar ichthyosis (10%) with mutations in the gene for keratinocyte transglutaminase (*TGM1*) on chromosome 14q11 in many patients
      iii. Mapping of a second locus for lamellar ichthyosis to chromosome 2q33-q35 (Permentier et al. 1996)
      iv. Rare reports of autosomal dominant lamellar ichthyosis
      v. Other clinically indistinguishable cases linked to chromosomes 3 and 19
   c. Common milder phenotypes
      i. Mild form of ichthyosis vulgaris (10%)
      ii. Recovery without sequelae: self-healing collodion babies: descried in a minority of collodion babies (10%)
         a) Two self-healing collodion baby siblings observed to have compound heterozygous transglutaminase 1 mutations G278R and D490G (Raghunath et al. 2003)
         b) An acral self-healing collodion baby caused by a new *TGM1* mutation (Mazereeuw-Hautier et al. 2009)
         c) Genotypic heterogeneity of *TGM1* mutations: can lead to nonbullous congenital ichthyosiform erythroderma, self-healing collodion baby (localized or generalized), lamellar ichthyosis, and bathing suit ichthyosis (Petit et al. 1997; Oji et al. 2006; Arita et al. 2007; Hackett et al. 2010)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_47,
© Springer Science+Business Media, LLC 2012

   d. Associated congenital ichthyosis
      i. Trichothiodystrophy
      ii. Poorly documented true collodion membrane
         a) Sjögren–Larsson syndrome (ichthyosis, spastic paraplegia, mental retardation, and retinopathy with abnormal levels of fatty aldehyde dehydrogenase activity in cultured fibroblasts)
         b) Netherton syndrome
         c) Gaucher disease type II
         d) Congenital hypothyroidism
         e) Conradi syndrome
         f) Dorfman Chanarin syndrome
         g) Ketoadipiaciduria
         h) Koraxitrachitic syndrome
         i) Ichthyosis variegata
         j) Palmoplantar keratoderma with anogenital leukokeratosis
2. Genes known to be associated with autosomal recessive congenital ichthyosis (ARCI) (Bale and Richard 2009; Hackett et al. 2010)
   a. *TGM1*: Mutations in *TGM1* account for 50–60% of all ARCI and 90% or more of severe LI
   b. *ALOXE3* and *ALOX12B* genes: Mutations in the two *ALOX* genes are present in an estimated 10% of individuals with NCIE or intermediate LI/NCIE phenotypes
   c. *NIPAL4* (*ICHTHYIN*): *NIPAL4* mutations appear to be less common
   d. *ABCA12*: The vast majority of individuals with harlequin ichthyosis and a few individuals with LI have mutations in *ABCA12*, including partial-gene deletions
   e. *CYP4F22*
   f. At least one gene remains unknown
3. Pathogenesis (Akiyama 1999)
   a. Pathogenesis not yet clarified
   b. The term "collodion baby" is considered a descriptive term for infants born encased in membrane-like thick scale and includes several heterogeneous conditions
   c. Several disorders of cornification showing this phenotype at birth
   d. A mutation of keratinocyte transglutaminase may play a role in lamellar ichthyosis, although lamellar ichthyosis is still considered genetically heterogeneous.
   e. Keratinocytes lacking specific transglutaminase will not cause cross-linked envelopes

Clinical features

1. Major clinical features (Sybert 1997)
   a. Newborn covered with a taut, shiny membrane resembling plastic wrap
   b. The membrane often fissured and cracked at birth
   c. Lamellar exfoliation cracks and peels over the course of several weeks to reveal underlying normal skin or skin with mild scaling that goes on to resolve
   d. Red/ivory-colored (erythematous) underlying skin
   e. Persistence of mild ichthyosis in some patients
   f. Ectropion (eversion of the eyelids)
   g. Eclabium (eversion of the lips)
   h. Crumpled pinnae
   i. Resolved tapered fingertips and partially flexed hands with shedding of the encasing membrane
2. Minor clinical features
   a. Secondary skin infections in the cracks and fissures
   b. Scarring in the areas of deep fissuring
3. Complications
   a. Difficulties in temperature regulation (hypothermia)
   b. Increased insensible water loss predisposing to hypernatremic dehydration
   c. Secondary infections from gram-positive organisms and *Candida albicans*
   d. Septicemia
   e. Pneumonia secondary to aspiration of squamous material in the amniotic fluid
   f. Respiratory difficulty due to restricted chest wall movement
   g. Possible loss of vision caused by corneal damage
   h. Constrictive bands of the extremities resulting in vascular compromise and edema (Van Gysel et al. 2002; Roberts and Adelson 2010)
4. Prognosis
   a. Long-term prognosis difficult to address at birth
   b. Infrequently, a collodion baby may have normal skin after exfoliation of the membranes

Diagnostic Investigations

1. Skin biopsy
   a. Transglutaminase assay
   b. Conventional and electron microscopy
      i. Hyperkeratosis with thick compact cornified layer (orthokeratotic stratum corneum)
      ii. Aberrant keratinized/cornified cells
      iii. Irregularly convoluted horny cells and numerous intercellular Odland bodies (lamellar granules) and nuclear debris in distal layer of the stratum corneum
2. Molecular genetic analysis
   a. *TGM1* sequence analysis: identification of mutation of keratinocyte transglutaminase 1 gene for severe form of autosomal recessive lamellar ichthyosis and self-healing collodion baby
   b. *TGM1* mutations include missense, nonsense, and splice site
   c. Carrier testing available to at-risk family members on a clinical basis once the mutation in *TGM1* has been identified in the proband
   d. Other gene mutations
3. Studies for other associated conditions
   a. Polarized light examination of hair and eye brows
      i. Trichothiodystrophy
      ii. Netherton syndrome
   b. Leukocyte lipid inclusions
      i. Dorfman Chanarin syndrome
      ii. Neonatal Gaucher disease
   c. Thyroid hormone level: congenital hypothyroidism
   d. Skeletal study: Conradi syndrome
   e. Neurosensory evaluation

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive inheritance: 25% recurrence risk
      ii. Autosomal dominant inheritance: not increased unless a parent is affected
   b. Patient's offspring
      i. Autosomal recessive inheritance: not increased unless the spouse is a carrier or affected
      ii. Autosomal dominant inheritance: 50%
2. Prenatal diagnosis: direct mutation analysis of the keratinocyte transglutaminase 1 gene on fetal DNA obtained from amniocentesis or CVS for severe form of autosomal recessive lamellar ichthyosis, provided the mutation in *TGM1* or other disease-causing mutation has been identified in the proband
3. Management: requiring intensive care (Shareef et al. 2000)
   a. Maintain skin integrity
      i. Assess open skin lesions
      ii. Minimal handling with precaution
      iii. Prevent secondary infection and avoid prophylactic use of antibiotics
   b. Maintain body temperature
      i. Avoid radiant heat
      ii. Use humidified incubator for dehydration and hypothermia
      iii. Pre-warm all linen used to absorb weeping
   c. Ophthalmological management of ectropion important for the prevention of conjunctivitis and keratitis
   d. Sedation with opioids indicated for severe pain
   e. Petrolatum-based creams/ointments to keep the skin soft, supple, and hydrated
   f. Retinoids in case of delayed shedding of the collodion membrane beyond 3 weeks
   g. Use keratolytics agents (e.g., alpha hydroxy acid preparations) or urea preparations to promote peeling and thinning of the stratum corneum as the child becomes older
   h. Release of collodion membrane on digits, when necessary, to maintain circulation and on the thorax for adequate respiration

Congenital Adrenal Hyperplasia

Congenital adrenal hyperplasia (CAH) refers to a family of inherited disorders of adrenal steroidogenesis. The common functional defect in each disorder is impaired cortisol secretion, resulting in hypersecretion of corticotropin-releasing hormone (CRH) and adrenocorticotropic hormone (ACTH) and consequent hyperplasia of the adrenal glands (Antal and Zhou 2009).

More than 90% of cases of CAH are caused by a defect in the enzyme 21-hydroxylase. Four other enzyme deficiencies in the steroid biosynthesis pathway, along with one cholesterol transport protein defect, account for the remaining cases. Depending on the severity of the enzyme deficiency, 21-hydroxylase deficiency is defined as classic (severe form) or nonclassic (mild form). Approximately, 75% of patients who have the classic form also have salt wasting due to inadequate aldosterone production, further subdividing the classification into classic simple virilizing and classic salt-wasting forms. This chapter will discuss 21-hydroxylase deficiency in detail with a brief discussion of the other forms of CAH.

21-hydroxylase deficiency is the most common type of congenital adrenal hyperplasia (CAH). The incidence of classic 21-hydroxylase deficiency is estimated to be 1/12,000–1/15,000 births. The nonclassical form of the disease, also called "late-onset" CAH, occurs in approximately 1 in 1,000 of the general population depending on the ethnic group and in up to 6% of hirsute women (Deneux et al. 2001).

Synonyms and Related Disorders

11-beta hydroxylase deficiency; 17-alpha-hydroxylase deficiency; 21-hydroxylase deficiency; 3-beta-hydroxysteroid dehydrogenase deficiency; Lipoid congenital adrenal hyperplasia

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. Biochemical and molecular basis
   a. Deficient 21-hydroxylase activity : the most common form (>90% of cases) of CAH
   b. Caused by mutations of *CYP21* (*CYP21A2*) gene, mapped on the short arm of chromosome 6 (6p21.3): present in duplicate
   c. A highly homologous pseudogene (*CYP21P*)
      i. Located in the same chromosomal region as the active gene
      ii. Severe mutations of the pseudogene incompatible with coding for a functional enzyme
   d. About 95% of mutant alleles generated by recombination events between *CYP21* and *CYP21P* (Forest et al. 1998)
   e. Relatively common exchange of genetic material between these two homologous genes, the major reason for the high incidence of 21-hydroxylase deficiency compared to other forms of CAH

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_48,
© Springer Science+Business Media, LLC 2012

3. Pathophysiology (New 2002)
   a. Classic form of 21-hydroxylase deficiency
      i. Prenatal exposure to potent androgens (testosterone and delta4-androstenedione) at critical stages (8–12 weeks) of sexual differentiation resulting in virilization of the external genitalia in genetic females, resulting in varying degrees of genital ambiguity (female pseudohermaphroditism) at birth
      ii. Subdivision of classic form
         a) Simple virilizing form (about 25%)
         b) Salt-wasting form (>75%) in which aldosterone production is inadequate and at risk of life-threatening salt-wasting crises
   b. Nonclassic "late onset" form of 21-hydroxylase deficiency
      i. Has only moderate enzyme deficiency
      ii. Present postnatally with signs of hyperandrogenism
      iii. Females with the nonclassic form: not virilized at birth
4. CAH due to 21-hydroxylase deficiency
   a. 21-hydroxylase
      i. A microsomal cytochrome P450 enzyme
      ii. Required to convert:
         a) 17-hydroxy-progesterone to 11-deoxycortisol
         b) Progesterone to deoxycorticosterone
   b. 21-hydroxylase deficiency
      i. Impairs the metabolism of cholesterol to cortisol, generating excessive level of 17-hydroxyprogesterone
      ii. Produces androstenedione and other androgens from the precursor (17-hydroxyprogesterone) via an alternative metabolic pathway
      iii. Aldosterone deficiency
         a) Inability to synthesize adequate amounts of aldosterone due to severely impaired 21-hydroxylation of progesterone in about 75% of patients
         b) Resulting in sodium loss via the kidney, colon, and sweat glands and excrete potassium from the renal tubules
   c. Cortisol deficiency
      i. Glucocorticoids
         a) Increase cardiac contractility
         b) Increase cardiac output
         c) Increase cardiac and vasculature sensitivity to the pressor effects of catecholamines and other pressor hormone
      ii. Absence of glucocorticoids
         a) Decrease in cardiac output
         b) Decrease in glomerular filtration leading to an inability to excrete free water and consequently to hyponatremia
   d. Shock and severe hyponatremia much more likely in 21-hydroxylase deficiency in which both cortisol and aldosterone biosynthesis are affected
5. Phenotype-genotype correlations (White 2001)
   a. Mutations in CYP21, such as deletions, frameshifts, or nonsense mutations
      i. Totally ablate enzyme activity
      ii. Most often associated with salt-wasting
   b. Mutations mainly consisting of the missense mutation Ile172Asn (Il72N)
      i. Yielding enzymes with 1–2% normal activity
      ii. Carried predominantly by patients with simple virilizing disease
   c. Mutations such as Val281Leu (V281L) and Pro30Leu (P30L)
      i. Producing enzymes with 20–60% of normal activity
      ii. Most often associated with the nonclassical disorder
   d. Two different CYP21 mutations
      i. Producing compound heterozygotes
      ii. Most often with a phenotype compatible with that of the less severe gene defects
   e. All patients homozygous or compound heterozygous for large deletions or gene conversions have a salt-wasting classic form.
6. Characteristics of other forms of CAH (Antal and Zhou 2009)
   a. 11-Beta Hydroxylase deficiency
      i. Incidence: 1:100,000
      ii. Gene involved: *CYP11B1*
      iii. Chromosome location: 8q24.3
   b. 17-alpha-hydroxylase deficiency
      i. Incidence: rare
      ii. Gene involved: *CYP17*
      iii. Chromosome location: 10q24.3
   c. 3-beta-hydroxysteroid Dehydrogenase deficiency
      i. Incidence: rare
      ii. Gene involved: *HSD3B2*
      iii. Chromosome location: 1p13.1

d. Lipoid CAH
   i. Incidence: rare
   ii. Gene involved: steroidogenic acute regulatory protein (*StAR*)
   iii. Chromosome location: 8p11.2

Clinical Features

1. Typical signs and symptoms of acute adrenal crisis (Antal and Zhou 2009)
   a. Decreased activity/fatigue
   b. Altered sensorium/unresponsiveness
   c. Poor feeding/weak suck
   d. Dry mucous membranes
   e. Hyperpigmentation
   f. Abdominal pain
   g. Vomiting
   h. Hyponatremia
   i. Hyperkalemia
   j. Hypoglycemia
   k. Metabolic acidosis
   l. Hypothermia
   m. Hypotension
   n. Dehydration
   o. Lack of weight gain
2. Classic CAH phenotype (New 2002; White 2001)
   a. Simple virilizing form (about 25% of patients)
   b. Salt-wasting form (>75% of patients)
      i. Adrenal crises present at 1–4 weeks of age in severely affected patients
         a) Severe dehydration
         b) Hypotension
         c) Severe hyponatremia, hyperkalemia, and hyperreninemia
         d) Progressing to adrenal crisis (azotemia, vascular collapse, hypovolemic shock, and death) if adequate medical care is not provided
         e) Affected infant boys who are not detected in a newborn screening program are at high risk of a salt-wasting crisis since their normal genitalia fail to alert physicians to the diagnosis of congenital adrenal hyperplasia.
      ii. Non-specific symptoms
         a) Poor appetite/feeding
         b) Vomiting
         c) Hypotension
         d) Lethargy
         e) Failure to gain weight (weight loss)
      iii. Improved sodium balance and more efficient aldosterone synthesis with age in patients known to have severe slat-wasting episodes in infancy and early childhood
      iv. Siblings may be discordant for salt wasting
      v. The degree of salt wasting may vary in individuals carrying identical mutations.
      vi. Patients with 3β-hydroxysteroid hydrogenase deficiency, aldosterone synthase deficiency, or lipoid hyperplasia
         a) Unable to synthesize aldosterone
         b) May present with salt-wasting crises
   c. Children with classic CAH
      i. Lack of sufficient amounts of cortisol to mount a stress response and frequently succumb to minor illnesses
      ii. Premature closure of the epiphyses resulting in short stature even though these children grow at an accelerated rate when young
   d. Growth disturbances
      i. Accelerated skeletal maturation in untreated patients due to high levels of androgen
      ii. Growth retardation in patients treated with excessive doses of glucocorticoids
      iii. Final height, despite careful monitoring and good patient compliance, usually averaging one to two standard deviations below the population mean or the target height based on parental heights
   e. Reproductive problems in affected females (White 2001)
      i. Ambiguous genitalia typically present in the neonatal period
         a) Clitoromegaly (mild)
         b) With or without partial fusion of the labioscrotal folds (intermediate)
         c) Complete fusion of the labioscrotal folds with the appearance of a penile urethra (severe)
      ii. Internal genitalia
         a) Normal ovaries, fallopian tubes, and uteri
         b) Normal upper third of the vagina but urogenital sinus may be present distally with one opening on the perineum
      iii. Signs of androgen excess in affected females without glucocorticoid replacement therapy (New 2002)

a) Clitoral enlargement
b) Excessive linear growth
c) Advanced bone age
d) Acne
e) Early onset of pubic and axillary hair
f) Hirsutism
g) Male pattern baldness
h) Menstrual abnormalities
i) Reduced fertility

iv. Adolescence (White 2001)
a) Late menarche in inadequately treated girls
b) Sonographic finding of multiple ovarian cysts similar to patients with polycystic ovarian syndrome
c) Anovulation
d) Irregular bleeding
e) Hyperandrogenic symptoms

v. Pregnancy and live-birth rates
a) Severely reduced in salt-wasting patients
b) Mildly reduced in simple virilizing patients
c) Normal in nonclassical patients

vi. Factors suggested responsible for the impaired fertility (Stikkelbroeek et al. 2003)
a) Adrenal overproduction of androgens and progestins (17-hydroxyprogesterone, progesterone, and androstenedione)
b) Ovarian hyperandrogenism
c) Polycystic ovary syndrome
d) Ovarian adrenal rest tumors
e) Neuroendocrine factors
f) Genital surgery
g) Psychosocial factors (delayed psychosexual development, reduced sexual activity, low maternal feelings)

vii. No evidence of an excess of congenital malformations in offspring of women with 21-hydroxylase deficiency (White 2001)

viii. Other types of congenital adrenal hyperplasia (White 2001)
a) 11β-hydroxylase deficiency: similar to 21-hydroxylase deficiency
b) 17α-hydroxylase deficiency: remains sexually infantile due to inability to synthesize sex hormones unless supplemented with estrogen
c) 3β-hydroxysteroid hydrogenase deficiency: slightly virilized due to high levels of dehydroepiandrosterone

f. Reproductive function and problems in affected males (New 2002; White 2001)
i. Signs of androgen excess in affected males without glucocorticoid replacement therapy
a) Penile enlargement
b) Small testes
c) Excessive linear growth
d) Advanced bone age
e) Acne
f) Early onset of pubic and axillary hair

ii. Ability to father children

iii. Testicular adrenal rests
a) Most often benign
b) Manifest as testicular enlargement
c) Seen most often in inadequately treated patients, particularly those with the salt-wasting form of 21-hydroxylase deficiency

iv. Other types of congenital adrenal hyperplasia
a) Men with 11β-hydroxylase deficiency: similar to those with 21-hydroxylase deficiency
b) Genetic males with 3β-hydroxysteroid hydrogenase deficiency, 17α-hydroxylase deficiency, or lipoid hyperplasia: usually raised as females and castrated during or before adolescence to prevent malignant transformation of abdominal testes

g. Effects on gender role, sexual orientation, and identity (White 2001)
i. Gender role
a) Referring to gender-stereotyped behaviors such as choice of play toys by young children
b) Girls with 21-hydroxylase deficiency may show low interest in maternal behavior, extending from lack of doll play in early childhood to lack of interest in childrearing in women.

ii. Sexual orientation
a) Referring to homosexual versus heterosexual preferences
b) Heterosexuality in most adult women with 21-hydroxylase deficiency

c) Homosexuality or bisexuality or increased tendency to homo-erotic fantasies in a small but significant proportion in women with 21-hydroxylase deficiency

iii. Gender identity
a) Referring to self-identification as male or female
b) Self-reassignment to the male sex is unusual in women with 21-hydroxylase deficiency
c) Severely virilized females are more likely to be raised as males in cultures that value boys more highly and/or in third world countries in which the diagnosis is likely to be delayed.

3. Nonclassic CAH phenotype (White 2001)
a. Having only moderate enzyme deficiency
b. Nonambiguous external genitalia, with normal or mild clitoromegaly, in females affected with mild, nonclassical form of 21-hydroxylase deficiency
c. Signs of androgen excess
i. Wide spectrum of symptoms and signs
ii. Asymptomatic in many affected individuals
iii. Children: premature pubarche
iv. Young women
a) Severe cystic acne
b) Hirsutism
c) Oligomenorrhea
d. Signs and symptoms suggesting mild CAH (Deaton et al. 1999)
i. Children
a) Moderate to severe recurrent sinus or pulmonary infections
b) Severe acne
c) Hyperpigmentation, especially of the genitalia
d) Tall for age
e) Early onset of puberty
ii. Adults
a) Childhood history as described above
b) Syncope or near-syncope
c) Shortened stature compared with either parent
d) Hypotension (21-hydroxylase deficiency)
e) Hypertension (11β-hydroxylase deficiency)
iii. Women
a) Clitoromegaly
b) Poorly developed labia
c) Premature adrenarche
d) Hirsutism
e) Menstrual disturbances
f) Infertility
g) Polycystic ovary syndrome

4. Clinical characteristics of other forms of CAH (Antal and Zhou 2009)
a. 11-Beta Hydroxylase deficiency
i. Ambiguous genitalia in females
ii. Rare adrenal crisis
b. 17-alpha-hydroxylase deficiency
i. Ambiguous genitalia in males
ii. No adrenal crisis
c. 3-beta-hydroxysteroid Dehydrogenase deficiency
i. Ambiguous genitalia in males
ii. Adrenal crisis present
d. Lipoid CAH
i. Ambiguous genitalia in males
ii. Severe adrenal crisis

Diagnostic Investigations

1. Newborn screening (New 2002; White 2001, 2009)
a. Objectives
i. Detect a common and potentially fatal childhood disease (classic form of CAH)
ii. Prevent serious morbidity and mortality by early recognition and treatment
iii. Prevent incorrect male sex assignment of affected female infants with ambiguous genitalia
iv. Detect most, but not all, cases of the nonclassic form of 21-hydroxylase deficiency
b. Filter-paper blood spot sample (White 2001)
i. Markedly elevated 17-hydroxyprogesterone by radioimmunoassay
ii. False positives
a) Samples taken in the first 24 h of life (elevated in all infants)
b) Variation of weight adjusted cutoff values among newborn screening programs
c) Infants with low birth weight or prematurity
c. Diagnosis is based on elevated levels of 17-hydroxyprogesterone, the preferred substrate for steroid 21-hydroxylase

d. Initial testing usually involves dissociation-enhanced lanthanide fluorescence immunoassay that has a low positive predictive value (about 1%), leading to many follow-up evaluations that have negative results
e. Second level of screening based on detection of actual mutations on DNA extracted from the same dried blood spots or liquid chromatography followed by tandem mass spectrometry
f. Main benefits of newborn screening
   i. Reduced morbidity and mortality
   ii. Reduced time to diagnosis of infants with 21-hydroxylase deficiency
   iii. Infants ascertained through screening
      a) Less severe hyponatremia
      b) Tend to be hospitalized for shorter periods of time

2. Diagnosis of CAH
   a. Female neonates
      i. With genital ambiguity
         a) Genital ambiguity highly distressing to the family
         b) Require urgent expert medical attention
         c) Need immediate comprehensive evaluation by a multidisciplinary team including specialists from pediatric endocrinology, psychosocial services, pediatric surgery/urology, and genetics
      ii. With or without salt loss
      iii. Presence of elevated concentration of serum 17-hydroxyprogesterone
         a) Only diagnostic of CAH when measured after the 3rd day of life
         b) Presence of relatively high concentrations in the immediate neonatal period in normal infants
      iv. Normal internal female genitalia on pelvic ultrasonography
      v. Normal female karyotype (46,XX)
   b. Male neonates
      i. Salt-losing crises
      ii. Presence of elevated 17-hydroxyprogesterone concentration
3. Clinical chemistry
   a. Important initial laboratory evaluation for patients suspected of experiencing adrenal crisis due to 21-hydroxylase deficiency (Antal and Zhou 2009)
      i. Glucose/dextrose stick at bedside
      ii. Chem-20 (including electrolytes and liver function panel): critical to assure that the potassium concentration is obtained from a nonhemolyzed sample to minimize the likelihood of a falsely elevated potassium value
      iii. Arterial blood gas/serum pH
      iv. Cortisol
      v. ACTH
      vi. 17-OHP
      vii. Pelvic ultrasonography
      viii. Karyotype
   b. ACTH stimulation test: necessary to evaluate adrenal function and differentiate among the various potential enzymatic defects (Antal and Zhou 2009)
   c. Comparison of baseline and cortrosyn-stimulated serum concentrations of the steroid precursor 17-hydroxyprogesterone (nonclassical)
   d. Increased serum levels of progesterone, 17-hydroxyprogesterone, and androstenedione in affected males and females with classic 21-hydroxylase deficiency
   e. Elevated serum levels of testosterone and adrenal androgen precursors in affected girls
   f. Salt losers
      i. Low serum bicarbonates, sodium, and chloride levels
      ii. Elevated levels of serum potassium and serum urea nitrogen
      iii. Hyponatremia and hyperkalemia usually not present before 7 days of age
      iv. Inappropriately increased urine sodium levels
      v. Elevated plasma rennin levels
      vi. Serum aldosterone level inappropriately low for the rennin level
4. Karyotyping or fluorescence in situ hybridization for sex chromosome material
   a. 46,XX in females with 21-hydroxylase deficiency
   b. 46,XY in males with 21-hydroxylase deficiency
5. Annual bone age radiography
6. Careful monitoring of linear growth
7. Transabdominal pelvic sonography
   a. Perform in patients with CAH undergoing vaginal reconstruction
   b. Provide adequate information about the anatomy of the vagina and urogenital sinus

c. Demonstrate presence or absence of a uterus or associated renal anomalies
8. Urogenitogram helpful to define the anatomy of the internal genitalia
9. Adrenal ultrasonography to detect enlarged, lobulated adrenals with stippled echogenicity invariably associated with CAH
10. Sonography or MRI for testicular adrenal rest tumors
11. Carrier detection (New 2002)
    a. Carriers: asymptomatic individuals who have one normal allele and one mutant allele
    b. ACTH stimulation test
        i. Resulting in slightly elevated serum concentrations of deoxycortisol and 17-hydroxyprogesterone
        ii. Overlap in serum concentration of 17-hydroxyprogesterone between carriers and noncarriers
        iii. No longer the preferred method of carrier detection
    c. Molecular genetic testing
        i. Molecular genetic testing of the *CYP21A2* gene available to at-risk relatives, given that the disease-causing mutation(s) have been identified in the proband
        ii. The preferred method of carrier detection
12. Molecular genetic testing (New 2002)
    a. Molecular genetic analysis for *CYP21A2* gene for a panel of 9 common mutations and gene deletions detect about 90–95% of disease-causing alleles in affected individuals and carriers.
    b. Complete gene sequencing detects more rare alleles in affected individuals in whom the panel of nine mutations and deletions reveals only one or neither disease-causing allele
    c. Applications
        i. Primarily used in genetic counseling for carrier detection of at-risk relatives and for prenatal diagnosis
        ii. Can be used for diagnosis in newborns with slight to moderate elevations of 17-hydroxyprogesterone
13. Laboratory characteristics of other forms of CAH (Antal and Zhou 2009)
    a. 11-Beta Hydroxylase deficiency
        i. Glucocorticoid values; decreased
        ii. Mineralocorticoid values: elevated
        iii. Androgens: elevated
        iv. Sodium concentrations: elevated
        v. Potassium concentrations: decreased
        vi. Elevated metabolites
            a) Deoxycorticosterone (DOC)
            b) 11-deoxycortisol
    b. 17-alpha-hydroxylase deficiency
        i. Glucocorticoid values: decreased
        ii. Mineralocorticoid values: elevated
        iii. Androgens: decreased
        iv. Sodium concentrations: increased
        v. Potassium concentrations: decreased
        vi. Elevated metabolites
            a) Deoxycorticosterone
            b) Corticosterone
    c. 3-beta-hydroxysteroid Dehydrogenase deficiency
        i. Glucocorticoid values: decreased
        ii. Mineralocorticoid values: decreased
        iii. Androgens
            a) Elevated in females
            b) Decreased in males
        iv. Sodium concentrations: decreased
        v. Potassium concentrations: elevated
        vi. Elevated metabolites
            a) Dehydroepiandrosterone (DHEA)
            b) 17-hydroxypregnenolone
    d. Lipoid CAH
        i. Glucocorticoid values: decreased
        ii. Mineralocorticoid values: decreased
        iii. Androgens: decreased
        iv. Sodium concentrations: decreased
        v. Potassium concentrations: elevated
        vi. Elevated metabolites: none

Genetic Counseling

1. Recurrence risk
    a. Genetic counseling according to autosomal recessive inheritance
        i. Most parents: heterozygotes with one normal allele and one mutated allele.
        ii. One percentage of probands having only one parent who is heterozygous since 1% of mutations occur de novo
        iii. In some instances, a parent, who was previously not known to be affected, was found to have the nonclassic form of 21-hydroxylase deficiency.

b. Patient's sib
   i. When the parents of a proband are both obligate heterozygotes
      a) Twenty-five percent risk of inheriting both altered alleles and being affected
      b) Fifty percent risk of inheriting one altered allele and being an unaffected carrier
      c) Twenty-five percent risk of inheriting both normal allele and being unaffected
      d) Two-third chance of unaffected sibs of a proband being a carrier
   ii. When a parent of a proband has 21-hydroxylase deficiency and the other is heterozygous
      a) Fifty percent risk of inheriting both mutant alleles and being affected
      b) Fifty percent risk of inheriting one mutant allele and being a carrier
c. Patient's offspring for a woman with classic 21-hydroxylase deficiency
   i. When the spouse status is unknown (Lo and Grumbach 2001)
      a) Risk of having an infant with the same disorder: approximately 1 in 120 births
      b) Risk of having an affected female infant: approximately 1 in 240 births
      c) Risk figures are based on an estimated 1 in 60 incidence of heterozygous individuals with a *CYP21* mutation, derived from newborn screening data
   ii. When the spouse is not a carrier or not affected: risk is not increased
   iii. Appropriate to offer molecular genetic testing of the *CYP21A2* gene to the spouse given the high carrier rate for 21-hydroxylase deficiency
d. Patient's offspring for a woman with nonclassic CAH and are compound heterozygotes with one severe *CYP21A2* mutation: Risk of having an affected infant with classic CAH is 1 in 4 pregnancies (or 1 in 8 pregnancies for an affected female infant) when the spouse is a known carrier of the severe form of *CYP21A2* deficiency.

2. Prenatal diagnosis
   a. Determination of amniotic fluid (AF) hormone levels
      i. Elevated 17α-hydroxyprogesterone
      ii. Elevated androstenedione
   b. Human leukocyte antigen (HLA) typing on cultured chorionic villus cells and cultured AF cells
      i. Basis for prenatal diagnosis: the gene for 21-hydroxylase has been linked to the HLA system on chromosome 6
      ii. HLA type
         a) Fetus with an HLA type identical to that of the proband with 21-hydroxylase deficiency predicted to be affected
         b) Fetus sharing 1 parental haplotype with the proband predicted to be a heterozygous carrier
         c) Fetus with both haplotypes different from the index case predicted to be homozygous normal
   c. Molecular DNA diagnosis
      i. Molecular genetic testing of the proband and both parents should be undertaken prior to conception:
         a) To identify the two disease-causing mutations
         b) To confirm both parents are carriers
      ii. Analysis of both parents
         a) To determine the phase of different mutations (whether they lie on the same or opposite alleles)
         b) To distinguish homozygotes and hemizygotes (individuals who have a mutation on one chromosome and a deletion on the other)
      iii. De novo mutations, found in patients with CAH but not in parents, observed in 1% of disease-causing CYP21B mutations
      iv. Before 10 weeks of gestation and prior to any prenatal testing, administer dexamethasone to the pregnant mother to suppress excess fetal adrenal androgen secretion and to prevent virilization of an affected female
      v. Obtain fetal cells to determine fetal sex by chromosome analysis or FISH using Y-chromosome specific probes
         a) CVS in the 10th–12th week of gestation (preferable because of early result)
         b) Amniocentesis at 16–18 weeks of gestation
      vi. If the fetus is a female and if the two *CYP21A2* disease-causing mutations have been identified in the proband:

a) Perform molecular genetic testing to determine whether the fetus has inherited both disease-causing alleles
b) Female fetus known to have 21-hydroxylase deficiency by DNA analysis or having an indeterminant status: continue dexamethasone treatment to term

vii. If the fetus is a male or unaffected female by DNA analysis: discontinue dexamethasone treatment

3. Management (White 2001)
   a. Replacement with glucocorticoids (hydrocortisone, prednisone, dexamethasone)
      i. Indicated in all patients with classic and symptomatic nonclassical patients with 21-hydroxylase deficiency
      ii. To suppress the excessive secretion of CRH and ACTH by the hypothalamus and pituitary
      iii. To reduce the abnormal blood levels of adrenal sex steroids
      iv. Situations in which increase hydrocortisone dose is needed in patients with classic 21-hydroxylase deficiency
         a) Febrile illness
         b) Surgery under general anesthesia
      v. Increase doe of hydrocortisone or prednisone in pregnancy due to pregnancy-induced alterations in steroid metabolism and clearance
      vi. Glucocorticoid replacement also required in patients with CAH caused by other enzymatic deficiencies
   b. Mineralocorticoid replacement
      i. Mineralocorticoid (fludrohydrocortisone) and sodium chloride supplements required in infants with the salt-wasting form of 21-hydroxylase deficiency
      ii. Treat patients with simple virilizing form of the disease by fludrohydrocortisone to aid in adrenocortical suppression and reduce the dose of glucocorticoid required to maintain acceptable 17-hydroxyprogesterone levels
      iii. Signs of overtreatment with mineralocorticoid and sodium replacement
         a) Hypertension
         b) Tachycardia
         c) Suppressed plasma rennin activity
      iv. Other indications of fludrohydrocortisone replacement
         a) 3β-hydroxysteroid hydrogenase deficiency
         b) Aldosterone synthase deficiency
         c) Lipoid hyperplasia
   c. Other pharmacological approaches
      i. A novel 4-drug regimen for 21-hydroxylase deficiency
         a) Consisting of flutamide (an androgen receptor blocking drug), testolactone (an aromatase inhibitor), and low dose of hydrocortisone and fludrocortisone
         b) Benefit: produce less bone age advancement and attain more appropriate linear growth velocity than standard treatment
         c) Side effect: occurrence of central precocious puberty requiring treatment with gonadotrophin releasing hormone analog
      ii. Experimental treatment with carbenoxolone, an inhibitor of 11β-hydroxysteroid dehydrogenase
   d. Corrective surgery
      i. Decision about surgery
         a) Made by the parents, together with the clinical team
         b) After disclosure of all relevant clinical information and all available options
         c) Obtain informed consent
      ii. Objectives
         a) Genital appearance compatible with gender
         b) Unobstructed urinary emptying without incontinence or infections
         c) Good adult sexual and reproductive function
      iii. Clitoroplasty, rather than clitoridectomy, done in infancy
      iv. Vaginal reconstruction
         a) Often postponed until the age of expected sexual activity
         b) Single-stage corrective surgery in children
   e. Adrenalectomy
      i. Questionable therapeutic alternative
      ii. Likely to be used, if at all, in patients with severe 21-hydroxylase deficiency refractory to standard medical management

f. Management of testicular adrenal rests
   i. Effective adrenal suppression with dexamethasone since many of these tumors are ACTH-responsive
   ii. Testis-sparing surgery for cases unresponsive to dexamethasone after imaging the tumor by sonography and/or MRI
g. Management of adolescence with classical and nonclassical CAH (Clayton et al. 2002)
   i. Psychological assessment and support of the patient
   ii. Counseling
      a) Sexual function
      b) Future surgeries
      c) Gender role
      d) Issues related to living with a chronic disorder
      e) Low risk of women with CAH or nonclassic CAH having an affected fetus
h. Management of pregnancy in women with classic 21-hydroxylase deficiency (Lo and Grumbach 2001)
   i. Factors contributing to lower fertility rates
      a) Masculinization of the external genitalia
      b) An inadequate introitus
      c) Factors relating to genital reconstructive surgery (poor surgical repair, vaginal stenosis, and clitoral dysfunction)
      d) Hormonal factors (increased levels of adrenal androgens and progestational steroid, and ovarian hyperandrogenism)
   ii. Recent improvement of fertility prognosis
      a) Earlier detection and treatment of 21-hydroxylase deficiency
      b) Surgical advances in genital reconstruction
      c) Higher patient compliance rates
   iii. Preconception issues for all women with classic 21-hydroxylase deficiency who desire pregnancy
      a) Need for glucocorticoid treatment
      b) Careful endocrine monitoring throughout gestation
      c) Ovulation induction with clomiphene citrate or gonadotropin therapy or in vitro fertilization for patients who do not achieve normal ovulatory cycles and fertility despite effective glucocorticoid therapy
      d) Most pregnancies are successful in carrying to term with a healthy outcome.
      e) Preconceptional counseling about the risk of having a child affected with 21-hydroxylase deficiency
   iv. Gestational management (Lo Lo and Grumbach 2001)
      a) Regular assessment of maternal clinical status, serum electrolytes, and circulating adrenal androgen levels during gestation to determine the need for increased glucocorticoid or mineralocorticoid therapy
      b) Signs of adrenal steroid insufficiency (excessive nausea, slat craving, and poor weight gain)
      c) Monitor hypertension and fluid retention in patients receiving mineralocorticoid therapy, particularly in the third trimester
   v. Labor and delivery (Lo and Grumbach 2001)
      a) Require stress doses of glucocorticoid therapy during labor and delivery
      b) Elective cesarean section considered for pregnant women with virilizing CAH, for cephalopelvic disproportion due to android pelvic characteristics and especially for those who have had reconstructive surgery of the external genitalia
   vi. Evaluation of the infant (Lo and Grumbach 2001)
      a) Clinical signs of adrenal suppression (hypotension, hypoglycemia), particularly in cases in which dexamethasone was administered during pregnancy
      b) Sign of ambiguous external genitalia
      c) Female pseudohermaphroditism secondary to either maternal hyperandrogenism or fetal 21-hydroxylase deficiency (if the father is a carrier)
i. Prenatal therapy
   i. Inclusion criteria (Clayton et al. 2002)
      a) A previously affected sibling or first-degree relative with known mutations causing classic CAH, proven by DNA analysis
      b) Reasonable expectation that the father is the same as the father of the proband
      c) Availability of rapid, high-quality genetic analysis
      d) Therapy started less than 9 weeks after the last menstrual period

e) No plans for therapeutic abortion
f) Reasonable expectation of patient compliance

ii. Dexamethasone
a) No salt-retaining activity
b) Not significantly metabolized by placental 11β-hydroxysteroid dehydrogenase
c) Able to cross the placenta

iii. Administer oral dexamethasone to the mother in pregnancies at risk for a female child affected with virilizing adrenal hyperplasia
a) To suppress fetal adrenal androgen production, beginning after conception and before the 7–8th week of gestation, to prevent ambiguity of the external genitalia in the female fetus with classic CAH
b) To prevent progression of virilization on therapy after 7–8th week of gestation
c) Chromosome analysis from fetal cells obtained from either CVS at 10–12 weeks of gestation or amniocentesis at 14–18 weeks of gestation
d) If the fetus is a female, additional molecular genetic testing is performed on the sample to determine if she has 21-hydroxylase deficiency (Antal and Zhou 2009)
e) If the fetus is affected, maternal dexamethasone administration is continued to term; if not, it can be discontinued

iv. Outcome of prenatally treated females (American Academy of Pediatrics 2000)
a) Approximately 70% born with normal or only slightly virilized genitalia with clitoromegaly, partial labial fusion, or both
b) Approximately 30% born with marked genital virilization

v. Disadvantage: 7 out of 8 fetuses unnecessarily treated since CAH is inherited as an autosomal recessive disease and only affected girls benefit from the treatment

vi. Prompt discontinuation of dexamethasone therapy to minimize potential risks of glucocorticoid toxicity if (White 2001):
a) Male sex determination by prenatal genetic diagnosis
b) *CYP21* genotype indicating that the fetus is unaffected

vii. Refer patient to centers with expertise in the prenatal management of pregnancies at risk for CAH.

viii. Long-term follow-up studies still needed for prenatally treated children

ix. Side effects of women treated to term (10%)
a) Features of Cushing syndrome (excessive weight gain, severe striae, hypertension, hyperglycemia)
b) Resolved when the treatment is discontinued

x. Side effects of women treated for a shorter time (10–20%)
a) Edema
b) Gastrointestinal upset
c) Mood fluctuations
d) Acne
e) Hirsutism

xi. Similar therapeutic approaches: effective in families at risk for 11β-hydroxylase deficiency, in which affected female fetuses may also suffer severe prenatal virilization

xii. Prenatal therapy not appropriate for nonclassic CAH

xiii. Parents of affected girls
a) Many opting for prenatal medical treatment because of severe psychological impact of ambiguous genitalia on the child and on the family
b) Obtain informed consent as to the potential fetal and maternal risks, some of which may yet to be recognized

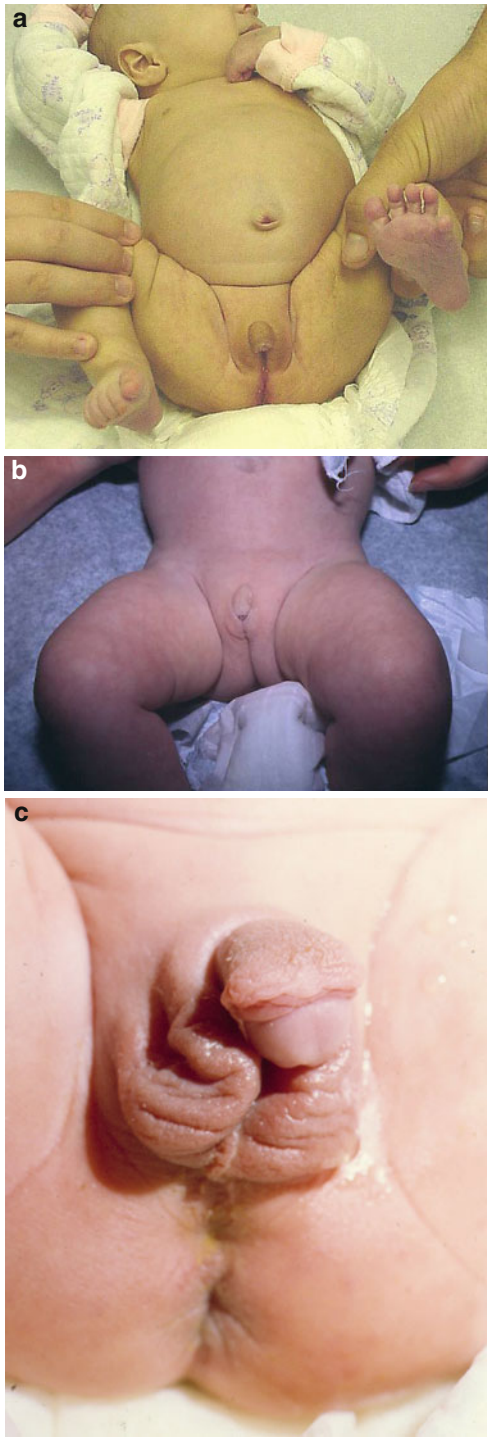

Fig. 1 (**a**–**c**) Female infants (46,XX) with classic form of CAH showing varying degree of virilization

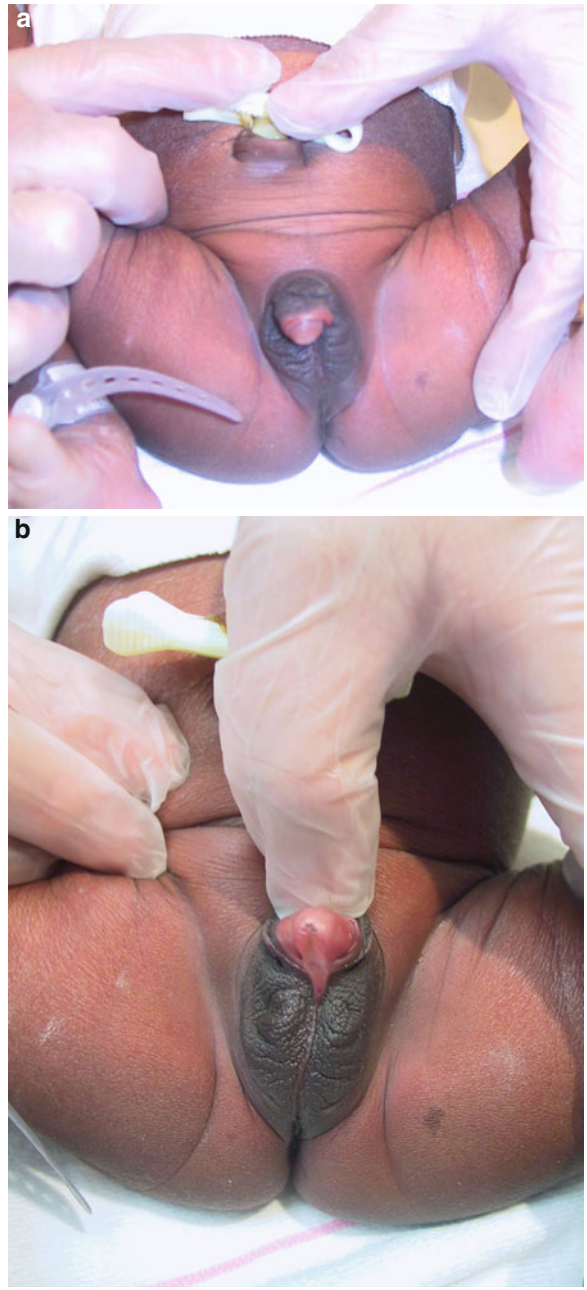

Fig. 2 (**a**, **b**) A newborn with congenital adrenal hyperplasia showing ambiguous genitalia. Newborn screening from filter paper showed total 17OHP of >240 ng/mL (normal <33). A pair of intron 2 mutations were detected by PCR

Congenital Cutis Laxa

Congenital cutis laxa is a rare inherited connective tissue disorder manifested by inelastic, loose, pendulous skin, giving the appearance of premature aging (Andiran et al. 2002).

Synonyms and Related Disorders

Cutis laxa, Debre type; Cutis laxa with growth and developmental delay

Genetics/Basic Defects

1. Genetic heterogeneity
   a. Autosomal recessive cutis laxa, a genetically heterogeneous condition: the most common type
      i. Type I autosomal recessive cutis laxa: less frequent than type II
      ii. Type IIA autosomal recessive cutis laxa (cutis laxa, Debre type; cutis laxa with growth and developmental delay; cutis laxa with or without congenital disorder of glycosylation)
      iii. Type IIB: cutis laxa with progeroid features
   b. Autosomal dominant cutis laxa
   c. X-liked recessive cutis laxa
      i. Previously called occipital horn syndrome
      ii. At present, best termed as Ehlers–Danlos syndrome type IX
2. Biochemical and molecular defects (Loeys et al. 2002)
   a. Autosomal recessive cutis laxa type I: Molecular studies in a large consanguineous Turkish family demonstrated the presence of a homozygous missense mutation (T998C) in the fibulin-5 (*FBLN5*) gene, resulting in a serine-to-proline (S227P) substitution in the fourth calcium-binding epidermal growth factor–like domain of fibulin-5 protein
   b. Type IIA autosomal recessive cutis laxa
      i. Caused by mutation in the ATPase, H + transporting, lysosomal, V0 subunit A2 gene (ATP6V0A2)
      ii. A combined disorder of N- and O-linked glycosylation has been described in children with congenital cutis laxa in association with severe central nervous system involvement, brain migration defects, seizures, and hearing loss (Morava et al. 2008).
      iii. Type IIB: caused by mutation in the *PYCR1* gene
   c. Autosomal dominant cutis laxa
      i. Can be caused by mutations in the elastin gene
      ii. Molecular heterogeneity cannot be excluded
   d. X-linked recessive cutis laxa (Byers et al. 1980; Gorlin and Cohen 1990)
      i. Caused by mutations in the *ATP7A* gene
      ii. Characterized by diminished activity of lysyl oxidase in the skin from affected males
      iii. Reduced serum copper and ceruloplasmin in affected males, suggesting that the lysyl oxidase deficiency may be secondary to a defect in copper metabolism
      iv. Now known to be allelic to Menkes disease

Clinical Features

1. Autosomal recessive cutis laxa (Gorlin 1990)
   a. More common than the autosomal dominant form

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_49,
© Springer Science+Business Media, LLC 2012

b. Autosomal recessive cutis laxa type I
   i. The poorest prognosis
   ii. Pulmonary emphysema
   iii. Umbilical and inguinal hernias
   iv. Gastrointestinal and vesicourinary tract diverticuli
c. Autosomal recessive cutis laxa type II, also called cutis laxa with joint laxity and developmental delay
d. Characteristic facies
   i. Appearing aged due to accentuation of skin folds
   ii. Downward slanting palpebral fissures
   iii. Blepharochalasis and, at times, ectropion, adding to the aged appearance
   iv. A broad flat nose
   v. Sagging cheeks
   vi. Long upper lip
   vii. Short columella
   viii. Large ears
e. Skin
   i. Prominent skin folds (loose skin) around the knees, abdomen, and thighs
   ii. No hyperelasticity, fragility, or difficulty in wound healing
f. Skeletal muscular abnormalities
   i. Dislocation of the hips
   ii. Joint hyperextensibility
   iii. Hernia
   iv. Osteoporosis
g. Cardiopulmonary abnormalities
   i. Severe pulmonary emphysema resulting from generalized elastolysis
      a) Tachypnea
      b) Pneumonitis
      c) Airway obstruction
      d) Severe hypoxia
      e) Respiratory failure
   ii. Cardiac abnormalities
      a) Right ventricular enlargement
      b) Cor pulmonale
      c) Bundle branch block
      d) Pulmonary artery hypoplasia and stenosis
      e) Dilated and tortuous carotid, vertebral, and pulmonary arteries
      f) Aortic aneurysm
h. Other abnormalities
   i. Hernias
      a) Inguinal
      b) Diaphragmatic
      c) Ventral
      d) Inguinal
   ii. Hollow viscus (pharynx, esophagus, and rectum) diverticula
   iii. Oral abnormalities
      a) Deep and resonant voice secondary to lax vocal cords
      b) Loose oral and pharyngeal mucosa
   iv. Genitourinary abnormalities
      a) Bladder diverticula
      b) Vaginal prolapse
   v. Dental caries
i. A shorter life span

2. Autosomal dominant cutis laxa
   a. Less common than the autosomal recessive form
   b. Cutaneous laxity
   c. Clinical features presenting in infancy (Andiran et al. 2002)
      i. Intrauterine growth retardation
      ii. Delayed fontanelle closure
      iii. Ligamental laxity
      iv. Episodes of edema may precede the skin changes, usually within the first 2 months of life.
      v. Aging appearance by the end of the second year
      vi. Pulmonary emphysema common due to a loss of elastic tissue in the lungs
   d. Skin changes presenting in adulthood
      i. Usually no internal defects
      ii. Having a normal life expectancy
   e. Aging appearance
      i. Drooping of eyelids
      ii. Sagging facial skin
      iii. Accentuation of the nasolabial and other facial folds
      iv. Often hooked nose with everted nostrils
      v. Long philtrum
   f. Few complications
      i. Hoarseness
      ii. Pulmonary artery stenosis

iii. Mitral valve prolapse
iv. Hernia
v. Bronchiectasis
vi. Joint dislocations
vii. Tortuosity and dilatation of carotid arteries and aorta
viii. Dilatation of sinuses of Valsalva
ix. Coarctation of the aorta

g. Normal life span

3. X-linked recessive cutis laxa (Brown et al. 1982)
   a. Long and thin face, neck, and trunk
   b. Mild hyperelastic (but not lax) and bruisable skin with resultant atrophic scars
   c. Musculoskeletal abnormalities
      i. Inferior cranial spurs (occipital horns)
         a) A constant feature
         b) May be palpated
         c) May become larger with age
         d) May represent ectopic bone formation within the trapezius and sternocleidomastoid aponeuroses
      ii. Skeletal dysplasia most prominent at the wrists and elbows
      iii. Limitation of extension of the elbows, shoulders, knees
      iv. Hypermobility of the finger joints
      v. Pes planus
      vi. Genu valga
      vii. Pectus excavatum or carinatum (40%)
   d. Obstructive uropathy secondary to bladder diverticula with bladder neck obstruction (60–70%)
   e. Various hernias (hiatal, femoral, and inguinal) (35%)
   f. Chronic diarrhea (40%)
4. Differential diagnosis
   a. Wrinkling skin syndrome
      i. A rare autosomal recessive disorder of the connective tissue
      ii. Wrinkled skin over abdomen and on the dorsum of the hands and feet
      iii. Poor skin elasticity in affected areas
      iv. Increased palmar and plantar creases
      v. A prominent venous pattern on the chest
      vi. Mental retardation
      vii. Microcephaly
      viii. Hypotonia
      ix. Musculoskeletal abnormalities
   b. De Barsy syndrome (Andiran et al. 2002; Gorlin 1990)
      i. Cutis laxa (wrinkled atrophic skin)
      ii. Retarded psychomotor development
      iii. Corneal clouding due to degeneration of the tunica elastica of the cornea
      iv. Intrauterine growth retardation
      v. Pseudoathetoid movement
      vi. Muscular hypotonia
      vii. Hypermobility of small joints
   c. Costello syndrome (Davies and Hughes 1994)
      i. Nasal papillomata
      ii. Coarse facies
      iii. Mental retardation
      iv. Growth retardation
      v. Cutis laxa
   d. SCARF syndrome (Koppe et al. 1989)
      i. An X-linked recessive disorder
      ii. Skeletal abnormalities
         a) Craniostenosis
         b) Enamel hypoplasia, hypocalcification of the teeth
         c) Short sternum
         d) Pectus carinatum
         e) Abnormally shaped vertebrae
         f) Abnormal modeling of long tubular bones
      iii. Cutaneous abnormalities
         a) Cutis laxa
         b) Wide-spaced nipples
         c) Diastasis recti
         d) Umbilical hernia
      iv. Ambiguous genitalia
         a) Micropenis
         b) Perineal hypospadias
      v. Retardation: mild to moderate psychomotor retardation
      vi. Facial abnormalities
         a) Multiple hair whorls
         b) Epicanthal folds
         c) Ptosis
         d) High and broad nasal root
         e) Low-set and posteriorly rotated ears
         f) Small chin

Diagnostic Investigations

1. Radiography
   a. Autosomal recessive cutis laxa
      i. Presence of a variety of hernias
         a) Femoral
         b) Inguinal
         c) Obturator
         d) Hiatal
      ii. Eventrations of the diaphragm
      iii. Rectal and uterine prolapse
      iv. Common intrathoracic abnormalities
         a) Hyperexpansion of the lungs
         b) Emphysema which may lead to cor pulmonale and death in childhood
         c) Upper airway obstruction caused by excessively lax vocal cords, leading to congestive heart failure
         d) Frequent peripheral pulmonary artery stenosis and aortic dilatation
      v. Diverticula involving the entire bowel but no functional significance
      vi. Diverticula of the urinary tract predisposing to infection or causing obstruction
      vii. Arteriographic changes
         a) Peripheral pulmonary stenosis
         b) Dilatation and tortuosity of the aorta
         c) A peculiar corkscrew appearance of the peripheral systemic arteries, similar to the arterial changes seen in Menkes syndrome
   b. X-linked recessive cutis laxa (Gorlin 1990)
      i. Occipital exostosis (horns) symmetrically located on each side of the foramen magnum
      ii. Short clavicles with a widened medullary cavity
      iii. Hammer-shaped distal extremities
      iv. Focal hyperostosis of the femora at sites of tendon and ligament insertion
      v. Carpal fusion involving capitate-hamate and trapezium-trapezoid coalescence (over 50%)
      vi. Deformation of humerus, radius, ulna, tibia, fibula (90%)
      vii. Osteoporosis (70%)
      viii. Narrowing of rib cage (65%)
      ix. Dislocation of radial head (40%)
      x. Mild platyspondyly
      xi. Coxa valga
      xii. Flattening of acetabular roofs
2. Histopathological abnormality: fragmentation and paucity of elastic fibers in the skin
3. X-linked cutis laxa
   a. Non-molecular testing
      i. Low serum copper concentration
      ii. Low serum ceruloplasmin concentration
      iii. Copper transport studies in cultured fibroblasts: impaired cellular copper exodus demonstrated by increased cellular copper retention in pulse-chase experiments with radiolabeled copper
      iv. Plasma and CSF catecholamine analysis: abnormal levels reflecting partial deficiency of dopamine-beta-hydroxylase, a copper-dependent enzyme critical for catecholamine biosynthesis
      v. Low activity of a copper-dependent enzyme, lysyl oxidase
   b. Molecular genetic testing
      i. Mutation analysis: multiplex PCR analysis, available on a clinical basis, to detect large *ATP7A* deletions
      ii. Sequence analysis: direct sequence analysis of the *ATP7A* coding region and flanking intron sequences, available on a clinical basis
      iii. Mutation scanning: heteroduplex analysis, available on a clinical basis, to detect small mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive cutis laxa: 25%
      ii. Autosomal dominant cutis laxa: not increased unless a parent is affected
      iii. X-linked recessive cutis laxa:
         a) When the mother is a carrier: 50% risk of brother will be affected and 50% of sisters carriers
         b) When mother is not a carrier: the recurrence risk is low but greater than that for the general population because the risk of germline mosaicism in mother is not known.

   b. Patient's offspring
      i. Autosomal recessive cutis laxa: not increased unless the spouse is a carrier or affected
      ii. Autosomal dominant cutis laxa: 50%
      iii. X-linked recessive cutis laxa: Males with occipital horn syndrome will pass the disease-causing gene to all of their daughters and none of their sons.
2. Prenatal diagnosis
   a. DNA-based analysis on fetal DNA obtained from amniocentesis or CVS for the previously characterized disease-causing mutation
   b. Fetal sex determination for X-linked recessive cutis laxa (occipital horn syndrome)
3. Management (Nahas et al. 1999; Strohecker 1995)
   a. Supportive therapy: antibiotic prophylaxis for bladder infection
   b. Surgery for bladder diverticula
   c. Plastic surgery to improve aging appearance
      i. Serial excisions of the skin
      ii. Blepharoplasty
      iii. Rhytidectomy
      iv. Rhinoplasty
      v. Shortening of the upper lip
      vi. Earlobe reduction
      vii. Neck lift
      viii. Correction of lower eyelid laxity, epiphora, and upper eyelid ptosis

Congenital Cytomegalovirus Infection

Congenital cytomegalovirus infection is the most common congenital infection in neonates in the USA, affecting approximately 0.5–1.5% of all live births and 30,000–40,000 newborns annually. Congenital infections result from transplacental transmission of cytomegalovirus (CMV).

Synonyms and Related Disorders

Intrauterine cytomegalovirus infection of fetus

Genetics/Basic Defects

1. Human cytomegalovirus
   a. A DNA virus belonging to the herpesvirus group (herpes simplex, varicella zoster, Epstein–Barr) (Brown and Abernathy 1998; Kuhlmann and Autry 2001)
   b. Ability of the virus (Pass 2002)
      i. To destroy host cells (lytic infection)
      ii. To infect a wide range of cells and tissues
      iii. To evade and interfere with host defense mechanisms
      iv. To persist indefinitely in the host
      v. To infect and destroy cells during productive infection (with release of progeny virus)
2. Transmission of CMV (Kuhlmann and Autry 2001)
   a. Horizontal transmission: Close intimate contact with another person shedding the virus in body fluids (saliva, blood, cervical secretions, semen, urine, or respiratory droplets)
   b. Vertical transmission: from mother to infant
      i. In utero by transplacental passage of maternal blood-borne virus
      ii. At birth by passage through an infected maternal genital tract
      iii. Postnatally by ingestion of CMV-positive human milk from seropositive mothers
   c. Infected organ or bone marrow transplantation
   d. Infected blood transfusion from CMV-seropositive donors
3. Primary sources of CMV infection for women of childbearing age
   a. Young children
   b. Sexual contacts
4. Types of CMV infection (Kuhlmann and Autry 2001)
   a. Primary (first experience)
   b. Secondary (recurrent)
      i. Reactivation of the original endogenous CMV
      ii. Reinfection with a new strain of CMV
   c. Latent infection: sites at kidney, bone marrow, monocytes
5. The most common vertically transmitted viral infection from mother to fetus in pregnancy (Kuhlman 2001)
   a. Recurrent infection: 1% risk of vertical transmission
   b. Primary infection: 1–4% risk of vertical transmission
6. Symptomatic congenital infections observed primarily among women undergoing a primary infection
7. Greatest risk occurring with infection during the first 22 weeks of gestation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_50,
© Springer Science+Business Media, LLC 2012

8. Congenitally infected newborns: may shed the virus for many years
9. Perinatal CMV infection acquired during birth or from mother's milk: not associated with newborn illness or CNS sequelae, except perhaps in very preterm newborns who have very low levels of passively acquired CMV antibody at the time of infection

Clinical Features

1. Symptomatic at birth in 5–10% of congenital CMV infections (Enders et al. 2001)
   a. Approximately 20% of these will die
   b. Ninety percent of survivors will develop major neurological sequelae
2. Asymptomatic or "silent" congenital infections at birth in vast majority (85–90%) of cases. 10–15% of the asymptomatic newborns will be afflicted by late sequelae such as mental retardation, deafness or hearing defects, usually during the first 2 years of life. (Enders et al. 2001)
3. Non-neurologic symptoms at birth
   a. Petechiae (most common non-neurologic symptom)
   b. Thrombocytopenia
   c. Purpura
   d. Ecchymoses
   e. Splenomegaly
   f. Hepatomegaly
   g. Jaundice
   h. Intrauterine growth retardation
   i. Chorioretinitis
   j. Pneumonitis
   k. Anemia
   l. Nonimmune hydrops
4. Neurologic symptoms at birth
   a. Hypotonia
   b. Lethargy
   c. Jitteriness
   d. Split sutures
   e. Immature primitive reflexes
   f. Feeding difficulties
   g. Microcephaly: the most specific predictor of mental retardation and major motor disability
   h. Seizures
5. Eye manifestations (Metz 2001)
   a. Chorioretinitis resulting in a chorioretinal scar
   b. Corneal opacities
   c. Bilateral anterior polar cataracts
   d. Optic nerve hypoplasia and optic nerve coloboma
   e. Cyclopia and anophthalmia
6. Later neurologic symptoms
   a. Sensorineural hearing loss
   b. Learning disability
   c. Mental retardation
   d. Cerebral palsy
7. Prognosis
   a. Neonatal clinical abnormalities expected to resolve spontaneously within weeks, except for those involving the CNS and hearing
   b. A leading cause of mental retardation and sensory impairment (50–90% of symptomatic newborns) and sensorineural hearing loss (7–15% of asymptomatic infants)
   c. An important cause of cerebral palsy and retinal damage
8. Long-term sequelae of congenital cytomegalovirus infection in children with and without symptoms at birth (Sharon and Schleiss 2007; Schleiss 2008)
   a. Overall incidence
      i. Symptomatic: 50–90%
      ii. Asymptomatic: 10–15%
   b. Hearing loss
      i. Symptomatic: 50–60%
      ii. Asymptomatic: 7–15%
   c. Cognitive deficits
      i. Symptomatic: 50–70%
      ii. Asymptomatic: ~4%
   d. Microcephaly
      i. Symptomatic: 35–40%
      ii. Asymptomatic: ~2%
   e. Ocular abnormalities
      i. Symptomatic: 25–50%
      ii. Asymptomatic: ~3%
   f. Seizures
      i. Symptomatic: 15–20%
      ii. Asymptomatic: ~1%
   g. Mild to moderate motor deficits
      i. Symptomatic: 25–30%
      ii. Asymptomatic: <1%
   h. Severe motor deficits
      i. Symptomatic: 15–25%
      ii. Asymptomatic: <1%
9. Maternal primary CMV infection
   a. Asymptomatic: vast majority of pregnant women

   b. Symptomatic (mononucleosis-like syndrome) in approximately 10% of infected pregnant patients
      i. Fever
      ii. Fatigue/malaise
      iii. Myalgia
      iv. Pharyngitis
      v. Cough
      vi. Nausea
      vii. Headache

Diagnostic Investigations

1. Children with symptomatic congenital CMV infection (Pass 2002)
   a. Cytomegalic inclusion bodies in the urine
   b. Elevated alanine aminotransferase (ALT >80 IU/mL)
   c. Thrombocytopenia (<100,000/mcL)
   d. Conjugated hyperbilirubinemia (direct bilirubin >2 mg/dL)
   e. Anemia
   f. Elevated CSF protein (>120 mg/dL)
   g. Abnormal CT scan (most common neurologic sign and the most sensitive predictor for mental retardation)
      i. White matter lucencies
      ii. Ventriculomegaly
      iii. Intracranial calcifications (usually periventricular)
      iv. Destructive encephalopathy
      v. Brain atrophy
      vi. Neuronal migration disorders
2. Evidence of infection with CMV (Kuhlman 2001)
   a. Fourfold rise in anti-CMV IgG titers
   b. Seroconversion from negative to positive
   c. Sensitivity of the CMV IgM assays (50–90%). The IgM titers may not become positive during acute infection.
3. Viral isolation (Kuhlman 2001)
   a. The most sensitive method to diagnose CMV infection
   b. Culture of CMV from virtually all body fluids, including saliva and urine of the newborn, semen, and cervicovaginal secretions
   c. Detection of CMV within the first 3 weeks of life: considered proof of congenital CMV infection
4. Identification of CMV DNA through PCR (sensitivity of 75–100%)
5. Newborn screening for congenital cytomegalovirus infection (Bale 2010)
   a. Universal screening methods by using polymerase chain reaction (PCR) analysis of newborn dried blood spots (Boppana et al. 2010)
   b. Cytomegalovirus infection
      i. Accounts for as much or more disability over the past 50 years than was associated with congenital rubella syndrome
      ii. Represents the most common nongenetic cause of permanent hearing loss among children in the USA
   c. The most effective strategy for reducing CMV-induced sensorineural hearing loss, as well as for eliminating CMV-associated neurodevelopmental disability, will not be universal screening but prevention of congenital CMV infection (Pass et al. 2009).

Genetic Counseling

1. Recurrence risk
   a. Preconceptional immunity to CMV provides substantial protection against intrauterine transmission and severe fetal infection.
   b. Presence of maternal humoral antibody: conferring no fetal protection in subsequent reinfection or reactivation
2. Prenatal diagnosis
   a. Prenatal ultrasonography
      i. Intrauterine growth retardation
      ii. Microcephaly
      iii. Ventriculomegaly
      iv. Periventricular calcifications
      v. Intrahepatic calcifications
      vi. Nonimmune hydrops
      vii. Fetal Ascites
      viii. Pericardial effusion
      ix. Hepatosplenomegaly
      x. Echogenic bowel
      xi. Cardiomegaly
      xii. Oligohydramnios
      xiii. Placentomegaly
   b. Prenatal diagnosis of congenital CMV infection by combined detection of CMV-DNA and CMV-IgM in fetal blood or by combined testing of AF

and fetal blood for CMV-DNA and IgM antibodies (sensitivity of 100%) (Enders et al. 2001)

c. Negative results of CMV culture or PCR in the amniotic fluid cannot formally exclude intrauterine infection (Bodéus et al. 1999).

d. Prenatal diagnosis of CMV infection remains a "long-standing problem still seeking a solution" as long as no assistance (treatment or prevention) can be offered to the pregnant women.

3. Management

a. Prevention

i. Complicated because both primary and secondary maternal infections give rise to disease in the offspring and absence of characteristic symptoms in CMV-infected mothers excludes clinical recognition of at-risk pregnancies.

ii. Routine screening of pregnant patients for CMV status: not currently recommended because no effective antiviral therapy is available during gestation and also there is no means to predict the outcome in an infected fetus

iii. Risk to CMV infection for women in high-risk environments (day-care centers, nurseries, elementary schools, or health care facilities)

iv. Strict hygiene practices for seronegative women to reduce the risk for the infection

b. Prospects of intervention (Cheeran et al. 2009)

i. Antiviral drugs (Ganciclovir, Valganciclovir, Foscarnet, Cidofovir, CMV immune globulin) are available for treatment of congenital CMV infection, and there is evidence that therapy ameliorates the severity of one of the CNS complications of infection, sensorineural hearing loss. Long-term neurodevelopmental follow-up studies should further clarify the value of antiviral therapy in congenitally infected infants.

ii. Uncontrolled studies of therapy in utero with CMV immune globulin have suggested an impact on neuropathogenesis, and controlled trials should be conducted with pregnant women.

iii. CMV vaccines may hold the greatest promise in reducing the neurodevelopmental consequences of congenital infection, although the immune correlates of protection of the fetus remain incompletely defined.

Congenital Generalized Lipodystrophy

Congenital generalized lipodystrophy (CGL), also called Berardinelli–Seip syndrome (BSCL) (Berardinelli 1954; Seip and Tryqstad 1963), is an extremely rare genetic disorder characterized by extreme paucity of adipose tissue from birth, extreme insulin resistance, hypertriglyceridemia, hepatic steatosis, and early onset of diabetes (Agarwal et al. 2002). Its prevalence is estimated to be 1 in 200,000 (Portugal) to 1 in 12 million people (USA) (Mandal et al. 2006).

Synonyms and Related Disorders

Berardinelli–Seip congenital lipodystrophy

Genetics/Basic Defects

1. Inheritance: autosomal recessive (Garg 2004)
2. Existence of two loci in a gene for congenital generalized lipodystrophy (Berardinelli–Seip congenital lipodystrophy)
   a. Berardinelli–Seip congenital lipodystrophy 1 (BSCL1)
      i. Identification of the aberrant gene, 1-acylglycerol-3-phosphate O-acyltransferase 2 (*AGPAT2*) in patients from several pedigrees in which the lipodystrophy was linked to chromosome 9q34
      ii. Several homozygous or compound heterozygous mutations in the *AGPAT2* gene identified in affected patients
      iii. *AGPAT2* (1-acylglycerol-3-phosphate O-acyltransferase 2)
         a) Encodes the enzyme AGPAT2 that is responsible for the production of an important intermediate in the synthesis of triglycerides or fat
         b) Mutations of *AGPAT2*: may cause CGL by inhibiting the fat synthesis and storage in adipocytes (fat cells)
   b. Berardinelli–Seip congenital lipodystrophy 2 (BSCL2)
      i. Identification of another disease locus (*BSCL2*) which is mapped to chromosome 11q13
      ii. Identification of mutations of *BSCL2* gene in all families linked to 11q13
      iii. *BSCL2* (*Seipin*) gene
         a) Highly expressive in the brain and testis
         b) Encodes a protein whose function remains unknown
   c. Berardinelli–Seip congenital lipodystrophy X (BSCLX): specific genetic locus has not been identified (Van Maldergem et al. 2002)
3. Several other genes are responsible for different types of inherited lipodystrophies:
   a. Lamin A/C (*LMNA*) gene in familial partial lipodystrophy Dunnigan variety (autosomal dominant familial partial lipodystrophy) mapped to 1q21-22
   b. *PPAR-γ* (peroxisome proliferator-activated receptor-γ) gene in autosomal dominant familial partial lipodystrophy

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_51,
© Springer Science+Business Media, LLC 2012

4. Cause
   a. CGL is caused by mutations in *BSCL2*, *AGPAT2*, and other as yet unmapped genes.
   b. This genetic heterogeneity is also accompanied by phenotypic heterogeneity.
5. Proposed pathogenesis: Genetic defect results in poor growth and development of metabolically active adipose tissue with preservation of mechanical disposition of the adipose tissue (Garg et al. 1999; Premkumar et al. 2002)

Clinical Features

1. BSCL1 (Garg 2000, 2004; Kobashi et al. 2007)
   a. Prevalent in African-Americans
   b. Less severe
   c. Usually comes to clinical attention in the second or third decade of life
   d. Demonstrates marked lack of metabolically active adipose tissue in subcutaneous tissues, muscles, bone marrow, and intra-abdominal and intrathoracic regions
   e. Normal intelligence
2. BSCL2
   a. Slightly more common than BSCL1 worldwide
   b. More severe
   c. Onset in the neonatal period or early
   d. Demonstrates marked lack of metabolically active adipose tissue in subcutaneous tissues, muscles, bone marrow, and intra-abdominal and intrathoracic regions
   e. In addition, characterized by a paucity of adipose tissue from anatomical areas in which it serves a mechanical function such as the palms, soles, orbits, scalp, and periarticular regions (Simha and Garg 2003)
3. BSCLX (Van Maldergem et al. 2002)
   a. A very rare type
   b. Tends to be severely affected
   c. Comes to clinical attention in early infancy
4. Extreme paucity (near complete absence) of adipose tissue from birth, resulting in a generalized muscular appearance (an essential diagnostic criterion)
5. Characteristic features during early childhood
   a. Accelerated linear growth
   b. Voracious appetite
   c. Increased basal metabolic rate (hypermetabolism)
   d. Advanced bone age
6. Acanthosis nigricans (dark velvety pigmentation of the skin)
   a. Common occurrence
   b. Usually appears by age 8
   c. May be widespread, involving the neck, axillae, groin, and trunk
   d. Can eventually cause skin tag formation
7. Umbilical hernia: common
8. Hepatosplenomegaly
   a. Almost universal presence of hepatomegaly from fatty liver, ultimately leading to cirrhosis
   b. Splenomegaly common
9. Acromegaloid appearance
   a. Enlarged hands and feet
   b. Prominent mandible
10. Premature thelarche and adrenarche
11. Affected women (Garg et al. 1999)
   a. Virilization (clitoromegaly and hirsutism)
   b. Oligo-amenorrhea
   c. Polycystic ovaries in postpubertal female patients
   d. Successful pregnancy rare
12. Affected males with normal reproductive potential
13. Multiple focal lytic lesions in the appendicular bones in postpubertal patients
14. Severe fasting and postprandial hyperinsulinemia and marked hypertriglyceridemia resulting in chylomicronemia, eruptive xanthomas, acute pancreatitis and predisposing to premature atherosclerosis
15. Abnormal glucose intolerance and diabetes mellitus develop during puberty or early adolescence. Diabetic nephropathy and nephropathy may develop during adulthood
16. Rare hypertrophic cardiomyopathy
17. Mental retardation in a few patients
18. Clinical diagnosis criteria (Van Maldergem 2010): three major criteria or two major criteria plus two or more minor criteria make a diagnosis of BSCL very likely
   a. Major criteria
      i. Lipoatrophy affecting the trunk, limbs, and face
         a) Generalized lipodystrophy: apparent at birth.

b) In some individuals, the face may be normal at birth with lipoatrophy becoming apparent during the first months of life.
c) Lipoatrophy gives an athletic appearance, especially because skeletal muscle hypertrophy is also present.

ii. Acromegaloid features:
a) Gigantism
b) Muscular hypertrophy
c) Advanced bone age
d) Prognathism
e) Prominent orbital ridges
f) Enlarged hands and feet
g) Clitoromegaly
h) Enlarged external genitalia in the male

iii. Hepatomegaly
a) Secondary to fatty liver early on
b) Progresses to cirrhosis late in the disease course

iv. Elevated serum concentration of triglycerides
a) Serum concentration of triglycerides can be elevated up to 80 g/L.
b) Sometimes associated with hypercholesterolemia.

v. Insulin resistance
a) Elevated serum concentrations of insulin and C-peptide may occur starting in the first years of life.
b) Overt clinical diabetes mellitus usually develops during the second decade.
c) Its early clinical expression is acanthosis nigricans of the groin, neck, and axillae, which may have, in some cases, a verrucous appearance.

b. Minor criteria
i. Hypertrophic cardiomyopathy: may be present in infancy or develop later in life
ii. Psychomotor retardation: mild (IQ: 50–70), moderate (IQ: 35–50)
a) Mild-to-moderate intellectual impairment observed in approximately 80% of individuals with mutations in *BSCL2*
b) Intellectual impairment observed in only 10% of individuals with mutations in *AGPAT2*

iii. Hirsutism
a) Manifests with low frontal and posterior hairline
b) Apparently independent of hormonal stimulation

iv. Precocious puberty in females: In a series of 75 individuals with BSCL, three females underwent puberty before age 7 years (Van Maldergem et al. 2002)

v. Bone cysts
a) Occur in 8–20% of affected individuals and have a polycystic appearance in X-rays
b) Located in the epiphyseal and metaphyseal regions of the long bones: often diagnosed during the second decade
c) Are mostly observed in individuals with mutations in *AGPAT2*

vi. Phlebomegaly: Prominence of the veins of the lower and upper limbs is observed, in part because of the lack of subcutaneous fat

19. Differential diagnosis with other genetic lipodystrophy (Agarwal and Garg 2006)
a. Other autosomal recessive lipodystrophies
i. Lipodystrophy associated with mandibuloacral dysplasia: characterized by hypoplasia of the mandible and clavicles and by acro-osteolysis (resorption of terminal phalanges) and other features (Simha and Garg 2002)
a) Partial lipodystrophy (type A pattern): *LMNA* (lamin A/C) mutations
b) Generalized lipodystrophy (type B pattern): *ZMPSTE24* (zinc metalloproteinase) mutations
c) Other varieties

ii. Lipodystrophy associated with SHORT (*s*hort stature, *h*yperextensibility of joints and/or inguinal hernia, *o*cular depression, *R*ieger anomaly, and teething delay) syndrome: characterized by defects in multiple organs and loss of adipose tissue

iii. Lipodystrophy associated with neonatal progeroid syndrome (Wiedemann-Rautenstrauch syndrome) (Pivnick et al. 2000)

b. Autosomal dominant lipodystrophies
i. Familial partial lipodystrophy (FPL): characterized by variable loss of body fat from

the extremities as well as from the trunk. The diagnosis is made easily in women but is difficult in men because even many normal men appear muscular. The diagnosis can be suspected in nonobese patients with early onset of diabetes and hypertriglyceridemia, particularly if they have marked loss of fat from the extremities and hips.
   a) Dunnigan variety (FPLD): LMNA (lamin A/C) mutations
   b) FPL associated with *PPARG* (peroxismal proliferator-activated receptor γ) mutations
   c) FPL associated with AKT2 (v-AKT murine thymoma oncogene homolog 2) mutations
   d) Other varieties
ii. Lipodystrophy associated with SHORT syndrome.
iii. Lipodystrophy associated with Hutchinson–Gilford progeria syndrome.
   a) Progressive and generalized loss of body fat during childhood resulting in severe lipodystrophy with increasing age.
   b) Most patients have a de novo synonymous heterozygous Gly608Gly mutation in the *LMNA* gene of paternal origin (Eriksson et al. 2003; De Sandre-Giovannoli et al. 2003).
iv. Puberty-onset generalized lipodystrophy due to *LMNA* mutations.
   a) Puberty-onset of generalized lipodystrophy
   b) Diabetes
   c) Progeroid features
   d) Reported to have novel missense mutations in *LMNA* (Caux et al. 2003)

Diagnostic Investigations

1. Clinical laboratory workup
   a. Marked insulin resistance
   b. Severe hyperinsulinemia
   c. Nonketotic insulin-resistant diabetes mellitus
   d. Hypertriglyceridemia with low serum high-density lipoprotein (HDL) and cholesterol concentration
   e. Chylomicronemia
   f. Markedly low plasma leptin levels
2. MRI (confirmatory) and necropsy (Garg et al. 1999)
   a. An extreme paucity of subcutaneous and intermuscular fat
      i. Intraabdominal sites (omental, mesenteric, and retroperitoneal areas)
      ii. Thoracic cavity (retrosternal, epicardial, and superior mediastinal areas)
      iii. Bone marrow
      iv. Parathyroid glands
   b. In contrast, a peculiar distribution of normal amounts of adipose tissue over whole body
      i. Orbits
      ii. Crista galli
      iii. Palms
      iv. Soles
      v. Scalp
      vi. Perineum
      vii. Vulva
      viii. Epidural area
      ix. Pericalyceal regions of the kidney
      x. Periarticular regions (knee, hip, shoulder, elbow, wrist, and ankle joints)
      xi. Some fat localizes in breasts, tongue, and buccal region
3. Skeletal radiography: Multiple focal lytic lesions appear in appendicular skeletons after puberty
4. Echocardiography to detect hypertrophic cardiomyopathy
5. Molecular genetic analysis of mutations in *BSCL2* (*Seipin*) gene and *AGPAT2* gene

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier or affected
2. Prenatal diagnosis (Van Maldergem 2010)
   a. Possible for pregnancy at risk for BSCL caused by *BSCL2* of *AGPAT2* mutations by analysis of fetal cell DNA obtained from amniocentesis or CVS, provided both disease-causing alleles of an affected family member must be identified previously.

   b. Preimplantation genetic diagnosis (PGD) may be available for families in which the disease-causing mutations have been identified.
3. Management (Agarwal and Garg 2006)
   a. Cosmetic management
      i. Facial reconstruction with free flaps, transposition of facial muscle, and silicone or other implants in the cheeks
      ii. Liposuction or lipectomy for removal of excessive facial or neck fat
      iii. Etretinate and fish oil may improve acanthosis in some patients
   b. Diet
      i. Avoidance of weight gain to reduce the risk of developing diabetes and dyslipidemia
      ii. Need sufficient energy to allow for growth and maturation in childhood
      iii. Low-fat diet for extreme hypertriglyceridemia to minimize chylomicron formation
      iv. Reduction in saturated fat and cholesterol intake to reduce LDL or non-HDL cholesterol levels reduces atherosclerosis risk
   c. Hypoglycemic drugs
      i. Require rigorous glycemic control by oral hypoglycemic drugs and/or insulin therapy
      ii. Require large dose of insulin to control hyperglycemia and prevent long-term complications of diabetes, such as nephropathy, retinopathy, neuropathy, and possibly atherosclerosis
   d. Lipid-lowering drugs
      i. Fibrates and, if needed, n-3 polyunsaturated fatty acids
      ii. Avoid estrogens for oral contraception or postmenopausal hormone replacement therapy in women because it can accentuate hypertriglyceridemia
   e. Clinical trial of adipocytes hormone leptin-replacement therapy has shown a marked reduction in the blood glucose and lipids and reverse hepatic steatosis, allowing discontinuation of several medications (Oral et al. 2002)
   f. Elucidation of the pathways underlying genetic lipodystrophies is expected to help in developing innovative therapeutic strategies for treating diabetes, hyperlipidemia, hepatic steatosis, and other metabolic complications

Congenital Hemihyperplasia

In 1822, Meckel first described congenital hemihypertrophy. Hemihypertrophy, also called hemihyperplasia, is defined as asymmetric body overgrowth of one or more body parts. The overgrowth may involve an entire half of the body, a single limb, and one side of the face or combinations thereof. There may be accompanying asymmetric visceromegaly. Hemihyperplasia can be isolated or can occur as part of a syndrome.

Synonyms and Related Disorders

Congenital hemihypertrophy

Genetics/Basic Defects

1. The asymmetric overgrowth, traditionally termed "hemihypertrophy," is more accurately referred to as hemihyperplasia, since the pathologic growth process involves an abnormal proliferation of cells (hemihyperplasia), rather than an increase in the size of existing cells (hemihypertrophy)
2. Isolated hemihyperplasia (IHH)
   a. Usually isolated: estimated prevalence as 1 in 13,200 to1 in 86,000 live births
   b. Familial occurrence
3. Part of well-defined syndrome
   a. Beckwith–Wiedemann syndrome
   b. Proteus syndrome
   c. Russell–Silver syndrome
   d. Neurofibromatosis type I (NF I)
   e. Klippel–Trénaunay–Weber syndrome
   f. McCune–Albright syndrome

Clinical Features

1. Clinical characteristics of isolated hemihyperplasia
   a. Birth incidence: 1:86,000 live births
   b. Females outnumber males two to one
   c. Increased birth weight (mean 3.8 kg)
   d. Diagnosis by exclusion
   e. Variable degree of asymmetry (mild cases are easily overlooked)
   f. Asymmetry becoming more pronounced or less noticeable with age with predominance of right-sided overgrowth
   g. Involves a discrepancy in both length and circumference of the affected limb in comparison to the contralateral side
   h. Observation of the enlargement of one kidney, adrenal, testis, or ovary with medullary sponge kidney, often an attendant finding
   i. Nervous system accompaniments: include unilateral peripheral nerve enlargement, sciatica, and hemimegalencephaly with frequent mental retardation
   j. Facial involvement may be present (cheek, lip, nasal, external ear, palpebral fissure, tongue, maxillary, mandibular, palatal, and/or tooth asymmetry)
   k. Natural history of IHH: varies markedly
      i. Average life span.
      ii. Prognoses for long-term survival may be modified by serious associated anomalies.
      iii. Leg length discrepancy may lead to pelvic tilt and scoliosis.
      iv. Renal function may be impaired by medullary sponge kidney.
   l. Predisposition to neoplasia (cancer) in isolated hemihyperplasia: well known

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_52,
© Springer Science+Business Media, LLC 2012

i. An overall incidence of 5.9%
ii. Embryonal neoplasms: similar to those noted in other overgrowth disorders
a) Wilms tumor: Hemihypertrophy occurs in approximately 3% of Wilms tumor cases
b) Adrenal cell carcinomas
c) Hepatoblastoma
d) Leiomyosarcoma

2. Malformation syndromes associated with hemihyperplasia
a. Beckwith–Wiedemann syndrome
i. Omphalocele
ii. Hypoglycemia
iii. Generalized overgrowth
iv. Macroglossia
v. Visceromegaly
vi. Ear lobe pits and creases
vii. Predisposition to neoplasia
viii. Inheritance: heterogeneous (autosomal dominant, autosomal recessive, dup 11)
b. Neurofibromatosis
i. Café-au-lait spots
ii. Hypopigmented patches
iii. Axillary freckling
iv. Neurofibromas
v. Iris Lisch nodules
vi. Macrocephaly
vii. Scoliosis
viii. Hypertension
ix. CNS tumors
x. Inheritance (autosomal dominant)
c. Klippel–Trénaunay–Weber syndrome
i. Hemangiomata
ii. Lymphatic anomalies
iii. Poly/syndactyly
iv. Oligodactyly
v. Macrocephaly
vi. Glaucoma
vii. Cataracts
viii. Inheritance (unknown; sporadic)
d. Proteus syndrome
i. Lipomata
ii. Hemangiomata
iii. Macrocephaly
iv. Scoliosis
v. Macrodactyly
vi. Gyriform changes on soles of feet
vii. Inheritance (unknown, sporadic)
e. McCune–Albright syndrome
i. Fibrous dysplasia of bones
ii. Irregular hyperpigmentation
iii. Precocious puberty
iv. Hyperthyroidism
v. Hyperparathyroidism
vi. Other endocrinopathies
vii. Inheritance (unknown; sporadic; female predominance)
f. Epidermal nevus
i. Epidermal nevi
ii. Pigmentary changes
iii. Mental deficiency
iv. Seizures
v. CNS malformations
vi. Kyphoscoliosis
vii. Potential for malignancy
viii. Inheritance (heterogenous; usually sporadic but autosomal dominant and recessive inheritance described)
g. Triploid/diploid mixoploidy
i. Large placenta with hydatidiform changes
ii. Incomplete calvarial ossification
iii. Microretrognathia
iv. Microphthalmia
v. Colobomata
vi. Cataracts
vii. Irregular skin pigmentation
viii. Syndactyly
ix. Chromosomal diploid/triploid mosaicism (may be found only in fibroblasts)
h. Langer–Giedion syndrome
i. Multiple exostoses
ii. Unusual facies with bulbous nose
iii. Long simple philtrum
iv. Microcephaly
v. Loose skin in infancy
vi. Sparse scalp hair
vii. Deafness
viii. Inheritance (heterogenous; chromosome anomaly del(8)(q23q24); autosomal dominant)
i. Multiple exostoses
i. Juxtaepiphyseal exostoses
ii. Forearm bowing
iii. Short stature
iv. Malignant transformation (sarcoma) in adulthood
v. Inheritance (autosomal dominant)

   j. Mafucci syndrome
      i. Enchondromata
      ii. Hemangiomata (especially phlebectasia)
      iii. Bowing of long bones
      iv. Chondrosarcoma
      v. Inheritance (unknown; sporadic)
   k. Osteochondromatosis (Ollier disease)
      i. Bilateral, asymmetric endochondromata
      ii. Fractures
      iii. Chondrosarcoma
      iv. Inheritance (unknown; sporadic)
3. Extent of involvement
   a. Range from enlargement of a single digit to an entire half of the body
   b. Segmental, unilateral, or crossed (affecting different anatomic areas on either side of the body)
   c. System involvement
      i. A single system
         a) Muscular
         b) Vascular
         c) Skeletal
         d) Nervous
      ii. Combination of all systems
   d. Total hemihypertrophy
      i. Right side more affected than the left
      ii. Males appear to be affected more frequently
   e. Associated anomalies found in about 50% of affected individuals
   f. Onset and course of asymmetry
      i. Almost always evident at birth
      ii. May be accentuated at puberty
      iii. Appears to be constant once developed
4. Facial involvement
   a. Involvement of the face only
   b. Unilateral facial enlargement accompanied by enlargement of the complete half of the body
   c. Variable degree of involvement
5. Skin and skin appendages
   a. Involved side
      i. Thicker with increased function of the sebaceous and sweat glands
      ii. Pigmentation as well as early development of varicose veins or a medusa-like plexus of veins in the lower abdomen and groin area
      iii. Supernumerary nipples as well as an enlarged breast
      iv. Thicker and coarser hair
      v. Abnormal nail growth
   b. Either involved or contralateral side: Telangiectasia and increased numbers of nevi
6. Skeletal system
   a. Unilaterally enlarged bones
   b. Other lesions
      i. Macrodactyly
      ii. Polydactyly
      iii. Syndactyly
      iv. Lobster claw deformity
      v. Scoliosis
      vi. Tilting of the pelvis
      vii. Club foot
7. Central nervous system
   a. Mental retardation in 15–20% of affected individuals
   b. Sciatica probably resulting from pelvic tilt
   c. Dilatation of the anterior basal cisterna
   d. Dilatation of the pupil on the affected side
8. Genitourinary system
   a. Kidney and adrenal: most frequently enlarged on the involved side
   b. Other anomalies
      i. Hypospadias
      ii. Cryptorchidism
      iii. Elevated level of urinary gonadotropin and short stature
      iv. Adrenogenital syndrome
      v. Embryonal tumors
      vi. Wilms tumor
      vii. Adrenal cortical carcinoma
9. Enlarged oral lesions on the involved side
   a. Enlarged and thickened tongue
   b. Oral soft and hard tissues such as lips, uvula, maxilla, mandible, tongue, alveolar process, and some teeth

Diagnostic Investigations

1. Radiographic studies of hemihypertrophy
2. Abdominal ultrasound for visceromegaly
3. Brain MRI for hemihyperplasia
4. Chromosome analysis, UPD analysis, or gene mutation studies depending on the types of the malformation syndromes

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Isolated case: a low recurrence risk
      ii. Familial case: Recurrence risk depends on mode of transmission
         a) Autosomal dominant: a low recurrence risk if parents are normal
         b) Autosomal recessive: a 25% risk
         c) Imprinting mechanism such as in Beckwith–Wiedemann syndrome
   b. Patient's offspring
      i. Isolated case: a low recurrence risk
      ii. Autosomal dominant: a 50% risk
      iii. Autosomal recessive: recurrence risk does not increase unless the spouse is a carrier or affected
2. Prenatal diagnosis
   a. Prenatal ultrasound/radiography for fetal hemihyperplasia
   b. Chromosome analysis from amniocentesis or CVS for triploidy or mixoploidy
3. Management
   a. Screening abdominal ultrasounds every 3–6 months to monitor Wilms tumor development in patients with idiopathic hemihypertrophy
   b. Orthopedic management for hemihypertrophy
   c. Management for neoplasm

Fig. 1 (**a**–**c**) A girl with hemihypertrophy of the right side of the body

Fig. 2 (**a**–**d**) A 7-year-old girl with hemihypertrophy of the right upper extremity. The radiograph of the forearms and hands showed osseous and soft tissue hypertrophy. She is otherwise normal

Fig. 3 (**a**–**c**) A 6-year-old girl with hemihypertrophy of the right upper and lower extremities. She also had talipes equinovarus (corrected) and abnormal pigmentation on the back

Fig. 4 A 60-year-old female was evaluated for mental retardation associated with left hemihypertrophy

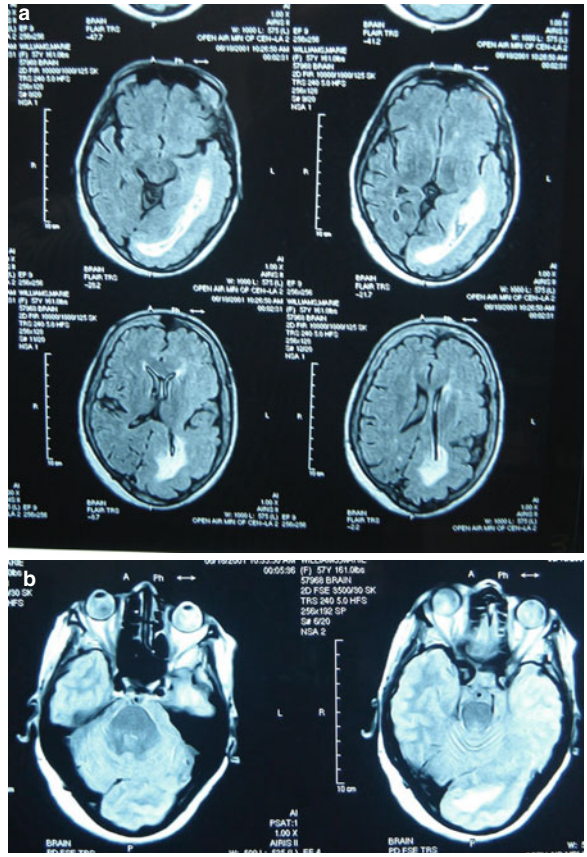

Fig. 5 (**a**, **b**) The patient's MRI of the brain showed cerebral asymmetry with left temporal, occipital, and parietal lobe hypertrophy associated with areas of macrogyria and lissencephaly, consistent with a congenital neuronal migration abnormality

Congenital Hydrocephalus

Congenital hydrocephalus is one of the most common CNS congenital anomalies. The incidence of congenital hydrocephalus is estimated as 3 per 1,000 live births. Hydrocephalus is defined as an increase in the cerebral spinal fluid (CSF) volume within the ventricular system independent of the actual head circumference.

Genetics/Basic Defects

1. Physiology of CSF production and absorption
   a. Production of CSF: by choroid plexus of lateral ventricles
   b. Pathway of CSF flow
      i. From lateral ventricles to third ventricle through foramen of Monro
      ii. From third ventricle to fourth ventricle through aqueduct of Sylvius
      iii. Out of the ventricular system: from fourth ventricle to spinal subarachnoid spaces through foramen of Magendie or to the basal cisterns through two lateral foramina of Luschka
   c. Site of CSF resorption into venous system: primarily through superior sagittal sinus via arachnoid granulations
2. Types and causes of hydrocephalus
   a. Overproduction of CSF: usually caused by choroid plexus tumors (very rare)
   b. Noncommunicating hydrocephalus
      i. Mechanical obstruction within the ventricular system causing impaired CSF absorption
         a) Foramen of Monro
         b) Aqueduct of Sylvius
         c) The fourth ventricle and its outlet channels
      ii. Causes
         a) Tumors
         b) Cysts
         c) Inflammatory scarring
         d) Intraventricular hemorrhage
         e) Rarely genetic disorders
   c. Communicating hydrocephalus
      i. Obstruction distally at the arachnoid granulations causing impaired absorption into blood stream
      ii. Causes
         a) Meningitis
         b) Trauma
         c) Intraventricular hemorrhage
3. Etiology of congenital hydrocephalus
   a. Tumors blocking CSF pathway
      i. Benign tumors such as choroid plexus papilloma
      ii. Malignant tumors
   b. CNS malformations/syndromes
      i. Congenital atresia of the foramina of Monro, Magendie, or Luschka
      ii. Dandy–Walker syndrome
         a) Atresia of the foramina of the fourth ventricle
         b) Dilation of fourth ventricle
         c) Extreme dolichocephaly
         d) Sac formation at the caudal end of the cerebellum filling the posterior cranial fossa
      iii. Aqueductal stenosis
      iv. X-linked hydrocephalus: Bickers–Adams syndrome characterized by:
         a) Stenosis of the aqueduct of Sylvius
         b) Severe mental retardation

c) An adduction-flexion deformity of the thumb
v. Chiari II malformation
vi. Cerebellar agenesis
vii. Neural tube defects
a) Meningomyelocele
b) Encephalocele
viii. Other Mendelian conditions with congenital hydrocephalus
a) Walker–Warburg syndrome
b) Hydrolethalus syndrome
c) Meckel syndrome
d) Smith–Lemli–Opitz syndrome
c. Chromosome abnormalities
i. Trisomy 13
ii. Trisomy 18
iii. Trisomy 9 and 9p (mosaic)
iv. Triploidy
v. Other aneuploidies
d. Skeletal dysplasias
i. Achondroplasia
ii. Craniosynostosis syndromes such as Crouzon syndrome or Apert syndrome
iii. Fanconi anemia
iv. Hurler or Hunter syndromes
e. Infections
i. Congenital CMV infection
ii. Congenital toxoplasmosis
iii. Congenital rubella infections
iv. Congenital syphilis
v. Meningitis
vi. Ventriculitis
vii. Abscess
f. Vascular malformation
g. In utero intraventricular hemorrhage
h. Birth trauma
i. Destructive lesions
i. Hydranencephaly
ii. Porencephaly
iii. Perinatal leukomalacia
4. Familial (X-linked) aqueductal stenosis (HSAS: hydrocephalus-stenosis of the aqueduct of Sylvius sequence)
a. X-linked recessive inheritance.
b. Linked to chromosome Xq28.
c. Mutations in *L1-CAM*, the major gene for X-linked hydrocephalus (accounting for 7–27% of all male cases).
d. *L1-CAM*, a neuronal surface glycoprotein, has been implicated in neuronal migration and axon fasciculation.
5. Traits known to be due to allelic mutations of *L1-CAM*
a. HSAS
b. MASA
i. Mental retardation
ii. Aphasia
iii. Shuffling gait
iv. Adducted thumbs
c. SP1 (complicated spastic paraparesis, type 1)
d. MR-CT (mental retardation–clasped thumbs)
e. ACC-DCC (agenesis or dysgenesis of the corpus callosum)
6. Pathogenesis of hydrocephalus-induced brain dysfunction: complex
a. Chronic ischemia in white matter related to changes in intracranial pressure and in the vasculature
b. Physical damage to periventricular axons with disconnection of neurons
c. Alterations in the extracellular chemical environment of neurons

Clinical Features

1. Children <2 years
a. Relatively benign course because infants can expand their cranium
b. Early signs
i. Increased head circumference (macrocephaly)
ii. Full anterior fontanelle
iii. Split cranial sutures
iv. Prominent scalp veins
v. Poor feeding
vi. Vomiting
vii. Irritability
viii. Reduced activity
ix. Delay or loss of developmental milestones
x. Hypertonia
xi. Hyperreflexia
c. Late signs
i. Lethargy
ii. Sixth cranial nerve palsy
iii. Limitation of upgaze resulting in a chronic downward deviation of the eyes (sunsetting sign)

2. Children >2 years
   a. Symptoms and signs more related to increased intracranial pressure due to inability of cranium to expand sufficiently to offset the mounting volume of CSF
   b. Headaches
   c. Nausea
   d. Vomiting
   e. Lethargy
   f. Loss of milestones
   g. School performance and behavioral change
   h. Sunsetting of the eyes
   i. Sixth cranial nerve palsy
   j. Papilledema
3. Natural history of untreated childhood hydrocephalus: poor. Handicaps resulting directly from hydrocephalus include the following:
   a. Disturbances in motor abilities, particularly gait
   b. Impaired cognitive development
   c. Hypothalamic dysfunction with delayed growth and short stature
4. X-linked neurological syndromes
   a. HSAS (*h*ydrocephalus-*s*tenosis of the *a*queduct of *S*ylvius sequence)
      i. Hydrocephalus
      ii. Macrocephaly
      iii. Adducted thumbs
      iv. Spasticity
      v. Agenesis of the corpus callosum
      vi. Mental retardation
   b. MASA syndrome
      i. *M*ental retardation
      ii. *A*phasia
      iii. *S*huffling gait
      iv. *A*dducted thumbs
      v. Hydrocephalus

Diagnostic Investigations

1. Fundoscopic examination
   a. Bilateral papilledema secondary to high intracranial pressure
   b. Normal finding in some cases of acute hydrocephalus
2. Lumbar puncture for measuring intracranial pressure
   a. Avoid if an increase in intracranial pressure is suspected due to obstruction since relief of pressure may cause herniation of the brainstem
   b. Perform only after imaging studies ruling out an obstruction
3. TORCH titers on the infant and mother if intrauterine infection is suspected
4. Chromosome analysis in cases of associated multiple congenital anomalies
5. Cranial sonography (provided anterior fontanelle is still open)
   a. Ventriculomegaly
   b. Intraventricular hemorrhage
6. CT scans
   a. Ventriculomegaly
   b. Cerebral edema
   c. Mass lesions
      i. Colloid cyst of the third ventricle
      ii. Thalamic tumor
      iii. Pontine tumor
7. MRI
   a. Ventriculomegaly
   b. Mass lesions
   c. Associated brain anomalies
      i. Agenesis of the corpus callosum
      ii. Chiari malformations
      iii. Disorders of neuronal migration
      iv. Vascular malformations
8. Molecular genetic diagnosis to identify *L1CAM* mutations, identified in 22.4% (15/67) of sporadic cases of clinically or prenatally suspected L1-disease

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic: low (4%)
      ii. Multifactorial trait (e.g., neural tube defect or in female infants with congenital hydrocephalus due to stenosis of the aqueduct of Sylvius): low recurrence risk (5%) for subsequent sibling; 10% risk if there are two affected siblings
      iii. Autosomal recessive traits (e.g., Dandy–Walker syndrome): 25% affected; 50% carriers; 25% normal

iv. X-linked hydrocephalus: 50% of brothers affected and 50% of sisters carriers if the mother is a carrier; negligible in males with "sporadic" hydrocephalus representing a new X-linked mutation

b. Patient's offspring
   i. Sporadic: low (4%)
   ii. Multifactorial trait: 3–4.5% recurrence risk
   iii. Autosomal recessive traits: not increased unless the spouse is a carrier or affected
   iv. X-linked hydrocephalus: All daughters will be carriers in case of an affected father

2. Prenatal diagnosis
   a. Ultrasonography
      i. Fetal ventriculomegaly
      ii. Additional CNS malformations
      iii. Extracerebral malformations
   b. Sonographic findings in HSAS or MASA syndromes
      i. Male fetus
      ii. Hydrocephalus
      iii. Hypoplasia or agenesis of the corpus callosum
      iv. Bilateral adducted thumbs
   c. Amniocentesis
      i. Alpha-fetoprotein and cholinesterase determination from amniotic fluid for neural tube defects
      ii. Chromosome analysis for suspected chromosomal disorder
   d. Molecular genetic diagnosis
      i. DNA diagnosis often requested in families with "isolated" hydrocephalus case due to high rate of *de novo* mutations, small family size, and the improved sensitivity of prenatal ultrasound scanning
      ii. Molecular diagnosis of prenatally suspected L1 spectrum disorders, even in cases without positive family history
3. Management (Hamid and Newfield 2001; Kestle 2003)
   a. Folic acid intake before and during the first trimester reduces the incidence of neural tube defects, thereby the incidence of hydrocephalus
   b. Shunting CSF from the ventricles
      i. Ventriculoperitoneal shunting (VP) devices with pressure-controlled valves under the scalp close to the burr hole
      ii. Ventriculopleural shunt
      iii. Ventriculoatrial shunt
      iv. Frontal or parietal ventriculostomy
      v. Does not completely reverse the pathologic alterations in the brain and, unfortunately, treatment by shunting is associated with frequent complications
   c. Major complication associated with shunt treatment: 81% of children with shunts suffer at least one and usually several malfunctions necessitating hospitalization
      i. Shunt obstruction
      ii. Valve malfunction
      iii. Disconnection
      iv. Hematoma
      v. Overdrainage
      vi. Outgrown shunt
      vii. Shunt fracture
      viii. Shunt-related infections, most often caused by staphylococcus aureus, with unexplained fever or frank meningitis
      ix. Signs of increased intracranial pressure with headache, lethargy, and vomiting
      x. Abdominal complications
         a) Peritonitis
         b) Perforation of an abdominal organ
         c) Peritoneal cysts
         d) Development of hydroceles in boys
      xi. Seizures
      xii. Allergic reaction to material
   d. A trial of in utero ventriculo-amniotic shunt for treating congenital hydrocephalus (Al-Anazi et al. 2008)

Congenital Hypothyroidism

All forms of congenital hypothyroidism occur in 1 in 4,000 live births worldwide. The dysgenetic form affects twice as many females as males. It is the most prevalent congenital endocrine disease. The incidence is approximately 1 in 32,000 in Blacks and 1 in 2,000 in Hispanics.

Synonyms and Related Disorders

Ectopic thyroid gland; Thyroid agenesis; Thyroid dysgenesis; Thyroid hypoplasia; Thyrotropin resistance

Genetics/Basic Defects

1. Inheritance (Ambrugger et al. 2001)
   a. Thyroid dysgenesis
      i. The most frequent cause of congenital hypothyroidism (85% of cases)
      ii. Morphological classification
         a) Ectopic thyroid gland: the most frequent malformation, observed most frequently at the base of the tongue
         b) Athyreosis (absence of any detectable thyroid tissue)
         c) Hypoplasia (partially absent thyroid)
      iii. Sporadic in most cases
      iv. Genetic factors contributing to the development of thyroid dysgenesis in 2% of cases with a positive familial history
      v. Molecular defects clarified only in few cases of thyroid dysgenesis (Grüters et al. 2002)
         a) TSH-receptor gene (thyroid hypoplasia, "apparent athyrosis")
         b) Transcription factors: Thyroid-specific transcription factor-1 (TTF-1) (hypothyroidism, chorea, choreoathetosis, respiratory distress), TTF-2 (thyroid hypoplasia, cleft palate, choanal atresia, curly hair, developmental delay), PAX-8 (thyroid hypoplasia, ectopy)
         c) NKX2A (athyrosis, hypoplasia, normally developed gland, choreoathetosis, pulmonary problems, mental retardation, pituitary abnormalities)
   b. Autosomal recessive defects of thyroid hormone biosynthesis with identification of the following candidate genes for congenital hypothyroidism
      i. Thyroid peroxidase (*TPO*) gene
         a) A hemoprotein responsible for tyrosine iodination and coupling
         b) Intriguing role of *TPO* mutations in the development of thyroid tumor
      ii. Sodium-iodide symporter (*NIS*) gene
      iii. Thyroglobulin (*TG*) gene
      iv. Pendrin (*PDS*) gene (Pendred syndrome)
      v. Thyroid oxidase 2 (*THOX2*) gene (Pfarr et al. 2006)
   c. Autosomal dominant transmission of congenital hypoplasia due to loss-of-function mutation of PAX-8 (Vilain et al. 2001)
2. Etiology of thyroidal congenital hypothyroidism (De Vijlder 2003)
   a. Disorders in development of the thyroid gland (85% of cases with congenital hypothyroidism)
      i. Absent thyroid
      ii. Under-development with migration failure
      iii. Under-development with normal migration

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_54,
© Springer Science+Business Media, LLC 2012

   b. Disorders in thyroid hormone synthesis (10–20%)
      i. TSH hypo-responsiveness (TSH-receptor abnormalities)
      ii. Defects in iodide transport from circulation into the thyroid cells
      iii. Defects in iodide transport from the thyroid cell to the follicular lumen, often combined with inner ear deafness (Pendred syndrome, sensorineural hearing loss, and goiter)
      iv. Defects in the synthesis of hydrogen peroxide
      v. Defects in the oxidation of iodide, iodination, and iodothyronine synthesis
      vi. Defects in processes involved in the synthesis or degradation of thyroglobulin
      vii. Defects in iodine recycling
3. Etiology of central (hypothalamic or pituitary) congenital hypothyroidism
   a. Disorders in development and/or function of the hypothalamus
   b. Disorders in development and/or function of the pituitary glands
   c. Disorders in development and/or function of the hypothalamus and pituitary glands
4. Transient form of primary congenital hypothyroidism (Moreno et al. 2002)
   a. Occurs in 5–10% of infants detected by newborn screening
   b. Represents about 5% of cases with congenital hypothyroidism
   c. Etiology
      i. Mothers with chronic autoimmune thyroiditis: transplacental passage of maternal TSH-receptor blocking antibodies leading to inhibition of TSH action on the infant's thyroid gland until the maternal antibodies disappear
      ii. Antithyroid drugs taken by pregnant women with thyroid autoimmune disease
      iii. Maternal dietary iodide deficiency
      iv. Maternal dietary goitrogen ingestion
      v. Exposure to excess iodine in the perinatal period
         a) Use of iodinated disinfectants
         b) Use of contrast agents
5. Down syndrome: Congenital hypothyroidism occurs approximately 28 times more common among infants with Down syndrome than in the general population with an incidence of 1% detected by newborn screening
6. Pathogenesis of mental retardation in congenital hypothyroidism: due to the central role of thyroid hormones in brain development, which takes place during fetal life and early postnatal life up to the second or third year of age (DeLange 1997)

Clinical Features

1. Most newborn are asymptomatic (Beltroy et al. 2003)
2. Severe dysgenetic and athyrotic hypothyroidism
   a. Early symptoms
      i. Feeding problems
      ii. Constipation
      iii. Growth failure
      iv. Hoarse cry
   b. Signs and symptoms in infants and toddlers
      i. Delayed linear growth
      ii. Hypotonia
      iii. Decreased activity
      iv. Lethargy
      v. Prolonged jaundice
      vi. Bradycardia
      vii. Hypothermia
      viii. Cold to touch
      ix. Dry/puffy/thick skin
      x. Sparse hair
      xi. Characteristic craniofacial appearance
         a) Coarse facial feature
         b) Puffy eyes
         c) Myxedematous facies
         d) Large fontanelles
         e) A broad, flat nose
         f) Pseudohypertelorism
         g) Large, protruding tongue
      xii. Delayed tooth eruption
      xiii. Occasional cardiomegaly
      xiv. Protuberant abdomen with umbilical hernia
      xv. Constipation
      xvi. Poor nail growth
      xvii. Delayed return of the deep tendon reflexes
      xviii. Irreversible growth failure and mental retardation

Diagnostic Investigations

1. Newborn screening: Ideally universal screening at 3–4 days of age should be done for detecting CH. Abnormal values on screening (T4 < 6.5 ug/dL, TSH > 20mu/L) should be confirmed by a venous sample (using age appropriate cutoffs) before initiating treatment
   a. Successful identification of infants with congenital hypothyroidism
   b. Enables early diagnosis and treatment of infants and prevention of mental retardation
   c. Newborn screening measures either TSH or T_4 in neonatal blood placed on filter paper
   d. Confirmation with a serum sample if the filter paper result is abnormal
      i. Primary congenital hypothyroidism
         a) Low serum T_4 levels
         b) Elevated serum TSH
      ii. Hypopituitary hypothyroidism
         a) Low total T_4 levels
         b) Low or normal TSH
      iii. Thyroxine-binding globulin (TBG) deficiency
         a) Low total T_4 but normal serum-free T_4 levels
         b) Normal TSH
   e. Screening programs for congenital hypothyroidism in premature newborns (Kugelman et al. 2009)
      i. Sick premature infants may display transient hypothyroxinemia secondary to immaturity of the hypothalamic-pituitary axis.
      ii. Therefore, early screening programs of such infants may be misleading.
      iii. Recommendations
         a) Screening programs should report thyroid stimulating hormone (TSH) as well as thyroxin (T4) levels in premature infants, which will allow the treating physicians to be aware of possible abnormality that needs to be followed.
         b) Sick premature infants and other populations at risk should undergo a full serum thyroid function evaluation including free T4 and TSH beyond the screening program at discharge or at 30 days of age, whichever comes first.
         c) Physicians should use their clinical judgment and experience even in the face of normal newborn thyroid screening test and reevaluate for hypothyroidism when there is a clinical suspicion.
   f. Pendred syndrome (Banghova et al. 2008)
      i. An autosomal recessive disorder characterized by sensorineural hearing loss and thyroid dyshormonogenesis
      ii. Caused by mutations in the *PDS/SLC26A4* gene
      iii. Present from birth
      iv. Can be diagnosed by newborn screening
2. Laboratory diagnosis
   a. Thyroid function tests
      i. Elevated serum TSH
      ii. Low serum T_4 levels
   b. Determine antithyroglobulin and antithyroid peroxidase antibodies if indicated
   c. Determine TBG levels for suspected TBG deficiency
3. Radiography for bone age
4. Ultrasonography, considered as the best noninvasive method for the anatomical assessment of the thyroid gland
5. Radionuclide scan (thyroid scintigraphy) using ^{99m}Tc or ^{123}I (DeLange 1997)
   a. To demonstrate the presence of ectopic thyroid tissue or thyroid aplasia
   b. Iodide transport defect
      i. Low or absent uptake of ^{123}I
      ii. Response to therapeutic doses of potassium iodide
   c. Defective organification of iodide
      i. Rapid uptake of ^{123}I
      ii. Marked decrease in thyroid radioactivity when perchlorate or thiocyanate is administered 2 h after administering radioiodine
      iii. Occasional sensorineural hearing loss (Pendred syndrome)
   d. Iodotyrosine-coupling defect
      i. Rapid uptake of ^{123}I
      ii. No discharge by perchlorate
      iii. Very high thyroid gland content of monoiodotyrosine (MIT) and diiodotyrosine (DIT)
      iv. Virtually undetectable T_4 and T_3
      v. Adequately iodinated thyroglobulin

e. Defects in thyroglobulin gene expression and thyroglobulin secretion
   i. Elevated uptake of ^{123}I
   ii. No discharge by perchlorate
   iii. Abnormal serum iodoproteins
   iv. Elevated protein-bound/T_4 iodine ratio
   v. Low or borderline serum thyroglobulin
f. Iodotyrosine deiodinase defect
   i. Rapid uptake and turnover of ^{123}I
   ii. Elevated serum and urinary iodotyrosines (MIT, DIT)
   iii. Response to iodine supplementation
6. Intelligence quotient (IQ) measurement for testing neuropsychological progress and outcome
7. Molecular genetic diagnosis by sequencing of select exons to identify mutations

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic cases: low recurrence risk
      ii. Autosomal recessive inheritance: 25%
      iii. Autosomal dominant inheritance: low recurrence risk unless a parent is affected
   b. Patient's offspring
      i. Sporadic cases: low recurrence risk
      ii. Autosomal recessive inheritance: low recurrence risk unless the spouse carries the recessive gene
      iii. Autosomal dominant inheritance: 50%
2. Prenatal diagnosis
   a. Ultrasonography and percutaneous fetal blood sampling
      i. Detection of fetal goiter
         a) A rare yet potentially dangerous condition
         b) A large goiter may cause hyperextension of the neck of the fetus caused by a large goiter, resulting in malpresentation and complicating labor and delivery
         c) Possibility of compressing the trachea and asphyxiating the neonate after birth
      ii. Fetal blood sample
         a) Elevated TSH
         b) Low T4
   b. Amniocentesis
      i. Determination of TSH concentration (markedly elevated TSH level) in amniotic fluid in the second trimester for the offspring of a couple both known to have an iodide (iodothyronine synthesis) enzymatic organification defect
      ii. Affected fetus with markedly increased TSH level in the amniotic fluid sample for the trimester
   c. Molecular genetic diagnosis possible by sequencing of select exons on fetal DNA for previously identified mutations in a research laboratory
3. Management
   a. Sodium L-thyroxine
      i. The treatment of choice
      ii. Early therapy (within 14 days) with appropriate doses of thyroxine (about 10 μg/kg/day) will prevent any brain damage even in case of evidence of fetal hypothyroidism, since thyroxine of maternal origin will reach and protect the fetus (DeLange 1997)
      iii. Avoid over treatment to prevent the following adverse effects (LaFranchi 1999):
         a) Premature cranial suture fusion
         b) Acceleration of growth and skeletal maturation
         c) Problems with temperament and behavior
   b. X-linked dominant thyroxine-binding globulin deficiency (causing a low total T4 but normal free T4): no need for thyroid hormone replacement
   c. Intrauterine treatment of fetus with a large goiter (Davidson et al. 1991)
      i. Indicated because of the morbidity associated with compression of the trachea and mechanical interferences during delivery
      ii. Intra-amniotic administration of levothyroxine presents the least invasive approach to fetal treatment
         a) Rapid decrease in the fetal goiter size
         b) Normalization of fetal thyroid function
   d. Intrauterine treatment of fetus affected with iodide organification defect with synthroid

Congenital Muscular Dystrophy

Congenital muscular dystrophy (CMD) refers to a group of genetic disorders in which weakness and an abnormal muscle biopsy are present at birth.

Synonyms and Related Disorders

Merosin-negative CMD; Merosin-positive CMD with mental retardation and neuronal migration defects (Fukuyama CMD, muscle-eye-brain disease, Walker-Warburg syndrome); Merosin-positive CMD (rigid spine disease, Ullrich disease, pure CMD)

Genetics/Basic Defects

1. Inheritance
   a. Genetic heterogeneity
   b. Most are autosomal recessive (Muntoni and Voit 2004)
2. Caused by genetic defects in proteins of the sarcolemmal membrane or its supporting structures. The proteins may also be expressed in the central nervous system, and many forms of CMD are associated with structural brain and eye anomalies
3. Classification of CMD according to biochemical defect (Cardamone et al. 2008)
   a. Extracellular matrix protein
      i. Merosin (lamin-α2) (*LAMA2*): Merosin-deficient CMD (MDC1A)
         a) Demyelinating neuropathy
         b) White matter signal changes on brain MRI
      ii. Collagen VI (*COL6A1*, *COL6A2*, *COL6A3*): Ullrich CMD, Bethlem CMD
         a) Proximal contractures
         b) Distal hyperextensibility
         c) Sandpaper rash
      iii. Integrin α7 (*ITGA7*): Merosin-positive CMD (mental retardation)
   b. Sarcolemmal protein (Plectin, *PLEC1*): CMD with epidermolysis bullosa (blistering skin rash from birth)
   c. Glycosyltransferases
      i. Fukutin (FCMD): Fukuyama CMD, Walker–Warburg syndrome
         a) Eye and structural brain anomalies
         b) Seizures
         c) Mental retardation
         d) Absent α-dystroglycan on muscle immunocytochemistry
      ii. Protein O-mannose β1.2 (N- acetylglucosaminyltransferase 1 (*POMGnT1*): Muscle-eye-brain disease
         a) Eye and structural brain anomalies
         b) Absent α-dystroglycan on muscle immunocytochemistry
      iii. Protein O-mannosyltransferase 1 (*POMT1*): Walker–Warburg syndrome, Limb-girdle muscular dystrophy, type 2K
         a) Eye and structural brain anomalies
         b) Seizures
         c) Mental retardation
         d) Absent α-dystroglycan on muscle immunocytochemistry
      iv. Protein O-mannosyltransferase 2 (*POMT2*)
         a) Walker–Warburg syndrome: hydrocephalus
         b) Muscle-eye-brain disease: severe structural brain anomalies, absent

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_55,
© Springer Science+Business Media, LLC 2012

α-dystroglycan on muscle immunocytochemistry
v. Unknown protein: Congenital muscular dystrophy type 1B (muscle hypertrophy, early respiratory failure)
vi. Fukutin-related protein (*FKRP*): Limb-girdle muscular dystrophy type 21, congenital muscular dystrophy type 1C, Fukuyama congenital muscular dystrophy, muscle-eye-brain disease, Walker–Warburg syndrome
a) Duchenne phenocopy
b) Cardiomyopathy
c) Absent α-dystroglycan on muscle immunocytochemistry
vii. LARGE congenital muscular dystrophy (*LARGE*): congenital muscular dystrophy type 1D
a) Severe mental retardation
b) White matter signal changes on brain MRI
viii. SIL1 (*SIL1*): Marinesco–Sjögren syndrome
a) Cerebellar ataxia
b) Congenital cataracts
d. Endoplasmic reticulum protein (Selenoprotein N, *SEPN1*)
i. Rigid spine muscular dystrophy
a) Thin habitus
b) Spinal rigidity
ii. Multicore myopathy: early respiratory failure
iii. Congenital fiber-type disproportion
iv. Myofibrillar myopathy
e. Nuclear envelope protein (Lamin A/C, *LMNA*): variable phenotype
i. Emery–Dreifuss MD
ii. Limb-girdle muscular dystrophy type 1B
iii. Congenital muscular dystrophy
iv. Dilated cardiomyopathy
v. Charcot–Marie–Tooth disease (CMT) type 2B1

Clinical Features

1. Typical features
a. Present in the first year of life
i. Hypotonia and weakness
ii. Respiratory insufficiency
iii. Bulbar dysfunction
iv. Arthrogryposis
b. Hypertrophy of the tongue and limb muscles, scoliosis, and contractures may develop with age
c. Weakness is static or slowly progressive
2. Merosin-negative CMD
a. Demonstrating clinical homogeneity
i. Severe hypotonia
ii. Multiple contractures
iii. Delayed developmental milestones
iv. Normal mentation
v. Variable degrees of central hypomyelination seen on neuroimaging
b. Patients with complete merosin deficiency
i. Typically presenting as floppy infants
ii. May or may not require ventilatory assistance
iii. Most patients stabilize and able to continue developing without mechanical ventilation
iv. Feeding difficulty leading to recurrent aspiration and poor nutrition in some patients
v. The best motor milestone achieved: standing with support
vi. Unable to ambulate
vii. Cognitive development
a) Generally normal
b) Mental retardation in patients with brain anomalies
viii. Epilepsy
c. Patients with partial merosin deficiency
i. Wide clinical spectrum
a) Marked hypotonia at birth, contractures, and severely delayed motor milestones
b) Limb-girdle muscular dystrophy-like presentation in the teen
c) An adult-onset proximal limb-girdle weakness with elevated CK concentration
ii. White matter abnormalities by MRI in all patients with documented merosin gene mutations
3. Merosin-positive CMD
a. Rigid spine disease
i. Onset in infancy
ii. Axial muscle weakness
iii. Early rigidity of the spine
iv. Prominent nasal voice
v. Nocturnal respiratory insufficiency
vi. Early respiratory failure
b. Ullrich disease
i. Proximal contractures
ii. Distal joint laxity

iii. Delayed motor milestones
  a) Ability to walk in some cases
  b) Wheelchair dependent in majority of cases
iv. Normal intelligence

c. Pure CMD
i. Normal intelligence
ii. Normal brain imaging

d. Other merosin-positive CMD

4. Merosin-positive CMD with mental retardation and neuronal migration defects
a. Fukuyama CMD
i. An autosomal recessive disorder
ii. Prevalent in Japan
iii. Early onset (before 9 months)
iv. Muscle weakness
v. Accompanied by joint contractures
vi. Hypotonia/hypokinesia
vii. Severe mental retardation
viii. Epilepsy
ix. Eye anomalies
  a) Myopia
  b) Congenital nystagmus
  c) Cortical blindness
  d) Optic atrophy
  e) Choreoretinal degeneration
x. Brain anomalies (cobblestone lissencephaly; type 2 lissencephaly)
  a) Micropolygyria
  b) Pachygyria
  c) White matter lucency
  d) Minor cerebellar alterations (cortical dysplasia

b. Muscle-eye-brain disease
i. An autosomal recessive disorder
ii. Mimics Walker–Warburg syndrome but overall changes tend to be much milder
iii. Present as a floppy infant with suspected blindness
iv. Severe mental retardation
v. Extensive neuronal migration disorder
  a) Pachygyria and polymicrogyria
  b) Brain stem hypoplasia
  c) Cerebellar dysgenesis
  d) Hydrocephalus
vi. Muscle involvement: typical features of muscular dystrophy with ongoing de- and regeneration
vii. Normal expression of laminin α2

c. Walker–Warburg syndrome
i. An autosomal recessive disorder
ii. Type II lissencephaly
  a) Micropolygyric "cobblestone" cortex
  b) Extensive white matter abnormalities
  c) Hydrocephaly with enlarged ventricles
  d) Brainstem hypoplasia
  e) Hypoplasia of the cerebellum, particularly the cerebellar vermis
iii. Ocular dysgenesis
  a) Megacornea
  b) Buphthalmos
  c) Corneal clouding
  d) Cataracts
  e) Abnormal vitreous
  f) Retinal hypopigmentation
  g) Hypoplasia of the optic nerve
  h) Clinically blind
iv. Muscular dystrophy
  a) Variable in severity: ranges from myopathy with increased variation of fiber size to severe, end-stage muscular dystrophy
  b) Well-preserved expression of laminin α2
v. Complete lack of psychomotor development (severe mental retardation) for those who survive for some years

Diagnostic Investigations

1. Markedly elevated serum creatine kinase (CPK) levels (Caramone et al. 2008).
2. Nerve conduction studies may show demyelinating neuropathy in merosin-deficient CMD (Quijano-Roy et al. 2004).
3. Electromyography (EMG) is myopathic.
4. Muscle biopsy shows typical dystrophic changes (degeneration and regeneration of muscle fibers, and proliferation of fatty and connective tissue).
5. Immunocytochemistry enables analysis of merosin, α-dystroglycan, collagen VI, and other muscle proteins (Jones and North 2003; Muntoni and Voit 2004).
6. Cerebral magnetic resonance imaging (MRI) may show abnormalities of neuronal migration and white matter signal.
a. Pachygyria (with normal cognitive function)
b. Cerebellar hypoplasia (with normal cognitive function but delay of speech development)

c. Cerebellar cysts (in connection with pure CMD)
d. Abnormal white matter signal (in connection with pure CMD of merosin-deficient type)
e. Large lissencephalic changes
f. Hydrocephalus

7. Molecular genetic analyses.
   a. Fukuyama CMD: Sequencing of entire coding region or select exons of *FCMD* gene
   b. Muscle-eye-brain disease: Sequencing of entire coding region or select exons or targeted mutation analysis of *POMGnT1* gene
   c. Walker–Warburg syndrome: Sequencing of entire coding region or select exons or mutation scanning of *POMT1* gene

Genetic Counseling

1. Recurrence risk (Sparks et al. 2011)
   a. Patient's sib
      i. Autosomal recessive: a 25% recurrence risk
      ii. Autosomal dominant (Ullrich congenital muscular dystrophy): a low recurrence risk but greater than that of the general population if both parents are clinically unaffected or if the disease-causing mutation found in the proband cannot be detected in the DNA of either parent, because of the possibility of germline mosaicism
   b. Patient's offspring:
      i. Autosomal recessive
         a) Many individuals not living long enough to reproduce
         b) All offspring are carriers
         c) Recurrence risk to offspring probably less than 1%
      ii. Autosomal dominant: a 50% risk
2. Prenatal diagnosis
   a. Possible for pregnancies at 25% risk for complete merosin deficiency, provided complete merosin deficiency has been documented in the muscle of the proband.
      i. The diagnostic testing must be done on a sample of direct and flesh-frozen chorionic villi obtained at about 10–12 weeks of gestation by immunostaining
      ii. Using molecular testing for mutations that have been previously identified in the proband by CVS or amniocentesis
   b. Prenatal diagnosis by DNA mutation analysis is available for pregnancies at increased risk of Fukuyama MD, muscle-eye-brain disease, Walker–Warburg MD, congenital muscular dystrophy type 1C and 1D, and congenital muscular dystrophy with early spine rigidity by analysis of fetal DNA, obtained by amniocentesis or CVS, provided both disease-causing alleles of an affected family member have been identified.
3. Management (Sparks et al. 2011)
   a. No definitive treatment available
   b. General approaches
      i. Weight control to avoid obesity
      ii. Physical therapy and stretching exercises
         a) To promote mobility
         b) To prevent contractures
      iii. Using mechanical devices to help ambulation and mobility
      iv. Surgical interventions for scoliosis and foot deformity
      v. Medications for seizure control
      vi. Respiratory aids as needed
      vii. Social and emotional support

Congenital Toxoplasmosis

Acute infection in a pregnant woman with a parasite, *Toxoplasma gondii*, can have serious consequences on the fetus, ranging from fetal loss to severe neurologic or ocular lesions. In other cases, infected newborns are asymptomatic at birth, but are at risk for developing retinal diseases during childhood or adolescence on *Toxoplasma* reactivation (Wallon et al. 2004). In the United States, the incidence of congenital toxoplasmosis is estimated to be 1 in 1,000 to 1 in 10,000 births and approximately 400–4,000 cases of congenital toxoplasmosis occur each year.

Synonyms and Related Disorders

Toxoplasma gondii infection in pregnancy

Genetics/Basic Defects

1. *Toxoplasma gondii* (Beasley and Egerman 1998)
   a. A protozoan parasite
   b. The causative agent of toxoplasmosis, a common infection throughout the world with estimated one billion people infected worldwide
   c. Life cycle: exists in three forms
      i. The oocysts, or soil form
      ii. The tachyzoite, or active infectious form
      iii. The tissue cyst, or latent form
2. Hosts
   a. Cats
      i. The primary host
      ii. Maintain the intestinal–epithelial sexual cycle of *Toxoplasma* development with the production of oocysts
   b. All other animals (humans, birds, rodents, and domestic animals)
      i. The intermediate or secondary hosts
      ii. Have an extraintestinal asexual cycle with resultant parasitemia and the production of tissue cysts
3. Routes by which *Toxoplasma* is transmitted to humans
   a. Principal routes
      i. Acquired
         a) Ingestion of raw or inadequately cooked infected meat (beef, pork, or lamb)
         b) Not washing hands thoroughly after handling raw meat or gardening
         c) Ingestion of oocysts, an environmentally resistant form of the organism that cats pass in their feces and human exposure to cat litter or contaminated soil (from gardening or unwashed fruits or vegetables)
      ii. Congenital: transplacental infection of unborn fetus by the newly infected mother
   b. Rare routes
      i. Blood and blood product transfusion
      ii. Organ transplant
      iii. Laboratory accident
   c. No evidence of direct human-to-human transmission other than from mother to fetus
4. Seventy percent of the obstetric population with negative antibodies: at risk for transmission to the fetus
5. Congenital toxoplasmosis usually occurs as a result of primary maternal infection
6. Maternal–fetal transmission rate depends on gestational age at the time of maternal infection
   a. Less than five percent before fifth week of gestation

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_56,
© Springer Science+Business Media, LLC 2012

   b. Twenty-five percent in the first trimester
   c. Seventy-five percent in the third trimester
   d. Greater than ninety percent in the last few weeks of pregnancy
7. Severity of the fetal infection inversely related to gestational age: The earlier infections being the most severe
8. Untreated maternal infections: About 50% of cases transmit to the fetus
9. An immunocompetent woman previously infected is considered immune and will not transmit *T. gondii* to her offspring. *Toxoplasma* infection leads to life-long immunity with the presence of *T. gondii*-specific IgG antibodies. Acute toxoplasmosis in the adult is often asymptomatic and usually does not result in complications
10. Reactivation can occur in immunocompromised pregnant woman (i.e., HIV) leading to parasitemia and fetal infection

Clinical Features

1. Unpredictable manifestations in the fetus and in the newborn
2. Maternal infections
   a. Generally asymptomatic in immunocompetent mothers
   b. Subtle symptoms in about 15–20% of infected mothers
      i. Cervical lymphadenopathy: the most common clinical manifestation
      ii. Fatigue
      iii. Flu-like symptoms
   c. In immunocompromised mothers
      i. Chorioretinitis
      ii. Encephalitis
      iii. Pneumonitis
      iv. Myocarditis
   d. Maternal infections early in pregnancy
      i. Less likely to be transmitted to the fetus than infections later in pregnancy
      ii. More likely to be severe than later infections
3. Fetal infections
   a. Usually resulting from a primary maternal infection with risk of developing congenital abnormalities. Reactivation of *T gondii* in an immunocompromised patient can render the fetus susceptible to infection.
   b. Infectivity: The incidence and severity of the fetal infection depend on the gestational age at the time of the maternal infection. The later the gestation, the higher the infectivity. However, the postnatal sequelae are severer when infection occurs early in gestation.
4. Natural history of congenital toxoplasmosis
   a. Free of symptoms at birth in vast majority of cases with congenital infection (70–90% of cases)
   b. About 15% of the infected children with signs or symptoms at birth or neonatal period
      i. Maculopapular rash
      ii. Generalized lymphadenopathy
      iii. Hepatosplenomegaly
      iv. Jaundice
      v. Thrombocytopenia
      vi. Consequences of intrauterine meningoencephalitis
         a) CSF abnormalities
         b) Hydrocephalus
         c) Microcephaly
         d) Chorioretinitis
         e) Seizures
      vii. Signs of the "classic triad" (hydrocephalus, intracranial calcifications, and chorioretinitis) without systemic signs of disease
   c. Sequelae during childhood or early adult life in 50–90% of cases
      i. Learning disability
      ii. Visual impairment
      iii. Chorioretinitis: the most frequent congenital manifestation and is progressive in >80% of patients by 20 years of age
      iv. Mental retardation
      v. Hearing loss
   d. Ocular lesions: the most frequent manifestations of congenital toxoplasmosis (Metz 2001)
      i. Strabismus (33%)
      ii. Nystagmus (27%)
      iii. Microphthalmia (13%)
      iv. Phthisis (4%)
      v. Microcornea (19%)
      vi. Cataract (10%)
      vii. Active vitritis (11%)
      viii. Active retinitis (11%)
      ix. Chorioretinal scars (79%)
      x. Optic atrophy (20%)

e. Severely affected congenital infection
   i. Die in utero
   ii. Die within a few days of life

Diagnostic Investigations

1. Serological testing (Beasley and Egerman 1998; Lynfield and Eaton 1995)
   a. IgM anti-*Toxoplasma* antibodies
      i. Produced 1–2 weeks after an infection
      ii. Levels detectable for years after the acute infection
   b. IgG anti-*Toxoplasma* antibodies
      i. Levels peak approximately 2 months after the initial infection
      ii. Remain positive for life
   c. IgA anti-*Toxoplasma* antibodies
      i. Parallels IgM production
      ii. Peak levels occur approximately 2 months after the initial infection and then rapidly decline
   d. IgE anti-*Toxoplasma* antibodies
      i. Detected early after an acute infection
      ii. Usually present for 4–8 months
      iii. May provide useful information regarding the timing of an acute infection
2. Detection of antibodies to toxoplasmosis in the neonatal period
   a. Specific *T. gondii* IgM antibody
      i. A positive IgM antibody in the newborn: diagnostic of congenital toxoplasmosis
      ii. A negative IgM antibody in the newborn does not exclude the diagnosis and may be due to the following reasons:
         a) Lack of production of IgM
         b) Waning of the IgM response by the time of birth
         c) Insensitivity of the assay
      iii. A positive IgM antibody in the mother
         a) Associated with recent maternal infection
         b) Would support the diagnosis of congenital toxoplasmosis
   b. Specific *T. gondii* IgA antibody: more sensitive test than IgM antibodies
   c. Neonatal screening with IgM or IgA antibodies fails to detect majority of children with congenital toxoplasmosis when the maternal infection occurred before the 20 week of pregnancy
3. Definitive postnatal diagnosis of congenital toxoplasmosis
   a. Detection of parasites in material collected from the newborn (blood, cerebrospinal fluid, or other clinical material) by inoculation into mice or tissue culture
   b. Detection of persisting specific IgG antibodies at the age of 1 year
   c. Reappearance of specific IgG antibodies in the child after cessation of postnatal antibiotic therapy
   d. Diffuse cerebral calcifications and hydrocephalus detected by radiography, ultrasonography, CT scan, or MRI of the brain
4. Other diagnostic evaluation of the infants
   a. Physical examination
   b. Dilated retinal examination
   c. Examination of the cerebrospinal fluid
      i. Protein
      ii. Glucose
      iii. Cell count
      iv. Antibody determination
   d. Audiologic screen
   e. Examination of the placenta
      i. Evidence of infection, although the gross appearance may not parallel the severity of fetal disease
      ii. Inoculation of the placental tissue into mice or tissue culture to attempt isolation of the parasite
      iii. The feasibility of placental analysis, in terms of sample recovery and rapid *T. gondii* detection by PCR, makes it a useful diagnostic tool for early monitoring and treatment of neonates at risk for congenital infection (Robert-Gangnex et al. 2010)

Genetic Counseling

1. Recurrence risk: women with previous infection not at risk for delivering a fetus with congenital toxoplasmosis unless immunosuppressed
2. Prenatal diagnosis
   a. Seroconversion during pregnancy
      i. Absence of specific *Toxoplasma gondii* IgG antibodies in the first serum sample obtained during gestation
      ii. Detection of specific IgG and IgM antibodies in the follow-up sample at a later prenatal visit or at birth

b. Suggestive but not diagnostic signs by prenatal ultrasonography (Beasley and Egerman 1998)
   i. Ventriculomegaly: the most common sonographic finding in utero
   ii. Intracranial calcifications
   iii. Hydrops
   iv. Microcephaly
   v. Choroid plexus cysts
   vi. Growth retardation
   vii. Hepatomegaly
   viii. Splenomegaly
   ix. Ascites
   x. A thickened placenta
c. Prenatal diagnosis of acute infection in the fetus
   i. Amniocentesis or cordocentesis
      a) Detection of parasites in amniotic fluid or in fetal blood by inoculation into tissue culture or mice
      b) Detection of anti-*Toxoplasma gondii* IgM, IgA, and IgE antibodies in the fetal blood. The diagnosis of fetal *T. gondii* infection before 22 weeks using cordocentesis is not possible because fetal IgM or IgA may not be produced before 22 weeks' gestation
      c) Detection of *T. gondii* DNA (B1 gene) by gene amplification in amniotic fluid: more accurate and faster diagnosis of congenital toxoplasmosis
   ii. Chorionic villus sampling not helpful because it will show placental but not fetal infection

3. Management
   a. Prevention of *Toxoplasma* infection
      i. Cook meat to a safe temperature to kill *Toxoplasma*
      ii. Peel or thoroughly wash fruits and vegetables before eating
      iii. Clean cooking surfaces and utensils after they have contacted raw meat, poultry, seafood, or unwashed fruits or vegetables
      iv. Avoid changing cat litter during pregnancy or use gloves and wash hands thoroughly
      v. Do not feed raw or undercooked meat to cats and keep cats inside to prevent acquisition of *Toxoplasma* by eating infected prey
      vi. Avoid risk factors for *T. gondii* infection including careful adherence to simple hygienic measures during pregnancy (decrease *Toxoplasma* infection by 60%)
   b. Treat *Toxoplasma* infection with spiramycin, pyrimethamine, sulfonamides, and folinic acid
      i. Reduce sequelae of congenital infection by treating the mother as soon as possible after the serologic screening program identifies the infection
      ii. Treat infected neonates: sooner the treatment, the better the outcome
   c. Newborn screening for *Toxoplasma*-specific IgM allows the identification and treatment of subclinical cases so that the sequelae of infection with toxoplasmosis may be prevented or attenuated

Conjoined Twins

Conjoined twins are incompletely separated monozygotic twins. They have long fascinated both medical profession and lay public. Such events are rare and occur in 1/50,000 to 1/100,000 births and 1 in 400 sets of monozygotic twins. Over 60% succumb in utero or are stillborn (Spitz 2005). It is a complication of monochorionic twinning at 13–15 days after conception.

Synonyms and Related Disorders

Cephalopagus; Craniopagus; Dicephalus; Diprosopus; Epigastrius; Fetus-in-fetu; Ischiopagus; Omphalopagus; Pygoparus; Rachipagus; Thoracopagus

Genetics/Basic Defects

1. Conjoined twins
   a. Rare variants of monozygotic, monochorionic twins
   b. Two theories of conjoined twin formation
      i. Resulting from the secondary union of two originally separate monovular embryonic disks
      ii. Resulting from an incomplete separation of the inner cell mass at around 13–15 days of gestation of the monovular twins
   c. Twins can be conjoined at any site from the cranium downward to the sacrococcygeal region
   d. Approximately 60% are stillborn
   e. Female predominance: approximately 3:1 female-to-male ratio
2. Embryologic classification of conjoined twins (Spencer 2000a; McHugh et al. 2006; Winkler et al. 2008): Greek word "pagus" is added to denote fixing to union site
   a. Ventral union (87%)
      i. Rostral (48%)
         a) Cephalopagus (11%): fusion from top of head to umbilicus; each twin has two arms and legs; separate lower abdomen and pelvis
         b) Thoracopagus (20–40%): position face to face, with fused thoraces and with a shared heart or single interatrial vessel
         c) Omphalopagus (18–33%): similar fusion to thoracopagus without shared heart or interatrial vessel
      ii. Caudal (11%) (ischiopagus): a large, conjoined pelvis, more commonly joined end to end; can be face to face with a conjoined abdomen; always shared external genitalia and anus
   b. Dorsal union (13%)
      i. Craniopagus (5%): joined by any portion of the skull except the face and foramen magnum, shared cranium, meninges, and occasionally, the brain
      ii. Rachipagus(2%): dorsal fusion above the sacrum
      iii. Pygopagus (6%): fused sacrococcygeal and perineal regions, typically with shared anus but separate rectums; spinal cord may be shared

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_57,
© Springer Science+Business Media, LLC 2012

   c. Lateral union (28%): Parapagus (side-to-side connection with shared pelvis and variable cephalad sharing), defined as follows:
      i. Dithoracic parapagus (separate thoraces and heads)
      ii. Dicephalic parapagus (separate head with fused thoraces)
      iii. Diprosopus parapagus (two faces on the same side of single head)
3. Anatomic classifications of conjoined twins, based on how the body axes of the twins are mutually oriented in the embryonic disk
   a. Notochordal axes facing each other
      i. Ventro-ventral
         a) Thoracopagus
         b) Xiphopagus
         c) Omphalopagus
      ii. Cranial ventro-ventral (cephalothoracopagus)
      iii. Caudal ventro-ventral (ischiopagus)
      iv. Cranial end to end (craniopagus)
      v. Caudal end to end (pygopagus)
   b. Notochordal axes facing side by side
      i. Dicephalus
      ii. Diprosopus
4. Anatomic classifications of conjoined twins, based on how the subsequent events of migration, growth, and body folding result in different types of conjoined twins
   a. Dipygus
   b. Fetus-in-fetu
      i. A fetiform mass located within a basically normal fetus (Spencer 2001)
      ii. Inclusion of a monozygotic diamniotic twin within the bearer is the best explanation
5. Duplicitas symmetros (symmetrical conjoined twins resulting from incomplete fission of the uniovum) (Gilbert-Barness et al. 2003)
   a. Terata katadidyma (twins joined at the lower part of the body and double above)
      i. Dicephalus (twins with two separate heads and necks side by side with one body; lateral conjugation)
      ii. Diprosopus (twins with two faces side by side, one head, and one body)
      iii. Ischiopagus (twins joined by the inferior margins of the coccyx and sacrum with two completely separate spinal columns; caudal conjugation)
      iv. Pygopagus (twins joined by posterior surfaces of the coccyx and sacrum, back to back; posterior conjugation)
      v. Craniothoracopagus
      vi. Ileothoracopagus
   b. Terata anadidyma (twins joined at the upper part of the body and double below)
      i. Craniopagus (twins joined at the top of cranial vaults; cephalic conjugation)
      ii. Dipygus (twins with one head, one thorax, one abdomen, and double pelvis with or without two sets of external genitalia and up to four legs; lateral conjugation)
      iii. Syncephalus (twins joined by the face; the faces turn laterally)
   c. Terata anakatadidyma (twins joined by the midportion of the body)
      i. Omphalopaus (twins joined from the umbilicus to xiphoid cartilage; anterior conjugation)
      ii. Xiphopagus (twins joined at xiphoid process)
      iii. Rachipagus (twins joint by the vertebral column; back to back)
      iv. Thoracopagus (twins joined at the chest wall; anterior conjugation)
6. Duplicatas asymmetros (asymmetrical conjoined twins resulting from unequal and incomplete fission of the uniovum and unequal placental circulation to twins)
   a. Cephalic conjugation
      i. Craniopagus parasiticus
      ii. Janus parasiticus
      iii. Epignathus heteropagus
   b. Anterior conjugation
      i. Thoracopagus parasiticus
      ii. Epigastrius
   c. Posterior conjugation
      i. Ischiopagus parasiticus
      ii. Pyopagus parasiticus
      iii. Sacral parasiticus

Clinical Features

1. Thoracopagus twins
   a. Represents 40% of conjoined twins
   b. Conjoined at the thoracic region
   c. Face to face

   d. Associated congenital heart defects
      i. Present in 75% of cases
      ii. Presence of varying degree of pericardial sac fusion
      iii. A conjoined heart with two ventricles and a varying number of atria (most frequent abnormality)
      iv. Ventricular septal defect in virtually all patients
2. Omphalopagus twins (fused umbilical region)/ Xiphopagus twins (fused xiphoid process of sternum)
   a. Constitutes one third of all types of conjoined twins
   b. The most readily separable conjoined twins since their union may involve only skin and portions of the liver, occasionally including portions of the sternum
   c. Most omphalopagus twins joined by a skin bridge that contains liver and bowel
   d. Conjoined liver in 81%
   e. Conjoined sternal cartilage in 26%
   f. Conjoined diaphragm in 17%
   g. Conjoined genitourinary tract in 3%
   h. Malformations of the abdominal wall (usually omphalocele) in at least one of the twins in 33%
   i. Congenital heart defects in at least one of the twins in 25%
      i. Ventricular septal defects
      ii. Tetralogy of Fallot
   j. Concordant congenital heart defects in only one out of nine sets of twins
3. Pygopagus twins
   a. Constitutes 19% of conjoined twins
   b. Conjoined at sacrum (buttocks and lower spine)
   c. Most commonly back to back (face away from each other)
   d. May share part of the sacral spinal canal
   e. May share common rectum and anus
   f. Often with fused genitalia
4. Ischiopagus twins
   a. Constitutes 6% of conjoined twins
   b. Conjoined back to back at the coccyx
   c. Often with a common large pelvic ring formed by the union of the two pelvic girdles
   d. May have four legs (ischiopagus tetrapus)
   e. May have three legs (ischiopagus tripus)
   f. Frequently share the lower gastrointestinal tract
      i. Intestines joined at the terminal ileum
      ii. Emptying into a single colon
   g. May have a single bladder and urethra
   h. Displaced anus
   i. Common vaginal anomalies
   j. Common rectovaginal communications
5. Craniopagus twins (fused at the cranial vault) (2%)
   a. Classification according to the area of junction
      i. Frontal craniopagus
      ii. Parietal craniopagus (most common)
      iii. Temporal craniopagus
      iv. Occipital craniopagus
   b. Classification based on surgical and prognostic purposes
      i. Partial type (brains separated by bone or dura with each brain having separate leptomeninges)
      ii. Complete type (presence of cerebral connection)
6. Rachiopagus twins (fused upper spinal column; back to back)
7. Pygodidymus twins (fused cephalothoracic region; duplicate pelves and lower extremities)
8. Pygopagus twins/pygomelus twins (joined back to back at the sacrum; additional limb or limbs at or near buttock)
9. Iniopagus twins/craniopagus occipitalis twins (fused head, at parasitic occipital region)
10. Epicomus twins/craniopagus parasiticus twins (smaller, parasitic twin joined to larger autosite at occiput)
11. Monocephalus twins (single head with two bodies)
12. Diprosopus twins (single body with two faces)
13. Dicephalus twins (symmetric body with two heads)
14. Dipygus parasiticus twins (head and thorax completely merged; pelvis and lower extremities duplicated)
15. Cephalopagus conjoined twins
   a. The rarest type of conjoined twins
   b. Fused from the top of the head to the umbilicus
   c. Presence of two faces on the opposite sides of the head with one face usually being rudimentary
   d. Separation of the lower abdomen
   e. With four arms and four legs
   f. Prognosis dismal dependent on the following factors
      i. Presence of associated anomalies
      ii. Degree of fusion of the intracranial, intra-thoracic, and/or intra-abdominal structures
      iii. Extent of venous connections

16. Epigastric heteropagus twins
    a. A rare type of conjoined twinning
    b. Resulting from an ischemic atrophy of one fetus at an early stage of gestation
    c. Pelvis and lower limbs of the ischemic fetus (incomplete parasitic twin; heteropagus) attached to the epigastrium of the well-developed fetus (the autosite)
17. Fetus-in-fetu
    a. The parasites embodied in the autosite, usually within cranial, thoracic, and abdominal cavities during the developmental process of the asymmetrical conjoined twins
    b. Most likely arise from inclusion of a monochorionic, diamniotic, monozygotic twin within the bearer due to anastomoses of vitelline circulation (Nastanski and Downey 2001)
18. Prognosis
    a. A high mortality rate
        i. Nearly 40% are stillborn.
        ii. One third die within 24 h of birth.
        iii. No prospect of survival when complex cardiac union is present.
    b. Causes of death
        i. Severely abnormal conjoined heart
        ii. Pulmonary hypoplasia due to distortion of fused thoracic cages
19. Examples of historically famous conjoined twins (Sills et al. 2001; Gilbert-Barness et al. 2003; Spitz 2005)
    a. So-called Biddenden Maids (1100–1134) in England
        i. Probably pyopagus twins
        ii. Their famous image imprinted on the "cakes"
        iii. Walks with their arms around each other
        iv. They lived together for 34 years and died within 6 h
    b. Chang and Eng Bunker (1811–1874) from Bangkok and settled in the USA ("Siamese twins")
        i. Born on a river boat in Siam
        ii. Joined at the xiphisternum by a short bank that stretched so they were eventually able to stand side by side
        iii. Taken by Hunter, a traveling Scottish merchant, to the USA where they were exhibited by the showman
        iv. Later married to twin sisters
        v. Fathered 22 children
        vi. Lived together for 63 years and one died shortly from other twin
    c. Blažek sisters (1878–1922) from Bohemia
        i. Two heads
        ii. Four arms
        iii. Four legs
        iv. Partially fused torso
        v. Combined reproductive organs
        vi. Delivered an infant through a single vagina but the gestation had occurred in the uterus of one of the twins

Diagnostic Investigations

1. Prenatal echocardiography
    a. Presence and extent of cardiac conjunction
    b. Associated cardiac defects
2. Prenatal radiography
3. Prenatal ultrasonography (including transvaginal two-dimensional sonography), especially three-dimensional sonographic examinations (The surface-rendered image of the conjoined twin and its demonstration on an axially rotating cine loop facilitates explanation of the precise nature of the abnormalities, especially in the case of cephalothoracopagus conjoining)
4. CAT scan and MRI of the abdomen and the chest
    a. Anatomy of the heart
    b. Anatomy of the livers
    c. Anatomy of the genitourinary systems
5. Gastrointestinal contrast studies to demonstrate the presence and level of conjunction of the intestinal tract
6. Ventrally fused conjoined twins
    a. Prenatal radiography/ultrasonography
        i. Fetal body parts on the same level
        ii. Constant relative fetal position
        iii. Fetal extremities in unusual proximity
        iv. Face-to-face fetal position
        v. Bibreech, less commonly bicephalic presentation
        vi. Hyperextension of one or both cervical spines
    b. Prenatal ultrasonography
        i. Nonseparable continuous external skin contour
        ii. Single heart sound by Doppler

iii. Solitary large liver and heart
iv. Multiple shared omenta
v. Solitary umbilical cord with >3 vessels

7. Cephalothoracopagus
   a. Prenatal radiographic criteria
      i. Both fetal heads at the same level
      ii. Backward fusion of the cervical spines
      iii. A narrow space between lower cervical and upper thoracic spines
      iv. No change in fetal relative positions after maternal movement
   b. Prenatal sonographic criteria
      i. Fusion of the skulls, face, thorax, and upper abdomen
      ii. Fetal body parts at the same level
      iii. Constant relative fetal motion
      iv. Fetal extremities in unusual positions
      v. Breech position
      vi. Hyperextension of both cervical spines
      vii. Nonseparable external skin contour
      viii. A solitary umbilical cord with multiple vessels
      ix. Polyhydramnios
      x. Two actively beating hearts
      xi. Two sets of pelves, limbs, and spine

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not higher according to family study
   b. Patient's offspring: report of delivery of a healthy male infant to the pygopagus Blažek sisters
2. Prenatal diagnosis
   a. Radiography
   b. 2D/3D ultrasonography: prenatal diagnosis made as early as 10–12 weeks' gestation
   c. Transcervical embryoscopy for first trimester embryonic evaluation of conjoined twins after a missed abortion
3. Management
   a. Early prenatal diagnosis: highly desirable, given the extremely poor prognosis of some types of conjoined twins
   b. Psychological and prognosis counseling
   c. Accurate preoperative investigation
   d. A team approach
   e. Previous experience
   f. Meticulous operative and postoperative management
   g. Substantial mortality rate related to the underlying conditions
   h. High likelihood of success if major associated anomalies are absent
   i. Options of obstetrical management
      i. Continue the vaginal delivery and deliver the twins intact
      ii. Deliver the twins vaginally after intrauterine separation or a destructive procedure
      iii. Cesarean section and deliver the twins intact
      iv. Cesarean section and deliver the twins after intrauterine separation or destruction
   j. Anesthetic management for separating operations
      i. Extensive cross circulation
         a) Through a liver bridge
         b) Common cerebral venous sinus
      ii. Mechanical problems
         a) One anesthetist required for each infant
         b) A third anesthetist to look after intravenous infusions and monitors
         c) A fourth anesthetist to look after massive blood loss, circulatory collapse, or other catastrophic occurrence
      iii. Anticipate complex congenital heart defects that was not diagnosed preoperatively
   k. Four separate time frames of management (Spitz 2005)
      i. Prenatal
         a) Define the anatomy of the union once the diagnosis of conjoined twins is suspected
         b) Termination can be considered in the event of complex cardiac fusion in thoracopagus twins or extensive cerebral fusion in craniopagus twins: required detailed echocardiography and accurate ultrasonography complemented as necessary with MRI scanning
         c) Obtain informed decision as to either terminate or proceed with the pregnancy
         d) Delivery by cesarean section at 36–38 weeks of gestation
      ii. Nonoperative treatment
         a) In the presence of complex cardiac fusion
         b) Where a severe unacceptable deformity would follow separation

iii. Emergency separation
   a) When one twin is dead or dying, threatening the survival of the remaining twin
   b) Presence of a life-threatening correctable congenital abnormality (e.g., intestinal atresia, malrotation with or without volvulus, ruptured omphalocele, or anorectal agenesis)
   c) Emergency separation carries a significantly higher mortality rate compared with elective procedures

iv. Elective separation
   a) Normally takes place between 2 and 4 months
   b) Allows time to stabilize, thrive, carry out detailed investigation to define the nature and the extent of union, and detailed planning of the operative procedure with all members of the operating team
   c) Survival rate: approaches 80%

Fig. 1 The conjoined twins are joined at the level of abdomen from umbilicus to the xiphoid cartilage (xiphoomphalopagus). This type of conjoined twins is the one most amenable to successful surgical correction because the incidence of complex anatomical anomalies is low. Left twin was successfully separated from the right twin who succumbed shortly after surgery to multiple congenital anomalies including exstrophy of the cloaca, left Bochdalek hernia, hypoplastic kidney, hypoplastic lungs, imperforate anus, and a large sacral meningomyelocele

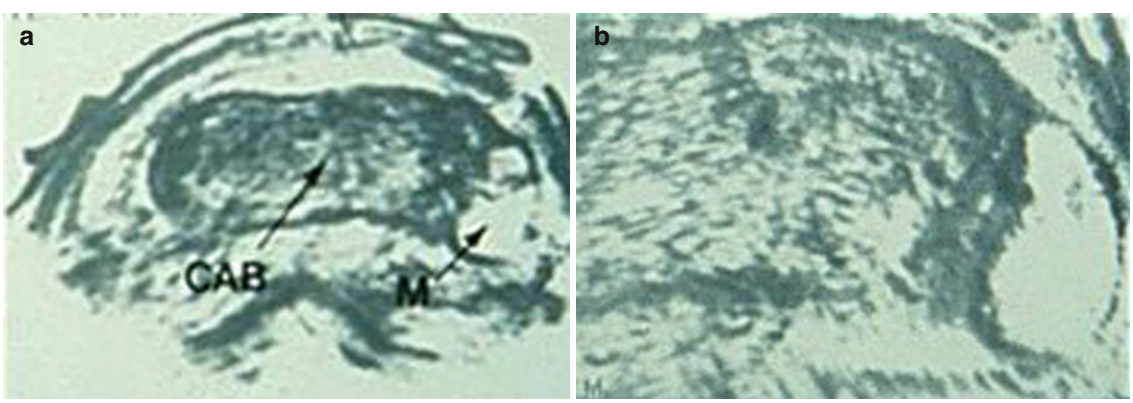

Fig. 2 Prenatal ultrasound (**a**) detected the above conjoined twins with a shared liver (CAB) and separate hearts, stomach, pelvis, and extremities. One fetus was noted to have a meningomyelocele (M). The magnified view (**b**) shows part of the shared liver and meningomyelocele

Fig. 3 These twins are thoraco-omphalopagus, connected at the thorax and upper abdomen. The heart showed complex anomalies with a common atrium and a single ventricle. Therefore, separation of the twins was not attempted

Fig. 4 The radiograph of the twins in Fig. 3 showing the connection at the thorax and the upper abdomen

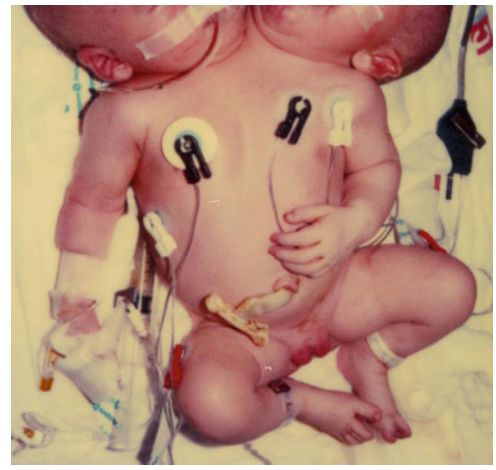

Fig. 5 Dicephalic conjoined twins. Two separate heads, two separate necks, and only one body are evident. The twins shared a common pericardium with complex cardiac anomalies, a common aorta at the level of iliac arteries, a common small intestine and other GI tract distally, a common bladder and urethra drained from a single kidney from each twin, and single normal female genitalia with normally placed fallopian tubes and ovaries. Surgical separation of the twins was deemed impossible and was not attempted

Fig. 6 Prenatal ultrasound study showed lateral view of the dicephalic twins with two heads side by side, one trunk with two overlapping vertebral columns, and two *upper* extremities

Fig. 7 Prenatal ultrasound study showed two separate vertebral columns

Fig. 9 The postnatal radiograph of the above conjoined twins showing separate heads, separate vertebrae, and separate *upper* GI tract. There is one pericardium sac and a fused liver

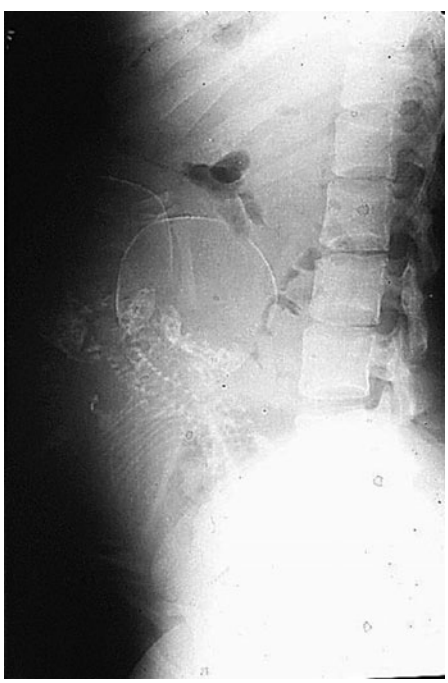

Fig. 8 Prenatal radiographic study showed dicephalic twins with two separate heads and two separate vertebral columns

Fig. 10 A stillbirth with dicephalic conjoined twins

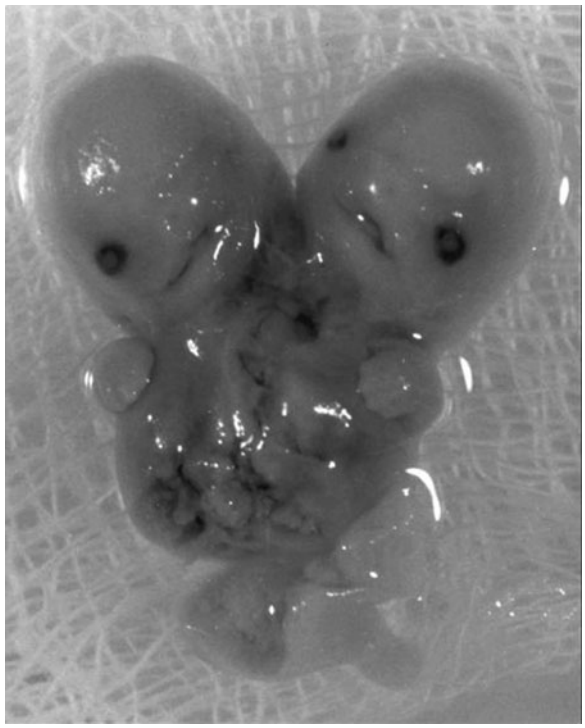

Fig. 11 A set of dicephalic conjoined twin embryos at 6–7 weeks of gestation

Corpus Callosum Agenesis/Dysgenesis

The corpus callosum is an interhemispheric structure that permits the integration of motor, sensory, and cognitive performance between the two cerebral hemispheres. Agenesis/dysgenesis of the corpus callosum is among the most common brain developmental malformation with a wide spectrum of associated clinical and pathologic abnormalities. The prevalence and clinical significance are uncertain. It is estimated to be 0.3–0.7% in the general population and 2–3% in the developmentally disabled (Jeret et al. 1985).

Synonyms and Related Disorders

Agenesis of corpus callosum; Dysgenesis of corpus callosum

Genetics/Basic Defects

1. Markedly heterogeneous etiology of agenesis/dysgenesis of the corpus callosum (Dobyns 1996)
   a. Sporadic in most cases
   b. Environmental factors
      i. Alcoholism
      ii. Maternal rubella
      iii. Maternal diabetes
   c. A multifactorial trait
   d. As a part of autosomal dominant syndrome
      i. Agenesis/dysgenesis of the corpus callosum
      ii. Apert syndrome
      iii. Basal cell nevus syndrome
      iv. Miller–Dieker syndrome
      v. Rubinstein–Taybi syndrome
      vi. Tuberous sclerosis
   e. As a part of autosomal recessive syndrome
      i. Agenesis/dysgenesis of the corpus callosum
      ii. Agenesis/dysgenesis of the corpus callosum with thrombocytopenia
      iii. Acrocallosal syndrome
      iv. Andermann syndrome
         a) Agenesis/dysgenesis of the corpus callosum with peripheral neuropathy
         b) Mapping of the gene to a 5-cM region in chromosome 15q13-15
      v. Cerebro-oculo-facio-skeletal (COFS) syndrome
      vi. Cogan syndrome (ocular motor apraxia)
      vii. Craniotelencephalic dysplasia
      viii. Dincsoy syndrome
         a) Multiple midline malformations
         b) Limb abnormalities
         c) Hypopituitarism
      ix. Fukuyama congenital muscular dystrophy
      x. Hydrolethalis syndrome
      xi. Joubert syndrome (cerebellar vermis agenesis)
      xii. Leprechaunism
      xiii. Lowry–Wood syndrome
         a) Epiphyseal dysplasia
         b) Microcephaly
         c) Nystagmus
      xiv. Meckel–Gruber syndrome
      xv. Microcephalic osteodysplastic primordial dwarfism type I/III
      xvi. Neu–Laxova syndrome
      xvii. Opitz G syndrome
      xviii. Peters plus syndrome
         a) Peters anomaly
         b) Short-limb dwarfism

  a) Microcephaly
  b) Microphthalmia
  c) Cerebral malformations
  d) Other anomalies

f. As a part of X-linked syndrome
  i. Agenesis/dysgenesis of the corpus callosum
  ii. Agenesis/dysgenesis of the corpus callosum with Hirschsprung disease
  iii. Agenesis/dysgenesis of the corpus callosum with hypohidrotic ectodermal dysplasia
  iv. Aicardi syndrome (retinovertebral anomalies in females)
  v. ATR-X syndrome (X-linked alpha thalassemia mental retardation syndrome)
  vi. Craniofrontonasal syndrome
  vii. Curatolo syndrome
    a) Agenesis/dysgenesis of the corpus callosum
    b) Chorioretinal abnormality
  viii. FG syndrome
    a) Mental retardation
    b) Large head
    c) Imperforate anus
    d) Congenital hypotonia
    e) Partial agenesis/dysgenesis of the corpus callosum
  ix. HSAS syndrome (*h*ydrocephalus due to congenital *s*tenosis of *a*queduct of *S*ylvius)
  x. Lenz dysplasia
    a) Microphthalmia/anophthalmia
    b) Associated anomalies
  xi. Lujan–Fryns syndrome
    a) X-linked mental retardation
    b) Marfanoid habitus
  xii. MASA syndrome
    a) *M*ental retardation
    b) *A*phasia
    c) *S*huffling gait
    d) *A*dducted thumbs
  xiii. MLS syndrome
    a) *M*icrophthalmia
    b) *L*inear *s*kin defects
  xiv. Opitz G syndrome
  xv. OFD I
  xvi. Proud syndrome
    a) X-linked syndrome
    b) Seizures
    c) Acquired micrencephaly
    d) Agenesis/dysgenesis of the corpus callosum
  xvii. XLIS syndrome (X-linked lissencephaly)

g. As a part of unknown-genesis syndrome
  i. Calloso-genital dysplasia
  ii. Delleman (oculocerebrocutaneous) syndrome
  iii. Frontonasal dysplasia
  iv. Opitz C trigonocephaly syndrome
  v. Sebaceous nevus syndrome

h. As a part of metabolic disorders
  i. Adenylosuccinase deficiency
  ii. Adipsic hypernatremia
  iii. β-hydroxyisobutyryl coenzyme A deacyclase deficiency
  iv. Glutaric aciduria type II
  v. Histidinemia
  vi. Hurler syndrome
  vii. Leigh syndrome
  viii. Menkes syndrome
  ix. Neonatal adrenoleukodystrophy
  x. Nonketotic hyperglycinemia
  xi. Pyruvate dehydrogenase deficiency
  xii. Zellweger syndrome

i. Associated chromosome abnormalities
  i. Trisomy 18
  ii. Trisomy 8
  iii. Trisomy 21
  iv. Trisomy 22
  v. Other trisomies

vi. Deletions
vii. Translocations
viii. Duplications
j. Agenesis of the corpus callosum with interhemispheric cyst: a heterogeneous group of disorders that have in common callosal agenesis and extraparenchymal cysts, both of which are among the commonest CNS malformations (Barkovich et al. 2001)
k. Incidental finding in normal individuals (isolated dysgenesis of the corpus callosum)

2. Embryogenesis of the corpus callosum
   a. Development of the corpus callosum
      i. A late event in cerebral ontogenesis
      ii. Taking place between 12 and 18 weeks of gestation
   b. An important brain commissure connecting the cerebral hemispheres (Achiron and Achiron 2001)
   c. Essential for efficient cognitive function (Achiron and Achiron 2001)
   d. Failure of development of the commissural fibers connecting the cerebral hemispheres produces dysgenesis or agenesis of the corpus callosum
   e. Diagnosis of agenesis: a challenge even for expert sonologists, particularly prior to 20 weeks of gestation
3. Types of agenesis
   a. Complete agenesis: commonly regarded as a malformation deriving from faulty embryogenesis
   b. Type I agenesis
      i. Not associated with other disorders
      ii. Usually absent or associated with mild neurologic manifestations
   c. Type II agenesis
      i. Associated with other migrational, genetic, and chromosomal disorders
      ii. Usually associated with severe neurologic manifestations
   d. Partial agenesis
      i. Referred to as dysgenesis
      ii. Either a true malformation or a disruptive event occurring at any time during pregnancy
      iii. Missing caudad portion (splenium and body) to varying degrees
4. Agenesis/dysgenesis of the corpus callosum (da-Silva 1988)
   a. Without other associated brain anomalies
   b. Frequently associated with other brain anomalies
      i. Defects of septum pellucidum and fornix
      ii. Hydrocephalus
      iii. Dandy–Walker malformation
      iv. Interhemispheric cyst
      v. Holoprosencephaly
      vi. Porencephaly
      vii. Polymicrogyria
      viii. Macrogyria
      ix. Cortical heterotopia and atrophy
      x. Lipoma
      xi. Encephalocele
      xii. Hypoplasia of cerebellum
   c. Frequently associated other anatomical anomalies
      i. Congenital heart defects
      ii. Costovertebral defects
      iii. Gastrointestinal anomalies
      iv. Genitourinary anomalies

Clinical Features

1. Craniofacial abnormalities
   a. Microcephaly
   b. Macrocephaly
2. Developmental anomalies
   a. Nonspecific mental retardation
   b. Developmental delay
   c. Learning disabilities
   d. Behavioral disorder
   e. Mental retardation
   f. Failure to thrive
3. Infantile spasms/seizures
4. Signs and symptoms related to type I and type II agenesis
   a. Type I
      i. Variable intelligence: normal to mild or moderate mental retardation
      ii. Seizure disorder
      iii. Impaired visual, motor, and/or bimanual coordination
      iv. Mild impairment of crossed tactile localization and skills requiring matching of visual patterns
   b. Type II
      i. Mental retardation
      ii. Seizures
      iii. Hydrocephaly

iv. Microcephaly
v. Hemiparesis
vi. Diplegia
vii. Spasticity
viii. Failure to thrive

Diagnostic Investigations

1. Psychometric tests (Finlay et al. 2000)
   a. Difficulties in motor coordination
   b. Difficulties in interhemispheric transfer of tactile information
   c. Difficulties in some areas of memory
   d. A marked difference in verbal IQ and performance IQ in children
2. EEG for seizure activities
3. CT and/or ultrasound of the brain (Gupta and Lilford 1995)
   a. Absence of the corpus callosum
   b. Absence of septum pellucidum
   c. Increased separation of the lateral ventricles
   d. Marked separation of the slit-like anterior horns of the lateral ventricles and dilatation of the occipital horns creating the typical "rabbit's ear" or "tear drop" appearance
   e. Upward displacement of the third ventricle
   f. Evidence of other migration disorders
4. Coronal radiographs showing a pathognomonic bat-wing ventricular pattern
5. Karyotyping for underlying chromosomal disorder
6. Metabolic studies for underlying inborn error of metabolism

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: depending on the etiology and the mode of inheritance
      i. Isolated agenesis/dysgenesis of the corpus callosum: recurrence risk not increased
      ii. Environmental factor: recurrence risk not increased by avoiding the environmental factor
      iii. Autosomal recessive inheritance: 25% of siblings affected, 50% siblings carriers, and 25% of siblings normal
      iv. Autosomal dominant inheritance: recurrence risk not increased unless a parent is affected in which case the recurrence risk is 50%
      v. X-linked recessive inheritance
         a) Carrier mother (50% of brothers affected; 50% of sisters carriers)
         b) Affected father (all brothers normal, all sisters carriers)
      v. X-linked dominant inheritance
         a) Affected mother (50% of brothers and sisters affected)
         b) Affected father (all brothers normal; all sisters affected)
      vi. Chromosomal disorder: recurrence risk increased, especially if a parent carries a balanced translocation
   b. Patient's offspring
      i. Environmental factor: recurrence risk not increased by avoiding the environmental factor
      ii. Autosomal recessive inheritance: recurrence risk not increased unless the spouse is also a carrier in which case the recurrence risk is 50%
      iii. Autosomal dominant inheritance: 50%
      iv. X-linked recessive inheritance
         a) Carrier female (50% of sons affected, 50% of daughters carriers)
         b) Affected male (all sons normal, all daughters carriers)
      v. X-linked dominant inheritance
         a) Affected female (50% of sons and daughters affected)
         b) Affected male (all sons normal, all daughters affected)
      vi. Chromosomal disorder: recurrence risk increased, especially if a parent carries a balanced translocation
2. Prenatal diagnosis
   a. Ultrasonography
      i. Prenatal detection of the agenesis of the corpus callosum usually not possible before 22 weeks of gestation (Bennett et al. 1996)
      ii. Direct demonstration of the absence or partial absence of the corpus callosum

iii. Failure to visualize the cavum septum pellucidum
iv. Third ventricle lying between widely separated lateral ventricles due to absent corpus callosum
v. Lateral ventricles more parallel to the midline than usual
vi. A cyst arising from the superior aspect of the third ventricle communicating with the lateral ventricles
vii. Vertical orientation of the gyri with agenesis instead of normal horizontal alignment
viii. Colpocephaly (locally dilated occipital horns of the lateral ventricle) forming an appearance on axial views similar to bulls' horns
ix. Absence of pericallosal artery
x. Up to 50% of cases with other associated anatomic defects
xi. Variable developmental outcome on prenatal detection of an isolated agenesis of the corpus callosum

b. MRI
   i. Allows more detailed visualization of the fetal brain than ultrasonography
   ii. Constitutes a useful additional procedure after ultrasonographic diagnosis or suspicion of corpus callosum agenesis
c. Amniocentesis recommended for karyotyping as there is 10–20% risk of aneuploidy associated with the agenesis of the corpus callosum
d. Prenatal counseling for ultrasonically diagnosed fetal agenesis of the corpus callosum remains very difficult, as giving precise information on outcome is impossible. (Moutard et al. 2003) The following observation, however, may be of help in prenatal counseling: (Gupta 1995)
   i. Isolated agenesis/dysgenesis of the corpus callosum (in the absence of other sonographically detectable anomalies) carrying apparent excellent prognosis
      a) 85% chance of a normal developmental outcome
      b) 15% risk of handicap
   ii. Agenesis/dysgenesis of the corpus callosum with other associated anomalies: poor outcome

3. Management
   a. Identification of actual deficits resulting from the absence of such a major structure (corpus callosum): clearly an issue
   b. Multidisciplinary team approach to intervention programs
   c. Anticonvulsants for seizures
   d. Management based on the underlying etiology

Craniometaphyseal Dysplasia

In 1954, Jackson et al. coined the term "craniometaphyseal dysplasia" for a hereditary bone disease with metaphyseal widening of the tubular bones and bony overgrowth of the facial and skull bones (leonteasis ossea).

Genetics/Basic Defects

1. Genetic heterogeneity (Beighton 1995)
   a. Autosomal dominant form [also called CMD, Jackson type (CMDJ)]:
      i. CMDJ locus mapped to 5p15.2-p14.1 within a region harboring the human homolog (*ANKH*) of the mouse progressive ankylosis (*ank*) gene
      ii. Mutations in ANKH have been associated in craniometaphyseal dysplasia in some families (Nürnberg et al. 2001; Reichenberger et al. 2001)
      iii. ANKH mutations that cause CMD most likely entail a loss of function (Kornak et al. 2010) or a loss of ANKH protein expression and activity in the plasma membrane as a result of aberrant intracellular protein trafficking (Zajac et al. 2010)
   b. Autosomal dominant form cosegregating with chondrocalcinosis
      i. Mutations in ANKH have been associated with familial chondrocalcinosis (OCAL2) in some families (Pendleton et al. 2002; Williams et al. 2003)
      ii. A family was reported with an *ANKH* mutations in which these conditions cosegregated in some affected family members (Baynam et al. 2009)
   c. Autosomal recessive form
      i. Rare
      ii. Ill-defined
      iii. Probably heterogeneous
      iv. Often difficult to diagnose with precision
      v. Autosomal recessive CMD locus mapped to 6q21-22
2. Basic defects
   a. Autosomal dominant form: caused by mutations in the human homolog of the mouse progressive ankylosis gene (*ANKH*) (Reichenberger et al. 2001)
   b. Autosomal recessive form (Beighton 1995)
      i. May involve dysfunctional osteoclasts because reported metabolic responses of affected children to therapy with calcitonin and clacitrol
      ii. Osteoclast-like cells derived from the bone marrow shown to lack expression of the osteoclast vacuolar proton pump

Clinical Features

1. Autosomal dominant form
   a. General features
      i. Good general health
      ii. Normal intelligence
      iii. Normal stature
   b. Bony overgrowth of the facial bone resulting in the typical facies:
      i. Frontal bossing
      ii. Hypertelorism
      iii. Paranasal bossing (30% of cases in childhood)
         a) May be present during infancy
         b) Tends to regress with age

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_59,
© Springer Science+Business Media, LLC 2012

c) Virtually absent by adolescence and early adulthood
d) May be associated with some degree of nasal obstruction and frequent mouth breathing

iv. Mild to moderate mandibular prognathism
v. An open mouth secondary to bony encroachment of the nasal passages
vi. Malalignment of the teeth
vii. Grotesque hyperostosis of the facial bones
viii. Decreased facial movement

c. Bony overgrowth of the cranial foramina resulting in the following features:
i. Cranial nerve paralysis
ii. Nystagmus
iii. Optic atrophy
iv. Facial palsy (30% of cases)
a) Common but variable
b) May be unilateral or bilateral
c) May occur at any age
d) The involvement often fluctuant in early childhood
e) May be permanent in adulthood
v. Deafness (50% of cases)
a) Due to compromised auditory nerve and inner ear by bone overgrowth
b) May be unilateral or bilateral
c) Often "mixed" in type due to chronic otitis media and upper respiratory tract infection secondary to minor anatomical abnormalities of the airway and sinuses
d) Usually partial and rarely profound
vi. Less commonly reported conditions (Kietzer and Paparella 1969)
a) Compression of the cerebellar tonsils and medulla secondary to a narrowed foramen magnum
b) Obstruction of Eustachian tube
c) Obstruction of nasolacrimal duct
d) Obstruction of nasal passages
e) Raised intracranial pressure: rare instances of a potentially lethal rise in intracranial pressure due to hyperostosis of the calvarium

d. Abnormal modeling of the metaphyses of the long bones
i. Metaphyseal widening of the long and short tubular bones
ii. Thin cortical layer
iii. Coarse trabeculations

e. Clinical and radiographic features improved in later childhood in the dominant form

2. Autosomal recessive form
a. Similar to, but more severe than, those seen in the dominant form
b. An increasing severity with age
c. Progressive overgrowth and craniofacial deformity
i. Very severe facial distortion
ii. A thick bony wedge over the bridge of the nose
iii. Dystopia canthorum
iv. Ocular hypertelorism
v. Enlarged malar prominences and mandible (marked prognathism)
vi. Wide alveolar ridge
vii. Narrowed nasal passages leading to mouth breathing
viii. Dental abnormalities
ix. Blindness
x. Facial palsy
xi. Deafness

d. Abnormal modeling of the metaphyses of the long bones
i. Gradual, club-shaped widening of the metaphyses
ii. Thin cortex and undermineralized medullary bone

3. Differential diagnosis (Cole and Cohen 1988)
a. Pyle disease (metaphyseal dysplasia)
i. Frequently confused with craniometaphyseal dysplasia. In Pyle disease, metaphyseal flaring occurs but there is minimal involvement of the skull
ii. Autosomal recessive inheritance

b. Craniodiaphyseal dysplasia (Cole and Cohen 1988)
i. Most severe thickening, distortion, and enlargement of the craniofacial region
ii. Characterized by diaphyseal endostosis
iii. Does not exhibit metaphyseal flaring
iv. Inheritance likely autosomal recessive

c. Frontometaphyseal dysplasia (Cooper 1974)
i. A pronounced bony supraorbital ridge
ii. Hirsutism
iii. Long-bone alterations
iv. Conductive deafness

d. Camurati–Engelmann disease (progressive diaphyseal dysplasia) (Cooper 1974)
   i. Presence of excess subperiosteal bone in the diaphyses of the long bone
   ii. Normal metaphyses
   iii. Rare craniofacial involvement
e. Van Buchem disease (hyperostosis corticalis generalisata) (Cooper 1974)
   i. Dense and thickened craniofacial skeleton
   ii. Generalized cortical thickening of the long bones mainly due to endosteal bone apposition

Diagnostic Investigations

1. Normal serum calcium, phosphorous, and alkaline phosphatase
2. Radiographic features (Beighton 1995)
   a. Autosomal dominant form: age-related radiographic features
      i. Characteristic hyperostosis and sclerosis of the skull
      ii. Paranasal bony bossing, most evident in early childhood
      iii. May be present with prognathism and asymmetry
      iv. Characteristic non-sclerotic widening of the metaphyses of the tubular bones: a major radiographic feature
         a) Most obvious at the lower end of the femur
         b) An "Erlenmeyer flask" configuration in childhood
         c) A "club" shape in adulthood
   b. Autosomal recessive form: severe radiographic manifestations (Penchaszadeh et al. 1980)
      i. Increasing severity with age
      ii. Sclerosis and hyperostosis of the calvarium, the base of the skull, and the facial bones and mandible
      iii. Increased bone deposition on the walls of the paranasal sinuses
      iv. Underpneumatization of mastoid cells
      v. Gradual, club-shaped widening of the metaphyses
      vi. Thin cortex and undermineralized medullary bone
3. Gross pathological features (Kietzer and Paparella 1969)
   a. Thickened "ivory-hard" facial and cranial bones
   b. Narrow cranial foramina
   c. Narrowing of the nasal chambers and posterior choanae
4. Histological features (Kietzer and Paparella 1969)
   a. Compact laminar cortical bone with dilated Haversian canals containing osteoblasts
   b. No osteoclasts identified in the periosteal or endosteal layers
   c. An increased amount of ground substance and excessive formation of subperiosteal and subendosteal bone
5. Molecular genetic analysis for human ankylosis gene (*ANKH*): Sequence analysis detects mutations in about 90% of individuals meeting the diagnostic criteria for CMD (Reichenberger and Chen 2010)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant form: 50% risk if one parent is affected, otherwise risk not increased
      ii. Autosomal recessive form: 25%
   b. Patient's offspring
      i. Autosomal dominant form: 50%
      ii. Autosomal recessive form: not increased unless the spouse is also a carrier in which case there is 50% recurrence risk
2. Prenatal diagnosis for pregnancies at risk may be available through laboratories offering custom prenatal testing if the disease-causing mutations in the family is known (Reichenberger and Chen 2010)
3. Management
   a. Medical treatment attempted with the following two hormones
      i. Calcitonin: has an inhibitory effect on bone formation
      ii. Calcitriol (Key et al. 1988)
         a) Stimulates resorption of bone by promoting osteoclast formation
         b) Partial resolution of facial nerve paralysis, increased size of the cranial nerve foramina, and demineralization of the

cranial base during treatment of one patient with high doses of calcitriol

b. Hearing aids for hearing loss
c. Psychological support for facial disfigurement
d. Surgical treatment with mixed results (Day et al. 1997)
   i. Resection of dysplastic bone arduous because it is highly mineralized with a consistency like thick ivory
   ii. Craniofacial reduction performed with some difficulty
   iii. Optic canal decompression for progressive visual loss
   iv. Facial nerve decompression
   v. Middle ear exploration and implantation of total ossicular replacement prosthesis for conductive hearing loss
   vi. Foramen magnum decompression for cervicomedullary encroachment

Cri-Du-Chat Syndrome

Cri-du-chat syndrome is a chromosome 5p deletion syndrome first described by Lejeune et al. in 1963. The name of the syndrome refers to the most characteristic clinical feature, a high-pitched crying similar to the mewing of a cat, which usually disappears in the first years of life. The incidence is estimated to be approximately 1 in 15,000 (Higurashi et al. 1990) to 1 in 50,000 births (Niebuhr 1978). The prevalence among mentally retarded individuals is approximately 1.5 in 1,000.

Synonyms and Related Disorders

Cat cry syndrome; Chromosome 5p deletion syndrome

Genetics/Basic Defects

1. Cause
   a. Caused by deletion of short arm of chromosome 5: The size of the deletion ranges from the entire short arm to the region 5p15 (Overhauser et al. 1994) and a deletion size ranging from 5 to 40 Mb (Simmons et al. 1995)
      i. De novo deletion (80%): paternally derived deletions in 80% of cases
      ii. Familial rearrangement (12%)
      iii. Mosaicism (3%)
      iv. Rings (2.4%)
      v. De novo translocation (3%)
   b. A high-resolution physical and transcription map generated a 3.5-Mb region of 5p15.2 that is associated with the Cri-du-chat syndrome region (Church et al. 1997)
2. Genotype–phenotype correlation (Gersh et al. 1997)
   a. Deletion of 5p15.3 results in a cat-like cry and speech delay (Gersh et al. 1995; Church et al. 1995)
   b. Deletion of 5p15.2 results in the distinct facial features associated with the syndrome as well as the severe mental and developmental delay
3. Hemizygosity of δ-catenin (*CTNND2*, mapped to 5p15.2), reported to be associated with severe mental retardation in cri-du-chat syndrome (Medina et al. 2000)
4. Deletion of the *telomerase reverse transcriptase* (h*TERT*) gene (mapped at 5p15.33) and haploinsufficiency of telomere maintenance is probably a genetic element contributing to the phenotypic changes in cri-du-chat syndrome (Zhang et al. 2003)

Clinical Features

1. Characteristic mewing cry (Niebuhr 1978)
   a. A high-pitched monochromatic cry with subtle dysmorphism and neonatal complications: commonly observed in infants with this syndrome
   b. Observed in many infants with cri-du-chat syndrome
   c. Not associated with other aneuploidies
   d. Usually considered diagnostic
   e. Loss of the characteristic cry by age 2 years in one third of children
2. Clinical findings during infancy
   a. Low birth weight
   b. Hypotonia

c. Microcephaly
d. Poor sucking/swallowing difficulties
e. Need for incubator care
f. Respiratory distress
g. Jaundice
h. Pneumonia
i. Dehydration
j. Failure to thrive/growth retardation
k. Early ear infections
l. Severe cognitive, speech, and motor delays
m. Facial features
    i. Round face with full cheek
    ii. Hypertelorism
    iii. Epicanthal folds
    iv. Down-slanting palpebral fissures
    v. Strabismus
    vi. Flat nasal bridge
    vii. Down-turned mouth
    viii. Micrognathia
    ix. Low-set ears
n. Cardiac defects
    i. VSD
    ii. ASD
    iii. PDA
    iv. Tetralogy of Fallot
o. Short fingers
p. Single palmar creases
q. Less frequent features
    i. Cleft lip and palate
    ii. Preauricular tags and fistulas
    iii. Thymic dysplasia
    iv. Gut malrotation
    v. Megacolon
    vi. Inguinal hernia
    vii. Dislocated hips
    viii. Cryptorchidism
    ix. Hypospadias
    x. Rare renal malformations
        a) Horseshoe kidneys
        b) Renal ectopia or agenesis
        c) Hydronephrosis
    x. Clinodactyly of the fifth fingers
    xi. Talipes equinovarus
    xii. Pes planus
    xiii. Syndactyly of the second and third fingers and toes
    xiv. Oligosyndactyly
    xv. Hyperextensible joints

3. Clinical findings in childhood
    a. Severe mental retardation
    b. Developmental delay
    c. Microcephaly
    d. Hypertonicity
    e. Premature graying of the hair
    f. Small, narrow, and often asymmetric face
    g. Dropped-jaw
    h. Open-mouth expression secondary to facial laxity
    i. Short philtrum
    j. Malocclusion of the teeth
    k. Scoliosis
    l. Short third-fifth metacarpals
    m. Chronic medical problems
        i. Upper respiratory tract infections
        ii. Otitis media
        iii. Severe constipation
        iv. Hyperactivity
4. Clinical findings in late childhood and adolescence
    a. Coarsening of facial features
    b. Prominent supraorbital ridges
    c. Deep-set eyes
    d. Hypoplastic nasal bridge
    e. Affected females reaching puberty and developing secondary sex characteristics and menstruate at the usual time (Martinez et al. 1993)
    f. Small testis and normal spermatogenesis in males
5. Dermatoglyphics
    a. Transverse flexion creases
    b. Distal axial triradius
    c. Increased whorls and arches on digits
6. Behavioral profile
    a. Hyperactivity
    b. Aggression
    c. Tantrums
    d. Stereotypic and self-injurious behavior
    e. Repetitive movements
    f. Hypersensitivity to sound
    g. Clumsiness
    h. Obsessive attachments to objects
    i. Able to communicate needs and interact socially with others
    j. Autistic-like features and social withdrawal: more characteristic of individuals who have a 5p deletion as the result of an unbalanced segregation of a parental translocation

7. Prognosis
   a. Ability of many children to develop some language and motor skills
   b. Ability of these children to attain developmental and social skills observed in 5- to 6-year-old children, although their linguistic abilities are seldom as advanced
   c. Older, home-reared children
      i. Usually ambulatory
      ii. Able to communicate verbally or through gestural sign language
      iii. Independent in self-care skills

Diagnostic Investigations

1. Conventional cytogenetic studies once the suspected diagnosis is established. The size of the 5p deletion may vary from the entire short arm to only 5p15. A small deletion of 5p may be missed by a conventional cytogenetic technique
2. High-resolution cytogenetic studies are required for a smaller 5p deletion
3. Molecular cytogenetic studies using fluorescent in situ hybridization (FISH)
   a. Allow the diagnosis to be made in the patients with very small deletions
   b. Use genetic markers that have been precisely localized to the area of interest
   c. The absence of a fluorescent signal from either the maternal or paternal chromosome 5p regions: indicative of monosomy for that chromosomal region
4. Comparative genomic hybridization (CGH) especially the CGH method based on DNA microarray and quantitative PCR (Mainardi et al. 2001; Rodriguez-Caballero et al. 2010)
5. Skeletal radiographs
   a. Microcephaly
   b. Retromicrognathia
   c. Cranial base malformations
      i. Reduced cranial base angle
      ii. Malformed sella turcica and clivus
   d. Disproportionately short third, fourth, and fifth metacarpals and disproportionately long second, third, fourth, and fifth proximal phalanges (frequent) (Fenger and Niebuhr 1978)
6. Echocardiography to rule out structural cardiac malformations
7. MRI of the brain (Kjaer and Niebuhr 1999)
   a. Atrophic brainstem, middle cerebellar peduncles, and cerebellar white matter
   b. Possible hypoplasia of cerebellar vermis with enlargement of the cisterna magna and fourth ventricle
8. Swallowing study for feeding difficulty
9. Comprehensive evaluation for receptive and expressive language. Most children have better receptive language than expressive language
10. Developmental testing and referral to early intervention and appropriate school placement

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Recurrence risk for a de novo case is 1% or less (possibility of gonadal mosaicism in one of the parents cannot be ruled out)
      ii. Rare recurrences in chromosomally normal parents: most likely the result of gonadal mosaicism for the 5p deletion in one of the parents
      iii. The risk is substantially high if a parent is a balanced carrier of a structural rearrangement. Risk should be assessed based on the type of structural rearrangement and its pattern of segregation
   b. Patient's offspring: Female patients are fertile and can deliver viable affected offspring, with an estimated recurrence risk of 50%
2. Prenatal diagnosis by amniocentesis, CVS, and PUBS for chromosome analysis to detect 5p deletion
3. Management
   a. Supportive care: No treatment exists for the underlying disorder
   b. Appropriate treatment for chronic medical problems
      i. Upper respiratory tract infections
      ii. Otitis media
      iii. Severe constipation
   c. Using the relatively good receptive skills to encourage language and communicative development rather than relying on traditional verbal methods (Cornish and Munir 1988)

d. Early intervention programs
   i. Physical therapy
   ii. Occupational therapy
   iii. Speech therapy
e. Introduction to sign language, an effective means of developing communication skills (>50% of children are able to use sign language to communicate) (Cornish and Munir 1988)
f. Behavior modification programs to successfully manage hyperactivity, short attention span, low threshold for frustration, and self-stimulatory behaviors (e.g., head-banging, hand-waving)
g. Surgical interventions
   i. Correction of congenital heart defects if indicated
   ii. Medical problems involving minor malformations such as strabismus and clubfoot
   iii. Gastrostomy in infancy to protect airway of patients with major feeding difficulties
   iv. Orchiopexy for undescended testes
   v. Issues important to anesthetic plan
      a) Anatomical abnormalities of the airway
      b) Congenital heart disease
      c) Hypotonia
      d) Mental retardation
      e) Temperature maintenance

Fig. 1 (**a**, **b**) Two infants with cri-du-chat syndrome. Note a round face with full cheeks, hypertelorism, epicanthal folds, and apparently low-set ears

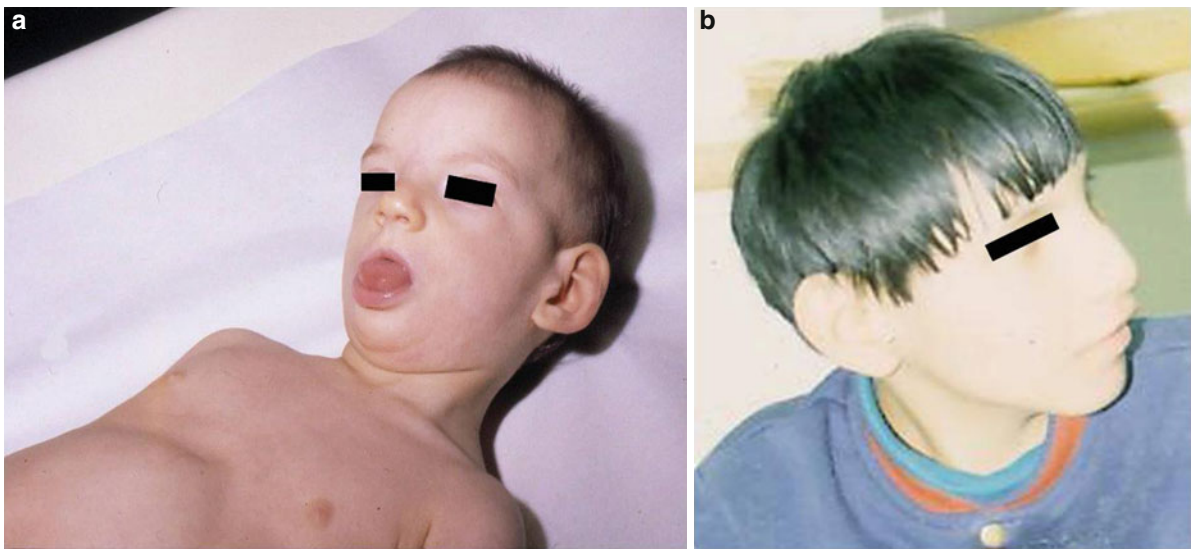

Fig. 2 (**a**, **b**) Cri-du-chat syndrome in an older child and a teenager showing a long and narrow face

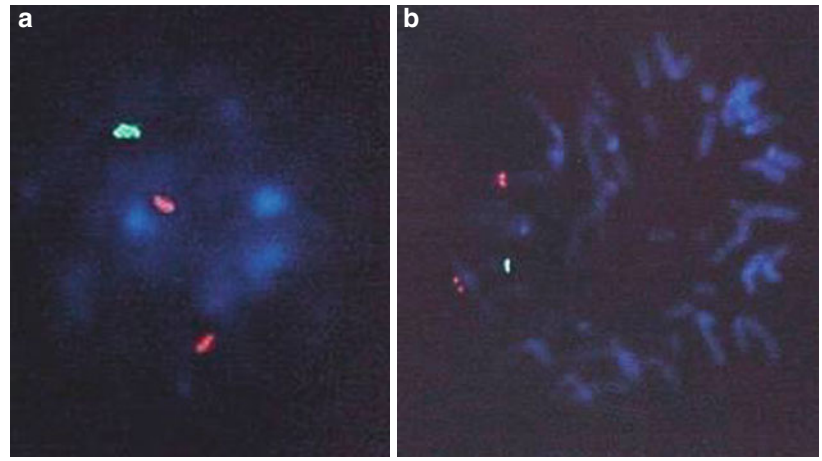

Fig. 3 (**a**, **b**) FISH of an interphase cell and a metaphase spread with two *orange* signals (LSI SpectrumOrange, D5S721) and one *green* signal (LSI SpectrumGreen, D5S23 chromosome 5p15.2-specific probe) indicating deletion of 5p15.2

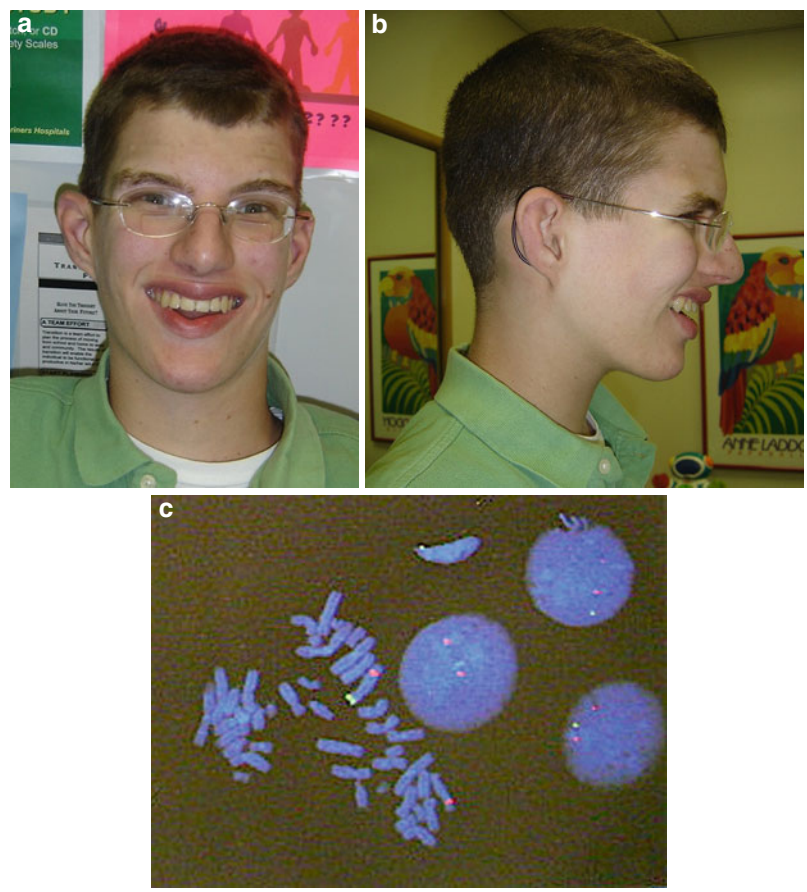

Fig. 4 (**a–c**) The 16-year-old boy was evaluated for developmental delay. He was noted to have unusual cry during early infancy, poor muscle control, and unable to hold his head up until 6 months of age. FISH using a locus specific for 5p11.2 cri-du-chat syndrome region showed 5p11.2 deletion (illustrated by a metaphase chromosome spread and interphase cells)

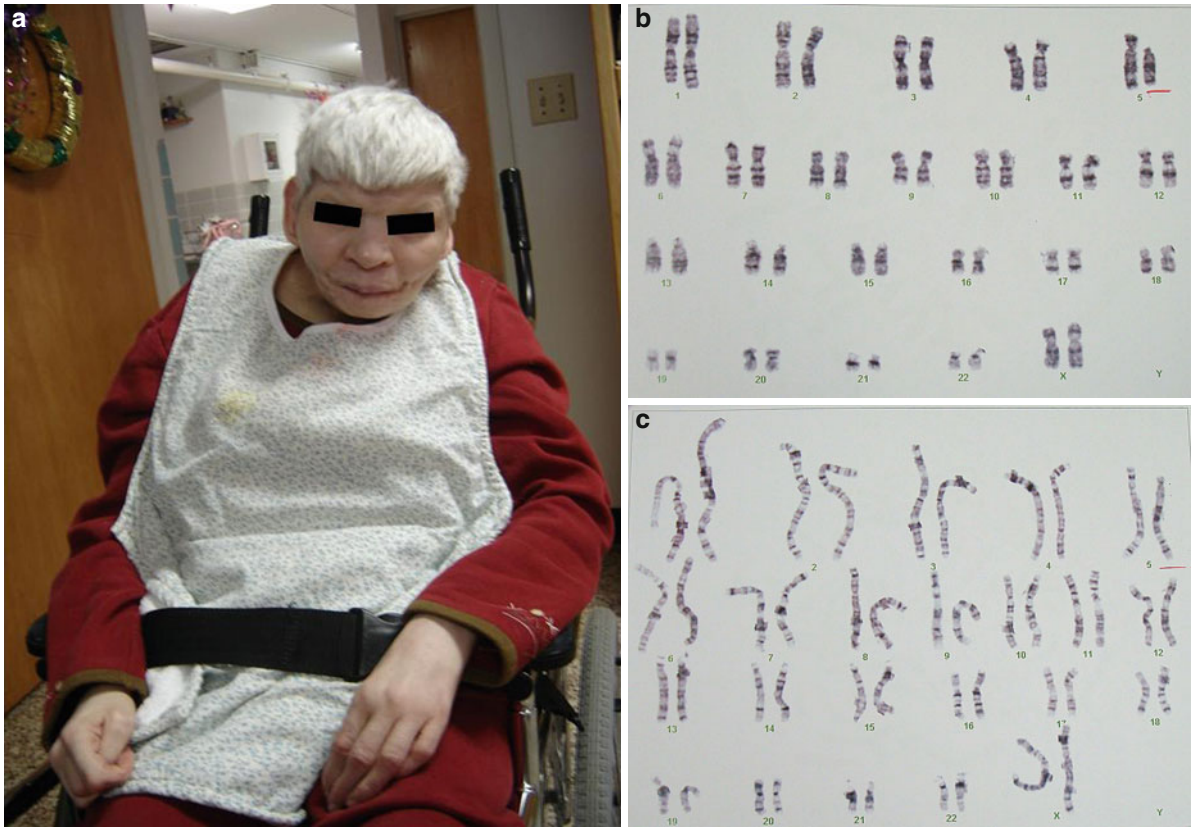

Fig. 5 (**a–c**) A blond-haired 60-year-old female with cri-du-chat syndrome, showing microcephaly with severe mental retardation. The karyotypes showed deletion of most of the short arm of a chromosome 4

Crouzon Syndrome

In 1912, Crouzon described the hereditary syndrome of craniofacial dysostosis in a mother and son. He described the triad of calvarial deformities, facial anomalies, and exophthalmos. Crouzon syndrome is characterized by premature closure of calvarial and cranial base sutures as well as those of the orbit and maxillary complex (craniosynostosis). Other clinical features include hypertelorism, exophthalmos, strabismus, beaked nose, short upper lip, hypoplastic maxilla, and relative mandibular prognathism. Prevalence is 1 per 60,000 (approximately 16.5 per 1,000,000) live births (Cohen and Kreiborg 1992). Crouzon syndrome makes up approximately 4.8% of all cases of craniosynostosis.

Synonyms and Related Disorders

Craniofacial dysostosis type I; Crouzon craniofacial dysostosis

Genetics/Basic Defects

1. Inheritance
   a. An autosomal dominant disorder with
      i. Complete penetrance
      ii. Variable expressivity
   b. Sporadic in 50% of patients resulting from new mutations
2. Cause
   a. Mutations in the fibroblast growth factor receptor-2 (*FGFR2*) gene which is mapped to 10q25-q26
   b. Mutations reported in the third immunoglobulins-like domain (Meyers et al. 1996)
   c. Different mutations detected in both exon IIIa and exon IIIc. Most of these mutations are missense, although several different mutations leading to alternative splicing have been recognized (Meyers et al. 1996)
   d. Crouzon syndrome exhibits locus heterogeneity with causal mutations in *FGFR2* and *FGFR3* in different affected individuals
   e. Crouzon syndrome with acanthosis nigricans (Crouzonodermoskeletal syndrome)
      i. Described as a separate entity from Crouzon syndrome (Cohen 1999)
      ii. Caused by the GAG to GCG transversion mutation in the *FGFR3* gene, leading to Ala391Glu substitution (Wilkes et al. 1996)
3. Pathophysiology
   a. Premature synostosis of the coronal, sagittal, and occasional lambdoidal sutures
      i. Begins in the first year of life
      ii. Completed by the second or third year
   b. Degree of deformity and disability determined by the order and rate of suture fusion
   c. After fusion of a suture
      i. Growth perpendicular to that suture becoming restricted
      ii. Fused bones acting as a single bony structure.
   d. Compensatory growth occurring at the remaining open sutures to allow continued brain growth
   e. Multiple sutural synostoses often extend to premature fusion of the skull base sutures causing the following effects
      i. Midfacial hypoplasia
      ii. Shallow orbit

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_61,
© Springer Science+Business Media, LLC 2012

iii. A foreshortened nasal dorsum
iv. Maxillary hypoplasia
v. Occasional upper airway obstruction.

Clinical Features

1. History
   a. Presence of mildly affected individuals in the family
   b. Craniofacial abnormalities often present at birth and may progress with time
   c. Decreased mental function in approximately 12% of the patients
   d. Headaches (29%) and failing vision due to elevated intracranial pressure
   e. Visual disturbance results from corneal injury due to exposed conjunctivitis and keratitis
   f. Conductive deafness common due to ear canal stenosis or atresia
   g. Causes of upper airway obstruction
      i. Septal deviation
      ii. Mid-nasal abnormalities
      iii. Choanal abnormalities
      iv. Nasopharyngeal narrowing
   h. Meniere disease
   i. Seizures (12%)
2. Skull and face
   a. Craniosynostosis
      i. Onset: commonly seen during the first year
      ii. Usually completing by the second or third year
      iii. Coronal suture most commonly involved
      iv. Acrocephaly
      v. Brachycephaly
      vi. Turricephaly
      vii. Oxycephaly
      viii. Flat occiput
      ix. High prominent forehead with or without frontal bossing
      x. Ridging of the skull usually palpable
   b. Cloverleaf skull
      i. Rare
      ii. Occurring in most severely affected individuals
      iii. Flattened sphenoid bone
      iv. Shallow orbits
      v. Hydrocephalus (progressive in 30%)
      vi. Midface (maxillary) hypoplasia
3. Eyes
   a. Exophthalmos (proptosis) (100%) secondary to shallow orbits resulting in frequent exposure conjunctivitis or keratitis
   b. Ocular hypertelorism (100%)
   c. Divergent strabismus
   d. Rare occurrence
      i. Nystagmus
      ii. Iris coloboma
      iii. Aniridia
      iv. Anisocoria
      v. Microcornea
      vi. Megalocornea
      vii. Cataract
      viii. Ectopia lentis
      ix. Blue sclera
      x. Glaucoma
      xi. Luxation of the eye globes
      xii. Blindness from optic atrophy
4. Nose
   a. Beaked appearance (parrot-like nose)
   b. Compressed nasal passage
   c. Choanal atresia or stenosis
   d. Deviated nasal septum
5. Mouth
   a. Mandibular prognathism
   b. Overcrowding of upper teeth
   c. Malocclusions
   d. V-shaped maxillary dental arch
   e. Narrow, high, or cleft palate and bifid uvula
   f. Oligodontia
   g. Macrodontia
   h. Peg-shaped
   i. Widely spaced teeth
6. Ears
   a. Narrow or absent ear canals
   b. Deformed middle ears
   c. Mild-to-moderate hearing losses
7. Other skeletal
   a. Cervical fusion (18%), C2–C3 and C5–C6
   b. Block fusions involving multiple vertebrae
   c. Subluxation of the radial heads
   d. Ankylosis of the elbows
8. Acanthosis nigricans (5%)
   a. Velvety, light-brown to black darkened, thickened skin with accentuated markings that occur in areas including the neck, axillae, groin, and breasts
   b. Usual age of onset: first decade (80%)

c. Only one case reported at birth (Koizumi et al. 1992)
d. Typical presentation (Arnaud-Lopez et al. 2007; Sharda et al. 2010)
   i. Crouzonoid facies
   ii. Acanthosis nigricans with atypical distribution
   iii. Choanal atresia
   iv. Hydrocephalus
   v. Oral abnormalities
   vi. Melanocytic nevi
   vii. Less frequent findings: vertebral abnormalities and deafness
9. CNS
   a. Chronic tonsillar herniation (approximately 73%). Of these, 47% have progressive hydrocephalus (Cinalli et al. 1995)
   b. Syringomyelia
   c. Mental retardation (3%)

Diagnostic Investigations

1. Skull radiographs
   a. Synostosis: The coronal, sagittal, lambdoidal, and metopic sutures may be involved.
   b. Craniofacial deformities
   c. Digital markings of skull
   d. Basilar kyphosis
   e. Widening of hypophyseal fossa
   f. Small paranasal sinuses
   g. Maxillary hypoplasia with shallow orbits
2. Cervical radiographs (Anderson 1997b)
   a. Butterfly vertebrae
   b. Fusions of the vertebral bodies and the posterior elements
      i. Cervical fusions in approximately 18% of patients
      ii. C2–C3 and C5–C6 affected equally
      iii. Block fusions may involve multiple vertebrae.
3. Limb radiographs
   a. Metacarpophalangeal analysis
   b. Subluxation of the radial head
4. Computed tomography (CT) scan: Comparative 3-D reconstruction analysis of the calvaria and cranial bases to precisely define the pathologic anatomy and to permit specific operative planning
5. Magnetic resonance imaging (MRI): Used to demonstrate occasional corpus callosum agenesis and optic atrophy
6. Molecular analysis
   a. *FGFR2* mutations in more than 50% of patients (*FGFR2* mutations also observed in Apert syndrome, Pfeiffer syndrome, and Jackson-Weiss syndrome)
   b. *FGFR3* ala391-to-glu mutation in all patients with associated acanthosis nigricans: Finding of acanthosis nigricans in a young child with Crouzon syndrome should prompt testing for the Ala391Gln substitution in *FGFR3* before testing for *FGFR2* mutations (Sharda et al. 2010)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected or with germinal mosaicism (Navarrete et al. 1991)
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Prenatal ultrasonography
      i. Exophthalmos
      ii. Ocular hypertelorism
   b. Identification of the disease-causing *FGFR2* mutation using
      i. CVS in the first trimester
      ii. Amniocentesis in the second trimester
      iii. Preimplantation genetic diagnosis (Harper et al. 2002)
3. Management
   a. Medical care
      i. No specific medical therapy available
      ii. Nasal continuous positive airway pressure device to relieve airway obstruction
      iii. Management of speech
   b. Surgical care
      i. Stage reconstruction to coincide with facial growth patterns, visceral function, and psychosocial development.
      ii. Early craniectomy with frontal bone advancement most often indicated to prevent or treat increased intracranial pressure because newborns with Crouzon syndrome develop multiple suture synostosis and fused synchondrosis.

iii. Fronto-orbital and midfacial advancements to help in the cosmetic reconstruction of facial dysmorphisms.
iv. A new technique, craniofacial disjunction, followed by gradual bone distraction (Ilizarov procedure) has been reported to produce complete correction of exophthalmos and improvement in the functional and esthetic aspects of the middle third of the face without the need for bone graft in patients aged 6–11 years.
v. Shunting procedures for hydrocephalus.
vi. Tracheostomy for airway compromise.
vii. Myringotomy to drain middle ear secretions secondary to distorted nasopharynx.
viii. Orthodontic management.

Cutis Marmorata Telangiectatica Congenita

In 1922, van Lohuizen1 first described cutis marmorata telangiectatica congenita (CMTC) as a pattern of reticulate erythema and telangiectasia, skin atrophy and/or ulceration.

Genetics/Basic Defects

1. Pathogenesis
   a. Unknown
   b. Most cases are sporadic
2. Hypothesis
   a. Environmental factors
   b. Multifactorial cause
   c. A nerve conduction defect (Bormann et al. 2001)
   d. A lethal gene surviving by mosaicism suggested by segmental distribution often with a sharp midline separation (Rogers and Poyzer 1982)
   e. Autosomal dominant inheritance with low or variable penetrance
      i. An affected parent showing more limited involvement than his offspring (Kurczynski 1982)
      ii. Two siblings with one having CMTC alone and the other showing associated anomalies (hypertension and acrocyanosis) (Andreev and Pramatarov 1979)

Clinical Features

1. Onset (Garzon and Schweiger 2004)
   a. Congenital: common
   b. Later onset (Way et al. 1974)
2. Reticulated vascular pattern
   a. Finely reticular or coarse pattern: will not resolve completely with warming of the skin
   b. Broad streaks of discolored skin in a "train-track-like" pattern
   c. Relatively fixed and discernable at rest
   d. Pallor of the skin between the vascular network pattern: often reported (Ben-Amitai et al. 2000)
   e. Often accompanied by:
      i. Phlebectasia (prominent veins)
      ii. Telangiectasias
      iii. Cutaneous and subcutaneous tissue atrophy: may manifest as hypoplasia of the affected limb (an inconsistent feature) (South and Jacobs 1978)
      iv. Ulceration of the affected skin, particularly involving the skin overlying the elbows and knees (Picascia and Esterly 1989)
      v. Hyperkeratosis
   f. The presence of atrophy and ulceration helps to differentiate CMTC from physiologic cutis marmorata
   g. Localized lesions
      i. Most commonly affecting the trunk and extremities
      ii. Sharp segmental pattern: easy to differentiate from physiologic cutis marmorata
   h. Generalized lesions
      i. Often unilateral
      ii. May involve face but mucosal involvement uncommon (Ben-Amitai et al. 2000)
      iii. Do not occur on the entire body surface (Devillers et al. 1999)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_62,
© Springer Science+Business Media, LLC 2012

3. Associated anomalies (27–80%) (Picascia and Esterly 1989; Devillers et al. 1999)
   a. Relatively high associated defects
      i. May represent true associations or coincidental
      ii. May represent a bias toward reporting cases with more severe anomalies
      iii. Inconsistency among authors regarding diagnostic criteria
   b. Asymmetry
      i. Limb asymmetry (hyperplasia or hypoplasia of a limb)
         a) The most common associated anomaly
         b) Cutaneous atrophy may be noted concomitantly with asymmetry
      ii. Facial asymmetry may occur
   c. Skeletal defects
      i. Syndactyly
      ii. Tendinitis stenosans
      iii. Hip dysplasia
      iv. Clubfoot
      v. Scoliosis
      vi. Macrocephaly
      vii. Skull asymmetry
      viii. Scaphoid scapula
      ix. Micrognathia
      x. Generalized osteoporosis
      xi. Consider Adams–Oliver syndrome and macrocephaly-CMTC if limb defects are present
   d. Other vascular anomalies
      i. May occur distant to the area of CMTC or within the same affected area (Picascia and Esterly 1989)
      ii. Capillary malformations (port-wine stains): the most commonly associated vascular birthmark occurring in 20% of patient (Ben-Amitai et al. 2000)
      iii. Sturge–Weber syndrome (Petrozzi et al. 1970)
      iv. Hemangiomas of infancy
      v. Multiple angiokeratomas
   e. Ocular anomalies
      i. Glaucoma
      ii. Infrequent anomalies
         a) Persistent arterial hyaloidia (an embryonic vessel that typically regresses)
         b) Granular retinal pigmentation
         c) Small optic disks
         d) Optic nerve atrophy
   f. Neurologic anomalies
      i. Macrocephaly: diagnostic feature of macrocephaly-CMTC syndrome
      ii. Hydrocephaly
      iii. Psychomotor retardation
      iv. Seizures
      v. Cerebral atrophy
      vi. Agenesis of the corpus callosum
      vii. Dilated ventricles
   g. Other cutaneous anomalies (may be coincidental) (Ben-Amitai et al. 2000)
      i. Congenital melanocytic nevi
      ii. Café au lait macules
      iii. Mongolian spots
   h. Other systemic anomalies (uncommon)
      i. Hypothyroidism
      ii. Cardiac defects
      iii. Genitourinary tract anomalies (Del Guidice and Nydorl 1986; Ben-Amitai et al. 2001; Sills et al. 2002; Fujita et al. 2003)
         a) Hypospadias
         b) Renal cysts
         c) Duplication of the renal collecting system
         d) Rectovaginal and ureterovaginal fistulae
         e) Absent clitoris
         f) Imperforate anus
         g) Unilateral ovarian agenesis
         h) Septate uterus
         i) Premature gonadal failure associated with de novo balance translocation affecting chromosomes 8 and 9
4. Suggested diagnostic criteria for cutis marmorata telangiectatica congenita (Kienast and Hoeger 2009)
   a. Major criteria
      i. Congenital reticulate (marmorated) erythema (27%)
      ii. Absence of venectasia (27%)
      iii. Unresponsiveness to local warming (27%)
   b. Minor criteria
      i. Fading of erythema within 2 years (18%)
      ii. Telangiectasia (5%)
      iii. Port-wine stain outside the area affected by CMTC (2%)
      iv. Ulceration (2%)
      v. Atrophy (2%)

5. Differential diagnosis
   a. Cutis marmorata (physiologic)
   b. Cutis marmorata (associated with genetic syndrome)
      i. Cornelia de Lange syndrome
      ii. Down syndrome
      iii. Homocystinuria
      iv. Divry and Van Bogaert syndrome
         a) A rare disorder
         b) Corticomeningeal angiomatosis
         c) Visual field defects
         d) Seizures
         e) "Marble" skin
   c. Reticulated capillary malformations
      i. A diffuse, generalized form of a "livedoid" capillary malformation involving the entire skin
      ii. Not associated with atrophy, ulceration or limb hypoplasia
      iii. Associated with a significant risk of associated visceral vascular anomalies (eye, brain, kidneys, and heart) and requires evaluation and follow-up (Enjolras and Garzon 2001)
   d. Bockenheimer syndrome (diffuse phlebectasia):
      i. A very rare disorder
      ii. Onset in infancy
      iii. Characterized by progressive venous varicosity
   e. Neonatal lupus erythematosus
   f. CMTC "syndrome"
      i. CMTC-macrocephaly syndrome
      ii. Adams–Oliver syndrome
      iii. CMTC phakomatosis pigmentovascularis

Diagnostic Investigations

1. Physical evaluation (Garzon and Schweiger 2004)
   a. Reticulated vascular pattern
   b. Limb length and girth
   c. Limb defects
   d. Scalp defects
   e. Head circumference
   f. Other associated anomalies
   g. Facial lesions
2. Ophthalmologic evaluation

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic cases: a low recurrence risk
      ii. A 50% risk if one of the parents is affected
   b. Patient's offspring: a 50% risk in autosomal dominant transmission, otherwise a low recurrence risk
2. Prenatal diagnosis: not reported
3. Management
   a. Careful physical examination to assess for other congenital anomalies
   b. Measurement of limb length and girth at the time of evaluation
   c. Baseline and follow-up ophthalmologic examinations should be performed when the vascular lesions affect the periocular skin
   d. Local supportive care including application of hydrocolloid dressings for ulcerations

Cystic Fibrosis

Cystic fibrosis (CF) is the most common Caucasian lethal genetic disorder (with gene frequency of 1 in 25) in the United States, where 4–5% of population have at least one CF allele. CF affects approximately 1 in 2,500 live births among Caucasians, 1 in 17,000 among African-Americans, and 1 in 90,000 among Asians. (Ruzal-Shapiro 1998)

Synonyms and Related Disorders

CFTR-related disorders; Congenital absence of vas deferens; Mucoviscidosis

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive
   b. *CF* gene mapped to chromosome 7q31.2
2. Molecular defect (Moskowitz et al. 2008)
   a. Caused by a single gene defect on chromosome 7 that encodes a cAMP-regulated chloride channel known as the cystic fibrosis transmembrane conductance regulator (CFTR)
      i. CFTR usually resides in the apical membrane of epithelial cells lining the airway, biliary tree, intestines, vas deferens, sweat ducts, and pancreatic ducts.
      ii. Insufficient fluid secretion secondary to inability of CFTR to transport chloride ion at the above sites causes higher viscidity of the protein portions of the secretions and obstructing the ducts, leading to plugging and dysfunction at the organ level.
      iii. CFTR also regulates the activity of other proteins that conduct ions and affects intracellular regulatory processes at the cellular level.
   b. Presence of close to 1,500 different disease-causing mutations of the *CFTR* gene (Ruzal-Shapiro 1998; O'Sullivan and Freedman 2009)
      i. Deletion mutations including delta F508 which, observed in over 70% of patients with CF, have a deletion of three contiguous base pairs resulting in the loss of a single amino acid, phenylalanine at codon 508)
      ii. Missense mutation (single base pair exchange within a normal length CFTR protein)
      iii. Nonsense mutations (exchange of a single base pair resulting in premature termination of the protein)
      iv. Frameshift mutations (the deletions or insertion of a single base pair)
   c. Classification of CFTR mutations (Culling and Ogle 2010)
      i. Class I mutations
         a) Introduce a stop codon prematurely
         b) Produce either an unstable mRNA with no detectable protein being made or an unstable protein that is rapidly degraded or has no functional capability
         c) No CFTR protein in the cell membrane
         d) E.g., G542X, 394delTT, 1717-1 G → A
      ii. Class II mutations
         a) Block the processing of the protein due to aberrant folding and subsequent

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_63,
© Springer Science+Business Media, LLC 2012

degradation when recognized as abnormal by cellular "quality control" mechanisms
   b) No CFTR protein at the apical cell membrane
   c) E.g., N1303K, ΔF508, 3905insT
iii. Class III mutations:
   a) Produce a CFTR protein that does not function as a chloride channel due to a block in regulation, despite being fully processed and correctly located
   b) Within this class there are mutations that have very little function (G551D), those where ATP is less potent at stimulating activity (S1255P) and those with reduced absolute activity (G551S, G1244E and G1349D).
iv. Class IV mutations
   a) Produce a fully processed and correctly located CFTR protein
   b) However, the conductance and/or gating properties of the channel have been altered by mutations in the membrane spanning domains
   c) Extent to which conduction is affected varies between mutations
   d) E.g., R117H, R347P
v. Class V mutations
   a) Result in a reduction in the synthesis of CFTR protein
   b) Include promoter mutations, the promotion of alternative splicing and inefficient protein maturation
   c) E.g., A455E, 2789 + 5G → A, IVS8-5T
vi. Class VI mutations
   a) Presence of functional but unstable CFTR protein at the apical membrane
   b) Decreased stability on CFTR protein
   c) E.g., Q1412X, 4326delTC, 4279insA

d. Genotype-phenotype correlations (Ruzal-Shapiro 1998)
   i. Phenotypic presentation of the disease: probably related to the underlying genetic abnormality
   ii. Patients with homozygous delta F508 typically have respiratory distress and malabsorption.
   iii. Patients with less severe variations of the disease or typical CF with borderline normal sweat tests may have other haplotypes

Clinical Features

1. Signs and symptoms of cystic fibrosis (O'Sullivan and Freedman 2009)
   a. General (any age)
      i. Family history of cystic fibrosis
      ii. Salty-tasting skin
      iii. Clubbing fingers and toes
      iv. Cough with sputum production
      v. Mucoid *Pseudomonas aeruginosa* isolated from airway secretions
      vi. Hypochloremic metabolic alkalosis
   b. Neonatal
      i. Meconium ileus
      ii. Protracted jaundice
      iii. Abdominal or scrotal calcifications
      iv. Intestinal atresia
   c. Infancy
      i. Persistent infiltrates on chest radiographs
      ii. Failure to thrive
      iii. Anasarca or hypoproteinemia
      iv. Chronic diarrhea
      v. Abdominal distention
      vi. Cholestasis
      vii. *Staphylococcus aureus* pneumonia
      viii. Idiopathic intracranial hypertension (vitamin A deficiency)
      ix. Hemolytic anemia (vitamin E deficiency causes anemia by increasing fragility and reducing lifespan of red blood cells)
   d. Childhood
      i. Chronic pansinusitis or nasal polyposis
      ii. Steatorrhea
      iii. Rectal prolapse
      iv. Distal intestinal obstruction syndrome or intussusceptions
      v. Idiopathic recurrent or chronic pancreatitis
      vi. Liver disease
   e. Adolescence and adulthood
      i. Allergic bronchopulmonary aspergillosis
      ii. Chronic pansinusitis or nasal polyposis
      iii. Bronchiectasis
      iv. Hemoptysis
      v. Idiopathic recurrent pancreatitis
      vi. Portal hypertension
      vii. Delayed puberty
      viii. Azoospermia secondary to congenital bilateral absence of the vas deferens

2. Classic clinical triad
   a. Exocrine pancreatic insufficiency
   b. Chronic obstructive pulmonary disease
   c. Elevation of sodium and chloride concentration in sweat
3. Chronic sino-pulmonary disease
   a. Varying widely in age of onset and rate of progression
   b. Clinical course
      i. Newborn with CF with histologically normal respiratory systems
      ii. First few months of age
         a) Epithelial chloride channel defect, leading to abnormal respiratory secretions, bronchopulmonary infections, and airway obstruction
         b) Clinical manifestations including cough, wheezing, retractions, and tachypnea
   c. Persistent endobronchial infection and inflammation with typical CF pathogens (Ruzal-Shapiro, 1998)
      i. *Staphylococcus aureus*
         a) Responsible for the majority of lung disease when CF was first described
         b) Commonly isolated in the first year of life from the sputum of patients with CF
         c) Typically controlled by antibiotic therapy
         d) Currently only 10% of adult patients with CF are chronically colonized by the pathogen.
      ii. Mucoid and non-mucoid *Pseudomonas aeruginosa*
         a) The most prevalent of the pathogens in CF, causing chronic infection in up to 90% of adults and 80% of children
         b) Initial colonization with non-mucoid forms
         c) Subsequent conversion to mucoid variants
      iii. *Hemophilus influenzae*
         a) Commonly seen in babies
         b) Rarely encountered in the adults
      iv. Other pulmonary pathogens
         a) *Burkholderia cepacia*
         b) Aspergillus
         c) Mycobacteria
         d) Respiratory viruses
   d. Upper airway disease
      i. Opacified or maldeveloped sinuses
      ii. Nasal polyps (up to 26% of patients)
      iii. Sinusitis
         a) Facial pain
         b) Swelling
         c) Tenderness
         d) Air-fluid levels on radiograph
   e. Pulmonary exacerbations
      i. Persistent cough and sputum production
      ii. Increased dyspnea
      iii. Reduction in pulmonary function
      iv. Increased hemoptysis: a life-threatening complication but fatal hemoptysis is rare
      v. Digital clubbing
      vi. Changes in chest radiographic findings
      vii. Bronchiolitis
      viii. Increased rales or rhonchi
      ix. Decreased air exchange
      x. Increased use of accessory muscles of respiration
      xi. Spontaneous pneumothorax (5–8%), a life-threatening complication
      xii. Obstructive airway disease, leading to respiratory insufficiency associated with bronchiectasis
4. Gastrointestinal abnormalities
   a. Intestine
      i. Meconium ileus at birth
         a) An obstruction of the distal ileum or proximal colon with thickened, viscous meconium in 15–20% of CF patients developed *in utero* in the second trimester
         b) Virtually diagnostic of CF
      ii. Meconium peritonitis (rupture of the intestine secondary to complete obstruction)
      iii. Meconium plug syndrome in the newborn infants, a more benign condition characterized by blockage of the colon
      iv. Distal intestinal obstruction syndrome later in childhood, adolescence, or adulthood (10%), presenting as crampy abdominal pain, usually with decreased stooling
      v. Rectal prolapse occurring in less than 1% of patients but may be the presenting symptom, particularly in infants
      vi. Occasional intussusception
      vii. Gastroesophageal reflux

b. Pancreas
   i. Pancreatic exocrine insufficiency
      a) Failure of the pancreas to produce sufficient digestive enzymes to allow breakdown and absorption of fats and protein
      b) Obstruction of the pancreatic duct *in utero* with resultant progressive loss of exocrine pancreatic acini and their function
      c) A hallmark of the disease, occurring in 90% of patients by 1 year of age
      d) Leads to frequent, bulky, foul-smelling, oily stools
      e) Steatorrhea (presence of excessive undigested fat in the stool)
      f) Failure to thrive is commonly in the patients with CF
   ii. Recurrent pancreatitis in few patients
   iii. CF-related diabetes mellitus (Nathan et al. 2010)
      a) Affect approximately one third of all CF patients
      b) Rare before 10 years of age
      c) Resulting from a loss of functional pancreatic β cells and a state of relative insulin deficiency
      d) Oral glucose tolerance test as a screening tool
      e) HbA1c, an accepted diagnostic test for diabetes in the general population (International Expert Report 2009), cannot be used as screening tool because levels are often falsely low (Holl et al. 2000).

c. Liver
   i. Prolonged obstructive jaundice in a few affected infants, presumably secondary to obstruction of extrahepatic bile ducts by thick bile along with intrahepatic bile stasis
   ii. Chronic hepatic disease manifested by clinical or histologic evidence of focal biliary cirrhosis or multi-lobular cirrhosis

5. Genitourinary manifestations (Ruzal-Shapiro 1998)
   a. Congenital bilateral absence of the vas deferens in most males
      i. Leading to azoospermia
      ii. A significant cause of infertility
   b. Infertility common in women
      i. Due to increased amounts of thick mucus in the cervical canal
      ii. An increased incidence of amenorrhea
      iii. Occasional patients carrying pregnancies to term without significant respiratory deterioration
6. Skeletal manifestations (Ruzal-Shapiro 1998)
   a. Hypertrophic pulmonary osteoarthropathy
      i. Rarely seen in children with CF
      ii. Increasing frequency with increasing age and severity of disease
   b. Triad of skeletal manifestations
      i. Clubbing of fingers and toes
      ii. Arthritis
      iii. Periosteal new bone formation
7. Nutritional abnormalities
   a. Failure to thrive, a common manifestation during infancy and beyond
   b. Poor appetite
   c. Weight loss
   d. Fatigue
   e. Prone to heat prostration
   f. Hypoproteinemia with or without edema, anemia, and deficient fat-soluble vitamins A, D, E, and K
   g. Peripheral neuropathy secondary to deficient vitamin E
   h. Delayed puberty largely due to nutritional factors
   i. Potentially lethal protein-energy malnutrition in some infants
   j. Development of some degree of malabsorption by 4 years of age in roughly 85% of patients
8. Salt losing syndromes
   a. Acute salt depletion
   b. Chronic hypochloremic or hyponatremic alkalosis
   c. Excessive salt loss in the sweat potentially fatal for patients exposed to moderate heat or during prolonged hot weather
9. Prognosis
   a. Respiratory failure: the leading cause of death in CF and occurs eventually in nearly all patients
   b. Current median survival: approximately 35 years in the United States
   c. Current data suggesting a lifespan exceeding 50 years for those diagnosed and treated early

Diagnostic Investigations

1. Newborn screening
   a. Measuring blood immunoreactive trypsinogen in dried blood spots
      i. Elevated levels in most CF infants (85–90% sensitive)
      ii. Associated with a relatively large number of false positive results
      iii. Diagnosis must be confirmed by sweat tests or genotyping (CF multimutational analysis)
   b. Use DNA-based testing on dried blood spots by CFTR multimutational analysis
2. Sweat test
   a. The traditional method of CF diagnosis
   b. Remains the most readily available and clinically useful way of making the diagnosis of CF, provided it is done according to strict guidelines with pilocarpine iontophoresis and a quantitative determination of chloride concentration (LeGrys et al. 2007)
   c. Reliably identifies the vast majority of patients with CF who have multiorgan involvement including the lungs and pancreas
   d. Using pilocarpine iontophoresis technique to produce sweat for chloride analysis
   e. Sweat chloride concentrations
      i. >60 mEq/L, observed in:
         a) CF patients with clinical manifestation of chronic pulmonary disease and/or pancreatic insufficiency
         b) CF patients with positive family history
         c) Untreated Addison disease
         d) Ectodermal dysplasia
         e) Certain types of glycogen storage diseases
         f) Untreated hypothyroidism
         g) A few normal adults
      ii. <60 mEq/L, observed in:
         a) Very few patients with CF (fewer than 1% of CF patients when they are well)
         b) CF patients with malnutrition and edema
3. Indications for sweat testing
   a. Meconium ileus or peritonitis (neonate)
   b. Jaundice (infancy)
   c. Hypochloremic alkalosis (infancy)
   d. Heat prostration (infancy or adulthood in males)
   e. Failure to thrive (infancy to childhood)
   f. Rectal prolapse (childhood)
   g. Nasal polyposis (childhood to adulthood)
   h. Panopacification of sinuses or pansinusitis (childhood)
   i. Pancreatitis (late childhood to early adulthood)
   j. Unexplained cirrhosis (childhood to adolescence)
   k. Gallstones (late childhood to early adulthood)
   l. Congenital bilateral absence of the vas deferens or azoospermia (any age but more obvious in adults)
   m. Recurrent or persistent pneumonia (any age)
   n. Staphylococcal pneumonia (any age but especially infants)
   o. Mucoid *Pseudomonas* in lung (any age)
   p. Bronchiectasis (any age)
   q. Positive family history in siblings or first cousins (any age)
4. Causes of false-positive or false-negative sweat test results (O'Sullivan and Freedman 2009)
   a. False-positive result
      i. Atopic dermatitis (eczema)
      ii. Malnutrition
      iii. Congenital adrenal hyperplasia
      iv. Mauriac syndrome
      v. Fucosidosis
      vi. Ectodermal dysplasia
      vii. Klinefelter syndrome
      viii. Nephrogenic diabetes insipidus
      ix. Adrenal insufficiency
      x. Hypothyroidism
      xi. Autonomic dysfunction
      xii. Environmental deprivation
      xiii. Munchausen syndrome by proxy
   b. False-negative result
      i. Dilution of sample
      ii. Malnutrition
      iii. Peripheral edema
      iv. Low sweat rate (quantity not sufficient)
      v. Hypoproteinemia
      vi. Dehydration
      vii. CFTR mutations with preserved sweat duct function (e.g., 3,849 + 10 kb C → T; Arg117His–7T)

5. Other clinical laboratory tests
   a. Prolonged prothrombin time secondary to deficient vitamin K
   b. Shortened red blood cell survival time secondary to deficient vitamin E
   c. Hypochloremic alkalosis secondary to high salt loss
   d. Isolation of organisms from the respiratory tract
      i. *Pseudomonas aeruginosa*
      ii. *Burkholderia cepacia*
      iii. *Staphylococcus aureus*
   e. Oxygen saturation
6. Radiographic findings
   a. Chest X-ray
      i. Earliest finding: hyperinflation often with right upper lobe mucus retention
      ii. Progression to widespread bronchial dilatation, cysts, linear shadows, and infiltrates
   b. Sinuses X-ray: nearly universal presence of pansinusitis
   c. Abdominal X-ray
      i. Uncomplicated meconium ileus: multiple loops of dilated small bowel
      ii. Meconium peritonitis
         a) Calcifications within the abdominal cavity or even within the scrotum
         b) Resulting from an in utero perforation or complicated meconium ileus associated with volvulus
   d. Skeletal X-ray
      i. Arthritis
      ii. Periostitis in the diaphysis of the tubular bones
7. CT scan, especially high-resolution CT scan (Ruzal-Shapiro 1998)
   a. Readily identify air-trapping in the expiratory phase
   b. Mosaic perfusion, a secondary sign of small airway abnormality
   c. Centilobular nodule characterized by a cluster of ill-defined nodules corresponding to branching terminal airways filled with secretions
   d. Classic findings of CF of progressive bronchiectasis involving the large airways
      i. Thick parallel bronchial walls seen as linear shadows or tram-line tracts
      ii. Ring shadows representing dilated thick-walled bronchi
      iii. Multiple nodular densities representing mucus plugging
8. Pulmonary function test
9. Molecular testing
   a. More than 1,000 different mutations described to date
   b. ΔF508 mutation (deletion of a phenylalanine residue at position 508 in the 1,480 amino acid protein)
      i. Present in about 70% of CF alleles in the U.S.
      ii. Homozygous ΔF508 mutation in about 50% of American CF patients
   c. Higher frequencies of certain mutations in different ethnic groups
      i. A455E mutation in Dutch CF patients
      ii. W1282X mutation in Ashkenazi Jewish CF patients
   d. Presence of two alleles with CF causing mutations confirms the diagnosis
   e. Conventional commercial genotyping testing for about 80 specific mutations in CFTR (including ΔF508 mutation) identifies about 95% of all CF alleles.
10. Carrier testing available for family members of known patients or for couples without a family history
11. In general, a diagnosis of cystic fibrosis can be made in a patient with clinical features of the disease if the concentration of chloride in sweat is greater than 60 mmol/L or if it is in the intermediate range (30–59 mmol/L for infants less than 6 months of age, 40–59 mmol/L for older individuals), and two disease-causing CFTR mutations are identified (Farrell et al. 2008).

Genetic Counseling

1. Recurrence risk
   a. Both parents carrying at least one abnormal copy of the *CF* gene
   b. Patient's siblings
      i. 25% with CF disease
      ii. 50% with CF carrier
   c. Patient's offspring: low recurrence risk unless the spouse is affected or a carrier of CF mutation

2. Prenatal diagnosis (Rosenstein 1998)
   a. Ultrasonography
      i. Hyperechogenic fetal bowel suggestive of intestinal obstruction: perform carrier testing for CF gene mutations in the parents
         a) Diagnosis of CF highly likely in the fetus if both parents are carriers of a CF mutation
         b) Confirmed CF diagnosis by direct mutation analysis of amniotic fluid cells
      ii. Meconium peritonitis secondary to small bowel perforation *in utero*
         a) Associated with CF in only 7% of cases
         b) Presence of abdominal calcification usually associated with causes of meconium peritonitis other than CF
         c) Absence of abdominal calcifications favors the diagnosis of CF, to be confirmed by parental CF carrier testing and mutation analysis of fetal cells in at-risk couples
   b. Molecular genetic analysis
      i. Prenatal diagnosis accomplished in most families with an affected member by mutation analysis from fetal cells obtained from CVS (10 weeks) or amniocentesis (15–18 weeks)
      ii. Preimplantation genetic diagnosis to screen embryos before implantation, an alternative for at-risk couples
         a) A cleavage stage biopsy of embryo on day 2 or 3 after in vitro fertilization
         b) Removal of one or two cells for genetic analysis by nested polymerase chain reaction and heteroduplex formation
         c) Transfer of normal or carrier embryos to establish pregnancy
         d) Followed by CVS or amniocentesis to confirm the original diagnosis
   c. Postnatal sweat testing mandatory in all cases in which the diagnosis of CF has been made or excluded on the basis of prenatal DNA analysis
3. Management
   a. Antibiotic treatment of acute respiratory infections and exacerbations of chronic endobronchial infections
      i. Purpose
         a) To improve pulmonary function
         b) To improve exercise tolerance
         c) To improve quality of life
      ii. Short term oral ciprofloxacin for mild exacerbations by pseudomonas agent with caution in the younger pediatric age patients
      iii. Intravenous antibiotics, a mainstay of treatment of acute exacerbations of pulmonary disease
         a) Aminoglycoside (usually tobramycin) and β-lactam antibiotics
         b) Implanted central lines or peripheral vein catheters to maintain IV access
      iv. Aerosol (inhaled) antibiotics such as tobramycin
      v. Other aerosol antibiotics such as colistin
   b. Airway clearance and exercise (Marshall and Samuelson 1998)
      i. Percussion and postural drainage in an attempt to keep the airways free of infected and obstructive secretions
      ii. Positive expiratory pressure (PEP) devices to promote mucous clearance by preventing airway closure and increase collateral ventilation
      iii. ThAIRapy Vest, a chest wall compression and oscillation system comprising a fitted vest coupled to a pneumatic compressor
      iv. Flutter valve vibrating devices
      v. Directed exhalation techniques
   c. Sodium cromolyn (Intal™) or nedocromil (Tilade™) beneficial in some patients
   d. Use of inhaled (aerosolized) bronchodilators such as β-adrenergics
   e. Use of inhaled alpha dornase (DNase) (Pulmozyme™) to reduce sputum viscosity by cleaving extracellular neutrophil-derived DNA and brings about sustained improvement in pulmonary function in many patients with CF
   f. Avoid cough depressants
   g. Oxygen therapy if indicated
   h. Anti-inflammatory therapies
      i. Glucocorticoids: useful in selected patients
      ii. Ibuprofen
   i. Nutritional support to prevent malnutrition
      i. Provide pancreatic enzyme supplements and vitamins to correct malabsorption
      ii. Provide normal or high-fat diets with essential fatty acids necessary for growth and development
      iii. Provide fat-soluble vitamin supplements

j. Management of gastrointestinal obstructive complications
   i. Gastrografin enema for treatment of fecal impaction with distal intestinal obstruction syndrome
   ii. Surgery for intussusception if indicated
   iii. Surgery necessary to correct obstruction due to meconium ileus in most newborns
k. Management of biliary tract disease
   i. Treatment of severe focal or multi-lobular biliary cirrhosis, portal hypertension, and hypersplenism
      a) Sclerosing of esophageal varices
      b) Hepatic shunt procedures
      c) Liver transplantation
   ii. Cholecystectomy for gallstones
   iii. Urodeoxycholic acid for selected cases of liver dysfunction
l. Management of CF-related diabetes mellitus
   i. Dietary management
   ii. Insulin often required
   iii. Complementary diabetes pharmaceutical agents: no current place in management of CF related diabetes (Nathan et al. 2010)
m. Management of pneumothorax
   i. Chest tube drainage
   ii. Followed by simple surgical oversewing of blebs if the initial air leak does not resolve
   iii. Followed by definitive pleural ablation if necessary
n. Management of hemoptysis
   i. Reassurance in most cases
   ii. Additional vitamin K
   iii. Discontinue drugs that may interfere clotting
   iv. Bronchial artery embolization by interventional radiologic techniques in unusual cases
o. Management of respiratory failure
   i. Oxygen administration
   ii. Tracheal intubation and mechanical ventilation in terminally ill patients on the lung transplant waiting list
   iii. Lung transplantation: now an accepted therapy in patients with end-stage lung disease (Rosenblatt 2009)
      a) Acceptable survival rate
      b) Good quality of life
      c) Overall survival, however, still lags behind other solid-organ transplants
      d) Despite the higher incidence of diabetes mellitus, poor nutrition, and colonization with both multi-resistant and pan-resistant Gram-negative organisms, the patients with CF clearly benefit from lung transplantation
   iv. Heart-lung and lung transplantation successfully applied to patients with end-stage CF patients (Zuckerman and Kotloff 1998)
p. Cystic fibrosis in pregnancy (Whitty 2010)
   i. Women with cystic fibrosis (CF): now living to childbearing age and many have successful pregnancies
   ii. Improvement of fertility and pregnancy outcome:
      a) Preconception care with optimization of pulmonary function
      b) Eradication of pulmonary infection
      c) Improved nutritional status
      d) Improved diabetes
   iii. Women with CF with poor pulmonary function and nutrition, and less than ideal body weight: more likely to suffer adverse outcomes
   iv. Women with CF and pulmonary hypertension: risk mortality
   v. Women with lung transplants can have successful pregnancy, but the risk of organ rejection and death are high
q. Fertility in men with cystic fibrosis (Smith 2010)
   i. Men with CF, now surviving longer, may wish to be fertile and want to have children regardless of the disease severity (Sawyer et al. 2005).
   ii. Obstructive azoospermia in men with CF are due to (Kaplan et al. 1968; Holsclaw et al. 1971):
      a) Congenital bilateral absence of the vas deferencs, or
      b) Atrophy or complete absence of the epididymis or seminal vesicles
   iii. Sperm capable of fertilizing mature oocytes by intracytoplasmic sperm injection in vitro can be extracted from the majority of men with cystic fibrosis

iv. Sperm may be retrieved either by aspiration from the caput of the epididymis or directly from the testis or other alternative procedures

r. Gene therapy in CF patients by *in vivo* gene transfers (targeted lung delivery of aerosolized gene vectors)

Fig. 1 This 5-month-old infant has history of failure to thrive, foul-smelling stools and excessive spitting. The patient is positive for two copies of the ΔF508 mutation

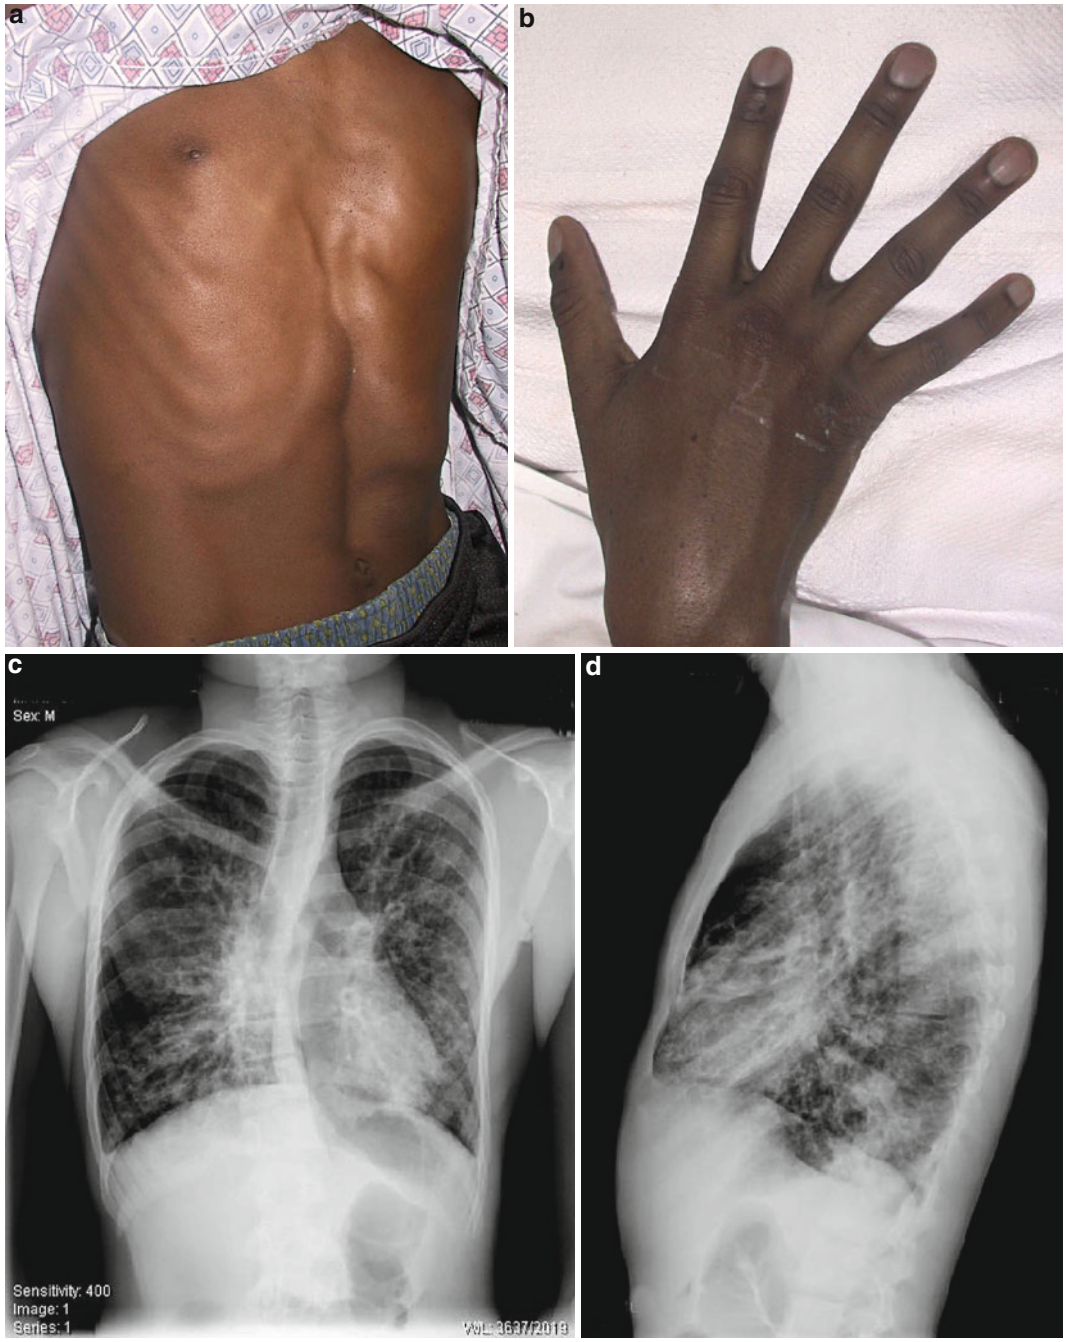

Fig. 2 (**a–d**) A 16-year-old boy with cystic fibrosis showing an emaciate chest, club fingers, and a honeycomb-like chest with air trapping illustrated by chest radiographs

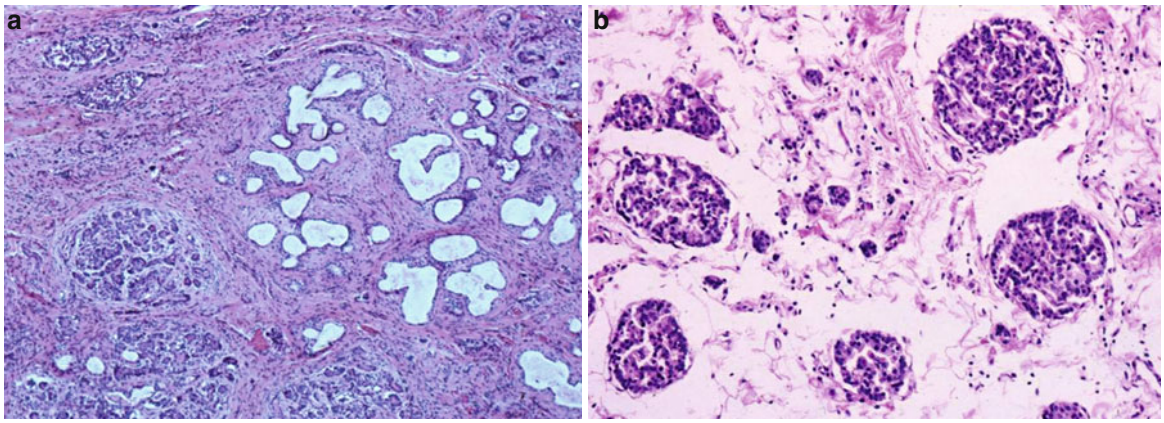

Fig. 3 (**a**, **b**) Photomicrograph of the pancreas of a 16-year-old male who died of bronchiectasis and bronchopneumonia. In the left photomicrograph, the exocrine glands (acini) are mostly absent. Irregularly dilated exocrine ductules are lined by flattened atrophic epithelium. Many unaffected islets of Langerhans are present at left lower corner. In the right photomicrograph with higher magnified, there are many islets of Langerhans but normal exocrine glands and ductules are absent

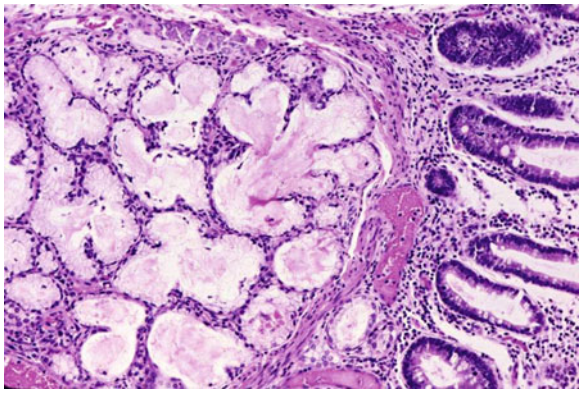

Fig. 4 Photomicrograph of the duodenum of the same patient. The Brunner's glands in the submucosa are distended by inspissated secretion. Three mucosal crypts are also slightly dilated

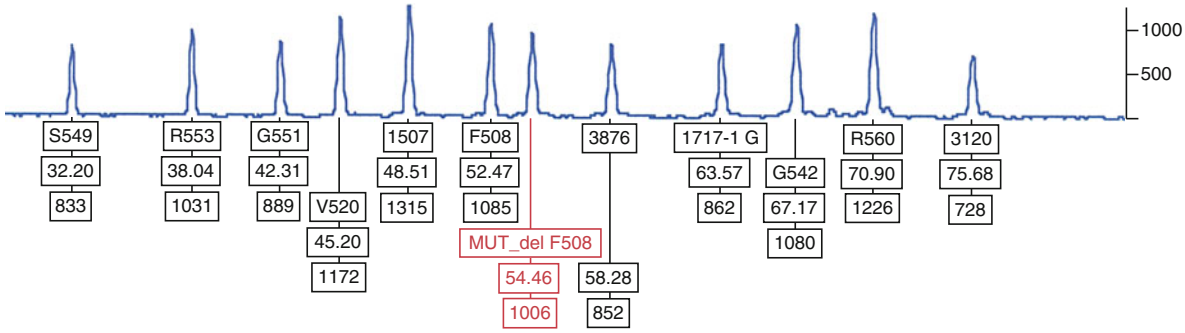

Fig. 5 Fragment size separation of CFTR mutations using capillary gel electrophoresis (ABI 310 genetic analyzer, Applied Biosystems). A mutation in ΔF508 is noted in *red*

Dandy–Walker Malformation

In 1954, Benda introduced the term Dandy–Walker syndrome to indicate the association of (1) ventriculomegaly of variable degree, (2) a large cisterna magna, and (3) a defect in the cerebellar vermis through which the cyst communicates with the fourth ventricle. Currently, the following findings are included in the Dandy–Walker syndrome or malformation: (4) cystic dilatation of the fourth ventricle, (5) dysgenesis of the cerebellar vermis, and (6) a high position of the tentorium. The Dandy–Walker malformation has prevalence of about 1 in 30,000 live births and found in 4–12% of infantile hydrocephalus.

Genetics/Basic Defects

1. Heterogeneous etiology
   a. Isolated
   b. A part of a Mendelian disorder
   c. A part of a chromosome disorder
      i. Trisomy 18
      ii. Triploidy
      iii. Trisomy 13
   d. Environmental factors
2. Uncertain significance of Dandy–Walker variant and mega-cisterna magna

Clinical Features

1. Maternal polyhydramnios/oligohydramnios
2. Fetal anomalies
   a. Echogenic bowel
   b. Effusions/hydrops
   c. Single umbilical artery
   d. Growth restriction
   e. Abundant nuchal folds
   f. Cystic hygroma
3. Neuropathologic triad
   a. Cystic dilatation of the fourth ventricle
   b. Hypoplasia of the cerebellar vermis
   c. Hydrocephalus
4. Associated intracranial anomalies (70% of cases)
   a. An enlarged posterior fossa
   b. Ventriculomegaly
   c. Atresia of the foramina of Magendie and Luschka
   d. Midline anomalies
      i. Agenesis of the corpus callosum
      ii. Holoprosencephaly
      iii. Occipital meningocele and encephalocele
   e. Porencephalic cyst
   f. Migrational disorder
   g. Gyral abnormalities
   h. Microcephaly
5. Non-CNS associated malformations
   a. Facial clefting
   b. Cardiovascular defects
   c. Diaphragmatic hernia
   d. Omphalocele
   e. Polycystic kidneys
   f. Spinal defects
   g. Limb defects
      i. Polydactyly
      ii. Syndactyly
6. Common presenting signs and symptoms
   a. Macrocrania
   b. Bulging fontanel
   c. Upward gaze palsy
   d. Hypertelorism
   e. Strabismus

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_64,
© Springer Science+Business Media, LLC 2012

f. Hypotonia
g. Headache and vomiting
h. Seizures
i. Hemiparesis
j. Facial palsy
k. Palpebral ptosis
l. Pyramidal signs
m. Cerebellar dysfunction
n. Motor dysfunction
o. Mental retardation: subnormal intelligence reported in 40–70% of cases

7. Prognosis
   a. Grim but not uniformly fatal
   b. Worst prognosis when there are associated anomalies and chromosome abnormalities
   c. Better chance of normal outcome for isolated Dandy–Walker variant

Diagnostic Investigations

1. Sonography
   a. Sonographic diagnosis of classic Dandy–Walker malformation: straightforward from mid-gestation
   b. Detection of Dandy–Walker malformation as early as 14 weeks using vaginal sonography
   c. In the transcerebellar view
      i. An enlarged cisterna magna connected to the area of the fourth ventricle through a defect in the cerebellar vermis
      ii. Presence of borderline-to-overt ventriculomegaly
      iii. Frequent association of other neural and extra-neural malformation
2. CT and MRI of the brain
   a. Large median posterior fossa cyst widely communicating with the fourth ventricle
   b. Cystic enlargement of the fourth ventricle
   c. Cerebellar vermis dysgenesis
   d. An upwardly displaced tentorium
   e. Hydrocephalus
   f. Atresia of the foramina of Magendie and Luschka
   g. Frequently associated CNS anomalies
      i. Agenesis of corpus callosum
      ii. Occipital encephalocele
      iii. Porencephalic cyst
      iv. Holoprosencephaly
      v. Others

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: a low recurrence risk in the order of 1–5% unless the Dandy–Walker malformation is a part of a mendelian disorder or associated with chromosome anomaly.
   b. Patient's offspring: not surviving to reproductive age because of severe neurologic deficits associated with major malformations.
2. Prenatal diagnosis
   a. Ultrasonography for detecting unique previously described CNS malformations
   b. MRI of the fetal CNS
   c. Prenatal amniocentesis for fetal karyotyping
3. Management
   a. Ventriculoperitoneal shunt
   b. Cyst-peritoneal shunt
   c. Ventriculocystoperitoneal shunt
   d. Posterior fossa craniectomy with cyst fenestration

Fig. 1 (**a–c**) An 8-month-old patient with Dandy–Walker malformation associated with multiple congenital anomalies including facial dysmorphism, skin tags (pseudotails) on the cheek, and limb anomalies

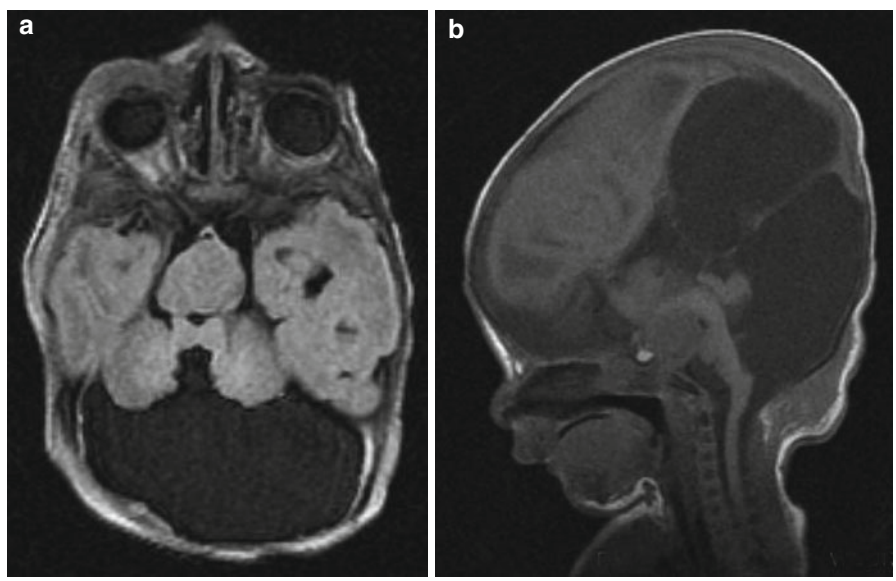

Fig. 2 (**a, b**) MRI of the brain of the patient in Fig. 1 shows Dandy–Walker malformation with a large posterior fossa cyst which communicates with dilated fourth ventricle. In addition, this patient also has agenesis of corpus callosum, hydrocephalus, and vermis dysgenesis

De Lange Syndrome

In 1933, Cornelia de Lange reported two non-familial infant girls with severe mental retardation and multiple abnormalities of the skull, face, and extremities. Earlier in 1916, Brachmann had described a child with similar features. The syndrome is also called Brachmann-de Lange syndrome or Cornelia de Lange syndrome. The prevalence is estimated to be 1 in 10,000 births (Opitz 1985).

Synonyms and Related Disorders

Brachmann-de Lange syndrome; NIPBL-related Cornelia de lange syndrome; SMC1A-related Cornelia de Lange syndrome; Typus degenerativus amstelodamensis

Genetics/Basic Defects

1. A heterogeneous clinical entity
   a. Sporadic in vast majority of cases (99%) (Russell et al. 2001)
   b. Striking concordance in MZ twins
   c. Rare familial occurrences
      i. Autosomal dominant inheritance
      ii. Autosomal recessive inheritance: unlikely
2. Inconsistent chromosome abnormalities occasionally associated with de Lange phenotype. In addition, the following significant cytogenetic findings were reported:
   a. Deletions of chromosome 5p13 where Cornelia de Lange syndrome gene (*NIPBL*) have been reported in two cases (Taylor and Josifek 1981; Hulinsky et al. 2005)
   b. An increased rate of precocious sister chromatic separation has been reported in affected individuals (Kaur et al. 2005)
3. Combined mutations in *NIPBL*, *SMC1A*, and *SMC3*: identified in nearly 60% of patients with a confident clinical diagnosis of de Lange syndrome (Dorsett and Krantz 2009)
   a. *Nipped-B-like* (*NIPBL*) gene on chromosome 5p13 (Krantz et al. 2004)
      i. At least 50% of cases are caused by loss-of-function mutations of *NIPBL* gene
      ii. Required for binding of the cohesion complex that mediates sister chromatid cohesion to chromosome (Dorsett 2007)
   b. *SMC1A* gene
      i. X-linked (on Xp11)
      ii. Encodes the SMC1 subunit of mitotic cohesion
      iii. Missense or small in-frame deletion was noted in approximately 5% of individuals with clinical diagnosis of de Lange syndrome
   c. *SMC3* gene
      i. On chromosome 10q25
      ii. Mutation is heteroallelic with a wild-type allele
4. De Lange syndrome, thus, considered to be a cohesinopathy, along with Roberts syndrome/SC phocomelia (Tekin and Bodurtha 2009)
5. Genotype-phenotype correlations
   a. More severe *NIPBL* mutations (such as deletions or truncations): usually cause more severe clinical manifestations than missense mutations
   b. Missense mutations in *NIPBL*: associated with mild phenotypic features

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_65,
© Springer Science+Business Media, LLC 2012

c. Mutations in SMC1A and SMC3: associated with a milder phenotype with absence of limb defects and other structural anomalies
d. In the mildest forms, affected individuals generally have mild to moderate mental retardation and, at least at a young age, typical facial characteristics

Clinical Features

1. Marked clinical variability
2. General history
   a. Prenatal and/or postnatal growth deficiency
   b. Prematurity
   c. Diminished sucking and swallowing ability
   d. Low pitched cry (74%) in the newborn period and in the early infancy but may disappear in the late infancy
   e. Global developmental delay
   f. Initial hypertonicity
   g. Recurrent respiratory tract infections
   h. Gastroesophageal reflux
   i. Failure to thrive
3. Growth
   a. Prenatal onset growth retardation
   b. Short stature
4. Skin
   a. Hypertrichosis (hirsutism) (78%): often with hairy whorls over the shoulders, lower back, and extremities
   b. Cutis marmorata (60%)
   c. Periorbital "cyanosis"
5. Characteristic craniofacial appearance
   a. Microcephaly (98%)
   b. Brachycephaly
   c. Hairy (low hairline) forehead
   d. Mask like (grim, devoid of expression) facies
   e. Hypertelorism
   f. Antimongoloid slant of palpebral fissures
   g. Synophrys (prominent bushy, confluent eyebrows joining at the nose) (99%)
   h. Long and curly eyelashes (99%)
   i. Depressed nasal bridge (83%)
   j. Small nose
   k. Anteverted nares (88%)
   l. Micrognathia (84%)
   m. Long bulging, prominent philtrum (94%)
   n. Thin upper lip (94%)
   o. Central depression below lower lip
   p. Down-turned corners of the mouth (94%)
   q. Late eruption of teeth
   r. Widely spaced teeth (86%)
   s. High-arched palate (86%)
   t. Low set, malformed, and hairy ears (70%)
   u. Low posterior hairline (92%)
   v. Short neck (66%)
6. Eye abnormalities (57%)
   a. Strabismus
   b. Nystagmus (37%)
   c. Myopia (60%)
   d. Ptosis (45%)
   e. Microcornea
   f. Astigmatism
   g. Optic atrophy
   h. Coloboma of the optic nerve
   i. Eccentric pupils
   j. Microphthalmia
   k. Blue sclerae
7. Limb abnormalities
   a. Upper extremities
      i. Micromelia (shortened limbs) (93%)
      ii. Ectrodactyly/oligodactyly/phocomelia (27%)
      iii. Clinodactyly of the fifth fingers (74%)
      iv. Small hands
      v. Proximally placed thumbs
      vi. Camptodactyly
      vii. Webbings of fingers
      viii. Brachydactyly
      ix. Flexion contractures of the elbows common (64%)
      x. Restriction of supination and pronations
      xi. Subluxation or dislocation of the radial head
   b. Lower extremities
      i. Small feet
      ii. Cutaneous syndactyly of the second and third toes (86%)
      iii. Tight Achilles tendon (equines deformity)
      iv. Pes planus
      v. Valgus heel
      vi. Flexion contractures of the knees
8. CNS anomalies
   a. Variable mental retardation to near-normal intellect

b. Seizures (23%)
c. Abnormal speech development
d. Hearing deficits (60–100%)
e. Hypoplasia of the vermis
f. Hypertonia/hypotonia

9. Behavior disorder
   a. Sleep disturbance (55%)
   b. Aggression (49%)
   c. Self-destructive tendencies (44%)
   d. Hyperactivity (40%)
   e. Low-pitched growling sound rather than cry
   f. Infrequent facial expressions of emotion
   g. Severe language delay
   h. Autistic-like behavior
   i. Repetitive stereotypic movement
   j. Eliciting pleasurable responses by vestibular stimulation or vigorous movement
10. Other anomalies
   a. Small hypoplastic nipples (55%)
   b. Small hypoplastic umbilicus (53%)
   c. Cardiovascular anomalies (15–20%)
      i. Ventricular septal defect
      ii. Atrial septal defect
      iii. Patent ductus arteriosus
      iv. Aortic valve anomaly
      v. Hypoplasia of the aorta
      vi. Persistent left superior vena cava
      vii. Pulmonary stenosis
      viii. Endocardial cushion defect
      ix. Tetralogy of Fallot
   d. Gastrointestinal anomalies
      i. Inguinal hernia
      ii. Hiatus hernia
      iii. Congenital diaphragmatic hernia
      iv. Gut duplication
      v. Malrotation of colon
      vi. Pyloric stenosis
   e. Genitourinary anomalies
      i. Hypoplastic, dysplastic, or cystic kidneys
      ii. Hypoplastic external genitalia, cryptorchidism or hypospadias in males
      iii. Small labia majora, bicornuate or septate uterus in females
   f. Abnormal dermatoglyphics
      i. Transverse palmar creases (51%)
      ii. Increased atd angle
      iii. Hypoplastic finger ridge patterns

Diagnostic Investigations

1. Radiography
   a. Skull
      i. Microcephaly: frequent
      ii. Brachycephaly: frequent
      iii. Trigonocephaly with orbital hypotelorism
      iv. Parietal foramina
      v. Micrognathia
      vi. High-arched palate
      vii. Cleft palate
   b. Spine
      i. Kyphoscoliosis
      ii. Platyspondyly
      iii. Scheuermann disease
      iv. Spina bifida
      v. Square vertebrae
      vi. Coxa valga
   c. Chest
      i. Aspiration pneumonia: frequent
      ii. Thin ribs
      iii. Short clavicles
      iv. Short hypoplastic sternum with reduced number of ossification centers
      v. Abnormal sternal angle
      vi. Cervical ribs
      vii. Hypoplasia of the first rib
      viii. Chronic pneumonia
      ix. Bronchiolitis
   d. Congenital heart diseases
   e. Gastrointestinal tract
      i. Swallowing dysfunction: frequent
      ii. Bowel rotation anomalies with bands: frequent
      iii. Hiatal hernia
      iv. Hypertrophic pyloric stenosis
      v. Duodenal stenosis
      vi. Colon duplication
      vii. Inguinal hernia
      viii. Umbilical hernia
   f. Genitourinary tract
      i. Incomplete rotation of the kidneys
      ii. Renal duplication
      iii. Polycystic kidneys
      iv. Chronic pyelonephritis
      v. Abnormal renal function with poor visualization on excretory urography

vi. Vesicoureteral reflux
vii. Divided uterine canal with septate vagina

g. Limbs
i. Micromelia: frequent
ii. Short humerus and/or forearm bones: frequent
iii. Elongated humeral neck (similar to femoral neck): frequent
iv. Subluxation or dislocation of malformed radius and/or ulna at elbow with fixation in flexion
v. Absent or hypoplastic ulna: frequent
vi. Retarded bone maturation with abnormal sequence of appearance of ossification centers: frequent
vii. Absent carpals, metacarpals, and fingers (ectrodactyly/oligodactyly): frequent
viii. Short, broad metacarpals, particularly one and five: frequent
ix. Hypoplastic phalanges particularly middle fifth (curved) and middle second fingers: frequent
x. Cutaneous syndactyly of second and third toes or other toes and fingers: frequent
xi. Cutis valgus
xii. Absent or hypoplastic radius
xiii. Lunate and triquetral fusion
xiv. Aplastic or hypoplastic ulnar styloid
xv. Double distal phalanges of thumbs and/or great toes
xvi. Congenital dislocated hips
xvii. Aseptic necrosis of femoral head
xviii. Broad ischial bones
xix. Large obturator foramina
xx. Short broad femoral necks
xxi. Absent tibia with deformed fibula
xxii. Fusion of phalanges of fifth toe
xxiii. Rocker-bottom foot
xxiv. Metatarsus adductus
xxv. Planovalgoid foot
xxvi. Talipes equinovarus
xxvii. Shortening of femur and/or leg bones
xxviii. Wide gap between first and second toes
xxix. Osteoporosis

2. Endocrinologic studies in patients with severe growth retardation
3. Echocardiography for evaluation of congenital heart defects
4. Abdominal ultrasonography for GU anomalies
5. EEG for seizures
6. High resolution chromosome analysis for associated chromosome anomaly
7. Mutation scanning and sequence analysis (Deardorff et al. 2006)
   a. Mutation scanning of *NIPBL* gene detected mutations in approximately 50% of 179 individuals from three studies (Borck et al. 2004; Gillis et al. 2004; Tonkin et al. 2004)
      i. Frameshift mutations
      ii. Nonsense mutations
      iii. Splice-site mutation
      iv. Missense mutations
   b. Study by Musio et al. (2006)
      i. A *NIPBL* mutation was identified in 44% (24/54) of probands
      ii. A *SMC1A* mutation was detected in 4% (2/54) of probands

Genetic Counseling

1. Recurrence risk (Deardorff et al. 2006)
   a. Patient's sib
      i. Autosomal dominant inheritance
         a) An empiric risk of about 1–4%
         b) Possibility of recurrence in siblings exists since gonadal mosaicism cases have been demonstrated (Niu et al. 2006)
      ii. X-linked recessive inheritance
         a) The risk to sibs depends on the carrier status of the mother
         b) If the mother of the proband has a disease-causing mutation, the chance of transmitting it in each pregnancy is 50%. Male sibs who inherit the mutation will be affected; female sibs who inherit the mutation will be carriers and will usually not be affected
         c) If the disease-causing mutation cannot be detected in the DNA of the mother of the only affected male in the family, the risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism
   b. Patient's offspring
      i. Autosomal dominant inheritance
         a) A 50% risk

b) While most familial recurrences are the result of germline mosaicism in a phenotypically normal parent, rare cases of a mildly affected individual having affected children have been reported

ii. X-linked recessive inheritance: Males with X-linked de Lange syndrome will pass the disease-causing mutation to all of their daughters and none of their sons

2. Prenatal diagnosis
   a. Ultrasonography (2-D and 3-D) (Sepulveda et al. 2009)
      i. Intrauterine growth retardation
      ii. Characteristic facies
         a) Long eyelashes
         b) A small bulging nose
         c) Hypoplastic nasal bone
         d) Depressed nasal bridge
         e) Anteverted nostrils
         f) A long philtrum
         g) Protruding and overhanging upper lip
         h) Micrognathia
      iii. Limb defects
         a) Micromelia
         b) Monodactyly
         c) Ulnar agenesis
      iv. Diaphragmatic hernia
   b. Molecular genetic diagnosis: Prenatal diagnosis is possible by demonstrating *NIPBL* mutation by DNA analysis of fetal cells obtained from amniocentesis or CVS
3. Management
   a. Adequate caloric intake
   b. Treat gastroesophageal reflux with thickened feeds in a upright position and pharmacotherapy
   c. Fitting of hearing aids and early consistent training for hearing impaired children
   d. Early intervention and special education programs for psychomotor delay
   e. Behavioral modification
   f. Correction of refractory errors with glasses
   g. Anticonvulsants for seizures
   h. Surgical repairs
      i. Fundoplication and gastrostomy feedings necessary in patients with severe esophagitis and progressive failure to thrive despite conservative intervention
      ii. Diaphragmatic hernia
      iii. Cardiac defect
      iv. Severe skeletal deformities
      v. Renal malformations
      vi. Ptosis obstructing the visual axis
      vii. Orchiplexy

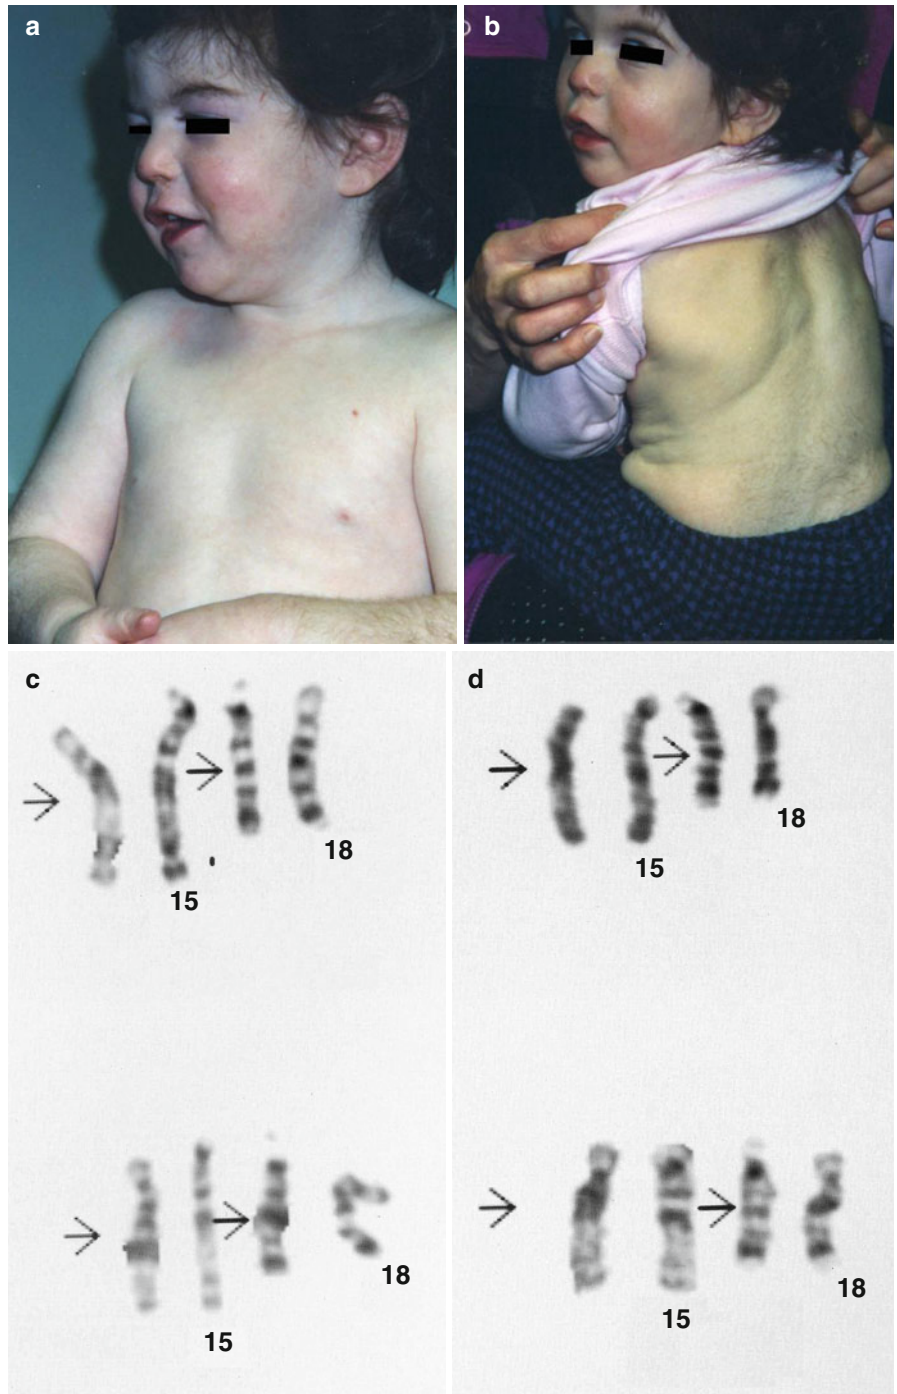

Fig. 6 (**a**–**d**) A child with t(15q;18q) showing de Lange phenotype

Fig. 7 (**a**, **b**) Two adults with de Lange syndrome showing hirsutism and mental retardation

Del(18p) Syndrome

de Grouchy in 1963 reported the syndrome, the first example of a partial monosomy compatible with life. The incidence is approximately 1 in 50,000 live-born infants (Turleau 2008).

Synonyms and Related Disorders

18p- syndrome; Monosomy 18p syndrome

Genetics/Basic Defects

1. Monosomy 18p syndrome (Turleau 2008)
   a. Refers to a chromosomal disorder, resulting from the deletion of all or part of the short arm of chromosome 18
   b. One of the most frequent autosomal terminal deletion syndromes
2. Types of 18p deletion
   a. Monosomies of the entire short arm as well as partial monosomies 18p have been reported (Schaub et al. 2002).
   b. De novo deletions in most cases (about two third).
   c. Consequences of an unbalanced whole arm translocation: usually occurring between the long arm of an acrocentric chromosome and the long arm of the chromosome 18 and resulting in a karyotype with 45 chromosomes (Wang et al. 1997).
   d. Consequences of malsegregation of a balanced parental translocation with a variable breakpoint on 18p and are accompanied by a partial trisomy for another chromosome.
   e. Cryptic subtelomeric deletions or translocations: evidenced using subtelomeric screening (Horsley et al. 1998; Babovic-Vuksanovic et al. 2004).
   f. Mosaicism or association with another aneuploidy.
   g. Ring 18 chromosome (Stankiewicz et al. 2001) or after recombination in a pericentric inversion leading to a 18p monosomy associated with a 18q trisomy (Leonard et al. 2000).
   h. Familial transmission of 18p- from one of the parents to the child reported in at least eight cases, all of them maternally inherited (Uchida et al. 1965; Velagaleti et al. 1996; Tonk and Krishna 1997; Rigola et al. 2001; Tsukahara et al. 2001; Maranda et al. 2006; Portnoi et al. 2007; Misceo et al. 2009).
      i. 18p- may be in a homogeneous or a mosaic state in the parent.
      ii. Intrafamilial clinical variability
3. The most distal segment of 18p contains the critical region of HPE4 (Overhauser et al. 1995).
   a. Mutations in the *TGIF* gene located on 18p11.3 have been shown to cause holoprosencephaly (Gripp et al. 2000).
   b. Hemizygosity of HPE4 does not automatically confer the phenotype of HPE, since only 10–15% of patients have features consistent with HPE, confirming that multiple genetic and environmental factors intervene in HPE spectrum phenotypes.

Clinical Features

1. Very frequent clinical features (Turleau 2008)
   a. Mental retardation with variable severity

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_66,
© Springer Science+Business Media, LLC 2012

b. Speech delay
c. Short stature
d. Hypotonia

2. Frequent clinical features
   a. Variable features of the holoprosencephaly (HPE) spectrum
   b. Ptosis
   c. Flat nasal bridge
   d. Wide mouth with short upper lip
   e. Small mandible
   f. Excessive caries
   g. Large, protruding ears
   h. Short, webbed neck
   i. Broad trunk
   j. Pectus excavatum
   k. Kyphoscoliosis
3. Rare clinical features
   a. Behavioral disorders
   b. Autoimmune diseases
   c. Alopecia
   d. Dystonia

Diagnostic Investigations

1. Cytogenetic analysis including subtelomeric FISH
   a. Patient: to detect absence of all or part of the short arm of one chromosome 18
   b. Parent: to determine if either parent is a balanced translocation carrier or has the unbalanced 18p deletion
2. Array-based comparative genomic hybridization (CGH)

Genetic Counseling

1. Recurrence risk (Turleau 2008)
   a. Patient's sib
      i. A de novo case
         a) Not significantly increased above that of the general population
         b) Caution: cryptic mosaicism may be present in one of the parents.
      ii. Presence of a structural rearrangement in one of the parents (most frequently balanced translocation, followed by pericentric inversion)
         a) Recurrence risk depends on the type of rearrangement, in which chromosomes are involved, and on the size of the rearranged segments.
         b) A high recurrence risk of either a monosomy or a trisomy for 18p for some rearrangement
      iii. One of the parents with a 18p deletion
         a) A 50% risk if the parent has non-mosaic 18p deletion
         b) Lower than 50% risk if the parent has mosaic 18p deletion
   b. Patient's offspring
      i. A 50% risk if the patient has non-mosaic 18p deletion
      ii. Lower than 50% risk if the patient has mosaic 18p deletion
2. Prenatal diagnosis
   a. Cytogenetic analysis including FISH: can detect deletion 18p when a parent is heterozygous for a balanced rearrangement involving 18p or carrier of a 18p deletion, following detection of a holoprosencephaly-type defect at sonography, or after the birth of a first affected child
   b. Deletion 18p is rarely observed in first-trimester abortions suggesting that this imbalance is not selected against
3. Management
   a. No specific treatment available
   b. Early rehabilitative and educations interventions, mainly speech therapy
   c. Physical therapy for hypotonia

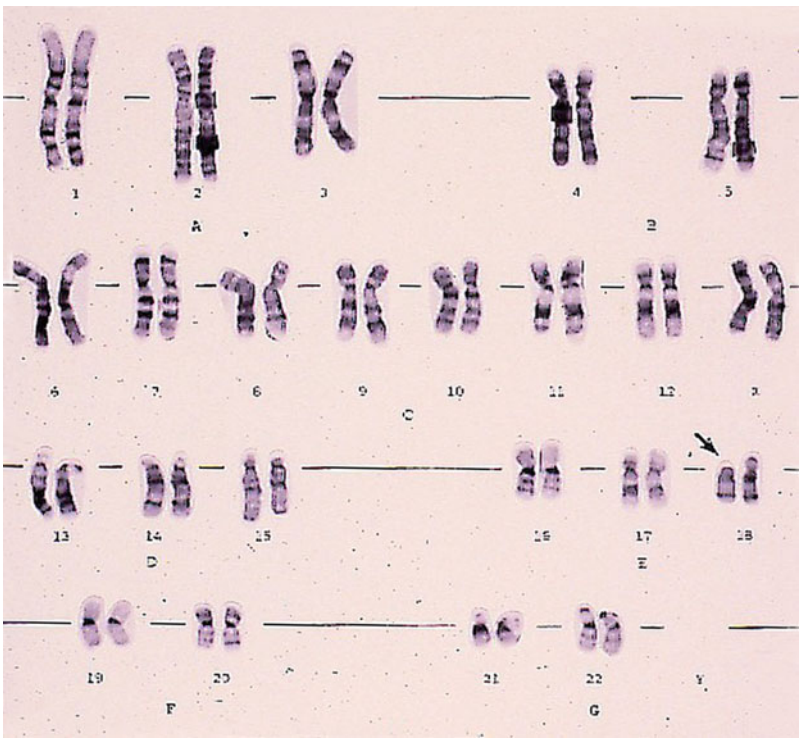

Fig. 2 Karyotype of the previous patient is illustrated here

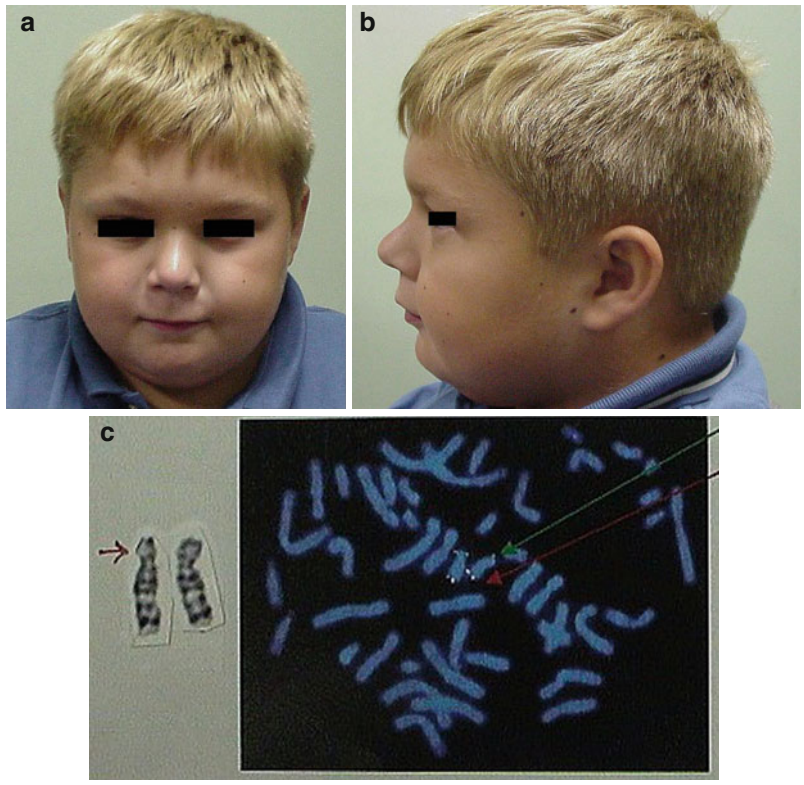

Fig. 3 (**a–c**) An 11-year-old boy with del(18p). He has short stature, mild mental retardation, IgA deficiency, a round face, tricuspid/mitral regurgitation, glandular hypospadias, and small hands and feet. A partial karyotype with FISH is illustrated here

Fig. 4 A young girl with monosomy 18p syndrome [Del(18p)-Del(18)(qter-p111)]. In addition to developmental and speech delay, the patient has a round face, short upper lip, broad philtrum, everted lower lip, and protruding ears

Del(22q11.2) Syndrome

The 22q11.2 deletion syndrome is one of the most common multiple anomaly syndrome and the most common microdeletion syndrome. It is the most common syndrome associated with palatal clefts and congenital velopharyngeal dysfunction (Kirschner 2005) and the second most common cause of developmental delay accounting for about 2.4% of affected individuals. The occurrence is approximately 1 in 4,000 live births (Botto et al. 2003; Óskarsdóttir et al. 2005).

Synonyms and Related Disorders

22q11.2 Microdeletion Syndrome; CATCH-22 syndrome; Cayler craniofacial syndrome associated with del(22q11.2); Congenital thymic hypoplasia associated with hypocalcemia; DiGeorge syndrome; Takao syndrome; Velocardiofacial syndrome (Shprintzen syndrome)

Historic overviews of the syndromes associated with 22q11.2 deletion:

1. Congenital thymic hypoplasia associated with hypocalcemia (1959)
2. DiGeorge syndrome (DGS) (1972)
   a. Congenital thymic hypoplasia
   b. Hypocalcemia
   c. T-cell dysfunction
   d. Typical facial anomalies
   e. Typical cardiac anomalies
3. Takao syndrome (conotruncal anomaly face syndrome) (1976)
   a. Conotruncal cardiac anomalies
   b. Typical facial appearance
   c. Velopharyngeal insufficiency
   d. Learning disability
4. Velocardiofacial syndrome (VCFS) (Shprintzen syndrome) (1978)
   a. Velophalangeal abnormalities
   b. Cardiac abnormalities
   c. Facial abnormalities
   d. The birth incidence of 1/1,800–1/4,000, making VCFS the second most common cause of congenital heart disease after Down syndrome
5. DiGeorge syndrome speculatively linked to chromosome 22 (1981)
6. Partial monosomy of chromosome 22 (1982)
7. "CATCH-22 syndrome" (1989): not a preferred term
   a. *C*ardiac disease
   b. *A*bnormal facies
   c. *T*hymic hypoplasia
   d. *C*left palate
   e. *H*ypocalcemia
   f. Associated with a deletion in chromosome-*22*
8. Cayler craniofacial syndrome associated with del (22q11.2) (1994)
   a. Asymmetric crying facies
   b. Phenotypic spectrum expanded to include extracardiac anomalies
   c. Associated with del(22q11.2)
9. Some cases of autosomal dominant Opitz G/BBB syndrome (1995)
   a. Hypertelorism
   b. Laryngotracheoesophageal cleft
   c. Cleft palate
   d. Swallowing difficulty
   e. Genitourinary defects
   f. Mental retardation
   g. Congenital heart defects

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_67,
© Springer Science+Business Media, LLC 2012

Genetics/Basic Defects

1. Inheritance
   a. De novo deletions in the majority of cases (80–90%) (Yamagishi and Srivastava 2003)
   b. The deletion can be transmitted as an autosomal dominant trait.
   c. Familial deletions identified in 7% of probands
2. Cause: hemizygous deletion of 22q11.2
   a. Deletions inherited from an affected parent (<14%)
   b. Up to 89% of patients show a typical phenotype of DiGeorge syndrome.
   c. Occupy roughly 15% of the patients with congenital heart disease
   d. Microdeletions detected by fluorescence in situ hybridization (FISH) probes
3. Molecular/cytogenetic basis
   a. DiGeorge critical region (300–600 kbp containing approximately 25–30 candidate genes), mapped to 22q11.2
   b. Candidate genes (Yamagishi 2002)
      i. Ubiquitin-fusion-degradation-1-like (*UFD1L*) gene, located in the DiGeorge critical region, which is most consistently deleted in patients with DGS (88%) or VCFS (76%). A significant percentage of cardiac patients with conotruncal cardiac malformations have a 22q11.2 deletion.
      ii. Mutation in *TBX1* gene (belongs to the T-box family of transcription factors), located in 22q11.2 region has been suggested as a rare cause of the syndrome (Yagi et al. 2003). *TBX1* haploinsufficiency is likely the major determinant of aortic arch defects in patients with 22q11.2 deletion syndrome.
4. Cardiac embryogenesis and branchial arch abnormalities
   a. Cardiac structures (derived from the cardiogenic cord in the embryonic mesoderm during very early embryogenesis)
   b. Conotruncus (outflow structures of the heart, derived from branchial arches IV and VI, which differentiate into aorta and pulmonary artery respectively). Malalignment of these structures and incomplete septation give rise to the following diverse congenital heart disease associated with DiGeorge syndrome:
      i. Arch abnormalities (interrupted aortic arch, aortic coarctation)
      ii. Conotruncal abnormalities (truncus arteriosus, pulmonary artery atresia)
      iii. Malalignment of the interventricular septum with the conotruncus (VSD, ASD, Tetralogy of Fallot, DORV)
      iv. Valvular or myocardium abnormalities (unusual)
   c. Branchial arches are also the embryological origin of the anterior facial structures, thyroid, thymus, and parathyroids. Their abnormalities are the phenotypic hallmark of the DiGeorge syndrome groups.
5. Heterogeneous etiology of congenital heart defects
   a. Deletion 22q11.2 (the second most common chromosomal cause of significant congenital heart disease)
   b. Aneuploidy (trisomy 21 remains the most common chromosomal cause of significant congenital heart disease)
   c. Single gene disorder
   d. Multifactorial trait
   e. Maternal disease such as diabetes mellitus
   f. Teratogen exposure

Clinical Features

1. Marked variability of phenotype
2. Endocrine abnormalities: common in patients with a 22q11.2 deletion (Weinzimer 2001)
   a. Hypocalcemia (30%)
      i. Invariably due to hypoparathyroidism, documented by aplasia or hypoplasia of the parathyroid glands at surgery or autopsy
      ii. Symptoms of hypocalcemia most likely manifest in the neonatal period, because maternal calcium supply by fetal circulation is abruptly interrupted at birth and the calcium intake within the first few days of life is usually insufficient.
         a) Seizures
         b) Tremors
         c) Tetany

iii. Other signs of hypocalcemia
a) Paresthesias
b) Muscle cramps
c) Rigidity
iv. Prevalence of hypocalcemia by phenotypic characteristics
a) DiGeorge syndrome (69–72%)
b) Velocardiofacial syndrome (13–22%)
c) Conotruncal anomaly face syndrome (10%)
d) 22q11.2 deletion (49–60%)
v. Autoimmune enteropathies
b. Growth disorders
i. Growth hormone deficiency
ii. Short stature
c. Thyroid disorders
i. Congenital hypothyroidism
a) Noted in 7% of patients with VCFS
b) Noted in 5% of patients with DGS
ii. Hyperthyroidism due to Graves disease
3. Immunodeficiency (highly variable) (77%)
a. Primary T-cell dysfunction (decreased production of T cells caused by impaired formation of thymic tissue) (67%)
b. Secondary T-cell functional defects (19%)
c. Humoral immune deficits (23%)
d. IgA deficiency (13%)
e. Associated autoimmune disease
i. Polyarticular juvenile rheumatoid arthritis, a frequency 150 times that of the general population rate
ii. Autoimmune hemolytic anemia
iii. Idiopathic thrombocytopenic purpura
iv. Autoimmune enteropathies (celiac disease)
v. Vitiligo
4. Cardiovascular malformations (75%, the most common structural anomaly)
a. Conotruncal heart defects
i. Tetralogy of Fallot (the most common heart anomaly)
ii. Pulmonary atresia with ventricular septal defect
iii. Truncus arteriosus (25%)
iv. Interrupted aortic arch type B (30%)
v. Atrial septal defect
b. Right-sided, cervical, or double aortic arch/aberrant subclavian artery
c. Pulmonary artery abnormalities
i. Discontinuity of the pulmonary arteries
ii. Diffuse hypoplasia
iii. Discrete stenosis
iv. Defect of arborization
v. Major aortopulmonary collateral arteries
d. Infundibulum abnormalities
i. Malaligned
ii. Hypoplastic
iii. Absent
e. Semilunar valve abnormalities
i. Bicuspid
ii. Severely dysplastic
iii. Insufficient
iv. Stenotic
5. Craniofacial features
a. Palate
i. Velopharyngeal incompetence (27%)
ii. Submucous cleft palate (16%)
iii. Overt cleft palate (11%)
iv. Bifid uvula (5%)
v. Cleft lip/palate (2%)
vi. Suspected velopharyngeal incompetence
vii. Normal
b. Ears
i. Low-set ears
ii. Over-folded helices
iii. Squared off helices
iv. Cupped, microtic, and protuberant ears
v. Preauricular pits/tags
vi. Narrow canals
vii. Chronic otitis media
viii. Conductive hearing loss
c. Nose
i. Prominent nasal root
ii. Bulbous nasal tip
iii. Hypoplastic alae nasae
iv. Nasal dimple/bifid nasal tip
v. Chronic sinusitis
d. Throat
i. Stridor caused by a vascular ring
ii. Laryngomalacia
iii. Laryngeal webs
e. Eyes
i. Tortuous retinal vessels (58%)
ii. Posterior embryotoxon (69%)
iii. Hooding of the upper and/or lower lid (47%)

iv. Ptosis (9%)
v. Epicanthal folds (3%)
vi. Distichiasis (3%)

6. Skeletal abnormalities
   a. Vertebral anomalies (19%)
      i. Coronal clefts
      ii. Hemivertebrae
      iii. Butterfly vertebrae
      iv. Scoliosis
   b. Rib anomalies including supernumerary ribs (19%)
   c. Hypoplastic scapulae
   d. Upper limb anomalies including pre/postaxial polydactyly (6%)
   e. Lower limb anomalies (15%)
      i. Postaxial polydactyly
      ii. Club foot
      iii. Over-folded toes
      iv. 2, 3 syndactyly
   f. Craniosynostosis
7. Renal abnormalities (37%)
   a. Calculi
   b. Single kidney
   c. Small kidneys
   d. Echogenic kidney
   e. Horseshoe kidney
   f. Bladder wall thickening
   g. Multicystic dysplastic kidney
   h. Duplicated collecting system
   i. Renal tubular acidosis
8. Neuromuscular development
   a. Developmental delays
   b. Hypotonia
   c. Feeding disorders
9. CNS manifestations
   a. Mental retardation
   b. Seizures (with or without hypocalcemia)
   c. Asymmetric crying facies
   d. Ataxia
   e. Cerebellar hypoplasia
   f. Enlarged Sylvian fissures
   g. Pituitary abnormalities
   h. Polymicrogyria
   i. Mega cisterna magna
   j. Neural tube defects
10. Behavior phenotype
    a. Attention deficit/hyperactivity disorder
    b. Autism spectrum disorder
    c. Nonverbal learning disability
    d. Language deficits
    e. Social/emotional concern
    f. Schizophrenia
11. Adult phenotype
    a. Lower rates of congenital heart defects
    b. Higher rates of palate anomalies, learning disabilities/mental retardation, and psychiatric disorders

Diagnostic Investigations

1. Cytogenetic studies
   a. High-resolution chromosome analysis to detect del(22q11.2)
   b. Fluorescence in situ hybridization (FISH) for the chromosome region 22q11 to detect submicroscopic deletion
2. Parental cytogenetic studies are warranted in all families with an affected child in order to identify mildly affected parents, as well as, to rule out low level mosaicism (McDonald-McGinn and Zackai 2008).
3. Molecular analysis: polymerase chain reaction (PCR)–based assays for detection of deletions of 22q11.2
4. Echocardiography for cardiovascular anomalies
5. Chest X-ray
   a. Presence of a heart defect
   b. Absence of thymus shadow
6. Renal ultrasound examination at irregular intervals for the development of renal stones
7. MRI of the brain: detects high prevalence of brain abnormalities that are most likely neurodevelopmental and may partially explain the high prevalence of learning disability and psychiatric disorder
   a. Cerebellar atrophy
   b. Agenesis of the corpus callosum
   c. White matter hyperintensities
   d. Cavum septum pellucidum
   e. Cerebral atrophy
   f. Widespread differences in white matter bilaterally
   g. Regional-specific differences in gray matter in the left cerebellum, insula, and frontal and right temporal lobes
8. Blood calcium levels
9. Immunological studies
   a. Impaired formation of thymic tissue
   b. Decreased production of T cells
   c. Secondary T-cell functional defects, humoral deficits, or both

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Low recurrence risk, provided parents are phenotypically normal and neither one is a carrier of del(22q11.2)
      ii. A higher recurrence risk in case of a parent with germline mosaicism for a microdeletion syndrome
      iii. A 50% recurrence risk if a parent is also found to have the 22q11.2 deletion syndrome
   b. Patient's offspring: 50% affected
2. Prenatal diagnosis
   a. Indications for prenatal testing for the 22q11.2 deletion
      i. A previous child with a 22q11.2 deletion or DiGeorge/velocardiofacial syndrome
      ii. An affected parent with a 22q11.2 deletion
      iii. In utero detection of a fetus with a conotruncal cardiac defect
   b. Prenatal ultrasonography and fetal echocardiography for a fetus at risk for the 22q11.2 deletion
      i. Conotruncal cardiac defect with associated anomalies
      ii. Conotruncal cardiac defect without associated anomalies
      iii. Aplasia or hypoplasia of the fetal thymus in the presence of conotruncal cardiac anomalies: very specific for deletion 22q11.2
      iv. Cardiac lesions with the deletion
         a) Interrupted aortic arch (50–80%)
         b) Truncus arteriosus (35%)
         c) Tetralogy of Fallot (15%)
         d) Rare in double outlet right ventricle and transposition of the great vessels
      v. Sensitivity of different sonographic features allowing discrimination of a subgroup likely to be associated with microdeletion 22q11.2
         a) Nuchal translucency (12%)
         b) Polyhydramnios (20%)
         c) IUGR (8%)
         d) Extracardiac anomalies (36%)
   c. Prenatal diagnosis of 21q11.2 deletion by amniocentesis or CVS
      i. Fluorescence in situ hybridization (FISH) analysis with probes from the DiGeorge chromosomal region (DGCR)
      ii. Preimplantation genetic diagnosis by FISH reported in an at-risk mother with a 22q11.2 deletion
      iii. Occasional detection of an unbalanced translocation or an interstitial deletion of 22q11.2 by cytogenetic analysis
      iv. Molecular genetic analysis
         a) Demonstrate failure to inherit a parental allele or hemizygosity in the deleted region
         b) Restriction fragment length polymorphism (RFLP) analysis and quantitative hybridization
         c) PCR assays using short tandem repeat polymorphisms (STRs) within the DGCR
      v. Limitations of prenatal testing for the 22q11.2 deletion
         a) DGS/VCFS, a heterogeneous disorder in which 10–15% of patients do not have the deletion. Therefore, FISH analysis is of limited value in couples who have had a previously affected child without a deletion.
         b) Atypical deletions of 22q11.2, unbalanced chromosomal translocations, deletions involving other chromosomes have not been detected by FISH using commercially available probes.
         c) Consider other causes of congenital heart defects such as aneuploidy, single gene defects, maternal diseases such as diabetes, and exposure to teratogens.
         d) Inability to predict accurately the phenotype prenatally
   d. Preimplantation genetic diagnosis: available for families in which the diagnosis of the 22q11.2 deletion syndrome has been established in an affected family member
3. Management (Sullivan 2008)
   a. Medical care
      i. Manage the feeding problems
         a) Modification of spoon placement when eating
         b) Treat gastroesophageal reflux with acid blockade, prokinetic agents, postural

therapy, and medication to treat gastrointestinal dysmotility and to facilitate bowel evacuation

ii. Early intervention programs including speech therapy for developmental delay

iii. Management of psychiatric disorder

iv. Hypocalcemia
   a) Asymptomatic hypocalcemia: treat with oral calcium supplements
   b) Severe symptomatic hypocalcemia: treat with prompt administration of parenteral calcium
   c) Goal of treatment: maintain calcium in the low-normal range (8–9 mg/dL) to minimize hypercalcinuria
   d) Over supplementation of calcium leads to nephrocalcinosis

v. Management of immunodeficiency
   a) Most patients have diminished T-cell numbers as a consequence of thymic hypoplasia.
   b) Most patients do not demonstrate a susceptibility to opportunistic infections.
   c) Risk of using live viral vaccines in infants seems to be low except for patients who have thymic aplasia and/or very low T-cell counts (McDonald-McGinn et al. 1999).
   d) Both the measles, mumps, rubella and the varicella vaccine are found to be safe and efficacious in children who had the deletion and who had mild to moderate T-cell compromise (Junker and Driscoll 1995; Pierdominici et al. 2003).
   e) Management of thymic aplasia: A thymus transplant, fully matched peripheral blood transplant, or donor lymphocyte infusions are required.

vi. Thyroid hormone for hypothyroidism

vii. Growth hormone therapy in growth hormone–deficient children with a 22q11.2: associated with sustained improvements in height and growth velocity

b. Surgical care

i. Congenital heart diseases
   a) Palliative operation
   b) Corrective operation

ii. Velopharyngeal dysfunction
   a) Pharyngoplasty
   b) Plastic surgery of cleft lip/palate

iii. Surgery
   a) Gastrointestinal anomalies
   b) Renal anomalies
   c) Musculoskeletal anomalies

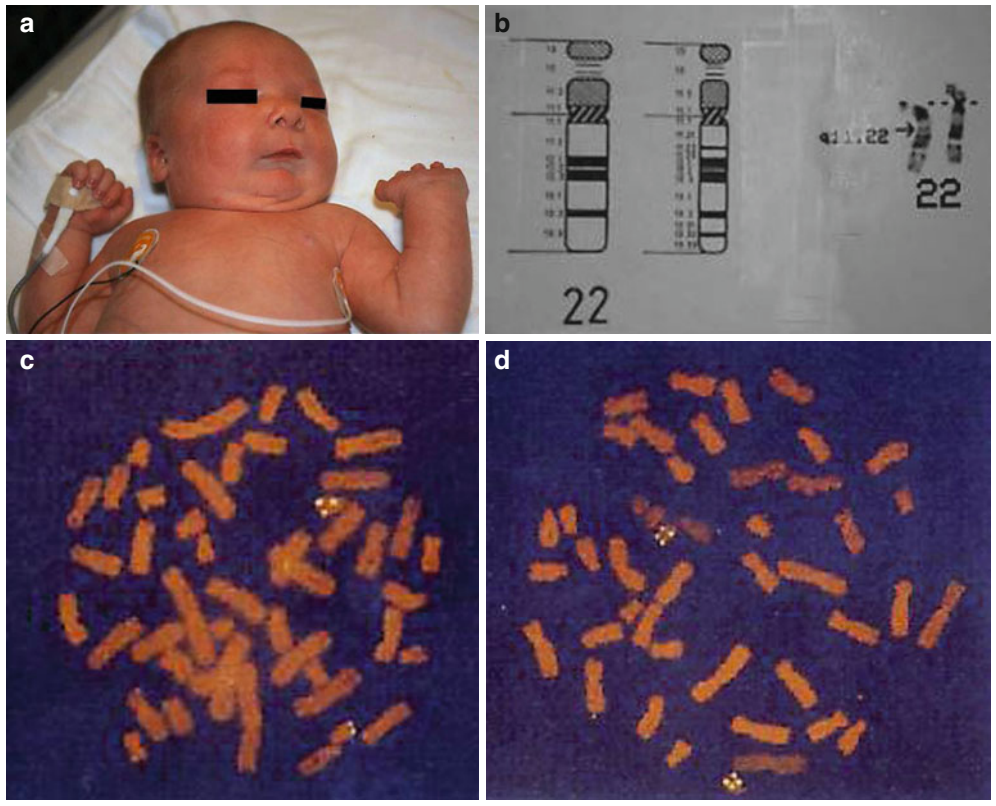

Fig. 1 An infant (**a**) with DiGeorge syndrome. The deletion of 22q11.2 was shown by partial karyotype with ideogram (**b**) and FISH with DiGeorge cosmid probe (**c**). The FISH in (**d**) is a control

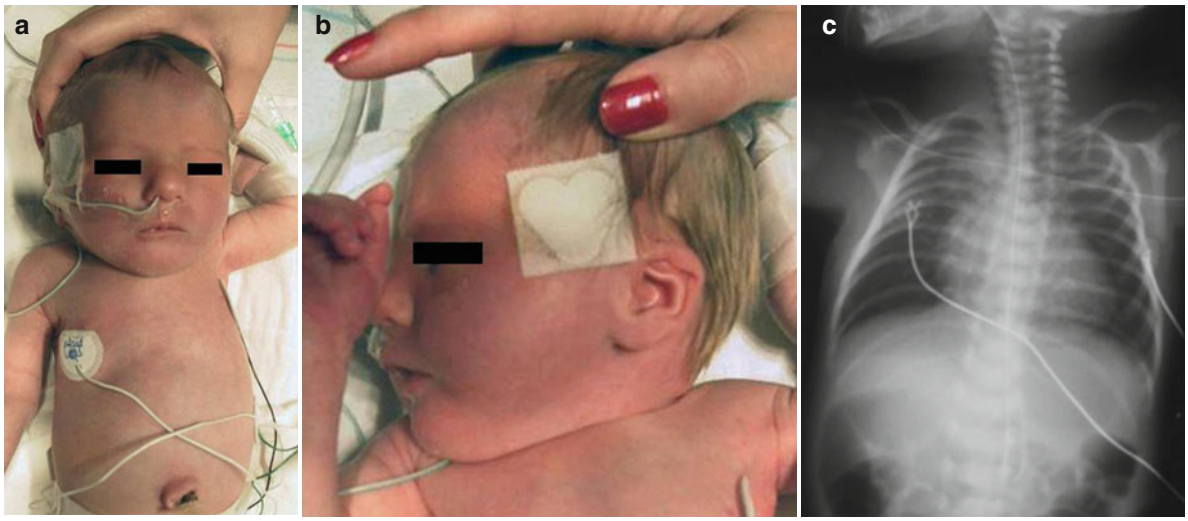

Fig. 2 (**a**–**c**) A newborn infant with conotruncal anomaly facies syndrome. The radiograph shows a conotruncal heart anomaly and absent thymus

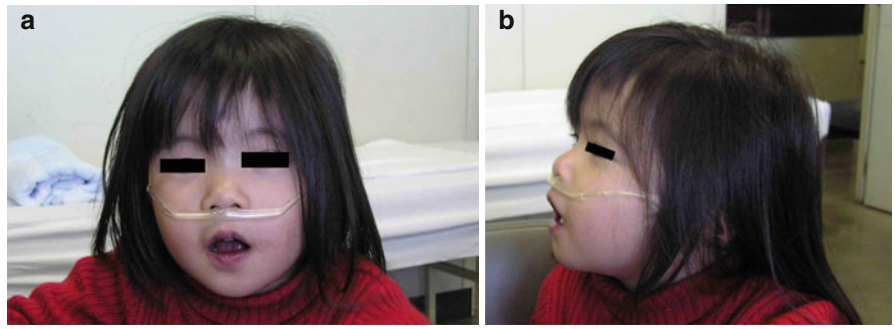

Fig. 3 (**a**, **b**) A 4 years and 6 months old girl with tetralogy of Fallot, growth retardation, developmental delay, and del(22q11.2)

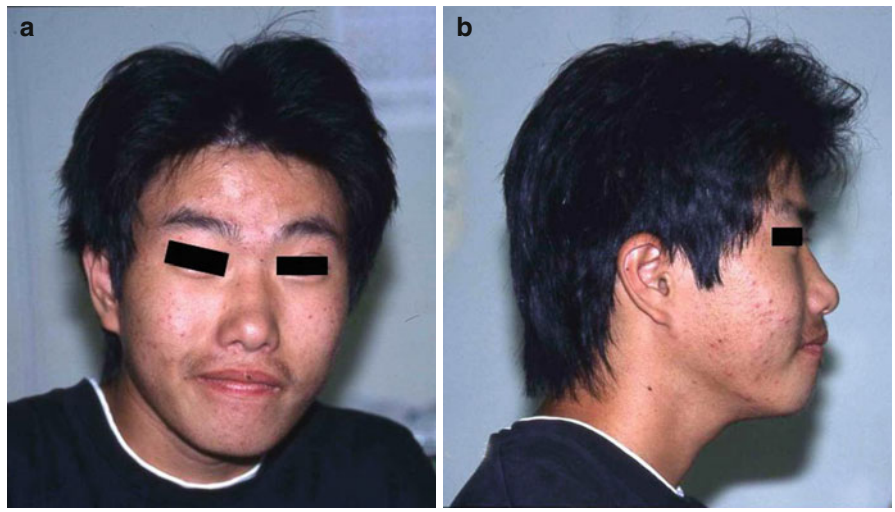

Fig. 4 (**a**, **b**) A 16-year-old boy with tetralogy of Fallot, inguinal hernia, developmental delay, bilateral conductive hearing loss (late onset at 15 years of age), and del(22q11.2) shown in the next figure

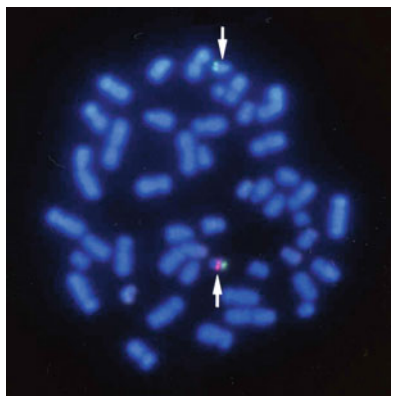

Fig. 5 FISH of the patient in the Fig. 1d. showing two green signals (a probe for 22q13 ARSA) and only one red signal (a probe for 22q11.2; TUPLE1) demonstrating del(22q11.2)

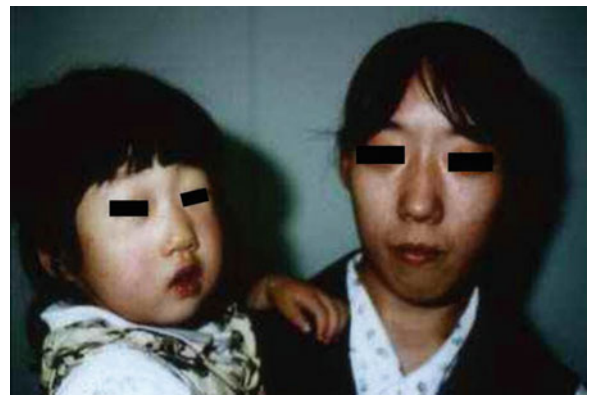

Fig. 6 A mother and daughter both have deletion 22q11.2

Del(Yq) Syndrome

In 1976, Tiepolo and Zuffardi first recognized the deletions of the long arm of the Y chromosome, large enough to be recognized by light microscopy, in six azoospermic men. Large structural rearrangements of the Y chromosome are known to be commonly associated with a 45,X/46,XY chromosomal mosaicism (Siffroi et al. 2000). Majority of Yq deletions are microdeletions and, therefore, require analysis by molecular means (Martin 2008).

Synonyms and Related Disorders

Chromosome Yq deletion syndrome

Genetics/Basic Defects

1. Role of Yq deletions in male infertility (Ma et al. 2000)
   a. Factors controlling human spermatogenesis: postulated to be located on the distal portion of the euchromatin segment of the long arm of the Y chromosome, Yq11 (Tiepolo and Zuffardi 1976)
   b. This spermatogenesis locus at Yq11.23, as demonstrated with high-resolution banding techniques, has since come to be known as the "azoospermia factor" or "AZF" (Bühler 1985).
   c. Further molecular investigations into genotype–phenotype correlation in azoospermic men led to the localization of the *AZF* locus to interval 6 of the Y chromosome (Vergnaud et al. 1986; Affara et al. 1986; Andersson et al. 1988).
   d. Microdeletions of the long arm of the Y chromosome
      i. Represents the most frequent molecular genetic cause of severe male infertility (Ferlin et al. 2006; Krausz and Degl'Innocenti 2006)
      ii. The first solid molecular evidence that failure of spermatogenesis may be caused by cytologically undetectable deletions on the Y chromosome: identification of two nonoverlapping microdeletions mapped to the distal region of intervals 5 and 6, carried by two azoospermic otherwise normal men (Ma et al. 1992)
      iii. Further studies led to the proposal of the existence of three *AZF* subregions termed *AZFa* (formerly JOLAR region), *AZFb*, and *AZFc* (formerly KLARD region) respectively (Vogt et al. 1996).
         a) Deletion of AZFa: associated with lack of germ cells or Sertoli cell-only syndrome.
         b) Deletion of *AZFb*: associated with spermatogenesis arrest.
         c) *AZFc* gene products: involved in the maturation process of postmeiotic germ cells (Vogt et al. 1996).
         d) The above hypothesis remains controversial and it is generally accepted that the completion of spermatogenesis requires multiple genes not only on the Y chromosome but elsewhere as well.
      iv. Recent description of another *AZF* subregion further complicated the issue: *AZFd*: localized between *AZFb* and *AZFc* (Kent-First et al. 1999).

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_68,
© Springer Science+Business Media, LLC 2012

v. The discovery of the two separate microdeletions on the Yq in infertile men subsequently led to the identification of four candidate gene families for *AZF*:
a) RNA-binding motif (*RBM*), previously named Y-linked RNA recognition motif (*YRRM*) (Ma et al. 1993)
b) Deleted in azoospermia (*DAZ*) (Reijo et al. 1995)
c) *Drosophila* fat facets related Y (*DFFRY*) (Brown et al. 1998)
d) *C*hromodomain Y (*CDY*) (Lahn and Page 1999)

e. Male infertility: most likely result from deletions and/or mutations of one or more of the myriad of genes necessary for spermatogenesis

2. 45,X cell line associated with large cytogenetically visible Yq deletions (Hwa et al. 2004; Cui et al. 2007)
a. Structural aberrations of the Y chromosome, such as large cytogenetically visible deletions of the long arm, ring Y, *iso*- or isodicentric short arm, are unstable and usually lost during mitosis, leading to mosaic 45,X (Hsu 1994; Kirsch et al. 2000; Siffroi et al. 2000; Bertini et al. 2005).
b. In the presence of a 45,X cell line, a fetus has a risk of being a phenotypic female with Turner syndrome manifestations or to have ambiguous external genitalia, whether the other cell line is Yp, Yq, Yp plus Yq, or even a free Y chromosome (Hsu 1994).
c. Patients with Turner syndrome with a Y-derived marker have milder phenotypic abnormalities than those with an X-derived marker. In general, patients with a Y-derived marker are not as short as, and have fewer somatic abnormalities than, patients with an X-derived marker chromosome (Schwartz et al. 1997).

Clinical Features

1. Deletion/microdeletion of the long arm of the Y chromosome
a. Men with deletions, in general, are infertile and therefore deletions are not transmitted to sons unless in vitro fertilization (IVF) and intracytoplasmic sperm injection (ICSI) are performed.
b. Associated with severe oligozoospermia

2. Phenotype–genotype correlative analyses (Cram et al. 2000)
a. Identified four subregions within AZF, called AZFa, -b, -d, and -c
b. Most deletions observed in infertile men occur in the AZFc region: associated with severe oligospermia or azoospermia and occasionally oligozoospermia
c. Men with more extensive deletions in the AZFb region that extend into the AZFa region: commonly exhibit histologic phenotypes such as germ cell arrest or Sertoli cell-only syndrome and as a result are usually azoospermic
d. Men with deletions localized exclusively to AZFd: present with mild oligozoospermia or even normal sperm counts associated with abnormal sperm morphology (Kent-First et al. 1999)

3. Phenotypes of 45,X/46,X,del(Y)(q11) (Hwa et al. 2004)
a. Phenotypic males (34.2%): Small testes, short stature, small penis, hypospadias, azoospermia, Turner syndrome, and gonadoblastoma (Hsu 1994).
b. Intersex (47.4%).
c. Phenotypic females (18.4%).
d. Only a few cases of mos45,X/46,X,del(Y) reported with normal male external genitalia (Bühler 1980; Hoshi et al. 1998).
e. The deletions of Y chromosomes are associated with abnormalities of the external genitalia, secondary sexual characteristics, and/or gonadal function.
f. These phenotypic differences are related not only to the presence or absence of the *SRY* gene on Yp, but also to the proportion of 45,X line in gonadal tissue.
i. A sufficient SRY transcript level is necessary to trigger testes formation: Once testes differentiate, male endocrine function is responsible for the rest of the events involving male phenotypic sexual differentiation.
ii. When the 45,X line is predominant in gonadal tissue, the phenotype of Turner syndrome would appear.

4. A case of Y chromosome with terminal deletion associated with nondisjunction, leading to mosaicism of three cell lines, has been reported (Cui et al. 2007): an azoospermic male with complete masculinization associated with karyotype 45,X/46,X,del(Y)/47,X,del(Y),del(Y)

Diagnostic Investigations

1. Diagnostic investigations of all infertile men (Bhasin 2007)
   a. Several semen analyses
      i. Sperm count
      ii. Sperm motility
      iii. Sperm morphology
   b. Hormone measurements (testosterone, LH, and FSH levels) to help determine:
      i. Low testosterone and low or inappropriately normal LH and FSH: gonadotropin deficiency: hypogonadotropic hypogonadism (Gnoth et al. 2005)
      ii. Low testosterone, elevated LH and FSH: obtain karyotype: primary testicular failure
      iii. Normal testosterone and LH, elevated FSH: spermatogenic failure, test for Yq microdeletion
      iv. High testosterone, elevated LH: androgen resistance
      v. Normal testosterone, normal LH, and FSH (Templeton 2000)
         a) Majority of infertile men: have normal testosterone, LH, and FSH levels
         b) Azoospermia: rule out obstruction by post-ejaculatory urine and seminal fructose and screen for Yq microdeletions
         c) Oligo/asthenozoospermia: exclude antisperm antibodies
2. Genetic testing of infertile couples and the offspring: important, especially in couples who are being considered for ICSI
   a. All infertile men with nonobstructive azoospermia, severe oligozoospermia, or very small testes should be offered a karyotype (Simpson and Lamb 2001; Allen et al. 2006).
   b. Screen infertile men with azoospermia or severe oligozoospermia for Yq microdeletions (Cram et al. 2006; Ferlin et al. 2007).
   c. Azoospermic men with at least one absent vas deferens or with evidence of normal spermatogenesis should be tested for CFTR mutations (Anguiano et al. 1992).
   d. Consider CREM mutations in men with postmeiotic maturation arrest (Blendy et al. 1996; Peri et al. 1998; Weinbauer et al. 1998).
   e. Genetic testing is indicated in men in whom personal or family history suggests disorders that have a genetic basis such as hemoglobinopathies and myotonic dystrophy (Takeda and Ueda 1977; Kletzky et al. 1979; Marchini et al. 2000); these patients also need genetic counseling.
3. Yq microdeletions are detected by PCR-based mapping of several conserved molecular markers or genes located within and outside the AZF region; these tests are available from commercial laboratories. With the availability of precise Y chromosome maps, more specific molecular markers have been developed, and guidelines for standardized testing of Yq microdeletions have been published by the European Molecular Genetics Network (Simoni et al. 2004). Array-comparative genomic hybridization (CGH) has emerged as a powerful new molecular tool for the high resolution for the detection of Yq deletions (Osborne 2007).

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Father without Yq deletion: Since most Yq microdeletions occur de novo, the recurrence risk to the male sibling is not significantly increased.
      ii. Father with Yq deletion: Father's Yq deletion will be transmitted to the male sibling.
   b. Patient's offspring
      i. The genetic defects responsible for infertility in the parent may be transmitted to the offspring through ICSI: Yq deletions will be transmitted to male offspring (Page et al. 1999; Cram et al. 2000; Simpson and lamb 2001; Ferlin et al. 2007).
      ii. Children born through ICSI have increased risk of sex chromosome aneuploidy (45,X and 47,XXY embryos) (Palermo et al. 1999; Ferlin et al. 2007).
      iii. Children born through ICSI to infertile couples may have a higher risk of being infertile or subfertile (Cram et al. 2006): may need counseling upon reaching adulthood and surveillance of their reproductive function.

2. Prenatal diagnosis
   a. Prenatal testing, including chorionic villous sampling, may be appropriate in some couples undergoing ICSI.
   b. A fetus with a prenatally diagnosed mosaic 45,X/46,X,del (Y)(q11.2) karyotype from amniotic fluid, in which the deletion was defined by polymorphic microsatellite markers analysis and multiplex STS-PCR.
3. Management (Krausz and Degl'Innocenti 2006; Bhasin 2007)
   a. Gonadotropin therapy: highly effective in gonadotropin-deficient men
   b. Intracytoplasmic sperm injection (ICSI): emerges as the treatment of choice for idiopathic male factor infertility
      i. Expensive
      ii. Associated with the following higher risks compared to naturally conceived pregnancies:
         a) Multiple gestation
         b) Low birth weight
         c) Preterm delivery
         d) Perinatal complications
         e) Chromosome aneuploidy
   c. Men with Yq microdeletions considering ICSI should be offered:
      i. Karyotyping
      ii. Yq microdeletion testing
      iii. Genetic counseling
         a) Obligatory transmission of Yq deletion to male offspring
         b) The phenotype of son: varies substantially and the extent of spermatogenic failure cannot be predicted entirely due to different genetic background and the presence or absence of environmental factors with potential toxicity to reproductive function
         c) A significant proportion of spermatozoa from men with Y microdeletion are nullisomic for sex chromosomes (Siffroi et al. 2000; Jaruzelska et al. 2001), indicating a potential risk for the offspring to develop 45,X Turner syndrome and other phenotypic anomalies associated with sex chromosome mosaicism, including ambiguous genitalia.
         d) Screening for Y chromosome microdeletions in patients bearing a mosaic 45,X/46,XY karyotype with sexual ambiguity and/or Turner stigmata has shown a relatively high incidence of AZFc deletions (33%) (Patsalis et al. 2002).
         e) Yq microdeletions could be associated with an overall Y chromosomal instability leading to the formation of 45,X cell lines (Le Bourhis et al. 2000; Jaruzelska et al. 2001; Patsalis et al. 2005).
         f) Despite this theoretical risk, the 36 babies (18 male and 18 female) born from fathers affected by Yq microdeletions are phenotypically normal (Krausz et al. 2003). This could be due to the reduced implantation rate and a likely higher risk of spontaneous abortions of embryos bearing a 45,X karyotype.
         g) In order to avoid the transfer of embryos with sex chromosome mosaicism, preimplantation diagnosis could be offered to the couple. This analysis, together with the abortion rate would provide a more realistic estimation about the real risks of 45,X/46,XY mosaicism and Turner syndrome.
   d. The screening for Yq deletions: of additional clinical utility in azoospermic men in which the type of deletion may have prognostic value for testicular sperm retrieval
   e. Testicular sperm extraction (TESE): not recommended for complete AZFa or AZFb deletions since the probability of the presence of mature sperm is virtually zero
   f. Advise cryoconservation of sperm as a preventive therapy since it is a noninvasive procedure.

Diabetic Embryopathy

Maternal diabetes adversely affects the fetus during pregnancy. The risk of developing congenital malformations has been well documented (Reece and Homko 2000; Correa et al. 2008). The frequency of congenital anomalies among insulin-dependent diabetic offspring is estimated at 3–6% of all infants at birth, representing a twofold to threefold increase, when compared with nondiabetics (Reece and Hobbins 1986).

Synonyms and Related Disorders

Infant of diabetic mother

Genetics/Basic Defects

1. Teratogenicity of maternal diabetes mellitus in human
   a. Occurring during embryogenesis at the end of blastogenesis and organogenesis between third and seventh weeks of gestation
   b. Leading to a spectrum of malformations known as diabetic embryopathy
2. Diabetic fetopathy
   a. Occurs during fetal development (after the tenth week of gestation)
   b. Not associated with malformations
   c. Fetal hyperinsulinism: the cause of macrosomia and numerous other postnatal complications
3. Potential pathogenetic mechanisms of diabetic embryopathy: most likely multifactorial (Chugh et al. 2003)
   a. Oxidant stress
   b. Perturbed biosynthesis of prostaglandins and DNA
   c. Altered expression of some of the morphogenetic regulatory molecules
      i. Extracellular matrix (ECM) proteins
      ii. Transcription factors
      iii. Proto-oncogen

Clinical Features

1. General features of infants of diabetic mothers
   a. Higher rate of congenital malformations
   b. Signs of diabetic fetopathy (Kousseff 1999b)
      i. Macrosomia (increase in adipose tissue and organomegaly) (Tyrala 1996)
         a) Classic appearance: a large, ruddy, puffy, fat, and often limp infant, with legs held in a flexed and abducted position
         b) Presence of prominent fat pads over the upper back and around the lower jaw to produce the image of a round cherubic face.
         c) A predisposing factor for the occurrence of a variety of birth trauma–related injuries
      ii. Birth trauma–related injuries due to difficult vaginal delivery secondary to shoulder dystocia
         a) Cephalohematoma
         b) Subdural hemorrhage
         c) Clavicular fracture
         d) Cranial nerve palsies
         e) Brachial plexopathy (palsy)
      iii. Hypoglycemia (hyperinsulinemia)
      iv. Polycythemia
      v. Hypomagnesemia
      vi. Hyperbilirubinemias (jaundice)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_69,
© Springer Science+Business Media, LLC 2012

vii. Hypocalcemia
viii. Cardiomyopathy (thickened interventricular septum)
ix. Renal vein thrombosis

c. Other features
i. Large for gestational age
ii. Higher fetal death rate
iii. Fetal growth retardation in diabetic women with vasculopathy
iv. Higher risk of respiratory distress (hyaline membrane disease)
v. Asphyxia
vi. Acidosis
vii. Apneic spells
viii. Sepsis
ix. Intracranial bleeding
x. Neuromuscular excitability
xi. Single umbilical artery
xii. Small left colon syndrome
xiii. Transient hematuria
xiv. Abnormal vernix caseosa
xv. Hirsutism

2. Spectrum of diabetic embryopathy: Malformations vary in extent and severity.
a. CNS abnormalities (Reece and Hobbins 1986)
i. Neural tube defects: a higher incidence of 19.5 per 1,000 in the diabetic gestation, compared with 1–2 per 1,000 in the general population
ii. Anencephaly
a) The most common anomaly affecting the CNS.
b) An incidence of 0.57% in the diabetic pregnancy, representing a threefold increase over the general population.
iii. Holoprosencephaly
iv. Hydrocephalus
v. Absent corpus callosum
vi. Arnold-Chiari anomaly
vii. Schizencephaly
viii. Microcephaly
ix. Macrocephaly
x. Agenesis of olfactory tracts
xi. Intracranial lipoma
xii. Facial nerve palsy
xiii. Calcified falx cerebi
xiv. Bizarre undergrowth or overgrowth of the brain
xv. Postnatal developmental delay

b. Facial features (85%)
i. Hemifacial microsomia (oculoauriculovertebral anomalies)
ii. Macrostomia/lateral facial cleft
iii. Cleft lip/palate
iv. Micrognathia
v. Branchial cleft cyst
vi. Frontonasal dysplasia
vii. Choanal atresia
viii. Short nose
ix. Nasal milia
x. Fat pad across nose
xi. Facial skin tags

c. Eye anomalies (48%)
i. Lens opacity
ii. Cataracts
iii. Microophthalmia/optic nerve hypoplasia
iv. Colobomas of iris or chorioretina
v. Anterior chamber dysgenesis
vi. Epibulbar dermoid/oculolipoma
vii. Laterally displaced inner canthi
viii. Tear duct obstruction

d. Ear anomalies (95%)
i. Microtia
ii. Sensorineural/conductive hearing loss
iii. Preauricular tags
iv. Anotia
v. Atretic ear canal
vi. Additional ear malformations

e. Cardiovascular anomalies
i. Complex transposition of the great vessels
ii. Single ventricle
iii. Hypoplastic left heart
iv. Tricuspid atresia
v. Tetralogy of Fallot
vi. Ventricular septal defect
vii. Atrial septal defect
viii. Double outflow right ventricle
ix. Pulmonary atresia
x. Coarctation of the aorta
xi. Subaortic stenosis
xii. Right aortic arch
xiii. Tricuspid regurgitation
xiv. Cleft mitral valve
xv. Symmetric hypertrophy of interventricular septum
xvi. Hypertrophic cardiomyopathy

f. Gastrointestinal anomalies

i. Situs inversus
ii. Pyloric stenosis
iii. Duodenal atresia
iv. Small bowel atresias
v. Small left colon (microcolon) syndrome
vi. Rectal atresia
vii. Anal atresia (imperforate anus)
viii. Meckel diverticulum
ix. Diaphragmatic hernia
x. Omphalo-enteric cyst/fistula

g. Genitourinary anomalies (19%)
i. Renal agenesis
ii. Cystic kidneys
iii. Ectopic kidney
iv. Hydronephrosis
v. Ureteral duplication
vi. Ureterocele
vii. Ambiguous genitalia
viii. Hypospadias
ix. Micropenis
x. Cryptorchidism
xi. Uterine agenesis
xii. Hypoplastic vagina

h. Skeletal anomalies (52%)
i. Hand anomalies (limb reduction defects)
a) Radial clubbing
b) Bifid thumbs
c) Hypoplastic/absent thumb
d) Radial hypoplasia
ii. Polysyndactyly
iii. Contractures
iv. Costovertebral anomalies
a) Fused cervical vertebrae
b) Hemivertebrae
c) Torticolis
d) Bifid/fused ribs
v. Hip dislocation
vi. Femoral hypoplasia
vii. Caudal regression (sirenomelia): very rare but it is one of the most unique and commonly associated lesion with maternal diabetes (occurring in 0.2–0.5% of infants of diabetic pregnancies, a 200-fold increase over the general population) (Reece and Hobbins 1986)
a) Agenesis of sacrum and lumbar spine
b) Hypoplasia of the lower extremities
c) Phocomelia
viii. Craniosynostosis

i. Skin anomalies
i. Aplasia cutis
ii. Cutaneous vascular dysplasia

Diagnostic Investigations

1. Complete blood cell count to detect polycythemia
2. Serum or whole blood glucose concentration to detect neonatal hypoglycemia
3. Serum magnesium concentration (ionized or total levels) to detect hypomagnesemia
4. Serum calcium concentration to detect hypocalcemia
5. Serum bilirubin level (total and unconjugated) to detect hyperbilirubinemia
6. Arterial blood gas to assess oxygenation and ventilation with evidence of respiratory distress
7. Radiography for cardiopulmonary distress and skeletal and vertebral anomalies
8. Echocardiography for detecting cardiomyopathy and congenital heart defects
9. Renal ultrasonography for renal anomalies

Genetic Counseling

1. Risk of congenital malformation in infants of mothers with insulin-dependent diabetes (Hajianpour 1993)
a. Relative risk (per 100 live births)
i. Major malformations: 7.9
ii. Major CNS malformations: 15.5
iii. Cardiovascular malformations: 18.0
b. Absolute risks (per 100 live births)
i. Major malformations: 18.4
ii. Major CNS malformations: 5.3
iii. Major cardiovascular malformations: 8.5
2. Risk of congenital malformation in infants of mothers with gestational diabetes mellitus who required insulin during the third trimester of pregnancy (Hajianpour 1993)
a. Relative risk: 20.6 times more likely to have major cardiovascular system defects than infants of nondiabetic mothers
b. Absolute risk: 9.7%
3. Prenatal diagnosis
a. Determination of glycosylated hemoglobin (HbA_{1c}) of the diabetic mother during the first trimester. There is a significantly higher incidence

of major congenital anomalies in the offspring of diabetic women with elevated first trimester HbA_{1c} values (>8%) (Reece and Hobbins 1986).

b. Maternal serum alpha-fetoprotein determination for the presence of associated neural tube defect.
c. Prenatal ultrasonography (Diabetic forum).
   i. Estimation of gestational age
   ii. Evaluation of congenital malformations
      a) Cardiac anomalies
      b) Skeletal anomalies
      c) CNS anomalies
      d) Renal anomalies
      e) Other anomalies
   iii. Evaluation of fetal growth
      a) Macrosomia
      b) Intrauterine growth retardation
   iv. Assessment of fetal status
   v. Maternal hydramnios
d. Fetal echocardiography for congenital heart defects

4. Management
   a. To reduce the rate of congenital malformations in offspring of mothers with diabetes mellitus (Reece and Hobbins 1986)
      i. Preconceptional care and counseling
      ii. Prepregnant glycemic control to provide endocrine milieu necessary for normal embryogenesis
   b. Plan of delivery
      i. Deliver newborn infant of the diabetic mother between 35th and 37th weeks of gestation
      ii. Anticipate Cesarean section with identification of the macrosomic fetus
   c. Management of respiratory distress
   d. Management of hypoglycemia, hypocalcemia, and hypomagnesemia
   e. Management of cardiomyopathy and heart failure
   f. Management of congenital anomalies

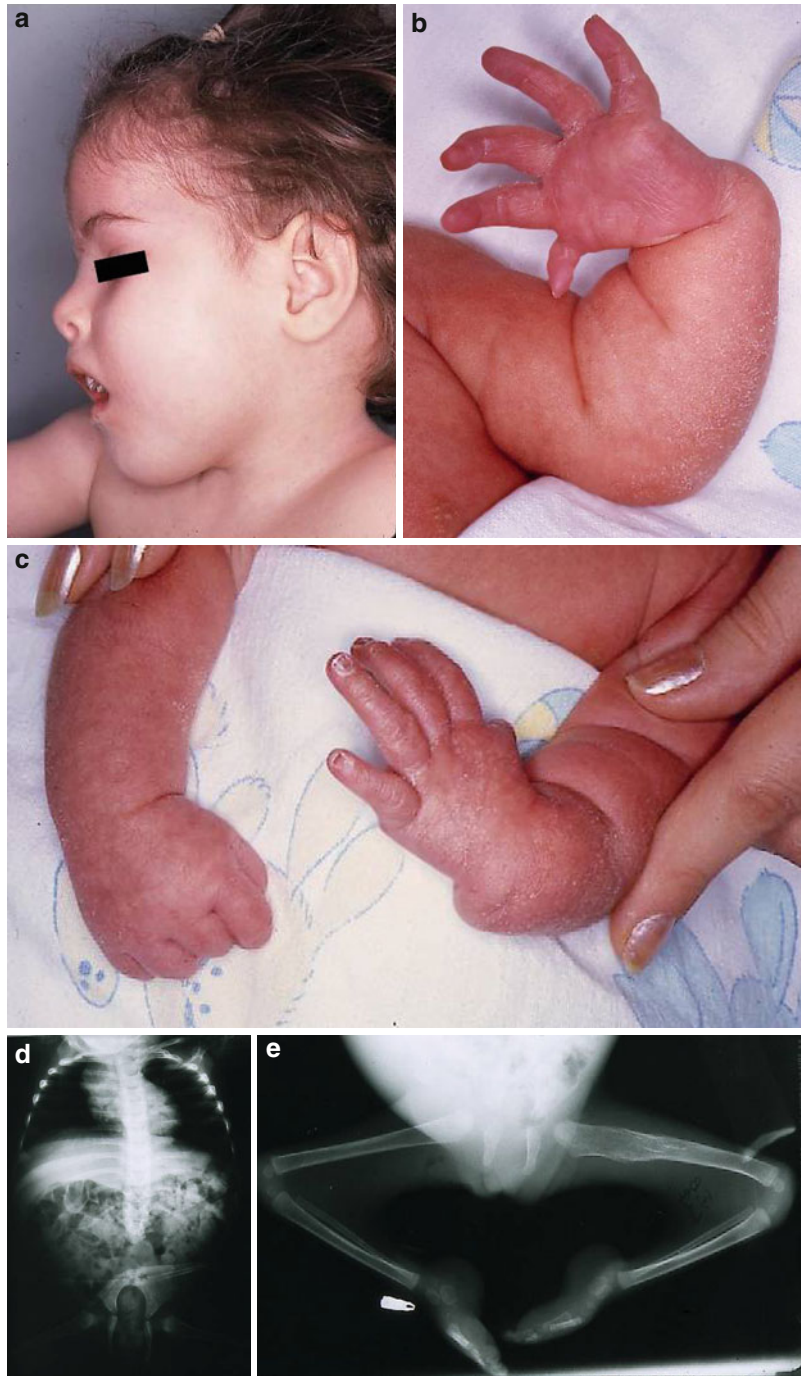

Fig. 1 (**a**–**e**) A 2 years and 9 months old girl with diabetic embryopathy showing left club hand with hypoplastic thumb and sacral agenesis with contractures of knees illustrated by radiographs

Fig. 2 (**a**–**d**) A newborn with diabetic embryopathy showing a large head due to hydrocephalus, depressed nasal bridge, short nose, micrognathia, microtia, right club hand, hemivertebrae, and caudal dysgenesis

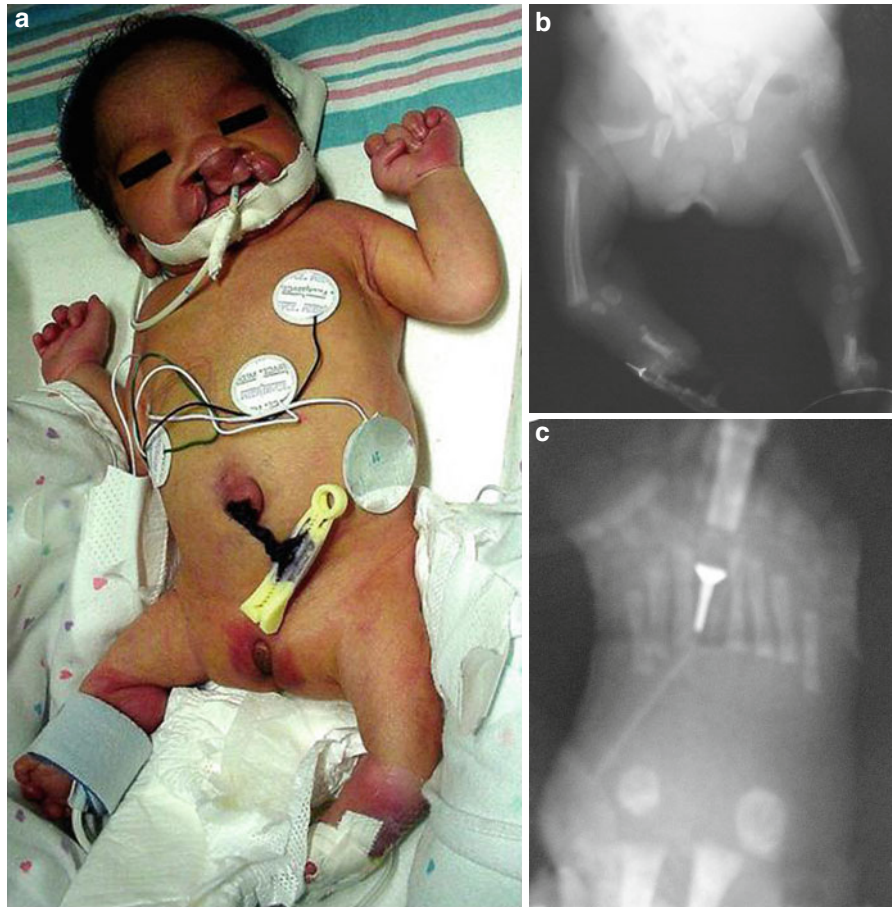

Fig. 3 (**a**–**c**) A newborn with diabetic embryopathy showing cleft lip/palate, caudal regression, femoral hypoplasia, and polydactyly

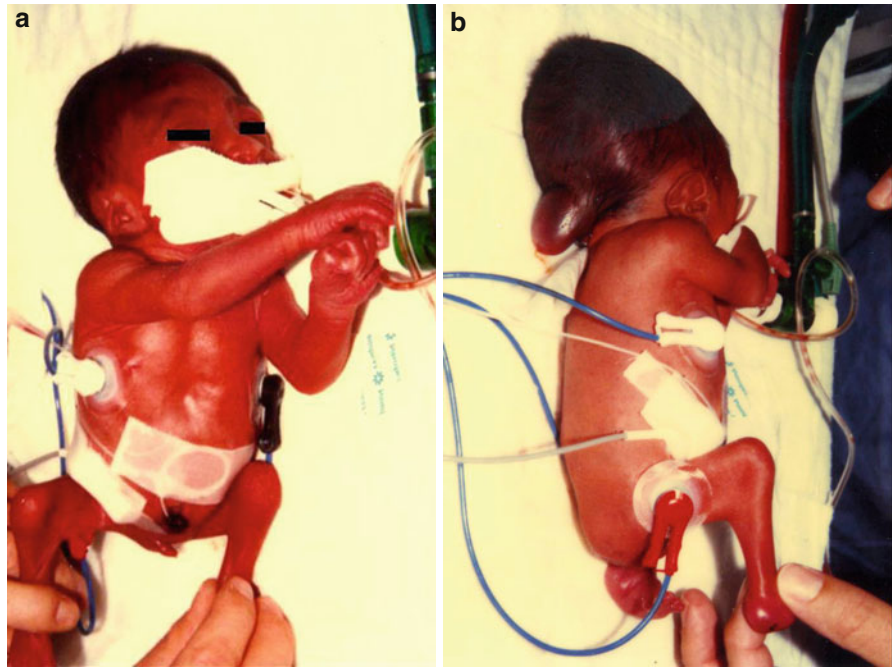

Fig. 4 (**a**, **b**) An infant born to the diabetic mother showing cystic hygroma with multiple contractures and multiple pterygia

Down Syndrome

In 1866, Down described clinical characteristics of the syndrome that now bears his name. In 1959, Lejeune and Jacobs et al. independently determined that Down syndrome is caused by trisomy 21.

Down syndrome is by far the most common, the best-known chromosome disorder in humans and the most common cause of intellectual disability (Peterson and Mikkelsen 2000). Mental retardation, dysmorphic facial features, and other distinctive phenotypic traits characterize the syndrome. Frequency is estimated to be 1 in 800 live births. Approximately 6,000 children are born with Down syndrome annually in the USA (Canfield et al. 2006).

Synonyms and Related Disorders

Trisomy 21 Syndrome

Genetics/Basic Defects

1. Caused by an extra chromosome 21
   a. Affect almost every organ system
   b. Result in a wide spectrum of phenotypic consequences
      i. Life-threatening complications
      ii. Significant alteration of life course (e.g., mental retardation)
      iii. Dysmorphic physical features
      iv. Decreased prenatal viability
      v. Increased prenatal and postnatal morbidity
2. Typical physical phenotype due to an extra copy of the proximal part of 21q22.3
   a. Mental retardation
   b. Characteristic facial features
   c. Hand anomalies
   d. Congenital heart defects
3. 21q22.1-q22.3 region containing the gene(s) responsible for the congenital heart disease observed in Down syndrome
4. Down syndrome critical region (DSCR): the region from 21q21 to 21q22.3 (McCormick et al. 1989; Rahmani et al. 1989)
5. DCR-1: a region with the largest number of associated features, including facial and hand phenotypes and mental retardation (Cold Spring Harbor meeting in 1997)
6. Types of trisomy 21
   a. Full trisomy 21 (94%)
   b. Mosaicism (2.4%)
   c. Translocations (3.3%)
      i. De novo (75%)
      ii. Familial translocation (25%)
   d. Isochromosome 21
7. Origin of nondisjunction: maternal nondisjunction in the first meiotic division (75%, most common)
8. Well-documented risk factor for maternal meiotic nondisjunction: advanced maternal age (Roitzen and Patterson 2003)
9. Down syndrome due to translocation occurs independent of maternal age and may be inherited from either parent (Tolmie 2002)
10. Majority of mosaic cases result from a trisomic zygote with mitotic loss of one chromosome 21

Clinical Features

1. Growth and development
   a. Short stature
   b. Hypotonia which improves with age
   c. Moderate-to-severe mental retardation with IQ range of 20–85 (mean IQ is approximately 50)
   d. Articulatory problems
   e. Sleep apnea occurring when inspiratory airflow from the upper airway to the lungs is impeded for 10 s or more, often resulting in hypoxemia or hypercarbia
   f. Seizure disorder (5–10%)
      i. Infantile spasms (most common type of seizures seen in infancy)
      ii. Tonic–clonic seizures (most commonly seen in older patients)
   g. Visual and hearing impairments in addition to the presence of mental retardation further limiting the child's overall function and may prevent the child from participating in significant learning processes and obtaining appropriate language development and interpersonal skills
   h. Obesity during adolescence
   i. Premature aging
      i. Decrease in skin tone
      ii. Early graying or loss of hair
      iii. Hypogonadism
      iv. Cataracts
      v. Hearing loss
      vi. Age-related increase in hypothyroidism
      vii. Seizures
      viii. Neoplasms
      ix. Degenerative vascular disease
      x. Loss of adaptive abilities
      xi. Increased risk of senile dementia of Alzheimer type
2. Behavior
   a. Natural spontaneity
   b. Genuine warmth
   c. Cheerfulness
   d. Gentleness
   e. Patience
   f. Tolerance
   g. Anxiety
   h. Stubbornness
3. Psychiatric disorders
   a. Prevalence among children (17.6%)
   b. Prevalence among adults (27.1%)
   c. Children and adolescents at a higher risk for
      i. Autism
      ii. Attention deficit hyperactivity disorder
      iii. Conduct disorder
      iv. Obsessive–compulsive disorder
      v. Tourette syndrome
      vi. Depressive disorder during the transition from adolescence to adulthood
4. Skull
   a. Brachycephaly
   b. Microcephaly
   c. Sloping forehead
   d. Vertical creases on the forehead when crying ("Woolley" sign, named after the late mentor, Dr. Woolley)
   e. Flat occiput
   f. Large fontanels with late closure
   g. Patent metopic suture
   h. Absence of frontal and sphenoid sinuses
   i. Hypoplasia of the maxillary sinuses
5. Eyes
   a. Up-slanting palpebral fissures
   b. Bilateral epicanthal folds
   c. Brushfield spots (speckled iris)
   d. Refractive errors (50%)
   e. Strabismus (44%)
   f. Nystagmus (20%)
   g. Blepharitis (33%)
   h. Conjunctivitis
   i. Tearing from stenotic nasolacrimal ducts
   j. Congenital cataracts (3%)
   k. Pseudopapilledema
   l. Spasm nutans
   m. Acquired lens opacity (30–60%)
   n. Keratoconus
6. Nose
   a. Hypoplastic nasal bone
   b. Flat nasal bridge
7. Mouth
   a. Open mouth
   b. Tendency of tongue protrusion
   c. Fissured and furrowed tongue

d. Mouth breathing
e. Drooling
f. Chapped lower lip
g. Angular cheilitis

8. Teeth
   a. Partial anodontia (50%)
   b. Tooth agenesis
   c. Malformed teeth
   d. Delayed eruption
   e. Microdontia (35–50%) in both the primary and secondary dentitions
   f. Hypoplastic and hypocalcified teeth
   g. Malocclusion
   h. Taurodontism (0.54–5.6%)
   i. Increased periodontal destruction
9. Ears
   a. Small
   b. Over-folded helix
   c. Chronic otitis media
   d. Hearing loss common. Between 66% and 89% of children have hearing loss of greater than 15–20 dB in at least one ear by auditory brainstem response.
10. Neck
    a. Atlantoaxial instability (14%) resulting from laxity of transverse ligaments that ordinarily hold the odontoid process close to the anterior arch of the atlas.
    b. Laxity causing backward displacement of the odontoid process, leading to spinal cord compression
11. Chest
    a. Narrow chest
    b. Decreased internipple distance
12. Congenital heart defects
    a. Common (40–50%)
    b. Frequently seen in hospitalized Down syndrome patients (62%)
    c. Common cause of death in the first 2 years of life
    d. Endocardial cushion defect/atrioventricular canal (43%, most common type): About 70% of all endocardial cushion defects are associated with Down syndrome.
    e. Ventricular septal defect (32%)
    f. Secundum atrial septal defect (10%)
    g. Tetralogy of Fallot (6%)
    h. Isolated patent ductus arteriosus (4%)
    i. Multiple cardiac defects (30%). The most common associated lesions are patent ductus arteriosus (16%) and pulmonic stenosis (9%)
13. Abdomen
    a. Diastasis recti
    b. Umbilical hernia
14. Gastrointestinal (12%)
    a. Duodenal atresia or stenosis
    b. Hirschsprung disease (less than 1%)
    c. TE fistula
    d. Meckel diverticulum
    e. Imperforate anus
    f. Omphalocele
15. Genitourinary
    a. Renal malformations
    b. Hypospadias
    c. Micropenis
    d. Cryptorchidism
16. Skeletal
    a. Atlantoaxial (and atlantooccipital) instability
       i. Occurring in approximately 15% of individuals (<21 years old)
       ii. Mildest asymptomatic form
       iii. Severe symptomatic subluxation or dislocation at the atlantoaxial joint may injure the spinal cord. Neurologic manifestations include:
          a) Easy fatigability
          b) Difficulties in walking
          c) Abnormal gait
          d) Neck pain
          e) Limited neck mobility
          f) Torticollis (head tilt)
          g) Incoordination and clumsiness
          h) Sensory deficits
          i) Spasticity
          j) Hyperreflexia
          k) Clonus
          l) Extensor-plantar reflex
          m) Other upper motor neuron and posterior column signs and symptoms
          n) Rarely progressing to paraplegia, hemiplegia, quadriplegia, or death
    b. Short and broad hands
    c. Clinodactyly of the fifth fingers with a single flexion crease (20%)

d. Hyperextensible finger joints
e. Increased space between the great toe and the second toe
f. Acquired hip dislocation (6%)

17. Endocrine
    a. Thyroid disease
        i. Primarily autoimmune disorder with a lifetime prevalence of 13–63%
        ii. Congenital hypothyroidism: about 28 times more common among infants with Down syndrome than in the general population with an incidence of 1% detected by newborn screening
            a) 0.7% permanent congenital hypothyroidism
            b) 0.3% transient congenital hypothyroidism
        iii. Hypothyroidism in 16–20% of young patients
    b. Diabetes
    c. Decreased fertility
        i. Almost invariably infertile in males
        ii. Decreased fertility in females
18. Hematologic
    a. Neonatal leukemoid reactions (i.e., pseudoleukemia) is common. To distinguish this from true leukemia is frequently a diagnostic challenge.
    b. 10- to 15-fold increased risk of developing leukemia in children with Down syndrome. Approximately 1 in 150 patients develops leukemia.
    c. Uniquely predisposed to clonal disorders affecting the megakaryocyte lineage in children with Down syndrome
        i. Transient myeloproliferative disorder (also known as transient leukemia)
            a) Resolves spontaneously in most cases
            b) Develops acute megakaryoblastic leukemia in up to 30% of cases
        ii. Acute megakaryoblastic leukemia
    d. An increased risk of hepatitis B carrier status if previously institutionalized
19. Immunodeficiency: Patients have about 12-fold increased risk of developing infectious diseases, especially pneumonia, secondary to impaired cellular immunity.
20. Upper airway obstruction
    a. Causes
        i. Large tonsils and adenoids
        ii. Lingual tonsils
        iii. Choanal stenosis
        iv. Glossoptosis
    b. Consequences
        i. Serous otitis media
        ii. Alveolar hypoventilation
        iii. Arterial hypoxemia
        iv. Cerebral hypoxia
        v. Pulmonary artery hypertension
        vi. Cor pulmonale
        vii. Heart failure
21. Skin
    a. Cutis marmorata
    b. Thickened nuchal folds
    c. Xerosis
    d. Localized hyperkeratotic lesions
    e. Elastosis serpiginosa
    f. Alopecia areata (up to 10%)
    g. Vitiligo
    h. Folliculitis
    i. Abscess formation
    j. Recurrent skin infections
22. Dermatoglyphics
    a. Distal axial triradius in the palms
    b. Transverse palmar creases
    c. A single flexion crease in the fifth finger
    d. Ulnar loops (often 10) in the digital patterns
    e. A pattern present in hypothenar and interdigital III regions
23. Significant health problems observed in adults with Down syndrome
    a. Untreated congenital heart anomalies
    b. Acquired cardiac disease
    c. Pulmonary hypertension
    d. Recurrent respiratory infections/aspiration leading to chronic pulmonary interstitial changes
    e. Presenile dementia/Alzheimer-type disease
    f. Adult-onset epilepsy
    g. Osteoarthritic degeneration of the spine
    h. Osteoporosis with resultant fractures of the long bones or vertebral bodies
    i. Untreated atlantooccipital instability
    j. Acquired sensory deficits
    k. Loss of vision due to early onset of adult cataracts, recurrent keratitis or keratoconus
    l. Significant hearing loss
    m. Behavioral problems

24. Prognosis
    a. Life expectancy
        i. Approximately 75% of conceptuses die in embryonic or fetal stage
        ii. Approximately 85% of infants survive up to 1 year
        iii. About 50% can be expected to live beyond the age 50 years
    b. Mobility and mortality
        i. Presence of congenital heart disease (most significant factor that determines survival)
        ii. Esophageal atresia with or without TE fistula, Hirschsprung disease, duodenal atresia, infection, and leukemia adding to mortality
        iii. Higher mortality rate later in life secondary to premature aging
    c. Phenotype of mosaic individuals: depends on the frequency and distribution of trisomic cells, with typical Down syndrome as the worst phenotype

Diagnostic Investigations

1. Serum triple screen
    a. Alpha-fetoprotein
    b. Unconjugated estriol
    c. Human chorionic gonadotrophin
2. Cytogenetic studies
    a. Clinical diagnosis should be confirmed with cytogenetic studies
    b. Karyotyping is essential for determination of recurrence risk
        i. Free trisomy 21 (93–96%)
        ii. Robertsonian translocation (2–5%)
        iii. Reciprocal translocation (<1%)
        iv. Isochromosome (<1%)
        v. Mosaicism (2–4%)
    c. In translocation or isochromosome Down syndrome, karyotyping of the parents and other relatives is required for proper genetic counseling
3. Interphase fluorescence in situ hybridization (FISH)
    a. Used for rapid diagnosis
    b. Successfully applied to both prenatal diagnosis and diagnosis in the newborn period
4. Extraction of fetal cells from maternal circulation: After fetal nucleated red blood cells have been sorted using different cell transferrin and glycophorin-A receptors on the cell surface, interphase FISH can determine chromosome constitution. Chromosome-specific probes for X, Y, 13, 18, and 21 permit diagnosis. The FISH finding should be confirmed by standard cytogenetic techniques
5. Thyroid function tests: TSH and T4 should be obtained at birth and annually thereafter.
6. Measurement of IgG
    a. Used to identify deficiency of IgG subclasses 2 and 4
    b. A significant correlation between decreased IgG subclass 4 and bacterial infections
    c. Cellular immunity deficits documented in individuals with gingivitis and periodontal disease
7. Skeletal radiography
    a. Craniofacial anomalies include
        i. Brachycephalic microcephaly
        ii. Hypoplastic facial bones and sinuses
    b. Cervical spine X-rays (lateral flexion and extension views)
    c. Required to measure the atlanto-dens distance for excluding atlantoaxial instability at 3 years of age
    d. Used prior to anesthesia if there are signs suggesting spinal cord compression
    e. Reduced iliac and acetabular angles in the young infant
    f. Short hands with shortened digits and clinodactyly due to hypoplastic middle phalanx of the fifth finger
8. Echocardiography: This test should be performed on all infants with Down syndrome for identification of congenital heart disease, regardless of findings on physical examination.
9. Auditory brainstem response (ABR), also known as brainstem auditory evoked response (BAER), to demonstrate hearing loss. Evaluation of ABR in 47 unselected children with Down syndrome, aged between 2 months and 3 1/2 years, demonstrated some degree of hearing loss in 66% of the children examined (28% unilateral, 38% bilateral).
10. Speech evaluation
11. Pediatric vision screening for ophthalmologic disorders
12. Modified Denver Developmental Screening Test chart for non-institutionalized children for assessing the developmental milestones

13. Growth charts available for children with Down syndrome
14. Prenatal ultrasonography
    a. Thickened nuchal fold (major marker)
    b. Cystic hygroma
    c. Slightly shortened femora
    d. Hyperechogenic bowel
    e. Pyelectasis
    f. Echogenic intracardiac focus
    g. Wider lateral flare of the iliac bones
    h. Other subtle sonographic signs
        i. Short ears
        ii. Hypoplasia of the middle phalanx of the 5th fingers (clinodactyly)
        iii. Choroid plexus cyst
        iv. Delayed fusion of the amnion and chorion
        v. Simian crease of the hand
        vi. Separation of the great toe ("sandal gap foot")

Genetic Counseling

1. Recurrence risk (Chen 2010)
    a. Patient's sib
        i. Non-disjunction type: about 1% for younger women and approximates the age-related risk for older women (Nussbaum et al. 2004)
        ii. De novo Robertsonian translocation type: 2–3%
    b. Familial Robertsonian translocation type
        i. Theoretical recurrence risk for a Robertsonian carrier parent to have a live-born Down syndrome offspring: 1 in 3
        ii. The actual risks to future offspring depend on parental sex:
            a) Mother with rob(Dq;21q): 10–11%
            b) Father with rob(Dq;21q): 2.4%
            c) Mother with rob(21q;22q): 14%
            d) Father with rob(21q;22q): 1–2%
    c. A carrier parent with a 21q21q translocation or isochromosome: a 100% recurrence risk
    d. Gonadal mosaicism postulated for having more than one trisomic child in the family with apparently normal parents
    e. Patient's offspring
        i. Affected individuals rarely reproduce
        ii. Females with trisomy 21: About 15–30% are fertile and have a 50% risk of having an affected child
        iii. Males with trisomy 21: no evidence of fathering a child
2. Prenatal screening
    a. Advanced maternal age
        i. The first prenatal diagnosis of Down syndrome made in 1968
        ii. Gradual introduction of screening women on the basis of advanced maternal age with amniocentesis into medical practice
    b. Maternal serum biochemical markers
        i. Low maternal serum alpha-fetoprotein (MSAFP) shown to be associated with Down syndrome in 1983
        ii. Later, elevated human chorionic gonadotropin (hCG) and low unconjugated estriol (uE3) found to be the additional markers for Down syndrome
        iii. By 1988, the three biochemical markers, together with maternal age were accepted as a method of prenatal screening for Down syndrome in the general population
        iv. Estimated detection rate when ultrasound is used to estimate gestational age: 20% when using only the MSAFP test, 59% using the double test (MSAFP and hCG), and 69% using the triple test (MSAFP, hCG, uE3). The false positive rate is 5%. Other factors for adjustment are maternal age and weight, insulin-dependent diabetes mellitus, multiple pregnancy, ethnic origin, previous Down syndrome pregnancy, and first or repeat test in a pregnancy. A positive screening test suggests only an increased risk for having a Down syndrome fetus and that definitive testing by amniocentesis with chromosome analysis is indicated
    c. First-trimester free beta-hCG and pregnancy-associated plasma protein A retrospective screening study achieved rates as high as those associated with MSAFP, hCG, or uE3 in the second trimester. Prospective studies are needed to further assess first-trimester screening
3. Prenatal diagnosis
    a. Ultrasonography
        i. Nuchal fold thickening identifies 75% of Down syndrome fetuses
        ii. Shortened humerus or femur length detects 31% of cases

iii. Cystic hygroma
iv. Duodenal atresia or stenosis (double-bubble sign)
v. Cardiac defects
a) Endocardial cushion defect with atrial and ventricular septal defects
b) Abnormal mitral and tricuspid valves
vi. Echogenic bowel
vii. Renal pyelectasis

b. Amniocentesis, CVS, or fetal blood sampling
i. FISH analysis of interphase cells or metaphase spreads
ii. Chromosome analysis

4. Management
a. Medical care
i. Early intervention programs
a) Physical therapy
b) Occupational therapy
c) Speech therapy
d) Special education programs
ii. Hearing evaluation
iii. Thyroid hormone for hypothyroidism
iv. Medical management of congenital heart defects
a) Digitalis and diuretics usually required
b) Subacute bacterial endocarditis prophylaxis
v. Prompt treatment of respiratory tract infections and otitis media
vi. Pneumococcal and influenza vaccines for children with chronic cardiac and respiratory disease
vii. Anticonvulsants for seizures
viii. Provide pharmacologic agents, behavioral therapy, and psychotherapy for behavioral/psychiatric disorders
ix. Treat skin disorders
a) Weight reduction
b) Proper hygiene
c) Frequent baths
d) Application of antibiotic ointment
e) Systemic antibiotics therapy
x. Prevent dental caries and periodontal disease
a) Appropriate dental hygiene
b) Fluoride treatments
c) Good dietary habits
d) Restorative care
xi. Megadoses of vitamins and minerals supplemented with zinc and/or selenium: have not shown benefits in a number of well-controlled studies

b. Surgical care
i. Presence of Down syndrome alone does not adversely affect the outcome of surgery in the absence of pulmonary hypertension
ii. Timely surgery of cardiac anomalies necessary to prevent serious complications
iii. Prompt surgical repair of the following gastrointestinal anomalies:
a) TE fistula
b) Pyloric stenosis
c) Duodenal atresia
d) Annular pancreas
e) Aganglionic megacolon
f) Imperforate anus
iv. Adenotonsillectomies may be required for obstructive sleep apnea.
v. Surgical intervention may be necessary to reduce the atlantoaxial subluxation and to stabilize the upper segment of the cervical spine if neurologic deficits are significant.
vi. Extract congenital cataracts, which occur in about 3% of children, soon after birth with subsequent correction with glasses or contact lenses to assure adequate vision
vii. Anesthetic airway management
a) Adequate evaluation of the airway and neurological status
b) Cervical spine radiography (flexion and extension views) when any neurologic deficits suggest spinal cord compression
c) Avoid hyperextension of the head during laryngoscopy and intubation
d) Prescribe anticholinergics to control airway hypersecretion
e) Aware of other airway complications (subglottic stenosis and obstructive apnea resulting from a relatively large tongue, enlarged adenoids, and midfacial hypoplasia)

Duncan Syndrome

In 1975, Purtilo et al. reported the Duncan pedigree in which six of 18 males died of a lymphoproliferative disorder. The boys, aged between 2 and 19 years, exhibited a progressive-combined variable immunodeficiency disease characterized by benign or malignant proliferation of lymphocytes, histiocytosis, and alterations in concentrations of serum immunoglobulins. This condition is now known as Duncan syndrome or X-linked lymphoproliferative syndrome (XLP) which is a rare T and NK cell immune deficiency which most frequently presents as fulminant infectious mononucleosis following infection with the Epstein–Barr virus (EBV) in most affected boys, leading to death in 50% of the cases.

Synonyms and Related Disorders

X-Linked Lymphoproliferative Disease

Genetics/Basic Defects

1. An X-linked recessive disorder.
2. The gene causing XLP, identified and described in 1998, was termed SH2D1A or SAP [signaling lymphocyte activation molecule (SLAM)-associated protein]. The gene encodes a protein which interacts with the SLAM (or CD150, a T-cell surface marker, and self-ligand) and several related receptors.
3. The immune response of XLP patients against EBV.
   a. Not efficient for the control of EBV expansion (in contrary to the coordinated immune response to EBV seen in normal individuals)
   b. Exhibit a dysregulated response characterized by an excessive accumulation of activated CD8+ T cells, natural killer (NK) cells, and macrophages and by the inability to control acute EBV infection.

Clinical Features

1. Diverse phenotype in affected boys
2. Fulminant infectious mononucleosis (FIM) with virus-associated hemophagocytic syndrome (VAHS)
   a. The most common and most dramatic manifestation of XLP with the worst prognosis (over 90% mortality)
   b. Clinically well until EBV infection, leading to a dysregulated and exaggerated immune response with proliferation of cytotoxic T cells, EBV-infected B cells and macrophages in tissues throughout the body
   c. Clinically manifests as pronounced lymphadenopathy and hepatosplenomegaly, resulting in extensive parenchymal damage with accompanying dysregulated cytokine release
      i. Most prominent in the liver, causing fulminant hepatitis and hepatic necrosis, and in the bone marrow, leading to profound marrow hypoplasia
      ii. Infiltration in other tissues
         a) Spleen (white pulp necrosis)
         b) Brain (perivascular mononuclear cell infiltrates)
         c) Heart (mononuclear cell myocarditis)
         d) Kidney (mild interstitial nephritis)

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_71,
© Springer Science+Business Media, LLC 2012

e) Postmortem hemophagocytosis observed in various tissue in 90% of XLP boys presenting with FIM

3. Dysgammaglobulinemia
   a. Extensive necrosis and lymphoid depletion throughout the lymphoreticular system that follows acute EBV infection
   b. Abnormal immunoglobulin (Ig) production after EBV infection: ranging from decreased levels of IgG to panhypogammaglobulinemia
   c. Humoral dysfunction may accompany cellular T and natural killer (NK) defects in more severe cases
4. Malignant lymphoma
   a. Found in approximately one third of boys with XLP, with B-cell lymphoma being the most common lymphoproliferative disorder observed
   b. Median age: 4–6 years
   c. Extranodal lesions: approximately 75% in ileocecal region and a smaller number in central nervous system, liver, and kidneys
   d. Almost all the lymphomas were of B-cell origin but tumors with a T-cell phenotype have also been described
   e. Lymphomas can be histologically classified as:
      i. Burkitt's lymphomas (53% of all B-cell lymphomas)
      ii. Immunoblastic lymphomas (12% of all cases)
      iii. Small cleaved or mixed cell lymphomas (12%)
      iv. Unclassifiable lymphomas (5% of all cases) (Harrington et al. 1987)
      v. Four cases of Hodgkin's disease were reported to the XLP registry
   f. Features of lymphomas in XLP: similar to those seen in other primary immunodeficiencies
      i. Extranodal involvement
      ii. High-grade histology
      iii. Evidence of clonality
      iv. Gene rearrangements
   g. Poor survival rate (35%)
   h. Remission can often be achieved with the use of standard pediatric lymphoma chemotherapy protocols but there is a high rate of relapse or development of the other manifestations of XLP
5. Other clinical manifestations
   a. Aplastic anemia can arise as a complication of fulminant infectious mononucleosis with hemophagocytosis, leading to marrow aplasia. However, 3% of all cases can present initially as aplastic anemia.
   b. Lymphoid vasculitis
      i. Another uncommon but well-described complication of XLP
      ii. Histological features: arterial wall destruction with aneurismal dilatation
   c. Accompanied by various degrees of hemophagocytic lymphohistiocytosis
6. Phenotype is likely determined by a number of factors, including the SAP mutation, and environmental and infectious factors on a background of disease modifier genes, as seen in other primary immunodeficiencies
7. XLP without EBV infection: at least 10% of cases of XLP are driven without EBV infection
8. Posttransplant lymphoproliferative disorder (PTLD)
   a. Related to EBV infection
   b. Estimated to occur in 2–5% of all transplant recipients
   c. More common in children since many children are EBV-naive at the time of transplant
   d. Protean manifestations of PTLD
      i. Local disease, such as graft dysfunction
      ii. Systemic disease, such as viral illness
   e. Mortality rates reported for children who develop PTLD: high and range from 36% to 69%
9. Diagnostic criteria for XLP (Conley et al. 1999)
   a. Definitive: male patients with a mutation in SAP
      i. Lymphoma/Hodgkin's disease
      ii. Fatal EBV infection
      iii. Immunodeficiency
      iv. Aplastic anemia or lymphohistiocytic disorder
   b. Probable
      i. Male patients experiencing lymphoma/Hodgkin's disease, immunodeficiency, plastic anemia or lymphohistiocytic disorder, resulting in death, following acute EBV infection
      ii. Maternal cousins, uncles, or nephews with a history of similar diagnoses, following acute EBV infection
   c. Possible: male patients with lymphoma/Hodgkin's disease, immunodeficiency, plastic anemia, or lymphohistiocytic disorder, resulting in death, following acute EBV infection

Diagnostic Investigations

1. Identification of SAP as the defective gene in XLP now allows unambiguous diagnosis of the condition
2. Screen all male patients with common variable immunodeficiency (CVID) since some patients previously labeled as having CVID have been shown to have mutations in the SAP gene
3. Prior to an encounter with EBV: no uniform abnormalities are observed on laboratory testing of individuals with XLP. Some individuals may have:
   a. Decreased numbers of lymphocyte subsets including decreased T cells, B cells, and NK cells
   b. Variably decreased NK cell function
   c. Dysgammaglobulinemia, most frequently manifest by low serum concentration of IgG with elevated serum concentration of IgM and/or IgA
4. Evidence of acute EBV infections supported by:
   a. Heterophil antibodies on monospot testing
   b. EBV detection by polymerase chain reaction (PCR)
   c. Detection of EBV-specific IgM antibodies
   d. Atypical lymphocytosis on peripheral blood smear
5. Specific tests suggesting the diagnosis of XLP in males with severe EBV infections:
   a. Markedly elevated liver transaminases
   b. Inverted CD4:CD8 ratio in peripheral blood
   c. Liver biopsy consistent with widespread necrosis during severe EBV infection
   d. Bone marrow biopsy with evidence of hemophagocytosis during severe EBV infection
   e. Positive EBV viral capsid antigen (VCA) titer, but negative Epstein–Barr virus nuclear antigen (EBNA) titer
6. Molecular genetic testing: clinically available
   a. Sequence analysis of the entire coding region of *SH2D1A* and exon/intron boundaries identifies nucleotide substitutions, small deletions, small insertions, small insertions/deletions, and small inversions
   b. PCR-based sequencing can detect about 97% of *SH2D1A* mutations in affected males who have two or more maternally related family members with an XLP phenotype and about 75% of mutations in obligate carrier females
   c. Large deletions account for about 25% of mutations in families with XLP
   d. Because males have one X chromosome, the absence of amplification of a region of a gene under stringent laboratory conditions implies that a large deletion or rearrangement is present and because females have two X chromosomes, amplification of a region occurs even in the presence of a large deletion because of the contribution of the second X chromosome; thus, PCR-based sequencing does not accurately detect a large deletion.
7. Carrier detection of at-risk female relatives: available on a clinical basis when the mutation has been identified in the proband or family relative

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: The risk to sibs depends upon the carrier status of the mother
      i. Mother is a carrier: the chance of transmitting the disease-causing mutation in each pregnancy is 50%
      ii. Male sibs who inherit the mutation will be affected
      iii. Female sibs who inherit the mutation will be carriers but asymptomatic and have no immunologic or biochemical markers of the disorder
      iv. Presence of germline mosaicism of the mother: even if the disease-causing mutation has not been identified in DNA extracted from the mother's leukocytes, her offspring are still at increased risk
   b. Patient's offspring
      i. Affected males will likely live to reproduce in the near-future following bone marrow transplantation and that the chemotherapy regimen used prior to BMT will not render them infertile
      ii. Males will pass the disease-causing mutation to all of their daughters and none of their sons
2. Prenatal diagnosis
   a. Fetal karyotyping to determine male fetus (46,XY)
   b. DNA extracted from fetal cells by amniocentesis or CVS analyzed for known gene mutation

3. Management
   a. All identified males receive immunoglobulin replacement to prevent bacterial and viral infections
   b. Allogeneic hematopoietic stem cell transplantation (HSCT): the only definitive cure for XLP, and prevention of EBV and non-EBV complications at present
   c. Treatment is difficult during the acute FIM phase of XLP, as demonstrated by the high mortality rate
      i. Treatment using antivirals (acyclovir/ganciclovir/foscarnet), high-dose immunoglobulin, immunosuppressive agents, and IFN-a and IFN-c have been disappointing
      ii. The high rate of hemophagocytosis associated with XLP has led to the use of antihistiocytic regimes with etoposide such as HLH 94, for the treatment of boys with XLP, shown to induce long-term remission or to stabilize the patient prior to allogeneic HSCT
      iii. Etoposide has also been included in the conditioning regime in combination with busulphan and cyclophosphamide for some patients
   d. Regular immunoglobulin replacement to prevent recurrent infection and additional bacterial prophylaxis in patients developing hypogammaglobulinemia post-viral infection. This may not prevent subsequent development of malignant lymphoma or aplastic anemia. Patients with lymphoma have been treated according to standard chemotherapy protocols but there is a high rate of relapse and patients may also develop other phenotypes of XLP.
   e. Prospect of gene therapy as a future treatment option with the identification of the XLP gene
      i. Recent success of gene therapy for the treatment of two forms of severe combined immunodeficiency offers hope for other immunodeficient conditions
      ii. Gene therapy for XLP is attractive in that the cellular defects are primarily confined to T and NK cells, both of which are readily accessible and can be efficiently transduced

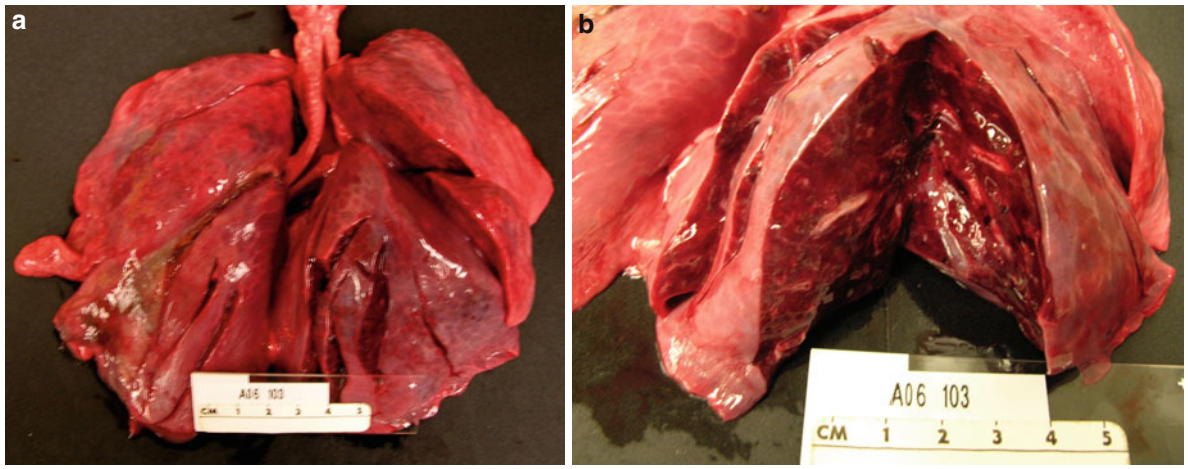

Fig. 1 (**a**, **b**) The deceased patient was a 4-year-old boy complained of fever, anemia, neutropenia, thrombocytopenia, and lymphadenopathy. He was noted to have cervical, axillary, and inguinal lymphadenopathy and hepatosplenomegaly. DNA analysis revealed a nonsense mutation, 172 C > T (Q56X), in the coding sequence of *SH12D1A* gene which confirmed the diagnosis of X-linked lymphoproliferative disease. A maternal first cousin is also affected with Duncan disease. On necropsy, both lungs appeared congested and the cut surface of both lungs was dark and airless with diffuse atelectasis

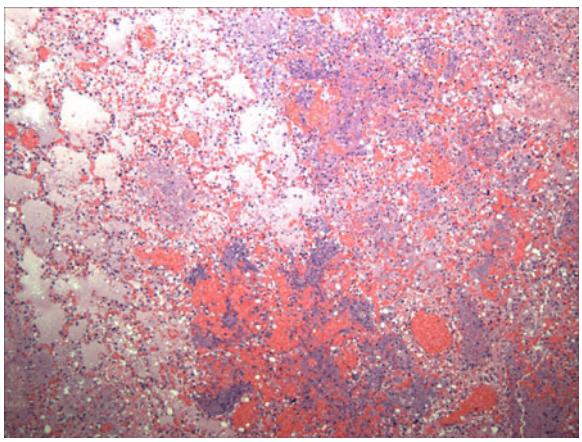

Fig. 2 Microscopic examination of the lungs showed congestion, hemorrhage, and edema with extensive gram-negative bacterial growth

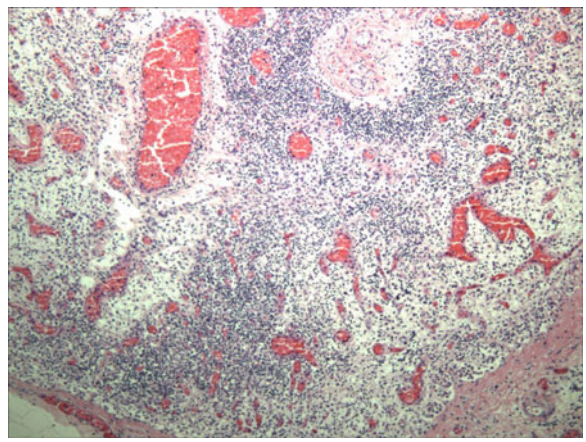

Fig. 3 The microscopic examination of the lymph nodes showed absence of germinal centers, depletion of the lymphocytes, sinus histiocytosis, and vascular congestion

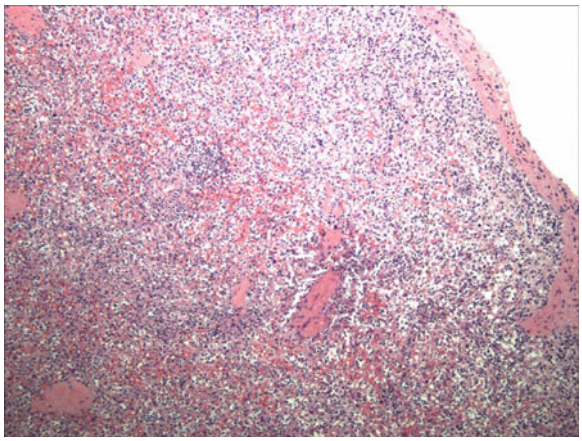

Fig. 4 Microscopic examination of the spleen showed lymphocyte depletion and rare megakaryocytes

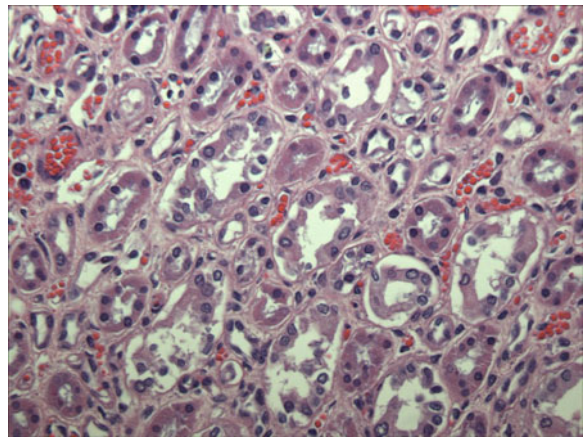

Fig. 7 Proximal tubules of the kidney were necrotic, consistent with ischemic changes

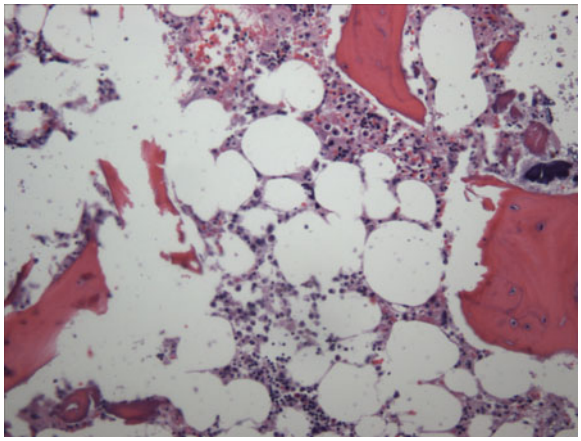

Fig. 5 Bone marrow was hypocellular with fat to cell ratio of 90:10 and very few mature lymphocytes

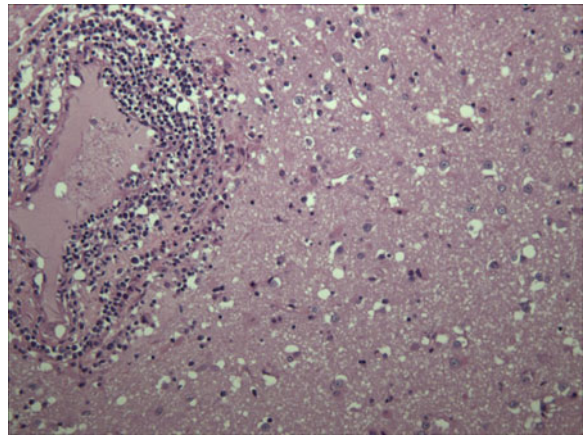

Fig. 8 The brain showed intense perivascular and mild patchy parenchymal infiltration with atypical reactive lymphocytes

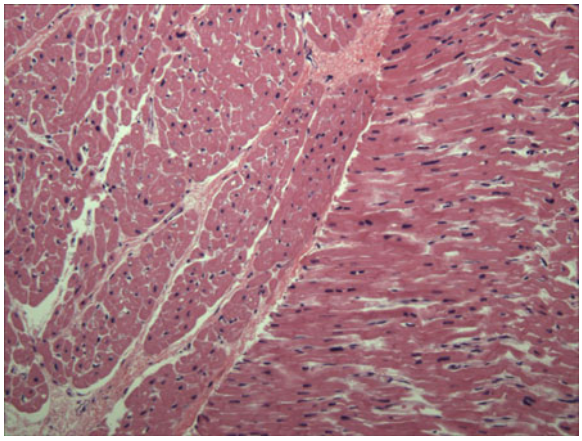

Fig. 6 Nuclei of heart muscles were enlarged, consistent with moderate hypertrophy

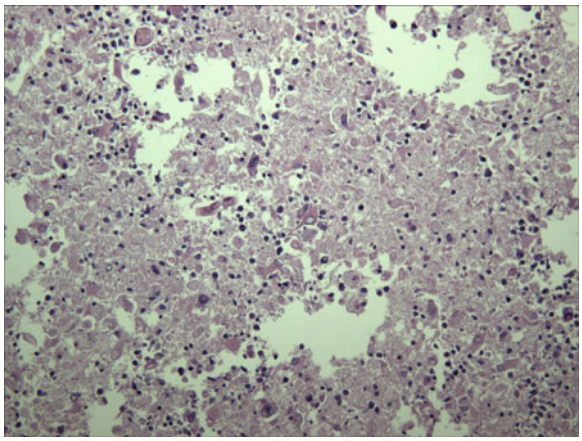

Fig. 9 The liquefied areas of the brain contained numerous foamy macrophages and the surrounding tissue contained numerous gemistocytes (active gliosis), in the RSFG, left corpus striatum, brain stem, and cerebellum

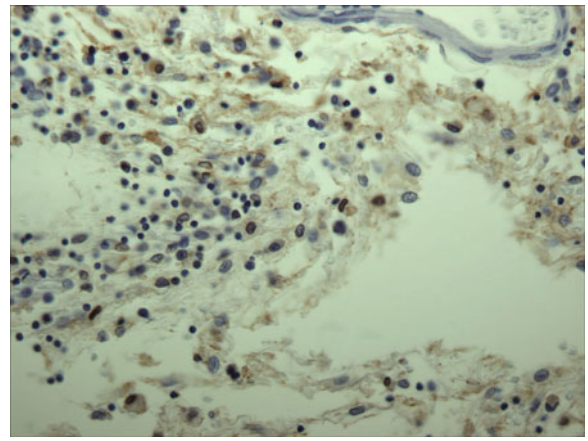

Fig. 10 Some cells in the infiltrate were positive for EB virus by FISH analysis

Dyschondrosteosis

Dyschondrosteosis is an autosomal dominant form of mesomelic dysplasia, first described by Leri and Weill in 1929. Langer mesomelic dysplasia, also called mesomelic dwarfism of the hypoplastic ulna, fibula, and mandible type, is a more severe form (homozygous state) of Leri–Weill dyschondrosteosis.

Synonyms and Related Disorders

Langer mesomelic dysplasia; Leri–Weill syndrome

Genetics/Basic Defects

1. Inheritance
   a. Dyschondrosteosis: autosomal dominant
   b. Langer mesomelic dysplasia: psuedoautosomal recessive
2. Molecular basis (Zinn et al. 2002)
   a. Caused by mutations and deletion of *SHOX* (short stature homeobox-containing) gene
      i. The *SHOX* gene is mapped to Xp22.3, based on the observation of unbalanced translocation involving the pseudoautosomal region of the short arm of the X and Y chromosomes (PAR1) in dyschondrosteosis patients and of some degree of Madelung deformity in Turner syndrome patients.
      ii. The Xp22.3 region encompasses the pseudoautosomal *SHOX* gene, which encodes isoforms of a homeo-domain transcription factor expressed in developing human limbs.
      iii. The gene in the Xp22.3 region escapes X-inactivation in females and participates in obligate recombination during male meiosis. Consequently, dyschondrosteosis segregates as an apparently "autosomal" dominant disorder.
   b. Haploinsufficiency of the *SHOX* gene, implicated in the following disorders:
      i. Turner syndrome: *SHOX* is haploinsufficient in females with 45,X Turner syndrome, accounting for approximately 2/3 of the characteristic growth deficit.
      ii. Idiopathic short stature: Observation that a point mutation that cosegregates with idiopathic short stature suggests that *SHOX* haploinsufficiency may also cause growth failure in the patients with normal karyotype. *SHOX* mutations have been found in 2–3% of patients with idiopathic short stature.
      iii. Leri–Weill dyschondrosteosis (including homozygous form of Langer mesomelic dysplasia)
   c. Identification of large-scale deletions or mutations in the *SHOX* gene in the majority of the cases
   d. *SHOX* mutations: causative for mesomelic growth retardation and Madelung deformity in Leri–Weill dyschondrosteosis and Langer mesomelic dysplasia
   e. Leri–Weill syndrome as a part of contiguous gene syndrome with deletion of Xp22.3

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_72,
© Springer Science+Business Media, LLC 2012

3. Langer mesomelic dwarfism
   a. A homozygous state of dyschondrosteosis gene (Espiritu et al. 1975a, b)
   b. Caused by deletion of both *SHOX* alleles (complete *SHOX* deficiency)
   c. Also associated with compound heterozygous mutations and deletions of the *SHOX* gene, mapped to the pseudoautosomal region 1 (PAR1) of the sex chromosomes Xp22.33 and Y11.32 or the downstream PAR1 where SHOX enhance elements are located
      i. A compound heterozygote with a deletion in the 3′ *SHOX* flanking region in one allele and the loss of the entire *SHOX* gene in the other has been described with a "mild" Langer mesomelic dysplasia phenotype (Fukami et al. 2005)
      ii. Detection of two different deletions in a proband with clinical features of Langer mesomelic dysplasia in the pseudoautosomal 1 region (PAR1) of the X and Y chromosomes: a *SHOX* encompassing deletion inherited from his father and a downstream PAR1 deletion not including *SHOX* inherited from his mother (Campos-Barros et al. 2007)

Clinical Features

1. Dyschondrosteosis
   a. Mesomelic dwarfism (disproportionate short stature)
   b. Phenotypic inter- and intrafamilial heterogeneity, a frequent finding
   c. Much more common and less severe than Langer mesomelic dysplasia
   d. Females more commonly and more severely affected (more severe Madelung deformity) than males
   e. Intelligence: normal
   f. Limbs
      i. Mesomelia (disproportionate forelimb shortening)
         a) Shortened forearms
         b) Shortened forelegs
      ii. A Madelung deformity of the forearms and wrists secondary to bowing of the radius and dorsal subluxations of the distal ulna
      iii. Reduced radiocarpal motion
      iv. Limited elbow and wrist pronation and supernation
      v. Genu varum
2. Langer mesomelic dysplasia
   a. The homozygous form of Leri–Weill syndrome (Espiritu et al. 1975a, b)
   b. Severe disproportionate short stature with marked mesomelic and rhizomelic limb shortening
   c. Parents of some children with Langer mesomelic dysplasia have features of the more common dominantly inherited mesomelic skeletal dysplasia Leri–Weill dyschondrosteosis.
   d. Intelligence: normal
   e. Limb malformations
      i. Aplasia or severe hypoplasia of the ulna and fibula
      ii. Thickened and curved radius and tibia
   f. Hypoplasia of the mandible
   g. A variable degree of Madelung deformity and mesomelic shortening in both parents
3. Prognosis
   a. Minimal disability from the Madelung deformities of the wrists
   b. Secondary arthrosis of the radiocarpal joint
   c. Osteoarthritis of the large joints
   d. Langer mesomelic dysplasia: much more severe phenotype than dyschondrosteosis

Diagnostic Investigations

1. Radiography
   a. Mesomelic dysplasia
   b. Madelung deformity of the wrists
      i. Short forearm
      ii. Bowed radius
      iii. Bowed ulna
      iv. Premature fusion of the ulnar half of the radial epiphysis
      v. A V-shaped deformity of the wrist with slanting at the distal radial contour and dorsal dislocation of the ulna
      vi. Wedging of the carpal bones between the deformed radius and protruding ulna, resulting in a triangular configuration with the lunate at the apex
      vii. Cubitus valgus
   c. Coxa valga

d. Lateral subluxation of the patella
e. Short tibia
f. Exostosis of the proximal medial tibia
g. Langer mesomelic dysplasia
   i. Aplasia or severe hypoplasia of the ulna and fibula
   ii. Thickened and curved radius and tibia

2. Cytogenetic analysis (Munns and Glass 2008)
   a. Rare patients with Leri–Weill dyschondrosteosis
      i. A contiguous gene syndrome caused by deletion in distal Xp22.3 (Ballabio et al. 1989; Spranger et al. 1999)
      ii. An unbalanced X;Y translocation (Shears et al. 1998)
      iii. Complex sex chromosome abnormalities (Wei et al. 2001)
   b. Submicroscopic deletions of SHOX causing the SHOX-related haploinsufficiency disorders: not usually detectable by G-banded karyotyping
3. Molecular genetic analysis
   a. *SHOX* deletions detected by FISH analysis using cosmid probe for *SHOX*
   b. MLPA for PAR1 deletions
   c. High-resolution melting (HRM), dHPLC and/or DNA sequencing for point mutations, small deletions and insertions of *SHOX*

Genetic Counseling

1. Recurrence risk
   a. Patient's sibs
      i. Leri–Weill dyschondrosteosis
         a) Neither parent is affected: not increased
         b) One parent is affected with Leri–Weill dyschondrosteosis: 50% affected with Leri–Weill dyschondrosteosis and 50% unaffected
         c) Two parents are affected with Leri–Weill dyschondrosteosis: 50% affected with Leri–Weill dyschondrosteosis, 25% affected with Langer mesomelic dysplasia, and 25% risk of having neither conditions
      ii. Langer mesomelic dysplasia (both parents with Leri–Weill dyschondrosteosis): 50% affected with Leri–Weill dyschondrosteosis, 25% affected with Langer mesomelic dysplasia, and 25% unaffected
   b. Patient's offspring
      i. Leri–Weill dyschondrosteosis
         a) Spouse is normal: 50% affected and 50% unaffected
         b) Spouse is affected with Leri–Weill dyschondrosteosis: 50% affected with dyschondrosteosis, 25% affected with Langer mesomelic dysplasia, and 25% having neither condition
      ii. Langer mesomelic dysplasia
         a) Spouse is normal: All children will be affected with Leri–Weill dyschondrosteosis
         b) Spouse is affected with Leri–Weill dyschondrosteosis: 50% affected with Langer mesomelic dysplasia and 50% affected with Leri–Weill dyschondrosteosis
2. Prenatal diagnosis possible for at-risk families
   a. Prenatal ultrasonography of skeletal features compatible with mesomelic dwarfism
   b. Molecular analysis of previously identified disease-causing *SHOX* mutations in the proband or a parent from the fetal DNA obtained from amniocentesis or CVS
   c. Preimplantation genetic diagnosis may be available for families in which the disease-causing mutation has been identified
3. Management
   a. Medical therapy of Madelung deformity
      i. May be helpful in skeletally mature individuals with Madelung deformity who have mild-to-moderate short-term wrist pain
      ii. Splints to relief joint pain
      iii. Decrease manual activity levels to manage symptoms without surgery
   b. Surgical therapy of Madelung deformity
      i. Primary goals: pain relief and cosmetic improvement of Madelung deformity
         a) Minimal improvement of range of motion, especially in pronation and supination
         b) Release of the Vickers ligament alone or in combination with an osteotomy
      ii. Osteotomy of radius
      iii. Radioulnar length adjustment
      iv. Ulnar resection
   c. Tibial osteotomy and lengthening combined with epiphyseodesis of the distal fibular epiphysis for the tibiofibular disproportion

d. Ongoing clinical trial with growth hormone therapy in patients with short stature due to *SHOX* mutations

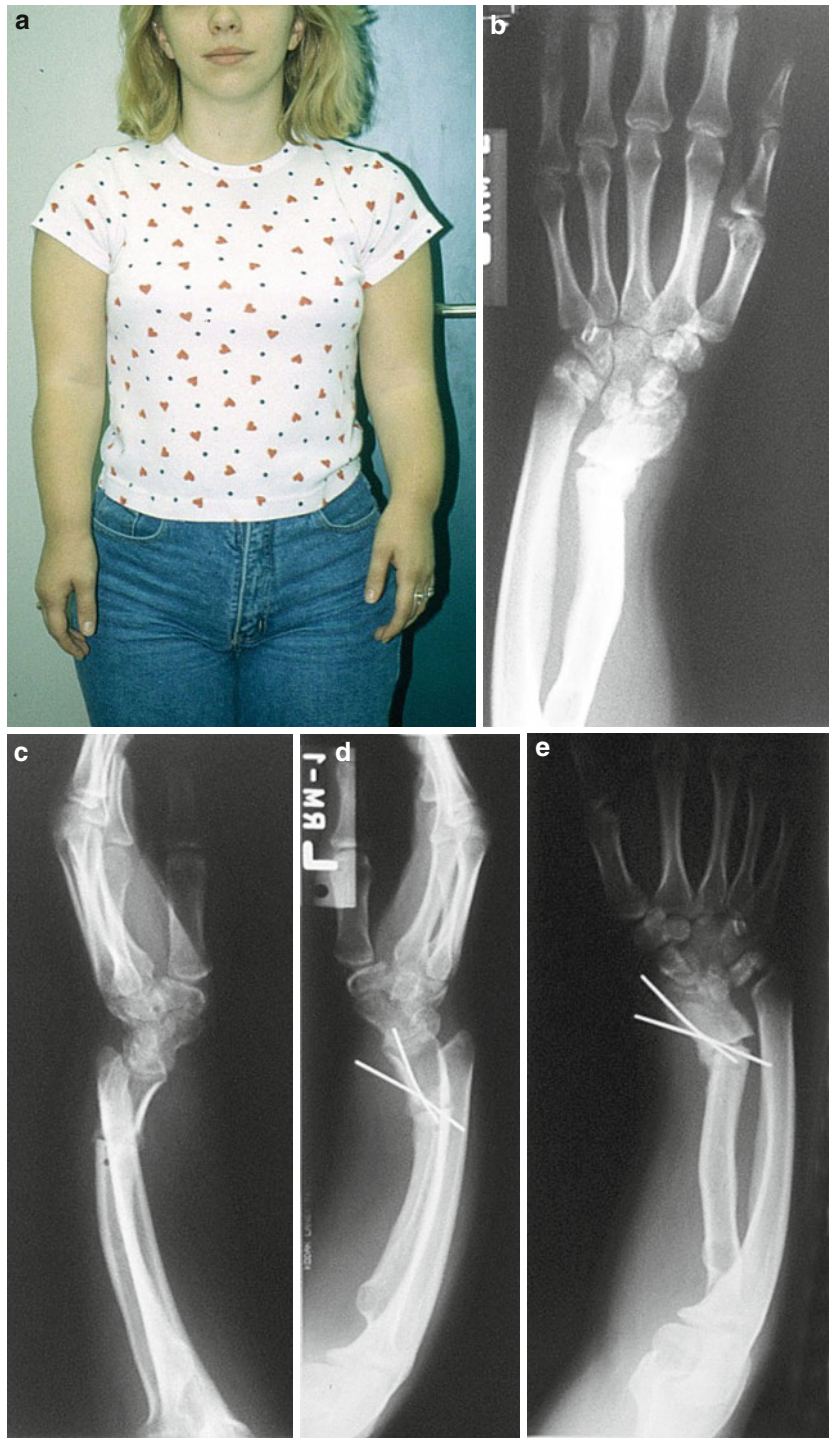

Fig. 1 (**a**–**e**) A young lady with Leri–Weill syndrome showing disproportionate short stature, short forearms and legs, and Madelung deformity of the wrists. Radiographs illustrate typical Madelung deformity (curved radius and ulna with triangular configuration) corrected by surgery

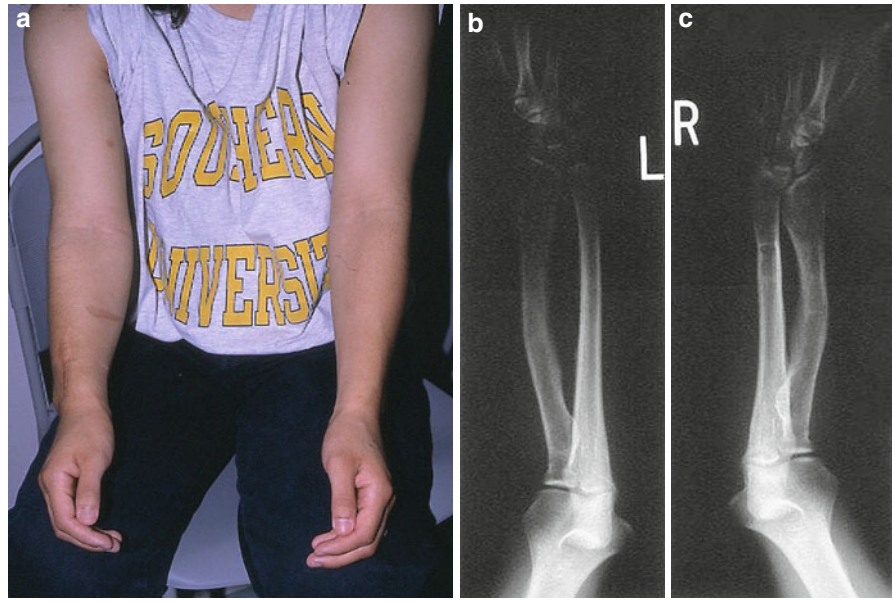

Fig. 2 (**a**–**c**) A young lady with Leri–Weill syndrome with short forearms and Madelung deformity demonstrated by radiographs

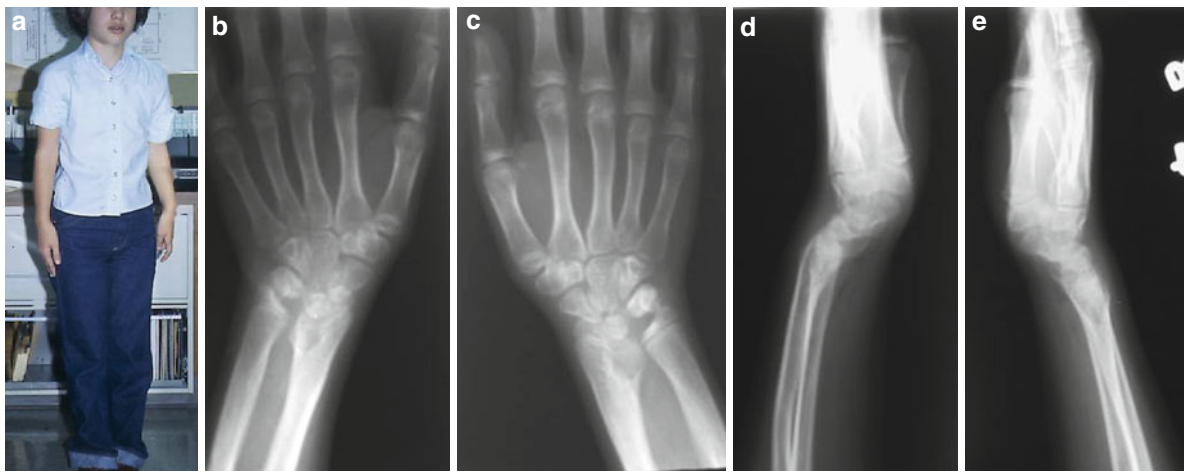

Fig. 3 (**a**–**e**) A young lady with Leri–Weill syndrome showing disproportionate short stature, short forearms and legs, and Madelung deformity illustrated by radiographs

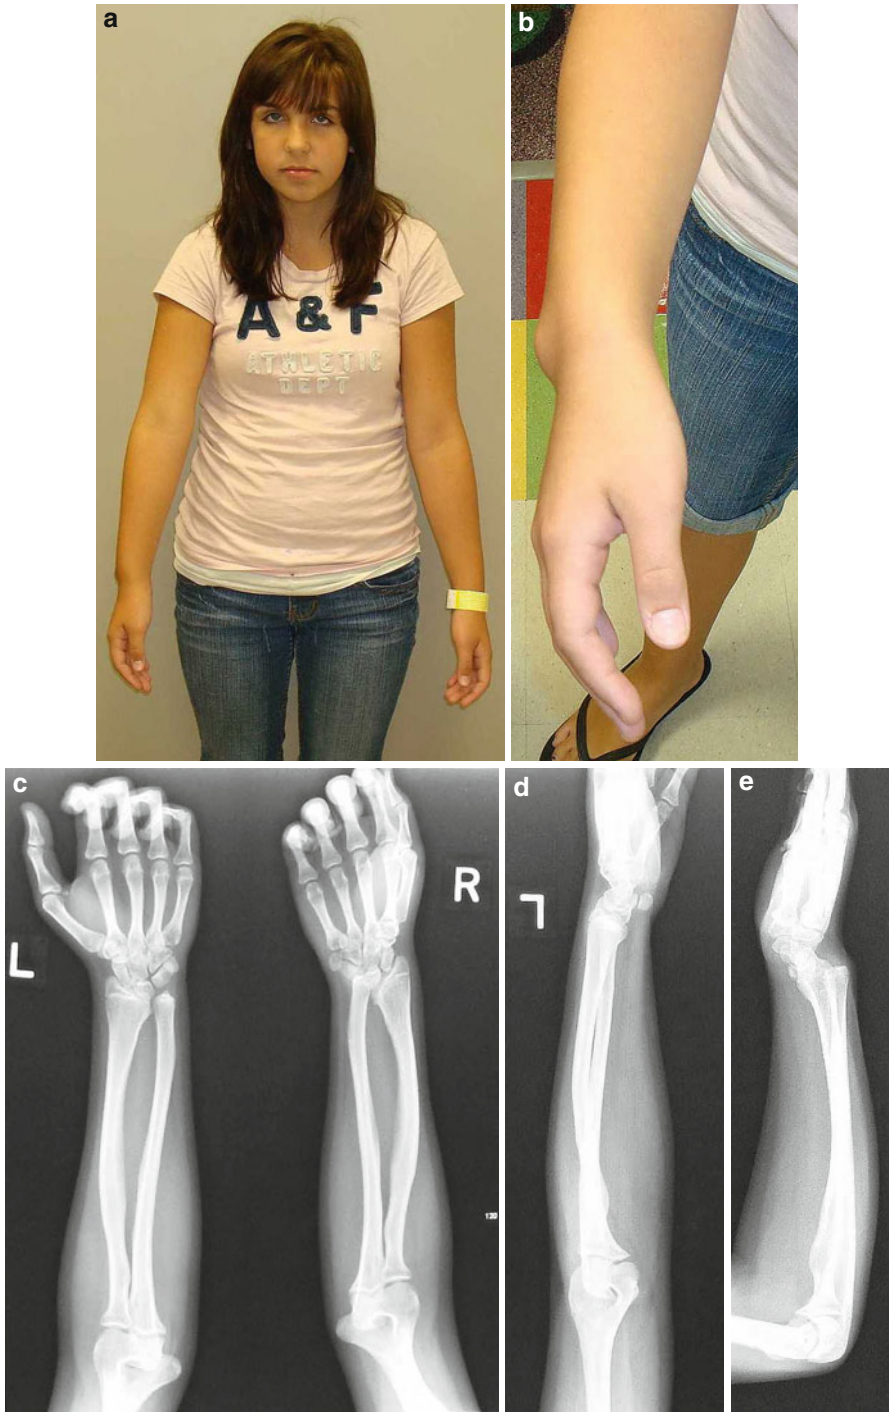

Fig. 4 (**a**–**e**) A 14-year-old girl with Leri–Weill syndrome showing disproportionate short stature, short forearms and legs, and Madelung deformity of the wrists. Radiographs illustrate typical Madelung deformity (curved radius and ulna with triangular configuration)

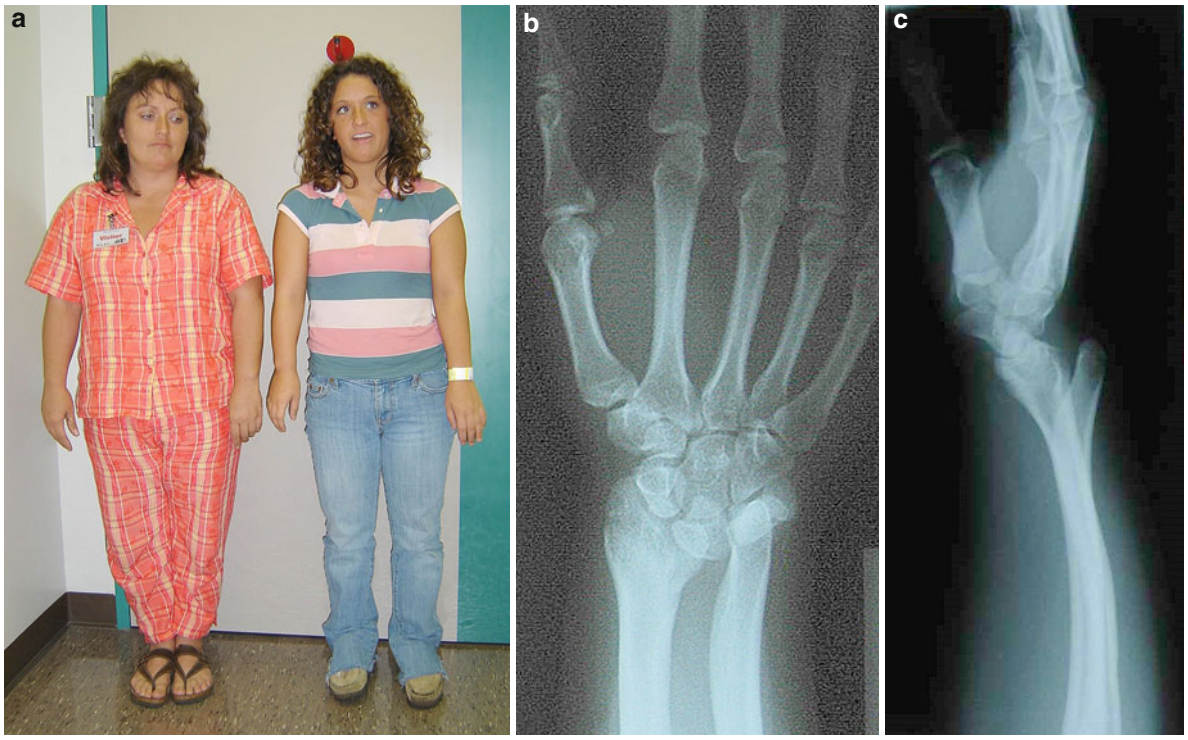

Fig. 5 (**a**–**c**) Mother and daughter with Leri–Weill syndrome with typical phenotype and wrist radiographs

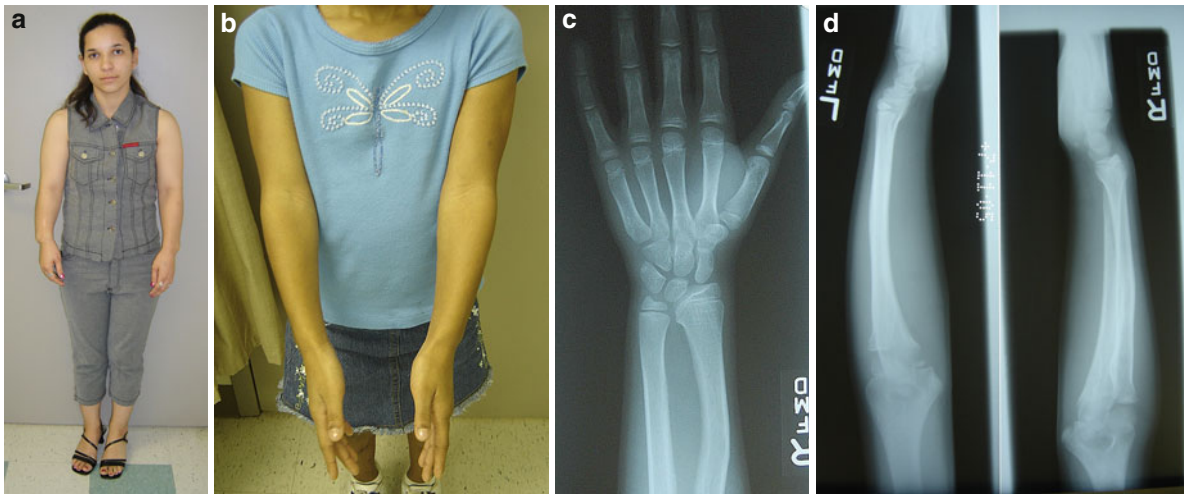

Fig. 6 (**a**–**d**) Another mother and daughter with Leri–Weill syndrome and forearm radiographs of the daughter

Fig. 7 (**a**–**m**) Two sibs with Langer mesomelic dysplasia showing severe mesomelic dwarfism, Madelung deformities, and radiographic features of bowed and foreshortened radius and ulna, hypoplastic/aplastic fibula, and short and thick tibia. Both parents have dyschondrosteosis (Espiritu et al. 1975a, b)

Fig. 8 (**a**, **b**) Radiograph of the mother of above two children showing typical Madelung deformity

Dysmelia

Dysmelia is a widely accepted term used to define a group of malformations in which there is hypoplasia, and partial or total aplasia of the tubular bones of the extremities, ranging from isolated peripheral hypoplasia to complete loss of the extremity. The condition is commonly known as limb deficiency or limb reduction defect. The prevalence rate for all types of limb deficiency is 0.69 per 1,000 (McGuirk et al. 2001).

Synonyms and Related Disorders

Amelia; Ectromelia (ectrodactyly); Limb deficiency/reduction; Phocomelia

Genetics/Basic Defects

1. Causes: heterogeneous
   a. Known syndromes
      i. Holt-Oram syndrome
      ii. Fanconi syndrome
      iii. Split hand deformity
      iv. EEC syndrome
      v. Thrombocytopenia-absent radius (TAR) syndrome
   b. Chromosome abnormalities
   c. Teratogens
      i. Thalidomide (Tseng et al. 1996; Radomsky and Levine 2001)
         a) A hypnosedative drug, introduced and marketed as Contergan in Germany in the 1950s
         b) Promoted as a safe sedative and was found to be useful as an antiemetic during pregnancy, resulting in its widespread use throughout Europe in late 1960
         c) Has been used in the past few decades in a variety of dermatologic conditions (e.g.,erythema nodosum leprosum, prurigo nodularis, actinic prurigo, discoid lupus erythematosus, aphthous stomatitis, Behcet syndrome, and graft-versus-host disease)
         d) Side effects: teratogenicity and peripheral neuropathy
         e) Producing a symmetrical pattern of deficiency (or polydactyly) on the preaxial side of both arms and legs
      ii. Misoprostol (prostaglandin E1 analog)
         a) Asymmetrical digit loss
         b) Constriction rings
         c) Syndactyly
   d. Fetal constraint
      i. Ectopic tubal gestation
      ii. Uterine structural anomalies
      iii. Early amnion rupture
   e. Vascular disruption
      i. Early chorionic villous sampling
         a) Symmetrical digit loss
         b) Constriction rings
         c) Syndactyly
      ii. Dilation and curettage
      iii. Exposure to ergotamine
      iv. Trauma to the abdomen and placenta
   f. Unknown causes

2. The pattern of malformation in dysmelia (Henkel and Willert 1969)
   a. A diminution of skeletal material
   b. Disturbance of maturation of remaining skeletal elements
   c. Relationship of the malformed extremities to each other
3. A diminution of skeletal material: common to all malformations of dysmelia
   a. Reduction tendencies of individual bones: The reduction of the skeletal material of the individual bone follows a certain direction and sequence:
      i. Thumb: The reduction tendency of the thumb directs from proximal to distal:
         a) Hypoplastic tubular bones of the thumb and the first metacarpal in the mildest cases
         b) Reduction of skeletal material beginning at the base of the first metacarpal in the more severe cases
         c) The shaft of the thumb becomes aplastic with increasing severity
         d) The last remnant of the first metacarpal is its head, followed by defective proximal phalanx.
         e) Preservation of the terminal phalanx until, in total aplasia, all bones of the thumb disappear
      ii. Big toe and first metatarsal: the reduction tendency same as the thumb
      iii. Radius and tibia: The reduction tendency directs from distal to proximal:
         a) Hypoplasia: the mildest degree of malformation of the radius or the tibia
         b) A defect seen in the distal part of the metaphysis with increasing severity, extending in a proximal direction with more severe deformities
         c) The head disappears last, before the radius or tibia becomes totally aplastic.
      iv. Humerus and femur: The reduction tendency directs from proximal to distal:
         a) Hypoplastic: the mildest cases of the axial form of ectromelia
         b) A defect of bone at the proximal end (just distal to the head of the humerus or in the region of the neck and the trochanter in the femur) in more pronounced cases
         c) Distal epiphysis represents the last part of the humerus or the femur until it disappears in total aplasia.
   b. Reduction tendency of the limb as a whole:
      i. Upper limb
         a) Mild manifestations of the deformity restricted to the radial ray of the hand
         b) With increasing severity, the radius becomes involved and only after the radius is either completely absent or its remnants have fused with ulna is the humerus affected.
      ii. Lower limb
         a) Impairment of the tibia and the tibial ray in mild cases
         b) The tibia need not be totally absent and its remnants need not be fused before the femur shows signs of reduction.
         c) The isolated malformations of the femur have been observed without impairment of the distal part of the limb.
      iii. Coincidental impairment of the shoulder and pelvic girdles with the reduction of the limb mass
         a) The degree of the impairment dependents on the severity of the humeral or femoral defect.
         b) Most pronounced in phocomelia and amelia
      iv. Reduction of the hand and fingers
         a) Strictly dependent on the severity of the defect of the skeleton of the arm
         b) A decrease in the number of remaining fingers as the defect of the skeleton of the arm increases
         c) Radial hypoplasia: All fingers may be present; their number is reduced to four or even three in the axial types and very often to one in phocomelia.
         d) The reduction of the hand starting at the thumb and progressing from the radial to the ulnar side, so that with increasing severity of the arm deficiency, the index, middle, and ring fingers are absent.
      v. Reduction of foot in dysmelia
         a) Reduction progresses from the tibial to the fibular rays.
         b) Isolated malformations of the tibial ray: extremely rare in dysmelia

c. The axis of malformation in dysmelia:
   i. Combination of the humerus, radius, and radial ray of the hand in an axis of malformation within the skeleton of the upper extremity, sparing the ulnar
   ii. Same combination seen in the lower extremity, where the axis is formed by the femur, the tibia, and the tibial ray of the foot, sparing the fibula
   iii. In the short axial types, the ulna or the fibula is the only long bone of the extremity that still exists.
d. Fusion of the adjacent bones:
   i. The skeletal elements undergoing fusion: always hypoplastic or partially aplastic
   ii. Fusion occurring in parallel bones (carpals, tarsals, metacarpals, metatarsals, radius, and ulna) or in bones arranged longitudinally (phalanges, humerus, and ulna)
   iii. Tendency toward synostosis in the lower extremity appears to be limited to the bones of the foot.

4. Disturbance of maturation of remaining skeletal elements
   a. Retardation of cartilage ossification in bones not directly involved in the defect
   b. Ossification centers far away from the part directly involved tend to ossify in a delayed manner.
5. Relationship of the malformed extremities to each other
   a. Bilateral and symmetrical in manifestation in most cases of amelia
   b. Presence of lower limbs is observed in most patients with dysmelia of the upper extremity, even if the arms are phocomelic or amelic.

Clinical Features

1. Classification of dysmelia (Henkel and Willert 1969)
   a. Ectromelia:
      i. Definition: used to include those dysmelia in which the radius and the tibia with their peripheral rays and the humerus or the femur are involved.
      ii. Classification (Henkel and Willert 1969): There is a need to subdivide into the distal, axial, and proximal forms of ectromelia because there are differences in manifestation and severity of skeletal abnormality and in some cases, synostosis occurs as well as reduction.
         a) Distal form of ectromelia
         b) Axial form of ectromelia
         c) Proximal form of ectromelia
   b. Phocomelia:
      i. Definitions
         a) Used to include those dysmelia in which no remnants of long bones are seen between the limb girdle and the peripheral part (hands and foot)
         b) Used to describe the congenital anomaly in which a limb is represented by a flipper-like appendage
      ii. Classification (Frantz and O'Rahilly 1961)
         a) Type I: complete phocomelia (hand or digits attached directly to trunk)
         b) Type II: proximal phocomelia (Forearm bones between hand and trunk)
         c) Type III: distal phocomelia (hand attached directly to humerus)
      iii. Unclassifiable limbs (Tytherleigh-Strong and Hooper 2003)
         a) Type A: an abnormal humerus with an abnormal single forearm bone
         b) Type B: an abnormal humerus with an abnormal radius and ulna
         c) Type C: an abnormal humerus fused to a forearm bone or bones
   c. Amelia: used to include the most severe degree of dysmelia in which there is total loss of an extremity
2. Distal form of ectromelia
   a. Confined to the distal part of the extremity
   b. Involving the radial ray of the hand and the radius only
      i. Thumb type: the mildest degree of dysmelia, affecting the first ray of the hand only with the following two different manifestations:
         a) Triphalangism of the thumb
         b) Hypoplasia of the thumb
      ii. Radial type: sparing the ulnar
         a) Hypoplasia of the radius
         b) Hypoplasia of the radius with radioulnar synostosis
         c) Partial aplasia of the radius
         d) Partial aplasia of the radius with radioulnar synostosis
         e) Total aplasia of the radius

c. Involving the tibial ray of the foot and the tibia only
   i. Big toe type
      a) Triphalangism of the big toe
      b) Duplication of the big toe
   ii. Tibial type: sparing the fibula
      a) Hypoplasia of the tibia
      b) Partial aplasia of the tibia
      c) Total aplasia of the tibia

3. Axial form of ectromelia
   a. Involvement of the distal as well as the proximal part of the limb
      i. Involving the radius, the radial ray of the hand, and the humerus
         a) Sparing the ulnar
         b) The malformed radius: hypoplastic, partly aplastic, or totally aplastic
         c) The remnants of the radius in partial aplasia: regularly fused with the ulna, presenting as radioulnar synostosis
      ii. Involving the tibia, the tibial ray of the foot, and the femur
         a) Sparing the fibula
         b) The remnant of the tibia not showing tendency toward synostosis
   b. The different degrees of reduction of the humerus or the femur leading to the upper and lower limb types:
      i. Upper limb type
         a) Long axial type of the arm: hypoplasia or partial aplasia of the humerus with partial aplasia of the radius and radioulnar synostosis or with total aplasia of the radius
         b) Intermediate axial type of the arm: subtotal aplasia of the humerus with partial aplasia of the radius and radioulnar synostosis or with total aplasia of the radius
         c) Short axial type of the arm: total aplasia of the humerus with partial aplasia of the radius and radioulnar synostosis or with total aplasia of the radius
      ii. Lower limb type
         a) Long axial type of the leg: hypoplasia or partial aplasia of the femur with partial or total aplasia of the tibia
         b) Intermediate axial type of the leg: subtotal aplasia of the femur with partial or total aplasia of the tibia
         c) Short axial type of the leg: total aplasia of the femur with partial or total aplasia of the tibia

4. Proximal form of ectromelia
   a. Can be found only in the lower limb
   b. No parallel defect in the upper limb
   c. Only involves the proximal part of the lower limb, the femur, which can display all different degrees of reduction, leading to the following subtypes:
      i. Long proximal type: hypoplasia of the femur, coxa vara or partial aplasia of the femur without impairment of the distal part of the limb
      ii. Intermediate proximal type: subtotal aplasia of the femur without impairment of the distal part of the limb
      iii. Short proximal type: total aplasia of the femur without impairment of the distal part of the limb

5. Phocomelia
   a. Absent humerus, radius, and ulna or femur, tibia, and fibula
   b. Remainder of the extremity
      i. Consisting of a malformed hand formed by one, two, or three ulnar finger rays and ulnar parts of the carpus or of a similarly affected foot
      ii. Directly attached to a hypoplastic shoulder girdle or to a misshapen pelvis

6. Amelia
   a. The most severe form of dysmelia
   b. Total absence of the arm or the leg
   c. Shoulder girdles: hypoplastic in the absence of the arms
   d. Pelvis: deformed in a box-like shape in the absence of the legs

7. Differential diagnosis (Tseng et al. 1996; Radomsky and Levine 2001)
   a. Transverse limb defects
      i. Adam-Oliver syndrome
      ii. Amniotic band sequence
      iii. Oromandibular limb hypogenesis syndrome
      iv. Poland anomaly
      v. Fetuses with homozygous α-thalassemia
   b. Preaxial limb defects
      i. Chromosome syndromes
      ii. Facio-radial syndromes (e.g., Nager syndrome)
      iii. Hemato-radial syndromes
         a) Aase syndrome
         b) Fanconi anemia
         c) TAR syndrome

iv. Holt-Oram syndrome
v. Poland anomaly
vi. Roberts syndrome
vii. VATER association

c. Central limb defects
i. EEC syndrome
ii. Poland anomaly

d. Postaxial limb defects
i. Cornelia de Lange syndrome
ii. Facio-ulnar syndromes (e.g., Miller syndrome)
iii. Femur-fibula-ulna complex
iv. Ulnar mammary syndrome

e. Amniotic band syndrome and other mechanical and constraint problems
i. Digital constrictions and amputations
ii. Transverse amputations of the distal and proximal limbs, with a normal limb above the amputation
iii. Amelia

f. Vascular compression, disruption thrombosis, embolization
i. Transverse amputations
ii. Postaxial and preaxial limb reduction defect
iii. Femoral hypoplasia
iv. Digital amputation or hypoplasia
v. Poland anomaly

g. Genetic diseases
i. Many dominant and recessive syndromes
a) Bilateral and unilateral limb reduction defect of preaxial or postaxial type
b) Ectrodactyly
c) Monodactyly
ii. Limb reduction defects as features of many different genetic disorders, such as absent radius with absence/hypoplasia of the thumb

h. Cytogenetic abnormalities (e.g., del(13q) syndrome and trisomy 18 syndrome)
i. Severe limb hypoplasia
ii. Polydactyly
iii. Absent thumb
iv. Absent radius
v. Other multiple congenital anomalies

i. Thalidomide embryopathy (Radomsky and Levine 2001)
i. Deformities of the upper and lower extremities: grossly symmetric, although opposite limbs are often unequally affected to some degree
a) Amelia
b) Phocomelia
c) Bone hypoplasia
d) Absence of bones
ii. Abnormalities of the external ears
a) Anotia
b) Micro pinna
c) Small or absent auditory canals
iii. Abnormalities of the eyes
a) Anophthalmia
b) Microphthalmos
c) Coloboma
d) Cataracts
iv. Face
a) Hypoplastic nasal bridge
b) Choanal atresia
v. CNS malformations
a) Facial nerve paralysis
b) Deafness
c) Marcus Gunn or jaw-winking phenomenon
d) Crocodile-tear syndrome
e) Seizure disorder
vi. Respiratory tract anomalies
a) Laryngeal and tracheal abnormalities
b) Abnormal lobulation of the lungs
vii. Cardiovascular anomalies
a) Capillary hemangioma, extending from dorsum of the nose to the philtrum in the midline
b) Congenital heart diseases (conotruncal defects)
viii. Gastrointestinal anomalies
a) Upper intestinal atresia
b) Congenital absence of the gall bladder and the appendix
c) Anal stenosis
d) Inguinal hernias
ix. Renal anomalies
a) Abnormal rotation of the kidney
b) Pelvic position of the kidneys
c) Horseshoe kidney
d) Hydronephrosis
e) Double ureter
x. Genital anomalies
a) Double vagina
b) Vaginal atresia

c) Rectovaginal fistula
d) Cryptorchidism
xi. Mortality: 40% at or shortly after birth
j. Warfarin and diphenylhydantoin
i. Digital hypoplasia
a) Usually mild
b) Can be severe
ii. Limb hypoplasia due to chronic exposure throughout gestation, usually very mild
k. Maternal diabetes
i. Femoral hypoplasia
ii. Sacral agenesis

Diagnostic Investigations

1. Radiography (Cobben et al. 1994)
   a. Evaluate limb defects
   b. Evaluate non-limb skeletal defects
2. Diagnostic protocol for preaxial defects
   a. Blood count including thrombocytes
   b. Hb F (electrophoresis)
   c. Urine sediment
   d. Renal sonography
   e. Echocardiography
   f. Chromosome analysis
   g. Audiologic evaluation
   h. Ophthalmologic evaluation

Genetic Counseling

1. Recurrence risk (Cobben et al. 1994)
   a. Patient's sib
      i. Genetic syndromes: depending on the inheritance pattern of the disorder
      ii. Chromosome abnormalities: about 1% unless the parent carries a translocation
      iii. Environmental factors: not increased unless the mother exposes to the teratogen during pregnancy
      iv. Non-syndromic nonfamilial reduction defects of one limb
         a) Transversal: <1%
         b) Postaxial: <1%
         c) Preaxial: Low
         d) Central: low
      v. Non-syndromic nonfamilial reduction defects of more than one limb
         a) Transversal: probably low
         b) Postaxial: probably low
         c) Preaxial: unknown
         d) Central: unknown
   b. Patient's offspring
      i. Genetic syndromes: depending on the inheritance pattern of the disorder
      ii. Chromosome abnormalities: patients usually not surviving to reproduction
      iii. Environmental factors: not increased unless patient exposes to the same teratogen during pregnancy
      iv. Non-syndromic nonfamilial reduction defects of one limb
         a) Transversal: <1%
         b) Postaxial: <1%
         c) Preaxial: probably low
         d) Central: probably low
      v. Non-syndromic nonfamilial reduction defects of more than one limb
         a) Transversal: possibly low
         b) Postaxial: possibly low
         c) Preaxial: unknown
         d) Central: autosomal dominant
2. Prenatal diagnosis
   a. Transvaginal sonography: an important element in the evaluation of any first trimester limb deficiencies
   b. Second trimester ultrasonography to detect limb deficiencies and other associated anomalies
   c. Chromosome analysis from amniocentesis or CVS to rule out chromosome anomaly
3. Management
   a. Avoid using teratogenic agents during pregnancy
   b. Management of malformation of the upper extremities
      i. Bilateral upper extremity: amelia and/or phocomelia
         a) Good prosthetic fitting of children based primarily on relating prosthetic function to the functional needs of the patient to be fitted
         b) Satisfactory foot function, a prerequisite to the prosthetic habilitation of the severe bilateral upper limb problem in children

c) Compensatory prehension patterns developed by the feet, helpful particularly in total toilet care and total dressing and undressing

ii. Upper extremity: paraxial hemimelica
   a) Passive stretching
   b) Application of splints to stabilize the wrists

iii. Bilateral transverse hemimelia: fit with standard prostheses with hooks as terminal devices

c. Management of malformation of the lower extremities
   i. Lower extremity phocomelia
      a) Fit with a special bucket on a pair of short skis to develop balance
      b) Prostheses to help walking
   ii. Bilateral transverse lower hemimelia: fit with conventional appliances

d. Occupational therapy: exercise and other treatment of the upper extremities to increase strength and dexterity to prepare to operate prostheses

e. Prosthetic training of the children

f. Parents' contribution
   i. Observation of the child's training session
   ii. Parent to learn to:
      a) Put on and remove prostheses
      b) Care and encourage use of the prostheses
      c) Cleanse the stump

g. Prosthetic devices
   i. Every effort to be made to develop a prosthesis that will compensate for the absence of functions and restore independence to the greatest possible degree
   ii. Main objectives
      a) To assist the child to develop a normal body image
      b) To construct a prosthesis based on sound anatomical principles which has an adequate range of motion
      c) To fit the prosthesis early so that, at a few months of age, the child unconsciously accepts it as a part of his body

h. Psychosocial counseling
   i. To assist parents to cope with the situation
   ii. To explain the plan of treatment to parents
   iii. Overall success of a given family in accepting and adjusting to a congenital deformity: related to its educational level and the usual pattern of behavior of its members under stress

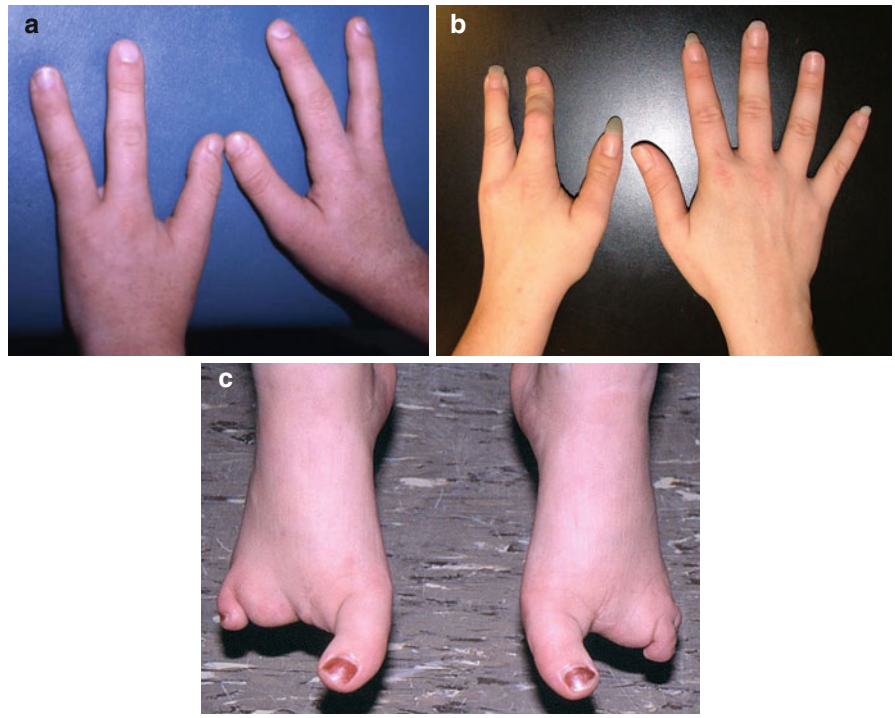

Fig. 1 (**a**–**c**) Ectrodactyly of hands and feet in three patients showing symmetric and asymmetric anomalies

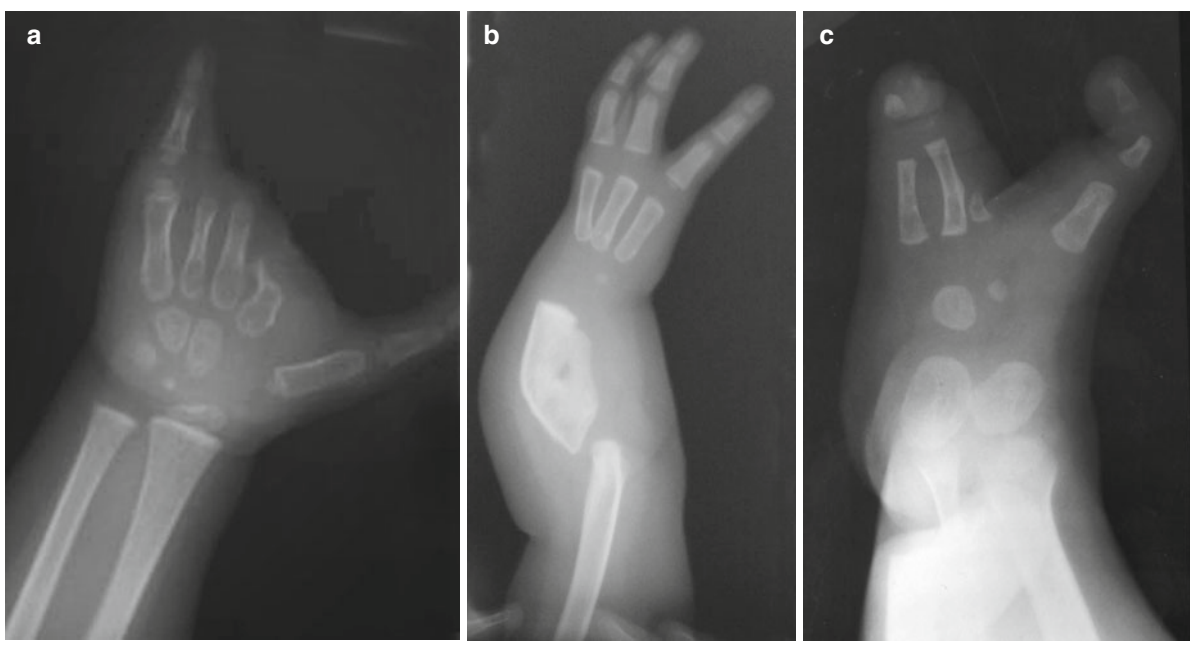

Fig. 2 (**a**–**c**) Radiographs of ectrodactyly (two hands and a foot) in three patients showing different types of ectrodactyly

Fig. 3 (**a**–**c**) An embryo with phocomelia showing deficient limbs, illustrated by radiograph

Fig. 4 (**a**, **b**) A neonate with amelia of the upper limbs and reduction malformations of the lower limbs

Fig. 5 A child with amelia showing complete absence of upper extremities

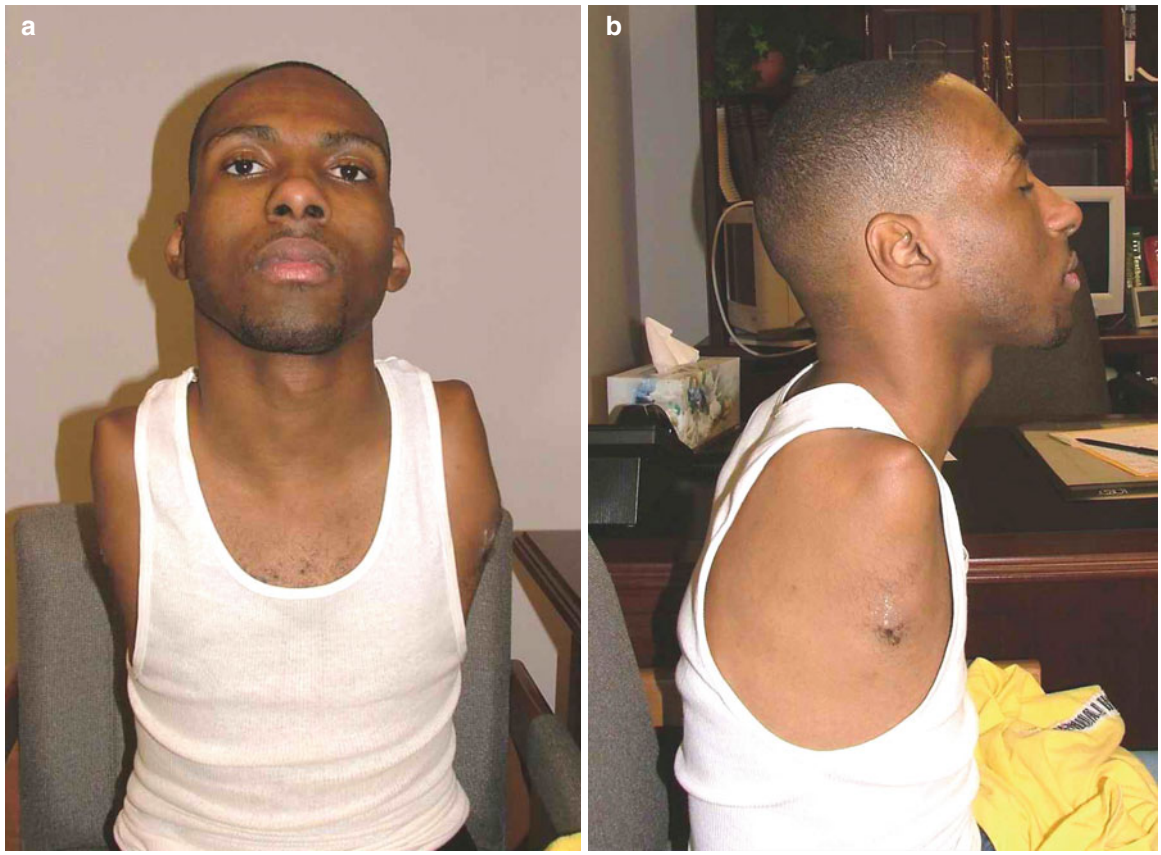

Fig. 6 (**a**, **b**) A patient with amelia of the upper extremities. He is intelligent, uses his chin and shoulder to write, and drives a car by using one foot to turn the driving wheel and one foot to pedal the accelerator and brake

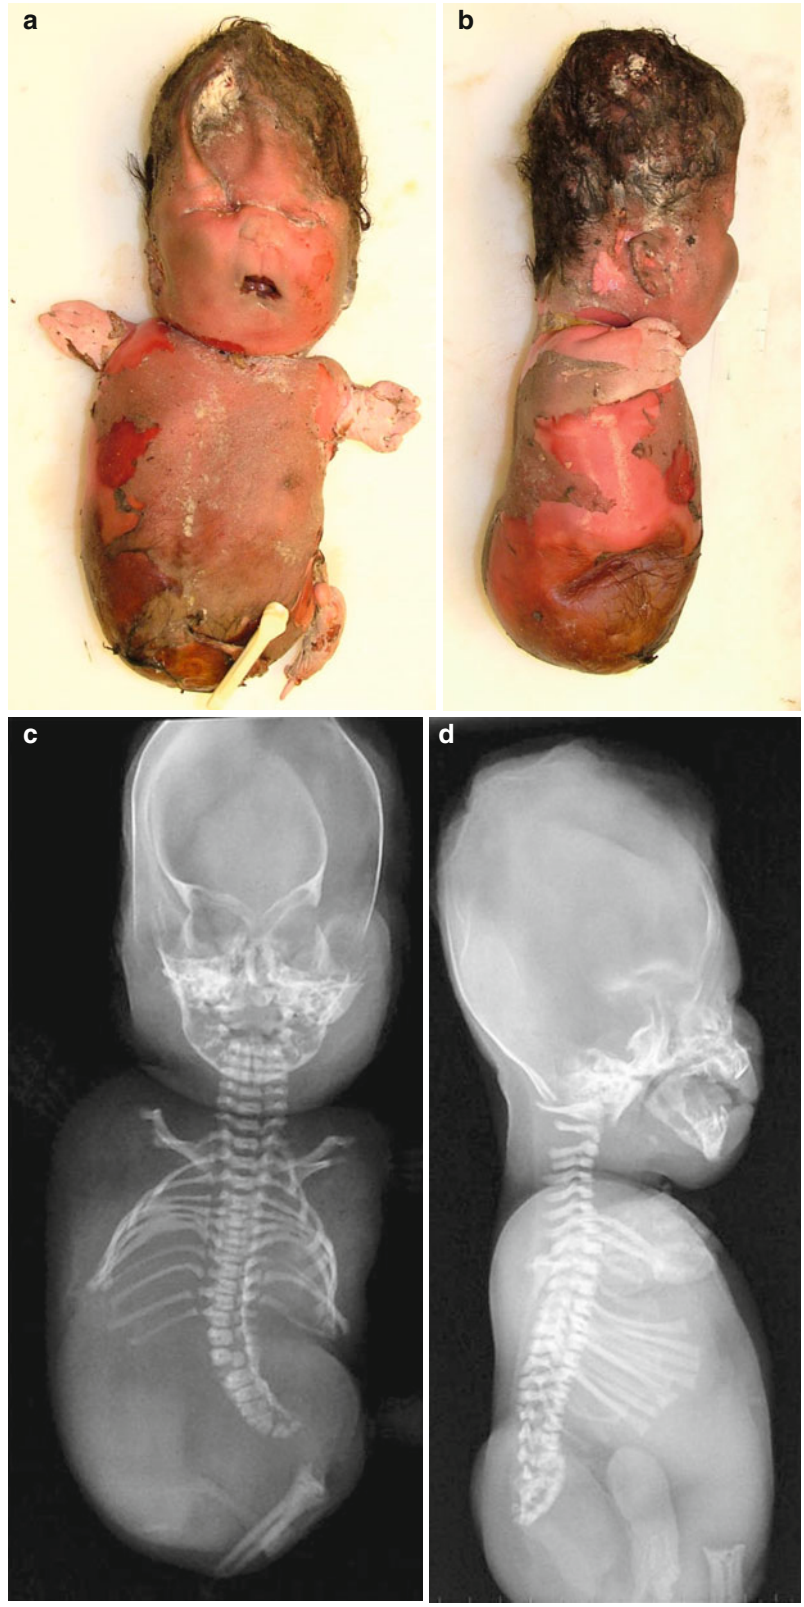

Fig. 7 (**a**–**d**) A macerated stillborn with phocomelia. Her upper extremities consist of hands attached to the shoulders with absence of the long bones. Her left lower extremity consists of a foot attached via thin twisted skin to the pelvic area with absence of the long bones. Right lower extremity was completely absent. There were severe dysplastic vertebrae, fusions of ribs, and absence of pelvic bones. In addition, the infant had blind vagina, absent right kidney, rudimentary left kidney, hypoplastic lungs, and microphthalmia

Fig. 8 (**a**–**g**) A girl and a lady with phocomelia showing flipper-like hands, illustrated by radiographs

Fig. 9 An infant with transverse reduction of the lower extremities

Fig. 10 An infant with unilateral transverse reduction of left upper extremities (intrauterine amputation), constriction ring of the left big toe, and syndactyly of the toes of both feet, secondary to amniotic band syndrome

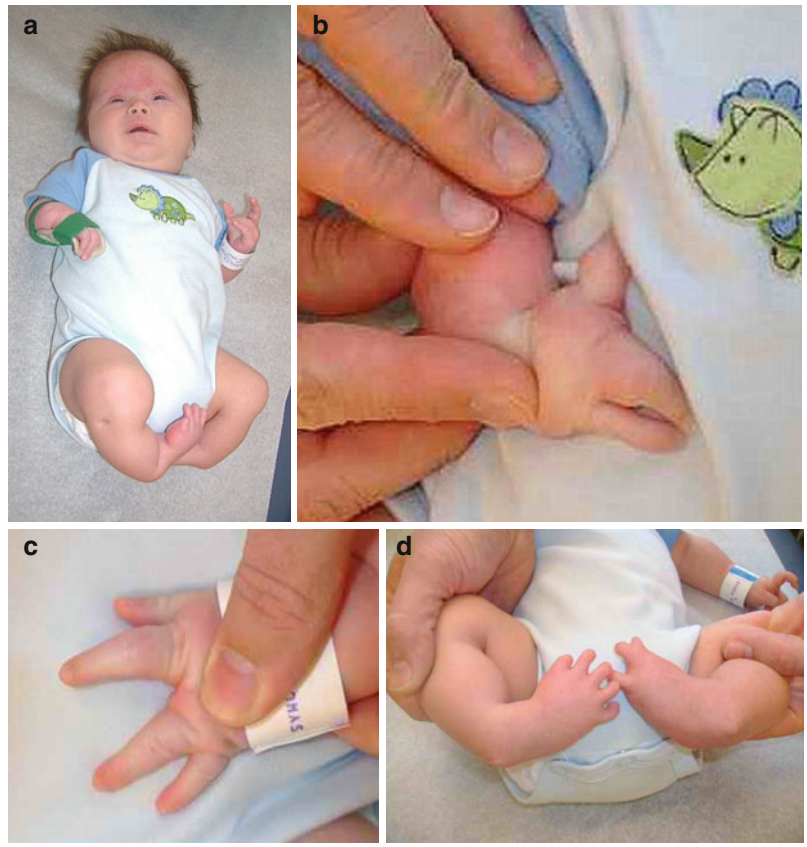

Fig. 11 (**a**–**d**) An infant with reduction malformations of both upper and lower extremities

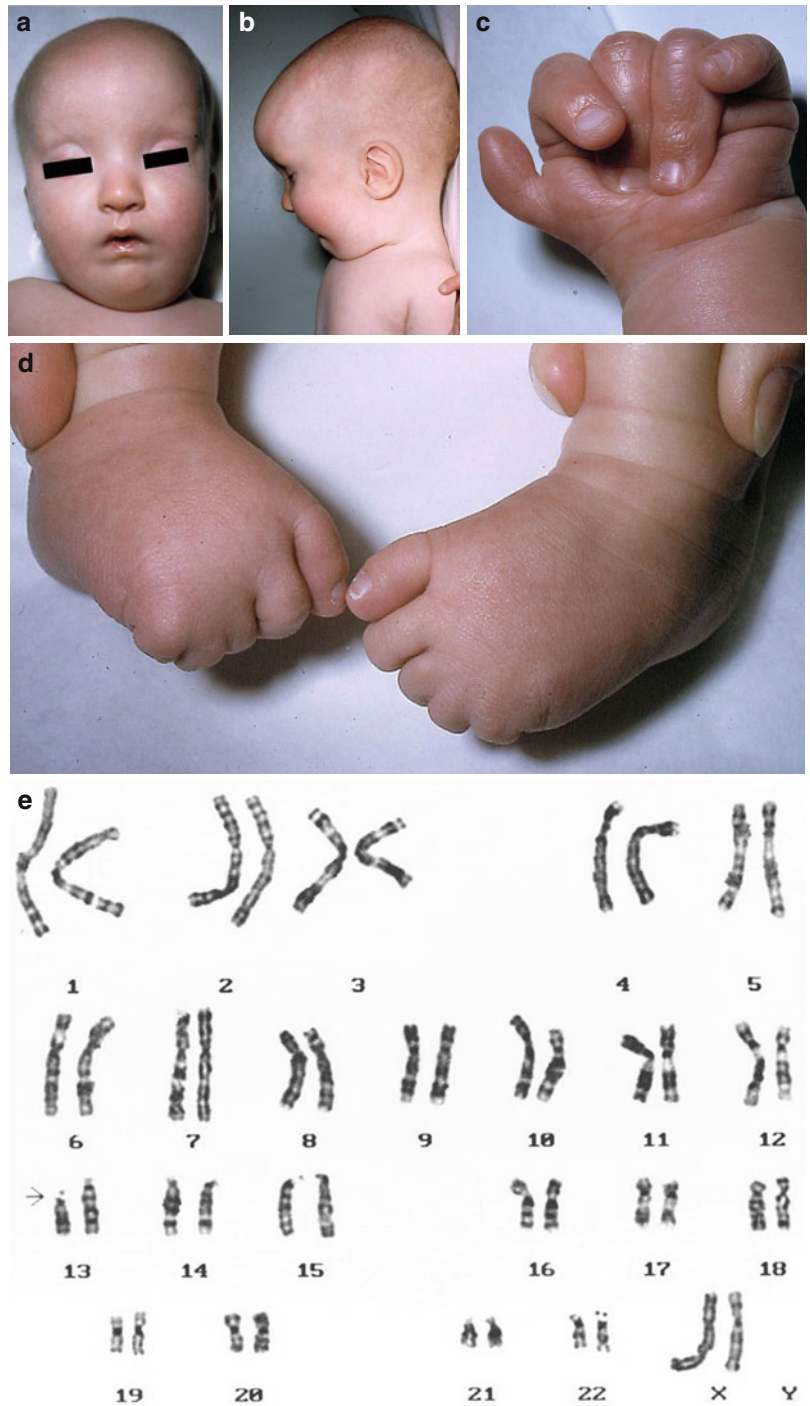

Fig. 12 (**a**–**e**) A neonate with del(13q) syndrome showing hypoplastic thumbs, syndactyly of toes, in addition to multiple congenital anomalies. The karyotype shows the deletion of 13q

Fig. 13 Radiograph of another neonate with del(13q) syndrome showing limb reduction anomalies of the upper extremities

Fig. 14 A neonate with trisomy 18 syndrome showing limb reduction defects of the upper extremities in addition to multiple congenital anomalies

Dysplasia Epiphysealis Hemimelica

Dysplasia epiphysealis hemimelica is a rare osteocartilaginous overgrowth involving one or multiple epiphyses or ossification centers, usually in the lower extremity on one side of the body. In 1926, Mouchet and Belot described a condition called tarsomegaly, which Trevor, later in 1950, called tarso-epiphyseal aclasis. As the tarsal bones are not the only bones involved, Fairbank in 1956 used the term dysplasia epiphysealis hemimelica. The term reflects the characteristic hemimelica involvement, typically affects either the medial or the lateral side of the epiphysis, with the medial side affected twice as frequently (Lang and Aztiuz 1997; Kuo et al. 1998; Araujo et al. 2006; Mann et al. 2010). The condition has been referred to as Trevor disease.

Synonyms and Related Disorders

Trevor disease

Genetics/Basic Defects

1. Inheritance:
   a. No known hereditary factor, except a report of a single family with seven members affected by different combinations of dysplasia epiphysealis hemimelica, intracapsular chondroma, extraskeletal osteochondroma, and typical osteochondroma (Hensinga et al. 1974)
   b. Male-to-female ratio: 3:1
2. Etiology and pathogenesis
   a. Etiology unknown
   b. A congenital disorder becoming clinically evident in the course of the development of the epiphyses
   c. Basic pathologic process: an abnormal proliferation of cartilage in an epiphysis, similar to osteochondroma

Clinical Features

1. Most frequent presentation: ages 2–14 years (birth to 63 years of age) (Gerscovich and Greenspan 1989)
2. Chief clinical signs
   a. Unilateral asymmetric bony hard swelling on the extremities
   b. Usually on the inner or outer aspect of the knee and/or ankle
   c. With or without pain
   d. With or without restriction of motion
   e. Slow progression
3. Apparent deformity
   a. Varus or valgus deformity depending on the site of involvement
   b. Genu valgum or varum depending on the site of involvement
   c. Flexion contracture
   d. Pes planus
   e. Pes equinus
4. Sites of involvement
   a. Lower extremities, more commonly affected than the upper extremities

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_74,
© Springer Science+Business Media, LLC 2012

i. Four most common locations of involvement (Rosero et al. 2007)
a) Talus-calcaneus (22%)
b) Distal tibia-fibula (22%)
c) Proximal tibia (11%)
ii. Proximal tibial epiphysis
iii. Tarsal navicular
iv. First cuneiform
v. Middle and lateral cuneiforms
vi. Metatarsals
vii. Phalanges

b. Upper extremities: very uncommon involvement (Vanhoenacker et al. 1999; Takagi et al. 2000; Rosero et al. 2007)
i. Carpal bones
a) Scaphoid
b) Lunate
c) Capitate
d) Hamate
e) Trapezium
f) Trapezoid
ii. Metacarpals
iii. Phalanges
iv. Proximal radius
v. Proximal and distal ulna
vi. Proximal and distal humerus
vii. Glenoid cavity
viii. Coracoid process of the scapula

c. Pelvis
i. Acetabulum
ii. Pubic bone
iii. Iliac bone

5. Affected limb
a. May be longer than the unaffected one due to:
i. The enlargement of several ossification centers
ii. Increased diaphyseal length
b. May be shorter due to focal early closure of the epiphyseal plate
6. Quiescent following epiphyseal plate fusion
7. Prognosis
a. Relatively benign condition
b. Malignant degeneration has not been reported
8. Classification based on degrees of involvement (Azouz et al. 1985)
a. Localized form
i. Usually affecting the bones of the hindfoot or ankle
ii. Also may affect an epiphysis

b. Classical form
i. Characteristic hemimelic distribution seen in more than one area in a single lower extremity (two third of the reported cases), particularly:
a) Talus
b) Distal femoral epiphyses
c) Distal tibial epiphyses
ii. Lesion localized to the ankle and foot, called Mouchet and Belot type

c. Generalized or severe form
i. Involving a whole lower extremity from the pelvis to the foot or ankle
ii. Involving femoral head, symphysis pubis, or triradiate cartilage of the acetabulum

Diagnostic Investigations

1. Radiography (Gerscovich and Greenspan 1989)
a. Skeletal survey to look for sites of involvement
b. Earliest radiographic sign
i. Appearance of secondary centers of ossification adjacent to an epiphysis
ii. Slow enlargement of these centers eventually merging with each other and then with the epiphysis
c. Asymmetric hemimelic distribution of overgrowth of one side of epiphysis with irregular contour and ossification
i. Generally only half or part (either the medial or lateral half) of an epiphysis or ossification center affected
ii. Rarely involving the entire epiphysis
d. Overgrowth of adjacent bones
e. Adjacent (probably secondary) metaphyseal and growth plate involvement
i. Exhibiting widening and streak-like metaphysis (as in Ollier disease)
ii. Spur formation (as in osteochondroma)
f. Mature lesions showing enlargement of one side of an epiphysis, simulating as osteochondromatous mass or enlargement of one side of an ossification center
g. Epiphysis irregularly calcified and ossified
h. Joints usually deformed
i. Advanced bone age in unaffected epiphyses
j. Less common findings

   i. Loose bodies in affected joints
   ii. Osteochondral fractures
   k. Bilateral involvement extremely rare
2. CT of the lesions
   a. Improving diagnostic accuracy in the growing skeleton
   b. Demonstration of the anatomic relationship of the involved structures
   c. Visualization of the soft tissues, bones, and tumorous mass
   d. Evaluation of the condition of the articular surfaces
3. MRI imaging (Keret et al. 1992; Peduto et al. 1999)
   a. To identify a definite plane of separation between the pathologic osteochondromatous mass and the normal epiphysis
   b. To accurately identify bony and cartilaginous structural abnormalities in multiple planes noninvasively without ionizing radiation
   c. To identify secondary changes in menisci, tendons, ligaments, and muscles
4. Histopathology
   a. Osteocartilaginous exostosis (with cartilaginous cap) arising from an epiphysis, apophysis, or round bone (Oates)
   b. Nests of cartilage cells showing active proliferation during growth of the lesions
   c. Diminishing amount and activity of the cartilage as the lesions mature
   d. Increased size of lesions in adults showing areas of actively proliferating cartilage
   e. Infrequently with an area of necrosis, presumably caused by inadequate nutrition
   f. Histological findings (Bahk et al. 2010)
      i. Identical to those of osteochondromas
      ii. Presence of caps of disorganized hyaline cartilage
      iii. Endochondral ossification of varying degrees underlying the caps

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased
2. Prenatal diagnosis: not been reported
3. Management
   a. Observation in asymptomatic cases; no cases of malignant transformation reported (Kuo et al. 1998)
   b. Surgical excision of the mass or corrective osteotomy generally recommended for the following lesions:
      i. Causing disabling pain
      ii. Interfering function
      iii. Increasing deformity of the involved joint
   c. Simple excision indicated if the cartilaginous overgrowth is not in the weight-bearing articular surface
   d. Extraarticular osteotomy indicated for correction of varus/valgus deformities if the arthrogram shows the smooth joint surface
   e. Anticipate recurrence of the angular deformity after the corrective osteotomy if the growth plate at the affected joint is open and active

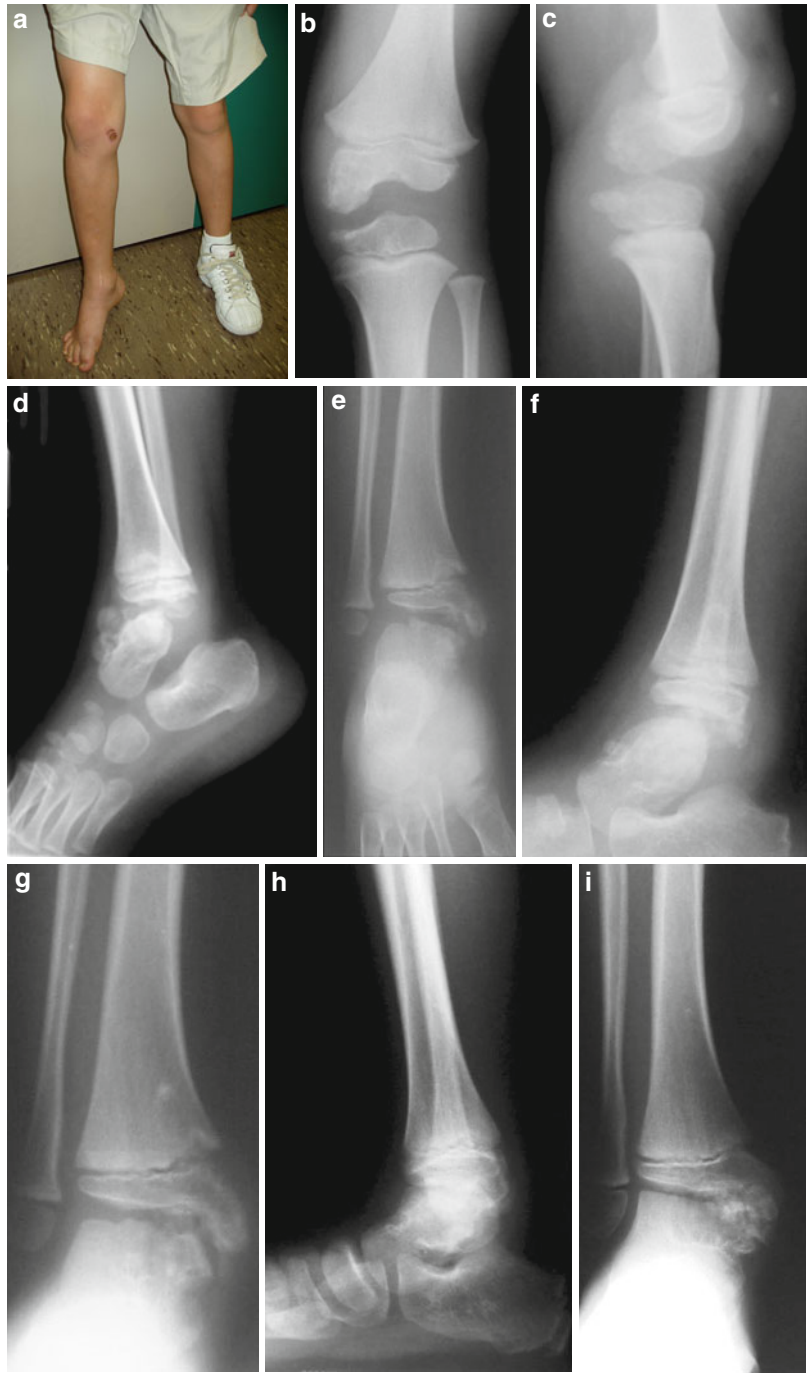

Fig. 1 (**a**–**i**) A 9-year-old boy with dysplasia epiphysealis hemimelica showing hard swellings on the inner sides of the knees and the ankle of the right lower extremities. The knee radiographs at 9 years of age show the secondary ossification center merged with the medial side of the epiphyses of the distal femur and that of the proximal tibia. The radiographs of ankles at 4, 5, and 9 years of age show irregularly calcified mass extending from medial malleolus of the distal tibia and involvement of the talus. The patient had bony protuberance of the right knee and right ankle without pain or restriction of motion. The age of onset was about 2 years of age

Fig. 2 A 5-year old boy was seen because of swollen right knee with complaint of knee pain and limping

Fig. 3 Note the swelling of the medial aspect of the right knee

Fig. 4 The knee radiograph shows second ossification center merged with the medial aspect of the epiphysis of the distal femur

Dystonia

Dystonia is characterized by sustained, nonsuppressible contractions of agonist and antagonist muscles, resulting in twisting and repetitive movements that typically lead to abnormal postures (Friedman and Standaert 2001; Brűggermann and Klein 2010).

Synonyms and Related Disorders

Dystonia (types 1–19); Primary (idiopathic) dystonia; Secondary dystonia

Genetics/Basic Defects

1. Genetically defined forms of the primary dystonias and dystonia-plus syndromes (Brűggermann and Klein 2010)
   a. Monogenic forms of dystonia have been assigned the acronym DYT according to the gene or gene locus involved
   b. This assortment of clinical rather than heterogeneous dystonias and dyskinesias is represented by a current list of 20 DYTs, in which monogenic forms of dystonia are included in chronological order based on first appearance in the literature
   c. Although this listing of DYTs can serve as an orientation, it does not represent a logical classification in the strict sense of the word. Rather, the monogenic forms can be pragmatically grouped as:
      i. Pure dystonias
         a) Part of the primary forms and thought to occur in the absence of neuropathologic changes
         b) Considered mainly to alter the function of neuronal basal ganglia circuits
      ii. Dystonia-plus syndromes: characterized by additional neurologic manifestations, such as parkinsonism and myoclonus (Albanese et al. 2006)
      iii. Paroxysmal dyskinesias: typically manifest episodically, dystonia usually is only one of several movement disorders present, and there are no interictal neurologic abnormalities
2. At least 19 different types of dystonia can be distinguished genetically as follows (Németh 2002; Brűggermann and Klein 2010):
   a. Dystonia type 1 (early-onset generalized primary torsion dystonia, Oppenheim dystonia)
      i. Autosomal dominant inheritance with reduced penetrance of about 30–40%
      ii. Locus: *DYT1* on chromosome 9q34
      iii. Mutations
         a) GAG deletion in the *DYT1* gene resulting in loss of Glutamic acid residues in the C-terminus of a novel ATP-binding protein, torsin A
         b) 18 base pair deletion resulting in loss of six amino acids (F323-Y328del) in a novel ATP-binding protein, torsin A

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_75,
© Springer Science+Business Media, LLC 2012

b. Dystonia 2 (autosomal recessive torsion dystonia)
   i. Autosomal recessive inheritance
   ii. Locus: *DYT2* (chromosome map unknown)
c. Dystonia 3 (X-linked dystonia-parkinsonism, "lubag")
   i. X-linked recessive inheritance
   ii. Locus: *DYT3* on chromosome Xq13.1
d. Dystonia 4 (whispering dysphonia)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT4* (chromosome map unknown)
e. Dystonia 5 (dopa-responsive dystonia-parkinsonism)
   i. Common autosomal dominant inheritance
      a) Locus: *GCH1* on chromosome 14q22.1–q22.2
      b) Caused by mutation in the *guanosine triphosphate cyclohydrolase I* gene, *GCH1*
   ii. Rare autosomal recessive form (Segawa syndrome)
      a) Associated with mutations in the tyrosine hydroxylase gene, *TH*
      b) Locus: *TH* on chromosome11p15.5
f. Dystonia 6 (adolescent-onset torsion dystonia of mixed type)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT6* on chromosome 8p21-8q22
g. Dystonia 7 (adult-onset focal torsion dystonia)
   i. Autosomal dominant inheritance
   ii. Locus: DYT7 on chromosome 18p
h. Dystonia 8 (paroxysmal nonkinesigenic dyskinesia)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT8* on chromosome 2q33-q25
i. Dystonia 9 (paroxysmal choreoathetosis with episodic ataxia and spasticity)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT9* on chromosome 1p21-p13.3
j. Dystonia 10 (paroxysmal kinesigenic choreoathetosis)
   i. Locus: *DYT10* on chromosome 16p11.2-q12.1
   ii. Autosomal dominant inheritance
k. Dystonia 11 (myoclonus-dystonia)
   i. Autosomal dominant inheritance
   ii. Locus: *DYST11* on chromosome 7q21
   iii. Caused by mutations in the ϵ-sarcoglycan gene in most families
l. Dystonia 12 (rapid-onset dystonia-parkinsonism)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT12* on chromosome 19q
m. Dystonia 13 (multifocal/segmental dystonia)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT13* on chromosome 1p36
n. Dystonia 14: recently redefined as *DYT5*
o. Dystonia 15 (myoclonus-dystonia)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT15* on chromosome 18p
p. Dystonia 16 (young-onset dystonia-parkinsonism)
   i. Autosomal recessive inheritance
   ii. Locus: *DYT16* on chromosome 2p
q. Dystonia 17 (autosomal recessive primary torsion dystonia)
   i. Autosomal recessive inheritance
   ii. Locus: *DYT17* on chromosome 20pq
r. Dystonia 18 (paroxysmal exertion-induced dyskinesia 2)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT18* on chromosome 1p
s. Dystonia 19 (episodic kinesigenic dyskinesia 2)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT19* on chromosome 16q
t. Dystonia 20 (paroxysmal nonkinesigenic dyskinesia 2)
   i. Autosomal dominant inheritance
   ii. Locus: *DYT20* on chromosome 2q

3. Secondary dystonia (Schlaggar and Mink 2003)
   a. Association with a number of disorders
      i. Hepatolenticular degeneration (Wilson disease)
         a) Dystonia in over a third of the patients
         b) Associated with lesions in the putamen in 80% of cases
      ii. Hallervorden–Spatz disease (pantothenate kinase-associated neurodegeneration)
      iii. Huntington chorea
      iv. Lesch–Nyhan disease
      v. Metachromatic leukodystrophy
      vi. Methylmalonic acidemia
      vii. Mitochondrial disorders
      viii. Ceroid lipofuscinosis
      ix. Gangliosidoses
      x. Glutaric aciduria
      xi. Ataxia telangiectasia
      xii. Niemann-Pick disease type C
      xiii. Early-onset parkinsonism

xiv. Corticobasal degeneration
xv. Certain forms of spinocerebellar ataxia
a) Spinocerebellar ataxia 3 (Machado–Joseph disease): The severity of the dystonic symptoms is related to the length of the trinucleotide repeat
b) Spinocerebellar ataxia 17 (caused by mutations in the thymine-adenine-thymine-adenine binding protein: Dystonia may be the presenting sign of the disorder
xvi. Other inherited disorders (Cloud and Jinnah 2010)

b. Other causes
i. Psychogenic
ii. Vascular lesions such as carotid occlusive disease and hemorrhagic stroke
iii. Anoxic brain injury (cerebral anoxia/hypoxia): a well-known cause of secondary dystonia
iv. Acute disseminated encephalomyelitis
v. Trauma
a) Head trauma: Dystonia is among the most common movement disorders following severe head injury
b) Peripheral trauma causing segmental dystonia
vi. Both acute and chronic use of dopamine blocking medications and other medications
a) Haloperidol
b) Resperidol
c) Fluphenazine
d) Thioridazine
e) Chlorpromazine
f) Metoclopramide
g) Phenytoin
h) Stonatrioran
vii. Other acquired and sporadic causes (Cloud and Jinnah 2010)

4. Pathophysiology: a new interpretive hypothesis involving multiple levels of the nervous system
a. Spinal cord: increased spinal motor neuron excitability in patients with generalized dystonia due to reduced presynaptic inhibition and compromised supraspinal inhibition systems
b. Basal ganglia: disturbed pattern of basal ganglia output neurons
c. Thalamus: disorganization of input–output properties and hyperactivity in thalamic neurons in two dystonic cynomolgus monkeys
d. Somato-sensory system: increased temporal discrimination thresholds for tactile stimuli
e. Sensorimotor integration and motor cortical function
i. Abnormal somatotopic arrangement of sensorimotor interaction
ii. Abnormal functioning of cortico-subcortical loops causing abnormalities of both intracortical inhibition and cortical excitability
5. Dystonia with unknown etiology

Clinical Features

1. Dystonia describes a symptom that may be part of many disorders with a variety of causes
a. An abnormal sustained posture that is often writhing or twisting in quality
b. Can be rapid or slow
c. Often painful
2. Classifications of dystonia
a. Classification based on distribution of dystonia
i. Primary/generalized dystonia
a) Occurs in childhood
b) Often begins focally in the legs and progresses to a generalized symptom involving the entire body
ii. Focal dystonia
a) May occur at any age
b) Typically starts in adulthood
c) Affects an isolated body area, such as hand and arm (writer's cramp), neck (cervical dystonia, previously known as spasmodic torticollis), vocal/laryngeal apparatus (dystonic adductor dysphonia or whispering dysphonia), mouth (oromandibular dystonia, musician's cramp), or eyelids (blepharospasm)
d) Multifocal dystonia (two or more noncontiguous parts affected)
iii. Segmental dystonia
a) May occur at any age
b) Typically starts in adulthood
c) Involves only the right or left side of the body

d) Cranial (two or more parts of cranial and neck musculature affected)
e) Axial (neck and trunk affected)
f) Brachial (one arm and axial; both arms, with or without neck, with or without trunk)
g) Crural (one leg and trunk; both legs, with or without trunk)

iv. Hemidystonia: affects ipsilateral arm and leg
v. Secondary dystonia
a) Can be generalized, focal, or segmental
b) Induced by a disease or ingested substance
c) Can occur at any time
d) Treated by identifying the underlying medical disorder or substance

b. Classification based on age of onset of dystonia
i. Early-onset dystonia
a) Often starts in a limb
b) Tends to generalize and frequently has a genetic origin
ii. Adult-onset dystonia
a) Usually spares the lower extremities
b) Frequently involves cervical or cranial muscles
c) A tendency to remain focal
d) Sporadic in most cases

3. Clinical characteristic in genetically defined forms of dystonia and dystonia-plus syndromes (Klein et al. 1999; Brűggermann and Klein 2010)
a. Dystonia type 1 (early-onset generalized primary torsion dystonia)
i. Early-onset torsion dystonia (onset usually childhood)
ii. May present as focal, usually in the limbs
iii. Often generalizes to other body parts as the disease progresses
b. Dystonia type 2 (autosomal recessive torsion dystonia)
i. Early onset
ii. Generalized or segmental torsion dystonia
c. Dystonia type 3 (X-linked dystonia-parkinsonism, "lubag") meaning "twist," a local dialect in the Island of Panay in Philippines)
i. Only described in individuals from the Philippines
ii. Usually males
iii. Onset usually adulthood
iv. Usually generalized dystonia
v. Parkinsonism (50% of cases) unresponsive to L-dopa
vi. Progressive neurodegenerative syndrome
d. Dystonia type 4 (whispering dysphonia)
i. Described in a single large Australian family
ii. Laryngeal and cervical dystonia
iii. Age of onset: 13–37 years
e. Dystonia type 5 (dopa-responsive dystonia-parkinsonism)
i. Childhood onset of dystonia
ii. Onset of dystonia in a limb, typically a leg, resulting in gait disturbance
iii. Gradual progression to generalized dystonia (usually more pronounced in the legs)
iv. Dystonia with concurrent or subsequent parkinsonism
v. Diurnal worsening of symptoms
a) Aggravation of symptoms toward the evening
b) Alleviation of symptoms in the morning after sleep
vi. A variety of atypical presentations
a) Generalized hypotonia
b) Proximal weakness
c) Gait disturbance
d) "Atypical cerebral palsy"
vii. A dramatic response to L-dopa
f. Dystonia type 6 (adolescent-onset torsion dystonia of mixed type)
i. Described in two Mennonite families
ii. Adolescent onset
iii. Mostly segmental torsion dystonia
iv. Focal or generalized (rare)
v. Cranial, cervical, or limb dystonia
g. Dystonia type 7 (adult-onset focal torsion dystonia)
i. Described in a single German family
ii. Adult-onset focal dystonia
iii. Torticollis
iv. Writer's cramp
v. Spasmodic dysphonia
vi. Blepharospasm

h. Dystonia type 8 (paroxysmal dystonic choreoathetosis)
   i. Variable age of onset (early childhood, adolescence or early adulthood)
   ii. Attacks of dystonia/choreoathetosis
   iii. Precipitated by stress, hunger, fatigue, alcohol, caffeine, nicotine, and chocolate
i. Dystonia type 9 (paroxysmal choreoathetosis with episodic ataxia and spasticity)
   i. Age of onset: 2–15 years
   ii. Attacks of dystonia, paresthesias, and double vision
   iii. Precipitated by exercise, fatigue, stress, alcohol
   iv. Spastic paraplegia between attacks
j. Dystonia type 10 (paroxysmal kinesigenic choreoathetosis)
   i. Attacks of dystonia/choreoathetosis
   ii. Precipitated by sudden unexpected movements
   iii. Respond to anticonvulsant therapy
k. Dystonia type 11 (myoclonus-dystonia)
   i. Onset usually in the first or second decade of life
   ii. Rapid, jerk-like movements
   iii. Responsive to alcohol
   iv. Combined with variable degrees of dystonia
l. Dystonia type 12 (rapid-onset dystonia-parkinsonism)
   i. Acute or subacute onset (develop over hours or weeks) of generalized dystonia
   ii. In combination with parkinsonism
m. Dystonia type 13 (multifocal/segmental dystonia)
   i. Described in a single Italian family
   ii. Juvenile or early adult onset of segmental dystonia
   iii. With prominent cranial-cervical and upper limb involvement
   iv. Some focal dystonia, some generalized dystonia
n. Dystonia type 15 (myoclonus-dystonia)
   i. Described in a single Canadian family
   ii. Characterized by jerky movements of the upper limbs, hands, and axial muscles
   iii. Myoclonus dystonia and limb dystonia: alcohol responsive
o. Dystonia type 16 (dystonia-Parkinsonism)
   i. Recessively inherited form of early-onset generalized dystonia associated with a homozygous missense mutation in the *PRKRA* gene (Camargos et al. 2008)
   ii. Described in three Brazilian families, sharing the same P222L mutation, inherited from a common founder
   iii. Clinical features
      a) Prominent bulbar involvement with dysphonia, dysarthria, and even dysphagia
      b) Parkinsonism: a less prominent feature (Klein 2008)
p. Dystonia type 17 (recessive torsion dystonia)
   i. Three sisters from Lebanese family suffering from recessively inherited primary focal torsion dystonia with onset in adolescence
   ii. Site of onset: cervical with progression to segmental in two sisters and generalized dystonia in one
   iii. Prominent features
      a) Dystonia: not levodopa responsive in this family
      b) Dysarthria
q. Dystonia type 18 (paroxysmal exertion-induced dyskinesia 2)
   i. The attacks: combination of chorea, athetosis, and dystonia in excessively exercised body regions
   ii. Legs: most frequently affected
   iii. Other features
      a) Epilepsy
      b) Hemolytic anemia
      c) Migraine
   iv. A ketogenic diet: an effective therapeutic regimen
   v. Closely resembles DYT type 9 (paroxysmal choreoathetosis with episodic ataxia and spasticity): remains to be seen whether DYT type 18 and DYT type 9 are the same condition
r. Dystonia type 19 (episodic kinesigenic dyskinesia 2): A second form of paroxysmal kinesigenic dyskinesia was designated DYT type 19

   s. Dystonia type 20 (paroxysmal nonkinesigenic dyskinesia 2)
      i. A second form of paroxysmal nonkinesigenic dyskinesia was described in a single Canadian family
      ii. Clinical features similar to those of DYT8 dystonia/dyskinesia
4. Important clinical "red flags" leading to correct diagnosis of a specific genetic form before molecular testing (Brűggermann and Klein 2010)
   a. Diurnal variation of symptoms and response to levodopa in DRD (DYT5)
   b. Prominent orobulbar and speech involvement (DYT6)
   c. A combination of dystonia with myoclonus, ameliorated by alcohol intake in myoclonus-dystonia (DYT11); and abrupt onset of severe dystonia and parkinsonism in RDP (DYT12)
   d. An inherited dystonia also should be considered in the case of an early onset and when a certain ethnic background and positive family history are present (e.g., a high prevalence of DYT1 dystonia in Ashkenazi Jews and of DYT3 X-linked dystonia-parkinsonism [XDP, "lubag"] in Filipinos)
   e. Notably, the presence of a heritable condition may be masked by a small number of family members, nonpaternity, or adoption
   f. Similarly, reduced penetrance, variable expressivity, and de novo mutations are potential reasons for a "pseudo"-negative family history
   g. With the exception of five rare forms (DYT2, DYT3, DYT5b, DYT16, and DYT17), all monogenic dystonias follow an autosomal dominant pattern of transmission with reduced penetrance

Diagnostic Investigations

1. Electromyography shows a simultaneous contraction of both agonist and antagonist muscles
2. MRI of the brain (Cloud and Jinnah 2010)
   a. Warranted for all ages
   b. Can identify a causal structural defect
   c. Can provide clues to some degenerative disorders in adults and specific treatable developmental or metabolic disorders in younger individuals, such as Wilson disease, glutaric aciduria, biotin-responsive basal ganglia disease
3. Dopa-responsive dystonia
   a. GTPCH1-deficient dopa-responsive dystonia
      i. Decreased concentration of both total biopterin (BP) and neopterin (NP) in cerebrospinal fluid in patients with GTPCH1 deficiencies
      ii. Phenylalanine loading test to detect a subclinical defect in phenylalanine metabolism
      iii. DNA mutation analysis to detect *GCH1* mutation
   b. TH-deficient dopa-responsive dystonia
      i. Normal BP and NP, and reduced-3-methoxy-4-hydroxy-phenylethyleneglycol in CSF
      ii. DNA mutation analysis to detect *TH* mutation
4. Mutational screening has become available on a commercial basis for most of the known dystonia-causing genes (www.genetests.org)
   a. For 10 of the 20 DYT loci (DYT1, DYT3, DYT5a, DYT5b, DYT6, DYT8, DYT11, DYT12, DYT16, and DYT18), genes have been identified (Brűggermann and Klein 2010)
   b. Current guidelines for genetic testing and counseling are based on criteria established by the European Federation of Neurological Societies that were revised in 2009
      i. Molecular testing for the GAG deletion in the *DYT1* gene is recommended in patients with limb-onset generalized dystonia and symptom onset before the age of 26 years, regardless of family history
      ii. Comprehensive mutational analysis for GCH1 mutations, including gene dosage studies, is recommended in patients with early-onset generalized dystonia and clear symptom relief following levodopa therapy, irrespective of family history
      iii. Mutational screening for *SGCE* mutations is recommended only in cases with the typical combination of dystonia and myoclonus and a suggestive family history
      iv. RDP and tyrosine hydroxylase (TH)–associated DRD (DYT5b) are exceedingly rare. XDP (DYT3) is restricted to a specific population. Therefore, no general recommendations have been proposed for these forms (Harbo et al. 2009)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive inheritance: 25%
      ii. Autosomal dominant inheritance: not increased unless one of the parent carries a mutant allele in which case, there is a 50% risk of having an affected sib
      iii. X-linked recessive inheritance; 50% of male sib will be affected given the mother is a carrier
      iv. Secondary dystonias: risk depending on the etiology
   b. Patient's offspring
      i. Autosomal recessive inheritance: not increased (all offspring are carriers) unless the spouse is also a carrier in which case, there is a 50% risk of having an affected offspring
      ii. Autosomal dominant inheritance: 50%
      iii. X-linked recessive inheritance: None of the sons will be affected; all of the daughters will be carriers
      iv. Secondary dystonias: risk depending on the etiology
2. Prenatal diagnosis is possible for some forms of dystonia by DNA analysis of the fetal blood obtained from amniocentesis of CVS provided the disease-causing allele(s) of an affected family member have been identified
3. Management (Goetz and Horn 2001; Klein and Ozelius 2002; Cloud and Jinnah 2010)
   a. Treatment of dystonia
      i. Begins with proper diagnosis and classification
      ii. An appropriate search for underlying etiology
      iii. An assessment of the associated functional impairment
      iv. Must be tailored to the individual needs of the patient
      v. Physical therapy and occupational therapy can be useful in many patients
      vi. Botulinum toxin: currently the mainstay of treatment for focal and segmental dystonia
      vii. Oral medications and deep brain stimulation: the mainstays of therapy for generalized dystonia
   b. Generalized idiopathic dystonia
      i. Medical therapy
         a) Anticholinergic agents (trihexyphenidyl): first choice (a moderate response in about 40–50% of dystonia patients)
         b) Benzodiazepines (diazepam, clonazepam)
         c) Dopamine depletors (tetrabenazine)
         d) γ-aminobutyric acidergics (baclofen)
         e) Atypical neuroleptics (clozapine, olanzapine)
      ii. Intrathecal baclofen infusion
      iii. Ablative therapies, reserved for patients in whom medical therapies fail
         a) Pallidotomy
         b) Thalamotomy
   c. Dopa-responsive dystonia
      i. A dramatic response to small dosages of levodopa (100 mg a day) (confirms the diagnosis)
      ii. Maintenance with low-dose levodopa for life may improve from severe inability to completely normal function
   d. Focal dystonias
      i. Unresponsive to systemic drug treatment in most case
      ii. Frequently well controlled by periodic botulinum toxin (BTX) injections into the muscles directly involved in the dystonia
      iii. Try with intrathecal baclofen and surgery if oral medications fail
   e. Cervical dystonias resistant to BTX: selective peripheral denervation

Fig. 1 A 7-year-old girl with progressive dystonia showing dystonic posturing with gait locking of the knees and swiveling of the hips to propel the legs forward. She developed normally until age 6 when she started to have loss of balance, falling, unable to get the foot off the ground, stiffing of lower and upper extremities, and slurring of speech. Plasma amino acids, urine organic acids, blood chemistry, lactate/pyruvate, ceruloplasmin, copper, arsenic, lead, 5-methyltetrahydrofolate, neurotransmitter metabolites/amines, tetrahydrobiopterin/neopterin, and various lysosomal enzymes were all normal. No mutations were detected on mitochondrial myopathy mtDNA, *DYT1*, and *PANK2*. MRI of the brain showed bilateral hyperdense basal ganglia lesions. Use of levodopa/dopamine agonists has at best, been minimally beneficial

Dystrophinopathies

The dystrophinopathies include a spectrum of muscle disease caused by mutations in the *DMD* gene that encodes the protein dystrophin. They are characterized by a spectrum of muscle disease that ranges from mild to severe. The mild end of the spectrum includes the phenotypes of asymptomatic increase in serum concentration of creatine phosphokinase (CK) and muscle cramps with myoglobinuria and isolated quadriceps myopathy. The severe end of the spectrum includes progressive muscle diseases that are classified as Duchenne muscular dystrophy (DMD) or Becker muscular dystrophy (BMD) when skeletal muscle is primarily affected and as X-linked dilated cardiomyopathy (XLDCM) when the heart is primarily affected. In this chapter, I will limit my discussion on DMD and BMD.

DMD is one of the most common types of muscular dystrophy in childhood, primarily affecting skeletal and cardiac muscle. It is one of the most common of all clinical genetic disorders. Its incidence is estimated to be approximately 1 in 3,500 live male births. BMD is a milder allelic form of dystrophin deficiency, affecting 1 in 30,000 male births.

Synonyms and Related Disorders

Becker and Duchenne muscular dystrophy

Genetics/Basic Defects

1. DMD
   a. Inheritance
      i. X-linked recessive
      ii. Exceptionally high mutation rate of 10^{-4} in both sperm and eggs
      iii. Approximately 1/3 of cases are due to new genetic mutations
      iv. Approximately, 2/3 of cases occurring by inheritance of the disease-causing gene from the carrier mother
      v. Only males affected (as a rule)
   b. *DMD* gene
      i. Observation of a series of young females affected clinically as Duchenne muscular dystrophy with an X-autosome translocation
         a) Breakpoint in the X chromosome in the same place (Xp21.1)
         b) Different autosomes involved for each affected female
         c) Mapping of dystrophin gene to chromosome Xp21
      ii. The largest human gene, covering 2.5 megabases and including 79 exons
      iii. The enormity of the DMD gene along with the spontaneous mutation rate of each base pair allows a high frequency of novel mutations.
   c. Dystrophin, the product (protein) of the human dystrophin gene (*dys*)
      i. Loss of dystrophin at the muscle membrane clearly related to mutations in the gene encoding dystrophin at band Xp21
      ii. Cloning of the dystrophin gene by positional cloning in the late 1980s constituted the initial proof that deletions in the Xp21 region were associated with the disease
      iii. The dystrophin gene (Muntoni et al. 2003)
         a) The largest gene of the 30,000 genes that encode proteins in the human genome

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_76,
© Springer Science+Business Media, LLC 2012

b) Consisting of 79 exons spanning more than 2.6 million bp of genomic sequence
c) Correspond to about 0.1% of the total human genome
d) Correspond to about 1.5% of the entire X chromosome

iv. Southern blot analysis of affected boys with a complete set of cDNA probes
a) Over 60% with detectable deletions
b) Six percent with duplications
c) A number of point mutations described recently

v. Consequences of absent dystrophin in skeletal and cardiac muscles in affected patients
a) Muscle contraction leading to membrane damage and activation of the inflammatory cascade
b) Progressing to muscle necrosis, fibrosis, and loss of function

d. The DMD phenotype most frequently due to mutations that cause a disruption in the reading frame (Wagner 2002)

2. BMD
a. Inheritance: X-linked recessive (same as DMD).
b. Also caused by mutations in the gene for dystrophin at Xp21.1.
c. The BMD phenotype most often due to mutations that preserve the open reading frame but in which portions of the protein are deleted. Frame deletions of the long rod segment of the gene are particularly forgiving and produce a mild phenotype (Wagner 2002).

3. Mechanism for female DMD and BMD
a. Turner syndrome with a *dystrophin* mutation on the remaining X chromosome (Chelly et al. 1986)
b. Skewed X inactivation either in the female DMD mutation carriers (Yoshioka et al. 1998)
c. Balanced X-autosome translocation patients (Verellen-Dumoulin et al. 1984)
d. Uniparental disomy of the entire X chromosome with mutations (Quan et al. 1997)
e. Co-occurrence of mutations in both dystrophin and androgen receptor genes (Katayama et al. 2006)
f. Double dystrophin mutations on both X chromosomes (Fujii et al. 2009)

Clinical Features

1. DMD (Roland 2000)
a. During early infancy
i. Asymptomatic
ii. Normal motor milestones
iii. Rare global developmental delay or delayed achievement of early motor milestones

b. Four to five years of age: onset of symptoms
i. A waddling gait
ii. Difficulty in climbing stairs due to pelvic weakness
iii. Difficulty in running
iv. Toe walking resulting from tight Achilles tendon
v. Inability to jump
vi. Frequent falling
vii. Neck flexor weakness with marked head lag when pulling to sit from the supine position

c. Progressive difficulty in rising from the floor secondary to weakness of proximal pelvic girdle and proximal leg muscle, resulting in the Gower's maneuver requiring the use of the hands to "climb up the legs"
d. Pseudohypertrophy of muscles, especially calf muscles: unusually firm and rubbery consistency on palpation
e. Compensatory lumbar lordosis to maintain an upright posture secondary to weakness of hip extensors
f. Weakness of the arms (proximal more severely affected than distal) apparent as the disease progresses
g. Marked laxity of the shoulder girdle musculature with prominent spontaneous winging of the scapulae
h. Inability to walk usually before 13 years of age
i. Rapid development of fixed skeletal deformities following loss of ambulation
i. Equinovarus deformities of the feet
ii. Scoliosis
iii. Wheelchair confinement by adolescence
j. Unexplained cardiac arrest and/or myoglobinuria: features of malignant hyperthermia during general anesthesia in rare instances

k. Progressive and restrictive respiratory deficit with nocturnal hypoventilation in the latter teens to early 20s secondary to weak intercostal muscles
l. Eventual respiratory failure requiring assisted ventilation
m. Some degree of mental impairment is usually present. Approximately 25% of patients have IQ below 75, presumably due to the lack of dystrophin in the brain.
n. Natural history
   i. Progressive and predictable deterioration of muscle function
   ii. Cause of death: cardiopulmonary insufficiency in the late second or third decade
o. Female carriers
   i. Usually asymptomatic
   ii. Manifesting female carriers (rare): Occasional, slow progressive myopathy of moderate severity with elevated CPK (>1,000) and associated symptoms in about 8% of carriers. Following conditions induce expression of the disease phenotype:
      a) Random X-inactivation: The extent of clinical involvement is dependent in part upon the degree of skewed X-chromosome inactivation in somatic cells.
      b) Turner syndrome having a single X chromosome
      c) X-autosome translocation that disrupts the dystrophin gene and causes nonrandom inactivation of the normal allele on the other X chromosome

2. BMD
   a. A more benign and variable presentation with later onset and slower progression
   b. Onset of symptoms after age 6–12
   c. Progressive symmetrical muscle weakness and atrophy
      i. Proximal greater than distal
      ii. Often with calf hypertrophy
      iii. Weakness of quadriceps femoris may be the only sign.
   d. Activity induced cramping in some patients
   e. Flexion contractures of the elbows may occur late in the course
   f. Wheelchair dependency, if present, after 16 years of age
   g. Preservation of the neck flexor muscle strength in BMD, differentiating it from DMD
   h. Rare BMD patients not diagnosed until adulthood and never lose ambulation
   i. A proportion of cases have some degree of mental impairment
   j. Heart failure from dilated cardiomyopathy, a common cause of morbidity and the most common cause of death, despite the milder skeletal muscle involvement
   k. Death usually in the fourth or fifth decade
   l. Female carriers
      i. Clinical features similar to DMD female carriers.
      ii. About 5–10% of female carriers show some degree of muscle weakness.
      iii. Often with calf hypertrophy.
      iv. May develop dilated cardiomyopathy.

Diagnostic Investigations

1. Determination of serum creatine kinase (CK-MM)
   a. Fifty-fold elevation (BMD) to 100-fold elevation (DMD) in affected boys, resulting from leakage of the muscle isoform
   b. Serum creatine kinase levels: range of values overlapping with the normal range in carrier females, making the test less than definitive
2. Determination of other enzymes: grossly elevated aldolase, SGOT, lactic dehydrogenase, and pyruvate kinase
3. Electrocardiography and echocardiography to detect cardiac involvement
   a. Electrocardiography
      i. Abnormalities in the early stage of the disease
         a) Tall R-wave
         b) Deep Q-wave
      ii. Arrhythmias
      iii. Progressive cardiomyopathy in the mid-teens
         a) Myocardial dilatation
         b) Myocardial thickening
   b. Echocardiography
      i. Left ventricular dilatation and dysfunction
      ii. Mitral regurgitation secondary to dilated cardiomyopathy or associated mitral valve prolapse

4. Radiography for scoliosis
5. Pulmonary function testing with negative inspiratory force and forced vital capacity as disease progresses
6. Cytogenetic analysis
   a. Males affected with DMD and other X-linked disorders such as retinitis pigmentosa, chronic granulomatous disease, McLeod red cell phenotype, glycerol kinase deficiency, and adrenal hypoplasia as part of contiguous gene deletion syndrome
      i. High resolution chromosome studies
         a) To detect visible deletions
         b) To detect chromosome rearrangements involving Xp21.1
      ii. FISH analysis with probes covering the *GK* and *NRDB1* genes in addition to exons in the *DMD* gene
   b. Females with classic DMD
      i. May have X chromosome rearrangement
      ii. May have deletion involving Xp21.1
      iii. May have complete absence of an X chromosome (45,X)
      iv. May have complete uniparental disomy of the X chromosome
      v. Warrant high-resolution chromosome studies
7. Electromyography (EMG) to distinguish a myopathic process from a neurogenic disorder
   a. Not diagnostic
   b. Demonstrating characteristic myopathy
   c. Reduction in the duration and amplitude of motor unit action potentials
   d. An enhanced frequency of polyphasic potentials
8. DNA analyses for diagnostic confirmation
   a. Deletion of the dystrophin gene in 60% of patients: 98% of all deletions which occur in hotspots within the dystrophin gene can be recognized by multiplex PCR which amplifies 18–25 of the gene's 79 exons from genomic DNA obtained from blood samples
   b. Duplications (6% of cases): the next most common mutation of the dystrophin gene, also detectable by multiplex PCR amplification
   c. Point mutations (1/3 of patients) difficult to identify due to the large size of the gene
   d. Enhanced single-strand conformation polymorphism (SSCP) and heteroduplex analysis: highly sensitive and possible to detect approximately 90% of patients with DMD
   e. RNA-based methods, such as reverse-transcriptase PCR (RT-PCR)
   f. Protein truncation test: to rapidly screen the DMD gene for translation terminating mutations
9. Muscle biopsy (needle biopsy vs. open biopsy under general anesthesia), frequently performed when a clinically suspected DMD patient does not have a large deletion or duplication by genomic DNA testing
   a. Histology
      i. Rounding of muscle fibers
      ii. Marked variability in muscle fiber size
      iii. Increased central nucleation
      iv. Fiber splitting
      v. Presence of necrotic and regenerating fibers along with large, round hyaline fibers
      vi. Virtual replacement of muscle fibers by fatty and fibrous tissue in late stage
   b. Dystrophin determination by Western blot analysis or immunostaining
      i. Usually little or no detectable dystrophin in patients with DMD
      ii. Dystrophin reduced in amount or abnormal in size in patients with BMD
10. Carrier testing (Mathews 2003)
   a. Carrier testing of young girls or genetic testing of siblings of patients with DMD should be delayed until they are old enough to participate in the decision-making process.
   b. Appropriate to test the mother who has an affected boy with deletion or duplication identified by standard DNA screening, especially if there are other female relatives of childbearing age who are at risk for being carriers.
   c. Possibility of gonadal mosaicism (up to 15%) exists when the mother does not carry the boy's mutation
      i. Her sisters could not have inherited the mutation.
      ii. Her daughter may have inherited the mutations.
   d. Offer linkage analysis to modify risk of carrier status if no mutation is known or if tissue for DNA analysis is not available
      i. Knowledge of a childhood CPK level in the at risk girl helpful
      ii. Elevated CPK in an at-risk female is presumptive evidence of her being a carrier
   e. Muscle biopsy: not a helpful test in determining carrier status.

Genetic Counseling

1. Recurrence risk
   a. Patient's sib given that the mother is a carrier (has a disease-causing mutation) (the carrier mother with one defective gene and one normal gene is usually not affected)
      i. Fifty percent risk to her son to receive the disease gene and express the disease.
      ii. Fifty percent risk to her daughter to receive the disease gene and become a carrier.
      iii. Mother, regardless of proven carrier status or does not have a *DMD* mutation detectable in her DNA, has an empiric risk of 15–20% of having an affected male fetus due to presence of maternal germinal mosaicism.
      iv. Mother with concomitant somatic and germline mosaicism: The risk to sibs of inheriting a DMD mutation may be higher than if the mother has germline mosaicism only (van Essen et al. 2003).
   b. Patient's offspring
      i. Males with DMD: Patient usually succumb or too debilitated to reproduce
      ii. Males with BMD
         a) May reproduce.
         b) None of the sons will inherit the mutation.
         c) All the daughters are carriers.
   c. Germline mosaicism (den Helderman-van Enden et al. 2009)
      i. Causes the presence of multiple affected offspring from apparently noncarrier parents.
      ii. In X-linked DMD/BMD, the recurrence risk for noncarrier females due to germ line mosaicism has been estimated to be between 14% and 20% (95% confidence interval) (Darras and Francke 1987; Bakker et al. 1987, 1989 van Essen et al. 1992) if the risk haplotype is transmitted.
      iii. A recurrence risk of 8.6% (4.8–12.2) if the risk haplotype is transmitted with a remarkable difference between proximal (15.6%) (4.1–27.0) and distal (6.4%) (2.1–10.6) deletions (den Helderman-van Enden et al. 2009). Overall, most mutations originated in the female. Deletions occur more often on the X chromosome of the maternal grandmother, whereas point mutations occur on the X chromosome of the maternal grandfather. In unhaplotyped de novo DMD/BMD families, the risk of recurrence of the mutation is 4.3%.
2. Prenatal diagnosis
   a. In case of a known and readily detectable gene defect
      i. Amniocentesis and mutation analysis of amniocytes, usually by multiplex PCR
      ii. Preimplantation diagnosis by single-cell PCR of blastomere or polar body
      iii. Fetal nucleated erythrocytes from maternal blood analyzed by multiplex PCR
   b. In case of unknown gene defect
      i. Fetal sexing, allowing females to proceed to term
      ii. Linkage analysis
      iii. Fetal muscle biopsy for quantitative dystrophin analysis may serve as a diagnostic option (Nevo et al. 1999)
   c. Comparative genomic hybridization (CGH) (Bovolenta et al. 2010)
      i. Molecular diagnosis of DMD: requires a great deal of effort due to enormous size of the gene and to allele heterogeneity.
      ii. While multiplex ligation-dependent probe amplification (MLPA) represents the standard molecular technique for detecting exonic DMD gene rearrangements (Kesari et al 2008), several comparative genomic hybridization (CGH) platforms have recently been reported to rapidly screen the entire DMD gene, as well as neighboring sequences, for deletions and duplications (Hegde et al 2008; del Gaudio et al 2008; Bovolenta et al 2008).
3. Management (Kapsa et al. 2003; Mathews 2003)
   a. Largely supportive
      i. Physical therapy to eliminate the need for surgical release of contractures
         a) Night splints with ankle foot orthoses (AFOs)
         b) Daily stretching
         c) Crucial to maintain ambulation as long as possible because its loss is associated with contractures and scoliosis, and, in turn, associated with restrictive lung disease

ii. Regular use of an incentive spirometer at home to prolong pulmonary function
iii. Continuous positive airway pressure (CPAP)
iv. Bilevel positive airway pressure BiPAP: more physiologic
v. Psychological support

b. American College of Chest Physician Statement on the respiratory and management of patients with Duchenne dystrophy undergoing anesthesia (Birnkrant 2009)
c. Treatment of dystrophic cardiomyopathy
i. An angiotensin-converting enzyme inhibitor
ii. With or without a β-blocker
iii. A diuretic
d. Pharmaceutical agents (steroids) shown great promise in delaying the progression of DMD
i. Prednisone
ii. Deflazacort (not FDA approved but used widely in Europe and Canada)
e. Orthopedic surgery
i. Release of joint contractures
ii. Spine fusion to minimize painful spinal deformity and secondary pulmonary complications
f. Prescribe wheelchair when dependency becomes inevitable
g. Careful monitoring of pulmonary function
h. Ventilation for respiratory failure
i. Genetic therapies in DMD: Use of viral and plasmid vectors to deliver dystrophin to dystrophin–deficient muscle in vivo (Kapsa et al. 2003)
i. Truncated dystrophin genes (minidystrophin and microdystrophin transgenes): improve force output and other features of the dystrophic *mdx* phenotype
ii. Tissue-specific promoters: Targeted transgene expression via muscle-specific promoters, a good platform for vector-mediated therapeutic delivery of *dys* to dystrophic muscle
iii. Plasmid vectors
iv. Viral vectors
a) Adenoviral vectors
b) Adenoassociated vectors
c) Retroviral vectors
d) Lentiviral vectors
e) Other viral vectors including herpes simplex virus, Epstein-Barr virus, and chimeric adeno-retrovirus

j. Corrective gene therapy (Kapsa et al. 2003; Nelson et al. 2009)
i. Targeted corrective gene conversion therapies
a) Introduction of construct of homologous DNA containing a nonhomologous sequence into mammalian cells in vitro induces specific genetic transformations in the host chromosomal DNA.
b) An attractive therapeutic strategy for DMD if the DNA can be delivered to the muscles efficiently.
ii. Small fragment homologous replacement (SFHR): involves the application of PCR amplicons to correct mutant loci in vitro or in vivo
iii. Chimeraplasty with hybrid RNA-DNA molecules (chimeraplasts) that promote gene conversion via intranuclear DNA mismatch repair mechanisms
iv. Gentamicin
a) An aminoglycoside antibiotics targeting functional complexes (typically ribosomes)
b) Causes a relaxation in codon recognition
c) Enables stop-codon read-through of the *mdx* nonsense mutation (a mutation that produces a stop codon in the transcribed mRNA) in exon 23 of the dystrophin gene in the *mdx* mouse
v. Cell-mediated delivery of *dys*
a) Use cell transplantation to deliver normal (non-dystrophic) *dys* to dystrophic muscle
b) Use donor myogenic precursor cells to remodel the dystrophic muscle of the recipient
c) Systemic applications of stem-cell subpopulations
d) Use autologous cells (as an alternative to donor cells) which can be isolated, genetically engineered, and used to deliver functional dystrophin to the dystrophic muscle

vi. Muscle derived precursor cells
   a) Delivery of normal dystrophin by the transplantation of non-dystrophic muscle derived precursor cells
   b) Resulting in some recovery of normal function in dystrophic muscle
   c) Greatly compromised by host immune response
vii. Non-muscle stem cells
   a) Induction of a few systemically injected bone-marrow cells to enter muscle after regeneration induced by injury.
   b) These cells with neuronal, osteogenic, myogenic, and haemopoietic expression profiles may provide alternatives for cell-based delivery of non-dystrophic loci to dystrophic muscle.
viii. Utrophin
   a) A 395 kDa ubiquitous protein homologue of dystrophin.
   b) Utrophin expression has a widespread sarcolemmal distribution in human dystrophic muscle.
ix. Other alternative approaches that may be useful in the support of functional improvement in dystrophic muscle include:
   a) $\alpha 7\beta 1$ integrin
   b) Myoprotective or myoproliferative cytokine factors such as leukemia inhibitory factor and insulin-like growth factor-1
   c) Inhibition of myostatin
x. Emerging genetic therapies to treat DMD
   a) A drug, PTC124, was identified that suppresses nonsense codon translation termination. PTC124 can lead to restoration of some dystrophin expression in human Duchenne muscular dystrophy muscles with mutations resulting in premature stops.
   b) Two drugs developed for exon skipping, PRO051 and AVI-4658, result in the exclusion of exon 51 from mature mRNA. They can restore the translational reading frame to dystrophin transcripts from patients with a particular subset of dystrophin gene deletions and lead to some restoration of dystrophin expression in affected boys' muscle in vivo.
   c) Both approaches have concluded phase I trials with no serious adverse events.

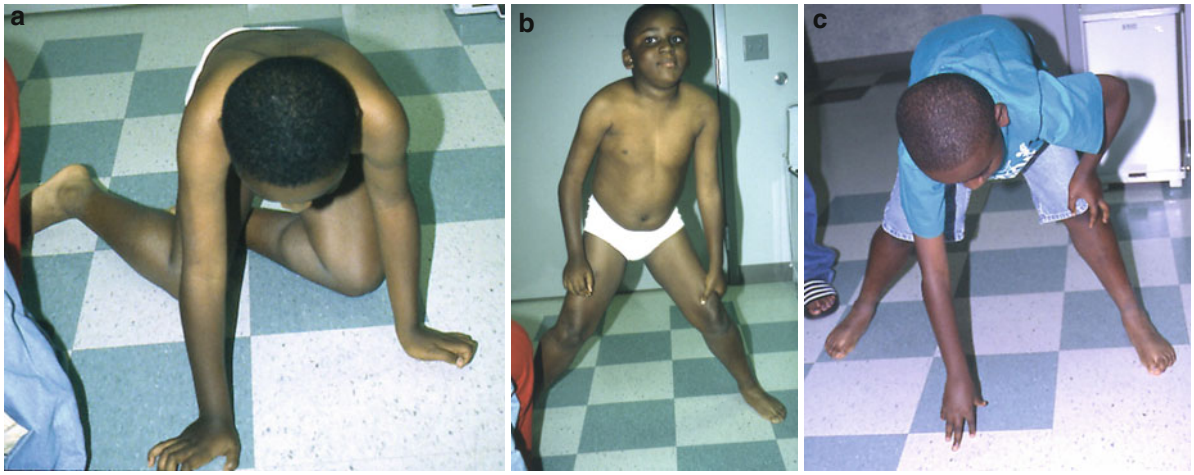

Fig. 1 (**a**–**c**) A 10-year-old boy with DMD showing Gower sign maneuver. He walked before 16 months of age and had trouble getting up. Radiography showed mild cardiomegaly. Muscle biopsy showed absence of dystrophin. Molecular genetic analysis revealed exons 45–50 deletion of the dystrophin gene

Fig. 2 A 12-year-old boy with DMD showing moderate calf hypertrophy. He began to fall frequently at school, could not get up from sitting position and had waddling gait, proximal muscle weakness, prominent lordosis, decreased deep tendon reflexes, and mild mental retardation. Muscle biopsy revealed absence of dystrophin

Fig. 3 A 10-year-old boy with DMD starting to use wheelchair for ambulation. He had tip toe walking at age of 6 and markedly elevated CPK at 24,000–26,000. Muscle biopsy of quadriceps femoris muscle showed marked variation in fiber size, moderate number of necrotic fibers, occasional regeneration fibers and hyalinized fibers, mild increase in internal nuclei, a few split fibers, and moderate increase in perimysial and endomysial connective tissue. Molecular genetic analysis revealed deletion of exon 45 of the dystrophin gene

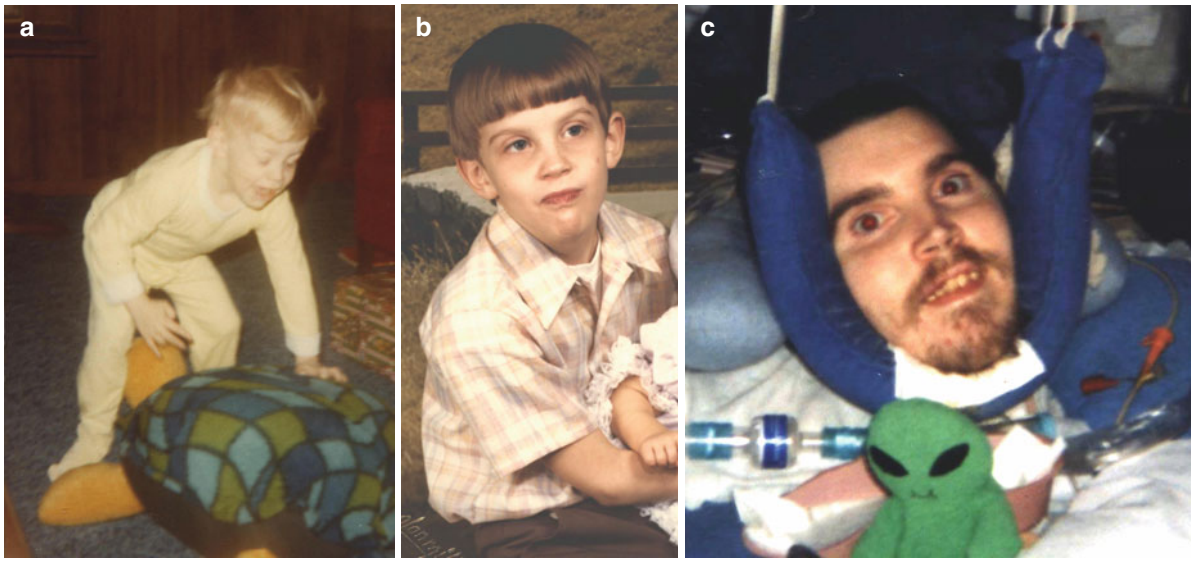

Fig. 4 (**a**–**c**) A male with DMD at 4-, 10-, and 29-year-old showing the progression of the disease. He has deletion of exons 49–54 of the dystrophin gene

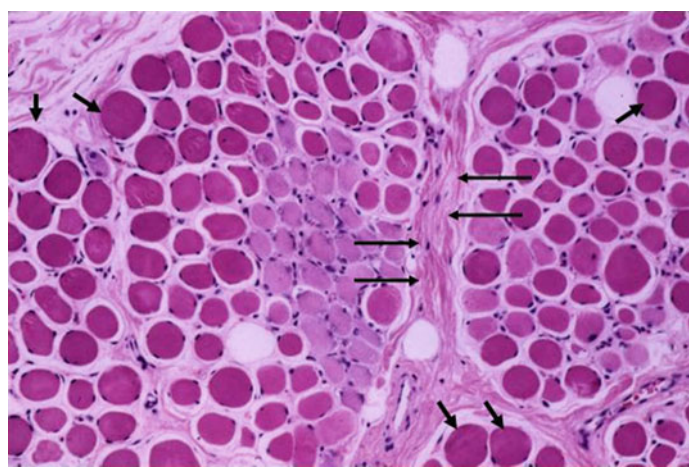

Fig. 5 Biopsy of left calf muscle of another patient at age 4 showed widening of perimysium (*large arrows*) and endomysium with fibrosis; variation of fiber size with presence of large rounded fibers (*small arrows*). Degenerative fibers were often seen (H & E, x400)

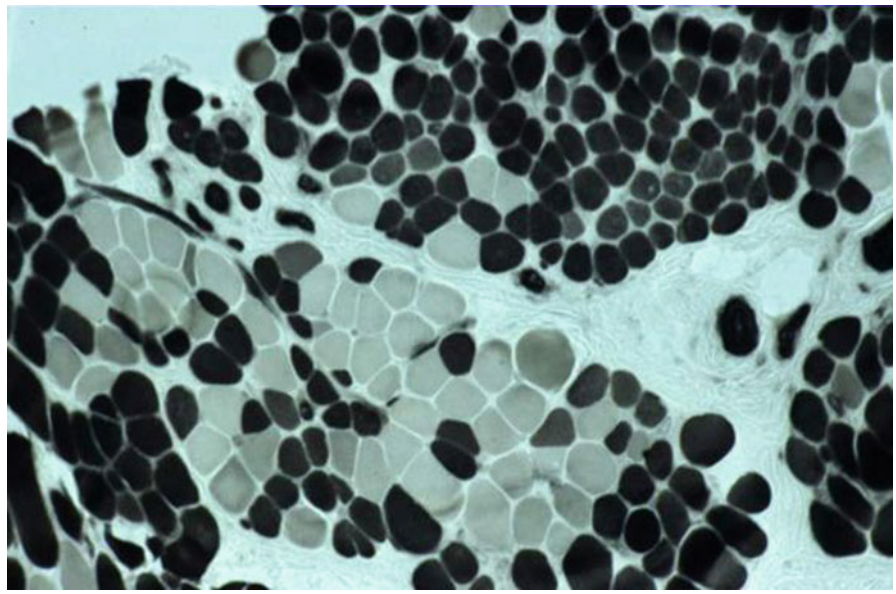

Fig. 6 Enzyme histochemical stain showed both type I (*dark stained*) and type II (*light stained*) fibers are randomly affected and there is a remarkable variation of fiber size even at the early stage (myosin ATPase at 4.6, x400)

Ectrodactyly-Ectodermal Dysplasia-Clefting (EEC) Syndrome

EEC syndrome is an ectodermal dysplasia syndrome associated with ectrodactyly and cleft lip/palate.

Genetics/Basic Defects

1. Inheritance (Akahoshi et al. 2003; Barrow et al. 2002; Clements et al. 2010)
   a. Familial cases (50%)
      i. Autosomal dominant inheritance
      ii. Variable clinical expression and incomplete penetrance (93–98%)
   b. Sporadic cases (50%): more severe phenotype than the familial cases
2. At least three distinctive EEC loci identified
   a. EEC1 (7q11.2-q21.3)
   b. EEC2 (chromosome 19 pericentromeric region)
   c. EEC3 (3q27)
3. Molecular basis of EEC
   a. Causative mutations for EEC syndrome have only been identified in *p63* with identification of heterozygous mutations in the DNA-binding domain of the *p63* gene at 3q27
   b. The p63 protein
      i. A member of the *p53* family
      ii. Implicated in apoptosis rather than tumor suppression. Increased susceptibility for cancer development has not been shown in patients with EEC syndrome.
   c. Pathogenic mutations in the *TP63* transcription factor have been identified as the molecular basis of EEC syndrome and to date 34 mutations have been reported (Clements et al. 2010). The majority of mutations involve heterozygous missense mutations in the DNA-binding domain of TP63, a region critical for direct interactions with DNA target sequences
4. Genotype–phenotype correlation
   a. A genotype–phenotype correlation described for *p63* mutations in EEC syndrome, limb-mammary syndrome, and isolated split hand/split foot malformation: a specific pattern of missense mutations exists in EEC syndrome that are not generally found in split hand/foot malformation or limb-mammary syndrome (Van Bokhoven et al. 2001)
   b. Emerging paradigm for genotype–phenotype correlation (Clements et al. 2010)
      i. EEC syndrome, the prototype of all TP63 ectodermal dysplasia disorders, is the most prevalent syndrome resulting from mutations in the *TP63* gene (Brunner et al. 2002; Bougeard et al. 2003) with more than 200 cases reported in the literature
5. EEC syndrome as a model of apoptosis disturbance
   a. Split hands and feet are caused by a failure of cell death between fingers and between toes
   b. Urogenital anomalies are due to abnormal regression of Wolffian or Mullerian duct
   c. Facial clefts are attributed to the abnormal elimination of excess cells during fusion of the archetypal plate

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_77,
© Springer Science+Business Media, LLC 2012

Clinical Features

1. Significant intra/interfamilial variability (Bigatà et al. 2003)
2. Cardinal signs (triad)
   a. Ectrodactyly
   b. Ectodermal dysplasia
   c. Orofacial clefts
3. Distal limb malformations: highly variable
   a. Ectrodactyly (84%)
      i. Also called split hand/foot malformation
      ii. A central reduction of the hands and feet that is often associated with syndactyly
   b. Present in all four or any combination of extremities involved or not present at all
4. Ectodermal dysplasia (77%): may exhibit the following signs:
   a. Sparse scalp hair
   b. Sparse eyebrows and eyelashes
   c. Thin and brittle nails
   d. Hypohidrosis
   e. Thin and dry skin with an increased susceptibility to eczema
   f. Dental anomalies
      i. Hypodontia
      ii. Coniform-shaped teeth
      iii. Enamel dysplasia
5. Characteristic face
   a. Bilateral cleft lip and/or palate (68%)
   b. Maxillary hypoplasia
   c. Short philtrum
   d. Broad nasal tip
   e. Choanal atresia
   f. Anomalies of the lacrimal ducts resulting in blepharitis, keratitis, and dacryocystitis (59%)
6. Urogenital defects (23%)
   a. Hydronephrosis
   b. Hydroureter
   c. Renal agenesis
7. Conductive hearing loss (14%)
8. Developmental delay
9. Occasional CNS malformations
   a. Rare growth hormone deficiency secondary to hypothalamic-pituitary insufficiency
   b. Holoprosencephaly associated with hypogonadotropic hypogonadism and central diabetes insipidus
   c. Isolated absent septum pellucidum
10. Phenotype overlapping with split hand/foot malformations
11. TP63-associated disorders (Clements et al. 2010): Clinical features overlap with EEC syndrome, although several distinct characteristics may help distinguish them
    a. AEC (ankyloblepharon, ectodermal dysplasia, clefting) (Hay–Wells) syndrome (McGrath et al. 2001): Typical features include:
       i. Ankyloblepharon filiforme (partial eyelid fusion)
       ii. Skin erosions are typical features
    b. ADULT (acro, dermato, ungula, lacrimal, tooth) syndrome (Chan et al. 2004): Common features include:
       i. Mammary gland/nipple hypoplasia
       ii. An absence of clefting
       iii. Increased skin freckling
    c. Rapp–Hodgkin syndrome (Bougeard et al. 2003; Chan et al. 2005): Typical features include:
       i. Similar to AEC syndrome
       ii. Usually an absence of ankyloblepharon
       iii. Characteristic facies with midfacial hypoplasia and microstomia
    d. Limb-mammary syndrome (Van Bolhoven et al. 1999)
       i. Similar limb defects to those seen in EEC syndrome, including absence or severe hypoplasia of digits and fusion/separation defects such as syndactyly
       ii. Additional clinical features
          a) Mammary gland/nipple hypoplasia
          b) Cleft palate only and limited
          c) No skin or hair abnormalities

Diagnostic Investigations

1. Ophthalmologic evaluation for tear duct obstruction
2. Early audiological assessment
3. Renal ultrasound for associate renal anomalies
4. Radiographic evaluation for ectrodactyly
5. Starch-iodine test (the skin is painted with tincture of iodine, air-dried, and sprayed with starch) after sweat stimulation with intradermal injections of pilocarpine to demonstrate hypohidrosis (Bigatà et al. 2003)
6. Direct molecular analysis is possible for EEC (TP63-related disorders) (www.genetests.org)

Genetic Counseling

1. Counseling according to autosomal dominant inheritance
   a. Patient's sib:
      i. Recurrence risk of 50% if a parent is affected
      ii. Recurrence risk not increased if both parents are normal
   b. Patient's offspring: recurrence risk of 50%
   c. Dilemmas in counseling due to highly variable clinical expression
   d. Consider the possibility of nonpenetrance due to gonadal mosaicism
2. Prenatal diagnosis
   a. Prenatal ultrasonography
      i. Cleft lip/palate
      ii. Ectrodactyly
      iii. Associated anomalies
   b. Molecular genetic analysis of p63 gene mutation (South et al. 2002)
      i. On fetal DNA extracted from CVS and amniocytes by direct sequencing and restriction endonucleases digestion (loss of *AciI* site on mutant allele)
      ii. Using a preimplantation genetic diagnostic approach
3. Management (Bigatà et al. 2003)
   a. Supportive (multidisciplinary team approach)
      i. Artificial tear for tear duct blockage
      ii. Anticipate recurrent ophthalmologic infections
      iii. Periodic odontologic management to prevent dental malocclusion and caries
      iv. Simple emollients for dry skin
   b. Surgery
      i. Early surgery for tear duct blockage
      ii. Surgery for all defects causing functional impairment
         a) Cleft lip/palate
         b) Ectrodactyly
         c) Associated anomalies

Ehlers-Danlos Syndrome

Ehlers-Danlos syndrome (EDS) is a group of clinically and genetically heterogeneous heritable connective tissue disorders affecting skin, ligaments, joints, blood vessels, and internal organs. EDS is characterized by skin extensibility, joint hpermobility, and tissue fragility. EDS result from mutations in genes involved in extracellular matrix formation and organization, leading to a predisposition for loss of structural integrity in tissues within multiple organ systems (Barabas 1967). The prevalence of EDS is estimated to be about 1 in 5,000 births.

Synonyms and Related Disorders

EDS I (Gravis type); EDS II (mitis type); EDS III (hypermobile type); EDS IV (arterial-ecchymotic type); EDS VI (kyphoscoliotic type); EDS VIIA, VIIB (arthrochalasis type); EDS VIIC (Dermatospraxis type); EDS VIII; EDS IX (occipital horn syndrome/X-linke cutis laxa); EDS IX (occipital horn syndrome/X-linke cutis laxa); EDS X; EDS XI

Genetics/Basic Defects

1. Classic type (includes EDS type I, gravis type and EDS type II, mitis type)
   a. Autosomal dominant inheritance
   b. Mutations in the *COL5A1* gene (mapped at 9q34.2-q34.3), *COL5A2* (mapped at 2q31), and *COL1A1* (mapped at 17q21.31-q22) genes result in EDS I. Mutations in the *COL1A1* is not a major cause of classic EDS
   c. Mutations in the *COL5A1* and *COL5A2* genes result in EDS II.
2. Hypermobile type (EDS type III)
   a. Autosomal dominant inheritance in the classic form of type III EDS.
   b. Mutations in *COL3A1*, typically cause EDS IV, also cause EDS III.
   c. Mutations in the *TNXB* gene that encodes tenascin-X (neither a collagen nor a collagen-modifying protein) result in a variation of the classic form of the Ehlers-Danlos syndrome.
      i. Autosomal recessive disorder
      ii. Clinical findings (joint hypermobility, soft hyperextensible skin, and easy bruising without skin scars) are compatible with Beighton's description of Ehlers-Danlos syndrome type III or "benign familial hypermobility."
3. Vascular type (EDS type IV, arterial-ecchymotic type)
   a. Autosomal dominant inheritance
   b. *COL3A1 l*ocus: 2q31
   c. Caused by mutations in the gene that encodes type III procollagen (*COL3A1*), which is the major component of blood vessels, viscera, and the uterus. Consequently, individuals with this type often experience life-threatening vascular and gastrointestinal complications.

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_78,
© Springer Science+Business Media, LLC 2012

4. Kyphoscoliosis type (EDS type VI, ocular-scoliotic type)
   a. Autosomal recessive inheritance
   b. *PLOD* gene mapped to 1p36.3-p36.2
   c. Caused by mutations in the *PLOD* gene encoding lysyl hydroxylase
   d. Caused by deficient activity of the enzyme procollagen lysyl hydroxylase
   e. EDS VIA: reduced activity of lysyl hydroxylase
   f. EDS VIB: normal enzyme level
5. Arthrochalasis type (EDS types VIIA and VIIB, arthrochalasis multiplex congenita)
   a. Autosomal dominant inheritance.
   b. EDS VIIA caused by mutations in the genes for type I collagen (*COL1A1*)
   c. EDS VIIB caused by mutations in the genes for type I collagen (*COL1A2*), mapped at 7q22.1.
6. Dermatospraxis type (EDS type VIIC)
   a. Autosomal recessive inheritance
   b. Caused by homozygous mutations in the *ADAMTS2* gene (5q23) encoding procollagen I N-terminal peptidase resulting in procollagen peptidase deficiency
7. Other types
   a. EDS type V
      i. X-linked recessive inheritance
      ii. Described in only two families with clinical features similar to EDS II
      iii. Molecular basis unknown
   b. EDS type VIII
      i. A rare type
      ii. Autosomal dominant inheritance
      iii. Similar to classic type except the presence of periodontal friability
   c. EDS type IX
      i. Previously redefined as occipital horn syndrome (X-linked cutis laxa)
      ii. An X-linked recessive condition allelic to Menkes syndrome
      iii. Abnormal copper utilization secondary to defective copper transport resulting in decreased activity of lysyl oxidase, an important copper-dependent enzyme required for cross-linking in collagen biosynthesis and elastin fibers
   d. EDS type X
      i. Autosomal recessive inheritance
      ii. Described only in a single family
      iii. Associated platelet aggregation due to a defect in fibronectin
   e. EDS type XI
      i. Termed familial joint hypermobility syndrome
      ii. Autosomal dominant inheritance
      iii. Previously removed from the EDS classification

Clinical Features

1. Classic type (EDS I and II) (Beighton et al. 1998; Malfait et al. 2011)
   a. Major diagnostic criteria: The presence of scars with joint hypermobility suggests the classical type.
      i. Skin hyperextensibility
      ii. Widened atrophic scars (the hallmark "cigarette-paper" scars, a manifestation of tissue fragility)
      iii. Joint hypermobility
      iv. Positive family history
   b. Minor diagnostic criteria
      i. Smooth, velvety skin
      ii. Molluscoid pseudotumors
         a) Fresh lesions associated with scars
         b) Frequently found over pressure points such as elbow and knees
      iii. Subcutaneous spheroids
         a) Small subcutaneous spherical hard bodies
         b) Frequently mobile and palpable on the forearms and shins
         c) May be calcified and detectable radiologically
      iv. Complications of joint hypermobility
         a) Sprains
         b) Dislocations
         c) Recurrent joint subluxations in the shoulder, patella, and temporomandibular joints
         d) Pes planus
      v. Muscle hypotonia
      vi. Delayed gross motor development
      vii. Easy bruising
      viii. Manifestations of tissue extensibility and fragility
         a) Hiatal hernia
         b) Anal prolapse in childhood
         c) Cervical insufficiency
      ix. Surgical complications (postoperative hernias)
      x. Positive family history

c. Other features
   i. Families with variable severity (mild, moderate, and severe) of the skin manifestations
   ii. Dyspareunia and sexual dysfunction: occasional complaints
   iii. Fatigue: a frequent complaint
2. Hypermobile type (EDS III)
   a. Major diagnostic criteria
      i. Skin involvement (variable hyperextensibility and/or smooth, velvety skin)
      ii. Generalized joint hypermobility (dominant clinical feature)
   b. Minor diagnostic criteria
      i. Recurrent joint dislocations (particularly shoulder, patella, and temporomandibular joints)
      ii. Chronic joint/limb pain (early onset, chronic, and possibly debilitating)
      iii. Positive family history
   c. Other features
      i. Early-onset, chronic, and possibly debilitating musculoskeletal pain
      ii. Aggravation of joint symptoms during pregnancy but a complete return to the former status is possible
   d. Natural history and manifestations (Castori et al. 2010)
      i. The most difficult form to diagnose
      ii. A diagnosis of exclusion for the following disorders:
         a) Underlying bone dysplasia
         b) Neuromuscular disorder (such as Bethlem myopathy)
         c) Various similar connective tissue disorders, including other types of EDS and the fibrillinopathies
      iii. Lack of a major clinical trait except for joint hypermobility
      iv. Lack of specific diagnostic laboratory tests, although tenascin-X monoallelic or biallelic inactivation can be documented in no more than 10% of the patients (Schalkwijk et al. 2001; Zweers et al. 2003).
      v. Clinical presentations
         a) Recurrent articular dislocations (also after surgical repair)
         b) Chronic/recurrent articular pain in adults or young adults with joint hypermobility and/or a history of infancy/childhood joint hypermobility
         c) Soft/velvety skin and/or easy bruising with joint hypermobility or a history of infancy/childhood joint hypermobility
         d) Chronic asthenia with recurrent articular pain and negative screening for inflammatory arthritis
         e) Acute thoracic pain due to spontaneous rib luxation/subluxation (rare)
         f) Early-onset uterine/vescical/rectal prolapse (19%)
         g) Chronic gastrointestinal discomfort including chronic recurrent dyspepsia/gastritis, gastro-esophageal reflux, irritable bowel disease, recurrent unexplained abdominal pain, and constipation/diarrhea
3. Vascular type (EDS IV)
   a. Major diagnostic criteria: The presence of any two or more major criteria is highly indicative of diagnosis of EDS IV; biochemical testing is strongly recommended to confirm the diagnosis.
      i. Thin translucent skin (especially noticeable on the chest or abdomen)
      ii. Arterial/intestinal/uterine fragility or rupture (presenting signs in 70% of adults with vascular type of EDS)
         a) Spontaneous arterial rupture peaks in the 3rd or 4th decade but may occur earlier, most commonly involves midsized arteries, and is the most common cause of sudden death. The sites of arterial rupture are the thorax and abdomen (50%), head and neck (25%), and extremities (25%).
         b) Intrapartum uterine rupture and pre-/postpartum arterial rupture result in 15% mortality. Vaginal and perineal tears may complicate pregnancies during delivery.
         c) Gastrointestinal ruptures occur in about 25% of patients, most common in the sigmoid colon.
         d) Ruptures of the small bowel and stomach are rare. The rupture may present as an acute abdomen.
      iii. Easy bruising
         a) Lifelong history
         b) Spontaneous or with minimal trauma

iv. Characteristic facial appearance in some affected patients due to a decrease in the subcutaneous adipose tissue
  a) Thin lips and philtrum
  b) Small chin
  c) Thin nose
  d) Large eyes
v. Family history of the vascular type of EDS

b. Minor diagnostic criteria: The presence of one or more minor criteria contribute to the diagnosis of the vascular type of EDS, but are not sufficient to establish the diagnosis
i. Acrogeria (an aged appearance of the extremities, particularly the hands)
ii. Hypermobility of small joints (usually limited to the digits)
iii. Tendon and muscle rupture (knee)
iv. Talipes equinovarus (clubfoot) (12%)
v. Early-onset varicose veins
vi. Arteriovenous, carotid-cavernous sinus fistula
vii. Pneumothorax/pneumohemothorax (common in childhood)
viii. Chronic joint subluxations/dislocations
  a) TMJ
  b) Patella
  c) Ankles
ix. Congenital dislocation of the hips
x. Gingival recession
xi. A positive family history consistent with autosomal dominant inheritance with sudden death in close relatives

c. Other features
i. An uncommon subtype: diagnosis often made only after a catastrophic complication or at postmortem examination
ii. Acute abdominal and flank pain (diffuse or localized): a common manifestation of arterial or intestinal rupture
iii. Subcutaneous venous pattern particularly apparent over the chest and abdomen
iv. Hypermobility of large joints and hyperextensibility of the skin: unusual in the vascular type
v. The teenage boys: at higher risk for arterial rupture possibly due to further weakening of the defective collagen during the prepubertal growth spurt
vi. Patients undergoing surgery: prone to have arterial rupture in the postoperative period, possibly due to increased collagenase activity after surgical trauma
vii. Aneurysms (if present) resulting from arterial tears with walled-in hematomas or pseudoaneurysms
viii. Danger of varicose-vein surgery in unrecognized cases since the extreme fragility of all blood vessels can lead to a loss of a limb or even loss of life

4. EDS V
a. An extremely rare X-linked, recessively inherited disorder
b. Clinically similar to EDS II
i. Joint hyperextensibility
ii. Slightly hyperelastic skin
iii. Skin subject to mildly abnormal scarring
c. Normal life span
d. Asymptomatic female carriers

5. Kyphoscoliosis type (EDS VI)
a. Major diagnostic criteria: Presence of 3 major criteria is suggestive of diagnosis of EDS, kyphoscoliosis type.
i. Generalized joint laxity (recurrent joint dislocations common in adults)
ii. Severe muscle hypotonia at birth
iii. Kyphoscoliosis, present at birth or within the first year of life, progressive (adults with severe kyphoscoliosis are at risk for restrictive lung disease and pneumonia)
iv. Scleral fragility and rupture of the ocular globe
b. Minor diagnostic criteria
i. Tissue fragility, including atrophic scars
ii. Easy bruising
iii. Marfanoid habitus
iv. Microcornea (most patients)
v. Radiologically considerable osteopenia (osteoporosis)
vi. Family history (e.g., affected sibs)
c. Other features
i. Pronounced muscular hypotonia leading to delayed gross motor development.

ii. Severe phenotype often results in loss of ambulation in the second or third decade.
iii. Scleral fragility leading to rupture of the ocular globe after minor trauma.
iv. Cardiovascular complications
a) Vascular rupture: the major life-threatening complication.
b) Both aortic dilatation/dissection and rupture of medium-sized arteries may occur.
c) Mitral valve prolapse common.
v. Differential diagnosis: severe neonatal form of Marfan syndrome.

6. Arthrochalasia type (EDS VIIA and VIIB)
a. Major diagnostic criteria:
i. Severe generalized joint hypermobility, with recurrent subluxations
ii. Congenital bilateral hip dislocation (present in all biochemically proven individuals, may lead to short stature)
b. Minor diagnostic criteria:
i. Skin hyperextensibility
ii. Tissue fragility, including atrophic scars
iii. Easy bruising
iv. Muscle hypotonia
v. Kyphoscoliosis (may lead to short stature)
vi. Radiologically mild osteopenia
c. Other features
i. Short stature resulting from complication of severe kyphoscoliosis and/or hip dislocation
ii. Differential diagnosis: Larsen syndrome

7. Dermatosparaxis type (EDS VIIC)
a. Major diagnostic criteria:
i. Severe skin fragility (wound healing not impaired, scars not atrophic)
ii. Sagging, redundant skin (redundancy of the facial skin resulting in an appearance resembling cutis laxa) analogous to the animal disease dermatosparaxia
b. Minor diagnostic criteria:
i. Soft, doughy skin texture
ii. Easy bruising (substantial)
iii. Premature rupture of fetal membranes
iv. Large hernias (umbilical, inguinal)
c. Other features
i. Blue sclera
ii. Palmar creases
iii. Micrognathia
iv. Joint laxity without subluxations

8. EDS VIII
a. Chronically inflamed, heavily pigmented, discrete, and pretibial plaques (granulomatous collagen degeneration)
b. Premature periodontal disease
c. Premature loss of teeth
d. Hypermobile joints
e. Thin, soft, and hyperextensible skin
f. Easy bruising skin
g. Skin prone to abnormal scarring
h. No consistent biochemical or structural changes detectable

9. Occipital horn syndrome (EDS IX)
a. Also called X-linked cutis laxa
b. Skeletal dysplasia
i. Occipital horns
ii. Broad clavicles
iii. Deformed radii, ulnae, and humeri
iv. Narrow rib cage
v. Undercalcified long bones
vi. Coxa valga
c. Unusual facial appearance
d. Hypermobility of finger joints
e. Limitation of extension of elbows
f. Chronic diarrhea
g. Genitourinary abnormalities
i. Bladder diverticulae
ii. Susceptible to rupture of the bladder
h. Vascular complications
i. Splenic artery aneurysm
ii. Hepatic artery aneurysm
i. Neuropathologic findings
i. Neovascularization and extreme reduplication of the cerebral arteries with cystic medial degeneration
ii. Cerebellar hypoplasia
iii. Focal cortical dysplasia
iv. Cerebellar heterotopias
j. Abnormal copper utilization
i. Depleted serum copper level
ii. Depleted serum ceruloplasmin level

10. Ehlers-Danlos syndrome with fibronectin deficiency (EDS X)
a. A mild, recessively inherited variant of Ehlers-Danlos syndrome

b. Resembling EDS types II and III
c. Thin, fragile, and easily scarred skin
d. Joint hypermobility
e. Excessive bruising
f. Abnormal platelet aggregation but correctable with normal fibronectin

Diagnostic Investigations

1. Classic type
   a. Ultrastructural studies
      i. Disturbed collagen fibrillogenesis
      ii. A characteristic "cauliflower" deformity of collagen fibrils
   b. Abnormal electrophoretic mobility of the proα1(V) and proα2(V) chains of collagen type V in some patients
   c. Demonstration of a mutation in *COL5A1* and/or *COL5A2* genes
   d. Echocardiogram to measure aortic root size
2. Hypermobile type: *TNXB* sequencing by research only
3. Vascular type
   a. Demonstration of structurally abnormal collagen type III produced by cultured skin fibroblasts
   b. Demonstration of a mutation in the *COL3A1* gene
   c. Surveillance of aneurysm by MRI or CT scan without contrast material or venous subtraction angiography
4. Kyphoscoliosis type
   a. Demonstration of deficient activity of the enzyme procollagen lysine hydroxylase in affected individuals, diagnosed by biochemical testing of the urine and enzyme assay of cultured fibroblasts
   b. Demonstration of an increased ratio of deoxypyridinoline to pyridinoline crosslinks in the urine measured by HPLC, a highly sensitive and specific test (Malfait et al. 2011)
   c. Demonstration of mutations of the *PLOD* gene that encodes the enzyme procollagen lysyl hydroxylase (Malfait et al. 2011)
   d. Echocardiogram to measure aortic root size
5. Arthrochalasis type
   a. Electrophoretic demonstration of pNα1(I) or pNα2(I) chains extracted from dermal collagen or harvested from cultured skin fibroblasts
   b. Mutation analysis (complete or partial exon 6 skipping in cDNAs of *COL1A1* or *COL1A2* respectively)
6. Dermatospraxis type: electrophoretic demonstration of pNα1(I) or pNα2(I) chains from collagen type I extracted from dermis in the presence of protease inhibitors, or obtained from cultured skin fibroblasts

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive: 25% risk of having an affected sib
      ii. Autosomal dominant: risk low (1–5%) unless the parent is affected or having somatic mosaicism or germline mosaicism
      iii. X-linked recessive: 50% risk of having an affected brother if the mother is a carrier
   b. Patient's offspring
      i. Autosomal recessive: risk not increased unless the spouse is a carrier.
      ii. Autosomal dominant: 50% risk of having an affected offspring.
      iii. X-linked recessive: None of the sons will be affected; all daughters will be carriers.
2. Prenatal diagnosis
   a. Possible by demonstrating the disease causing mutation in the fetal cells from CVS or amniocentesis or by linkage analysis for families in which linkage has been established
   b. Possible by biochemical assay on cultured fetal cells for demonstrating biochemical defect in the specific type of collagen
3. Management
   a. General approach: conservative and preventive management of most skin and joint problems
      i. Avoid tension when sutures are applied
      ii. Leave removable sutures in place for twice the usual time
      iii. Physical therapy to strengthen the muscles that need to provide support for the loose ligaments
   b. Classic type (Malfait et al. 2011)
      i. Medical intervention limited to symptomatic therapy and prophylactic measures
      ii. Wear protection pads or stocking
      iii. Avoid contact sports
      iv. Physiotherapy for children with hypotonia and delayed motor development

v. Antimicrobial prophylaxis for patients with mitral valve prolapse
vi. Ascorbic acid helps avoid easy bruising but does not change the basic clinical picture

c. Hypermobile type (Levy 2010)
i. Physical therapy tailored to the individual
ii. Assisted devices
a) Braces to improve joint stability
b) Wheelchair or scooter to offload stress on lower-extremity joints
c) Suitable mattress to improve sleep quality
iii. Pain medication tailored to symptoms: severe pain may need pain specialist's help
iv. Appropriate therapy for gastritis/reflux/delayed gastric emptying/irritable bowel syndrome
v. Possible beta-blockade or rarely surgical approach for progressive aortic enlargement
vi. Psychological and/or pain-oriented counseling

d. Kyphoscoliotic type
i. Orthopedic management of kyphoscoliosis
ii. Physical therapy for older children, adolescents, and adults
iii. Antimicrobial prophylaxis for patients with mitral valve prolapse
iv. Aggressive control of blood pressure
v. Improve with large doses of ascorbic acid because vitamin C is a cofactor for the enzyme that is deficient (Pyeritz 2000)
a) Improve urinary excretion of hydroxylysine
b) Improve muscle strength and wound healing

e. Vascular type (Pyeritz 2000; Pepin and Byers 2011)
i. The most severe form of EDS
ii. Prompt recognition of the major complications
iii. Difficult to repair ruptured arteries because of the pronounced vascular fragility
iv. Rupture of the bowel, a surgical emergency
v. Avoid pregnancy because the risk of vascular rupture is especially high during pregnancy
vi. Minimize risk of trauma by avoiding contact sport, heavy lifting, and weight training
vii. Treat high blood pressure aggressively
viii. Elective surgical management of vascular disorders in EDS patients using open and endovascular procedure (Brooke et al. 2010)
a) Associated with good outcomes
b) Can be safely performed and should not be withheld until rupture or acute symptoms arise
ix. Patient education
a) Possible complications
b) Need for close monitoring
c) Attention to sudden unexplained pain

Fig. 1 (**a**, **b**) Hyperextensible joints enable a girl and two sisters with EDS to exhibit difficult hyperextensible joint maneuvers

Fig. 2 Familial Ehlers-Danlos syndrome in the son (**a**–**d**), the daughter (**e**), and the father (**f**–**h**) exhibiting hyperextensible joints and hyperelastic skin. The son also has fascia weakness presenting as a hernia on the lower chin

Fig. 3 (**a**–**f**) A male and a female with EDS showing hyperextensible joints and hyperelastic skin

Fig. 4 (**a**–**c**) Three siblings (12-year-old boy, 10-year-old girl, and 7-year-old girl) with Ehlers-Danlos syndrome showing markedly stretchable abdominal walls. Their mother is also affected with a history of hyperextensible joints with subluxations of sternum-collar bone junction, TMJ, hip, and knees

Fig. 5 (**a**, **b**) A 40-year-old female with hypermobile type of Ehlers-Danlos syndrome showing hyperextensible joints and stretch marks of the skin. She suffers from rectal, bladder, and uterine prolapses. She had four placental abruptions and had ventral hernias repaired twice. She had shoulder dislocations three times and patella dislocations more than ten times. She had a history of recurrent articular and abdominal pain and episodic constipations and diarrheas

Fig. 6 Typical EDS showing easy bruises and scars of the skin

Fig. 7 (**a**, **b**) An 8-year-old girl with Ehlers-Danlos syndrome showing marked scarring of the skin

Ellis-van Creveld Syndrome

In 1940, Ellis and van Creveld described a syndrome, characterized by ectodermal dysplasia, polydactyly, chondrodysplasia, and congenital heart disease. Ellis-van Creveld syndrome, also called chondroectodermal dysplasia, is relatively common in inbred communities, such as the Amish of Lancaster County where it occurs in 1/5,000 births compared to 1/60,000 births in the general population.

Synonyms and Related Disorders

Chondroectodermal dysplasia

Genetics/Basic defects

1. Inheritance
   a. Autosomal recessive inheritance
   b. Parental consanguinity in 30% of cases
2. Basic defect (Arya et al. 2001)
   a. Generalized dysplasia of endochondral ossification
      i. Delayed in the primary centers
      ii. Premature in the secondary centers
      iii. Leads to short stature with progressive distal shortening of the extremities
   b. Caused by mutations in a novel gene, *EVC1*, which is mapped to chromosome 4p16.1 (Ruiz-Perez et al. 2000)
   c. Caused by mutations in a second gene, called *EVC2*, that gives rise to the same phenotype of the syndrome (Galdzicka et al. 2002)
   d. Molecular heterogeneity and possibility of involvement of other genes) suggested by more mutations in both *EVC1* and *EVC2* in two thirds of the patients (Tompson et al. 2007)
   e. May be allelic to Weyers acrodental dysostosis

Clinical Features

1. A clinical tetrad (Al-Khenaizan et al. 2001; Arya et al. 2001)
   a. Chondrodystrophy
      i. The most common feature affecting the tubular bones
      ii. Disproportionate dwarfism
      iii. Progressive distal limb shortening
         a) Symmetrical
         b) Affects the forearms and lower legs
   b. Polydactyly
      i. A constant finding
         a) Bilateral
         b) Post-axial
      ii. Polydactyly of the hands observed in most cases
      iii. Polydactyly of the feet observed only in 10% of cases
   c. Hidrotic ectodermal dysplasia (up to 93%)
      i. Nails
         a) Hypoplastic
         b) Dystrophic
         c) Friable
         d) Completely absent in some cases
      ii. Teeth
         a) Neonatal teeth
         b) Partial anodontia
         c) Small teeth
         d) Delayed eruption

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_79,
© Springer Science+Business Media, LLC 2012

e) Enamel hypoplasia commonly resulting in abnormally shaped teeth with frequent malocclusion
iii. Occasional sparse hair
d. Cardiac anomalies (50–60%)
i. A single atrium
ii. AV canal
iii. Ventricular septal defect
iv. Atrial septal defect
v. Patent ductus arteriosus
vi. The major cause of shortened life expectancy
2. Other clinical findings
a. Other oral lesions (Cahuana et al. 2004)
i. A fusion of the anterior portion of the upper lip to the maxillary gingival margin
a) Resulting in absence of mucobuccal fold
b) Causing the upper lip to present a slight V-notch in the middle
ii. Multiple labiogingival frenula frequent
iii. Lower alveolar ridge often serrated
b. Musculoskeletal anomalies
i. Low-set shoulders
ii. A narrow thorax
iii. Frequently lead to respiratory difficulties
iv. Knock knees (genu valgum)
v. Lumbar lordosis
vi. Broad hands and feet
vii. Sausage-shaped fingers
c. Genitourinary anomalies (22%)
i. Hypospadias
ii. Epispadias
iii. Hypoplastic penis
iv. Cryptorchidism
v. Vulvar atresia
vi. Focal renal tubular dilation in medullary region
vii. Nephrocalcinosis
viii. Renal agenesis
ix. Megaureters
d. CNS
i. Normal intelligence in most patients
ii. Occasional CNS anomalies or mental retardation

Diagnostic Investigations

1. Radiography (Arya et al. 2001)
a. Essential features
i. Postaxial polydactyly
ii. Progressively distal shortening of segments (acromesomelia with relative shortening of the distal and middle segment of the limbs and phalanges)
iii. Generalized thickness and coarseness of bones
b. Other features depending on disease severity and age
i. Curvature of the humerus
ii. Enlargement of distal ends of the radii and ulnae
iii. Hypoplastic distal phalanges
iv. Short, broad middle phalanges
v. Fusion of metacarpals
vi. Fusion of the hamate and capitate bones of the wrists
vii. Supernumerary carpal bone centers
viii. Clinodactyly
ix. Synostosis
x. Wedge-shaped tibial epiphyses
xi. Genu valgum with hypoplasia of the upper lateral tibia
xii. Fibula disproportionately smaller than the tibia
xiii. Pelvic dysplasia with low iliac wings and spur-like downward projections at the medial and lateral aspects of the acetabula
xiv. Narrow thorax with short ribs
2. Echocardiography for cardiac malformations
3. Histopathology: disorganization of chondrocytes in the physeal growth zone of the long bones and vertebrae in the prenatal period and retardation of physeal growth zones in the childhood
4. Mutation analysis

Genetic Counseling

1. Recurrence risk
a. Patient's sib: 25%
b. Patient's offspring: not increased unless the spouse is a carrier
2. Prenatal diagnosis
a. Fetoscopy
b. Ultrasonography (Arya et al. 2001)
i. A narrow chest
ii. Postaxial polydactyly
iii. Short limbs, especially middle and distal segments
iv. A single atrium

c. Molecular genetic testing
   i. Using linked microsatellite markers flanking the *EVC* locus (Arya et al. 2001)
   ii. Mutation analysis of *EVC1* and *EVC2* genes (www.genetests.org)

3. Management
   a. Dental cares (Cahuana et al. 2004)
      i. Childhood
         a) To prevent caries by dietary counseling, plaque control, and oral hygiene instruction
         b) Crown or composite buildups for microdonts
         c) Partial dentures to maintain space and improve mastication, esthetics, and speech because of congenitally missing teeth
         d) Orthodontic treatment
      ii. Adulthood: require implants and prosthetic rehabilitation to replace congenitally missing teeth
   b. Cardiac surgery to correct cardiac anomalies
   c. Urologic management for genitourinary anomalies
   d. Orthopedic cares
      i. Polydactyly excision
      ii. Surgery for genu valgum

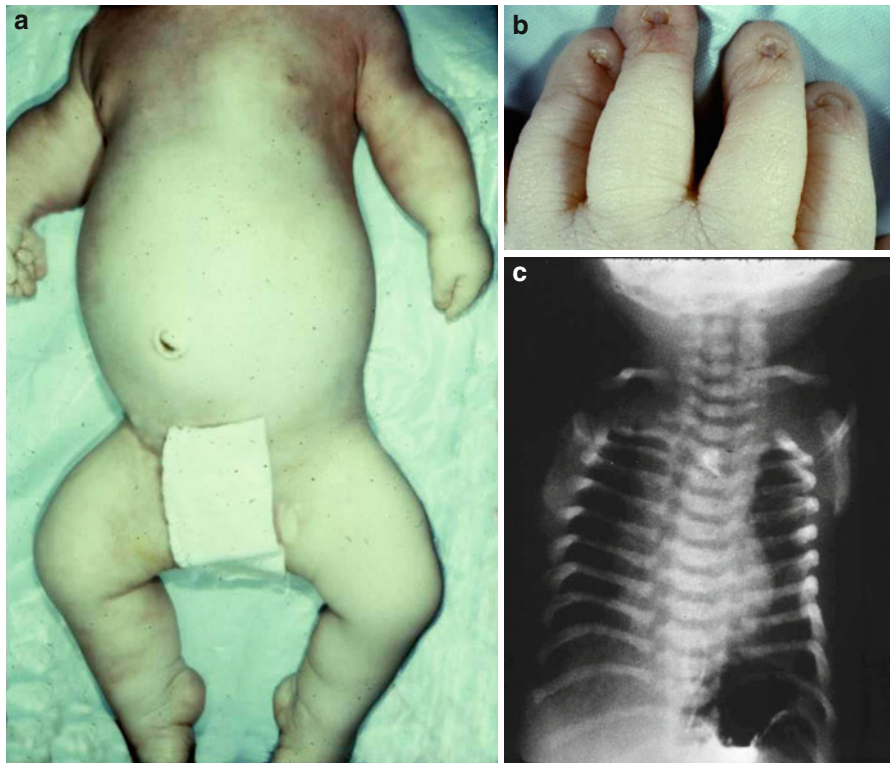

Fig. 1 (**a**–**c**) A neonate with small chest and short extremities. The fingernails are small and deformed. The baby had six fingers on each hand. Radiograph of the chest shows short ribs but the vertebral bodies are normal

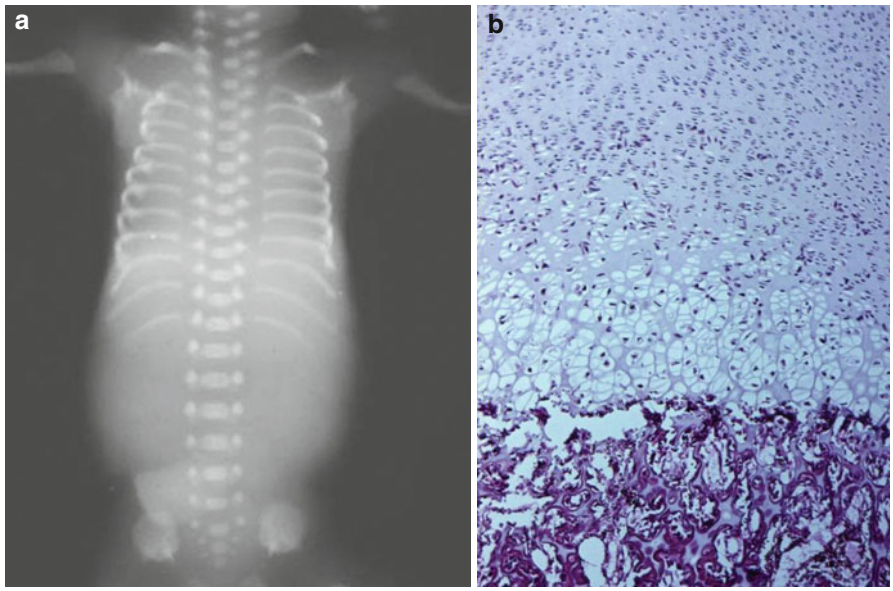

Fig. 2 (**a**, **b**) Radiograph of a fetus with Ellis-van Creveld syndrome showing short ribs and vertically shortened ilia. The vertebral bodies are unremarkable. Photomicrograph of femoral physeal growth zone shows disorganization of chondrocytes. The physeal growth zone of vertebrae showed better columnization

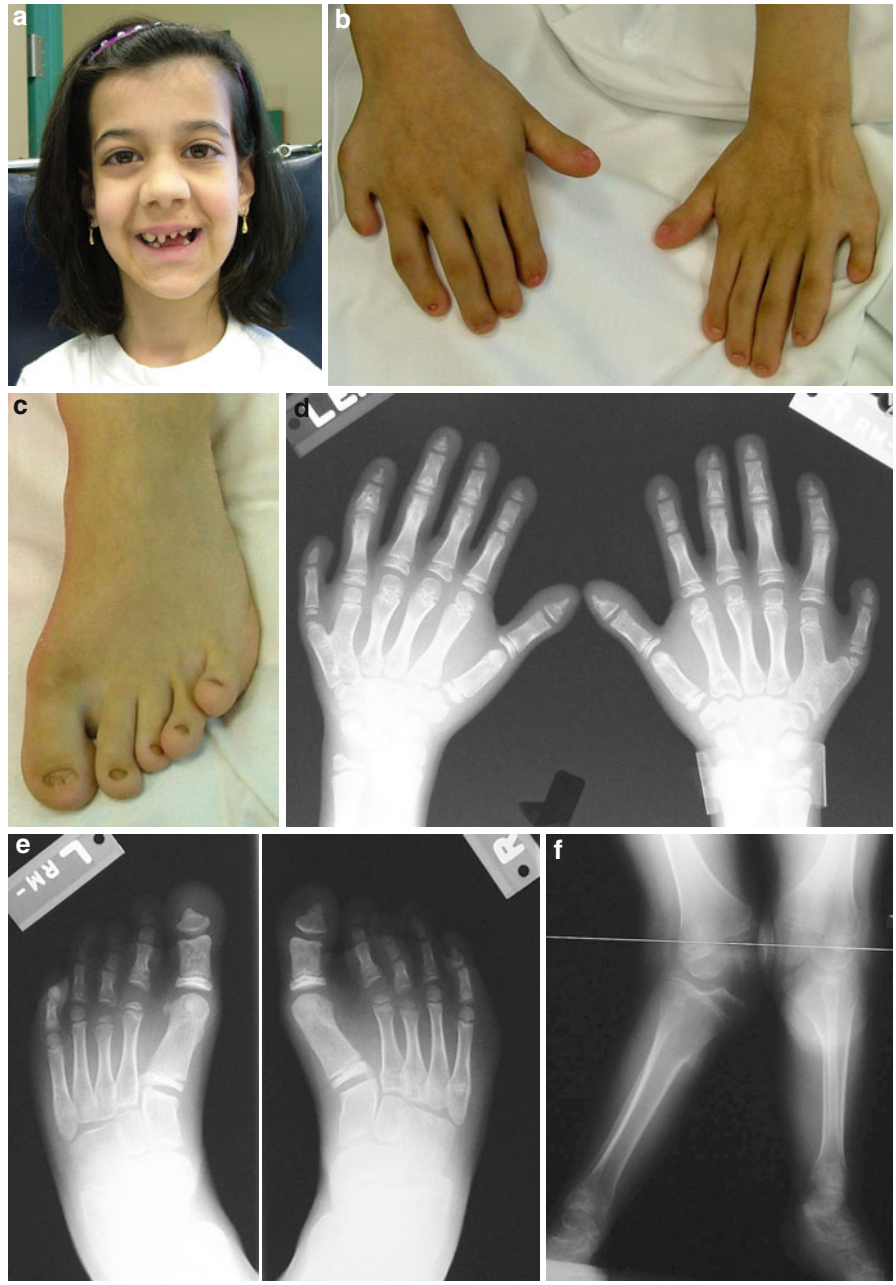

Fig. 3 (**a**-**f**) A 10-year-old Lebanese girl, a product of a consanguineous parents, with Ellis-van Creveld syndrome showing oligodontia and malformed teeth, severe nail hypoplasia of the hands and feet, and broad hands with bilateral post-axial polydactyly. Radiographs show polydactyly, fusion of metacarpals and carpal centers, cone epiphyses of the middle and distal phalanges, and genu valgum

Enchondromatosis

Enchondromas are benign cartilaginous growth in the intramedullary region of the bones, predominantly affecting the metaphyses of long bones (Silve and Jüppner 2006). When two or more bones are affected with enchondromas, the condition is called multiple enchondromatosis. Maffucci first described the syndrome of multiple enchondromas and subcutaneous hemangiomas in 1881, 18 years before Ollier described multiple enchondromatosis.

Synonyms and Related Disorders

Maffucci syndrome; Ollier syndrome

Genetics/Basic Defects

1. Inheritance
   a. Maffucci syndrome
      i. Not hereditary
      ii. A congenital disorder
   b. Ollier syndrome
      i. Not hereditary
      ii. A congenital disorder
   c. Obvious inheritance of enchondromatosis: unusual
   d. No candidate loci identified
   e. Ollier syndrome and Maffucci syndrome: possibly a spectrum of the same disease process (Mellon et al. 1988). The latter condition is complicated by vascular anomalies and hemangiomas.
2. Basic Defect and Pathogenesis
   a. Enchondromas believed to be a part of a generalized mesodermal dysplasia
   b. Appearance of enchondromata close to the epiphysis can severely affect the progressive development of a bone, resulting in distortion in the shape and length of the bone
3. Proposed origin of enchondroma formation
   a. Endochondral bone ossification: a highly regulated process, requiring the progression of undifferentiated mesenchymal cells into hypertrophic chondrocytes and the subsequent replacement of a cartilaginous matrix by mineralized bone
   b. Development of enchondromas in the metaphysis of long tubular bones in close proximity to the growth plate
   c. Consequently, enchondromas resulted from abnormalities in signaling pathways controlling the proliferation and differentiation of chondrocytes, leading to the development of intraosseous cartilaginous foci
   d. Osteochondromatosis possibly results from abnormal regulation of proliferation and terminal differentiation of chondrocytes in the adjoining growth plate, since enchondromas are usually present in close proximity to, or in continuity with, growth-plate cartilage (Hopyan et al. 2002)
      i. Parathyroid hormone related protein (PTHRP) delays the hypertrophic differentiation of proliferating chondrocytes.
      ii. Indian hedgehog (IHH) promotes chondrocytes proliferation.
      iii. Identification of a mutant PTH/PTHRP type I receptor (PTHR1) in human enchondromatosis that signals abnormally

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_80,
© Springer Science+Business Media, LLC 2012

in vitro and causes enchondroma-like lesions in transgenic mice
   a) The mutant receptor constitutively activates Hedgehog signaling.
   b) Excessive Hedgehog signaling is sufficient to cause formation of enchondroma-like lesions.
4. Hereditary nature of the disorder reported
   a. Generalized enchondromatosis observed in a son of the father who presented with mild skeletal dysplasia but without evidence of enchondromas
   b. A heterozygous mutation (R150C) in the PTH/PTHrP receptor (*PTHR1* gene) was inherited from the father in one of these cases (Hopyan et al. 2002)
   c. Heterozygous mutations in PTHR1 that impair receptor function participate in the pathogenesis of Ollier disease in some patients (Couvineau et al. 2008)

Clinical Features

1. Maffucci syndrome (Lewis and Ketcham 1973; Kaplan et al. 1993)
   a. Age of onset
      i. Bony or soft tissue abnormalities at birth in 27% of cases
      ii. Average age of onset: 4 years (ranging from birth to 30 years of age)
   b. Skeletal lesions: multiple enchondromas
      i. Can occur anywhere in the body
      ii. Most commonly in the hands, followed by tibia/fibula, foot, femur, humerus, radius/ulna, ribs, pelvis, scapula, and head
      iii. Common long bone involvement
      iv. Kyphoscoliosis caused by direct involvement of the spine
      v. Progressive skeletal deformities
         a. Enlarged fingers
         b. Bowed legs
         c. Asymmetric limb shortening
         d. Pathological fractures
      vi. High incidence (23%) of malignancies, especially chondrosarcomas (15%) which lead to greater tissue destruction
      vii. Vascular malignancies may occur occasionally
   c. Vascular lesions: subcutaneous and sometimes visceral hemangiomas
      i. Occur anywhere in the body
      ii. Most commonly in the hands, followed by foot, arm, leg, trunk, and head/neck
      iii. Hemangiomas also reported in the leptomeninges, eyes, pharynx, tongue, trachea, and intestines
      iv. Appear as blue subcutaneous nodules that sometimes can be emptied by pressure or by elevating the lesions above the level of the heart
      v. Unilateral or bilateral lesions
      vi. Phlebitis often results from thrombi forming within the hemangiomatous vessels
      vii. Characteristic calcified thrombi
      viii. Histologic types of hemangiomas
         a) Venous: most often
         b) Capillary
         c) Mixed venous/capillary type
      ix. Lymphangioma, a rare aspect of the mesodermal dysplasia in Maffucci syndrome
      x. Spindle cell hamangiomatosis as a component of Maffucci syndrome
   d. Neoplastic changes
      i. Overall malignancy rate: 37% (Kaplan et al. 1993)
      ii. Chondrosarcoma (15%) (Albregts and Rapini 1995; Abdelmalek and Stanko 2008)
         a) The neoplasm most commonly associated with Maffucci syndrome.
         b) Average age of onset is 40 years (ranging from 13 to 69 years of age).
         c) The most common sites: pelvis, shoulder girdle, distal femur, and proximal tibia (Goto et al. 2003).
      iii. Malignant astrocytoma
      iv. Ovarian tumors
      v. Pancreatic tumors
      vi. Hemangiosarcoma
      vii. Lymphangiosarcoma
      viii. Other neoplasms
   e. Normal intelligence
   f. Short stature
   g. Minimally affected individuals
      i. No major functional impairment
      ii. Unrestricted employment

iii. Moderate cosmetic deformity only
iv. Reconstructive or corrective surgery, limited to one or two major procedures with acceptable final results
v. Ablative surgery, restricted to amputation of a finger or a toe

h. Moderately affected individuals
i. Significant functional impairment
ii. Self supporting and able to work most of the time
iii. Ambulatory
iv. Reconstructive surgery or amputation and prosthesis helpful
v. Ablative surgery restricted to potentially functional (transfemoral or transhumeral) amputation

i. Severely affected individuals
i. Severe functional impairment
ii. Inability to work
iii. Chronic invalidism
iv. No surgical rehabilitation possible
v. Forequarter or hindquarter amputation required

2. Ollier syndrome
a. Nonhereditary cartilage dysplasia of bone
i. A form characterized by enchondromas located mainly at the extremities (hand)
ii. Consisting of multiple, asymmetrically distributed, intraosseous cartilaginous foci and subperiosteal deposition of cartilage, either exclusively or predominantly involving one side of the body
iii. Can be symmetric lesions as in our case 2 and cases presented by Khoo et al. 2008; Choh and Choh 2009)
iv. Multiple enchondromas as described in Maffucci syndrome
v. Enchondromata in infancy and early childhood:
a. Quite innocuous
b. Appearing as small radiolucent defects
vi. Characteristic lesions develop as the skeletal growth progresses:
a. Localized asymmetric impairment of growth
b. Asymmetric shortening & bowing of extremity parts (especially forearm and/or lower leg)
vii. No increase in size of the lesions after the cessation of the normal growth

b. Taut-elastic skin over hyaline cartilage distensions
c. Marked asymmetry of swellings with local growth deficiency
d. Firm, indolent, rounded distensions continuous with bone on one or more fingers or toes
e. Kyphoscoliosis
f. Joint impairment
g. Spontaneous fractures in affected area
h. Rare malignant (chondrosarcoma) transformation
i. Major orthopedic manifestations (Fang et al. 2009)
i. Asymmetrical limb shortening and deformity
ii. Swelling and deformity of the hands or feet
iii. Pathological fracture
j. Prognosis: difficult to assess
i. In general, cases with early onset have more severe prognosis.
ii. Localized cartilaginous changes, especially in a very young child, may induce major shortening of a lower extremity leading to limb asymmetry; in contrast, patient with numerous lesions may have a better prognosis.
iii. Early development of enchondromas in phalanges may lead to major finger deformities.
iv. Neural compressions: less frequently observed than in hereditary multiple exostosis.
v. Malignant transformation of enchondromas into chondrosarcomas usually occurs in young adults. The estimated incidence of malignant transformation is 5–50% of the cases.
vi. Association of Ollier disease with other tumors, such as ovarian juvenile granulosa tumor, has been reported.

3. Differential diagnosis: Other types of enchondromatosis (Kozlowski and Masel 2002; Bovée 2008)
a. Metachondromatosis
i. An autosomal dominant disorder
ii. A rare disorder exhibiting, synchronous, both multiple osteochondromas and enchondromas in children, involving the bones of the hands and feet

iii. Painless swelling of the hands and feet
iv. Normal intelligence
v. Short stature
vi. Radiographic features intermediate between exostosis and enchondromatosis

b. Spondyloenchondromatosis: characterized by platyspondyly
c. Spondyloenchondromatosis with basal ganglia calcification
d. Dysspondyloenchondromatosis: characterized by malsegmentation of the spine
e. Genochondromatosis I
   i. Enchondromatosis with celery type of metaphyseal lesions
   ii. Characteristic thickening of the clavicles
   iii. Regressive without any complications
f. Genochondromatosis II
   i. Enchondromatosis with celery type of metaphyseal lesions
   ii. Moderately severe hand involvement with long dense streaks and more irregular radiolucent channels
   iii. Regress without any complications
g. Dysplasia epiphysealis hemimelica (tarso-epiphysial aclasis) (Trevor disease) (Oestreich et al. 2002)
   i. A developmental disorder with cartilaginous overgrowth of a portion of one or more epiphyses.
   ii. Exostosis of epiphyseal growth centers and their equivalents that grow solely by enchondral ossification with no membranous ossification in the lesions.
      a) Apophyses
      b) Carpal bones
      c) Tarsal bones
      d) Sesamoids including the patella
   iii. Predominantly affects the lower extremity on one side of the body, usually restricted to either the medial (most frequent) or lateral side of the limb (hemimelica).
h. Hereditary multiple exostoses: see chapter on Hereditary multiple exostoses
   i. An autosomal-dominant disorder
   ii. A genetically heterogeneous disorder associated with mutations in *EXT1* or *EXT2* genes, which are both tumor suppressor genes
   iii. Clinically characterized by the development of benign tumors, multiple osteochondromas (exostoses), growing outward from the metaphyses of long bones
   iv. The most important criterion to distinguish enchondromas from osteochondromas seen in hereditary multiple exostoses (radiographic distinction) (Silve and Jüppner 2006)
      a) Osteochondromas are located at the bone surface
      b) Enchondromas are located in the center of bones

Diagnostic Investigations

1. Diagnosis of Ollier disease (Silve and Jüppner 2006)
   a. Based on clinical and conventional radiological evaluations
   b. Histological analysis
      i. Limited role
      ii. Mainly used if malignancy is suspected
   c. Additional studies such as scintigraphy, ultrasound, MRI
      i. Not useful for establishing the diagnosis
      ii. Indicated for the evaluation and surveillance of lesions that become symptomatic, such as pain and increase in size
2. Radiography (Kaufman 1973)
   a. Enchondromas
      i. Lesions usually arise within the medullary cavity, replacing the normal cancellous bone with the abnormal cartilage.
      ii. Lytic lesions initially contain calcifications in a punctate pattern.
      iii. Advanced lesions assume a ground glass appearance.
      iv. Predilection for the metaphysis or diaphysis.
      v. Bone often expands but with intact cortex.
      vi. Often with a scalloped border.
      vii. Pathologic fractures not uncommon.
      viii. Multiple asymmetric enchondromas of long and flat bones(characteristic ovoid or pyramid-shaped, linear translucent defects in metaphyses).
   b. Massive metaphyseal enlargement in any bones, particularly metacarpals and fingers

   c. Enchondromatosis with destruction and calcification
   d. Streaks of unossified cartilage in the metaphyses, sometimes extending into the diaphyses
   e. Madelung deformity
   f. Shortening of extremities
   g. Spinal deformity
   h. Occasional malignant degeneration
3. Major radiographic features (Fang et al. 2009)
   a. Oval/elongated radiolucent lesions, often with longitudinal striations
   b. Erosion of the cortices and subsequent calcification of the lesion producing a diffusely speckled appearance typical of enchondromata
   c. Long bones and small bones of hands and feet typically the most commonly affected sites
   d. Enchondromata almost exclusively in the metaphyseal region in long bones, possibly extending to the diaphysis
   e. Epiphysis affected at later age after closure of the growth plate
   f. Affected areas substantially enlarged and shortened cortical thinning associated with pathological fracture
4. Bone scan
   a. Exhibiting intense and increased uptake
   b. To locate polyostotic lesions
5. CT scan
   a. To delineate the extent of bone involvement
   b. A good diagnostic tool to demonstrate the high attenuation coefficient (classic in bone affected by fibrous dysplasia)
6. MRI
   a. To delineate the extent of bone involvement
   b. Enchondromas
      i. Low signal intensity on T1-weighted images
      ii. High signal intensity on T2-weighted images
      iii. High signal intensity on gradient recalled echo images similar to articular cartilage
7. F-18 FDG PET-CT imaging may prove to be useful in detecting malignant transformation of enchondromas in Maffucci syndrome. (Makis et al. 2010)
8. Histopathology
   a. Gross view of enchondromas: usually shows multiple oval-shaped or round cartilaginous nodules in osseous portions of bone.
   b. Individual nodules
      i. Limited at their periphery by woven or lamellar bone
      ii. Separated from each other by intertrabecular marrow spaces
   c. Cartilaginous tumor matrix: usually solid with myxoid changes, manifesting as frayings of the matrix
   d. Characteristics of enchondromas and chondrosarcomas
      i. Presence of a striking heterogeneity and diversity in the degree of cellularity and chondrocyte phenotype.
      ii. Because of the increased cellularity, the distinction between enchondroma and grade *I* chondrosarcoma in the context of enchondromatosis is extremely difficult or even impossible, the diagnosis therefore relies on the combination of radiographical (cortical destruction, soft tissue extension), clinical, and histological criteria.
9. Fine needle aspiration cytology
   a. Workup of soft tissue tumors
      i. An outpatient procedure
      ii. Minimal risk of complications
      iii. Can easily be performed from different parts of a large tumor
   b. Workup of bone tumors: comparable to cutting needle biopsy

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased
   b. Patient's offspring: not increased unless in rare familial cases
2. Prenatal diagnosis: bone lesions unlikely to manifest in the prenatal period
3. Management (Flach et al. 2001)
   a. Requires no treatment in the absence of clinical problems.
   b. Relief of symptoms.
   c. Early detection of malignancies.
      i. Suspect malignancy change if skeletal or soft-tissue lesions enlarge or become painful without antecedent trauma
      ii. Biopsy

d. Surgery indicated in case of complications.
   i. Pathologic fractures
   ii. Growth defect
   iii. Malignant transformation
e. Operative procedures.
   i. Corrective osteotomy
   ii. Epiphysiodesis
   iii. Hemiepiphysiodesis
   iv. Physeal stapling
   v. Lengthening of an arm or leg
   vi. Curettage and packing with bone graft material
   vii. Sclerotherapy, irradiation, and surgery for the vascular lesions
f. Serial surgery for distortion of knees and unequal leg length.
g. Limb lengthening, either gradual bone grafting or callus distraction: the most common method of correcting deformities in the lower limb.
h. Amputation in suspected malignancy with severe deformity of the limb due to intraosseous cartilaginous foci.
i. Radiotherapy: provide palliative benefit in patients with inoperable chondrosarcoma.
j. Annual surveillance of the enchondromas recommended for children and adults.
k. Periodic surveillance of the brain and abdomen for occult lesions indicated in patients who have enchondromatosis.
l. Long-term consideration to address the potential for malignant changes.
m. Interdisciplinary efforts of health care professionals from medicine, nursing, physical and occupational therapy, recreational therapy, and social services. Long-term consideration must address the potential for malignant changes.

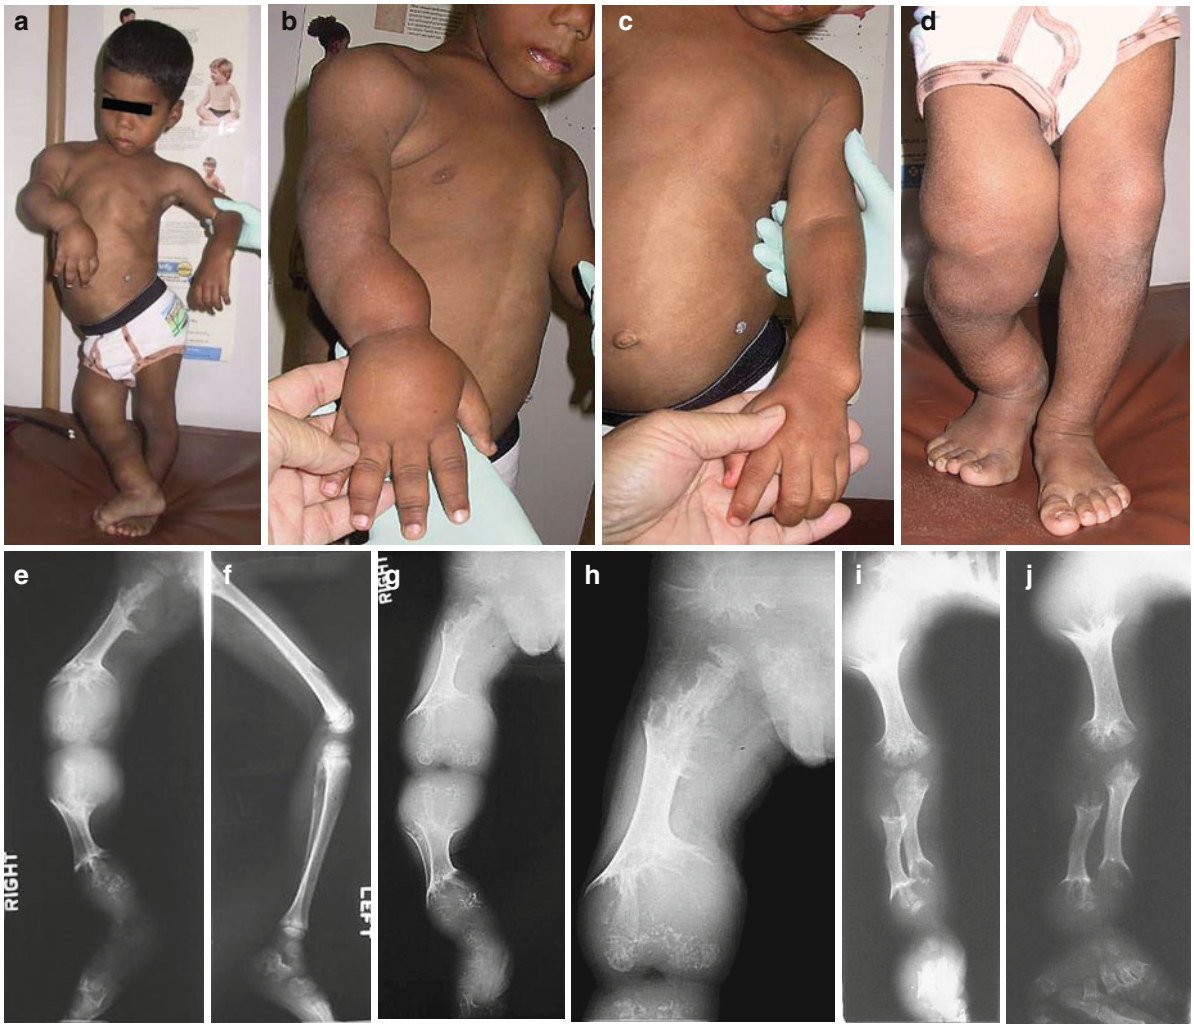
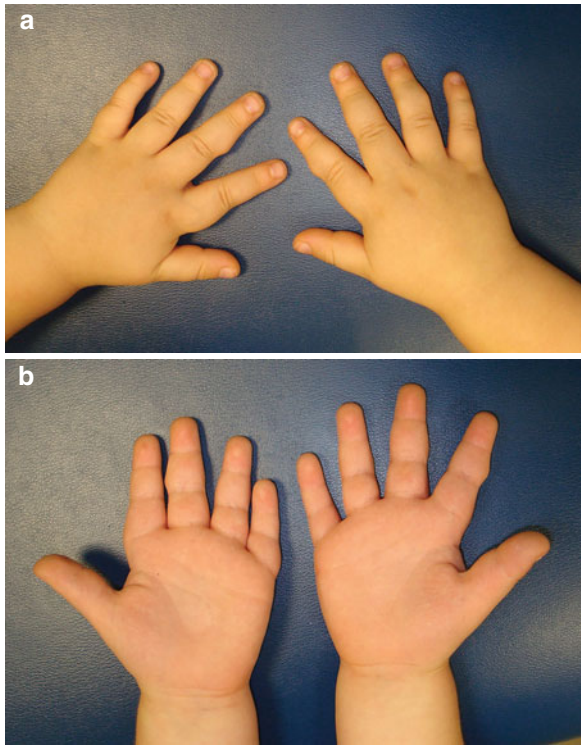
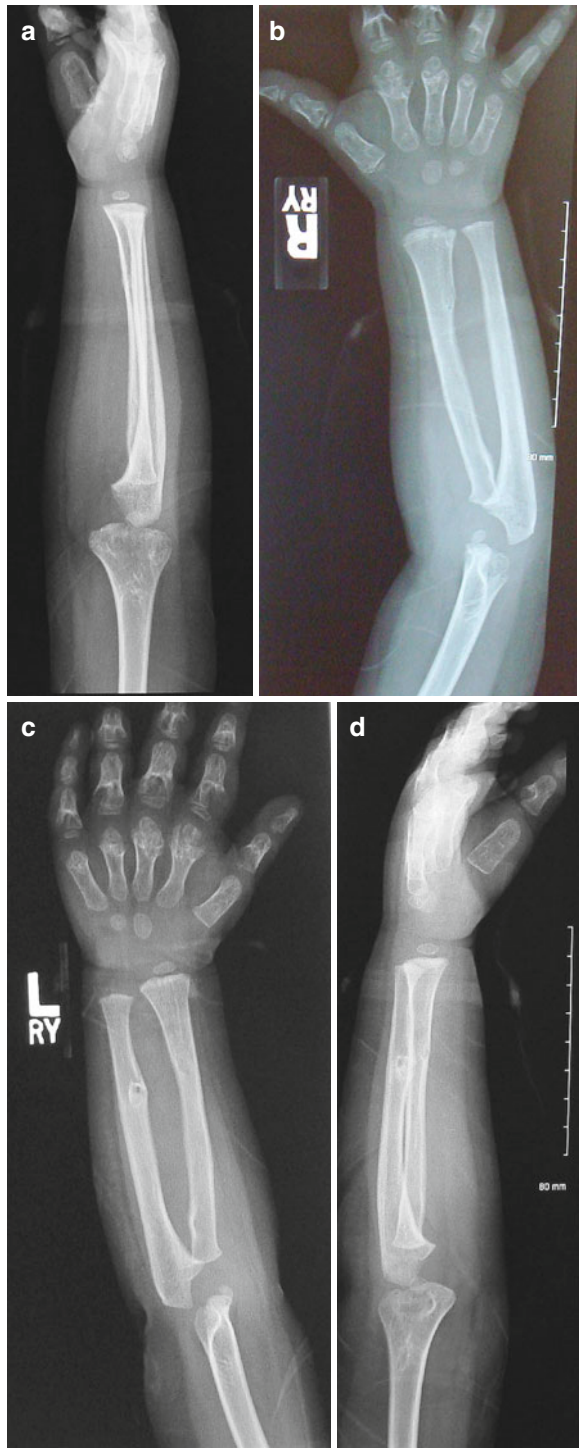


Figs. 1 (**a**–**j**) A 4-year-old boy with Ollier syndrome showing short stature, scoliosis, and severe limb deformities. The *right* limbs were affected by larger lesions with more prominent limb shortening. Marked swellings were evident on the right wrist and fingers. The left hand showed Madelung deformity. The radiographs showed massive metaphyseal enchondromatous lesions in the right upper and lower extremities. Streaks of radiolucency due to the abnormal cartilage extended into the diaphyses. The left femur, tibia, and fibula also showed lytic lesions

Fig. 2 A 4-year-old boy was seen because of swelling of phalangeal joints of multiple fingers on both hands with occasional joint pain. No vascular malformation was detected. Clinical and radiographic findings are consistent with Ollier disease



Figs. 3 (**a**, **b**) Close-up view of both hands showing multiple joint swelling on multiple fingers



Figs. 4 (**a**–**d**) Radiographs of both forearms and hands show multiple enchondromas involving phalanges and metacarpals of both hands and an enchondroma involving the midshaft of the left ulna

Fig. 5 Right hand radiograph shows multiple enchondromas (multiple well-defined osteolytic lesions with endosteal scalloping, cortical thinning, and bony expansion) involving proximal metaphyses of the second to fourth middle and proximal phalanges and the distal metaphyses of the second to third metacarpals

Fig. 6 Left hand radiograph shows multiple enchondromas involving proximal metaphyses of the second to fourth middle phalanges and the second to fifth proximal phalanges

Epidermolysis Bullosa

Epidermolysis bullosa (EB) is a rare group of inherited disorders of skin fragility, characterized by a reduced resistance of the skin and mucous membranes to trauma, manifesting as blistering or erosion of the skin and the epithelial lining of other organs. Epidermolysis bullosa can be classified into three major types, namely, the simplex, the junctional, and the dystrophic types, based on the level of the epidermis or basement membrane zone in which blister is formed.

All types and subtypes of EB are rare. The overall incidence and prevalence of the disease within the USA is approximately 19 per 1 million live births and 8 per 1 million population, respectively (Fine 2010)

Synonyms and Related Disorders

Dystrophic epidermolysis bullosa; Epidermolysis bullos simplex; Junctional epidermolysis bullosa; Kindler syndrome

Genetics/Basic Defects

1. Epidermolysis bullosa simplex (EBS) (Eady 2001; Fine 2010)
   a. Autosomal dominant simplex type EB (most common type)
      i. Caused by mutations in the cytoskeleton structural proteins, keratin 5 (*KRT5*) and keratin 14 (*KRT14*) genes, leading to disruption of basal cells and the formation of bullae in the basal and parabasal cell zone
      ii. Keratins 5 and 14: expressed exclusively in basal cell layer of epidermis keratinocytes and essential for the maintenance of normal structural integrity
      iii. Disease severity correlates with the location within the keratin gene mutation
         a) Mutations in highly conserved genetic sequences leading to severe disease
         b) Mutations in less critical keratin gene regions manifesting as milder, more localized symptoms: Koebner variant (generalized blistering but no mucosal or nail changes) and Weber-Cockayne form (blistering is confined primarily to the easily traumatized palms and soles)
   b. Autosomal recessive simplex types (rare type)
      i. EBS with muscular dystrophy due to abnormal plectin, a protein involved in hemidesmosome formation (currently also classified as a subtype of hemidesmosomal epidermolysis bullosa)
      ii. EB without muscular dystrophy in patients homozygous for *KRT14* gene abnormalities
      iii. Skin fragility syndrome (a form of ectodermal dysplasia but can also be classified as acantholytic EB simplex variant) with formation of acantholytic vesicles within the epidermis due to plakophilin 1 (*PKP1*) gene mutations
      iv. Lethal acantholytic epidermolysis bullosa
         a) The first case report (Jonkman et al. 2005): Recessive mutations in *DSP* leading to truncation of the complete desmoplakin C-terminus (intermediate filament binding); loss of the intermediate filament

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_81,
© Springer Science+Business Media, LLC 2012

binding domain of desmoplakin in both isoforms caused loss of keratin insertion of desmosomes which still had an inner and an outer dense plaque
   b) A novel homozygous deletion in *DSP* gene, encoding desmoplakin, in two infants born to same consanguineous parents (Bolling et al. 2010): Novel recessive *DSP* mutation predicted to result in truncation as well
2. Junctional epidermolysis bullosa
   a. Inheritance: autosomal recessive in most cases
   b. Herlitz type (epidermolysis bullosa letalis)
      i. Cause by mutations in laminin 5 gene
      ii. Associated with premature death
   c. Non-Herlitz type
      i. Caused by mutation in laminin 5 and type XVII collagen (*COL17A1*) genes
      ii. Generally associated with a good prognosis
   d. Junctional epidermolysis associated with pyloric atresia (Chung and Uitto 2010)
      i. Caused by mutations in a hemidesmosomal component, $\alpha_6\beta_4$ integrin (*ITGA6*, *ITGB4*)
      ii. Currently also classified as a subtype of hemidesmosomal epidermolysis bullosa
3. Dystrophic epidermolysis bullosa
   a. Inheritance: either autosomal dominant or autosomal recessive
   b. Molecular basis: abnormalities of collagen VII
      i. Caused by mutations in type VII collagen gene. *COL7A1* gene mutations have been identified in most cases in both recessive and dominant forms
      ii. Type VII collagen is a major component of the anchoring fibrils that tether the basement membrane structure and overlying epidermis to its dermal foundation
      iii. Severity of the phenotype dictated by missense mutation that alters a glycine residue in dominant dystrophic epidermolysis bullosa versus a nonsense or frameshift mutations in recessive dystrophic epidermolysis bullosa
4. Kindler syndrome
   a. Inherited in an autosomal recessive manner
   b. Pathogenesis of Kindler syndrome involves loss-of-function mutations in a newly recognized actin cytoskeleton-associated protein, now known as fermitin family homolog 1 and encoded by the gene *FERMT1* (Jobard et al. 2003)

Clinical Features

1. Epidermolysis bullosa simplex (Pai and Marinkovich 2002)
   a. General characteristics
      i. The most common heritable blistering process
      ii. Intraepidermal blistering at the level of the basal cell
      iii. Typical healing of blisters without scarring
      iv. Little involvement of other organ systems
      v. Extent and severity of disease improves with age
   b. EBS Koebner type
      i. Commonly involves hands, feet, and extremities
      ii. Onset at birth to early infancy
      iii. Often present with palmar-plantar hyperkeratosis and erosions
      iv. Mildly involves nails, teeth, and oral mucosa
   c. EBS Weber-Cockayne type
      i. Relatively mild variant of EBS
      ii. Commonly involves palms and soles only after a clearly identifiable traumatic event
      iii. May not present until adulthood
      iv. Hyperhidrosis of the palms and soles
      v. Most common complications involve secondary infections of blistering lesions on the feet
   d. EBS Dowling-Meara type
      i. A more severe subtype of EBS
      ii. Involves a more generalized distribution of blisters occurring at, or shortly after, birth
      iii. Pronounced inflammation with milia formation in infancy
      iv. Spontaneous blisters occurring in-groups on the trunk and proximal extremities
      v. Usually healing without scarring later in life
      vi. Hyperkeratosis may develop at age 6 or 7 years
      vii. Unlike the previous two subtypes, heat does not appear to exacerbate blistering
   e. Lethal acantholytic epidermolysis bullosa (Jonkman et al. 2005; Bolling et al. 2010)
      i. Striking phenotypic findings
         a) Extensive nonbullous epidermal dislodgment
         b) Universal alopecia
         c) Anonychia
         d) Rapid postnatal demise

ii. Malformed ears
iii. Cardiac enlargement and dysfunction in utero

2. Junctional epidermolysis bullosa
   a. General characteristics
      i. Blistering at the level of the lamina lucida
      ii. More severe blistering process
      iii. Presenting spontaneously or at sites of trauma with generalized blistering
   b. Herlitz or junctional epidermolysis letalis
      i. The commonest form of JEB formerly known as "lethal JEB"
      ii. Characterized by generalized blistering at birth
      iii. Extensive dental enamel hypoplasia
      iv. Tracheolaryngeal involvement leading to a hoarse cry, cough, and/or other respiratory difficulties
      v. Gastrointestinal involvement and genitourinary involvement leading to infection and obstructive sequelae
      vi. Rarely survives beyond 6 months secondary to chronic anemia, failure to thrive, and sepsis
      vii. Rare survivors: develop exuberant granulation tissue at sites of erosion, especially at the perioral region
   c. Non-Herlitz junctional epidermolysis bullosa
      i. Early clinical course similar to that found in Herlitz type JEB
      ii. Often survives infancy
      iii. May improve clinically with age
      iv. Rare and mild pulmonary involvement
      v. Scalp, nail, and tooth abnormalities common
      vi. Prominent non-healing periorificial lesions
      vii. Erosions in the mucous membranes resulting in strictures
   d. Generalized atrophic benign epidermolysis bullosa
      i. Generalized cutaneous blistering at birth
      ii. Blisters heal with a distinctive atrophic appearance
      iii. Blisters confined to sites of trauma
      iv. Alopecia
      v. Dental anomalies
      vi. Rare severe nail and mucosal involvement
   e. Junctional epidermolysis associated with pyloric stenosis
      i. A syndromic association of skin fragility and congenital gastrointestinal atresia, most frequently pyloric, although duodenal atresia with skin fragility has also been reported
      ii. Often with severe skin blistering and extensive multisystem mucosal blistering
      iii. Presence of pyloric and/or duodenal atresia
      iv. Often with urologic abnormalities
         a) Hydronephrosis
         b) Nephritis
      v. Many patients die during infancy
3. Dystrophic epidermolysis bullosa
   a. General characteristics
      i. Clinical hallmarks (Bruckner-Tuderman 2010)
         a) Trauma-induced blisters
         b) Healing with scarring
      ii. Sub-lamina densa blistering
      iii. Characterized by dermolytic blisters resulting in scarring and milia formations
      iv. Dystrophic scarring follows cutaneous blistering
   b. Dominantly inherited dystrophic epidermolysis bullosa
      i. Mild phenotype
      ii. Present with generalized blistering at birth or during infancy
      iii. Blistering at sites of maximal trauma
      iv. Healing with scarring and small keratinaceous cysts (milia)
   c. Transient bullous dermolysis of the newborn
      i. An uncommon variant
      ii. Blistering at sites of trauma that heals after several months without scarring
      iii. Variable mucous membrane and nail involvement
   d. Recessively inherited dystrophic epidermolysis bullosa: Hallopeau-Siemens type (the most severe form)
      i. Excessive fragile skin leading to blisters with minimal trauma
      ii. Extensive scarring leading to contractures and fusion of digital web spaces (pseudosyndactyly, "mitten deformities") that require surgical correction
      iii. Extremely itching and painful skin
      iv. Regular mucosal blistering leading to eating and swallowing disorders and ocular abnormalities
      v. Tendency to growth retardation and anemia

vi. Devastating complications unique to recessively inherited dystrophic epidermolysis bullosa
a) Increased propensity for cutaneous malignancy at sites of scarring (>40% of patients develop malignancy by age 30 years)
b) Aggressive nature of malignancy (squamous cell carcinoma)

4. Kindler syndrome
a. Trauma-induced blistering
b. Poikiloderma
c. Skin atrophy
d. Mucosal inflammation
e. Varying degrees of photosensitivity

Diagnostic Investigations

1. EM of skin biopsy (Pai and Marinkovich 2002)
a. A gold standard of laboratory diagnosis
i. To determine the level at which blistering occurs
ii. To obtain additional information on the morphology of various basement membrane zone components
b. Epidermolysis bullosa simplex
i. Cytolysis of the basal cells
ii. Distinctive clumping of the keratin tonofilaments
c. Junctional epidermolysis bullosa: rudimentary hemidesmosomes
d. Dystrophic epidermolysis bullosa: absent or altered anchoring fibrils
e. Hemidesmosomal epidermolysis bullosa: separation at the level of hemidesmosome just inside the basal keratinocytes
2. Transmission electron microscopy findings among selected EB subtypes (Fine 2010)
a. EB simplex (suprabasal) (EBS)
i. EB simplex superficialis: subcorneal cleavage
ii. Lethal acantholytic EB:
a) Suprabasal cleavage
b) Acantholysis
c) Perinuclear retraction of keratin filaments
iii. EBS, plakophilin deficiency:
a) Mid-epidermis cleavage
b) Perinuclear retraction of keratin filaments
c) Small suprabasal desmosomes
b. EBS (basal)
i. EBS, localized: basal keratinocyte cleavage
ii. EBS, Dowling-Meara
a) Basal keratinocyte cleavage
b) Clumped keratin filaments
iii. EBS, generalized other: basal keratinocyte cleavage
iv. EBS, autosomal recessive
a) Basal keratinocyte cleavage
b) Absent or reduced keratin filaments within basal keratinocytes
c. Junctional EB (JEB)
i. JEB, Herlitz
a) Intra-lamina lucida cleavage
b) Markedly reduced or absent hemidesmosomes
c) Absent subbasal dense plates
d) Absent anchoring filaments
ii. JEB, non-Herlitz
a) Intra-lamina lucida cleavage
b) Hemidesmosomes may be normal or reduced in size and number
iii. JEB with pyloric atresia
a) Intra-lamina lucida cleavage
b) Small hemidesmosome plaques with attenuated subbasal dense plates
d. Dominant dystrophic EB (DDEB)
i. DDEB, generalized
a) Sub-lamina densa cleavage
b) Normal or reduced numbers of anchoring fibrils
ii. DDEB, bullous dermolysis of the newborn
a) Sub-lamina densa cleavage
b) Electron-sense stellate shaped bodies within basal keratinocytes
c) Reduced numbers of anchoring fibrils
e. Recessive dystrophic EB (RDEB)
i. RDEB, severe generalized
a) Sub-lamina densa cleavage
b) Absent or rudimentary appearing anchoring fibrils
ii. RDEB, generalized other (generalized mitis)
a) Sub-lamina densa cleavage
b) Reduced or rudimentary appearing anchoring fibrils
3. Immunofluorescent microscopy (Pai and Marinkovich 2002)
a. Provide additional information on the level of blistering
b. Provide important clue to the underlying molecular defects

c. Antibodies against intracellular hemidesmosomal component such as BP230 and a lamina densa protein such as type IV collagen
   i. Samples from EBS: both antibodies localized to the floor of the blister
   ii. Samples from JEB
      a) Antibodies against BP230 localized to the roof of the blister
      b) Antibodies against type IV collagen localized to the floor
   iii. Samples from DEB: both antibodies localized to the roof of the blister
d. Samples lacking staining with antibodies specific to laminin 5 support a JEB diagnosis
e. Samples lacking staining with antibodies specific to type VII collagen support a DEB diagnosis
f. Absence of staining for BP180 supports a diagnosis of generalized atrophic benign epidermolysis bullosa

4. Laboratory approach to epidermolysis bullosa (Castiglia and Zambruno 2010)
   a. At first use of immunofluorescence epitope mapping (IFM) and transmission electron microscopy (TEM) examination of a skin biopsy to determine the level of skin cleavage and the presence of morphologic alterations of epithelial adhesion structures and the defective expression of specific protein components
   b. IFM and TEM enable definition of the major EB type and, in most cases, the subtype and identification of the protein component targeted by the mutations
   c. These analyses define the candidate genes for mutation screening and they must precede molecular testing, which should be primarily considered when:
      i. Prenatal or preimplantation diagnosis is being planned
      ii. The mode of genetic transmission cannot be delineated from the family pedigree in combination with IFM and TEM findings
      iii. Gene-replacement therapy protocol is foreseen
5. Linkage analysis of linked markers within or flanking the particular EB gene in families in which the inheritance pattern is known
6. Mutation detection for all forms of epidermolysis bullosa
   a. Mutation analysis
   b. Sequence analysis
7. Lethal acantholytic epidermolysis bullosa (Bolling et al. 2010)
   a. Electron microscopy
      i. Loss of keratin filament insertion and
      ii. Loss of the inner dense plaque
   b. A panel of antibodies directed against the desmoplakin C-terminus and the N-terminus/rod domain for immunofluorescence microscopy on a representative fresh frozen skin sample can provide an early diagnosis

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal dominant
         a) 50% if a parent is affected
         b) Low recurrent risk when the parents are clinically unaffected
         c) Low recurrent risk but greater than that of the general population because of the possibility of germline mosaicism when the disease-causing mutation cannot be detected in the DNA of either parent
         d) Parental germline mosaicism have been reported in both EBS (Nagao-Watanabe et al. 2004) and DEB (Rouan et al. 1998; Cserhalmi-Friedman et al. 1999, 2001)
      ii. Autosomal recessive
         a) Carrier status of parents needs to be confirmed by molecular genetic testing because germline mosaicism and uniparental isodisomy have been reported (Takizawa et al. 2000; Cserhalmi-Friedman et al. 2002; Fassihi et al. 2005)
         b) Recurrence risk: 25%
   b. Patient's offspring
      i. Autosomal dominant
         a) A 50% risk of inheriting the mutation
         b) A 75% risk of having at least one mutation in the rare instance in which both parents have an autosomal dominant mutation such as in consanguineous union
      ii. Autosomal recessive: recurrence risk not increased unless the spouse is a carrier or affected

2. Prenatal diagnosis (Eady 2001; Fassihi and McGrath 2010)
   a. Fetal skin biopsy with EM analysis and/or immunohistochemistry with following drawbacks
      i. Drawbacks
         a) Fetal biopsy can only be obtained fairly late in gestation ($\geq$17 weeks)
         b) A relatively high rate of miscarriage
         c) Fetal status can only be determined by an expert in the ultrastructure of fetal skin who is qualified to make the diagnosis
      ii. An alternative option for rare families in which mutations cannot be identified and linked markers are not available to be used for prenatal diagnosis
   b. Villous trophoblasts, sampled during the first trimester, display immunoreactivity to $\alpha_6\beta_4$ integrin and plectin, thereby permitting diagnosis/exclusion of EB associated with pyloric atresia through tissue diagnosis (D'Alessio et al. 2008)
   c. DNA-based diagnosis on fetal DNA obtained by amniocentesis or CVS for all forms of epidermolysis bullosa
      i. Before any prenatal test, samples from both parents and any previous affected siblings are analyzed for pathogenic mutations
      ii. In autosomal recessive EB, ideally both parents must be shown to be heterozygous carriers of the pathogenic mutation(s)
      iii. The possibility of de novo mutations, nonpaternity, and uniparental disomy (the inheritance of both copies of a chromosome pair from just one parent) should be excluded before considering the suitability of the prenatal test
   d. Linkage analysis by linked markers within or flanking the *COL7A1* gene in several DEB families in which the inheritance pattern was known
   e. Preimplantation genetic diagnosis, an alternative to first-trimester prenatal diagnosis
      i. Involves in vitro fertilization, usually by intracytoplasmic sperm injection
      ii. Followed by the biopsy of a single cell from the eight-cell blastocysts (embryo)
      iii. Using complex polymerase chain reaction analysis to determine whether DNA from the single cell caries the parental mutations

3. Management (Herod et al. 2002; Bello et al. 2003)
   a. A multidisciplinary team approach, tailored to the severity and extent of skin involvement
   b. Blister management and dressing technique
      i. Avoidance of trauma as a primary goal
      ii. Puncture fresh blisters with a sterile needle and drain blister fluid with the blister roof left in situ so that the blister fluid cannot extend
      iii. Use white petrolatum-impregnated gauzes, hydrogels, fenestrated silicone dressings or absorbent foam silicone dressings for open wounds
      iv. Keep intravenous lines in place by using soft roller-gauze bandages
      v. Avoid dressing with adhesive tapes
      vi. Prevention and treatment of infections
   c. Prevention and treatment of complications (Pai and Marinkovich 2002)
      i. Change dressing regularly
         a) To control blistering and infection
         b) To prevent the debilitating contractures secondary to bullae formation in dystrophic EB
      ii. Physiotherapy
         a) To maintain mobility
         b) To decrease contracture formation
      iii. Corrective surgery recommended for digital fusion (mitten pseudosyndactyly) and contractures
      iv. Nutritional support
      v. Gastrointestinal management
         a) Dilatation of esophageal strictures
         b) Colonic interposition for advanced cases of strictures
         c) Gastrostomy tube insertion to provide nutrition
         d) Laxatives and increased dietary fiber for constipation, anal fissures, and perianal ulceration
      vi. Care for eye lesions
         a) Moisture chambers and ocular lubricants
         b) Treat corneal erosions with antibacterial ointments and use of cycloplegic agents to reduce ciliary spasms and provide comfort
      vii. Oral care
         a) Good oral hygiene
         b) Gentle cleaning of the mucosal surfaces with normal saline rinses
         c) Softest brush for regular cleansing

d. Pain management (Herod et al. 2002)
   i. Acute phase: experience considerable pain and discomfort caused by the expanding and often tense bulla
   ii. Chronic wounds: experience considerable pain caused by chronic wounds with denuded areas of skin and by therapeutic procedures
   iii. Analgesics
      a) Combination of paracetamol and ibuprofen or diclofenac for dressing changes associated with small wounds
      b) Potent analgesia and sedation required for large dressing changes (oral morphine solution and midazolam)
e. Management of anesthesia and surgery: should be undertaken in specialized centers familiar with the many complex aspects of EB care
f. Tumor detection in recessively inherited DEB
g. Advanced therapy to treat hard to heal wounds
   i. Cultured keratinocytes
   ii. Acellular dermal allograft plus ultrathin autografts
   iii. Living dermal skin substitute
   iv. Living bilayered skin equivalents
      a) Composite cultured skin (CCS)
      b) Graftskin
      c) Dermagraft

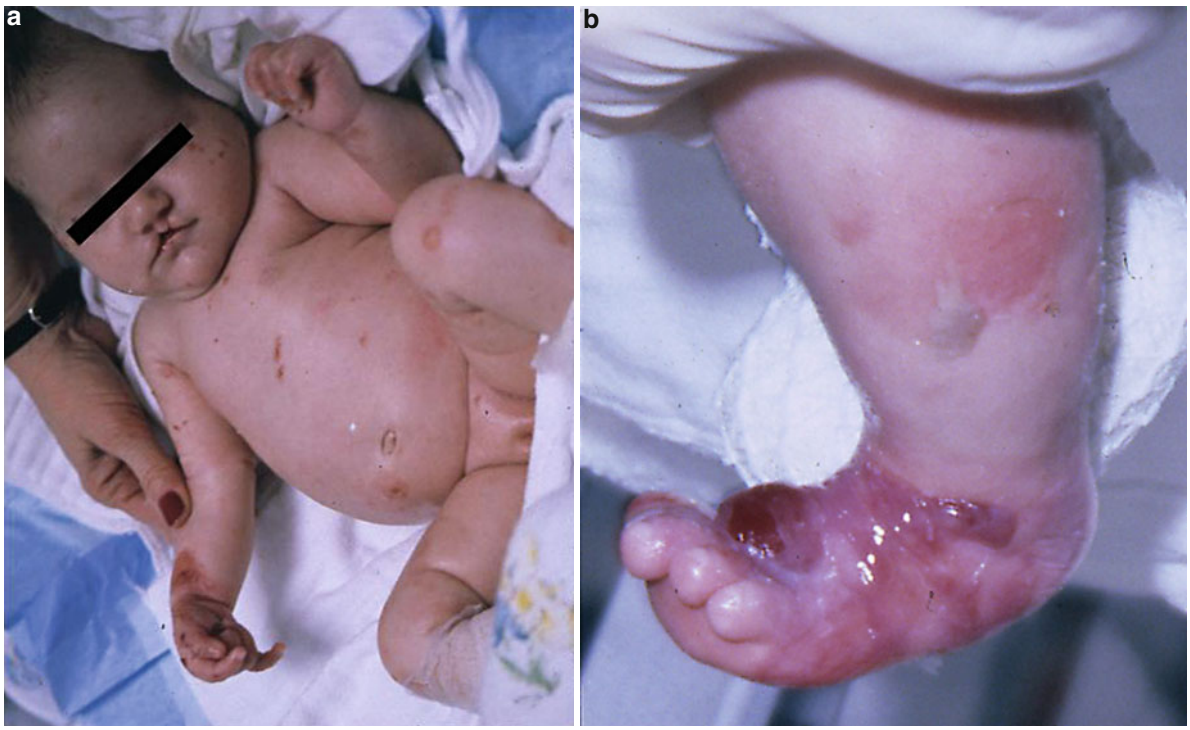

Fig. 1 (**a**, **b**) An infant with epidermolysis bullosa showing large blisters on the foot and smaller blisters on other part of the body

Fig. 2 (**a–d**) A 19-year-old female with recessively inherited dystrophic epidermolysis bullosa (Hallopeau-Siemens type) who was born with generalized blisters involving skin and mucosa, especially blisters and skin sloughing on the fingers and legs (**a**). She showed excessive fragile skin leading to blisters with minimal trauma, excessive scarring leading to contractures of the right foot and fusion of first and second toe on the right foot requiring surgical separation. She also had syndactyly of the second, third, and fourth toes of the left foot. The lesions were extremely itchy and painful and more severe on the lower extremity (**b**, **c**). At the time of these photos, the patient still had swallowing difficulty secondary to blistering lesion in the throat

Fig. 3 This infant was born with blisters on his hands, fingers, ankles, feet, toes, and oral mucosa, and part of the body. A biopsy of the lesion was consistent with dystrophic epidermolysis bullosa. In addition, he had a single umbilical artery, esophageal atresia, a single kidney, penile hypospadias, and unilateral preaxial polydactyly. At 12-weeks of age, he still showed scars on the oral mucosa and the chest and dystrophic lesions on the fingers

Epidermolytic Palmoplantar Keratoderma

Epidermolytic palmoplantar keratoderma (EPPK), first described by Vörner in 1901, may be the most common form of diffuse keratoderma and is characterized by keratosis restricted to the palms and soles. The disease is also known as keratosis palmaris et plantaris familiaris. The estimated incidence is at least 4.4 per 100,000 in Northern Ireland (Covello et al. 1998)

Synonyms and Related Disorders

Keratosis of Greither; Keratosis palmaris et plantaris; Localized epidermolytic hyperkeratosis; Vorner type plamoplantar keratoderma

Genetics/Basic Defects

1. Inheritance:
   a. Autosomal dominant
   b. Highly penetrant
2. Cause
   a. Keratin 9 (K9)
      i. A type 1 keratin gene (*KRT9*, located at 17q12-q21), a type 1 keratin expressed exclusively in the suprabasal keratinocytes of palmoplantar epidermis
      ii. Nearly 20 distinct pathogenic mutation in KRT9 have been identified in various ethnic kindreds with EPPK (Chen et al. 2009)
   b. Mutations in keratin 1 gene (*KRT1*) underlies mild EPPK (Terron-Kwiatkowski et al. 2002, 2006)

Clinical Features

1. Characteristic hyperkeratosis (Covello et al. 1998)
   a. Early onset: present at birth or during the first months of life
   b. Diffuse thick yellowish hyperkeratosis, distinctly limited to the palms and soles, with sharply bordered erythematous margins (virtually diagnostic of EPPK)
   c. Absence of associated features
2. Differential diagnosis (Lee et al. 2008)
   a. Diffuse hereditary PPK without associated features (Hatsell et al. 2001)
      i. Diffuse nonepidermolytic PPK (NEPPK)
         a) NEPPK: an autosomal dominant disorder
         b) Clinically difficult to distinguish between EPPK and NEPPK
         c) Histologically, EPPK shows epidermolysis of keratinocytes in the suprabasal layers, a characteristic not observed in NEPPK
         d) In mild cases of EPPK, diagnosis can still be problematic as detection of epidermolysis can be difficult
      ii. Progressive PPK
         a) Hyperkeratosis extends onto the dorsa of the hands and the feet with characteristic involvement of the Achilles tendon
         b) Hyperhidrosis common
         c) Intrafamilial phenotypic variation common
         d) Course of the disease: worsen during childhood, static after puberty, and improves in the fifth decade of life

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_82,
© Springer Science+Business Media, LLC 2012

iii. Gamborg-Nielson PPK
  a) An autosomal recessive disorder
  b) Severe form of PPK delineated in two families with six patients in Sweden
  c) Thick, diffuse keratoderma with knuckle pads
  d) Occasional keratosis on the dorsa of the hands
  e) Mutilating changes due to constricting bands surrounding the fingers have been described

b. Diffuse hereditary PPK with associated features
  i. Mal de Meleda
    a) Described initially in inhabitants of the Adriatic Island of Meleda (Miljet)
    b) An autosomal recessive disorder
    c) Diffuse, thick keratoderma with prominent erythematous border extending onto the dorsa of the hands and the feet
    d) Constricting bands around digits resulting in spontaneous amputation
    e) Well-circumscribed psoriasis-like plaques or lichenoid patches on the knees and the elbows
    f) Hyperhidrosis
    g) Periorbital erythema and hyperkeratosis
    h) Nail changes (koilonychias, subungual hyperkeratosis)
    i) Other associated features (lingua plicata, syndactyly, hair on the palms and the soles, high arched palate, left handedness)
  ii. Vohwinkel PPK mutilans
    a) An autosomal dominant disorder
    b) Honeycomb-like keratosis of the palms and soles in infancy
    c) Constricting fibrous bands on the digits, leading to progressive strangulation and autoamputation
    d) Starfish-shaped keratosis on the dorsa of the fingers and the knees
    e) Other associated features (alopecia, deafness, spastic paraplegia, myopathy, ichthyosiform dermatosis, and nail abnormalities)
  iii. Olmsted mutilating PPK with periorificial keratotic plaques (Olmsted syndrome) (Da Rosa Santos et al. 1997; Tao et al. 2008)
    a) An autosomal dominant disorder
    b) Onset in the first year of life
    c) Symmetric, sharply circumscribed PPK, surrounded by erythema with flexion deformities of the digits, leading to constriction and spontaneous amputation (Poulin et al. 1984)
    d) Presence of hyperkeratotic plaques with a periorificial pattern (Atherton et al. 1990; Lucker and Steijlen 1994)
    e) Onychodystrophy
    f) Universal congenital alopecia
    g) Oral leukokeratosis
    h) Joint hyperlaxity
  iv. PPK with sclerodactyly
    a) An autosomal dominant disorder
    b) Sclerodactyly
    c) Diffuse keratoderma more marked on the soles than the palms
    d) Nail abnormalities
    e) Hypohidrosis
    f) Associated with squamous cell carcinoma
  v. PPK with periodontitis
    a) An autosomal recessive disorder
    b) Diffuse trangrediens palmoplantar dermatosis
    c) Periodontosis, unless treated, results in severe gingivitis and loss of teeth by age 5 years
    d) Increased susceptibility to infection
    e) Scaly, erythematous lesions often observed over the knees, the elbows, and the interphalangeal joints
    f) Hyperhidrosis with malodor
  vi. Clouston hidrotic ectodermal dysplasia
    a) Diffuse, papillomatous PPK
    b) Nail dystrophy
    c) Universal sparsity of hair
    d) Other associated features (sensorineural deafness, polydactyly, syndactyly, finger clubbing, mental retardation, dwarfism, photophobia, and strabismus)
  vii. Diffuse NEPPK and sensorineural deafness
    a) An autosomal dominant disorder
    b) Diffuse palmoplantar hyperkeratosis
    c) Associated with a slowly progressive, bilateral, high-frequency hearing loss
    d) Deafness precedes the skin changes

c. Focal (nummular) PPK without associated features
   i. Focal NEPPK
      a) An autosomal dominant disorder
      b) Palmar keratosis with a nummular, linear, membranaceous, fissured, or periungual configuration
      c) Plantar keratosis with a nummular appearance, localized to pressure points
   ii. Focal epidermolytic PPK
      a) An autosomal dominant disorder
      b) Nummular keratotic lesions,located mainly on plantar pressure points
      c) Painful lesions
   iii. Siemens PPK areata/striata
      a) An autosomal dominant disorder
      b) Marked variable phenotypic expression
      c) Marked erythema initially, followed by islands of linear hyperkeratosis
d. Focal (nummular) hereditary PPK with associated features
   i. Oculocutaneous tyrosinemia (tyrosinemia type II)
      a) Focal, painful PPK
      b) Bilateral, pseudoherpetic corneal ulceration, leading to corneal scarring and glaucoma
      c) Mental retardation
      d) Occasional hyperkeratotic lesions on the elbows, knees, and tongue
      e) Hyperhidrosis
      f) Occasional bullous lesions
   ii. Pachyonychia congenita
      a) Autosomal recessive disorder
      b) Localized areas of hyperkeratosis on the palms and the soles
      c) Discoloration and thickening of the nails
   iii. Keratosis palmaris and plantaris with carcinoma of the esophagus
      a) Autosomal dominant disorder
      b) Age of onset: 5–15 years
      c) Focal PPK
      d) Increased susceptibility to developing carcinoma of the esophagus (38-fold increase)
      e) Variable oral leukokeratosis and follicular keratosis
   iv. Focal palmoplantar and oral mucosa hyperkeratosis
      a) Autosomal dominant disorder
      b) Focal PPK, especially on weight-bearing areas
      c) Oral hyperkeratosis
      d) Increased severity with age
      e) Subungual and circumungual hyperkeratosis
e. Papular PPK without associated features
   i. Keratosis palmoplantaris punctata
      a) Autosomal dominant disorder
      b) Asymptomatic, tiny hyperkeratotic papules present on the palmoplantar surface
      c) Absence of associated features in most patients
      d) Spastic paralysis, ankylosing spondylitis, facial sebaceous hyperplasia reported
      e) Possible association with gastrointestinal malignancy
   ii. Acrokeratoelastoidosis
      a) Autosomal dominant disorder
      b) Round or oval, yellowish, hyperkeratotic papules that can appear umbilicated
      c) Distribution of the lesions: along the border of the palms and the soles
      d) Associated hyperhidrosis
   iii. Focal acral hyperkeratosis
      a) Autosomal dominant disorder
      b) Condition similar to acrokeratoelastoidosis
      c) Insidious onset in childhood, reaching maximum in early life
      d) Race: African origin
f. Papular PPK with associated features
   i. Rare single-pedigree syndromes
      a) Syndrome of cystic eyelids, punctate PPK, hypotrichosis, and hypodontia (Schopf–Schulz–Passarge syndrome)
      b) Punctate PPK with ankylosing spondylitis
      c) Punctate PPK with facial sebaceous hyperplasia
      d) Punctate PPK with spastic paralysis
      e) PPK with lipomata
   ii. Punctate PPK and cancer
g. Acquired palmoplantar keratoderma
   i. Inflammatory and reactive dermatoses
      a) Hyperkeratotic eczema
      b) Psoriasis
      c) Reiter syndrome
      d) Lichen planus
      e) Pityriasis rubra pilaris

f) Lupus erythematosus
g) Callosities
h) Darier disease

ii. Infective causes
a) Dermatophytes
b) Viral (human papilloma virus) warts mimicking keratoderma
c) AIDS-related psoriasis with discrete keratotic pustular keratoderma
d) Late secondary syphilis in patients with HIV with diffuse, symmetric keratoderma or papular PPK
e) Yaws
f) Leprosy

iii. Drugs
a) Chronic arsenic exposure with multiple, irregular, warty keratosis
b) Lodine: manifestation of drug hypersensitivity

iv. Cutaneous features of systemic disease
a) Myoedema with hyperkeratosis
b) Diabetes with discrete plantar keratosis
c) Cutaneous T-cell lymphoma with subungual hyperkeratosis

v. Haxthausen keratoderma climactericum
a) Onset in the 40s
b) Initial lesion: pressure areas on the soles
c) Erythema and hyperkeratosis with fissuring making walking painful
d) Minimal pruritus
e) Discrete and centrally confined palmar involvement

vi. Keratoderma associated with internal malignancy
a) Keratoderma as a paraneoplastic phenomenon, such as acrokeratosis paraneoplastica of Bazex associated with squamous cell carcinoma of the upper gastrointestinal tract and acanthosis palmaris associated with gastric or pulmonary malignancy in 90% of cases
b) Keratoderma as evidence of predisposition to malignancy such as late-onset punctate keratoderma associated with cutaneous and internal malignancy

h. Syndromes with PPK as an associated features
i. Basal cell nevus syndrome
ii. Congenital bullous ichthyosiform erythroderma
iii. Congenital nonbullous ichthyosiform erythroderma
iv. Darier disease
v. Epidermodysplasia verruciformis
vi. Epidermolysis bullosa herpetiformis
vii. Ichthyosis vulgaris
viii. Incontinentia pigmenti
ix. Keratitis, ichthyosis, and deafness (KID) syndrome
x. Lamellar ichthyosis

Diagnostic Investigations

1. Histology and ultrastructures: cytolysis of keratinocytes and abnormal aggregation of tonofilaments in the suprabasal layers of the epidermis
2. Molecular genetic analysis
   a. *KRT9* mutations analysis
      i. Sequencing of entire coding region
      ii. Sequencing of select exons
      iii. Targeted mutations analysis
   b. *KRT1* mutation analysis for patients with no mutations in *KRT9*

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: not increased unless a parent is affected in which case there is a 50% risk
   b. Patient's offspring: 50%
2. Prenatal diagnosis
   a. Not usually requested because of mild nature of the disease
   b. Possible to pregnancy at-risk, provided the disease-causing mutation has been identified in the proband
   c. Accomplished in a Chinese kindred affected by EPPK for detection of c. T470C (p.M157T) of the keratin 9 gene from fetal DNA obtained by amniocentesis (Chen et al. 2009)
3. Management
   a. Topical keratolytics
   b. Topical retinoids such as tretinoin

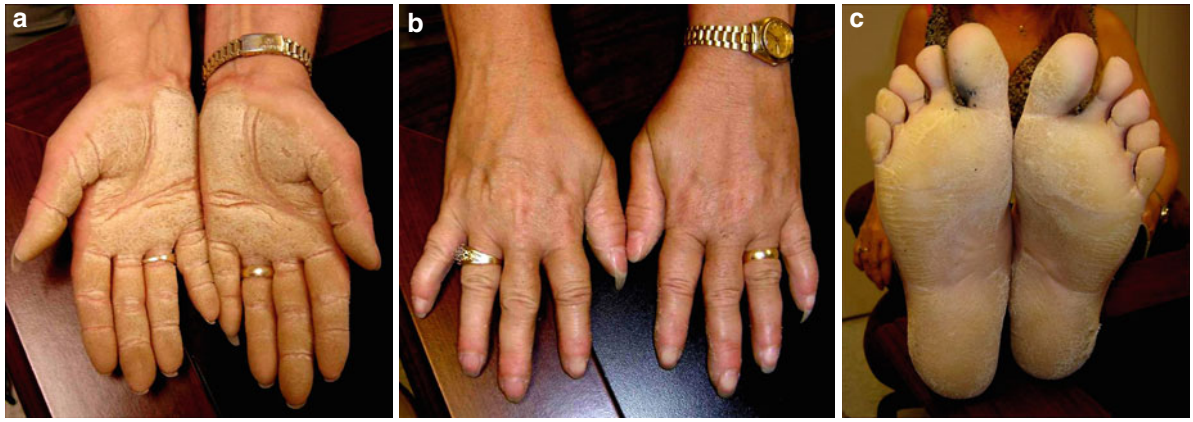

Fig. 1 (**a**–**c**) A 47-year-old woman with epidermolytic palmoplantar keratoderma showing diffuse keratoderma affecting both the palms and the soles. The keratoderma had erythematous border at the margins of both palms and soles and was completely restricted to the palms and soles. The dorsa of the hands and soles were spared. This patient has multiple affected relatives in several generations

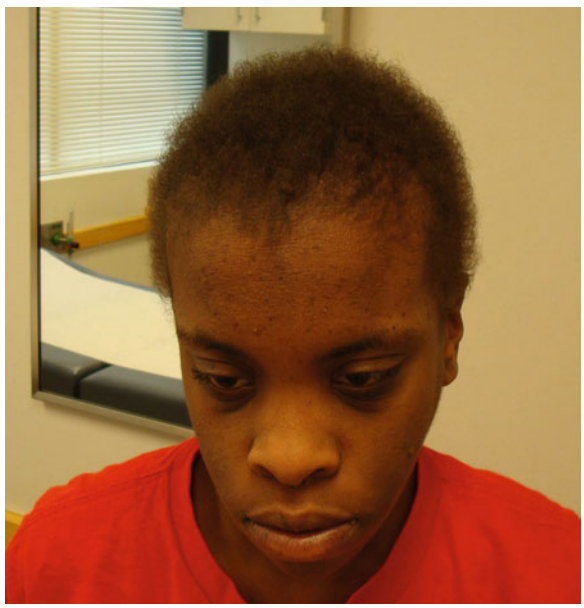

Fig. 2 This 17-year-old girl was seen for hyperkeratosis of the palms and soles associated with severe nail hyperplasia of the toes. She has mental retardation and short stature. Clinically she has type IV epidermolytic palmoplantar keratoderma with pachyonychia congenita

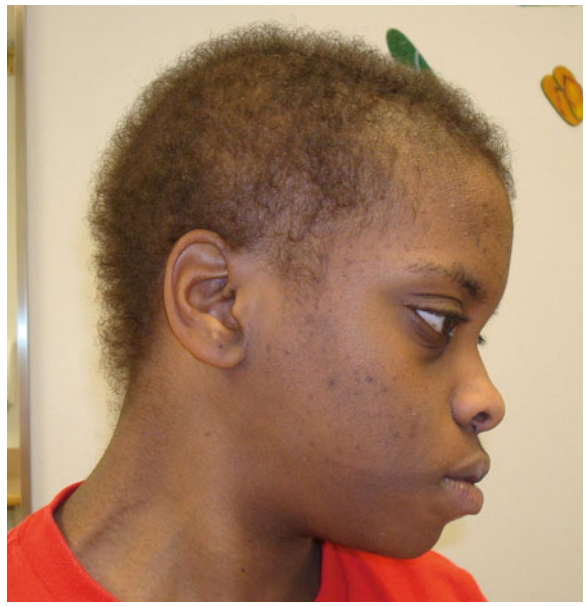

Fig. 3 She has marked midfacial hypoplasia

Fig. 4 Diffuse *thick* yellowish hyperkeratosis was noted on her palms. Her soles also have same *thick* yellowish hyperkeratosis

Fig. 5 Her toe nails show subungual keratinous mass pushing the nail bed upward

Faciogenital (Faciodigitogenital) Dysplasia

Faciogenital dysplasia (FGDY) was first described by Aarskog in 1970 (Aarskog 1970) as a familial syndrome of short stature associated with facial and genital anomalies. The occurrence of ligamentous laxity was emphasized by Scott in 1971 (Scott 1971). The syndrome is also known as Aarskog syndrome, Aarskog–Scott syndrome, and facio-digito-genital syndrome (Sugarman et al. 1973).

Synonyms and Related Disorders

Aarskog syndrome; Aarskog–Scott syndrome;

Genetics/Basic Defects

1. Inheritance
   a. X-linked recessive inheritance with occasional partial expression in the heterozygote
   b. Caused by mutations in the *FGDY* gene (*FGDY1*) affecting multiple skeletal structures including craniofacial bones, vertebrae, ribs, long bones, and phalanges
   c. First case of deletion of *FGD1* gene reported in a boy with Aarskog–Scott syndrome (Bedoyan et al. 2009)
2. The *FGDY1* gene (Schwartz et al. 2000)
   a. Mapped to the pericentromeric region of the X chromosome by the observation of an X;8 translocation in an affected mother and son (breakpoint at Xp11.21) (Pasteris et al. 1997)
   b. Encoding a guanine nucleotide exchange factor that specifically activates the P21 GTPase Cdc42, a member of the Rho (Ras homology) family of GTPase proteins (Gorski et al. 2000)

Clinical Features

1. Typical triad of the syndrome
   a. Facial appearance
      i. Rounded facies
      ii. Prominent metopic ridge
      iii. Widow's peak hair anomaly
      iv. Ocular hypertelorism
      v. Ptosis
      vi. Antimongoloid obliquity of palpebral fissures
      vii. Small and short nose
      viii. Anteverted nares
      ix. Broad nasal bridge
      x. Broad long philtrum
      xi. Maxillary and mandibular hypoplasia
      xii. Slight crease below lower lip
      xiii. Low-set ears with fleshy earlobes and incomplete outfolding of upper helices
   b. Digital anomalies
      i. Hands
         a) Short and broad hands
         b) Hypermobility of fingers
         c) Cutaneous syndactyly (interdigital webbing)
         d) Clinodactyly with hypoplasia of middle phalanges
         e) Transverse palmar crease
      ii. Feet
         a) Short and broad feet
         b) Bulbous toes
         c) Metatarsus varus
         d) Hypoplasia of the middle or terminal phalanges

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_83,
© Springer Science+Business Media, LLC 2012

   c. Genital abnormalities
      i. Shawl scrotum (scrotal folds encircling the base of the penis)
      ii. Cryptorchidism
      iii. Phimosis
      iv. Hypoplasia
      v. Renal hypoplasia
2. Growth
   a. Failure to thrive
   b. Delayed puberty
   c. Slight to moderate (disproportionate acromelic) short stature (71%)
3. Intelligence and behavioral disorders
   a. Most individuals with normal intelligence: hyperactive and attention deficits present in 61% of these individuals, which usually regress after 12–14 years of age
   b. Individuals with subnormal to mentally retarded (30%): hyperactive and attention deficits present in 84% of these individuals
4. Dental abnormalities
   a. Hypodontia
   b. Retarded dental eruption
   c. Orthodontic problems
5. Ocular features
   a. Strabismus
   b. Nystagmus
   c. Amblyopia
   d. Bilateral blepharoptosis
   e. Astigmatism
   f. Hyperopia
   g. Anisometropia
   h. Corneal enlargement
   i. Deficient ocular elevation
   j. Blue sclera
   k. Posterior embryotoxon
   l. Ophthalmoplegia
   m. Tortuosity of the retinal vessels
6. Musculoskeletal anomalies
   a. Cervical vertebral anomalies
   b. Spina bifida occulta
   c. Mild pectus excavatum
   d. Genu recurvatum
   e. Joint restriction
   f. Prominent umbilicus
   g. Inguinal hernias
7. Other rare signs
   a. Gastrointestinal obstruction and volvulus in a few patients
   b. Rare perinatal occurrence of severe cerebrovascular accidents
8. Clinical variability and changing phenotype with age
9. Carrier females often present with minor manifestations of disorder, especially relatively short stature and subtle craniofacial anomalies (Pasteris et al. 1997)

Diagnostic Investigations

1. Ophthalmic examination
2. Radiography
   a. Ocular hypertelorism
   b. Short tubular bones with widened metaphysis
   c. Brachydactyly
   d. Clinodactyly of fifth fingers
   e. Hypoplastic middle phalanges
   f. Mild interdigital webbing
   g. Cubitus valgus
   h. Splayed toes with bulbous tips
   i. Metatarsus adductus
   j. Broad flat feet
   k. Cervical vertebral anomalies
      i. Odontoid hypoplasia
      ii. Fused cervical vertebrae
      iii. Spina bifida occulta
   l. Scoliosis
   m. Additional pairs of ribs
   n. Retarded bone age
3. Mutation analysis: by sequencing entire coding region of *FGD1* gene available clinically

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 50% risk of having affected brothers if the mother is a carrier; otherwise recurrence risk not increased
   b. Patient's offspring: 50% of his daughters to be carriers; no increased risk to his sons
2. Prenatal diagnosis
   a. Ultrasonography: possible with a positive family history of a previously affected child by demonstrating ocular hypertelorism, short long bones, vertebral defects, and digital anomalies in a male fetus
   b. Mutation analysis of fetal DNA from amniocytes or CVS provided the mutation has been previously identified in the proband

3. Management
   a. Supportive management
   b. Ophthalmological evaluation of the ocular problems for treatable causes of visual loss
   c. Surgery for cryptorchidism and inguinal hernia
   d. Reports of growth hormone treatment indicate a positive effect on growth and adult height in treated patients (Petryk et al. 1999)

Fig. 1 (**a**–**c**) Two patients (*top* two photos are same patient) with faciogenital dysplasia showing short stature, round face, broad forehead, hypertelorism, mild ptosis, short nose with anteverted nostrils, long philtrum, low-set ears, and broad hands with webbing of fingers

Fig. 2 (**a**–**d**) Shawl scrotums observed in four patients with faciogenital dysplasia

Fig. 3 (**a**–**c**) A 3-year-old boy with faciogenital syndrome showing typical facial features (round face, prominent metopic ridge, ocular hypertelorism, low-set ears) and digital anomalies (short and broad hands and cutaneous syndactyly)

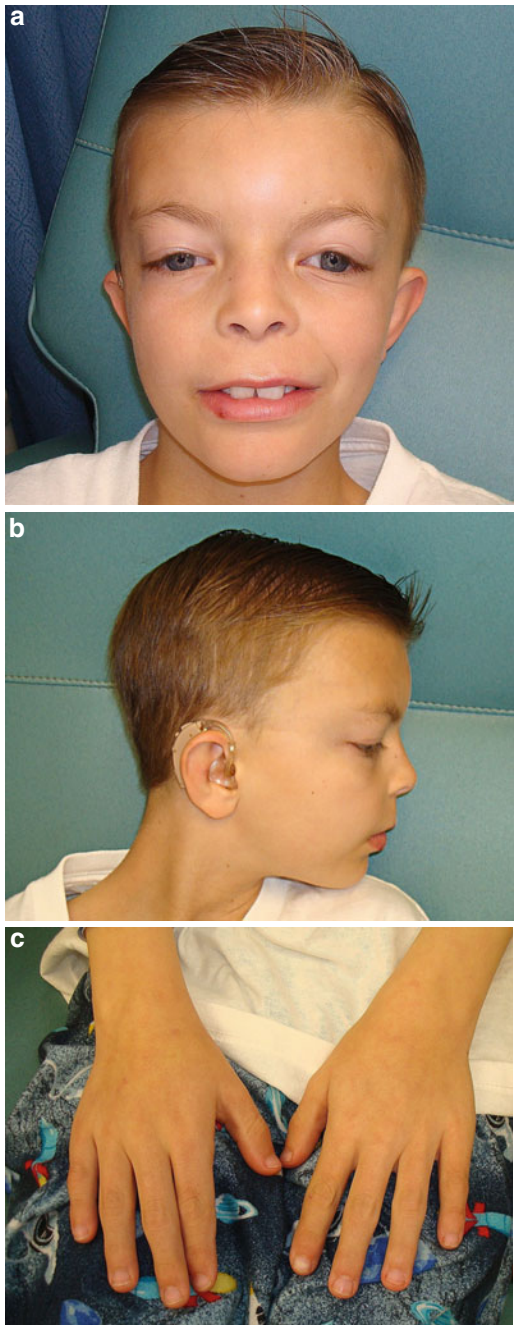

Fig. 4 (**a**–**c**) A 12-year-old boy was evaluated for short stature. On physical examination, he had ocular hypertelorism, ptosis, antimongoloid palpebral fissures, long philtrum, short and broad hands, and shawl scrotum. DNA sequencing identified a one basepair insertion at nucleotide 527 of the *FGDI* gene (c.527insC). This change is expected to cause a shift in the reading frame resulting in a truncated protein. This result is consistent with a diagnosis of Aarskog syndrome. In addition, he had sensorineural hearing loss. DNA sequence analysis indicated normal GJB2, connexin 26 (Cx26) gene

Fig. 5 His mother showed ocular hypertelorism, ptosis, and a long philtrum. She may represent a carrier with partial expression. Unfortunately, *FGS1* gene sequencing was not performed

Facioscapulohumeral Muscular Dystrophy

Facioscapulohumeral muscular dystrophy (FSHD) is the third most common neuromuscular disorder after Duchenne muscular dystrophy and myotonic dystrophy. It is characterized by progressive weakness and atrophy of the facial and shoulder girdle muscles. The other muscles are also involved. Its prevalence is estimated to be 1 in 20,000 in Europe (Lunt and Harper 1991).

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant
   b. Almost complete penetrance (95%)
2. *FSHD1* gene
   a. Mapped to the subtelomeric region of chromosome 4q35
   b. Closely linked to the highly polymorphic locus D4F104S1
   c. Deletion of 3.3-kb tandemly repeated D4Z4 within the *Eco*RI fragment on chromosome 4q35: associated with the disease in 85–95% of FSHD families
   d. The deletion is pathogenic only when it is hypomethylated and resides in a 4qA161 allele (Lemmers et al. 2007)
   e. Candidate genes for FSHD not yet elucidated
   f. Nature of the precise mutation: still unknown
   g. Approximately 5% of FSHD families fail to exhibit linkage to 4q35, presumably indicating the presence of a second *FSHD1* locus (Upadhyaya et al. 1999)
3. Genotype-phenotype correlation
   a. Patients with a large gene deletion
      i. Tendency to have a higher chance of exhibiting severe clinical phenotypes
      ii. Higher chance of central nervous system abnormalities
   b. Patients with small *Eco*RI fragments
      i. Tendency to have earlier-onset disease
      ii. More rapid progression
   c. Correlation between the size of the disease-associated 4q35-*Eco*RI fragment and the following parameters
      i. Age at onset of symptoms
      ii. Age at loss of ambulation
      iii. Muscle strength as measured by quantitative isometric myometry
   d. De novo mutations
      i. Association with smaller *Eco*RI fragments (on average) than those segregating in families
      ii. Tendency of patients with de novo mutations to have findings the more severe end of the phenotypic spectrum
   e. Reduced penetrance in females bearing the FSHD small fragment as compared to the penetrance in males with the FSHD small fragment
4. Categories of FSHD (Padberg and van Engelen 2009)
   a. Severe disease, infantile form, onset usually before the age of 10 years with one to three residual D4Z4 repeats
   b. Moderate disease or classical phenotype with four to seven repeats and with a widely variable course, encompassing a large percentage of asymptomatic carriers older than 50 years, and 60% lower limb involvement with 20% wheelchair use after this age

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_84,
© Springer Science+Business Media, LLC 2012

c. Mild disease with eight to ten residual D4Z4 repeats, probably with frequent nonpenetrant gene carriers and muscle involvement limited to the upper limbs

Clinical Features

1. Marked clinical variability
   a. Age at onset
      i. Usually between the first and second decade
      ii. Progress gradually over time
   b. Pattern of muscle involvement
      i. Progressive weakness and atrophy of the facial and shoulder girdle muscles
      ii. Other muscles affected in a specific order
         a) Abdominal muscles involved first
         b) Followed by foot-extensor and upper arm muscles
         c) Finally involving pelvic girdle and lower arm muscles
   c. Intrafamilial variability
   d. Inter-familial variability
   e. Phenotype ranging from almost asymptomatic forms to more severe wheelchair-bound forms
2. A distinctive distribution of progressive muscular weakness involving the following muscles (Kissel 1999)
   a. Facial muscles
      i. Typically involved:
         a) Orbicularis oculi
         b) Orbicularis oris
      ii. Clinical signs
         a) Often asymmetric involvement
         b) Facial weakness
         c) Unable to turn up the corners of the mouth when smiling
         d) Difficulty in whistling
         e) Unable to purse lips
         f) Sleeping with eyes partially open, the most common early sign
         g) Bury eyelashes when attempting to close eyelids tightly
         h) Sparing of extraocular, eyelid, and bulbar muscles
   b. Scapular stabilizer muscles
      i. Affected muscles
         a) Latissimus dorsi
         b) Trapezius
         c) Rhomboids
         d) Serratus anterior
      ii. Clinical signs
         a) Sloping shoulder posture at rest
         b) Anterior axillary folds
         c) Straight (horizontally placed) clavicles
         d) Pectoral muscle atrophy
         e) Scapular winging, the most common initial finding
         f) Preferential weakness of the lower trapezius muscle, resulting in characteristic upward movement of the scapula when attempting to flex or abduct the arms
   c. Proximal arm muscles
      i. Biceps and triceps selectively involved, resulting in atrophy of the upper arm
      ii. Distal progression of wasting and weakness of upper arm muscles, leading to eventual weakness of wrist and finger extensors
      iii. Deltoids minimally affected until late in the disease
      iv. Sparing of the forearm muscles, resulting in so-called "popeye arms" appearance
   d. Abdominal muscles
      i. Abdominal muscle weakness resulting in:
         a) Protuberance of the abdomen
         b) Exaggerated lumbar lordosis
      ii. Selective involvement of the lower abdominal muscles, resulting in Beevor's sign (upward displacement or occasionally downward movement of the umbilicus upon flexion of the neck in a supine position)
         a) Present in 90% of patients
         b) Helpful early sign in patients with equivocal findings, as it is rarely found in other muscle disorders
         c) Positive Beevor's sign may be caused by spinal cord injury at or below the level of Th10 (Eger et al. 2010)
   e. Lower extremity muscles
      i. Anterior compartment muscles of the distal leg (anterior tibial and peroneal muscles)
         a) Usually the first and most severely affected
         b) Resulting in the typical complaints of a foot slap while walking or frank foot drop

c) Frequent tripping or unstable walking, particularly on uneven ground
ii. Pelvic girdle muscles
a) Less common
b) Involving hip flexors and hip abductors
c) Resulting in early and relatively severe gait involvement
3. Degree of muscle involvement
a. Extremely variable
b. Wide range of muscle involvement
i. Very mildly affected patients unaware of the disease symptoms
ii. Isolated facial weakness
iii. Severe generalized weakness
iv. Eventually requiring a wheelchair in approximately 20% of patients
c. Sex difference in penetrance: males more severely affected than females
4. Clinical course of muscle involvement
a. Early involvement of facial and scapular muscles with eventual spreading to pelvic and lower limb muscles
b. A slowly progressive course
c. A stepwise course with periods of rapid deterioration occurring against a background of stability
d. Aggravation of muscle weakness during pregnancy but recover quickly in the puerperium
e. Bulbar and pharyngeal muscles, extraocular muscles, and respiratory muscles typically spared
5. Extra muscular involvement (uncommon)
a. Coats syndrome
i. Neurosensory hearing loss (64%)
ii. Retinal vasculopathy (49–75%)
a) Tortuosity of retinal arterioles (microaneurysms)
b) Telangiectasia
b. Mental impairment
c. Cardiac involvement (5%)
i. Conduction defects
ii. Supraventricular arrhythmia
d. Neurologic manifestations
i. Preserved sensation
ii. Often diminished reflexes
6. Diagnostic criteria include the following four main elements: The diagnosis of FSHD often remains a clinical diagnosis (Kissel 1999).
a. Onset of disease in the facial or shoulder girdle muscles, sparing the eyes, pharynx, tongue, and heart
b. Facial weakness in more than 50% of affected family members
c. Autosomal dominant inheritance in familial cases
d. Evidence of myopathic disease by electrodiagnostic studies and muscle biopsy in at least one affected family member

Diagnostic Investigations

1. Serum creatine kinase (CK)
a. Normal to elevated levels
b. Usually not exceeding three to five times the upper limit of the normal range
2. Audiogram for sensorineural hearing loss
3. Fluorescein angiography to demonstrate retinal vasculopathy
4. EMG: nonspecific myopathic features
a. Fibrillations
b. Positive waves in resting muscle
c. Early recruitment of short duration motor unit action potentials
5. Muscle biopsy: nonspecific features
a. Underlying process: myopathic and help to exclude the following primary muscle diseases that can present with a FSHD-like phenotype (Kissel 1999):
i. Congenital myopathies
a) Nemaline (rod) myopathy
b) Centronuclear myopathy
ii. Inflammatory myopathies
a) Polymyositis
b) Inclusion body myositis
iii. Other dystrophies
a) Scapuloperoneal dystrophy
b) Limb-girdle dystrophy
iv. Others: desmin-storage myopathy
b. Increased variation in fiber size
c. Increased internalized nuclei
d. Variable degrees of endomysial inflammatory cells
e. Angulated “neuropathic-like” myofibers
f. Mononuclear inflammatory reaction (75%)

6. Molecular genetic testing (Kissel 1999)
   a. Mutation analysis
      i. Detection of the short fragment in affected individuals
         a) High sensitivity and specificity of the 4q35 deletion for FSHD
         b) Using probe p13E-11 (D4F104S1), which hybridized to 4q35, to detect small *Eco*RI digestion fragments (Felice and Moore 2001)
         c) Deletion within the D4Z4 repeat region of chromosome 4q35 (demonstrable short fragment), observed in 95% of patients clinically affected with FSHD, whether familial or sporadic
         d) Approximately 98% of patients with such a short fragment have clinically demonstrable FSHD
         e) Confirms the diagnosis with a high degree of certainty
      ii. Large deletions in the 4q35 region (producing a smaller short fragment)
         a) Associated with more severe expression of the disease
         b) Manifest earlier onset of disease
         c) More severe degree of weakness
         d) Shorter fragment size generally associated with sporadic cases with an earlier age of onset than with familial cases
      iii. Variability in fragment size: unable to explain the significant clinical variability sometimes seen within FSHD families, since the deletion size appears to remain stable from generation to generation
      iv. Findings of a short but less intensively hybridizing p13E-11/*Eco*RI/*Bln*I fragment strongly suggest germinal mosaicism. Minor clinical signs in parents may point toward germline mosaicism
   b. Genetic diagnosis (Tawil et al. 2010)
      i. The large majority (>95%) of patients with FSHD have a partially deleted D4Z4 repeat array on one of their chromosomes 4 (FSHD1).
      ii. This repeat array is polymorphic in copy number, with alleles varying between 11 and 100 units in the general population
      iii. Patients with FSHD1 carry one allele with one to ten D4Z4 units (Tawil and van der Maarel 2006)
      iv. In order to be pathogenic, this shortened D4Z4 repeat array needs to reside on the 4qA background of chromosome 4
   c. Absence of identifiable D4Z4 deletions in approximately 5% of individuals with FSHD

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. 10% risk for a sib of a de novo case being a carrier. The figure of 10% is based on the observation that both somatic and germinal mosaics are detected, indicating that both types of mutations occur early in embryogenesis and therefore will give rise to a high percentage of mutated germ cells (Bakker et al. 1996)
      ii. 50% recurrence risk if a parent is affected
   b. Patient's offspring: Each offspring of an affected individual having a 50% chance of inheriting the deleted region within the D4Z4 repeat motif for FSHD
2. Prenatal diagnosis (Tawil et al. 2010)
   a. Available for fetuses at 50% risk for FSHD
   b. Molecular genetic testing: follow a de novo mutation in a subsequent generation by analyzing DNA extracted from fetal cells obtained by (Bakker et al. 1996):
      i. CVS: preferred over amniocentesis since genetic diagnosis for FSHD can take several weeks to complete
      ii. Amniocentesis
   c. Conditions for inclusion for prenatal diagnosis
      i. Confirmed FSHD1 in the family
      ii. Availability of DNA from parents and index case
   d. Preimplantation genetic diagnosis (PGD)
      i. Southern blot genetic test: not applicable to single cell PGD
      ii. Consequently, the disease-associated D4Z4 repeat can only be detected indirectly with the use of polymorphic markers, but the relatively high recombination frequency and the

availability of few polymorphic markers specific for the region proximal to D4Z4 hampers PGD significantly

3. Management (Kissel 1999; Figlewicz 2003)
   a. Lack of effective treatment
   b. Unpredictability of the clinical course
   c. Management of pain in the shoulders, back, abdomen, and leg
      i. Use of nonsteroidal anti-inflammatory drugs
      ii. Range-of-motion exercise
      iii. Gentle stretching through a physical therapy program
   d. Physiotherapy
   e. Supportive treatment of complications from progressive weakness
      i. Judicial use of bracing
      ii. Ankle and foot orthoses to improve mobility and prevent falls in patients with foot drop
      iii. Surgical fixation of the scapula to the chest wall (thoracoscapular fusion) or to the ribs (scapulocostal fusion)
         a) Often improving range of motion of the arms
         b) Short-lived effect in patients with rapidly progressive disease
   f. Pharmacologic treatment
      i. Limited to the use of corticosteroids in patients with evidence of inflammation on muscle biopsy
      ii. Possible effect of albuterol, a β2 adrenergic agent
         a) Improvement of lean body mass
         b) Modest improvement in strength
   g. Treat respiratory dysfunction which occurs in <1% of patients with FSHD (Wohlgemuth et al. 2004)
   h. Treat cardiac dysfunction which is seen in about 5% of patients (Laforet et al. 1998)
   i. Pregnancy in FSHD
      i. Pregnancy outcomes in FSHD: are generally good although two case series have conflicting reports about an increased incidence of operative deliveries and preterm births (Rudnik-Schoneborn et al. 1997; Ciafaloni et al. 2006)
      ii. Pregnant women with FSHD be followed by high risk obstetricians and that delivery occurs in a center that can provide comprehensive perinatal care
      iii. Additionally, it is recommended that pregnant women with FSHD and reduced lung function have serial monitoring of their FVC during the course of their pregnancy
   j. Required assistance in caring the infants after delivery due to weakness in the shoulder girdle

Fig. 1 A child with FSHD showing periscapular wasting and weakness resulting in scapular winging and inability to abduct the arm above the horizon

Fig. 2 An adult with FSHD showing scapular winging and wasting of proximal arm muscles

Fig. 3 An adult with FSHD showing facial weakness and inability to smile, purse the lips, and whistle

Fig. 4 (**a–c**) A 14-year-old boy with FSHD showing sloping shoulders, inability to raise arms above shoulders, and inability to close his eyelids completely. In addition, he had difficulty in pursing the lips and could not whistle (onset at about 2 years of age). His CPK was 1,295 (normal: 0–200 U/L). Molecular genetic analysis revealed FSHD allele 1 of 18 kb and FSHD allele 2 of >48 kb (FSHD deletion, 12–37; marginal, 38–41; no deletion, ≥42). The mother and several other family members are also affected

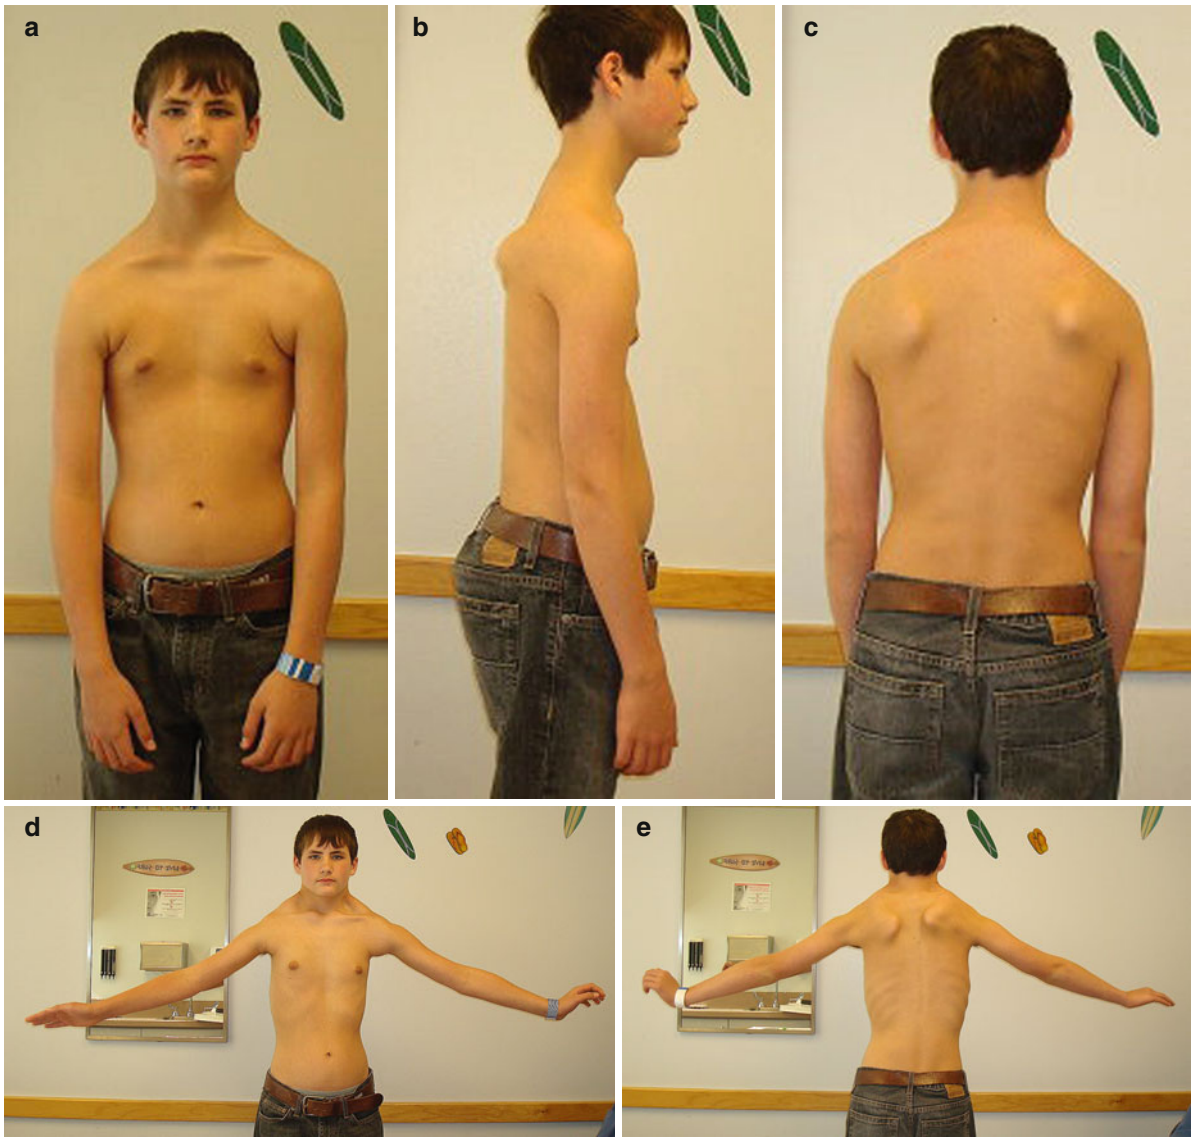

Fig. 5 (**a**–**e**) A 13-year-old boy was evaluated for his scapula deformities. He could not purse his lips, whistle, or smile. He could not raise his arms above his shoulders for the last 6 months. He had an elevated CK of 717 (normal: 35–232). On physical examination, he was noted to have sloping shoulder posture at rest, winging scapular, pectoral muscle atrophy, and mild atrophy of the upper arms. Molecular genetic testing revealed an FSHD gene mutation with allele 1 of 13 kb and allele 2 of >48 kb consistent with the diagnosis of facioscapulohumeral muscular dystrophy

Familial Adenomatous Polyposis

Germline mutations in the adenomatous polyposis coli (*APC*) gene cause the most common form of hereditary polyposis syndromes termed "familial adenomatous polyposis (FAP)." The incidence is approximately 1 in 8,300 to 1 in 13,000 live births.

Synonyms and Related Disorders

Adenomatous intestinal polyposis; Familial polyposis of the colon

Genetics/Basic Defects

1. Inheritance
   a. Autosomal dominant with high penetrance (80–100%)
   b. Spontaneous mutations account for approximately 30% of cases
2. Caused by germline mutations in the adenomatous polyposis coli (*APC*) gene on chromosome 5q21 (Lynch and Hoops 2002)
   a. More than 300 different disease-causing mutations of the *APC* gene are currently identified
   b. Nonsense or frameshift mutations that result in a truncated protein in nearly all of the germline mutations in APC
   c. Nearly 80% of FAP families have identifiable germline mutations in one allele of *APC* in affected individuals
   d. Similar high incidence of germline mutations is seen in the FAP variant, Gardner syndrome
3. *APC* gene
   a. A large gene consisting of approximately 6 kb in length
   b. A tumor suppressor gene encoding for a 2,843-amino acid protein with a putative role in:
      i. Cell adhesion
      ii. Signal transduction
      iii. Transcriptional activation
   c. The causative germline defect of *APC* gene predisposes to the following conditions:
      i. FAP
      ii. Nearly obligatory colorectal cancers
   d. Loss of second *APC* allele either by somatic mutation or loss of heterozygosity in the earliest premalignant lesions:
      i. Dysplastic aberrant crypt foci
      ii. Small adenomatous polyps
   e. Adenoma formation (Robbins and Itzkowitz 2002)
      i. Beginning with loss of function of the APC tumor suppressor gene
      ii. Followed by activation of the K-ras oncogene
      iii. Subsequent loss of function of genes on chromosome 18q and inactivation of p53 ushers in malignant degeneration
4. Colorectal carcinogenesis: involves two principal pathways (Robbins and Itzkowitz 2002):
   a. Chromosomal instability
      i. Deletion of portions of a chromosome results in loss of specific genes and abnormal amounts of DNA per cell (aneuploidy). This pathway accounts for:
         a) All cases of colorectal cancers associated with FAP
         b) Nearly 85% of sporadic colorectal cancers

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_85,
© Springer Science+Business Media, LLC 2012

ii. The pathway of *c-myc* and *β-catenin* as downstream targets appears to impact on the kinetochore and microtubule attachment.
iii. Mutations in *APC* interfere with the way that epithelial cells divide and distribute their nuclear DNA.

b. Microsatellite instability
i. Produced by defects of the DNA base mismatch repair system
ii. This pathway accounts for:
a) 15% of sporadic colorectal cancers
b) Most cases of hereditary non-polyposis colorectal cancer

5. Genotype-phenotype correlation
a. FAP phenotype expressed in an individual depends in part on the site of the germline *APC* mutation
i. Attenuated familial adenomatous polyposis coli occurs when there is a truncating mutation in the extreme ends of the *APC* coding sequence
ii. Mutations between codons 169 and 1,393 resulting in classic FAP
iii. Mutations between codons 1,250 and 1,464, especially around codon 1,300, resulting in profuse colorectal polyposis and earlier onset of gastrointestinal polyps
iv. Retinal lesions (congenital hypertrophy of the retinal pigment epithelium, a condition present at any age in 60% of FAP families) occur only with mutations between codons 457 and 1,444 (Lynch and Hoops 2002; Cruz-Correa and Giardiello 2003)
v. Up to 60% of patients with mutations between codons 1,445 and 1,580 result in desmoids (Leggett 2002)
b. Limited clinical application of genotype-phenotype correlation: Considerable phenotypic variability exists even among individuals and families with identical genotypic mutations.

Clinical Features

1. Spectrum of disease activity (Half et al. 2009)
a. Attenuated FAP (AFAP): mild form of FAP
i. Fewer number of adenomatous polyps: less than 100
ii. A later age of adenoma development and onset for colorectal cancers
b. Fulminant FAP
i. With hundreds to thousands of polyps at a young age
ii. A nearly 100% risk of developing colorectal cancers by the age of 40
2. Usually asymptomatic until puberty when colonic polyps begins to develop, the adenomas become large and numerous so as to cause rectal bleeding or even anemia
3. Average age of onset of polyps: 25 years
4. Presenting signs and symptoms
a. Rectal bleeding: the most common symptom
b. Anemia
c. Abdominal pain
d. Change in bowel habits, constipation, or diarrhea, occurring approximately 8 years later
e. Palpable abdominal masses
f. Weight loss
g. Above signs and symptoms in young patients can lead to recto-sigmoid examination and identification of polyps suggestive of FAP
5. Relative and approximate contributions of familial causes to the incidence of colorectal cancer (Half et al. 2009)
a. About 85% of cases are sporadic
b. Approximately 10% are familial cancer
c. Three to five percent are hereditary nonpolyposis colorectal cancer (Lynch syndrome)
d. Less than one percent are FAP, familial juvenile polyposis, and Peutz–Jeghers syndrome
6. Colonic manifestations of FAP
a. Characterized by the presence of hundreds to thousands of colorectal adenomas of different sizes. Today this is rarely seen in countries with well-developed public health services
b. In the majority of patients polyps begin to develop during childhood, mostly in the distal colon (rectosigmoid) as small intramucosal nodules
c. By the time of adolescence, the polyps are usually identified throughout the colon and, thereafter, increase in size and numbers.
d. About half of FAP patients develop adenomas by 15 years of age and 95% by age 35 years (Petersen et al. 1991)
e. Generally, cancers start to develop a decade after the appearance of the polyps. So, if the

colon is left intact, the majority of patients with FAP eventually develop CRC by the ages 40–50 years.
f. Although uncommon, colorectal cancers can develop in children or in older adults
g. Other gastrointestinal manifestations
i. Gastric polyps (fundic gland polyps) develop in the stomach in 90% of patients with FAP
a) Typically benign
b) Adenomatous in rare cases
c) An increased rate of gastric cancer in some kindreds
d) Gastric cancer occur more frequently than duodenal cancer in Japanese FAP kindreds (Opposite is true for FAP kindreds with European Caucasian descent)
e) Gastric adenomas occur in 50% of Japanese FAP kindreds
ii. Duodenal or periampullary adenomatous polyps (5–10% lifetime risk)
a) May progress to cancer
b) Five percent of these patients develop malignant transformation within 20 years after the onset of polyps
iii. Other small intestinal tract polyps: rare
h. Adenomas of the ileal pouch may follow proctocolectomy
7. Extraintestinal manifestations
a. Pancreatic (2%) and biliary tract cancers: rare
b. Adrenal adenomas: rare
c. Papillary thyroid carcinomas
i. Affect about 1–2% of patients with FAP
ii. A hundred-fold increased risk in the women with FAP
iii. Activation of *ret*/*ptc1* oncogene in FAP-associated thyroid papillary carcinomas
d. Hepatoblastomas: a 1–3% risk of developing hepatoblastomas from birth until 6 years of age in infants and children who are at risk or known APC mutation carriers
e. Brain (medulloblastoma) (<1%)
f. Osteomas
g. Congenital hypertrophy of retinal pigment epithelium
i. Multiple and bilateral lesions: a sensitive phenotypic marker that can direct clinical screening tests prior to or in lieu of genetic screening in an at-risk member of an FAP kindred
ii. Generally a benign condition but low-grade adenocarcinoma of the retina has been reported in several individuals with this condition
h. Dental abnormalities
i. Unerupted teeth
ii. Congenital absence of one or more teeth
iii. Supernumerary teeth
iv. Dentigerous cysts
v. Odontomas
i. Cutaneous lesions: rarely malignant
i. Fibromas
ii. Lipomas
iii. Sebaceous and epidermoid cysts
iv. Nasopharyngeal angiofibromas
8. Desmoid tumors
a. Also known as mesenteric fibromatosis
b. A relatively common complication of FAP (Sturt and Clark 2006)
i. A lifetime risk for men: 8%
ii. A lifetime risk for women: 13%
c. No metastatic potential but can be both life-threatening or problematic in treatment when the lesions slowly expand:
i. To involve the intra-abdominal cavity
ii. To surround the nervous or vascular systems
d. Conditions which may accelerate the growth:
i. Surgery
ii. Estrogen receptor antagonists
iii. Radiation
iv. Chemotherapy
e. Common recurrence
9. FAP variants
a. Gardner syndrome
i. Refers to FAP with additional extra intestinal phenotypic manifestations accompanying colonic polyposis
a) Osteomas
b) Sebaceous cysts
c) Lipomas
d) Desmoids
e) Dental abnormalities
ii. Caused by mutations in the *APC* gene
b. Attenuated FAP
i. Characterized by the development of significantly fewer colonic adenomas (<100)
ii. Typically right-sided polyps

iii. Seventy percent of patients develop colorectal cancers by age 65 if polypectomy is not performed
iv. Presence of fundic gland polyps, a clue to the possible diagnosis of AFAP

c. Turcot syndrome
i. Characterized by medulloblastoma in association with colonic polyposis and colorectal cancers
ii. Caused by germline *APC* mutations
iii. Variable inter- and intrafamilial phenotypic expression

10. Differential diagnosis with two other main polyposis syndromes and one nonpolyposis syndrome, all of which are associated with an increased risk of GI cancer, especially colorectal cancer (Järvinen 2003)
a. Juvenile polyposis
i. An autosomal dominant disorder
ii. Caused by at least two separate genes
a) *SMAD4/DPC4* in chromosome 18q21
b) *BMPR1A/ALK3* in chromosome 10q21-22
iii. Characterized by multiple juvenile polyps of the colorectum
iv. Also involves the stomach and the small intestine
v. Large polyps
a) Commonly lobulated
b) Adenomatous dysplasia in 50% of cases, giving rise to the increased risk of colorectal cancer

b. Peutz–Jeghers polyposis
i. An autosomal dominant disorder
ii. Caused by mutations of the *LKB1* gene on 19p13.3
iii. Characteristics
a) Mucocutaneous melanin pigmentation
b) Hamartomatous intestinal polyposis
iv. Sites of polyps
a) Affect small intestine preferentially
b) Also affect stomach and large intestine

c. Hereditary nonpolyposis colorectal cancer syndrome (Lynch syndrome)
i. An autosomal dominant disorder
ii. Caused by mutations of three DNA mismatch repair genes
a) *MSH2* (2p21-23)
b) *MLH1* (3p21)
c) *MSH6* (2p16)
iii. More common than the polyposis syndromes
iv. Predominant tumors
a) Colorectal cancer
b) Endometrial cancer
v. Other cancer types: cancers of the stomach, ovary, ureter and renal pelvis, bile ducts, kidney, small intestine, and brain tumors

Diagnostic Investigations

1. Basis of diagnosis of classic FAP
a. Suggestive family history
b. Clinical findings
c. Confirmed by genetic testing whenever possible
2. Screening in FAP (Boardman 2002)
a. Colonoscopic examination for at-risk and *APC* mutation carriers, initiate at 10–12 years of age
b. Flexible sigmoidoscopy for at-risk individuals with unknown mutation status
i. Annually from age 10 to 15
ii. Biennially from age 26 to 35
iii. Every third year from age 36 to 50
c. Upper GI tract endoscopy for at-risk individuals with colorectal polyps and known gene carriers
d. Annual physical examination to assess thyroid nodules
e. Hepatoblastoma screening in children with FAP (at-risk or mutation-positive carriers until age 6)
i. Annual screening by liver ultrasonography
ii. Annual serum α-fetoprotein levels
f. Medulloblastoma screening: brain imaging for symptomatic or known Turcot syndrome kindreds
g. Imagings (King et al. 2000)
i. CT scan for desmoid tumors of the mesentery
ii. MRI to delineate vascular involvement and to predict desmoid growth
3. Screening in AFAP
a. Colonoscopy required for individual at risk for AFAP
b. Continued screening in the individual with AFAP because of the later age of onset of polyps
4. Detection of FAP in known kindreds
a. Retinoscopy: Presence of more than three pigmented ocular fundic lesions confirms the diagnosis of FAP

b. Flexible sigmoidoscopy
c. Presymptomatic *APC* gene testing
   i. Indications (Leggett 2002)
      a) Children and siblings of affected individuals with FAP or AFAP: usually delayed until the early teenage years (10 years or older) when screening by flexible sigmoidoscopy would normally commence
      b) Patients with an unusually high number of colorectal adenomas for their age but not enough to be clinically diagnostic of classical FAP ($\geq$20 cumulative colorectal adenomas, suspected AFAP)
      c) $\geq$100 colorectal adenomas
   ii. Methods (Boardman 2002)
      a) Protein truncation testing of peripheral blood lymphocytes: detects *APC* mutation in more than 80–90% of affected families
      b) Conformation strand gel electrophoresis
      c) Single-strand conformation polymorphism
      d) Direct sequencing
      e) Linkage analysis to markers on chromosome 5q
   iii. Germline *APC* testing: the most efficient means for identifying gene carriers within an FAP kindred
   iv. Direct sequencing targeted at the known region of the *APC* gene if a mutation has already been detected within one member of a kindred
      a) Cost-effective
      b) Nearly 90% accurate means of *APC* testing

5. Genetic tests for *MUTYH* (Half et al. 2009)
   a. A subset of patients that presents with clinical AFAP harbor a recessive disorder caused by the inheritance of mutations in the base-excision-repair gene *MUTYH* (Castellsagué et al. 2008)
   b. *MUTYH* mutation causes the polyposis condition known as *MUTYH* Attenuated FAP (MAP)
   c. It is recessively inherited and patients have either a homozygous or compound heterozygous germline mutations of the *MUTYH* gene.
   d. Recommended for all patients who have tens to hundreds of colorectal adenomas with no identified germline mutation in the *APC* gene and with a family history compatible with an autosomal recessive and rarely autosomal dominant modes of inheritance
   e. Therefore, DNA screening of the *MUTYH* gene should look for both heterozygous and homozygous mutations (Olschwang et al. 2007)

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Not increased in a de novo case
      ii. 50% if a parent is affected
   b. Patient's offspring: a 50% risk of inheriting the condition and virtually all children who inherit the condition will develop polyposis (Leggett 2002)
2. Prenatal diagnosis
   a. Molecular genetic testing of the *APC* gene on fetal DNA obtained from amniocentesis or CVS for fetuses at 50% risk for FAP if a clinically diagnosed relative has an identified disease-causing *APC* gene alteration
   b. Linkage analysis if the family is informative for linked markers
3. Management (Boardman 2002)
   a. Pre- and post-test genetic counseling
      i. A pre-test counseling session covering:
         a) The nature of the disease itself
         b) The genetic aspects
         c) The implications of positive and negative test results on future screenings
         d) On insurability and family relationships
      ii. A post-test counseling session
         a) Disclosure of the results
         b) Addressing psychological consequences
   b. Potential consequences of genetic testing for hereditary colorectal cancer (Trimbath and Giardiello 2002)
      i. Positive consequences if the result is gene positive (the disease-causing mutation detected)
         a) Removal of uncertainty
         b) Early detection of polyps and prevention of cancer
         c) Greater ability to plan the future including family and career decisions

d) Increased compliance with colonic screening/surveillance
e) Greater choice of surgical and medical management

ii. Negative consequences if the result is gene positive (the disease-causing mutation detected)
a) Psychological distress, including anxiety, depression, anger, or denial
b) Changes in family psychosocial dynamics
c) Stigmatization
d) Increased fear about surgery or death
e) Children at 50% risk of disease
f) Guilt/worry about children
g) Colon surgery and possible lifestyle changes

iii. Positive consequences if the result is gene negative (truly negative for gene mutation identified in family)
a) Removal of uncertainty
b) Children not at risk
c) Fewer medical exams and costs
d) Better insurability

iv. Negative consequences if the result is gene negative (truly negative for gene mutation identified in family)
a) Survival guilt (guilt about being unaffected when other family members are affected)
b) Changes in family psychosocial dynamics

v. Negative consequences if the result is inconclusive (no pedigree mutation found or variant of unknown significance)
a) False sense of security
b) Does not rule out risk for disease
c) Need for continued screening
d) Confusion/anxiety

c. FAP
i. Prophylactic surgery remains the best means to minimize the risk of developing colorectal cancers
ii. Consider colectomy
a) By late teen years for cancer prophylaxis for both gene carriers and at-risk individuals with polyposis
b) Without colectomy, colorectal cancer is inevitable, appearing approximately 10–15 years after the onset of polyposis
iii. Specific surgical recommendation
a) Proctocolectomy with mucosectomy
b) Ileal pouch anal anastomoses
c) Ileorectal anastomosis
iv. Surgical removal of osteomas for cosmetic reasons
v. Treatments for desmoid tumors
a) Surgical excision: associated with high rates of recurrence
b) Non-steroidal anti-inflammatory drugs (sulindac, celecoxib) (use before colectomy): remains experimental
c) Antiestrogens
d) Cytotoxic chemotherapy
e) Radiation
vi. Celecoxib, a selective cyclooxygenase-2 (prostaglandin synthetase) inhibitor (Corredor et al. 2001)
a) Reduces by 28% the mean number of polyps in adult patients with FAP
b) Potential use of this class of drugs as chemopreventive and therapeutic agents: subject of intense current investigation

d. AFAP
i. Endoscopy and polypectomy
ii. Surgery: ileorectostomy rather than ileal pouch anal anastomosis is recommended because the rectum is relatively spared by polyposis
a) For recurrent, numerous polyposis
b) For the presence of aggressive histologic features
iii. Continued need for annual endoscopic evaluation of the rectal remnant

e. Prognosis (Half et al. 2009)
i. Most patients with clinical FAP can be identified and have their diagnosis confirmed by genetic testing
ii. Individuals with FAP carry a 100% risk of colorectal cancer that is reduced almost absolutely when patients enter a screening and treatment program
iii. Once proctocolectomy has been performed, the risk of ampullary and duodenal cancer is significant and requires lifelong upper gastrointestinal surveillance that has been shown to save lives of FAP patients
iv. Desmoids need to be identified early while small and not causing local perturbations

v. Duodenal cancer and desmoids are the two main causes of mortality after total colectomy has removed the risk for CRC
vi. The sociological, psychological, and physiological issues related to the diagnosis and treatment of FAP need to be addressed
vii. The colectomy and ensuing change in bowel habits frequently lead to dietary changes that can be unbalanced and lead to vitamin–mineral deficiencies.

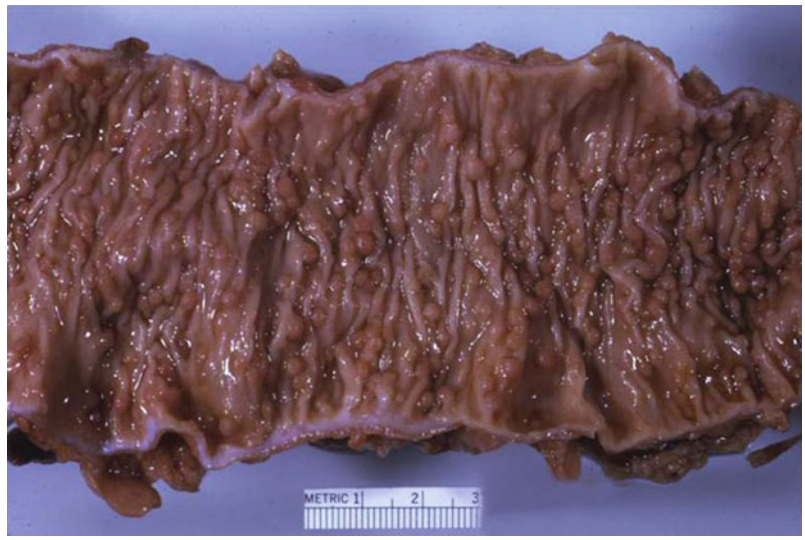

Fig. 1 Colon of an 8-year-old girl with familial adenomatous polyposis. Numerous small polyps were present on the mucosal surface of the entire colon. The polyps measured up to 3 mm in size. Occasional polyps had a slender stalk, up to 2 mm in length. Histologically, the polyps were of tubular (adenomatous) type

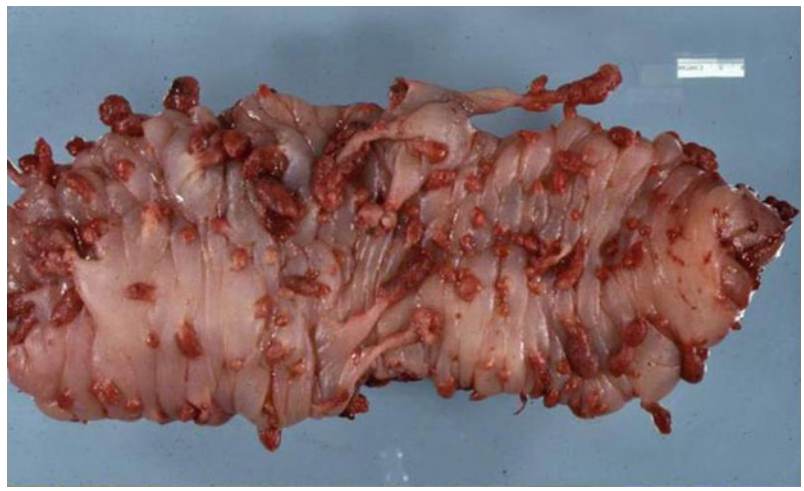

Fig. 2 A segment of colon showing juvenile polyposis. The polyps are large and lobulated. Stalks are present in some of them. The number of polyps is not as numerous as seen in Fig. 1 (AFP)

Fig. 3 A 50-year-old female had a history of multiple removals of numerous pedunculated and sessile polyps (adenomatous) during past 12 years. Her mother was diagnosed with colon cancers and had most colon surgically removed. Molecular testing of the patient showed intron 3 alteration [IVS3(−3)T > A]. Aberrations within the intron can affect normal splicing of RNA. Whether this is a disease-causing mutation or a normal variant cannot be determined without determination of the mother's DNA status

Familial Hyperlysinemia

Familial hyperlysinemia is an inborn error of metabolism caused by a defect in the bifunctional protein α-aminoadipic semialdehyde synthase.

Synonyms and Related Disorders

Alpha-aminoadipic semialdehyde synthase deficiency; L-lysine NAD-oxido-reductase deficiency; Lysine: alpha-ketoglutarate reductase deficiency

Genetics/Basic Defects

1. Inheritance: autosomal recessive
2. A heterogeneous group of at least three disorders
   a. Caused by mutations in the gene (mapped to 7q31.3) encoding α-aminoadipic semialdehyde synthase (AASS), the bifunctional protein that contains both lysine-ketoglutarate reductase (LKR) and saccharopine dehydrogenase (SDH) activity.
   b. Deficiency in lysine-ketoglutarate reductase (LKR) and/or saccharopine dehydrogenase (SDH) activities leads to a clinical phenotype characterized by hyperlysinemia, lysinuria, and variable saccharopinuria.
   c. Deficiency in saccharopine oxidoreductase activity, along with deficient LKR and SDH activities, is also observed in children with familial hyperlysinemia.

Clinical Features

1. Mental retardation of varying degree
2. Other neuromuscular manifestations
   a. Poor muscle tone (hypotonia)
   b. Muscle weakness
   c. Clumsy hand movements
   d. Cross adductor reflexes
   e. Ankles clonus
   f. High-arched feet
   g. Awkward gait
   h. Hyperactive deep tendon reflexes
   i. Seizures
   j. Progressive spastic paraparesis/diplegia
3. Developmental delay, especially speech delay
4. Hyperactive behavior
5. Ligamentous laxity
6. Ocular manifestations
   a. Bilateral subluxated lenses (ectopia lentis)
   b. Lateral rectus muscle paresis
   c. Bilateral spherophakia
7. Hyperlysinemia alone may not be associated with a clinical phenotype.
8. Differential diagnosis
   a. Hyperlysinemia: periodic hyperlysinemia with ammonia intoxication
   b. Ectopia lentis
      i. Marfan syndrome
      ii. Homocystinuria
      iii. Weill-Marchesani syndrome
      iv. Ehlers–Danlos syndromes
      v. Dominant and recessive forms of inherited subluxation of the lens

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_86,
© Springer Science+Business Media, LLC 2012

Diagnostic Investigations

1. Plasma amino acid quantitative analysis: hyperlysinemia
2. Urinary amino acid quantitative analysis: hyperlysinuria
3. Urinary organic acid analysis: variable saccharopinuria
4. Cultured skin fibroblasts: absent lysine-ketoglutarate reductase and saccharopine dehydrogenase activities
5. Molecular genetic study: homozygous deletion in *AASS* gene
6. EEG for seizures

Genetic Counseling

1. Recurrence risk
   a. Patient's sib: 25%
   b. Patient's offspring: not increased unless the spouse is a carrier in which case 50% of the offspring will be affected
2. Prenatal diagnosis has not been reported.
3. Management
   a. Dietary control with reduction in lysine intake
   b. Other supportive therapies

Fig. 1 A 27-year-old female with hyperlysinemia showing global delay, spasticity, rigidity, and multiple joint contractures. She was diagnosed to have hyperlysinemia since about 1 1/2 years of age with markedly elevated serum lysine of 1,618 μM (45–144). As a neonate, she had frequent emesis and noted to be stiff and irritable with progressive developmental delay. She began to walk with a ramp and rails until approximately 4 years of age when she started to develop increased spasticity and significant scissoring, necessitating adductor release. On the recent plasma amino acid analysis, lysine was markedly elevated at 1,252 μM (41–225)

Familial Mediterranean Fever

Familial Mediterranean Fever (FMF), also known as an autoinflammatory syndrome, is the most frequent periodic fever syndrome, affecting not only eastern Mediterranean people such as non-Ashkenazi Jews, Armenians, Arabs, and Turks but also reported throughout the world's populations.

Genetics/Basic Defects

1. An autosomal recessive disorder caused by missense mutations in the *MEFV* gene, located on the short arm of chromosome 16 (16p13.3). The *MEFV* gene is responsible for encoding a protein called pyrin or marenostrin.
2. Pathogenesis
   a. Partially elucidated only after the identification of pyrin or marenostrin
   b. A new macromolecular complex, called inflammasome, seems to play a major role in the control of inflammation and it might be involved in the pathogenesis of FMF.
3. Phenotype expression of the FMF should depend on the presence of a homozygote or heterozygote genotype for the *MEFV* gene mutations.
4. Genotype-phenotype correlation, however, is complex due to influence of genotype and the ethnic and environmental factors, playing a role in the clinical outcome with a very wide clinical spectrum
5. Etiology of the periodicity and the self-limited nature remain largely unexplained

Clinical Features

1. Clinical manifestations (Fonnesu et al. 2009)
   a. Onset of the disease: occurs before the age of 30 in almost all patients
   b. Recurrent attacks
      i. Last 1–4 days on average
      ii. Resolve spontaneously with a frequency varying from once a week to once every 3–4 months or, sometimes, years
      iii. Severity and frequency of attacks have an inter- and intra-individual variations
   c. Presence of fever: absent in rare cases
   d. Gastrointestinal symptoms
      i. Abdominal pain: localized or diffuse
      ii. Stypsis/diarrhea
      iii. Associated disease
   e. Musculoskeletal symptoms
      i. Arthralgia: transient or abortive
      ii. Arthritis
         a) Acute asymmetric nondegenerative mono/oligoarthritis
         b) Protracted arthritis
         c) Chronic degenerative arthritis
         d) Migrating polyarthritis: usually induced by exertion
      iii. Myalgias
      iv. HLA-B27 negative sacroiliitis during the prodromes or the attack
   f. Cardiopulmonary symptoms
      i. Pleuritis
      ii. Pericarditis

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_87,
© Springer Science+Business Media, LLC 2012

   g. Cutaneous symptoms: erysipelas-like erythema
   h. Vasculitis
      i. Henoch–Schoenlein purpura
      ii. Polyarteritis nodosa
      iii. Behcet disease
   i. Other manifestations
      i. Acute orchitis
      ii. Mollaret's meningitis
      iii. Splenomegaly
      iv. Retinopathy
2. Known trigger factors
   a. Physical and emotional stress
   b. Exposure to cold
   c. Fat-rich meals
   d. Banal infections
   e. Drugs such as cisplatin
   f. Menstrual cycle
   g. Presence of *Helicobacter pylori*
3. Secondary amyloidosis: the most devastating and important long-term complication
   a. Predominantly renal
   b. Genetic risk factors
      i. Genetic factors linked to *MEFV* gene
      ii. Genetic factors linked to modifier genes (Seroamyloid A gene – SAA – and Major Histocompatibility Complex class 1 chain-related A gene – MICA)
   c. Nongenetic factors
      i. Male gender: males four times higher than in females
      ii. Environmental factors: country identified as the primary risk factor for renal amyloidosis (e.g., Armenians residing in Armenia have higher incidence than those who reside in the USA)
4. Two phenotypes of FMF (Shohat et al. 2009)
   a. FMF type I
      i. Characterized by recurrent short episodes of inflammation and serositis including:
         a) Fever
         b) Peritonitis
         c) Synovitis
         d) Pleuritis
         e) Rarely pericarditis and meningitis
      ii. Inter-individual and intra-familial variation of symptoms
      iii. Amyloidosis which can lead to renal failure is the most severe complication of FMF type I
   b. FMF type II: characterized by amyloidosis as the first clinical manifestation of disease in an otherwise asymptomatic individual (Pras 1998; Langevitz et al. 1999; Shohat et al. 1999; Koné Paut et al. 2000)
5. Differential diagnosis (Lidar and Livneh 2007)
   a. Abdominal attacks (recurrent peritonitis)
      i. Appendicitis
      ii. Diverticulitis
      iii. Cholecystitis
      iv. Pyelonephritis
      v. Pelvic inflammatory disease
      vi. Pancreatitis
   b. Recurrent abdominal attacks (without peritonitis)
      i. Peptic disease
      ii. Renal colic
      iii. Endometriosis
      iv. Menstruation pain
      v. Irritable bowel syndrome
   c. Chest attacks (recurrent pleuritic chest pain)
      i. Pulmonary embolism
      ii. Pleuritis (idiopathic, infectious, autoimmune)
      iii. Pericarditis (idiopathic, infectious, autoimmune)
   d. Joint attacks (recurrent synovitis)
      i. Gout
      ii. Pseudogout
      iii. Spondyloarthropathy
      iv. Juvenile idiopathic arthritis
   e. Febrile attacks (recurrent)
      i. Lymphoma
      ii. Infections (malaria, relapsing fever)
      iii. PFAPA (periodic fever, aphtous stomatitis, pharyngitis, adenopathy)
   f. Non-FMF inflammatory disorders (Ozen 2003)
      i. Inflammatory bowel disease
      ii. Hyper IgD syndrome
      iii. Tumor necrosis factor receptor–associated periodic fever syndrome
      iv. Acute intermittent porphyria
      v. Familial cold urticaria or familial cold auto-inflammatory syndrome
   g. Systemic lupus erythematosus
   h. Adult Still disease
   i. Muckle–Wells syndrome
   j. Chronic infantile neurological cutaneous arthropathy
   k. Neonatal onset multi-system inflammatory disease syndrome
   l. Periodic fever-adenopathy-pharyngitis-aphtosis syndrome

Diagnostic Investigations

1. Pras diagnostic criteria (Pras 2002)
   a. Recurrent short inflammatory attacks
   b. A favorable response to colchicine treatment
2. Tel-Hashomer diagnostic criteria (Livneh et al. 1997; Fonnesu et al. 2009)
   a. Major criteria
      i. Fever and serositis
      ii. Amyloidosis AA (without risk factors or other chronic inflammatory diseases)
      iii. Effectiveness of colchicine
   b. Minor criteria
      i. Recurrent attacks of fever
      ii. Erysipela-like erythema
      iii. Relatives affected by FMF
   c. Definitive diagnosis: two major criteria or one major criterion and two minor criteria
   d. Probable diagnosis: one major criterion and one minor criterion
3. Tel-Hashomer revised diagnostic criteria (Fonnesu et al. 2009)
   a. Presence of typical attacks
      i. Fever
      ii. Serositis
   b. Positive response to colchicine
4. Criteria for the diagnosis of FMF (Lidar and Livneh 2007)
   a. Major criteria: typical attacks (recurrent, febrile, and short)
      i. Peritonitis (generalized)
      ii. Pleuritis (unilateral) or pericarditis
      iii. Monoarthritis (hip, knee, ankle)
   b. Minor criteria
      i. Incomplete (painful and recurrent) attacks involving one or more of the following sites:
         a) Abdomen
         b) Chest
         c) Joint
      ii. Exertional leg pain
      iii. Favorable response to colchicine
   c. Supportive criteria
      i. Family history of familial mediterranean fever
      ii. Appropriate ethnic origin
      iii. Age <20 years at disease onset
      iv. Features of attacks
         a) Severe, requiring bed rest
         b) Spontaneous remission
         c) Symptom-free interval
         d) Transient inflammatory response with one or more abnormal test result(s) for white blood cell count, erythrocyte sedimentation rate, serum amyloid A, and/or fibrinogen
      v. Episodic proteinuria/hematuria
      vi. Unproductive laparotomy or removal of "White" appendix
      vii. Consanguinity of parents
   d. Requirements for diagnosis of FMF
      i. Greater than or equal to one major criteria, or
      ii. Greater than or equal to two minor criteria, or
      iii. One minor plus >5 supportive criteria
5. Molecular genetic study of the MEFV gene to confirm the diagnosis
6. General clinical laboratory findings
   a. Leukocytosis
   b. Leukopenia associated with colchicine treatment
   c. Elevated acute-phase reactant proteins such as ESR, CRP, fibrinogen, haptoglobin, C3, C4, and serum amyloid A (SAA) protein
   d. Urinalysis for the presence of proteinuria
7. Diagnostic algorithm (Lidar and Livneh 2007)
   a. Clinical criteria
   b. Results of MEFV mutation analysis
   c. Therapeutic trial, monitored by clinical response and SAA levels
8. Renal biopsy: indicated in all FMF patients who develop proteinuria or nephrotic syndrome

Genetic Counseling

1. Recurrence risk
   a. Both parents carrying at least one *MEFV* gene mutation
   b. Patient's sib
      i. Twenty-five percent with MFM
      ii. Fifty percent with MFM carrier
   c. Patient's offspring
      i. All offspring inherit one *MEFV* gene mutation from the proband
      ii. Low recurrence risk unless the spouse is affected or a carrier of *MEFV* gene mutation
2. Prenatal diagnosis (Shohat et al. 2009)
   a. Possible for pregnancies at increased risk by analysis of DNA extracted from fetal cells obtained by amniocentesis or chorionic villus

sampling, giving that both disease-causing alleles of an affected family member must be identified or linkage established in the family before prenatal testing can be performed

b. Prenatal diagnosis of FMF, a treatable condition associated with a good prognosis with early treatment, may be controversial if the testing is being considered for the purpose of pregnancy termination rather than early diagnosis

3. Management
   a. Colchicine
      i. Should be introduced as soon as the diagnosis is made and continued for life
      ii. Reduces the attack frequency, severity, and duration in most FMF patients
      iii. Can prevent, arrest, and even reverse renal amyloidosis, even if it fails to stop the attacks (Lidar et al. 2004; Kallinich et al. 2007)
      iv. Also recommended for treatment of amyloidosis
      v. Higher colchicines dosage, up to 2 mg/day, may be needed in high-risk patients such as after kidney transplantation or patients with amyloidosis
   b. No effective mean to treat acute attacks of FMF
      i. Methylprednisolone may relieve abdominal pain and tenderness (Erken et al. 2008), although steroids in general play no role
      ii. Interferon (IFN)-α injection at the earliest signs of an attack may provide some benefit (Tunca et al. 2004; Tweezer-Zaks et al. 2008)
   c. Controversy in treating asymptomatic individuals with mutations in the *MEFV* gene who may or may not develop FMF in the future

Fig. 1 A 40-year-old female was diagnosed to have familial Mediterranean fever. She has a history of low grade fever, abdominal pain, joint pain, and peritonitis. She responded well to colchicine treatment. She is a compound heterozygote for two different mutations: MM680I and V726A, in exon 10 of the *MEFV* gene which confirms the clinical diagnosis. Her brother and sister are similarly affected. Her 5-year-old daughter was found to be heterozygous for the V726A FMF mutation. The parents are from Egypt

Fanconi Anemia

In 1927, Fanconi described a familial form of aplastic anemia in three brothers with short stature, hypogonadism, and skin pigmentation. The incidence of Fanconi anemia (FA) is estimated to be 1 in 360,000 births. The carrier frequency is estimated as 1 in 300 in Europe and the United States. Founder mutations have been described in Ashkenazi Jews, who have carrier frequency of 1 in 89 (Tischkowitz and Hodgson 2003).

Genetics/Basic Defects

1. Inheritance
   a. Autosomal recessive
   b. Genetically and phenotypically heterogeneous
2. Presence of at least 13 complementation groups delineated by cell fusion studies (Dokal 2000; Blom et al. 2004)
   a. FA-A (65–70%)
   b. FA-B (<2%)
   c. FA-C (10–15%)
   d. FA-D1
   e. FA-D2
   f. FA-E (2–5%)
   g. FA-F (<2%)
   h. FA-G (10%)
   i. FA-I
   j. FA-J
   k. FA-L
   l. FA-M
   m. FA-N
3. The FA pathway is composed of at least 13 genes. Each of these genes, when biallelically mutated causes FA. (Green and Kupfer 2009)
   a. *FANCA*, mapped to 16q24.3
   b. *FANCB*, mapped to Xp22.31
   c. *FANCC*, mapped to 9q22.3
   d. *FANCD1*, mapped to 13q12.13
   e. *FANCD2*, mapped to 3p25.3
   f. *FANCE*, mapped to 6p21.22
   g. *FANCF*, mapped to 11p15
   h. *FANCG*, mapped to 9p13
   i. *FANCI*, mapped to 15q25-26
   j. *FANCJ*, mapped to 17q22-24
   k. *FANCL*, mapped to 2p16.1
   l. *FNACM*, mapped to 14q21.3
   m. *FNACN*, mapped to 16p12
4. A candidate-gene approach leads to the breast cancer susceptibility gene BRCA2 as the gene defective in FA-D1 patients. The Fanconi–BRCA pathway is activated in response to certain kinds of DNA damage, particularly DNA agents that cause double-strand breaks in DNA such as ultraviolet light, ionizing radiation, and cisplatin.
5. FA cells are hypersensitive to cross-linking agents such as diepoxybutane (DEB), nitrogen mustard (NTM), and mitomycin C (MMC): induction of chromosomal aberrations (breaks and rearrangements) (Blom et al. 2004)
6. Reserved mosaicism
   a. Not infrequent in Fanconi anemia
   b. Presence of two populations of lymphocytes in mosaic Fanconi anemia patients
      i. One being hypersensitive to the clastogen
      ii. The other normal
   c. Phenotypic reversion to normal
      i. Correlated with intragenic homologous recombination in compound heterozygous

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_88,
© Springer Science+Business Media, LLC 2012

patients giving rise to the segregation of a wild type allele at the disease locus
ii. The resulting cells are thus essentially cured from the disease.
iii. Progeny from a reverted stem cell expected to have a proliferative advantage over affected cells and thus may gradually expand and take over hematopoiesis
d. Patients with a high proportion of reverted cells may be falsely diagnosed as negatives.
7. Defective FA functional pathway
a. Defective DNA repair
b. Prolonged G2/M transition in the cell cycle
c. Increased oxygen sensitivity
d. Abnormally regulated apoptosis and accelerated telomere shortening
e. Defective hemopoiesis

Clinical Features

1. Variable clinical expression and severity
2. Hematological abnormalities secondary to bone marrow failure (>90%)
a. Clinical hallmark of Fanconi anemia
b. Usually starting in childhood
c. Increased incidence of aplastic anemia, myelodys plastic syndrome, and acute myeloid leukemia
d. Initial presentation
i. Pallor
ii. Bleeding
iii. Recurrent infections
e. Thrombocytopenia or leukopenia typically preceding anemia
f. Severe progressive pancytopenia due to loss of hematopoietic stem cells: the cardinal clinical feature
g. Increased risk of infections due to neutropenia
h. Sweet syndrome (neutrophilic skin infiltration) reported in a few patients with Fanconi anemia and myelodysplastic syndrome
3. Diverse congenital abnormalities (>63%)
a. Growth retardation
b. Short stature (60%)
c. Upper limb anomalies (50%)
i. Mainly radius and thumb abnormalities
a) Absent, hypoplastic, or supernumerary thumbs with hypoplastic thenar eminence
b) Absent, hypoplastic radii, and ulnae associated with abnormal thumbs
c) Absent first metacarpal
ii. Clinodactyly
iii. Polydactyly
iv. Short fingers
v. Transverse palmar crease
d. Other skeletal abnormalities
i. Short webbed neck with low hairline
ii. Spine anomalies
a) Spina bifida
b) Scoliosis
c) Sacrococcygeal sinus
d) Other vertebral anomalies
iii. Lower limb anomalies
a) Toe syndactyly
b) Pes planus
c) Abnormal toes
d) Congenital hip dislocation
e. Skin pigmentary changes (65%)
i. Generalized hyperpigmentation
ii. Café au lait spots
iii. Hypopigmentation
f. Eye anomalies (25%)
i. Microphthalmia
ii. Strabismus
iii. Epicanthal folds
iv. Hypertelorism/hypotelorism
v. Ptosis
vi. Cataracts
vii. Epiphora
viii. Nystagmus
g. Ear anomalies (10%)
i. Deafness, usually conductive secondary to middle ear abnormalities
ii. Abnormal pinna
iii. Stenosis or atresia of the external auditory meatus
iv. Low-set ears
h. Heart disease
i. Congenital heart disease
a) Patent ductus arteriosus
b) Ventricular septal defect
c) Pulmonary stenosis
d) Aortic coarctation

ii. Cardiomyopathy
i. Renal anomalies (25%)
i. Kidney
a) Pelvic kidneys
b) Horseshoe kidneys
c) Hypoplastic/dysplastic kidneys
ii. Collecting system (hydronephrosis, hydroureter, reflux)
iii. Abnormal artery
j. Gastrointestinal problems
i. Atresia
a) Esophagus
b) Duodenum
c) Jejunum
ii. Tracheoesophageal fistula
iii. Anteriorly placed anus
iv. Imperforate anus
v. Persistent cloaca
vi. Meckel diverticulum
vii. Umbilical hernia
viii. Abnormal biliary ducts
ix. Megacolon
x. Abdominal diastasis
xi. Budd–Chiari syndrome
xii. Annular pancreas
k. CNS abnormalities
i. Microcephaly
ii. Hydrocephalus
iii. Absent septum pellucidum
iv. Neural tube defects
l. Hypogonadism in males
i. Underdeveloped gonads
ii. Cryptorchidism
iii. Hypospadias
iv. Defective spermatogenesis (infertility)
v. A few males with Fanconi anemia fathered children
m. Hypogonadism in females
i. Hypogenitalia
ii. Bicornuate uterus
iii. Absent uterus or vagina
iv. Ovarian atresia
v. Delayed menarche
vi. Irregular menses
vii. Early menopause
viii. Successful pregnancies with live-born children observed
n. Absence of obvious congenital abnormalities in approximately 33% of patients with Fanconi anemia
4. Predisposition to malignancy
a. Hematologic tumors (60%)
i. Acute myelogenous leukemia (30%)
ii. Myelodysplastic syndrome (26%)
iii. Acute lymphocytic leukemia
iv. CMMOL
v. Burkitt lymphoma
b. Non-hematologic tumors (40%)
i. Liver tumors (9%)
a) Adenoma
b) Hepatocellular carcinoma
c) Adenocarcinoma
ii. Brain tumor (2%)
a) Medulloblastoma
b) Astrocytomas
iii. Renal tumors (3%)
a) Wilm tumor
b) Renal cell carcinoma
c) Nephroblastoma
iv. Squamous cell carcinoma (20%)
a) Head and neck
b) Vulvar
c) Cervix
d) Cutaneous
e) Anus
f) Esophagus
v. Miscellaneous tumors (6%)
a) Breast carcinoma
b) Basal cell carcinoma
c) Neuroblastoma
d) Desmoid tumor
e) Gonadoblastoma
f) Melanoma
g) Neurilemmoma
h) Osteogenic sarcoma
5. Cumulative probability of developing leukemia, liver tumors, and solid tumors in FA patients
a. Close to 40% by age 30
b. About 50% by age 45
c. An astounding 76% by age 45
6. Prognosis
a. Mean survival: 16 years
b. Main causes of death

i. Pancytopenia which develops in the first decade of life
ii. Associated progressive microcytosis
iii. Extremely high probability of developing bone marrow failure
iv. A predisposition to malignancy, particularly acute myeloid leukemia and aplastic anemia

7. Differential diagnosis (Tischkowitz and Hodgson 2003)
   a. VATER/VACTERL association overlap with FA
      i. Vertebral defects
      ii. Tracheo-esophageal atresia
      iii. Renal defects
      iv. Radial ray defects
   b. Diamond–Blackfan anemia (Aase syndrome)
      i. Defective erythroid progenitor maturation
      ii. Normochromic or macrocytic anemia
      iii. Congenital malformations in over one third of patients
         a) Head (micrognathia, cleft lip)
         b) Upper limb defects
         c) Genitourinary anomalies
      iv. A heterogeneous disorder
         a) Sporadic in most cases
         b) Autosomal dominant in some cases
         c) Rarely autosomal recessive inheritance
   c. Nijmegen breakage syndrome
      i. A rare autosomal recessive disorder
      ii. Resulting from mutations in NBS1, which codes for the nibrin protein
      iii. Clinical characteristics
         a) Immune deficiency
         b) Microcephaly
         c) Hypersensitivity to ionizing radiation
   d. Other chromosomal breakage syndromes (Bloom syndrome, ataxia-telangiectasia)
      i. Also exhibit high rates of spontaneous chromosomal breakage
      ii. Only FA cells exhibit increased chromosomal breakage in response to DEB
   e. Thrombocytopenia-absent radii (TAR) syndrome
   f. Holt–Oram syndrome

Diagnostic Investigations

1. Difficult to diagnose FA because of phenotypic diversity
2. Hematologic investigation
   a. Progressive decrease in peripheral blood counts, often present by 7–8 years of age
      i. Thrombocytopenia
      ii. Leukopenia
      iii. Anemia
   b. Macrocytic red blood cells, often with increased fetal hemoglobin
   c. Generally increased serum erythropoietin concentration
   d. Hypocellular or dysplastic bone marrow
   e. Bone marrow failure with pancytopenia
   f. Bone marrow cytogenetic testing: Cytogenetic abnormalities may progress to leukemia or myelodysplastic syndrome
3. DEB testing
   a. 10- to 100-fold increased chromosomal breakage (breaks, rearrangements, radials, exchanges) of Fanconi anemia cells after incubation of the patient's cells with chemical clastogen, DEB
   b. Highly sensitive and specific test for Fanconi anemia
   c. Allowing diagnosis of Fanconi anemia in persons with diverse clinical features including those without clinically detectable congenital abnormalities
   d. Used successfully in prenatal diagnosis of Fanconi anemia
   e. Remains underutilized mainly because there are some clinical conditions in which FA is not usually suspected
   f. Disadvantage
      i. Requires a high degree of cytogenetic expertise and meticulous attention to cell culture and safety conditions
      ii. Fails to distinguish among Fanconi anemia patients in different complementation groups
      iii. Fails to identify heterozygote carriers of mutant Fanconi anemia genes
4. Cell cycle test
   a. Alternative to cytogenetic testing
   b. Diagnostic potential of the cell cycle test for Fanconi anemia
   c. Based on the observation that Fanconi anemia cells experience difficulties in traversing the S and G2 compartments of the cell cycle
   d. Limitation of cell cycle test
      i. Applicable only to nonleukemic cells
      ii. Confirmatory DEB studies required in cases with evidence for G2-phase arrest

5. Molecular genetic testing
   a. Used primarily for carrier detection and prenatal diagnosis
   b. Complicated by the presence of 13 genes, which are responsible for the 13 FA complementation groups [A, B, C, D1 (BRCA2), D2, E, F, G, I, J, L, M, and N]
   c. Sequence analysis for *FANCA*, *FANCB*, *FANCC*, *FANCE*, *FANCF*, *FANCG*, and *FANCI*
   d. Mutation analysis for the common Ashkenazi Jewish *FANCC* mutation (IVS4+4A>T)
   e. Linkage analysis once a family has been assigned to a complementation group by a functional assay or by the detection of a specific mutant allele using highly polymorphic microsatellite markers located in close proximity to both FAA and FAAC genes
      i. Used for carrier detection
      ii. Used for prenatal diagnosis
6. Cancer surveillance
   a. Annual bone marrow examination provides early evidence for myelodysplastic syndrome or leukemia
      i. Aspirate for cell types
      ii. Biopsies for cellularity
      iii. Cytogenetics
   b. Liver function tests and ultrasound examinations to identify adenomas or hepatomas before becoming symptomatic
   c. Screening for solid tumors: more complex because of multiplicity of cancer types
      i. Direct visualization of the oropharynx and fiberoptic endoscopy for screening for aerodigestive cancers and precancerous lesions
      ii. Gynecologic examinations for vulvar and cervical tumors beginning with menarche

Genetic Counseling

1. Recurrence risk (Taniguchi 2008)
   a. Patient's sib
      i. Autosomal recessive inheritance in all but one of the FA complementation groups
         a) Twenty-five percent chance of inheriting both mutation alleles and being affected
         b) Two third chance of being carriers in unaffected sibs who have a normal DEB test
      ii. X-linked recessive inheritance (FANCB mutation)
         a) Risk to sibs depends upon the carrier status of the mother
         b) Fifty percent of male sibs who inherit the mutation will be affected
         c) Female sibs who inherit the mutation will be carriers and will usually not be affected
         d) Risk to sibs is low but greater than that of the general population because of the possibility of germline mosaicism if the disease-causing mutation cannot be detected in the DNA extracted from leukocytes of the mother of the only affected male in the family
   b. Patient's offspring: recurrence risk not increased unless the spouse is a carrier, in which case 50% of offspring will be affected; otherwise all offspring of the affected parent will be carriers who will be asymptomatic
2. Prenatal diagnosis
   a. Prenatal ultrasonography to evaluate fetal anomalies consistent with FA
   b. Prenatal diagnosis available to at-risk families by CVS, amniocentesis, or cordocentesis
      i. Demonstration of chromosome instability by DEB test
      ii. Molecular genetic testing of FA gene (*FANCA*, *FANCB*, *FANCC*, *FANCE*, *FANCF*, *FANCG*, and *FANCI*) mutations if the disease-causing mutations are previously characterized in a given family
      iii. Preimplantation genetic diagnosis possible for families in which the disease-causing mutations have been identified by using molecular methods, resulting in implantation of an embryo without FA mutations
3. Management
   a. Supportive care
      i. Developmental assessment
      ii. HLA typing of the patient, sibs, and parents in anticipation of possible bone marrow transplantation
      iii. Full blood typing
      iv. Packed red blood cells transfusions for symptomatic anemia
      v. Platelet transfusions for symptomatic thrombocytopenia
      vi. Antimicrobials for secondary infections

b. Surgical care
   i. Splinting and hand surgery indicated for thumb and radial anomalies
   ii. Surgery for congenital heart defects and gastrointestinal anomalies such as TE fistula
c. Transient response
   i. Androgens (oxymetholone) shown to improve the blood counts in approximately 50% of patients
   ii. Corticosteroids
   iii. Cytokines
   iv. Granulocyte-macrophage colony-stimulating factor and granulocyte colony-stimulating factor (shown to improve the neutrophil count in some patients) for symptomatic Neutropenia
d. Hematopoietic stem cell transplantation may cure aplastic anemia and prevent myelodysplastic syndrome or leukemia
   i. Peripheral blood stem cells
   ii. Allogenic bone marrow transplant with a histocompatible sibling donor: treatment of choice
   iii. Umbilical cord blood offers a potential source of hematopoiesis stem cells for Fanconi anemia patients without sibling matches
e. Successful transplantation obtained by using in vitro fertilization and preimplantation genetic diagnosis of hematopoietic stem cells from a donor selected on the basis of specific, desirable disease and HLA characteristics
   i. Select embryos which are HLA-identical to the patient and unaffected by FA for intrauterine transfer and let the pregnancy continue to term
   ii. Obtain the umbilical cord blood from the healthy newborn infant and use it as the source of HLA-identical hematopoietic stem cells to reconstitute normal hematopoiesis in the affected sibling
f. Follow up surveillance for solid malignancies
g. Gene therapy not currently available

Femoral Hypoplasia – Unusual Facies Syndrome

In 1973, Daentl et al. delineate a distinctive pattern of malformation which includes femoral hypoplasia and unusual facies in four unrelated individuals. The syndrome is also known as femoral facial syndrome.

Synonyms and Related Disorders

Femoral-facial syndrome

Genetics/Basic Defects

1. Inheritance
   a. Sporadic in most cases
   b. Familial cases with autosomal dominant inheritance reported
   c. Multifactorial trait in some families
   d. Maternal diabetes causative in more than 20% of the reported cases
2. Possible causes
   a. Fetal constraint (deformation) due to severe oligohydramnios
   b. Maternal diabetes (disruption)
   c. Undetermined etiology

Clinical Features

1. Characteristic facial features
   a. Up-slanting eyes
   b. A short nose with broad tip
   c. Elongated philtrum
   d. Thin upper lip
   e. Micrognathia
   f. Cleft palate
   g. Low-set ears
2. Hypoplasia/aplasia of the femurs
   a. Usually asymmetric
   b. Presence of some degree of shortened lower extremities in most cases
   c. Variable shortening of the lower extremities depending on the absence or degree of hypoplasia of the femurs, with or without absent fibulas
3. Short stature due to reduced length of the lower extremities
4. Normal intelligence
5. Other anomalies
   a. Club foot in most cases
   b. Occasional polydactyly/syndactyly
   c. Sprengel's deformity
   d. Upper extremity hypoplasia
   e. Restricted motion of the elbows
   f. Stiff shoulders
   g. Pelvic and spinal abnormalities
   h. Inguinal hernia
   i. Genitourinary anomalies
      i. Hypoplastic/dysplastic kidneys
      ii. Polycystic kidneys
      iii. Cryptorchidism
      iv. Genital hypoplasia
         a) Hypoplastic penis
         b) Hypoplastic labia majora
      v. Inferiorly placed kidneys
      vi. Septated urinary bladder
   j. Rare cardiovascular anomalies
      i. Ventricular septal defect
      ii. Pulmonary stenosis
      iii. Truncus arteriosus

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_89,
© Springer Science+Business Media, LLC 2012

6. Differential diagnosis (Pryde et al. 2003)
   a. Kyphomelic dysplasia
      i. Femur
         a) Symmetrically short
         b) Severe bowing
      ii. Other long bones
         a) Mild shortening
         b) Minimal bowing
      iii. Genitourinary: no abnormalities
      iv. Face: micrognathia
      v. Scapulae: normal
      vi. Others
         a) Mild small thorax
         b) Male sex predilection
      vii. Prognosis
         a) Good developmental prognosis
         b) Ambulatory
      viii. Genetics: autosomal recessive
   b. Campomelic dysplasia
      i. Femur
         a) Symmetric mild shortening
         b) Moderate-to-severe bowing/amputation
      ii. Other long bones
         a) Tibial bowing more marked than femora bowing
         b) Hypoplastic fibulae
      iii. Genitourinary
         a) Ambiguous genitalia
         b) Sex reversal in XY
      iv. Face
         a) Micrognathia
         b) Cleft palate
      v. Scapulae: hypoplastic
      vi. Others
         a) Occasional lateral ventriculomegaly
         b) Cardiac anomalies
         c) Talipes
      vii. Prognosis
         a) Often lethal in early infancy
         b) Survivors often severely disabled
      viii. Genetics
         a) Autosomal dominant
         b) *SOX*-9 mutations
   c. Antley–Bixler syndrome
      i. Femur; symmetric short, severely bowing
      ii. Other long bones
         a) Radiohumeral synostosis
         b) Joint contractures
      iii. Genitourinary: occasional abnormalities
      iv. Face
         a) Frontal bossing
         b) Depressed nasal bridge
      v. Scapulae: severely hypoplastic
      vi. Others
         a) Craniosynostosis
         b) Arachnodactyly
      vii. Prognosis
         a) Occasional death
         b) Normal neurodevelopment
         c) Severe orthopedic disability
      viii. Genetics: autosomal recessive

Diagnostic Investigations

1. Radiography
   a. Mandibular hypoplasia
   b. Femoral hypoplasia including proximal femoral focal deficiency
   c. Less frequent thoracocostovertebral anomalies
      i. Thorax: congenital elevation of the scapula (Sprengel's deformity)
      ii. Ribs
         a) Absent
         b) Hypoplastic
         c) Fused
      iii. Spine
         a) Dysplastic vertebrae
         b) Hemivertebrae
         c) Spina bifida occulta
         d) Lumbar scoliosis
         e) Sacral dysgenesis
      iv. Pelvis
         a) Small iliac wings
         b) Wide obturator foramen
         c) Hypoplasia/aplasia of the acetabula with dislocation of the hips
   d. Less frequent upper extremity anomalies
      i. Hypoplasia of the humerus
      ii. Radiohumeral/radioulnar synostosis
      iii. Ulnar deviation of the hands
2. Histopathology
   a. Femur from one infant showed hyaline cartilage with foci of fibrous dysplasia
   b. A disorganized growth plate and relative decrease in the resting cartilage matrix in another patient

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Sporadic cases: not increased
      ii. Autosomal dominant inheritance: not increased unless one of the parents is affected
      iii. Maternal diabetes: risk is significantly increased
   b. Patient's offspring: 50% if the patient has the autosomal dominant form of the syndrome
2. Prenatal diagnosis possible by ultrasonography in at-risk families
   a. Micrognathia
   b. Cleft palate
   c. Other facial features
   d. Short, bowed femora
3. Management
   a. Cleft palate repair
   b. Care for cardiovascular and genitourinary complications
   c. Orthopedic management of limb deformity and hip dysplasia

The radiograph showed hip dysplasia and bilateral proximal femoral hypoplasia

Fetal Akinesia Deformation Sequence

Fetal akinesia deformation sequence (FADS) refers to the condition of decreased intrauterine fetal movement and its consequent manifestations of multiple joint contractures, pulmonary hypoplasia, and abnormal face present at birth. It is also known as Pena–Shokeir phenotype (Hall 2009). The incidence is estimated to be 1 in 12,000, reflecting causal heterogeneity.

Synonyms and Related Disorders

Arthrogryposis multiplex congenita with pulmonary hypoplasia; Fetal akinesia sequence; Pena–Shokeir phenotype

Genetics/Basic Defects

1. Genetics
   a. Sporadic in majority of cases
   b. Familial cases
      i. Autosomal recessive inheritance
      ii. Possible X-linked recessive inheritance
2. Heterogeneous causes (Beemer 1990)
   a. Inadequacy of the intrauterine fetal environment
      i. Etiologic factors
         a) Ovarian cyst
         b) Bicornuate uterus
         c) Umbilical cord wrapping
         d) Twins
         e) Extrauterine pregnancy
         f) Insufficient placental circulation
         g) Maternal tetanus, drug treatment
         h) Amniotic bands
      ii. Oligohydramnios sequence
         a) Facial deformities (Potter's facies)
         b) Arthrogryposis
         c) Lung hypoplasia
      iii. Types of defects determined by the timing of constraint
         a) Early in pregnancy leading to limb reduction defects, syndactyly, and polydactyly
         b) Later in pregnancy (third trimester) leading to genu recurvatum, dislocated hips, and deviated wrists
         c) Various developmental defects occurring earlier in the upper than in the lower limbs
         d) Embryonic onset of immobility interferes with limb development and results in joint fixation and pterygium formation, in contrast to fetal-onset immobility, which causes joint contractures alone.
   b. Pena–Shokeir phenotype or sequence (Hall 2009)
      i. Pena–Shokeir syndrome
         a) Originally described by Pena and Shokeir in 1974
         b) Syndrome consisting of camptodactyly, multiple ankyloses, facial anomalies, pulmonary hypoplasia, and lethal outcome
         c) Currently the term "Pena–Shokeir phenotype or sequence" is recommended instead of Pena–Shokeir syndrome
         d) This form clearly exists as an autosomal recessive trait with frequent consanguinity and even incest reported

H. Chen, *Atlas of Genetic Diagnosis and Counseling*, DOI 10.1007/978-1-4614-1037-9_90,
© Springer Science+Business Media, LLC 2012

ii. Curarization of fetal rats during pregnancy (study by Moessinger 1983) resulted in better understanding of fetal akinesia deformation sequence with the following features almost identical with those described in the Pena–Shokeir syndrome:
  a) Multiple contractures or arthrogryposis
  b) Pulmonary hypoplasia
  c) Craniofacial anomalies
  d) Polyhydramnios
  e) Intrauterine growth retardation
  f) Short umbilical cord
iii. Currently the term "Pena–Shokeir phenotype or sequence" is recommended instead of "Pena–Shokeir syndrome"

3. Fetal akinesia not associated with primary malformations (Grubben et al. 1990)
  a. Mechanical causes
    i. Oligohydramnios
    ii. Polyhydramnios
    iii. Premature rupture of the membrane
    iv. Chorioamnionitis
  b. Congenital infections
    i. Rubella
    ii. CMV
    iii. Toxoplasmosis
  c. Physical or chemical agents
    i. Toxic agents
    ii. Drugs
    iii. X-rays
    iv. Hyperthermia
  d. Fetal hypoxia
    i. Fetal anemia
      a) Blood loss
      b) Hemolysis
    ii. Compression of umbilical cord
    iii. Placental insufficiency
    iv. Severe toxemia
  e. Maternal myasthenia gravis
4. Role of fetal akinesia in heterogeneous syndromes and conditions (Grubben et al. 1990)
  a. Cerebro-oculo-facio-skeletal (COFS) syndrome
  b. Potter sequence
  c. Neu–Laxova syndrome
  d. Syndrome described by Herva et al. (1985)
  e. Osteochondrodysplasias
    i. Thanatophoric dysplasia
    ii. Achondrogenesis
    iii. Diastrophic dysplasia
  f. Lethal multiple pterygium syndrome
  g. CNS anomalies
    i. Hydranencephaly
    ii. Dandy–Walker malformation with hydrocephalus
    iii. Schizencephaly
    iv. Olivo-ponto-cerebellar degeneration
  h. Skin/connective tissue disorders
    i. Restrictive dermopathy
    ii. Epidermolysis bullosa
    iii. Congenital ichthyosis
  i. Metabolic disorders
    i. Lysosomal storage disorders
    ii. Generalized gangliosidosis syndrome type I
    iii. Glycogenosis type VII (Moerman et al. 1995)
  j. Neuromuscular disorders
    i. Congenital muscular dystrophy
    ii. Congenital myotonic dystrophy
    iii. Congenital spinal muscular atrophy
    iv. Central core disease
    v. Nemaline myopathy
  k. Other disorders causing restrictive fetal akinesia
    i. Loss of anterior horn cells
    ii. Radical disease
    iii. Peripheral neuropathy
    iv. Congenital myasthenia gravis
    v. Amyoplasia congenita
    vi. Prader–Willi syndrome
    vii. Cohen syndrome
    viii. Angelman syndrome
    ix. Neurofibromatosis I
    x. Moebius syndrome
    xi. Bilateral dislocation of the hips
    xii. Exstrophy of cloaca and bladder
    xiii. Chromosome abnormalities
      a) Fetal triploidy
      b) Trisomies 4p, 9, 9q, 9p, 10q, 11q, proximal 14, proximal 15, and 18
      c) Monosomies 4p and 13q
    xiv. Miscellaneous
      a) Cornelia de Lange syndrome
      b) Catel–Manzke syndrome
      c) Opitz–Frias syndrome
      d) Bowen–Conradi syndrome
      e) Marden–Walker syndrome
5. Pathogenesis of fetal akinesia sequence (Hageman et al. 1987)
  a. Spinal cord lesions observed most often (28%)
  b. Brain lesions (19%)

c. Miscellaneous or connective tissue disorders (11%)
d. Combined brain and spinal cord lesions (9%)
e. Mechanical restriction (7%)
f. Muscle disorders (5%)
g. Peripheral neuropathy and myasthenia gravis (1%)
h. No underlying defect observed in 14% of cases

6. Molecular basis of lethal fetal akinesia phenotype (Vogt et al. 2008, 2009)
   a. Mutations in the acetylcholine receptor subunits *CHRNA1*, *CHRNB1*, *CHRND*, and Rapsyn (*RAPSN*) can also result in a MPS (multiple pterygium syndrome)/FADS phenotype
   b. Whereas incomplete loss of *DOK7* function may cause congenital myasthenia, more severe loss of function can result in a lethal fetal akinesia phenotype

Clinical Features

1. Pregnancy history (Grubben et al. 1990)
   a. Feeble fetal movement
   b. Polyhydramnios
   c. Oligohydramnios
   d. Craniofacial abnormalities
      i. Ocular hypertelorism
      ii. Micrognathia
      iii. Low-set ears
      iv. Depressed nasal tip
      v. Short neck
   e. Limb anomalies
      i. Lack of normal growth
      ii. Limitation of joint movement
      iii. Abnormal shape
      iv. Abnormal position
      v. Decreased bone calcification
2. Phenotype present at birth
   a. Multiple joint contractures
   b. Limb pterygia
   c. Craniofacial abnormalities
   d. Pulmonary hypoplasia
   e. Short umbilical cord
   f. Growth retardation
3. Lethal outcome with pulmonary hypoplasia
4. Identifiable familial forms of Pena–Shokeir phenotype/fetal akinesia deformation sequence
   a. Classic Pena–Shokeir syndrome (type I)
      i. Classic signs of fetal akinesia deformation sequence (lack of normal fetal movement in utero)
         a) Intrauterine growth retardation
         b) Joint contractures
         c) Short gait
         d) Short umbilical cord
         e) Pulmonary hypoplasia
         f) Characteristic facial features: hypertelorism, prominent nasal bridge, posteriorly rotated low-set ears, depressed tip of the nose, micrognathia, and cleft palate (probably related to micrognathia and lack of in utero tongue movement)
      ii. Stick-like limbs with flexion or extension contractures
      iii. Feet usually in severe equinovarus position but rocker bottom feet may be present
      iv. Elbows usually flexed
      v. Hypoplastic dermatoglyphics
      vi. Normal CNS and most skeletal muscle, although muscle biopsies often show disuse atrophy, no myopathy changes and rarely fatty, fibrous replacement
      vii. Other often reported features
         a) Disproportionately large head
         b) Short limbs
         c) Thin ribs and long bones
         d) Clenched hands
         e) Ankylosis of large joints
         f) Thoracic kyphosis
   b. Lower motor neuron disorder with generalized decrease in anterior horn cells (Chen type) (Chen et al. 1983)
      i. Intrauterine growth retardation
      ii. Polyhydramnios
      iii. Lack of fetal movement in the early second trimester
      iv. Pulmonary hypoplasia
      v. Characteristic facial appearance
         a) Nasal bridge: depressed or high
         b) Long philtrum
         c) Small mouth
      vi. Limb abnormalities
         a) Flexion contractures
         b) Hyperextended and overlapping distal phalanges
         c) Ulnar deviation of fingers

d) Radioulnar synostosis
e) Clubfeet
vii. Other findings
a) Mild kyphosis
b) Hypoplastic adrenals
viii. Small muscles with disuse atrophy
ix. Cases reported by Abe et al. (1989), Moerman et al. (1983), Moerman and Fryns (1990), and possibly Imamura et al. (1981) and Gullino et al. (1993) appear to have this subtype

c. Lethal congenital contractures syndrome type 1 (LCCS-1) (GLE mRNA export mediator gene mapped at 9q34) (Herva et al. 1988, 1985; Vuopala et al. 1994)
i. An autosomal recessive disorder frequently seen in Finland
ii. Intrauterine growth retardation
iii. Pulmonary hypoplasia
iv. Micrognathia
v. Short neck
vi. Thin ribs
vii. Thin, stick-like limbs which may fracture, associated with decreased muscle mass
viii. Extended legs, often with flexed arms
ix. Dislocated hips always present
x. Striking and characteristic feature: decrease of anterior horn cells in the ventral part of the spinal cord with normal cerebellum
xi. Prenatal diagnosis possible by molecular testing of mutations in the messenger RNA export mediator GLE (*GLE1*) (Nousiainen et al. 2008)

d. Lethal congenital contracture syndrome type 2 (LCCS-2) (Landau et al. 2003)
i. Described in two Israeli Bedouin consanguineous kindreds
ii. Clinical features
a) Extended elbows
b) Flexed knees
c) Mild IGUR
d) Micrognathia
e) Hydronephrosis
f) Distended bladders
iii. Generally decreased anterior horn cells in the spinal cord and muscle wasting suggesting a neuropathic etiology
iv. *ERBB3* gene mapped at 12q13

e. Lethal congenital contracture syndrome type 3 (LCCS-3)
i. Represented by a large consanguineous Israeli Bedouin kindred
ii. Clinical features identical to LCCS-2 without bladder involvement
iii. *PIP5K1C* gene mapped at 19p13

f. Lethal lower motor neuron deficiency (Vuopala et al. 1995a)
i. Described in 11 families
ii. Considered to be a disorder of the degeneration of anterior horn cells leading to lethality
iii. Clinical features
a) Legs and arm: hyperextended or flexed
b) Mild IUGR
c) Usually born near term
d) Craniofacial: micrognathia, high nasal bridge, underdeveloped nasal tip, posteriorly rotated ears, short neck
e) Early death due to respiratory failure
iv. This disorder mapped to 5q

g. Families with apparent increase in monozygotic twinning (Chen et al. 1983; Lindhout et al. 1985; Ho 2000)
i. Affected twins and affected singletons occur in the same families
ii. Clinical features
a) Polyhydramnios
b) Increased fetal movement signal problems
c) Severe pulmonary hypoplasia
d) IUGR
e) Mildly webbed necks
f) Multiple flexion contractures including camptodactyly and clubfeet
g) Relatively large head compared to short trunk
h) Triangular face
i) Ocular hypertelorism
j) Clenched jaw
k) Posteriorly angulated ears
iii. Other features in some affected infants
iv. Relationship between MZ twinning and this type of PSP/FADS
a) Unclear
b) Potentially they are cases of classic Pena–Shokeir syndrome

h. Normal in utero growth, macrocephaly, and Pena–Shokeir phenotype (Lammer type)
   i. Affected brothers described by Lammer et al. (1989)
   ii. Clinical features
      a) Normal intrauterine growth
      b) Died with severe pulmonary hypoplasia
      c) Trismus
      d) Micrognathia
      e) Hydronephrosis
      f) Macrocephaly
      g) Choanal atresia in one brother
i. Absence of pyramidal cells, immature CNS development, adducted thumbs, kyphoscoliosis, and severe pulmonary hypoplasia (Biscegli type)
   i. Described in a consanguineous family
   ii. Clinical features
      a) Polyhydramnios
      b) IUGR
      c) Immaturity or delayed development of CNS
      d) Marked ocular hypertelorism
      e) Hypoplasia and atrophy of skeletal muscles
      f) Extension contractures of arms and legs
      g) Camptodactyly with abducted thumbs
      h) Clubfeet
      i) Marked congenital kyphoscoliosis
j. CNS dysgenesis and degeneration, seizures, trismus, and abdominal wall herniation (Erdl type)
   i. Sibs described by Erdl et al. (1989)
   ii. Clinical features
      a) IUGR
      b) Extended knees
      c) Trismus
      d) Seizures (intrauterine and after birth)
      e) Generalized edema at birth
      f) Severe lung hypoplasia
      g) Died shortly after birth
      h) Abdominal herniation (muscle defect) in the first sib
      i) A short and extremely thin umbilical cord
      j) Left lung trilobation and large thyroid and adrenal glands
      k) Polyhydramnios
      l) Fetal hydrops at 30–34 weeks of gestation
      m) CNS abnormalities: internal hydrocephalus, hypoplasia of basal ganglia, reduced or degenerating anterior horn cells, and other dystrophic brainstem and cerebellar changes
k. Skeletal muscle maturation defect
   i. Finish female siblings described by Vuopala et al. (1994)
   ii. Clinical features
      a) Polyhydramnios
      b) Severe pulmonary hypoplasia
      c) Congenital scoliosis
      d) Normal birth weight for gestation
      e) Edema
      f) One sib stillborn and other lived only 7 weeks
      g) Normal CNS
      h) Skeletal muscle immature with small muscle fibers and prominent atypical spindles
l. Pyramidal tract degeneration
   i. Two female sibs described by Vuopala et al. (1994)
   ii. Pena–Shokeir phenotype
   iii. Presence of pyramidal tract degeneration
   iv. Normal brain in one sib
   v. Holoprosencephaly in other sib
   vi. May represent an upper motor neuron disorder or a variation on holoprosencephaly
m. In utero seizures, scoliosis, together with cerebral and cerebellar hypoplasia in males (Persutte type)
   i. Two male sibs in a consanguineous family described by Persutte et al. (1988)
   ii. Clinical features
      a) Congenital scoliosis apparent at 18 weeks of gestation
      b) Decreased fetal movement
      c) Polyhydramnios
      d) IUGR
      e) Severe pulmonary hypoplasia leading to death within a few minutes after birth
      f) Flexion contractures
      g) Relatively large head
      h) Short neck
      i) Small low placed ears

j) CNS anomalies: agenesis of the corpus callosum and septum pellucida, hydrocephaly, hypoplastic cerebellum, and brain stem

iii. A family of male sibs with similar structural anomalies was described by Skrupski et al. (1996)

iv. This disorder could be X-linked recessive

n. Microphthalmia, microtia, and normal birth size (Thomas type)

i. Two male sibs described by Thomas et al. (1993)

ii. Clinical features

a) Polyhydramnios
b) Normal size at birth
c) Multiple congenital contractures
d) Died of respiratory insufficiency
e) Persistent truncus arteriosus
f) Micro-ophthalmia
g) Microtia
h) One had duodenal atresia, hydronephrosis, and dilated bladder

o. Olivo-ponto-cerebellar hypoplasia

i. A family of three siblings reported by Goutieres et al. (1977)

ii. Clinical features

a) Contractures
b) Anterior horn disease
c) Olivo-ponto-cerebellar hypoplasia
d) Death shortly after birth due to pulmonary hypoplasia

p. Failure to myelinate peripheral nerve

i. Affected male and female siblings reported by Penã et al. (1968)

ii. Clinical features

a) Multiple congenital contractures
b) Lack of myelination of peripheral nerve

q. Holoprosencephaly with hypokinesia and congenital contractures in an X-linked recessive pattern of inheritance

i. First reported by Morse et al. (1987) and then by Hockey et al. (1988)

ii. Other clinical findings with typical features of FADS

r. Hydrancephaly, calcification of basal ganglion, and proliferative Vasculopathy (Fowler type)

i. Families reported by Fowler et al. (1972), Harper and Hockey (1983), and Harding et al. (1995)

ii. Clinical findings

a) Polyhydramnios
b) Lack of fetal movements
c) Generalized edema
d) Cleft palate
e) Pterygia of large joints

s. Calcification of leptomeninges, the surface of cerebral convolutions, neurons, muscles, and vessels (Illum type)

i. A family of male and female siblings reported by Illum et al. (1988)

ii. Other clinical findings

a) Multiple congenital contractures
b) Camptodactyly with ulnar flare and clubfeet
c) Round face, depressed nasal bridge, long philtrum, short nose, puckered mouth, a deep horizontal crease below the lower lip, and trismus
d) Early lethality

t. Familial intrauterine anoxia and/or ischemia and PSP/FADS can be associated with the following situations

i. Maternal cocaine
ii. Monozygotic twins at increased risk for this type of change because of their vascular connection
iii. Polymicrogyri
iv. Oligogyri
v. Atrophy of cerebellum and cerebrum
vi. Cerebral neuronal loss and gliosis
vii. Cyst of the brain
viii. Heterotopia
ix. Decreased number of anterior horn cells with ferrigination
x. Dilated ventricles with calcification

Diagnostic Investigations

1. Radiography
   a. Thin tubular bones
   b. Gracile ribs

c. Multiple fractures possible at mid-diaphyses of humeri, distal diaphyses of femora, proximal diaphyses of tibiae, and fibulae
d. Camptodactyly

2. Histopathologic and other laboratory studies
   a. Trophoblastic inclusions in the chorionic villi of placenta:
      i. Triploidy
      ii. Lethal multiple pterygium syndrome
   b. Lung hypoplasia
   c. Bones
      i. Unremarkable resting cartilage
      ii. Normal cartilage cell columns at the chondro-osseous junctions
      iii. Marrow bony spicules often unusually thin and underossified
      iv. Irregular and focal areas of extreme diaphyseal thinning: a consistent finding
   d. CNS, muscles, and other organ systems
   e. Biochemical studies for lysosomal storage disease
   f. Analysis for chromosome abnormality
3. Molecular genetic diagnosis: *DOK7*- and *RAPSN*-related fetal akinesia deformation sequence available clinically

Genetic Counseling

1. Recurrence risk
   a. Patient's sib
      i. Autosomal recessive inheritance: 25%
      ii. A recurrence risk of 10–15% suggested in the nonfamilial sporadic cases
   b. Patient's offspring: a lethal entity not surviving to reproductive age
2. Prenatal diagnosis by ultrasonography in high-risk pregnancies after the birth of a previous child with a heritable (mostly autosomal recessive) form of fetal akinesia sequence
   a. Marked decreased fetal activity
      i. Restricted limb movements
      ii. Decreased fetal chest movements
   b. Hydramnios/oligohydramnios
   c. Intrauterine growth retardation
   d. Hydrops noted in some affected babies late in pregnancy
   e. Some affected babies often die in utero if not shortly following birth
   f. Other echographic abnormalities associated with fetal akinesia
      i. Brain
         a) Microcephaly
         b) Holoprosencephaly
         c) Hydranencephaly
         d) Meningomyelocele
         e) Lissencephaly
         f) Dilated ventricles
         g) Absence of septum pellucidum
      ii. Spinal cord: sacrococcygeal agenesis
      iii. Gastrointestinal tract
         a) Omphalocele
         b) Gastroschisis
      iv. Renal
         a) Bilateral renal agenesis
         b) Renal malformations
      v. Craniofacial
         a) Hypertelorism
         b) Hypotelorism
         c) Micrognathia
         d) Cleft palate
      vi. Limbs
         a) Contractures (arthrogryposis)
         b) Camptodactyly
         c) Webbing
         d) Syndactyly
         e) Polydactyly
         f) Overlapping fingers and toes
         g) Abnormal position
         h) Clubfoot
         i) Partial absence or shortness
      vii. Cardiopulmonary
         a) Pulmonary hypoplasia
         b) Cardiac defects
3. Management: no effective treatment for pulmonary hypoplasia

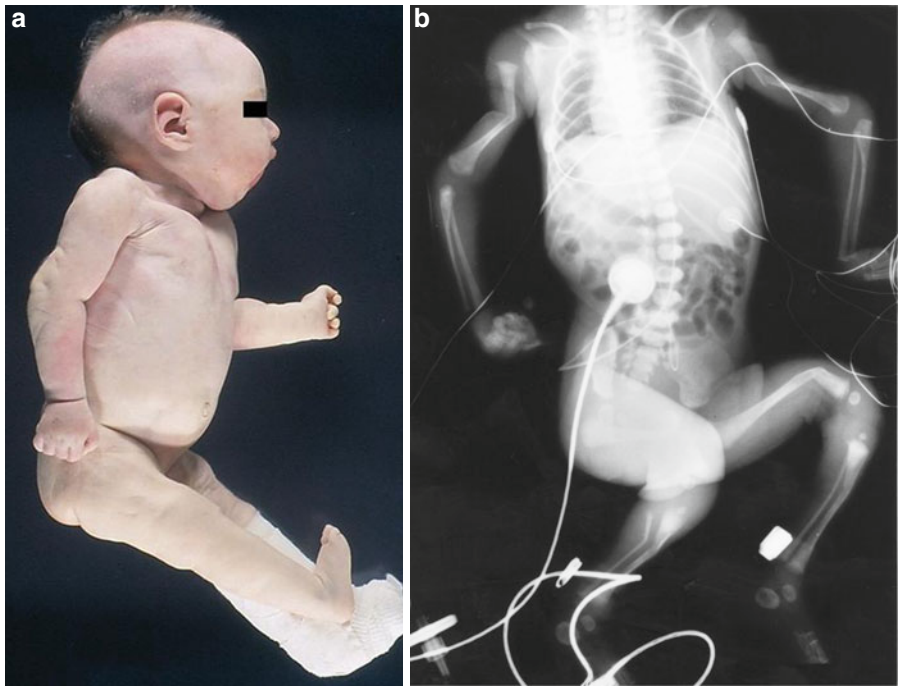

Fig. 1 (**a**, **b**) A neonate with fetal akinesia sequence showing micro/retrognathia, short neck, narrow thorax, flexion contractures of hips, fixed extension of the right knee, and inverted and rotated feet. The radiograph showed gracile ribs, thin long bones with multiple fractures at mid-diaphyses of humeri, distal diaphysis of femora, and proximal diaphyses of both tibiae and left fibula, and club hands

Fig. 2 (**a**, **b**) A neonate with fetal akinesia sequence showing micrognathia and multiple contractures. The radiograph showed gracile ribs and fractures at mid-diaphyses of humeri

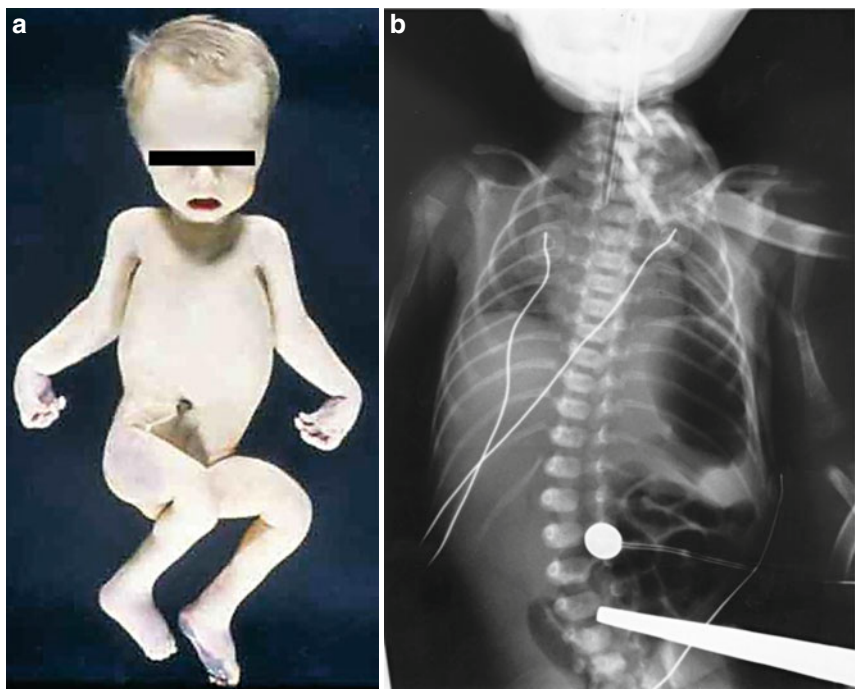

Fig. 3 (**a**, **b**) A neonate with Pena–Shokeir sequence (Chen type) showing hypertelorism, a short nose with depressed nasal bridge, long philtrum, a small and recessed jaw, low-set malformed ears, a short neck, clenched hands, multiple contractures at the hip, elbows, knees, ankles, and clubfeet. The infant had scalp edema and pulmonary hypoplasia. Neuromuscular histology showed lower motor neuron disorder with generalized decrease in anterior horn cells

Fig. 4 Radiographic study of the infant showed gracile ribs, thin long bones, and multiple contractures at the hip, elbows, knees, and ankles, and clubfeet

Fig. 5 Prenatal ultrasonography showed hydramnios, retrognathia, low-set ears, scalp edema, and flexion contractures at the elbows and knees

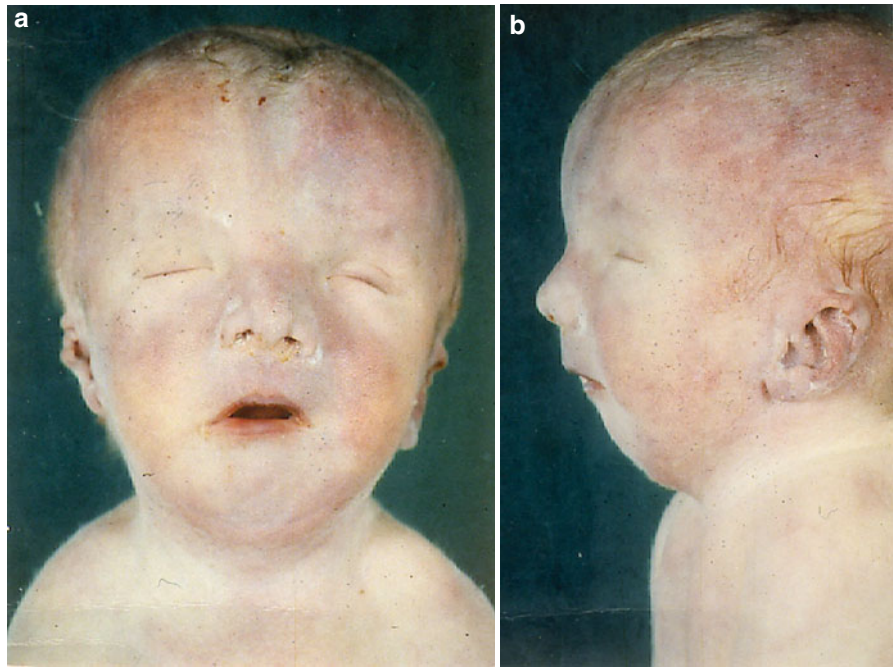

Fig. 6 (**a**, **b**) An infant in a family with MZ twinning. Note small jaw, ocular hypertelorism, antimongoloid slant of the palpebral fissures, high bridge of the nose, posteriorly rotated large ears, triangular shaped face, and short-appearing mildly webbed neck

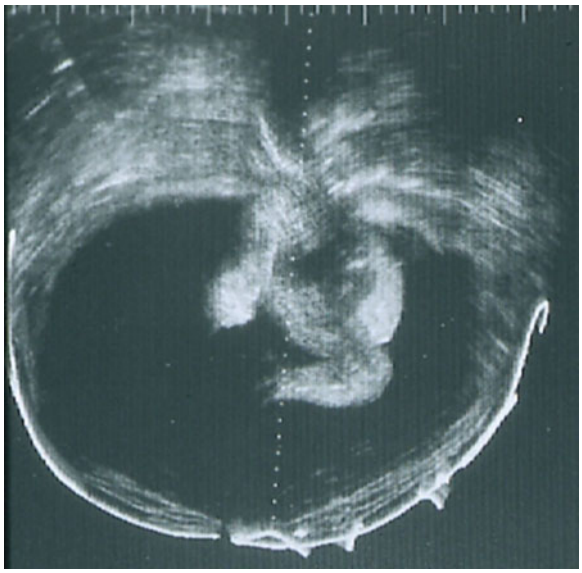

Fig. 7 Prenatal ultrasound of this fetus showed polyhydramnios, IUGR, and flexion contractures of the knees

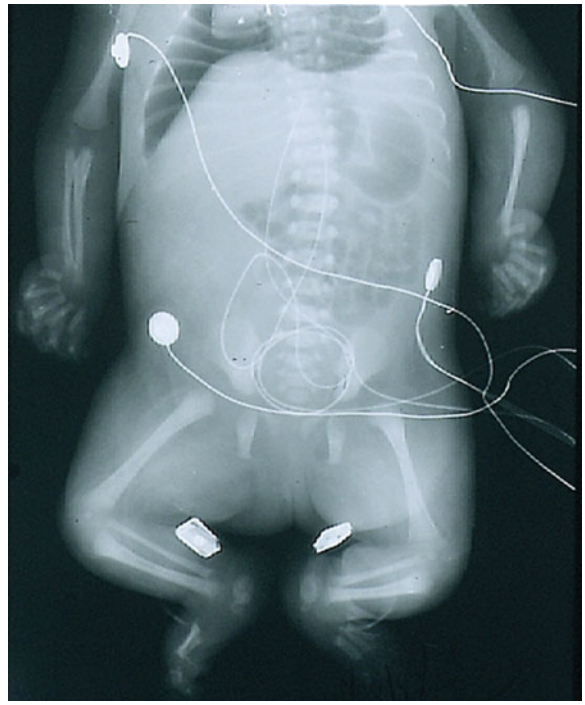

Fig. 8 Radiograph showed gracile ribs, thin long bones, flexion contractures at the elbows and knees, and clenched hands

Fetal Alcohol Spectrum Disorders

In 1973, Jones et al. described, in the American medical literature, a constellation of features in children born to alcoholic mothers, now known as fetal alcohol syndrome (FAS). In 1996, the Institute of Medicine further defined criteria of FAS and proposed two new terms: alcohol-related neurodevelopmental disorder (ARND) and alcohol-related birth defects (ARBD) to include structural CNS and cognitive abnormalities in children in whom fetal exposure to alcohol has been confirmed.

It is established that prenatal exposure to alcohol produces a range of morphological and cognitive-behavioral outcomes in the offspring, commonly referred to as fetal alcohol spectrum disorder (FASD) (Kodituwakku 2007). Fetal alcohol syndrome refers to severely affected children on the spectrum displaying a pattern of altered growth and morphogenesis, characterized by prenatal and postnatal growth retardation, craniofacial anomalies, abnormal brain function reflected by cognitive deficits, and developmental delays. The majority of children (about three times as many children as those with FAS) with substantial prenatal alcohol exposure show only some of the above mentioned features (Sampson et al. 1997), commonly referred to having fetal alcohol effects (FAE). The term FAE, however, has been replaced by two new terms: ARND and ARBD.

The incidence of FAS in the United States is estimated to be about 1–3 per 1,000 live births. The incidence is higher in certain population, such as Native Americans (Gleason 2001).

Synonyms and Related Disorders

Alcohol-related birth defects (ARBD); Alcohol-related neurodevelopmental disorder (ARND); Fetal alcohol syndrome

Genetics/Basic Defects

1. Genetics (Thackray and Tifft 2001)
   a. Genetic susceptibility
      i. Observation of differences in the severity and spectrum of FAS based on genetic background.
      ii. Higher concordance of FAS in monozygotic twins than in dizygotic twins supports the concept of genetic factors in the fetal effects of alcohol.
   b. Possible mechanism of heritable susceptibility to FAS: genetically encoded differences in alcohol dehydrogenase, the enzyme responsible for metabolizing alcohol in the liver
      i. Mother of children with FAS: possibly with less functional enzyme resulting in higher peak blood alcohol concentration after the ingestion of alcohol.
      ii. Fetuses with FAS: possibly with deficient alcohol dehydrogenase activity and thus less tolerance to elevated maternal alcohol levels.

2. Pathogenesis (Thackray and Tifft 2001)
   a. Clinical features of FAS: result from exposure of the developing fetus to toxic levels of alcohol and its metabolites at critical periods in development.
   b. Specific pathophysiology unknown: may involve free radical formation that causes cellular damage in the developing tissues of the fetus.
   c. Exposure in the first trimester
      i. Affects organogenesis and craniofacial development, leading to minor and major malformations such as the characteristic facial features and ARBD.
      ii. Excessive cell death in the midline of the developing embryo may account for the development of these facial features.
   d. Continuous use of alcohol by the mother later in pregnancy resulting in low birth weight and affecting postnatal growth.
   e. Alcohol exposure at varying times in pregnancy may result in similar CNS neurodevelopmental effects.
   f. Detrimental defects on the fetus when there is concomitant maternal use of other drugs (marijuana, nicotine, caffeine).
3. Key risk factors for alcohol-induced brain damage
   a. Peak blood alcohol concentration rather than the length of alcohol exposure: the critical variable in determining risk for adverse effects on brain development.
   b. Cessation of drinking alcohol at any time during pregnancy likely to be beneficial on developing brain.
   c. Cerebellum particularly vulnerable to alcohol-induced growth restriction as well as neuronal loss following alcohol exposure during the brain growth spurt (third trimester in humans).
   d. Heavy alcohol consumption during the first trimester associated strongly with craniofacial abnormalities in humans.

Clinical Features

1. Characteristic craniofacial features in the young child (Clarren 1981; Gleason 2001)
   a. Discriminating features
      i. Short palpebral fissures
      ii. Flat midface
      iii. Indistinct (smooth, flat) philtrum
      iv. Thin upper lip
   b. Associated features
      i. Epicanthal folds
      ii. Low nasal bridge
      iii. Minor ear anomalies
      iv. Short nose
      v. Micrognathia
2. Growth retardation (Hanson et al. 1976)
   a. Low birth weight for gestational age (prenatal growth deficiency) (97%)
   b. Decelerating weight over time not due to nutrition (Postnatal growth deficiency) (97%)
   c. Disproportionate low weight to height
3. Alcohol-related birth defects (ARBD): birth defects associated with in utero alcohol exposure
   a. Ocular abnormalities
      i. Strabismus
      ii. Retinal vascular anomalies
      iii. Optical nerve hypoplasia
      iv. Refractive problems secondary to small globes
      v. Coloboma
   b. Cardiovascular abnormalities
      i. Atrial septal defect
      ii. Ventricular septal defect
      iii. Aberrant great vessels
      iv. Tetralogy of Fallot
   c. Hepatic abnormality: extrahepatic biliary atresia
   d. Skeletal abnormalities
      i. Hypoplastic nails
      ii. Shortened fifth digits
      iii. Radioulnar synostosis
      iv. Flexion contractures
      v. Camptodactyly
      vi. Clinodactyly
      vii. Pectus excavatum/carinatum
      viii. Klippel–Feil syndrome
      ix. Hemivertebrae
      x. Scoliosis
   e. Muscular abnormalities
      i. Hernias
         a) Diaphragm
         b) Umbilicus
         c) Inguinal
      ii. Diastasis recti
